Adams State College, Dept. Of Psychology, Alamosa, Colorado 81102. In this experiment, rats were tested on conditional and simple instrumental tactile or visual discrimination in a T-maze to test the hypothesis that the cholinergic projection system from the nucleus basalis magnocellularis (NBM) to the medial prefrontal cortex (MPF) is necessary for configural but not simple association learning. Six lesion groups (n=5/group) were included in this experiment: 1) bilateral MPF-ablation (MPF-A), 2) bilateral MPF-quisqualate (2ul/min) lesion group (MPF-Q), 3) bilateral NBM quisqualate (.8ul/min) lesion group (NBM-Q), 4) combined cross quisqualate lesion group (a unilateral NBM-Q lesion on one side and a unilateral MPF-Q lesion, contralateral to the NBM-Q lesion; CONTRA), 5) ipsilateral combined quisqualate lesion group (a unilateral NBM-Q lesion and a unilateral MPF-Q lesion on the same side; IPSI), and 6) sham operate or control group (CTL). All surgeries were performed prior to behavioral testing. Results from this experiment suggest that there is a dissociation among groups on both simple and conditional discrimination. The MPF-A rats were significantly slower at acquiring the tactile discrimination than the rest of the groups. NBM-Q and MPF-Q lesion groups did not reach criterion on the conditional (visual-tactile) discrimination task. The NBM may be important for this particular type of configural association task.

## 270.10

**THE EFFECTS OF TOTAL AND PARTIAL PARIETAL CORTEX LESIONS ON MEMORY FOR AN OBJECT/SPATIAL LOCATION PAIRED ASSOCIATE TASK IN RATS.** J.M. Long\*, J. Mellen, R.P. Kesner. Dept. of Psychology, University of Utah, Salt Lake City, UT 84112.

Previous research has suggested that large lesions of rodent parietal cortex (PC) impairs performance on an object/spatial location paired associate (O/SL-PA) task (Long and Kesner, 1995, Soc. Neuro. Abst. p.1215). The present experiment was conducted in order to test the hypothesis that more restricted lesions of the PPC would result in O/SL-PA deficits. Long-Evans rats were either given a dorsal, ventrolateral, or dorsal plus ventrolateral PC lesion, or a control surgery under Nembutal anesthesia. After a one-week recovery period the rats were tested either on an object or a spatial location go/no-go successive discrimination task. After reaching criterion (a minimum of a 5 sec. difference between reward and non-reward trials) they were trained on the other discrimination. After reaching criterion on the second discrimination all rats were trained on a successive discrimination, go/no-go task in which they had to remember which object/spatial location pairs had been associated with reward. Two objects and two spatial locations served as stimuli. Ten reward and ten non-reward trials were given daily until they reached criterion (same as above) or for 600 trials. Preliminary data indicate that compared to controls none of the PC lesions impaired object or spatial location discrimination. In the O/SL-PA task, data indicate that dorsal plus ventrolateral and dorsal PC lesioned, but not ventrolateral PC lesioned rats, were impaired relative to controls. These results suggest that dorsal PC is not involved in either object or spatial location discrimination, but rather is involved in discrimination of the combination of object and spatial location information.

**ALPHA2C-ADRENOCEPTOR OVEREXPRESSION IMPAIRS DEVELOPMENT OF NORMAL WATER MAZE SEARCH STRATEGY IN MICE.**

M.G. Bjorklund\*, M. Riekkinen<sup>1</sup>, J. Puolivali<sup>1</sup>, P. Santtila<sup>1</sup>, J. Sirvio<sup>2</sup>, J. Sallinen<sup>3</sup>, M. Scheinin<sup>4</sup>, A. Haapalinna<sup>4</sup> and P. Riekkinen Jr.<sup>1</sup>. <sup>1</sup>Department of Neurology, University of Kuopio, P.O. Box 1627, FIN-70211 Kuopio, Finland, <sup>2</sup>A.I.V.-institute, Kuopio, <sup>3</sup>Department of Pharmacology, University of Turku, <sup>4</sup>Orion-Farmos Ltd, Turku.

We investigated the role of  $\alpha 2C$ -adrenoceptors ( $\alpha 2C$ -AR) in the regulation of cognitive functions by studying the behavior of female FVDA mice that overexpress  $\alpha 2C$ -adrenoceptors (OE). We evaluated non-spatial (visible platform) and spatial (hidden platform) reference memory in a water maze (WM) test. The distribution of swimming during a free swim trial was similar in OE and control (C) mice. On the contrary, the OE mice were impaired compared with the C mice in developing normal search strategy during the visible and hidden platform stages: OE mice swam more in the peripheral incorrect annulus than C mice. Both at the visible and hidden platform stages DEX 5 ug/kg further increased searching from the incorrect peripheral annulus only in OE mice. Daily treatment with ATI before the training trial normalized search strategy of OE mice. However if ATI treatment was discontinued OE mice exhibited again the abnormal search strategy. The effect of  $\alpha 2C$  OE on the cortical EEG activity was analysed to study if  $\alpha 2C$ -AR mediate the sedative effect of  $\alpha 2$ -agonists and are important for cortical EEG arousal. No differences were observed on cortical EEG activity between the OE and C mice and DEX as effectively increased slow waves in OE and C mice. Passive avoidance training and testing trial behavior and dose responses of ATI and DEX treatments were identical in the OE and C mice. Our results suggests that  $\alpha 2C$ -AR OE impairs execution of navigation strategies, but does not affect arousal or anxiety. **THE EFFECTS OF REPEATED DISORIENTATION IN THE RAT: I. BEHAVIORAL IMPAIRMENTS.**

J.P. Goodridge\*, P. Dudchenko, and J.S. Taube. Department of Psychology, Dartmouth College, Hanover, NH 03755.

This study examined the effects of disorientation on the acquisition of two reference memory, spatial tasks. The first task was an 8-arm radial maze where one arm was consistently baited with water. The second task was a Morris water maze containing a submerged platform. Female, Long-Evans rats were assigned to one of three groups. One group (CLEAR) was transported to the maze room in a clear container with an open top and resided in this container during the intertrial intervals. A second group (OPAQUE) was identical to the first, except that an opaque container was used. The third group (OPAQUE+DISORIENTATION) was gently rotated back-and-forth in an opaque container in an attempt to produce disorientation. Across 45 acquisition days on a radial maze, 7/8 animals in the CLEAR group, 2/8 OPAQUE animals, and 0/8 OPAQUE+DISORIENTATION animals acquired the task. In the Morris water maze, however, no group differences in acquisition were observed.

To explore the dissociation between the two tasks further, partitions were placed into the water maze to create a swimmable version of the 8-arm radial maze. At the end of one of these arms was a submerged platform. Results revealed that disoriented animals were able to learn this task in 14 days and did not appear to differ from animals placed in a clear container. These findings suggest that the effects of disorientation may depend on the motivational system demanded by the task.

## 270.14

**THE EFFECTS OF REPEATED DISORIENTATION IN THE RAT: II. HEAD-DIRECTION AND PLACE CELL STABILITY.**

P. Dudchenko\*, J.P. Goodridge, and J.S. Taube. Department of Psychology, Dartmouth College, Hanover, NH 03755.

A previous study demonstrated that repeated "disorientation" of a rat may interfere with the stimulus control exerted by salient visual cues over the spatial orientation of place and head direction (HD) cells (Knierim et al., 1995). Recent work in our lab, described in a separate abstract (Goodridge et al., 1996), has also shown that disorientation appears to impair acquisition of an appetitively-motivated radial arm maze (RAM) task. In the current study, we were interested in whether the HD and place cells in the animals that displayed this spatial deficit would subsequently exhibit a lack of orientation to salient visual cues in the environment following disorientation procedures.

Long-Evans rats, with recording electrodes in either the anterior thalamic nucleus or the CA1 hippocampus, were screened for cells in a cylindrical apparatus containing a white cue card. Before and after each recording session, the rats were rotated back-and-forth in an opaque container. Identified HD or place cells were recorded following rotation of the white cue card in the cylinder, and when possible, following rotation of a white cue curtain on the RAM. A total of 21 cue card rotation sessions in the cylinder have been conducted with 8 HD cells and 2 place cells. In 20/21 sessions, rotations of the cue led to a shift in the cell's preferred direction or firing field. On the RAM, rotation of the white cue curtain resulted in a corresponding shift in the HD cells preferred directions in all instances (8/8), though on one occasion a reorientation to the cue curtain was observed across recording days. These results suggest that the acquisition impairment attributed to disorientation in our previous study may not be due to an impaired perception of landmark stability per se, but rather to the animals' inability to utilize this landmark information to guide spatial behavior. Supported by NIMH Grants MH 10843, MH 48924, MH 01286.

## 270.15

**IMPAIRMENT OF LONG-TERM BUT NOT SHORT-TERM MEMORY FOR A SOCIALLY TRANSMITTED FOOD PREFERENCE TASK IN TRANSGENIC MICE WITH A SELECTIVE LOSS OF LTP IN THE THETA FREQUENCY RANGE.** R. Bourtechouladze\* and M. Mayford. Ctr. Neurobiol. & Behav., Columbia Univ., New York, NY 10032.

The standard behavioral paradigms used to analyze the structural, physiological, and molecular contributions to learning and memory generally do not assess ecologically relevant learning and memory used by animals in their everyday behavior. We have adapted and developed the social transmission of food preferences paradigm, originally used for rats (Galef and Wigmore, 1983) for studying memory in genetically modified mice. Our pilot studies on C57/BL6 and DBA/2J mice showed that during social interaction olfactory cues pass from a recently fed mouse (a demonstrator) to a naive conspecific (observer) influencing that observer's subsequent diet selection. The observer exhibits enhanced preference for the diet its demonstrator ate. Using this paradigm we assessed learning and memory in CaMKII-Asp-286 transgenic mice. CaMKII-Asp-286 transgenic mice have a selective loss of hippocampal LTP in the range of the theta frequency and an impairment of spatial memory (Mayford et al., 1995). In the present study, memory for food preference was tested immediately (short-term memory) or 24 h after social training (long-term memory). Both transgenics and wild-type controls acquired the food preference normally. However, transgenic mice displayed significant loss of memory compared with controls when tested 24 h after social learning. These findings indicate that hippocampal LTP in the range of the theta frequency might be selectively involved in a long-term, but not short-term retention of natural, ecologically important memory. Supported by NIMH and NYSPI.

**MOTIVATION AND EMOTION: BRAIN STIMULATION**

## 271.1

**CHLORISONDAMINE FAILS TO ATTENUATE LATERAL HYPOTHALAMIC BRAIN STIMULATION BUT BLOCKS ITS POTENTIATION BY NICOTINE.** P. Baucó\*, R.A. Wise. Ctr. Stud. Behav. Neurobiol. and Dept. of Psychol., Concordia Univ., Montréal, Que., Canada, H3G 1M8.

A cholinergic projection from the pedunculo-pontine tegmental nucleus to the ventral tegmental area is thought to play an important role in the rewarding effects of lateral hypothalamic (LH) brain stimulation. Ventral tegmental dopamine neurons have both muscarinic and nicotinic receptors; thus we determined the effects of nicotinic blockade on LH self-stimulation. Chlorisondamine (CHL), a nicotinic antagonist, induces long term blockade of the locomotor stimulant and rewarding effects of nicotine. We assessed the ability of CHL to block self-stimulation and to block nicotine's ability to potentiate self-stimulation. Rats were first trained to lever press for LH stimulation using the rate-frequency curve-shift paradigm and then treated with CHL (10mg/kg, s.c.; n=7) or saline (n=6). Two days after treatment all animals were tested drug-free and then tested following nicotine (0.4mg/kg s.c.). Drug-free self-stimulation thresholds were normal but were not decreased by nicotine in CHL pretreated animals whereas they were decreased by an average 30% in animals not treated with CHL. Thus nicotinic receptors were effectively blocked by the treatment and do not normally play a significant role in LH self-stimulation.

## 271.2

**LATERAL HYPOTHALAMIC SELF-STIMULATION RELEASES ACETYLCHOLINE IN THE VENTRAL TEGMENTAL AREA (VTA).** P.V. Rada, G. Gibbs, J. S. Yeomans\*, B. G. Hoebel. Dept. of Psychology, Princeton University, Princeton, NJ 08544-1010, USA

Research suggests that the behavior reinforcement circuit from the lateral hypothalamus (LH) to the mesolimbic dopamine system includes a descending pathway to the midbrain and pons where cholinergic cells project to dopamine cells in the VTA and from there to forebrain dopamine terminal regions (Yeomans et al. 1993). To find additional evidence for this cholinergic link, acetylcholine (ACh) was sampled by microdialysis in the VTA every 20 min for 1 hr before, during and after rats performed electrical self-stimulation of the LH with implanted electrodes. The result was a 100% increase in VTA extracellular ACh during the self-stimulation period in 5 out of 5 animals. At a lower current, just above threshold for self-stimulation, ACh increased 40%. Similar results were obtained with automatic, non-contingent LH stimulation.

Atropine infused into the VTA by reverse dialysis in the same rats inhibited self-stimulation completely. These two experiments that (1) measure ACh and (2) block ACh receptors suggest that a cholinergic input to the VTA is important for hypothalamic self-stimulation. Apparently ACh neurons project from the midbrain and pons to the VTA carrying information necessary for the reinforcement of instrumental behavior as seen in the self-stimulation phenomenon. ## 271.3

EFFECTS OF ADENOSINE A2 RECEPTOR-SELECTIVE LIGANDS ON BRAIN STIMULATION REWARD THRESHOLDS IN THE RAT. B.A. Baldo\* and G.F. Koob. Dept. of Neuropsychopharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The nucleoside adenosine exerts inhibitory effects upon neural function throughout the brain. Several cell-surface G protein-linked adenosine receptors have been cloned which differ from one another in their pharmacologic binding profiles, regional distributions, and purported roles in behavioral regulation. The high-affinity adenosine A2a receptor exhibits the highest degree of specificity in its anatomical distribution within the brain, being highly expressed in nucleus accumbens, olfactory tubercle, and striatum. Within striatum, A2a receptors are co-localized with D2 receptors on striatal output neurons, where they are thought to exert a negative modulatory influence upon dopaminergic function. In accordance with that hypothesis, agonists selective for A2 receptors exhibit dopamine antagonist-like effects in several behavioral assays. In order to assess the role of adenosine A2 receptors in modulating reward-related behavioral performance, the effect of a selective A2 receptor agonist, CGS 21680, and a selective A2 receptor antagonist, 8-(3-chlorostyryl)caffeine (CSC), on brain stimulation reward (BSR) thresholds was assessed. In accordance with the hypothesis that A2 agonists exert dopamine antagonist-like effects, CGS 21680 (0.1-1.0 mg/kg) significantly elevated BSR thresholds at doses which did not affect response latency or extra responses. In contrast, CSC (0.01-10.0 mg/kg) did not have any significant effects on BSR thresholds, extra responses, or response latency. These results suggest that stimulation of A2 receptors modulates central reward processes in the rat. This effect may be due to the interaction of the adenosine system with dopaminergic function. ALTERATIONS OF REWARDING BRAIN STIMULATION AND CENTRAL MONOAMINES ASSOCIATED WITH CYTOKINE ADMINISTRATION. L. Kokkinidis\*, C. Song, Z. Merali & H. Anisman. Dept. of Psychology, Univ. of Saskatchewan, Saskatoon, Canada, School of Psychology, University of Ottawa, Ottawa, Canada, Institute of Neuroscience, Carleton University, Ottawa, Canada.

Cytokines released from activated immune cells may serve as messengers between the immune and central nervous system. Indeed, cytokines have been shown to influence endocrine and transmitter functioning, and may thus come to induce behavioral alterations. In the present investigation we demonstrate that interleukin (IL)-2 provokes a relatively sustained disruption of responding for rewarding brain stimulation from the medial forebrain bundle. Systemic IL-1 $\beta$  administration likewise induced a disruption of responding, but this effect was less marked than that induced by IL-2, and was relatively transient. In contrast to these treatments, IL-6 was without effect on responding for rewarding brain stimulation. Since, the rewarding value of lateral hypothalamic brain stimulation may involve DA activity within the nucleus accumbens, DA release was assessed in freely moving rats following cytokine treatment. Both IL-2 and IL-6 provoked marked inhibition of DA release from the accumbens, while IL-1 had little effect in this respect. Administration of IL-1 and IL-6 both were found to increase interstitial 5-HIAA, whereas IL-2 had no effect. Evidently, although cytokines have marked central amine effects, the alterations of responding for rewarding stimulation cannot simply be attributed to variations of accumbal DA activity.

## 271.7

SELF-INFUSION OF D1 AND D2 AGONISTS INTO THE NUCLEUS ACCUMBENS OF RATS. S. Ikemoto\*, B.S. Glazier, J.M. Murphy, and W.J. McBride. Inst. of Psychiatric Res., Dept. of Psychiatry, Indiana Univ. Sch. of Med. and Dept. of Psychology, Purdue Sch. of Sci., IUPUI, Indianapolis, IN 46202.

The dopamine (DA) system within the nucleus accumbens (ACB) has been strongly implicated in brain reward processes. Rats self-administer amphetamine directly into the ACB and exhibit conditioned place preference following microinjection of DAergic agonists into the ACB. The objective of the present study was to examine the involvement of D1 and D2 receptors within the ACB in rewarding processes using the intracerebral self-administration paradigm. Rats ( $n = 7$ ) were given the opportunity to self-infuse one of the following into the shell region of the ACB (100 nl/infusion): artificial CSF, the D1 agonist SKF 38393 (SKF, 0.5 and 1.0 mM), the D2 agonist quinpirole (QUIN, 0.5 mM), or the combination of 0.5 mM SKF and 0.5 mM QUIN. During the 3 hour session, the mean self-infusions ( $\pm$ SEM) were 11.9 ( $\pm$ 1.5) for artificial CSF, 14.6 ( $\pm$ 2.7) for 0.5 mM SKF, 14.3 ( $\pm$ 3.1) for 1.0 mM SKF, 11.5 ( $\pm$ 3.1) for 0.5 mM QUIN, and 29.4 ( $\pm$ 3.4) for 0.5 mM SKF plus 0.5 mM QUIN; rats obtained statistically more infusions of the SKF/QUIN mixture than any of the other solutions,  $p < 0.01$ . Six out of 7 rats, when receiving the SKF/QUIN mixture, responded more on the lever that produced infusions than on the control lever that had no consequence. These results suggest that simultaneous activation of D1 and D2 receptors within the ACB shell produces a more potent rewarding effect than the activation of either receptor subtype alone. (Supported by the NIAAA, AA09619)

## 271.4

ENHANCED REWARD OF VENTRAL TEGMENTAL AREA SELF-STIMULATION OBSERVED WITH AMPHETAMINE INJECTIONS INTO THE CORE, BUT NOT THE SHELL, OF THE NUCLEUS ACCUMBENS. K. L. Sweet and D. B. Neill\*. Department of Psychology, Emory University, Atlanta, GA 30322.

Amphetamine injections into the nucleus accumbens have been shown to increase the number of responses in intracranial self-stimulation (ICSS) of the ventral tegmental area (VTA). We used a rate independent method of ICSS -- autotitration self-stimulation, to examine this phenomenon. In our version of autotitration, the intensity of the stimulation dropped 3  $\mu$ A every fifth lever press. A single response on a separate lever reset the intensity back to an individually determined maximum. Sprague-Dawley rats bearing electrodes in the VTA were trained on this procedure. Intra-accumbens injections of amphetamine sulfate (2.5, 5, and 10  $\mu$ g in 1  $\mu$ l) were made just prior to VTA ICSS sessions. Our findings showed that amphetamine injections into the core region of the nucleus accumbens, but not the shell, lowered the mean reset intensity. This was interpreted as reward enhancement.

## 271.6

PEDUNCULOPONTINE TEGMENTAL LESIONS AND MEDIAL FOREBRAIN BUNDLE SELF-STIMULATION. M. Waraczynski\* and M. Perkins. Dept. of Psychology, Univ. of Wisconsin-Whitewater, Whitewater, WI 53190.

Many studies of the neuroanatomical substrate supporting medial forebrain bundle (MFB) self-stimulation have involved lesioning forebrain targets suspected of contributing to that substrate. These lesions have had mixed success in revealing brain areas important to conducting the reward signal generated by MFB stimulation. This study investigated the role of a midbrain region, the pedunculopontine tegmentum (PPT). Monopolar stimulating electrodes were implanted in the lateral hypothalamus (LH) and ventral tegmental area (VTA) of male rats. At the same time, a lesioning electrode was implanted in the PPT area. The rats were trained to self-stimulate at both the LH and VTA sites, where possible, and baseline rate-frequency data were collected at three stimulating currents (typically 200, 400, and 800  $\mu$ A) on a daily basis, until the frequency required to maintain half-maximal responding stabilized around some central value. The PPT lesion was then made by passing 300  $\mu$ A of anodal current through the lesioning electrode for 60 seconds. In some cases these lesions resulted in modest but stable upward shifts in the frequency required to maintain half-maximal responding, at both the LH and VTA stimulation sites. This suggests that PPT lesions remove some part of the substrate supporting the rewarding effect of MFB stimulation.

This research is supported by FIRST grant #MH52588 from the National Institute of Mental Health to the first author.

## 271.8

TOWARDS A DOSE-RESPONSE ANALYSIS OF INTRACRANIAL DRUG SELF-ADMINISTRATION. J.R. Stellar\*, J. Chevette, & G. W. Hesse. Department of Psychology, Northeastern University, Boston, MA, 02115.

In an advance over the intracranial drug self-administration (ICSA) pump previously reported (Stellar & Lindenfeld *Neurosci. Abstr.* 1994), we have developed a new pump based on a small stepper motor that drives a threaded plunger into a Delrin block to expel 10  $\mu$ l of fluid through PE tubing. The tubing is connected to a 30g stainless steel injector tip that is inserted through a guide cannulae into the accumbens of the rat brain. A Plastic One lead provides a head anchor for and mechanical support to the drug containing tubing.

Amphetamine (1.66  $\mu$ g/injection) is self-infused by pressing a trans-illuminated response key on a VI-3 second schedule. After a drug injection is earned a 3 minute black out period occurs during which the key light is out and responding is ineffective. When the key light is again illuminated, the first ICSA response starts up the VI. In 30 or 60 minute sessions, rats are observed to respond up to 300 responses per hour during the VI schedule time, some 10 times what had been previously reported. When the amphetamine was discontinued, ICSA behavior underwent extinction followed by re-acquisition when the drug was reinstated.

Having established high rates of ICSA responding, we are now attempting to create an effective dose-response curve allowing an ED-50 analysis of drug reward potency that is much like that seen with electrical self-stimulation in the standard rate-frequency curve.

## 271.9

VENTRAL PALLIDUM SELF-STIMULATION (VP-SS) FOLLOWING MORPHINE INJECTED, EITHER SYSTEMICALLY OR INTO THE MESOLIMBIC DA SYSTEM. G. Panagis\*, A. Kastellakis and C. Spyrali. Lab. Pharmacology, Dept. Basic Sciences, School of Medicine, University of Crete, Heraklion 71110, Greece.

The dopaminergic and enkephalinergic systems have been known to modulate brain stimulation reward. Recently we reported that VP-SS is influenced by pharmacological manipulations of the DA neurotransmission (Panagis and Spyrali, 1996, Psychopharmacology, 123: 280-288). We have also shown that enkephalinergic-DAergic interactions exist between the pallidum and the NAC (Anagnostakis and Spyrali, 1994, Brain Res. Bull., 34: 275-282). In the present study, the influence of morphine on VP-SS was assessed using the curve-shift paradigm. Rats received treatment with morphine administered either systemically (1.25; 2.5 mg/kg, i.p.) or into the VTA (1.25; 2.5; 5.0 µg/0.5 µl/site) or the NAC (0.625; 1.25; 2.5; 5.0; 10.0 µg/0.5 µl/site). The effects of the different doses of the drug on threshold and asymptotic rate were determined immediately or one hour after administration and for a period of 1-3 hours. We observed that systemic morphine at only one dose (1.25 mg/kg, i.p.) significantly increased (25-30%) the VP-SS threshold but not the bar-pressing rate. Morphine injections into the VTA did not influence VP-SS threshold or performance. A tendency for lower VP-SS thresholds was noticed after some doses of morphine (1.25-5.0 µg) injected into the NAC. The results with systemic morphine were unexpected and point to an antagonistic effect of the drug on VP-SS reward. Furthermore the results with the intracerebral injections show that enkephalinergic manipulations within the mesolimbic DA system have a marginal effect, if any, on VP-SS reward. The results suggest that morphine lacks a facilitatory role in VP-SS. Due to the known excitatory effect of morphine on DA neurons, the results also raise questions about the involvement of DA mesolimbic system in the mediation of VP-SS reward. Supported by PENED 665 (C.S.) and a U.C. predoctoral fellowship (G.P.)

## 271.11

FOS EXPRESSION IN THE CAUDAL DIENCEPHALON AND BRAINSTEM FOLLOWING LATERAL HYPOTHALAMIC SELF-STIMULATION. A. Arvanitogiannis\*, C. Flores, and P. Shizgal. CSBN, Concordia University, Montréal, Québec, Canada H3G 1M8.

Expression of immediate early genes provides a means of visualizing activated neurons. Previously, we employed Fos immunohistochemistry to stain forebrain neurons driven by rewarding stimulation of the lateral hypothalamus (LH). In the present study, we assessed the effect of such stimulation on Fos-like immunoreactivity (FLIR) in the caudal diencephalon, midbrain and hindbrain. During a 1 h test session, rats worked for 0.5 s stimulation trains composed of 0.1 msec, 800-1000 µA pulses, at the minimal stimulation frequency required to maintain asymptotic responding. The rats were perfused 15 min later, and their brains were then removed and processed for FLIR. Among the areas where FLIR was greater ipsilateral to the stimulation electrode are the posterior LH, arcuate nucleus, dorsomedial hypothalamus (DMH), central gray, ventral tegmental area (VTA), pedunculo-pontine area (PPTg), pontine nuclei, locus coeruleus, and parabrachial nucleus (PBN); cells in the dorsal and median raphe nuclei were stained bilaterally. It has been proposed that transsynaptically activated neurons in the VTA and PPTg contribute to the rewarding effect of MFB stimulation. Although lesion results fail to confirm a role for DMH or PBN neurons in MFB self-stimulation, the role of many of the other groups of Fos-positive cells has not been evaluated by means of modern lesion methods.

## 271.12

THE EFFECTS OF CHOLECYSTOKININ-8 ON FEEDING AND REWARD THRESHOLDS INDUCED BY ELECTRICAL STIMULATION OF THE LATERAL HYPOTHALAMUS. S.L. Kubelka\* and C.H. Bielajew. School of Psychology, Univ. of Ottawa, Ottawa, Ontario, Canada K1N 6N5.

We had demonstrated (Society for Neuroscience Abstracts, 1991) that bombesin, a putative satiety peptide, increased thresholds for stimulation-induced feeding (SIF) without influencing self-stimulation (SS) thresholds elicited from the same electrode, suggesting that the neural pathways mediating feeding and reward are pharmacologically distinct. The present study evaluates whether cholecystokinin octapeptide (CCK-8), a related satiety peptide, has the same effect. Two groups of animals were used; those that exhibited both SIF and SS from the same lateral hypothalamic electrode, and a second group from which only SS was observed; this second group was included in order to investigate the effects of CCK-8 in a SS site that did not support feeding. The frequency thresholds associated with each current were assessed following 0, 3, 6, and 9 µg/kg intraperitoneal injections of CCK-8. The results of a randomized block anova showed no significant effect of current level or dose of CCK-8 on the frequency thresholds of either behaviour when compared to the saline condition; likewise, the SS rates varied negligibly throughout the course of the study. Others studying CCK-8 have reported a dose-dependent reduction when food intake rather than feeding threshold is measured. Unlike our earlier findings with bombesin, SIF thresholds appear to be less sensitive to the peripheral effects of CCK-8; we are currently evaluating central CCK's effects using more resolved SIF measures. [This research was funded by a Natural Sciences and Engineering Research Council of Canada grant.]

## 271.10

EXAMINATION OF AMINOGLUTETHIMIDE INDUCED SENSITIZATION OF LATERAL HYPOTHALAMIC SELF-STIMULATION (LHSS) IN FOOD RESTRICTED RATS, G.C. Abrahamsen\*, M. Kandawire and K.D. Carr. Dept. of Psychiatry, NYU Med. Ctr., New York, NY 10016.

A number of recent studies have suggested that corticosterone may play an important role in stress induced sensitization of drug effects. We have recently shown that acute decreases in circulating corticosterone have no effect on the sensitization of LHSS observed in food restricted rats. Furthermore, the steroid synthesis inhibitor aminoglutethimide further sensitizes LHSS in food restricted rats two hours following administration when blood corticosterone is back to pre-injection levels. Two experiments were conducted to examine the possible mechanisms underlying this effect. Experiment 1 demonstrated that aminoglutethimide (50 mg/kg) sensitized LHSS in food restricted rats following systemic, but not central, administration. Systemic aminoglutethimide also produced elevated serum levels of the steroid precursor pregnenolone in food restricted rats. Given that prior studies have shown that adrenocortical precursors of corticosterone can alter brain GABA<sub>A</sub> receptor activity, a second study was conducted to assess the effects of pregnenolone and progesterone on LHSS in food restricted and control rats. Systemic administration of pregnenolone and progesterone (.1, 1 and 10 mg/kg each) each failed to affect LHSS in food restricted or control subjects. Current studies examining the opioid and GABAergic contribution to aminoglutethimide sensitization of LHSS in food restricted rats will be discussed.

## 271.12

REWARDING EFFECTS OF INTRA-ACCUMBENS INJECTIONS OF TESTOSTERONE. A. Cornell, M. G. Packard, G. M. Alexander, & B. King\*. Dept. of Psychology, University of New Orleans, N.O., LA, 70148.

Peripheral injections of testosterone have rewarding effects in male rats as measured in a conditioned place preference paradigm, a technique commonly used to study the affective properties of drugs. The present study examined the neuroanatomical bases of the rewarding properties of testosterone by administering the hormone directly into the nucleus accumbens of male rats. On alternating days, rats implanted with bilateral cannulae in the nucleus accumbens received intracerebral injections of testosterone in a water-soluble cyclodextrin inclusion complex (0.125, 0.25, or 0.5 µg/0.5 µl), or saline immediately prior to being confined for 30 minutes to one of two compartments of a place preference apparatus. All rats received 8 days of pairings (4 hormone pairings, 4 saline pairings). On day 9 the rats were given a 20 minute test session during which they had access to all compartments of the apparatus. No hormone was injected prior to the test session. On the test day, rats spent significantly more time in the compartment previously paired with bilateral intra-accumbens injections of testosterone (0.25 and 0.5 µg/0.5 µl) than in the compartment previously paired with saline injections. The findings indicate that intra-accumbens injections of testosterone are sufficient to produce reward. The rewarding affective properties of testosterone may, in part, mediate the role of the hormone in enhancing sexual motivation. The findings also add tentative support to the hypothesis that androgenic anabolic steroids may possess addictive properties in humans.

## 271.14

TREATMENT EFFECTS OF PAROXETINE ON REWARDING MEDIAL FOREBRAIN BUNDLE STIMULATION IN RATS. A.T.M. Konkle and C.H. Bielajew\*. School of Psychology, Univ. of Ottawa, Ont., K1N 6N5, Canada.

In order to assess the self-stimulation paradigm as a potential animal model of depression in which to study the effects of the selective serotonergic re-uptake inhibitor, Paroxetine, the acute and chronic treatment effects on the thresholds obtained from rewarding medial forebrain bundle stimulation were determined. Male rats were implanted with a monopolar stimulating electrode in either the lateral hypothalamus or ventral tegmental area, and trained to self-administer rewarding stimulation. Animals received daily systemic injections of one of three doses of paroxetine, either with or without stimulation, and the third group received the same number of vehicle injections with stimulation. Threshold values were collected over a period of six hours on day 1 (acute phase); no marked difference in the thresholds were observed. The animals were tested every third day thereafter (chronic phase), for a total of ten sessions. Paroxetine produced a delayed facilitation in self-stimulation similar to the time course of the effects observed clinically. In addition, the animals' weight and food intake were monitored daily. A marked difference between the control and stimulated groups in % efficiency of food utilization, measured by calculating the ratio of weight change to food intake, was observed during drug treatment. Interestingly, this effect persisted only in animals not receiving stimulation, in that they continued to demonstrate a gradual weight loss throughout the study, while animals receiving stimulation recovered and in fact, showed a weight gain. This suggests that stimulation counteracts the anorectic effects of chronic Paroxetine treatment.

**DISCREPANCY BETWEEN RESPONSE RATE AND TIME ALLOCATION AS MEASURES OF RESPONSE STRENGTH: IMPLICATIONS FOR THE MEASUREMENT OF REWARD MAGNITUDE.** K. Conover, S. Fulton, R. D'Abramo, and P. Shizgal. CSBN, Concordia University, Montréal, Québec, Canada H3G 1M8.

The single-operand matching law relates response strength to the relative value of an experimenter-controlled reinforcer and competing sources of reinforcement not under experimental control. In deriving these relationships from first principles, Heyman assumed that response rate and time allocation are equivalent measures of response strength. To test this assumption, we examined the distribution of inter-response times (IRTs) in rats working for brain stimulation reward (BSR). If the rats divide their time between working for BSR and other activities (e.g. exploring or grooming), responses for BSR should occur in bursts, and a log-survivor analysis should reveal two populations of IRTs, a "work" distribution with a shorter mean and a "leisure" distribution with a longer mean. As the value of the experimenter-controlled reinforcer is increased, so should the proportion of IRTs belonging to the work distribution. These predictions were confirmed. However, contrary to Heyman's assumption, the mean of the work distribution increased linearly with the variable interval (VI), and response rates changed dramatically over a range of VIs where time allocation was asymptotic. These results have implications for matching-based analyses of the effects of drugs, lesions, hormones and physiological manipulations on response strength. Time allocation may prove superior to response rate as an index of the magnitude of reinforcement and the sensitivity of the neural circuitry that computes this value.

## 271.17

**PERFORMANCE FOR BRAIN STIMULATION REWARD AS A FUNCTION OF THE RATE AND MAGNITUDE OF REINFORCEMENT.** P. Shizgal, K. Conover, and A. Arvanitogiannis. CSBN, Concordia University, Montréal, Québec, Canada H3G 1M8.

The curve-shift paradigm has been used to distinguish whether drugs and lesions alter performance for brain stimulation reward (BSR) by changing the magnitude of the BSR or the performance capacity of the subject. We show that in principle, such a distinction cannot be drawn unambiguously because identical changes in the function that maps stimulation strength into response strength can be produced either by altering the rate of reinforcement or by simultaneously altering both the magnitude of BSR and the performance ceiling. These effects can be disambiguated by measuring performance as a function of both reinforcement rate and stimulation strength. We dub the resulting three-dimensional (3D) structure "the reinforcement mountain." Analysis of how the mountain shifts in the 3D space can reveal whether lesions, drugs, or physiological manipulations alter BSR before or after the output of the ("reward-growth") function that translates the electrically-induced impulse flow into the magnitude of reinforcement. Among the questions that can be addressed by means of this 3D analysis are whether basal forebrain neurons with descending medial forebrain bundle (MFB) projections constitute an early stage in the circuit subserving MFB self-stimulation and whether dopamine neurons contribute to BSR before or after the output of the reward-growth function.

## 271.16

**REWARDING BRAIN STIMULATION INDUCES ONLY SPARSE C-FOS IMMUNOREACTIVITY IN DOPAMINERGIC NEURONS**  
Iain S. McGregor\* and Glenn E. Hunt Departments of Psychology and Psychiatry, University of Sydney, NSW 2006, Australia

FOS immunohistochemistry was used to map brain areas activated by rewarding brain stimulation. Rats were implanted with monopolar electrodes aimed at the lateral hypothalamus. Prior to their first and only one-hour test session, the rats were randomly divided into three groups: self-stimulators (n=4), yoked controls (n=4) and unstimulated controls (n=6). For the self-stimulators, a nose-poke response triggered delivery of 0.5 sec pulses of brain stimulation to themselves as well as to their yoked partner in an adjacent chamber. Nose pokes did not initiate the stimulus for the yoked-controls or in unstimulated controls. In the test session, self-stimulating rats completed 1000 responses in 40 minutes (or less) and were perfused 1hr later.

A high density of FOS immunoreactivity was seen in both self-stimulators and yoked animals, but not in unstimulated controls. FOS was particularly prominent in the lateral septum, nucleus accumbens (shell), and the paraventricular, dorsomedial and lateral hypothalamus. Other less densely activated areas included the medial prefrontal cortex, the medial and lateral preoptic areas, the bed nucleus of the stria terminalis, the anterior ventral tegmental area and the locus coeruleus. Co-staining of FOS and tyrosine hydroxylase (TH) was seen in only a small proportion of A10 dopamine neurons in the VTA. FOS was also present in the retrorubral fields but not in TH positive neurons. In contrast, the FOS expressed in the locus coeruleus was co-labeled with TH indicating that almost all of these A6 neurons were activated after electrical stimulation. Other TH positive neurons that were FOS positive included many of the A5 and A7 noradrenergic neurons located in the brain stem, and a few A12 dopamine neurons in the hypothalamus. Double labelling was not present in the intra-hypothalamic dopaminergic cells (A11, A13 or A14 cells).

Thus when neuronal activation is indexed by FOS immunoreactivity, rewarding brain stimulation does not appear to preferentially activate dopaminergic neurons.

## 271.18

**REWARDING ELECTRICAL STIMULATION OF THE VENTRAL TEGMENTAL AREA ATTENUATES PAIN DURING THE FORMALIN TEST.** R.M. Anderson\* & P.-P. Rompré. Psychiatry Department, University of Montréal(Québec), Canada, H3C 3J7.

Anderson and colleagues (1995) have shown that rewarding electrical stimulation of the ventral tegmental area (VTA) abolished the aversion produced by stimulation of the nucleus reticularis gigantocellularis (Gi). Given that the Gi is involved in pain, they hypothesized that VTA electrical stimulation-induced analgesia, and the present study was designed to test this hypothesis. Male rats were implanted with a right VTA stimulating electrode and were separated into three groups: VTA-self-stimulation, VTA-trained, VTA-sham (never stimulated). Phasic and tonic pain were induced by a 0.05 ml injection of 1.5% formalin into the left or right rear paw and pain scores were rated according to the scale of Dubuisson & Dennis (1979) in each group of rats for one hour. Results show that pain scores were significantly lower in the VTA-self-stimulation compared to VTA-trained and VTA-sham rats, and the level of analgesia was not dependent upon the side of formalin injection. This analgesic effect, however, was observed only at stimulation frequencies that sustained asymptotic rates of responding. Moreover, reward thresholds were not significantly altered either during the formalin test, or the following day. These results provide evidence that rewarding electrical stimulation of the VTA has analgesic properties, a finding that may have clinical implications for the relief of chronic pain.

## BIOLOGICAL RHYTHMS AND SLEEP: CIRCADIAN RHYTHMS AND SLEEP

## 272.1

**SLEEP DEPRIVATION AND STATE COLLEGE STUDENTS.** L. Amini-Sereshtki\* and J. Allard. Biology and Psychology Departments, Worcester State College, Worcester, MA 01602.

This study was conducted to examine the effect of amount of sleep on the academic performance of randomly selected state college students. Sixty seven students were included in this study. Twenty-two and a half% reported that during weekdays they received 8-9 hours of sleep per night, 76.1% received 5-7 hours of sleep, and 1.5% less than 4 hours of sleep. On weekends, however, 28 of the 57 students (49%) received 8-9 hours of sleep per night, another 49% received 5-7, and the remaining 2% received only one to four hours of sleep per night. Sleep time was described by 62.7% as insufficient. There was a significant relationship between the frequency of difficulty in concentrating in the classroom and insufficient sleep time. Thirty five % reported that sleepiness interferes with their concentration in class at least twice per week and 6% reported that they often had difficulty concentrating in class because they were sleepy. Thirty four and a half % of the students experienced a poor examination performance due to sleepiness more than once during the academic year. Seventy % of the students worked in addition to attending school. Twenty one % worked less than 10 hours/week, 46% 10-20 hrs/wk, 29% 21-40 hrs/wk, and 4% more than 40 hrs/wk. Working was not related to whether students felt they were getting enough sleep, but the number of hours they worked was related to whether they felt they were getting enough sleep. This preliminary study suggested that insufficient sleep interferes with the students academic performance. This work was in part supported by a WSC grant to L.A.

## 272.2

**3D SPECTRAL REPRESENTATION SOFTWARE. APPLICATIONS IN HUMAN SLEEP STUDIES OF NORMAL AND TEMPORAL LOBE EPILEPTIC SUBJECTS.**

R. Fernández-Mas, A. Martínez-Cervantes, A. Valdés-Cruz, V.M. Magdaleno-Madrigal and R. Salceda\*. Div. De Invest. En Neurociencias, Inst. Mex. Psiquiatría, México, 14370 D.F.

Automatic sleep evaluation and scoring algorithms do not provide 100% reliability yet. In our sleep recordings, we need very high temporal resolution to allow the quantification of small micro-stage changes in the EEG. This is done by means of visual comparison of the power spectra distribution of each EEG channel. This method consists of a main tridimensional (3D) power spectra graph, and adjacent subbands indicating the absolute or relative power in the electrooculogram (EOG) and the electromyogram (EMG) channels, using false color spectral display. This graphical approach to the solution of the quantification of sleep, of course, depends on the operator's experience on sleep scoring, but offers more data in terms of the architecture of the Fourier coefficients as a function of time, and can be used to calibrate the band select criteria of automatic sleep scoring programs.

We used this method in normal and epileptic subjects to compare the visual manual scoring criteria with online quantification, and to measure the micro frequency-shifting of the Alpha rhythm, sleep spindles and other subtle changes in the EEG embedded rhythms. The system was designed using a SUN workstation for the graphical display and a parallel machine using DSP chips devoted to Fourier estimations in real time. This software was written using C++ SPARC compiler and the graphical generation using the X window environment.

We conclude that the on-line quantification of sleep loses some relevant data on the frequency domain. This software can be used as an aid, where high resolution in the frequency domain evolution is needed in a multi channel real time recording. Work partially supported by IMP grant #3410 and CONACyT #3605N, DGAPA-UNAM IN-202894 and PUIS-UNAM.

## 272.3

THE RELATIONSHIP OF AUDITORY STIMULATION TO THE K-COMPLEX. M.L. Brazas\*, Psychology Department, University of South Florida, Tampa, FL 33620.

Previous studies of the K-complex of stage 2 sleep in humans have failed to exclude the possibility that the K-complex is an auditory evoked response. Past work has been confounded by the ability of the subjects to hear sounds, thus raising the possibility that all K-complexes produced were the result of auditory stimulation.

This study tested the hypothesis that spontaneous K-complexes occur in the absence of auditory stimulation.

The EEG of four congenitally deaf subjects (2 male and 2 female) were recorded overnight using an ambulatory EEG recorder. An age and sex matched control group was also recorded. Both spontaneous and evoked-type K-complexes were found in all records. Sleep staging demonstrated sleep parameters consistent with a first night of lab recording. The perimental group, however, had slightly higher REM sleep percentages and shorter REM latencies than the control group. These results were also different from normative data collected. The presence of K-complexes in a group of subjects incapable of processing sounds clearly demonstrates that the K-complex cannot be an auditory evoked event.

This study was sponsored in part by Oxford Instruments, INC., Clearwater, FL.

## 272.5

VIGILANCE STAGES DURING NOCTURNAL HYPOTHERMIA IN WELL-FASTED PIGEONS. M.E. Rashtotte\*, E.L. Polyakov\*, R.P. Henderson\* and Yu.F. Pastukhov\*. <sup>1</sup> Program in Neuroscience, Dept. of Psychology, Florida State Univ., Tallahassee, FL 32306-1051; <sup>2</sup> Sechenov Institute of Evolutionary Physiology & Biochemistry, St. Petersburg, Russia.

Vigilance stages in feeding and in fasted pigeons have been reported to be similar, unlike in other birds studied (doves, geese and penguins). Fasting was more severe in the latter cases, however, and we now report that deeper fasting results in changed nocturnal vigilance stages in pigeons also. Cortical EEG, EOG, neck and pectoral muscle EMG, EKG, abdominal body temperature (Tb), and behavior were recorded for 24h periods when food was ad lib and after fasting had induced ~ 20% loss in body weight (LD 12h:12h; Ta = 21 °C). Six pigeons (~ 350g original body weight) were studied. Dark-phase electrophysiological data were scored in 1s epochs for vigilance stage: wakefulness (W), transitional stages (T), slow wave sleep (SWS), and paradoxical sleep (PS). Fasting induced about 3.6 °C decrease in nocturnal Tb (36.3 °C vs. 39.9 °C). Total sleep time/night (SWS + PS) was higher in fasting (86%) than in feeding (75.5%), and the PS/SWS ratio was lower in fasting (0.18 vs. 0.22). In fasting, W and T decreased by 75% and 20%, respectively, and SWS increased by 15%. SWS episode duration increased by 30%. The only significant change in PS occurred in one bird (a decrease from 11.4% to 8.6% per night); the other birds showed small increases or decreases. Detailed examination of Tb, vigilance stages, EKG, and pectoral EMG in different parts of the dark phase suggests interactions which might relate to energy conservation in shallow daily nocturnal hypothermia in pigeons, and also to the criteria for identifying PS in birds. The pigeon may be an interesting model system in which to study the relationship between vigilance stages and shallow torpor, and to examine the possibility that experimentally-induced larger changes in sleep stages would result in deeper torpor. Supported by NSF Grants IBN-9421924 and IBN-9222369.

## 272.7

THE EFFECTS OF TIME OF DAY AND DECIBEL ON THE ACOUSTIC STARTLE RESPONSE OF THE EGYPTIAN SPINY MOUSE, ACOMYS CAHIRINUS. C.C. Chabot\*, S.R. Boulé, and J.P. DelPrete. Department of Natural Sciences, Plymouth State College, Plymouth, NH. 03264.

Previous studies with rats have demonstrated a daily modulation of the acoustic startle response (ASR) amplitude. Until now this modulation had yet to be demonstrated in any other mammal. We report here similar findings in the Egyptian spiny mouse. ASR amplitude of male and female Egyptian spiny mice (*Acomys cahirinus*, n=11 and 5 respectively; 72-79 days old) was measured over four sessions in a twenty-four hour period. The animals were housed in an LD 12:12 cycle, 4/cage in a light-tight chamber with food available ad libitum. During testing, mice were placed individually in a 5 x 5 x 8 cm wire cage in a sound attenuated chamber where they were allowed to acclimate for ten minutes before each session. Each session consisted of 10 trials each at 80, 90, 100, 110, and 120 db (42 msec white noise) with an interstimulus interval of 22 sec. Differences between means were assessed using repeated measures ANOVA (p<0.05) and pre-planned mean contrasts. We found a significant effect of time of day and db on response amplitude. Pre-planned contrasts indicated significantly increased responses during D versus L. There was a significant effect of db, but not time of day on latency. There were no significant effects of sex on either response amplitude or latency. These results are essentially identical to those seen previously in rats and thus extends these findings to another mammalian species. Funded by the Department of Natural Sciences, Plymouth State College.

## 272.4

EFFECTS OF THE GENERAL ANESTHETIC ISOFLURANE ON GAMMA RHYTHMS AND CONSCIOUSNESS IN HUMANS.

G. Plourde, C. Villemure, P. Fiset, A. Achim, S. Backman\*. Dept. of Anesthesia, Royal Victoria Hospital and McGill University; LNC, UQAM, Montreal (Quebec) Canada H3A 1A1.

Whether gamma rhythms reflect physiological processes linked to consciousness is controversial. We examined the effects of isoflurane (ISO) on consciousness and gamma rhythms, using the 40 Hz auditory steady-state response (ASSR) in 10 volunteers (18-35 yrs). Stimuli were 500 Hz tonebursts (10 ms: 82 dB PeSPL; right ear; 35-45/sec). Consciousness was defined as responsiveness to verbal commands. EEG was recorded from Cz-M2 (0.1-100 Hz). Responses to 18,000 stimuli were averaged for each period. The periods were: baseline; ISO 0.50; ISO 0.38; ISO 0.26 (end-tidal vol% concentration with 15 mins equilibration) and recovery. ASSR amplitude (measured by FFT) ( $\mu V$ ) was [mean (SD)] 0.31 (0.26) during baseline; 0.04 (0.03) for ISO 0.50; 0.09 (0.05) for ISO 0.38; 0.28 (0.26) for ISO 0.26 and 0.29 (0.33) during recovery. Significant differences (P<0.05 - ANOVA/Tukey's HSD) were: baseline and recovery > ISO 0.38 and ISO 0.50; ISO 0.26 > ISO 0.38 > ISO 0.50. The number of unconscious subjects was 0, 4 and 9 for ISO 0.26, 0.38 and 0.50 respectively. We conclude that the concentration ranges for suppression of consciousness and maximal attenuation of the ASSR by isoflurane are similar.

## 272.6

MATERNAL DEPRIVATION ALTERS A REM SLEEP ASSOCIATED BEHAVIOR. C.M. Anderson\*, A.J. Mandell\*, K.A. Selz\*, L.M. Terry\*, S.L. Andersen\* & M.H. Teicher\*. <sup>1</sup>Dept. of Psychiatry, Harvard Med. Sch. & Developmental Biopsychiatry Research Program, McLean Hospital, Belmont, MA 02178.

<sup>2</sup>Dept. of Psychiatry & Behavioral Sciences, Emory Univ. Sch. of Med., Atlanta, GA 30322.

<sup>3</sup>Dept. of Psychology, College of Liberal Arts, Florida Atlantic Univ., Davie, FL 33314.

Periods of maternal deprivation (MD) in 2 to 10-day-old neonatal rats resulted in acute changes in spontaneous sequences of nuchal muscle atonia (NA) associated with REM sleep. We analyzed these highly variable recordings (surface EMG sampled for 2 hours @ 300 Hz) with Hurst's rescaled range analysis (Range normalized by S.D.; R/S), which affords comparisons between time series of fluctuations with non-convergent statistical moments. This analysis indicated that spontaneous fluctuations in NA in neonatal rats over short time scales was statistically similar to longer time scales (i.e., fractal in time). NA sequences in neonatal rats, which are in a REM sleep-like state > 50% of the time, were also found to be described by long-tailed convolutionally stable self-similar Lévy distributions. When neonates were subjected to 2 hours of MD, an increase of the mean length of NA and a decrease in episode number was observed over and above normal maturation changes compared with 0 hours of MD. Also a significant increase in the Hurst exponent  $F(1,24) = 5.692$ ,  $p<0.05$  and a decrease in the Lévy  $\alpha$  exponents were found (e.g., animals with 2 hours of MD collapsed across age were found to be significantly different from 0 hours of MD,  $F(1,4) = 415.028$ ,  $p<0.0001$ ) suggesting that MD changes the nature of the underlying probability density distributions resulting in more clustered behavior in time. Rats MD and cold stressed 4 hrs/day from P2 to P20, demonstrated the same differences from controls at P50 in spontaneous pauses in locomotor activity. These findings suggest that mathematical tools sensitive to subtle changes in self-similar clustering of spontaneous highly variable behaviors over multiple time scales may have utility for studying children or adults who suffered early stress, abuse or neglect. (Supported by MH-43743-07, MH-53636-01A1 the FAU foundation and ONR Biological Intelligence Div.)

## 272.8

LIGHT-DARK CYCLE MASKING OF WHEEL-RUNNING IS REDUCED IN AGED MICE. M.J. Bradbury\*, M.J.H. Kas, W.C. Dement and D.M. Edgar. Stanford Sleep Research Center, Stanford University School of Medicine, Stanford CA, 94305.

Aging leads to dampened amplitudes of entrainable circadian rhythms in rodents, possibly due to impaired photic transduction mechanisms within the SCN. While light entrains the SCN, modulation of behaviors by light-dark (LD) cycles in SCN-lesioned mammals demonstrates that neurons outside of the SCN can generate masking signals. It is not known if the transduction of LD masking is also attenuated with age. Therefore, we employed a short-day photoperiod regime to assess age-differences in light-dark masking of wheel-running activity in male, C57BL/6 mice. In LD 12:12 cycle (30 lux), 8 young (3 months of age) and 7 old (26 months of age) mice ran more during the dark phase ( $p=0.0008$  and 0.02, respectively). However, old mice ran less than young mice during the dark phase ( $p=0.0002$ ). Twenty-four hours of a LD 1:1 cycle, a photoperiod outside of the range of entrainment, (30 lux) started at former ZT 13. Young, but not old mice ran more during the former ZT 12-23 than former ZT 0-11 (young,  $p=0.0006$ ). Data from this 24 hour trial were divided into quartiles based on the former LD cycle. Running during dark pulses and light pulses was expressed as the proportion of total running in each quartile. Masking, as assessed by the inhibition of wheel-running during light, was greater in young mice than in old. Young rats ran less during the light pulses than during dark pulses in all quartiles (former ZTs: 12-17,  $p=0.0001$ ; 18-23,  $p=0.0002$ ; 0-5,  $p=0.01$ ; 6-11,  $p=0.04$ ). Old mice ran less during light pulses than during the dark pulses corresponding to the former ZT hours of 18-23 ( $p=0.001$ ) and 6-11 ( $p=0.04$ ) only. Thus, LD 1:1 fragments the waveform of wheel-running in aged mice more than in young mice. In addition, inhibition of running during 1 hour light pulses was attenuated in aged mice. Supported by AG06490.

## 272.9

THE EFFECT OF TIME OF TESTING ON THE BEHAVIOR OF RATS AS DETERMINED IN A DRUG DISCRIMINATION PARADIGM. E. Fisher\* and B.L. Stringer, Pharmaceutical Sciences, SW OK State Univ., School of Pharmacy, Weatherford, OK 73096

It is well known that a large number of drug effects are influenced by circadian rhythms, and that rats can be trained to discriminate phencyclidine from saline. The research performed was designed to determine if the time of day that testing occurred would effect the learning of rats trained in a drug discriminative stimulus paradigm. Twelve rats were divided into two equal groups designated as AM and PM. The AM group was injected at the beginning of a 12 hour light cycle; the PM group at the end of this cycle. Following a double alternation schedule, rats were injected with 2 mg/Kg of phencyclidine or physiological saline. Rats underwent daily 15 minute training sessions Monday through Friday in a modified Skinner box containing two levers. Reinforcements were obtained on a fixed-ratio schedule of 32 with only the phencyclidine appropriate, or the saline appropriate lever activated. Training continued for a total of 100 sessions. Upon statistical analyses, the PM group showed a statistically higher response rate ( $P=0.028$ ), and a higher percent correct lever responding ( $P=0.001$ ) when injected with saline than did the AM group. The AM group showed a statistically higher response rate ( $P=0.005$ ), and a higher percent correct lever responding ( $P=0.020$ ) when injected with phencyclidine than did the PM group. These results indicate a definite circadian influence on the effects of phencyclidine as measured in this drug discrimination paradigm.

This project was financially supported by a Southwestern Oklahoma State University School of Health Sciences Research Grant.

## 272.11

CIRCADIAN ACTIVITY IN THE MONGOLIAN GERBIL: BOTH NOCTURNAL AND DIURNAL RHYTHMS. J. Hallonquist\*, P. Gray-Allan, T. Lao and R. Wong, Dept. Psychology, Univ. British Columbia, Vancouver, B.C., Canada V6T 1Z4.

Because reports of circadian rhythms in *Meriones unguiculatus* conflict, we monitored wheel-running in LD 12:12 -- first in 34 gerbils from Tumblebrook Farms. The last of 6 wks indicated 21 to be nocturnal (N), 5 to be diurnal (D), and 8 to be "questionable" ("?)") due to inactivity or unstable phase, thus confirming existence of both night- and day-active gerbils of each sex.

Second, after 10 wks in LD 12:12, 15N & 10D gerbils were exposed to an 8-hr delay of the LD cycle. Except for 2N gerbils reclassified as "?", all maintained phase positions re. to the shifted LD cycle for 7 wks, often with delaying transients. Thus N & D rhythms reflect circadian differences rather than mere inverse masking.

Finally, we monitored another 10N & 6D gerbils for 22 wks. Phase positions remained stable, despite restriction from running during wks 18 & 19 in 6N & 4D animals. Only 2 (1N, 1D) changed -- to "?" before wheel restriction. Thus it appears unlikely that differences in feedback from activity to the circadian oscillator are alone responsible for N and D rhythms in gerbils.

Studies of heredity/environment interaction and physiological mechanisms determining phase position in gerbils may increase understanding of circadian regulation and its dysfunction. Support: MRC of Canada grant to JH.

## 272.10

EFFECTS OF ACUTE STRESS ON THE CIRCADIAN CYCLE OF VIGILANCE IN THE RAT: AN INTER-INDIVIDUAL ANALYSIS. J.J. Bouyer\*, J.M. Deminière, W. Mayo, H. Simon and M. Le Moal, INSERM U.259, Université de Bordeaux II, 33077 Bordeaux Cedex, France.

Acute stress is given to modify circadian rhythmicity and stress hormones such as glucocorticoids and melatonin are involved in vigilance cycles. Sleep-wakefulness parameters are submitted to inter-individual differences and they have been used to characterize individuals -animals and humans- into "early vs. late subjects" and "short vs. long sleepers", their combination defined for a given individual a relatively stable structure which define a stable relation between the parameters across time. The aim of the present study was to verify the existence of such structure in the laboratory rat, to test the effect of acute stress and to examine whether after stress the individual was able to recover its pre-stress parameters. Intra-individual stability and inter-individual variability were assessed through four circadian parameters: 24 hr mean quantity of wakefulness ( $25.3 \pm 0.6$  min/h), amplitude of cycle ( $15.2 \pm 0.9$  min/h), beginning time of active period ( $19:18 \pm 12$  min) and its duration ( $8$  hr  $49$  min  $\pm 27$  min). The parameters remained unchanged during three recordings and even if environmental factors such as an immobilization stress (IS) transiently modified them, they returned to baseline values some days later. IS induced a phase advance of beginning time of the active period ( $17:30 \pm 42$  min,  $p < 0.05$ ) and increased its duration ( $10$  hr  $05$  min  $\pm 27$  min,  $p < 0.05$ ). Inter-individual differences between short and long sleepers ( $p < 0.001$ ) was faded after IS (ns): short sleepers slept more, long sleepers slept less. These modifications were attributed to the stress, without any implication of the sleep deprivation inherent to immobilization. To sum up, in all subjects, stress induced phase advance and lengthened the active period. However, inter-individual analysis evidenced a stress effect on the wakefulness quantity different according to subjects.

## 273.1

TOPOGRAPHICAL DISTRIBUTION OF THETA WAVES AND DESYNCHRONIZATION ON CORTICAL SURFACE IN DESYNCHRONIZED SLEEP OF THE RAT. <sup>1</sup>L.V. Venturini, <sup>2</sup>G. Ballester, <sup>1</sup>K. Sameshima and <sup>1</sup>C. Timolaria\*, <sup>1</sup>Univ. São Paulo School of Medicine; <sup>2</sup>Fed. Univ. São Paulo Medical School (EPM). 01246-903 São Paulo SP, Brazil.

The theta waves and the desynchronization occur in the alert wakefulness and in the dreaming activity, where the spectra of these rhythms change in relation to the behavior type and in relation to the different cortical areas. This study aimed at realizing the electro-oscillographic mapping of the cortical surface during wake and dreaming activity to develop the hypothesis of that each rhythm is associated with a phylogenetic age of the specific cortical areas and represent different degrees of attention. The electro-oscillograms are obtained by intra-muscle electrodes, for the monitoring of the behavior type, and cortical electrodes, arranged as matrices and implanted by stereotaxy on the cortical surface of Wistar rats. In the phylogenetically older areas, theta waves are recorded during wake and dreaming activity, with frequency and extent of the theta relating with the intensity and the type of attentive behavior. In the frontal cortex (area 10), that is a more recent phylogenetic acquisition than posterior areas, a desynchronization is recorded. Areas of electro-oscillographic transition are observed in the posterior portion of the area 10, area 6 and frontal portion of the areas 3 and 4, where subtle change in the spectral pattern occurs at neighboring coordinates belonging to the same cytoarchitectonic area. It is concluded that the desynchronization is a command signal phylogenetically more recent than the theta rhythm, and that both mobilize specific neuronal groups. The increase of the theta rhythm frequency tending to the desynchronization, in transitional areas, reflects the functional affinity of these areas with the frontal cortex and shows the relation of the desynchronization with higher degrees of attention.

## 273.2

CHANGES IN PROTEIN PHOSPHORYLATION PATTERNS IN THE BRAIN DURING THE SLEEP-WAKING CYCLE. C. Cirelli\* and G. Tononi, The Neuroscience Institute, San Diego, CA 92121

Sleep and waking are associated with strikingly different behavioral and electroencephalographic patterns. Little is known, however, concerning differences between these two states at the cellular level. Cellular responses to many extracellular signals occur through changes in phosphorylation of intracellular proteins, which depend on a precise equilibrium between the activity of protein kinases and phosphatases. In this study, we used antibodies suited to the immunocytochemical detection of proteins phosphorylated on serine, threonine (Zymed), and tyrosine (Transduction Lab) residues to determine whether changes in cellular phosphorylation patterns accompany the electrophysiological changes occurring during the sleep-waking cycle. WKY rats implanted for chronic polysomnographic recordings were sacrificed during the light period after either 3h of sleep (S-L, n=6) or 3h of gentle sleep deprivation (W-L, n=6). In all cases, the levels of protein phosphorylation on both serine and threonine residues were markedly higher in rats sacrificed after 3h of waking than in rats sacrificed after 3h of sleep, particularly in the cerebral cortex. In two animals (W-L and S-L), the calcium chelator BAPTA AM (Calbiochem) was added during the perfusion in order to block phosphatase 2B activity, but the difference in serine and threonine phosphorylation levels between waking and sleep was still present. With the anti-phosphotyrosine antibodies used in this study (a polyclonal and a monoclonal), the staining of microglial cells masked that of neurons, and changes in neuronal tyrosine phosphorylation were difficult to determine. In another series of experiments, we asked whether the increase in protein phosphorylation during waking was due to changes in the activity of neuromodulatory systems with diffuse projections, such as the noradrenergic locus coeruleus (LC), which are highly active during waking and less active during sleep. Unilateral lesions of LC were produced by local injection of 6-hydroxydopamine (see Tononi et al., this meeting). In animals sacrificed after 3h of spontaneous or forced waking (n=6), phosphoserine and phosphothreonine staining in the cerebral cortex was high on the side in which noradrenergic fibers were still present, and low on the lesioned side. These results suggest that the release of norepinephrine, which is high during waking and low during sleep, is a major factor determining the increase of protein phosphorylation that is observed during waking. ## 273.3

CHANGES IN GENE EXPRESSION BETWEEN WAKEFULNESS AND SLEEP REVEALED BY mRNA DIFFERENTIAL DISPLAY. M. Pompelano\*, C. Cirelli, and G. Tononi. The Neurosciences Institute, San Diego, CA 92121

The expression of the immediate early genes *c-fos* and *NGFI-A* is powerfully modulated during the sleep-waking cycle. The protein products of these genes can act as transcription factors, suggesting that the expression of other genes may also be modulated by sleep and waking. In this study we employed a modified version of mRNA differential display (DD) to systematically investigate changes in gene expression between sleep and waking. WKY rats were implanted for chronic polysomnographic recordings. To distinguish among genes whose expression is related to sleep and waking *per se*, and genes expressed in relation to circadian factors or stress, 3 groups of rats were considered. A first group (S-L, n=7) was sacrificed after 3h of sleep during the light period. A second group was sacrificed after 3h of sleep deprivation during the same circadian period (W-L; n=7). A third group (W-D, n=6) was sacrificed after 3h of spontaneous waking during the dark period. Total RNA was isolated from the cerebral cortex and reverse transcribed. cDNAs of each individual animal were amplified by PCR in the presence of  $\alpha$ -33P dATP (Dupont), by using one out of three 3' composite anchor primers E1T12M (E1=5'CGGAATTCGG, M=A, C, or G) and one out of twenty-seven 20mers 5' composite arbitrary primers. PCR products for each animal were run in duplicate on denaturing polyacrylamide gels. Dried gels were exposed to X-ray film and autoradiographs were scanned using a phosphorimager. So far, 20 combinations of 3' and 5' primers have been examined, and 13 differentially expressed bands have been identified. Eight bands were expressed more in W-L and W-D rats than in S-L rats, 4 bands were expressed more in S-L rats than in W-L and W-D rats, and 1 band was expressed more in S-L and W-L rats than in W-D rats. Six out of the 13 bands have been subcloned into the pCRII vector (Invitrogen). *In situ* hybridization to confirm the cloned bands and nucleotide sequence analysis are being performed. These results indicate that the expression of several genes is modulated by the physiological sleep-waking cycle. The identification of these genes may help elucidate the functional consequences of sleep and waking. (Supported by Neurosciences Research Foundation).

## 273.5

NEURONS WITH REM-SELECTIVE DISCHARGE ARE PRESENT IN THE TRAPEZOID BODY IN FREELY BEHAVING CATS. Mahesh M. Thakkar\*, Priyattam J. Shiromani, Donald G. Rainnie and Robert W. McCarley. Dept. of Psychiatry, Harvard Medical School, Brockton VA Med. Ctr., Brockton, MA 02401, USA.

Auditory stimulation is known to enhance REM sleep. The trapezoid body has been implicated to have a crucial role in brainstem auditory processing. However, no existing studies have looked at the firing properties of neurons in the trapezoid body across behavioral states. Hence, we recorded single units from this region across behavioral states, in freely behaving, naturally sleeping cats. Male adult cats, anesthetized with an intravenous injection of sodium pentobarbital (35 mg/kg), were implanted with chronic sleep recording electrodes and a mechanical microdrive containing two cannulae in which two bundles of seven insulated flexible stainless steel microwires (32  $\mu$ m) were inserted. Seven to ten days were allowed for the animals to recover from surgery before the recordings were started. The microwires were advanced in steps of 25-50  $\mu$ m until a single neuron spike with a signal to noise ratio of at least 3:1 was encountered. The unit activity was continuously monitored to rule out artifacts. Recording sites were histologically verified. Polygraphic records were classified into five different states: active wake (AW), quiet wake (QW), slow wave sleep (SWS), REM sleep without eye movements (REM-) and REM sleep with eye movements (REM+). The firing pattern of all the neurons were then categorized in relation to these behavioral states. A total of 43 neurons were recorded. Preliminary results indicate that all the neurons recorded showed alterations in their firing pattern with behavioral states. Out of 39 neurons analyzed 18 (46%) showed increased firing during REM sleep, 19 (49%) showed increased firing during both waking and REM sleep and 2 (5%) neurons showed decreased firing during REM sleep. Supported by NIMH grant MH39683, Dept. Vet. Affairs.

## 273.7

THE EFFECTS OF 192 IgG-SAPORIN LESIONS OF THE BASAL FOREBRAIN CHOLINERGIC NEURONS ON THE CORTICAL EEG DURING DIFFERENT BEHAVIOURAL STATES IN RAT. W.J. Fortin\* and K. Semba. Dept. of Anat. & Neurobiol., Dalhousie Univ., Halifax, N.S. B3H4H7 Canada.

Basal forebrain cholinergic neurons are thought to play an important role in cortical EEG desynchronization. Noradrenergic and serotonergic neurons are also implicated for a similar role during waking; however, these neurons are quiescent during REM sleep and therefore cannot account for EEG desynchronization in that state. We examined whether selective lesions of the cholinergic basal forebrain neurons differentially affect the frequency content of the EEG in REM sleep and waking in freely behaving rats. Rats were microinjected with 192 IgG-saporin (100ng/0.2 $\mu$ l) into the right basal forebrain and were chronically implanted with EEG and EMG electrodes. The animal's activity and behavioural state were observed and noted during recording sessions. The FFT power spectra were computed between DC and 100Hz for 16s EEG epochs. AChE histochemistry revealed almost complete depletion throughout the ipsilateral cortex. Inspection of EEG records together with the FFT indicates the following preliminary results. Large amplitude slow wave bursts (3-6Hz; 2-8s duration) were present intermittently during active exploration. Similar bursts were occasionally seen during REM sleep, although they were much less prevalent. In general no obvious changes were seen in the delta component of the EEG during REM sleep; however, there was an apparent reduction in power in the beta and gamma ranges. These reductions were not seen during active exploration. These data suggest that selective lesions of the basal forebrain cholinergic neurons reduce the high frequency components of the cortical EEG in REM sleep and induce intermittent slow activities in the waking cortical EEG. The lack of dramatic slowing of the EEG in REM sleep suggests that even in the absence of cholinergic, noradrenergic and serotonergic inputs, mechanisms exist to induce cortical EEG desynchronization. ## 273.4

CORRELATION OF SLEEP STATES WITH EXPRESSION LEVELS OF IMMEDIATE EARLY GENES IN THE RAT CEREBRAL CORTEX.

C. Paylides\*, S. Ribeiro and C. Mello. The Rockefeller University, New York, NY, 10021.

It is known that sleep deprivation leads to increased levels of the immediate early gene (IEG) *NGFI-A* in various brain regions, whereas long periods of sleep decrease *NGFI-A* levels. However, the specific contributions of slow-wave sleep (SWS) and rapid-eye movement-sleep (REM) are unknown. Our primary goal was to compare the expression patterns of the plasticity-related IEGs *NGFI-A*, *NGFI-B* and *Krox-20* in the rat brain after wakefulness (WK), SWS or REM. Adult male rats were chronically implanted with electrodes in the dentate gyri for EEG recording. After a 5-day recovery period, each rat was placed inside an isolation box where behavior was observed and EEG recorded in order to identify WK, SWS or REM. Thirty minutes after engaging in one of these states animals were decapitated and their brains processed for *in situ* hybridization. We found a decrease in cortical expression of all three genes in the REM group when compared to WK animals, while SWS rats exhibit intermediate levels. The results show a correlation between REM sleep and low expression levels of early genes thought to be involved in neuronal modification. We speculate that this gene expression pattern may represent a generalized and transient decrease of plasticity in the cortex during REM. To test whether this phenomenon is related to sleep-mediated memory processing, rats exposed to enriched environment prior to sleep are presently being studied.

## 273.6

State-dependent discharge of neurons in the rat posterior hypothalamus.

T. L. Steininger\*, Md. N. Alam, R. Szymusiak and D. McGinty V.A. Med Ctr., Sepulveda, CA 91343; Depts. of Med. and Psych., UCLA, Los Angeles, CA.

The posterior hypothalamus (PH) has long been thought to be important for the maintenance of waking, since Von Economo described neuropathology in this region resulting in a profound and persistent somnolence. The role of this region in the control of EEG arousal is supported by lesion studies in several species. The histaminergic tuberomammillary nucleus (TM), in the ventral PH has diffuse projections throughout the brain. Histamine has potent effects on arousal. Studies in the unanesthetized cat have shown that TM neurons fire in relation to waking, i.e. they are nearly silent in non-rapid eye-movement (NREM) and REM sleep, whereas PH neurons fire in correlation with complex movements, and fire at peak rates during both waking and REM sleep. To date, these findings have not been replicated in the rat.

In the present study, chronic single-unit recording techniques in the freely-moving rat were utilized to investigate the state-dependent firing of PH and TM neurons. Our results agree with findings in the cat, i.e. histaminergic TM neurons fired at a tonic rate during waking, ceased firing prior to the onset of NREM sleep (and EEG synchronization), and did not fire during REM sleep. Several classes of PH neurons were observed. The majority were tonically active at low rates during waking (0.5-2 Hz), fired at even lower rates during NREM, and fired at waking rates during REM (36% of cells). Another class of PH neurons fired at higher rates (10-15 Hz) in relation to waking movements, slowed their firing during NREM sleep, and increased their firing rates during REM sleep (24% of cells). Other cells recorded in the region dorsal to TM had irregular activity which was either a combination of tonic and movement related activity, or unrelated to behavioral state. (Supported by Dept. Veterans Affairs, and HHS MH47480)

## 273.8

CARBACHOL INFUSION INTO THE MEDIAL PONTINE RETICULAR FORMATION OF RATS ENHANCES REM SLEEP. G. A. Marks\* and C. G. Birabli. Dept. of Psychiatry, Univ. of Texas Southwestern Med. Center, Dallas, TX 75235

Micro injection of the cholinergic agonist carbachol into the medial pontine reticular formation of cats produces long lasting and dramatic increases in the time spent in REM sleep. Similar studies utilizing rat have thus far failed to reach a consensus as to the most efficacious site of infusion or dose infused. Carbachol effects on REM sleep, when found, also are typically much less dramatic than that reported for cat. Preliminary to an investigation of the mechanisms of cholinergic induction of REM sleep in the rat, we sought to determine whether manipulating time of day and bilateral versus unilateral infusions might lead to an increase in the magnitude of the carbachol effect.

Under anesthesia, Long-Evans Hooded rats were surgically prepared for chronic sleep recording and additionally implanted with bilaterally symmetric guide cannulae. Cannula-pairs were aimed at medial sites through the anterior-posterior extent of the pontine reticular formation. After one week recovery from surgery, animals were adapted to the unrestrictive, recording environment were they remained tethered for the duration of the experiment. Starting during adaptation, each animal was handled for at least five minutes every day at the time of day of drug infusion. A 60 nl volume of carbachol (0.5 $\mu$ g, 50ng, or 10ng) and/or saline were bilaterally administered in every combination in counter-balanced order across animals. The six hour electrographic recordings were conventionally scored in 15 sec. epochs into wake, slow wave and REM sleep.

We find that bilaterally injected carbachol typically does not increase REM sleep beyond that of either left or right unilateral injections and, most often, leads to less of an increase or to a decrease compared to saline control values. Time of day is a variable influencing the effect of carbachol on REM sleep. Diminished effects were found with mid-light period infusions. Increases in REM sleep were greater when infusions occurred at one hour before lights-out and tended to be even greater at lights-on but accompanied by increased variability.

## 273.9

**STEREOTYPED PATTERN OF SUPPRESSION OF UPPER AIRWAY MOTOR TONE DURING THE CARBACHOL-INDUCED, REM SLEEP-LIKE ATONIA.** L. Kubin, V. Fenik, A.I. Pack and R.O. Davies\*. University of Pennsylvania, Philadelphia, PA 19104.

We have previously shown that microinjections of carbachol into the rapid eye movement (REM) sleep-triggering region of the dorsal pontine tegmentum of decerebrate cats produce, in addition to postural atonia, a stereotyped suppression of respiratory motor output to respiratory pump muscles (diaphragm, and inspiratory/expiratory intercostals), and a profound suppression of hypoglossal (XII) nerve activity (Kimura et al., J. Appl. Physiol., 68: 1435, 1990). EMG recordings in humans and chronically instrumented animals suggest that the magnitudes of suppression present in distinct upper airway muscle groups during natural REM sleep also follow a stereotyped pattern. To assess this, we recorded the efferent activities of the vagus, recurrent laryngeal (RL), pharyngeal branch of the vagus, genioglossal branch of XII nerve, phrenic and a C4 branch innervating postural neck muscles in decerebrate, paralyzed, vagotomized and artificially ventilated cats. Pontine injections of carbachol were performed to produce postural atonia and respiratory depression and atropine injections to reverse the carbachol effects. There was a differential pattern of the carbachol-induced suppression among the upper airway nerves studied (4 cats, 7-11 measurements of the change in activity of different nerves). The inspiratory activity of the XII nerve was suppressed the most (to about 12% of the control), followed by the pharyngeal expiratory activity (about 24%), inspiratory RL nerve activity (about 56%) and phrenic (about 66%). This pattern, albeit exaggerated, is consistent with that observed during natural REM sleep. (HL42236)

## 273.11

**THE EFFECTS OF TEMPERATURE AND SYNAPTIC BLOCKADE *IN VITRO* ON NEURONS OF THE HORIZONTAL LIMB OF THE DIAGONAL BAND OF BROCA IN THE RAT BASAL FOREBRAIN.** T. Hays\*, S. Moraitis, R. Szymusiak and D. McGinty. Neurophysiology Lab, V.A.M.C. (151A3), Sepulveda, California 91343

Since sleep and thermoregulation appear to be coupled in the preoptic area/anterior hypothalamus (POAH) and because the horizontal limb of the diagonal band of Broca (HDB) has sleep regulatory functions similar to those in the POAH, we examined the thermosensitivity of HDB neurons. Using a microwire electrode (15  $\mu$ m wire, 2 M $\Omega$  impedance), we studied the thermosensitivity of rat HDB neurons *in vitro* under normal conditions and under conditions of a low calcium-high magnesium synaptic blockade (SB). Of 52 HDB neurons tested, thirty-four neurons (65%) were warm sensitive (WS), three (6%) were cold sensitive (CS), eleven (21%) were temperature insensitive (TI) and four (8%) were both warm and cold sensitive (WS/CS). Of 34 neurons tested for thermosensitivity under SB, 11 were WS, 4 were CS and 19 were TI. Nearly half (48%) of the WS neurons maintained warm sensitivity under SB, 43% became TI and 9% became CS. Baseline firing rates of neurons significantly decreased during SB and then increased during recovery from SB. In addition, a distinct anatomical distribution of thermosensitive neurons was found in the HDB. The most ventral aspect of the HDB (interaural +0.9-1.3 mm) had proportionally fewer temperature sensitive neurons than areas more dorsal (interaural +1.3-1.7 mm), and only one of seven ventral HDB neurons remained thermosensitive during SB. In the dorsal HDB, over half of the neurons (65%) maintained thermosensitivity during SB. These results demonstrate that the HDB contains inherently thermosensitive neurons in the HDB, and may be a site at which thermosensitive neurons interact with sleep-regulatory mechanisms.

## 273.13

**HUMAN BRAIN ACTIVATION DURING REM SLEEP DETECTED BY fMRI.** J.P. Sutton\*, H.C. Breiter, J.B. Caplan, F.R. Huang-Hellinger, K.K. Kwong, J.A. Hobson and B.R. Rosen. Neural Systems Group and NMR Center, Massachusetts General Hospital, Harvard Medical School, Bldg. 149, 13th St., Charlestown, MA 02129.

We have studied ten subjects during sleep using simultaneous functional magnetic resonance imaging (fMRI) and electrophysiological measurements, including the EEG, EOG and EMG. Here, we report on visual and medial temporal cortical activation of a subject during REM sleep. The subject (m, 36 yrs) was studied for four hours using a head coil and asymmetric spin echo instancan sequence at 1.5 T (TE=20, TR=20,000). Cz (EEG), both orbits laterally (EOG) and the submental region (EMG), all referenced to a mastoid lead, were recorded. Ten contiguous 7 mm axial slices were examined, including most of the neocortex and the brainstem, and the data were motion corrected. Following two hours of sleep, an eight minute segment of REM sleep was identified, in part, by rapid eye movements on the EOG and significant eye motion relative to the head based on imaging data. Physiological motion precluded a quantitative comparison of absolute fMRI signal changes across states. However, significant increases in correlated activity within V1, and between V1 and the medial temporal cortex, were observed in REM sleep relative to NREM sleep (p<.0001). These findings are consistent with state-dependent differences in human brain activation, including V1.

Supported by NIH grant K21 MH01080 and the MacArthur Foundation. The authors thank L. Borg-Graham and G. McCormack for their help with this work.

## 273.10

**PREMOTOR TRIGEMINAL INTERNEURONS ACTIVATED DURING CARBACHOL-INDUCED ACTIVE SLEEP.** F.R. Morales, S. Sampogna, J. Yamuy, K. Kohlmeier and M.H. Chase\*. Department of Physiology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The present report is an anatomical description of medullary interneurons that innervate trigeminal motor nuclei; these neurons are also those that express *c-fos* during the state of active sleep induced by carbachol microinjection in the pontine reticular formation (AS-Carbachol). Premotor neurons that project to the trigeminal motor nuclei were identified by retrograde labeling following the microinjection of the b subunit of Cholera toxin (CTb) into the trigeminal motor pool. In each cat, two weeks after CTb injection, an AS-Carbachol state of approximately two hours length was induced. The cats were then perfused for immunohistochemistry. A block of tissue that included the brainstem was frozen and cut in 15  $\mu$ m serial sections. Neuronal activation during AS-Carbachol was determined by *c-fos* expression (Yamuy et al., J. of Neurosci., 1993, 13: 2703-2718). A population of double-labeled neurons was observed in the ventromedial medulla ipsilateral to the recording site. This region is located medially to the posterior third of the facial nucleus and extends caudally to the rostral pole of the inferior olive. Between 600 and 800 double-labeled neurons were contained in this region. Most of these neurons were relatively large-sized, multipolar cells (40-50  $\mu$ m, soma longest diameter). Others were medium-to-large-sized neurons with a fusiform cell body (30-50  $\mu$ m, soma longest diameter). Based upon the fact that this is a unique population of premotor interneurons that express *c-fos* during the AS-Carbachol state, we postulate that they are the interneurons responsible for the postsynaptic inhibition of trigeminal motoneurons during active sleep. Supported by USPHS grants MH 43362, NS 23426 and NS 09999.

## 273.12

**EXTRACELLULAR LABELING OF SINGLE NEURONS BY BIOTIN-CONTAINING COMPOUNDS SHOWS BROAD-SPIKE NEURONS IN THE LATERODORSAL TEGMENTAL NUCLEUS TO BE CHOLINERGIC.** Y. Koyama<sup>1</sup>, M. Kusakabe<sup>1</sup>, Y. Kayama<sup>1</sup>, T. Honda<sup>2</sup> and Y. Sugiura<sup>2</sup>, Depts. of Physiol.<sup>1</sup> and Anat.<sup>2</sup>, Fukushima Med. Coll., Fukushima Japan 960-12.

The neurons encountered in and around the laterodorsal tegmental nucleus (LDT) can be divided into two populations by the shape of their action potentials; one generates action potentials with longer duration (broad-spike neurons), while the other has those with shorter duration (brief-spike neurons). After anatomical and physiological studies, we have proposed that the broad-spike neurons are cholinergic, although no direct evidence has not been obtained. Using glass pipette electrode, we recorded activity of single neurons extracellularly in and around the LDT of urethane anesthetized rat. Biocytin (3-6 %) or Neurobiotin (4 %) was ejected iontophoretically from the recording electrode; they were uptaken in a single neuron. The frontal sections of 50  $\mu$  thickness were made and the compounds were revealed fluorescently with Texas red. The sections were then processed for NADPH-diaphorase (NADPH-d) histochemistry or anti-choline acetyltransferase. In the LDT, we have succeeded to recover Biocytin or Neurobiotin in 13 neurons with spike width (positive component of action potential) longer than 0.75 m sec and found that 12 of them were NADPH-d positive. All of 22 neurons which had spike width shorter than 0.7 m sec were NADPH-d negative. The quality of labeling was similar in two tracers. The results support the proposal that the majority of broad-spike neurons in the LDT are cholinergic, while brief-spike neurons are non cholinergic.

## 273.14

**SLEEP PROMOTION BY THE ROSTRAL HYPOTHALAMUS: A POTENTIAL MECHANISM.** J.E. Sherin\*, J.K. Elmquist, and C.B. Saper. Dept. of Neurology, Harvard Medical School/Beth Israel Hospital, Boston, MA 02115.

We recently identified a discrete population of sleep-activated ventrolateral preoptic neurons that project to the histaminergic tuberomammillary nucleus, a caudal hypothalamic cell group thought to promote behavioral arousal. As an intact rostral hypothalamus has long been known to be necessary for the expression of normal sleep, this sleep-activated circuit was hypothesized to use inhibitory neurotransmitters and thereby subserve a sleep-promoting mechanism. The present study was conducted to determine the neurotransmitter(s) used in this pathway. Using retrograde tracing in combination with immunocytochemistry, we report here that GABAergic and galaninergic markers colocalize in the vast majority of ventrolateral preoptic neurons which innervate the tuberomammillary nucleus. Both of these neurotransmitters have been shown to inhibit post-synaptic targets, and, in this pathway, may promote sleep by decreasing the activity of histaminergic neurons. Further, galaninergic markers may serve to identify a population of sleep-activated neurons in the preoptic area.

## 274.1

THE SONGBIRD HIPPOCAMPUS IS A SITE OF HIGH AROMATASE ACTIVITY. C.J. Saldanha\*, V.T. Cam. & B.A. Schlinger. Dept. of Physiological Science and the Laboratory of Neuroendocrinology-BRI, UCLA, Los Angeles, CA 90095.

In songbirds, the hippocampus (HP) plays a fundamental role in memory-intensive behaviors such as the storage and retrieval of food. Estrogens (E) influence the morphology and physiology of neurons in the vertebrate HP. We have found that aromatase (estrogen-synthetase) mRNA is expressed at high levels in the zebra finch (ZF) HP. Thus, aromatase may provide local E to regulate steroid-dependent neural function. We asked whether aromatase activity was detectable in the HP of developing and adult ZF. We also compared aromatase activity in the HP of several songbird species and in a non-songbird. In a 15 min incubation with  $^3\text{H}$ -androgen and measurement of formed E, aromatase was found to be high in HP-enriched primary cultures of 3-6 day old ZF ( $1.07 \pm 0.225$  pmolesE/mg protein) and similar to telencephalic cultures ( $1.73 \pm 0.98$  pmolesE/mg protein). Additionally, there is no apparent influence of sex on aromatase in the HP since HP-enriched cultures from female and male birds show similar levels of activity ( $4.70 \pm 0.99$  and  $3.65 \pm 0.30$  fmolesE/well respectively). Likewise, in adults, aromatase activity is similar in homogenates of female and male HP ( $3.06 \pm 0.77$  and  $2.34 \pm 0.63$  pmolesE/mg protein respectively). Hippocampal aromatase seems unique to songbirds since we have found it to be high in ZF, canaries, and house sparrows, but undetectable in a non-songbird (budgerigar). Thus, songbirds may be excellent animal models for the study of estrogenic modulation of hippocampal function. Supported by CA Dept of Health Services 95-23342.

## 274.3

THE ROLE OF GONADAL HORMONES AND ENVIRONMENTAL CONDITIONS ON THE DISTRIBUTION OF ARGININE VASOTOCIN IMMUNOREACTIVITY (AVTir) IN MALE ZEBRA FINCH BRAINS. C.F. Harding\* & S.R. Barclay. Biopsychology Program, Hunter College, CUNY, New York, NY 10021.

Arginine vasotocin is the primary hormone regulating water and electrolyte balance in birds, allowing them to adapt to changes in water availability. In zebra finches, reproduction is cued by water availability rather than changes in photoperiod. It therefore seemed possible that AVT might be involved in the regulation of reproductive behavior in this species. We examined the effects of hormonal status and water availability on the distribution of AVTir in male finch brains.

Two groups of males (castrated and intact) were housed for five weeks in conditions which typically stimulate high levels of reproduction: unlimited water, high humidity, fresh greens. The third group (intact) was housed in nonstimulatory conditions: limited water, low humidity, no greens.

AVTir was distributed in many areas involved in the regulation of male reproductive behavior, including vocal control and auditory nuclei, the bed nucleus of the stria terminalis, and the lateral septum. Castration strongly reduced staining in many of these areas, suggesting AVT plays a role in coordinating reproductive behavior in zebra finches. Decreased water availability did not cause such striking changes in AVTir.

REPRESENTATION OF SONG COMPONENTS IN THE AUDITORY FOREBRAIN OF CANARIES. S. Ribeiro\*, G. Cecchi, M. Magnasco and C. Mello. The Rockefeller University, New York, NY, 10021.

Song playbacks induce expression of the immediate early gene ZENK in the caudo-medial neostriatum (NCM), a portion of the auditory telencephalon of songbirds. We have taken advantage of this phenomenon to address in detail how song, a complex and natural auditory stimulus, is represented in NCM. Adult canaries were presented with playbacks of various types of song stimuli, and ZENK protein expression revealed by immunocytochemistry. Maps of labeled cells in NCM were reconstructed and analysed on a computer workstation equipped for image processing. Whole canary songs resulted in labeling of cells throughout NCM, whereas isolated syllables revealed more discrete domains of activation. For example, syllables resembling pure tones resulted in labeled cells mostly restricted to the rostral third of NCM. Each tone-like syllable activated a distinct domain, with lowest frequencies mapping dorsally and highest frequencies ventrally, in a graded fashion. Thus, rostral NCM appears to be tonotopically organized. When tone-like syllables were presented simultaneously or in close sequence, labeled cells were also seen in more posterior regions, where presumably combination-sensitive neurons are present. Finally, the caudal third of NCM appears to be mainly sensitive to rapid frequency modulations. These results indicate that frequencies are represented in the dorso-ventral axis and stimulus complexity in the rostro-caudal axis. A computer program for tridimensional reconstruction of ZENK activation patterns in NCM is currently being developed. We believe that an understanding of the birdsong processing rules will give some key insights into how complex external objects are represented in the vertebrate brain. ## 274.2

IMMUNOCYTOCHEMICAL LOCALIZATION OF AROMATASE-IMMUNOREACTIVE CELLS AND THE DEFINITION OF PREOPTIC NUCLEI IN THE ZEBRA FINCH BRAIN. P. Absil\*, G.F. Ball, N. Harada and J. Balhazart. Lab. Biochemistry, Univ. Liège, Belgium; Dept. Psychol., Johns Hopkins Univ., Baltimore, MD 21218, and Molec. Genetics, Fujita Univ., Toyooka, Japan.

A polyclonal antibody raised against quail recombinant aromatase was used to localize by immunocytochemistry cells immunoreactive for the enzyme aromatase (ARO-ir) in the forebrain of male zebra finches. Staining was enhanced in some birds by the administration of the non-steroidal aromatase inhibitor, R76713 (racemic Vorozole) prior to the perfusion of the birds as previously described in Japanese quail. Large numbers of ARO-ir cells were found in nuclei in the preoptic region and in the tuberal hypothalamus. A nucleus was identified in the preoptic region based on the high density of ARO-ir cells within its boundaries that appears to be homologous to the preoptic medial nucleus (POM) described previously in Japanese quail. In several birds alternate sections were stained for immunoreactive vasotocin, a marker of the paraventricular nucleus (PVN). These data facilitated the clear separation of the POM in zebra finches from nuclei that are adjacent to the POM in the preoptic area-hypothalamus, such as the PVN and the ventromedial nucleus of the hypothalamus. ARO-ir cells were also detected widely throughout the telencephalon. They were discerned in medial parts of the ventral hyperstriatum and neostriatum near the lateral ventricle and in dorsal and medial parts of the hippocampus. They were most abundant in the caudal neostriatum where they clustered in the dorso-medial neostriatum, and as a band of cells coursing along the dorsal edge of the lamina archistriatalis dorsalis. They were also present in high numbers in the ventro-lateral aspect of the neostriatum and in the nucleus taeniae. None of the telencephalic vocal control nuclei had appreciable numbers of cells immunoreactive for aromatase within their boundaries with the possible exception of a group of cells that may correspond to the medial part of magnocellular nucleus of the neostriatum. The distribution of immunoreactive aromatase cells in the zebra finch brain is in excellent agreement with the distribution of cells expressing the mRNA for aromatase that has recently been described in this species. This widespread telencephalic distribution of cells immunoreactive for aromatase has not been described in non-song bird species such as the Japanese quail, the ring dove and the domestic fowl.

## 274.4

EFFECTS OF DSP-4 ON DISTRIBUTION OF DOPAMINE-BETA-HYDROXYLASE IMMUNOREACTIVITY (DBHir) IN MALE ZEBRA FINCH BRAINS. S.A. Waterman\* & C.F. Harding. Biopsychology Program, Hunter College, CUNY, New York, NY 10021

Systemic or central administration of the neurotoxin DSP-4 decreases courtship singing in male zebra finches. As expected, DSP-4 treatment decreased norepinephrine (NE) levels in telencephalic vocal control nuclei, but it also reduced NE levels in hypothalamic nuclei in these birds. In mammals, DSP-4 preferentially affects noradrenergic function in cortical areas leaving hypothalamic areas relatively unaffected. To assess the extent of DSP-4's effects on the noradrenergic innervation of the finch brain and to allow more direct comparison with mammalian studies, we used immunocytochemical techniques to determine how DSP-4 treatment affected the distribution of DBHir in male zebra finch brains. Males were pretreated twice with zimelidine (20mg/kg) to protect serotonergic neurons and then given either DSP-4 (50mg/kg) or saline ip. Birds were perfused 10 days after the second treatment. DSP-4 treatment significantly reduced innervation by DBHir fibers throughout the finch brain. Specifically, DBHir staining decreased in the cerebellum, optic tectum, telencephalic and hypothalamic nuclei compared to controls. In areas where DBHir processes were seen in DSP-4 treated animals, they often appeared swollen and shortened. In zebra finches, DSP-4 is not highly selective for neurons which project to the telencephalon but also affects those which project to the hypothalamus. Funded by PSC CUNY Grants 664280 & 665221 and NIH Grant RR08176

## 274.6

EXPRESSION OF c-FOS PROTEIN IN ADULT ZEBRA FINCH HVC AND RA IS INDUCED BY THE MOTOR ACT OF SINGING. R.R. Kimpso\* and A.J. Doupe. Neuroscience Graduate Program, Departments of Psychiatry and Physiology, UCSF, San Francisco, CA 94143.

Bird song is a complex learned behavior involving auditory and vocal motor systems. We investigated both auditory and motor aspects of song by measuring the induction of the protein product of *c-fos* (FOS), an immediate early gene (IEG), in brains of awake behaving male adult zebra finches. IEG expression is a useful marker for neuronal activation; previous studies in the songbird brain have shown that the IEG ZENK is expressed in auditory regions, including areas surrounding song nuclei, in response to auditory stimulation, especially with conspecific song (Mello et al, 1992, 1994). In this study we show that FOS immunoreactivity is evident within song nuclei; however, FOS was not induced by auditory stimulation but by the motor act of singing.

Birds were presented with tapes of conspecific songs for 50 min, and only those which countersang during stimulation had FOS immunoreactive (IR) cells in HVC and RA, two song nuclei known to have premotor activity. To help determine whether FOS expression was due to the motor act of singing and/or the resulting auditory feedback, we deafened birds by bilateral cochlear removal. Singing was induced in deaf and hearing birds by exposing them to zebra finch female(s) for 50 min. Birds that did not sing had no FOS-IR cells in the two song nuclei while both deaf and hearing birds that sang had numerous FOS-IR cells in HVC and RA. There was a positive correlation between singing time and FOS-IR cell density in these song nuclei.

These experiments demonstrate strong IEG induction due to the motor act of singing and independent of auditory feedback in song nuclei HVC and RA. Since juveniles undergoing song learning are more dependent on auditory feedback than adults for normal song production, this method may reveal differences in neuronal activation of song nuclei at different stages of song learning.

## 274.7

RETINOIC ACID IN THE BRAIN OF ADULT SONGBIRDS: A POTENTIAL ROLE FOR ALDEHYDE DEHYDROGENASE EXPRESSION IN THE SONG SYSTEM. N. Denisenko\*, F. Nottebohm and C. V. Mello.

The Rockefeller University, New York, N.Y., 10021

We have previously identified an mRNA that is highly-enriched in three song control nuclei - HVC, IMAN and RA - using PCR-based mRNA differential display. We have now isolated a full-length clone from a zebra finch forebrain cDNA library. Sequence analysis revealed homology to class I (cytosolic) aldehyde dehydrogenase (ALDH) of different species. ALDH1 expression in HVC and IMAN, as analysed by *in situ* hybridization, was high and comparable at all ages tested (20, 38, 50, 60 day-old juveniles and adults). Expression in RA appears to be age dependent: it peaked at day 38, declined thereafter, and disappeared by day 60. Thus, ALDH1 expression in RA appears to correlate with the duration of the "sensitive period" for song acquisition in zebra finches. In other systems, expression of class I ALDH has been implicated in retinoic acid production. To test whether retinoic acid can also be detected at sites of ALDH1 expression in the brain of adult zebra finches, we used a retinoic acid sensitive cell line. These cells contain an exogenous  $\beta$ -galactosidase gene under the control of a retinoic acid sensitive element. Coculturing HVC explants with these cells resulted in a blue color reaction, indicating the presence of retinoic acid in the HVC explants. Explants from the "shelf" - a region immediately adjacent to HVC that does not express ALDH1 - did not induce any color reaction in these cells. Pretreatment of HVC explants with 50  $\mu$ M disulfiram (a specific inhibitor of class I ALDH) prior to the coculture prevented the induction of the color reaction. These results suggest that ALDH1 expression in song nuclei of adult songbirds is related to retinoic acid production. We are currently investigating the possible role of retinoic acid in these brain regions. (NIH grant # MH 18343)

## 274.9

SINGING INDUCES GENE EXPRESSION IN SELECTED NUCLEI OF THE AVIAN SONG SYSTEM. E. D. Jarvis\* & F. Nottebohm. Lab. of Animal Behavior, The Rockefeller University, NY, NY 10021.

The direct motor pathway from HVC to RA is involved in the acquisition and production of learned song in songbirds; the recursive loop from HVC to Area X to DLM to IMAN is thought to be involved just with song learning. This study explored the relation between singing and expression of the immediate early gene ZENK, which has been implicated in the formation of song memories in the auditory forebrain. Male canaries were stimulated to sing by exposing them to tape recorded playbacks of conspecific song. After 30 min. from the onset of singing, the birds were killed, their brains removed and ZENK expression was analyzed by *in-situ* hybridization. We found that birds who sang within the 30 min. period had increased levels of ZENK mRNA in 6 forebrain song nuclei: Area X, medial and lateral MAN, HVC, RA, and Av (avalanche). ZENK levels were higher (up to 10 fold) the more the bird sang and was not detectable in birds that did not sing. ZENK expression peaked 30-40 min. after the 30 min period of singing and declined to non-detectable levels 1-2 hrs after the end of singing and expression was lower if the bird continued to sing thereafter. Cutting the syringeal nerve or deafening did not prevent ZENK induction even though the song produced was aberrant or could not be heard. Zebra finches also showed ZENK expression in their song nuclei after singing. Our results raise basic questions about the role gene expression plays in song production and in particular in nuclei, such as Area X and IMAN which are not needed for the maintenance of learned song. Perhaps a little bit of learning occurs every time a bird sings or perhaps ZENK expression may be needed to replenish proteins used during the act of singing -- it could be both. Research supported by a training grant to E. Jarvis (NIH 2T32MH 15125-17A1)

## 274.11

DEVELOPMENTAL REGULATION OF mRNA FOR THE NMDAR1 SUBUNIT IN ZEBRA FINCHES M.E. Basham\*, E.J. Nordeen, S.N. Haber and K.W. Nordeen. Brain and Cognitive Sciences and Neuroscience Program, Univ. of Rochester, Rochester, NY, 14627

Activation of NMDA receptors is important for many forms of neural and behavioral plasticity including song learning in zebra finches. Males of this species learn to sing during a restricted ontogenetic period, and several discrete neural regions are necessary for normal song development. In one of these regions, the IMAN, the density of NMDA receptors declines as song behavior develops. In the present study, *in situ* hybridization methods revealed that the mRNA for the constitutive subunit of the NMDA receptor (NMDAR1) is regulated developmentally in both the IMAN and another song control region, Area X.

An oligonucleotide probe designed to recognize all splice variants of the NMDAR1 subunit mRNA labeled many structures throughout the forebrain and brainstem of juvenile and adult male zebra finches. As predicted by the earlier receptor binding studies, the levels of mRNA for the NMDAR1 within the IMAN declined between 30 days of age and adulthood. In contrast, within Area X, mRNA levels for the NMDAR1 subunit increased during this same period. At 30 days of age, the hybridization signal within Area X was not different from that in the surrounding tissue. However, in older birds, Area X was distinct due to elevated mRNA expression. The pattern and intensity of mRNA expression in birds raised as isolates until 60 days of age did not differ significantly from age-matched controls or normal adults. Thus, during vocal development, the NMDAR1 subunit is transcriptionally regulated within several song control regions, but this regulation is not dependent upon exposure to a song model. NIMH MH 45096.

## 274.8

CYTOCHEMICAL STAINING FOR PROTEIN KINASE C IN THE SONG CONTROL NUCLEI OF ZEBRA FINCH DURING SONG LEARNING. H. Sakaguchi<sup>1,2\*</sup>. Dept. of Physiology, Dokkyo Univ. Sch. of Med.<sup>1</sup>, PRESTO, Research Development Corporation of Japan<sup>2</sup>, Mibu Tochigi 321-02 Japan.

Bird song learning during the sensitive period is closely related to synaptic plasticity in the song control nuclei. Protein kinase C (PKC) has been used as a molecular marker for synaptic plasticity in memory and learning. In order to visualize the most plastic neurons, the distribution of PKC was studied in the song control nuclei during the sensitive period of song learning.

The male zebra finch was studied at three developmental ages: 30 and 50 days after hatching and in adults. Cytochemical staining was performed using rhodamine-conjugated bisindolylmaleimide (Rim-1), a fluorescent derivative that inhibits PKC. Rim-1 stained the soma of some neurons in the song control nuclei, high vocal center (HVC), robust nucleus of the archistriatum (RA), lateral magnocellular nucleus of the archistriatum (LMAN) and area X at all three developmental ages. Furthermore, PKC was strongly expressed in the soma and dendrites of RA neurons at day 50. The results suggest that PKC may be a specific substance related to the synaptic plasticity of RA neurons involved with song learning in the zebra finch.

## 274.10

THE SONG SYSTEM OF EUROPEAN STARLINGS EXHIBITS DEVELOPMENTAL CHANGES IN THE DISTRIBUTION OF NMDA RECEPTORS DURING THE FIRST YEAR OF LIFE

L.M. Casto\*, A. Pahlavanian, and G.E. Ball. Dept of Psychology, Behavioral Neuroendocrinology Group, Johns Hopkins University, Baltimore, MD 21218, USA

In adult European starlings (*Sturnus vulgaris*), 3 song control nuclei can be discerned from the surrounding neural tissue based on N-Methyl-D-Aspartate (NMDA) receptor density. HVC and IMAN exhibit low NMDA receptor density relative to surrounding structures. In contrast, area X is defined by high receptor density relative to the surrounding lobus parolfactorius (LPO). We used *in vitro* receptor autoradiography for NMDA receptors (defined by MK-801 binding) in order to assess the distribution of NMDA receptors at days 20, 50, 100, 150, 210, and 345 in HVC, IMAN, and area X of young starlings.

No sex differences in NMDA receptor density exist in IMAN, or HVC, between days 20 and 210. NMDA receptor density in IMAN decreases between days 20, 50, and 100. Receptor density then remains constant between days 100 and 210. In contrast, NMDA receptor density in HVC remains constant between days 20 and 210. Between days 210 and 345, males, but not females, exhibit decreases in IMAN and HVC receptor density. These sex-specific decreases in NMDA receptor density in both HVC and IMAN may be related to sex differences in the hormonal milieu associated with the onset of reproduction.

Unlike adults, 20 and 50 day old starlings exhibit low NMDA receptor density in area X relative to the LPO. Throughout development area X exhibits decreases in NMDA receptor density, however, receptor density in LPO decreases more rapidly, so that by day 210 area X can be defined by high receptor density relative to the LPO. These developmental patterns of NMDA receptor distribution may be related to song system sexual differentiation and the process of song learning.

## 274.12

DEVELOPMENTAL REGULATION OF NMDA RECEPTOR MODULATORY SUBUNITS IN MALE ZEBRA FINCH K.W. Nordeen\*, M.E. Basham and E.J. Nordeen. Brain and Cog. Sci. and Neurosci. Program, U. of Rochester, NY

Song memorization in zebra finches normally occurs between 20-60 days of age, and requires activation of NMDA receptors. Within the IMAN, a brain region necessary for normal song learning, ontogenetic changes in the binding properties of NMDA receptors suggest regulation of receptor function. Since different modulatory subunits (NR2A-NR2D) confer different functional properties to the NMDA receptor, we explored whether NR2 subunits are developmentally regulated within regions implicated in song learning.

A polyclonal antibody that recognizes the NR2A/2B subunits in rats also recognizes protein in male zebra finches that is the expected weight of these subunits. However, unlike the widespread immunolabeling seen in rats, labeling in the zebra finch brain was restricted largely to the LPO. In all 10 day and some 20 day old males, dark immunopositive cells were present throughout the LPO including the song-control region Area X. In older males, Area X was distinct from the surrounding LPO due to more darkly labeled neuropil, and immunostaining that outlined rather than filled cell bodies.

Because the immunoreactivity was highly restricted compared both to that seen in rat, and to the known distribution of NMDA receptors in zebra finches, we suspect that this antibody does not recognize both NR2A and NR2B in zebra finches. Preliminary *in situ* hybridization studies show that the mRNA for the NR2B subunit is distributed widely throughout the telencephalon at all ages examined (30days-adult). Low levels of expression are evident within the IMAN, another area implicated in song learning, and no developmental changes in the expression of this message have been detected. We are determining if developmental changes in NR2A mRNA might underlie the pattern of results seen in the ICC. NIMH MH 45096.

## 274.13

**NADPH-d NEURONS IN VOCAL CONTROL NUCLEI OF THE BUDGERIGAR.** Steven E. Brauth\*, Wennu Liang and Stuart K. Amateau. Department of Psychology, Univ. of MD, College Park, MD. 20742.

We identified neurons staining for nicotinamide adenine dinucleotide phosphatase diaphorase (NADPH-d) in these 5 telencephalic vocal control nuclei in both adult and nestling (1-4 weeks posthatch) budgerigars (*Melopsittacus undulatus*): the central nucleus of the anterior archistriatum (AAc), central nucleus of the lateral neostriatum (NLc), oval nucleus of the hyperstriatum ventrale (HVc), medial oval nucleus of the anterior neostriatum (NAom) and magnicellular nucleus of the lobus parolfactorius (LPom).

All 5 vocal nuclei contain labeled neurons in adults including most of the large projection neurons in both the dorsal and ventral subdivisions of AAc (AAcd and AACv). Both HVc and NAom contain many labeled neurons, although the density of these appears less than that of AAc. Prominent, large stained neurons in LPom are scattered throughout the nucleus; many also exhibit prominent dendritic shafts. NLc contains a lower density of labeled neurons in adults compared to other vocal nuclei and surrounding fields.

In nestlings, AAcd, AACv, NLc and LPom contain large numbers of NADPH-d+ cells at 1 week posthatching. All nuclei except NAom exhibit higher densities of labeled cells at 2-4 weeks posthatch than in adults. Differences in NADPH-d expression in nestlings and adults may reflect developmental changes related to either pathway formation and/or the emergence of vocal learning functions. Supported by NIH grant MH40698 to S.E.B.

## 274.15

**DEVELOPMENTAL EFFECTS OF SONG DEPRIVATION IN ZEBRA FINCHES.** C.E. Collins\*, D. Airey, J. Guzman, V. Lisi, N.Y. Nam, K. Tremper and T.J. DeVogel. Department of Psychology, Developmental Neuroscience Group, Cornell University, Ithaca, NY 14853.

Song learning in zebra finches (*Taeniopygia guttata*) takes place during a juvenile sensitive period. Environmental manipulation deprived one group of zebra finches of the opportunity for song learning. Individuals in this group untutored condition (GU) were raised by their female parent only in the presence of siblings, while individuals raised in the normal social condition were raised in an aviary with both parents and siblings. Normal socially reared zebra finches and GU finches were studied for possible neuroanatomical, behavioral and hormonal differences. Longitudinal behavioral data, collected between 25 days of age and 120 days of age, indicate no significant differences in the development of or time of onset of 6 species-typical behaviors, including song. Birds in both conditions begin to produce plastic song around 38 days of age. Preliminary analysis of song structure between the two groups of birds indicates a highly significant difference in a measure of note rate, i.e. number of note types produced per unit of time ( $p < .01$ ). The time of song crystallization in the two groups is currently being studied as well as other details of song structure. Measures of testosterone (T) titers throughout development demonstrate significantly higher levels of T in the GU condition males and females compared to their normally reared counterparts ( $p < .02$ ). The divergence in T levels begins around 60 days of age and declines around 110 days of age. Anatomical measures in song structure HVC reveal significant differences in synaptic density in 55d old zebra finch males, with no between group differences in HVC volume or cell density. RA volume differs significantly between the two groups at 55d of age and may reflect a trend toward a higher song rate in normally raised male zebra finches compared to GU males.

## 274.17

**BENGALIAN FINCHES DEPEND UPON AUDITORY FEEDBACK FOR MAINTENANCE OF STABLE ADULT SONG.** S.M.N. Woolley and E.W. Rubel\*. Virginia Merrill Bloedel Hearing Research Center, University of Washington, Seattle, WA 98195

The Bengalese finch, *Lonchura striata*, is an age-limited song learning species; once song has crystallized by the age of sexual maturity, it normally does not change over time. In this regard, song learning in Bengalese finches is quite similar to that of the closely related Zebra Finch. Although both species depend on auditory feedback for song learning, the role of auditory feedback in adult song is less clear. Classical studies suggest that once song is crystallized in age-limited learners, auditory feedback is not necessary for maintenance of stable song. We now know, however, that Zebra Finches show significant changes in song 8-16 weeks after deafening (Nordeen & Nordeen, *Behav. & Neural Biol.* 57: 58, 1992). To determine whether Bengalese finches also depend on auditory feedback for maintenance of crystallized song, we deafened adult males.

We recorded song from 12 adult (>160d) male Bengalese finches monthly for 3 months. We then deafened 6 of the 12 birds by surgical cochlear removal. Song from all 12 birds was recorded weekly for 6 weeks after surgery and then again at 12 weeks. The 6 control birds continued to sing stereotyped and stable song over months. Deafened finches, however, showed rapid and marked changes in song. As early as 1 week, we observed degradation of syllable order, truncation and compression of syllables, and the appearance of new or unrecognizable syllables. This degradation became more exaggerated over time. Our results demonstrate that Bengalese finches depend more heavily upon auditory feedback to maintain a stable motor pattern for song than has been reported for other age-limited song learning species. Supported by NIDCD grant DC00395 & GM10708.

## 274.14

**EVIDENCE FOR A SENSITIVE PERIOD FOR SENSORIMOTOR INTEGRATION DURING SONG DEVELOPMENT IN THE ZEBRA FINCH.** C. Pytte\* and R. A. Suthers. Dept. of Biol. and Sch. of Med., Indiana University, Bloomington, IN 47405

Zebra finches develop song in reference to an auditory song model acquired during a sensitive period of song learning. Song development also appears to require subsong and plastic song production during which motor commands are thought to be matched with auditory feedback which is compared with the memorized song model. To determine whether or not subsong and plastic song production must occur within a sensitive developmental period in order for normal song development, we reversibly paralyzed bilateral ventral syringeal muscles using local injections of botulinum toxin (Botox) at various times during song development. Botox blocks acetylcholine release thereby preventing synaptic transmission at the neuromuscular junction. The effects of syringeal Botox injections on the acoustic structure of song at the doses used in this study (3.0  $\mu$ m) were reversed in adults by 3-4 weeks. Juveniles injected prior to, or early in the period of subsong (20-25 days) developed normal songs which crystallized at about day 90. However, birds injected with Botox immediately prior to the usual period of late plastic song and song crystallization (days 80-90) did not develop normal songs, although the abnormal songs did become stable and highly stereotyped. These results suggest that auditory matching of a bird's own song with that of the model is not necessary for crystallization to occur since experimental birds crystallized songs which had not been heard as juveniles. In addition, there appears to be a sensitive period for sensorimotor integration in the zebra finch, after which the bird does not continue to change motor commands necessary to copy his tutor's song. Supported by grants NIH NS 29467 and NSF IBN 941191 to R.S. and an NIH NIDCD Research Training Grant DC-00012 to Indiana University.

## 274.16

**LONG-TERM EFFECTS OF SONG PERTURBATION ON SONG PRODUCTION IN ZEBRA FINCHES.** G.E. Hough II\* and S.F. Volman. Dept. of Zoology, Ohio State Univ., Columbus, OH 43210.

When adult zebra finches (*Taeniopygia guttata*) are deafened by cochlear removal, their learned songs become profoundly degraded within 16 weeks (Nordeen & Nordeen, 1992). Cochlear removal prevents auditory feedback from song, but it also may induce neuronal changes in brain areas necessary for song production. To ask whether correct auditory feedback alone is necessary for song maintenance, we used a reversible technique that distorts vocal output and does not damage the auditory system.

Birds were implanted with a flexible bead made from a dental impression material (Permastic, Kerr Inc.). The 1-2 mm diameter beads were inserted between the two internal tympanic membranes of the syrinx, altering the biomechanics so that song was distorted. Aberrations in syllable structure included low volume, upward frequency shifts, missing harmonics, or more complex effects. Four out of five birds tested thus far also deleted at least one syllable from the ends of their motifs within four weeks after bead insertion. We removed the beads after 16 weeks. Birds healed from surgery within one week, and by that time all distorted syllables had returned to their pre-bead phonology. In no case, however, did deleted syllables reappear.

The quick recovery of syllable fine structure following bead removal indicates that auditory feedback is not necessary to maintain syllable morphology. However, the permanent deletion of song syllables suggests that auditory feedback and/or continual song production is required to preserve the complete song pattern.

## 274.18

**EFFECTS OF HVC LESION ON SONG PREFERENCES IN FEMALE ZEBRA FINCHES.** S. MacDougall-Shackleton, S.H. Hulse\* & G.E. Ball. Behavioral Neuroendocrinology Group, Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218.

The oscine song control nucleus HVC (high vocal center) has been demonstrated to function in song production. However, neurons in HVC also exhibit auditory properties, and HVC has been shown to be important for conspecific song discrimination by female canaries. We tested preferences of female zebra finches (*Taeniopygia guttata*) for conspecific and heterospecific song both prior to and following lesion of HVC. We also tested female preferences for complex songs (containing 12 different syllables) over simpler songs (containing 3 different syllables). Birds were implanted with Silastic tubes containing 17- $\beta$  estradiol and were isolated in sound attenuating chambers for at least 10 days. Next birds were presented with 4 minutes of each type of song interspersed with 4 minutes of silence. Response of the birds was videotaped and the number of copulation solicitation displays were scored. Following response, we made bilateral electrolytic lesions to HVC (experimental group) or elsewhere in the telencephalon (control group). Prior to lesion, female zebra finches performed a greater number of solicitation displays to conspecific song than to heterospecific song. Females also tended to perform more displays to 12-syllable songs than to 3-syllable songs. Following lesion, control-lesion birds maintained these preferences. Preliminary data indicate that HVC-lesion females, however, displayed equally to all song stimuli, including heterospecific song. Funded by NIH grant MH50388 and NSF grant IBN-9317868.

## 274.19

EARLY VOCAL AND NEURAL DEVELOPMENT IN THE BUDGERIGAR. W.S. Hall\*, K.K. Cookson, J.T. Heaton, T. Roberts, S. Shea, and S.E. Brauth. Dept. of Psychology, Univ. MD., College Park, MD, 20742-4411.

We investigated the early development of vocal behavior and general cytoarchitecture of vocal nuclei in budgerigars (*Melopsittacus undulatus*). The duration and internal acoustic organization of vocalizations were analyzed from hatching to six weeks of age. Vocal development during this period exhibits five transitions: (1) innate foodbegs with relatively short durations and few repeated segments at week 0; (2) more mature foodbegs with slightly longer durations and more repeated segments at 1-2 weeks; (3) immature transitional calls with very long durations and peak numbers of repeated segments at 3-4 weeks; (4) more mature transitional calls with shorter durations and fewer repeated segments at 5-6 weeks; and (5) socially learned contact calls at 6+ weeks. Observation of general cytoarchitectural organization suggests asynchronous maturation of vocal nuclei. The nXII of the hindbrain has an adult-like appearance by 1 week posthatching. The dorsomedial nucleus of the intercollicular midbrain (DM) has an adult-like appearance by 2 weeks posthatching. The central nucleus of the archistriatum (AAC), the central nucleus of the neostriatum (NLC), the oval nucleus of the neostriatum (NAO), and the oval nucleus of the hyperstriatum ventrale (HVo) have an adult-like appearance by 2-4 weeks posthatching. Transitions in budgerigar vocal development are similar to transitions in human vocal development from birth to single word utterances. These similarities may be due to similar patterns of neural implementation and asynchronous maturation of vocal centers.

## 274.20

EFFECTS OF VOCAL ARCHISTRIATAL LESIONS AND EARLY DEAFENING ON VOCAL DEVELOPMENT IN THE BUDGERIGAR. J.T. Heaton\* & S.E. Brauth. UMCP, College Park, MD 20742.

The production of socially learned contact calls in budgerigars depends upon descending projections from the central nucleus of the anterior archistriatum (AAC) to brainstem syringeal and respiratory nuclei. In order to examine the role of this pathway in vocal development we lesioned the vocal archistriatum in nestlings aged 5, 9, 13, 22, 26, and 33 days posthatch. In addition, we deafened 5 nestlings at 9-10 days to assess the role of auditory feedback in call development.

Call development in budgerigars can be described as a series of 5 periods or transitions (Hall et al., this session) from simple patterned food begging calls (Periods 1 & 2 - up to 2 weeks posthatch), to longer, harsh-sounding calls (Period 3 - around week 3), to complex patterned begs (Period 4 - weeks 4-5) which decrease in duration near the time of fledging and form the first contact calls (period 5). Lesioned and deafened nestlings both demonstrated nearly normal period 2-3 calls, however these birds continued to produce noisy, harsh-sounding calls similar to period 3 calls into adulthood, thus failing to develop both complex begs and contact calls. Call durations for AAC-lesioned birds remained very long compared to controls, while those of deafened birds were only slightly longer than controls.

Pre-grammatical vocal development in humans can also be described in terms of 5 periods. Like that of budgerigars, human vocal development also exhibits dependence on auditory feedback at period 4, which may mark the initiation of forebrain vocal control in both humans and budgerigars.

## INVERTEBRATE LEARNING AND BEHAVIOR II

## 275.1

A STUDY OF HABITUATION OF eat-4, A PROSPECTIVE LEARNING MUTANT IN *C. ELEGANS*. S.R. Wicks and C.H. Rankin\*. Dept. of Psychol., U. of British Columbia, Vancouver, BC, CANADA V6T 1Z4.

We have demonstrated that the tap withdrawal reflex of *C. elegans* displays habituation, dishabituation and sensitization. The genetic analysis of learning in our lab takes the form of a mutant screen for animals that show disrupted non-associative learning. As a complement to this screen we have been assessing habituation in a variety of mutants isolated by the *C. elegans* community. One such mutant, eat-4, isolated by Leon Avery's lab, appears to possess many of the characteristics of a true learning mutant—the withdrawal reflex is intact; the modulation of the reflex by experience is exclusively altered—and may be used to illustrate what types of changes a habituation screen should be sensitive to.

Habituation of eat-4 animals is very rapid compared to wild-type worms. Controls trained at a 10-s interstimulus interval (ISI) generally reach an asymptotic level of responding after about 8 stimuli. By contrast, eat-4 animals appear to be unresponsive after just 2 or 3 stimuli. The asymptotic phase of habituation is also affected by the mutation. The eat-4 worms rarely respond after habituation to asymptote, while control worms generally continue to respond, albeit at depressed levels, even after prolonged stimulation. Recovery from habituation in eat-4 animals is also delayed. Habituation training at short (2-s and 10-s) ISIs leads to a relatively rapid recovery in intact animals; wild-type worms show significant recovery by a 30-s time point and are fully recovered by a 5 min time point. eat-4 worms show retarded recovery from both 2-s and 10-s ISIs.

The eat-4 gene is thought to encode a transporter required for glutamate neurotransmission. Our results suggest that, although the initial levels of responding are normal in eat-4 animals, habituation of the tap withdrawal reflex is broadly affected. This work was funded by NSERC and HFSP grants.

## 275.3

PRESYNAPTIC RECEPTORS FOR NEUROMODULATORS EVOKING SHORT-TERM HETEROSYNAPTIC PLASTICITY IN *APLYSIA* ARE DISTRIBUTED DIFFERENTIALLY. Z.-Y. Sun\*, B. Kauderer and S. Schacher. Cntr Neurobiol. & Behav., Columbia Univ., Coll. of P & S, NYSPI, New York, NY 10032.

The efficacy of *Aplysia* sensorimotor connections is modulated up and down by 5-HT and FMRFamide. Previous *in vivo* studies indicated that short-term changes in efficacy of these connections require the actions of the neuromodulators at or near the sensory neuron (SN) terminals. Other changes evoked by 5-HT appear to require the actions of 5-HT at or near the SN cell body. To explore the regional distribution of 5-HT and FMRFamide receptors mediating changes in synaptic efficacy and excitability, we combined methods using dissociated cell culture of SN-L7 connections, epifluorescent light microscopy to visualize sites of synaptic contacts, electrophysiology, and focal applications of neuromodulators to four sites on the SN (cell body, axon, SN varicosities contacting L7, and processes contacting L7 but without varicosities). We found that short-term changes in synaptic efficacy were evoked only when the neuromodulators were applied to regions containing SN varicosities. Applications to neighboring regions that had the very same SN neurites, but no varicosities, failed to evoke a change in synapse efficacy. The two neuromodulators differed in the location of receptors mediating changes in excitability. Whereas an excitability increase was evoked only when 5-HT was applied to the cell body, an excitability decrease was evoked only when FMRFamide was applied to regions containing SN varicosities. The functional distribution of these receptors on the SNs *in vitro* parallels the distribution of varicosities that are immunoreactive for the respective transmitters *in vivo*. These results suggest that receptors for neuromodulators evoking short-term changes in the properties of SNs are distributed and expressed differentially along the surface of the SN as it interacts and forms connections with the motor cell. Subsequent studies will examine whether the same sites enriched for receptors are also critical for the expression of long-term synaptic plasticity. Supported by GM32099 and BNS9421438.

## 275.2

HABITUATION STUDIED USING AN *APLYSIA* PREPARATION WITH TWO SETS OF INDEPENDENT SENSORY INPUTS. L. Guan\*, Y. Tsau and J.-Y. Wu. Department of Neurology and Institute for Cognitive and Computational Sciences, Georgetown University Medical Center, Washington DC, 20007

During habituation of the gill withdrawal reflex, a large number of neurons in the *Aplysia* abdominal ganglion underwent a non-uniform reduction in their response to siphon stimulation (Falk et al. J. Neurosci. 13:4072, 1993). Part of this change can be assigned to the homo-synaptic depression of synapses from sensory neurons to motor neurons and interneurons. However, there may be other components of habituation related to higher level of processing and are not directly related to the sensory neurons. In order to distinguish these two kinds of habituation, we have modified the reduced siphon-ganglion-gill preparation. In our modified preparation there were two isolated parts of siphon skin attached to the abdominal ganglion via separate branches of siphon nerve. When the parts of the siphon were placed into two separate chambers and bathed with high  $Mg^{++}$  and low  $Ca^{++}$  saline while ganglion and gill were in normal sea water, two independent sets of sensory inputs to the abdominal circuitry were established. A light touch to either part of siphon elicited a normal gill withdrawal reflex. Habituation could be induced by repeated (1/min) touches to either part of the skin. There were no noticeable changes in the reflex elicited from the control side after a complete habituation induced by touching the other part of the siphon. We are presently analyzing the spiking data optically recorded from a large number of abdominal neurons. (Supported by NIH NS 31425).

## 275.4

THRESHOLD REVERSAL FOR SYNAPTIC FACILITATION AND INCREASED EXCITABILITY WITH SEROTONIN AND TAIL NERVE STIMULATION IN *APLYSIA* SENSORY NEURONS. S.A. Bunge\*, J. Mauelshagen\*, T.J. Carew\*,<sup>1,2</sup> Yale University, Departments of Biology<sup>1</sup> and Psychology<sup>2</sup>, New Haven, CT, 06520.

Tail shock induces sensitization of the tail and siphon withdrawal reflexes in *Aplysia*. Tail shock also induces a number of modulatory effects in the tail sensory neurons (SNs), including increased excitability and facilitation of synaptic transmission from tail SNs to motor neurons. Both of these modulatory effects are mimicked by exogenous application of serotonin (5HT) (Walters et al., 1983).

Recently we have shown that the different modulatory effects induced by 5HT in the SNs have different activation thresholds (Stark et al., 1996, Emptage et al., 1996). To extend these observations, in the present study we examined the activation thresholds for increased excitability and synaptic facilitation, induced either by 5HT ( $n=7$ ) or by electrical stimulation of the tail nerve P9 ( $n=15$ ). Using exogenous 5HT, we found that the threshold concentration (2  $\mu M$ ) sufficient to produce significant excitability increases ( $p<.02$ ) produced no significant synaptic facilitation. Conversely, the intensity of nerve stimulation sufficient to produce significant synaptic facilitation (median increase = 209% of baseline,  $p<.001$ ) produced no excitability changes. We subsequently observed significant synaptic facilitation with 30-60  $\mu M$  5HT (median increase = 166%,  $p<.05$ ) and significant increased excitability with higher intensity nerve stimulation ( $p<.005$ ), indicating that both 5HT and nerve stimulation were capable of inducing both forms of modulation. The reversal of relative thresholds for these modulatory effects may reflect the differential access of exogenous 5HT and endogenous 5HT (released by tail nerve stimulation) to the SN cell body and synaptic terminals respectively.

Support by NIH grant R01-MH-1083 to T.J.C.

## 275.5

**POSTTETANIC POTENTIATION AND ACTIVITY-DEPENDENT FACILITATION AT APLYSIA CULTURED SENSORY-MOTOR NEURON SYNAPSES INVOLVE BOTH PRE- AND POSTSYNAPTIC MECHANISMS.** J.-X. Bao\* and R.D. Hawkins. Ctr. Neurobiol. & Behavior, Columbia Univ., NY, NY 10032.

Both posttetanic potentiation (PTP) and activity-dependent facilitation (ADF) induced by pairing tetanic stimulation and the facilitatory transmitter serotonin (5-HT) at *Aplysia* sensory-motor neuron synapses have been thought to be entirely presynaptic. We have further studied their cellular mechanisms at pleural sensory-L7 and sensory-LFS synapses in isolated cell culture. Tetanic stimulation (20 Hz for 2 s) of the sensory neuron or a single puff of 5-HT (50  $\mu$ M) produced a short-lasting potentiation of evoked release, while pairing tetanus with 5-HT induced a larger and longer-lasting facilitation. Consistent with previous results (Eliot et al., 1994a,b), PTP and ADF of evoked release were accompanied by a large increase in the frequency but not the amplitude of spontaneous release. In addition, PTP was almost completely blocked by presynaptic injection of EGTA, a  $Ca^{2+}$  chelator with slow kinetics, and ADF was significantly reduced by presynaptic injection of a peptide inhibitor of protein kinase A. However, PTP and ADF were also significantly reduced by postsynaptic injection of BAPTA, a  $Ca^{2+}$  chelator with fast kinetics, or strong postsynaptic hyperpolarization during the tetanus (Bao & Hawkins, 1995). By contrast, postsynaptic hyperpolarization had no effect on the increase in the frequency of spontaneous release during PTP or ADF. These results suggest that during PTP and ADF at *Aplysia* sensory-motor neuron synapses, a postsynaptic increase in intracellular  $Ca^{2+}$  may lead to formation of a retrograde messenger which interacts in some way with presynaptic residual  $Ca^{2+}$  (PTP) or cAMP (ADF) to enhance evoked (synchronized) release. Supported by NIMH and Human Frontier Science Program Foundation.

## 275.7

**SYNAPTIC FACILITATION IS INDEPENDENT OF SPIKE DURATION IN SENSORY NEURONS OF JUVENILE APLYSIA.** L.L. Stark\* and T.J. Carew. Interdepartmental Neuroscience Program and Department of Psychology, Yale University, New Haven, CT, 06520.

In adult *Aplysia*, serotonin (5HT) activates two forms of presynaptic facilitation at the synapse between tail sensory neurons (SNs) and tail motor neurons (MNs). One form, associated with major (>15%) SN spike broadening (SB), is predominantly expressed in non-depressed synapses. A second, spike duration independent (SDI) form is predominantly expressed in depressed synapses. During the last stage of juvenile development, 5HT-induced SB is not fully mature; major SB is often absent (Marcus & Carew, 1990, 1992). Thus, we could examine the impact of minor and major SB on non-depressed synapses at this immature stage. We found that 5HT-induced minor SB ( $\bar{x}$ =8.03% increase) was associated with significant synaptic facilitation ( $\bar{x}$ =130.60% increase;  $p$ =.05,  $N$ =7). However, major SB ( $\bar{x}$ =43.68%) produced no significant facilitation ( $\bar{x}$ =10.79%,  $N$ =7). Moreover, minor SB was associated with significantly greater synaptic facilitation than major SB ( $p$ <.04). In adults the reverse was observed: major SB produced significantly more facilitation than did minor SB ( $p$ <.04). Therefore, even in non-depressed synapses, SDI facilitation is the predominant, if not exclusive, form of synaptic facilitation in juveniles. This difference is not due to the inability of the juvenile SN to show synaptic facilitation associated with SB, since directly broadening the SN action potential with 25 $\mu$ M 4-AP resulted in significant SB and synaptic facilitation, with no significant difference between juveniles and adults.

In adults, 5HT increases cAMP in the SNs, leading to increased excitability and minor SB. In juveniles, we found that the cAMP analog 8-br-cAMP ( $\bar{x}$ =5.9nM,  $N$ =10) significantly increased excitability ( $\bar{x}$ =156.60%,  $p$ <.001) and induced minor SB ( $\bar{x}$ =11.38%,  $p$ <.03). However, preliminary evidence indicates that 8-br-cAMP does not facilitate synaptic transmission, suggesting that another second messenger underlies SDI facilitation in juvenile *Aplysia*. Supported by NIH grant 5-F31-MH10673 to LLS & NSF, IBN9221117 to T.J.C.

## 275.9

**ROLE OF PKC IN INTERMEDIATE FORMS OF MEMORY: MODULATION OF SYNAPTIC TRANSMISSION AND EXCITABILITY.** F. Manseau, W. S. Sossin and V.E. Castellucci\*. Lab. de Neurobiologie, IRCM, Département de Physiologie, Univ. de Montréal, H2W 1R7, Canada.

Previous studies indicate that at least two second messenger activated kinases (PKA and PKC) contribute to short-term facilitation of sensorimotor synapses by 5-HT in *Aplysia* withdrawal reflex. Little is known about the contribution of these systems in the newly described intermediate-term facilitation (Ghirardi et al. 1995). On the other hand, biochemical observations (Sossin et al. 1994; Yanow & Sossin 1996) suggest that PKC could be implicated. Using a dissociated cell culture preparation, we have compared the strength of sensorimotor connections before and at 3 hours after pharmacological activation of PKC (PDBU 100 nM, 90 min.). We found a significant increase of EPSP amplitude: +160% ( $n$ =14) as opposed to: -8% ( $n$ =12) for control synapses (inactive isomer 4- $\alpha$ -PDBU). These results are consistent with those recently published by Wu et al. (1995). While performing these experiments we noticed a change in the excitability of sensory neurons at the 3 hour time-point after PDBU treatment. Excitability was measured as the number of action potentials discharged over a specific range of depolarizing currents before and after treatment with PDBU or 4- $\alpha$ -PDBU (100 nM, 90 min.). At 3 hours post-treatment, PDBU (100 nM, 90 min.) caused a significant increase of excitability (+109%;  $n$ =28  $p$ <.001) which was still observed after 24 hours (+83%;  $n$ =16  $p$ <.05). Inactive isomer had no effect at either time points (+4%;  $n$ =25 n.s. and +3%;  $n$ =22 n.s.). These intermediate- and long-term effects were only partially blocked by a protein synthesis inhibitor, and could also be induced by a short (5 min.) exposure to PDBU. The increase in excitability was not associated with a change in cell resistance. We propose that PKC might be implicated in an intermediate form of memory and that one component is independent of protein synthesis. Sources of funding: FCAR and MRC of Canada.

## 275.6

**GROWTH FACTOR-INDUCED LONG-TERM SYNAPTIC FACILITATION IN TAIL SENSORIMOTOR SYNAPSES OF APLYSIA.** S.E. McKay\* and T.J. Carew, Dept. Psychology, Yale University, New Haven, CT

Neurotrophic factors have long been known to mediate events in the developing nervous system of vertebrates, including proliferation, differentiation, neurite outgrowth, and cell survival. Recently it has been suggested that neurotrophins may play a role in both developmental and adult forms of synaptic plasticity in both vertebrates and invertebrates. To explore this possibility we have begun to investigate neurotrophin effects in the mollusc *Aplysia*. Monosynaptic connections between tail sensory neurons (SNs) and motor neurons (MNs) in the intact ganglia show both short-term (minutes) and long-term (days) facilitation in response to serotonin. In our studies, 63% of synapses ( $n$ =8) showed long-term, but not short-term, facilitation following 30-60 minute treatments with 30 ng/ml brain-derived neurotrophic factor (BDNF). Among the synapses showing a response to BDNF ( $n$ =5) the  $\bar{x}$ % increase in EPSP amplitude was 112%, while controls, treated with 30 ng/ml cytochrome c ( $n$ =2) showed an average 17% reduction in EPSP amplitude ( $U$ =0.00,  $p$ =0.047). Treatment with BDNF resulted in no change in either the membrane resistance or resting potential of SNs and MNs, or in the threshold for spike initiation among the SNs. These results suggest that BDNF may alter synaptic efficacy by producing long term molecular or structural changes in either the SNs or the MNs. Further studies with other neurotrophins, including NGF, NT-3, EGF, and CNTF are currently underway; preliminary results suggest that only a specific set of growth factors may be capable of mediating the changes associated with synaptic plasticity.

We are grateful to Amgen for providing the BDNF and NT-3 used in these studies. Supported by NIH grant R01-MH-14-1083.

## 275.8

**ALTERNATIVE SPLICE VARIANT OF THE VOLTAGE-GATED  $Na^+$  CHANNEL OF APLYSIA IS MISSING PKA CONSENSUS SITES.**

1,2 W.L. Johnston, 2 V.E. Castellucci and 1 R.J. Dunn\*, 1 Centre for Research in Neuroscience, McGill University, Montreal General Hospital Research Institute, Montreal, Canada; 2 Institut de Recherches Cliniques de Montréal and Université de Montréal, Montréal, Canada.

We recently cloned the voltage-gated  $Na^+$  channel from the marine invertebrate, *Aplysia*. RNase protection analysis, using a probe derived from the first intracellular loop, demonstrates that this channel is specific to the nervous system. We also used RT-PCR to amplify the first intracellular loop, which contains all four of the channel's PKA consensus sites. In addition to the previously cloned version, we also identified a splice variant in which all four PKA sites are missing. Sequence analysis demonstrated that splicing results in a shorter version in which a 450 base pair segment is missing, beginning in the middle of the first PKA consensus site and ending 140 base pairs downstream of the forth PKA consensus site. It is predicted that this channel should be insensitive to phosphorylation by PKA. We are actively investigating the physiological roles of these two isoforms of the  $Na^+$  channel and their possible contribution to short- and long-term facilitation in the *Aplysia* nervous system.

## 275.10

**Cloning of Conditioning-Associated Protein cp20, a Calcium- and GTP-binding Protein which Enhances Membrane Excitability** T.J. Nelson\*, C.-L. Yi, S. Cavallaro, D. McPhie, B. G. Schreurs, A. Favit, and Daniel L. Alkon. Laboratory of Adaptive Systems, NINDS, National Institutes of Health, Bethesda MD 20892 and Harvard Medical School, McLean Hospital, 115 Mill St., Belmont MA 02178 USA.

Cp20, a low-MW learning-specific GTP-binding protein that has also been implicated in Alzheimer's disease, was cloned from squid optic lobe and expressed. In addition to binding GTP, the cloned protein bound 2 molecules of  $Ca^{2+}$ , with a  $K_s$  of  $\approx 400$  nM. The cDNA sequence of cp20 bore a close homology with the sarcoplasmic calcium-binding protein scpl as well as low-MW GTP-binding proteins such as adenosine ribosylation factor (ARF). Cp20 was also a high-affinity substrate ( $K_m$ =5nM) for the  $\alpha$ -isoform of protein kinase C. Phosphorylation of cp20 was markedly inhibited by GTP. Cloned cp20 was microinjected into *Hermisenda* photoreceptor neurons and rabbit Purkinje cells. In both cases, cp20 was highly effective at enhancing membrane excitability; e.g., purkinje cell excitability was increased by 25%. This effect is consistent with cp20's known reduction of both  $i_A$  and  $i_{Ca-K}$  potassium currents and with our previous demonstration of correlations of cp20 phosphorylation with memory storage. The unprecedented combination of calcium- and GTP-binding activity exhibited by cp20 suggests that it may have a pivotal role as a point of convergence between these two critical signalling pathways.

## 275.11

**A NOVEL NEUROACTIVE PEPTIDE FROM THE ATRIAL GLAND OF APLYSIA.** Samuel K. Moore, Frederick W. Kauer, Valerie L. Begnoche, and Earl Mayeri\*. Dept. of Physiology, University of California, San Francisco, CA 94143-0444 USA.

The atrial gland is an exocrine gland located in the reproductive tract of the marine mollusk *Aplysia*. It expresses large amounts of biologically active peptides of the egg-laying hormone (ELH) gene family, which are thought to play important roles in regulation of reproductive physiology and behavior. Using HPLC purification methods we have isolated and partially characterized a novel peptide from the gland. Amino acid composition, partial sequence analysis and mass spectrometry indicate that the peptide has 31 amino acids, is about 3400 Da and is unrelated to the ELH gene family or other biologically active peptides. Application of the peptide at 1-5  $\mu$ M concentration to identified cells in the abdominal or cerebral ganglia produces prolonged excitation, in which a silent cell is depolarized by a few millivolts and fires action potentials at a steady rate for 30 min or more. Many other cells in the CNS are unaffected by the peptide, and it has no obvious effects on reproduction or behavior when injected into intact animals. The peptide is present in the gland in very high amounts, approximately 120  $\mu$ g per 446 gm animal, suggesting that it is important for reproductive control. (Supported by NIH grant NS16490.)

## 275.13

**TEMPORAL ASPECTS OF ACTIVATION OF ADENYLYL CYCLASE BY  $Ca^{2+}$  AND NEUROTRANSMITTER: POSSIBLE MECHANISM FOR CS-US SEQUENCE PREFERENCE DURING CONDITIONING.** Depts. of Pharmacology & Anesthesiology, University of MD School of Medicine, Baltimore, MD 21201. C. Onyike and T.W. Abrams\*.

During classical conditioning of the defensive withdrawal reflex in *Aplysia*, within the sensory neurons of the conditioned stimulus pathway, the dually-regulated  $Ca^{2+}$ /CaM-sensitive adenylyl cyclase may serve as an associative integrator for the cellular signals from the conditioned and unconditioned stimuli (CS & US). Conditioning is more effective when CS onset precedes US onset. If adenylyl cyclase is a critical molecular integrator, it should be more effectively activated when  $Ca^{2+}$  (the signal from the CS) precedes 5HT (the signal from the US) than when stimulus onset is simultaneous. We previously observed that a  $Ca^{2+}$  pulse prior to a 5HT pulse produces better activation of *Aplysia* neural cyclase than the backwards sequence. Comparison of the temporal activation profiles of *Aplysia* cyclase has now indicated that the  $Ca^{2+}$ /CaM response onset is slower than the 5HT response onset. More detailed studies of the activation profile of recombinant mammalian brain type I adenylyl cyclase revealed that stimulation by a pulse of  $Ca^{2+}$  actually rose after, and persisted after, free  $Ca^{2+}$  declined, providing a possible brief memory of neuronal activity. Why does cyclase stimulation by CaM persist seconds after a  $Ca^{2+}$  pulse? By activating CaM, and then lowering free  $Ca^{2+}$  <1 sec before a CaM pulse reached the cyclase-containing membranes, we found CaM in solution had no memory for  $Ca^{2+}$ . Using a photoactivatable linker attached to CaM, we are characterizing the time course of persistent CaM-to-cyclase coupling once free  $Ca^{2+}$  levels have dropped. Supported by RO1 MH55880-02 from NIMH.

## 275.15

**PROTEIN PHOSPHATASE INVOLVEMENT IN LEARNING-PRODUCED CHANGES IN *Hermissenda* TYPE B CELLS** H. Huang\* and J. Farley. Programs in Neural Science, Indiana University, Bloomington, IN 47405.

The possible involvement of protein phosphatases in the production of memory-related changes in type B cell excitability was assessed by exposing isolated nervous systems to five pairings of light and electrical stimulation of statocyst hair cells (*in vitro* conditioning), in the presence or absence of calyculin A, an inhibitor of PP1 & PP2A. Type B cells from control preparations ( $n=5$ ) depolarized by  $7.2 \pm 0.84$  mV (mean  $\pm$  sem). In contrast, preparations exposed to a 20 nM bath-concentration of calyculin depolarized by only  $1.75 \pm 2.47$  mV. However, these preparations had depolarized by  $12.5 \pm 2.12$  mV before the start of *in vitro* conditioning. In separate experiments, leakage of calyculin A from the recording electrode into the B cell prior to conditioning reduced the subsequent development of cumulative depolarization by at least 75%, after correction for the effects of leakage. Thus, calyculin A appears to occlude the depolarization of B cells that is produced by conditioning. Comparison of the effects of bath-applied calyculin upon synaptically-intact vs. -isolated B cells from untrained specimens, over a 20 min time period, revealed that the rate of depolarization was ~10-fold greater in the former case ( $\sim 1.65$  mV/min vs 0.15 mV/min) but input resistance increases were less pronounced. These results suggest that in addition to inhibition of B cell phosphatases, bath application of calyculin A also changes B cell excitability through its effects upon cells presynaptic to B cells. Collectively, our results suggest that basal PP1 and/or PP2A-activity counteract the effects of basal, as well as conditioning-produced, protein kinase activity upon B cell excitability. Supported by grants from NIH.

## 275.12

**NERVE INJURY, BUT NOT 5HT TREATMENT, RAPIDLY INACTIVATES THE TRANSCRIPTION FACTOR NF- $\kappa$ B IN APLYSIA AXONS.** M. Povelones, K. Tran, D. Thanos, R. T. Ambrose\*. Depts. of Anatomy and Cell Biology and Biochemistry and Molecular Biophysics, Columbia University, New York, NY 10032.

There is considerable evidence for a convergence of intracellular signaling pathways for axon regeneration and 5HT-induced learning. Divergent pathways must exist also, since regeneration, but not learning, requires extensive growth and pathfinding. The transcription factor NF- $\kappa$ B normally resides in the cytoplasm via an association with an inhibitory subunit, I $\kappa$ B, which masks its nuclear localization signal (NLS). In response to extracellular signals, I $\kappa$ B is destroyed and NF- $\kappa$ B is imported into the nucleus. We have identified a protein in axoplasm from *Aplysia* (ap) that has the properties of NF- $\kappa$ B. The apNF- $\kappa$ B binds to  $\kappa$ B oligonucleotide probes and the binding is inhibited by mammalian I $\kappa$ B- $\alpha$ . Constitutively active and latent apNF- $\kappa$ B were present and, like its vertebrate counterpart, the latent form was activated by deoxycholate. Since axoplasmic proteins that contain an NLS can be retrogradely transported to the nucleus, active apNF- $\kappa$ B could signal the nucleus about events in the axon periphery. To see how apNF- $\kappa$ B responds to injury, peripheral nerves to the body wall were crushed; surprisingly, there was a loss of apNF- $\kappa$ B binding at the crush site and, within 15 min, as far as 2.5 cm along the axon. By 45 min there was a reduction in the soma. In contrast, exposure of either the intact animal or the nervous system *in situ* to levels of 5HT that induce learning had no effect on apNF- $\kappa$ B activity. This indicates that the events regulated by apNF- $\kappa$ B are incompatible with regeneration and that they do not influence events induced by 5HT. Supported by the NIH

## 275.14

**RECIPROCAL OCCLUSION OF EXCITABILITY CHANGES IN *Hermissenda* TYPE B PHOTORECEPTORS BY PHORBOL ESTER AND ASSOCIATIVE TRAINING** R. McEwen, M. Smith, J. Jin, and J. Farley\*. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Previous research has implicated activation of protein kinase C (PKC) in the induction and maintenance of memory-related changes in *Hermissenda* Type B photoreceptors. Here, we asked if the acute effects of phorbol ester stimulation on type B cell excitability were attenuated if animals were first exposed to associative training, *viz.* repeated pairings of light and rotation. Synaptically-intact Type B cells ( $n=6$ ) from untrained animals responded to  $10^{-7}$  M phorbol 12-myristate 13-acetate (PMA) stimulation with an average (mean  $\pm$  sem) steady-state light response enhancement of  $+4.83 \pm 0.73$  mV. In contrast, B cells ( $n=5$ ) from associatively-trained animals responded to PMA stimulation with a decrease in their steady-state light response ( $-3.20 \pm 0.94$  mV). In parallel experiments, we also examined the ability of phorbol ester stimulation to occlude short-term excitability changes in type B cells produced by *in vitro* conditioning. In control preparations ( $n=8$ ), five pairings of light and intracellular current stimulation of a statocyst caudal hair cell produced an average  $8.43 \pm 0.31$  mV of cumulative depolarization. In contrast, B cells ( $n=5$ ) from preparations pretreated with PMA showed only  $3.50 \pm 0.92$  mV of depolarization, a significant reduction of ~58%. Collectively, our results provide additional support for the involvement of PKC in both short- and long-term changes in associatively-produced changes in B cell excitability. The failure of PMA to completely occlude *in vitro* conditioning-produced changes in B cell excitability implies the involvement of additional signal transduction pathways, probably involving a tyrosine kinase (see Jin & Farley abstract, this volume). Supported by grants from NIH.

## 275.16

**REGULATION OF TRANSLATION BY PKC AND PKA DURING INTERMEDIATE PHASES OF FACILITATION IN APLYSIA.** S. K. Yanow and W. S. Sossin\*. Montreal Neurological Institute, McGill Univ., Montreal, QC H3A 2B4.

Long-term facilitation in *Aplysia* provides a model in which to study cellular mechanisms involved in long-term memory. In *Aplysia*, serotonin (5-HT) induces an intermediate phase of facilitation that is translation-dependent yet independent of transcription (Ghirardi M, Montarolo PG, Kandel ER (1995) Neuron 14: 413-20). In clusters of sensory neurons, 5-HT stimulates an initial decrease in translation followed by a transient increase in protein synthesis that are both independent of transcription (Barzilai A, Kennedy TE, Sweatt JD, Kandel ER (1989) Neuron 2: 1577-86). This regulation of translation may be important for the induction of intermediate memory. We found that 5-HT induced identical changes in translation when whole pleural ganglia were used. In this system, we asked which protein kinases activated by 5-HT were important in mediating the changes in translation. Inhibition of PKC with Chelerythrine (10 $\mu$ M) blocked both the initial decrease and the transient increase in translation. Blocking PKA activation with RpcAMP (500 $\mu$ M) only blocked the transient increase. This suggests a model where PKC mediates the decrease in translation, but both PKC and PKA activation are required for the transient increase. These conclusions are further supported by experiments where addition of phorbol esters (200nM) is sufficient to induce the initial decrease in translation, but does not stimulate the transient increase. These results suggest that both PKC and PKA are required for the induction of intermediate memory. This work is supported by grants from the EJLB Foundation and the MRC of Canada.

## Molecular Cloning of a DCO like Catalytic Subunit of the Protein Kinase A from Honeybee Neuronal Tissue

H. Rosenboom, P. Braun and U. Müller\*

Inst. f. Neurobiologie, Freie Universität Berlin, 14195 Berlin, Germany

Using PCR with degenerated primers against a conserved sequence of catalytic subunit of the protein kinase A (PKA) we obtained a cDNA fragment from a honeybee brain cDNA library. Screening the same library with the fragment gave a full length clone. The protein encoded by the open reading frame has at least 90% aminoacid identity compared to drosophila DCO PKA catalytic subunit. As in drosophila, this isoform seems to be prominent in the brain, since 25 isolated clones from the honeybee library tested so far, coded for the DCO like isoform.

This honeybee PKA catalytic subunit sequence information is the basis for an antisense approach to reduce PKA activity in cultured neurones from honeybee brain.

Two assay systems for testing the PKA activity and concentration in cultured honeybee neurones were established. Kinase activity is examined with a phosphorylation assay. The concentration is measured with an ELISA using an antiserum against the drosophila DCO isoform.

Employing these assays, several antisense oligonucleotides are screened on their PKA reducing activity. First results will be presented.

## HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR II

## 276.1

## USING THE DIFFERENTIAL DISPLAY POLYMERASE CHAIN REACTION TO IDENTIFY PROGESTERONE RESPONSIVE mRNA IN THE RAT HYPOTHALAMUS C. J. Krebs\*, E. D. Jarvis, R. E. M. Scott and D. W. Pfaff. Laboratory of Neurobiology and Behavior, Rockefeller University, New York, NY 10021.

The sexual behavior of the female rat, termed lordosis, is known to be facilitated by the effects of progesterone (P) on the hypothalamus. P is the ligand for the progesterone receptor (PR), a member of the steroid hormone receptor superfamily that modulates gene expression in response to steroids in the brain and throughout the body. One event thought to contribute to lordosis is a PR mediated change in gene expression within the ventromedial nucleus (VMN) of the hypothalamus. We are applying the differential display (DD) technique of Liang and Pardee to identify mRNAs that are altered in response to P in the female rat hypothalamus. Total RNA was isolated from the hypothalamus of ovariectomized, estradiol primed rats treated with either P or vehicle for 3 hours. DD-PCR reactions were performed on each RNA sample, independently. To date, we have screened 1/8th of the mRNA populations and have identified six differentially regulated bands. To verify the regulation of these mRNAs, we are screening their corresponding cDNAs by slot blot with probes generated from the mRNAs of P treated and vehicle treated animals. We will further characterize these mRNAs by sequencing and in situ hybridization. These studies will identify the genetic targets of the PR within the rat hypothalamus and should contribute to our understanding of lordosis behavior at the molecular level.

This research is funded by NRSA training grant # MH15125-17A1 to C.J.K.

## 276.2

## Sex Difference and Lateral Asymmetry in Rat Hippocampus: Relation to Androgen Receptor Activity. Murali N. Naidu, Neil V. Watson &amp; S. Marc Breedlove\*, Dept. Psychology, Univ. California, Berkeley, CA 94720.

Sex differences in spatial learning ability have been reported in both rats and humans and a variety of studies have implicated the hippocampal formation as important in such learning. Thus there are reports of sex differences in the size of various hippocampal components, including the granule cell layer of the dentate in rats (Roof & Havens, 1992).

Sprague-Dawley rats, 117-123 days old, were sacrificed and perfused. The brains were removed, postfixed at least a week in paraformaldehyde, frozen sectioned coronally in 50  $\mu$ m thickness. Every 4th section was mounted and stereologically examined using a microprojector by an observer blind to group membership. We found that the volume of the hippocampal formation was larger in males than in females ( $p < .05$ , t-test,  $N = 6$  per group). There was also lateral asymmetry in hippocampal volume in males only ( $p < .05$ , matched-pairs t-test), such that the sex difference in volume was significant on the right but not on the left.

	Left Hip.	Right Hip.	Total Hippocampus
Males	43.7 $\pm$ 0.97	46.2 $\pm$ 1.52	89.9 $\pm$ 2.45 (mm <sup>3</sup> )
Females	38.9 $\pm$ 2.22	40.2 $\pm$ 1.69	79.1 $\pm$ 3.87

We will examine the hippocampus of androgen-insensitive males and of perinatally androgenized females. Supported by NS28421.

## 276.3

NEURONAL SIZE IN THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS (SNB): DIRECT MODULATION BY ANDROGEN IN ANIMALS WITH MOSAIC GENETIC ANDROGEN INSENSITIVITY. Neil V. Watson<sup>1</sup>, Louise M. Freeman<sup>2</sup> and S. Marc Breedlove\*, Dept. Psychology, Simon Fraser University, Burnaby, BC, V5A 1S2, <sup>1</sup>University of California, Berkeley, CA, 94720.

Motoneurons of the SNB innervate the perineal muscles bulbocavernosus and levator ani (BC/LA). Both the SNB and BC/LA express androgen receptors (AR), and display profound androgen-dependent sexual dimorphism, being virtually absent in untreated females. Interestingly, the developmental SNB dimorphism arises indirectly, through the action of androgen on the SNB's target muscles. Androgen prevents perinatal regression of the BC/LA, which thereafter inhibits SNB degeneration. Androgens also affect the adult SNB: castration reduces mean soma sizes, while androgen treatment increases them. However, it is unknown whether this effect is mediated directly via the SNB cells' AR, or indirectly via androgen's effects on the BC/LA.

We generated rats that were genetically mosaic for the X-linked *gfm* mutation, with roughly 50% of SNB cells expressing the normal, androgen-sensitive wild-type (WT) AR, and 50% expressing the defective *gfm* AR. We provided mosaics with either testosterone (T) or blank implants, and subsequently used AR immunocytochemistry to identify the two cell types within each animal's SNB. As shown here, testosterone increased soma size only in WT SNB cells. If the effects of androgen on cell size were mediated indirectly, the presence or absence of AR in the SNB cells would not matter and the effect on cell size would be equivalent between the cell types. Instead, these data provide strong evidence that androgens act directly on SNB motoneurons, via their AR receptors, to alter soma size in adulthood. (Supported by NIH NS28421)

## 276.4

## EFFECTS OF NEONATAL TESTOSTERONE ON THE DEVELOPMENT OF THE SENSORY PUDENDAL NERVE IN RATS. S. E. Gang\*, R. H. White, and C. L. Moore, Dept. of Psychology, Univ. Massachusetts, Boston, MA 02125.

The sensory pudendal nerve is larger in males than in females, and its axons are larger, more thickly myelinated, and more numerous in males. To determine whether these differences can be reversed with testosterone, female neonates were treated with 500  $\mu$ g testosterone propionate ( $n = 4$ ) on the day of birth and compared with neonatally oil-treated males ( $n = 4$ ) and females ( $n = 5$ ) at 21 days of age. Treatment significantly increased the cross-sectional area of the nerve, the size of myelinated axons, and the number of both myelinated and unmyelinated axons (all  $p$  values  $< 0.05$ ). A comparison of the 21-day-olds in this study with adults from a previous study (Moore & White, Neuroscience Abstracts, 1994) indicated no change with puberty in the number of myelinated axons. However, these axons were significantly larger in adults ( $p < 0.0001$ ), particularly among males ( $p < 0.06$ ). The cross-sectional area of the nerve was also larger in adults than in juveniles of the same sex ( $p < 0.0001$ ), but growth was significantly greater in males (sex  $\times$  age interaction,  $p < 0.0001$ ). The results suggest that myelinated axon number in this nerve is established by 21 days, partially in response to neonatal testosterone. However, the full extent of sex difference in axonal size and myelination is not established before puberty (Supported by HD07772 to SEG and NSF IBN 91-21238 to CLM.).

## 276.5

EFFECT OF SEX AND ADULT TESTOSTERONE TREATMENT ON FOS INDUCTION IN FERRET OLFACTORY BULB AND FOREBRAIN BY ODORS FROM ESTROUS FEMALES. **K.R. Keliher\***, **S.R. Wersinger** and **M.J. Baum**. Department of Biology, Boston University, Boston, MA 02215

Chemosensory cues from conspecifics may contribute to sexual partner preference and other aspects of reproductive success in breeding ferrets. Using nuclear Fos protein immunoreactivity (Fos-IR) as a marker, we made a sex comparison of neuronal activation in the main and accessory olfactory bulbs (OB) and in forebrain regions which receive olfactory inputs after exposure to odors from estrous female ferrets. We also assessed the ability of testosterone propionate (TP) to modulate the effects of olfactory cues on neuronal Fos-IR in males and females. Adult ferrets were gonadectomized and given TP or oil vehicle for 5 weeks. Subjects were isolated for two days, then placed either in a clean cage or in a cage containing bedding from an estrous female for 90 min. and perfused with 4% paraformaldehyde; brains were later processed for Fos-IR. The number of Fos-IR neurons was significantly greater in the granular layer of the main and accessory OB and in the medial amygdala (MA) of both males and females exposed to estrous bedding. In female subjects exposed to estrous bedding there were also significantly more Fos-IR neurons in the medial preoptic area/anterior hypothalamus (mPOA/AH) and in the ventro-lateral aspect of the ventromedial nucleus of the hypothalamus (VLH); no such effect occurred in males. Adult treatment with TP generally augmented regional Fos responses to chemosensory cues when they occurred in either sex; this effect of TP attained statistical significance in the main OB and mPOA/AH of females. Neuronal responses to estrous bedding were similar in the peripheral stages (i.e., OB, MA) of the olfactory projection pathway, suggesting that the detection and initial processing of chemosensory stimuli is similar in the two sexes. By contrast, the subsequent processing of chemosensory inputs by more central forebrain neurons (i.e., mPOA/AH, VLH) is sexually dimorphic. (Supported by HD 21094; MH 00392)

## 276.7

DIFFERENTIAL EFFECTS OF PREOPTIC/ANTERIOR HYPOTHALAMIC LESIONS ON SEXUAL PARTNER PREFERENCE AND MATING IN MALE FERRETS. **H.A. Kindon\***, **R.G. Paredes** and **M.J. Baum**. Dept. Of Biology, Boston University, Boston, MA 02215

In a previous study (J. Neurosci. 15:6619-6630, 1995) we found that bilateral excitotoxic lesions of the medial preoptic area/anterior hypothalamus (mPOA/AH), which included but were not restricted to the sexually dimorphic male nucleus (Mn) of the mPOA/AH, caused male ferrets to approach and interact sexually with a stud male as opposed to an estrous female in T-maze tests given while subjects were gonadectomized and treated daily with estradiol benzoate (EB). In the present study electrolytic lesions, which caused extensive bilateral damage to the mPOA/AH including the Mn-POA/AH, caused males to shift their mean preference from an estrous female to a sexually active stud male. The partner preference of males with extensive mPOA/AH damage more closely resembled that of sham-operated females than that of sham-operated males or that of males with either partial bilateral POA/AH damage, including only unilateral Mn-POA/AH destruction, or with lesions outside the mPOA/AH. Males with extensive bilateral mPOA/AH lesions showed an even stronger preference to approach the stud male in tests in which subjects could see, hear and smell, but not physically contact the stimulus animals. When given testosterone propionate, males with either extensive or partial bilateral damage to the mPOA/AH showed significant reductions in their copulatory performance, regardless of whether they were tested with a sexually receptive male or female. Heterosexual partner preference in male ferrets depends on the functional integrity of sexually dimorphic mPOA/AH neurons. When these neurons are either destroyed (males with extensive bilateral mPOA/AH damage) or absent (sham-operated females), subjects' preference is apparently maintained by non-behavioral, distal incentive cues from the stud male. Supported by HD21094 and MH00392.

## 276.9

ADULT SEX REVERSAL IS ASSOCIATED WITH CHANGES IN AVT mRNA EXPRESSION IN THE PREOPTIC AREA. **J. Godwin**, **B. Sawby**, **R.R. Warner**, **D. Crews** and **M.S. Grober**\*, Dept. of Zool., Univ. of Texas, Austin, TX 78712; Dept. of Biol. Sci., Univ. of Idaho, Moscow, ID, 83844 and #Dept. of Eco. Evo. & Mar. Bio., UCSB, Santa Barbara, CA, 93106.

Arginine vasotocin (AVT) is an important regulator of social and reproductive behaviors in many vertebrates. The sex-changing Caribbean bluehead wrasse, *Thalassoma bifasciatum*, provides a useful model for examining behavioral actions of AVT between and within sexes. This species is a diandric protogynous hermaphrodite. Individuals begin life in the initial phase (IP) as either females or males. Dependent upon specific social stimuli, either IP sex may transform into a terminal phase (TP) male. All three sexual phases exhibit unique combinations of secondary sexual characters, courtship behavior, and territorial aggression, which change rapidly (on the order of seconds to minutes) in response to social cues. Using *in situ* hybridization, we estimated relative preoptic area AVT-mRNA abundance in wild caught females, the two alternate male morphs, and females undergoing sex change induced through removal of large males from reefs. Unmanipulated females showed the lowest abundance of AVT mRNA. Both IP and TP males exhibited significantly greater abundance than females (220% and 360% of female values respectively), but the male morphs did not differ significantly from each other. Sex changing females showed all sexual and aggressive behaviors characteristic of TP males and exhibited hybridization signals not different from IP or TP males (398% of unmanipulated female values). The assumption of a dominant male behavioral phenotype, via sex or role change, is associated with increased abundance of AVT-mRNA in the preoptic area, suggesting AVT may play a role in generating within- and between-sex behavioral differences in this species. Supported by grant NIH-N509219 (JG), NSF-DEB 91-17379 and NSF-OCE 92-01320 (RRW), NIMH-41770 (DC), and NSF-IBN 9309555 and NIH-1P20RR09181-01 (MSG).

## 276.6

SEXUALLY DIMORPHIC PROCESSING OF SOMATOSENSORY AND CHEMOSENSORY INPUTS TO FOREBRAIN LHRH NEURONS IN MATED FERRETS. **S.R. Wersinger\*** and **M.J. Baum**. Department of Biology, Boston University, Boston, MA 02215

Mating induces a preovulatory LH surge in the estrous female ferret but significantly inhibits LH secretion in the breeding male. This dimorphism is reflected in a sex difference in Fos-IR in both LHRH and non-LHRH neurons after mating. We used the immunocytochemical localization of Fos and LHRH to ask whether the sex dimorphism occurs in the initial transmission or in the central processing of sensory stimuli? We also assessed the contribution of mating-associated sensory stimuli vs chemosensory cues alone to the neuronal Fos responses. Breeding male and female ferrets were allowed to intromit for up to 90 minutes. Additional chemosensory-stimulated subjects were placed in a cage in which an opposite-sex breeding-condition ferret had been housed for 48h. Unpaired control ferrets were placed alone in a clean testing cage. All subjects were perfused 90 min after the beginning of the stimulation period. In both sexes mating augmented Fos-IR in the granular layer of the olfactory bulbs, in the midbrain central tegmental field (CTF), and the medial amygdala (MA), regions situated early in the input pathway to the hypothalamic LHRH neurons. Other than the CTF, these same forebrain regions were activated in both sexes after exposure to chemosensory cues alone. However, more central forebrain regions (the preoptic area (POA), the bed nucleus of the stria terminalis (BNST), the ventro-lateral portion of the ventromedial hypothalamus (VLH)) as well as the LHRH neurons were activated by mating only in the female. In females, but not in males, chemosensory stimuli alone augmented Fos-IR in the medial POA and the VLH but not in the BNST or LHRH neurons. These results suggest that the sex dimorphism in mating-induced LH secretion reflects a sex difference in central processing, since chemosensory and genital-somatosensory stimuli activate forebrain regions early in the input pathway to the LHRH neurons equivalently in both sexes. Chemosensory cues are also processed in a dimorphic fashion; however, even in females, these cues are insufficient to activate fully the input pathway or LHRH neurons. ## 276.8

BEHAVIORAL MASCULINIZATION IN ESTROGEN RECEPTOR GENE DEFICIENT TRANSGENIC FEMALE MICE. **Sonoko Ogawa**<sup>1</sup>\*, **J. Taylor**<sup>2</sup>, **D.B. Lubahn**<sup>2</sup>, **K.S. Korach**<sup>3</sup>, & **D.W. Pfaff**<sup>1</sup> <sup>1</sup>Lab. Neurobiol. & Behav., The Rockefeller University, NY, NY10021, <sup>2</sup>Dept. Biochem. & Child Health, Univ. of Missouri-Columbia, Columbia, MO 65211 & <sup>3</sup>Lab. Reprod. & Develop. Toxicol., NIEHS, Research Triangle Park, NC 27709

Previously, we have reported that estrogen receptor (ER) gene disruption reduced specific sexual and aggressive behaviors and feminized open-field behaviors in male mice. In the present study, behavioral consequences of loss of functional ER were determined in female estrogen receptor deficient transgenic (ERKO) mice. Gonadally intact ERKO and age-matched wild-type (WT) female mice were individually housed and tested for sexual, aggressive, maternal and open-field behaviors at the age of 17-30 weeks. In sexual behavior tests, in the home cage of individually housed stud Swiss Webster (SW) male mice, all ERKO females (6/6) were vigorously attacked instead of being mounted by resident males with short latencies. The same males showed attempted mounts to diestrous WT females and mounts and intromissions to estrus WT females. When introduced into the home cage of individually housed SW female mice, ERKO females (3/6) showed male-type offensive attacks toward resident female mice. In pup-retrieving tests, only 2 out of 6 ERKO females retrieved pups (3-6 days old) to their nest and crouched over them while all 6 WT females showed both retrieving and crouching. Moreover, it was found that ERKO females used significantly less nest materials and made poor nests compared to WT females. Finally, in contrast to male ERKO mice which were more active than WT males, ERKO females tended to be less active in open-field tests (i.e., showed lower number of line crossings and entered less frequently to the center area) compared to WT female mice. These findings collectively suggest that ER gene disruption produced partial masculinization of behavioral phenotype in female mice. (Supported partially by Harry Frank Guggenheim Research Grant to SO.)

## 276.10

SEXUAL ALLOMORPHISM: INDIVIDUAL VARIATION BETWEEN THE SEXES. **T.O. Fox**<sup>1</sup>\*, **S.A. Tobet**<sup>1</sup> and **M.J. Baum**<sup>2</sup>. Program in Neuroscience, Harvard Med. Sch., Boston MA 02115<sup>1</sup>, and Department of Biology, Boston Univ., Boston MA 02215<sup>2</sup>

Sex differences develop in response to the actions of gonadal steroid hormones interacting with experiential factors. Traits can be sexually dimorphic, with one type expressed in females and another in males (e.g., gonadal structure; certain brain structures). For many other traits, some individuals of either sex may be "sex-typical" or "sex-atypical." Such traits are sexually allomorphic; i.e., mean values differ between the sexes, but significant between-sex overlap and within-sex gradation exist (e.g., many brain structures; neuronal phenotypes; behaviors; cognitive styles).

One specific example of a sexually allomorphic trait is sexual partner preference in ferrets. When adult ferrets were gonadectomized, injected daily with estradiol benzoate, and tested in a T-maze, on average, females preferred to approach and interact with a sexually active stud male whereas males preferred to approach and interact with a receptive estrous female. There was considerable variation, however, in the distribution of preference scores, such that 26% of the 57 male subjects tested preferred to approach the stud male. By contrast, only 6% of the 53 female subjects tested preferred to approach the estrous female. These data represent control ferrets from several experiments conducted over a decade.

Previously we would have referred to any sex difference as a sexually dimorphic trait, sometimes accompanied by the qualifier that some animals were atypical. By describing certain traits as sexually allomorphic, we emphasize that individual variations are typical in the population and that "female" and "male" are not stereotypical and bipolar conditions. Supported by NIH and NSF grants.

## 276.11

DEVELOPMENTAL EXPRESSION OF NEURAL ANDROGEN RECEPTOR IN MOUSE BRAIN: SEX DIFFERENCES. S. Lu and N.G. Simon\*. Dept. of Biological Sciences, Lehigh University, Bethlehem, PA 18015.

The presence of androgen receptor (AR) in neural target tissue is critical for the production of androgen-mediated effects. During sexual differentiation of the brain these effects include, for example, masculinization of structures regulating gonadotrophin secretion and sensitization of neural substrates underlying male-typical reproductive and aggressive behaviors. The expression of AR was assessed in male and female mice at several time points from birth to puberty to assess whether sex differences in AR were associated with the androgen-dependent ontogeny of these dimorphic characteristics. All maintenance and care procedures of CF-1 mice fully complied with Federal guidelines. Brain extracts from male and female mice aged day 1, 4, 7, 14, 21, 28, and 35 were prepared from limbic tissue blocks that included regions that express high levels of AR. AR protein levels were determined by Western blot-ECL using an anti-AR antibody, PG-21 (a gift from Dr. G. Prins). Scanning densitometry of the resulting blots showed a specific 97 kD band that presumably represents AR in both sexes. Over the period studied, there were significant sex differences in the expression of this protein, with males exhibiting higher densities and a more rapid increase in AR expression and in age-related increase in AR expression in both sexes. This profile of AR expression in neural tissue provides additional insights into the relationship between receptor density and the development of neural target tissue sensitivity to androgen.

Supported by NIH (1R15HD 31696) and NSF (IBN-9512015).

## 276.12

ANDROGEN METABOLISM IN THE BRAIN OF THE GREEN ANOLE LIZARD. I. Wade\*. Department of Psychology and Program in Neuroscience, Michigan State University, East Lansing, MI 48824.

Both androgenic and estrogenic metabolites of testosterone (T) are important for activating sexual behavior in the green anole lizard, *Anolis carolinensis*. For example, male sexual behavior is abolished by castration and can be elicited in either males or females by treatment with T or 5 $\alpha$ -dihydrotestosterone (DHT). Ovariectomy inhibits receptivity in females, and the behavior can be reinstated with either estradiol (E) or T treatment. In an effort to begin to directly test the role of neural steroid metabolism, assays to measure the activity of aromatase (which catalyzes the conversion of T to E) and 5 $\alpha$ -reductase (which catalyzes the conversion of T to DHT) were conducted in whole homogenates and subcellular preparations of brain tissue from male and female anoles. Assays were done during the breeding season using <sup>3</sup>H-T as substrate. In incubations using tissue pooled from males and females, production of <sup>3</sup>H-DHT was substantially higher than formation of <sup>3</sup>H-E. These results suggest that 5 $\alpha$ -reductase is more active than aromatase. In addition, preliminary evidence suggests that incubation temperature affects the two enzymes differently. Further characterization of the enzymes and an investigation of potential sex differences in their activity should help elucidate the role of androgen metabolism in the activation of sexual behaviors in the green anole lizard. Supported by MH54985.

## DRUGS OF ABUSE: ETHANOL, BARBITURATES, AND BENZODIAZEPINES II

## 277.1

COGNITIVE AND MOTOR DEFICITS ARE ASSOCIATED WITH CHRONIC ETHANOL CONSUMPTION IN C57BL/6J MICE. B. Koller, C. Taylor, D.E. Krug\*, R. Reynolds, H. Lal, and M.J. Forster. Department of Pharmacology, University of North Texas Health Science Center, Fort Worth, TX 76107-2699.

Chronic alcohol abuse is associated with impaired performance on sensorimotor and visuospatial tasks. The current studies investigated the extent to which analogous deficits result from chronic ethanol exposure in mice. C57BL/6J mice were given a liquid diet including alcohol (0, 5, 10, or 20 mg/kg/day) or a mouse chow diet for either 5 or 7 months. Pair fed control mice were maintained at caloric equivalence with sucrose/dextrin. Four weeks after the diet was discontinued, the mice were evaluated on cognitive, motor, and sensorimotor tasks. In a water maze task, the 5 month alcohol group had a general decrease in spatial performance. Other general effects of chronic alcohol included impaired ability to traverse an elevated path, an impaired ability to tread or remain hanging from a horizontal wire, and a reduction of total locomotion, rears, and stereotypy counts. In several tasks, the 7 month-alcohol mice were less impaired than the 5 month-alcohol mice including both the spatial memory and active avoidance tasks. The current findings suggest that mice can provide a useful model of chronic alcohol-induced brain dysfunction. [Supported by NIH grant AA09622]

## 277.3

ETHANOL PLACE-PREFERENCE CONDITIONING IN C57BL/6 MICE: A PRELIMINARY STUDY. C. Nocjar\*, M. Tavernetti, and L.D. Middaugh. Dept. of Psychiatry, CDAP, Med. Univ. of SC, Charleston, SC 29425.

Recently, it was reported that ethanol preferring rats (P rats) do not show a conditioned place preference (CPP) for ethanol (Stewart et al., 1996). The present study assessed whether C57BL/6 mice, which consume amounts of ethanol comparable to P rats, would show ethanol CPP. Male and female mice were given a non-drug pretest to determine baseline preferences for the black and white sides of the CPP apparatus with free-access to the entire chamber. Mice then received 8 pairings of 1.75 g/kg ethanol (ip) in their non-preferred side and 8 pairings of saline in their preferred side of the chamber. Drug conditioning sessions (10 min) began immediately post injection to include drug onset effects. Motor activity was assessed during conditioning sessions. Chamber preferences were then re-assessed during a non-drug posttest where animals once again had free-access to both sides of the CPP apparatus. Ethanol stimulated motor activity and produced a CPP (15-20% increase in the amount of time spent in the ethanol paired chamber when compared to pretest times). Gender did not influence these effects. The ethanol drug-seeking behavior evidenced in this study suggests that the C57BL/6 mouse may be a good model for the study of alcohol addiction since this mouse strain will not only self-administer large quantities of the drug but also seek out its reinforcing effects. (AA10761)

## 277.2

POSTNATAL ETHANOL EXPOSURE ALTERS SEIZURE SUSCEPTIBILITY IN YOUNG RATS R. Sircar\*, D. Kim. Dept. Psychiatry and Neurology, Albert Einstein Coll. of Med., Bronx, NY 10461.

Timing of exposure to ethanol during development is important for the long-term detrimental effects of ethanol (Thomas et al., Neurosci. Abs. Vol 21 (3) 824.1, 1995). Majority of studies have focused on the effects of ethanol during the prenatal period or the early neonatal period. NMDA receptors have been implicated as neurochemical correlates underlying the behavioral effects of ethanol. Ontogenic studies of the NMDA receptor suggest that it becomes functional during the second postnatal week. To test the hypothesis that exposure to ethanol during late postnatal period, i.e., period of NMDA receptor maturation, has long-term behavioral effects, we exposed rats to ethanol (2.5 mg/kg/day; intragastric) from postnatal day 10 till day 20. Control rats received equivalent volumes of water. Rats were tested behaviorally in the pentylenetetrazol-induced seizure paradigm between postnatal days 29 and 31. The frequency of and latency to reach each seizure stage was measured (twitches, clonic and generalized tonic-clonic seizure). All control rats exhibited generalized tonic-clonic seizure whereas a significantly lower percentage of ethanol-exposed rats had generalized tonic-clonic seizure. Also, the latency to reach generalized tonic-clonic seizure was significantly longer in ethanol-treated rats compared to controls. The latency to clonic seizure or twitches did not differ between the two groups and there was no difference in the frequency to these seizure stages between control and experimental rats. Postnatal ethanol-treated rats were less susceptible to PTZ-induced seizures compared to controls. These data indicate that the developing glutamatergic system may play an important role in the behavioral effects of ethanol exposure during late postnatal period.

## 277.4

THE EFFECTS OF ETHANOL OF THREE TESTS OF IMPULSIVE DECISION MAKING IN THE RAT John Evenden\*. Dept of Behavioural and Biochemical Pharmacology, CNS Research and Development, Astra Arcus, S-151 85 Södertälje, Sweden.

Ethanol has popularly been supposed to increase impulsive behaviour in man. This is generally assumed to be manifested in the form of impulsive aggressive behaviour. However, many of the effects of ethanol appear to depend upon expectations which are culturally and environmentally determined. In the present study objective tests of appetitively motivated decision making in rats were designed emphasising different aspects of impulsivity previously studied in man. These reflect the stages of preparation to make the decision, execution of the action decided upon, and assessment of the expected outcome. These were assessed by versions of an uncertain visual discrimination test, fixed consecutive number tests and the delay of reinforcement procedure, respectively. The same motivation (food deprivation), reinforcer (food pellets) and response (lever pressing) were employed in all three tests. Ethanol (0.1 - 1.0 g/kg i.p.) had no effect on reaction time nor the number of correct choices in the uncertain visual discrimination test. Ethanol (0.3 - 3.0 g/kg p.o.) had no effect on the chain length or local measures of response rate in the fixed consecutive number test. However at doses of 0.1 - 1.0 g/kg i.p., ethanol produced a significant shift in the preference for immediate reinforcement rather than delayed reinforcement in the delayed reinforcement procedure. Recent published data indicated that rats showing a preference for immediate reinforcers ("impulsive" rats) also show an increased preference for consuming ethanol. In combination with the data presented here, these suggest that ethanol consumption can lead to a circle of increased preference for immediate reinforcers, leading to increased ethanol consumption, which leads to a further preference for immediate reinforcers. Since preparation and execution of behaviour were unaffected by the drug at the same doses, the behavioural substrate for maintaining this vicious circle remain intact until ethanol consumption reaches motivationally disabling levels.

## 277.5

INTERACTIONS OF ETHANOL AND HYPOGLYCEMIA ON RAT MOTOR ACTIVITY. P. Duncan. Psychology Dept. Old Dominion Univ., Norfolk, VA 23529.

Hypoglycemia (HG) produces mental confusion and anxiety in humans, and reduces motor activity in rats. Ethanol (ETH) also produces dose-related decreases in rat locomotion. The primary purpose of this experiment was to determine the effects of ETH at 0, 300, 600, and 1000 mg/kg on locomotor activity in hypoglycemic, compared to euglycemic rats. Acute ETH effect on blood-glucose (BG) level was also of interest. Insulin (2 units/kg) or saline was injected IP 30 min prior to a BG measurement, which was followed immediately by an IP injection of ETH or saline, and then a 60-min activity-recording period. A within-subjects factorial design was used, with each of nine rats receiving all eight combinations of insulin and ETH treatments. Insulin produced marked HG at both 30 min (70 vs 48 mean mg/deciliter) and 90 min (68 vs 28) post-injection. ETH in the euglycemic state significantly lowered motor activity only at the highest dose (0-962, ETH 1000-403 mean counts/60 min). Activity was decreased by insulin treatment, which also shifted the ETH dose-response to the left, with a significant difference seen at the lowest dose (0-639, 300-121, 600-177, 1000-138). ETH slightly lowered BG (71 vs 60), and ETH 1000 in combination with insulin tended to further decrease BG (mean at 90 min post insulin-22). These results show that a state of moderate to severe HG greatly increases the behavioral depressant effects of ETH. Since HG was only slightly increased by the highest ETH dose, the behavioral potentiation probably results from the summation of two separate types of CNS impairment.

CHRONIC ETHANOL NORMALIZES TONIC GRASP OF NRTP-DAMAGED RATS AT DOSES THAT DO NOT AFFECT GRASP OF NORMAL RATS. R.M. Chesire & B.E. Digman. Col. Health Sci. & Psych. Dept., Univ. Hawaii-Manoa, Honolulu, HI 96822.

Changes in the ability to cling to a horizontal rod with the forepaws have been used to indicate drug- or neural damage-induced dysfunction in rats. Normal rats cling briefly in such positions, but rats made cataleptic by dopamine deficiency (e.g., systemically administered haloperidol, electrolytic lesions of the lateral hypothalamus) show exaggerated tonic grasp and can cling for extended periods of time. Rats given lesions of the nucleus reticularis tegmenti pontis (NRTP) show a variety of symptoms, including rapid forward locomotion and excessive tonic grasp. We have demonstrated that alcohol does not impair and can actually improve some motor functions of NRTP-damaged rats. We report here that tonic grasp is among these. The number of seconds spent clinging to a microspatula were measured in normal and NRTP-damaged rats administered tap water (TW), TW+25% sucrose (SU) or TW+SU+5%-30% ethanol (ETOH) in their water bottles over a period of  $\approx 85$  days. Increases in ETOH doses (1% per unit time) were determined by performance on the tilting plane test. Unoperated rats showed no differences in any condition, but did cling significantly less than NRTP-damaged rats ( $F=14.8; p<0.01$ ). NRTP-damaged rats showed significantly reduced length of tonic grasp at doses from 10%-26% ETOH ( $F=4.44; p<0.036$ ). The results provide further support for the idea that, in the presence NRTP dysregulation, normalization of motor function creates an appetitive stimulus for substance abuse.

## 277.9

INDUCTION AND MAINTENANCE OF MODERATE BLOOD ETHANOL LEVELS BY ATRAUMATIC PUSATILE GASTRIC INFUSIONS IN "EXPERIENCED" RATS: EFFECTS ON BRAIN OPIOMELANOCORTINERGIC ACTIVITY. Rasmussen D.D., Bryant C.A., Boldt B.M., Colasurdo E.A., Wilkinson C.W., V.A. Medical Center and Univ. Of Washington, Seattle, WA 98195

Forebrain neurosecretion of pro-opiomelanocortin (POMC)-derived peptides, especially the potent opioid  $\beta$ -endorphin ( $\beta$ END), appears to mediate some responses to ethanol administration. However, attempts to characterize ethanol-induced changes in activity of this opiomelanocortinergic system have yielded variable results, perhaps in part due to confounding non-specific stress responses. We have developed a model in which "experienced" rats (previously introduced to ethanol administration, so the subjective response is not a novel stimulus) receive pulsatile intragastric ethanol infusions during the dark (active) photophase to produce and sustain (for 3 h) moderate (0, 50, 90-100, or 120-150 mg/dl) blood alcohol levels (BALs). BALs of approximately 50 mg/dl did not significantly alter  $\beta$ END concentrations in any brain area examined at 30 min after initiation of infusion, whereas 90-100 mg/dl increased ( $p<0.05$ )  $\beta$ END concentrations in the ventral tegmental area (VTA) and 120-150 mg/dl increased both VTA ( $p<0.05$ ) and nucleus accumbens ( $p<0.01$ )  $\beta$ END concentrations. None of the dosages significantly altered  $\beta$ END concentrations in the amygdala, preoptic area, or mediobasohypothalamus (MBH) after 30 min, although there were trends toward increases. BALs of 120-150 mg/dl (but not lower levels) also increased ( $p<0.05$ ) MBH cytoplasmic POMC mRNA concentrations at the end of the 3 h infusion period (but not at 30 or 60 min) as well as at 3 h after termination of the infusions (i.e., 6 h after initiating treatment). These results demonstrate that atraumatic induction of physiologically meaningful BALs acutely activates the forebrain opiomelanocortinergic system, consistent with evidence the  $\beta$ -endorphinergic mechanisms mediate some responses to alcohol ingestion. ETHANOL-INDUCED ATAXIA IN MICE LACKING SEROTONIN 1B RECEPTORS. G.L. Schafer and J.C. Crabbe. Dept. of Veterans Affairs and Oregon Health Sciences University, Portland, OR 97201

Serotonergic pathways have been implicated in a variety of ethanol (EtOH) related effects. Recently, knockout mice have been developed that lack the serotonin-1b (5-HT1b) receptors (Saudou et al, 1994). These mice present a useful tool for investigating the role of these receptors in mediating CNS sensitivity to EtOH. We have begun to test these mutant mice (5-HT1b<sup>-</sup>) and their wild-type (wt) counterparts for various EtOH-induced behaviors, including ataxia. Previous studies from our lab have indicated that wt mice are more sensitive to grid-test ataxia (Crabbe, et al, submitted). Other studies in our lab have demonstrated that ataxia is not a genetically uniform trait. Therefore we decided to test 5-HT1b<sup>-</sup> and wt mice using other measures of EtOH-induced ataxia. 5-HT1b<sup>-</sup> and wt mice were tested for sensitivity to EtOH-induced ataxia using a fixed-speed rotarod. Initially, mice were given practice on an accelerating rotarod until a stable performance level was achieved. The results from these practice sessions indicated that 5-HT1b<sup>-</sup> mice took longer to achieve the same performance level than the wt mice. Twenty-four hours the last practice test, mice were tested on the fixed-speed rotarod immediately after an injection of 2.5 g/kg EtOH (i.p.). Latency to fall and brain EtOH concentration (BrEC) at time of fall were measured. The results indicated that 5-HT1b<sup>-</sup> mice were more sensitive to EtOH than wt mice as indicated by a lower BrEC ( $1.30 \pm .11$  mg/kg vs.  $1.65 \pm .09$  mg/kg, respectively). It is unclear why opposite results from grid test were observed. However, it is probable that these tasks may reflect different physiological components of ataxia. Studies are currently in progress to assess differences in acute functional tolerance to EtOH in these lines of mice. Supported by NIAAA grants AA10760 and T32AA07468 (GLS).

## 277.8

ONTOGENY OF ETHANOL SLEEP TIME: AGE-RELATED ALTERATIONS IN ETHANOL SENSITIVITY AND ACUTE TOLERANCE. M.M. Silveri and L.P. Spear. Center for Developmental Psychology, Binghamton University, Binghamton, NY 13902-6000.

The purpose of the present study was to examine the ontogeny of acute tolerance and sensitivity to ethanol in terms of ethanol-induced sleep time. Male and female Sprague-Dawley rats at postnatal days P16, 26, 36, 46, 56, and 96 received intraperitoneal injections of 3.5, 4.0, 4.5, or 5.0 g/kg ethanol. Sleep time (interval between loss and regain of righting reflex) was determined, animals were sacrificed immediately following regain of the righting reflex, and trunk blood samples were collected. Blood samples were analyzed via gas chromatography for blood alcohol content (BAC) at time of awakening. EtOH sleep time increased with age, with a gender effect (males sleeping longer than females) evident at P56 and 96. In addition, BAC levels at time of awakening significantly decreased across age with P96 animals exhibiting the lowest BAC. Acute tolerance (indexed by the magnitude of the slope of the linear regression obtained from plotting dose of ethanol vs. BAC at the time of awakening) also decreased during ontogeny, with little evidence of acute tolerance for this measure being seen in P46 and older animals. Initial sensitivity to ethanol was shown to increase with age; these estimates of initial brain sensitivity to ethanol at each age were derived by plotting sleep time versus BAC at awakening, with the extrapolated point at zero sleep-time serving as an index of initial brain sensitivity. These findings suggest that increases in ethanol sleep time seen during development may be related both to an ontogenetic increase in brain sensitivity to ethanol as well as an ontogenetic decrease in the development of acute tolerance during the ethanol-induced sleep. Supported by NIAAA grant R01 AA10228.

## 277.10

DIFFERENTIAL ETHANOL (ETH) CONSUMPTION IN ROMAN HIGH-AVOIDANCE (RHA) AND LOW-AVOIDANCE (RLA) RATS. O. Giorgi, M.G. Corda, M. Oriandi, V. Valentini, G. Carboni, V. Fan and G. Di Chiara. Dept. of Toxicology, Univ. of Cagliari, via. A. Diaz 182, 09126 Cagliari, ITALY.

Selective breeding techniques have been used extensively to examine the role of genetic factors in the control of ETH intake. Moreover, preference for ETH has been observed also in lines of rats selectively bred for behaviors other than ETH consumption. This is the case of RHA and RLA rats, two lines selected and bred for rapid versus poor acquisition of two-way avoidance behavior in a shuttle box. RHA and RLA rats show many other behavioral differences related to emotional factors, RLA rats being emotionally more reactive. In addition, a number of differences in dopaminergic (DAergic) and GABAergic function in the CNS have been reported in these two lines. Given the role of DA and GABA in the regulation of ETH consumption, the present study was undertaken to characterize the differences in ETH intake and preference between RHA and RLA rats. ETH solutions were presented on alternate days in a free choice with water. The initial ETH concentration was 2% and 1% increments were applied every second day until a final concentration of 10% was reached by day 18. RHA rats consumed significantly larger amounts of ETH than did RLA rats. In addition, RHA rats, but not their RLA counterparts, displayed significant preference for ETH over water. To examine ETH intake and preference stability, animals were subsequently switched to daily presentations of 10% ETH for 18 consecutive days. The line-related differences in ETH intake and preference remained stable throughout the test period. These results indicate that RHA and RLA rats can provide a useful model to investigate the biochemical mechanisms involved in the behavioral responses to ETH. Studies aimed at characterizing the effects of ethanol on DAergic neurotransmission in the CNS of these two lines of rats are in progress in our laboratory.

## 277.11

## ETHANOL PREFERENCE AND BEHAVIOR IN THE NAPLES HIGH- AND LOW-EXCITABILITY RAT LINES.

M.P. Pellicano and A.G. Sadile<sup>1</sup>, (SPONSORED BY THE EUROPEAN BRAIN AND BEHAVIOR SOCIETY). Lab. Eating Behavior, Food Science & Technol. Inst., CNR, Avellino; <sup>1</sup>Lab. Neurophysiol. Behav. & Neural Networks, Dept. Human Physiol. "F. Botazzi", SUN, Naples, I.

The aim of this project was to investigate the long-term effects of ethanol consumption on behavior in animal models. Adult male albino rats of the Naples High (NHE) and Low-Excitability (NLE) lines and of a random-bred control line (NRB) were housed in single cages with pelleted food and four bottles containing either tap water or 5, 10 and 20 % ethanol solution. A control group for each line consisted of rats with no access to ethanol. Food intake and fluid consumption were monitored three times a week during a 6-wk period at the beginning of the dark phase of the light-dark cycle. Body weight was measured every week. At the end of the experimental period, ethanol-exposed and control rats were exposed to a L-maze during three 10-min periods separated by a 24-h interval. Behavior was monitored and stored on videotape for off-line analysis of frequency of corner-crossings and rearings, and duration of rearing episodes. On day 1, total ethanol intake was higher in both NLE/NHE-rats compared to NRB controls. Ethanol preference for the different concentrations as percent of the total ethanol consumption, was lower for the 5% solution in both NLE/NHE rats, as compared to NRB-rats, whereas it was higher for 10 and 20 % in both strains. On day 2-42, total ethanol intake increased in all strains, but more in NLE/NHE-rats compared to NRB-rats. Ethanol preference was higher for 5 % solution in NHE and NRB-rats. In contrast, NLE-rats preferred the 20 % solution. Thus, the NLE/NHE rats appear as a useful model to study the neural substrates of ethanol preference, tolerance and dependence. (Supported by CNR STRA094 and MURST95 grants).

## 277.13

NEUROCHEMICAL DIFFERENCES BETWEEN ETHANOL-NAIVE AND ETHANOL-EXPOSED WISTAR, ALCOHOL PREFERRING (P) AND ALCOHOL NON-PREFERRING (NP) RATS. A.D. Smith<sup>1</sup> and E. Weiss. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Ethanol preference versus non-preference in genetically selected rat lines is believed to involve differences in dopamine (DA) and serotonin (5HT) function. Tissue studies have reported lower levels of DA and 5HT in the nucleus accumbens in P rats versus NP rats. This deficiency has been implicated in the heightened voluntary intake of ethanol in P rats. In the present study, quantitative in vivo microdialysis was used to investigate differences in the basal extracellular levels of DA and 5 HT in ethanol-naive and ethanol-exposed P, NP and Wistar rats. Rats were implanted with guide cannulae aimed at the nucleus accumbens. Animals were injected with saline or ethanol (1g/kg IP) for 5 days. Microdialysis was performed on the 6th day using the point of no net flux method. Alcohol-naive P rats showed higher basal extracellular 5 HT levels and no differences in DA levels compared to alcohol-naive NP and Wistar rats. 5HT levels in Wistar rats were also higher than NP rats. Repeated ethanol exposure resulted in increased basal DA extracellular concentration in Wistar and P rats with no changes in DA levels in NP rats. Basal 5 HT levels increased in Wistar and NP rats whereas a trend toward decreased 5HT levels was observed in P rats in accordance with findings of earlier tissue studies. The possibility of strain differences in the response of the DA system to ethanol challenge is currently under investigation in ethanol-naive and ethanol-exposed rats. (Supported by NIAAA AA 10531).

## 277.15

SHIFT-WORK PHOTOPERIODS INFLUENCE THE VOLUME OF ETHANOL SELF-ADMINISTERED "AFTER HOURS" IN RATS D.V. Gauvin<sup>1</sup>, R.J. Briaune, T.J. Baird, M. Vallett, S.A. Vanecek, & F.A. Holloway; Dept Psychiat & Behav Sci, O.U.H.S.C., Okla. City, OK 73190

Thirty-six male Sprague-Dawley rats were conditioned to self-administer 10% w/v ethanol (ETOH) in tap water using a modified Samson-sucrose fading procedure. Rats were given ad lib access to food and water and offered access to the ETOH solution for 1/2 hr a day in their home-cages (0600-0630h). Once consumption stabilized to  $\pm 10\%$  variability over seven consecutive days, rats were placed in an isolated AAALAC-accredited colony room with a separate light-controlling timer. Lights were scheduled to cycle similar to the photoperiods experienced by humans working on a "southern-swing" shift for two consecutive months. Rats were given the 1/2 hour access to ETOH during a time-frame analogous to 1 hr after the human's work shift was over. On "days off" access was given at 0800-0830h. The amount of ETOH consumed, expressed in mls. or in g/kg, varied across the work shift cycle. Access to ETOH after the afternoon shift produced the highest voluntary ETOH consumption (approx. 2g/kg). Post day-shift access produced moderately high drinking (1.25-2 g/kg). Days off and post-midnight shifts produced the lowest rates of drinking (approx. 1.0 g/kg). For each work-shift schedule, rats drank more during the second month of exposure when compared to the first months drinking. These data suggest that the stress of shift work photoperiod changes may be a contributing factor to sustained increases in voluntary ETOH consumption. ## 277.12

TASTE REACTIVITY CONCENTRATION-RESPONSE FUNCTIONS FOR ALCOHOL AND SUCROSE SOLUTIONS IN OUTBRED MICE, H.J. Kaczmarek, K.G. Hill, and S.W. Kiefer<sup>1</sup>. Dept. of Psychology, Kansas State Univ., Manhattan, KS 66506-5302.

Preliminary results from taste reactivity tests with outbred mice indicated that these animals did not respond differentially to a range of alcohol solutions (3%-12%, v/v) and that the response to alcohol resembled taste reactivity responses to single concentrations of sucrose, sodium chloride, quinine hydrochloride, and hydrochloric acid solutions. The lack of discriminative responding in mice to taste solutions was explored in two additional studies. Experiment 1 (n=16) involved taste reactivity testing to a range of alcohol concentrations (5%, 10%, 20%, 30%, and 40%) and Experiment 2 (n=26) involved five sucrose concentrations (0.01 M, 0.05M, 0.10 M, 0.50 M, and 1.0 M). Mice were presented with one solution per day for 60 s (rate = 0.2 ml/min); order of concentrations was determined randomly for each mouse. As a general characterization, predominant response profiles for mice, regardless of taste solution or concentration, consisted of tongue protrusions (ingestive), gapes, and forelimb flails (both aversive). Mice showed a significant increase in tongue protrusions for increasing concentrations of both alcohol and sucrose. Further, mice made significantly fewer gapes as the concentration of sucrose was increased. The present results demonstrate that concentration-dependent reactivity profiles, at least for tongue protrusions, are found in mice when a wide range of alcohol concentrations is used. Mice also show discriminative responding for sucrose solutions as reflected by increasing tongue protrusions and decreasing gape responses.

Research supported by NIAAA grant AA09335.

## 277.14

IN VIVO MICRODIALYSIS RECORDINGS OF STRIATAL DOPAMINE IN RATS SELECTIVELY BRED FOR DIFFERENTIAL CNS ETHANOL SENSITIVITY. A.F. Hoffman<sup>1</sup>, M.A. Segall, G.A. Gerhardt, T.A. French, and N. Weiner. Dept. of Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262.

Interactions between ethanol and central catecholamine systems have been reported to play a role in a variety of behavioral effects produced by alcohol. In the present study, we investigated the effects of ethanol on dopamine (DA) release in the striatum of both high alcohol sensitivity (HAS) and low alcohol sensitivity (LAS) rats. Animals were anesthetized with urethane (1-1.25 g/kg, i.p.) and stereotactically implanted with single 4 mm dialysis probes in the lateral striatum. Probes were perfused with an artificial CSF (aCSF) solution. Samples were collected every 20 minutes and analyzed by high pressure liquid chromatography coupled with electrochemical detection. Following an 80 minute period to allow for stabilization of metabolite levels, modified aCSF containing 100 mM KCl was applied for 20 minutes. After a 60 minute washout with normal aCSF, animals were injected with a 1.0 g/kg, i.p. dose of ethanol. Twenty five minutes later, the potassium stimulus was repeated. Preliminary results showed that basal DA levels were similar between HAS and LAS rats (27  $\pm$  4 and 38  $\pm$  10 nM, respectively). Basal levels of the DA metabolites 3,4-dihydroxyphenylacetic acid and homovanillic acid were slightly higher in HAS (6.7  $\pm$  0.53  $\mu$ M; 7.9  $\pm$  1.1  $\mu$ M) than in LAS rats (4.3  $\pm$  0.52  $\mu$ M; 5.7  $\pm$  0.62  $\mu$ M). Potassium-evoked release of DA in both lines was similar prior to ethanol administration. A 30% decrease in the potassium-evoked DA release was found 45 minutes following ethanol treatment in HAS rats, versus a 2% decrease in LAS rats. These results suggest that differences in both DA release and metabolism may exist between rats which are selectively bred for alcohol sensitivity. Experiments are in progress which will further elucidate both the nature and functional consequences of these differences. Supported by NS09199 and NIAAA 03527.

## 277.16

DIFFERENTIAL ETHANOL AND AMPHETAMINE BEHAVIORAL SENSITIZATION IN DBA/2Abg, C57BL/6Abg, AND Abg:GHSC MICE. T. TRITTO<sup>1</sup>, S. CHENOWETH, and B.C. DUDEK. Psych. Dept., University at Albany, SUNY, Albany, NY, 12222

Repeated exposure to some drugs of abuse have been shown to produce behavioral sensitization which is thought to contribute to a drug's addiction liability. The present studies examined both ETOH (2.0 g/kg)- and AMPH (2.5 mg/kg)-induced behavioral sensitization in two inbred strains, DBA/2Abg (D2) and C57BL/6Abg (B6), and one heterogeneous stock, Abg:GHSC (GHS). The protocol was that used by Phillips et al. (1994) with the addition of a saline and a drug group which did not receive exposure to the activity test chamber until the final day of testing. This allowed for testing of a possible conditioning component. Cross-sensitization of AMPH to ETOH was also tested. Whereas both the D2 and B6 strains showed AMPH sensitization, only the D2 strain showed ETOH sensitization. Although there was a trend towards cross-sensitization in both inbred strains, this was not significant. The GHS stock did not show ETOH sensitization or cross-sensitization, and showed only conditioned AMPH sensitization. This lack of sensitization in this heterogeneous stock is consistent with previous findings in our lab and possible explanations for this lack of sensitization are discussed. [Supported, in part, by NIH grant AA09038]

## 277.17

APPROACH AND AVOIDANCE CONDITIONING IN RATS BRED FOR ALCOHOL PREFERENCE. M.R. Blankenship\*, P.R. Finn, J.E. Steinmetz. Dept. Of Psychology/Program in Neural Science, Indiana Univ., Bloomington, IN 47405

The development of an animal model for alcoholism has provided invaluable knowledge of the physiological and biochemical basis of the disease. However, these genetically selected characteristics give rise to a spectrum of, as yet, uncharacterized behaviors. Behavioral analysis of ETOH preferring (P) and ETOH nonpreferring (NP)(Li et al., 1994) rats appears to be a crucial step in identifying the factors that define the disease of alcoholism. It has been hypothesized that alcohol-seeking behavior may be driven by deficient reward systems or poor conditionability to negative consequences. In a paradigm that is designed to assess conditioning to both rewarding (approach) or aversive (avoidance) consequences in P and NP rats, several results suggest a distinct constellation of behaviors that may contribute to alcohol preference. When trained on the avoidance task first, P rats attain higher avoidance response rates than NP's ( $p < .0004$ ). A three-way interaction of ETOH preference, task and session suggests that P rats learn faster on the approach task, while NP rats learn the avoidance task slowest ( $p < .044$ ). When trained on the approach task first, NP rats reach higher response rates ( $p < .021$ ). The fact that the order of task presentation is important in determining performance implies strong contextual carry-over effects. However, the difference between naive rats' performance may be based upon the contingencies of the tasks (P rats condition well to punitive contingencies and NP rats condition well to appetitive contingencies). Such differences may be reflected in the animal's predisposition to ETOH preference.

## 277.19

EFFECTS OF MORPHINE ON ETHANOL PREFERENCE IN HIGH ALCOHOL-SENSITIVE RATS. B. Hina\*. Univ. of Puerto Rico School of Pharmacy, San Juan, PR 00936.

This experiment was conducted to determine whether morphine would increase 10% ethanol (ET) drinking in rats genetically selected for high alcohol sensitivity (HAS), that drink ET sparingly ( $< 1.5$  g/kg/day) in preference tests. Two groups of 7 singly-caged female HAS rats (U. of Colorado generation #27, 77-90 days old), equated on the basis of prior daily water intake, were administered three 1.5 mg/kg s.c. morphine sulfate (MS) or saline (SAL) injections during a standard ET preference test (Li-Alcohol.Clin.Exp.Res. 8:485, 1984): once before 3 days of 10% ET as the sole fluid source and also at the end of the first and second weeks of the 3-week ET/water preference test.

This MS dose regimen produced a transient (24-hour) increase in ET consumption ( $p < .05$  g/kg/day;  $p = .052$  ET/water preference ratio) only after the second MS dose, relative to SAL. However, the major effect of MS was to decrease ET intake during the 3 days of 10% ET ( $p = .036$ ) and to produce a 39-64% reduction in ET consumption/preference measures over the 3-week test period.

The relative decrease in ET preference might be due to a high sensitivity to the depressant effect of MS and/or biological characteristics requiring a higher basal ET preference in these rats for MS to increase drinking. Thus, the data are difficult to interpret, with respect to the opioid "deficiency" or "surefit" hypotheses of alcoholism. Supported by University of Puerto Rico (CIDIC) funds.

## DRUGS OF ABUSE: COCAINE—GLUTAMATERGIC INFLUENCES

## 278.1

CONDITIONED EFFECTS OF COCAINE IN RATS: INFLUENCE OF MK-801 ON BEHAVIORAL AND GENOMIC RESPONSES. T.R. Franklin\*, C. Walters, Y. Zhu, G. Aston-Jones and J.P. Druhan. Psychiatry Dept., Medical College of Pennsylvania and Hahnemann University, Phila., PA 19102.

Studies in human cocaine abusers indicate that conditioned cocaine-like responses can be elicited by environmental stimuli previously associated with administration of the drug. In the present study, immunohistochemical localization of Fos protein was used as a genomic marker of cellular activation in rats to identify potential CNS sites involved in this conditioning process. Conditioned hyperactivity and Fos expression within the CNS were determined in rats exposed to a test chamber previously paired with 10.0 mg/kg cocaine. Rats in this 'Paired' group were found to exhibit higher levels of behavioral activity and increased numbers of Fos-positive cells within the lateral septum relative to 'Unpaired' rats that received cocaine in the colony room or 'Control' rats that never received cocaine. In contrast, there was no evidence of conditioned hyperactivity or conditioned Fos expression within the septum in rats that received injections of the NMDA receptor antagonist, MK-801 (0.25 mg/kg), prior to conditioning sessions. The correspondence between the expression of conditioned hyperactivity and genomic activation in the lateral septum, and the blockade of both effects by MK-801, suggests that the septum may play an important role in the expression of conditioned responses to cocaine-related stimuli. Quantification of Fos-positive cells in several other regions is currently underway to determine whether a similar correspondence can be found in other CNS sites. (Supported by NIDA grant #DA08381 to JPD).

## 277.18

ETHANOL, GENETICS AND THE C-FOS RESPONSE. B. Hitzemann, V. Patel, I. Cipp\* and R. Hitzemann. Department of Psychiatry, SUNY at Stony Brook, NY 11794-8101 and Psychiatry and Research Services, VAMC, Northport, NY 11768.

The C57BL/6 (B6) and DBA/2 (D2) inbred mouse strains differ in their response to ethanol. For example, modest doses of ethanol increase locomotor activity in the D2 but not the B6 strain. The B6 and D2 strains also differ in a variety of paradigms which are thought to measure ethanol preference and/or reward. The mechanisms underlying these differences are not clear but may involve differential ethanol effects on the basal ganglia and related structures. In an attempt to support this hypothesis, we have compared the c-Fos response between strains after the administration of low to modest doses (0.25-1g/kg) of ethanol. For both strains and at all doses, a significant increase in c-Fos IR was detected in the dorsal striatum and the shell and core of the nucleus accumbens. In these regions there was a trend to a greater effect for the B6 strain. There was no detectable ethanol effect in the globus pallidus, the entopeduncular nucleus and the substantia nigra zona reticulata. Ethanol markedly increased (strain independently) c-Fos IR in the paraventricular thalamic nuclei. A marked difference between strains was noted in the central amygdaloid nucleus ( $B6 \gg D2$ ) and the bed nucleus of the stria terminalis ( $D2 > B6$ ). Overall, although these data suggest that relatively low doses of ethanol have marked effects on synaptic activity, the reasons for the marked strain differences are less clear. Supported by AA 11034.

## 278.2

NOVELTY AS AN APPETITIVE STIMULUS: PRETREATMENT WITH MK-801, AND PARALLEL EFFECTS WITH COCAINE. R. A. Bevins\*, N. A. Brown & M. T. Bardo. Psychology Dept., Univ. of Kentucky, Lexington, KY 40506.

The present work assessed whether repeated access to novel objects could serve as an appetitive (rewarding) stimulus in a place conditioning procedure. Using a three compartment box, rats were placed in a center gray area and allowed access to adjacent black or white compartments. Subsequent conditioning included eight 10-min confined exposures (1/day), four in each end compartment. Group Paired received access to an object in the nonpreferred side; they were exposed to the other side without an object. The Unpaired Control received equal compartment and novel object exposure, except objects were presented in the home cage. When rats were re-tested for their side preference, Group Paired increased their time spent in the nonpreferred side. The Unpaired Control did not show this change. Between group differences were again found in a separate experiment using a control that received no exposure to the objects. Cocaine (IV, 0.5 mg/kg), when used as the appetitive stimulus in the above procedures, produced a data pattern similar to that of the novel objects. Both Paired and Control novelty rats pretreated with the NMDA receptor antagonist MK-801 (0.1 mg/kg, IP) spent less time in the nonpreferred side than untreated rats (i.e., place aversion). Thus, the apparent partial MK-801 blockade in Group Paired was the product of an aversion conditioned by MK-801 competing with an increased preference conditioned by the novel object. The present procedures could be used to study the suggested similarities between the appetitive properties of abused drugs and novelty.

NIH grants DA05623 to R.A.B. and DA07746 to M.T.B supported this work.

## 278.3

**GABA<sub>B</sub> AGONISTS ATTENUATE THE REINFORCING EFFECTS OF COCAINE IN RATS.** M. M. Andrews\* and D.C.S. Roberts. Neuroscience Institute, Life Sciences Research Center, Carleton University, Ottawa, Canada, K1S 5B6

The effect of three GABA<sub>B</sub> agonists on cocaine self-administration in rats was examined. In the first study, rats were trained to self-administer cocaine (0.18, 0.38, 0.75, 1.5 mg/kg/inj) on a progressive ratio schedule. The response requirements for each injection during the session escalated according to the series: 1,2,4,6,9,12,15,20,25... The number of injections self-administered before responding ceased was defined as the breaking point. Pretreatment with baclofen (1.25, 2.5 or 5.0 mg/kg), SKF 97541 (0.05, 0.1 or 0.2 mg/kg) or CGP 44532 (0.125, 0.25 or 0.5 mg/kg) dose dependently reduced breaking points at doses that did not significantly affect food reinforced responding on an identical PR schedule. In a second series of experiments, rats were trained to self-administer cocaine on a discrete trials schedule. Animals were given the opportunity to respond for a single injection of cocaine (1.5 mg/kg/inj) during a 10 min trial. Discrete trials began at 30 min intervals continually for two weeks. Delivery of 45 mg food pellets was contingent on a response on a second lever which was continuously available. Injections of baclofen, SKF 97541 or CGP 44532 reduced cocaine intake for approximately 4 hours without affecting food intake. These data suggest that GABA<sub>B</sub> agonists might be useful in the treatment of cocaine addiction. Supported by NIDA Contract No. N01DA-3-7302.

## 278.5

**ANTISENSE OLIGODEOXYNUCLEOTIDE MODULATION OF GABA-TRANSAMINASE ALTERS COCAINE-INDUCED SEIZURES IN MICE.** M.S. Abel\* and N. Kohli. Dept. of Cell Biology & Anatomy, FUHS/The Chicago Medical School, North Chicago, IL 60064.

We have previously shown that antisense oligodeoxynucleotide (AS-ODN) blockade of GAD<sub>67</sub> mRNA decreases the threshold for cocaine-induced seizures. We hypothesized that AS-ODN blockade of GABA-T mRNA would have the opposite effect, i.e. increase the threshold for cocaine-induced seizures. The lateral ventricles of male BALB mice (20-25g) were unilaterally infused with 1) AS-ODN (0.29, 0.87, 1.15, or 1.44 nmoles) in artificial CSF, 2) equivalent amounts of random ODN in artificial CSF, or 3) artificial CSF alone. After surgery, animals were allowed to recover for 15 hours before analysis of GABA levels and/or behavioral testing. Mice were injected i.p. with cocaine (50, 60, or 70 mg/kg), and seizure behavior was evaluated. The seizures consisted of severe tremors initially, followed by tonic-clonic extensions and contractions. At 0.29 and 0.87 nmoles of AS-ODN, all mice seized at all cocaine doses. Seizure latency and duration were not significantly different between groups. At 1.15 and 1.44 nmoles, AS-ODN had a protective effect (0-11% seized), as compared to controls (100% seized), at 70 mg/kg cocaine. There was a time-dependent effect of the AS-ODN, such that at 8 hours a qualitative difference in seizures was observed, and by 36 hours, the protective effect was gone. These data suggest that 15 hours after ICV injection, GABA levels are increased sufficiently to reduce either a) widespread tonic inhibition by GABA, or b) specific inhibitory GABAergic pathways.

**SELECTIVE D1 (SCH23390) AND D2 (ETICLOPRIDE) DOPAMINE ANTAGONISTS ELEVATE INTRAVENOUS COCAINE SEIZURE THRESHOLDS IN RATS.** C.E. Reigel\* and A.T. Lovering. Dept. of Pharmacol., Texas Tech Univ. Health Sci. Center, Lubbock, TX 79430.

Although cocaine blocks the uptake of dopamine, dopaminergic involvement in cocaine-induced seizures has been largely ignored. D1 and/or D2 selective antagonists were administered intravenously at various doses in a volume of 0.2 ml/kg, 3 min prior to a 10 mg/kg-min infusion of cocaine. Cocaine infusions were continued until the onset of behavioral convulsions, thereby establishing cocaine seizure thresholds. SCH23390 produced a maximal 29.5 percent elevation of cocaine seizure threshold at 0.5 mg/kg. By 1.5 mg/kg, SCH23390 decreased cocaine seizure threshold 20.3 percent, possibly due to a loss of D1 specificity at this dose. Eticlopride produced a dose-dependent elevation of cocaine seizure threshold that reached a maximum of 84.2 percent at 0.5 mg/kg. The combination of D1 and D2 antagonists maximally elevated cocaine seizure threshold 84.6 percent at a dose of 0.5 mg/kg SCH23390 and 0.1 mg/kg eticlopride, comparable to the maximal elevation achieved by higher doses of eticlopride alone. Thus both D1 and D2 receptors appear to at least partially mediate the convulsant effects of cocaine, with a greater effect demonstrated at D2 receptors. The existence of a maximal ceiling for dopamine antagonist elevation of cocaine seizure threshold suggests that cocaine possesses an additional seizure mechanism. Effects of D1 and D2 antagonists were also determined against intravenous bupropion-, imipramine- and procaine-induced seizures. (Supported in part by NS 28118.)

## 278.4

**U50,488, A KAPPA OPIOID AGONIST, AND COCAINE'S REWARD-RELEVANT EFFECTS.** C.L. Hubbell\*, T.M. Bar-ringer, P.M. Gonzales, C.M. Moran and L.D. Reid. Lab. for Psychopharmacology, Rensselaer, Troy, NY 12180.

Rats were fixed with chronically indwelling, bipolar electrodes for the direct electrical intracranial stimulation (ICS) of the lateral hypothalamus. Subsequently, they were trained to press a bar in a Skinner box for ICS. During their initial days of pressing, the intensity of ICS was varied while observing rates of pressing. Two intensities were selected and used throughout the balance of testing: (a) a low intensity sustaining low rates of pressing and just above the threshold for intracranial reinforcement, and (b) a high intensity sustaining high, but not maximal, rates. Across days, a pattern of injections was introduced: placebos, cocaine (5.0 mg/kg), cocaine plus U50,488, cocaine, and placebos. This pattern was repeated until 3 doses of U50,488 (1.0, 3.0 & 10.0 mg/kg, 20 min before the session, i.p.) were tested. Cocaine, as expected, produced a significant increase in pressing. Any drug that might block cocaine's enhancement of pressing for ICS without reducing rates of pressing to below that without cocaine is apt to be a good candidate for a pharmacotherapy for cocaine abuse. It would block cocaine's reward-relevant effects without having deleterious side-effects. The low dose of U50,488 reliably enhanced pressing beyond that produced by cocaine alone. The medium intensity had no reliable effects on cocaine-enhanced rates of pressing. The high dose significantly reduced pressing to levels below that of placebos. None of the doses of U50,488, therefore, met the standard for a pharmacotherapy for cocaine-abuse. Supported by grant DA08937, National Institute on Drug Abuse.

## 278.6

**SLOW ONSET, LONG LASTING DOPAMINE REUPTAKE BLOCKERS AS POTENTIAL MEDICATIONS FOR THE TREATMENT OF COCAINE ABUSE.** M. Froimowitz\*, K.-M. Wu, and R.D. Spealman, Pharm-Eco Laboratories, Lexington, MA 02173 and Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772.

The abuse potential of cocaine has been linked to its blockade of dopamine (DA) reuptake into presynaptic terminals in the central nervous system. An important factor in the abuse of cocaine is its rapid onset of action. In developing a medication to substitute for cocaine and reduce its illicit use, it is believed that a slow onset DA reuptake blocker would have more limited abuse potential. Using rational drug design and a pharmacophore model of DA reuptake blockers, a series of slow onset, long lasting compounds have been synthesized. A lead compound, CDTP #30,640, has been evaluated for its *in vivo* time course of action using locomotor activity in mice and schedule-controlled behavior in squirrel monkeys. The compound produced dose-related increases in behavior in both species but with a slow onset of action of about 30 min to initial effects. In addition, peak effects in monkeys occurred on the second and third days after administration with effects lasting as long as four to six days. Thus, CDTP 30,640 is a slow onset, long lasting DA reuptake blocker suitable for further evaluation as a potential medication for the treatment of cocaine abuse. This work was supported by DA48313 (to MF) and DA00499 and RR00168 (to RDS). The mouse locomotor assay was performed by the NIDA Intramural Research Program, Psychobiology Section.

## 278.8

**MODIFICATION OF COCAINE SELF-ADMINISTRATION BY NITRIC OXIDE SYNTHESIS INHIBITION: A POTENTIAL TREATMENT FOR COCAINE ADDICTION?** C.M. Pudiak\* & M.A. Bozarth. Addiction Research Unit, Department of Psychology, University at Buffalo, Buffalo, NY 14260.

Studies have shown that animals reliably self-administer stimulants intravenously and that the neurotransmitter dopamine is critically involved in their reinforcing effects. Recently, nitric oxide-containing neurons have been identified in many dopamine-rich brain areas (e.g., striatum, ventral tegmental area), and neurochemical studies have shown that nitric oxide (NO) can modulate stimulant-evoked dopamine release. Results from this laboratory have shown that NO-synthesis inhibition blocks the development of cocaine sensitization and that such inhibition produces a shift in the time course of cocaine's effect on brain stimulation reward without altering cocaine's overall effect.

This study examined the role of NO in mediating cocaine reinforcement. Laboratory rats were tested for intravenous cocaine self-administration 3 hrs/day, 5 days/week with 2 days of no testing intervening between each 5-day block of testing. Once animals showed stable cocaine intake, a 5-day protocol was initiated. Animals self-administered cocaine on all days of testing, and on Day-2 and on Day-5 an intraperitoneal injection of N<sup>o</sup>-nitro-L-arginine methyl ester (L-NAME; 3, 30, 300 mg/kg) or saline was administered 45 to 60 minutes into a 3-hr test session. Each injection was separated by a minimum of 72 hrs, and all doses were administered according to a Latin square design.

The results show that L-NAME significantly alters the reinforcement profile of cocaine by decreasing the amount of cocaine self-administered and by increasing the inter-response time between successive cocaine injections. These data suggest that L-NAME prolongs the rewarding effects of cocaine, probably through a pharmacokinetic action. This pharmacokinetic action appears to delay the onset of drug action, to diminish the peak CNS concentration, and to retard elimination from the CNS. Thus, the use of NO inhibitors may prove valuable in the treatment of cocaine addiction by modifying cocaine reinforcement through altered pharmacokinetics.

## 278.9

ATTENUATION OF COCAINE-INDUCED INCREASE IN MESOACCUMBENS DOPAMINE AND BEHAVIORAL ACTIVATION BY SYSTEMIC TREATMENT WITH THE AMPA/KAINATE ANTAGONIST, LY-293558. C.W. Bradberry<sup>2</sup> and M. Selim. Yale Univ. Sch. of Med., Depts. of Psychiatry and Laboratory Medicine, and the West Haven Veterans Administration Hospital, West Haven, CT 06516.

This study investigated the impact of the systemically available antagonist of the AMPA/kainate excitatory amino acid receptor subtype, 6-(2-(1H-tetrazol-5-yl) ethyl) decahydroisoquinoline-3-carboxylic acid (LY-293558) on cocaine-evoked increase in extracellular dopamine (DA) in the nucleus accumbens (NAS) and locomotor activity, using *in vivo* microdialysis in awake animals. Systemic (IP) pretreatment with LY-293558 blocked the ability of cocaine-HCl (15 mg/kg, IP) to elevate extracellular DA in the NAS in a dose-dependent manner. At 0.1 mg/kg, LY-293558 resulted in a 20 % reduction of cocaine-induced elevation in DA levels ( $F=1.24$ ,  $p=0.3$ , by two-way ANOVA, Vs. Controls). The 0.3 mg/kg dose reduced cocaine's response by 44% ( $F=1.39$ ,  $p=0.19$ ), whereas pretreatment with the 1.0 mg/kg dose completely blocked the effects of cocaine on extracellular DA (76% reduction,  $F=3.06$ ,  $p=0.002$ ). Concomitant observation of locomotor activity indicated a trend toward an attenuation of the cocaine-induced hyperlocomotion by both the 0.3 and 1 mg/kg doses of LY-293558 ( $p<0.05$ , by a one-tailed *t*-test). LY-293558 (0.3 and 1 mg/kg), by itself, had no effect on locomotion and did not alter basal activity. The highest dose of LY-293558 (1 mg/kg), when administered by itself, caused a reduction in basal DA levels in NAS microdialysates ( $F=2.3$ ,  $p=0.03$ ). These results are consistent with a growing body of literature which indicates that excitatory amino acid antagonists can inhibit both the behavioral and neurochemical actions of cocaine, and provide evidence for a potential role of AMPA/kainate antagonists in the pharmacotherapy of cocaine abuse.

## 278.11

THE EFFECTS OF FLUPENTHIXOL ON COCAINE-INDUCED LOCOMOTOR ACTIVITY IN MICE, G.J. Schaefer<sup>1</sup>, K.S. Regan, A. Shemer and J.B. Terrill, MPI Research, Mattawan, MI 49071, Pfizer, Inc., New York, NY 10017 and the National Institute on Drug Abuse, Rockville, MD 20857.

*Cis:trans*-flupenthixol (HCl)<sub>2</sub> (FLU) has been proposed as a treatment to reduce the use of cocaine. The present study was conducted to examine the interaction of FLU with cocaine. Male Swiss-Webster mice were divided into 12 groups of 10 animals each. On days 1-14, animals received an IP injection of saline or FLU (0.3 or 1.5 mg/kg). On days 1, 7 and 14 animals received an additional IP injection of either saline or cocaine (10, 50 or 70 mg/kg) two hours after the saline/FLU administrations. Evaluations of spontaneous locomotor activity (Omnitech Digiscan) on days 1, 7 and 14 revealed that cocaine alone produced a biphasic effect on horizontal activity. The maximum increase occurred at 10 mg/kg while the highest dose, 70 mg/kg, produced a response that was less than that of the saline. FLU alone decreased horizontal activity and also decreased activity when administered at both doses tested together with cocaine. In animals receiving cocaine alone, seizures and tremors were observed in animals on days 1 and 7, particularly in the animals receiving the high dose, and these tended to be blocked with 1.5 mg/kg FLU. Thus, both the hyperactivity as well as the gross neurological signs produced by cocaine were blocked by FLU. Supported by NIDA Contract No. NOIDA-2-9307.

SYNTHESIS, PHARMACOLOGY AND MOLECULAR MODELING STUDIES ON A SERIES OF N-SUBSTITUTED 4',4"-DIFLUORO-3 $\alpha$ -DIPHENYLMETHOXYTROPANE ANALOGS. A.H. Newman<sup>1</sup>, G.E. Agoston, J.H. Wu, R.H. Kline, S. Izenwasser, J.L. Katz, Psychobiology Section, NIDA-DIR, Baltimore, MD 21224.

A series of N-substituted-4',4"-difluoro-3 $\alpha$ -diphenylmethoxytropene analogs were prepared from the N-nor analog via acylation followed by hydride reduction of the amide or by direct alkylation. All of the analogs displaced [<sup>3</sup>H]WIN 35,428 from the dopamine transporter ( $K_i$  range = 8-2300 nM) and blocked dopamine reuptake ( $IC_{50}$  range=10-5400 nM) in rat caudate putamen. Further, none of the compounds demonstrated high affinity for serotonin or norepinephrine transporters. Several analogs (NH, NCH<sub>3</sub>, N-butyl, N-allyl, N-butylphenyl) that demonstrated high affinity for the dopamine transporter ( $K_i$  range=8-30 nM), with a range of binding affinities at muscarinic m<sub>1</sub> receptors ( $K_i$ =6->500 nM) were evaluated as psychomotor stimulants and for their effects on cocaine-induced behavior. None of these analogs demonstrated efficacious locomotor stimulant actions in mice nor did they fully substitute for the discriminative stimulus effects in rats trained to discriminate 10 mg/kg of cocaine from saline. Interestingly, their effects on cocaine in the drug discrimination paradigm varied significantly and may be related to their binding affinities at muscarinic receptors. Specifically, those compounds with high affinity for both the dopamine transporter and muscarinic receptors potentiated the effects of cocaine. Whereas, when the muscarinic binding affinities were lower, the potentiation was lost. Molecular modeling studies of these compounds at both the dopamine transporter and muscarinic m<sub>1</sub> sites have been initiated as well as additional behavioral testing to further elucidate the roles of both the dopamine transporter and muscarinic receptors in the behavioral pharmacology of these compounds. These studies will provide an improved understanding of the mechanistic basis from which the development of a cocaine abuse therapeutic may result.

## 278.18

THE EFFECTS OF THE DOPAMINE PARTIAL AGONIST TERGURIDE ON COCAINE SELF-ADMINISTRATION. L. Pulvirenti<sup>1</sup>, C. Balducci, M. Piercy and G.E. Koob, Dept. of Neuropharmacol., Scripps Res. Inst., La Jolla, Ca 92037 and <sup>2</sup> "Mondino-Tor Vergata" Ctr for Exp Neurobiol, Un. of Rome "Tor Vergata", Rome, Italy.

Terguride (TG) is a partial dopamine agonist, acting at the D2 receptor site with high affinity and low intrinsic activity. TG acts as a functional antagonist in conditions of high dopamine tone and shows an agonistic profile in conditions of dopamine depletion. The present study was undertaken to assess the pharmacological effects of TG on cocaine reward magnitude and the abuse liability of TG. Intraperitoneal (IP) acute pretreatment with TG (0.025-0.4 mg/kg IP) induced a dose-dependent blockade of cocaine self-administration in rats. Using a within-session dose-effect curve of self-administration of cocaine at various doses (0.06-0.5 mg/injection), TG (0.2-0.4 mg/kg IP) was shown to produce a shift to the right of the inverted U-shaped dose-effect function curve of cocaine. This profile reflects an antagonistic action of TG on the reinforcing effects of cocaine, independent of the rate of responding. Acute pretreatment with TG (0.2-0.4 mg/kg IP) reduced the maximum FR of responding for cocaine thus indicating a reduction of the reward magnitude of cocaine. Finally, the reinforcing properties of TG were tested by substituting TG for cocaine. Animals trained to IV self-administer cocaine readily substituted apomorphine (a full dopamine agonist), but failed to substitute TG for cocaine. These results suggest that TG can block the reinforcing effects of cocaine but, that TG does not possess reinforcing properties by itself in rodents. (Supported by NIH DK26741)

## 278.12

SYNTHESIS AND EVALUATION OF 2-PHENYL-(3-AMINOMETHYL)-ALKANES AS POTENTIAL COCAINE ABUSE TREATMENT AGENTS. H.M. Deutsch<sup>1</sup>, D.M. Collard, K. Burnham, S.G. Holtzman and M.M. Schwan<sup>2</sup>. School Chemistry and Bio-chemistry, Georgia Tech, Atlanta GA 30332; <sup>2</sup>Emory University School of Medicine, Atlanta, GA 30322; <sup>3</sup>Merceder University School Medicine, Macon GA 31207.

We have synthesized a series of 2-phenyl-(3-aminomethyl)-alkanes (1), modeled on the selective dopamine uptake inhibitor LR5182. The synthesized compounds were tested for their ability to inhibit [<sup>3</sup>H]WIN 35,428 binding and [<sup>3</sup>H]dopamine uptake and were also examined for antagonism against the behavioral effects of cocaine (COC). The compounds were initially evaluated by their DISCRIMINATION RATIO (DR) which is defined as the ratio of  $IC_{50}$  values for the inhibition of [<sup>3</sup>H]dopamine uptake to [<sup>3</sup>H]WIN 35,428 binding. Thus, compounds with high DR values would be relatively poor inhibitors of [<sup>3</sup>H]dopamine uptake at a given [<sup>3</sup>H]WIN 35,428 binding.  $IC_{50}$  values for binding for this series varied from 16 to 4200 nM.  $IC_{50}$  values for uptake varied from 34 to 8900 nM. Compounds with both high (6.5) and low (1.9) DR values were tested for their ability to substitute for cocaine in male Sprague-Dawley rats that were trained to discriminate between COC (10 mg/Kg) and saline. The synthesis, inhibition assays, structure-activity relationships and animal behavioral testing will be discussed in detail. Supported by NIDA (DA06305).

**Analysis of QTLs Affecting Response to Methamphetamine in the BXD Recombinant Inbred Mouse Strains** J.K. Belknap\*, J.E. Grisel, C.M. Wenger, & J.C. Crabbe VAMC and OHSU, Portland OR 97201

Genetic influences on phenotypes related to drug abuse tend to be quantitative in nature and therefore have been difficult to study using classic genetic analyses. Quantitative Trait Locus (QTL) mapping is a method used to examine genetic contributions to some of these traits by correlating allelic polymorphisms at a marker locus with variation in expression of a drug-related trait. A significant association indicates the probable existence of a gene near the marker that influences drug responsiveness. Much of this research has been performed in the BXD panel of recombinant inbred (RI) strains which, along with the C57BL/6J (B6) and DBA/2J (D2) progenitors, have been genotyped for over 1600 markers. In the present study, B6, D2 and 24 of their RI strains were evaluated for effects of METH (0, 4, 8 and 16 mg/kg) on exophthalmos, body temperature, horizontal activity and the stereotypic climbing response. Strains differed in response to METH-- indicative of a significant genotypic contribution to variability in these traits. Some QTLs were correlated with several METH-induced responses suggesting common neural substrates underlying the responses to METH. For example, significant associations between an array of METH-related phenotypes and loci thought to modulate glutamatergic and cholinergic transmission were found (Glud, Ache and markers near genes encoding delta and gamma subunits of the acetylcholine receptor), consistent with pharmacological evidence supporting a role for these candidate genes. Finally, QTLs suggested by these analyses were compared with QTLs hypothesized to underlie cocaine responsiveness (Tolliver et al. '94; Milner & Marley, '95) providing evidence for loci with pleiotropic influences on responsiveness to multiple psychostimulants. PHS #PO1 AA08621 & T32 AA07468, and NIDA # 271-90-7405.

## 279.3

**INDIVIDUAL DIFFERENCES IN SUCROSE INTAKE ARE PREDICTIVE OF INTRAVENOUS AMPHETAMINE SELF-ADMINISTRATION LEVELS.**

N.J. DeSessa<sup>1</sup>, D.E.A. Bush<sup>1</sup>, and F.J. Vaccarino<sup>1,2</sup>. Department of Psychology<sup>1</sup>, University of Toronto, Toronto, ON, M5S 1A1, Canada; Clarke Institute of Psychiatry<sup>2</sup>, Toronto, ON, M5T 1R8, Canada.

Rats exhibit significant individual differences in sucrose intake, and may be categorized as either low (LF) or high (HF) sugar feeders. Psychostimulant treatment has been shown to differentially affect nucleus accumbens (NAcc) dopamine (DA) release, sucrose intake, and exploratory locomotion in these groups. The present experiments examined the relationship between sucrose intake and psychostimulant self-administration.

In exp. 1, male Wistar rats were divided into LF and HF based on a median split of their sucrose intake in response to a saline injection. Rats were then surgically implanted with indwelling catheters into the jugular vein. Following recovery, they were placed in operant boxes containing two levers for 10 daily 30 minute sessions. Depression of the active lever resulted in an intravenous (i.v.) infusion of d-amphetamine (AMPH; 10 µg), while depression of the inactive lever had no programmed consequences. In exp. 2, an AMPH dose-response (1, 3, 10, 30, 100 µg/infusion) analysis was conducted using the same animals.

Results from exp. 1 showed that i.v. AMPH self-administration response rates were lower in LF than in HF across the 10 day acquisition period. Results from exp. 2 indicated that LF demonstrated a blunted AMPH dose-response with no horizontal shift in comparison to HF. These data support the hypothesis that the propensity to ingest sucrose is predictive of the motivational effects of psychostimulant drugs. Supported by a Medical Research Council of Canada grant to F.J.V.

## 279.5

**AGE-DEPENDENT EFFECTS OF AMPHETAMINE ON SEVERAL COMPLEX BEHAVIORS IN RHESUS MONKEYS.** P. Morris, M.P. Gillam, S. Lensing, R.R. Allen, G.E. Schulze and M.G. Paule<sup>1</sup>. Division of Neurotoxicology, National Center for Toxicological Research, FDA, Jefferson, AR 72079-9502.

The effects of acute amphetamine hydrochloride (AMP) administration (0.01 to 3.0 mg/kg, intravenously) on several complex brain functions were studied in adolescent (3 years of age, N=11) and young adult (6 years of age, N=9) rhesus monkeys. Several food-reinforced operant behaviors, used to model motivation (M), learning (L), color and position discrimination (CPD) and short-term memory (STM) were monitored. The lowest dose of AMP that significantly disrupted these behaviors was consistently lower in young adults than it was in adolescents (M: 0.3 vs 1.0; L: 0.1 vs 1.0; CPD: 1.0 vs 3.0; STM: 0.3 vs 1.0; respectively, all in mg/kg). Thus the sensitivity to the behaviorally disruptive effects of AMP increases with age, such that young adults are on average about three times more sensitive to such effects than adolescents. Presuming that AMP causes its behavioral effects by interacting with catecholaminergic mechanisms, changes in the sensitivity to the behavioral effects of AMP may reflect the functional status of these systems in relation to age. Supported in part by Interagency Agreement #224-89-003 with NIDA.

## 279.2

**PREDISPOSITION TO SELF-ADMINISTER AMPHETAMINE: THE ROLE OF INDIVIDUAL DIFFERENCES IN RESPONSE TO NOVELTY AND PRIOR EXPOSURE TO THE DRUG.** Pierre, P. J.\* and Vezina, P. Department of Psychiatry, University of Chicago, Chicago, IL 60637.

Prior exposure to stimulants leads to sensitized behavioral responding to subsequent administrations of these drugs and increases the likelihood that animals will self-administer them. A rat's response to a novel environment has also been suggested to predict this animal's predisposition to self-administer drug. The present experiment examined the relationship between response to novelty and drug preexposure and its contribution to an animal's subsequent lever pressing for drug. Rats showing a high (HR) or low (LR) locomotor response to novelty were given nine daily injections of amphetamine (1.5 mg/kg, i.p.) or saline. Starting one week later, rats were submitted to a ten day self-administration procedure in which presses on an active lever delivered 10 µg amphetamine/kg/infusion and presses on an inactive lever delivered no drug. On the first day of self-administration testing, lever press behavior did not reflect drug preexposure condition. However, with successive days, amphetamine preexposed rats maintained higher active lever pressing than saline preexposed rats, which showed decreasing pressing of both levers. Interestingly, only HR rats preexposed to amphetamine maintained increased active lever responding. LR rats exhibited decreasing levels of lever pressing over days regardless of drug preexposure condition. These data suggest that response to novelty may be a predictor more closely linked to an animal's propensity to become sensitized to the facilitatory effects of a drug rather than to an animal's liability to self-administer the drug. Supported by NIDA grant DA09397 to P.V.

## 279.4

**Novelty Seeking Predicts Individual Differences in Amphetamine Disrupted Bar Pressing.** J.E. Klebaur\*, M. Marion, R.A. Bevins, J. Carney, & M.T. Bardo. Depts of Psychology and Pharmacology Univ of Kentucky, Lexington, KY 40506-0044.

Past work has shown that individual differences can predict acquisition of amphetamine self-administration, locomotor response to stimulants, and development of amphetamine sensitization. The increase in activity observed when a rat is exposed to an inescapable novel environment is thought to reflect escape behavior due to stress. To assess approach to novelty in a free-choice test, we examined the ability of the novelty-induced place preference test to predict individual differences in amphetamine disrupted responding. Using this test to categorize a random population of rats as either high or low novelty seekers, it was found that high novelty seekers were more sensitive to the response suppressant effects of amphetamine than low novelty seekers. These results suggest that differences in response to novelty can predict sensitivity to the rate suppressant effects of amphetamine. (Supported by USPHS grant DA05312)

## 279.6

**DISSOCIABLE EFFECTS OF DORSAL VS. VENTRAL SUBICULUM LESIONS IN ANIMAL MODELS RELEVANT TO DRUG ABUSE AND SCHIZOPHRENIA.** S.B. Caine\*, R.B. Whittle, T.W. Robbins and B.J. Everitt. Department of Experimental Psychology, University of Cambridge, Cambridge, England, CB2 3EB.

Utilizing measures of locomotor activity, sensorimotor gating and iv drug self-administration, this study tested the hypothesis that the output pathways of the hippocampal formation originating in the dorsal and ventral subiculum differentially modulate the behavioral effects of systemically administered psychostimulant drugs. Previous studies showed that excitotoxic lesions of the hippocampus potentiated hyperactivity associated with increased nucleus accumbens extracellular dopamine after amphetamine challenge in rodents (Wilkinson et al., Behav. Brain Res. 55:143, 1993). Conversely however, selective lesions of the ventral subiculum of the hippocampal formation attenuated the psychostimulant and conditioned reinforcement enhancing properties of intra-accumbens amphetamine (Burns et al., *ibid.*, p.119).

Bilateral excitotoxic lesions of the dorsal subiculum produced hyperactivity with enhanced responsiveness to amphetamine (shift to the left in the dose-effect function). In contrast, lesions of the ventral subiculum did not alter spontaneous activity but attenuated the psychostimulant effects of low dose amphetamine challenge. In the same animals as well as in drug naive animals, dorsal subiculum lesions increased acoustic startle reactivity without altering prepulse inhibition of startle (PPI). Conversely, ventral subiculum lesions did not alter startle reactivity but profoundly attenuated PPI. Importantly this deficit diminished in a session-dependent manner with repeated tests until baseline levels of PPI were normal; nevertheless these rats remained more sensitive to the PPI disrupting effects of a low dose amphetamine challenge. Finally, neither type of lesion unequivocally altered the self-administration of cocaine, though rates of drug intake tended to be lower in dorsal subiculum lesioned animals and higher in ventral subiculum lesioned animals across a range of cocaine doses, relative to sham-operated controls. The results suggest different roles for the dorsal and ventral subiculum in hyperactivity and sensorimotor gating, respectively, and perhaps subtle, opposing influences on cocaine self-administration. Supported by a Human Frontiers Science Program Long-term Fellowship to S.B.C.

## 279.7

**REINFORCING EFFECTS OF d-AMPHETAMINE AND MORPHINE DEMONSTRATED USING AN INSTRUMENTAL-APPROACH PLACE CONDITIONING PROCEDURE.** W.D. Esman\* and L. Lucki. Depts. of Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

This study reports an instrumental place-preference (IPP) procedure designed to examine both the acute reinforcing effects of drugs as well as their ability to sustain a conditioned approach response. Using a two-chambered apparatus, animals were trained against their initial preference to locomote from a start box to a goal box to receive an injection of saline (SAL), d-amphetamine (AMPH; 0.32, 1.8 or 5.6 mg/kg) or morphine (MORPH; 5, 10 or 20 mg/kg). The time to enter the goal box (TEG) was recorded for each subject. Changes in TEG across training days provided a measure of the acute positive reinforcing effects of the training injections. A second preference test was then given to determine whether the side preferred initially was altered by IPP training.

IPP training with AMPH produced three distinct patterns depending on the training dose. The low dose of AMPH decreased TEGs, the medium dose of AMPH produced TEGs which did not differ from SAL, and the highest dose of AMPH tended to produce an increase in TEGs. In contrast, all doses of MORPH produced TEGs of shorter latencies than SAL, although the highest dose was not significantly different. During post-training preference tests, all AMPH and MORPH animals demonstrated a robust preference for the goal box; the side preference of SAL animals did not differ significantly from the pretest. These results suggest that an instrumental training procedure can demonstrate acute appetitive (low doses of AMPH and all doses of MORPH) and aversive (high dose of AMPH) effects of drugs of abuse. In addition, since all animals demonstrated a significant preference for the drug-paired environment regardless of acute effects of their training dose, these results are consistent with a differentiation between the reinforcing effects of drug doses and their ability to induce drug "craving". Supported by NIDA DA 05186.

**THE EFFECTS OF NUCLEUS ACCUMBENS CCK<sub>B</sub> RECEPTOR ACTIVATION ON AMPHETAMINE SELF-ADMINISTRATION.** D.E.A. Bush<sup>1</sup>\*, N.J. DeSousa<sup>1</sup> and F.J. Vaccarino<sup>1,2</sup>. Department of Psychology<sup>1</sup>, University of Toronto, Toronto, ON, M5S 1A1, Canada; Clarke Institute of Psychiatry<sup>2</sup>, Toronto, ON, M5T 1R8, Canada.

The mesolimbic dopamine (DA) pathway terminating in the nucleus accumbens (NAcc) is a critical substrate involved in the mediation of reward. Cholecystokinin (CCK) is co-localized with DA in a subset of mesolimbic neurons and its actions at CCK<sub>B</sub> receptors inhibit NAcc-DA neurotransmission. The present experiment examined the effects of NAcc microinjections of pentagastrin, a selective CCK<sub>B</sub> receptor agonist, on i.v. d-amphetamine (AMPH) self-administration. Six male Wistar rats were surgically implanted with indwelling catheters into the jugular vein, and with bilateral guide cannulae aimed at the rostral portion of the NAcc. Rats were trained to press a lever for 100µL infusions of AMPH (50 µg/kg i.v. infusion) during daily 3 hour sessions. Animals received intra-NAcc microinjections (0.5µL) of pentagastrin (0, 0.05, 0.5, and 5.0 nM) in a counterbalanced order following 3 day periods of stable responding. Results showed that intra-NAcc pentagastrin dose-dependently (0.05 and 0.5 nM) increased response rates for i.v. AMPH. The compensatory increase in AMPH self-administration in the presence of intra-NAcc pentagastrin is consistent with the hypothesis that NAcc CCK<sub>B</sub> receptor activation attenuates dopamine-mediated reward. Supported by a grant from the Medical Research Council of Canada to F.J.V.

## 279.11

**c-fos ANTISENSE OLIGONUCLEOTIDE INFUSION INTO MOUSE STRIATUM BLOCKS METHAMPHETAMINE-INDUCED LOCOMOTOR ACTIVITY IN A REVERSIBLE MANNER.** T. Umekage<sup>\*</sup>, M. Namima<sup>\*</sup>, K. Fukushima<sup>\*</sup>, S. Sugita<sup>\*</sup> and Y. Watanabe<sup>\*</sup>. \*Dept. of Pharmacology, <sup>†</sup>Center for Laboratory Animal Science, The National Defense Medical College, Tokorozawa, 359, Japan

Dramatic behavioral changes occur after exposure to a psychomotor stimulant such as methamphetamine (MAP). It has been reported that amphetamine induces immediate early gene c-fos in striatum neurons. c-fos encodes transcription factors that may lead to activation of late effector genes and permanent changes in brain function. To investigate the involvement of immediate early gene in MAP-administered mice, we have examined locomotor activity and the expression of c-Fos protein after c-fos-antisense oligodeoxynucleotide (ODN) infusion into mice striatum. MAP(2mg/kg)-induced locomotor activity was significantly suppressed by stereotactic injection of c-fos antisense ODN (2mM, 1µl) into male ddY mice striatum. The suppression of activities was observed transiently and reproducibly. The effect was associated with an elimination of expression of c-Fos immunoreactivity within the infused region of the striatum. These results suggest that c-Fos may be the key molecule regulating the functional output in the MAP-induced mouse motor mechanism.

## 279.8

**ROLE OF BEHAVIORAL AND PHARMACOLOGICAL VARIABLES IN THE RETENTION OF TOLERANCE TO AMPHETAMINE HYPOPHAGIA.** K.M. Hughes\* and D.L. Wolgin. Dept. of Psychology, Florida Atlantic Univ., Boca Raton, FL 33431.

Tolerance to amphetamine hypophagia is lost when drug injections are suspended while feeding tests are continued (Wolgin & Hughes, in press). In this experiment, we determined whether the loss of tolerance is a function of drug withdrawal *per se*. Male Sprague-Dawley rats received amphetamine (2 mg/kg, ip) before daily milk tests, to induce tolerance. The rats were then assigned to one of three groups. During the next 21 trials (the retention phase), the After Group received amphetamine after the milk tests, so that feeding was no longer disrupted by drug-induced stereotyped movements. The Saline Group was withdrawn from the drug entirely, and received only saline injections, while the Before Group continued to receive amphetamine injections prior to milk. Dose-response tests revealed that the Before Group retained tolerance, whereas the Saline Group lost tolerance. The After Group lost tolerance at doses of 2 and 4 mg/kg, but retained tolerance at 1 mg/kg. These results demonstrate that the loss of tolerance to the higher doses of amphetamine was not due to drug withdrawal *per se*, but may have been due to the unlearning of behavioral strategies previously acquired under the drug.

## 279.10

**ROLE OF HIPPOCAMPUS ON AMPHETAMINE INDUCED CONDITIONED LOCOMOTOR RESPONSE.** S. Mandillo<sup>\*</sup>, A. Felici<sup>\*</sup>, S. Cahib<sup>\*</sup>, A. Oliverio<sup>\*</sup> and A. Mele<sup>\*</sup>. Dip. Genetica e Biologia Molecolare, Università di Roma "La Sapienza" and Ist. di Psicobiologia e Psicofarmacologia, C.N.R., Rome, Italy.

It has been shown that hippocampus plays a focal role in different kind of associative learning. The purpose of this study was to assess whether lesions of the main hippocampal efferent pathway would have in some way affected development of context dependent sensitization to amphetamine. Electrolytic lesion of the fimbria fornix was performed in CD1 mice. Sham and lesioned mice were then divided into three groups: the first group received saline injections before the exposure to 45 min activity session and saline 2 hrs after being returned to the home cage (CONTROL), the second group received saline injection before activity and amphetamine (2.5mg/kg) in the home cage (UNPAIRED), the last group received amphetamine (2.5mg/kg) before activity and saline in the home cage (PAIRED). After five days of treatment the animals was given a saline injection before the exposure to the test cage. Electrolytic lesions of the fimbria fornix enhanced spontaneous activity in mice, response to amphetamine was also enhanced even if not a significant way. Conditioned response on day six in the PAIRED group however was not modified by the lesion. Experiments with more selective lesions of hippocampal-accumbens pathways are on going in order to assess the role of hippocampus in amphetamine induced conditioning and sensitization (A.F. is supported by a "Mariano Scippaccola Foundation" fellowship).

## 279.12

**A DOSE-EFFECT COMPARISON OF TWO MEASURES OF PSYCHOMOTOR ACTIVATION PRODUCED BY INTRAVENOUS AMPHETAMINE OR COCAINE.**

Hans S. Crombag\*, Kaitlin E. Browman, Karen Lapidus, Aldo Badiani and Terry E. Robinson.

Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48109.

There is almost no data available on the effects of dose of intravenously (IV) administered psychostimulants on psychomotor activation. We sought here to remedy this situation in anticipation of dose-effect studies on psychomotor sensitization produced by IV drug administration. Thus, we characterized the effects of dose of IV cocaine (COC) or amphetamine (AMPH) on two indices of psychomotor activation: rotational behavior in rats with unilateral 6-OHDA lesion and locomotor activity in intact rats. It was found that for doses ranging from 0.125 to 16.0 mg/kg (IV) there was a progressive increase in rotational behavior. A progressive increase in locomotor crossovers was only observed for doses between 0.25 and 2.0 mg/kg. There was a decrease in locomotor crossovers for doses greater than 4.0 mg/kg due to the emergence of stereotyped behaviors. Finally, when a challenge dose was given to test for the development of sensitization only rotational behavior showed significant sensitization. Thus, with IV administration an increase in drug effect is characterized by a linear increase in rotational behavior over a wide range of doses, whereas this is not true for locomotor activity. Therefore, the rotational behavior model may be particularly useful when studying phenomena associated with changes in drug effect, such as sensitization. (Supported by Grant # DA 04294)

## 279.13

THE EFFECTS OF INTRA-PREFRONTAL CORTEX D-AMPHETAMINE ON SUBCUTANEOUS D-AMPHETAMINE-INDUCED HYPERACTIVITY. O. Ben-Shahar\* and A. Ettenberg. Behavioral Pharmacology Lab, Dept of Psychology, University of California, Santa Barbara, CA 93106

The mesolimbic dopaminergic pathway (with its cell bodies in the ventral tegmental area (VTA) and terminals in the nucleus accumbens (NAC)) has been implicated in the neural mediation of the hyperlocomotor response to amphetamine. This pathway is also involved in the sensitization to amphetamine-induced hyperactivity, observed after repeated administration of amphetamine. Dopamine cells within the VTA also project to the medial prefrontal cortex (mPFC) and recent anatomical, physiological and behavioral research has identified a functional link between these two projection areas of the VTA (i.e. the NAC and the mPFC). The present study was therefore devised to examine the effects of intra-mPFC amphetamine on amphetamine-induced hyperactivity. On each of 3 consecutive days, rats received bilateral intra-mPFC injections, of either 5 µg d-amphetamine/0.5 µl saline or 0.5 µl saline, and a SC injection of either 1 mg d-amphetamine/ml/kg or 1ml/kg saline. Immediately after the drug treatment each rat was placed into the locomotor chamber for 60 mins. Intra-mPFC d-amphetamine did not block the acute locomotor response to SC d-amphetamine, however, it did attenuate the sensitized hyperlocomotor effects of SC amphetamine that developed over trials/days.

LOCOMOTOR EFFECTS OF AMPHETAMINE THROUGHOUT THE LIGHT DARK CYCLE Christopher Lewis, O. Gavtan, A. Swann\*, and N. Dafny Dept. of Neurobiology and Anatomy, and Dept. of Psychiatry, UT Medical School at Houston, P.O. Box 20708, Houston, TX 77225

Low doses of amphetamine (Amp) cause increases in the level of locomotor activity such as forward ambulation and rearing. The amount of locomotor activity varies significantly between the light and dark phases of the rat, and so it became of interest to study whether the locomotor effect elicited by amphetamine (i.e., forward ambulation and rearing) differs if the time of drug administration is varied. 96 male Sprague-Dawley rats (about 200 g each) were housed in computerized activity monitoring system test cages after 7 days of acclimation to L/D cycle (07:00/19:00). Continuous recording was begun (10 min bins) for 3 days as follows: Days 1 & 2 - baseline activity data; and Day 3 - rats were randomized for s.c. treatment of saline, 0.6, or 1.2 mg/kg Amp at one of the following times (08:00, 14:00, 20:00, or 02:00). Data collected immediately after injection (day 3) were compared to baseline activity data (days 1-2) at the corresponding time to obtain the drug effect. Data were subjected to a two-factor (dose and treatment time) ANOVA. The motor indices of total distance and vertical activity are presented. Compared to vehicle, both Amp doses markedly elevated the counts of the locomotor indices studied across all treatment times ( $p < 0.01$ ). There was no dose-by-time interaction in the two-factor ANOVA for either total distance or vertical activity, indicating an absence of circadian rhythmicity in the dose-response relationship. However, the magnitude of the Amp effect on vertical activity was significantly greater when injected at 20:00 ( $p < 0.01$ ) as compared to all other injection times. In conclusion, the magnitude of the Amp effect on rearing is dependent on the time of injection, but the locomotor response to different Amp doses was similar for both indices at all 4 injection times.

## 279.17

IBOGAINE INTERFERES WITH THE ESTABLISHMENT OF AMPHETAMINE PLACE PREFERENCE LEARNING. I. Moroz, J. A. Parker\*, and S. Siegel <sup>1</sup>Department of Psychology, Wilfrid Laurier University, Waterloo, Ontario and <sup>2</sup>Department of Psychology, McMaster University, Hamilton, Ontario.

The present series of experiments assessed the ability of a single injection of ibogaine (40 mg/kg), a proposed anti-addictive agent, to modify the establishment of amphetamine-induced place preference learning, when administered 24 hours prior to amphetamine conditioning. Ibogaine pretreatment blocked the establishment of an amphetamine place preference after one or two conditioning trials, but was not effective after four trials (Experiments 1 and 2). The attenuation of ibogaine's ability to interfere with place preference conditioning after multiple trials may be the result of the development of tolerance to this effect of ibogaine (Experiment 3). Supported by the Natural Sciences and Engineering Research Council of Canada.

## 279.14

EFFECT OF METHAMPHETAMINE ON VARIOUS ASPECTS OF MOTOR BEHAVIOR AT COLD AND AMBIENT TEMPERATURES R. A. Mohaghegh\*, T. A. Ansah and D. C. Shockley, Meharry Medical College, Department of Pharmacology, Nashville, TN 37208.

We have previously shown that methamphetamine (MAMPH) induced a spectrum of thermic and motor activities at different ambient temperatures. However, the data from motor effect of MAMPH were only evaluated subjectively. In this experiment, we studied the effect of i.p. MAMPH (0.01 to 10 mg/kg at 22 ± 1°C, and 1.25 to 10 mg/kg at 7 ± 1°C) on motor behavior of rats in a quantitative way. We also compared the effect of a toxic dose of MAMPH (5.0 mg/kg), amphetamine (10 mg/kg), and cocaine (60 mg/kg) at 21 ± 1 and 7 ± 1°C. The motor behavior of male Sprague-Dawley rats were recorded and analyzed via Digiscan Animal Activity Monitor every five minutes for four hours; one hour after saline and three hours after either MAMPH, amphetamine or cocaine, or equivolume saline. MAMPH at low doses increased the horizontal, vertical, and ambulatory activities of the rat, while, MAMPH, amphetamine, and cocaine increased the stereotypic activities only at high doses. Further analysis of the data are in progress. This research was supported in part by T32-MH 19843-02 and DA06686.

## 279.16

COMPARISON OF CS\*-INDUCED CHANGES IN DOPAMINE IN THE NUCLEUS ACCUMBENS OF RATS FOLLOWING EITHER SELF- OR YOKED- ADMINISTRATION OF d-AMPHETAMINE. P. Di Ciano, C.D. Blaha and A.G. Phillips\*, Department Psychology, University of British Columbia, Vancouver, B.C., Canada V6T 1Z4.

We have previously demonstrated (Di Ciano et al., Soc Neuro Abstr 21:2103, 1995) that repeated pairings of either cocaine or d-amphetamine with a compound environmental stimulus (odour, light) produced conditioned increases in both locomotor activity and extracellular dopamine (DA) concentrations in the nucleus accumbens (NAC), when rats were exposed to the compound CS\* in the absence of the drug. In the present study, *in vivo* chronoamperometry was used to monitor extracellular concentrations of DA in the NAC, when rats were exposed to a CS\* (flashing light) that had been paired repeatedly with either self-administered or yoked d-amphetamine injections (0.25 mg/kg/injection). On the seventh, and final consecutive day of d-amphetamine treatment, d-amphetamine produced significant increases in the DA signal in both the self-administering rats and those that received yoked infusions, of ~9 nA and ~7 nA, respectively, by the end of the 3 hour session. When presented with the CS\* as a prime and at 30 min intervals, in the absence of drug on the eighth day, rats that had previously self-administered the drug showed significant increases in DA concentrations that continued to increase steadily over the 3 hour session, reaching a maximum of ~6 nA by the end of the session. These conditional changes in the DA signal were significantly lower than those observed during self-administration of the drug. By comparison, the yoked group showed a pattern of conditional increases, similar to the self-administering rats, which plateaued at ~7 nA; a change that was not significantly different from those seen during drug sessions. The present study provides support for the hypothesis that DA in the NAC is involved in the conditioned incentive effects of drugs of abuse. In addition, the present experiment also suggests that these conditioned incentive effects are different following either self- or yoked- administration of d-amphetamine. Supported by MRC, Canada.

AMPHETAMINE INFUSIONS INTO THE VENTROLATERAL STRIATUM PRODUCE CONDITIONED PLACE PREFERENCE. D.A. Baker\*, S.E. Specio, L.T.L. Tran-Nguyen, T.L. Archer, J.L. Neisewander, Department of Psychology, Arizona State University, Box 871104, Tempe, AZ 85287-1104.

The effects of amphetamine infusions into the ventrolateral striatum (VLS) on conditioned place preference (CPP) and motor behaviors were investigated in rats. Five 2-day conditioning trials were conducted over consecutive days in a CPP apparatus with 2 distinct compartments. On one day of the trial, rats received bilateral infusions of amphetamine (0, 5, 10, or 20 µg/0.5 µl/site) into the VLS and were then confined to a compartment for 30 min. On alternate days, rats received sham infusions and were then confined to the other compartment for 30 min. The order of these treatments and the compartment paired with amphetamine were counterbalanced. Motor behaviors, including locomotion, oral stereotypies, sniffing, rearing, and grooming, were assessed during conditioning. CPP was measured 24 hr following the last day of conditioning. Intra-VLS infusion of amphetamine did not alter locomotion, sniffing, rearing, or grooming relative to saline controls. However, intra-VLS infusion of the 10 µg dose of amphetamine produced an increase in oral stereotypies relative to saline controls. Intra-VLS infusion of the 10 µg dose also produced CPP, whereas the other doses of amphetamine produced a trend towards CPP. These results suggest that intra-VLS administration of amphetamine produces CPP at a dose that also produces oral stereotypies. (Supported by DA07730 and HHMI)

279.19

**LACK OF MU-OPIOD AGONIST MODULATION OF THE DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE AND D-AMPHETAMINE IN RATS** P. R. Woolfolk\* and S. G. Holtzman, Department of Pharmacology, Emory University School of Medicine, Atlanta, Georgia 30322

Mu-opioid receptor agonists increase the activity of dopamine neurons and could, therefore, modulate the behavioral effects of drugs mediated by the dopamine system. Morphine has been shown to potentiate the discriminative stimulus effects of cocaine in squirrel monkeys (Spealman & Bergman, 1992). The ability of morphine (mor), methadone (meth), buprenorphine (bup) and nalbuphine (nalb), to modulate the discriminative stimulus effects of d-amphetamine (amph) and cocaine (coc) in rats was tested. Two separate groups of Sprague-Dawley rats were trained to discriminate 1.0 mg/kg amph or 10 mg/kg coc from saline in an avoidance/escape procedure. Rats were pretreated (sc) with saline, mor or meth (0.3-3.0 mg/kg), bup (0.03-0.3 mg/kg), or nalb (3.0-10 mg/kg), then dose-response curves for amph (0.1-1.0 mg/kg, ip) or coc (1.0-10 mg/kg, ip) were generated by cumulative dosing. In both groups of rats, there was substantial intersubject variability. For example, mor and meth enhanced the stimulus effects of coc in some coc-trained rats, but not in others. The 0.03 mg/kg dose of bup enhanced coc's cue in some rats, while the higher doses of bup blocked these effects in some rats, as did nalb. Neither the potency of coc, nor that of amph, as discriminative stimuli was altered significantly by any of the opioids when results were averaged across animals. These results suggest that any enhancement of dopaminergic neurotransmission that occurs from mu-opioid receptor stimulation by the agonists tested in this study is not sufficient to consistently change the stimulus effects of amph and coc in rats. (Supported in part by NIH Grant DA00561 and by KO5 DA00008.)

279.20

**PMMA AS A DISCRIMINATIVE STIMULUS.** R. Young\*, M. Dukak, L. Malmusi, and R.A. Glennon. Department of Medicinal Chemistry, MCV/VCU, Richmond, VA 23298.

PMMA (N-methyl-1-(4-methoxyphenyl)-2-aminopropane), a structural hybrid of paramethoxyamphetamine and methamphetamine, has been previously shown to lack amphetamine-like or hallucinogen-like discriminative stimulus effects in animals. PMMA does, however, produce MDMA ("Ecstasy" or N-methyl-1-(3,4-methylenedioxymethyl)-2-aminopropane)-appropriate responding in animals trained to discriminate MDMA from vehicle. In order to further characterize this seemingly unique agent, we trained a group of six Sprague-Dawley rats to discriminate 1.25 mg/kg of PMMA (ED<sub>50</sub> = 0.44 mg/kg) from saline. The PMMA stimulus failed to generalize to the CNS stimulant S(+)-amphetamine or to the hallucinogen DOM(1-(2,5-dimethoxy-4-methylphenyl)-2-aminopropane). Stimulus generalization occurred to (±)MDMA (ED<sub>50</sub> = 1.32 mg/kg) and S(+)-MDMA (ED<sub>50</sub> = 0.48 mg/kg). Partial generalization occurred with R(-)-MDMA. The PMMA stimulus also generalized to the α-ethyl homolog of PMMA (EH/PMMA, ED<sub>50</sub> = 1.32 mg/kg). Other agents examined included R(-)-PMMA, S(+)-PMMA, conformationally restricted analogs of PMMA, and the N-desmethyl analogs of PMMA, i.e., (±)PMA, R(-)-PMA, and S(+)-PMA. Taken together, the results of these studies suggest that PMMA is an MDMA-like agent that lacks the amphetamine-like stimulant character of MDMA. These findings support our previous suggestion that PMMA be considered the structural parent of the MDMA-like family of designer drugs. (Supported in part by NIDA grant DA-01642).

## SYMPOSIA

## MONDAY PM

280

**SYMPOSIUM. MODULATION OF NEURONAL EXCITABILITY AND BEHAVIOR.** J.L. Feldman, UCLA & R.M. Harris-Warrick, Cornell Univ. (Chairpersons); R.L. Calabrese, Emory Univ.; & D.A. McCormick, Yale Univ.

Modulation of neuronal excitability has been extensively studied at the cellular level, but the consequences of these changes in neuronal firing patterns for behavior are less well understood. The aim of this symposium is to show how modulation of cellular properties of identified neurons alters function at the network and higher levels of organization and leads to changes in behavior. Harris-Warrick will introduce the topic and discuss possible cellular targets of neuromodulation in behavioral networks. Calabrese will discuss experimental and modeling approaches to study a two-neuron mutually inhibitory oscillator network driving heartbeat in the leech. He will describe the role of several identified K<sup>+</sup> currents in the generation of the heartbeat rhythm and its modulation by the peptide FMRFamide. Harris-Warrick will describe the effect of dopamine on several currents in identified neurons of the pyloric motor pattern generator in the lobster stomatogastric ganglion, and will show how these currents affect phasing of neuronal activity in the rhythmic motor pattern. Feldman will describe the modulation of the respiratory motor pattern in the rat, showing how a set of neuromodulators affects respiratory motoneurons and their pre- and postsynaptic interactions to provide a cascade control of coarse and fine tuning of breathing. McCormick will describe the ionic mechanisms for modulation of excitability of thalamic and cortical neurons and their neuronal circuits during different waking and sleep states, when both network interactions (such as the propensity to generate seizures) and responsiveness to sensory input are profoundly changed. We hope that this symposium will encourage discussion of the behavioral consequences of neuromodulation.

281

**SYMPOSIUM. CELL CYCLE REGULATION AND CNS DEVELOPMENT: IS ONE DIVISION LIKE ANY OTHER?** M. Elizabeth Ross, Univ. of Minn. (Chairperson); Patrick O'Farrell, UCSF; Yuh-Nung Jan, UCSF & HHMI; Susan McConnell, Stanford Univ.; Nathaniel Heintz, Rockefeller Univ. & HHMI.

Early observers of the ventricular neuroepithelium considered the region to be comprised of "indifferent" cells that acquire neuronal identity only after they cease to divide. However, neural proliferation must be exquisitely controlled in a stage and area specific manner as the CNS develops to provide appropriate cell numbers for regional morphogenesis, implying a need for intermediate phases of progenitor fate determination. Substantial evidence has accumulated to suggest that neural identity is progressively established even as CNS progenitors proliferate. This symposium will examine recent advances in cell cycle regulation in the context of normal development and discuss special challenges to proliferation posed by CNS histogenesis. Mechanisms integrating neurodevelopment with decisions to progress through, or exit from the cell cycle will be discussed and emerging models for the interrelationship of cell cycle regulation, neurodifferentiation and programmed cell death will be presented. O'Farrell will provide an overview of molecular interactions governing cell division and discuss the relationship between developmental programming and the cell cycle in *Drosophila*. Jan will discuss neuronal determination in *Drosophila* and propose that an organizer of cell division provides position cues for mitotic spindle orientation and asymmetric gene expression in neural precursors. McConnell will discuss the role of asymmetric divisions in the control of neuronal fate in the cerebral cortex and will present evidence for the progressive restriction of developmental potential over time in the ventricular zone. Heintz will consider the role of cell cycle progression in CNS apoptosis. Evidence will be presented supporting involvement of cell cycle proteins in programmed cell death under some, but not all circumstances.

## NEURONAL DEATH IV

284.1

**ROLE OF PRION PROTEIN IN RESISTANCE TO OXIDATIVE STRESS AND REGULATION OF SUPEROXIDE DISMUTASE.** D.R. Brown\* and H.A. Kretschmar. Department of Neuropathology, University of Göttingen, Robert-Koch-Strasse 40, Göttingen, D-37075, Germany.

The function of the cell surface prion protein is unknown. Mice lacking PrP<sup>C</sup> expression develop and behave normally. In the present study cell culture of cerebellar cells was used to examine differences between PrP<sup>C</sup> deficient mice and wild type mice. Cell culture studies have revealed that cerebellar cells lacking PrP<sup>C</sup> are more sensitive to oxidative stress and undergo cell death more readily than normal cells. Assays of protein extracts from mouse brain indicate that Cu/Zn superoxide dismutase has reduced activity in PrP<sup>C</sup> deficient mice. Oxidative stress applied to cultured cerebellar cells normally increases superoxide dismutase activity but cells from PrP<sup>C</sup> knockout mice show no upregulation of Cu/Zn superoxide dismutase in cultures of normal cerebellar cells. Our findings suggest that PrP<sup>C</sup> may regulate the activity of superoxide dismutase. PrP<sup>C</sup> expression may be important for cellular resistance to oxidative stress. Our results suggest that PrP<sup>C</sup> functions to aid cells resist oxidative stress that would otherwise activate the cell suicide pathway. Funded by the Bundesministerium für Bildung, Forschung und Technologie (01KI 9461/8), the Wilhelm Sander-Stiftung (89.036.2) and the Fritz Thyssen-Stiftung (1992/2/54) of Germany.

284.2

**PROTECTIVE ROLE OF HEME OXYGENASE-1 IN OXIDATIVE STRESS INDUCED NEURONAL INJURY.** W.D. LE\*, W.J. XIE, R. KONG, X. ZHAO, S.H. APPEL. DEPT. OF NEUROLOGY, BAYLOR COLLEGE OF MEDICINE, HOUSTON, TX 77030

Heme oxygenase-1 (HO-1) is an inducible stress protein in response to variety of oxidative challenge and stimuli. In primary hippocampal and hybrid neuronal cultures, HO-1 expression was significantly elevated in response to an increase in the production of reactive oxygen species in a time-dependent manner after exposure to synthetic human β-amyloid<sub>1-40</sub> and hydrogen peroxide. The induction of HO-1 could be seen in both astrocytes and neurons in mixed hippocampal cultures. The levels of HO-1 in primary and cell line cultures however were dropped when the cultured cells started degeneration. To understand the role of HO-1 in oxidative stress-induced neuronal injury, we used HO-1 antisense oligonucleotide to inhibit expression of HO-1 in hybrid neuronal cell cultures. After 24 hr treatment with HO-1 antisense, the expression of HO-1 was dramatically decreased as documented by immunostaining and immunoblot. Although low concentration of HO-1 antisense did not affect the cell viability, high concentration of the antisense caused cell death. Down regulation of HO-1 expression with HO-1 antisense increased the neuronal cells 3-5 times more vulnerable to β-amyloid and hydrogen peroxide induced cytotoxicity. These findings support the role of HO-1 as an important cellular antioxidant defense protein in protecting neurons from oxidative stress-induced injury.

## 284.3

**PKC-DEPENDENT MODULATION OF NEURONAL APOPTOSIS AND OXIDATIVE STRESS BY BDNF.** B.J. Gwyne<sup>1</sup> and D.W. Choi<sup>2</sup>. <sup>1</sup>Dept. of Pharmacology, Ajou Univ. School of Medicine, Suwon 441-749, Korea; <sup>2</sup>Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Near-pure neuronal cortical neuronal cell cultures undergo cycloheximide-sensitive neuronal apoptosis following serum deprivation. Inclusion of 100 ng/ml brain-derived neurotrophic factor (BDNF) or insulin-like growth factor I (IGF-I) attenuated serum deprivation-induced neuronal apoptosis. Concurrent treatment with 0.3 - 10  $\mu$ M Go 6976, a selective inhibitor of PKC  $\alpha$  and  $\beta$ 1, reversed this protective effect of BDNF, but not that of IGF-I. Wortmannin, an inhibitor of phosphatidylinositol-3-kinase (PI-3-kinase), partially reversed both the protective effects of BDNF and IGF-I.

Free radical stress was induced in mixed cultures of cortical neurons and glia by exposure to 30  $\mu$ M Fe<sup>2+</sup> or 1 mM buthionine-sulfoximine (BSO), leading to submaximal neuronal necrosis over 24 hrs. Inclusion of BDNF or IGF-I potentiated such free radical-mediated neuronal necrosis. This cell death potentiation by BDNF or IGF-I was prevented by addition of cycloheximide, suggesting a requirement for new protein synthesis. As with the protective effects of the growth factors on serum deprivation-induced apoptosis, the harmful effects of BDNF but not IGF-I were blocked by inclusion of Go 6976, and both BDNF and IGF-I injury potentiation was partially sensitive to wortmannin. Present data provide evidence that both the attenuation of neuronal apoptosis and the potentiation of neuronal necrosis induced by BDNF are sensitive to inhibition of PKC  $\alpha$  and  $\beta$ 1 as well as possibly, PI-3-kinase. Supported by NIH NINDS grant NS 30337 (DWC).

## 284.5

**NEURONS AND MICROGLIA COLLABORATE VIA AN EXTRACELLULAR PROTEOLYTIC CASCADE TO PROMOTE NEURONAL DEGENERATION.**

S.E. Teirka<sup>1</sup>, A.D. Rogove<sup>2</sup>, T.H. Buoge<sup>3</sup>, J.L. Degen<sup>4</sup> and S. Strickland<sup>5</sup>. <sup>1</sup>Department of Pharmacology, Program in Genetics, and MSTP Program, University Medical Center at Stony Brook, Stony Brook, NY 11794-8651, <sup>2</sup>Division of Developmental Biology, Children's Hospital Research Foundation, Cincinnati, OH 45229

Mice lacking the serine protease tissue plasminogen activator (tPA) are resistant to excitotoxin-mediated hippocampal neuronal degeneration. We have used genetic, cellular, and biochemical analyses to study the role of tPA in neuronal cell death. Mice deficient for the zymogen plasminogen, a known substrate for tPA, are also resistant to excitotoxins, implicating an extracellular proteolytic cascade in degeneration. The two components of this cascade, tPA and plasminogen, are both synthesized in the mouse hippocampus. tPA mRNA is found in neurons and microglia, with microglia contributing the majority of enzymatic activity upon injury. In contrast, plasminogen mRNA is found exclusively in neurons, suggesting a collaboration of neighboring cell types in effecting degeneration. Consistent with the model that extracellular proteolysis is required at the time of excitotoxic injury, infusion of plasminogen activator inhibitor-1 into the hippocampus of wild-type mice confers resistance to excitotoxin-induced neuronal degeneration.

## 284.7

**GLUTAMATE INDUCED RELEASE OF NEUROTOXIN IN RAT HIPPOCAMPAL NEURONS.** K.W. Yoon<sup>1</sup>, P.T. Shah<sup>2</sup> and M.L. Klein<sup>3</sup>. Dept. of Neurosurgery & Surgical Research Institute, St. Louis University Health Science Center, St. Louis, MO 63110-0250.

The central neurotoxicity of the excitatory amino acid glutamate may be responsible for neuronal damage associated with certain acute insults including hypoxia-ischemia, epilepsy & trauma. Exposure of dissociated rat hippocampal culture (1-2 week in vitro) to glutamate (500  $\mu$ M, 1 min) produced toxicity which could be transferred to a naive non-treated culture. After 1 min exposure, glutamate was washed away & the naive culture treated with ECF collected at 5 min from treated culture. This toxicity is only transiently expressed with the maximum effect seen when ECF is transferred within 5 minutes following glutamate insult while no significant toxicity can be demonstrated at 30 minutes. Glutamate concentration in the transferred ECF was measured & found to be < 30 nM/ml at 5 min. NMDA & non-NMDA antagonists MK-801 (10  $\mu$ M) & CNQX (30  $\mu$ M) blocked the neuronal cell death when added to the donor culture (90.81  $\pm$  9.76 % reduction in cell death, n=6). However, MK-801 & CNQX did not block neurotoxicity in the recipient culture indicating involvement of some other neurotoxin.

We have previously shown that traumatized neuronal culture can release a neurotoxin involving cyclooxygenase dependent mechanism. However, Indomethacin (10 & 100  $\mu$ M) had no significant effect on toxicity when added to both donor & recipient culture. Dantrolene (30  $\mu$ M) significantly blocked toxicity when added to the recipient culture (88.23  $\pm$  20.21 % reduction in cell death, n=5). Therefore glutamate may propagate neurotoxicity by inducing release of a soluble & transferable toxin. This toxin may be different from the previously described trauma induced toxicity.

**FREE OXYGEN RADICALS MEDIATE EXCITOTOXIC AND APOPTOTIC NEURONAL DEGENERATION.** J.H.M. Probst<sup>1</sup>. Dept. of Pharmacol. & Toxicol., FB 16, Philippe-Universität, Ketzerbach 63, 35032 Marburg, Germany

Overactivation of glutamate receptors (excitotoxicity) and activation of a conserved cell death program (PCD) have been implicated in the degeneration of neurons in stroke, Parkinson's and Alzheimer's disease. The present study was undertaken to evaluate the involvement of reactive oxygen species in both types of cell death.

Cultured rat hippocampal neurons were derived from neonatal (P1) Fischer rats and cultured for 10 - 14 days. Excitotoxic injury was induced by a 10 min exposure to the selective glutamate agonist NMDA (30-300  $\mu$ M), and apoptotic cell death by exposure to staurosporine (0.01-0.5  $\mu$ M). Production of free oxygen radicals (superoxide anions) was monitored using the specific fluorescent probe dihydroethidium (HET) in combination with digital microfluorimetry. Exposure to 300  $\mu$ M NMDA induced an immediate increase in the rate of conversion of HET to its oxidized form ethidine. This was followed by extensive neuronal degeneration assessed 18 hours later. Exposure to 30  $\mu$ M NMDA neither induced a significant increase in free radical production, nor any significant cell death. In contrast to the acute response to NMDA, exposure to staurosporine (0.5  $\mu$ M) induced a delayed production of free oxygen radicals with peak production 120 min after staurosporine exposure (increase of 81.5  $\pm$  7.0 %;  $p < 0.001$ ) and persistent elevation for 6 hours. Administration of the antioxidants U74500A (1-10  $\mu$ M), dihydrolipoic acid (1-10  $\mu$ M) or vitamin E (10-100  $\mu$ M) significantly reduced both staurosporine- and NMDA-induced neuronal death.

These results demonstrate the importance of increased free oxygen radical production in the initiation of both NMDA receptor-mediated excitotoxic injury and PCD. Antioxidant therapy may therefore be useful in the treatment of neurodegenerative disorders.

**DIFFERENTIAL SCREENING FOR NMDA-INDUCED GENES IN PRIMARY NEURONAL CULTURES.** J.R. Naranjo<sup>1</sup> and B. Mellström<sup>2</sup>. Cajal Institute, C.S.I.C., Madrid, Spain

Neuronal death produced by over-stimulation of excitatory amino acid receptors is a well established phenomenon. A rapid induction of immediate early genes occurs after receptor stimulation and announce a second wave of changes in gene expression that might direct the final events leading to cell death or survival after excitatory amino acid receptor stimulation. In order to identify those genes we prepared cDNA libraries from control neuronal primary cultures and from cultures four hours after a pulse of NMDA. Here we present data indicating that the gas1 (growth arrest specific gene 1) gene, whose product is known to be a marker of the G<sub>0</sub> phase of the cell cycle, is induced in cultured cortico-hippocampal neurons committed to die after a brief exposure to NMDA. Induction of gas1 also occurred in rat brain areas that show delayed neuronal death after intraperitoneal injection of kainic acid. Blockage of Gas1 function with antisense gas1 oligodeoxynucleotide or by expression of antisense gas1 mRNA in stably transfected NB69 neuroblastoma cells, prevented NMDA-induced excitotoxic neuronal death and reduced staurosporine-induced apoptosis, respectively. In addition, overexpression of Gas1 in NIH3T3 cells produced a marked reduction in the number of viable cells by an apoptotic mechanism. Interestingly, Gas1 function was attenuated by coexpression of the human Bcl-2 protein.

## 284.8

**LASTING SER-73 PHOSPHORYLATION OF c-JUN, SUPPRESSION OF ATP-2 AND ACTIVATION OF c-JUN N-TERMINAL KINASES (SAPK) IN ADULT RAT BRAIN FOLLOWING SEIZURES, ISCHEMIA AND AXOTOMY.** T. Herdegen<sup>1</sup> (1), T. Kallunki (3), A. Martin (2), T. Buschmann (2), M. Karin (3); Univ. Kiel (1) and Univ. Heidelberg (2), Germany; (3) Univ. San Diego, USA.

c-Jun expression is related to cell death in embryonic and to regeneration/survival in adult neurons following neuronal damage. We have visualized the activated form of c-Jun by a specific antibody against the phosphorylated Ser-73 of c-Jun (p-c-Jun), expression of ATF-2 and the activity of their regulating kinases JNKs (SAPKs) by in-gel- and kinase assays. In the untreated rat brain, JNK has a basal activity, but p-c-Jun is not detectable in areas with constitutive c-Jun expression. Following axotomy of retina and substantia nigra, ischemia and seizures p-c-Jun is exclusively present in neurons with c-Jun expression up to 30 days, whereas ATF-2 completely disappears. JNK-2 (less JNK-1) is activated for days in homogenates of axotomized, ischemic or postictal areas. Induced c-Jun is phosphorylated and ATF-2 is suppressed, too, in dying DRG neurons following UV-irradiation, and both, p-c-Jun and cell death is prevented by the pretreatment of the calcineurin-inhibitor FK-506. These data suggest a novel interplay between JNK, c-Jun phosphorylation and ATF-2 suppression due to neurodegeneration in the adult brain.

## 284.9

**APOPTOTIC DNA FRAGMENTATION IS ASSOCIATED WITH MODULATION OF BCL-2, BCL-X, BAX, AND C-FOS EXPRESSION FOLLOWING FOCAL CEREBRAL ISCHEMIA IN RATS.** F. Gillardon, C. Lenz, S. Krajewski, J. C. Reed, W. Kuschinsky, and M. Zimmermann. Physiologisches Institut, Universität Heidelberg, 69120 Heidelberg, Germany, and ‡La Jolla Cancer Research Foundation, La Jolla, CA 92037, USA.

Permanent occlusion of the middle cerebral artery (MCA) in rats was used to assess the effects of focal cerebral ischemia on the expression of members of the *bcl-2* gene family which have been implicated in the regulation of programmed cell death. Six hours of intraluminal MCA occlusion lead to ischemic cell damage within the ipsilateral caudate putamen, basolateral cortex, and parts of the thalamus as detected by nitro blue tetrazolium staining of rat brain sections. In the infarcted cortex and thalamus fragmentation of genomic DNA was frequently observed using *in situ* end-labeling of DNA breaks by terminal transferase, whereas only scattered labeled nuclei were visible in the infarcted caudate putamen. Immunohistochemical analysis revealed activation of c-Fos in neurons of the infarcted cortex and thalamus and in the non-infarcted cingulate cortex. A decrease in neuronal immunoreactivity for Bcl-2, and Bcl-X and an increase in immunostaining for Bax was observed within the ischemic cortex and thalamus. Intensity of immunostaining did not change in neurons located at the border (pennumbra) of the infarcted brain regions. Within the infarct core (caudate putamen) however, protein levels of all Bcl-2 family members declined and c-Fos remained absent. RT-PCR analysis revealed a pronounced decrease in *bcl-2* mRNA levels in the ischemic hemisphere, whereas the amount of *bax* mRNA was significantly elevated despite an ischemia-induced suppression in total RNA synthesis. Thus, a shift in the ratio of cell death repressors Bcl-2 and Bcl-X<sub>LONG</sub> to cell death promoter Bax following focal cerebral ischemia may lead to a derepression of the cell death programme. A concomitant sustained activation of c-Fos may contribute to neuronal apoptosis within the ischemic cortex and thalamus.

## 284.11

**BAX IS REQUIRED FOR DEATH OF SYMPATHETIC NEURONS BY TROPHIC FACTOR DEPRIVATION AND DURING DEVELOPMENT.** T.L. Deckwerth\*, C.M. Knudson, S.J. Korsmeyer\*, and E.M. Johnson, Jr.\* Washington University School of Medicine, Departments of Molecular Biology and Pharmacology\*, Medicine and Pathology\*, St. Louis, MO 63110, USA.

Members of the BCL2 family of proteins either promote or repress programmed cell death. Given the existence of multiple death-promoting members, a question exists as to whether a single member can be of paramount importance in controlling apoptosis. We tested whether BAX, a death-promotor, is required for neuronal death by trophic factor deprivation and during development. Wild type neonatal sympathetic neurons depend on nerve growth factor (NGF) for survival and die by apoptosis when deprived of NGF. In contrast, *Bax*-deficient sympathetic neurons showed long-term survival in the absence of NGF. These salvaged neurons displayed remarkable soma atrophy and a reduced elaboration of neurites; yet, they proved capable of responding to re-addition of trophic factor with soma hypertrophy and enhanced neurite outgrowth. Developmental cell death of sympathetic neurons was also diminished in the absence of BAX. These results demonstrate that NGF deprivation-induced death of sympathetic neurons is *Bax*-dependent and that BAX regulates naturally occurring developmental neuronal death. Supported by NIH grants NS24769, AG12947, and CA49712.

## 284.10

**BAX IS REQUIRED FOR MOTONEURON DEATH FOLLOWING AXOTOMY AND DURING DEVELOPMENT.** J.L. Elliott\*, C.M. Knudson\*, S.J. Korsmeyer\*, and W.D. Snider\*. CSNSI, Depts. of Neurology<sup>1</sup>, and Pathology<sup>2</sup>, Washington University School of Medicine, St. Louis, Mo. 63110.

Members of the *bcl-2* family, acting as either inhibitors (*bcl-2*, *bcl-xl*) or promoters (*bcl-xs*, *bax*, *bad*, *bak*), have been implicated as important regulators of cell progression along an apoptotic death pathway. Recent investigations have established the importance of *bcl-2* and *bcl-x* in promoting neuronal survival, whereas the important pro-apoptotic *bcl-2* family members *in vivo* are unknown. We have generated mice with targeted disruptions of *bax* alleles to determine whether *bax* is critical for programmed neuronal death *in vivo*.

We have used the paradigm of neonatal facial axotomy to test the role of *bax* in regulating motoneuron death after target deprivation. The right facial nerve was transected in post-natal (PN) 1 wild type *bax*<sup>+/+</sup>, heterozygous *bax*<sup>+/-</sup>, and homozygous *bax*<sup>-/-</sup> mice. 7 days later, the animals were sacrificed and motoneuron counts were performed. Both *bax*<sup>+/+</sup> and *bax*<sup>+/-</sup> mice demonstrated a similar degree of facial motoneuron survival (14% and 12% respectively) on the axotomized side. In contrast, 86% of facial motoneurons survived axotomy in *bax*<sup>-/-</sup> mice. Remarkably, facial motoneurons in *bax*<sup>-/-</sup> mice were alive even at 4 weeks (the longest time period assessed) after a PN1 axotomy, although they had become markedly atrophic. Total facial motoneuron counts were performed in *bax*<sup>+/+</sup>, *bax*<sup>+/-</sup>, and *bax*<sup>-/-</sup> mice. *Bax*<sup>-/-</sup> mice exhibited a 51% increase in the number of facial motoneurons as compared to wild type mice. *Bax*<sup>+/-</sup> mice had a small but significant increase (13%) in facial motoneurons vs. wild type.

The results of this study demonstrate that a single gene product, *bax*, is necessary for motoneuron death in the setting of trophic factor deprivation. Although motoneurons lacking *bax* survive neonatal axotomy, even for extended time periods, they become markedly atrophic. Mice deficient in *bax* also demonstrate an increase in motoneuron number in a gene dose dependent fashion, suggesting *bax* regulates naturally occurring cell death.

**ABNORMALLY PHOSPHORYLATED TAU ( $\tau$ ) AND PRION PROTEIN AMYLOIDOSIS.** B. Ghetti<sup>1</sup>, P. Piccardo<sup>1</sup>, M. R. Farlow<sup>1</sup>, S.R. Dlouhy<sup>1</sup>, E. Tagliavini<sup>2</sup>, G. Giaccone<sup>2</sup>, and Q. Bugiani<sup>2</sup>. <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN 46202; <sup>2</sup>Istituto Carlo Besta, Milano, Italy.

Prion protein (PrP) amyloid as well as neurofibrillary tangles, neuropil threads, and abnormal neurites are consistently present in Gerstmann-Sträussler-Scheinker (GSS) disease with mutations in the *PRNP* gene at codon 198 (F198S) and 217 (Q217R) as well as in PrP cerebral amyloid angiopathy with mutation at codon 145 (Y145Stop). In these disorders, PrP parenchymal or vascular amyloid deposition is severe in the cerebral and cerebellar cortex. We have analyzed the neurofibrillary changes of GSS disease with mutation at codon 198 (Indiana kindred) using monoclonal antibody AT8 which recognizes abnormally phosphorylated epitope Ser-202/Thr-205 on PHF  $\tau$  protein. Serial coronal brain slices from five patients of the Indiana kindred were labeled with antibodies AT8 and 3F4. The latter recognizes epitopes corresponding to residues 109-112 of human PrP. AT8 immunoreactivity is strong in the neocortex, caudate nucleus, putamen, claustrum, and amygdala, it is weak in the globus pallidus and thalamus, it is virtually absent in the cerebellum. 3F4 immunopositivity is strong in the neocortex, caudate nucleus, putamen, claustrum, and cerebellum. In the caudate nucleus and putamen, PrP deposition is not associated with severe amyloidosis. Thus, the topography of neurofibrillary changes and PrP deposits overlap in the cerebrum, but not in the cerebellum. Our data indicate that in some variants of hereditary PrP amyloidosis, abnormal phosphorylation of  $\tau$  occurs in the cerebrum and it may be linked to the presence PrP degradation products. (Supported by PHS R01 NS 29822).

## 285.2

**CHEMICAL CHAPERONES STABILIZE THE NATIVE CONFORMATION OF THE PRION PROTEIN.** J. Tatzelt\*, S.B. Prusiner, W.J. Welch. University of California, San Francisco, CA 94143-0518. Prion diseases include kuru, Creutzfeldt-Jakob disease (CJD), Gerstmann-Sträussler-Scheinker syndrome (GSS) and fatal familial insomnia (FFI) of humans, as well as scrapie and bovine spongiform encephalopathy (BSE) of animals. A conformational change in the cellular prion protein (PrP<sup>C</sup>) is thought to be a decisive factor in these diseases. Formation of the pathogenic scrapie isoform (PrP<sup>Sc</sup>) likely involves a transition from the  $\alpha$ -helical form PrP<sup>C</sup> into one predominantly consisting of  $\beta$ -sheet. Here we show that incubation of scrapie-infected mouse neuroblastoma (ScN2a) cells with various reagents known to stabilize proteins in their native conformation results in a substantial reduction in the rate and extent of PrP<sup>Sc</sup> formation. Such reagents include the cellular osmolytes glycerol and trimethylamine N-oxide (TMAO), and the organic solvent dimethylsulfoxide (DMSO). These so-called "chemical chaperones" inhibited PrP<sup>Sc</sup> formation as a function of both dose and time of exposure. Chemical chaperones did not appear to affect the existing population of PrP<sup>Sc</sup> in ScN2a cells; instead, they interfered with the conversion of newly synthesized PrP<sup>C</sup> to PrP<sup>Sc</sup>. We suspect that the chemical chaperones act to stabilize the  $\alpha$ -helical form(s) of either full length PrP<sup>C</sup> or degradation intermediates of PrP<sup>C</sup>. Stabilization of the  $\alpha$ -helical form would reduce or prevent the acquisition of a  $\beta$ -sheet conformation and the subsequent formation of detergent-insoluble PrP aggregates.

## 285.3

**PRION PROTEIN FRAGMENT INDUCES  $[Ca^{2+}]_i$  INCREASE IN MICROGLIA.** J. W. Herms\*, A. Madlung, D. B. Brown and H. A. Kretzschmar, Department of Neuropathology, University of Göttingen, Robert-Koch-Strasse 40, Göttingen, D-37075, Germany.

Microglia in a reactive state are known to be associated with neurodegenerative changes in prion diseases. Using the synthetic PrP fragment PrP 106-126, known to be toxic for neurons as a model for investigating neurodegeneration in these diseases, we have previously shown that exposure to PrP 106-126 alters microglial activity and viability. It is thought that PrP 106-126 is toxic to neuronal cultures by inducing increased release of oxygen radicals from microglia (Brown et al. Nature 380:345-347).

To further elucidate how the peptide activates microglia, we investigated the effects of PrP 106-126 on intracellular free  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ) in cultured, LPS-treated microglia by using Fura-2 imaging. Exposure to 100  $\mu$ M PrP 106-126 induced a marked increase in  $[Ca^{2+}]_i$  within 10  $\pm$  6 minutes in the microglia of normal (C57black/SV129) as well as PrP-deficient mice. From basal levels of  $52 \pm 25$  nM in both populations, the increase was significantly lower in PrP-deficient mice with  $150 \pm 40$  nM (n=6) than in control mice ( $376 \pm 190$  nM (n=11)). Predominantly these cells showed a transient calcium increase, which decreased to near basal values within 20 minutes after maximal response was observed.

Based on the assumption that microglia activation may be the initial process leading to loss of neurons in prion diseases, our findings demonstrate the earliest reaction of microglia to a PrP-fragment known so far. This finding may help to elucidate the sequence of events leading to neuronal damage in prion diseases. (Supported by BMBF grant 01K1 9461/8 to HAK)

## 285.5

**E200K MUTATION: EFFECT ON PRION PROTEIN**

S. Capellari, P. Parchi, C. B. Uriag, S. L. Richardson, C. Russo, P. Gambetti and R. B. Petersen\*, Institute of Pathology, Case Western Reserve University, Cleveland, OH, 44106

Prion diseases are neurodegenerative illnesses that can be sporadic, infective or inherited. On the basis of their clinical and neuropathological manifestations they are divided in three main groups: Creutzfeldt-Jakob disease (CJD), Gerstmann-Sträussler Scheinker and Fatal Familial Insomnia. They are all characterized by the presence, in the CNS, of a protease resistant isoform that derives from a normal protein referred to as the cellular prion protein (PrP<sup>C</sup>). Inherited prion diseases are autosomal dominant disorders caused by mutations in the prion protein gene.

A replacement of Lys for Glu at residue 200 (E200K) in PrP<sup>C</sup> is the most common cause of inherited CJD. To understand the effect of this mutation on PrP<sup>C</sup> synthesis and processing, we transfected human neuroblastoma cells with the normal or the E200K mutated human PrP coding sequence. Both mutant PrP (PrP<sup>M</sup>) and PrP<sup>C</sup> are detectable in the cell lysate as well as on the cell surface and migrate in gels as three major isoforms: unglycosylated, monoglycosylated, and fully (di) glycosylated. The E200K mutation has a profound effect on the unglycosylated isoform which shows: 1. an aberrant electrophoretic mobility, 2. decreased solubility in detergents, 3. lower quantity at the cell surface, and 4. decreased susceptibility to PIPLC cleavage. Glycosylation partially corrects these changes. The E200K results in the slight increase of a 12kDa aminoterminal truncated fragment. The mutation also affects glycan processing: the fully glycosylated PrP<sup>M</sup> migrates faster and appears to be more heterogeneous than PrP<sup>C</sup> due to differences in the complex glycans. Changes similar to those of the mutated cells are observed in brains from affected subjects with the E200K mutation. The accumulation of the 12 kDa PrP peptide in these brains is especially striking. These findings confirm the validity of our cell model. Supported by NIH grant AG-0812, AG-08992, AG-08155 and the Britton Fund

## 285.7

**THE MACHADO-JOSEPH DISEASE GENE PRODUCT MJD1 IS A CYTOPLASMIC PROTEIN EXPRESSED WIDELY IN THE CENTRAL NERVOUS SYSTEM.** H. Paulson, S. Das, P. Crino, M. Perez, S. Patel, K. Fischbeck and R. Pittman\*, Depts. of Neurology and Pharmacology, Univ. of Penn., Philadelphia PA 19104

Machado-Joseph disease is one of at least five neurodegenerative triplet repeat diseases caused by an expanded CAG/polyglutamine tract within the protein coding region of the disease gene. Using RT-PCR, we isolated multiple splice variants of the *MJD1* gene from patient lymphoblastoid cells and normal human brain. A nearly full length splice variant was used to create a fusion protein, against which antiserum was generated. On Western blot, the antiserum specifically recognized normal and expanded MJD1 protein from patient lymphoblastoid cells and from transfected cells. In nonneuronal tissues, several other species were detected which may correspond to splice variants. In contrast, in human brain the antiserum detected a single major species, a doublet corresponding to full length MJD1, that was present in all regions examined by Western blot (cortex, caudate/putamen, pons and cerebellum). Immunohistochemistry demonstrated cytoplasmic staining in select populations of neurons throughout the brain, including anterior horn cells in the spinal cord, Purkinje cell and granule cell layers in the cerebellum, and infrequent neurons within the caudate and putamen. Immunofluorescence of a motor neuron-hybrid cell line transfected with MJD1 cDNA confirmed a cytoplasmic localization. Further studies with this antiserum may help elucidate the function of MJD1. Funded in part by postdoctoral grants from the Howard Hughes Medical Institute and the American Academy of Neurology.

## 285.4

**SIMILAR POSTTRANSLATIONAL MODIFICATIONS OF THE PRION PROTEIN IN FAMILIAL, SPORADIC AND IATROGENIC CREUTZFELDT-JAKOB DISEASE (CJD).** P. Parchi, S. Capellari, S. G. Chen, B. Ghetti\*, J. Miko\*, C. Vital\*, E. I. Cochran\*, J. O. Trojanowski\*, D. W. Dickson\*, R. B. Petersen, P. Gambetti\*, Div. Neuropath., CWRU, Cleveland, OH, 44106, Indianapolis, IN\*, Paris\* and Bordeaux\*, France, Chicago IL\*, Philadelphia, PA\*, Bronx, NY\*

Prion diseases are caused by an infectious agent that shows strain variations and is thought to consist solely of the protease-resistant form of the prion protein (PrP<sup>Sc</sup>). Recent data suggested that self-propagation of PrP<sup>Sc</sup> with distinct conformations could be the molecular basis of prion strains. Previously, we examined PrP<sup>Sc</sup> in sporadic CJD and in two familial prion diseases, fatal familial insomnia (FFI) and CJD<sup>178</sup>. In order to determine the full spectrum of PrP<sup>Sc</sup> characteristics in CJD we now analyzed PrP<sup>Sc</sup> in other subtypes of familial CJD and in iatrogenic CJD. We examined 5 subjects carrying the E200K mutation, 3 with insertion mutations (96,120 and 144 bp), 1 with the V210I mutation and 1 with iatrogenic CJD (growth hormone), and we compared the data with those obtained from 25 sporadic CJD, 11 FFI and 7 CJD<sup>178</sup>. Western blot and epitope mapping showed that in all cases PrP<sup>Sc</sup> comprised 3 major glycoforms of a N-terminal truncated fragment. Based on the electrophoretic mobility only two sizes of the fragment were observed. PrP<sup>Sc</sup> type 1 (size of unglycosylated form-20-21 kDa) was detected in most sporadic CJD, in 2 insertion mutations and in the E200K, D178N-129V, V210I mutations, whereas PrP<sup>Sc</sup> type 2 (size of unglycosylated form-18-19 kDa) was found in atypical sporadic CJD, in the 120 bp insertion, in the subject with iatrogenic CJD and in FFI. Within each of the two groups, the ratio of the 3 PrP<sup>Sc</sup> glycoforms did not significantly differ between sporadic, iatrogenic and familial CJD except for the E200K and D178N mutations which showed an underrepresentation of the unglycosylated form. These data provide indirect evidence for the existence of two major prion strains in humans causing CJD. Supported by AG08012, AG08155, AG08992 and the Britton Fund.

## 285.6

**IDENTIFICATION OF A CYCLIN-DEPENDENT KINASE-5 BINDING PROTEIN USING THE YEAST TWO-HYBRID SYSTEM.** S. Guidato\*, D. M. McLoughlin, J. P. Brion\* and C. C. J. Miller, Departments of Neuroscience and Neurology, The Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, UK. \* Laboratory of Pathology and Electron Microscopy, Université Libre de Bruxelles, 808 route de Lennik, Bldg C-10, 1070 - Brussels, BELGIUM.

Cdk5 is a neuronal cdc2-like kinase that display neuronal specific activity. In common with other members of the cdk family, cdk-5 requires association with another protein (activator) for activity. Known activators of cdk5 are p35 and a homologue p39. A further protein, p67 has also been shown to modulate cdk-5 activity. In order to understand further the mechanisms regulating cdk-5 activity, we have attempted to identify proteins that interact with cdk-5. We utilised the yeast two-hybrid system with cdk-5 as a "bait" to screen a human brain library for putative regulators of cdk-5. One such cdk-5 interacting protein was identified. Immunoprecipitation experiments confirmed that cdk-5 interacts with this protein in co-transfected COS cells. Studies on the *in vivo* expression of this cdk-5 binding protein and its effect on cdk-5 activity are currently underway. Cdk-5 is a kinase known to phosphorylate both neurofilaments and tau; aberrant phosphorylation of these proteins is seen in some neurodegenerative diseases such as Alzheimer's disease, motor neurone disease and Lewy body pathologies. Understanding the mechanisms that regulate cdk-5 activity therefore has relevance to these neurodegenerative diseases.

This work was supported by grants from the Wellcome Trust and MRC to CCJM. DMM is supported by a UK Alzheimer's Disease Society training fellowship. SG is supported by a Wellcome Prize Studentship.

## 285.8

**LOSS OF NEURONS AND SYNAPSES IN THE BASAL GANGLIA OF MICE WITH TARGETED DISRUPTION OF THE HUNTINGTON'S DISEASE GENE.** J. R. O'Kusky\*, J. Nasir\* and M. R. Hayden\*, Departments of \*Pathology and Laboratory Medicine and \*Medical Genetics, University of British Columbia, Vancouver, B.C., Canada V2Z 1M9.

We have created a targeted disruption in exon 5 of *Hdh* (*Hdh*<sup>Δ5</sup>), the murine homologue of the HD gene. Morphometric analyses were performed in light and electron microscopy to determine the numerical density and total number of neurons in the caudate-putamen, globus pallidus, subthalamic nucleus and substantia nigra of 7 *Hdh*<sup>Δ5</sup> heterozygotes and 7 normal littermates at 4 months of age. In *Hdh*<sup>Δ5</sup> heterozygotes there was a significant decrease in the total number of neurons in the globus pallidus (29%,  $p < 0.001$ ) and subthalamic nucleus (51%,  $p < 0.001$ ). Total glial cell density was significantly increased in both regions (18-20%,  $p < 0.02$ ), although there was no hypertrophy of astrocyte processes by electron microscopy to indicate active gliosis. In the subthalamic nucleus there was a significant decrease in the density of symmetric synapses (45%,  $p < 0.01$ ) with no significant difference in the density of asymmetric synapses, suggesting a relatively selective loss of pallido-subthalamic afferents. Sporadic degenerating axon profiles were observed by electron microscopy in the globus pallidus and subthalamic nucleus in approximately two-thirds of the *Hdh*<sup>Δ5</sup> heterozygotes, but in none of the control mice. These results indicate that the *Hdh* gene plays a role in the normal development of the murine basal ganglia. Furthermore, the data suggest that disinhibition of the subthalamic nucleus through loss of pallido-subthalamic afferents contributes to the motor deficits previously documented in these mice.

## 285.9

DECREASED THYROTROPIN RELEASING HORMONE (TRH) RECEPTOR mRNA IN SPINAL MOTONEURONS OF WOBBLER MOUSE EARLY IN MOTONEURON DISEASE IS FOLLOWED BY A LATER INCREASE, L.L. Vacca-Galloway\* and S.H. Zhang, Dept. of Anatomy, Univ. of Hong Kong, Hong Kong.

In situ hybridization, applied to spinal cord frozen sections (after anesthesia and perfusion) from old (age 3-4 mo) and young (age 3 wk) Wobbler and control littermate mice, shows lower numbers of TRH receptor (r) mRNA ventral horn neurons (VHNs) in Wobbler specimens. Lower amounts of TRHr mRNA are detected by photometry in young Wobbler specimens. Prior autoradiography shows a lower TRHr level in Wobbler VH compared with controls. In old Wobblers amounts of TRHr mRNA are greater in normal-looking VHNs compared with controls, whereas detection of TRHr by autoradiography shows lower levels. The increase of TRHr mRNA may result from VHN shrinkage known to occur in old Wobblers; decrease in young Wobblers may be due to VHN swelling. Alternatively translation is faulty. Vacuolated VHNs also produce TRHr mRNA. Early decrease of TRHr message in VHNs correlates with early sprouting of nearby TRH processes; later (secondary?) increase with later sprouting. ## 285.11

GAIN-OF-FUNCTION NEUROTOXIC EFFECTS OF MUTANT SOD-1 PROTEINS IN A PRIMARY CULTURE MODEL OF AMYOTROPHIC LATERAL SCLEROSIS. H.D. Durham<sup>1</sup>, J. Roy<sup>1</sup>, L. Dong<sup>2</sup>, and D.A. Falek<sup>1,2</sup>, <sup>1</sup>Montreal Neurological Institute, McGill University, Montreal, Canada H3A 2B4; <sup>2</sup>Dept. of Neurology and <sup>3</sup>Dept. of Neurobiology & Anatomy, Univ. of Rochester Medical Center, Rochester NY 14642.

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder characterized by loss of cortical, brainstem, and spinal motor neurons. Mutations in the CuZn superoxide dismutase (SOD-1) gene underlie some familial cases of ALS (FALS). To examine the mechanism of neuronal death in SOD-1 FALS, 4 different SOD-1 cDNAs bearing mutations found in FALS patients (mSOD), or wild type human SOD-1 cDNA (SOD<sup>wt</sup>), were subcloned into an expression vector. cDNA constructs were microinjected into nuclei of motor neurons in primary cultures of murine spinal cord, achieving expression of human SOD-1 protein in >80% of injected cells. Many features of motor neuron disease seen in human ALS and in mSOD transgenic mice were reproduced within 2 weeks, including hyperphosphorylation and bundling of neurofilaments, appearance of small vacuoles and inclusions, and cell death with evidence of apoptosis. Approximately 80% of spinal motor neurons injected with mSOD constructs died by postinjection day 12, compared to less than 20% injected with SOD<sup>wt</sup> or vector. mSOD was not lethal to dorsal root ganglion neurons over the same time period, indicating differential susceptibility of neurons in culture to toxicity of mSOD. A novel observation was the abnormal aggregation of mSOD protein in up to 50% of mSOD-expressing motor neurons. The aggregates, never observed in motor neurons expressing SOD<sup>wt</sup> enzyme, were not located in lysosomes or peroxisomes, suggesting they were cytosolic. It is concluded that mutations in different regions of the SOD-1 gene predispose the protein to intracellular aggregation which contributes to the toxicity of mSOD in motor neurons. ## 285.10

THE TRANSGENIC SOD-1 MOUSE MODEL OF ALS: SELECTIVE OXIDATIVE STRESS IN MOTOR NEURONS. Smith M.A., Dal Canto M., Richey P.L., and Perry G.\* Institute of Pathology, Case Western Reserve University, 2085 Adelbert Road, Cleveland, Ohio 44106 USA

Genetic evidence linking a small number of genetically-based amyotrophic lateral sclerosis (ALS) cases to an alteration in the antioxidant enzyme Cu/Zn superoxide dismutase (SOD-1) suggests at the minimum that oxidative damages can lead to ALS. Such a notion is supported by the development of a mouse transgenic for mutant SOD-1 that rapidly develops many of the clinical and pathological correlates of ALS.

Over the past two years our laboratory has become increasingly focussed on the role of oxidative protein modifications in age-related neurodegenerative diseases. Here, we present evidence for oxidative modifications in motor neurons in ALS and transgenic mice overexpressing mutant SOD-1. Using our recently developed *in situ* hydrazine technique we localized free carbonyl groups, as a measure of oxidative damage, in motor neurons and axons in the transgenic and control mice. Further, there was a striking increase in the level of heme oxygenase-1 (HO-1) in the transgenic mice that was limited to motor neurons showing vacuolation and neurofibril accumulation. Since HO-1 catalyzes the rate limiting step converting heme, a prooxidant, to bilirubin, an antioxidant, HO-1 induction indicates oxidative stress for the degenerating neurons resulting from mutant SOD-1 expression.

These data suggests a link between oxidative stress and the ALS phenotype of cytoskeletal disruption and motor neuron death. Understanding the types and extent of oxidative damage in ALS will provide new insight as to how one could prevent neuron damage by providing a rational therapeutic strategy that is likely to include antioxidants and free radical or carbonyl scavengers.

Supported by grants from the NIH, AHAF, and AFAR.

## CALCIUM CHANNELS: PHYSIOLOGY, PHARMACOLOGY, AND MODULATION III

## 286.1

RAPID MODULATION OF N- AND L-CALCIUM CHANNELS IN CEREBELLAR GRANULE NEURONS BY INSULIN-LIKE GROWTH FACTOR-1 IS DEPENDENT ON TK ACTIVATION OF PI 3-KINASE. L.A.C. Blair\* and J. Marshall, Pharmacology, Yale University, New Haven, CT, and Molecular Pharmacology and Biotechnology, Brown University, Providence, RI.

IGF-1 rapidly increased the activity of a subset of voltage-activated Ca channels in cultured cerebellar granule cells. Following superfusion of low, 20 ng/ml, concentrations of IGF-1, Ca channel currents carried by 20 mM barium increased ~2-fold in 10sec; no cells responded to addition of vehicle saline alone. The increase in activity was specifically mediated by IGF-1 receptors. Insulin produced only modest responses at 20,000 ng/ml, a concentration that can activate IGF-1 receptors. Additionally, the tyrosine kinase (TK) inhibitor Lavendustin A (1µM) fully blocked the IGF-1-induced increase, while its inactive analog Lavendustin B had no effect. IGF-1-increases in Ca channel activity were also dependent on activation of phosphatidylinositol 3-OH kinase (PI 3-kinase). Responses were inhibited by pretreatment with the membrane permeable PI 3-kinase inhibitors wortmannin (100nM) and LY294002 (10-50µM); vehicle additions were without effect. Similarly, PI 3-kinase activity assayed *in vitro* increased >5-fold after 10 sec exposure to 20 ng/ml IGF-1, but failed to increase if cells had been pretreated with Lavendustin A, wortmannin or LY294002; Lavendustin B was without effect. Finally, IGF-1 apparently modulated only a subset of Ca channels. The entire IGF-1-dependent increase in Ca channel activity could be accounted for by ω-CgTx GVIA- and DHP-sensitive channels. Furthermore, each Ca channel subtype appeared to be modulated within a specific voltage range, suggesting both altered voltage-dependence and, as opposed to insertion of new channels, modification of existing active channels.

## 286.2

LOW- AND HIGH-VOLTAGE-ACTIVATED Ca<sup>2+</sup> CURRENTS IN GUINEA PIG PIRIFORM CORTEX NEURONS. J. Magistretti\* and M. de Curtis, Dept. of Exper. Neurophysiology, Istituto Nazionale Neurologico "C. Besta", Milan, Italy.

Olfactory cortex is known to be organized in four layers, each with different cell composition. In layer II only pyramidal and semilunar neurons are found at high density. In layer III both pyramidal and multipolar neurons are present at lower density, whereas layer IV (or endopiriform nucleus) contains essentially only multipolar neurons. These different neuron types have received little attention as to their intrinsic membrane properties. Calcium (Ca<sup>2+</sup>) conductances have been proposed to play a crucial role in shaping delayed EPSPs and in promoting epileptiform potentials in the piriform cortex. Here we characterize the voltage-activated Ca<sup>2+</sup> currents of piriform-cortex layer II neurons. The study will be extended to layer III and IV neurons.

The anterior piriform cortex of 15 to 30-day-old guinea pigs was cut into 500 µm-thick coronal slices and layer II was dissected out under microscopic control. Neurons were acutely isolated with enzymatic treatment (1 mg/ml pronase, 15 min at 34°C) followed by gentle mechanical dissociation. Voltage-clamp recordings were performed with the whole-cell mode of the patch-clamp technique. Voltage-activated Ca<sup>2+</sup> currents, isolated by opportune intra- and extracellular blockers and ionic substitutes, were recorded in 55 cells. High-voltage-activated (HVA) Ca<sup>2+</sup> currents were present in all cells, and could be evoked with test pulses (tp) positive to -40/-30 mV from a holding potential (hp) of -50 mV. With hp of -100 mV, a sizeable low-voltage-activated (LVA) current could be evoked in 30% of the cells with tp positive to -70 mV. LVA current i) could be isolated either by subtraction or pharmacologically; ii) decayed monoexponentially with τ of ca. 25 ms at -30 mV; iii) was fully steady-state inactivated at -60 mV and fully reprimed at -105 mV. LVA current density was 7.3 ± 3.4 pA/pF at -30 mV. LVA current detection did not depend on the amount of available cell membrane, since membrane capacitance was 10.3 ± 3.5 in the group of cells displaying LVA current and 11.5 ± 2.6 in the other group. These data suggest that two neuronal sub-populations exist in layer II piriform cortex as to the expression of LVA currents.

## PROTEIN KINASE C REGULATES CALCIUM CHANNELS LOCALIZED TO A VESICULAR POOL IN APLYSIA BAG CELL NEURONS.

B. H. White<sup>1</sup>, T. A. Nick<sup>2</sup>, T. J. Carew<sup>2</sup>, and L. K. Kaczmarek<sup>1</sup>.  
 Dept. of Pharmacology<sup>1</sup> and Psychology<sup>2</sup>, Yale University, New Haven, CT 06520

Cultured bag cell neurons from adult *Aplysia* express two types of calcium channels, one of which (BCCA-I) resides in vesicles distributed primarily to somata and growth cones (White and Kaczmarek (1996) *Soc. Neurosci. Abstr.*: 508.5). We have analysed the expression of this channel in the bag cell neurons of juvenile *Aplysia* (5-10 g) using channel-specific antibodies and find that vesicular expression of BCCA-I occurs in juvenile bag cell neurons but is chiefly restricted to cell somata. Further, the percentage of cultured bag cell neurons displaying a vesicular distribution of BCCA-I ranged from 4% to over 80% in juvenile animals, raising the possibility that juvenile calcium current magnitudes may also vary.

Bag cell neurons have two calcium conductances, one of which is observed only after stimulation of protein kinase C (PKC). Simultaneous sampling of calcium currents in bag cell neurons from different juvenile animals by whole-cell patch clamp techniques showed that the percentage of cells containing BCCA-I vesicles was significantly correlated with the magnitude of the PKC-sensitive calcium current ( $p=0.02$ ), but not the PKC-insensitive current. These results strongly suggest that BCCA-I channels carry the PKC-sensitive calcium current in bag cell neurons. They are consistent with a model in which the PKC-recruited channels are translocated from the vesicular pool to the plasma membrane.

## CALCIUM-DYNAMICS IN VISUAL INTERNEURONS AFTER PHARMACOLOGICAL STIMULATION IN VITRO T.G.Oertner\*, T.M.Brotz and A.Borst

Friedrich-Miescher-Laboratory of the Max-Planck-Society, Spemannstr.37, D-72076 Tübingen, Germany.

Intracellular calcium is thought to play a significant role in dendritic processing of synaptic signals. Using the large motion sensitive tangential cells in the lobula plate of the blowfly (*Calliphora erythrocephala*) as our model system, we are interested in the functional role previously described calcium transients play for dendritic information processing in these cells (Borst, A. & Egelhaaf, M. *PNAS* 89, 4139, 1992; Egelhaaf, M. & Borst, A. *J. Neurophysiol.* 73, 2540, 1995). A pharmacological blocking specifically dendritic calcium channels would be an important tool in this analysis. A recently developed *in vitro* preparation of the fly brain allows for the study of calcium dynamics in visual interneurons of the blowfly under defined conditions (Brotz, T. M., Egelhaaf, M. & Borst, A. *J. Neurosci. Meth.* 57, 37-46, 1995). After injecting the cells with the calcium-sensitive dye fura-2<sup>TM</sup> we stimulate the cells iontophoretically with the cholinergic agonist carbachol. The spatio-temporal changes in relative fluorescence (up to -30 %) representing the intracellular  $Ca^{2+}$ -concentration are optically monitored simultaneously with intracellular recordings of the membrane potential. The onset of the calcium transient in the dendritic region next to the stimulus electrode, the soma, and the axon terminal is correlated with the electrical signal while a slower wave of increasing calcium concentration spreads along the dendrite with the diffusion of carbachol in the tissue. From that we conclude that the cell is equipped with different types of voltage-gated calcium channels: Calcium channels with a low activation threshold which are concentrated at the soma and the axon terminal, and high threshold  $Ca^{2+}$ -channels in the dendrite. The calcium influx can be blocked by  $Co^{2+}$  ions (2mM) or by removing extracellular calcium. More specific blocking agents are currently under evaluation to characterize the pharmacology of  $Ca^{2+}$ -channels in blowfly tangential cells.

## 286.7

## COMPARISON OF THE ATP MEDIATED INHIBITION OF N- AND P/Q-TYPE CALCIUM CURRENTS IN BOVINE ADRENAL CHROMAFFIN CELLS. K.P.M. Currie\* and A.P. Fox. Dept Pharm. &amp; Physiol. Sci., Univ of Chicago, Chicago IL 60637.

N- and P/Q-type calcium channel currents ( $I_{Ca}$ ) were recorded from adrenal chromaffin cells in the presence of nisoldipine to block any L-type  $I_{Ca}$ . The remaining  $I_{Ca}$ , isolated using selective toxins, was  $48 \pm 2\%$  N-type and  $45 \pm 2\%$  P/Q-type  $I_{Ca}$  ( $n = 21$ ). Extracellular ATP, acting through  $P_{2U}$  purinoceptors, inhibited  $I_{Ca}$  in a pertussis toxin sensitive manner typical of many neurotransmitters. However, the N- and P/Q-type currents were differentially targeted. Peak N-type  $I_{Ca}$  was inhibited by  $67 \pm 2\%$  and P/Q-type current by  $38 \pm 2\%$  ( $n = 24$ ;  $p < 10^{-4}$ ). Inhibition of  $I_{Ca}$  by neurotransmitters is comprised of a voltage insensitive component and a voltage sensitive component which can be relieved by depolarizing pre-pulses to very positive potentials. The P/Q-type current, in addition to being inhibited to a lesser extent, exhibited a smaller proportion of inhibition that was voltage sensitive. The voltage sensitive pathway suppressed the peak N-type current by  $46 \pm 2\%$  compared to the P/Q-type current which was inhibited by  $19 \pm 2\%$  ( $n = 17$ ;  $p < 10^{-4}$ ). In contrast the voltage insensitive pathway inhibited both current components to a similar degree ( $22 \pm 2\%$  and  $18 \pm 1\%$  ( $n = 17$ ) for the N- and P/Q currents respectively). The voltage sensitive inhibition was investigated further and it was found that the pre-pulse voltage required to give half maximal relief of the inhibition was shifted about -15 mV (to +42 mV) for the P/Q-type current relative to the N-type current ( $n = 4$ ). The duration of the pre-pulse and the time between pre- and test pulse were also varied to determine rates of unblock and reblock of the channels respectively. Preliminary data suggested only small differences in these parameters for the two current components. N- and P/Q-type  $I_{Ca}$  are both involved in transmitter release and are targets for inhibitory neuromodulation. Here we show that although the mechanism of inhibition is qualitatively similar for the two current types there are subtle differences, especially in the voltage sensitive inhibitory pathway.

## 286.4

## THE p38 MAP KINASE PATHWAY MEDIATES INHIBITION OF NEURONAL CALCIUM CURRENT BY BRADYKININ. M.A. Wilk, Blaszczyk\* and F. Belardetti. Dept. Pharmacology, UT Southwestern, Dallas, TX 75235.

In NG108-15 cells, bradykinin (BK) produces slow inhibition of the voltage-dependent  $Ca^{2+}$  current ( $I_{CaV}$ ) and activation of a voltage-independent  $K^{+}$  current. We have previously determined that these effects are mediated by two G proteins,  $G_{13}$  and  $G_{q/11}$ , respectively (Neuron, 12, 109; 13, 1215, 1994). We have now investigated whether the effect of  $G_{13}$  on  $I_{CaV}$  is mediated by a member of the MAPK (mitogen-activated protein kinase) family. Using whole-cell patch-clamp recording (10 mM EGTA in pipette), we find that blockade of the classical ERK (extracellular signal-regulated kinase) pathway with PD98059 (20  $\mu$ M in pipette,  $n=6$ ) did not depress the inhibition of  $I_{CaV}$  produced by BK (or by Leu-Enk, which is mediated by  $G_{q/11}$ ). In contrast, inclusion in the pipette of SB203580 (20  $\mu$ M;  $n=11$ ), an inhibitor of p38 MAPK, but not of SKF106978 (an inactive analog; 20  $\mu$ M,  $n=11$ ), blocked inhibition of  $I_{CaV}$  by BK (but not by Leu-Enk). Application of SB203580 did not block activation of the  $K^{+}$  current by BK ( $n=6$ ). The p38 MAPK pathway may be important in mediating slow inhibition of  $I_{CaV}$  by neurotransmitters. Supp. in part by NIH GM47721

## CONDUCTANCE AND PHARMACOLOGICAL PROPERTIES OF 2 CALCIUM CHANNELS IN PHYSIOLOGICAL LEVELS OF EXTERNAL CALCIUM. P.J. Church\* and E.F. Stanley SMS, NINDS, NIH, Bethesda, MD 20892

Due to the relatively low conductance of  $Ca^{2+}$  through HVA calcium channels little is known about the transport rates of single calcium channels in the physiologically relevant 1-4mM  $Ca^{2+}_{ext}$  range. To examine single channel currents in this range, we recorded from dissociated chick ciliary ganglion neurons using the on-cell patch clamp technique with low noise, quartz micropipettes.

An L-type calcium channel current was identified based on voltage dependence of activation and inactivation, sensitivity to the dihydropyridines S(-)-BayK8644 and Nifedipine, insensitivity to  $\omega$ -conotoxin GVIA and a unitary conductance of 26pS in 110mM  $Ba^{2+}$ . This channel had a unitary conductance of 8.8pS in 110mM  $Ca^{2+}$  and 2.4pS in 2mM  $Ca^{2+}$ . A second current fluctuation was present in  $Ca^{2+}$ , but not  $Ba^{2+}$ . This current had a voltage dependence similar to the L-type, but was insensitive to S(-)-BayK8644, Nifedipine, and  $\omega$ -conotoxin GVIA and had a unitary conductance of 12pS in 110mM  $Ca^{2+}$  and 2.4pS in 2mM  $Ca^{2+}$ .

Fitting the concentration dependence of both conductances with a Langmuir isotherm gave dissociation constant ( $K_D$ ) estimates of approximately 5mM. Thus,  $Ca^{2+}$  transport through these channels is particularly sensitive to changes in external  $Ca^{2+}$  concentrations in the physiological range and approaches saturation at about 10mM. Supported by the NINDS, NIH, Intramural Research Program.

## 286.8

## EFFECTS OF VOLTAGE AND NOREPINEPHRINE ON SINGLE N-CHANNEL GATING IN FROG SYMPATHETIC NEURONS. Hye Kyung Lee &amp; Keith S. Elmslie.\* Department of Physiology, Tulane University Medical School, New Orleans, LA 70112.

N-type calcium current is steeply voltage dependent with minimal to maximal activation occurring over a range of -40 mV. Norepinephrine (NE) shifts activation to higher voltages and increases the voltage range required to reach full activation. We recorded from single N-channels to understand the voltage dependence of channel gating and how gating is altered by NE.

Single N-channel events were measured after filtering at 1 kHz using 50% threshold detection.  $P_o$  increased from 0.1 at +20 mV to 0.8 at +50 mV. This increase in  $P_o$  was due in part to changes in mean open time ( $\tau_o$ ), which increased 3 fold from +10 mV to +40 mV ( $n = 4$ ). This was unexpected since  $\tau_o$  has been shown to be voltage-independent for many channels.

Addition of 100  $\mu$ M NE to the pipet solution induced a voltage-dependent inhibition of single N-channels. Ensemble currents showed a slow component to activation and current amplitude was facilitated following strong depolarization (+70 mV). Facilitation was due to an increase of  $P_o$ , which resulted in part from a decrease in the latency to first opening. However, a change in  $\tau_o$  also appeared to contribute to the increase in  $P_o$ .  $\tau_o$  measured at +40 mV was 1.9 ms in control patches ( $n=5$ ), but decreased to 1.3 ms in NE patches ( $n=3$ ). Strong depolarization returned  $\tau_o$  to control values (1.8 ms,  $n=3$ ). We are investigating the decrease in  $\tau_o$  to determine if it is consistent with predictions of the 'willing-reluctant' model of N-channel gating.

## 286.9

**BIOPHYSICAL AND PHARMACOLOGICAL PROPERTIES OF Q-TYPE  $\text{Ca}^{2+}$  CHANNEL CURRENTS IN RAT NEUROHYPOPHYSIAL TERMINALS.** G. Wang & J. Lemos, Worcester Foundation for Biomedical Research, Shrewsbury, MA 01545

Voltage-dependent  $\text{Ca}^{2+}$  channels play an essential role in depolarization-secretion coupling at nerve terminals. We have previously reported the co-existence of three (L, N & Q) types of  $\text{Ca}^{2+}$  channel currents in the isolated terminals of the rat neurohypophysis and that all three are important for vasopressin release (Wang et al., 1994, Neurosci. Abs. 20: 629). The present study focuses on characterizing the Q-type  $\text{Ca}^{2+}$  channel current using the whole-terminal, perforated patch-clamp method. The whole-terminal Q-type  $\text{Ba}^{2+}$  current is high-voltage-threshold ( $>10$  mV) activated and transient. Its inactivation time constant is 22.7 ms, vs. 30.7 ms for the N- and 172.6 ms for the L-type currents. The N- and Q-type  $\text{Ba}^{2+}$  currents have very similar steady-state inactivation curves, with initiation of inactivation at -80 mV and complete inactivation at -60 mV, both of which are much more negative than that for the L-type current. Pharmacologically, the L-type current is much more sensitive to  $\text{Cd}^{2+}$  and to dihydropyridines than is the N or Q. In terms of the sensitivity of the currents to  $\omega$ -conotoxins GVIA/MV1IC and to AgA IVA, the nerve terminals can be divided into two groups. One group exhibited three approximately equivalent  $\text{Ba}^{2+}$  currents: one highly sensitive to nifedipine, one to GVIA, and the other to MV1IC/AgA IVA. However, the other group demonstrated, in addition to a similar proportion of nifedipine-sensitive  $\text{Ba}^{2+}$  current, a much larger proportion of GVIA-sensitive but a relatively smaller proportion of MV1IC/AgA IVA-sensitive  $\text{Ba}^{2+}$  current. Binding rate constants for MV1IC to the Q-type  $\text{Ca}^{2+}$  channel is  $1.7 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$  vs.  $2.5 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$  to the N-type  $\text{Ca}^{2+}$  channel. These results suggest that (1) N- and Q-type  $\text{Ca}^{2+}$  channel currents in the neurohypophyseal terminals have similar gating kinetics but different pharmacological sensitivity; (2) there is heterogeneity in the N- and Q-type  $\text{Ca}^{2+}$  channel densities among the neurohypophyseal terminals. This heterogeneity of channel types might be due to differential localization in vasopressin- vs. oxytocin-releasing terminals. (Supported by NIH grant NS29470)

## 286.11

**INHIBITION OF NEURONAL APOPTOSIS BY A CHARGED 1,4-DIHYDROPYRIDINE L-TYPE CALCIUM CHANNEL BLOCKER.**

R.P. Mason\*, P. Leeds†, M.F. Walter, C. Hought, K.-G. Zhang†, P.E. Mason, and D.-M. Chuang†. Neurosciences Research Center, Medical College of Pennsylvania & Hahnemann University, Allegheny Campus, Pittsburgh, PA 15212 and †National Institute of Mental Health, NIH, Bethesda, MD 20892.

Amlodipine (AML) is a charged L-type  $\text{Ca}^{2+}$  channel blocker widely used in the treatment of cardiovascular disorders. Increases in intracellular  $\text{Ca}^{2+}$  levels that have been observed in association with apoptosis may be attenuated by  $\text{Ca}^{2+}$  channel blockers. In this study, the neuroprotective effect of AML was examined using an age-induced apoptosis model (J. Neurochem. 66:928;1996) consisting of a primary culture of rat cerebellar granule cells (CGC). AML significantly delayed age-induced apoptosis of CGC beyond the normal average of 17 days *in vitro* (DIV). The neuroprotective effect of AML was biphasic with a maximum at 1-10 nM; increasing doses resulted in a loss of neuroprotection. The observed neuroprotection was most effective when AML was repeatedly administered after 6 DIV. Other L-type  $\text{Ca}^{2+}$  channel blockers were also neuroprotective with a rank order of potency of AML>nifedipine>nifedipine>inactive nifedipine metabolite. Within the effective concentration range, neither AML nor nifedipine significantly affected the increase in intracellular  $\text{Ca}^{2+}$  levels triggered by NMDA receptor activation which is involved in age-induced apoptosis. However, AML (1-1000 nM) attenuated in a dose-dependent manner the intracellular calcium increases elicited by KCl depolarization. Moreover, AML exhibited dose-dependent antioxidant activity at nanomolar concentrations in reconstituted liposomes. The results of these studies suggest that L-type  $\text{Ca}^{2+}$  channel blockade and antioxidant mechanisms contribute to the potent neuroprotective effects of AML. These findings have therapeutic implications for the use of AML in neurodegenerative disorders.

**$\beta$ -adrenergic receptor-mediated inhibition of a long-lasting form of L-type calcium channel facilitation in rat hippocampal neurons.** R.K. Cloues\* and N.V. Marrion. Vollum Institute, OHSU, Portland, OR 97201.

We have characterized a novel, long-lasting form of prepulse facilitation exhibited by L-type  $\text{Ca}^{2+}$  channels and its modulation by  $\beta$ -adrenergic receptor activation in acutely dissociated hippocampal CA1 neurons. Single channels, sensitive to nimodipine (1  $\mu\text{M}$ ), were recorded from cell-attached patches using low concentrations of Ba or Ca (5-10 mM) as the charge carrier, in the absence of dihydropyridine agonists. Following a depolarizing prepulse to +40 mV (50-200 ms), a large increase in sustained channel activity at membrane potentials between -60 and -20 mV was observed. We have called this behavior "delayed facilitation" because it typically began several hundred milliseconds after the prepulse and decayed over several seconds. Prepulses caused a mean seven-fold increase in open probability measured over a six second time segment by increasing both the channel opening frequency and the proportion of longer duration openings ( $\tau = 3.0$  ms). Delayed facilitation was inhibited by the  $\beta$ -adrenergic receptor agonist, isoproterenol (1  $\mu\text{M}$ ). Isoproterenol reduced the channel opening frequency and the proportion of longer openings to control levels. Control sustained activity was not affected nor was standard activation of L-type  $\text{Ca}^{2+}$  channels, measured during 150 ms depolarizing steps to 0 mV. Isoproterenol-induced inhibition of delayed facilitation was reversed by the  $\beta$ -adrenergic receptor antagonist, propranolol (10  $\mu\text{M}$ ), and mimicked by application of 8-CPT cAMP, a membrane permeable analog of cAMP. Thus, an increase in cAMP mediated by activation of  $\beta$ -adrenergic receptors selectively inhibits delayed facilitation of L-type  $\text{Ca}^{2+}$  channels in the hippocampus. (Supported by NIH grant 29806)

## 286.12

**AMYOTROPHIC LATERAL SCLEROSIS (ALS) IgGs INCREASE  $\text{K}^{+}$ -EVOKED  $[\text{H}^{3}]\text{NORADRENALINE}$  RELEASE FROM RAT CEREBRAL CORTEX SYNAPTOSOMES.** C. Grassi\*, M. Martini\*, C. Cannizzaro\*, M. Lo Monaco\*, E. Carbone\* and G.B. Azzena\*. Institutes of \*Human Physiology, \*Pharmacology and \*Neurology, Catholic University "S. Cuore", Rome, \*Dept. of Neuroscience, University of Turin, Italy.

ALS is a neurodegenerative disease characterized by spinal cord and cortical motoneuron death. Experimental evidence suggests that neuronal vulnerability may be related to increased levels of intracellular  $\text{Ca}^{2+}$  and that autoantibody interaction with voltage-operated  $\text{Ca}^{2+}$ -channels (VOCCs) may be involved in the pathogenesis of sporadic ALS. Aim of the present study was to verify whether ALS IgGs can modify noradrenaline (NA) release from rat brain synaptosomes by affecting calcium influx through VOCCs. Cortical synaptosomes were incubated at 37 °C with 0.05  $\mu\text{M}$   $[\text{H}^{3}]\text{NA}$  for 15 min and then perfused with medium containing IgGs (0.1-0.2 mg/ml), purified from sera of either control subjects or ALS patients. Synaptosomes were depolarized with 9 mM KCl for 90 s, fractions were collected every minute and the areas under the time course release curves were measured. ALS IgG treatment (0.2 mg/ml) enhanced NA release from  $8.9 \pm 0.4$  to  $12.3 \pm 0.7$  (means of the areas  $\pm$  S.E.M.,  $n=6$ ), with a mean increase of 38.2%. This effect was dose-dependent, the maximum increase induced by 0.1 mg/ml IgGs being 11.4%. Pre-incubation of synaptosomes with ALS IgGs produced greater increases in NA release (up to 170%), along with changes in basal release and NA uptake. The blockade of N-type  $\text{Ca}^{2+}$ -channels ( $\omega$ -conotoxin GVIA, 3.0  $\mu\text{M}$ ) reduced NA release by only 18-25% of control values. These data suggest that ALS IgGs can enhance NA release from rat synaptosomes, probably by increasing  $\text{Ca}^{2+}$  influx through different VOCCs subtypes. Supported by CNR and Telethon grants.

## ISCHEMIA: NEUROPROTECTION

## 287.1

**HIGH DOSE BACLOFEN PROTECTS BRAIN AFTER TEMPORARY MCA OCCLUSION** Catherine Jackson-Friedman, Patrick D. Lyden\*, Veterans' Administration Medical Center, San Diego, CA 92161

We have previously shown that GABA-A agonists are neuroprotective (Stroke 23:1463-1470, 1992). Although neuroprotection has not been shown with low doses of the GABA-B agonist, Baclofen, we decided to study a higher dose since Baclofen inhibits excitatory transmission.

**Methods:** Using the method of Zea Longa we occluded the middle cerebral arteries (MCA) of male, Sprague Dawley rats anesthetized with Halothane. The animals were kept normothermic during ischemia. To generate a quantal bioassay, a range of occlusion durations were used. Five minutes after occlusion onset we injected either placebo, 10mg/kg, or 20mg/kg Baclofen intraperitoneally. Behavior was rated normal/abnormal at 48 and 72 hours post ischemia. After intravenously infusing 200 $\mu\text{l}$  of 2% Evans Blue brains were examined post mortem to verify MCA occlusion.

**Results:** The ED<sub>50</sub> is the duration of MCA occlusion that renders 50% of the subjects abnormal. The ED<sub>50</sub> for vehicle was ( $n=19$ ) 24.7 $\pm$ 1.96 min, for Baclofen 10mg/kg ( $n=16$ ) 31.9 $\pm$ 2.79 min, and for Baclofen 20mg/kg ( $n=18$ ) 81.4 $\pm$ 4.62 min ( $p<.05$  for each dose vs. control). Subjects with intracerebral hematoma or subarachnoid blood were excluded: 1/20 control, 12/28 at 10mg/kg Baclofen, and 9/27 at 20mg/kg Baclofen (Chi Square,  $p<.01$ ).

**Conclusion:** Higher doses of Baclofen can provide significant neuroprotection after MCA occlusion in a rodent suture model. However, there was an increase in the number of hemorrhages in Baclofen treated groups which may nullify this protective effect. (Supported by the Medical Research Service, Department of Veterans Affairs).

## 287.2

**NEUROPROTECTION BY LUBELUZOLE THROUGH THE SIGNAL TRANSDUCTION PATHWAYS OF ANOXIA AND NITRIC OXIDE.** J.A. Benjamins\*, M. TenBroeke, J. Kue, and K. Maiese. Dept. of Neurology, Center for Molecular Medicine, Wayne State Univ. Sch. of Med., Detroit, MI, 48201

Neuronal survival following ischemic injury is determined through the induction of several biological pathways. Some neuroprotective agents, such as metabotropic glutamate agonists, exert their effects through the signal transduction pathways of nitric oxide (NO) (Maiese, et al. *J Neurochem* (in press)). Lubeluzole, a benzothiazole compound, has recently been demonstrated to be efficacious in both clinical and experimental models of cerebral ischemia. In primary hippocampal neurons, we examined whether Lubeluzole modulated the signal transduction mechanisms of NO, a "downstream" mediator of anoxic neurodegeneration. Neuronal injury was assessed by using a 0.4% trypan blue dye exclusion method 24 hours following exposure to anoxia (95% N<sub>2</sub>, 5% CO<sub>2</sub>) or treatment with sodium nitroprusside (300 $\mu\text{M}$ ) or SIN-1 (300 $\mu\text{M}$ ). Approximately 70% of the neurons die over a 24 hour period following exposure to anoxia or NO. Co-administration of increasing doses of Lubeluzole (0.3nM to 1000nM) during anoxia or NO exposure increased neuronal survival from approximately 30% (anoxia or NO only) to a maximum of approximately 70% (Lubeluzole and anoxia/NO). Statistically significant protection was demonstrated with the Lubeluzole concentrations of 500nM to 1000nM ( $n=6$ ,  $p<0.001$ ). Protection was stereospecific since the R-isomer did not alter neuronal survival. Post-treatment with Lubeluzole (750nM) at 2, 4, 6, 12, and 24 hours following anoxia or NO application significantly increased neuronal survival for a period of 4 to 6 hours following neuronal injury ( $n=6$ ,  $p<0.001$ ). We conclude that neuroprotection by Lubeluzole involves the direct modulation of the NO pathway during a "protective window" period. Further investigation of the signal transduction mechanisms below the level of NO generation may elucidate the specific cellular events responsible for ischemic neurodegeneration.

## 287.3

**THE REDOX AGENT PYRROLOQUINOLINE QUINONE (PQQ) IS NEUROPROTECTIVE IN A SLICE MODEL OF HYPOXIA/ISCHEMIA** F.E. Jansen\*, and E. Williams. Div. Neurosci., Children's Hosp.<sup>1</sup>, Harvard Med. Sch., Boston, MA 02115

PQQ is a putative essential nutrient that has been shown *in vitro* to diminish NMDA-evoked current and neurotoxicity by direct oxidation of the NMDA receptor redox site (*J. Neurosci.* 1992;12:2362-2369). PQQ is a putative essential nutrient with redox cycling ability. We have previously shown that administration of PQQ following hypoxia/ischemia in a rodent stroke model significantly reduces infarct size (*Neurosci.* 1994;62:399-406). While *in vitro* neuronal culture results indicate a direct effect of PQQ at the NMDA redox site, the mechanism of action *in vivo* or in the presence of intact synapses is still unclear. The present study was undertaken to establish whether PQQ interacted with the redox site in a hippocampal slice model of hypoxia/ischemia, where transmission at endogenous synapses remains intact. Slices (400  $\mu$ m thick) were prepared from adult rats and incubated in ACSF bubbled with 95% O<sub>2</sub>/5% CO<sub>2</sub>. Hypoxia/ischemia was simulated by an 8 min exposure of the slices to glucose-free ACSF bubbled by 95% N<sub>2</sub>/5% CO<sub>2</sub>. Extracellular recordings of area CA1 population spikes were obtained in response to Schaffer collateral stimulation every 30 sec before, during, and after O<sub>2</sub>/glucose deprivation. Control slices rapidly became isoelectric and failed to recover (n=7). In contrast, slices exposed to PQQ (200  $\mu$ M, n=7) throughout the experiment had significantly better recovery to near baseline responses (p<0.01). The addition of SOD (20  $\mu$ g/ml) and catalase (10  $\mu$ g/ml) did not attenuate or alter the neuroprotective effect of PQQ (n=5). These results are the first to show a protective effect of the redox agent PQQ in a slice model of hypoxia/ischemia, and suggests the possibility that PQQ may act on synaptically mediated excitotoxic events. Supported by AHA, NS31718, NS32570 (FEJ).

## 287.5

**NGF INDUCTION BY CLENBUTEROL AND PROTECTIVE EFFECTS IN A RAT MODEL OF MCA-OCCLUSION** C. Cui\*, J. Semkova, H. Vedder\*, M.K.H. Schäfer, E. Weihe, & J. Krieglstein. Inst. Pharmacol. & Toxicology, Philipps Univ. Marburg, D-35032 Marburg, Germany

Delivery of neurotrophins to the CNS is one of the largest obstacles in developing effective therapies of neurodegenerative disorders, because these proteins are unable to cross the blood-brain barrier. In our laboratory the induction of NGF-synthesis by clenbuterol has been shown to protect rat hippocampal neurons from excitotoxic damage *in vitro*. Based on these findings we attempted to find out whether the lipophilic  $\beta_2$ -adrenergic agonist clenbuterol could also protect brain tissue from ischemic damage in a model of permanent middle cerebral artery (MCA) occlusion in Long Evans rats. After clenbuterol administration the changes of NGF-mRNA in the ischemic rat cortex were investigated by reverse transcription-polymerase chain reaction (RT-PCR) and *in situ*-hybridization. The concentration of NGF-protein in rat brain tissue was determined with two-site NGF-immuno assay. Pretreatment with clenbuterol (0.1-0.5 mg/kg in rats) administered intraperitoneally 3 h before permanent MCA-occlusion produced statistically significant (p<0.001) reductions of infarct volume. Analysis of the RT-PCR-product showed an increase in NGF-mRNA 6 h after clenbuterol treatment *in vivo* (0.1-10 mg/kg). Additionally, a marked increase in NGF-mRNA in the dentate gyrus of the lesioned hemisphere was found with *in situ*-hybridization of rat brain slices. The results concerning NGF-mRNA induction were supported by evaluation of protein levels in the rat brain tissue: a three-fold increase in NGF-protein concentration was measured 10 h after clenbuterol administration. In conclusion, clenbuterol induces NGF-mRNA and NGF-protein synthesis in rat brain tissue and furthermore, provides neuroprotective effects against brain damage caused by ischemia. The results suggest that induction of growth factors in brain tissue by systemically administered lipophilic drugs could become a useful therapeutic strategy for neurodegenerative disorders and stroke.

## 287.7

**LONG-LASTING INCREASED HYPOTIC TOLERANCE BY PRECEDING *IN VIVO* CHEMICAL HYPOXIA - 'CHEMICAL PRECONDITIONING'** M. W. Riepe\*, K. Kasischke\*, A. Raupach\*, F. Esclaire\*, J. Hugon\* and A. C. Ludolph\*. Department of Neurology, Humboldt University (Charité), 10098 Berlin, Germany and Department of Histology, University of Limoges, Limoges, France<sup>2</sup>

Sublethal ischemia preceding sustained ischemia is cytoprotective in heart and brain - 'ischemic preconditioning'. We show that clinically inapparent systemic pretreatment with a chemical inhibitor of mitochondrial complex II, 3-nitropropionic acid (3-np), increases hypoxic tolerance in rat hippocampal slices.

In slices prepared from untreated control animals ('c-slices') neuronal density after 15 min of hypoxia is 52  $\pm$  15 % (mean  $\pm$  SD) of c-slices without hypoxia. In slices prepared from animals treated by a single i.p. injection of 20 mg/kg body weight 3-np ('p-slices') posthypoxic neuronal density improved to 97  $\pm$  23 % (p < 0.01). The amplitude of the CA1 population spike (psap; stimulation of Schaffer collaterals with 0.1 Hz) in c-slices and p-slices at the end of 15 min hypoxia is about 10 %. Upon 45 min of recovery psap is 31  $\pm$  9 % in c-slices and 90  $\pm$  7 % (p < 0.01) in p-slices (1 hour time interval between *in vivo* treatment and preparation of slices). With four days interval, posthypoxic recovery was 66  $\pm$  30 % (p < 0.05) in p-slices. Increased hypoxic tolerance is partly abolished by additional treatment with glibenclamide prior to hypoxia and is completely abolished by additional treatment with NMDA antagonists.

We conclude that mild selective chemical hypoxia increases hypoxic tolerance in experimental animals - 'chemical preconditioning'. Increased hypoxic tolerance is diminished by glibenclamide, an antagonist at K<sub>ATP</sub>-channels, and APV, an antagonist at NMDA-receptors.

Supported by a grant from the Deutsche Forschungsgemeinschaft to MWR and ACL.

## 287.4

**PROTECTION AGAINST CA1 HYPOXIC NEURONAL INJURY WITH INHIBITORS OF ADP-RIBOSYLATION** R.A. Wallis and K.L. Panizzon. Dept. of Neuro., UCLA Sch. of Med. and Sepulveda VAMC, Sepulveda, CA 91343. The production of nitric oxide induces ADP-ribosylation of multiple proteins. We have previously found that inhibitors of both mono- and poly-ADP-ribosylation are protective against trauma and NMDA exposure, but not against injury from AMPA or kainate. Since NMDA receptor activation plays a prominent role in hypoxic injury, we assessed the neuroprotective potential of ADP-ribosylation inhibitors against CA1 hypoxic injury using the hippocampal slice. Slices exposed to hypoxia showed evidence of severe neuronal injury with mean orthodromic and antidromic PS recovery to 3  $\pm$  3% and 3  $\pm$  2% of initial amplitude. Inhibitors of both mono- and poly-ADP-ribosylation were strongly protective against hypoxic injury. With the mono-ADP-ribosylation inhibitor, novobiocin 500  $\mu$ M, recovery of CA1 orthodromic and antidromic PS improved to 95  $\pm$  3% and 96  $\pm$  2%. Similarly, meta-iodobenzylguanidine 20  $\mu$ M, showed increased orthodromic and antidromic PS recoveries of 93  $\pm$  2% and 93  $\pm$  3%. The inhibitor of poly-ADP-ribosylation, 3-methoxybenzamide 500  $\mu$ M, also improved orthodromic and antidromic PS recovery to 92  $\pm$  2% and 94  $\pm$  2%. Likewise, 3'-aminobenzamide 1 mM, demonstrated hypoxic protection with orthodromic and antidromic PS recovering to a mean 77  $\pm$  13% and 79  $\pm$  14%. Although nicotinamide 10 mM, acts as an inhibitor of poly-ADP-ribosylation and provides protection from traumatic injury, nicotinamide actually exacerbated hypoxic injury, suggesting that other nicotinamide effects are deleterious during hypoxia. In conclusion, the findings of this study suggest that the processes of both mono- and poly-ADP-ribosylation are important in the evolution of CA1 hypoxic injury. ## 287.6

**POST-ISCHEMIC INFUSION OF SUPEROXIDE DISMUTASE OR SOD:TET451 REDUCES CEREBRAL INFARCTION FOLLOWING TEMPORARY FOCAL ISCHEMIA/REPERFUSION IN RATS** J.W. Francis\*, J.M. Ren, L. Warren, R.H. Brown, Jr., and S.P. Finklestein. Cecil B. Day Neuromuscular Research and CNS Growth Factor Research Laboratories, Mass. Gen. Hospital, Charlestown, MA 02129.

Oxygen free radicals play a major role in neuronal cell injury following cerebral ischemia/reperfusion. The free radical scavenging enzyme, Cu/Zn superoxide dismutase (SOD-1) ameliorates various types of brain injury resulting from temporary CNS ischemia. We have compared the cerebroprotective properties of human SOD-1 (hSOD-1) with a novel recombinant SOD-1 hybrid protein, SOD:Tet451, composed of hSOD-1 linked to the neuronal binding fragment of tetanus toxin (TtTx). Following 2 hours of temporary middle cerebral artery occlusion, rats infused with equivalent activities of either hSOD-1 or SOD:Tet451 for the initial 3 hours of reperfusion showed reductions in cerebral infarct volume of 43% and 57%, respectively, compared to saline-treated controls (p<0.01). Serum hSOD-1 concentrations in rats receiving SOD:Tet451 were 7-fold higher than those in rats receiving the native enzyme. Animals treated with SOD:Tet451 also demonstrated an extended persistence of hSOD-1 in the bloodstream during drug washout as compared to animals given free enzyme. Immunohistochemical examination of brain sections from an SOD:Tet451-treated ischemic rat showed positive immunoreactivity in the ipsilateral cerebral cortex using either anti-TtTx or anti-human SOD-1 antibodies. Our results document that both hSOD-1 and SOD:Tet451 significantly reduce brain infarct volume in a model of transient focal ischemia/reperfusion in rats. Additionally, our findings suggest that the cerebroprotective effects of SOD-1 may be enhanced by neuronal targeting as seen with the hybrid protein, SOD:Tet451. ## 287.8

**LESIONS OF DEEP PREPILIFORM CORTEX RESULT IN NEUROPROTECTION DURING ISCHEMIA VIA ATTENUATION OF RISES IN EXTRACELLULAR GLUTAMATE CONCENTRATION** R.P. Simon, K. Kawaguchi and M. Huerbin\*. Department of Neurology, University of Pittsburgh, Pittsburgh, PA 15261.

A small region of deep prepiriform cortex (area tempestas, AT), acting in part via excitatory amino acid (EAA) neurotransmission, modulates epileptic activity throughout the limbic system. We have shown that pharmacologic blockade of EAA receptors at AT attenuates cell death during limbic seizures independent of reduction in seizure duration (*Neurosci* 61:817-822, 1994). We therefore investigated a possible role of EAA neurotransmission at AT in modulating neuronal injury in a different form of excitotoxic injury, that occurring during global ischemia induced by 10 minutes of 4 vessel occlusion. EAA neurotransmission at deep prepiriform cortex was modulated either by bilateral infusion of NBQX at AT (0.5  $\mu$ l containing 5 nmol) or by lesioning AT by stereotaxic injection of kainate bilaterally at 72 hours before ischemia (anticonvulsant pretreatment precluded seizures). NBQX injected 1 mm medial to the target served as an anatomic control. Morphologic endpoints were assessed in the CA1 and CA3 hippocampal subsectors. Neuronal injury was quantified with HSP72 immunocytochemical staining at 24 hours following ischemia and neuronal cell death by cell counting of viable cresyl violet stained neurons at 72 hours after ischemia. Both NBQX infusion and AT lesions produced attenuation of neuronal injury and death in target neurons. NBQX injection 1 mm medial to AT was not neuroprotective. In a separate set of experiments lesioned animals and controls had microdialysis probes placed in the hippocampus during the ischemic insult. The controls, but not the lesioned animals, demonstrated the well known glutamate peak; neuroprotection was confirmed in lesioned rats at 7 days. Thus, excitatory neurotransmission at AT effects ischemic cell death in hippocampal neurons and does so via modulation of ischemia-induced glutamate concentrations. (Supported by NS-35965; RPS)

## 287.9

**Protection Against Focal Ischemic Infarction Elicited By Stimulation of the Cerebellar Fastigial Nucleus Results From Excitation of Intrinsic Neurons.** S. Glickstein, E.V. Golanov, K. Kobylarz and D.J. Reis. Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Electrical stimulation of the cerebellar fastigial nucleus (FN) of rat for 1h reduces, by over 50%, the focal ischemic infarction produced by occluding the middle cerebral artery (MCAO) (Reis et al., 1991), even 2 wks later. Electrical stimulation of FN excites intrinsic neurons and axons, each having different actions: chemical stimulation of intrinsic neurons lowers arterial pressure (AP) and rCBF (Chida et al., 1990), while electrical stimulation of FN, after excitotoxic destruction of intrinsic neurons, elevates AP and rCBF, the fastigial pressor response (FPR) (Miura & Reis, 1969). We assessed whether the neuroprotection elicited by FN stimulation is mediated by intrinsic neurons or fibers of passage. In anesthetized spontaneously hypertensive rats ibotenic acid (IBO) (23 nmol in 300 nl, each side) was microinjected into FN (n=14) or into cerebellar dentate nuclei (DN, n=5), stimulation of which is not neuroprotective. Five days later animals were reanesthetized, instrumented, an electrode inserted into FN, and the MCA occluded. After determining the threshold for the FPR (elevation of AP by 15 mmHg), the FN was stimulated for 1h (1 sec on/1 sec off, 0.5 msec, 50 Hz, 5x threshold) before MCAO. Twenty four h later rats were sacrificed and lesions measured. In sham controls the FN was not stimulated prior to MCAO. IBO microinjected into FN destroyed >90% of neurons in the nucleus while injections in DN destroyed the majority of DN but spared FN neurons. In 5 uninjected controls sham stimulation of the FN resulted in a FPR whose threshold was  $30 \pm 6 \mu A$  and a lesion of  $137 \pm 37 \text{ mm}^3$ . The FPR threshold after DN lesions was  $35 \pm 2 \text{ mA}$  (NS) and infarction volume was reduced by 45% to  $75 \pm 27 \text{ mm}^3$  ( $p < 0.05$ ), salvage comparable to that produced by FN stimulation alone (Golanov et al., 1996). In rats with FN lesions the FPR threshold was unchanged ( $35 \pm 2 \text{ mA}$ ) (indicating preservation of local axons) but FN stimulation no longer reduced lesion size ( $120 \pm 33 \text{ mm}^3$ ,  $n=14$ ,  $p > 0.05$ ). We conclude: the central neurogenic neuroprotection elicited from FN is mediated by activation of intrinsic neurons while the FPR results from excitation of axons projecting into or through the nucleus.

## 287.11

**Neuroprotective Electrical Stimulation of the Cerebellar Fastigial Nucleus Suppresses Expression of Peri-infarction Depolarizing Waves.** E.V. Golanov\* and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Electrical stimulation of the cerebellar fastigial nucleus (FN) in rat for 1h reduces, up to 50%, the volume of the focal cerebral infarction produced by middle cerebral artery occlusion (MCAO) performed even two weeks later. MCAO also immediately generates recurrent peri-infarction depolarizing waves (PIDS) which appear to exacerbate ischemic damage (Hossmann, 1994). We investigated whether FN stimulation could modify the expression of PIDS. Sprague-Dawley rats were anesthetized, paralyzed, and ventilated controlling blood gases and body temperature. Cerebral blood flow (rCBF), EEG and DC potentials were recorded over that region of the cortex salvaged by FN stimulation for 3h after permanent MCAO occlusion. Within 2 to 3 min after MCAO PIDS appeared over the ischemic penumbra consisting of typical negative DC potentials which peaked at  $-25.2 \pm 2.8 \text{ mV}$   $23.1 \pm 7.2 \text{ sec}$  after their onset and recovered by  $192.0 \pm 126 \text{ sec}$  (mean  $\pm$  SEM;  $n=5$ ). PIDS appeared randomly at a frequency of 0.038/min for a total of ~6 events over the 3h of observation and were accompanied by EEG flattening and reduction in rCBF. One h of FN stimulation synchronized the EEG but did not alter DC potentials. However, MCAO performed 1h later resulted in a ~50% reduction in the numbers of PIDS ( $5.8 \pm 2.9$  to  $2.6 \pm 1.3$ ;  $p < 0.05$ ) and in lengthening of the latency to the first wave (from  $3.2 \pm 1.4$  to  $8.3 \pm 2.1 \text{ min}$ ;  $p < 0.05$ ). Comparable stimulation of the rostral ventrolateral medulla (RVL) ( $n=5$ ), which does not salvage cortex (Golanov et al., 1994) did not affect PIDS. Stimulation of FN for 1h abolished all PIDS in 5 rats in which MCAO was performed 72h later. Site-specific stimulation of FN almost immediately initiates a marked suppression of the expression of PIDS. Such suppression may, along with reduced expression of proinflammatory molecules in cerebral microvessels (Galea et al., Soc. Neurosci. Abstr., 1996), add to the conditioned central neurogenic neuroprotection elicited from FN.

## 287.10

**Electrical Stimulation of the Cerebellar Fastigial Nucleus Reduces the Delayed Neuronal Death Produced by Global Cerebral Ischemia.** F. Liu\*, E.V. Golanov and D.J. Reis. Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Electrical stimulation of the cerebellar fastigial nucleus (FN) reduces, by 50%, the volume of a focal cerebral infarction elicited by occlusion of the middle cerebral artery (Reis et al., 1991). We investigated whether FN stimulation would reduce the delayed death of hippocampal neurons of the CA1 subfield elicited by transient global ischemia. Sprague-Dawley rats were anesthetized, instrumented to record cerebral blood flow (rCBF) and EEG, electrodes placed in FN and the vertebral arteries coagulated. Animals were ventilated with 100%  $O_2$  ( $P_{aO_2} = 463 \pm 113 \text{ mmHg}$ ). Blood gases and body temperature were monitored and maintained. Groups of 5 rats were subjected to reversible occlusion of common carotid arteries for 10, 20, 30 or 40 min. Neuronal death directly related to duration of occlusion. 40 min of occlusion destroyed ~90% of neurons, a time used thereafter. Occlusion immediately reduced rCBF to 4-7% and flattened the EEG in 8-3 sec. After clamps were released, rCBF and EEG were restored and animals returned to the home cages. Five days later, they were sacrificed, brains removed, sectioned, stained, and the density of pyramidal neurons in the CA1 measured. In sham (non-stimulated) animals, 40 min of ischemia reduced the number of neurons from  $210 \pm 5$  to  $33 \pm 11/\text{mm}$  ( $p < 0.05$ ;  $n = 6$ ). Electrical stimulation of the FN (1 sec on/1 sec off, 50 Hz, pulses 0.5 msec, 70-100  $\mu A$ ) for 1h immediately before occlusion increased the number of surviving neurons (to  $134 \pm 9$  neurons/mm ( $p < 0.05$ )) representing a salvage of ~57%. FN stimulation 24h before ischemia comparably protected hippocampal neurons ( $141 \pm 6/\text{mm}$ ,  $p < 0.05$ ). FN stimulation also reduced the intensity of the local cellular inflammatory reaction in the CA1 reducing numbers of infiltrating cells and reactive microglia. We conclude: (a) electrical stimulation of FN can reduce the delayed neuronal degeneration of hippocampal neurons of the CA1 subfield elicited by transient forebrain ischemia; (b) the protective effect persists for at least 24h; (c) conditional central neurogenic neuroprotection elicited from FN is effective against global as well as focal ischemia.

## 287.12

**CONDITIONAL STIMULATION OF THE CEREBELLAR FASTIGIAL NUCLEUS (FN) REDUCES INFLAMMATORY REACTIVITY OF BRAIN MICROVESSELS.** E. Galea\*, D.L. Feinstein, E.V. Golanov, D.L. Reis Dept. Neurol. and Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Electrical stimulation of the FN results in up to a week-long protection against brain infarctions. FN also inhibits the expression of inducible nitric oxide synthase (iNOS) in microvessels (MV) in the salvaged zone (Galea et al., J Cereb Blood Flow Metab 15: Suppl 1, S91, 1995). We investigated whether FN stimulation alone could suppress cytokine-stimulated expression of endothelial iNOS measured by quantitative RT-PCR *in vitro*. Spontaneously hypertensive rats were stimulated in the FN (1s on/1s off, 0.5 ms/pulse, 50 Hz, 70  $\mu A$ ) or sham-stimulated for 1h. Twenty four h later MV were isolated by gentle homogenization, centrifugation in 18% dextran, and filtration through 5- $\mu m$  nylon screens. Alkaline phosphatase activity, a brain endothelium marker, was comparably enriched in control (3.3-fold) and FN-conditioned MV (4.4-fold) respect to whole brains ( $n=4$ ). MV were incubated in DMEM with IL-1 $\beta$  (0.1-100 ng/ml), TNF- $\alpha$  (1-100 ng/ml) or IFN- $\gamma$  (100 U/ml) at 37°C for 2-24h. After 24h of incubation, mitochondrial dehydrogenases in control and FN-conditioned MV were respectively reduced to  $52\% \pm 14$  ( $n=3$ ) and  $47\% \pm 17$  ( $n=3$ ) of values in fresh MV, indicating comparable decrease of metabolic viability over time in both fractions. Maximal iNOS mRNA expression was observed after 5-h exposure to IL-1 $\beta$  (10 ng/ml). However, while expression was  $9.6 \pm 0.9$  times over basal in control MV ( $n=4$ ), it was reduced to  $2.25 \pm 0.77$  over basal in FN-conditioned MV ( $n=4$ ). These results suggest that FN stimulation may render brain microvasculature refractory to inflammatory activation. Such conditioned suppression of iNOS may contribute to central neurogenic neuroprotection elicited from FN. Supported by NHLBI (HL18974).

## VISUAL CORTEX: EXTRASTRIATE—DORSAL STREAM I

## 288.1

**FIXATIONAL EYE MOVEMENTS AFFECT THE VISUAL RESPONSES OF NEURONS IN THE SUPERIOR TEMPORAL SULCUS (STS)** W. Bair\*, L.P. O'Keefe, J.A. Movshon. HHMI and Center for Neural Science, New York Univ., New York, NY 10003.

We measured eye movements (EMs) made by an awake, fixating, macaque monkey, and analyzed their effects on the neuronal discharge of 40 directionally selective neurons in the STS. The monkey maintained fixation within 1.5 deg of a small fixation spot; he fixated before (0.2 s) and during (2 s) the presentation of a visual stimulus to the neuron's receptive field, which lay 5-15 deg from the center of gaze. On many trials, the monkey made one or more small EMs, beginning 0.1-0.3 s after initial fixation. The average frequency of these small movements was near 0.5/trial, and peaked 0.5-1.0 s after stimulus onset.

We examined neuronal responses around the time of EMs that occurred while the visual stimulus was present in the receptive field. Mean EM duration was 25 ms; mean amplitude was 0.7 deg. EMs often occurred as pairs of oppositely directed micro-saccades separated by 250 ms. The distribution of EM directions was roughly uniform, but underrepresented movements toward the target, perhaps because the animal was trained not to make saccades to the stimulus. Between 40 and 80 ms after an EM, neuronal discharge was often altered, in a manner that depended on the direction of eye and stimulus movement. When the eye movement induced retinal slip in the neuron's preferred direction, response was often increased, especially when the ongoing visual stimulus elicited relatively little response. When the slip was in the neuron's non-preferred direction, response was strongly reduced, especially if the ongoing visual stimulus elicited a strong response.

EMs during fixation influence neuronal discharge in a direction-specific manner. Nominally identical stimuli may thus differ on the retina, and this difference will influence spike train statistics, including estimates of correlation between neurons.

Supported by the Howard Hughes Medical Institute.

## 288.2

**FIRST- AND SECOND-ORDER MOTION PROCESSING IN SUPERIOR TEMPORAL SULCUS NEURONS OF THE ALERT MACAQUE.** L.P. O'Keefe\* and J.A. Movshon. Center for Neural Science and Howard Hughes Medical Institute, New York University, New York 10003.

Extrastriate visual cortical areas in the superior temporal sulcus (STS) provide behaviorally relevant signals about visual motion, but it is unclear whether these neurons provide relevant signals about both first- and second-order motion. Our earlier recordings in anesthetized macaques suggested that directional signals for second-order motion stimuli were weak or absent in most MT neurons. We have now examined responses of STS neurons to first- and second-order motion in an alert macaque.

We measured responses of single neurons in the STS of an alert macaque monkey to several first- and second order motion stimuli. For each neuron, we measured directional tuning and contrast response with two types of first-order gratings and two types of "drift-balanced" second-order gratings created by spatiotemporal modulation of the contrast or flicker rate of a random texture. Nearly all neurons gave vigorous, direction-selective responses to first-order motion. Responses to second-order motion varied widely, with most neurons exhibiting weaker responses and less selectivity for the direction of second-order gratings. We measured contrast responses from each neuron in the preferred and null direction for each class of motion, and generated neurometric functions representing their sensitivity to these targets. Thresholds for first-order motion were usually between 0.005 and 0.1, while thresholds for second-order motion spanned a range of contrasts roughly 10 times higher. In nearly half the neurons, thresholds for second-order motion were too high to be reliably established.

While some neurons in the STS carry reliable information about the motion of second-order targets, overall levels of responsiveness and selectivity are much lower for these stimuli than for first-order targets. We are examining the behavioral significance of these motion signals in parallel psychophysical experiments. Supported by HHMI.

ORGANIZATION OF DISPARITY SELECTIVITY IN MACAQUE AREA MT. G. C. DeAngelis, J. M. Groh\*, and W. T. Newsome. Dept. of Neurobiology, Stanford University, Stanford CA 94305.

Primate visual area MT contains a high percentage of directionally selective neurons that are organized into columns according to preferred direction of motion (Albright et al. 1984). In addition, most neurons in macaque MT are selective for binocular disparity (Maunsell and Van Essen 1983). We have examined whether neurons in MT are also organized systematically according to disparity preference.

Experiments were carried out with two adult rhesus monkeys that performed a visual fixation task. We recorded multi-unit activity and local field potentials (LFP) at equally-spaced intervals (100  $\mu$ m apart) along electrode penetrations through area MT. Whenever possible, we also recorded the activity of isolated single units. At each recording site, we measured direction tuning (at the estimated preferred disparity) and disparity tuning (at the measured preferred direction) by presenting coherently moving random-dot patterns. Stimuli were rendered in depth using the red-green anaglyph technique.

Along oblique penetrations through area MT, we found regions of strong disparity selectivity (usually 500-1000  $\mu$ m long) interspersed among poorly-tuned regions of roughly similar dimensions. Within the strongly-tuned regions, nearby recording sites usually had similar preferred disparities, and we often observed a smooth progression of preferred disparities from near to far, or vice-versa. At sites where single units were recorded, the disparity tuning of these units closely matched that of the multi-unit activity and the LFP. Within regions of MT where multi-unit and LFP activity were poorly tuned for disparity, single units also tended to be poorly tuned. We have not yet observed any systematic relationship between patterns of disparity and direction tuning.

Our results suggest that neurons with strong and weak disparity selectivity are compartmentalized in area MT. Regions of strong selectivity appear to contain an orderly map of disparity preferences.

MT RESPONSES DO NOT MATCH PERCEPTUAL REPORTS DURING VIEWING OF COLOR-SEGMENTED MOTION DISPLAYS. Lisa J. Croner\* and Thomas D. Albright, Salk Institute, La Jolla, CA 92037.

The use of color as a segmentation cue strongly enhances human subjects' ability to discriminate direction of targets moving in dynamic noise (Croner & Albright, 1994, *I.O.V.S. (Suppl.)*, 35:1643). We previously found that direction discrimination capacity of individual MT neurons (which are thought to be important for perceptual choice based on motion signals) is not influenced by color segmentation cues when monkeys do not make directional judgements (Croner & Albright, 1995, *Soc. Neurosci. Abstr.*, 21:281). In this study, we investigated whether MT responses correlate with the segmentation-enhanced percept when monkeys perform a direction discrimination task.

We recorded activity of single neurons in area MT of fixating rhesus monkeys while the animals discriminated direction in visual stimuli presented in the neurons' receptive fields. Stimuli were dynamic displays of bright dots, a variable fraction of which moved in the same direction at the same speed (motion signal), while the remaining dots were displaced randomly (noise). Two stimulus configurations were used. In the *homochromatic* condition, all dots were the same color. In our novel *heterochromatic* condition, signal dots were a different color from noise dots. ROC analysis generated neurometric functions expressing each neuron's capacity to discriminate motion in its preferred versus anti-preferred direction. These were compared with simultaneously obtained psychometric functions showing the monkeys' perceptual performance.

As for human subjects, segmentation by color enhanced the monkeys' ability to discriminate signal direction. For the majority of neurons studied, however, homochromatic and heterochromatic discrimination thresholds were statistically indistinguishable. Thus, the capacity of individual MT neurons to discriminate direction is not influenced by color segmentation cues, even when concurrent perceptual reports demonstrate that color segmentation improves directional discriminability.

## 288.7

SELECTIVE EFFECTS OF LESIONS OF CORTICAL AREAS MT AND MST IN THE MACAQUE MONKEY. K. K. Rudolph\* and T. Pasternak. Depts. of Neurobiology & Anatomy, Brain & Cognitive Science, and Center for Visual Science, University of Rochester, Rochester, NY 14642.

Areas MT and MST, components of the dorsal pathway, are thought to represent intermediate stages in the processing of visual motion. Lesions of these areas disrupt performance on some motion discrimination tasks but leave others intact. To explore in depth the nature and the selectivity of these lesion effects, we trained monkeys with unilateral ibotenic acid lesions of areas MT/MST to discriminate differences in the direction and/or orientation of a variety of random-dot and grating stimuli. On each trial, two comparison stimuli appeared successively in the same retinal location and the monkeys were rewarded for judging them as "same" or "different". Performance was assessed by either reducing the contrast of gratings, broadening the direction range of dot stimuli, or by masking gratings and dot stimuli with dynamic noise. Thresholds were measured in intact and lesioned hemifields at about the same time. MT/MST lesions produced a large, permanent deficit in the discrimination of direction of moving gratings masked by noise but did not affect contrast thresholds. Similarly, performance on tasks requiring integration of local motion signals was affected only in the presence of random directional noise. This susceptibility to noise was motion specific, since the discrimination of grating orientation in the presence of spatial noise was unaffected. Such effects were not observed in monkeys with lesions of area V4, a major component of the ventral pathway implicated in processing stimulus form. Our results suggest that the removal of areas MT and MST, rich in directionally selective neurons, substantially reduces the brain's ability to extract motion signal in the presence of noise. These results also strongly support the notions of specialization of MT/MST for motion processing and segregation of motion processing to the dorsal pathway.

REPRESENTATION OF THREE-DIMENSIONAL SURFACES IN PRIMATE VISUAL AREA MT. G. I. Caman\* and T. D. Albright. Sloan Center and Vision Center, Salk Institute, San Diego, CA 92186.

**Premise:** The rapid and accurate perception of the three-dimensional (3D) depth, orientation, and shape of the surfaces of general objects may be supported by explicit representations of these geometric attributes within the primate visual pathway. **Methods:** We recorded from neurons in the superior temporal sulcus of three alert monkeys as they viewed 3D surfaces presenting controlled motion and/or stereo cues to the depth, orientation, and shape of their surfaces. Neurons were initially characterized by their tuning for direction, disparity, and speed using surfaces positioned within the classical receptive field. Neurons were then characterized by their response to surfaces extending outside the classical receptive field. **Results:** Neurons responded vigorously to the combination of motion and stereo cues such as occurs during natural viewing of 3D objects. We observed three types of neuronal selectivity, defined by the position of surfaces relative to the zero-displacement and zero-disparity horopter: (1) near cells, responsive to surfaces nearer than the horopter; (2) horopter cells, responsive to surfaces about the horopter; and (3) far cells, responsive to surfaces farther than the horopter. These selectivities were clustered, suggesting a systematic organization into columns of preferred stereo disparity as well as of preferred direction of motion. Furthermore, response to surfaces within classical receptive fields could be modulated by surfaces extending into the surrounds, in a manner consistent with normalization of response by viewing distance, which may play a role in perceptual constancy. **Conclusion:** Our findings support the hypothesis that neurons in area MT integrate motion and stereo cues to provide a representation of 3D depth of surfaces in the visual field. MEASUREMENTS OF INFORMATION RATES IN MONKEY MT NEURONS IN RESPONSE TO TIME-VARYING STIMULI. G. Buračas\*, A. Zádor, M. DeWeese, and T. Albright, VCL, MNL, and Sloan Center, Salk Institute, P.O.Box 85800, San Diego, CA 92186.

The traditional notion of a tuning curve relates the time-average firing rate of a neuron to the constant characteristics of the stimulus in its receptive field; this firing rate is typically measured in windows of several hundreds of milliseconds. How does the appropriate time window change when the stimulus changes with time? Inspired by work on a motion-sensitive neuron in the fly (Bialek et al., *Science*, 1991 252:1854-7), we presented visual stimuli with rich temporal structure to alert fixating macaque monkeys while recording extracellularly from neurons in area MT. The stimulus consisted of a Gabor patch whose direction of motion performed a random walk. For one stimulus ensemble, the spike train exhibited modulation on a 10 millisecond time scale (cf. Bair and Koch, 1996); under these conditions, the spike train encoded nearly all of the 30 bits/second available in the stimulus. This information could have been extracted only if spikes were detected with a precision of order 10 millisecond. By contrast, a traditional analysis based on counting the number of spikes in much longer epochs would have underestimated the information rate by an order of magnitude. These results suggest that the notion of a tuning curve can be extended to the analysis of time-varying stimuli, provided that the window size is appropriately small. These experiments may have implications for understanding cortical processing of natural time-varying stimuli. Supported by EY07605 and Salk-Sloan center for Theoretical Neurobiology.

## 288.8

LESIONS OF AREAS MT/MST IN THE MACAQUE MONKEY LIMIT SHORT-TERM MEMORY FOR MOTION. T. Pasternak\* and K. K. Rudolph. Depts. of Neurobiology & Anatomy, Brain & Cognitive Science, Center for Visual Science, University of Rochester, Rochester, NY 14642.

Despite strong evidence of functional specialization of areas MT/MST for motion processing, lesions of these areas appear to spare a number of measures of motion perception, including contrast sensitivity and range thresholds for discriminating opposite directions of motion (see Rudolph and Pasternak, *NSC* 1996). To assess how robust these apparently preserved directional signals are in the absence of MT/MST neurons, we used tasks requiring the retention of motion information over time. Monkeys with unilateral ibotenic acid lesions of areas MT/MST were trained to fixate while performing a short-term memory task with stimuli placed into the lesioned and intact portions of the visual field. On each trial, a sample stimulus moving in one of eight directions was followed by a test stimulus moving in the same or opposite direction, and the animal made a same-different judgment. The retention of direction information was assessed by increasing the direction range of dot stimuli, or by decreasing grating contrast, and measuring thresholds over a range of temporal delays interposed between sample and test stimuli. Performance declined with increasing delays in both hemifields. However, the rate of this decline was a factor of 2-3 more rapid in the lesioned hemifield. As a result, the deficit, which was minimal at shorter delays (up to 1.5 sec), increased dramatically at longer delays. Thus, in the absence of MT/MST neurons, retention of information about motion direction is severely limited.

**THE HUMAN KINETIC OCCIPITAL (KO) AREA INVESTIGATED WITH fMRI.** S. Van Oostende<sup>1</sup>, S. Sunaert<sup>1</sup>, P. Van Hecke<sup>2</sup>, G. Marchal<sup>1</sup> and G.A. Orban<sup>3</sup>. <sup>1</sup>Afdeling Radiologie, UZ-Gasthuisberg, <sup>2</sup>Biomedische NMR-Eenheid, Campus Gasthuisberg, <sup>3</sup>Lab. Neuro- en Psychofysiologie, KU Leuven, Campus Gasthuisberg, B-3000 Leuven, Belgium.

Previous PET studies (Orban *et al.* PNAS, 92:993-997, 1995; Dupont *et al.* Soc. Neurosci. Abstr. 21:663, 1995) have revealed an area in lateral occipital cortex specialized in processing of kinetic contours. In the present fMRI study we investigated this area in single subjects. In all experiments subjects viewed randomly textured pattern (RTP) stimuli (3 deg central) while fixating a point. Subtraction of uniform motion (all pixels move together) from kinetic gratings (strips of pixels move in opposite direction) revealed an activation of KO in 14 subjects bilaterally ( $R > L$ ). This region is 20 mm posterior from area MT defined by uniform motion minus static (all pixels stationary). Comparing different dynamic stimuli to static (5 subjects), revealed that KO was more activated by kinetic gratings than by uniform motion, transparent motion or luminance gratings, dynamic noise being the least effective. This profile was different from that of MT. In a final experiment (6 subjects) we showed that KO is located laterally from V3, visualized by the comparison of horizontal and vertical meridians. These results confirm that KO is specialized in the processing of kinetic boundaries and is distinct from known visual areas.

## 288.11

**SELECTIVE DEFICITS OF FIRST OR SECOND ORDER MOTION IN STROKE PATIENTS PROVIDE FURTHER EVIDENCE FOR SEPARATE MECHANISMS.** L.M. Vaina<sup>1</sup>\* and A. Cowey<sup>2</sup>. Boston University, Dept. of Biomedical Eng. & Neurology, Boston, MA, USA<sup>1</sup> and Dept. of Experimental Psychology, Oxford University, England<sup>2</sup>

Psychophysical studies suggest that there may be at least two motion systems: a 1st-order system responds to spatio-temporal variations in luminance, and a 2nd-order system responds to spatio-temporal variations in attributes such as contrast. The 2nd-order motion is visible to human observers but invisible to 1st-order motion mechanisms. Single cell recording studies in the macaque also dissociate 1st-order and 2nd-order motion, and suggest that while 1st-order motion is first registered in V1, the detection of 2nd-order motion is accomplished in MT. We have previously reported on a stroke patient with a unilateral lesion permanently impaired on 2nd-order motion but not on 1st-order motion (Vaina *et al.*, 1993; Vaina & Cowey, 1996).

Here we report a double dissociation of deficits between 1st-order and 2nd-order motion in two patients (F.D. and R.A.) with focal unilateral brain lesions confirmed by MRI. F.D.'s lesion involved the dorsolateral caudal aspect of the temporal lobe while R.A.'s involved mostly the rostral-medial occipital cortex. We used several 1st- and 2nd-order stimuli to measure FD and RA's ability to discriminate direction in local and global motion. The results revealed a double dissociation of deficits: F.D. was impaired on all 2nd-order motion tasks, but normal on the 1st-order tasks. R.A. displayed the opposite deficit. In both patients this dissociation was stable over two years of repeated testing and all the deficits were present only in the visual field contralateral to the lesion. Our results provide further evidence for the view that 1st- and 2nd-order motion are mediated by separate neuronal circuitry, but do not support the view that MT is crucial for the detection of 2nd-order motion. The locus of the lesions suggests that probably 2nd-order, but not 1st-order motion is mediated by a region in the visual cortex adjacent and dorsal to area MT (F.D.'s lesion), and cortical areas such as V1 and V3 are probably not significantly involved (R.A.'s lesion) in this motion. ## 288.10

**CONTRAST MODULATION IN A PASSIVE VIEWING TASK OF MOTION REVERSAL: A PET STUDY.** L. Cornette<sup>1,2</sup>, P. Dupont<sup>1,2</sup>, J. Joniau<sup>1</sup>, A. Rosier<sup>1,2</sup>, W. Spileers<sup>3</sup>, L. Mortelmans<sup>3</sup> and G.A. Orban<sup>1</sup>. <sup>1</sup>Lab. Neuro- en Psychofys., Medical School, KU Leuven, GHB, <sup>2</sup>PET Centre, Dep. Nuclear Med., UZ, GHB, <sup>3</sup>Dep. Ophthalmol. UZ, GHB, B-3000 Leuven, Belgium.

In this  $H_2^{18}O$ -PET study, we specifically investigated human brain activations during reversal phase of contrast modulated motion. Ten male subjects were engaged in a passive viewing task. The stimulus was a 5 degree square random dot pattern (13.08 cd/m<sup>2</sup>) on a luminated background (4.3 cd/m<sup>2</sup>), with a density of 29 dots/degree<sup>2</sup>. Dots were moving at 4 degree/sec on a single horizontal axis, while subjects were fixating a central fixation point. The following contrast-modulated (0 to 8.7%) conditions were presented: reversal of motion (a), continuous motion to the right (b), and a static random dot pattern (c). As control, reversal and static conditions were repeated without contrast modulation (d) (e). Human brain regions ( $P_{uncorr} < 0.001$ ) activated by simple reversal (d minus e) are: dorsal cuneus (V3), BA 2/40 (2v), superior parietal lobe and lateral frontal eye field. The absence of prominent activation in what is considered the homologue of monkey MT/V5 might be due to the use of motion in only one direction axis. Contrast modulated continuous motion (b minus c) yields activation only in dorsal cuneus. Accentuating motion reversal phase by means of contrast modulation (a minus c) reveals new foci ( $P_{corr} < 0.05$ ): anterior bank of the parieto-occipital sulcus (BA 19, homologue of monkey area PO), lateral sulcus (BA 47 and BA 44) and claustrum. As PO receives magnocellular input and as it is only activated by adding contrast modulation on a reversal stimulus, we suggest PO is specifically activated by changes in motion direction. Activation of BA 47 (and claustrum) might reflect sustaining voluntary fixation (Brain, 1994, 117:1073). BA 44 activation could be related to supramodally perception of fast temporal variations in a stimulus. (Supported by NFWO 3.0227.95)

**A MODEL USING MOTION-OPPONENT OPERATORS TO COMPUTE TRANSLATIONAL AND ROTATIONAL HEADING PARAMETERS FOR A MOVING OBSERVER.** C. S. Royden\*. Computer Science Department, Wellesley College, Wellesley, MA 02132.

As people move about the world, the images of objects move on the retina. This image motion contains much information about the observer's trajectory. Psychophysical studies have shown that people can judge their motion accurately for both straight line and curved-path motion. This implies that they must be able to compute both translation and rotation components of heading from visual information. Longuet-Higgins and Prazdny (*Proc. R. Soc. Lon. B*, 1980) showed how one can use local differences in the image motion to compute the translation and rotation components of observer motion. One can approximate the calculation of the observer translation components using motion-opponent operators with properties similar to cells in the Middle Temporal area (MT) of primates. I present a model that uses motion-opponent operators to compute the translation parameters for observer motion. The outputs of these operators feed forward in a radial pattern to large-field cells, similar to those in the primate Medial Superior Temporal visual area (MST). Observer translation is computed as the center of expansion of the maximally responding cell in this second layer. Observer rotation is computed by comparing the output of the motion-opponent cells with that of pure direction-selective cells to find the component of flow perpendicular to the radial translation pattern. The result of this comparison feeds into large field cells that prefer patterns associated with particular observer rotations. These cells also have receptive fields similar to some found in MST. Computer simulations show that this model computes heading parameters well for a variety of conditions.

## LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS IV

## 289.1

**LEARNING-RELATED ACTIVATION OF VISUAL CORTEX BY AN AUDITORY STIMULUS: EXPLANATION THROUGH ANALYSIS OF NEURAL INTERACTIONS**

AR McIntosh<sup>1</sup>\*, RE Cabeza<sup>1</sup>, NJ Lobaugh<sup>2</sup>, S Houle<sup>3</sup>, <sup>1</sup>Rotman Research Inst of Baycrest Centre, <sup>2</sup>Psychol Research, Hosp for Sick Children, <sup>3</sup>PET Centre, Clarke Inst; Univ of Toronto, ON, Canada, M6A 2E1

The complete perception of our world is formed by the interactions between sensory modalities. To help characterize these areas, PET was used to measure regional cerebral blood flow in 11 subjects as they learned an association between visual and auditory stimuli. Moreover, using path analysis, the interactions mediating this association were quantified. When the auditory stimulus (FM tone) had a high probability of preceding a visual stimulus (circular geometric figure), activation of dorsal extrastriate cortex was observed when the tone was presented by itself. When expressed in terms of a functional network, learning-related changes in feedback effects from tertiary visual and dorsolateral prefrontal cortices seemed to mediate this change in extrastriate activity. Specifically, suppressive effects from prefrontal cortex reduced, and enhancement from tertiary visual cortex increased, during tone presentation as the association between stimulus events was learned. The approach of mapping activity across the entire brain and expressing data in terms of neural interactions thus provides key insights into some of the processes involved in cross-modal interactions. (Supported by NSERC grant to ARM)

## 289.2

**REPRESENTATIONS OF STIMULUS AND RESPONSE DURING DIFFERENTIAL SENSORY LEARNING IN HUMANS: SPATIAL PATTERN ANALYSIS USING PARTIAL LEAST SQUARES.** NJ Lobaugh<sup>1</sup>\*, N Rajah<sup>2</sup>, JM Jennings<sup>3</sup>, S Houle<sup>3</sup>, AR McIntosh<sup>1</sup>, <sup>1</sup>Psychol Research, Hosp for Sick Children, <sup>2</sup>Rotman Research Inst Baycrest Ctr, <sup>3</sup>PET Ctr. Clarke Inst; Univ of Toronto, ON, Canada M6A 2E1

Integration of information between sensory modalities is a key property of nervous system operations and is fundamental to learning and memory. Using PET measures of regional cerebral blood flow (rCBF), we have shown that a tone preceding visual stimuli leads to activation of dorsal extrastriate cortex. To further explore this activation, the present study used a differential associative learning paradigm. Healthy young subjects ( $n=11$ ) pressed a button to one of two visual stimuli. Two tones were also presented; one (T1) predicted a visual stimulus (target or distractor) and the other its absence (T2). PET rCBF measures were taken during training: the distractor was presented alone on the first and last of 8 scans, and the intervening 6 scans alternated between T1 alone or T2 alone. Differential reaction times (RTs) to the two tones emerged during training. A new image analysis method, Partial Least Squares (PLS, McIntosh, *et al.*, Neuroimage, in press) was used to extract sets of distributed activity patterns related to 1) experimental design, and 2) learning-related changes in RT (brain-behaviour). The first PLS pattern related to design included right parahippocampal and dorsolateral prefrontal cortices, and reflected task acquisition. Dorsal extrastriate regions were part of a second pattern that distinguished tones from visual stimuli; activity of this area may be related generally to conditioned expectancy. A third pattern, related to the predictive significance of T1 and T2, included bilateral posterior thalamus and retrosplenial cortex. In the brain-behaviour PLS, dorsal extrastriate and retrosplenial cortices, and posterior thalamus defined a spatial pattern that differentiated T1 from T2. These three regions may code the signal value of the tones, in preparation for the appropriate response. (Supported by NSERC grant to ARM).

## 289.3

NEURAL MACHINERY INVOLVED IN WORKING MEMORY: A WHOLE BRAIN FMRI STUDY. Y.S. Mattay\*, A.K.S. Santha, J. Callicott, A. Bertolino, K. Tallent, T. Goldberg, R. Coppola, J.A. Frank and D.R. Weinberger. CBDB/NIH, Bethesda, MD

Converging evidence suggests that the prefrontal cortex plays a predominant role in working memory with support from multiple regions of association cortex. We explored the potential of fMRI to outline this distributed network within individuals and to assess the level and variability of recruitment of the different regions involved. We studied eight normal volunteers (4 males and 4 females, mean age = 28 yrs) with whole brain isotropic multislice gradient echo EPI while they performed two working memory tasks with increasing working memory load (2 back and 2 back with catch) and a sensorimotor control task intermingled with the resting state. Student's *t* test at 97.5 % confidence level with the probability threshold adjusted by Bonferroni correction for about 15000 cortical voxels in the brain, was used to identify activated voxels. Analysis of the working memory - control task 'activation' maps shows that while there was considerable intersubject variation in the total and regional number of activated voxels, all subjects showed prominent activation in prefrontal cortex [(Brodmann areas 9, 10 and 45) ~ 33 % of 'activated' voxels] and parietal cortex [(Brodmann areas 5, 7, 39 and 40) ~ 45 % of 'activated' voxels]. Additional regions of activation with individual variations included the insular, anterior and posterior cingulate, extrastriate, premotor and supplementary motor regions. The extent of activation increased globally and in the above cortical regions with increasing memory load in all subjects, with individual variations as to which region showed more activation with respect to the other regions. The results display the potential of fMRI to map the neural machinery involved in working memory and also to map the relative individual differences in the level of recruitment of the different cortical areas required in performing working memory tasks. The variation in each individual's activation pattern with increasing working memory load may reflect alteration in the cognitive strategy that is unique to each individual as they adapt to the increased load.

## 289.5

EPISODIC RETRIEVAL OF CONTENT AND TEMPORAL CONTEXT ACTIVATE SIMILAR REGIONS OF THE PREFRONTAL CORTEX: A FUNCTIONAL MRI STUDY. L.T. Eyler Zorrilla\*, M.D. Esposito, G.K. Aguirre, E. Zarahn. Depts. of Psychology and Neurology, U of Penn, Phila, PA 19104

Lesion studies in humans and animals support a double dissociation between content memory and memory for temporal context, emphasizing the importance of medial temporal lobe (MTL) in the former and lateral prefrontal cortex (PFC) in the latter. In a previous study (unpublished observations) we have confirmed the role of the PFC in judgments of recency using fMRI with healthy volunteers. However, neuroimaging studies of episodic content memory by many researchers have failed to find MTL involvement in retrieval, and instead consistently have shown PFC activation. We therefore directly compared the activation associated with retrieval of temporal context to that seen in retrieval of content in order to determine whether unique regions were activated during performance of either task. Nine subjects learned two lists of words prior to scanning. On recognition trials, subjects indicated whether the word had appeared on either list; on list discrimination trials, they indicated on which list the word appeared. These tasks were performed during fMRI scanning with a 1.5 T magnet. Data were analyzed using a general linear model for correlated observations. No areas of unique activation were revealed when recognition and list discrimination were compared directly. These results suggested that similar regions are activated by retrieval of content and temporal context. This hypothesis was tested directly in an additional subject who performed a sensorimotor control task in addition to the memory trials. Results confirmed that both types of retrieval led to significant increases in activity in the same regions of prefrontal cortex relative to the control. Our findings suggest that similar cognitive processes may be involved in memory for 'what' and 'when' and that the PFC contributes to episodic retrieval of both content and temporal context. Supported by McDonnell-Pew and NIH grant NS01762.

## 289.7

AGE-RELATED CHANGES IN REGIONAL CEREBRAL BLOOD FLOW (rCBF) DURING MEMORY ENCODING AND RETRIEVAL. R. Cabeza\*, E. Tulving, A. R. McIntosh, C. L. Grady, J. M. Jennings, S. Kapur, L. Nyberg, S. Houle, F. J. M. Craik. Rotman Research Institute of Baycrest Centre, University of Toronto

Changes in rCBF in healthy young and older adults were measured by positron emission tomography (PET) while they were either reading, encoding, recognizing, or recalling word pairs. Compared to reading, encoding in young subjects was associated with higher rCBF (activation) in the left prefrontal, medial temporal, and anterior cingulate regions. Activation in these regions was weaker in old adults. Areas more active during recognition than during reading in young subjects were the right prefrontal, anterior cingulate, and inferior parietal cortices. Older subjects activated these regions to a lesser degree, but activated the precuneus region, which was not active in young subjects. Compared to reading, recall in young subjects was associated with activity in right prefrontal, anterior cingulate, parietal, lentiform, thalamic, and cerebellar regions. Older subjects showed less activity in these regions, but activated a left prefrontal region that was not active in young subjects. In sum, old subjects showed weaker activations than young subjects in several regions, including frontal, medial temporal, anterior cingulate, and parietal regions, but activated some regions that were not active in young subjects. The first result is consistent with evidence of neural decay in the aging brain. The second result suggests a reorganization of brain function, like the one observed after brain damage. Since old subjects performed as well as young subjects, despite their weaker activations, this functional reorganization may reflect a compensatory mechanism.

This study was supported by a fellowship of the International Human Frontier Science Program to R. Cabeza.

## 289.4

PREFRONTAL MEDIATION OF EPISODIC MEMORY PERFORMANCE. A.D. Wagner\*, J.D.E. Gabrieli, J.E. Desmond, S. Joaquin, and G.H. Glover. Depts. of Psychology and Radiology, Stanford University, Stanford, CA 94305.

Functional neuroimaging studies have revealed activation in right anterior prefrontal cortex (at or near BA 10) during performance of episodic memory tasks. This activation may reflect processes associated with retrieval search and effort, rather than processes associated with retrieval success (e.g., Schacter et al., 1996). Here, prefrontal activation during various levels of episodic memory performance was examined at the individual subject level using fMRI. A levels-of-processing study manipulation served to vary probability of successful yes-no recognition at test. There were three memory conditions: (1) High Performance, consisting of memory judgments for well-learned words; (2) Low Performance, consisting of memory judgments for less well-learned words; (3) New, consisting of memory judgments for unstudied words. In three scans, activation during each of these memory conditions was compared to Baseline (reading unstudied words). In a fourth scan, activation during the High and Low Performance conditions was directly compared. Each scan consisted of 6 memory/baseline cycles during which functional images were collected continuously from 8 coronal slices through prefrontal cortex ( $y = +15$  to  $+64$  mm) using a T2\*-weighted gradient echo spiral sequence (1.5T, 6 mm thick slices, 1 mm inter-slice spacing, TR=720, TE=40, flip angle=65). Results revealed that, relative to Baseline, all three memory conditions led to (a) right anterior prefrontal activation, (b) right posterior prefrontal activations (near BA 45, 47, 46, and 9), and (c) in some subjects, left anterior and posterior prefrontal activations. The right anterior activations tended to be stronger in the High vs. Baseline comparison than in the Low vs. Baseline and New vs. Baseline comparisons. However, some subjects demonstrated comparable or greater activation in these latter conditions. Further, the direct comparison of High vs. Low yielded minimal activation differences in all but one subject. These data suggest that right anterior prefrontal activation reflects processes associated with retrieval search and effort, with retrieval context affecting when these processes are engaged. Supported by the NSF and NIH (AG12995).

## 289.6

FUNCTIONAL MAPPING OF IMPLICIT AND EXPLICIT MEMORY USING REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION (rTMS), T.A. Blanton\*, E.M. Wassermann, E.A. Hoffman, E.S. Ojeltky, M. Hallett, W.H. Theodore. National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892.

We used rTMS to map memory function in 11 temporal lobe epilepsy patients with unilateral disease (8 left, 3 right). All were left language dominant as determined by amyltal exam. rTMS was delivered during encoding to left and right frontal (speech arrest site and contralateral reflection), mid/superior temporal (1cm above top of ear), and posterior temporal (2-3cm posterior to mid/superior site) regions as subjects named color photographs of objects and read words aloud during 3 s presentations. rTMS was delivered randomly on half of the study trials at 10 Hz and <100% of motor threshold intensity. 3050 ms pulse trains began 50 ms before stimulus presentation. Memory for items named correctly during encoding was tested using nonstimulated implicit category member production and explicit semantic cued recall with category label cues. Items were counterbalanced across memory tasks, stimulation conditions, and stimulated brain regions across subjects. Memory was better for pictures than for words on both tests. Comparing memory performance on stimulated versus nonstimulated study trials, rTMS delivered to both left and right frontal regions disrupted explicit recall of pictures. Implicit picture priming (relative to nonstimulated baseline) was disrupted by left and right frontal as well as mid/superior temporal stimulation. Posterior temporal rTMS did not affect performance on either memory task, although left posterior temporal stimulation disrupted naming during encoding. These disruption mapping results converge substantially (though not completely) with prior findings from activation mapping studies. (This work supported by the NIB/NINDS.)

THE NEURAL BASIS OF VISUAL SKILL: AN FMRI STUDY OF MIRROR READING. R. A. Poldrack\*, J. E. Desmond<sup>1,2</sup>, G. H. Glover\*, and J. D. E. Gabrieli<sup>1</sup>. Departments of Psychology<sup>1</sup> and Radiology<sup>2</sup>, Stanford University, Stanford CA, 94305

The reading of mirror-reversed text has been extensively examined as an example of perceptual-motor learning, but its neural basis has remained poorly understood. fMRI was used to examine the brain systems involved in mirror reading performance. Mirror-reversed and normal letter strings were presented in alternating blocks of 10 items. Half of the strings in each block were words and half were pronounceable pseudowords. Subjects performed a lexical decision for each item, indicating whether it was a word or not.

Functional data were acquired from ten 6mm coronal slices at 1.5 T using a gradient echo spiral sequence (TR = 900, TE = 40, flip angle = 70°). A method for online registration was used to place the slices from Y = -25 mm to Y = -95 mm in Talairach space. Data were analyzed using the cross-correlation method described by Friston et al. [Human Brain Mapping, 1994]. Two scans were performed for each subject, each with a unique word list.

Comparison of mirror reading to normal text reading revealed several areas of significant ( $p < .01$ ) activation consistently across subjects. There was extensive activation bilaterally in the middle and superior occipital gyri (corresponding to Brodmann's areas [BA] 18 and 19). There was also consistent right parietal activation in the superior parietal lobule (corresponding to BA 7) and less extensive activation in this area on the left. There were no extensive activations for normal text reading compared to mirror reading. These data suggest that multiple visual and visuospatial systems are involved in mirror reading, and that these systems are a superset of those involved in the processing of normal text.

**FUNCTIONAL MRI STUDIES OF MENTAL ROTATION AND OBJECT IDENTIFICATION PROCESSES.** B. Rypina\*, M.A. DeBell, J.D.E. Gabrieli, V. Prabhakaran, M.F. Zabinski, J.E. Desmond, G.H. Glover. Depts. of Psychology and Radiology, Stanford Univ., Stanford, CA 94305.

Recent brain imaging studies of mental rotation have shown that parietal lobe is activated during mental rotation. We sought to determine the role of parietal mental rotation mechanisms in object identification by contrasting tasks which produce angle-dependent mental rotation functions (determination of the left-right, or parity, status of objects) with tasks that do not produce mental rotation functions (object identification). In the present study, brain regions responsible for mental rotation and object identification were mapped using functional Magnetic Resonance Imaging. Each subject was scanned three times in tasks that required subjects to either determine if two misoriented Snodgrass-Vanderwart pictures had the same or different identities or to determine if the two objects would face the same or different directions. Each of these tasks was compared against a sensorimotor control task in which subjects were required to press a button as soon as an object pair appeared on the screen. Brain images were collected in 10 oblique coronal planes perpendicular to the AC-PC line. fMRI was obtained with T2\*-weighted gradient echo spiral pulse sequence (1.5T, TR=900, TE=40, flip angle=70 degrees, interslice spacing=1.5 mm, slice thickness=5.0 mm). Activations associated with determining the identity status of the two objects was strongest in temporal lobe and cerebellar regions. Activation associated with parity determination was also found in temporal and cerebellar regions but was considerably greater in parietal regions. These results suggest (1) that processes related to mental rotation and identity determination may be independent and (2) that brain regions associated with mental rotation may be activated mainly when tasks require parity determination but minimally activated when subjects are required to determine the identity of objects.

This research was funded by grants from NIH and NIA.

## 289.11

**FUNCTIONAL NEUROANATOMY OF MOTOR SEQUENCE LEARNING IN HUMANS: A PET STUDY.**

M. Honda\*, M.P. Deiber, V. Ibañez, P. Zhuang, C. Toro, M. Hallett. Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892

The serial reaction time paradigm (SRT) involves implicit and explicit motor sequence learning. To examine the neural basis of each learning process, we studied 12 healthy right-handed volunteers using positron emission tomography (PET). The modified SRT was employed in which each session consisted of 10 repetitions of a test sequence of 10 visually presented numbers. Subjects were requested to push a separate button in response to each number. Sessions including the same test sequence were repeated 7 times in total. The effect of explicit and implicit learning was assessed separately by the correct generation of the test sequence after each session and the RT change without any successful generation of the sequence, respectively. Regional cerebral blood flow during each session was measured by PET scanning using H<sub>2</sub><sup>15</sup>O and analyzed in correlation with each behavioral indicator.

The correlation map with correct generation of the sequence revealed significant involvement of bilateral inferior parietal lobes, precuneus, premotor cortices, dorsal prefrontal cortices, and contralateral SMA and cingulate cortex, in the explicit learning. In contrast, the correlation map with RT during pure implicit learning phase showed significant involvement of the contralateral primary sensory-motor cortex adjacent to the hand representation. These results suggest that the different cortical areas are involved in the two different kinds of motor sequence learning.

## 289.10

**BLOOD FLOW INCREASES IN LEFT DORSAL PREMOTOR CORTEX DURING SENSORIMOTOR INTEGRATION LEARNING.** M. Jacoboni, R.P. Woods, J.C. Mazziotta\*. UCLA Brain Mapping Division, Neuropsychiatric Institute, UCLA School of Medicine, Los Angeles, CA 90095.

We have previously observed that learning in visuo-motor integration produces blood flow increases in left prefrontal, dorsal premotor, and motor areas in the human brain. We have also observed that visuo-motor learning is not associated with blood flow decreases (Jacoboni et al., J Neurophysiol, in press).

Here we investigate blood flow changes associated with practice in a sensorimotor task in which auditory stimuli were used. We measured reaction times and regional cerebral blood flow (rCBF) changes with positron emission tomography (PET) and H<sub>2</sub><sup>15</sup>O in seven normal subjects performing a response choice task to lateralized tones of 1000 Hz. Twelve rCBF measurements were performed in each subject. Reaction times shortened with practice (p<0.04). Serial rCBF increases fitting the reaction time slope (p<0.05, corrected for multiple spatial comparisons) were observed in the dorsal premotor cortex of the left hemisphere. No significant rCBF decreases were observed.

Our data suggest a modality-independent role of the left dorsal premotor cortex in human sensorimotor integration learning. Our data also support the notion that, at variance with other types of learning frequently associated with blood flow decreases (Raichle et al, Cereb Cortex 1994; 4: 8-26), human sensorimotor integration learning seems to be associated with blood flow increases only.

**A PET STUDY OF MOTOR MEMORY CONSOLIDATION.** R. Shadmehr\*, H.H. Holcomb, K. Akhavan-Toyserkani. Depts. Biomedical Eng. & Radiology, Johns Hopkins Univ., Baltimore, MD 21205, & Maryland Psychiatric Res. Cent., Univ. Maryland, Baltimore, MD 21228.

Elsewhere in this volume we report psychophysical evidence that learning a motor skill (control of arm movements in a haptic field) sets in motion neural processes that continue to evolve after practice has ended. The consolidation of the skill could be disrupted within a window of a few hours after initial learning, but not after that period. Here we report on the changes in the neural representation of the skill during this consolidation period. PET was used to measure rCBF of 8 subjects during 5 conditions: moving the robot in a null field, in a random field, early learning of a curl field, late learning of the curl field, and 6 hours later in the same field. Based on previous results, during the 6 hours a consolidation process may have taken place. In comparing the rCBF while subjects were moving in the field in the late stage of learning vs. when same movements were performed 6 hours later, we found a significant reduction bilaterally in the dorsolateral prefrontal cortex ( $z = 4.82$  and  $z = 4.54$ , corrected  $p < 0.006$  and  $p < 0.02$  for right and left sides respectively, SPM95). In comparison, bilateral reductions were not observed in a separate study of 8 subjects where a similar number of movements in the field were performed without the passage of 6 hours (Brashers-Krug et al, in prep). One possibility is that the prefrontal lobe may play a critical role in the initial binding of visual to motor information, but that with time, this role may be lessened as more direct connections between the visual and motor regions come to represent the learned skill. Funded by Whitaker Foundation, NIH, and ONR.

## PARKINSON'S DISEASE

## 290.1

**CONTROVERSIAL ISSUE: BENEFICIAL EFFECTS OF NITRIC OXIDE RADICALS (NO) IN THE CENTRAL NERVOUS SYSTEM.** C.C. Chiueh, P. Rauhala, & J. Sziraki\*. Unit on Neurotoxicology & Neuroprotection, Laboratory of Clinical Science, NIMH, NIH, 10/3D-41, Bethesda, MD 20892

It has been proposed that free radicals may be involved in degenerative brain disorders such as idiopathic Parkinson's disease and MPTP- or 6-OH-dopamine-induced parkinsonism. Similar to MPP+, oxidant stress-induced nigral injury has been consistently demonstrated *in vivo* with hydroxyl radicals (OH) generated by iron complexes [i.e., ferrous citrate & sodium nitroferricyanide (sodium nitroprusside)].

Intracerebral infusion of NO or NO donor compounds did not induce lipid peroxidation and neuronal death *in vivo*. In fact, NO released from non-iron containing NO donors protected nigral neurons against oxidative nigral injury elicited by OH generated by ferrous citrate because exogenous NO is a potent inhibitor of brain lipid peroxidation catalyzed by submicromolar iron (Rauhala et al., *Free Radical Biol. Med.* in press). Moreover, NO also suppressed sodium nitroprusside-induced brain lipid peroxidation through inhibition of OH generation.

In conclusion, NO may be a potent endogenous antioxidant to protect iron-containing nigral neurons against progressive free radical damage. Debate of the controversial issue of whether NO radicals is friend or foe to injured brain neurons (Choi, 1993) could alter current concept for developing neuroprotective strategies and agents. ## 290.2

**INHIBITION OF NEURONAL NITRIC OXIDE SYNTHASE PREVENTS MPTP INDUCED PARKINSONISM IN BABOONS.** P. Hantraye\*, E. Brouillet, R. Ferrante, S. Palfi, R. Dolan, R.T. Matthews, M.F. Beal. URA CEA-CNRS 2210, SHFJ, DRIPP, DSV, Orsay FRANCE, GRECC, VA medical Center, Boston University School of Medicine, Bedford MA 02118 and Neurochemistry Lab, Neurology Service, Mass Gen Hosp and Harvard Med Scholl, Boston MA 02114.

MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) produces clinical, biochemical and neuropathologic changes reminiscent of those which occur in Parkinson's disease (PD). 7-nitroindazole (7-NI) is a relatively selective inhibitor of the neuronal isoform of nitric oxide synthase (NOS) which blocks MPTP neurotoxicity in mice. We now show that 7-NI protects against profound striatal dopamine depletions and loss of substantia nigra tyrosine-hydroxylase positive neurons in MPTP treated baboons. The use of an automated video-based movement analysis system showed that 7NI completely blocked the severe hypokinesia and bradykinesia induced by MPTP. Furthermore, the use of the Object retrieval detour task, a task dependent on the functional integrity of the frontostriatal pathway and highly sensitive to striatal dopamine depletion, demonstrated that while MPTP animals were unable to perform, MPTP/7NI or 7NI treated animals showed responses similar to control animals. These results strongly implicate a role of nitric oxide in MPTP neurotoxicity, and suggest that NOS inhibitors selective of the neuronal isoform might be useful in treating PD. ## 290.3

NEURAL EFFECTS AND REGULATION OF TRANSCRIPTION OF GDNF, A TGF $\beta$ -SUPERFAMILY MEMBER. C. Suter-Crazzolara\*, L. Farkas, T. Lenhard and K. Unsicker. Dept. of Anat. & Cell Biol., Univ. Heidelberg, INF 307, D-69120 Heidelberg, Germany.

GDNF is a potent neurotrophic factor for several neuron populations in the CNS and PNS. We shall present data concerning mechanisms that may be involved in the protective actions of GDNF. To test the hypothesis that GDNF may act in part through the regulation of Ca $^{2+}$ -binding proteins we have begun to study effects of GDNF on calretinin (CalR) expression in embryonic striatal and toxically impaired hippocampal neurons. We show that GDNF induces, de novo, CalR immunoreactivity in striatal neurons and elevates CalR mRNA in glutamate-exposed hippocampal neurons. Similar, but weaker effects can be elicited by NT-3, NT-4, FGF-2 and CNTF. Another important aspect of the physiological actions and putative therapeutic applicability of GDNF concerns its regulation of expression in glial cells, a principal source of GDNF. Towards this end, we have studied regulation of GDNF mRNA in C6 glioma cells by a large battery of cytokines, hormones, and neuropeptides using a competitive PCR approach. Our data suggest that FGF-2, in contrast to many other molecules, can up-regulate GDNF mRNA levels. Finally, to analyze the regulation of GDNF at molecular levels in more detail, we have begun to study the regulatory promoter elements of the human GDNF gene. Supported by DFG (Un34/16-2)

## 290.5

TIME-COURSE OF STRIATAL, PALLIDAL AND THALAMIC  $\alpha$ 1,  $\alpha$ 2 AND  $\beta$ 2/3 GABA $_A$  RECEPTOR SUBUNIT CHANGES INDUCED BY UNILATERAL 6-OHDA LESION OF THE NIGROSTRIATAL PATHWAY. H.J. Caruncho\*, J. Liste, G. Rozas, E. Lopez, M.J. Guerra and J.L. Labandeira. Dept. of Morphological Sciences. Univ. of Santiago School of Medicine. 15705-Santiago de Compostela. Galicia. Spain.

A semiquantitative immunocytochemical analysis of several GABA $_A$  receptor subunits in the brain of unilaterally 6-OHDA lesioned rats showed an increase in the lesioned striatum for the  $\alpha$ 2 and  $\beta$ 2/3 subunits 3 and 7 days after the lesion when compared with the unlesioned side, whereas after 4 and 12 weeks of lesioning these changes were not significant. The same was observed for the  $\alpha$ 1 subunit that was decreased in the ipsilateral globus pallidus. In addition, the  $\alpha$ 1 subunit was decreased in several relay thalamic nuclei in the lesioned side, whereas the  $\alpha$ 2 subunit was increased in the intralaminar thalamic nuclei of the lesioned side. Again, these changes were apparent 3 and 7 days after the lesion but disappeared in samples from rats sacrificed 4 and 12 weeks after the lesion. These results suggest the existence of an early adaptation to the lesion in terms of changes in GABA $_A$  receptor expression. The compensation of these changes after 4 or 12 weeks is due not only to a partial reversion of the changes in the lesioned side but also to changes in the unlesioned side in comparison with the expression found in control (unlesioned) rats. Supported by grants from XUGA and the Spanish DGICYT.

## 290.7

NEURONAL CELL DEATH BY APOPTOSIS *IN VIVO* IN THE 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP) MOUSE MODEL OF PARKINSON'S DISEASE (PD).

A.M. Janson\*. Dept. of Neuroscience, Karolinska Institutet, Doktorsringen 17, S-171 77 Stockholm, Sweden.

Apoptosis may represent an important mechanism of cell death in some experimental models of neurodegeneration as well as in human neurodegenerative disorders. Although the MPTP mouse model of PD has been studied extensively over the last decade, the mechanism by which the neuron ultimately dies remains unknown.

A single dose of MPTP (40 mg/kg, sc.) was given to 10 weeks' old male C57 BL/6 mice. The nuclear alterations were studied in midbrain sections and analyzed with stereological unbiased quantitative techniques at various time points after the lesion. Two different *in situ* labeling techniques analyzing DNA fragments were compared. The first one uses DNA polymerase I, which detects the 3'-OH-ends of single-stranded DNA breaks. The second technique employs terminal deoxynucleotidyl transferase labeling the 3'-OH-ends of both single- and double-stranded DNA breaks.

The results for the first time indicate a role of apoptotic-like cell death mechanisms in the MPTP mouse model *in vivo*, possibly also related to the pathogenic mechanism in PD.

Supported by the Swedish Medical Research Council (grant 10816).

## 290.4

CHANGES IN SPONTANEOUS MOTOR BEHAVIORS ASSOCIATED WITH ANATOMICAL DECREASES IN IMMUNOHISTOCHEMICAL AND NEUROCHEMICAL INDICES OF DOPAMINE IN 6-HYDROXYDOPAMINE TREATED RATS C.G. van Hoesen\*, M. Hebert, S. Eken, G.A. Gerhardt, and B.J. Hoffman. Dept. of Pharmacology, U. of Colorado H.S.C., Denver, CO. 80262, and Dept. of Neurosurgery, Brigham and Women's Hospital, Boston, MA. 02146

Previous studies of the unilateral 6-hydroxydopamine (6-OHDA) lesion model of Parkinson's disease (PD) have focused primarily on drug-induced rotational behaviors related only to changes in the nigrostriatal portion of the ascending midbrain dopaminergic system. Therefore, we investigated spontaneous motor behaviors as well as drug induced rotations and measured immunohistochemical and neurochemical alterations in the ventral tegmental area (VTA) and ventral striatum/nucleus accumbens (VS/NA) in addition to the nigrostriatal pathway. Our objectives were to produce both full and selective lesions and to compare the behavioral changes to the anatomical distribution and neurochemical extent of the lesions. Male Fischer 344 rats were injected with 6-OHDA into either the medial forebrain bundle (full lesions) or into the cell body region of the substantia nigra (SN, selective lesions). Apomorphine-induced (0.05mg/kg, s.c.) rotational behavior was recorded for 90 minutes. Spontaneous activity was recorded in 10 minute bins for 60 minutes in automated activity chambers (Omnitech Inc.) and reported as activated activity (AA, first 10 minutes) and habituated activity (HA, a 10 minute average of the last 3, 10 minute bins). The density of tyrosine hydroxylase (TH) immunohistochemical staining was evaluated by image analysis for the SN, VTA, VS/NA, medial dorsal striatum (DS), and lateral DS. Whole tissue levels of dopamine (DA) in the SN, VTA, NA, and striatum were determined by HPLC. The fully lesioned group had significantly greater rotations compared to the selective group and also demonstrated significantly reduced HA scores for total distance, cm/movement, movement number, and stereotypy. Rearing activity was significantly lower during the AA and there was no significant difference in velocity for either time point. Although the selective group showed significantly greater TH densities in the VS/NA and VTA compared to the fully lesioned group, significantly higher levels of DA, however, were only found in the VTA and not the VS/NA. Thus, several differences in the behavioral profiles of the fully and selectively lesioned rats are associated with anatomical variations in the density of TH staining and DA levels. (Supported by NS09199)

## 290.6

ANTIPARKINSONIAN ACTIVITY OF THE NMDA2B ANTAGONIST RO 25-6981 IN RATS

P.-A. Lechmann, U. Wüllner\*, J.B. Schulz, G. Fischer, J.A. Kemp, T. Klockgether, University of Tübingen, Dept. of Neurology, 72076 Tübingen, Germany; Hoffmann-La Roche Ltd, Preclinical Research, 4070 Basel, Switzerland

Experimental and clinical evidence indicate that degeneration of nigral dopamine (DA) neurons leads to secondary changes of neuronal activity in the basal ganglia involving increased glutamatergic excitation in the striatum and the basal ganglia output nuclei. Competitive antagonists of the NMDA subtype of glutamate receptors potentiate the antiparkinsonian activity of direct DA agonists or L-DOPA in MPTP treated primates and 6-OHDA lesioned rats. However, unselective inhibition of NMDA receptors throughout the central nervous system limits the therapeutic benefit of such compounds and leads to side-effects such as ataxia and psychosis. A more specific approach would involve the selective inhibition of glutamatergic pathways overactive in Parkinson's disease. The message for the 2B subunit of the NMDA receptor is differentially expressed in the brain with high densities within the basal ganglia. Ro 25-6981 has been characterized as a non-competitive antagonist with selectivity for the NMDA receptors containing the NR2B subunit (see Trube et al., this meeting). This compound has no affinity for the known sites of non-competitive antagonists such as PCP or MK-801. In 6-OHDA substantia nigra lesioned rats, Ro 25-6981 alone induced contralateral rotations while the competitive non-selective NMDA antagonist CPP had no effect. Contralateral rotations induced by direct DA agonists such as apomorphine or lisuride or L-DOPA (plus benserazide) were dose-dependently potentiated by co-treatment with Ro 25-6981. Compared to CPP, this effect was observed over a wider range of doses. NMDA2B antagonists could be useful adjuvants for treatment of Parkinson's disease with a reduced propensity to induce side effects known for unselective NMDA antagonists.

## 290.8

PET IMAGING REVEALS REDUCED [C-11](+)-McN5652 BINDING TO 5-HT TRANSPORTERS IN PARKINSON'S DISEASE. Z. Szabo\*, T. Preziosi, R. Hoehn-Saric, U. Scheffel, S. Palmon, W.B. Mathews, H.T. Ravert, R.F. Dannals. Departments of Radiology, Neurology and Psychiatry, The Johns Hopkins University, Baltimore, MD 21205.

Post-mortem studies indicate multisystemic (DA, 5-HT, NE, acetylcholine) damage in Parkinson's disease (PD). The purpose of this study was to assess deficits in 5-HT transporters (5-HTT) in the brain of living PD patients by measuring the binding of the 5-HTT specific [C-11](+)-McN5652<sup>1</sup> using positron emission tomography (PET). Six healthy subjects and four patients with mild PD were injected with 18±3 mCi high specific activity [C-11](+)-McN5652. Sequential PET scans were acquired over 95 minutes and regional time-activity curves were processed using metabolite corrected arterial plasma activity as the input function. The impulse response function at 75 minutes post injection (*irf*) was calculated by matrix regularization to represent radioligand retention. Compartmental parameters of uptake ( $K_1$ ), release ( $k_2$ ) and distribution volume ( $DV = K_1/k_2$ ) were obtained as well.

In PD both  $K_1$  and *irf* were reduced while  $k_2$  was increased. Reduction of radioligand uptake ( $K_1$ ) was more prominent in cortical (27-45%) than subcortical regions (15-27%). By contrast, increases in radioligand release ( $k_2$ ) were more pronounced in subcortical (180-980%) than cortical regions (44-107%). In subcortical regions (pons, hypothalamus, caudate nucleus, putamen, and thalamus) reduction in *irf* exceeded reduction in  $K_1$ . By ANOVA, the variance of *irf* was partially attributable to  $K_1$ , but the main effect of disease remained significant after removal of the covariance effect of  $K_1$  ( $F=21.7$ ,  $p<0.001$ ). Thus, both delivery and specific binding of [C-11](+)-McN5652 are reduced in PD. In brain areas abundant in 5-HTT reduction of specific binding exceeds reduction of delivery, providing evidence for decreased 5-HTT in PD.

<sup>1</sup>McN5652 = 1,2,3,5,6,10b-hexahydro-6-[4-(methoxythio)phenyl]pyrrolo [2,1-a]isoquinoline.

TRANSGENIC MICE WITH INCREASED NUMBER OF DOPAMINE TRANSPORTERS (DAT) SHOW GREATER SENSITIVITY TO MPTP. V. Kostic<sup>1</sup>, D. Donovan<sup>1</sup>, R. Yokoyama<sup>1</sup>, S. Przedborski<sup>1\*</sup>, and G.R. Uhl<sup>2</sup>. <sup>1</sup>Dept. Neurol., Columbia Univ., New York, NY 10032; and <sup>2</sup>NIDA-IRP and Dept. Neurol. & Neurosci., JHUSM, Baltimore, MD 21224.

MPTP damages dopamine (DA) neurons of the substantia nigra pars compacta (SNpc) as seen in Parkinson's disease. A major step in the MPTP toxic pathway is the selective accumulation of its active metabolite MPP<sup>+</sup> in DA neurons by DAT. Blockade of DAT prevents MPTP effects, but whether more DATs can enhance MPTP DA toxicity in vivo is unknown. Thus, we assessed MPTP DA toxicity in transgenic mice expressing the rat DAT gene in catecholamine neurons. These mice exhibit increased SNpc [3H]mazindol binding compared to their non-transgenic littermates, thus indicating that these transgenic mice have greater SNpc DAT density. Adult mice were injected with MPTP (15 mg/kg, 4q2 hr) and 1 week after the last injections the number of tyrosine hydroxylase (TH)-positive neurons through the entire SNpc was counted. This MPTP regimen caused ~34% reduction in SNpc TH-positive neuron number in the non-transgenic animals. However, this MPTP regimen caused ~50% reduction in SNpc TH-positive neuron number in the transgenic mice compared to saline-injected controls. The difference in the percent of MPTP-induced SNpc cell loss between the transgenic and non-transgenic mice is highly significant ( $p < 0.01$ ). This study demonstrates that increased density in DAT enhances the susceptibility of SNpc DA neurons to MPTP toxicity. This finding may have major implications for Parkinson's disease.

Anatomical Configuration of Fetal Mesencephalic Grafts in MPTP Monkeys R.A.E. Bakay \* Emory University School of Medicine, Atlanta GA 30322

The organotypic patterns of tyrosine hydroxylase (TH) reactive cells in successful mesencephalic grafts is well established. The location of these cells in the outer edges of the graft has not been explained. The center of the graft contain the other cells in the mesencephalon. Immunocytochemical studies document the cells to be primary GABA immunoreactive. Cellular pattern and connections resemble Substantia Nigra pars reticulata.

EFFECTS OF VISUAL INFORMATION AND PRACTICE ON NORMAL AND PARKINSONIAN SUBJECTS. W. A. Hening<sup>1,2</sup>, M. Rollen<sup>2</sup>, and J. Gordon<sup>3,4</sup>. Neurology Depts., UMDNJ-RW Johnson Med Sch<sup>1</sup>, New Brunswick, NJ and VAMC<sup>2</sup>, Lyons, NJ; Ctr for Neurobiology & Behavior<sup>3</sup>, Columbia Univ, NYC; and NY Medical College<sup>4</sup>, Valhalla, NY. Background: Some investigators have reported reduced accuracy when Parkinson's disease patients (PDPs) make movements without visual task information. In previous work, we found that PDPs achieved normal accuracy when allowed practice. In those studies, however, subjects were given some practice with visual input in each session before testing. We now asked whether practiced PDPs would be inaccurate if required to make movements when a session began without visual input. Design/Methods: 8 PDPs (Hoehn & Yahr stages I[1], II[5], and III[2]) tested at end of medication doses and 9 controls, all experienced, responded to 4 targets presented on a computer monitor requiring hidden movements of 8 to 32 cm over a digitizing tablet. Blocks had either simple (S: 5 of each successively) or choice (C: 20 randomized targets) trials. The first 4 blocks (2 S, 2 C) presented minimal task information (MTI): no knowledge of results and no screen feedback of hand position or display of target after the "go" signal. Subjects were then given 40 practice trials with visual information, followed by further S and C blocks with MTI. Results: PDPs were less accurate than controls, but the difference was significant only before the visual information. Both subject groups undershot the large target, while PDPs used more in-course corrections. Conclusions: When MTI is presented before practice with visual information, even experienced PDPs are less accurate. PDPs use more trajectory updating to improve accuracy, adaptively using slower movements. For all subjects, accuracy is compromised before practice. STIMULATION THRESHOLD ANALYSIS REDUCES RISK TO INTERNAL CAPSULE IN PALLIDOTOMY PROCEDURES. R.C. Frysinger<sup>\*</sup>, J. M. Bronstein, E. Behnke, T. Fields and A. De Salles. Depts. of Neurobiology, Neurology, Surgery and the Brain Research Institute, UCLA Med. School, Los Angeles, CA 90095. Accurate placement of radio frequency lesions in the globus pallidus internus (GPi) is required for maximal remission of motor symptoms of Parkinson's disease (PD) and avoidance of damage to the neighboring internal capsule (IC) and optic radiations (OR). We performed intraoperative stimulation at up to 5 sites along each of 35 electrode penetrations in 31 non-demented patients aged 34-77 years with medically refractory PD undergoing ventroposterior pallidotomy (trains of constant voltage biphasic 1 msec pulses at 2 Hz and 50 Hz). Voltage was increased at each frequency to a limit of 4 volts or to a perceptible motor response. Phasic motor activation at 2Hz was assumed mediated through IC. One case showed transient post-operative facial weakness after a lesion at a site with a 2 Hz threshold of 1V. The subsequent 28 cases had 2 Hz thresholds above 1.5 volts (mean=2.73V, s.d.=±0.65), and a good clinical response free of symptoms of IC damage. Positive PD signs at 50 Hz were assumed mediated through GPi. Thresholds below 3V were consistently associated with positive outcomes (2.33, ±0.95V). Proximity to OR was indicated by visual phenomena associated with either frequency at less than 4 V amplitude. Threshold analysis in conjunction with accurate and flexible MR based stereotactic targeting can help to simplify the pallidotomy protocol and minimize the number of electrode penetrations required. Supported by NIH NS01596 and an AAN Research Fellowship to JMB

CORRELATION ANALYSIS OF MULTINEURON RECORDINGS IN HUMAN THALAMUS AND GLOBUS PALLIDUS. J.M. Hurtado, C.M. Gray\*, L.B. Tamas, K.A. Sigvardt, S. Starsinic, H. Richard and E.A. Franz. Center for Neuroscience, Univ. of Calif., Davis, CA 95616 and Pacific Neurosciences Institute, Lafayette, CA 94549.

The neurosurgical treatment of the symptoms of Parkinson's disease by thalamotomy and pallidotomy incorporates electrophysiological recording of neuronal activity to verify the site of lesion placement. We have developed and employed a method for recording from two independently movable microelectrodes or tetrodes during this procedure. This technique increases the accuracy of the mapping protocol while also decreasing its duration. Moreover, it has provided the first opportunity to investigate the incidence and properties of both local and long-range interactions among the neurons in these structures. The data collected to date demonstrates a wide range of neuronal firing characteristics in the Putamen, GP<sub>e</sub>, and GP<sub>i</sub> of the Basal Ganglia, and D<sub>an</sub>, V<sub>an</sub>, and V<sub>c</sub> of the Thalamus. Cells in these various regions can be distinguished on the basis of the incidence and properties of rhythmic firing, the incidence and magnitude of synchronized firing, as well as spontaneous firing rates, propensity to fire in bursts, action potential duration, and responses to kinesthetic or tactile stimulation. Cells that rhythmically fire at tremor frequencies of 4-6 Hz, as well as higher frequencies of 10-20 Hz, synchronize their activity with little or no average phase lag. Supported by NIH (CMG, KAS) and NSF (CMG).

## 290.14

IMPAIRED TACTILE DISCRIMINATION OF GRATING ROUGHNESS AND ORIENTATION IN PARKINSON'S DISEASE. K. Sathian\*, A. Zangaladze, J.L. Vitek & M.R. DeLong. Dept. of Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322.

Somatosensory abnormalities, both tactile and kinesthetic, have been reported in Parkinson's disease (PD) by Schneider et al. (Neurology, 37:951-6, 1988). We explored this issue further in a psychophysical investigation of tactile perception at the index fingerpad in patients with PD, who were candidates for or had undergone pallidotomy. We used gratings of alternating ridges and grooves, which have proven useful in characterizing tactile perception psychophysically and neurophysiologically (Sathian, *TINS*, 12:513-519, 1989).

Three tasks were used to assess discrimination thresholds, corresponding to 75% correct performance in two-alternative, forced-choice paradigms. One task measured spatial acuity as the groove width required to discriminate the orientation of gratings impressed into the immobilized fingerpad. In the other two tasks, subjects actively scanned gratings that differed in either groove or ridge width, and their ability to discriminate grating roughness was assessed. Patients with PD were impaired on all three tasks, relative to age-matched normal controls. Our results imply a general impairment of tactile perception in PD and provide impetus to investigation of its neural basis.

## 291.1

**LOCALIZATION OF A FINE-GRAINED CATEGORY OF SHAPE: AN EXTRASTRIATE LETTER AREA REVEALED BY fMRI.** M.J. Farah<sup>1</sup>, T.A. Polk<sup>1</sup>, M. Stallcup<sup>1</sup>, G.K. Aguirre<sup>2</sup>, D. Alson<sup>3</sup>, M. D'Esposito<sup>2</sup>, J. Deitre<sup>2\*</sup>, and E. Zarahn<sup>4</sup>. Depts. of Psychology<sup>1</sup>, Neurology<sup>2</sup>, Radiology<sup>3</sup>, and Neuroscience<sup>4</sup>, Univ. of Penn., Philadelphia, PA 19104.

The principle of localization of function has been extended within the visual system to include cortical areas dedicated to perceptual categories such as color, motion, and even face perception. Are finer category distinctions also localized, i.e. represented in segregated regions, or are they intermixed in a distributed manner within a system of coarse-grained localization? We used fMRI to study the degree to which shape representation is localized or distributed at the level of the categories letter, digit, and geometric shape (e.g. triangle, circle, star) in left occipitotemporal cortex.

Five normal right-handed subjects passively viewed two sets each of strings of letters, digits, geometric shapes and fixation points, each displayed for 150msec, one per second, in eight 40s blocks per run (1.5T, TR 2, 5" surface coil over left occipitotemporal cortex). Multiple runs per subject were collected (with the block order counterbalanced across runs) and data were analyzed using a variant of the general linear model for correlated observations proposed by Worsley & Friston (1995). Statistically significant segregation was observed in individual subjects. Letter-specific and shape-specific areas were observed in most subjects within the left occipitotemporal region under study ( $p < 0.05$ , corrected). No digit-specific areas were observed in any subjects in this region. Some areas were significantly activated by all three stimulus types compared with fixation ( $p < 0.05$ , corrected).

These results demonstrate that in some individuals there is segregation of cortical shape representation according to the category of shape, with letters being represented in areas that do not represent simple geometric shapes or even digits and geometric shapes being represented in areas that do not represent letters or digits. The fact that letters and digits cannot be distinguished by their visual features suggests that experience plays a role in establishing the segregation of letter processing.

## 291.3

**FLUENCY ASSOCIATED WITH SIZE OF BROCA'S AREA IN SCHIZOPHRENIA.** L.L. Phillips<sup>1</sup>, J.M. Kuldau<sup>2\*</sup>, E.R. Gautier<sup>3</sup>, P. Zuffante<sup>4</sup>, R.M. Bauer<sup>5</sup>, M.J. Beyer<sup>6</sup>, A.A. Mancuso<sup>7</sup> & C.M. Leonard<sup>8</sup>. Depts. of Neuroscience<sup>1</sup>, Psychiatry<sup>2</sup>, Health & Clinical Psychology<sup>3</sup> & Radiology<sup>4</sup>, University of Florida, Gainesville, FL 32610.

Previous studies have suggested an involvement of the frontal lobes in the deficits of verbal fluency and other cognitive abilities associated with schizophrenia. This study used magnetic resonance imaging to investigate the relationship of pars triangularis, a frontal lobe structure involved in the generation of speech, with measures of verbal fluency (FAS), phonemic awareness, IQ and the positive and negative symptoms (PANSS) of 26 male schizophrenic patients (mean age = 40.3). Other brain measures included the midsagittal area, right and left hemispheric widths, brain length, corpus callosum area and planum temporale surface. Analyses revealed no significant differences in any of the anatomical variables from those of 17 age and sex matched controls. As expected, the schizophrenic subjects had significant deficits on tests of phonemic awareness, fluency, and IQ. Only pars triangularis demonstrated a significant relationship with any of the cognitive variables. This relationship was indicated in two ways: (1) the surface area of the left pars triangularis decreased with declining verbal fluency in the schizophrenic patients ( $r = 0.53$ ,  $p < 0.02$ ); and (2) the right pars triangularis was positively correlated with positive symptoms. The absence of the expected fluency/Broca's area correlation in the controls may reflect their ability to distribute cognitive load over wide functional networks. Such flexibility may be impaired in the schizophrenic patients due to developmental neural errors in association cortex.

Supported by a RAGS grant from the VA Medical Research Service.

## 291.5

**FUNCTIONAL MAGNETIC RESONANCE IMAGING OF PHONOLOGICAL PROCESSING.** J.A. Frost, J.R. Binder, T.A. Hammeke, P.S. Bellgowan, J.A. Springer, R.E. Newby, R.W. Cox, S. Jaradeh<sup>\*</sup>. Medical College of Wisconsin, Milwaukee, WI 53226.

Functional magnetic resonance imaging was used to identify brain areas involved in phonological manipulation of speech sounds. Whole-brain imaging was performed on a 1.5T GE scanner using 3-axis gradient and insertable transmit/receive RF coils with a gradient echo echo-planar sequence (40 ms TE, 4 s TR, 24 cm FOV, 64 x 64 matrix, and 7 mm slice thickness). Ten healthy right-handed human subjects (5 female, 5 male) ages 16-30 were scanned during three auditory tasks. During the phoneme deletion task, subjects deleted /s/ and /t/ from non-words and blended the resulting non-word. In the phonetic discrimination control task, subjects detected occurrences of /s/ and /t/ in syllable sequences. During the phonological working memory control task, subjects detected repeat occurrences of non-words. Statistical parametric maps, thresholded at  $p < .0001$ , were generated showing t values for the deletion-discrimination and deletion-working memory comparisons.

Compared with the discrimination control task, the deletion task activated cortex on both banks of the intraparietal sulcus bilaterally, involving the medial supramarginal and angular gyri and the lateral superior parietal lobule. Other bilateral activation foci, more extensive on the right, were identified in the inferior frontal gyrus and the precentral sulcus, involving the pars opercularis and pars triangularis. The deletion task requires phonetic perception, working memory, and phoneme segmentation, deletion and blending. While the discrimination task controls for low-level phonetic perception, it does not place great demands on working memory. Therefore, some of the regions active in this comparison may be due to the working memory component of the deletion task.

When the deletion task was compared with the working memory control task, the main activation focus was in the left precentral sulcus extending into the pars opercularis and pars triangularis, suggesting that this region is critical for phonological processes involving segmentation, deletion, and blending.

## 291.2

**ABSTRACT, NOT VISUAL, ORTHOGRAPHIC KNOWLEDGE ENCODED IN EXTRASTRIATE CORTEX: AN fMRI STUDY.** T.A. Polk<sup>1</sup>, M. Stallcup<sup>1</sup>, G.K. Aguirre<sup>2</sup>, D. Alson<sup>3</sup>, M. D'Esposito<sup>2</sup>, J. Deitre<sup>2</sup>, E. Zarahn<sup>4</sup>, and M.J. Farah<sup>1\*</sup>. Depts. of Psychology<sup>1</sup>, Neurology<sup>2</sup>, Radiology<sup>3</sup>, and Neuroscience<sup>4</sup>, Univ. of Penn., Philadelphia, PA 19104.

In a previous PET study, Petersen et al. (*Science* 249:1041, 1990) found areas of left medial extrastriate visual cortex that were significantly more activated by passive viewing of words and pseudowords than consonant strings. Are these areas responding to the visual form of orthographically legal stimuli or to their abstract form—the specific sequence of abstract letters they contain, independent of their visual form (case, font, size, etc.)? These alternatives can be distinguished by the use of aLErNaTiNg case stimuli, which correspond to naturally occurring abstract, but not visual, word forms.

During an fMRI session, subjects passively viewed two sets each of concrete words, pronounceable pseudowords, consonant strings, and fixation points, each displayed for 150msec, one per second, in eight 40s blocks per run (1.5 T, TR 2, 5" surface coil over left temporal cortex). Multiple runs per subject were collected (with the block order counterbalanced across runs) and data were analyzed using a variant of the general linear model for correlated observations proposed by Worsley & Friston (*Neuroimage* 2:173, 1995). Left medial extrastriate visual areas were found to be significantly more activated by alternating case words and pseudowords than consonant strings in individual subjects ( $p < 0.05$ , corrected).

These results demonstrate that the so-called "word form" area in extrastriate cortex encodes abstract word forms based on orthographic regularities, rather than just the visual form of word-like stimuli.

**SPATIO-TEMPORAL BRAIN DYNAMICS OF AUDITORY LANGUAGE COMPREHENSION PROCESSES: COMPARISON BETWEEN POSITRON EMISSION TOMOGRAPHY AND ELECTRICAL EVENT-RELATED POTENTIAL MAPPING.** B. Doyon, G. Thierry, J.F. Démonet<sup>\*</sup>, INSERM 1455, Service de Neurologie, CHU PURPAN, 31059 TOULOUSE Cedex, France.

Démonet et al. (1), in a previous Positron Emission Tomography (PET) study described different patterns of brain activation associated with two monitoring tasks, a lexical semantic task using real words and a phonological task using consonant-vowel pseudo-words. The present study replicated the same cognitive experiment and compared PET findings with auditory event-related potentials (ERP) recorded over 32 channels, in twelve normal right-handed volunteers. The phoneme task consisted to discriminate between the successive occurrence of phonemes /d/ and /b/ in tetra-syllabic pseudo-words versus others configurations. The semantic task consisted to discriminate, in a list of adjective-noun pairs, the animals of small size preceded by an adjective bearing a 'positive' feature versus others configurations. Although the general shape of ERPs were similar in both tasks, the waves differed in time course. ERPs elicited by words occurring earlier than those associated with pseudo-words. This advance probably reflects fast and massively parallel mode of processing, for the lexical semantic task and serial, delayed processing for phonological analysis, both involving interconnected neural assemblies. The spatial distribution of such an advance observed throughout the scalp matched the pattern of regional cerebral blood flow (rCBF) changes observed between tasks in the PET study, and dipole analysis (BESA) confirmed this matching. Overall, across-task rCBF differences might reflect distinct modes of activation of a large-scale neural ensemble, differentially operated over time, rather than spatially segregated neural entities specialized for phonology or semantics.

## 291.6

**INTERACTIONS BETWEEN SEMANTIC PROCESSING AND RESPONSE MODE IN BRAIN ACTIVATION: DIFFERENCES IN FUNCTIONAL CONNECTIVITY.** J.M. Jennings<sup>\*</sup>, A.R. McIntosh, S. Kapur, E. Tulving, & S. Houle. Rotman Research Institute of Baycrest Centre; Clarke Institute of Psychiatry; University of Toronto; Toronto, ON, Canada, M6A 2E1.

We investigated the proposition that brain regions associated with semantic processing would be the same regardless of how subjects made a response. Subjects underwent 6 PET scans, in which they made semantic or lexical word judgments, responding "yes" or "no" in three different modes: mouse-clicking, spoken response, or silent thought. Analyses showed a significant increase in rCBF associated with semantic processing in the left inferior frontal cortex, the anterior cingulate, and the right cerebellum for all three response conditions. However, there was also a significant interaction: semantic processing was associated with greater rCBF to the left superior temporal gyrus in the mouse-click condition, the left medial frontal gyrus in the spoken response condition, and the right dorsolateral prefrontal cortex in the silent thought condition. To understand why the effects of semantic processing and response mode combined in this non-additive, interactive manner, we examined the functional connectivity between the common left inferior frontal region and the rest of the activated brain by calculating reference pixel correlations. This analysis revealed a different set of correlations for each response mode. For example, rCBF in the left medial frontal gyrus was strongly associated with rCBF in the left inferior frontal cortex for the spoken response condition but not the other response modes. We suggest that there is a core network associated with semantic processing, which is activated regardless of response mode, however, additional and distinct areas of the brain are recruited into this network depending on how subjects have to organize their responses. In short, cognitive and behavioral processes combine non-additively, a result which is best understood through the examination of neural interactions.

## 291.7

**IMPAIRED RETRIEVAL OF CONCEPTUAL AND LEXICAL KNOWLEDGE FOR ACTIONS FOLLOWING LEFT PREMOTOR/PREFRONTAL DAMAGE.** JA. Fiez<sup>2</sup>, D. Tranel, H. Damasio, AR. Damasio, Div. Cog. Neurosci., Dept. Neurology, Univ. of Iowa College of Medicine, Iowa City, IA 52242.

In a previous study, we reported that a subject with damage to the left premotor region had impaired retrieval of words for actions (verbs), but normal retrieval of words for concrete entities (nouns). To pursue this result, we developed a standardized Action Recognition and Naming Battery in normal subjects which can be used to measure the ability of brain-damaged subjects to retrieve both conceptual and lexical knowledge for actions. This standardized test battery was administered to 68 brain-damaged subjects selected from our Patient Registry. All had single, stable lesions in various sectors of the telencephalon.

In 10 subjects with left frontal lesions, we replicated our initial result regarding the association of action word retrieval failure with damage to the left frontal region. Neuroanatomical analysis in these subjects revealed that the lesions clustered in the inferior motor and premotor regions, with the maximal lesion overlap occurring in the inferior frontal gyrus and the inferior sector of the precentral gyrus (5 subjects). The overlap tapered both into more anterior prefrontal regions, and posteriorly into the supramarginal gyrus. In all 10 subjects, the defect in word retrieval was paralleled by defects in the retrieval of conceptual knowledge for actions. In other words, defects in the retrieval of conceptual and lexical knowledge tend to co-occur regularly with regard to actions, which contrasts with frequent dissociations we have obtained between these two capacities with regard to some concrete entities (e.g., animals). The findings suggest that as far as actions are concerned, the separation of neural systems dedicated to conceptual and lexical knowledge retrieval may be minimal.

## 291.9

**KNOWLEDGE ABOUT NATURAL KINDS AND ARTIFACTS: A PET STUDY OF LEXICAL ACCESS.** S.F. Cappa<sup>1</sup>, D. Perani, T. Schnur, F. Grassi, F. Fazio Universities of Milano and Brescia, INB CNR, S. Raffaele Scientific Institute, Milan, Italy.

The double dissociation between disorders of recognition of natural kinds and artifacts has been suggested to reflect a selective disruption of access to structural knowledge in the case of living stimuli, and of access to functional information for man-made tools. In a previous PET study, we found that the recognition of animal pictures was associated with bilateral inferior temporo-occipital cortex activation, while a significant activation of left dorsolateral frontal cortex was present with artifacts (Perani et al., Neuroreport 1995). In this PET experiment, we contrasted directly the access to structural and functional-associative knowledge related to natural kinds and artifacts from visual words. Twelve right handed male volunteers underwent 12 consecutive scans of the following six conditions, repeated twice: 1. Baseline; 2. Detection of the letter "e" in legal pseudowords; 3. Living, structural: decide whether the animal corresponding to the word presented on the screen had a long or short tail with respect to the body; 4. Living, associative: decide if the animal was typically found in Italy; 5. Artifact, structural: decide whether the object was longer-than-wider or vice-versa; 6. Artifact, associative: decide whether the object was typically used as a kitchen tool. Scans were obtained using a PET tomograph GE-Advance (General Electric Medical System, Milwaukee, WI). Image manipulations and statistical analysis were performed using statistical parametric mapping (SPM-95, MRC Cyclotron Unit, London, UK). While letter detection in pseudowords was associated with an extensive bilateral activation of occipital and parietal areas, access to semantic knowledge engaged extensively the left dorsolateral and medial frontal cortex, and the posterior cingulus. Furthermore, access to structural knowledge was associated with significant bilateral activation in the inferior parietal and inferior temporal lobe. Whereas access to associative knowledge activated right fusiform gyri and posterior cingulus bilaterally. Significant differences were also present according to semantic category: right lateral occipital for natural kinds, left medial occipital for artifacts. The present findings are in agreement with the clinical evidence for both category and modality effects in semantic memory disorders. *Sources of funding:* C.N.R., Italy; HFSP.

## 291.11

**CORTICAL ORGANIZATION FOR LANGUAGE IN NATIVE DEAF AND HEARING SIGNERS. Part II: WRITTEN ENGLISH.** D. Bavelier<sup>1</sup>, D. Corina<sup>2</sup>, P. Jezzard<sup>3</sup>, V. Clark<sup>3</sup>, A. Braun<sup>4</sup>, R. Turner<sup>5</sup>, H. Neville<sup>6</sup>, Georgetown U., Washington DC<sup>1</sup>; UWashington, Seattle WA<sup>2</sup>; NIMH<sup>3</sup> & NIDCD<sup>4</sup>, Bethesda MD; Inst. Neurol., London UK<sup>5</sup>; UOregon, Eugene OR<sup>6</sup>.

In our companion abstract (see, Corina et al.), we described the cortical organization for ASL in native signers. In the present study, the role of the language modality is further assessed by examining the same subjects as they processed another visually presented language, written English. Ss were scanned while reading English sentences that alternated with consonant strings. Eight monolingual native English speakers (HG) were also included.

When processing English both HG and HOD Ss displayed a left lateralized pattern of activation including the classical language areas in the prefrontal cortex (Broca and DLPFC), the left STS and left angular gyrus. The same HOD Ss when tested on ASL (see Part I) displayed a clear bilateral pattern of activation. Thus, the increased right hemisphere activation during the processing of ASL cannot be attributed simply to the sensory modality through which language is perceived.

In contrast to the results for HG Ss and HOD Ss, deaf subjects when reading English showed a bilateral pattern of activation, with a tendency for a larger activation in the right posterior STS and right angular gyrus. Future research will need to determine the contributions of various factors to this pattern of results, including increased reliance on the visual features of English, delayed learning of English or the unique experience of acquiring solely a visual language as a natural language. (Part I and Part II supported by NINDS DC00128 and the McDonnell-Pew Foundation)

## 291.8

**NEURAL CORRELATES OF LEXICAL ACCESS AS SHOWN BY fMRI.** M. Kroll, S. Kremen, B. Soher, R.N. Bryan, B. Gordon, and J. Hart, Jr.\* Depts. of Neurology, Radiology, Biomedical Engineering, Cognitive Science and the Zanvyl Krieger Mind/Brain Institute, The Johns Hopkins University, Baltimore, MD 21287.

We have used functional magnetic resonance imaging (fMRI) to help determine what cortical regions are activated during visual processing of letter strings to determine their lexicality.

We studied 9 normal young adults, 6 men and 3 women, using a behavioral paradigm with a baseline condition of visual detection and an activated condition of word/nonword lexical decision. fMRI data were gathered using 10 mm thick coronally oriented sections ranging from the occipital pole to the temporal pole. Scanning parameters were TR/TE/α=60/60/40°. Regions of activation in each section were detected by cross correlation analysis (Bandettini et al., J. Magn. Res. Med. 30:161, 1993), and were superimposed upon collocated T1 weighted anatomic images.

Eight of nine subjects studied exhibited significant signal changes. 6/8 showed changes in the inferior occipitotemporal gyri bilaterally, 8/8 in inferior parietal lobe (5 bilateral, 3 left only) and 7/8 in the superior temporal gyrus (2 bilateral, 5 left only). There was activation in the superior parietal lobule and middle and inferior temporal gyri on a less consistent basis.

These data strongly suggest that lexical processing engages a network of discrete cortical regions. The patterns of signal change indicate bilateral activation of the ventral occipitotemporal region—presumably in an early stage of visual processing and not necessarily specific to lexicality. Signal changes in the left inferior parietal and superior temporal regions likely reflect processes that are engaged in lexical judgments.

## 291.10

**CORTICAL ORGANIZATION FOR LANGUAGE IN NATIVE DEAF AND HEARING SIGNERS. Part I: AMERICAN SIGN LANGUAGE.** D. Corina<sup>1</sup>, D. Bavelier<sup>2</sup>, P. Jezzard<sup>3</sup>, J. Rauschecker<sup>2</sup>, A. Braun<sup>4</sup>, R. Turner<sup>5</sup>, H. Neville<sup>6</sup>, UWashington, Seattle WA<sup>1</sup>; Georgetown U., Washington DC<sup>2</sup>; NIMH<sup>3</sup> & NIDCD<sup>4</sup>, Bethesda MD; Inst. Neurol., London UK<sup>5</sup>; UOregon, Eugene OR<sup>6</sup>.

The study of the cortical organization for ASL in two groups of native signers, deaf (D) and hearing (HOD), provides an opportunity to determine the contributions of language modality and sensory experience in cortical organization for language. Changes in blood oxygenation/flow level (MR imaging at 4T: 8 sagittal slices (5 mm), gradient echo MBEST, 64x64, TR=400ms, TE=28ms, FOV=16cm) were recorded while 12 genetically, congenitally deaf subjects and 10 hearing subjects born to deaf parents viewed filmed ASL sentences alternating with nonsigns formally similar to ASL signs.

Processing ASL in D Ss led to a bilateral pattern of activation. Left prefrontal regions (Broca and DLPFC) and left posterior temporal areas classically associated with language were also robustly active in the right hemisphere. Surprisingly, activation along the superior temporal sulcus (STS) was more robust in the right than in the left hemisphere. In addition, whereas the left angular gyrus (AG) usually recruited during reading was not active, the right AG was active. Finally, no activation was observed in the supramarginal gyrus, an area linked to spoken language comprehension.

This pattern of activation contrast with standard views on the neurobiology of language. To determine whether this reorganization reflects the visuo-spatial processing demands of ASL or the unique sensory experience of deaf subjects, HOD Ss were run in the same paradigm. As in D Ss, HOD Ss displayed a bilateral pattern of activation. However, comparison of these groups show subtle differences in superior temporal and parietal activation which may be attributed to differences in sensory/language experience.

## 292.1

**NMDA RECEPTOR ANCHORING TO ACTIN CYTOSKELETON MEDIATED BY  $\alpha$ -ACTININ IN DENDRITIC SPINES.** M. Wyszynski\*, A.H. Beggs, A. Rao, A.M. Craig, E. Nigh, and M. Sheng. Howard Hughes Medical Institute and Dept. of Neurobiology, Mass General Hospital and Harvard Medical School, Boston, MA 02114; Dept of Medicine, Childrens Hospital, Boston, MA. 02115; Dept of Cell and Structural Biology, University of Illinois, Urbana, IL 61801.

The NMDA receptor subclass of glutamate-gated cation channels is implicated in mechanisms of activity-dependent plasticity and excitotoxicity. NMDA receptors are clustered at postsynaptic sites in neurons, and their activity shows mechanosensitivity and dependence on integrity of the actin cytoskeleton. In this study,  $\alpha$ -actinin2 is identified as a brain postsynaptic density protein which colocalizes with NMDA receptors in dendritic spines, and which specifically binds via its central rod domain to the C-terminal cytoplasmic tail of the NMDA receptor subunit NR1.  $\alpha$ -actinins belong to the spectrin/dystrophin superfamily of actin binding proteins, and actin is a major component of dendritic spines, thus this interaction could mediate NMDA receptor anchoring to the postsynaptic actin cytoskeleton. The NR2 subunits of NMDA receptors are known to bind the postsynaptic density protein PSD-95. The interaction between  $\alpha$ -actinin and NR1 signifies therefore that different subunits of the heteromeric NMDA receptor interact with distinct sets of intracellular proteins to mediate NMDA receptor connections to cytoskeleton and intracellular signaling molecules. (Supported by National Research Service Award CA66268-02 (M.W.), the Charles H. Hood Foundation (A.H.B.), the Lucille P. Markey Charitable Trust and NIH grant NS33184 (A.M.C). M.S. is an assistant investigator of the Howard Hughes Medical Institute.)

## 292.3

**A MUTATED RESIDUE IN THE M3-M4 LINKER OF THE NMDA RECEPTOR FILLS THE GLYCINE BINDING POCKET.** M.W. Wood, H.M.A. Vandongen, K.S. Jones, and A.M.J. VanDongen. Department of Pharmacology, Duke University Medical Center, Durham, NC 27710.

One property distinguishing the NMDA receptor from other ionotropic glutamate receptors is its requirement for the co-agonist glycine. A recent topology model of ionotropic glutamate receptors includes a hairpin pore structure similar to that found in voltage-gated K<sup>+</sup> channels. The model places the region linking the third and fourth putative transmembrane domains (TM3 and TM4) in the extracellular space. This conclusion is incompatible with studies describing functional phosphorylation sites in the M3-M4 linker of non-NMDA glutamate receptors. We engineered a canonical consensus site for protein kinase A (PKA) into the M3-M4 linker of the NR1 subunit of the NMDA receptor at a position analogous to a functional PKA site described for GluR6. The mutation resulted in a decrease in the apparent affinity for the co-agonist glycine by two orders of magnitude. Ablation of the serine residue within the artificial PKA site further decreased the glycine affinity, eliminating the possibility that the phenotype arose from phosphorylation of this site. Point mutations of the residues comprising the PKA site implicate a single position as the dominant residue affecting glycine affinity (Ala714 to Leu). Reversion of this residue within the artificial PKA site restores most of the affinity. Additional mutations at position 714 also vary glycine affinity. The side chain volume of residues at this position correlates with the resulting affinity. An engineered N-linked glycosylation site at position 711 maps this region to the extracellular space. Mutation of position 714 to a cysteine increases the receptor's sensitivity to a thiol selective reagent, supporting extracellular localization. This series of experiments supports the three transmembrane topology model for the NMDA receptor and implicates alanine 714 as a residue within the binding pocket for the co-agonist glycine.

## 292.5

**LOCALIZATION OF NMDAR-ASSOCIATED PROTEINS IN CULTURED HIPPOCAMPAL NEURONS** <sup>1</sup>A. Rao\*, <sup>2</sup>E. Kim, <sup>2</sup>M. Wyszynski, <sup>2</sup>M. Sheng and <sup>1</sup>A.M. Craig. <sup>1</sup>Dept. Cell and Structural Biology, University of Illinois, Urbana, IL 61801 and <sup>2</sup>HIMI and Dept. Neurobiol., MGH and Harvard Med. School, Boston, MA 02114.

Several proteins that interact with the NMDA receptor have recently been identified using the yeast two-hybrid system (Kornau et al., 1995, Science, 269:1737-1740; Niethammer et al., 1996, J. Neurosci. 16:2157-2163). Amongst these, the related proteins PSD-95 and chapsyn-110 bind the NR2 subunit of the NMDA receptor, while the actin-binding protein  $\alpha$ -actinin binds the NR1 subunit. We describe here the subcellular localization and developmental profile of these three proteins in cultured embryonic rat hippocampal neurons as determined by immunocytochemistry. In mature cultures, all three proteins were concentrated at excitatory glutamatergic synapses, colocalized with clusters of GluR1 or NR1. None of these proteins were present at inhibitory synapses containing GABA receptor clusters. PSD-95 and chapsyn-110 clusters were observed at essentially all GluR1- or NR1-containing synapses. In contrast,  $\alpha$ -actinin colocalized with GluR1 and NR1 at excitatory spiny synapses on pyramidal cells but not at excitatory shaft synapses on GABA cells.  $\alpha$ -Actinin, therefore, is not necessary for clustering of GluR1 or NR1 on dendritic shafts, but may have a role in the formation of spiny excitatory synapses. Consistent with this idea,  $\alpha$ -actinin was concentrated at spiny synapses as soon as they could be detected during development of the neurons in culture. PSD-95 and chapsyn-110 were present at both spiny and shaft GluR1 and NR1 clusters from early times in development, consistent with a role for these two proteins in formation of excitatory synapses. Supported by NIH and the Markey Charitable Trust.

**SUB- AND MAIN CONDUCTANCE STATES OF A MUTANT NMDA-CHANNEL HAVE DIFFERENT MONOVALENT CATION SELECTIVITIES.** R. Schneggenburger\* and P. Ascher. Neurobiologie, Ecole Normale Supérieure, 75005 Paris, France.

There are numerous examples of ion channels with multiple conductance states, and it has generally been assumed that the different states have a similar ionic selectivity. We have obtained data indicating that this assumption may not hold in all cases. Recordings of NMDA-induced whole-cell currents were made in HEK cells expressing a mutant NMDA-channel, NR1(N598Q)-NR2A. Under bionic conditions (150 mM Cs<sup>+</sup> inside, 150 mM Na<sup>+</sup> outside or vice versa), pronounced current noise was observed at the apparent reversal potential. This phenomenon was absent in symmetrical Na<sup>+</sup> solutions, indicating that NMDA might activate two conductances with different ionic selectivities.

In outside-out patches (2  $\mu$ M [Ca]<sub>o</sub>) from oocytes expressing the mutant NMDA-channels, NMDA induced openings to a sub- and a main conductance level. In symmetrical 150 mM Cs<sup>+</sup>-solutions the slope conductances were  $\approx$  50 pS and  $\approx$  100 pS and the two reversal potentials were close (within  $\leq$  2 mV) to 0 mV. However, in bionic conditions, the reversal potential of the sub level shifted to  $\approx$  +15 mV (Cs<sup>+</sup> inside, Na<sup>+</sup> outside) or to  $\approx$  -15 mV (Na<sup>+</sup> inside, Cs<sup>+</sup> outside), whereas the reversal potential of the main conductance level remained close to 0 mV. Thus, while the permeability ratio P<sub>Na</sub>/P<sub>Cs</sub> is  $\approx$  1 for the main conductance level, it is  $\approx$  1.8 for the pore of the subconductance level. **UPREGULATION OF AMPA RECEPTOR SUBUNIT GLUR2 FLOP MRNA DURING CEREBELLAR GRANULE CELL MATURATION IN VITRO COINCIDES WITH THE APPEARANCE OF AMPA NEUROTOXICITY.**

P. Longone\*, F. Impagnatiello, E. Costa and A. Guidotti. The Psychiatric Institute, Department of Psychiatry, University of Illinois at Chicago, Chicago, IL 60612.

The neurotoxic response of cerebellar granule neurons to the application of AMPA (50  $\mu$ M) in the presence of cyclothiazide (10  $\mu$ M) increases from 2 days *in vitro* (DIV), when it is almost absent, to 6 DIV, when it becomes approximately 100%. We examined whether the increased susceptibility to the neurotoxic effect of AMPA is related to changes in the expression of AMPA GluR2 flip/flop splice variant mRNAs. The mRNAs were measured by competitive RT-polymerase chain reaction (RT-PCR). Primer sequences were chosen to amplify the flip/flop splice region of this subunit. The primer set was demonstrated to amplify the correct size mRNA fragment. Total RNA was reverse transcribed and co-amplified with the internal standard which utilizes the primers for the canonic sequence, except for an internal restriction site (BglII) created by site-directed mutagenesis. To determine the amount of the GluR2 flip and flop mRNA forms, the resulting amplification product was cut with a restriction enzyme specific for each of the two splice forms (Aval R2 flip, StuI R2 flop). The mRNA content of GluR2 at 2 DIV (flip+flop: 13 $\pm$ 1.7 attomol/ $\mu$ g RNA; n=3) increased by  $\approx$  2-fold at 6 DIV. The flip/flop ratio shifted from 2.5 at 2 DIV to 0.3 at 6 DIV. Thus, whereas the flip variant of GluR2 mRNA content does not change significantly, the flop variant increases dramatically (about 5-fold) from 2 to 6 DIV. Our results agree with the view that the upregulation of AMPA receptor subunit GluR2 mRNA expression and the shift in its splice variant flip/flop ratio may participate in the increased neurotoxic susceptibility of cerebellar granule cells to AMPA. To examine whether in addition to changes in AMPA subunit GluR2 flip/flop mRNAs, the other AMPA receptor subunit mRNAs undergo similar modifications, we have constructed the appropriate primers and internal standard for quantitative RT-PCR analysis of GluR1, 3, and 4 flip/flop mRNA subunit expression. The regulation of their expression during culture maturation is now under investigation. NS 2813 0-06.

**RESCUE OF NMDAR1 KNOCK OUT MICE USING TRANSGENIC MOUSE TECHNOLOGY.** T. Iwasato, D. F. Chen, T. Sasaoka\*, S. Tonegawa. Center for Learning and Memory, MIT, Cambridge MA 02139

Gene disruption of the key subunit of the NMDA receptor (NMDAR1) results in neonatal lethality, which has limited the use of the knock out mouse technology in investigation of the role of the NMDA receptor in the process of neural development and synaptic plasticity. To rescue the lethality of NMDAR1 knock out mice, we have generated several lines of transgenic mice using constructs carrying NMDAR1 cDNA under the control of a constitutive promoter or a putative NR2D promoter. They were crossed with NMDAR1 heterozygous mice (NR1<sup>+/+</sup>) to generate transgenic-homozygous mutant mice (NR1<sup>-/-</sup>,tg). We have focused on two lines of transgenic mice. One of them (tgA) carries NMDAR1 cDNA under the control of a constitutive promoter and expresses transgene in every tissue including brain. About half of the NR1<sup>-/-</sup>,tgA mice could survive to the adult stage. The rescued NR1<sup>-/-</sup>,tgA mice are slightly smaller and breed less efficiently than other littermates. The general anatomical structure of brain appeared normal. Whisker related patterns were shown to be restored in the level of brainstem, thalamus, and cortex. The other line of transgenic mice (tgB) carries NMDAR1 cDNA under control of a putative NMDAR2D promoter. However, we found it expressed the transgene in the cortex in addition to the subcortical region, probably because of the positional effect of the integration site of the transgene. About 20% of NR1<sup>-/-</sup>,tgB mice could survive much longer than knock out mice (NR1<sup>-/-</sup>), though almost all died at or before weaning time. These rescued NR1<sup>-/-</sup>,tgB mice were smaller in size than other littermates. Like NR<sup>-/-</sup>,tgA mice, the general anatomical structure of brain appeared normal. In contrast, these mice did not have the whisker related patterns in the levels of principal nucleus of brainstem, thalamus or cortex. These two mice (NR1<sup>-/-</sup>,tgA and NR1<sup>-/-</sup>,tgB) should be useful to study the mechanisms of the activity-dependent refinement process in the developing central nervous system.

## 292.7

GENERATION OF TRANSGENIC MICE EXPRESSING AN EMBRYONIC SUBUNIT OF THE NMDA RECEPTOR IN THE POSTNATAL FOREBRAIN. S. Okabe<sup>1</sup>, C. Collin<sup>2</sup>, N. Meiri<sup>3</sup>, J. Bengzon<sup>4</sup>, M. B. Kennedy<sup>5</sup>, M. Segal<sup>6</sup>, and R. D. G. McKay<sup>1</sup>. LMB and LAS<sup>1</sup>, NINDS/NIH, Bethesda, MD 20892, <sup>2</sup>Div. of Biology, California Inst. of Tech., Pasadena, CA 91125, <sup>3</sup>Weizmann Inst., 76100, Israel.

To test the effects of expressing an embryonic NR2 subunit in mature forebrain neurons, we created mice carrying NR2D gene under the control of the promoter of the  $\alpha$  subunit of the Ca<sup>2+</sup>/calmodulin-dependent protein kinase (CaMKII $\alpha$ ). Transgene-derived transcripts were abundant in adult cortex, hippocampus, and striatum. Western blotting of transgenic hippocampus showed that transgene-derived NR2D protein amount increased significantly from postnatal 2 to 8 weeks, and remained stable thereafter. Histological examination revealed no gross anatomical abnormality, which is consistent with the postnatal up-regulation of the transgene. Adult (8-17-week-old) transgenic mice expressed large amount of NR2D with a concomitant reduction of NR2B and autoactive CaMKII. Juvenile (3-week-old) transgenic mice had moderate expression of NR2D protein and the NR2B and autoactive CaMKII amount was normal. The age-dependent shift of NMDA receptor composition and modulation of post-synaptic kinase activity were correlated with the change of synaptic plasticity in hippocampus, which will be presented in the accompanying paper (C. Collin et al.).

TRANSMEMBRANE TOPOLOGY OF THE NMDA RECEPTOR SUBUNIT NR1: THE M3-M4 LOOP REGION IS EXTRACELLULAR AND PARTICIPATES IN GLYCINE BINDING. J. Kuhse, H. Hirai, J. Kirsch, B. Laube, U. Ernsberger<sup>\*</sup> and H. Betz. Max-Planck-Institute für Hirnforschung, Deutschordenstr. 46, 60528 Frankfurt/Main, Federal Republic of Germany.

The N-methyl-D-aspartate (NMDA) subtype of ionotropic glutamate receptors is a hetero-oligomeric membrane protein composed of homologous subunits. Here, we investigated the transmembrane topology of the ligand-binding NR1 subunit of recombinant NR1/NR2B receptors and the contribution of its M3-M4 loop to ligand binding. The cellular localization of epitope-tags engineered into the NR1 protein was analyzed by confocal laser scanning microscopy after heterologous expression in a human cell line. Epitopes in the N-terminus and the putative M3-M4 loop were found to be exposed extracellularly, whereas a C-terminal epitope was localized intracellularly. Substitution of aromatic residues at positions 735 or 736 of the M3-M4 loop produced a 15 to 30-fold reduction in apparent glycine affinity without affecting the binding of glutamate and the competitive glycine antagonist 7-chlorokynurenic acid; mutation of both residues caused a >100-fold decrease in glycine affinity. These results substantiate an extracellular location of the M3-M4 loop of the NR1 subunit and provide the basis for modelling the glycine binding pocket of the NMDA receptor.

IMPAIRED MOTOR PERFORMANCE AND CEREBELLAR SYNAPTIC PLASTICITY IN MICE LACKING THE mGluR4 SUBTYPE OF METABOTROPIC GLUTAMATE RECEPTOR. R. Pekhietki<sup>1</sup>, R. Gerlai<sup>2</sup>, L.S. Overstreet<sup>3</sup>, X.-P. Huang<sup>4</sup>, N. Agonyan<sup>5</sup>, N.T. Slater<sup>6</sup>, W. Abramow-Newerly<sup>7</sup>, J.C. Roder<sup>8</sup>, and D.R. Hampson<sup>1</sup>. <sup>1</sup>Faculty of Pharmacy, Univ. of Toronto, Toronto, Canada. <sup>2</sup>Samuel Lunenfeld Res. Inst. & Depart. of Med. Genetics, Univ. of Toronto, Toronto, Canada. <sup>3</sup>Depart. of Physiol. & the Northwestern Univ. Inst. of Neurosci., Northwestern Univ. Med. School, Chicago, USA.

The glutamate analog, L-2-amino-4-phosphobutyric acid (L-AP4) is a selective ligand at a subset of metabotropic glutamate receptors (mGluRs). Although previous studies have suggested that receptors for L-AP4 may be involved in the regulation of glutamate release, the function of these receptors in the brain remains largely unknown. To provide a better understanding of the biological role of L-AP4 receptors, we have generated and studied knockout mice (KO) lacking the mGluR4 subtype of mGluR.

The mGluR4 mutant mice displayed normal spontaneous motor activity in the open field test and no impairment on the bar cross test suggesting that disruption of the mGluR4 gene does not cause gross motor abnormalities, impairments of novelty-induced exploratory behaviours, or alterations of fine motor coordination. In contrast, the mutant mice were significantly impaired compared to their wild type littermates on the rotating rod motor learning test, suggesting that the mGluR4 KO mice may have a decreased ability to learn this motor task.

Patch-clamp recordings from Purkinje cells in cerebellar slices demonstrated that, unlike wild type littermates, the mutant mice were insensitive to the suppressant effects of L-AP4 on synaptic transmission. This was accompanied by significant impairments in measures of presynaptic short-term synaptic plasticity including a reduction in paired-pulse facilitation and post-tetanic potentiation. These findings indicate that an important function of mGluR4 is to provide a presynaptic mechanism for maintaining synaptic efficacy during repetitive activation by limiting exhaustion of synaptic vesicle stores. This work was supported by the MRC, Canada and the NIH, USA.

## 292.8

ALTERED HIPPOCAMPAL PLASTICITY BUT UNIMPAIRED SPATIAL LEARNING IN TRANSGENIC MICE OVEREXPRESSING NR2D RECEPTORS. C. Collin<sup>1</sup>, S. Okabe<sup>1</sup>, N. Meiri<sup>2</sup>, M. B. Kennedy<sup>3</sup>, M. Segal<sup>4</sup>, and R. D. G. McKay<sup>1</sup>. <sup>1</sup>LMB, <sup>2</sup>LAS, NINDS/NIH, Bethesda MD, 20892; <sup>3</sup>CALTECH, Pasadena, CA 91125; <sup>4</sup>The Weizmann Institute, Rehovot 76100, Israel.

Behavioral and electrophysiological plasticity were assessed in transgenic mice overexpressing the NR2D subunit of the NMDA receptor (see Okabe et al.). Two transgenic (Tg) lines expressed significantly different patterns of exploratory activity in an open field compared to control mice; they moved less and crossed the center of the field less than controls. These differences were not caused by a motor impairment, as all groups behaved the same on a rotary rod. Also, there were no differences between the controls and the transgenic mice in acquisition and retention of spatial memory in a water maze. Slices of hippocampus of 3 week (juvenile) and 2-3 months (adult) control and Tg mice were recorded in an interface chamber at 30°C, using extracellular electrodes. Field EPSPs from stratum radiatum were not different between control and Tg slices. Tetanic stimulation (100Hz for 1 sec) produced a smaller long term potentiation (LTP) in Tg (18±8% above baseline) than in control (55±7% above baseline) adult slices. By contrast, juvenile slices of Tg's and controls expressed similarly sustained LTP. Depotentiation was induced in both adult and juvenile slices by stimulation at a rate of 1 Hz for 10 minutes, 30 minutes after the LTP evoking tetanus. Only the control slices of both age groups expressed marked depotentiation. Furthermore, in non-tetanzed, juvenile slices long term depression (LTD) can be evoked by 1-5 Hz stimulation. LTD was seen only in the control and not in the Tg slices. The Tg slices were able to express non-NMDA mediated LTP, evoked by a 200Hz stimulation in presence of an NMDA antagonist, 2-APV. These studies indicate that NR2D overexpressing mice are deficient in NMDA-mediated LTP and LTD, but express normal cognitive behavior.

THE ROLE OF N-TERMINAL RESIDUES OF NR2B IN THE MODULATION OF NMDA RECEPTORS. Gallagher, M.J., Huang, H., and Lynch, D.R., Department of Pharmacology and Pediatrics, University of Pennsylvania, Children's Seashore House, Philadelphia, PA 19104-4318

There are several compounds which modulate the NMDA receptor in a subunit specific manner. The drugs ifenprodil and haloperidol, and the endogenous polyamine spermidine all exert preferences for receptors containing NR2B over NR2A. We have determined using chimeric NR2A/NR2B subunits and site-specific mutants that two residues of NR2B (E201 and R337) are directly involved in the modulation of NMDA receptors. Glycine-independent spermidine stimulation and haloperidol high affinity inhibition of NMDA receptors are both affected by mutation of E201. Replacing E201 with the negatively charged aspartate (E201D) caused only moderate reduction in polyamine stimulation, while mutation to the positively charged arginine (E201R) eliminated polyamine stimulation. None of the mutations of E201 caused any change in affinity for ifenprodil, which provides additional evidence that ifenprodil and polyamines interact at distinct sites on the NR2B subunit. Mutation of another residue Arginine 337, previously shown to be crucial for ifenprodil inhibition, has no effect on either haloperidol inhibition or polyamine stimulation, demonstrating the ifenprodil specificity of this residue. We have also mutated the corresponding residues of NR2A (N200 and Q336) in an effort to confer NR2B specific properties to the NR2A subunit. The receptor NR1A/Q336(NR2A) exhibited 3-5 fold greater apparent ifenprodil affinity than native NR2A containing receptors. The mutant N200E(NR2A) showed significant polyamine stimulation, while haloperidol inhibition was not improved. ## 292.12

A TETRAMERIC SUBUNIT STOICHIOMETRY FOR A GLUTAMATE RECEPTOR/CHANNEL COMPLEX

I. Mano and Y. J. Teichberg<sup>\*</sup>

Department of Neurobiology, the Weizmann Institute of Science, Rehovot 76100, Israel.

Until recently, the glutamate receptors (GluRs), as other ligand-gated channels, were thought to form pentameric structures assembled from subunits, each having four transmembrane segments. However, as evidence has been presented that GluRs harbor only three transmembrane segments in addition to a potassium-channel-like P-loop segment, the generally accepted view that the GluR channel complexes are made of five subunits was here questioned. We study the properties of the wild-type (WT) GluR1 subunit of the  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA) receptors coexpressed in *Xenopus* oocytes with the L646A GluR1 mutant, which present identical levels of expression and apparent affinity to KA, exhibits the same current-voltage relation, and its ability to form heterocomplexes with another AMPA receptor subunit - GluR2 - is indistinguishable from that of the WT GluR1. However, this mutant remarkably differs from the WT in its ~100 fold reduced sensitivity to co-application of the desensitizing agonist Quisqualate (QA). Comparing the contribution of WT-like receptors to the mixed response we show that desensitization of a kainate (KA) - activated channel complex requires the interaction of QA with only one subunit. Using the analysis developed by MacKinnon to determine channel stoichiometry, we provide now evidence suggesting that homomeric GluR1 channel complexes have a tetrameric structure. Thus, the GluR pore structure and subunit stoichiometry present the hallmark of voltage-gated channels.

## 293.1

**PSI EXPRESSION IN PLATELETS AND NEURAL CELL LINES.** R. Vidal and B. Frangione\*. Dept. Pathology, New York University Medical Center, New York, NY 10016  
 Alzheimer's  $\beta$  protein ( $A\beta$ ) circulates as a complex preferentially with apoJ, a carrier for  $A\beta$  in both plasma and CSF. Platelets are the main source of soluble  $\beta$  protein precursor (BPP) or Nectin II. BPP as well as apoJ are stored in platelet's  $\alpha$ -granules and are released into extracellular fluid following activation. Carboxyl end immunoreactivity of the presenilin 1 (PS1) protein, (to which most cases of early-onset FAD are linked), has been reported in senile plaques of familial and sporadic AD. We studied PS1 expression in platelets, megakaryocytes and neural cell lines by RT-PCR. PCR products were characterized by restriction enzyme analysis and DNA sequencing and the purity of platelet's RNA was estimate after RT-PCR for the beta chain gene of HLA-DR (marker of mononuclear cells). PS1 transcripts were found to be present in all samples analyzed, with full-length PS1 as the predominant isoform. Transcripts with and without the VRSQ sequence (exon 3) were observed in almost equimolecular amounts. Alternative splicing of exon 8 (a possible hotspot for PS1 mutations) resulting in a shorter isoform more prominent in leukocytes, was observed to constitute a very low percentage of PS1 transcripts. Similar results were obtained using RNA isolated from human neuroblastoma cell lines (SHSY5Y and NT-2) and cells of the thrombocytic lineage. We also found a novel splice variant that results in the loss of exon 10 (codons 319-376). Loss of this exon does not alter the reading frame of the PS1 molecule. The significant of this new variant is difficult to predict without knowledge of the PS1 function. Expression of PS1 was assessed by immunoblotting analysis using a polyclonal anti-N terminus PS1 antibody, recognizing mainly a 44/50 kDa band in neuroblastoma and megakaryocytic cell lines. The relationship of presenilin mutations to the amyloidogenesis of AD is unclear. As with BPP, the expression of PS1 is not limited to regions of the brain affected by the neuropathological changes observed in AD. The analysis of the expression of presenilins should be considered as a step towards the understanding of their physiological function and their role in AD.

**S182 / PRESENILIN-1 PROTEIN AND mRNA IN AD**  
 D. Schemmel, EG Stopa, BS Rubin, V Kuo-Leblanc, PC Song, JC King, K Boteva, N Mitsuda, JR Gilbert and MP Vittek\*  
 Bryan Alzheimer's Disease Research Center, Duke Univ. Med. Ctr., Durham, NC; Dept. Anatomy and Cell Biol., Tufts Univ. Sch. of Med., Boston, MA; Dept. Pathology, Brown Univ. Sch. of Med., Providence, RI; GlaxoWellcome Res. Inst., Res. Trian. Park, NC 27709

Some early onset familial Alzheimer's disease is associated with mutations of the S182 or Presenilin-1 gene located on chromosome 14 and of the homologous STM2 or Presenilin-2 gene located on chromosome 1. As little is known about the function or location of either gene's products, we probed their distribution in human brains. In the present study, 8 micron sections taken from 10 different brain areas (2-8 hrs PMI) of 7 AD and 5 age-matched controls were immunohistochemically stained with specific antibodies to Presenilin protein. *In situ* hybridization with a cRNA probe specific for PS-1 was performed on these same sections.

In all cases, neuronal staining was prominent where PS-protein immunoreactivity displayed a perinuclear distribution. Some immunoreactivity was also associated with senile plaques. The *in-situ* hybridization signal was present in most neurons throughout the 10 brain regions examined. In AD patients, this signal was clearly reduced as a function of neuronal loss. A consistent finding in both AD and control cases was the increased staining for PS-1 mRNA in the CA2 region of the hippocampus when compared to CA1 and CA3.

Our data indicate that PS-1 protein and mRNA are widely expressed in neurons throughout the brain and that gene expression may be reduced in sporadic Alzheimer's disease. Supported by AG 10682, AG 05128, AG 12851.

## 293.5

**PROTEOLYTIC PROCESSING AND UBIQUITIN-DEPENDENT DEGRADATION OF ALZHEIMER-ASSOCIATED PRESENILIN 1 AND 2.** T.-W. Kim\*, R. D. Moir, W. P. Pettingell, O. G. Hallmark, D. M. Kovacs, W. Wasco, R. E. Tanzi. Genetics and Aging Unit, Massachusetts General Hospital, Harvard Medical School, MA 02129.

The presenilin genes (PS1 and PS2) appear to be responsible for the majority of early onset familial Alzheimer's disease (FAD). The biological roles of the presenilins and how their pathogenic mutations confer FAD are unknown. In this study, we set out to examine the processing and degradation pathways of PS1 and PS2. For regulated expression of PS2, we have established inducible cell lines expressing either wild-type or mutant forms of PS2 under the tight control of the tetracycline-responsive transactivator. Western blot analysis revealed that FLAG epitope-tagged PS2 was detected as a 53-55 kDa as well as high molecular weight forms. We have found that 55 kDa PS2 is proteolytically processed into two stable cellular polypeptides including a 35 kDa N-terminal fragment and a 20 kDa C-terminal fragment which was localized to the detergent-insoluble cellular fraction (e.g. cytoskeleton). PS2 was found to be polyubiquitinated *in vivo*; an inhibitor of the 26S proteasome complex led to the accumulation of polyubiquitinated forms of PS2. Interestingly, in cells expressing PS2 with the Volga/German FAD mutation (N141I), the 20 kDa fragment accumulated at higher concentrations than in cells expressing wild-type PS2. Similar to that found for PS2, 45-50 kDa full-length PS1 was also processed to generate 27 kDa N-terminal and a detergent-insoluble 19 kDa C-terminal fragments. The proteasome blocker also caused the accumulation of the polyubiquitinated PS1, indicating that both PS1 and PS2 are degraded via the ubiquitin-proteasome pathway. Our studies raise the possibility that abnormal processing and/or inefficient degradation of PS1 and PS2 are involved in pathogenic mechanisms of presenilin mutations.

## 293.2

**EXPRESSION OF PRESENILIN 1 (PS-1) AND 2 (PS-2) IN MOUSE BRAIN, AND IN NORMAL AND ALZHEIMER'S DISEASE HUMAN BRAINS.** D.P. Huynh\*, V.V. Ho, and S.M. Puls. CSMC Burns and Allen Research Institute, UCLA, 8700 Beverly Boulevard, Los Angeles, CA 90048.  
 We investigated the expression of two familial Alzheimer's disease (AD) proteins (presenilins) in mouse brains, and in normal and AD human brains. Affinity-purified antibodies (ABs) were generated in rabbits and chicken against three peptides of presenilin 1 and to two peptides of presenilin 2. In Western blot analyses, all PS-1 ABs detected a single 53 kDa protein and PS-2 ABs detected a 43 kDa protein in mouse, human brains, as well as in neuronal and glial human cell lines. In mouse CNS, expression of PS-1 and PS-2 was seen in areas known to be affected in AD such as CA1-CA4 areas, entorhinal cortex, dentate gyrus, subiculum, amygdaloid nuclei, and pyramidal neurons of the neocortex. However, neurons normally not affected in AD such as thalamic nuclei, Purkinje cells, DRG, and spinal cord also expressed PS-1 and PS-2. In normal human brains, pyramidal neurons in the neocortex and hippocampus were stained, but no staining was seen in glial cells. In AD brains, identical staining patterns were observed, but reactive astrocytes were strongly stained. In conclusion, we have produced several highly specific presenilin antibodies that will be useful molecular tools in future investigations of presenilin function. The strong staining of reactive astrocytes in FAD brains suggest a role for these cells in the pathogenesis of FAD. Expression of presenilins in areas not affected by AD suggests that other proteins may interact with presenilins to cause cell type specific neuronal death. Supported by the Carmen and Louis Warsaw Endowment Fund for Neurology and the Ruth and Laurence Harvey Endowment Fund for Neuroscience.

## 293.4

**Presenilin Fragments in Cerebro-Spinal Fluid and Brain Tissue**  
 T. Wisniewski, W. Dowjat, A. Golabek, D. Miller\*, B. Frangione. Dept. of Neurol. and Pathol., NYU Medical Center, NY 10016

The majority of early-onset familial Alzheimer disease (FAD) has been linked to a gene located on chromosome 14, presenilin-1 (PS-1). Numerous mutations in this gene have been associated with early-onset FAD. To investigate the involvement of PS-1 in AD we raised polyclonal antibodies to the amino terminus of PS-1 (residues 48-70) and the carboxyl terminus (residues 448-467). Previously we have shown that this carboxyl terminal antibody immunoreacts with AD neuritic plaques of both sporadic and FAD patients suggesting that PS-1 may have a general role in the pathogenesis of AD and not just in the rare FAD cases. Further immunohistochemical studies with these antibodies in sporadic AD and Down Syndrome (DS) patient's brains have found carboxyl terminal immunoreactivity in both the amyloid deposits of neuritic plaques and cerebral vessels. In biochemical extractions of neuritic plaque amyloid from sporadic AD and DS patient brains we found by Western blotting, that proteins which specifically immunoreact with our anti-PS-1 antibodies, co-purify with amyloid  $\beta$  ( $A\beta$ ). In AD amyloid that is partially purified by homogenization in SDS and sucrose gradients we found a 17 kDa fragment band which is recognized by the anti-carboxyl PS-1 antibody, as well as a PS immunoreactive 44 kDa band that most likely represents the intact protein. On the other hand, in both normal and AD cerebrospinal fluid (CSF), we detect a 27 kDa protein that is labeled by the amino terminal anti-PS-1 antibody. These results suggest that PS is normally degraded to at least two fragments (or these are products of different transcripts): a 27 kDa amino terminal protein that is released in the CSF and a 17 kDa carboxyl terminal fragment found in brain tissue. Supported by NIH grants AG05891 and AG00542

## 293.6

**SUBCELLULAR LOCALIZATION OF PROTEOLYTIC FRAGMENTS DERIVED FROM NORMAL AND AD-ASSOCIATED PRESENILINS.**  
 D. M. Kovacs\*, S. D. Schmidt, T.-W. Kim, W. Wasco and R. E. Tanzi. Genetics and Aging Unit, Massachusetts General Hospital, Boston, MA 02129 USA.

The large majority of familial Alzheimer's disease (FAD) is caused by mutations in one of two recently identified genes, presenilin 1 (PS-1) and presenilin 2 (PS-2). We have recently reported (*Nature Med.* 2:224, 1996), that PS-1 and PS-2 mRNAs are expressed in similar neuronal populations of rat and human brains, with virtually identical regional distributions. Both PS proteins were mainly detected in the nuclear envelope, ER, and Golgi membranes of transiently transfected mammalian cell lines. These data indicate that the pathogenic effect of mutations in the presenilins begins in the intracellular membranes of neuronal populations. However, FAD-associated mutations did not alter significantly the subcellular localizations of those two proteins. We have since shown both PS-1 and PS-2 to undergo proteolytic cleavage into two fragments. The C-terminal products of both PS-1 and PS-2 have been detected in the detergent-resistant cellular fraction, indicating a potential association with the cytoskeleton (Kim et al., submitted). To further investigate this possibility, we have performed immunofluorescent studies of stably and transiently transfected cell lines to compare the subcellular localization of the presenilin N- and C-terminal fragments produced by wild type versus mutant PS constructs. In addition, we have assessed the effects of the cytoskeletal disrupting agents, nocodazole and cytochalasin D, on the subcellular distributions of PS-1 and PS-2, and found a significant redistribution of both proteins in the presence of these agents. Supported by the French Foundation, NIA, and NINDS.

## 293.7

## METABOLISM OF THE ALZHEIMER'S DISEASE PRESENILIN-1 PROTEIN IN TRANSFECTED AND PRIMARY CELL CULTURES.

Cai'ne Wong, Henrike Hartmann, Matthias Staufenbiel\* and Bruce A. Yankner\*, Dept. Neurology, Harvard Medical School and the Children's Hospital, Boston, MA. \*Sandoz Pharma Ltd., Basel, Switzerland.

Mutation of the presenilin-1 (PS-1) gene has been implicated as the most common cause of early onset familial Alzheimer's Disease (FAD). The PS-1 sequence predicts a 54 kD protein with at least 7 transmembrane domains. Immunoprecipitation and Western blotting of PS-1 cDNA-transfected COS cells revealed predominant 40-43 kD and 30-33 kD species. The same species were detected in cells transfected with mutant PS-1 cDNAs. Similar species were also detected in non-transfected COS, neuroblastoma, FAD and normal fibroblast, and human cortical cultures. In addition, we have identified a 12-16 kD protein that is immunoreactive with the PS-1 antibody, is increased with PS-1 transfection, and is absent in antibody preabsorbed controls. This 12-16 kD protein is the major PS-1 immunoreactive species in primary human fibroblast and cortical cultures, but is a relatively minor species in transfected COS cells. The 12-16 kD fragment is likely to be either a proteolytic product or an alternatively spliced variant of PS-1. The abundance of this species in primary cell cultures suggests that it may have functional biological significance. Support by NINDS, Alzheimer's Association and Sandoz Pharma Ltd.

The majority of individuals with Familial Alzheimer's disease (FAD) have mutations in two genes: *presenilin 1* (PS1, chromosome 14) and *presenilin 2* (PS2, chromosome 1). In an attempt to identify proteins that interact with PS1, N-terminal and loop fragments from PS1 were screened in the yeast two-hybrid system using a rat forebrain, random primed cDNA library. We report that the hydrophilic "loop" region of PS1 interacts with a fragment of the rat homologue of human flamin (ABP-280) in the two-hybrid system. The candidate interacting flamin-related polypeptide was coimmunoprecipitated with full-length PS1 from HEK293 cells using polyclonal antibodies directed to the loop region of PS1. We are currently characterizing this interaction further via coimmunoprecipitation and colocalization in brain and cell culture. We are also in the process of identifying additional PS1 interacting proteins. Characterization of the cellular biochemistry of the interactions of these candidate proteins with PS1 will provide important insights into the biology of Alzheimer's disease.

Mutations in the presenilin 1 (PS1) and presenilin 2 (PS2) genes segregate with the majority of early-onset familial Alzheimer's disease (FAD) pedigrees. PS1 and PS2 are integral transmembrane proteins homologous to *sel-12*, a *C. elegans* protein involved in intracellular signaling pathway mediated by members of the Notch/tin-12 family of receptors. Little is known about the physiological functions of PS or the effects of PS mutations on the cellular abnormalities characteristic of AD. In order to begin to examine the *in vivo* role of PS1 during development and aging, we ablated the expression of the PS1 gene by homologous recombination in embryonic stem cells and have generated mice heterozygous for the targeted allele. Mice homozygous for PS1 targeted allele are being generated to analyze the impact of the PS1 null state on the development, structure and functions of the nervous system. Efforts are underway to generate mice with functionally inactivated PS2 genes. Supported by grants from NIH (AG05146 and NS20471), Develbiss Fund and Alzheimer's Association.

The majority of early-onset cases of FAD are linked to mutations in two related genes, *Presenilin 1* (PS1) and *Presenilin 2* (PS2). We have used three highly specific antibodies, generated against non-overlapping epitopes of PS1 to examine the expression and metabolism of PS1 *in vivo*. In stably transfected cell lines, PS1 is synthesized as a 43 kDa polypeptide. However, full-length PS1 undergoes proteolytic processing *in vivo*, and the preponderant PS1-related species that accumulate in the cell lines, as well as brains of rodents, primates, and humans are ~27-28 kDa N-terminal and ~16-17 kDa C-terminal derivatives. The site of cleavage is being determined by biochemical and molecular approaches, but our epitope mapping studies indicate that cleavage occurs in a region in which ~58% of PS1 missense mutations occur. Furthermore, an FAD-linked PS1 variant encoded by mRNA that lacks exon 9 is not subject to endoproteolytic cleavage.

We have also examined the protein topology of PS1 *in vivo* using a novel chimera-based strategy and have demonstrated that the N-terminus of PS1 is oriented towards the cytoplasm. Using this approach, we have also demonstrated that hydrophobic residues 280-300 within the proposed "loop" domain of PS1 can be used as a transmembrane helix. We are currently assessing the membrane orientation of the hydrophilic "loop" domain of PS1 using N-glycosylation antibody tagging methods in combination with antibody decoration approaches.

Medical College<sup>6</sup>, New York, NY; Mammalian Genetics Lab<sup>7</sup>, National Cancer Inst., Frederick, MD.

The majority of cases of early-onset familial Alzheimer's disease are linked to mutations in two related seven-nine transmembrane proteins termed the presenilins 1 (PS1) and 2 (PS2), respectively. To begin to examine the metabolism of the presenilins *in vivo*, and to develop model systems to investigate pathogenic mechanisms, we have produced transgenic mice expressing human (Hu) wt and mutant PS1, using cDNA transgenes driven by the murine prion protein promoter. Our initial analysis of ten lines of mice expressing wt Hu PS1, revealed that 42 kDa wt Hu PS1 proteins are normally cleaved to generate stable 27 kDa (N-terminal) and 18 kDa (C-terminal) fragments. Among these lines of mice, the levels of Hu PS1 mRNA and full-length 42 kDa polypeptide were proportional; increased levels of transgene-derived mRNA led to increased levels of the 42 kDa precursor. However, the levels of accumulated 27 and 18 kDa derivatives plateaued (~3-fold over nontransgenic littermates), indicating that a saturable process governs the production or accumulation of these derivatives. We are examining the influence of wt and mutant PS1 on the processing of the amyloid precursor protein (APP) as well as the consequences of expressing these proteins in the murine nervous system. Supported by the NIH (AG05146 and NS20471), the Develbiss Fund, and the Alzheimer's Association.

## 293.12

EXPRESSION OF FAD-LINKED MUTANT PRESENILIN 1 IN TRANSGENIC MICE. M.K. Lee<sup>1</sup>, D. Borchelt<sup>1</sup>, G. Thinakaran<sup>1</sup>, H. Slunt<sup>1</sup>, G. Kim<sup>1</sup>, T. Ratovitski<sup>1</sup>, L. Martin<sup>1</sup>, S. Gandy<sup>2</sup>, A. Levy<sup>3</sup>, N. Jenkins<sup>4</sup>, N. Copeland<sup>4</sup>, D.L. Price<sup>1,5,6</sup> and S.S. Sisodia<sup>1,6</sup>.

Mutations in genes encoding related proteins, termed presenilins 1 (PS1) and 2 (PS2), are linked to the majority of cases with early-onset familial Alzheimer's disease (FAD). To examine the pathogenic mechanism(s) of FAD, we have produced transgenic mice expressing either wild type (wt) or mutant human PS1, using cDNA transgenes driven by murine prion protein promoter. Initial immunohistochemical and light microscopic analysis of mice expressing human PS1 and PS1 with the A246E missense mutation reveals somatodendritic and axonal localization of human wt or mutant PS1 proteins. Remarkably, our initial biochemical analyses reveal that, relative to the wt human PS1, endoproteolytic processing and/or accumulation of the mutant PS1 is qualitatively different. We have also generated additional transgenic mice expressing the FAD-linked M146L PS1 variant and a PS1 variant that lacks exon 9. The expression, metabolism and subcellular distributions of these PS1 variants in transgenic mice will be discussed. Supported by the NIH, the Develbiss Fund, and the Alzheimer's Association.

## 293.13

**APOPTOSIS AND THE ALZHEIMER'S DISEASE GENE PRESENILIN-1** Henrike Haftmann\*, Jorge Busciglio, Caïne W. Wong, Matthias Staufenbiel, and Bruce A. Yankner. Dept. Neurology, Harvard Medical School and the Children's Hospital, Boston, MA, + Sandoz Pharma Ltd., Basel, Switzerland

Most early-onset familial Alzheimer's disease (AD) is caused by mutation of the presenilin 1 (PS-1) or presenilin 2 (PS-2) genes. A recent report suggested that transfection of a cDNA encoding a C-terminal fragment of the mouse homolog of PS-2 protected against apoptosis (Vito et al., 1996). We therefore investigated if PS-1 overexpression is able to rescue cells from apoptotic cell death. COS cells were transiently transfected with PS-1 cDNA; controls were transfected with either the vector alone or with the vector encoding  $\beta$  galactosidase ( $\beta$ Gal). Western blot analysis with an antibody to PS-1 revealed two endogenous bands - a major species migrating at 30-33 kD and another species at 40-43 kD. Transfection of PS-1 cDNA increased the levels of these species, which were absent in antibody preabsorption controls. Comparison of the major transfection-induced 43 kD band with the 125 kD  $\beta$ gal band showed similar transfection efficiencies. To test the effect of PS-1 overexpression on apoptosis, cells were treated with either tert-butyl-hydrogen peroxide (tbh) or staurosporine. The cells were then fixed and immunostained with the PS-1 or  $\beta$ gal antibodies and apoptotic cells were identified by characteristic morphological criteria. Under these conditions, PS-1 did not protect against apoptosis induced by either drug. We also investigated fibroblast cell lines from the FAD1 family and from age-matched controls for susceptibility to apoptosis induced by tbh or staurosporine. Both groups showed similar sensitivity to cell death induced by these agents. In conclusion, our data do not support the hypothesis that PS-1 exerts a protective effect against apoptotic cell death.

## 293.14

**PS2 PARTICIPATES IN CELLULAR APOPTOSIS.** B. Wolozin\*, P. Vito, K. Ganji, K. Iwasaki, E. Lacana and L. D'Adamio. Section on Geriatric Psychiatry, NIMH and T-cell Molecular Biology Unit, NIAID, Bethesda, MD 20892.

Recent discoveries have shown that mutations in the presenilin genes on chromosomes 1 & 14 cause familial Alzheimer's disease (AD), however, the function of these genes is not known. The importance of PS2 for AD lead us to directly examine the role of PS2 levels in neuronal apoptosis. Undifferentiated PC12 cells (udPC12) or neuronally differentiated PC12 cells (nPC12) were transfected with pcDNA3 vectors containing mouse PS2 in sense or antisense orientation as well as ALG3 or  $\phi$ -64 inserts, which are dominant negative mutants for PS2. Two days after the transfection, the udPC12 cells were treated with agents known for their cytotoxicity: glutamate, hydrogen peroxide, the free radical MPP<sup>+</sup>, A23187 or  $\beta$ -amyloid<sub>1-42</sub>, while the nPC12 cells were deprived of NGF. Following the treatment the cells were either analyzed using the MTT assay or fixed and stained for apoptotic nuclei using the TUNEL method. Transfection with antisense PS2, ALG3 and  $\phi$ -64 protected udPC12 cells against glutamate toxicity, but did not affect sensitivity to the other insults. Antisense PS2, ALG3 and  $\phi$ -64 also partially protected the nPC12 cells against NGF-withdrawal, increasing the reactivity in an MTT assay 3-fold and reducing the number of TUNEL positive cells below baseline. Conversely, transfection with sense presenilin increased the number of apoptotic neurons. Thus, expression of PS2 is necessary for some forms of apoptosis, and reduction of PS2 levels by transfection with vectors containing either PS2 antisense, ALG3 or  $\phi$ -64, provides protection against glutamate toxicity of withdrawal of trophic support.

## NEUROPSYCHIATRIC DISORDERS: POSTMORTEM I

## 294.1

**PROTEIN KINASE C IN THE POSTMORTEM BRAIN OF TEENAGE SUICIDE VICTIMS.** G. N. Pandey\*, Y. Dwivedi, S. C. Pandey, R. Conley, R. Roberts, and C. Tamminga. Psychiatric Institute, Department of Psychiatry, University of Illinois at Chicago, Chicago, IL 60612

Several lines of evidence indicate that 5HT<sub>2A</sub> receptors are upregulated in the postmortem brain of suicide victims. 5HT<sub>2A</sub> receptors have been shown to be linked to the phosphatidylinositol signaling system, of which protein kinase C (PKC) is an important component. The role of PKC in suicide is presently unclear. To investigate the role of PKC, we studied [<sup>3</sup>H]phorbol dibutyrate (PDBU) binding to PKC in the frontal cortex (Brodman's areas 8 and 9) of teenage suicide victims and normal controls. Postmortem brain samples were obtained from the Brain Collection Program of the Maryland Psychiatric Research Center. K<sub>D</sub> and B<sub>max</sub> of [<sup>3</sup>H]PDBU binding to PKC were determined in membranous and cytosolic fractions of the brain by the radioligand binding technique. We observed that B<sub>max</sub> of [<sup>3</sup>H]PDBU binding to PKC was significantly decreased in the membranous fraction of the frontal cortex obtained from suicide victims (n = 16) compared to normal control subjects (n = 19); however, B<sub>max</sub> in the cytosolic fraction and K<sub>D</sub> in both membranous and cytosolic fractions remained unaltered. These results suggest an abnormality of PKC in the brain of suicide victims and that PKC may have an important role in the pathophysiology of teenage suicide. Further studies are under way to determine whether the decrease in PKC is isozyme specific.

## 294.3

**CORTICAL  $\alpha_1$ -ADRENERGIC BINDING IN ALCOHOLISM AND SUICIDE.** M.J. Bakalian\*, M.D. Underwood, J.J. Mann, N. Paykina, S.A. Kassir, M. Douglass, S. Gapon, D.A. Brent, S.P. Ellis, S. Li, and V. Arango. Department of Neuroscience, Columbia University, New York, NY 10032.

We previously reported reduced  $\beta_1$ -adrenergic binding (Allen et al., Soc. Neurosci. Abstr., 1993) as well as reduced  $\alpha_2$ -adrenergic binding (Mann et al., Soc. Neurosci. Abstr., 1996) in the prefrontal cortex (PFC) of alcoholics who died by suicide and other causes, compared to controls. Using quantitative autoradiography, we sought to compare binding to  $\alpha_1$ -adrenergic sites in the same three groups of subjects (n=14 matched triplets). Assays were performed as previously described (Arango et al., Brain Res., 1993) using PFC coronal sections from the right hemisphere and 4nM <sup>3</sup>H-prazosin. The coroner or medical examiner ruled whether the cause of death was suicide. Alcohol dependence was determined by psychological or physical autopsy. Quantitative analysis of  $\alpha_1$ -adrenergic binding was performed by identifying isodensity bands that correspond in gyri to layers I, II, III, IV-V and VI. In sulci, there are three bands over layers I-II, III and IV-VI. Data were tested using variance component analysis with age, sex and PMI as covariates. Binding was lower (8% to 16%) in alcoholics than in controls in dorsolateral (area 9), ventrolateral (areas 46 and 47) and orbital PFC (area 12 sulcus). Similarly, binding in suicide alcoholics was lower (9% to 14%) than in controls in gyrus area 9 and sulcus area 12. Binding decreased with age, but not with PMI, in the dorsolateral and lateral PFC. No sex differences were detected. In conclusion, the suicide and nonsuicide alcoholic groups did not differ from each other but had lower binding than controls, suggesting that the effect of alcohol overrides any increase in binding present in nonalcoholic suicides (Brain Res., 1993).

Supported by PHS grants AA09004, MH40210, MH47097 and MH46745.

## 294.2

**MORPHOMETRY OF LOCUS COERULEUS NEURONS IN ALCOHOLISM AND SUICIDE.** M.D. Underwood\*, D.K. Pauler, V.V. Arkhipov, J.J. Mann, D.A. Brent and V. Arango. Department of Neuroscience, Columbia University, New York, NY 10032.

We have reported fewer locus coeruleus (LC) neurons in alcoholics, suicides and alcoholics who died by suicide compared to controls (*Alcohol. Clin. Exp. Res.* 1996, In Press). We then sought to determine whether LC neuron morphometry is distinct in alcoholism and suicide.

Fixed brainstems were sectioned and Nissl-stained. Controls (n=11; ages: 17-69y) were free of drugs, by toxicological screen, and known psychiatric or neurologic disorders. Diagnosis of alcohol-dependence (n=7; ages: 32-70y) was determined by psychological autopsy or investigative report. Suicide as cause of death, with alcoholism (n=7; ages: 20-58) or without (n=6; ages: 23-84), was determined by the coroner. LC neurons were examined at three coronal levels: the decussation of the trochlear nerves, 2.5mm rostral and 5mm caudal. Neuron measurements (area, perimeter, form factor) were made with an image analysis system (Imaging Research, Inc.). Potential covariates age and postmortem interval were not significant (p>0.05). Neuron area in the left LC was larger than the right LC (p<0.05) in controls; this effect was more pronounced in females than in males. Neuron area was greater in rostral portions than caudal of the LC (p<0.05). In alcoholics, the area of LC neurons at the rostral level was smaller than controls (897±33 vs. 816±64  $\mu$ m<sup>2</sup>, p<0.05). LC neuron area at other levels and in suicides did not differ. Neuron shape depended on rostral-caudal level, but did not differ between groups. Reduced noradrenergic neurotransmission in alcoholics, but not suicides, may be due to neuronal degeneration or selective loss of larger neurons in rostral portions of the LC. Suicides and alcoholics appear to have distinct noradrenergic morphometric abnormalities. (Supported by the American Suicide Foundation, and PHS grants AA09004, MH47097 and MH46745)

## 294.4

**ALTERATIONS IN  $\alpha_2$ -ADRENERGIC BINDING DISTINGUISH ALCOHOLIC SUICIDE VICTIMS FROM ALCOHOLICS.** J.J. Mann\*, M.D. Underwood, D.A. Brent, S.A. Kassir, V.L. Johnson, M. Douglass, S.P. Ellis, S. Li, and V. Arango. Department of Neuroscience, Columbia University, New York, NY 10032.

Suicide rates are markedly elevated for alcoholics. In addition to changes in the serotonergic system, other neurotransmitter systems seem to be involved in suicidal behavior and alcoholism. We previously reported that  $\beta_1$ -adrenergic binding is reduced in the brain of alcoholics and then sought to determine whether  $\alpha_2$ -adrenergic binding is also altered. We performed quantitative autoradiography in coronal sections of the right prefrontal cortex (PFC), just anterior to the genu of the corpus callosum. We compared alcohol-dependent suicide victims to alcohol-dependent nonsuicides as well as normal controls. Toxicological screens were negative for all drugs, except alcohol. We matched cases on age, sex and postmortem interval (PMI, n=14 triplets). Sections (20 $\mu$ m) were pre-incubated, pre-washed and incubated in 4nM <sup>3</sup>H-p-aminoclonidine (<sup>3</sup>H-PAC) to label  $\alpha_2$ -receptors as described previously (Arango et al., Brain Res., 1993). The distribution of  $\alpha_2$ -adrenergic receptors was the same in both groups and formed five isodensity bands corresponding to layer I, layer II, upper layer III, layers III-IV and layers V-VI. Binding was densest in layer I and upper layer III and least dense in layers V-VI. Data were examined using a variance component analysis with age, sex and PMI as covariates. The nonsuicide alcoholic group did not differ from the control group in the level of  $\alpha_2$ -adrenergic binding in any of the areas studied. The alcoholic suicide group had approximately 25% less binding than the controls in lateral and ventral PFC (p<0.01). Binding decreased with age, but not with PMI. No sex differences were detected. Lower  $\alpha_2$ -adrenergic binding in ventrolateral PFC may reflect a component of altered noradrenergic function that contributes to suicidal behavior, so prevalent in alcoholics. (AA09004, MH47097 and MH46745)

## 294.5

**PATTERNS OF 5-HT<sub>1A</sub> BINDING IN ALCOHOLISM AND SUICIDE.** V. Arango, M.D. Underwood, S.A. Kassir, D.A. Brent, A. Khaibula, V. Arkipov, S.P. Ellis, S. Li, and J.J. Mann. Dept. of Neuroscience, Columbia University, NY 10032.

Serotonin alterations have been reported in suicidal behavior. Serotonin is also involved in the regulation of alcohol preference and intake. Using quantitative autoradiography, we compared 5-HT<sub>1A</sub> binding in the prefrontal cortex (PFC) of alcohol-dependent individuals (suicide and nonsuicide) and normal controls with negative toxicological screens for other drugs. Alcohol-dependence was determined by physical and/or psychological autopsy. Subjects were matched for postmortem delay (PMI), age and sex (N=16 triplets). Coronal sections (20µm) were incubated with 2nM [<sup>3</sup>H]-8-OH-DPAT as described previously (Arango *et al.*, Brain Res., 1995). 5-HT<sub>1A</sub> receptor distribution across cortical layers was similar in all groups, forming five isodensity bands. Binding was approximately 30% higher in ventral and medial cortex than in dorsal and lateral cortex. The alcoholic group had 20% less 5-HT<sub>1A</sub> binding than the controls in lateral PFC (area 46,  $p=0.036$ ), but not in other areas. When a variance component analysis was done, with an additional 56 subjects of matched nonalcoholic suicides (n=28) and controls (n=28), a total of 104 subjects, the alcoholic nonsuicides had reduced binding in all areas of ventrolateral PFC (45 and 46). The alcoholic suicides had reduced binding in area 45. Binding increased with age in lateral and orbital prefrontal cortex and decreased with PMI in the same areas. Females had more binding than males in lateral, orbital and medial PFC. We conclude that: 1. 5-HT<sub>1A</sub> binding is decreased in some brain regions of alcoholics; and 2. Binding in alcoholics changes in the opposite direction to that in nonalcoholic suicides. This study provides further evidence linking serotonin to alcoholism, suggesting a serotonergic deficiency in alcoholic suicide victims. (AA09004, MH40210, MH47097 and MH46745)

## 294.7

**DECREASED CYTOSOLIC [<sup>3</sup>H]cAMP BINDING IN BIPOLAR DISORDER (BD) POSTMORTEM BRAIN.** S. Rahman, P.P. Li\*, L.T. Young, S.J. Kish, O. Kofman and J.J. Walsh. Clarke Institute of Psychiatry, University of Toronto, Toronto, ON, Canada

Although hyperfunction of the G protein-coupled adenylyl cyclase pathway has been implicated in BD (Avissar and Schreiber, Biol. Psychiatry, 31:435, 1992), direct evidence to support altered cAMP signaling in this disorder is still elusive. cAMP-dependent protein kinase (PKA), a tetrameric protein composed of 2 regulatory (R) and 2 catalytic subunits, is the primary target of intracellular cAMP signaling. PKA R-subunit levels are modulated by changes in cytosolic cAMP levels consequent to activation of receptors coupled to this second messenger pathway. We assessed here whether [<sup>3</sup>H]cAMP binding, a measure of PKA R-subunit levels, is altered in postmortem BD brain regions in which higher G<sub>o</sub> protein levels have been previously identified. [<sup>3</sup>H]cAMP binding was measured by the procedure of Takeda *et al.* (J. Biochem. 105:327, 1989). In temporal cortex membrane fractions, [<sup>3</sup>H]cAMP binding was saturable and specific with K<sub>d</sub> values of 0.89 ± 0.1 nM (site 1) and 3.6 ± 0.47 nM (site 2), and B<sub>max</sub> of 154 ± 28 fmol/mg protein (site 1) and 283 ± 37 fmol/mg protein (site 2), respectively. Cytosolic [<sup>3</sup>H]cAMP binding was best described by single site binding with K<sub>d</sub> and B<sub>max</sub> of 0.73 ± 0.04 nM and 232 ± 7 fmol/mg protein, respectively. Compared with age and postmortem-delay matched controls (n=5-10), specific [<sup>3</sup>H]cAMP (5 nM) binding was significantly reduced (F=6.545,  $df$ [1,80],  $p=0.012$ ) in cytosolic fractions across all examined regions of BD brain (frontal [-22%], temporal [-23%], occipital [-22%] and parietal cortex [-15%], and cerebellum [-36%] and thalamus [-13%]), but there were no differences in [<sup>3</sup>H]cAMP binding in the membrane fractions from these same regions. Lithium levels measured in BD temporal cortex did not correlate significantly with [<sup>3</sup>H]cAMP binding. The reduced cytosolic [<sup>3</sup>H]cAMP binding may reflect modulatory changes secondary to altered cAMP signaling in BD brain. The possibility that antemortem lithium and/or other mood stabilizer treatment may contribute to the above changes cannot be ruled out, however. (Supported by the grants from the MRC (JJW&LTY). SR is a Clarke Institute Research Foundation fellowship recipient and LTY an Ontario Career Scientist awardee)

## 294.9

**EFFECT OF NEUROLEPTICS ON THE SUBREGIONAL DISTRIBUTION OF GLUTAMATE DECARBOXYLASE-IMMUNOREACTIVE TERMINALS IN THE HIPPOCAMPUS OF CONTROL AND SCHIZOPHRENIC SUBJECTS (SZs).** M.S. Todtenkopf and F.M. Benes.\* Laboratory for Structural Neuroscience, McLean Hospital, Belmont, MA; Department of Psychiatry and Program in Neuroscience, Harvard Medical School, Boston, MA.

Recent findings of increased GABA<sub>A</sub> receptor binding on NPs in sector CA<sub>3</sub> and a reduced density of nonpyramidal neurons (NPs) in sector CA<sub>2</sub> of SZs has prompted interest in the question of whether there may be a loss of GABAergic activity in the regio inferior of patients with this disorder. In order to test this hypothesis, an extensive and reliable method for localizing the 65 kD isoform of glutamate decarboxylase (GAD) has been developed and applied to a cohort of controls (CONs) (N = 11) and SZs (N = 11) matched for age (59 and 57 yrs, respectively), postmortem interval (18 and 20 hrs, respectively) and gender. The data revealed no difference in the density of GAD<sub>65</sub>-immunoreactive (IR) terminals on pyramidal cells (PNs), NPs or in neuropil (NPL) of sectors CA<sub>1-4</sub>. Similarly, no differences were observed in the strata moleculare, radiatum or oriens of any of CA subfields. Regression analysis, however, revealed a highly significant **positive correlation** between neuroleptic dose (CPZ) and the density of GAD<sub>65</sub>-IR terminals on PNs ( $r=0.81$ ;  $p=0.002$ ) and NPs ( $r=0.78$ ;  $p=0.005$ ) of sector CA<sub>4</sub> and in the stratum oriens of sectors CA<sub>3</sub> ( $r=0.70$ ;  $p=0.016$ ) and CA<sub>2</sub> ( $r=0.77$ ;  $p=0.009$ ). Overall, these data are consistent with a model in which subtle losses of inhibitory activity, particularly in sectors CA<sub>3</sub> and CA<sub>2</sub> of SZs may be compensated for, at least in part, by CPZ-induced increases of GABAergic terminals in the stratum oriens of these same sectors. Supported by MH42261, MH00423 and MH31154.

## 294.6

**SUICIDE AND THE HUMAN 5-HT<sub>1D</sub> RECEPTOR AND GENE.** Y. Huang\*, R. Grailhe, M. Zhou, R. Hen, V. Khait, V. Arango and J.J. Mann. Dept. of Neuroscience, New York State Psychiatric Institute, New York, N.Y. 10032.

Knockout of 5-HT<sub>1B</sub> gene in mice results in reduced latency aggression and increased aggression. We decided to study the 5-HT<sub>1D</sub> gene and receptor binding in the brain of suicide victims to determine whether this gene is involved in suicide. Here we report the detection of two 5-HT<sub>1D</sub> receptor gene polymorphisms of the coding sequence and the allelic association of 5-HT<sub>1D</sub> receptor genes with receptor-binding indices in both suicide and control groups. Single-strand conformational polymorphism (SSCP) analysis and DNA sequencing technique were used to screen the entire coding region of the 5-HT<sub>1D</sub> gene for possible variations in genomic DNA isolated from postmortem human brain tissue (N=58). Amplification of the genomic DNA was accomplished with three primer pairs. To optimize the sensitivity of the SSCP analysis, PCR fragments were further digested with different restriction endonuclease enzymes (Eae I, Sty I, Sac II and Bmy). The binding indices (B<sub>max</sub>, maximal binding sites; K<sub>d</sub>, binding affinity) of the 5-HT<sub>1D</sub> receptor were determined in Brodmann area 9 of postmortem brain tissue using 5-hydroxy[<sup>3</sup>H]tryptamine as the ligand and sumatriptan as the displacer. B<sub>max</sub> and K<sub>d</sub> did not differ in suicides and controls (44.0 vs 41.3 fmol/mg pr. and 1.3 vs 1.1 nM respectively). Two common polymorphic patterns were identified in the 5-HT<sub>1D</sub> gene with allelic frequencies of 0.76 and 0.24 in the control subjects (N=29), and they did not differ from frequencies of 0.69 and 0.31 in the suicide subjects (N=29). The SSCP variants were caused by a silent C to T substitution at nucleotide 129 and a silent G to C substitution at nucleotide 861 of the coding region. No significant correlation between B<sub>max</sub> and genotype was observed. The data suggest that there are two silent mutation points in the coding sequence of 5-HT<sub>1D</sub> receptor gene and that 5-HT<sub>1D</sub> receptor-binding characteristics and gene polymorphism are not correlated. This study did not find evidence of an abnormality in the gene or gene product for the 5-HT<sub>1D</sub> receptor in suicide victims. (Supported by MH40210 and MH46745)

**METHODOLOGICAL PROBLEMS WITH THE DOPAMINE D<sub>4</sub> SUBTRACTION METHOD IN POSTMORTEM BRAIN STUDIES.** M. Li, H. Fang, D. Helms and S.W. Tang.\* Depts. of Psychiatry and Pharmacology, University of California, Irvine, Irvine CA 92717.

The ability to quantify dopamine D<sub>4</sub> receptors in various psychiatric and neurological disorders is hampered by the lack of a specific dopamine D<sub>4</sub> ligand. A compromise using the differential labeling properties of [<sup>3</sup>H]-raclopride (D<sub>2</sub> and D<sub>3</sub>) and [<sup>3</sup>H]-nemonapride (D<sub>2</sub>, D<sub>3</sub> and D<sub>4</sub>) was proposed by Seeman *et al.* (1993) and applied to postmortem schizophrenic brain tissues. Several groups have since replicated this method, producing variable results. Our data show that the conditions of assay, specifically the selection of agents used to define specific binding, appear to be the most critical. Sulpiride, as originally described by Seeman *et al.* (1993), appeared to be the most specific, yet produced no D<sub>4</sub> differential consistently in seven normal control brains. Haloperidol and butaclamol baseline both included a substantial  $\sigma$  component and produced an apparent "D<sub>4</sub> differential", part of which is  $\sigma$ . Data indicated that additional binding sites are also defined by these compounds, but not by sulpiride. A full Scatchard analysis of tissues is also essential as a 6 nM concentration of [<sup>3</sup>H]-raclopride and a 1 nM concentration of [<sup>3</sup>H]-nemonapride yield a positive differential in all 7 brains, with 6 nM [<sup>3</sup>H]-raclopride being close to (75% of B<sub>max</sub>) but not at the saturation point. Our results caution the application of the subtraction method to measure dopamine D<sub>4</sub> receptors (postmortem brain tissues obtained from NRRSB, VAMC, LA).

**RELATIVE DISTRIBUTION OF PYRAMIDAL (PN) AND NONPYRAMIDAL (NP) NEURONS IN THE HIPPOCAMPUS OF SCHIZOPHRENIC (SZ) AND MANIC DEPRESSIVE (MD) BRAIN.** F.M. Benes, E. Kwok, S.L. Vincent.\* Laboratory for Structural Neuroscience, McLean Hospital, Belmont, MA; Department of Psychiatry and Program in Neuroscience, Harvard Medical School, Boston, MA.

Recent postmortem studies have suggested that there may be a decrease of GABAergic neurons and/or activity in layer II of the anterior cingulate and prefrontal cortices of SZs. The recent finding of a preferential upregulation of the GABA<sub>A</sub> receptor on NPs in CA<sub>3</sub> has suggested that this subregion may also be a potential site for defective GABAergic modulation in SZ. To explore this possibility, a comparison of the relative distribution of PNs and NPs in sectors CA<sub>1-4</sub> from normal control (N = 11) and SZs (N = 10) cases matched for age, postmortem interval and gender has been undertaken. All neurons in a single cross-section of the hippocampus (approximately 3000 neurons/case) at the level of the lateral geniculate nucleus were determined to be either a PN or NP. For PNs, there were no differences in the average number, density or size in any of the sectors examined. In contrast, there was a 40% reduction in the number ( $p=0.05$ ) and a 50% decrease in the density ( $p=0.01$ ) of NPs in sector CA<sub>2</sub>, but not CA<sub>1</sub>, CA<sub>3</sub> or CA<sub>4</sub>. MD patients (N = 5) also showed a selective reduction in the total number and density of NPs in sector CA<sub>2</sub> only; however, both neuroleptic-treated and neuroleptic-free SZs and MDs showed a reduction of NPs in CA<sub>2</sub>, indicating that this finding is probably not related to an antipsychotic drug effect. Taken together, these data are consistent with the idea that a possible reduction of disinhibitory GABAergic activity in CA<sub>2</sub> of SZs may be related to a selective loss of NPs in sector CA<sub>2</sub>. Overall, however, these data implicate the regio inferior as a central site for GABAergic dysfunction in both SZ and MD brain. Supported by MH00423, MH42261 and MH31862.

**NEURONAL SIZE, SHAPE, AND ORIENTATION IN THE NORMAL LEFT AND RIGHT HIPPOCAMPUS ARE ALTERED IN SCHIZOPHRENIA.** D.W. Zaidel\*, M.M. Esiri†, and P.J. Harrison‡. \*Dept. of Psychology, UCLA, Los Angeles, USA; †Clinical Dept. of Neuropathology, Radcliffe Infirmary, Oxford, UK; ‡University Dept. of Psychiatry, Warneford Hospital, Oxford, UK.

The morphological cytoarchitecture of the hippocampus, on either side, is poorly delineated in normal (NRM) or in schizophrenic (SCZ) individuals. We studied the two hippocampi in 14 chronic SCZ and 17 NRM using 10 microns nissl-stained sections. All brains were neuropathologically normal; groups were matched for age, post-mortem delay, and fixation time, and were coded for data collection. Neurons in several regions within hippocampal subfields CA1 - 4 and subiculum were captured on a computer with a video camera attached to a microscope (objective x10). Total magnification was x250. The digitized images were analyzed semi-automatically for size, shape, and orientation on a Macintosh computer. Minimal left-right differences in NMR were observed. In SCZ, neuronal size was consistently smaller in subfields of the left hippocampus than left NRM. Cell shape was significantly different in SCZ in subfields of both hippocampi, being less triangular (more ovoid) than in NRM. There were no group differences in variability of neuronal orientation. The findings provide further indications of abnormal hippocampal cytoarchitecture in SCZ and suggest that some changes in the disease may affect the two hippocampi asymmetrically.

**SENILE DEGENERATION IN THE BRAINS OF COGNITIVELY IMPAIRED, ELDERLY SCHIZOPHRENICS.** A.J. Dwork, E.S. Susser, C. Wanick, J. Keilp, D. Liu\*, M.A. Kaufman, I. Prohovnik. New York State Psychiatric Institute and Columbia University, New York, NY.

Schizophrenia is frequently associated with cognitive impairment that increases with age and contributes significantly to poor social functioning. In order to determine whether senile degenerative changes contribute to this impairment, we evaluated neuritic (Alz 50-immunoreactive) senile plaques (nSP) and neurofibrillary tangles (NFT) in neocortex and hippocampus from 66 chronically institutionalized schizophrenics, aged 45-105, and 26 similarly aged, chronically institutionalized individuals with mood disorder. These were compared to autopsy specimens from 14 patients without psychiatric disease. Schizophrenics judged by review of medical records to have definite cognitive impairment (DCI) were older and had significantly more nSP and NFT than did those without DCI. Restriction of the analysis to schizophrenics aged <85 eliminated the age difference, but the differences in nSP and NFT persisted. Levels of nSP and NFT in the schizophrenics without DCI were significantly and substantially lower than in nonpsychiatric patients without cognitive impairment. This difference was not found when the nonpsychiatric patients were compared to the mood disorder patients without DCI, who were from the same institutions as the schizophrenics and had received similar somatic treatments. It thus appears that cognition in chronically institutionalized schizophrenics shows an increased sensitivity to senile degeneration, and that this cannot be ascribed to institutionalization or to the side effects of therapy. **COGNITIVE DEFICITS WITHOUT A CHOLINERGIC CAUSE: CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE PARIETAL CORTEX OF 95 ELDERLY SCHIZOPHRENICS.** P. Powchik\*, K.L. Davis, and V. Haroutunian. Dept. Psychiatry, Mount Sinai School of Medicine and Bronx VA Medical Center, New York.

Cognitive deficits are among the prominent symptoms of schizophrenia in chronically ill elderly patients. The neurobiological substrates of these cognitive deficits are unknown. Although a variety of neuropathological and neurochemical abnormalities have been reported in postmortem specimens from elderly schizophrenics, none have been found to account adequately for these cognitive deficits. Because Alzheimer's disease and the cortical cholinergic deficits associated with it is the most common cause of cognitive dysfunction in the elderly, it is possible that a disproportionate number of elderly schizophrenics suffer from either Alzheimer's disease and/or cortical cholinergic deficits associated with it. We compared the activity of choline acetyltransferase, a marker of cholinergic function, and neuropathological indices of Alzheimer's disease in the parietal cortex of 20 normal elderly controls, 95 elderly schizophrenics, and 135 Alzheimer's disease cases. Neither choline acetyltransferase, nor neuropathological indices of Alzheimer's disease accounted for the antemortem or postmortem assessed cognitive deficits in these patients. This study of a large, antemortem assessed and diagnosed cohort of elderly schizophrenics demonstrates that neurological lesion other than those associated with Alzheimer's disease or cortical cholinergic dysfunction must be responsible for the severe cognitive deficits suffered by this population.

**LOSS OF SUBICULAR MAP-2 IMMUNOREACTIVITY IN PSYCHIATRIC DISORDERS.** G. Rosoklija, A.P. Hays, N. Latov, S.A. Sadiq, M. Kaufman, C. Wanick, J. Keilp, I. Prohovnik, A.J. Dwork\*. New York State Psychiatric Institute and Columbia University.

Loss of subicular MAP-2 immunoreactivity in schizophrenia has been reported in two small studies. We now report a larger study that confirms this finding but finds it not to be specific for schizophrenia. The current study examines MAP-2 immunoreactivity in the brains of 96 chronically institutionalized, mostly aged psychiatric patients, 51 with schizophrenia and 45 with dementia, mood disorder, and other psychiatric conditions. These were compared to 14 nonpsychiatric patients from a general hospital. MAP-2 immunoreactivity was evaluated subjectively by 2 observers blind to the source of the specimens and by 2 computerized densitometry protocols conducted by a similarly blinded operator. In all nonpsychiatric cases, subicular MAP-2 immunoreactivity was similar to that in CA4. Among the psychiatric cases, there was much greater variability, with subicular MAP-2 levels that were both higher and lower than in CA4. Consistent with our earlier finding in schizophrenia, low levels of subicular and CA1 MAP-2 were present in approximately one-third of psychiatric patients, regardless of diagnosis (schizophrenia, dementia, mood disorder, and "other"). Among dementia cases, results were similar for those with and without neuropathologically verified Alzheimer's disease. We conclude that there is an association between MAP-2 abnormalities and disturbed mentation that may be constant across various illnesses.

**$\alpha_1$  ACID GLYCOPROTEIN DOES NOT MODIFY [ $^3$ H]-CITALOPRAM BINDING OR [ $^3$ H]-5-HT UPTAKE BY THE HUMAN SEROTONIN TRANSPORTER *IN VITRO*.** M. J. Owens\*, W. N. Morgan and C. B. Nemeroff. Lab. of Neuropsychopharmacology, Dept. Psychiatry & Behavioral Sciences, Emory University School of Medicine, Atlanta GA 30322.

$\alpha_1$  acid glycoprotein is the major serum protein responsible for nonspecific protein binding of basic drugs. Although a normal constituent of serum,  $\alpha_1$  acid glycoprotein is an acute phase protein produced in large amounts by the liver, and perhaps other organs including the brain, under stressful conditions. Our group (Arch Gen Psychiat 47:337-342, 1990) and others have observed a significant increase in serum  $\alpha_1$  acid glycoprotein concentrations in depressed patients. Additionally, others have reported that this protein can directly interact with, and modify the function of, the serotonin transporter (SERT). Because of the role of the SERT in the mechanism of action of antidepressants and, perhaps, the pathophysiology of depression, we have scrutinized the effects of human  $\alpha_1$  acid glycoprotein on [ $^3$ H]-citalopram binding and [ $^3$ H]-5-HT uptake in cells stably expressing the human SERT.  $\alpha_1$  acid glycoprotein ( $10^{-9}$  -  $10^{-4}$  mol/L) did not alter either the  $K_d$  or  $B_{max}$  of [ $^3$ H]-citalopram binding. These concentrations of  $\alpha_1$  acid glycoprotein did dose-dependently decrease free [ $^3$ H]-citalopram concentrations as predicted from clinical pharmacokinetic studies. Identical concentrations of  $\alpha_1$  acid glycoprotein also failed to alter either the  $K_m$  or  $V_{max}$  of [ $^3$ H]-5-HT uptake. Although direct modulation of the SERT by  $\alpha_1$  acid glycoprotein is very intriguing, our studies suggest that any allosteric modulation is not a direct action of  $\alpha_1$  acid glycoprotein on the SERT molecule. **Mammalian Brain PROT is Substantially Enriched in Highly Purified Synaptic Vesicles.** R. T. Freeman, Jr., D. Kleven, and B. Domin. Dept. of Pharmacol., Duke University Medical Center, Box 3813, Durham, NC 27710.

The mammalian, brain-specific, high affinity L-proline transporter (PROT) is expressed by a subpopulation of glutamatergic neurons in rat brain (Velaz-Faircloth et al., J. Biol. Chem. 270:15755-15761, 1995). Ultrastructural immunogold-silver labeling studies revealed that the PROT protein is localized to presynaptic excitatory nerve terminals in the dorsal striatum and stratum oriens of the CA1 region of the hippocampal formation (Freeman et al., Soc. Neurosci. Abstr., Vol. 21, part 3, p. 2062, 1995). Only a subset of the morphologically-identified excitatory nerve terminals were immunolabeled. Surprisingly, in the labeled terminals the majority of immunogold-silver particles were found over synaptic vesicles. To further explore the unexpected vesicular localization of PROT, we isolated highly purified synaptic vesicles from nerve terminals and monitored the distribution of PROT during the purification in comparison to several synaptic vesicle and plasma membrane markers. We report that PROT is substantially enriched in the highly purified synaptic vesicle fraction compared to the markers for the plasma membrane. These results confirm that the immunoreactive PROT protein is targeted to synaptic vesicles in specific excitatory nerve terminals. PROT is the only protein characterized at the molecular level that is localized to synaptic vesicles in a specific subset of excitatory nerve terminals. To develop a model system for examining the subcellular targeting of the PROT protein we generated stably transfected MDCK cell lines. Immunofluorescent staining revealed that PROT is localized to a population of intracellular vesicles in the cytoplasm of MDCK cells. Little, or no plasma membrane staining was observed. These results indicate that the PROT protein contains within its primary amino acid sequence information necessary for targeting to intracellular vesicles. Supported by NIH NS32501.

## 295.3

**MOLECULAR CLONING AND CHARACTERIZATION OF THE *rosA* MUTANT IN DROSOPHILA.** C. Geng, M. G. Burg\*, G. Koliantz, Y. Guan, and W. L. Pak. Dept. of Biological Sciences, Purdue University, West Lafayette, IN 47907

Among the collection of mutants in the Pak laboratory, those that are known to be defective in photoreceptor cell function include a class of mutants known as the receptor oscillation (*ros*) mutants, which are characterized by rapid oscillations in the electroretinogram (ERG) in response to a light stimulus. We report the molecular cloning of the *rosA* (receptor oscillation  $\Delta$ ) gene using a positional cloning strategy. The *rosA* locus was mapped to the 24F6-25A1 region of chromosome 2L. We obtained P1 clones that were reported to cover this region from the *Drosophila* Genome Project. We performed Northern blot analysis using individual fragments from these genomic clones as probe and identified two DNA fragments that detected a significant reduction in a 3.7 kb transcript in several *rosA* mutants. These fragments were used as probe to isolate clones from a *Drosophila* adult head cDNA library. The largest cDNA clone obtained (3.6 kb) was used to rescue the *rosA* mutant phenotype via P-element mediated germline transformation, using a heat shock promoter to drive the expression of cDNA. All transformant lines generated (N=14) demonstrated a heat-induced rescue of the *rosA* mutant phenotype. The largest open reading frame in the cDNA encodes a protein of 777 amino acids which shares homology to a class of membrane transporters. These results indicate that the *rosA* gene product is a membrane transporter that is required for normal photoreceptor cell function. Supported by NIH grants MH49727 and EY00033.

## 295.5

**MODULATION OF CREATINE TRANSPORTER ACTIVITY BY PROTEIN KINASES.** Tea N. Kekelidze\* and Mario D. Saltarelli. Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322

The creatine kinase/phosphocreatine (CK/PC) system plays an important role in cellular ATP homeostasis. An adequate supply of creatine is necessary for the maintenance of PC levels and is achieved through the action of a high-affinity, sodium- and chloride-dependent creatine transporter (CREAT), which has been recently cloned and identified as a member of norepinephrine/GABA transporter gene family. The deduced amino acid sequence of CREAT demonstrates the presence of putative sites for phosphorylation by protein tyrosine kinase (PTK) and protein kinase C (PKC). Creatine transport activity may provide a site for the regulation of creatine homeostasis. When rat muscle (L6) and glial (C6) cell lines were grown in creatine-free media, sodium-dependent high-affinity [ $^3$ H]creatine uptake ( $V_{max}$ ) increased markedly in a time-dependent manner. To examine the role of protein kinase-mediated regulation of CREAT activity, we assessed the effects of the PTK inhibitor herbimycin and the PKC activator phorbol 12-myristate 13-acetate (PMA) on sodium-dependent [ $^3$ H]creatine uptake in L6 myoblasts. When L6 cells were incubated with 10 nM PMA for 40 min, specific [ $^3$ H]creatine uptake decreased by 30 $\pm$ 3% (X $\pm$ S.E.M; N=5; p<0.002) when compared to parallel wells incubated in either the inactive  $\alpha$ -phorbol or vehicle. The effect of PMA on [ $^3$ H]creatine uptake was both time- and concentration dependent. Additionally, when cells were incubated for 24 hr in the presence of 50 nM herbimycin during exposure to creatine-free medium, specific [ $^3$ H]creatine uptake was reduced by 22 $\pm$ 3% (X $\pm$ S.E.M; N=5, p<0.002) when compared to vehicle controls. However, when L6 cells were incubated with herbimycin (1-24 hr) in 5 mM creatine medium, specific [ $^3$ H]creatine uptake was unaltered, demonstrating that herbimycin is selectively inhibiting the mechanism which leads to CREAT up-regulation in creatine-free medium. These data suggest that CREAT activity may be modulated by two distinct protein kinases. Supported by NINDS NS01651 (MDS) and a Markey CNS Fellowship (TNK).

**Transport-related current by D-amphetamine in HEK-293-cells stably expressing the human dopamine transporter.**

H.H. Sitte<sup>1</sup>, S. Huck<sup>2\*</sup>, C. Piffl<sup>1</sup>

<sup>1</sup>Inst. of Biochemical Pharmacology and <sup>2</sup>Inst. of Neuropharmacology, University of Vienna, A-1090 Vienna, Austria.

The dopamine transporter is a member of the family of Na<sup>+</sup>/Cl<sup>-</sup>-dependent neurotransmitter-transport molecules. Interest in this plasmalemmal protein stems from its role as a terminating factor of dopaminergic neurotransmission and from its involvement in the action of the psychostimulants amphetamine and cocaine. To study the mechanism of translocation of substrates we measured transport-coupled charge transfer by the patch-clamp technique in the whole-cell configuration.

Human embryonic kidney 293-cells were transfected with the cDNA of the human dopamine transporter in the expression vector pRC/CMV and stably expressing cell clones were selected by neomycin resistance. From the different cell lines obtained we used a clone for electrophysiological studies which expressed a maximal dopamine transport rate of 1.6  $\pm$  0.3 fmol/min/cell (at 37 $^{\circ}$  C). At a holding potential of -70 mV, dopamine and amphetamine induced inward currents in a concentration-dependent manner when added by rapid superfusion system. The EC<sub>50</sub> of the effect of amphetamine was 0.4  $\mu$ M. At 10  $\mu$ M, D-amphetamine induced an inward current of 8-12 pA/100 pF (n=5). At 30  $\mu$ M, the maximal inward current induced by D-amphetamine was higher than that induced by dopamine. Effects of dopamine and D-amphetamine were blocked by 30  $\mu$ M cocaine, which per se did not evoke an inward current.

These results show that D-amphetamine behaves electrophysiologically like a substrate for the dopamine transporter and suggest that D-amphetamine is translocated into the cell at least at the same rate as the natural substrate dopamine.

## 295.4

**CLONING AND EXPRESSION OF A NEURONAL-SPECIFIC K-Cl COTRANSPORTER IN RAT BRAIN.** J. A. Payne, T. J. Stevenson, and L. F. Donaldson\*. Depts. of Human Physiology and Biological Chemistry, Univ. of Calif. Sch. of Med., Davis, CA 95616.

Using a combination of database searching, PCR, and library screening, the full-length cDNA of a K-Cl cotransporter isoform (KCC2) was identified in rat brain that is specifically localized in neurons. A cDNA of 5566 bases was obtained from overlapping clones that encoded a protein of 1116 amino acids with a core molecular mass of 124-kDa. Over its full-length, the amino acid sequence of KCC2 is 67% identical to the widely distributed K-Cl cotransporter isoform (KCC1) but only 26% identical to other members of the cation-chloride cotransporter gene family. Structural analysis indicates 12 putative transmembrane (TM) segments with 4 putative glycosylation sites on an external intermembrane loop between TM5 and TM6. HEK-293 cells stably transfected with the full-length cDNA expressed a ~50-fold greater furosemide-sensitive <sup>86</sup>Rb influx than control cells. This <sup>86</sup>Rb influx absolutely required external Cl<sup>-</sup> but not external Na<sup>+</sup>. Rat tissue Northern blot analysis revealed a very highly expressed ~5.6-kb transcript in brain only. Reverse-transcriptase PCR revealed that KCC1 was present in rat primary astrocytes and rat C6 glioma cells but that KCC2 was absent from these cells, suggesting that KCC2 is not of glial cell origin. *In situ* hybridization studies demonstrated that the KCC2 transcript was expressed at very high levels in neurons throughout the central nervous system, including pyramidal neurons of the hippocampus, granular cells and Purkinje neurons of the cerebellum, and many groups of neurons throughout the brainstem. It is proposed that KCC2 is a major Cl<sup>-</sup> efflux pathway in neurons and helps maintain low cell [Cl<sup>-</sup>] and an inwardly-directed Cl<sup>-</sup> electrochemical gradient for the proper function of ligand-gated Cl<sup>-</sup> channels (i.e. GABA<sub>A</sub> receptor) in postsynaptic inhibition. (Supported by start-up funds)

## 295.6

**CYTOSOLIC ASPARTATE AMINOTRANSFERASE BINDS TO NEURONAL PLASMA MEMBRANES.** John C. Lehmann\*, Denis Karkov and Angela Harty. Dept. Neurosurgery MS 407, Medical College of Pennsylvania and Hahnemann University, Philadelphia PA 19102-1192.

Two genes encode aspartate aminotransferase (AAT), one which is incorporated into mitochondria (mAAT) and one which is found in the cytosol (cAAT). High cAAT-like immunoreactivity has been used in the past to map putative glutamatergic neurons. cAAT converts 2-oxoglutarate (2OG) into glutamate. A high affinity sodium dependent carrier exists in the plasma membrane for 2OG.

Data obtained from Western blots suggests that cAAT binds to the neuronal plasma membrane in brain with a heterogeneous regional distribution, correlating with the known density of glutamatergic innervation of the brain. The hypothesis is entertained that cAAT is bound to the internal surface of the glutamatergic neuronal membrane to rapidly convert 2OG, released from astrocytes, to neurotransmitter glutamate. Extracellular glutamate exerts a negative feedback inhibition of 2OG uptake. EY10140

## 295.8

**NEURONAL AND ASTROCYTIC EXPRESSION OF EAAC1, A HIGH-AFFINITY GLUTAMATE TRANSPORTER, IN THE CEREBRAL CORTEX.** E. Conti\*, A. Minelli, M. Melone, S. DeBiasi\*, and J.D. Rothstein\*. Inst. Hum. Physiol., Univ. of Ancona, Ancona, Italy; \*Dept. Physiol. and Biochem., Univ. of Milano, Milano, Italy; and \*Dept. of Neurology, Johns Hopkins Univ., Baltimore, MD, 21287, USA.

The cellular localization, distribution, morphology, and transmitter content of neocortical cells expressing EAAC1, a high-affinity glutamate transporter, have been studied by immunocytochemistry with antipeptide antibodies (Rothstein et al., 1994) raised in rabbits against the C-terminal amino acid sequence (DKSDDTISFTQTSQF) of the transporter (Kanai et al., 1992, 1995; Bjoras et al., 1996). Adult rats were perfused through the ascending aorta with 4% paraformaldehyde for light microscopy, or with 4% paraformaldehyde and 0.5% glutaraldehyde for electron microscopy.

Light microscopic analysis showed that: i) EAAC1-positive neurons are present throughout the cortical mantle, although they are more numerous in layers V-VI and II-III; ii) EAAC1-positive neurons are mostly pyramidal, but some are non-pyramidal; and iii) some EAAC1-positive glial cells are present in the white matter underlying the neocortex. Co-localization studies performed using the paired surface method (Kosaka et al., 1985) showed that: i) most EAAC1-positive pyramidal neurons are Glu-positive; ii) most EAAC1-positive non-pyramidal neurons are GAD-positive; and iii) most EAAC1-positive glial cells of the white matter are GFAP-positive. At the electron microscopic level, EAAC1 immunoreactivity in the cerebral cortex is present in neuronal perikarya and dendritic processes, but not in axon terminals, and in some distal astrocytic processes.

The present results suggest that the function of EAAC1 may not be limited to the termination of Glu-mediated synaptic transmission. Indeed, the expression of EAAC1 in Gluergic and GABAergic neurons and in astrocytes, but not in Gluergic axon terminals, seems to indicate that this transporter plays a major role in the overall regulation of Glu metabolism. (Funded by MURST and NIH)

## 295.9

**Na<sup>+</sup>, K<sup>+</sup>, AND H<sup>+</sup> FLUX COUPLING IN A GLUTAMATE TRANSPORTER**  
J.L. Wadiche\*, N. Zernig, and M.P. Kavanaugh. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201

Although glutamate uptake kinetics are slow relative to the fastest events in excitatory synaptic transmission (Wadiche et al. Neuron 14:1019 1995), glutamate transport controls steady-state concentration of transmitter, which can in turn influence receptor activity over long time scales (Trussel & Fischbach Neuron 3:209 1989). A human neuronal glutamate transporter (EAAT3) was expressed in *Xenopus* oocytes and transport-specific radiotracer flux, electrical currents, and BCECF fluorescence changes were measured under voltage clamp. Forward transport resulted in an intracellular acidification which decreased with increasing pK of the amino acid substrate, suggesting transport of a protonated species. Both influx and efflux were reduced in the presence of kainate, a competitive transport antagonist which does not itself induce a current and is not transported. The reversal potential of the kainate-sensitive transport current was shifted by increasing [L-Glu]<sub>o</sub> (32mV/decade), [Na<sup>+</sup>]<sub>o</sub> (101mV/decade), [K<sup>+</sup>]<sub>o</sub> (-31mV/decade), and [H<sup>+</sup>]<sub>o</sub> (25mV/decade). The transport reversal potential,  $\Psi$ , was related to the transmembrane concentration gradients for Glu<sup>-</sup>, Na<sup>+</sup>, K<sup>+</sup>, and H<sup>+</sup> according to the function:

$$\Psi = (RT/2F) \ln \left( \frac{([Glu]_o/[Glu]_i)([Na]_o/[Na]_i)^{3.16}([K]_o/[K]_i)^{0.97}([H]_o/[H]_i)^{0.78}}{1} \right)$$

The data suggest that permeation of one glutamate molecule is coupled to permeation of three Na<sup>+</sup> ions and one proton, with counterflux of one K<sup>+</sup> ion. This transport cycle results in a free energy change capable of maintaining a transmembrane glutamate concentration gradient exceeding 10<sup>6</sup> in normal ionic conditions and an inwardly directed gradient over the range of ionic conditions typically encountered in pathological conditions such as ischemia.

## 295.11

**GLUTAMATE TRANSPORTERS AND UPTAKE IN PLATELETS AS POSSIBLE PERIPHERAL MARKERS IN NEURODEGENERATIVE DISORDERS.**

C.Ferrarese\*, T.Cogliati\*, C. Zoia, G.Bianchi, M.Bugiani, G.Cavaletti, M.Frigo, N.Pecora, and L.Fratola. Department of Neurology, University of Milan - Ospedale San Gerardo, Monza and \*Scientific Institute "E.Medea", Bosio Parini-ITALY.

Since modifications of glutamate uptake have been described in brain samples in degenerative disorders and appear related to excitotoxicity, we aimed to investigate these processes in platelets, as possible peripheral markers of excitotoxic mechanisms.

We first used polyclonal anti-peptide antibodies that specifically recognize EAAC1, GLT-1 and GLAST glutamate transporters (provided by Prof. JD Rothstein, Baltimore, MD) to assess, by Western-blot and electron microscopy coupled with the immunogold method, the type of transporter present in platelets. Uptake experiments were then performed using [<sup>3</sup>H]glutamate; glutamate content was also investigated by reverse-phase HPLC with pre-column derivatization with o-phthalaldehyde and fluorimetric detection.

Data from platelets of normal volunteers were then compared to those of 34 Parkinson's Disease (PD) patients and 10 age related controls. Studies on Alzheimer's disease and Amyotrophic Lateral Sclerosis patients are now in progress.

Western blot and the immunogold studies revealed that both the neuronal- and glial-type transporters are present in human platelets.

A significant 35 % reduction of glutamate uptake ( $p < 0.05$ ) was observed in PD patients, respect to controls. The decrease was more consistent and significant ( $p < 0.01$ ) in the subgroup of idiopathic PD and correlated with the severity of PD, measured by the UPDRS ( $r = -0.61$ ;  $p < 0.05$ ).

Source of funding was the University of Milan.

**HIGH K<sup>+</sup> AND ENERGY FAILURE INDUCE NON-VESICULAR GLUTAMATE EFFLUX BY DIFFERENT ROUTES: EVIDENCE FOR NON-THERMODYNAMIC CONTROL.** M.C. Longuemare\*, K. Farrell, and R.A. Swanson. Dept. of Neurology, Univ. of California and VAMC, San Francisco, CA 94121.

Glutamate may be released from astrocytes via anion channels and by reversal of uptake. The thermodynamic model of Na<sup>+</sup>-dependent glutamate transport predicts that increased [K<sup>+</sup>]<sub>o</sub> will increase [glutamate]<sub>o</sub> via reversal of glutamate uptake. Glutamate was measured in media of rat astrocyte cultures. Cultures exposed to isosmolar elevations in [K<sup>+</sup>]<sub>o</sub> released far less glutamate than predicted by the thermodynamic model. In contrast, glutamate release during 60 min of energy failure (glycolytic and oxidative blockade) approached the predicted maximal value. Glutamate release also appears to occur by different routes during energy failure and high [K<sup>+</sup>]<sub>o</sub>. Pre-loading cultures with PDC, a competitive inhibitor of Na<sup>+</sup>-dependent glutamate transport, reduced glutamate efflux by 70% during energy failure but had no effect on K<sup>+</sup>-induced release. The anion channel blocker SITS had opposite effects, causing a 65% reduction in efflux during high [K<sup>+</sup>]<sub>o</sub> but minimal effect on efflux during energy failure. Taken together, these results suggest that reversal of glutamate uptake can be regulated by factors other than thermodynamic forces. Uptake reversal may be the primary mechanism of efflux during energy-failure, while K<sup>+</sup>-induced glutamate release may occur primarily through anion channels. Supported by NIH RO1 NS31914

**PORTACAVAL-SHUNTING AND HYPERAMMONEMIA SELECTIVELY STIMULATE THE UPTAKE OF L-ARGININE BUT NOT OF L-NITROARGININE INTO RAT BRAIN SYNAPTOSOMES.** V.L. Raghavendra Rao, R.M. Audet and R.F. Butterworth\*. Neuroscience Research Unit, Hôpital Saint-Luc (University of Montreal), Montreal, Quebec, Canada H2X 3J4

Elevated activities of nitric oxide synthase (NOS) have been previously described in the brains of portacaval-shunted (PCS) rats (Raghavendra Rao et al., J. Neurochem. 65, 677-681, 1995). As L-arginine availability for nitric oxide synthesis depends on specific uptake mechanisms in neurons, we studied the kinetics of L-[<sup>3</sup>H]arginine uptake into synaptosomes prepared from the brains of PCS rats. L-arginine uptake was significantly increased in cerebellum, cortex, hippocampus, striatum and olfactory bulb (+24% to +60%,  $p < 0.01$ ) of PCS rats compared to sham-operated controls. Hyperammonemia also stimulated the transport of L-arginine significantly. Kinetic analysis revealed that the elevated uptake is due to an increased V<sub>max</sub>. Incubation of cerebellar synaptosomes with NH<sub>4</sub>Ac for 10 min resulted in a dose-dependent stimulation of L-arginine uptake. This stimulation was blocked by the NOS inhibitor, N<sup>G</sup>-monomethyl-L-arginine acetate but not by N<sup>G</sup>-nitro-L-arginine or N<sup>G</sup>-nitro-L-arginine methyl ester. Neither PCS nor hyperammonemia had any significant effect on the uptake of L-nitroarginine into synaptosomes. These results suggest that increased NOS activity observed in HE is due to increased availability of L-arginine due to a direct stimulatory effect of ammonia on L-arginine transport. (Funded by MRC Canada)

## PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING III

**INTRINSIC REGULATION OF THE AXONAL ARBOR OF MESENCEPHALIC DOPAMINERGIC NEURONS.** A. Heller\*, H. Choi and L. Won. Dept. of Pharmacol. & Physiol. Sci., The University of Chicago, Chicago, IL 60637.

A variety of studies indicate that both competition and intrinsic regulation play a role in determining the size of specific afferent axonal arbors innervating particular brain nuclei during development. In order to assess the role of these factors in determining dopaminergic (DA) axonal arbor size, mesencephalic DA neurons were grown in three-dimensional reaggregate culture in which striatal target cells were present in excess of that required for quantitative DA neuronal survival. Since a ratio of 1:2 (mesencephalic: striatal cells) provides sufficient target for quantitative survival of DA neurons, higher ratios of up to 1:50 provided excess target to allow for possible expansion of the dopaminergic axonal arbor if it were limited by axonal competition. Determination of dopamine content and axonal arbor size per DA neuron in the aggregates revealed that the size of the DA axonal arbor, over the first three weeks of development, remains constant in the face of increasing target availability. The use of three-dimensional reaggregate culture provides a new approach to the examination of the role of competition for target space in determining axonal arbor size. The findings provide direct evidence that during development, the size of the DA axonal arbor is limited by an intrinsic regulatory program which is independent of the extent of availability of target space. Supported by NIMH grant #MH 28942.

## 296.2

**NERVE CORD REPAIR IN 3-D COLLAGEN GEL CULTURES.** S.E. Blackshaw\*, C. Cameron & J.A. Davies<sup>1</sup>. Institute of Biomedical & Life Sciences, Joseph Black Building, University of Glasgow G12 8QQ, Scotland and <sup>1</sup>Sussex Centre for Neuroscience, Sussex University, Falmer, Brighton BN1 9QG, UK.

Our aim was to establish whether 3-D collagen gels, widely used to reconstruct extracellular matrices for mammalian cells, would support the growth *in vitro* of leech neurons and other cell types involved in neural repair. Collagen was prepared as an acid extract of rat tail tendons in Leibovitz-15 culture medium, and its composition and pH adjusted to give a gel that sets at room temperature. Ganglia or isolated pieces of connectives from the ventral nerve cord of *Hirudo medicinalis* were embedded in the gel and maintained for up to 2 weeks. During this time nerve fibre outgrowth into the gel was consistently seen from the cut ends of both nerve roots and connectives. The gel was also clearly penetrable by cells migrating out from the cut ends of connectives. When the connectives between two ganglia were completely severed, or when two ganglia with shortened connectives were apposed, repair occurred within the gel in such a way that the gap between the cut ends was bridged within 2-5 days in culture. Cells emigrating from the cut ends of the connectives appeared to contribute to the repair process. In summary, 3-D collagen gels provide an *in vitro* system in which we can reliably obtain repair of nerve cords in the dish and visualise cell behaviour underlying regenerative growth at the damage site. Supported by BBSRC

## 296.3

PMCA AND SV-2 EXPRESSION IN DEVELOPING SYNAPTIC TERMINALS. J.T. Fujii\* and E.T. Su. Dept. of Anatomy & Cell Biology, Wayne State U. Sch. of Med., Detroit, MI 48201

Although the plasma membrane calcium ATPase pump (PMCA) is typically located in the plasma membrane, in recent fine structure studies PMCA immunoreactivity has been found associated with cholinergic synaptic vesicles in the calyciform terminals formed by Edinger-Westphal neurons in the chick ciliary ganglion (Fujii et al., in press). To further study the relationship of PMCA with synaptic vesicles, expression of PMCA immunoreactivity in the ciliary ganglion during development was compared with that of the synaptic vesicle protein SV-2.

SV-2 immunoreactivity appears early in the development of the ciliary ganglion (Hamburger & Hamilton stages 27-29) in a fine, punctate pattern outlining neurons and defining processes. In contrast, patterns of PMCA immunoreactivity are not punctate, appearing instead to coarsely outline the boundaries of neurons. However, as calyciform terminals begin to coalesce and mature morphologically (stages 36-37), patterns of PMCA immunoreactivity come to resemble those of SV-2 very closely, with both heavily labelling newly formed calyciform terminals. This shift in the pattern of PMCA immunoreactivity suggests that PMCA may become associated with synaptic vesicles only as they become part of a mature synaptic terminal, the earlier staining pattern being associated with unrelated PMCA expression in other parts of the cells. Alternatively, it is also possible that PMCA immunoreactivity is associated with a membrane compartment that is distinct from synaptic vesicles and becomes co-localized with them as the synaptic terminals mature. Supported by NIH RO1 EY09768.

## 296.5

NITRIC OXIDE (NO<sup>•</sup>) STABILIZES FILOPODIA WHILE NITROSONIUM DONORS (NO<sup>+</sup>) INDUCE OUTGROWTH BY RAT RETINAL GANGLION CELLS IN VITRO. Wing Cheung, Ishir Bhan, and Stuart A. Lipton\*. Dept. of Neurol., Children's Hospital; Progr. in Neuroscience, Harvard Med Sch, Boston, MA 02115.

Recent observations suggest that NO donors can either increase or decrease filopodial and neurite activity (Wang et al., 1993; Hess et al., 1993; Renteria et al., 1994). To explain these seemingly discordant findings, we wondered if different redox-related species of the NO group could display differential effects on outgrowth, analogous to previous findings reporting that NO<sup>•</sup> donors could be neuroprotective while NO<sup>+</sup> donors participate in neurodegenerative pathways (Lipton et al., 1993). Here, 450 acutely isolated retinal ganglion cells from P1-P3 rat pups were identified with specific fluorescent tags and monitored over a 5 min period for filopodial outgrowth under computer-enhanced video microscopy (AVEC-DIC) in the presence or absence of various NO donors or membrane permeant cyclic nucleotide analogs. In parallel, digital Ca<sup>2+</sup> imaging was performed with fluo-3 under confocal microscopy. In the presence of SOD/catalase to prevent peroxynitrite (ONOO<sup>-</sup>) formation from NO<sup>•</sup> and O<sub>2</sub><sup>•-</sup>, NO<sup>•</sup> donors (e.g., DEA/NO) or cGMP led to stabilization of filopodia. In contrast, donors capable of transferring NO<sup>+</sup> to thiol (e.g., S-nitrosocysteine + SOD/catalase) led to filopodial growth. Under conditions in which low concentrations of ONOO<sup>-</sup> could form (DEA/NO or S-nitrosocysteine, each in the absence of SOD/catalase), outgrowth was markedly enhanced. These results suggest that oxidation of critical thiol (s) of growth-associated proteins may enhance filopodial elongation while cGMP formation via NO<sup>•</sup> may halt or stabilize filopodia.

OBSERVATIONS OF THE DEVELOPMENT OF POLARITY IN CULTURED HIPPOCAMPAL NEURONS BY TIME-LAPSE VIDEO MICROSCOPY. J. Cooper and G. Banker\*. Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, Virginia, 22908.

Hippocampal neurons developing in culture initially extend several apparently identical neurites, termed minor processes. Previous work from this laboratory suggests that the minor processes grow and retract for several hours until one of them begins to grow much more than the others, becoming the cell's axon. To gain further insight into what triggers this emergence of polarity and how one process is chosen to become the axon, we examined these events by time-lapse video microscopy of individual neurons. Observations were begun 8 hours after plating and continued for several hours after the axon had formed. Our results show that prior to axon formation the minor processes undergo spurts of rapid growth lasting for 30 to 40 minutes followed by periods of quiescence or retraction. The emergence of the axon occurs when one of the processes, which is otherwise indistinguishable from the others, exhibits a novel pattern of growth. It undergoes a spurt of growth that is not significantly faster than other growth spurts, but that persists for a much longer time without interruption. As this occurs, there is also a noticeable decrease in the growth of the cell's other neurites. Thus the first steps in the emergence of neuronal polarity are marked by a change in the pattern of neurite outgrowth that involves all of the cell's processes, not just the emerging axon itself. Supported by NIH grant NS17112.

## 296.4

THE NEURAL CELL ADHESION MOLECULE L1 UTILIZES TWO DISTINCT MECHANISMS IN PROMOTING NEURITE OUTGROWTH FROM NEURONAL CELLS. P. Yip, X. Zhao, and C.-H. Siu\*. Banting and Best Department of Medical Research, University of Toronto, Toronto, Ontario M5G 1L6, Canada.

L1 is an important neural cell adhesion molecule, which contains six immunoglobulin (Ig)-like domains, five fibronectin type III repeats, a transmembrane domain and a cytoplasmic domain. L1 mediates cell-cell adhesion via homophilic binding and promotes neurite outgrowth from a variety of primary neurons. We have demonstrated that the Ig-like domain 2 (Ig2) of L1 contains both homophilic binding and neurite outgrowth activities (*J. Biol. Chem.* 270:29413-29421). Using fusion proteins containing different portions of the L1 extracellular domain, we have identified a second neurite outgrowth site in Ig-like domain 6 (Ig6). Primary neurons were cultured on different substrate-coated proteins for 20 hr and neurite lengths were measured. In addition to Ig2, fusion proteins containing Ig6 were able to promote neurite outgrowth from dorsal root ganglion cells and hippocampal cells. In contrast, neural retinal cells responded to Ig2-containing proteins only. The neurite outgrowth activity of L1 Ig6 was inhibited when assayed in the presence of soluble fusion protein or domain-specific antibodies. L1 Ig6 contains a RGD sequence, suggesting that it may interact with an integrin. When RGD-containing synthetic peptides were included in the assay, neurite outgrowth was inhibited in a dose-dependent manner. These results indicate that L1 utilizes two distinct mechanisms to induce neurite outgrowth from neuronal cells, one involving L1-L1 homophilic interaction and the other one involving L1-integrin interaction. (Supported by the Medical Research Council of Canada.)

## 296.6

NON-UNIFORM PRESENTATION OF LAMININ CAN DIRECT AXON FORMATION IN CULTURED RAT HIPPOCAMPAL NEURONS. T. Each\* and G. Banker\*. Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, Virginia, 22908.

Cultured hippocampal neurons growing on polylysine-coated coverslips initially extend several apparently identical neurites, termed minor processes. Previous experiments from this laboratory have suggested that any of the minor processes may become the cell's axon, and that which process does become the axon is determined by chance. In the present experiments, we examined the ability of locally presented, substrate-associated molecules to increase the probability that a given minor process will become the axon. We plated neurons on coverslips patterned with alternating stripes of laminin and polylysine and determined whether the minor processes whose growth cones extended on a laminin stripe were more likely to become an axon. Cells were fixed and examined 24 hours after plating. In cells that had at least one process contacting each substrate, 80-90% of the axons formed on laminin, many more than would be expected by chance. This effect was seen most consistently in cells whose somata were on polylysine. To examine this phenomenon more closely, neurons were followed by time-lapse video recording during the first 24 hours in culture. Of particular interest were cells whose minor processes initially developed on a polylysine stripe. In many of these cells, if the growth cone of one minor process crossed onto a laminin stripe, that process immediately entered a prolonged period of growth, becoming the cell's axon. These results indicate that local, substrate-associated cues can influence which of a cell's minor processes becomes its axon. This work was supported by NIH grant NS17112.

## 296.8

PURIFICATION AND MOLECULAR CLONING OF AN INHIBITOR TO CNS REGENERATION

Spillmann\*, A.A.; M.S. Chen, M.S.; M.E. Schwab. Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland.

We have previously characterized a high molecular-weight (250 kd) protein purified from bovine myelin. This 250 kd protein inhibits neurite outgrowth from NGF treated PC12 cells, it also induces DRG growth cone collapse. These inhibitory activities can be fully neutralized by IN-1, a monoclonal antibody raised against NI250, which enhances regeneration of lesioned nerve fibers in vivo. This 250 kd protein, bNI250, from bovine myelin is therefore likely to be the bovine equivalent of the rat derived NI250.

We have now further demonstrated that this potent inhibitor activity of bovine myelin is specific to bNI250, but not other proteins of similar molecular weight. Treatment with partially purified C6 metalloprotease suppresses the bNI250 inhibitor activity to the similar extent as IN-1 treatment, in contrast to chondroitinase digestion, which does not alter bNI250 activity. When subjected to deglycosylation treatment, the mobility of bNI250 did not change, indicating that bNI250 is not likely to be extensively glycosylated. Microsequencing of gel eluted bNI250 has produced several novel peptide sequences. Antisense oligonucleotides were synthesized from back translation of these peptide sequences, and their effects on the inhibitor activity of cultured oligodendrocytes are studied. Oligonucleotides with sequences derived from bNI250 peptide sequences were also used for both library screening and rapid amplification of cDNA end (RACE). Multiple clones isolated from library screening, as well as 5' and 3'RACE are currently being analyzed.

## 296.9

A NEUROTRANSMITTER IS RELEASED FROM VARIOUS REGIONS OF NEURITES. H. Soeda<sup>1</sup>, H. Tatsumi<sup>2</sup> and Y. Katayama<sup>1\*</sup>. <sup>1</sup>Department of Autonomic Physiology, Medical Research Institute, Tokyo Medical and Dental University, <sup>2</sup>PRESTO JRDC, Japan.

Growing neurites of rat dorsal root ganglion (DRG) neurons in culture formed growth cones at their tips. Glutamate released from these growth cones was detected by using a whole cell patch-clamp recording from an acutely dissociated hippocampal neuron containing glutamate receptors; inward currents were recorded from the hippocampal neuron as a biotector positioned on the growth cones of the DRG neurons in response to the DRG cell body stimulation. Electrophysiological and pharmacological properties of the inward currents indicate glutamate release. Inward currents were also recorded when a biotector was positioned on flat tips and flat branching regions of neurites. All of these inward currents were the same in their properties, suggesting the glutamate release from the flat structures of neurites as well as the growth cones. The inward currents were abolished by a  $\text{Ca}^{2+}$  free external solution or  $\omega$ -agatoxin IVA (300 nM). Intracellular calcium ion concentration ( $[\text{Ca}^{2+}]_i$ ) in the growth cones and the other release-sites of neurites increased in response to DRG cell body stimulation, whereas the elevation of  $[\text{Ca}^{2+}]_i$  was not observed either in the presence of TTX (1  $\mu\text{M}$ ) or in a  $\text{Ca}^{2+}$  free external solution. These results suggest that growth cones and the flat neurite regions are already endowed with much of the machinery for neurotransmitter release even before making a structure for synaptic transmission.

This study was supported by a Grant-in-Aid for Scientific Research from The Ministry of Education, Science and Culture of Japan.

## 296.11

DIACYLGLYCEROL LIPASE INHIBITION REVERSIBLY SLOWS *XENOPUS* RETINAL GROWTH CONES *IN VITRO* AND *IN VIVO*. B. Lom<sup>\*</sup>, S. McFarlane, & C.E. Holt. Biology, UCSD, La Jolla, CA 92037

The *Xenopus* retinotectal projection is a uniquely accessible system to study retinal ganglion cell (RGC) growth and guidance. Fibroblast growth factor-2 (FGF-2) stimulates *Xenopus* RGC axon extension *in vitro*, while inhibiting FGF receptors (FGFR) slows axon extension *in vitro* and *in vivo* (McFarlane et al. *Neuron* 15: 1017; *Soc. Neurosci. Abstr.* 21: 1293). Activated FGFRs are thought to transmit signals by phospholipase C phosphorylation to produce diacylglycerol (DAG) that is converted to arachidonic acid (AA) by DAG lipase, causing  $\text{Ca}^{2+}$  influx and neurite extension (Williams et al. *Development* 120: 1685). To determine if *Xenopus* RGC axon extension employs this signaling cascade, DAG lipase activity was blocked by RHC-80267 *in vivo* and *in vitro*.

*In vitro* application of 100  $\mu\text{M}$  RHC-80267 halted *Xenopus* RGC growth cone extension within minutes. Growth cones then collapsed, withdrawing their lamellipodia and filopodia, and eventually retracted. Thirty minutes after washing out the DAG lipase inhibitor, growth cones reformed active lamellipodia and filopodia, and resumed forward extension. *In vivo*, RGC extension rates were also significantly and reversibly reduced by DAG lipase inhibition. Chronic application of 500  $\mu\text{M}$  RHC-80267 to exposed *Xenopus* brains during the stage when RGCs extend along the optic pathway significantly shortens optic projection lengths. When individual RGC growth cones were observed *in vivo* by time-lapse video microscopy, extension rates were significantly reduced within minutes of 500  $\mu\text{M}$  RHC-80267 application. Growth cones consistently stalled in the optic pathway, occasionally collapsed, but rarely retracted. Extension rates and growth cone morphologies rapidly recovered after inhibitor removal. These results suggest that DAG lipase mediated conversion of DAG to AA is involved in RGC axon extension.

## 296.13

THE INTERACTION OF CORTICAL NEURON EPH RECEPTORS REK7 AND SEK WITH THE ASTROCYTIC LIGAND AL-1. Ai Shih, Janet Valverde-Beck, Paul Moran, Gary Laramée, Robert Soriano\*, Klaus Beck, Ingrid Caras, John Winslow. Dept. of Neuroscience, Genentech, Inc. S. San Francisco, CA 94080.

AL-1 is a member of the GPI-linked family of ligands for the eph tyrosine kinase receptors, and is the human homologue of RAGS, the retinal ganglion axonal guidance factor which influences topographical innervation of the chick tectum. We have shown that AL-1 and its receptor REK7 (EHK1 or bsk) is also involved in the axonal fasciculation of rat embryonic cortical neurons. We demonstrate that cortical neuron fasciculation *in vitro* requires cell contact between cortical neurons and astrocytes, and correlates with increased neuronal REK7 autophosphorylation upon co-culture. The activation of cortical neuron REK7 by astrocytic AL-1 is consistent with the neuronal and astrocytic expression of REK7 and AL-1 mRNA, respectively. A REK7-IgG fusion protein blocks fasciculation when added at the time that cortical neurons are plated on an astrocyte monolayer, but only partially blocks upon delayed addition, suggesting that neuronal-astrocytic contact results in an early, irreversible reaction supporting fasciculation. A soluble AL-1-IgG fusion protein potentially activates the tyrosine kinase of the eph receptor SEK in addition to that of the REK receptor, in both transfected cells and cortical neurons. Together with mRNA expression of REK7 and SEK in cortical neurons, these results suggest that multiple eph receptors may be involved in cortical neuronal function such as axonal fasciculation and guidance.

## 296.10

CATECHOLAMINES AND BASIC FIBROBLAST GROWTH FACTOR DIFFERENTIALLY REGULATE CYTOSKELETAL PROTEINS DURING NEURITE OUTGROWTH IN A BASAL FOREBRAIN CELL LINE. J. Kwon<sup>1</sup>, M. Downen<sup>1</sup>, L. Roback<sup>2</sup>, E. Eves<sup>2</sup> and B.H. Wainer<sup>3</sup>. Dept. <sup>1</sup>Path., Albert Einstein Med. College, Bronx, NY 10461; <sup>2</sup>Ben May Inst., Univ. of Chicago, Chicago, IL 60637; <sup>3</sup>Emory Univ., Atlanta, GA, 30329.

Neurite outgrowth in the developing nervous system has been shown to be influenced by growth factors and neurotransmitters. We have previously described the generation of an embryonic day 14-15 rat basal forebrain neuronal cell line (Soc. Neurosci. Abs. 17:37, 1991) that undergoes neuritogenesis in response to catecholamines and basic fibroblast growth factor (bFGF). The catecholamines, via activation of  $\beta_2$ -adrenergic receptors, induce a stellate morphology with neurite outgrowth evident within 60 minutes while bFGF induces a bipolar morphology evident within 24 hours. Two-dimensional gel electrophoresis with isoelectric focusing and SDS-PAGE of cytoskeletal preparations and [ $^{32}\text{P}$ ]-orthophosphate incorporation studies indicate that  $\beta_2$ -adrenergic agonist and bFGF treatments result in the differential regulation of cytoskeletal elements. Further studies indicate that post-translational modifications of tubulin are differentially segregated in response to  $\beta_2$ -adrenergic agonists and bFGF. The distribution of the post-translationally modified tubulins is similar to that seen in primary basal forebrain neurons. These results suggest that neurite outgrowth in the developing basal forebrain is dependent upon both neurotransmitters and growth factors, which differentially regulate cytoskeletal proteins. (Supported by NS 25787 and AECOM BRSG.)

## 296.12

THE FUSION PROTEIN, AL-1 IgG, CAUSES COLLAPSE AND RETRACTION OF CORTICAL NEURONS. L. Meima, J. Kljavin, P. Moran, A. Shih, J. Winslow\*, and J. W. Caras. Department of Neuroscience, Genentech, South San Francisco, CA 94080.

Previous experiments using cultured cortical neurons suggest that the Eph-related receptor, REK7, and its ligand, AL-1, are involved in axon fasciculation. From this, together with recent findings that the chick homologue of AL-1, RAGS, acts as a repellent axon guidance molecule in the chick visual system, we hypothesized that AL-1 may act as a repellent guidance molecule in the rat cortex as well as in the visual system.

Using video microscopy, we show that an AL-1 IgG fusion protein causes growth cone collapse and axonal retraction when added to cultures of rat retinal ganglion cells and E16-E17 cortical explants. Growth cone morphologies were classified as collapsed, partially collapsed, and normal (did not respond to treatment) for scoring purposes. Experiments with 7.1  $\mu\text{g}/\text{mL}$ , 1.4  $\mu\text{g}/\text{mL}$ , and 0.14  $\mu\text{g}/\text{mL}$  of AL-1 IgG demonstrate that the growth cone response is dose dependent, and that the ratio of collapsed to partially collapsed growth cones increases with increasing AL-1 IgG concentration. In contrast, the number of growth cones that did not respond to AL-1 IgG treatment was virtually unchanged at the three concentrations, suggesting that a subset of neurons are unresponsive to AL-1 IgG. Immunostaining with an anti-REK7 antibody suggests that responsiveness to AL-1 IgG is mediated by REK7.

Changes in growth cone morphology are thought to be associated with cytoskeletal changes. Consistent with this, AL-1 IgG induces a rapid and dramatic reorganization of the actin cytoskeleton in cortical growth cones, similar to the effects of cytochalasin D. This suggests that AL-1 IgG induces growth cone collapse by perturbing actin polymerization.

BOTULINUM NEUROTOXIN C1 INDUCES GROWTH CONE COLLAPSE. M. Igarashi<sup>1</sup>\*, S. Kozaki<sup>2</sup>, S. Terakawa<sup>3</sup>, S. Kawano<sup>4</sup>, C. Ide<sup>4</sup>, Y. Komiya<sup>1</sup>. <sup>1</sup>Dept Molec Cell Neurobiol, Gunma Univ Sch Med, Gunma; <sup>2</sup>Dept Vet Med, Osaka Pref Univ, Osaka; <sup>3</sup>Photon Med Ctr, Hamamatsu Med Sch, Shizuoka; <sup>4</sup>Dept Anat, Univ Kyoto, Kyoto, Japan.

The most likely cause of the membrane expansion for axonal growth is that vesicles in the central domain of growth cones are added to growth cone plasmalemma through exocytosis. A molecular model for vesicular targeting in exocytosis has recently been proposed, referred as the SNARE hypothesis. To test the hypothesis is applicable to membrane expansion for axonal growth, we observed the effect of neurotoxin C1 of *Clostridium botulinum*, cleaving syntaxin, which is essential to targetin of synaptic vesicles as a t-SNARE, to the growth cone. C1 caused growth cone collapse and inhibition of axonal growth. Video-enhanced microscopic study showed (a) that C1 selectively blocked the central domain at the initial stage, but not the lamellipodia; and (b) that large vacuole formation occurred through fusion of smaller vesicles from the central domain to the most distal segments of normal axonal growth. Our results demonstrate that syntaxin is involved in axonal growth, indicating that syntaxin may participate directly in membrane expansion in the central domain, in a SNARE-like way.

**INTRACELLULAR CALCIUM MODULATES NCAM POLYSIALYLATION IN DEVELOPING NEURONS.** Juan L. Brusés\* and Urs Rutishauser. Departments of Genetics and Neurosciences, Case Western Reserve University, Cleveland OH 44106.

The expression of NCAM in its high polysialic acid (PSA) form on developing motoneurons is down-regulated by the interaction of neurons with muscle. This regulation appears to occur at the level of PSA synthesis. To study the mechanism of the regulation, the chicken cDNA encoding polysialyltransferase (PST), the enzyme responsible for PSA synthesis, was cloned and the developmental expression of the PST mRNA in the chick ciliary ganglia was studied by northern blot analysis. PST transcript levels were found to remain constant during the period of target innervation and to decrease before hatching (St 41-42). However, no change in PST mRNA level was detected at the time of synaptogenesis, when PSA synthesis is sharply reduced (St 36-37). Therefore, non-transcriptional mechanisms that could control PST activity were investigated. It was found that NCAM polysialylation is suppressed by calcium ionophores (A23187 [1  $\mu$ M] and ionomycin [10  $\mu$ M]) after 90 minutes of incubation, and by thapsigargin [10  $\mu$ M], an intracellular calcium pump inhibitor. However, NCAM polysialylation was not affected by other drugs that increase cytosolic calcium such as caffeine or ryanodine. These results suggest that the ionophore and thapsigargin induced decreases in PST activity were due to a depletion of calcium in intracellular stores. This  $Ca^{2+}$ -related inhibition of NCAM polysialylation was found to occur specifically at the level of PSA synthesis, in that maturation of the carbohydrate core on which PSA is added was not affected by A23187. These results suggest a direct and rapid mechanism for regulation of NCAM polysialylation via changes in calcium concentration in intracellular compartments. ## PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING IV

## 297.1

**REGULATION OF CEREBELLAR PURKINJE CELL GROWTH BY CERAMIDE GENERATED FROM SPHINGOMYELIN.** S. FURUYA\*, and Y. HIRABAYASHI, Lab. for Cellular Glycobiology, FRP, The Institute of Physical and Chemical Research (RIKEN), Saitama 351-01, Japan.

There is accumulating evidence that ceramide released by sphingomyelinases in response to various stimuli influences cell growth, differentiation, and programmed cell death in many types of cells. Ceramide has now emerged as a new type of lipid messenger, and is postulated to have a role in CNS by the fact of an abundance of sphingomyelin in brain. Immunohistochemical examination using anti-sphingomyelin monoclonal antibody demonstrated that a particular type of sphingomyelin is present in dendrites and cell bodies of restricted populations of neurons including cerebral pyramidal neurons and cerebellar Purkinje cells. To ascertain whether ceramide-mediated signaling mechanism functions in the growth of brain neurons, we examined effects of *in vitro* manipulations of ceramide generation on the dendritic development and survival of Purkinje cells using a dissociate cultures prepared from rat embryos. Inhibition of ceramide biosynthesis by a specific inhibitor for serine palmitoyltransferase, ISP-1, reduced the amount of cellular sphingomyelin in cultures. The ISP-1 treatment caused the aberrant growth of Purkinje cells with few dendritic branches and decreased the number of these cells in a dose dependent manner without affecting other cerebellar neurons. Conversely exposure to a bacterial sphingomyelinase promoted the sprouting of dendritic branches and improved the survival. Treatment with cell-permeable ceramide also caused similar effects on Purkinje cell growth. These observations indicate that hydrolysis of sphingomyelin into ceramide play an important role in the morphological development and survival of cerebellar Purkinje cells.

This study was supported partially by the Grants-in-Aid for Scientific Research (no. 07780710 to S. F., no. 07278248 to Y. H.) from the Ministry of Education, Science and Culture of Japan.

**ECTOPIC ADENOVIRAL VECTOR DIRECTED EXPRESSION OF SEMAPHORIN(D)III/COLLAPLIN-1 IN SPINAL CORD EXPLANTS REPELS GROWING AXONS OF PRIMARY SENSORY NEURONS.** R.J. Giger, R.J. Pasterkamp, J. Verhaagen, (SPON: Eur. Neurosci. Ass.) Graduate school Neurosci., Netherlands Inst. for Brain Res., Amsterdam, The Netherlands.

Semaphorin(D)III/collapsin-1 (sema/coll), the first cloned chemorepellent, is a 100 kDa glycoprotein which has been shown to selectively induce growth cone collapse and paralysis of NGF-responsive dorsal root ganglion neurons *in vitro*. The expression profile of sema/coll mRNA in the embryonic spinal cord suggest a role of this chemorepellent in patterning ingrowing primary sensory neurons. By homologous recombination we constructed a first-generation adenovirus based gene transfer vector AdCMVcol, containing an expression cassette of rat sema/coll in the E1 region of the viral genome. Transgene expression from the recombinant viral genome was confirmed by *in situ* hybridization and Northern blot analysis of AdCMVcol infected Vero cells. *In vitro* translation of the corresponding sema/coll cRNA revealed a product of 85 kDa confirming an open reading frame in AdCMVcol encoding full length sema/coll. To test the biological activity of viral vector derived sema/coll we infected dorsal root ganglia explants of E15-E17 rat embryos with AdCMVcol and compared the axonal growth pattern to uninfected and AdCMVlacZ infected cultures. In control cultures neurites did grow in a regular radial orientation and formed only small fascicles. In contrast, in AdCMVcol infected cultures, axonal growth was slower and the regular radial pattern was clearly disturbed. Neurites exhibited a tendency to bend away from non-neuronal cells and formed fascicles in attempt to avoid sema/coll expressing cells visualized by *in situ* hybridization. Defasciculation apparently occurs when axon bundles have passed sema/coll positive cells. To investigate the function of sema/coll in embryonic spinal cord explants we micro-injected AdCMVcol in the dorsal horn of E15 rat spinal cord slices to locally overexpress the recombinant protein. The altered growth pattern of ingrowing sensory fibers was visualized by Dil injection in the dorsal root ganglia. This study shows that recombinant adenoviral vectors are powerful tools to manipulate gene expression in primary cells in neural explants and may be applied *in vivo* thus, representing an attractive alternative to transgenic mice. Visitor grant (3440747) from NWO-MW, NL.

**cAMP-MEDIATED EFFECTS OF SOMATOSTATIN ON PC12 CELLS DIFFERENTIATION.**

G. Traina, C. Petrucci and P. Bagnoli\*. Dept. of Physiology and Biochemistry, University of Pisa, 56127 Pisa, Italy.

The peptide somatostatin (SS) has been shown to play a role as a differentiation factor in the developing nervous system. Indeed, SS modulates cell growth by inhibiting proliferation and promoting differentiation. However, the molecular mechanisms underlying SS roles in neuronal differentiation are still to be clarified. In particular, whether SS effects on developing neurons depend on intracellular levels of cAMP still remains unclear. This study was aimed to investigate the effect of SS on neurite outgrowth in PC12 pheochromocytoma cells. Cells were cultured at 37° C in RPMI 1640 medium. They were then plated on glass coverslips coated with poly-L-lysine and examined every 24 hrs for neurite formation. Our results can be summarized as follows: a) SS application ( $10^{-8}$  M) does not induce neurite outgrowth; b) neurite outgrowth is promoted by nerve growth factor application (NGF, 100 ng/ml); c) NGF treatment in combination with dibutyl cAMP application (dbcAMP, a membrane permeable cAMP analog,  $10^{-3}$  M) additively promotes cell differentiation; d) forskolin application (an adenyl cyclase activator,  $10^{-3}$  M) induces neurite outgrowth within 3/4 days from the treatment; e) NGF-, dbcAMP- and forskolin- induced neurite outgrowth is enhanced by SS application; f) application of MDL 12330A (an inhibitor of adenyl cyclase,  $10^{-5}$  M) does not induce cell differentiation; g) NGF-, dbcAMP- and forskolin-induced neurite outgrowth is inhibited by application of MDL 12330A; h) neurite outgrowth inhibition induced by MDL 12330A is prevented by SS application. Our results demonstrate that SS can influence cell differentiation by enhancing neurite outgrowth as induced by the application of substances which increase intracellular cAMP levels.

## 297.4

**FUNCTIONAL ANALYSIS OF NEURITE PROMOTING FACTOR(NPF)**

H.Nishimune\*, A.Uyeda\*, M.Nogawa\*, Y.Shigeri, K.E.Fujimori\*\* and T.Taguchi. Dept. Organic Materials, Osaka Nat'l. Res.Inst. AIST, Ikeda 563, Japan, \*Fac.Eng.Sci.,Osaka Univ., Toyonaka 560,Japan, \*\*Dept.Anat.,Fukui Med. Sch.,Yoshida 910-11,Japan

Neurite promoting Factor(NPF) was cloned from denervated muscle and telencephalon of chick. Recombinant protein of NPF promoted neurite outgrowth of telencephalic neurons most significantly but not diencephalon, mesencephalon and rhombencephalon, *in vitro*. In the present study, extracellular secretion of NPF was confirmed by expression in COS7 and immunohistochemistry of cultured living neurons from telencephalon, although stereotype signal peptide for secretion was not found at N-terminal. Expression of NPF in other tissues and developmentally regulated expression in telencephalon and crus muscle were analyzed by northern blot and western blot, respectively. From GenBank data base search, highly homologous gene was found to exist in human. But the product of this gene and its function have been unknown. We confirmed the expression of this gene product in human brain by PCR amplification of human fetal brain cDNA library and determination of the nucleotide sequence. Biological activity of NPF on other NPF expressing nervous tissues, spinal cord, DRG and sympathetic ganglion was studied *in vitro*. This work was supported in part by grants from AIST, NEDO and JRDC. H.N. is a postdoctoral fellow of JRDC.

## 297.5

EXTRACELLULAR GTP INCREASES INTRACELLULAR CALCIUM IN PC12 CELLS. J.W. Gysbers<sup>1</sup>, M.A. Marigoi<sup>2</sup>, T. Pietrangelo<sup>2</sup>, G. Fanó<sup>2</sup>, and M.P. Rathbone<sup>1</sup>. <sup>1</sup>Dept. Biomedical Sci., McMaster University, Hamilton, Canada L8N 3Z5 and <sup>2</sup>Instituto di Fisiopatologia Medica, Università di Chieti, Italy.

Extracellular GTP can enhance the effects of NGF to synergistically increase the proportion of rat pheochromocytoma (PC12) cells that extend neurites to levels significantly greater than that induced in the presence of NGF alone. These cells have specific binding sites for extracellular GTP, which do not bind ATP or UTP. Recently we have determined that the addition of GTP leads to a large and sustained increase of intracellular  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ) in these cells. The calcium response to GTP addition is different than that to addition of ATP. This increase can be blocked by the addition of the L-type calcium channel inhibitor, nifedipine. In parallel experiments, the addition of nifedipine or other L-type  $Ca^{2+}$  channel inhibitors verapamil and diltiazem were found to inhibit the effects of GTP in enhancing NGF-stimulated neurite outgrowth, but do not affect neurite outgrowth stimulated by NGF alone.  $Ca^{2+}$  induced  $Ca^{2+}$  release (CICR) from specific stores present in PC12 cells may be involved in neurite outgrowth, as dantrolene treatment (blocks  $Ca^{2+}$  release from these stores), or pretreatment of PC12 cells with thapsigargin (an inhibitor of internal store  $Ca^{2+}$ -ATPase) also blocks the enhancement of neurite outgrowth by GTP. Another specific CICR blocker, ryanodine, also inhibits the increase of  $[Ca^{2+}]_i$  by GTP. Other guanine based nucleotides: GMP, GDP, affect neither neurite outgrowth nor increases in  $[Ca^{2+}]_i$ . Data also suggest that PKC activation may be involved, and that this response can be inhibited by cGMP. (Supported by Amyotrophic Lateral Sclerosis Society of Canada).

SCHWANN CELLS ACCOMPANY NERVE SPROUTS INDUCED IN MUSCLE BY INSULIN-LIKE GROWTH FACTORS. W.J. Thompson\* and D.M. Kopp. Dept. Zoology, Univ. Texas at Austin, Austin, Texas 78712.

Partial denervation or muscle paralysis results in sprouting of intact motor neurons. Experiments on rat neuromuscular junctions have shown that Schwann cells at denervated junctions grow extensive processes that induce nearby axons to sprout and then guide their growth. Previous studies also suggest that insulin-like growth factors (IGFs) are involved in the induction of sprouting. IGFs may be released from muscle following injury, and administration of IGFs to normally innervated muscle induces sprouting (Caroni and Grandes, J. Neurosci., 110:1307-1317). We have investigated the involvement of Schwann cells in IGF-induced sprouting. Adult rats were given subcutaneous injections (50  $\mu$ l of 5  $\mu$ g/ml, twice a day) of IGF-1, IGF-2, or a control solution, directly over one levator auris longus muscle (LAL) for 7 days. LALs were removed and examined by immunocytochemistry for nerve sprouts (antibody to neurofilament) and Schwann cells (antibody to S-100). Terminal sprouts 2-8  $\mu$ m in length were observed at 13.6% of endplates in muscles treated with IGF-1 (n=2), 13.7% of endplates in IGF-2 muscles (n=2), but only 1.5% of control muscles (n=3). Sprouts emerging from the preterminal axon were observed at 11.2% of endplates after IGF-1 (n=2), 5.4% after IGF-2 (n=2), and 1.5% of control muscles (n=3). In the IGF-2 muscles, 3% of endplates examined had sprouts connecting adjacent endplates, while only 0.08% of controls showed this phenomenon. All sprouts induced in muscles that received either IGF-1 or IGF-2 were accompanied by S-100 immunopositive Schwann cell processes. In a few cases, Schwann cell processes appeared to extend in advance of their associated nerve sprout. We suggest that the induction of nerve sprouting by IGFs involves the extension of Schwann cell processes, similar to that following partial denervation or paralysis. EFFECTS OF LATERAL AND MEDIAL MIDBRAIN GLIAL CONDITIONED MEDIUM IN MIDBRAIN NEURONS. J. Garcia-Abreu<sup>1,2</sup>, E.F. Tovar<sup>1</sup>, V. Moura Neto<sup>1</sup> and L.A. Cavalcante<sup>2\*</sup>. <sup>1</sup>Inst. Biofísica, <sup>2</sup>Depto. Histologia e Embriologia / ICB, UFRJ, 21941-590 Rio de Janeiro, Brazil.

It is now well documented that astrocytes from different brain regions are heterogeneous with respect to morphology, membrane receptors, and interactions with other cells. Lateral (L) and medial (M) midbrain astroglial cells differ in their ability to support neuritic growth. The effects of conditioned medium from L (cL) and M (cM) astroglial cells on lateral (l) and medial (m) midbrain neurons were analyzed. Confluent L and M monolayers were washed 3 times with PBS and kept in DMEM/F12 without serum during 48 h. cL and cM were obtained and used as cultivating medium to grow l and m midbrain neurons. After 24 h the neuritic morphology was observed by staining with an anti- $\beta$  tubulin III antibody. The results show that l or m neurons cultivated in cM present short or no neurites (% of  $\beta$  tubulin III+ cells without neurites >18%). By contrast, l or m neurons cultivated in cL grow more neurites (% of  $\beta$  tubulin III+ cells without neurite < 1.5%). The total length of neurites in cells with 1, 2 or 3 or more processes is consistently larger in cL- than in cM-treated cultures. However, cL-treated neurons still have processes 2-3 times shorter than those of neurons in either lL or lM cocultures. The results show that astroglial secreted factors are partially responsible for differential effects of astroglia upon neurons.

## 297.8

RHO A REGULATES NEURITE OUTGROWTH IN PC12 CELLS. A.Sebök, D.J. Fischer, N. Nusser, M.F. Santos, Y. Zheng and G.Tigvi\*. Dept. of Physiology and Biochem., Univ. of Tenn., Memphis, TN 38163. Clostridial toxins, which selectively modify the Rho-family of small molecular weight GTPases enhance neurite outgrowth in PC12 cells exposed to NGF. C3 toxin from *C.botulinum*, which ADP-ribosylates Rho proteins, induces neuronal differentiation in PC12 cells, characterized by neurite outgrowth and the induction of neuronal marker genes. C3 toxin induces neurite outgrowth in M-M17-27 and A126-1B2 cells expressing dominant negative Ras and protein kinase A, respectively. Toxins A & B from *C. difficile*, which glycosylate CDC42, Rac and Rho, do not induce neurite outgrowth alone, but greatly enhance neurite outgrowth in NGF-stimulated PC12 cells. To study the role of Rho in the neuronal differentiation of PC12 cells, stable transfectants carrying dominant negative (N19-RhoA) and constitutively active (V14-RhoA) mutants were generated. In cell clones expressing either wild type or the mutant RhoA protein driven by a strong constitutive promoter, neither mutation caused the spontaneous outgrowth of neurites. Similarly, microinjection of recombinant RhoA, and V14RhoA proteins into wild-type PC12 failed to induce neurite outgrowth. Three clones expressing N19-RhoA all extended neurites in response to NGF, dbcAMP+PMA, and the combination of the three. In contrast, neurite outgrowth, in four V14-RhoA clonal cell lines, was greatly diminished following treatment with NGF or dbcAMP+PMA, whereas, the combination of the three, induced neurite outgrowth similar to that found in mock-transfected cells. We propose that the Rho family of GTPases and RhoA in particular, play an essential role in neurite outgrowth in differentiating PC12 cells. ## 297.8

EFFECTS OF ASTROCYTES, SCHWANN CELLS AND NEUROTROPHIC FACTORS ON POLARIZATION AND AXON GROWTH OF MOTONEURONS IN VITRO. H. Hammarberg, E. Piehl, S. Cullheim\*. Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden

Neurotrophic factors in muscle and Schwann cells have in recent *in vitro* and *in vivo* studies been shown to support the survival of rat spinal alpha motoneurons. The aim of the present study was to investigate the effects of supporting cells related to motoneurons on polarization and neurite growth of these neurons. Purified embryological (E15) rat motoneurons from the lumbar spinal cord were cocultured with Schwann cells, type I astrocytes, leptomeningeal cells and epineurial fibroblasts or treated with the neurotrophic factors bFGF, BDNF, NT-3, NT-4/5, GDNF, IGF-1, IGF-2 and CNTF. Axon properties of neurites were established by the presence of immunopositivity for GAP-43 and RT 97, and immunonegativity for MAP 2. For each motoneuron, the cell soma area, the number of neurites and the length of the longest neurite (axon) were determined. The effects on GAP-43 mRNA expression was evaluated with radioactive *in situ* hybridization histochemistry. Astrocytes and in particular Schwann cells showed significant stimulatory effects on polarization, neurite growth and GAP-43 mRNA levels, whereas fibroblasts seemed to have an inhibitory influence on these parameters. All studied neurotrophic factors stimulated neurite growth, but in the case of bFGF, the growth pattern was directed towards a production of many branching neurites, while CNTF induced lengthening of single neurites. CELL-CELL CONTACT AFTER NEUROTRANSMITTER RELEASE FROM GROWTH CONES OF RAT CENTRAL NEURONS: ESTIMATION OF PROPERTIES OF THE CONTACT USING LASER TWEEZERS. H. Tatsumi, <sup>+</sup> and Y. Katayama\*. <sup>+</sup>Department of Autonomic Physiology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan. <sup>#</sup>PRESTO JRDC Japan.

Neurons protrude growth cones during development and also during axon sprouting after damage. Evoked release of acetylcholine (ACh) from the growth cones of central cholinergic neurons in culture was monitored using whole-cell patch clamp recording from ACh-receptor-rich neuron placed close to the growth cones as a sensor of ACh release. Simultaneous video-enhanced DIC imaging of growth cones showed contacts between growth cones and the sensor neuron after ACh release. Adhesion was also observed between growth cones and latex beads, when growth cones were exposed to high potassium solution. After beads attached on the growth cone membrane, 1 pN of laser optical pressure was required for moving the beads about 0.1 to 1  $\mu$ m on the growth cone surface. The surface viscosity of the growth cone membrane was estimated by analyzing the video images. This study was supported by a Grant-in Aid for Scientific Research from The Ministry of Education, Science and Culture of Japan and JRDC.

**AN IMMUNOSUPPRESSANT, FK506, PREVENTS MOSSY FIBER SPROUTING INDUCED BY KINDLING STIMULATION.** A. Moriawaki\*, Y.-F. Lu, K. Tomizawa, H. Onuma, and H. Matsui, The First Department of Physiology, Okayama University Medical School, Okayama 700, Japan.

Kindling stimulation induces expansive growth of the axons of the dentate granule cells, the mossy fiber, into several areas of the hippocampus including supragranular layer, hilus, and CA3. A relationship between the sprouting and the development kindling is obscure. Intraperitoneal injection (1 mg/kg) of the immunosuppressant drug FK506, which is a specific inhibitor of  $\text{Ca}^{2+}$ -calmodulin dependent phosphatase, calcineurin, prevented the full development of kindling. The FK506 injected rats developed stage 3 behavioral manifestation but did not develop into stage 4 or 5. Further the FK506 injected rats showed less mossy fiber sprouting evaluated with Timm histochemistry compared with vehicle injected and kindled rats. These inhibitory effects of FK506 were reversible. The results show a correlation between mossy fiber sprouting and the development of kindling. The results suggest also that calcineurin has a promoting role in mossy fiber sprouting and subsequent synaptogenesis.

**Nonimmunosuppressive Ligands for Neuroimmunophilins Promote Nerve Extension *In Vitro* and *In Vivo*.**

J.P. Steiner\*, M.A. Connolly\*, H.L. Valentine\*, G.S. Hamilton\*, T.M. Dawson\*, J. Hester\*, and S.H. Snyder\*, Department of Research, Guilford Pharmaceuticals Inc., Baltimore, MD 21224 and Departments of Neurology and Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD, 21205.

Previously, we have shown that the immunosuppressive drugs FK506 and rapamycin promote neurite outgrowth in PC12 cells and sensory neuronal cultures (Lyons, et al., Proc. Nat'l Acad. Sci. USA 91, 3191-3195, 1994; Steiner, et al., Soc. Neurosci. Abstr. 21, 1772a, 1995). Picomolar concentrations of FK506 and rapamycin elicit neurite outgrowth in both systems by increasing sensitivity to nerve growth factor. We have now determined that the nonimmunosuppressive analogs of FK506 and rapamycin, L-685,818 and WAY-124,466 respectively, potentially promote neurite outgrowth in both PC12 cells and sensory neuronal cultures of dorsal root ganglia. In the sensory ganglion cultures, the neuroimmunophilin ligands induce nerve extension in the absence of exogenously added nerve growth factor. Likewise, cyclosporin A (CSA) and a nonimmunosuppressive analog of CSA promote neurite outgrowth in PC12 cells and sensory neuronal ganglion cultures. The concentrations of neuroimmunophilin ligands necessary to promote nerve extension correlate with doses that inhibit the rotamase activity of the respective neuroimmunophilin, FKBP-12 and cyclophilin, suggesting that inhibition of rotamase activity is sufficient to elicit neurotrophic effects of these compounds. Furthermore, FK506 and L-685,818 treatment of rats with crushed sciatic nerves induces the functional and morphological recovery of the injured nerve. These studies demonstrate the neurotrophic activities of the neuroimmunophilin ligands, and suggest that these ligands may possess therapeutic implications in treatment of neurodegenerative disorders and peripheral neuropathies.

## 297.15

**NEURONAL GROWTH CONE FILOPODIA ARE REGULATED IN A CELL-TYPE SPECIFIC MANNER.** S. Cheng, J. M. Bonsall, V. Rehder\*, Department of Biology, Georgia State University, Atlanta, GA 30302.

We have previously demonstrated the importance of the free intracellular calcium concentration ( $[\text{Ca}^{2+}]_i$ ) in regulating the length and number of growth cone filopodia on identified neurons of the snail *Helisoma trivolvis*. The present study investigates the signaling pathways downstream of calcium. The major target of calcium is calmodulin, since fluphenazine (10 mM), a specific inhibitor of calmodulin, blocked the calcium mediated effects on filopodia. We next tested whether calcium's effects are mediated via two prominent targets of calmodulin, namely myosin-light chain kinase (MLCK) and CaM kinase II (CaMK II). Inhibitors of MLCK (ML-7, 5mM), and CaMK II (KN-93, 2μM) decreased filopodial length and number when applied alone at higher concentrations, suggesting that actin-myosin interactions are important in filopodial regulation. At lower concentrations, these inhibitors did not block the calcium-mediated effects on filopodia, indicating that  $[\text{Ca}^{2+}]_i$  may not act via MLCK or CaMK II to affect filopodial length and number. Two other potential targets of  $[\text{Ca}^{2+}]_i$ , protein kinase C (PKC) and calpains, were investigated. Inhibiting the activity of calpain, an intracellular protease, caused significant elongation of filopodia, suggesting that protease activity may play an important role in controlling the actin-based cytoskeleton. We did not find evidence suggesting that PKC is involved in mediating calcium's effects.

Filopodial regulation by calcium does not appear to be a mechanism used by all cell types. Growth cones of dorsal root ganglion neurons (DRG) from E9-E11 chick embryos grown on laminin surfaces did not show significant changes in filopodial disposition when treated with medium containing elevated potassium concentrations (20, 40, 65 mM). These  $[\text{K}^+]$  caused significant elevation in  $[\text{Ca}^{2+}]_i$ , as evidenced by fura-2 measurements but failed to affect filopodia. In contrast to *Helisoma* neurons, filopodia on chick DRG growth cones seem to be controlled by PKC. Activation by phorbol esters (PMA, 2.5-5μM) caused a decrease in filopodial length and an increase in filopodial number, while inhibiting PKC with bisindolylmaleimide I (2.5μM) produced the opposite effect.

**FKBP12 BINDING DOMAIN ANALOGUES OF IMMUNOSUPPRESSIVE DRUG FK506 ARE POTENT, NONIMMUNOSUPPRESSIVE NEUROTROPHIC AGENTS IN VITRO** G.S. Hamilton\*, W. Huang, M.A. Connolly, P.D. Suzdak, and J.P. Steiner, Guilford Pharmaceuticals, Inc., 6611 Tributary Street, Baltimore, MD 21224.

The immunophilins FKBP and cyclophilin are "receptors" for the immunosuppressant drugs FK506 and cyclosporin A, respectively. Recently it has been discovered that these immunophilins are enriched 10-40 fold more in the brain than in the immune tissues. Within neural tissues, they influence neuronal process extension, and may have potential therapeutic applications in neurodegenerative disorders. Using the X-ray crystal structure of the FKBP-FK506 complex as a basis, we have used the principles of structure-based drug design to prepare novel small molecule neuroimmunophilin ligands which possess neurotrophic actions, but are devoid of immunosuppressive activity. We have evaluated the trophic effects of a number of these structures in cultured sensory neurons from chick dorsal root ganglia. Compounds such as GPI 1080 ( $\text{ED}_{50} = 0.61 \text{ nM}$ ) and GPI 1080 ( $\text{ED}_{50} = 0.09 \text{ nM}$ ) potently promote neurite outgrowth in these cultures at picomolar concentration. The response and morphology elicited by these compounds is strikingly similar to the effects of maximal doses of nerve growth factor (NGF); however, the compounds exert their effects on the neuronal cultures without the need for added exogenous NGF. These compounds suggest a novel approach to the development of potent, systemically active orally bioavailable neurotrophic drugs for the treatment of neurodegenerative disorders. This work was supported by Guilford Pharmaceuticals, Inc.

## 297.14

**Novel Neuroimmunophilin Ligands for FKBP-12 Possess Potent Neurotrophic Activity in the Mouse MPTP Model of Parkinson's Disease**

D.T. Ross\*, H.L. Valentine, H. Guo, G.S. Hamilton, W. Huang, P.D. Suzdak, and J.P. Steiner, Department of Research, Guilford Pharmaceuticals Inc., Baltimore, MD 21224

We have developed specific and selective inhibitors of the neuroimmunophilin FKBP-12 which possess neurotrophic activity in chick sensory neuronal cultures (See the adjacent poster, Hamilton et al.), but are devoid of immunosuppressive activity. In order to determine the *in vivo* efficacy of these compounds, we extended our *in vitro* studies to determine whether these small molecules could promote nerve regrowth and neuronal repair in an animal model of Parkinson's Disease. Using N-methyl-4-phenyltetrahydropyridine (MPTP) to induce lesioning of dopaminergic neurons, we found that systemic treatment of lesioned mice with the neuroimmunophilin ligand GPI 1125 caused the striking recovery of tyrosine hydroxylase-positive innervation of the striatum. GPI 1125 treatment of lesioned animals spares medial forebrain bundle axons and rescues dopaminergic cell bodies in the substantia nigra, pars compacta. Furthermore, treatment of MPTP-lesioned mice with GPI 1125 did not effect the initial decrease in vertical locomotor activity (or rearing) associated with MPTP administration on day 3, but did lead to increased rearing (back to non-lesioned sham control levels) within 10 days. These data suggest that GPI 1125 may act both to rescue degenerating neurons and increase the plasticity of spared projections. As such, these systemically active small molecules promote neuronal recovery of degenerated neurons and define a novel class of therapeutic agents for the treatment of neurodegenerative disorders, such as Parkinson's Disease.

## 297.16

**THE ROLE OF INNERVATION IN MUSCLE PATTERNING IN *DROSOPHILA*** J.L. Fernandes\* and H. Keshishian, Dept. of Biology, Yale University, New Haven, CT 06520.

In *Drosophila* it has been proposed that motoneurons can specify the identity and patterning of adult muscles. We have tested this idea by using a laser to cut the nerve innervating the Dorsal Longitudinal flight Muscles (DLMs). These fibers develop during pupation from three persistent larval muscles that split in two (MFs 9, 10, 19'), and the innervating motoneurons are restructured during this period. We cut the nerve between the persistent larval muscles in early third instars to denervate fibers 9 and 10. The success of the operation was confirmed by dissecting late third instars 2 days later. During early pupation (8-12h) muscles distal to the nerve cut did not show any HRP immunoreactivity, showing that they are completely denervated at this stage. Nevertheless, the formation of a correct muscle fiber pattern is initiated prior to reinnervation, although with a 2-4 hr delay compared to controls. It appears that muscle splitting which takes place soon after myoblast fusion is initiated, can occur in the absence of innervation, suggesting that this process is muscle autonomous. However, the delay in the progression of myogenesis suggests that other steps of myogenesis are likely to be influenced by innervation. Muscle fibers that develop from MF10 are reinnervated earlier than those that develop from the more distally located MF9. Our studies also suggest that attractive cues from the muscle are likely to cause reinnervation. We are currently examining the reinnervation to determine whether the native motor neurons are involved. Supported by NSF and NIH.

## 297.17

APPLICATION OF SPECIFIC INHIBITORY PEPTIDES TO STUDY THE ROLE OF ENDOGENOUS CaMKII IN THE DEVELOPMENT OF THE XENOPUS RETINOTECTAL PROJECTION. D.J. Zou<sup>1</sup>, B.J. Burbach<sup>2</sup> and H.T. Cline. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724

We have tested the possibility that a CaMKII pathway could be involved in the activity dependent mechanisms controlling the development of the frog retinotectal projection. When the constitutively active CaMKII is expressed in tectal cells with a recombinant vaccinia virus, elevated postsynaptic CaMKII activity modifies the elaboration of presynaptic retinal axon arbors, suggesting that CaMKII plays a role in the coordinated development of retinotectal system. To further study the role of CaMKII in regulating the formation of retinotectal projection, we plan to decrease endogenous CaMKII activity in the tectal cells by expressing specific inhibitory peptides. We have determined the potency and specificity of two CaMKII inhibitory peptides by using kinase assays in the homogenates of stage 48 *Xenopus tadpole* brains. We found that a synthesized peptide, AIP (Autocamtide-2-related Inhibitory Peptide) developed and generously provided by Dr. H. Fujisawa, has potent and highly specific inhibitory effects on the CaMKII activity. The  $IC_{50}$  of AIP on CaMKII was about 400 nM. AIP was 50 times more potent than the other CaMKII inhibitor [Ala<sup>286</sup>]CaMKII<sub>(281-302)</sub> with an  $IC_{50}$  around 20  $\mu$ M. At 10  $\mu$ M, AIP decreased CaMKII activity to  $7\% \pm 3\%$  ( $n=4$ ) of the controls but did not inhibit PKC activity ( $94\% \pm 9\%$  of controls,  $n=4$ ) in the same homogenate assayed in parallel. The  $IC_{50}$  of AIP on PKC was greater than 100  $\mu$ M. Based on the AIP dose response curves, AIP was about 500 times more potent in blocking CaMKII than PKC *in vitro*. These results indicate that AIP is a potent and highly selective CaMKII inhibitor in frog neurons and is valuable for studying the role of endogenous CaMKII activity in controlling the formation of the retinotectal projections. We thank Dr. K.P. Giese for bringing AIP to our attention and Dr. H. Fujisawa at Asahikawa Medical College in Japan for the generous gift of AIP. Supported by NIH.

## 297.19

GABAERGIC MODULATION OF REGENERATIVE PROCESS OUTGROWTH BY ISOLATED ADULT SALAMANDER RETINAL PHOTORECEPTORS. David M. Sherry<sup>1\*</sup> and Ellen Townes-Anderson<sup>2</sup>

<sup>1</sup>College of Optometry, University of Houston, Houston, TX 77204-6052;  
<sup>2</sup>Department of Neurosciences, UMDNJ-NJMS, Newark, NJ 07103-2714

Adult retinal photoreceptors regenerating in culture preferentially establish presynaptic varicosities onto target neurons containing the neurotransmitter GABA, suggesting that GABA may modulate regenerative neurite outgrowth and synapse formation by adult photoreceptors. A similar role for GABA has been postulated in retinal development. To test the role of GABA in modulating regenerative growth by adult photoreceptors, cultured retinal cells were treated with drugs acting at GABA<sub>A</sub> receptors, the GABA receptors expressed by salamander photoreceptors, for 1 day, 1 week, or 2 weeks. Cultures were then fixed and the number of neurites and presynaptic varicosities regenerated by photoreceptors in treated and age-matched control cultures from the same animal were compared. Treatment with the GABA<sub>A</sub> receptor antagonist bicuculline reduced the number of neurites and varicosities regenerated by photoreceptors in a dose dependent manner, with greatest effect noted at 2 weeks post-isolation. Treatment with muscimol, an agonist at GABA<sub>A</sub> receptors, produced only a very slight increase in the number of neurites and varicosities regenerated by photoreceptors, suggesting that endogenous levels of GABA in the cultures produce a maximal response on photoreceptor neurite growth. Pharmacological treatments did not appear to affect photoreceptor survival. These data suggest that GABA modulates regenerative growth and formation of synaptic structures by adult photoreceptors via GABA<sub>A</sub> receptors. Supported by College of Optometry, University of Houston (DMS) and EY06135 (ETA).

NITRIC OXIDE INDUCED RAPID NEURITE ELONGATION AND GROWTHCONE ASYMMETRY OF RAT DRG NEURONS. S. TSUKADA\* and J. FUKUDA

Department of Physiology, National Defense Medical School, Tokorozawa, Saitama, JAPAN.

Nitric oxide has been implicated as a diffusible second messenger molecule that can act as modification of neuronal differentiation and establishment of neural connections. It has already been known that nitric oxide rapidly inhibits growth of neurites of rat dorsal root ganglion neurons. Here we report that nitric oxide promotes neurite extension and growthcone motility within a limited range of concentrations. NOR3, nitric oxide donors FK409, was focally applied by pulsatile ejection from micropipette that placed 50  $\mu$ m away from the growthcones. Small amount of nitric oxide rapidly enhanced neurite outgrowth and filopodial elongation. Shapes and motility of growthcone also changed in a short period of time. Topical application of NO caused filopodial asymmetry. These chemotropic effects were abolished by methylene blue, an inhibitor of soluble guanylate cyclase. Caged cyclic GMP that was flash photolysed at nerve growthcone also mimicked the effects of nitric oxide. Our results thus indicate that NO-cGMP pathway might play an important role during the establishment of ordered connections by developing neurons.

## 297.20

GLIAL-DEPENDENT BASAL FOREBRAIN NEURITOGENESIS ELICITED BY NT-3 IS MEDIATED BY A DIFFUSIBLE FACTOR S. Sample\*, J.B. Black, and C.F. Dreyfus, Dept. Neuroscience & Cell Biology, Robert Wood Johnson Medical School/UMDNJ, Piscataway, NJ 08854

Our previous observations suggested that NT-3 elicits neurite extension from developing basal forebrain (BF) cholinergic neurons grown in the presence of glia (Sample et al., Soc Neur Abs 1994). To begin defining the glial-neuronal interaction regulated by NT-3, we sought to identify the factors involved and determine the specificity of the interaction. Embryonic day 17 rat BF cultures were treated with NT-3 or vehicle control and grown for 2 days under conditions that foster the establishment of glia. Media conditioned (CM) by these cultures were harvested and applied to freshly dissociated BF cells for 7 days. An anti-NT-3 antibody added to the CM neutralized remaining NT-3 bioactivity. CM generated by NT-3-treated cultures mimicked the NT-3 effect on cholinergic cells. Yet, membranes from cultures treated with NT-3 failed to elicit outgrowth at protein concentrations as great as 80  $\mu$ g/ml. Similarly, extracellular matrix produced by cells treated with NT-3 did not promote outgrowth. These data suggest that NT-3-elicited outgrowth by BF cholinergic neurons grown in the presence of glia is mediated by a diffusible factor(s).

To determine whether other projection neurons of the basal forebrain exhibit enhanced outgrowth, we treated glial-neuron BF cultures with NT-3 and examined GABAergic neurons. NT-3 also enhanced neurite extension by GABAergic neurons grown in the presence of glia. Thus, glial-neuronal interactions, regulated by NT-3, may provide local cues within the BF that promote outgrowth by different projection neurons. (Support: NICHD: HD23315)

RESTRUCTURING OF NEURITES: POST-TRANSCRIPTIONAL CONTROL BY NMDA AND CALCIUM\*\*

WL Severt, V. Calabrese\*, S. Sombati, C. Gerwin, R. Delorenzo and E. Jakoi

Department of Neurology, Medical College of Virginia, Richmond, VA 23298

Activation of NMDA receptors may direct neuronal plasticity by promoting neurite extension at low levels of receptor activity and retraction at high levels. Molecular mechanisms that follow the influx of calcium through NMDA receptors that can account for alterations in neuronal phenotype remain largely unexplained. Given the importance of calcium in regulating gene expression, and the emerging evidence that polyribosomes and select neuronal mRNAs exist at the synapse, we hypothesize that NMDA receptor activation regulates neuronal gene expression locally by modulating mRNA levels. We have recently demonstrated (Panchision et al, 1995) that NMDA and calcium decrease the stability of the mRNA encoding ligatin, a 10kd, fatty-acylated protein localized to distal dendrites. To explore the contribution of this down-regulation to neuronal restructuring, we used antisense oligodeoxynucleotides (ODNs) to knock-down ligatin protein in cultured hippocampal neurons. An ODN targeted to the coding region suppressed expression of ligatin protein and caused neurites to withdraw or to fail to extend, depending on cell age. These cells also showed decreased EPSPs and decreased dendritic levels of NMDA receptors and CaM kinase II, without decreased total cellular quantities of these proteins. Both IPSPs and GABA-A receptor levels remained unchanged. We also tested a second ODN targeted to a sequence within the 3'-UTR which has potential for directing transport of the mRNA to the synapse. This ODN did not alter ligatin protein levels, but did induce the expression of short neurites terminating in an exuberance of sprouts. These results implicate ligatin in neurite restructuring and suggest that post-transcriptional control of mRNA stability provides a mechanistic link by which synaptic activity could govern synaptic protein synthesis and neuronal remodeling in response to environmental stimuli more rapidly than that governed by nuclear control. ## 298.2

LOCALIZATION OF DIFFERENT GLUTAMATE RECEPTORS ON AN IDENTIFIED *LYMNAEA* NEURON, AND THEIR ROLE IN THE GROWTH CONE COLLAPSE. O.Nesic\*, N. Syed, K. Lukowiak and A.G.M. Bulloch, Neuroscience Research Group, HSC, University of Calgary, Calgary, AB, T2N 4N1, Canada.

Glutamate is a putative transmitter in the *Limnaea* CNS and central neurons possess different types of glutamate receptors. We propose that the same neuron can have various types of glutamate receptors, localized differentially, with possible diverse physiological roles. In this study we examined the effect of glutamate on both the soma and growth cones of the identified neuron cerebral one (C1), *in vitro*.

Pressure application of glutamate to the soma of neuron C1 caused hyperpolarization. Application of glutamate (1 mM, for 15 min) to the growth cone of neuron C1, caused growth cone retraction or collapse. The glutamate response, measured at different membrane potentials, showed a reversal potential of  $\sim -90$  mV, indicating the opening of K<sup>+</sup>-selective conductance. Further, bath application of TEA (51mM) blocked this response. However, TEA did not prevent glutamate-induced growth cone collapse. Bath application of 0.1 mM kainic acid to neuron C1 caused depolarization and irreversible growth cone collapse. The kainic acid response was reduced by the Ca<sup>2+</sup> channel blocker, cadmium (Cd<sup>2+</sup>, 2mM), and by the application of low Ca<sup>2+</sup> saline. Application of low Ca<sup>2+</sup> or Cd<sup>2+</sup>, however, did not affect the hyperpolarizing glutamate response, but Cd<sup>2+</sup> did indeed prevent glutamate-induced growth collapse.

We propose that neuron C1 possesses different glutamate receptors coupled to different ionic conductances: one, a K<sup>+</sup>-selective, TEA-sensitive conductance, and the other a Ca<sup>2+</sup>-permeable, Cd<sup>2+</sup>-sensitive conductance. We suggest that both types of receptors are present on the soma, but only the Cd<sup>2+</sup>-sensitive receptor is present on the growth cone. This receptor could be involved in the navigation of axons extending from neuron C1. Supported by MRC (Canada).

## 298.3

**INJURY-INDUCED CHANGES IN NEURONAL EXCITABILITY ARE INDEPENDENT OF PROCESS OUTGROWTH.** M.J. Zoran\* and N.L. Aches. Department of Biology, Texas A&M University, College Station, TX 77843.

*Helisoma* neuron B5, regenerating axons following nerve crush, displays an initial, transient (<24 hrs) reduction in excitability followed by a period of maintained, enhanced excitability (>9 d). Membrane potential of B5 in reduced ganglia was current-clamped to a level of -60 mV and current pulses were applied for 3 seconds. The average number of action potentials (APs) elicited in B5 prior to axotomy was  $18.2 \pm 3.9$  APs (n=12). Maximal spiking was significantly decreased to  $5.5 \pm 2.0$  APs (n=12) several hours after nerve crush ( $p < 0.01$ ). Several days later, hyperexcitability of B5 was observed such that maximal spiking on day 9 post-axotomy was  $27.0 \pm 1.7$  APs.

To examine whether these changes in neuronal excitability were governed by intrinsic neuronal mechanisms or extrinsic factors, we examined excitability in axotomized neurons following isolation into cell culture. Neuron B5, *in vitro*, expressed a similar pattern of hypo- and hyperexcitability during neurite outgrowth. However, elevations in excitability were only present in conditioned medium (CM) containing trophic-factors released from injured neural tissue. In addition, following 5 days post-isolation into cell culture maximal spiking dropped to levels similar to those of newly isolated neurons indicating that sustained hyperexcitability requires support not present in CM.

Neurons were isolated into culture conditions that prevent neurite outgrowth. Changes in electrophysiological properties of spherical B5s were identical to those demonstrated for neurite-bearing neurons. Therefore, B5 hyperexcitability was induced by factors associated with injured neural tissue and was independent of process outgrowth. Whether specific components of conditioned medium govern differentially changes in excitability and outgrowth remains unknown.

**EFFECTS OF DEPOLARIZATION ON NEURITE OUTGROWTH IN CULTURED CEREBRAL CORTEX NEURONS.** Ger J.A. Ramakers\* and J. van Pelt. Neuros and Networks, Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam ZO, The Netherlands.

Bioelectric activity has profound effects on neurite outgrowth. In cultured *Helisoma* neurons electrical stimulation result in a reversible arrest of neurite extension in a calcium-dependent manner, whereas in *Xenopus* neurons, depolarization with high potassium stimulates neurite extension. DC electric fields moreover have a strong effect on the direction of neurite outgrowth, with growth cones moving towards the cathode. We are investigating the effects of depolarization with elevated potassium chloride on neurite outgrowth of dissociated fetal rat cerebral cortex neurons in primary cultures, using time-lapse video recording and quantitative image analysis. Depolarization was found to increase the surface area of lamellipodia within three min, an effect which lasted at least 20 min. Effects on filopodia were also observed. Continued depolarization resulted in an increased rate of neurite extension for at least 24 hrs. The role of calcium and downstream signal transduction events are currently being investigated to link depolarization to the changes in the growth cone cytoskeleton responsible for alterations in growth cone morphology and neurite outgrowth.

## 298.7

**INTRACELLULAR CALCIUM INCREASES IN TWO POPULATIONS OF EMBRYONIC NEURONS AS A RESPONSE TO AN APPLICATION OF SOLUBLE LIMBIC SYSTEM-ASSOCIATED MEMBRANE PROTEIN (LAMP).** V.Zhukareva\*, N.Chernyskaya, M.Nowycky, and P.Levitt. Dept. of Neuroscience and Cell Biology, Robert Wood Johnson Medical School - UMDNJ, Piscataway, NJ 08854 and Dept. Anatomy and Neurobiology, Med.Col. PA. Philadelphia, PA 19129.

Limbic system-associated membrane protein (LAMP) is a GPI-anchored protein, Ig-superfamily member with selective neurite outgrowth promoting effect on fetal neurons. As a GPI-anchored molecule, LAMP potentially could be released from the membrane surface and may interact with its counterpart and/or its receptor as a soluble protein. To investigate a possible role of second messengers in the cascade of events triggered by LAMP, we applied soluble recombinant LAMP on two populations of rat E17 embryonic neurons, from hippocampus that express LAMP (LAMP+) and visual cortex that do not express LAMP (LAMP-). Intracellular calcium levels were measured in cells loaded with fluor-3 using confocal laser microscopy. Bath application of LAMP caused mostly delayed (10 - 20 min.) sustained elevation of  $[Ca^{2+}]_i$  (up to 60 min.) in hippocampal neurons. The number of cells responding (from 30% responders at 5-6 DIV to 60% at 12 DIV) and the magnitude of response varied with regard to the neuronal age in culture. In contrast, the number of responders to the LAMP application from the visual cortex (18% responders at 7-8 DIV), the amplitude and the duration of  $[Ca^{2+}]_i$  increase (10 - 20 min., with a return to the base line) were smaller. These results suggest that LAMP application triggers an intracellular signaling cascade involving changes in  $[Ca^{2+}]_i$  and that the kinetics of the response are specific for different regions of the developing brain. Supported by MH45507 (PL) and NS22281 (MN).

## 298.4

**EFFECT OF NEUROMUSCULAR ACTIVITY ON SPROUTING DEPENDS ON THE EXTENT OF PARTIAL DENERVATION.** S.L. Tam, V. Archibald, R.B. Stein\*, N. Tyerman, and T. Gordon. Dept. of Pharmacol., and \*Dept. of Physiol., Div. of Neurosci., Univ. of Alberta, Edmonton, Canada T6G 2S2.

To extend our initial study where moderate exercise was not found to be detrimental to sprouting (Soc. Neurosci. 1994, Abstr.#545.3), we, in the present study, used a rat model of partial denervation to test the hypothesis that high levels of neuromuscular activity compromise the sprouting during the acute phase of motoneuron diseases. Four hindlimb muscles, tibialis anterior, medial gastrocnemius, soleus and plantaris, were partially denervated (PD) by cutting either the L4 or L5 spinal root and subjected immediately to increased activity: daily functional electrical stimulation (FES, 8hr, 20Hz) or natural stimulation (8hr running on exercise wheels, 1200m/day). Within a month, MU force and number of sprouts in muscles which experienced normal cage activity increased to an upper limit of 3-5 times normal. A one month period of increased neuromuscular activity significantly reduced MU enlargement in extensively denervated muscles (PD>75%). In moderately denervated muscles (PD<75%), the effect was not significant although the same trend was seen. These results show that 1) normal physiological activity is conducive for maximal sprouting during the acute phase of motoneuron diseases, and 2) while high levels of neuromuscular activity can be detrimental to sprouting in extensively denervated muscles, it does not appear to be harmful for sprouting after moderate denervation. Therefore, although exercise generally appears to be helpful, these results suggest that exercise regimes must be used with caution. ## 298.6

**REGIONAL LASER INACTIVATION OF TYPE 1 INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR AFFECTS GROWTH CONE MORPHOLOGY AND MOTILITY IN CHICK DRG NEURONS.** K. Takei<sup>1,2</sup>, D. G. Jay<sup>2</sup> and K. Mikoshiba<sup>1</sup>. Lab. of Cell Biol., Calciocisignal Net Project, ERATO, Res. Dev. Corp. of Japan, Tokyo 153<sup>1</sup>, Dept. of Mol. and Cell. Biol., Harvard Univ., MA 02138<sup>2</sup>.

The inositol 1,4,5-trisphosphate receptor (InsP<sub>3</sub>R) acts as an InsP<sub>3</sub>-gated  $Ca^{2+}$  release channel. Type 1 InsP<sub>3</sub> receptor (InsP<sub>3</sub>R1) is the major neuronal member of the InsP<sub>3</sub>R family in the central nervous system. Alteration of intracellular concentration of  $Ca^{2+}$  in the growth cone regulates neurite outgrowth but what processes  $Ca^{2+}$  regulates and the molecular mechanisms of the regulation are unclear. We asked if InsP<sub>3</sub>R is required for neurite outgrowth by observing growth cone motility in response to the acute and localized loss of the InsP<sub>3</sub>R. This was achieved by applying microscale chromophore-assisted laser inactivation (micro-CALI) to the InsP<sub>3</sub>R1 in chick dorsal ganglia (DRG) neuronal growth cones cultured on laminin. Micro-CALI directs spatially restricted photogenerated free radical damage to targeted proteins via dye-labeled antibodies that by themselves do not affect growth cone behavior. The neurons were loaded with dye-labeled antibodies by microinjection. Subregions of growth cones were subjected to a laser micro-beam, and subsequent changes in motility and morphology were observed by time lapse video microscopy. Micro-CALI of the InsP<sub>3</sub>R1 caused lamellipodial collapse, marked change of the growth cone morphology and subsequently growth arrest of neurite. Laser irradiation of neurons loaded with dye-labeled non-specific antibodies or without antibodies did not affect growth cone motility and morphology. These results suggest that InsP<sub>3</sub>R1 act on growth cone morphology and motility and the InsP<sub>3</sub>-gated  $Ca^{2+}$  release may play important roles in the growth cone behavior and neurite outgrowth.

## 298.8

**L-TYPE CALCIUM CHANNELS IN GROWTH CONES.**

K. Ohbayashi<sup>1,2</sup>, H. Fukura<sup>1</sup>, Y. Komiyama<sup>1</sup>, M. Igarashi<sup>1</sup>. Departments of <sup>1</sup>Molecular and Cellular Neurobiology and <sup>2</sup>Neurosurgery, Gunma University School of Medicine, Gunma 371, Japan.

Intracellular calcium ( $[Ca^{2+}]_i$ ) in the growth cone is important for neurite elongation, axonal pathfinding, and accurate synaptogenesis. Recent studies have indicated that L-type  $Ca^{2+}$  channels in growth cones are closely involved in regulation of  $[Ca^{2+}]_i$ . To characterize L-type  $Ca^{2+}$  channels in growth cones, we isolated growth cone membranes (GCM) from fetal and neonatal rat forebrain, and pharmacologically characterized the channels using [<sup>3</sup>H]PN200-110.  $B_{max}$  values for [<sup>3</sup>H]PN200-110 in GCM gradually decreased from embryonic day 17 (E17) (0.716 pmol/mg protein) to postnatal 7 (P7) (0.341). To examine the change of  $[Ca^{2+}]_i$  through L- or N-type  $Ca^{2+}$  channels, we measured  $[Ca^{2+}]_i$  of GCP by fluorescence spectrometry using Fura 2/AM. Bay K 8644, an L-type agonist, increased  $[Ca^{2+}]_i$  in GCP at all ages. The increase of  $[Ca^{2+}]_i$  in embryonic GCP was larger than that of synaptosomes. Diadenosine pentaphosphate (ApsA), an agent known to potentiate N-type channels selectively (Panchenko et al., Neuroscience 70:353-360, 1996), increased  $[Ca^{2+}]_i$  in postnatal GCP but had no effect on embryonic GCP. Elevation of  $Ca^{2+}$  in GCP by ApsA was blocked by  $\omega$ -Conotoxin GVIA. To examine the effect of L-type activation on  $Ca^{2+}$ -dependent phosphorylation, we labeled GCP proteins using [<sup>32</sup>P]orthophosphate. Under these conditions, a 45- and a 80- kDa proteins, identical to GAP-43 and MARCKS, were primarily phosphorylated; Bay K 8644 enhanced phosphorylation of these proteins. Our results suggest that L-type  $Ca^{2+}$  channel activity modulates growth cone functions by regulating  $[Ca^{2+}]_i$ , and that N-type  $Ca^{2+}$  channels develop at later stages of synaptogenesis.

## 299.1

**HEPATOCYTE GROWTH FACTOR-SCATTER FACTOR (HGF) EXHIBITS NEUROTROPHIC ACTIVITY AND ACTS ON GABAergic AND CALBINDIN D EXPRESSING NEURONS**  
D. Lindholm<sup>1</sup>\*, T. Litzénburger<sup>2</sup>, L. Korhonen<sup>1</sup>, N. Inagaki<sup>2</sup>, and E. Castrén<sup>2</sup> 1.Dept. Dev. Neuroscience, BMC, Box 587, S-75123 Uppsala, Sweden. 2.Dept. Neurochem. Max-Planck-Institute for Psychiatry, Am Klopferspitz 18a, D-82152 Martinsried, Germany.

Hepatocyte growth factor-scatter factor (HGF) and its receptor, c-met are expressed in specific areas of the central nervous system. To study the function of HGF in neurones we transfected pheochromocytoma PC12 nnt5 cells with a chimeric construct consisting of the extracellular part of Trk receptor and the intracellular domain of c-met. Addition of nerve growth factor (NGF) to this cell line, lacking endogenous Trk receptors, activates c-met and induces neurite outgrowth of the cells. Studies using human NT-2 cells which normally express c-met showed that HGF increased survival of serum deprived hNT. These data show that activation of c-met transduces signals promoting both neuronal differentiation and survival. In searching for primary neurons responsive to HGF neuronal cell cultures were made from embryonic rat brain. Addition of HGF specifically enhanced neurite outgrowth of cultured GABAergic neurons from septum and hippocampus. HGF also increased the number of hippocampal neurons expressing the calcium binding protein, calbindin D. The present results show that HGF has potent neurotrophic activities on specific neurons in brain and HGF increases both the survival and differentiation of responsive neurons. Supported by Cancerfonden, Sverige and the Max-Planck-Society, FRG.

## 299.3

**PREMARIN INCREASES THE GROWTH OF NEURONS FROM THE CEREBRAL CORTEX.**  
R.D. Brinton\*, M. Montoya, and D. Hsieh. Molecular Pharmacology & Toxicology, The STAR Program, Univ. of Southern California, School of Pharmacy, Los Angeles, CA. 90033.

Premarin is a complex mixture of estrogenic and progesterone steroids and is the leading prescribed pharmaceutical estrogen replacement therapy for postmenopausal women. Recent evidence indicates that postmenopausal women not receiving estrogen replacement therapy are at greater risk for developing cognitive dysfunction, a compromised stress response and Alzheimer's Disease relative to their estrogen replaced contemporaries. Regulation of both the growth of neuronal extensions and the survival of neurons involved in cognitive function can have a significant impact on the function of neural networks involved in memory and other cognitive processes. We therefore investigated the effect of Premarin and select estrogenic steroids contained within Premarin on the growth of neurons derived from the cerebral cortex, a brain region critical to cognitive function. Results of this investigation demonstrated that the complex formulation of Premarin significantly increased the growth of cortical neurons as indicated by a significant increase in the number of neurites ( $p < .05$ ), number of branches ( $p < .05$ ), branch length ( $p < .05$ ), and in the number of microspikes ( $p < .05$ ). We further investigated the neurotrophic action of individual components of Premarin and found that equilin, a major component of Premarin, induced highly significant increases in the growth of both the macro features of cortical nerve cell morphology as well as the micro features ( $p < .05$ -.001). Results of a cortical regional selectivity analysis indicated that the regional distribution for both 17  $\beta$ -estradiol and equilin-induced nerve cell growth exhibited some parallels, most notably the consistent significant induction of occipital nerve cell growth. In addition, equilin induced a significant increase in the growth of frontal and parietal cortical neurons on some morphological measures ( $p < .01$ -.001) whereas 17  $\beta$ -estradiol exhibited only a trend towards statistically significant increases in these brain regions. We pursued the mechanism of equilin-induced nerve cell growth by investigating the impact of blocking the NMDA glutamate receptor on equilin-induced occipital cortex nerve cell growth. Results of these experiments indicate that the growth promoting effects of equilin (100 nM  $p < .01$ ) were completely abolished in the presence of the NMDA receptor antagonist AP5.

## 299.5

**EFFECT OF GLIAL GROWTH FACTOR 2 (rhGGF2) ON THE SURVIVAL OF AXOTOMIZED RETINAL GANGLION CELLS IN ADULT RATS.**

S.A. Singel<sup>1</sup>, M.A. Jarpe<sup>2</sup>, G.M. Bray<sup>1</sup>\* 1Centre for Research in Neuroscience, The Montreal General Hospital Research Institute and McGill University, 1650 Cedar Ave., Montréal, QC H3G 1A4. 2Cambridge Neuroscience Inc., Cambridge, MA 02139.

Retinal ganglion cells (RGCs) in embryonic and adult rats express members of the erbB tyrosine kinase family, which act as receptors for neuregulins. One of the neuregulins, glial growth factor 2 (rhGGF2), enhances the survival and axonal growth of embryonic and neonatal rat retinal cells *in vitro* (Birmingham-McDonogh et al., Development 1996, in press). The purpose of the present study was to determine the effect of rhGGF2 on the survival of retinal ganglion cells (RGCs) *in vivo* after optic nerve (ON) transection. RGCs in adult Sprague-Dawley rats were retrogradely labelled from their main target, the superior colliculus. Seven days later, the left optic nerve was cut close to the eye and a single dose (5  $\mu$ l) of 250  $\mu$ g/ml rhGGF2 or 5  $\mu$ l control acetate buffer (pH 6.5) was injected into the vitreous chamber. RGC densities were determined for groups of retinas 7, 10, and 14 days later. At 7 days, RGC densities in the GGF-treated retinas were not significantly different from those of control retinas. At 10 and 14 days, approximately twice as many RGCs survived in the rhGGF2-treated retinas. This increased RGC survival after rhGGF2 administration is less than that observed with BDNF or NT-4/5 but indicates that GGF can affect the survival of some injured adult RGCs. (Supported by Cambridge Neuroscience, Inc. and Boehringer Ingelheim Fonds)

## 299.2

**SPECIFIC, INCREASED SURVIVAL OF DOPAMINERGIC AND NON-DOPAMINERGIC NEURONS IN A MESENCEPHALIC CELL CULTURE, BY INHIBITORS OF MONOAMINE OXIDASE B.** J. W. Commins<sup>1</sup>\*, J.F.M. Finberg<sup>2</sup>, M.B.H. Youdim<sup>3</sup>, Takao Takekoshi<sup>4</sup>, LMB, NINDS, NIH, Bldg. 36/3D02, Bethesda, MD 20892; <sup>1</sup>Dept. Pharmacol., Fac. Med., Technion-Israel Inst. Tech., Bat-Galim, Haifa 31096, Israel; <sup>2</sup>Div. Neurol., Inst. Neurol. Sci., Tottori Univ. Sch. Med., 86 Nishimachi, Yonago 683, Japan.

Deprenyl, a specific inhibitor of Monoamine Oxidase (MAO) B has been shown to increase the survival of fetal dopaminergic neurons in culture (Roy and Bedard (1993), NeuroReport 4: 1183-1186). Subsequently, it was shown that deprenyl also increased the survival of axotomized, somatic motoneurons, and that this effect was independent on inhibition of MAO [Ansari et al. (1993), J. Neurosci. 13: 4042-4053]. We have therefore used optimal conditions to test clorgyline, (-) methamphetamine, deprenyl and rasagiline [R(+)-N-propargyl-1-aminindane mesylate, or TVP-1012], all at  $10^{-4}$  -  $10^{-5}$  M, on rat E14, post-mitotic cells of the ventral mesencephalon [Shimoda et al., (1992), Brain Res. 586: 319-331]. The cells were cultured for 7 days and then double stained to visualize the neuronal marker MAP2 and the specific marker for dopaminergic neurons in this culture, tyrosine hydroxylase (TH). Clorgyline and methamphetamine did not exert a measurable effect at any of the doses tested. Deprenyl, at  $10^{-4}$  and  $10^{-5}$  M, caused a significant ( $P < 0.01$ ) increase in dopaminergic neurons only. However, TVP-1012, also at  $10^{-4}$  and  $10^{-5}$  M, increased both neuronal (MAP2-pos) survival as well as the survival of TH-pos neurons ( $P < 0.05$ ). Interestingly, GABAergic neurons, which account for about 50% of the neurons in the culture, were not affected by either deprenyl, or rasagiline. We conclude that both MAO B inhibitors, deprenyl and rasagiline are able to increase the survival of dopaminergic neurons in culture, but that additionally, rasagiline can increase the survival of an unknown subset of neurons in the culture. Since the MAO A inhibitor clorgyline was ineffective, the mechanisms involved in both cases are unlikely to be related to inhibition of MAO. Supported by DIR-NINDS. Thanks to Teva Pharmaceutical, Inc., for rasagiline and deprenyl.

## 299.4

**THE SEMISYNTHETIC GLYCOSPHINGOLIPID (GSL) LIGA20 POTENTIALLY PROTECTS NEURONS AGAINST NECROSIS AND APOPTOSIS.** A. Guidotti\*, M. Saito<sup>b</sup> and E. Costa\*. <sup>a</sup> The Psychiatric Institute, Department of Psychiatry, University of Illinois at Chicago, Chicago, IL 60612. <sup>b</sup> N.S. Kline Institute for Psychiatric Research, Orangeburg, NY 10962.

LIGA20 (Lyso GMI with N-dichloroacetyl-sphingosine) added to neuronal cultures of newborn rats prevents glutamate-induced necrosis with a potency several-fold higher than that of natural (GMI, GD1B, GD1A, GT1B) or other semisynthetic GSLs (*JPET* 252: 419, 1990). In the present study the neuroprotective effect of LIGA20 and that of other GSLs on apoptotic neuronal death was examined in cerebellar granule cells. In primary cultures of these cells prepared from newborn rats, apoptotic death was induced by: a) serum deprivation and non-depolarizing culture media (5mM K<sup>+</sup>); or b) adding to the normal medium 10  $\mu$ M nimodipine, a voltage-sensitive Ca<sup>2+</sup> channel blocker. We have recently observed (*JPET* in press) that Pb<sup>2+</sup> in a concentration-dependent manner accelerates apoptosis in granule cell cultures. Thus, we studied the neuroprotective action of GSLs in these three experimental conditions. In all apoptotic conditions LIGA20 (EC<sub>50</sub> ~ 5  $\mu$ M) was more potent than GMI and other GSLs in protecting neurons from death. The protection afforded by GSLs against apoptotic death was confirmed biochemically by the reduction of the typical internucleosomal DNA fragmentation. The data suggest that the neuroprotection against necrosis or apoptosis elicited by LIGA20 and other GSLs depends on a pleiotropic mechanism of action. NS 28130-06.

## 299.6

**CEP-1347 PREVENTS EXCITOTOXIN-INDUCED DEATH OF NEURONS IN BASAL FOREBRAIN: A QUANTITATIVE RETROGRADE LABELING STUDY IN ADULT RAT.** F. Haun\*, A. DiCamillo, C. Murakata\*, S.

Carswell, M. Miller and N. Neff. Cephalon, Inc., West Chester, PA, 19380, and <sup>\*</sup>Kyowa-Hakko Kogyo Co., Tokyo, Japan.

The functional loss of basal forebrain cholinergic neurons is thought to be a major contributor to Alzheimer's disease (AD). A number of potential AD therapeutics, including the structurally novel indolocarbazole CEP-1347, have been shown to prevent loss of cholinergic markers in the cortical targets of neurons in nucleus basalis magnocellularis (nbm) following experimental lesion of this basal forebrain region. The present study examined whether this prevention of cortical cholinergic loss by CEP-1347 reflects protection against neuron death. The retrograde tracer Fluoro-Gold (FG) was injected bilaterally into frontal and parietal cortices of adult Sprague-Dawley rats. 7-10 days later these animals received unilateral ibotenic acid lesions of the nbm, followed 18 h later by CEP-1347 (s.c. 0.03 mg/kg, Q.O.D.) for 18 days. FG-labeled neurons were then counted throughout the nbm immediately adjacent to the ventral and medial borders of the globus pallidus. Significantly more neurons remained in the rostral portion of the nbm in animals receiving CEP-1347 ( $84 \pm 4.6\%$  of the unlesioned side), compared to the vehicle controls ( $45.5 \pm 4.6\%$ ). Counts of ChAT and GAD immunopositive neurons from adjacent sections showed an identical pattern of protection against both cholinergic and GABA-ergic neuron loss in rostral nbm. These results demonstrate directly that CEP-1347 is neuroprotective against excitotoxin-induced cell death in the basal forebrain, and suggest that this compound may be useful in preventing the degeneration of multiple classes of neurons.

## 299.7

**CEP-1347 REDUCES NEURONAL DAMAGE FOLLOWING NMDA LESION OF THE ENTORHINAL CORTEX.** T. M. Engber\*, S. A. Dennis, C. Murakata\*, M. Miller and P. C. Contreras. Cephalon, Inc., West Chester, PA 19380 and \*Kyowa-Hakko Kogyo Co. Ltd., Tokyo, Japan.

In Alzheimer's disease, there is a severe loss of glutamatergic neurons in the entorhinal cortex (EC) as well as cholinergic neurons in the basal forebrain. Since the EC provides the major cortical input to the hippocampus and EC lesions in animals cause memory deficits, loss of neurons in this region likely contributes to the cognitive impairments in Alzheimer's disease. The neurotrophic compound CEP-1347, a structurally novel indolocarbazole which lacks excitatory amino acid receptor antagonist activity, has been shown to protect cholinergic neurons in the nbm and septum from experimental lesions in animal models. We have investigated whether CEP-1347 also protects glutamatergic neurons of the EC. Rats were given a unilateral lesion of the EC via stereotaxic injection of NMDA (15 nmols per site at 2 sites). Immediately afterwards and then daily for 14 days, rats were treated with either CEP-1347 (1 mg/kg s.c.) or vehicle (5% Solutol in PBS). The survival of neurons in layer 2 of the EC was assessed in horizontal sections stained with Cresyl violet, while the integrity of their axon terminals in the molecular layer of the dentate gyrus was determined in alternate sections stained with Timm's stain. NMDA lesioning destroyed 62±11% of EC layer 2 and decreased the area of the dentate gyrus middle molecular layer by 19±6%. CEP-1347 reduced the loss of EC layer 2 to 22±10% ( $p<0.05$ ) and prevented the decrease in area of the middle molecular layer ( $p<0.05$ ). Thus, CEP-1347 protected neurons in the EC from an excitotoxic lesion and maintained the integrity of their axon terminals in the dentate gyrus. The efficacy of CEP-1347 in protecting both cholinergic neurons of the basal forebrain and glutamatergic neurons of the EC in animal models suggests that this small neurotrophic molecule may be useful in treating the neurodegeneration associated with Alzheimer's disease.

## 299.9

**MORPHOLOGIC CHANGES OF ChAT- OR p75-IMMUNOPOSITIVE NEURONS IN THE AGED RAT FOLLOWING TREATMENT WITH GM1 GANGLIOSIDE.** T.G.Fong\*, N.H. Neff and M. Hadjiconstantinou. Departments of Pharmacology, Psychiatry, and the Neuroscience Program, The Ohio State University College of Medicine, Columbus, OH 43210

To extend our previous studies which demonstrated that GM1 can correct cholinergic neurochemical and behavioral deficits in the aged rat, we have investigated whether GM1 can also affect neuronal morphology. Aged (21-22 months old) and young (3 months old) Sprague Dawley rats were given GM1, 30 mg/kg ip, or saline for 30 days. Using either antibodies to choline acetyltransferase (ChAT) or to the low-affinity NGF receptor (p75), immunopositive neurons in the medial septum (MS), vertical limb of diagonal band (VDB), nucleus basalis (NB), and the striatum were analyzed for average cross-sectional size and cell number, using a computerized image analysis system. Aged animals treated with saline demonstrated a 15-20% decrease in size of both p75- and ChAT-immunopositive neurons in all regions measured, whereas aged animals treated with GM1 were not different in size from young. Further, GM1 treatment in aged animals reversed decreases in ChAT-immunopositive cell number in the MS and striatum of rats, and the number of p75-immunopositive cells in the MS and NB. GM1 had no effect on the ChAT-positive cells of young animals, but increased the cell size of p75-immunopositive neurons in the MS and VDB. These findings suggest that in addition to its ability to restore neurochemical and behavioral impairment in the aged rat, GM1 treatment will promote recovery of neuronal morphology as well. These studies were supported in part by NIA grant AG10530, and NIH grant MH 19936.

**MELATONIN RESCUES DEVELOPING AND/OR MPP+ DAMAGED DOPAMINE NEURONS FROM CELL DEATH IN CULTURE.** L. Jaceviti\*, K. Johnston and N.D. Stull. Dept. of Neurobiology and Anatomy, MCP and Hahnemann University, Philadelphia, PA.

The pineal neurohormone, melatonin, is believed to be a potent endogenous scavenger of hydroxyl radicals. This antioxidant action of melatonin is thought to protect against certain types of cellular damage. In this study, we sought to determine whether melatonin can specifically protect dopamine (DA) neurons from damage or death following the oxidative stress associated with 1) growth factor deprivation or 2) MPP+ toxin. E15 rat DA neurons were grown in culture at low ( $5 \times 10^3$  cells/80mm<sup>2</sup>) or high ( $5 \times 10^5$  cells/20mm<sup>2</sup>) density and maintained on serum-free media. In low density cultures, nearly all neurons were dead by day 6, presumably due to growth factor deprivation. However, supplementation with melatonin (0.1-500µM), resulted in the dose dependent survival of robust process-bearing DA neurons. No difference in survival or growth was observed in healthy high density cultures treated with melatonin. In cultures exposed to 2.5 µM MPP+ for 24hrs, there was a 50% decline in the number of DA neurons surviving 3 days later. Treatment with 500µM melatonin during the post-MPP+ period, however, restored the number of surviving DA neurons to nearly control levels (86%). We conclude that melatonin can act as a trophic agent to developing DA neurons in low density culture and can rescue from impending death DA neurons treated with the neurotoxin MPP+. These trophic and neuroprotective properties may reflect melatonin's antioxidant action. (Supported by NIH NS 32519).

**EVIDENCE THAT S100β FUNCTIONS TO MAINTAIN SYNAPSES IN THE DENTATE MOLECULAR LAYER OF THE ADULT RAT.** K.M. Faber\*, C.C. Wilson and J.H. Haring. Dept. of Anatomy and Neurobiology, Saint Louis Univ. Sch. of Med., St. Louis, MO 63104.

S100β is a calcium binding protein produced by astrocytes that has been shown to function as a neurotrophic factor. Furthermore, the synthesis and secretion of S100β is stimulated by 5-HT via astrocytic 5-HT<sub>1</sub> receptors, particularly in the developing CNS. We have reported that both 5-HT depletion by PCA or 5-HT<sub>1</sub> antagonist treatment of adult rats results in a significant loss of synaptic densities in the molecular layer of the fascia dentata 7 days after drug administration. Moreover, we have also reported that S100β immunoreactivity is significantly reduced after 5-HT depletion in adult rats. The purpose of this study was to determine whether a reduction in available S100β without 5-HT depletion would result in a loss of synaptic densities. Male Sprague-Dawley rats (200-300g) were the subjects of this experiment. Rats were anesthetized with sodium pentobarbital and placed in a stereotaxic instrument. Cannulae were placed in the lateral ventricle and connected to an osmotic pump containing rabbit anti-S100β IgG or normal goat serum diluted 1:250 with PBS. Rats were perfused 7 days later and the area dentata was prepared for EM. Analysis of electron photomicroscopic montages through the molecular layer indicated that the infiltration of anti-S100β for 7 days resulted in a significant reduction in the number of synaptic densities observed in the molecular layer (79% of serum control,  $p<0.01$ ). These data together with previous observations suggest that stimulation of astrocytes by 5-HT produces a basal secretion of S100β that is important for the maintenance of synapses in the adult molecular layer. Supported by NS31574.

## 299.10

**NEUREGULINS IN MYELINATING GLIAL CELLS.** Timothy D. Raabe and George H. DeVries\*. Department of Cell Biology, Neurobiology, and Anatomy, Loyola University Medical Center, Maywood, IL, 60153, and Research Service, Hines VA Hospital, Hines, IL, 60141.

Neuregulins (NRGs) consist of a family of growth factors which include NDF, GGF, ARIA, and HRG. Previous reports suggest that NRGs play an essential role in the development and differentiation of both Schwann cells (SC) and oligodendrocytes (OLG). The NRGs which influence SC and OLG development are presumed to be of neuronal origin since neurons with which these glial cells interact express NRGs. We now report that SC and OLG themselves contain NDF. Immunocytochemical data demonstrated NDF immunoreactivity throughout the cytoplasm of SC and OLG. In addition, NDF immunoreactivity was observed on SC plasma membranes. Western blot analyses of SC and OLG lysates revealed NDF isoforms ranging in molecular weights from 15 kDa to 75 kDa. We have also detected NDF in conditioned media from cultured SC and OLG which corresponds to the mature 45 kDa form of NDF. Furthermore, we have identified mRNA for NDFα and NDFβ in cultured SC and OLG. Our data suggest that NRGs are synthesized and secreted by SC and OLG. The NRGs produced by SC and OLG could possibly function via an autocrine loop during development or following injury. (Supported by a grant from the National Multiple Sclerosis Society RG2076B6).

## 299.12

**PIGMENT EPITHELIUM-DERIVED FACTOR (PEDF) PROTECTS CEREBELLAR GRANULE CELLS AGAINST APOPTOSIS.** T. Araki, T. Taniwaki\*, S.P. Becerra\*, G.J. Chader\*, J.P. Schwartz. Clinical Neuroscience Branch, NINDS, \*Lab. Retinal Cell and Molecular Biology, NEI, NIH, Bethesda MD 20892

Pigment epithelium-derived factor (PEDF) has a neuroprotective effect against glutamate toxicity for cerebellar granule cells (CGCs). In the present study, we have investigated the ability of PEDF to protect against apoptosis in 2 paradigms. Apoptosis was measured by assaying for DNA fragmentation and number of live cells by MTS. Under normal culture conditions (medium containing 25 mM KCl), 55% of CGCs have died of apoptosis after 12 days in vitro (DIV 12). PEDF, when added to CGCs at DIV 1, rescued ~40% of those CGCs, whereas addition of PEDF on DIV 5 did not rescue any cells. Apoptosis can also be induced by changing the medium from high potassium (25 mM) to low potassium (5 mM) at DIV 2 or DIV 6. When apoptosis is induced by lowering KCl at DIV 2, the addition of PEDF 24 hrs earlier or simultaneously significantly reduces CGC loss measured 24 hrs later. However, when apoptosis is induced at DIV 6, addition of PEDF up to 24 hrs earlier has little protective effect. These data show that PEDF can protect neurons against low potassium-induced apoptotic cell death at DIV 2, but not at DIV 6. The finding that PEDF has antiapoptotic effects only on immature CGCs (DIV 1 or 2) suggests the possibility that the PEDF receptor or its signal transduction system may undergo changes during this developmental time course.

## 299.13

EARLY PREGNANCY FACTOR REGULATES BRAIN GROWTH OF THE EARLY POSTIMPLANTATION (E9) MOUSE EMBRYO. S.J. Lee<sup>1</sup>, S.J. Servoss<sup>1</sup>, A.C. Cavanagh<sup>2</sup>, P.F. Alewood<sup>2</sup>, H. Morton<sup>2</sup>, D.E. Brenneman<sup>1</sup> and J.M. Hill<sup>1</sup>. <sup>1</sup>Lab of Developmental Neurobiology, NIH / NICHD, Bethesda, MD. 20892; <sup>2</sup>Dept. Surgery, Univ. Of Queensland, Australia.

During the early post-implantation period of development (E9-E11 in mouse), the regulation of both brain and body growth is influenced by a number of factors which coordinate early morphogenic events. Present in maternal serum during the first half of gestation, early pregnancy factor (EPF), a member of a highly conserved family of heat shock proteins, is an essential component which regulates cell proliferation and is necessary for embryonic well-being (Eur.J.Biochem. 1994, 222:551-60). The current study examines the role of EPF in brain and body growth during the early post-implantation period of ontogenesis. Whole mouse embryos (E9) in culture were treated with EPF ( $10^{-12}$  M -  $10^{-6}$  M), anti-EPF (1:100 dilution) or co-treated with EPF ( $10^{-6}$  M) and anti-EPF for four hours. Somite growth, body and head growth, DNA and protein contents were measured. The results revealed a significant and dose-related increase in somite number, DNA and protein contents. The dose response curve showed a bimodal distribution with significant growth occurring at  $10^{-11}$  M,  $10^{-9}$  M,  $10^{-8}$  M and  $10^{-7}$  M EPF. EPF also had a proportionately greater effect on brain growth than on body growth. Anti-EPF significantly inhibited growth of both brain and body but had a proportionately greater inhibitory effect on the brain. These data suggest that EPF may play an important role during neurogenesis and may regulate embryonic growth.

## 299.15

NEUROBASAL MEDIUM PROMOTES GREATER SURVIVAL OF EMBRYONIC CHICK SYMPATHETIC NEURONS THAN HAM'S F12 MEDIUM. D.B. Pettigrew\* and K.A. Crutcher, Dept. of Neurosurgery, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0515.

Optimal conditions for culturing primary neurons often require addition of serum and/or neurotrophic factors. For example, the survival-promoting activity of nerve growth factor (NGF) for embryonic sympathetic neurons is well established. However, it is not clear to what extent NGF acts to offset suboptimal conditions of the media used for such cultures. B27-supplemented Neurobasal medium (NBM) (GIBCO/BRL Life Technologies) was developed as a defined medium for cultures of primary neurons of the CNS. The extent to which this medium is suitable for culture of neurons of neural crest origin has not been extensively investigated. The suitability of NBM for cultures of embryonic (E9) chick sympathetic neurons was assessed in this study. Lumbar sympathetic ganglia were dissociated with trypsin and dissociated cells were cultured in either F12 media or NBM with or without exogenous NGF (1 ng/ml) using 96 well plates pretreated with poly-ornithine substrate, and the time course of the effects of these conditions were followed up to five days. Neuronal survival was assessed by labeling the cells with a fluorescent vital dye and subsequent quantification of cell number from digitized images using a cell counting macro with NIH Image software. NBM was found to promote greater survival of sympathetic neurons at all time points when compared with F12 whether or not NGF is present. These results suggest that NBM may be useful for primary cultures of embryonic sympathetic neurons. (Supported by NIH NS17131.)

## 299.17

A FEMTOMOLAR-ACTING NEUROPROTECTIVE PEPTIDE DERIVED FROM ACTIVITY DEPENDANT NEUROTROPHIC FACTOR, Douglas E. Brenneman\* and Ilana Gozes. SDMP, LDN, NICHD, NIH, Bethesda, MD; Dept. Clin. Biochem., Sackler School of Medicine, Tel Aviv Univ., Israel.

A novel 14-amino acid peptide is revealed that exhibited neuroprotection at unprecedented concentrations. This peptide prevented neuronal cell death associated with the envelope protein from the human immunodeficiency virus (glycoprotein 120), with excitotoxicity (N-methyl D-aspartate), with the beta amyloid peptide (putative cytotoxin in Alzheimer's disease), and with tetrodotoxin (electrical blockade). The peptide is derived from a new neuroprotective protein secreted by astroglial cells in the presence of vasoactive intestinal peptide. The neurotrophic protein was isolated by sequential chromatographic methods combining ion exchange, size separation and hydrophobic interaction. The protein (14,000 Daltons and pI 8.3 ± 0.25) was named activity dependent neurotrophic factor, as it protected neurons from death associated with electrical blockade. Peptide sequencing led to the synthesis of the novel 14-amino acid peptide that was homologous, but not identical to an intracellular stress protein: heat shock protein 60 (HSP 60). Neutralizing antiserum to HSP 60 produced neuronal cell death that could be prevented by co-treatment with the novel protein, suggesting the existence of extracellular stress-like proteins with neuroprotective properties. Recombinant HSP 60 had no detectable survival-promoting activity in CNS cultures. This is the first demonstration of a neurotrophic factor whose activity was mimicked by a synthesized peptide and whose neuro-protective activity was evident at femtomolar concentrations. These studies identify a potent neuroprotective peptide that provides a basis for developing treatments of currently intractable neurodegenerative diseases.

## 299.14

PC12 CELL PHENOTYPE IS ALTERED IN RESPONSE TO ENDOGENOUS EXPRESSION OF THE HUMAN PLEIOTROPHIN (PTN) GENE. N. Zhang, H.-J. Yeh, R. Zhong, S.P. Han, C.L. Young, M. Shen, and T.F. Deuel\* Washington University, Departments of Medicine and Biochemistry and Molecular Biophysics, St. Louis, MO 63110.

Pleiotrophin (PTN) exhibits mitogenic, angiogenic, and neuronal and oligodendrocyte progenitor cell outgrowth promoting activity *in vitro*. *In vivo*, PTN is differentially expressed in both a cell type and temporally regulated manner during development. To further investigate the roles that PTN may have in regulating cell growth and differentiation, we expressed the human PTN cDNA under control of the SV40 promoter in PC12 cells derived from a rat adrenal pheochromocytoma. PTN dramatically changed the morphology of PC12 cells. Two populations of cells that expressed human PTN were readily distinguished from homogenous populations of parent PC12 cells. One cell population developed the appearance of sympathetic neurons by neurite outgrowth and branching and retained neuronal markers. The other cell population became larger and the cell body became flat. Importantly, sympathetic neural precursor and chromaffin cell precursor markers, including NF200, sympathoadrenal (SA) antigens 1-5 and phenylethanolamine-N-methyltransferase (PNMT) were strikingly reduced, and lowered levels of production of the sympathetic neuronal transmitters including L-dopa, dopamine, and nor-epinephrine were observed in these cells. Both phenotypically altered cell types displayed attenuation of anchorage independent growth and lessened tumor formation in the nude mouse, supporting a role of PTN in driving PC12 cells to a more differentiated state. (Supported by NIH grant CA49712)

## 299.16

ATTEMPT TO PURIFY A NOVEL NEUROTROPHIC FACTOR DERIVED FROM BOVINE BRAIN TISSUE. K. Ishii<sup>1</sup>, N. Sahara<sup>1</sup>, H. Mori<sup>1</sup>, K. Watanabe<sup>2</sup>

<sup>1</sup>Dept. of Mol. Biol., Tokyo Inst. of Psychiatry, Kamikitazawa, Tokyo 156, Japan.

<sup>2</sup>Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo 173, Japan.

Neuronal cells mostly survive, grow and differentiate dependently on neurotrophic factors. Recently, some of the neurotrophic factors are expected to use for one of the therapy of degenerative disorders. We examined activities of growth and survival factors derived from bovine brain tissue. We used a primary culture of rat embryonic neocortical neurons. The activity was measured by MTT assay after 4 days of culture. Bovine brains were homogenized with PBS and fractionated by ammonium sulfate, DEAE sephacel, gel filtration, Resource Q, Heparin affinity chromatography, Phenyl superose and HPLC-gel filtration (Superdex 75). We focused a survival activity in the 0.08-0.1M NaCl fractions of Resource Q chromatography to avoid the contamination by well-known growth activities such as Annexin V and NSE. The active fraction in the last step was found to still contain several proteins on SDS-PAGE. Of these proteins, two proteins with Mr 28K and 22K were particularly focused because their presence was found to parallel to the activity. These proteins are further purified to be sequenced. We suppose that this fraction contains a new growth and survival factor because of its specific activity and its unique behavior in the chromatographies.

## 299.18

A 14-AMINO ACID PEPTIDE PROTECTS AGAINST ALZHEIMER'S-ASSOCIATED NEUROTOXICITY *IN VIVO*. I. Gozes\*, A. Davidson, A. Bardea, M. Bechar, E. Giladi and D. E. Brenneman. Clin. Biochem., Sackler Med. Sch., Tel Aviv Univ., Israel and NICHD, NIH, Bethesda, MD 20892.

A potent neuroprotective peptide, ADNF-14, was designed and synthesized to contain a sequence derived from a new neuroprotective protein, activity-dependent neurotrophic factor (ADNF). This protein exhibited structural similarity to a stress protein, heat shock protein 60 (hsp60). Two Alzheimer's related models were assessed for the *in vivo* neuroprotective effects of ADNF-derived peptides: cholinergic blockade and deficiencies in apolipoprotein E (ApoE). Cholinotoxicity was achieved in rats by blockade with ethylcholine aziridium (AF64A) and was associated with impairments in spatial learning and memory. Chronic intranasal delivery of ADNF-14 prevented cognitive impairments associated with cholinergic blockade. Furthermore, we now show that ApoE-deficient mice (Cell 71, 343, 1992) exhibited retardation in the acquisition of developmental milestones. Brains from these mice displayed a marked reduction in the mRNA encoding for the ADNF secretagogue, vasoactive intestinal peptide, as well as reduced cholinergic activity. Daily treatment with ADNF-derived peptides resulted in a significant acceleration in the acquisition of behavioral milestones, in comparison to either control or ApoE-deficient animals. These studies identify a potent neuroprotective hsp-like glial protein and peptides that provide a basis for developing novel treatments for Alzheimer's and other neurodegenerative diseases.

Supported in part by the US-Israel Binational Science Foundation.

## 299.19

IDENTIFICATION OF AN ACTIVE SITE FOR ACTIVITY-DEPENDENT NEUROTROPHIC FACTOR. A. Davidson\*, Y. Gozes, I. Hauser, D. E. Brenneman, and I. Gozes. Clin. Biochem. Sackler Med. Sch., Tel Aviv Univ., Israel; NICHD, NIH, Bethesda, MD 20892.

Activity-dependent neurotrophic factor (ADNF), secreted by astroglial cells in the presence of vasoactive intestinal peptide (VIP), protected neurons from death associated with electrical blockade at concentrations as low as  $5 \times 10^{-15}$ M. Other known growth factors (insulin-like growth factor-I, platelet-derived growth factor, fibroblast growth factor and nerve growth factor), did not increase neuronal survival in tetrodotoxin-treated spinal cord cultures at concentrations (0.1pM to 10 nM) known to be biologically active in other systems. To further assess ADNF activity, antibodies were elicited in mice following sequential injections of purified ADNF. At a dilution of 1:10,000, anti-ADNF ascites fluid decreased neuronal cell counts to 35-50% of untreated rat cerebral cortical cultures, while control antiserum had no effect. Administration of 1pM purified ADNF prevented the neuronal death associated with the antiserum. Similar results were obtained in dissociated mouse spinal cord cell cultures and in mouse hippocampal cell cultures. ADNF-14 is a 14 amino-peptide with hsp60-like sequences that is derived from ADNF. The antibody-associated neuronal cell death was also prevented by femtomolar concentrations of ADNF-14. *In vitro* association between the antiserum and ADNF-14 was also demonstrated utilizing size exclusion chromatography. These studies identify an active site in ADNF that is also a prominent immunogenic epitope. Furthermore, these data indicate that electrically active CNS cultures contain an endogenous ADNF-like neuronal survival factor.

Supported in part by the US-Israel Binational Science Foundation.

## 299.21

CHARACTERIZATION OF A NEUROTROPHIC FACTOR SECRETED BY CULTURED SCIATIC NERVES. B. Villegas\*, G.M. Villegas, D. Balbi, B. Maquieira, M. Longart, F. Iribarren, and M. Hernández. Instituto de Estudios Avanzados (IDEA), Apartado 17606, Caracas 1015A, Venezuela.

The present communication deals with further attempts to purify and characterize a previously described neurotrophic factor found in a medium conditioned by rat sciatic nerves (SNCM) (Brain Res., 685: 77-90, 1995). The neurotrophic activity, assayed by its neurite-promoting effect on PC12 cells, was associated with two protein peaks of 65 and 45 kDa. The previous purification procedure, consisting of ultrafiltration, heparin chromatography and size exclusion HPLC, was improved by using a 30,000 MWCO ultrafiltration membrane (Millipore) and by replacing the heparin column by an ionic exchange column (HiTrap Q, Pharmacia). These changes led to an improvement in resolution and relative enrichment of the 65 and 45 kDa peaks, as well as an increase in the activity of the 45 kDa peak. Investigation is continued to identify the active protein(s). We have also reported that the SNCM produced survival and differentiation of 8-day chick embryonic dorsal root and ciliary ganglia neurons. In an attempt to characterize the phenotypic changes induced by the SNCM, RNA from treated-PC12 cells was analyzed by RT-PCR. The relative amount of choline acetyl transferase (ChAT), tyrosine hydroxylase (TH) and  $\beta$ -actin mRNA seems to remain unmodified after 3 days treatment. However, a sharp increase in the number of cell granules and a two-fold increase in ChAT enzymatic activity were observed. Additional work is needed to establish the mechanisms responsible for this survival and differentiation activity.

Supported by IDEA, CONICIT Venezuela (Grants S1-2180 and S1-95000709) and the Vollmer Research Fund of CEC-Caracas.

## 299.23

$\gamma$ -PYRONE-TYPE NOVEL LOW MOLECULAR WEIGHT EXOGENOUS SUBSTANCE WITH NEUROTROPHIC ACTIVITY. N. Nishiyama\*<sup>1)</sup>, T. Moriguchi<sup>1)</sup>, H. Katsuki<sup>1)</sup>, H. Matsuura<sup>2)</sup>, Y. Itakura<sup>2)</sup> and H. Saito<sup>2)</sup>. 1) Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo 113, Japan, 2) Instit. for OTC Res., Wakunaga Pharmaceut. Comp. Ltd., Hiroshima 739-11, Japan.

In our preceding study, aged garlic extract exerted dose-dependent neurotrophic activity on rat hippocampal neurons. On our way to isolate pure chemical substance(s) in the extract, we found for the first time that  $\gamma$ -pyrone type substance allixin (3-hydroxy-5-methoxy-6-methyl-2-pentyl-4H-pyrone) enhanced neuronal survival and axonal branching. A disperse neuron cell culture was prepared from embryonic rat and tested chemicals were added in the culture medium a day later. The number of surviving neurons were counted after 3 days exposure to the chemicals. Neuron cell morphology was recorded at 1 and 2 days after exposure. Allixin increased the number of surviving neurons prepared from all brain regions tested concentration-dependently (1-100 ng/ml). It also promoted the branching of the longest neurite in hippocampal neurons. At higher concentrations (>1000 ng/ml), however, allixin started to kill all the cells, indicating its strong cytotoxicity. Thus a number of analogous chemicals were obtained or synthesized, and examined for their neurotrophic activities, aiming to find a substance with less cytotoxicity. Among the numerous chemicals, DHP (2,6-dimethyl-3-hydroxy-4H-pyrone) possessed strong neurotrophic activity at more than 10 ng/ml without any obvious cytotoxicity up to 10  $\mu$ g/ml. DHP also retained the activity to enhance the neurite branching. These results indicate that allixin and DHP are novel exogenous low molecular weight substances with strong neurotrophic activity. These substances will make helpful leading chemicals for developing therapeutic and/or prophylactic drugs for neurodegenerative disorders.

LIVER DERIVED NEURONAL ACTIVATOR (LDNA) ENHANCES NEURITE REGENERATION FROM AGED HUMAN RETINA. H. Horie\*<sup>1)</sup>, M. Takano<sup>2)</sup>, T. Kadoya<sup>3)</sup>, Y. Inagaki<sup>1)</sup>. Depts. Physiol.<sup>1)</sup> and Ophthalmol.<sup>2)</sup>, Yokohama City Univ., Sch. of Med., Yokohama 236 and Pharmaceut. Lab., Kirin Brewery Co., Maebashi 371, JAPAN.

Liver derived neuronal activator (LDNA) enhanced neurite regeneration and their survival from nerve-transected terminals of rat adult dorsal root ganglia (DRG) with associated nerve bundles. This factor is different from known neurotrophic factors (Neurosci. abst., 1995) and promoted neurite regeneration from adult rat retina explants. LDNA was expected to promote neurite regeneration from aged retinal explants. We introduced three-dimensional collagen gel culture system and compared neurite regeneration capability of 24-month-old mouse retina with that of 3-month-old one. The number of regenerating neurites from aged explants was one third smaller than that from young explants 6 days after in culture. This result showed that neurite regeneration capability decreased with aging. When LDNA was applied to the aged retina explant, it enhanced neurite regeneration. This enhancement indicates that LDNA works as a neural activator in aged central nervous tissues. This activity was also proved in an aged human retina. The human retina was obtained at surgery from 70-year-old patient with retinoblastoma. When LDNA was applied to the cultured human retinal explant, it enhanced the neurite regeneration. Since LDNA from rat liver works as a neuronal activator in either mouse or human aged retina, this activity is thought to be preserved among mammalian. (Supported by MESJ, Japan)

## 299.22

EFFECTS OF SCIATIC NERVE GRAFTS ON CHOLINE ACETYLTRANSFERASE AND P75 EXPRESSION IN TRANSECTED ADULT HYPOGLOSSAL MOTONEURONS. E. Frezzato, G. Stipa, C. Provenzano and M. Rende\* Dept. Exp. Med., Sect. Anatomy, Univ. of Perugia Sch. of Med., Italy

We previously reported that a permanent transection of adult rat sciatic and hypoglossal nerves resulted in distinct temporal changes in both p75 and ChAT immunoreactivity (-Ir). Permanent axotomy of hypoglossal motoneurons induced a progressive loss of ChAT-Ir and a persistent expression of p75-Ir, phenomena which were not observed in spinal motoneurons. These observations indicated that spinal and brainstem motoneurons respond to permanent axotomy with a differential modulation of p75 and ChAT expression. Such differences in expression could be ascribed to specific intrinsic properties of each population of motoneurons or to different factors present in the nerve stump "target" region. The aim of the present study was to test these two possibilities by determining if a segment of sciatic nerve transplanted to a transected hypoglossal nerve counteracts the loss of ChAT and the expression of p75 in injured hypoglossal motoneurons. Prior to grafting, the segments of sciatic nerve were prepared by one of three methods: (i) a fresh piece; (ii) a degenerated piece; and (iii) a heated piece. Seven days following the placement of grafts, hypoglossal motoneurons were analysed for p75 and ChAT. The results revealed that viable sciatic grafts (fresh and degenerated) attenuated the loss of ChAT in the injured hypoglossal motoneurons. In addition, viable sciatic grafts decreased the expression of neuronal p75-Ir, thus inducing these motoneurons to acquire a pattern more characteristic of the uninjured state. These effects indicate that adult hypoglossal motoneurons retain responsiveness to factors released from the sciatic nerve, and that differential expression patterns between these two motoneuron populations is due, at least in part, to different factors released by distal hypoglossal and sciatic nerve segments. TROPHIC INTERACTION BETWEEN BASAL FOREBRAIN NEURONS AND CORTICAL NEURONS IN DISSOCIATED CO-CULTURES. D.H. Ha\*, R.T. Robertson, and J.H. Weiss. Depts of Neurology and Anatomy/Neurobiology, U.C. Irvine, Irvine CA 92717.

We have previously shown that cortical neurons are able to enhance survival and morphologic characteristics of basal forebrain cholinergic neurons (BFCNs) when they are co-cultured together (Ha, et al., Neurosci. Abs., 1995). Staining of basal forebrain (BF)-cortical co-cultures with SMI-32, a monoclonal antibody against non-phosphorylated neurofilament epitopes reported to label subsets of pyramidal neurons in cortex, revealed a subset of strongly stained neurons that displayed unusually large cell bodies and long axons. These "large SMI-32(+) neurons" were not present in cultures of either BF or cortical cells alone. Using double labeling techniques, we failed to find evidence of choline acetyltransferase (ChAT), GABA or acetylcholinesterase labeling in large SMI-32(+) neurons, suggesting that they are neither cholinergic nor GABAergic. Furthermore, treating co-cultures with 192-IgG-saporin (a toxin linked to antibody against the low affinity NGF receptor, p75, which has been reported to selectively kill BFCNs in vivo) resulted in the apparent loss of SMI-32(+) neurons as well as ChAT(+) neurons. We are currently preparing BF-cortical co-cultures from wild-type mice and from  $\beta$ -galactosidase expressing transgenic mice, to determine the origin of the large SMI-32(+) neurons. While large SMI-32(+) neurons could be of BF origin, results to date suggest the hypothesis that they are of cortical origin, and that trophic influences from BFCNs in co-cultures enhance their morphologic features. Supported by NIH grants NS 30884 (JHW) and NS 30109 (RTR).

**SCHWANN CELL-DORSAL ROOT GANGLION NEURON CO-CULTURE CAUSES AN INCREASE IN SODIUM CHANNEL mRNA EXPRESSION AND SODIUM CURRENT.** Amy A. W. Hinson, Xiang Gu, Sulayman Dib-Hajj, Joel A. Black and Stephen G. Waxman. Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT and Neuroscience Res., VA Med. Ctr., West Haven, CT 06516

The pattern of expression of Na channel  $\alpha$  and  $\beta$ -subunits in neurons is spatially and developmentally regulated, yet the factors that govern the expression of these subunits are not known. At least seven neural subtypes of the Na channel  $\alpha$ -subunit-I, II/III, III, NaG, Na6, SNS and hNE-Na have been described, while only two genes for  $\beta$ 1 and  $\beta$ 2 subunits have been cloned. Electrophysiological data has shown that dorsal root ganglion neurons (DRGN) display several distinct types of Na currents during development, which may reflect differential expression of Na channel  $\alpha$  and/or  $\beta$ -subunits. Previously, this laboratory has demonstrated that the expression of Na channel mRNA in DRGN from E17 rats is influenced by exposure to NGF. In order to study the role of Schwann cells (SC) in modulating Na channel expression in DRGN and to correlate Na current characteristics with molecular structure, we used *in situ* hybridization cytochemistry to examine the expression of Na channel  $\alpha$  and  $\beta$  mRNAs in DRGN isolated from E15 rats cultured in the absence or presence of SC. DRGN in culture with SC demonstrated an increase in expression for  $\alpha$ -subunits II, NaG, Na6, SNS and for  $\beta$ -subunits. In addition, the increase in sodium channel mRNA expression in DRGN co-cultured with SC coincided with an increase in sodium current and current density. These observations demonstrate that a SC-derived factor differentially up-regulates Na channel  $\alpha$  and  $\beta$ -subunit mRNA expression in DRGN isolated from E15 rats. (Supported in part by the VA and NMSS)

## 299.27

**CONDITIONED MEDIUM FROM GLIAL CELLS PREVENTS APOPTOSIS OF CULTURED NEURONS.** X.F. Wang\* and M. S. Cynader. Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, BC, Canada, V5Z 3N9.

Cultured primary cortical neurons from E18 rat embryo survive poorly at low densities ( $5 \times 10^4$  cells/cm<sup>2</sup>). However, when co-cultured with a glial cell monolayer in a non-contact method, the survival rate is much increased with over 80% of cultured neurons surviving at DIV (day in vitro) 5. When the glial cell monolayer was removed at DIV 3, the cultured neurons died rapidly (74% within 24 hours, 98% within 48 hours). Cell death occurred by apoptosis, as assessed by morphological criteria, including blebbing, cell shrinkage, and nuclear condensation. We used this model to test the effects of conditioned medium and other potential survival factors on neuronal apoptosis. At DIV 3, the glial cell monolayer was removed, and conditioned medium or potential survival factors were added. The surviving neurons were counted 24 hours later. Glial-conditioned medium containing 10% Fetal Calf Serum (FCS) resulted in fewer surviving neurons (21%) than a glial-conditioned medium containing albumin (5mg/ml) without FCS (88%). NGF, BDNF, GDNF (100ng/ml and 10ng/ml, respectively) were all tested in albumin-containing medium. None of these neurotrophic factors had any observable effect on neuronal survival (<20% survival rate). These results suggest that glial cells may secrete a factor or factors which can improve the survival of cultured neurons, and that these factors are unlikely to be known neurotrophins. The identity of the factor(s) in question is being sought.

**PURIFICATION OF A SURVIVAL-PROMOTING FACTOR FROM CULTURED NEURONS FROM BOVINE SERUM, AND ITS IDENTIFICATION AS A SELENOPROTEIN P-LIKE PROTEIN.** J. Yarr\* and J. N. Barrett. Dept. of Physiology and Biophysics, Univ. of Miami Sch. of Med., Miami, FL 33101

The neuronal survival-promoting activity in serum is enriched in a 45-80 kD gel filtration fraction (Kaufman and Barrett, 1983 Science 220:1394). We purified from bovine serum a glycoprotein that promotes survival of cultured rat embryonic neurons from several brain regions including septum in a 7 day survival assay. About 10,000 fold purification was achieved using a combination of ammonium sulfate precipitation, metal-chelating chromatography, Cibacron-blue F3GA dye affinity chromatography, ABx ion exchanger and preparative SDS-PAGE. The concentration required for the half maximal survival effect is about 10 ng/ml for the final fraction. This protein has an apparent molecular weight of 56 kD on SDS-PAGE. Amino acid sequencing after cyanogen bromide cleavage yielded two sequences, both of which match with regions of deduced sequence of a bovine selenoprotein P-like protein. The cDNA of this molecule was cloned from the cerebellum (Sajoh et al., 1995 Mol Brain Res 30:301), but the protein had not been purified previously. We generated antibodies against a synthetic peptide matching 16 amino acids of the predicted bovine SPP-like protein sequence. The antibodies neutralized most of the survival-promoting activity in the partially purified fractions. The SPP-like protein may contribute to the neuronal survival-promoting activity of serum by playing a role in selenium homeostasis and antioxidative defense mechanisms.

**POSTTRANSLATIONAL REGULATION OF  $Ca^{2+}$ -ACTIVATED  $K^+$  CURRENTS BY A TARGET-DERIVED FACTOR IN DEVELOPING CHICK CILIARY GANGLION NEURONS** Priya Subramony, Sanja Raucher, \*Laurence Dryer & Stuart E. Dryer\* Prog. Neurosci., Florida State University, Tallahassee, FL 32306 and \*Dept. Neurobiol., Harvard Medical School, Boston, MA 02115

Macroscopic  $I_{K(Ca)}$  is not expressed at normal levels in chick ciliary ganglion (CG) neurons prior to synapse formation with target tissues or in neurons developing *in vitro* or *in situ* in the absence of target tissues. Here, we have examined the mechanisms underlying target-dependent stimulation of  $I_{K(Ca)}$ . Two chick CG *slo* partial cDNAs encoding  $I_{K(Ca)}$  channels were isolated, cloned and sequenced. Both *slo* transcripts, which appear to be splice variants, were readily detected by RT-PCR in developing CG neurons prior to or in the absence of target tissue interactions. When E9 CG neurons developed *in vitro* for 4 d in the presence of target tissue (iris) extracts, a normal whole-cell  $I_{K(Ca)}$  was expressed. The effects of iris extracts did not require protein synthesis and were apparent within 5-7 hr. This activity was detectable throughout the stages of synapse formation in the iris (E9-13) but was not present in E6-7 iris, prior to synapse formation. The active component of iris extract is a heat- and trypsin-sensitive protein with an apparent molecular weight of 40-60 kD. Large-conductance  $I_{K(Ca)}$  channels were readily detected in excised inside-out patches from acutely-isolated E13 CG neurons or in E9 neurons cultured for 4 d in the presence of iris extracts. These channels were activated by bath application of 1  $\mu$ M  $Ca^{2+}$ . Large-conductance  $K^+$  channels kinetically similar to  $I_{K(Ca)}$  were also observed in E9 CG neurons cultured for 4 d in the absence of iris extracts. However, those channels had abnormal gating properties as they typically did not increase their activity in the presence of 1  $\mu$ M  $Ca^{2+}$ . RO1-NS-32748 and AMERICAN HEART ASSOC. (FL AFFILIATE).

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS—NGF I

## 300.1

**NEUROTROPHINS PREVENT DEGENERATION OF PROXIMAL STUMPS OF TRANSECTED SENSORY AXONS IN ADULT RAT SPINAL CORD**

F. Sayer\*, M. Oudega & J. T. Hagg

Dept. Anatomy & Neurobiology, Dalhousie Univ., Halifax, B3H 4H7, Canada; \* The Miami Project to Cure Paralysis, Miami Univ. Sch. Med., FL33136.

We and others have shown that neurotrophic factors can promote axonal regeneration in the CNS. Here, we investigated whether neurotrophins can prevent degeneration of the proximal ends of transected axons, i.e., an event that may contribute to poor regeneration in the adult CNS. Adult Sprague-Dawley rats received a transection of the ascending sensory tract (dorsal column) and descending corticospinal motor tract at thoracic level T9-10. One or 3 days before further analysis, the right sensory and left corticospinal axons were anterogradely labeled with cholera toxin B injected into the right sciatic nerve and left lumbar motor cortex. Sensory and motor axon terminals swelled and formed terminal clubs over the first day after injury and degenerated further over the next few weeks. A mixture of neurotrophins was injected into the lesion site immediately after the injury (nerve growth factor, 1  $\mu$ g, Cedar Lane Inc; brain-derived neurotrophic factor and neurotrophin-3, 7  $\mu$ g each, a gift of Regeneron Pharmaceuticals). After 1 day, the number of terminal clubs of sensory axons in neurotrophin-treated animals was ~25% of that in PBS injected ones and they were much smaller. The effects of the neurotrophin mixture was less clear 7 days after the injection and negligible after 14 days. At a 3-fold higher dose, each factor alone was as effective as the mixture, suggesting that they have additive effects. Surprisingly, the neurotrophins had no clear effects on the degeneration of the motor axons. Support: International Research Institute for Paraplegia and Rick Hansen Man in Motion Foundation.

## 300.2

**REVERSAL OF IMPAIRED CALCIUM INFLUX IN AGING BY NERVE GROWTH FACTOR MAY BE MEDIATED BY DECREASED INHIBITORY G PROTEIN FUNCTION** K.E. Hall\*, J. M. Spitsbergen\*, W. D. Steers\*, J. B. Tuttle\*, J. W. Wiley. Dept. Internal Medicine, U. of Michigan, Ann Arbor, MI 48109, and \*Depts. of Urology and Neuroscience, U. of Virginia, Charlottesville, VA 22908.

The aim of this study was to determine whether nerve growth factor (NGF) could reverse age-associated decreased neuronal calcium influx. Dissociated dorsal root ganglion (DRG) neurons from young (Y: 4-6 months), middle-aged (M: 12-14 months) and old (O: 22-26 months) Fisher 344 x BN F1 hybrid rats were incubated in serum-free medium containing NGF (100 ng/ml), or in control (no NGF) medium for 24 to 96 hours. Medium was changed daily. Mean NGF levels measured by radio-immunoassay were  $445 \pm 65$  pg/ml ( $n=8$ ) in NGF-treated dishes. NGF treatment was associated with significantly more neurite out-growth and neuronal interconnections at all age levels. Calcium current density ( $I_{Ca}$ ; pA/pF) was recorded in single, acutely dissociated DRGs using the whole-cell variant of the patch-clamp technique. DRGs from aged animals had a smaller mean amplitude of  $I_{Ca}$  ( $68 \pm 43$ ;  $n=6$ ) than neurons from young and middle-aged animals (Y:  $108.5 \pm 13.3$ ;  $n=10$ , M:  $93.0 \pm 24.0$ ;  $n=8$ ). NGF treatment increased  $I_{Ca}$  in all three age groups by 48 hours (Y:  $136.8 \pm 35$ ;  $n=4$ , M:  $146.0 \pm 20$ ;  $n=8$ ;  $P<0.05$ , O:  $203 \pm 54$ ;  $n=5$ ;  $P<0.01$ ). Using a two step (pre-pulse/test-pulse) "facilitation" protocol that transiently blocks the predominately inhibitory tonic G protein modulation of calcium channels, we noted that NGF treatment significantly decreased % facilitation (Y:  $16 \pm 2$ ;  $n=3$ ;  $P<0.01$ , O:  $15 \pm 3$ ;  $n=3$ ;  $P<0.05$ ) compared to controls (Y:  $41 \pm 6$ ;  $n=6$ , O:  $23 \pm 4$ ;  $n=5$ ). In summary, calcium influx in sensory neurons from aged animals was significantly decreased compared to youthful controls. NGF treatment restored calcium influx in aged neurons to youthful levels, while decreasing the percentage of tonic inhibition of  $I_{Ca}$ . These results indicate that NGF may increase  $I_{Ca}$  by decreasing tonic inhibition of the G protein-calcium channel complex. Funding by the Claude Pepper Older Americans Independence Center.

## 390.3

**NGF TREATMENT *IN-VIVO* RESCUES DRG THAT ARE PROGRAMMED TO DEGENERATE BY INCREASING PROLIFERATION.** R.S. Goldstein, and R. Geffen. Dept. Life Science, Bar-Ilan Univ. 52900 Ramat-Gan, ISRAEL.

A striking element of patterning within the meristic series of DRG, is the disappearance of the five or six most rostral ganglia early in the embryonic development of birds and mammals. These transient DRG have been named "Frobie's ganglia" for their nineteenth century discoverer.

We have examined the ontogeny of the longest surviving Frobie's ganglion of the chick embryo, DRG C2. In detail (Rosen et al J. Neurobiol., June 1996). At St. 18 (E2.5+), the C2 DRG had the same shape and volume as permanent ganglia C5 and C8. C2's development first diverged from that of normal DRG at St. 19 (E3-), when C2 was observed to be half the size and shaped differently from its neighbors.

Since growth factors modulate both proliferation and apoptosis, we postulated that these molecules and/or their receptors might be responsible for the difference in fate between C2 and C5. We have now treated embryos with NGF *in-ovo* in order to begin to evaluate this possibility. NGF treatments (1µg- St 17 & 21) partially rescued C2, producing a 50% reduction in the normal difference in size between C2 and C5 at St. 23. At least part of this rescue could be accounted for by increased proliferation in the NGF-treated C2 compared to that in control embryos. Proliferation in normal DRG C5 was unaffected by NGF application. NGF treatment rescued DRG cells in both C2 and C5 from cell death. Staining of pyknotic nuclei revealed that NGF dramatically reduced the death in the C2 ganglia, until it became equivalent

mental stage. Examination of NGF treated embryos at St.28 revealed that at least some of the cells rescued in the C2 DRG are neurons.

Our finding is the first direct evidence for a role for NGF in control of DRG cell proliferation *in-vivo*. Supported by the Familial Dysautonomia Inc.

## 390.5

**THE INFLUENCE OF NEUROTROPHIC FACTORS ON NEURITE- FORMATION OF AGING MOUSE DORSAL ROOT GANGLION CELLS.** T. Ninomiya<sup>1,2</sup>, M. Yamauchi<sup>2</sup> and H. Terasawa<sup>1,2</sup>. Dep. of Anatomy<sup>1</sup> & Anesthesiology<sup>2</sup>, Sapporo Med. Univ. Sch. of Med., Sapporo, 060 Japan.

In aging dorsal root ganglion (DRG) cell culture, DRG cells display the multipolar, bipolar or pseudounipolar forms. Some pseudounipolar neurons had many thin neurites elongated from the junction of the stem process or a structure-like swelling body or glomerulus (atypical pseudounipolar cell). These structures were not seen in fetal or newborn mouse DRG cell cultures. In order to study the effect of neurotrophic factor (NTF) on neurite formation of adult mouse DRG cells, dissociated DRG cells from 15-month-old mice were grown on poly-L-lysine coated dishes in alpha MEM serum-free (SF-M) supplemented with nerve growth factor (NGF), neurotrophin-3 (NT-3), neurotrophin-4 (NT-4) or brain derived neurotrophic factor (BDNF). After 6 days, cultures were stained with anti-neurofilament protein (anti-NFP) and microtubule-associated protein 2 (anti-MAP2). Cultured DRG neurons were classified into bipolar, multipolar, typical pseudounipolar or atypical pseudounipolar neuron.

Atypical neurons appeared with an incidence of about 5% in aMEM-SF without NTF or supplemented with NT-3, NT-4 or BDNF. However atypical pseudounipolar neurons increased about 30% in aMEM-SF supplemented with NGF. There is no difference of the number of surviving neurons in each of culture medium. The appearance of this type cell was affected by NGF, not affect other neurotrophic factors.

## 390.7

**THE EFFECT OF ELECTRICAL STIMULATION ON TRK ACTIVATION AND IMMEDIATE EARLY GENE EXPRESSION IN SENSORY NEURONS.** Y. Hao and K.M. Mearrow<sup>\*</sup>, Basic Medical Sciences, Memorial University of Newfoundland, St. John's, NF, A1B 3X6.

The collateral sprouting of intact DRG neurons is NGF-dependent, and electrical stimulation of these neurons results in an acceleration of the growth response. In an effort to discern early events which may contribute to this response, the expression of several IEGs, known to be influenced by stimulation or NGF, was examined. In addition, the possibility that alterations in *trk* and/or its phosphorylation state might be involved was investigated. The dorsal cutaneous nerves of adult rats were subjected to one of the following treatments: 1) electrical stimulation (8V, 20Hz, 1 min) or 2) isolation (adjacent nerves were cut), or 3) isolation + stimulation. Subsequently (1, 4, 8hrs, 1, 2, 4 d), animals were anaesthetized, DRGs were removed and used for RNA or protein extraction or for cryosectioning. IEG expression was examined by immunocytochemistry with antibodies to cJUN, EGR1, OCT2 and pCREB. RT-PCR was carried out using specific primers to detect EGR1, OCT2 and CREB sequences; cyclophilin was used as an internal control. *Trk* and *trk* phosphorylation levels were analyzed by immunoprecipitation, and subsequent SDS-PAGE and Western analysis with either *trk* or phosphotyrosine antibodies.

With respect to the IEGs, about 30% of the DRG neurons displayed basal expression of pCREB, OCT2, EGR1 and cJUN, which was confined to small neurons. Following stimulation, there was a decrease in the % of pCREB and EGR1-positive neurons observed at 1, 4 and 8 hrs; RT-PCR analysis provided the same results. However, a significant increase in the % of positive cells was found in the stimulation + isolation condition between d1 and d2, which subsequently returned to the control levels. Preliminary results indicated little or no change in *trk* protein levels and *trk* phosphorylation in the DRGs; analysis of potential increases in retrograde transport is underway. Supported by NSERC.

## 390.4

**RECEPTIVE PROPERTIES OF CUTANEOUS SENSORY NEURONS IN TRANSGENIC MICE LACKING THE NEUROTROPHIN RECEPTOR p75.** M. Koltzenburg<sup>\*</sup> and C.L. Stucky. Dept. of Neurology, University of Würzburg, D-97080 Würzburg, Germany.

The neurotrophin receptor p75 interacts with all known neurotrophins. Transgenic mice which lack the p75 receptor (p75<sup>-/-</sup>) exhibit decreased sensitivity to both noxious mechanical and thermal stimuli, reduced innervation density of the skin and approximately 50% loss of sensory neurons. We used neurophysiological techniques to investigate whether p75 has a role in the survival or function of specific subtypes of cutaneous sensory fibers. The sural nerve with innervated skin was dissected from adult p75<sup>-/-</sup> and wildtype (p75<sup>+/+</sup>) mice. Standard electrophysiological techniques were used to record from single afferent fibers *in vitro* (p75<sup>-/-</sup>: n=103; p75<sup>+/+</sup>: n=70). Fibers were characterized by their conduction velocity and response to controlled mechanical and thermal stimuli. Large myelinated fibers (Aβ) were classified as either slowly adapting (SA) or rapidly adapting (RA) low threshold mechanoreceptors. There was no difference in the percentages of SA (38%) and RA (62%) fibers in p75<sup>-/-</sup> mice compared to controls (SA: 41%; RA: 59%) or in their response properties to mechanical stimuli. Thin myelinated fibers (Aδ) were classified as either nociceptive high threshold mechanoreceptors (AM) or low threshold D-hair receptors. The percentage of AM fibers in p75<sup>-/-</sup> mice (42%, n=57) was significantly (p<0.05,  $\chi^2$ ) reduced compared to p75<sup>+/+</sup> mice (68%, n=34). Unmyelinated C-fibers responded to mechanical stimuli or to heat and mechanical stimuli. Whereas the mechanical stimulus response functions of AM fibers in p75<sup>-/-</sup> mice were normal, the firing frequency of C-fibers to mechanical stimuli was decreased in p75<sup>-/-</sup> mice compared to controls. These data suggest that the decrease in behavioral sensitivity to noxious stimuli in p75<sup>-/-</sup> mice may be due to decreased number of AM fibers as well as reduced sensitivity of C-fibers. (Supported by the DFG, SFB 353).

## 390.6

**EFFECTS OF OVARECTOMY AND ESTROGEN ON LUMBAR DORSAL ROOT GANGLION NEURONAL NEUROFILAMENT GENE EXPRESSION.** S.A. Scoville, S.M. Bufton, M.J. Swierczewski, F.J. Liuzzi and D.E. Scott<sup>\*</sup>. Dept. of Anatomy and Neurobiology, Dept. of Urology and the Molecular Neurobiology Lab., the Diabetes Institutes, Dept. of Internal Medicine, Eastern Virginia Med. Sch., Norfolk, VA 23501.

Recently, estrogen receptor expression by dorsal root ganglion (DRG) of adult female rats was shown by Sohrabji and her colleagues (1994). Previous studies have shown the presence of receptors on the DRG neurons for both low (p75) and high (trkA) affinity nerve growth factor (NGF) receptors. In subpopulations of DRG neurons, these receptors colocalize with the estrogen receptor. More interestingly, endogenous and exogenous estrogen has been shown to up-regulate the message for the NGF receptors and down-regulate the estrogen receptor. Previous research has also demonstrated that neurofilament (NF) is regulated by NGF in those DRG neurons with high affinity NGF receptors. The current study investigated the effects of estrogen on 68kD NF gene expression. The four groups of female Sprague-Dawley rats were: normal, ovariectomized, ovariectomized with estrogen replacement and ovariectomized with 10X replacement. A P<sup>33</sup>-labelled cRNA probe was used to localize 68kD mRNA in DRG neurons by *in situ* hybridization. Ovariectomy reduced NF mRNA levels compared to those in DRGs of normal animals. Estrogen replacement increased DRG neuronal NF mRNA levels. These data suggest that estrogen may act synergistically with NGF to regulate the expression of the 68kD NF gene in DRG neurons.

This work was supported in part by a grant from C.R. Bard to MJS and funds from the Diabetes Institutes Foundation, Norfolk, VA.

## 390.8

**CONTROL OF AXONAL TRANSPORT BY RECOMBINANT HUMAN NGF IN CULTURED MOUSE DORSAL ROOT GANGLION CELLS.**

S.Yuki, T.Takenaka<sup>\*</sup>, T.Kawakami<sup>\*</sup>, I.Sakai<sup>\*</sup> and K-I.Saito<sup>\*</sup>. Pharmaceuticals Lab.1, Yokohama Research Center, Mitsubishi Chemical Corporation, Aoba-ku, Yokohama, 227 Japan.

Department of Physiology, Yokohama City University, Fukuura, Yokohama, 236 Japan.

Control of axonal transport and its related signal transduction mechanism by recombinant human NGF (rhNGF) were studied using cultured mouse dorsal root ganglion cells. The transported particles were measured with a computer-assisted video-enhanced differential interference contrast microscope system.

rhNGF increased the number of transported particles with dose-dependent manner in both anterograde and retrograde directions, and also increased the velocity of particles. The effects of rhNGF were continued for 1 hour, and did not decrease immediately after wash out of rhNGF. K252a, a *trkA* linked tyrosine kinase inhibitor, completely antagonized the effects of rhNGF. This result suggested that the tyrosine kinase signal transduction system took a part in the control of axonal transport.

## 300.9

**TYROSINE HYDROXYLASE-IMMUNOREACTIVE AXONS FORM PLEXUSES AROUND TRIGEMINAL NEURONS OF TRANSGENIC MICE OVEREXPRESSING NERVE GROWTH FACTOR IN GLIAL CELLS.** G.S. Walsh and M.D. Kawaja\*. Dept. Anatomy and Cell Biology, Queen's University, Kingston, Ontario CANADA K7L 3N6.

Transgenic mice overexpressing NGF under control of the GFAP promoter in glial cells were found to have significantly higher levels of NGF protein in the trigeminal ganglia when compared with control mice (based on ELISA data obtained in Dr. Keith Crutcher's laboratory). Higher levels of NGF mRNA expression were also found in the transgenic ganglia and brainstem. The consequences of such overexpression were examined through immunohistochemical localization of NGF and various phenotypic markers. NGF-immunostained neurons were present in both transgenic and wild-type ganglia, with a higher proportion evident in the former. In transgenic ganglia, however, axons immunostained for tyrosine hydroxylase formed perineuronal plexuses surrounding NGF-positive neurons. Following transection of the infraorbital nerve, NGF mRNA was up-regulated in the ipsilateral transgenic ganglia and brainstem. Neither the proportion of NGF-immunostained neurons nor the neuronal intensity of immunostaining for neurotrophin receptors and neuropeptides was altered between transgenic and wild-type ganglia, with and without nerve transection. From these data, we propose that accumulation and putative release of NGF by adult sensory neurons induce the formation of perineuronal axon plexuses, presumably sympathetic in origin, but do not appear to alter patterns of immunostaining for phenotypic proteins expressed by trigeminal neurons. (Supported by the MRC of Canada and NIH NS17131).

## 300.11

**SCG NEURITE OUTGROWTH MODULATED BY CO-CULTURE WITH SPLEEN.** S.L. Carlson\* and M. Parrish. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Immune tissues normally receive innervation by fibers of the sympathetic nervous system. We have found that immune tissues (spleen and peripheral lymph nodes) of nerve growth factor (NGF)-transgenic mice have a robust hyperinnervation of specific compartments in these tissues compared to controls, including the splenic marginal zone and lymph node medulla and capsule (Carlson, et al., J. Neurosci. 15:5892, 1995). This result was not expected since the NGF transgene was overexpressed in skin, and not in immune tissues. To determine if the immune tissues of the transgenic mice express a factor that promotes sympathetic ingrowth, co-cultures of superior cervical ganglion (SCG) and spleen pieces were established. The tissues were placed in collagen gels with a distance of 1-2mm between the spleen and SCG, cultured for 5 days in the presence or absence of NGF, and sympathetic neurites visualized with anti-tyrosine hydroxylase. SCGs from control animals had extensive neurite outgrowth when cultured with control spleen in the presence of NGF. In contrast, control SCG produced more blunted neurites with greater amounts of fasciculation when cultured with transgenic spleen and NGF. Generally the reverse pattern was observed in cultures with transgenic SCGs: neurite outgrowth was more extensive in the presence of transgenic spleen than control spleen. The possibility that a difference in cytokine production from control vs transgenic spleen is involved in the altered neurite pattern will be investigated. (Supported by MH48644 to SLC).

## 300.13

**OVEREXPRESSION OF NGF IN SKIN OF TRANSGENIC MICE INDUCES SYMPATHETIC PROJECTIONS TO LARGE TRKA NEURONS.** B. M. Davis\*, A. Soria, K. M. Albers\*, and T. P. Goodness. Depts of Anatomy & Neurobiology and Pathology\*, Univ. of Kentucky College of Medicine, Lexington, KY 40536.

Previous studies in our laboratories have shown that overexpression of NGF in skin of transgenic mice induces novel sympathetic projections to primary sensory neurons similar to that seen following peripheral nerve ligation (Davis et al., 1994; McLachlan et al., 1993). In the ligation model, sympathetic "baskets" form primarily around large neurons typically considered non-trkA expressing and not responsive to NGF. To test the similarities of the two models we used double labeling ICC to analyze the relationship between trkA expressing neurons and TH-positive sympathetic baskets. 39.2% of all neuronal profiles in trigeminal ganglion were trkA positive and 33.6% of all neurons were surrounded by sympathetic projections. Of the cells receiving sympathetic input, 84% were trkA-positive neurons of large to medium diameter. We have previously shown that sensory ganglia of transgenic mice contain supernormal levels of retrogradely transported NGF. That sympathetic neurons project almost exclusively to trkA-positive neurons suggests that sympathetic fibers are responding to the high levels of NGF in these sensory neurons. How NGF induces the sympathetic projection is not clear. However, the observation that similar populations of sensory neurons receive sympathetic projections in ligation and transgenic models suggests a common underlying mechanism. Supported by NS31826 (BMD) and NS33730 (KMA).

**NEURITE OUTGROWTH AND EXPRESSION OF NERVE GROWTH FACTOR (NGF), NEUROFILAMENT (NF), and CALCITONIN GENE-RELATED PEPTIDE (cGRP) IN NGF-TRANSGENIC AND NORMAL MOUSE DORSAL ROOT GANGLIA CULTURES.** K. Byrd, P. Resig, and B.F. Siaken\*. Center for Biomedical Engineering and Dept. of Anatomy and Neurobiology, University of Kentucky, Lexington, Kentucky 40506.

Dorsal root ganglia (DRG) from fetal transgenic mice that overexpress NGF in the skin (Albers et al., 1994) and nontransgenic mice were used to determine if the presence of additional retrogradely-transported NGF altered neurite outgrowth (length and number, Siaken et al., 1995) and the expression of peptides Nerve Growth Factor (NGF), Neurofilament (NF), and Calcitonin Gene-Related Peptide (cGRP) in explant cultures. DRG were dissected and placed in Matrigel-coated wells and fed with Dulbecco media containing 10% fetal calf serum, glutamine and antibiotics. No exogenous NGF was added to the culture medium. After five days *in vitro* the cultures were fixed with 4% paraformaldehyde. No differences were found in peptide content between transgenic and normal DRG. Neurite outgrowth, defined as neurite length and neurite number, was measured on photographs. Results indicate that there were significantly more neurites ( $p > 0.05$ ) in DRG from transgenics compared to normal DRG but there was no difference in neurite length between transgenics and normal DRG. The enhanced sprouting found *in vitro* parallels skin hyperinnervation found *in vivo* in NGF transgenic mice (Albers et al., 1994). Supported in part by ElectroPharmacology Inc., Pompano Beach, FL and the Lyman T. Johnson Fellowship to KB.

**NGF SELECTIVELY REGULATES BRADYKININ BINDING SITES IN ADULT SENSORY NEURONS VIA THE NEUROTROPHIN RECEPTOR p75.** M. Petersen\*, G. Segond von Banchet, B. Heppelmann and M. Koltzenburg. Institute of Physiology and \*Department of Neurology, University of Würzburg, 97070 Würzburg, Germany.

The neurotrophins NGF, BDNF and NT-3 selectively bind to distinct members of the trk receptors, however, all bind to the neurotrophin receptor p75 (p75<sup>NTR</sup>). Since NGF is known to regulate the chemosensitivity of sensory neurons, we asked whether neurotrophins can regulate the expression of bradykinin (BK) binding sites. Dorsal root ganglion cells from adult wild-type mice and p75 (-/-) knockout mice were enzymatically isolated and grown on poly-L-lysine coated cover slips. Neurons were maintained in F12 medium, supplemented with serum, L-glutamine, penicillin and streptomycin and kept for 0.8 or 1.8 days under culture conditions. BK binding sites were visualized by silver enhanced gold (1.4 nm) labeled BK (3 nM) and quantified using an image analyzing system. BK binding sites were constitutively expressed in 32% of neurons from wild-type animals when grown in the presence or absence of NGF for 0.8 days. In p75 (-/-) mice the percentage of neurons expressing BK binding was only 16%, suggesting a developmental loss of this population. The percentage of neurons from wildtype mice expressing BK-binding increased significantly to 72% in the presence of NGF (100 ng/ml) when grown for 1.8 days. However, this upregulation was not observed in neurons isolated from p75 (-/-) mice or from wild-type mice treated with antibodies against p75<sup>NTR</sup>, indicating that binding of NGF to trk receptors alone is insufficient to convey the regulatory signal. Surprisingly, treatment with either BDNF or NT-3 did not result in an upregulation of BK binding sites. These results indicate that the induction of BK binding sites on sensory neurons depends specifically on the interaction of NGF with the p75<sup>NTR</sup> (Supported by the DFG Pe 299/3-1, He 1919/2-3, M.K. SFB 353).

**PROPERTIES OF INDIVIDUAL CUTANEOUS AFFERENT FIBERS AND THEIR SPINAL PROJECTIONS IN TRANSGENIC NEONATAL MICE OVEREXPRESSING NGF.** K. Mimics\*, B.M. Davis, K.M. Albers and H.R. Koerber. Dept. of Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261 and Depts. of Anatomy, Neurobiology and Pathology, University of Kentucky, Lexington, KY 40536.

Cold anesthetized pups aged P0-P6 were perfused with cold (4°C) oxygenated artificial cerebrospinal fluid (CSF). Spinal cords (SC) with attached L1-L6 dorsal root ganglia (DRG) and peripheral nerves were isolated and placed in a recording chamber and warmed to 31°C. DRG somata were impaled using electrodes containing 3M K-acetate, or 5% neurobiotin (NB) in 1M K-acetate. Somal action potentials (APs), input resistance, maximum firing frequencies, rheobase and conduction delays from saphenous or sural nerve stimulation were recorded. One cell per DRG was injected with NB and after allowing 4-6 hr. for diffusion the tissue was fixed with 4% paraformaldehyde. Frozen serial sections (50µm) of the SC and DRG were obtained and reacted with HRP-coupled avidin and visualized using DAB with Ni-intensification. To date 87 somata have been impaled at three different stages of development: P0 (37); P2 (26); P6(24). Fibers in transgenic animals showed slower average conduction velocities and longer somal AP durations in all stages compared to controls. The difference in AP duration was most likely due to the fact that BS with inflexions were more prominent in transgenic animals (e.g. 24/27 at P0 and 26/28 at P2 vs. 8/10 and 12/24 in controls). The rostrocaudal extent and the number of collateral branches entering the dorsal horn in transgenic animals were comparable to those in controls, however, the individual collaterals in transgenic animals exhibited more branching complexity and occupied a greater mediolateral portion of the dorsal horn. Roughly half of the stained transgenic fibers had the normal relationship between somal APs and laminar distribution of terminals, i.e., broad spikes with inflexions and projections confined to laminae I & II or narrow spikes supporting terminals in laminae III-V. The rest had broad spikes and terminals throughout laminae I-VI. This latter population represents a phenotype not seen in controls. NS23725 (HRK); NS31826 (BMD, KMA).

## 300.15

## REGULATION BY NGF OF THE EXPRESSION OF P75 LINGFR ON SYMPATHETIC AND SENSORY IRIDIAL NERVES OF YOUNG AND AGED RATS.

I. Gavazzi\* and T. Cowen, Dept. of Anatomy and Developmental Biology, Royal Free Hospital School of Medicine, London NW3 2PF, UK

Upregulation of p75 LINGFR accompanies collateral sprouting of sensory and sympathetic neurons in response to NGF or increased target size in mature rats. In the rat iris the density of innervation of both sensory and sympathetic nerves is increased by NGF treatment, but the response of sensory nerves is greater as compared to sympathetic nerves. Furthermore, sensory nerve response is not affected by ageing, whilst the response of sympathetic nerves is impaired in old rats. Differences in the level of expression of p75 on sensory and sympathetic nerves and/or different ability to upregulate the expression of the receptor may explain the difference in responsiveness. We have investigated this issue evaluating p75 expression on mature and aged sympathetic and sensory nerve fibres on the rat iris following NGF treatment. Sprague-Dawley rats, aged 6 weeks or 24 months, received 4 weekly transcleral injections of either 100µg/ml Cytochrome C (Cyt C) or NGF at a concentration of 25, 100 or 200 µg/ml. One week after the final injection the rats were sacrificed and their irides double immunolabelled with anti-p75 antibodies and either antibodies against TH (a sympathetic marker) or CGRP (a marker for a subpopulation of sensory neurons). The density of p75-positive innervation was measured by computerized image analysis on confocal images. The intensity of p75 staining decreased by approximately 20% on old irises, indicating a decreased density of the receptor on aged nerves. p75 was expressed on over 80% of CGRP-positive untreated nerves in both young and old rats, and p75 expression was upregulated similarly on young and aged sensory nerves following NGF treatment. On the other hand, 50-60% of sympathetic nerves expressed p75, and p75 upregulation was impaired on aged sympathetic axons. These results suggest that p75 expression on sensory and sympathetic nerves, untreated or following NGF treatment, correlates with their ability to respond to NGF with increased innervation density. Supported by BHF project grant n. PG93027.

## THE MORPHOMETRIC AND IMMUNOHISTOCHEMICAL STUDY OF THE EFFECT OF NERVE GROWTH FACTOR ON DORSAL ROOT GANGLIA IN STREPTOZOTOCIN INDUCED DIABETIC RAT. S. H. Park, E. I. Baik, H. C. Han, K. A. Park. Dept. of Anatomy, Kon-Kuk Univ. College of Med. Chung Ju and Yonsei Univ. Seoul, Dept. of Physiology, Ajou Univ. College of Med. Suwon and Korea Univ. Seoul, Korea.

This experiment was performed to identify the effect of nerve growth factor (NGF) on L5 dorsal root ganglia (DRG) in streptozotocin induced diabetic rat morphometrically and immunohistochemically. Thirty diabetic Sprague Dawley rats (200-250 gm) were prepared by a single intraperitoneal injection of 65 mg/kg streptozotocin in saline. 4 weeks later, L5 DRG were serially sectioned (6 µm) and each section was stained for thionin and immunostained for NGF(1:1000), SP(1:1000) and CGRP(1:2000). The total number of Nissl and immunostained L5 dorsal root ganglia(DRG) cells were counted and cross sectional area was measured with image analyzer.

The results obtained are as follows;

1. In control group, total number of type A and B cells were 1268 and 8479 in L5 DRG, respectively. In diabetic group, total number of type A and B cells were 68.8 % and 44.6 % reduced in L5 DRG, respectively. In NGF administered diabetic group, total number of type A and B cells were recovered to normal control group level.
2. In control group, total number of immunoreactive for NGF, SP and CGRP cells were 2056, 1858 and 2776 in L5 DRG, respectively. In diabetic group, total number of immunoreactive for NGF, SP and CGRP cells were 49.7 %, 78.7 % and 81.5 % decreased in L5 DRG, respectively. In NGF administered diabetic group, total number of immunoreactive for NGF, SP and CGRP cells were recovered to the number of control group.

## IN VIVO EFFECTS OF NGF AND NT3 ON DEVELOPING SYMPATHETIC CHICK GANGLIA.

David von Schack, Georg Dechant\*, Yves-Alain Barde, Max-Planck-Institute for Psychiatry, Department of Neurobiochemistry, D-81252 Martinsried, Germany.

*In vitro* studies with chick sympathetic neurons have shown that both NT3 and NGF support the survival of these neurons. In order to investigate if the effects of these factors can also be observed *in vivo*, chick embryos were treated *in ovo* at E3 with hybridoma cells secreting functionally blocking antibodies against NT3 or with NGF or NT3 protein. Cell numbers were determined using a method based on the stoichiometric incorporation of a fluorescent dye (Hoechst dye H33258) into dsDNA. Anti NT3 treatments of chick embryos lead to a small reduction in sympathetic cell numbers (~20%) with a significant decrease at E11-E13, a time when these neurons become dependent on target derived factors. When either NGF or NT3 were injected daily between E3 and E5 cell numbers per ganglion were increased by about 2 fold. Several marker-genes for sympathetic neurons such as tyrosine hydroxylase, choline acetyl transferase, trk A, trk C, p75, were assayed for differential regulation by NGF and NT3. Tyrosine hydroxylase protein was upregulated only after treatment with NGF, detected by Western blot experiments, trk A message was downregulated after the same treatment as determined by RT-PCR.

## NGF, BUT NOT BDNF NOR NT3, ELICITS AXONAL GROWTH FROM ADULT SENSORY NEURONS IN COMPARTMENTED CULTURES. K. Kimpinski\* and K.M. Meador, Basic Medical Sciences, Memorial University of Newfoundland, St. John's, NF, A1B 3V6

The *in vivo* model of sensory axon collateral sprouting has shown that the sprouting response requires NGF, while the regeneration following injury does not. While this model has been invaluable in demonstrating the role of NGF in these phenomena, it cannot be easily manipulated to study, for example, signal transduction mechanisms, or the contribution of the different receptor types to the response. We have thus taken an *in vitro* approach to study the regulation of adult sensory neurite growth by neurotrophins.

Using the Campenot compartmented culture system we have examined the effects of the neurotrophins NGF, NT3 and BDNF on neurite growth from both neonatal and adult rat DRG neurons. DRG neurons were dissociated using standard techniques and plated in the centre chambers in the absence of neurotrophin (NT); the side chambers contained either no NT or varying concentrations of NT (1, 10 or 100 ng/ml). While the adult neurons survived in the absence of any NT in the centre and side compartments, the neonatal neurons required access to a side chamber containing NGF for prolonged survival. Our results demonstrated that only NGF elicited neurite growth into the side chambers and that the density of growth was increased at higher NGF concentrations. No neurite growth was observed into chambers with BDNF or NT3. We then asked whether the regrowth (subsequent to *in vitro* axotomy) of neurites that had originally grown into NGF still required NGF. The results demonstrated that, unlike the *in vivo* regeneration, the *in vitro* regrowth did require NGF, and that neither BDNF nor NT3 was able to substitute for NGF. We are currently examining the differential distribution of p75 and trkA between the cell body and distal neurite compartments, using immunocytochemistry, Western blotting and RT-PCR. Supported by the Neuroscience Network.

## THE ACTIVATION OF PHOSPHATIDYLINOSITOL-3 KINASE (PI3-KINASE) IS MORE IMPORTANT FOR THE SURVIVAL OF SYMPATHETIC THAN SENSORY NEURONS. S. E. Bartlett, A. J. Reynolds and I. A. Hendry\* Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, Australia.

The survival of developing sympathetic and sensory neurons depends on nerve growth factor (NGF) released by the target tissues they are innervating. The signalling pathway mediating this survival message is unknown. Yao and Cooper, 1995 have shown that PI3-kinase is required for the survival of PC12 cells; these cells are also dependent on NGF for their survival. Therefore this study aimed to determine if this enzyme was important for the survival of sympathetic and sensory neurons. We grew dissociated chick 8 day sensory neurons or 12 day sympathetic neurons in cell culture maintained with a dose response to either NGF and in the presence of increasing concentrations of Wortmannin (0.01 nM-10 µM), an inhibitor of PI3-kinase. We found that Wortmannin (10 nM) inhibited the survival of sympathetic neurons by ~50-60% compared to control cells. This concentration has been reported to inhibit the activity of PI3-kinase by ~60% *in vitro* (Yao and Cooper, 1995). However, in sensory neurons the concentration of Wortmannin required to cause a 50% inhibition of survival was a 100 fold greater, 1µM which completely inhibits PI3-kinase. This suggests that the full activation of PI3-kinase is essential for the survival of sympathetic neurons. However, the survival of sensory neurons requires either a much lower level of PI3-kinase activation or some other pathway is utilised. Thus these experiments demonstrate a difference in the second messenger pathways required for the survival of sympathetic and sensory neurons.

## P75 EXPRESSION AFFECTS THE NGF DEPENDENCY OF SYMPATHETIC NEURON SURVIVAL IN TRANSGENIC MICE. C. Brennan\*† H.S. Phillips\* and S.C. Landis†. †Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH 44118; # Dept. of Neuroscience, Genentech, Inc. San Francisco, CA 94080

Nerve growth factor (NGF), which is required for the survival of sympathetic neurons, binds to two receptors, trkA and p75, the low affinity neurotrophin receptor. TrkA is responsible for signal transduction and few sympathetic neurons survive in trkA deficient mice. The role of p75, however, in mediating NGF effects is unclear. p75 has been suggested to increase the sensitivity of trkA bearing cells to NGF. To determine how p75 and NGF interact to influence sympathetic neuron survival *in vivo*, we crossed two transgenic lines in which the coding regions of p75 or NGF were disrupted to obtain mice which lacked p75 and were homozygous wild-type or heterozygous for the NGF deletion. At 8 weeks, there was no significant difference in the number of sympathetic neurons in the superior cervical ganglia (SCG) of mice lacking p75 (NGF<sup>+/+</sup> p75<sup>-/-</sup>, 11942±1058 n=3) and of wild-type mice (NGF<sup>+/+</sup> p75<sup>+/+</sup>, 15760±1119 n=3). As expected, the SCG of mice which were NGF<sup>+/+</sup> p75<sup>+/+</sup> had significantly fewer neurons (7585±518 n=3; p<0.01) than wild-type, consistent with the notion that the NGF content of target tissues is limiting. Surprisingly, in the absence of p75 (p75<sup>-/-</sup>), the number of SCG neurons in mice which were NGF<sup>+/+</sup> (12594±1573 n=3) was indistinguishable from wild-type. Similar results were obtained when the effect of genotype on neuron number was examined in stellate, thoracic, and lumbar ganglia. In contrast to cell number, neuron area was unaffected by genotype. The increase in neuron number in NGF<sup>+/+</sup> mice which lack p75 suggests that p75 *in vivo*, at low NGF concentrations, does not act to enhance the efficiency of NGF binding or trkA signal transduction. Rather, our results are consistent with two other roles that have been put forward for p75. p75 may participate in a signaling pathway involving sphingomyelin that leads to neuronal cell death when NGF levels are reduced. Alternatively or additionally, p75 may decrease the ability of neurotrophin-3 to bind trkA and compensate for the lack of NGF. Supported by NS023678 (SCL) and T32NS07118 (CB).

## 300.21

MECHANISM OF REGULATION OF  $Ca^{2+}$  CHANNELS IN AN ADULT SYMPATHETIC NEURONE BY NERVE GROWTH FACTOR. S. Lei, W.F. Dryden\* & P.A. Smith, Dept. Pharmacol., Univ. Alberta, Edmonton, T6G 2H7 Canada.

Although nerve growth factor (NGF)-induced differentiation of PC12 cells into sympathetic-like neurones is accompanied by increases in  $Ca^{2+}$  channel currents ( $I_{Ca}$ ), it is not known whether NGF maintains the integrity of ion channels in sympathetic neurones throughout adulthood. We have been using standard whole-cell recording methods to study the effects of NGF on  $I_{Ca}$  in identified B-cells of bullfrog sympathetic ganglia maintained for 12d in a neurone-enriched, serum-free, defined medium culture (Lei et al., *Biophys. J.* 68 A209 1995). Although total current increased as the cells extended neurites, current density was unchanged. The neurotrophin may therefore be involved in adjusting the size of  $I_{Ca}$  to match the increase in size that occurs during growth. NGF-induced increases in  $I_{Ca}$  were mediated via a tyrosine kinase (presumably *TrkA*) as they were inhibited by 20  $\mu$ M genistein or by 10  $\mu$ M lavendustin A. The inactive isomer of genistein (daldzein, 20  $\mu$ M) failed to prevent the effect of NGF. Higher concentrations of genistein (100  $\mu$ M) suppressed  $I_{Ca}$  recorded in the absence of NGF. This may reflect non-specific actions or may suggest that  $I_{Ca}$  is maintained by tonic tyrosine kinase activity. Downstream effects of NGF do not seem to be mediated via the phosphatidylinositol-3-kinase pathway as they were not antagonised by wortmannin (100nM) or by LY 294002 (30  $\mu$ M). The possible involvement of other downstream transduction mechanisms from *TrkA* remains to be investigated.

## 300.23

ALTERED STRUCTURE AND NEUROCHEMISTRY OF SUPERIOR CERVICAL GANGLION NEURONS IN ADULT TRANSGENIC MICE OVEREXPRESSING NERVE GROWTH FACTOR. G.E.A. Coome\* and M.D. Kawaja, Dept. Anatomy and Cell Biology, Queen's University, Kingston, Ontario CANADA K7L 3N6.

This investigation examines the effects of elevated endogenous levels of nerve growth factor (NGF) on the structural and neurochemical features of neuronal cell bodies of the superior cervical ganglion (SCG). Transgenic mice, which overexpress this neurotrophin in GFAP-producing astrocytes of the brain, appear normal at birth and into adulthood. These transgenic mice differ from their age-matched wild-type counterparts, in that they have a dense plexus of SCG axons in their cerebellum; this aberrant sprouting of new sympathetic axons was attributed to the markedly increased levels of NGF mRNA and protein. The adult transgenic mice also had larger SCG than control mice, due to increases in both neuron size and number (30% more). NGF-immunostaining in SCG neurons of postnatal transgenic mice was more intense compared to wild-type mice, but comparable between adults. EM analysis of transgenic neurons revealed more lysosomes and disrupted perinuclear Golgi apparatus. *In situ* hybridization for the high-affinity NGF receptor (*trkA*) showed that the ratio of grain density per neuron did not differ between transgenic and wild-type mice, despite the increase in size of transgenic neurons. It remains to be determined whether levels of mRNA for the low-affinity receptor are likewise unaltered in transgenic neurons. These data provide new evidence that elevated levels of endogenous NGF produced in the intact mammalian brain can induce structural and neurochemical remodelling of SCG neurons. (Supported by MRC of Canada)

## 300.25

NERVE GROWTH FACTOR (NGF) INDUCES APOPTOSIS IN HUMAN MEDULLOBLASTOMA CELL LINES THAT EXPRESS TRKA RECEPTORS. Y. Muragaki\*, T. T. Chou\*, D. R. Kaplan\*, J. Q. Trojanowski\* and V. M. -Y. Lee\*, 1 Dep. of Neurosurgery, Tokyo Women's Medical College, Tokyo, Japan 162. 2 Dep. of Pathology and Laboratory Medicine, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104. 3 ABL-Basic Research Program, National Cancer Institute, Frederick Cancer Research and Development Center, Frederick, MD 21702.

Neurotrophins act through their cognate receptors to promote the differentiation and/or survival of neuronal progenitor cells, immature neurons and other cells. Here we examined the effects of NGF and its cognate receptor (*Trk* or *TrkA*) on the survival of a common childhood brain tumor, i.e. medulloblastoma, a tumor that resembles CNS neuroepithelial progenitor cells. To do this, we engineered two human medulloblastoma cell lines (i.e. D283 MED and DAOY cells) to express human *TrkA* using a retroviral expression vector.

Surprisingly, NGF treated medulloblastoma cells expressing the *TrkA* receptor underwent massive apoptosis which could be prevented by K252a or anti-NGF antibodies. Similar treatment did not induce apoptosis in wild type uninfected cells, cells expressing an empty vector or cells engineered to express the human p75 NGF receptor.

NGF/*TrkA* signal transduction pathway could activate apoptotic cell death programs in CNS neuroepithelial progenitor cells and childhood brain tumors.

Supported in part by grants from the National Institutes of Health and by a Zenith Award from the Alzheimer's Association.

MODULATION OF SYMPATHETIC SYNAPSES BY NGF. S.T. Lockhart\*, G.G. Turrigiano and S.J. Birren, Department of Biology and Volen Center, Brandeis University, Waltham, MA 02254.

Neurotrophins modulate synaptic strengths in the CNS and at the neuromuscular junction. We have shown that Nerve Growth Factor (NGF) modulates noradrenergic synaptic connections between cultured sympathetic superior cervical ganglion (SCG) neurons and cardiac myocytes from neonatal rat. Intracellular stimulation of a presynaptic neuron results in an increase in myocyte beat frequency. This increase in beat rate is rapidly and reversibly potentiated by 50 ng/ml NGF (200% of control,  $p < 0.02$ ). Preliminary data indicate that this effect is presynaptic, since the increase in beat rate produced by puffing norepinephrine onto myocytes is not potentiated by NGF. Potentiation of synaptic transmission by NGF is blocked by the tyrosine kinase inhibitor K-252A (200 nM). Although K-252A alone has no effect, in the presence of this drug, NGF depresses synaptic transmission to 0% of control ( $p < 0.05$ ). This suggests that in the absence of receptor tyrosine kinase (*trk*) signaling, NGF signals via an alternate pathway. The low affinity neurotrophin receptor, P75, is expressed both in SCG neurons and in cardiac myocytes, as measured by RT/PCR. Together, these data support the hypothesis that NGF potentiates synaptic transmission via *trk* signaling. Further, these data raise the possibility that NGF modulates synaptic transmission by activating distinct and antagonistic signal transduction pathways through the p75 and *trk* receptors. Supported by research grants from the Whitehall Institute (SJB) and NSF and the Whitehall Institute (GGT) and NIH training grant NS 07292 to Brandeis University (STL).

## 300.24

CONCENTRATION-DEPENDENT RESPONSE OF CEREBROVASCULAR AXONS TO INTRACRANIAL INFUSION OF NGF. W.L. Nixdorf, M. Mareska, J.T. Oris, R.G. Sherman\* and L.G. Isaacson, Center for Neurosci, Dept Zoology, Miami Univ, Oxford, OH 45056

Following a 2 week intracerebroventricular infusion of nerve growth factor (NGF; 15  $\mu$ g) into the young adult rat, we observed a sprouting response by perivascular axons associated with intradural internal carotid artery (ICA), most of which originate in the superior cervical ganglia. In those studies we used electron microscopy (EM) to evaluate axonal growth and found that axons associated with the ICA were increased by 150%. Our present goal was to examine the relationship between the amount of NGF infused and the sprouting response by cerebrovascular axons. Young adult rats received 2 wk infusions of cytochrome C (VEH) or NGF at concentrations of 100  $\mu$ g/ml (NGF:n = 6; VEH:n = 6), 50  $\mu$ g/ml (NGF:n=4; VEH:n=2), 20  $\mu$ g/ml (NGF: n=6; VEH:n=2), and 10  $\mu$ g/ml (NGF:n=2; VEH: n=1). Approximately 150  $\mu$ l infusate entered the ventricular system, resulting in infusions of 15  $\mu$ g, 7.5  $\mu$ g, 3.0  $\mu$ g and 1.5  $\mu$ g, respectively. Analysis of EM data revealed a linear relationship between the number of perivascular axons and the  $\mu$ g NGF infused. No change in axonal number was observed following infusion of 1.5  $\mu$ g NGF, though infusions of 3.0  $\mu$ g NGF or higher resulted in a significant increase in axons when compared with VEH of similar concentration. No change in axons was observed following VEH infusions. These findings reveal a positive relationship between the response of perivascular axons and the amount of NGF infused during the 2 wk infusion period. (Supported by NS32876 to LGI)

## 300.26

A STUDY OF SALIVARY NERVE GROWTH FACTOR (NGF) ACTIVITY IN FEMALE HOUSE MICE (*Mus domesticus*) OF VARYING ESTRUS STAGES. B. M. Jubilan\*, P. Leonard and K. A. Hild, Behavioral Neuroscience Program, Allentown College of St. Francis de Sales, Center Valley, PA 18034.

The saliva of mice has been demonstrated to contain significant concentration of nerve growth factor (NGF). The functional significance of this observation has been the subject of speculation. The present study predicts that NGF concentration fluctuates in accordance with hormone levels during different phases of the estrus cycle in female mice.

Rat pheochromocytoma cell line (PC-12) was used for NGF bioassay. The number of neurite bearing cells was used as the dependent measure. Saliva was collected by placing a sterile cotton ball of known weight under the tongue of the anesthetized female mouse and left to soak for 45 min. The cotton soaked with saliva was then weighed to measure the amount of saliva collected. Female estrus cycles were identified as either "estrus" or "diestrus" based on the histological composition of vaginal smears stained with methylene blue solution. The cotton ball containing the saliva was then dropped in plates containing known concentration of PC-12 cells. The salivary bioassay was run simultaneously with purified NGF bioassay.

Initial results show more neurite bearing cells in PC-12 cultures with saliva from estrus female mice compared to PC-12 cultures with saliva from diestrus females. Further analysis is being done to consider the rate of saliva secretion and interpolated NGF concentration in interpreting these results.

## 300.27

EXPRESSION OF A BIOLOGICALLY ACTIVE ANTI-NGF MONOCLONAL ANTIBODY BY TRANSFECTION INTO CELLS OF NEURONAL LINEAGE. Dao-Chao Huang\*, Marc Pinard, Moshe Szylf and A. Claudio Cuello. Department of Pharmacology and Therapeutics, McGill University, 3655 Drummond Street, Montreal, Quebec, Canada, H3G 1Y6.

To develop a transgenic model expressing neutralizing anti-nerve growth factor (NGF) antibodies within the nervous system at specific sites and specific times in development, we cloned the cDNAs encoding the monoclonal anti-NGF30 antibody which neutralizes the biological activity of NGF. Nucleotide sequence analysis revealed that these cDNAs differ from other known variable regions. The heavy (H)- and light (L)-chains variable and constant regions of the gene were obtained by RT-PCR amplification from the mRNA of  $\alpha$ NGF30 hybridoma cells. To secure antibody expression in neuronal cell types, cDNAs were cloned into plasmid expression vectors under control of a neuron-specific enolase (NSE) promoter. The recombinant  $\alpha$ NGF30 have been successfully expressed in the neuroblastoma cell line N18TG2 under NSE promoter control and examined by ELISA, immunofluorescence and immunocytochemistry. Transfected cell supernatants containing recombinant mAbs were tested for their ability to block the NGF-induced stimulation of neurite outgrowth in PC12 cells. These experiments demonstrate the feasibility of applying recombinant antibodies, expressed by cells of neuronal lineage, as tools for specific inactivation of specific molecules in the CNS and PNS. The relevance of these cDNA constructs towards the generation of transgenic animals is discussed. Initially supported by the Neuroscience Network (Canadian NCE) and completed with support from MRC (Canada).

NGF INCREASES THE TRANSCRIPTION OF THE NA CHANNEL GENE EXPRESSED BY PANCREATIC  $\beta$  CELLS. VidalTamayo, R., Rosenbaum, T. and Hiriart, M.\*. Dept. Neurosciences, Inst. Cell. Physiol., UNAM, MEXICO.

We have previously shown that NGF induces morphological and physiological changes in pancreatic  $\beta$ -cells. After 5-7 days in culture, approximately 50% of  $\beta$  cells treated with 50 ng/mL of 2.5SNGF extend neurite-like processes (*Endocrine* 4:19-26); a similar effect was also observed in the  $\beta$ -cell line RINm5F (Polak et al., *PNAS* 90:5781-5785). Moreover, in  $\beta$  cells treated with NGF we observed a 30% increase on peak Na-current density, with no change on the steady state inactivation of Na current nor on the conductance-voltage relationship. These data suggest that NGF induces an increase on the number of functional Na channels in  $\beta$ -cell membrane. In this study we used the RT-PCR technique to assess if NGF could increase the transcription of the Na-channel gene expressed by  $\beta$  cells. We found that  $\beta$ -cells express a product similar to the brain Na-channel type III. After 5 days in culture in the presence of NGF, we observed a 3-4 fold increase in Na channel gene transcription of RINm5F cells. In primary cultures of  $\beta$ -cells this effect was not observed. However, NGF did not induce the expression of a different Na-channel gene. We are evaluating if this increase could be observed earlier. These data suggest that NGF could elicit in  $\beta$ -cells a cellular response similar to the one observed in chromaffin and PC12 cells. This work was supported by DGAPA UNAM through grant IN212194, and by scholarships to R. VidalTamayo and T. Rosenbaum.

DOWN-REGULATION OF PROTEIN KINASE C PREVENTS THE ACTION OF NERVE GROWTH FACTOR ON CALCIUM UPTAKE INTO PC12 CELLS. G. Dickens, M. Lavarreda, W.-H. Zheng\*, and G. Guroff Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892.

Nerve growth factor (NGF) treatment of PC12 cells produces a modest, transient increase in the uptake of  $^{45}\text{Ca}^{2+}$  into PC12 cells. Pre-treatment of the cells for 24 hours with phorbol 12-myristate 13-acetate prevented this action of NGF. Pre-treatment with PMA was specific in that it did not prevent the stimulation of  $^{45}\text{Ca}^{2+}$  uptake by the L-channel agonist, Bay K 8644, nor by ATP. The action of NGF was prevented by either calphostin C or staurosporine, inhibitors of kinase C. It was also prevented by GO 6976, an inhibitor specific for the  $\alpha$ ,  $\beta$ , and  $\gamma$  forms of kinase C. Since previous work from this laboratory has shown that our PC12 cells are deficient in the  $\beta$ - and  $\gamma$ -forms of kinase C, these data implicate protein kinase  $\alpha$  in the stimulation of  $^{45}\text{Ca}^{2+}$  uptake by NGF.

AMYLOID PRECURSOR PROTEIN ALTERS NGF BINDING IN PC12 CELLS

C.A. AKAR, H.Y.T. YANG\* AND W.C. WALLACE GRC,NIA Baltimore, MD and LBG, NIMH Neuroscience Center St. Elizabeth's Hospital, Washington, D.C.

Amyloid precursor protein (APP) is expressed throughout the brain. However, physiological function of the protein has not yet been well characterized. We have previously observed that APP induces neurite outgrowth and potentiates neurotrophic activity of NGF on PC12 cells. This potentiation is also reflected in the tyrosine phosphorylation of several proteins in the NGF signal transduction pathway (e.g. ERKs 1 and 2). In order to determine the molecular basis for this potentiation, we have examined the effect of APP on NGF receptor binding in PC12 cells. The binding assay was performed on suspended whole cells using  $^{125}\text{I}$ -NGF (40pM-1nM) in the presence and absence of APP (2nM). Nonspecific binding was determined in the presence of NGF (400nM). Free ligand was separated from the bound by centrifuging through 0.15 M sucrose. The  $K_D$  for NGF binding was reduced in the presence of APP from 7.7 nM to 1.2 nM. This increase in NGF binding suggests that APP may potentiate the effects of NGF by increasing the affinity of NGF binding sites. (Supported by IRP, NIA)

NGF REGULATES VOLTAGE-GATED POTASSIUM CHANNELS THROUGH A CNTF-LIKE AUTOCRINE LOOP IN NEUROBLASTOMA CELLS. T.M. Holmes, S.S. Lesser, and D.C. Lo\*, Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Neurotrophic factors strongly influence neuronal function through their regulation of electrical excitability. We have previously shown that prolonged NGF treatment increases levels of voltage-gated Na, Ca, and K currents in SK-N-SH neuroblastoma cells, while CNTF increases K currents only. Moreover, we showed that the K channels regulated by NGF and CNTF are functionally indistinguishable. We thus hypothesized that NGF and CNTF regulate K channel levels through a common pathway, perhaps involving an autocrine or paracrine substance.

We first tested if NGF induces the secretion of a substance into conditioned medium (CM) that can increase K channel levels. SK-N-SH cells were treated with NGF for several days and CM transferred to naive cells; NGF in the CM was neutralized by addition of excess anti-NGF antibody. Using whole-cell patch clamp recording, we found that NGF-depleted CM was still able to induce K currents. Thus, NGF induces the secretion of a substance into CM that is sufficient to induce K currents in the absence of NGF.

To test if a CNTF-like molecule could be this autocrine substance, we treated SK-N-SH cells with NGF together with a neutralizing anti-CNTF antibody—this antibody completely blocked the ability of NGF to induce K currents. In contrast, NGF could still induce Na and Ca currents in the presence of the anti-CNTF antibody, indicating that the effects of this antibody were specific upon K channel regulation. Thus, a secreted, CNTF-like activity is necessary for induction of K currents by NGF. Together, these findings suggest that NGF regulates Na and Ca channels directly while its induction of K currents occurs via a CNTF-like autocrine/paracrine loop.

We thank Regeneron Pharmaceuticals for their generous provision of CNTF; this work was supported by grants from the Alfred P. Sloan and Ruth K. Broad Foundations, the NIH (NS32742), and the Duke Mechanisms of Behavior Program.

## 301.1

EFFECT OF SYSTEMICALLY-INJECTED NGF ON SP AND CGRP RELEASE FROM RAT SPINAL CORD IN VITRO. M. Malcangio, N.E. Garrett, D.R. Tomlinson and N.G. Bowery\* Depts of Pharmacology, Queen Mary and Westfield College, Mile End Road, London E1 4NS and Medical School, Edgbaston, Birmingham B15 2TT, U.K.

Nerve growth factor (NGF), which is a classical member of the polypeptide growth factor family, is synthesized in target tissues and then retrogradely transported by sensory neurons to dorsal root ganglia (DRG) neuronal cell bodies. Systemically injected NGF is also transported to DRG where it regulates substance P (SP) and calcitonin gene-related peptide (CGRP) expression.

In the present study we have investigated whether 2-week treatment of rats with human recombinant NGF (1 mg/kg s.c.) could influence basal outflow and electrically-evoked release of endogenous SP and CGRP from spinal cord slices *in vitro*.

Dorsal horn slices (350 µm thick) were obtained from the lumbar enlargement and release of neuropeptides induced by electrical stimulation of dorsal roots attached to the tissue. Peptide content in collected fractions was determined by radioimmunoassay. Sub-chronic treatment with NGF induced a significant 2 fold-increase in SP- and CGRP- basal outflow (in controls:  $10.0 \pm 2.0$  and  $4.8 \pm 0.6$  fmol/8ml-fraction, respectively). The evoked release of SP was increased by 2 fold over control evoked release ( $22.8 \pm 3.2$  fmol/8ml-fraction) and that of CGRP by 5 fold over evoked release in controls ( $21.2 \pm 0.9$  fmol/8 ml-fraction).

These findings whilst giving the first evidence that NGF can increase SP and CGRP pools which are available within the spinal cord to be tonically and electrically released from primary afferent fibres, supports a role for NGF in modulation of pain perception at segmental level.

Thanks to Genentech for NGF supply and British Diabetic association for support

## 301.3

BDNF, aFGF, bFGF, IGF-I, AND VARIOUS ANTI-OXIDANTS DO NOT PREVENT THE APOPTOTIC DEATH OF DEVELOPING BASAL FOREBRAIN CHOLINERGIC NEURONS FOLLOWING NGF WITHDRAWAL IN VITRO. J.N.C. Kew and M.V. Sofroniew\* MRC Cambridge Centre for Brain Repair and Department of Anatomy, University of Cambridge, Cambridge CB2 2PY, U.K.

We investigated whether multiple growth factors might interact to regulate the survival of developing basal forebrain cholinergic neurons *in vitro*. Septal cholinergic neurons grown in 'sandwich cultures' in serum-free, completely defined medium are partially dependent on NGF during a critical period of their development, such that NGF withdrawal during this period results in the protein synthesis-dependent, apoptotic death of most, but not all, of these neurons. Here we report that BDNF, acidic and basic FGF, and IGF-I applied in this culture system were all not able either to support the development of septal cholinergic neurons from plating, or to prevent the cell death of these neurons induced by NGF withdrawal. Various antioxidants also did not prevent the apoptotic death of developing septal cholinergic neurons induced by NGF withdrawal. These findings suggest that in the absence of serum and other additives, BDNF, acidic and basic FGF, and IGF-I do not interact with NGF to regulate the survival of developing basal forebrain cholinergic neurons *in vitro*. The findings also suggest that the apoptotic death of septal cholinergic neurons induced by NGF withdrawal is not mediated by oxidative stress or free radical generation.

## 301.5

Effects of NGF-Secreting Cells on Cholinergic Neurons in Aged Primates. M.H. Tuszynski<sup>1,2,\*</sup>, D. Smith<sup>1</sup>, F.H. Gage<sup>3</sup>, J. Roberts<sup>4</sup>. <sup>1</sup>Dept Neurosci., Univ Calif-San Diego, La Jolla, CA; <sup>2</sup>VA Med Ctr, San Diego, CA; <sup>3</sup>Salk Institute, La Jolla, CA; <sup>4</sup>UC-Davis, Davis, CA.

Spontaneous degeneration of basal forebrain cholinergic (BFC) neurons occurs in Alzheimer's disease and in aged rats and monkeys. Deficits on selected cognitive tasks also occur in aged rats and monkeys. Nerve growth factor (NGF) reduces age-related cognitive decline in rats and prevents injury-induced BFC degeneration in primates. In the present study, we examined the effects of NGF, delivered by gene transfer, on spontaneous BFC neuronal atrophy in aged rhesus monkeys.

BFC neuron numbers and size were quantified throughout the Ch4 region in 16 aged rhesus monkeys, 8 of whom received NGF-secreting autologous cell grafts as previously described. Non-stereological methods were used since comparisons between NGF- and control-grafted subjects were sought rather than estimates of total neuron numbers. Results were compared to young control monkeys.

Preliminary results from quantification of neurons in the Ch4-Intermediate division reveal that aged monkeys (n=2) show a 16±10% decline in p75-immunoreactive neuron numbers compared to young adult monkeys (n=4), but NGF-grafted monkeys (n=5) show a decline of only 1.4±5%. Both aged groups show hypertrophy in neuronal area compared to young subjects, however. Results from additional subjects across Ch4 subregions will be presented.

## 301.2

ELEVATION OF BRAIN mRNA FOR NEUROTROPHINS BY ORAL AIT-082 IN MICE. A.J. Glasky<sup>1</sup>, R.F. Ritzmann<sup>1</sup>, L. Priscarelli<sup>1</sup>, S. Santos<sup>1</sup>, K. Kafi<sup>1</sup>, M.P. Rathbone<sup>2</sup>, P.J. Middlemiss<sup>2</sup> and C. Crocker<sup>2</sup>. <sup>1</sup>ERI, Olive View UCLA Medical Center, Sylmar, CA 91342 and Dept. Biomed. Sci., McMaster Univ., Hamilton, ONT, Canada L8N 3Z5

The object of this study was to determine whether AIT-082, an analog of hypoxanthine, modified the levels of neurotrophins in the brains of aged mice. Previous studies have shown that AIT-082 increased the levels of mRNA for NGF, NT-3 and bFGF but not BDNF in cultures of astrocytes. Thirteen month old C57BL/6 mice received AIT-082 in their drinking water (equiv. to 30 mg/kg/day) for ten months. A control group received no drug in their drinking water. During this period, mice were tested for working memory performance in the win-shift paradigm, a delayed alternation positive reinforcement task which measures the duration of the memory trace. At 23 months of age, there was a clear difference between controls (no memory) and AIT-082 treated (in which 50% of the mice exhibited no deficit). Mice were sacrificed and brain tissue analyzed for neurotrophin mRNA using RT-PCR technology. There was a significant increase in the mRNA for NGF and NT-3 in the frontal cortex and hippocampus but not the cerebellum of animals that had functionally intact memory when compared to animals that could not perform the memory task. AIT-082 is orally active, rapidly penetrates the blood brain barrier and induces the production of multiple growth factors at the appropriate target site in the central nervous system. Supported by grants from National Institute on Aging (AG09911), ALS Society of Canada, Ontario Mental Health Foundation and Advanced ImmunoTherapeutics.

## 301.4

NERVE GROWTH FACTOR INDUCES GALANIN EXPRESSION IN RAT BASAL FOREBRAIN: IMPLICATIONS FOR TREATMENT OF CHOLINERGIC DYSFUNCTION. B. Planas<sup>1</sup>, P.E. Kolb, M.A. Raskind and M.A. Miller. Dept. of Psychiatry & Behav. Sci., University of Washington, Seattle, WA 98195.

Galanin (GAL) messenger RNA is coexpressed by a limited number of cholinergic neurons in the basal forebrain (BF) of adult male rats. GAL, co-secreted with ACh, may inhibit cholinergic-based memory functions since GAL infusion (icv) has been shown to impair performance on memory tasks. Nerve growth factor (NGF) is a potent stimulator of choline acetyltransferase (ChAT) in the BF and has been proposed as a therapeutic agent for the treatment of human age- and disease-related cholinergic dysfunction. However, the effects of chronic NGF administration on GAL gene expression within the BF have not been studied. We used *in situ* hybridization and quantitative autoradiography to assess GAL and ChAT gene expression within the BF of young adult male rats following chronic infusion (icv) of NGF or cytochrome c. Confirming the effectiveness of NGF infusion, the number of ChAT mRNA-expressing neurons ( $p < 0.0002$ ) and their intensity of labeling ( $p < 0.0001$ ) were enhanced in all regions of the BF. NGF infusion also induced a significant increase in the number of GAL mRNA-expressing neurons ( $p < 0.0005$ ) in the BF and in their average labeling intensity ( $p < 0.0013$ ). The effects of NGF on GAL gene expression were restricted to the BF since the number of GAL expressing neurons and the cellular GAL mRNA content in another forebrain region, the bed nucleus of the stria terminalis, were unaffected. NGF induction of GAL in the BF was specific, since the expression of another neuropeptide, neuropeptide Y, present within non-cholinergic BF neurons was unchanged. These data provide the first evidence that *in vivo* infusion of NGF enhances GAL gene expression in the cholinergic BF. These results suggest that the ameliorating effects of NGF treatment on cholinergic dysfunction could be antagonized by the concomitant induction of the inhibitory neuropeptide GAL in the cholinergic BF. ## 301.6

C-FOS INDUCTION IN A RAT MODEL OF CYSTITIS: ROLE OF NGF. N. Dmitrieva<sup>1</sup>, R. Iqbal, D. Shelton<sup>1</sup> and S.B. McMahon. Dept. Physiol., UMDS, London, UK and <sup>2</sup>Dept. Neuroscience, Genentech, South San Francisco, USA.

Fos protein expression was studied by immunohistochemistry in the dorsal horn after experimental inflammation of the urinary bladder and after intraluminal instillation of putative inflammatory mediators.

Experimental inflammation with turpentine (50% in olive oil - a model of Interstitial Cystitis, McMahon et al., 1995, Brit J Anaesth. 75:132-144) and intravesical treatments with murine TNF (20 ng/ml in saline) or human recombinant NGF (10 µg/ml, in 10% DMSO in saline) for 3 hours in urethane anaesthetised rats (1.25 g/kg, i.p.) all resulted in a high levels of expression of c-fos immunoreactivity in spinal segments L5 to S1. The pattern of induction was remarkably constant with all stimuli: most immunoreactive cells were seen in laminae I/II and lamina X, with fewer cells in the deep dorsal horn and the intermediolateral cell column. The total number of c-fos expressing cells (estimated from serial sections) with these treatments was 5780 to 6120 significantly greater than saline (460) or DMSO (4140),  $P < 0.05$  in all cases, t-test.

The involvement of endogenously produced NGF in the response to turpentine was also examined by pre-treating some animals with an NGF sequestering molecule, trkA-IgG (1mg/kg, i.v., 1 hour before turpentine). Here c-fos expression was significantly reduced ( $P < 0.005$ , ANOVA) compared to turpentine alone.

The results suggest that c-fos induction after turpentine-induced inflammation depends critically upon the up-regulation of NGF that is known to occur.

## 301.7

# COGNITIVELY IMPAIRED AGED RATS DO NOT DISPLAY REDUCED NGF-IMMUNOREACTIVITY WITHIN THE MEDIAL SEPTUM. Y. Charles<sup>1</sup>, M. Say, E.J. Mufson, T.J. Collier and J.H. Kordower. Research Center for Brain Repair and Dept. Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago Ill. 60612.

Recently we reported that remaining cholinergic basal forebrain neurons in Alzheimer's disease express diminished immunoreactivity for retrogradely transported nerve growth factor (NGF; Mufson et al., 1995). Similarly, NGF-immunoreactivity is reported to be decreased within cholinergic basal forebrain neurons of senescently accelerated mice (Ohnishi et al., 1995). These data suggest that the degeneration of cholinergic neurons and resulting cognitive deficits may result from impaired NGF-related trophic support. To test this hypothesis, young (3 month) and aged (27 month) rats were examined for cognitive abilities using the Morris water maze. Aged rats were cognitively impaired relative to young controls. Following behavioral testing, rats were sacrificed by perfusion with 2% paraformaldehyde and 0.2% paraquinone. Sections through the forebrain were then immunostained for NGF using a polyclonal antibody. Relative optical density measurements for NGF-immunoreactivity were quantified using the NIH image analysis system on three sections matched for level through the medial septum of each rat by an investigator blinded to the animals age or behavioral performance. All neurons on each section were measured. No differences in the relative optical density measurements were observed between the two groups ( $p > .05$ ). The data suggest that reduced NGF-immunoreactivity is not associated with age-related changes in medial septal neurons. (Supported by AG09466)

## 301.9

# ELECTROPHYSIOLOGICAL EFFECTS OF OX-26-NGF ON MEDIAL SEPTAL NEURONS. D. Albeck<sup>1</sup>, G.M. Rose<sup>2,3</sup>, L. Yeng<sup>2</sup>, R. Bartus<sup>4</sup>, and A.-C. Granholm<sup>1,2</sup>. Depts. of Basic Science<sup>1</sup> and Pharmacology<sup>2</sup>, Univ of Colorado HSC, and VAMC<sup>3</sup>, Denver, CO 80262, Alkermes Inc<sup>4</sup>, Cambridge MA 02139

Nerve growth factor (NGF) is a neurotrophin which has actions on cholinergic cells in the medial septum. Recent reports have shown that NGF affects the electrophysiological characteristics of these cells; both acute and long term effects have been described. Conjugation of NGF to a transferrin receptor antibody (OX-26-NGF) allows peripherally administered NGF to cross the blood-brain barrier and exert effects in the brain. The present study was undertaken to characterize the action of OX-26-NGF upon medial septal neurons *in vivo*. Both untreated young (3-6 months) and aged (24 months) male Fischer 344 rats were studied. Aged rats were given long term OX-26-NGF treatment using one of two different treatment protocols. Rats received i.v. injections either weekly (50µg) for 3 months (long-term, LT), or weekly for the first month followed by no injections for 2 months (short-term, ST). Rats were anesthetized with urethane and prepared for recording. Following the isolation of a medial septal area neuron, baseline activity was recorded before and after i.v. injection of either OX-26-NGF (50µg) or unconjugated NGF and antibody (control solution). Neither solution had consistent effects upon neuronal activity in the young rats. In contrast, in cells recorded in aged ST rats, OX-26-NGF (but not control solution) injections caused a prolonged elevation of firing. This effect was not observed in aged LT rats. Taken together, these data suggest that NGF affects medial septal neuron electrophysiology in aged rats which have not received NGF for a prolonged period but not in young rats, and that the effect seen in the aged rats is normalized by long term treatment with OX-26-NGF. ## 301.11

# EXPRESSION OF THE IMMEDIATE EARLY GENE ZIF268 IN MONOCULARLY DEPRIVED RATS: EFFECTS OF NGF. M. Caleo<sup>1</sup>, L. Pizzorusso<sup>1</sup>, C. Lodovichi<sup>2</sup> and L. Maffei<sup>1,3</sup>. (1) Scuola Normale Superiore, (2) Scuola Superiore S. Anna, (3) Istituto Neurofisiologia CNR, 56127 Pisa (Italy).

We have tested the effects of NGF administration in monocularly deprived rats by using immunodetection for zif268 as an assay of cortical activity with single-cell resolution. Animals were monocularly deprived for 10 days during the critical period and provided every other day with intravitreal injections of NGF (3-4 µg) or cytochrome C as control. At the end of the deprivation period we tested the ability of the deprived eye to drive the response of cortical neurons. The deprived eye was re-opened and the normal eye silenced by means of intraocular TTX injection, 5 hours later the animals were sacrificed and the brains processed for immunohistochemistry. In cytochrome C-treated animals staining for zif268 was restricted to the monocular visual cortex contralateral to the re-opened eye and no staining at all was observed in the binocular segment, where virtually all cells had become dominated by the TTX-eye. In contrast, in NGF-treated animals many activated cells were found in the binocular region and the overall pattern of staining resembled that observed in normally-reared, TTX-injected animals. This result is consistent with previous electrophysiological reports showing that exogenous supply of NGF prevents the effects of monocular deprivation on the ocular dominance distribution. One possible explanation of the result is that NGF potentiates the electrical activity of the deprived pathway. To address this issue, immunodetection for zif268 was performed during the period of monocular deprivation. We found a considerable reduction of zif268 immunostaining in the monocular visual cortex contralateral to the deprived eye. In monocularly-deprived, NGF-treated animals zif268 staining was still reduced in the monocular region, suggesting that NGF does not interfere with neural activity in the visual cortex.

Supported by Italian CNR and HFSP grant RG93/93.

## 301.8

# ANTIOXIDATIVE MECHANISM OF NGF-MEDIATED NEUROPROTECTION IN A 3-NP MODEL OF HUNTINGTON'S DISEASE. W.R. Galpern<sup>1,3</sup>, D.M. Frim<sup>1</sup>, R. Matthews<sup>2</sup>, M.F. Beal<sup>2</sup> and O. Isacson<sup>1,2</sup>. <sup>1</sup>Neuroregeneration Laboratory, McLean Hospital and Program in Neuroscience, Harvard Medical School, Belmont, MA; <sup>2</sup>Neurology Service, Massachusetts General Hospital, Boston, MA; <sup>3</sup>University of Massachusetts Medical Center, Worcester, MA

Systemic administration of 3-nitropropionic acid (3-NP) produces striatal lesions characteristic of the neurodegeneration of Huntington's disease and is associated with increased production of hydroxyl radicals and the oxidant peroxynitrite. Inhibition of neuronal nitric oxide synthase (NOS) protects against 3-NP induced lesions and attenuates hydroxyl radical and peroxynitrite formation. We have previously shown that NGF-secreting fibroblasts protect against the striatal neurodegeneration induced by 3-NP. In the present study, we have investigated the mechanism of NGF-mediated neuroprotection. Rats were grafted in the corpus callosum with NGF[+] or NGF[-] fibroblasts. In the first series of experiments, rats were sacrificed 7 days after implantation and brains were evaluated for expression of catalase as well as striatal levels of ATP. In the second series of experiments, rats received a series of 3 systemic injections of 3-NP 7 days after grafting, and the generation of peroxynitrite was evaluated by measuring the striatal levels of 3-nitrotyrosine by HPLC. Implantation of NGF-secreting fibroblasts was associated with an increase in catalase expression at the graft site and a concomitant decrease in striatal ATP levels. In addition, NGF grafts significantly decreased the 3-NP induced generation of 3-nitrotyrosine, presumably by decreasing peroxynitrite formation. These findings suggest that NGF may protect against neuronal death by enhancing the levels of antioxidant enzymes as well as by decreasing the production of oxidative agents such as peroxynitrite. Furthermore, the attenuation of peroxynitrite formation suggests NGF neuroprotection may be mediated in part by increased scavenging of superoxide radicals. (Supported in part by the Milton Fund/Harvard Medical School and NIH grants NS 16367 and NS 31579)

## 301.10

# ELECTROPHYSIOLOGICAL STUDIES OF NGF EFFECTS ON MEDIAL SEPTAL TRANSPLANTS. C. Backman<sup>1</sup>, C. Lupica<sup>1</sup>, R. Bartus<sup>4</sup>, A.-C. Granholm<sup>1,2,3</sup>. Neuroscience Program<sup>1</sup>, Depts. of Basic Science<sup>2</sup> and Pharmacology<sup>3</sup>, University of Colorado HSC, Denver, CO80262. Alkermes Inc.<sup>4</sup>, Cambridge, MA.

Cholinergic neurons of the medial septal nucleus in the basal forebrain are sensitive to nerve growth factor (NGF). It has been demonstrated that an anti-transferrin receptor antibody (OX-26) conjugated to NGF (OX-26-NGF) crosses the blood-brain barrier, stimulating survival and growth of these neurons in isolated transplants *in oculo*. In the present study we investigated the effects of chronic OX-26-NGF treatment on single neuronal activity stimulated by acute local NGF application in intracortical grafts of septal tissue. Fetal septal tissue containing cholinergic neurons was grafted into the anterior chamber of the eye of adult Fischer 344 albino rats. A mixture of OX-26 and NGF (co-mixture) or OX-26-NGF was injected (10µg/injection) into the tail vein of recipient rats once every two weeks for a period of 3 months following transplantation. Preliminary results of extracellular recordings showed that acute administration of NGF has a slow-onset, long lasting excitatory effect on the spontaneous firing of neurons in septal grafts treated chronically with the co-mixture. In contrast, acute administration of NGF does not seem to have such an excitatory effect on the spontaneous activity of grafted septal neurons chronically treated with the OX-26-NGF conjugate. Intracellular recordings will also be undertaken on the septal grafts, and intracellular labeling with biocytin in conjunction with ChAT immuno-staining will determine the identity of recorded neurons. These data suggest that chronic treatment with exogenous NGF gives rise to a desensitization of acute NGF effects on individual neurons in the septal area. Supported by USPHS grant AG12122.

## 301.12

# CHRONIC NERVE GROWTH FACTOR ADMINISTRATION ENHANCES HIPPOCAMPAL PRIMED BURST POTENTIATION IN AGED, BUT NOT YOUNG, MALE FISCHER 344 RATS. G.M. Rose<sup>1,2</sup>, K.L. Herman<sup>1</sup> and L.R. Williams<sup>3</sup>. <sup>1</sup>Dept. of Pharmacology, UCHSC and <sup>2</sup>Medical Research, VAMC, Denver CO 80262; <sup>3</sup>Amgen Neuroscience, Thousand Oaks, CA 91320

In aged rats, chronic administration of nerve growth factor (NGF) has been shown to enhance spatial learning and memory. In contrast, similar treatment of young rats has sometimes resulted in learning impairments. The goal of the present study was to evaluate the effect of i.c.v. NGF administration on hippocampal primed burst (PB) potentiation, a measure of long-term synaptic plasticity. Male F344 rats at either 3 or 23 months of age were given four weeks of i.c.v. NGF (6 µg/day) or vehicle infusion via Alzet osmotic minipump. During the fourth week, the rats were anesthetized with pentobarbital and responses were recorded from the CA1 pyramidal cell layer in response to electrical stimulation of commissural afferents. Hippocampal plasticity was assessed using PB potentiation (5 stimuli) and conventional LTP (200 stimuli). Consistent with our previous *in vitro* studies, PB potentiation, but not LTP, was significantly reduced in the hippocampus of aged rats. NGF, but not vehicle, administration enhanced PB potentiation in the aged rats. In contrast, NGF administration to young animals caused a severe attenuation of PB potentiation. Taken together, these results support the idea that alterations in hippocampal plasticity induced by aging or NGF treatment could have functional consequences, and support the involvement of cholinergic mechanisms in these processes. Supported by AG10755, the VAMRS and Amgen, Inc.

## 301.13

NGF-INDUCED IMPROVEMENTS IN SPATIAL WORKING MEMORY PERSIST AFTER DISCONTINUATION OF NGF INFUSION IN AGED RATS. K.M. Frick\*, R.R. Sukhov, D.L. Price, V.E. Koliatsos, & A.L. Markowska. Depts. of Psychology, Pathology, Neurology, and Neuroscience, The Johns Hopkins University, Baltimore, MD 21218.

Nerve growth factor (NGF) infusion significantly reduces spatial working memory deficits in aged rats. However, the persistence of this NGF-induced memory improvement after discontinuation of infusion has not previously been assessed and is of crucial importance for the potential clinical use of this compound. The present experiment measured the duration of the NGF-induced improvement of spatial working memory, a type of memory that is significantly deteriorated in Alzheimer's disease. Spatial working memory was tested in a Morris water maze delayed nonmatch-to-position task. In addition to memory, sensorimotor (SM) skills were also examined with a battery of tasks. Four and 22 month-old rats were tested preoperatively, infused intraventricularly with recombinant human NGF or vehicle, and tested both during the 4 week infusion period and during the 4 weeks after discontinuation of infusion. NGF significantly improved working memory during the fourth week of infusion and for up to four weeks after discontinuation of infusion in 22 month-old rats only. Although NGF did not affect SM skills during infusion in either age group, SM skills were significantly improved 2 and 4 weeks after discontinuation of infusion in 22 month-old rats. These findings demonstrate that the beneficial effects of NGF on spatial working memory and SM skills can persist for up to 1 month after discontinuation of infusion and suggest that NGF can be used intermittently for the treatment of age-associated memory dysfunction and Alzheimer's disease. (Supported by NIA Program Project P5020417 and USPHS grant NS AG05146)

## 301.15

TRKA ACTIVATION IN THE RAT VISUAL CORTEX BY ANTI-RAT TRKA IgG PREVENTS THE EFFECT OF MONOCULAR DEPRIVATION ON OCULAR DOMINANCE DISTRIBUTION.

T. Pizzorusso, N. Berardi, K. Venstrom, L.F. Reichardt, L. Maffei. Scuola Normale Superiore; Istituto Neurofisiologia CNR, I-56127 Pisa, ITALY; Howard Hughes Medical Institute, Dept. Physiology UCSF, CA U.S.A. (SPON: European Brain and Behaviour Society).

It has been recently shown that intraventricular injection of NGF prevents the effects of monocular deprivation. We have tested the molecular nature of the NGF receptor responsible for this effect by infusing anti-rat trkA IgG polyclonal antibodies that has been shown to act as specific agonist of trkA (Clary et al. Mol. Biol. Cell, 5:549-563, 1994) into the visual cortex of monocularly deprived (MD) rats. Rats were monocularly deprived for one week at the peak of cortical plasticity (P22-P29). Anti-rat trkA IgG (1.4 mg/ml) was delivered either by osmotic minipumps (Alzet 1007D, pumping rate 0.5  $\mu$ l/h) connected via a PE tubing to a cannula implanted (L 1 mm, AP 0 mm from  $\lambda$ ) into, or by topical application every other day of fibrin soaked with 5  $\mu$ l of anti-rat trkA IgG onto, the visual cortex contralateral to the deprived eye. Control rats consisted of MD rats treated with saline by either local application or minipump implant. At the end of the deprivation period ocular dominance distribution (ODD) was assessed by extracellular single cell recordings from the binocular primary visual cortex. We found that the shift in ODD towards the ipsilateral, non deprived eye was largely prevented by anti-rat trkA IgG treatment (N=5, Ipsilateral Index I.I. 0.085 $\pm$ 0.06). Strong ODD shift was found in control animals (N=3, I.I. 0.64 $\pm$ 0.04) with respect to normals (N=4, I.I. 0.07 $\pm$ 0.01). These results suggest that NGF action in visual cortical plasticity is mediated by TrkA receptors. Supported by HFSP grant RG 93/93.

## 301.17

BASAL FOREBRAIN CHOLINERGIC NEURONS ARE MAXIMALLY SENSITIVE TO NGF DEPRIVATION DURING EARLY POSTNATAL DEVELOPMENT. M. Molnar\*, E. Torigiorgi, F. Ruberti, L. Domenici and A. Cattaneo. International School for Advanced Studies (ISAS), 34014 Trieste, Italy; Istituto di Neurofisiologia, CNR, 56127 Pisa, Italy.

Cholinergic neurons of basal forebrain (BF) present receptors for NGF and are sensitive to NGF. In many structures of CNS, including the BF region, the expression of NGF and its receptors is developmentally regulated. To test whether BF neurons depend on NGF during restricted time windows of postnatal development, we antagonized the endogenous NGF by implanting in the lateral ventricle of the rat hybridoma cells producing blocking antibodies. These antibodies do not recognize other neurotrophins. Hybridoma cells were implanted under anaesthesia at three different postnatal ages: postnatal day 2 (P2), P8 and P15. Myeloma implanted rats were used as controls. One week after implants the brain of rats was fixed by perfusion and immunohistochemistry for choline acetyltransferase developed. To assess the presence of antibodies we used an enzyme-immunoassay. We found that cholinergic neurons of BF drastically reduced in number when endogenous NGF was antagonized during the first postnatal week. Hybridoma cells implanted at P8 and P15 did not result in any significant reduction of cholinergic neurons. In parallel experiments performed in normal rats by using double immuno-in situ histochemistry we found that after the first postnatal week, virtually all BF neurons presenting trkA co-express also trkB, while at P2-4 the co-expression was not complete. We conclude that BF cholinergic neurons are sensitive to NGF deprivation during early postnatal development. We hypothesize that BF cholinergic neurons at later developmental stages, when they widely coexpress TrkA and TrkB, are sustained by multiple neurotrophic factors and therefore loose the sensitivity to a single neurotrophin, namely the NGF.

## 301.14

AUTOCRINE/PARACRINE VS TARGET-DERIVED RESPONSIVENESS OF CHOLINERGIC NEURONS OF THE BASAL FOREBRAIN TO TROPHIC STIMULATION. L. Hu\*, K. McLaren, S. Cote, A. Ribeiro-da-Silva and A. C. Cuello. Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, Canada H3G 1Y6

It is well known that exogenous NGF can dramatically affect the phenotype of cholinergic neurons of the basal forebrain in normal, aged and lesioned animals. However, it is not clear whether NGF acts at the distal or the proximal ends of these neurons *in vivo*. To clarify this issue, we delivered NGF locally into the cortex or corpus striatum adjacent to the nucleus basalis magnocellularis (NBM) in naive or cortically devascularized mature rats, respectively. NGF delivered into either the cortex or the corpus striatum for two weeks caused ipsilateral hypertrophy of the cholinergic neurons of the NBM in naive rats and rescued the NBM cholinergic neurons from retrograde degeneration in lesioned animals. Thus, exogenous NGF can exert biological effects at the distal fields (terminals and distal axons) or at the proximal fields (dendrites, proximal axons and cell bodies) when offered at different regions. These findings suggest a possible paracrine or autocrine role for NGF in these NBM cholinergic neurons. This idea is further strengthened by the detection of immunoreactivity to NGF associated with the rough endoplasmic reticulum and the Golgi apparatus in ChAT-immunoreactive neurons. *In situ* hybridization studies indicate that NGF mRNA expression is abundant in the cerebral cortex (pyramidal neurons and glia), which is consistent with the well characterized target-derived role of NGF in this system. The presence of this message in the NBM area is currently under investigation. Finally, the distribution of TrkA antigenic sites in the basalo-cortical cholinergic pathway would indicate that besides the target-derived function of NGF, a paracrine/autocrine role of this neurotrophin is conceivable as E.M. investigation revealed TrkA sites in cell bodies and dendrites, which were internalized from these sites after the administration of NGF to adjacent tissue.

## 301.16

CHRONIC INTRAVENTRICULAR INFUSION, BUT NOT ACUTE APPLICATION OF NGF REVERSES THE DEFICIT IN HIPPOCAMPAL SYNAPTIC PLASTICITY OF THE *ngf*<sup>+/+</sup> MICE. N. Shinsky\*, M. C. Nishimura, K. S. Chen, H. S. Phillips and W.-Q. Gao. Department of Neuroscience, Genentech, Inc., South San Francisco, CA 94080.

We have previously shown that there is a significant deficit in maintenance of long-term potentiation (LTP) or late phase of LTP (L-LTP, 3 hours after tetanic stimulation), recorded from hippocampal slices prepared from adult mice, heterozygous for NGF gene deletion (*ngf*<sup>+/+</sup>) as compared to the wild-type animals (*ngf*<sup>+/+</sup>) (*Soc. Neurosci. Abstr.*, 21: 548, 1995). In addition, the *ngf*<sup>+/+</sup> mutant mice showed a significant decrease in the magnitude of paired-pulse facilitation (PPF) obtained by giving 2 pulses with an interval of 50-250 msec. In the present experiments, we are interested in determining whether acute or chronic administration of NGF can reverse the deficits in the L-LTP and prevent the decrease in the magnitude of PPF in the *ngf*<sup>+/+</sup> mice.

While acute perfusion (2 hours) of NGF to the slices prepared from *ngf*<sup>+/+</sup> mice had no effect, intraventricular infusion of NGF by osmotic minipump (50  $\mu$ g/ml, 0.25  $\mu$ l/hr) for 2 weeks completely rescued the L-LTP, and partially reversed the decrease in the magnitude of PPF in the *ngf*<sup>+/+</sup> mice. Application of BDNF to the slice chamber for 2 hours elicited no effect on slices prepared from *ngf*<sup>+/+</sup> animals, although this enhanced short-term post tetanic potentiation and resulted in a rapid decay of L-LTP in slices from *ngf*<sup>+/+</sup> mice. These findings suggest that the mechanisms for actions of NGF and BDNF on synaptic plasticity are different. Most likely, NGF does not directly act on synaptic transmission in the hippocampus, but rather works indirectly by rescuing the deficit of cholinergic input to the hippocampus from the septum in the *ngf*<sup>+/+</sup> mice.

## 301.18

TRANSGENIC MICE EXPRESSING NGF ANTIBODIES DURING POSTNATAL LIFE. A. Cattaneo\*, F. Ruberti. Int School for Adv. Studies (SISSA) 34013 Trieste ITALY

NGF plays a role in neural plasticity both in developing and adults animals. To study the actions of NGF in postnatal life, we exploited an experimental approach based on the ectopic expression of recombinant antibodies. The monoclonal antibody aD11 was chosen as it is very efficient in neutralizing the actions of NGF, but not of other known neurotrophins, both *in vitro* and *in vivo*. The variable regions of mAb aD11 were cloned, joined to human constant regions, and placed under the transcriptional control of the cytomegalovirus early promoter. Transgenic mice were produced by microinjection of plasmid DNA into fertilized eggs. Both single and double transgenic founder mice were obtained, but the latter did not produce offspring, over a two years time period. Therefore we crossed mice transgenic for aD11 heavy chain with mice transgenic for the light chain. The resulting offspring express a functional aD11 antibody. The expression of the antibody chains was studied by ribonuclease protection analysis, immunohistochemistry and ELISA. The results show that the transgenic antibody chains are expressed in different tissues, brain, kidney, heart and spleen. The transgenic antibody chains are widely expressed in almost every CNS region of adult mice, with highest levels found in the hippocampus, cerebellum and cortex. The expression appears to be developmentally regulated, being very low during embryonic and early postnatal life, and reaching high levels only after one month. Functional circulating aD11 antibodies are undetectable in the serum of p8 mice, while their concentration reaches 50-100 ng/mL in the serum of adult mice. Also in the brain the levels of antibodies at p8 are much lower than those found in adult mice. As a consequence, classical NGF target cells (cholinergic neurons of the basal forebrain, sensory neurons in dorsal root ganglia) are spared in these mice, with the exception of a 30% reduction of neurons in superior cervical ganglia. Thus aD11 transgenic mice provide a useful model to study the role of NGF in adult mice, after a normal development has occurred. Supported by HFSP (RG93/93)

## 301.19

CHOLINERGIC FUNCTION IN THE HIPPOCAMPUS OF JUVENILE RATS CHRONICALLY DEPRIVED OF NGF: AN ELECTROPHYSIOLOGICAL STUDY. E. Avignone, M. Molnar, A. Cattaneo, M. Sciancalepore\* and E. Cherubini, Biophys Lab, Int Sch Adv Studies (SISSA), 34013 Trieste, Italy.

In the hippocampus, nerve growth factor (NGF) and NGF mRNA are highly expressed in regions innervated by cholinergic fibres, suggesting that this neurotrophin is a potential maintenance factor for the survival of cholinergic neurons. Responses to muscarinic receptor stimulation were studied with intracellular recordings from CA1 hippocampal neurons in slices from P15-P18 rats. In these animals endogenous NGF was antagonized by blocking antibodies, produced by hybridoma cells ( $\alpha$ D11) implanted (at P2) in the lateral ventricle. As controls, P3U myeloma implanted rats of the same age were used. The presence of antibodies in the cerebral cortex and contralateral hippocampus was assessed with an enzyme-immunoassay (ELISA). Resting membrane potential, input resistance or time constant were similar in the two experimental groups. Stimulation of cholinergic fibres in the alveus (at 15-30 Hz, for 2 s), in the presence of the AChE inhibitor eserine (3  $\mu$ M) induced slow ACh-mediated EPSPs whose amplitude and duration were similar both in the  $\alpha$ D11- or P3U-treated animals. When the muscarinic agonist carbachol was applied directly to the postsynaptic cells in the presence of tetrodotoxin (TTX, 1  $\mu$ M), differences between the two experimental groups were observed. In comparison with P3U, the dose-response curve to carbachol of the  $\alpha$ D11-treated animals was shifted to the left. The  $EC_{50}$  for carbachol was 2.6  $\mu$ M in P3U- and 0.6  $\mu$ M in  $\alpha$ D11-treated animals, respectively. The increase in sensitivity of CA1 neurons to ACh might reflect a compensatory mechanism for the loss of cholinergic innervation in animals deprived of endogenous NGF during development.

## 301.21

ROLE OF *c-fos* IN TRANSACTIVATION OF THE CHOLINE ACETYLTRANSFERASE GENE IN NERVE GROWTH FACTOR-TREATED CULTURED BASAL FOREBRAIN NEURONS. Julie Pongrac\* and R. Jane Rylett. Depts. Pharm./Toxicol. and Physiology, Univ. Western Ontario, London, Canada.

Basal forebrain neurons respond to nerve growth factor (NGF) by enhancing the cholinergic phenotype. This occurs through increases in choline acetyltransferase (ChAT) activity, high-affinity choline transport and acetylcholine (ACh) synthesis, content and release. Increases steady-state levels of ChAT mRNA following NGF administration have been measured in basal forebrain *in vivo* and *in vitro*, thus a plausible mechanism for NGF-mediated increases in cholinergic phenotypic markers involves transcription. This hypothesis is further advanced by the presence of NGF-responsive elements in the promoter region of ChAT gene sequences containing AP-1 sites. Immediate early genes (IEGs) known to be induced by NGF in PC12 cells include *c-fos*, *c-jun* and *jun-B* of which the protein products combine to form AP-1 transcription factors. We determined the role of transcriptional events, in particular, the induction of *c-fos*, in NGF-mediated increases in ChAT activity in non-transformed cholinergic neurons. Using rat basal forebrain neurons cultured in chemically defined medium, blockade of *c-fos* with antisense oligonucleotides and assays of ChAT activity, we show that *c-fos* participates in the NGF-mediated changes in ChAT activity. NGF (100 ng/ml) increased ChAT activity of cultures greater than 2 fold above basal levels as measured by radioenzyme assay. In sister cultures, 20  $\mu$ M of antisense oligonucleotides targeting the initiation codon of *c-fos* were administered 6 and 12 h prior to NGF treatment. This resulted in a 34% and 94% reduction in the NGF-mediated ChAT activity, respectively. Similar treatment with 20  $\mu$ M of a mismatch oligonucleotide control did not block increases in ChAT activity mediated by NGF. These experiments suggest that *c-fos* transactivation of the ChAT gene is involved in NGF-mediated changes in the cholinergic phenotype. ## 301.23

NERVE GROWTH FACTOR (NGF) ENHANCES TRANSMISSION AT A DOPAMINERGIC SYNAPSE IN THE MOLLUSC, *LYMNAEA STAGNALIS*. N.S. Magoski\* and A.G.M. Bulloch. Neuroscience Research Group, The University of Calgary, Calgary, Alberta, T2N 4N1, Canada.

We examined an excitatory synapse from interneuron Right Pedal Dorsal one (RPeD1) to neurons Visceral Dorsal two and three (VD2/3) in the *Lymanaea* CNS. The synaptic latency was relatively rapid, at  $24.1 \pm 5.2$  ms ( $n=27$ ), and the synapse appeared to be dopaminergic. The RPeD1 - VD2/3 EPSP and the VD2/3 bath-applied dopamine (100  $\mu$ M) response displayed a similar decrease in input resistance ( $n=5$  & 7) and a similar predicted reversal potential ( $-31.1$  mV vs  $-25.5$  mV;  $n=7$  & 7), suggesting that the synapse and exogenous dopamine activate the same conductance. In addition, as previously shown (J Neurophysiol 74:1287), the synapse and the dopamine response were blocked by the D-2 antagonist, (+) sulpiride (100  $\mu$ M;  $n=11$  & 6). There is evidence for the involvement of neurotrophic factors in the plasticity of *Lymanaea* neurons (Neth J Zool 44:317). To explore this further, the effect of 1 day organ culture in either defined medium (DM), brain-conditioned medium (CM), or defined medium supplemented with 400 ng/ml of 2.5S murine Nerve Growth Factor (NGF), on the magnitude of the EPSP, was tested. The EPSP was measured at the same synapse before, and after, 1 day of organ culture. Following culture in CM, the EPSP increased by 100.0% ( $n=9$ ), while in parallel controls, the EPSP showed no significant change following culture in DM ( $n=12$ ). NGF mimicked the effect of CM, with the EPSP showing an increase of 46.2% following culture in NGF ( $n=18$ ). Again, in parallel DM controls the EPSP showed no significant change ( $n=15$ ). None of the culture conditions had a significant effect on the membrane potential or input resistance of VD2/3. The ability of NGF to mimic the effects of CM indicates that the component of CM responsible for enhancement of synaptic efficacy is likely an NGF-like molecule. This provides further evidence for the presence of neurotrophins in *Lymanaea*, and suggests that an NGF-like molecule may regulate synaptic transmission in the adult CNS.

## 301.20

THE EFFECTS OF NERVE GROWTH FACTOR ON THE DISTRIBUTION OF TRANSGANGLIONICALLY TRANSPORTED CHOLERAENOID AND SUBSTANCE P FOLLOWING TRANSECTION OF THE SCIATIC NERVE IN THE ADULT RAT. N.P. Eriksson\*, H. Aldskogius, G. Grant and C. Rivero-Molina

Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden

In the intact rat spinal cord transganglionically transported choleraenoid does not label primary afferents in the outer part of lamina II ( $II_0$ ) and only weakly in lamina I. Following transection of the sciatic nerve, however, the distribution of transganglionically transported choleraenoid occurs also in lamina  $II_0$  and increases in lamina I. The mechanism underlying this expansion is unknown but it is believed to involve myelinated afferents. Since nerve growth factor (NGF) seems to be important as a survival factor for small-sized trkA-positive dorsal root ganglion (DRG) neurons, out of which the majority contain substance P (SP), it is conceivable that it may also affect the axotomy-induced expansion of the spinal cord projection. The aim of the present study was therefore to investigate the effect of NGF in this system with the tracer choleraenoid. The efficacy of the NGF administration was assessed by analyzing the extent of SP-like immunoreactivity.

The sciatic nerve was transected bilaterally, at which time NGF or cytochrome C was applied unilaterally during the total postoperative survival time ranging from eight to 32 days. NGF was applied in one lower and one higher dose. Two days before sacrifice, the animals were injected bilaterally with choleraenoid.

In the early postoperative period, laminae I,  $II_0$  and the zone of Lissauer on the transected, non-treated side showed choleraenoid-like immunoreactivity, while on the NGF-treated side, regardless of dosage, these regions were almost totally devoid of labelled profiles. At longer postoperative survival times this effect gradually declined in a dose-dependent fashion and after 32 days survival there was no effect. SP-like immunoreactivity was markedly reduced in the dorsal root ganglia and in the superficial part of the dorsal horn on the transected, non-treated side. On the transected, NGF-treated side this decrease was counteracted in a dose-dependent fashion.

The conclusion from this study is that peripheral nerve injury induced expansion of primary afferent choleraenoid labelling in the spinal cord dorsal horn is the result of insufficient supply of NGF to axotomized NGF-responsive dorsal root ganglion neurons. NGF can reverse these changes including the downregulation of SP in a dose-dependent fashion. This study was supported by the Swedish Medical Research Council.

## 301.22

INTRASEPTAL INJECTION OF NGF LOCALLY EFFECTS EDEMA FORMATION AND MAST CELLS FOLLOWING SEPTAL INJURY IN RATS. L.S. Janis\*, J.W. Heyburn\*, Z. Fulop\* and D.G. Stein\*. <sup>1</sup>Inst of Animal Behav, Rutgers University, Newark, NJ 07102 and <sup>2</sup>Dept of Neurology, Emory Univ Sch of Med, Atlanta, GA 30322.

Following injury to the central nervous system, NGF is generally thought to induce recovery through cholinergic neurons. However in models of a single administration of NGF, behavioral recovery is often seen without the sparing of cholinergic neurons. Alternatively, NGF may induce recovery by mediating immune reaction. In order to examine this possibility, the formation of edema and the presence of mast cells were examined. Rats with electrolytic lesions of the medial septum received a single intraseptal injection of either NGF or saline immediately following surgery. The formation of edema was then assessed at 6, 24, 48, 72, and 120 hr's following the lesion. Edema formation was detected as early as 6 hr's in both groups. However, by 48 hr's following surgery, the NGF-treated rats had significantly less edema formation than their lesion alone counterparts. We also examined the septum for the presence of mast cells. Mast cells were identified near the damaged tissue and vascular walls in both groups. Initially, by 2 hr's the NGF-treated rats had more cells than the lesion alone rats. However, by 72 hr's fewer mast cells were seen in the NGF rats compared to the lesion alone rats. These results can be taken to indicate that NGF may alter locally mediating events that limit the effects of reactions associated with the inflammation of damaged tissue.

SHORT TERM ACTIONS OF NGF AND EXTRACELLULAR MATRIX PROTEINS ON HIGH VOLTAGE ACTIVATED CALCIUM CURRENTS OF MOLLUSCAN MOTONEURONS. W.C. Wildering\* and A.G.M. Bulloch. Neuroscience Research Group, HSC, University of Calgary, Calgary, Alberta, T2N 4N1, Canada.

Previously, we demonstrated that mouse 2.5S Nerve Growth Factor (NGF) modulates high-voltage activated  $Ca^{2+}$  currents in molluscan motoneurons within minutes (Wildering et al. 1995, J. Neurophysiol. 74: 2778). More recently we extended our studies to the short term actions of extracellular matrix (ECM) proteins on neuronal physiology and their possible interaction with neurotrophin signalling. Motoneurons taken from the brain of the gastropod mollusc *Lymanaea stagnalis* were plated in defined medium on untreated plastic culture dishes. One day after plating HVA  $Ca^{2+}$  currents were recorded using standard gigaseal whole cell voltage clamp techniques. Addition of fibronectin (0.1  $\mu$ g/ml) to the superfusing saline induced a change in the amplitude and inactivation properties of the HVA  $Ca^{2+}$  current within a few minutes. The effect of fibronectin appeared to be specific since it could be mimicked by superfusion of synthetic analogues of the integrin binding motif (RGD-peptides). These results raise the possibility that in addition to neurotrophins, ECM proteins may also be involved in short term modulation of neuronal physiological properties.

Supported by MRC, AHFMR and the NCE Neuroscience Network (Canada).

TRK RELATED TYROSINE KINASE RECEPTORS CLONED FROM THE *LYMNAEA* CNS. A.G.M. Bullock\*, R.E. van Kesteren, G. Hauser, M. Fainzilber, C. Ibanez, J. van Minnen, A.B. Smit, W.P.M. Geraerts and E. Vreugdenhil. Neuroscience Research Group, Univ. Calgary, HSC, Calgary, AB, T2N 4N1 Canada; Molecular Neurobiology, Berzelius Laboratoriet, Plan 3, Karolinska Institute, Doktorsringen 12A, S 17177 Stockholm, Sweden; Faculty of Biology, Vrije Universiteit, 1081 HV, Amsterdam, The Netherlands; The University of Leiden, Leiden, The Netherlands.

Neurons from the CNS of the mollusc *Lymnaea* have been shown to respond to the mammalian neurotrophic factors, NGF and CNTF. In order to analyze the transduction mechanism involved in the response of these neurons to NGF, a PCR strategy was employed to search for receptors related to the trk family of tyrosine kinase neurotrophin receptors. Primers based on conserved sequences in the tyrosine kinase domain were used to amplify cDNA templates from the CNS. A number of tyrosine kinase products were obtained and sequenced, and homology searches suggest that the products obtained are similar to a number of tyrosine kinase receptors. A full length sequence from a cDNA clone representing one of the trk-like products was obtained revealing the entire intracellular and extracellular domains of this receptor, which is designated as Ltrk. The intracellular domain of Ltrk shows highest homology to trkA; strikingly this homology is much closer than the homology between Ltrk and the non-neurotrophin receptor-like gene from *Drosophila*, Dtrk. The extracellular domain of the Ltrk protein is amino-terminally extended by ~100 amino acids, the existence of which was confirmed by *in vitro* translation. Northern blot analysis revealed that one Ltrk transcript is expressed in the CNS, which is not up-regulated following injury. *In situ* hybridization showed expression of this receptor by a number of neurons and a group of endocrine cells. Efforts are underway to express these clones for functional expression studies. This is the first molecular data supporting the existence of the neurotrophin receptor family in the invertebrates, supporting previous indications that these molecules emerged early in evolution.

## HORMONES AND DEVELOPMENT: SEX STEROIDS

## 302.1

IMPLICATIONS OF FOS IMMUNOREACTIVITY IN THE PREOPTIC AREA OF NEONATAL RATS. H.R. Besmer<sup>1</sup>\*, G.M.O. Keidan<sup>2</sup>, R.B. Gibbs<sup>3</sup>, and M.M. McCarthy<sup>1</sup>. <sup>1</sup>Dept. of Physiol., Univ. of MD, Baltimore, MD, <sup>2</sup>Dept. of Biol., Coll. of Wooster, Wooster, OH, and <sup>3</sup>Univ. of Pitt. Sch. of Pharm., Pittsburgh, PA.

The sexually dimorphic nucleus of the preoptic area (SDN-POA) is 5-7 times larger in male rats than in females. The mechanisms that establish and maintain this sex difference are largely unknown. During the postnatal critical period for sexual differentiation, the dam grooms the anogenital region of pups to stimulate urination and defecation. Male pups are groomed significantly more often than females and this is critical for expression of male sexual behavior in adulthood. To test the hypothesis that anogenital grooming is important to brain sexual differentiation, we stimulated the anogenital region of 3-day-old pups (PN3) with a stiff-bristle paint brush. Control animals were handled in the same manner but not stimulated. One hour later brains were removed and processed for Fos-like immunoreactivity (Fos-ir) as an indicator of neuronal activation. Significantly more Fos-ir cells were detected in the POA of stimulated animals than in controls (2-way ANOVA,  $p < .05$ ). There was no sex difference in Fos-ir cells in either control or stimulated animals. The majority of Fos-ir cells detected was found in the ventral POA.

Sex differences in the volume of SDN-POA are likely related to differential cell death during postnatal development. In a separate study, brains from 3-, 5-, 7-, and 12-day-old animals were examined for correlations between Fos expression and cell death. No Fos-ir cells were detected in SDN-POA of either sex. In addition, there was no sex difference in the number of pyknotic cells detected in the SDN-POA. However, when the area surrounding the SDN-POA of females was also included so as to equal the survey area of males, significantly more pyknotic cells were detected in 5-, 7-, and 12-day-old females than in the SDN-POA of males (2-way ANOVA,  $p < .01$ ), with a maximum 3-fold difference detected on PN7.

These data suggest that maternal anogenital grooming activates neurons in the POA, possibly decreasing cell death and thereby contributing to masculinization of this region of the brain. Supported by R29MH52716 (MMM) and R01NS28896 (RBG).

## 302.3

EFFECTS OF NEONATAL ADMINISTRATION OF THE NEUROSTEROID ALLOPREGNANOLONE ON THE VOLUME OF THE SDN-POA IN RATS. M.J. Sackel\*, and M.M. McCarthy. Dept. of Physiology, Univ. of Maryland at Baltimore School of Medicine, Baltimore, MD

The SDN-POA, or sexually dimorphic nucleus of the preoptic area, is an intensely staining nucleus in the hypothalamus that is 2-8 times greater in volume in male rats than in female rats, and has a dense concentration of GABA<sub>A</sub> receptors. These receptors are known to have sexual dimorphic modulation in the adult rat. Allopregnanolone, a neurosteroid metabolite of progesterone, is a positive allosteric modulator at the GABA<sub>A</sub> receptor. Because of the high density of GABA<sub>A</sub> receptors in the SDN-POA, we decided to investigate the neuroanatomical effects of neonatal allopregnanolone administration on the volume of the SDN-POA.

Once the rats were anesthetized with cold, we subcutaneously administered 5 µg or 200 µg doses of allopregnanolone in a .05 ml sesame oil vehicle, or just the sesame oil vehicle, daily from PN2 through PN5. Injections were at 2 hours after the start of the dark phase of the light cycle. After sacrificing the rats at PN22, we collected and sectioned the brains, and stained the sections with cresyl violet. We measured the volume of the SDN-POA using camera lucida drawings and NIH Image software. The data indicate a strong trend that allopregnanolone decreases the volume of the SDN-POA in both males and females (t-test,  $p < .08$ ). There was evidence for a dose response in males, but not in females. In males, the 5 µg dose of allopregnanolone caused a 67% decrease in volume while the 200 µg dose caused an almost 80% decrease in volume. We hypothesize that the SDN-POA is modulated by changes in GABAergic neurotransmission during the critical period for sexual differentiation. Additional studies will replicate and extend these findings. This research was supported by grant R29MH52716 to MMM.

## 302.2

SEX DIFFERENCES IN HORMONAL RESPONSIVENESS OF ARCULATE ASTROGLIA IN NEONATAL RAT BRAIN. J.A. Mong\*, A.M. Davis, R.L. Kurzweil, and M.M. McCarthy. Departments of Pharmacology and Physiology University of MD Baltimore, MD, 21201.

It is established that estrogen mediates sexual differentiation of the brain via direct effects on neurons. However, *in vitro* studies indicate that estrogen induces astroglial differentiation. The present study investigates the effect of estrogen on astroglia *in vivo* during the critical developmental period.

Based on glial fibrillary acidic protein immunoreactivity (GFAP-ir), the surface area of astroglial cells in the arcuate nucleus of the hypothalamus was measured and compared between five hormonally different groups: 1) castrate males injected with testosterone propionate (TP, 50µg), or 2) oil vehicle, 3) gonadally intact males injected with oil vehicle, 4) gonadally intact females injected with TP, or 5) oil vehicle. All gonadally intact animals received sham operations. The treatments were performed on the day of birth (PN 0), and the animals were sacrificed on PN 1. The surface area of GFAP-ir cells was evaluated with computerized video densitometry. The data demonstrate an increased GFAP-ir surface area in castrate males compared to gonadally intact females and gonadally intact males. Moreover, intact females have an increased surface area compared to intact males (ANOVA  $p < 0.01$ ). The increase in GFAP-ir surface area seen in castrate males was attenuated by TP administration and resulted in GFAP-ir surface area comparable to intact males. Finally, TP administered to intact females was without effect in this paradigm. There was no difference in astroglial cell number between groups.

It is hypothesized that the absence of testosterone during a critical period in the developing male brain results in a loss of astroglial differentiation. The cells have a stellate morphology but their processes are short and thick. In contrast, the glial processes are thin and extended in intact males and castrate males injected with TP. We further hypothesize that in intact females, glial cells remain partially undifferentiated, which may be important to the glial plasticity seen in the adult female arcuate. Supported by NSF grant IBN-9511328 to MMM.

## 302.4

LONG-TERM SURVIVAL OF SONG CIRCUIT ELEMENTS IN CULTURED SLICES OF ZEBRA FINCH BRAIN. C.C. Holloway and D.F. Clayton\*. Dept. of Cell and Structural Biology and Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

The avian song control circuit is an attractive model for study of how specific brain circuits are formed in development. The organization of the circuit involves discrete nuclei rather than cortical areas or lamina, and some of these nuclei become connected only after the rest of the brain has developed (25 to 35 days post-hatch). In the zebra finch, a critical component of the circuit is formed only in males but not in females: the projection from nucleus HVC to RA. The goal of the present study is to define conditions for the *in vitro* maintenance of brain slices containing this projection, in order to determine the molecular signals and mechanisms responsible for its selective formation in juvenile males. Brain slices are made by cutting the brain parasagittally every 400 µm on a MacIlwain tissue chopper. The slices are maintained in a static culture system (Stoppini et al., J. Neurosci. Meth. 37: 173, 1991), in media developed for zebra finch primary cultures (Goldman et al., J. Neurosci. 12: 2532, 1992) in a 5% CO<sub>2</sub> incubator at 37°C. <sup>35</sup>S-methionine incorporation studies show that cells in the slice stay alive for at least six weeks *in vitro*. Axon-tracing studies using the lipophilic dye Dil show that the HVC-RA connections in an adult male brain are maintained during this time in culture as well. Long-term survival of neurons in these slices is further supported by sustained immunoreactivity against the neuron-specific antigens neurofilament (an intermediate filament of the cytoskeleton), MAP-2 (a protein associated with stabilization of microtubules), and synelfin (a pre-synaptic marker). Supported by NS25742

## 302.5

## PRE-HATCHING INHIBITION OF AROMATASE ACTIVITY MASCLINIZES SYRINGEAL AND GONADAL TISSUE BUT NOT THE SONG SYSTEM IN ZEBRA FINCH FEMALES.

A. Gong\* and A. P. Arnold. UCLA Dept. of Physiological Science and Brain Research Institute, Los Angeles, CA 90095-1527

To test how gonadal secretions affect sexual differentiation of the Zebra Finch song system, we injected Fadrozole (CGS 16949A), an aromatase inhibitor, into eggs on day 3 of incubation; controls received saline. Since ovarian development is estrogen-dependent, fadrozole injection on day 5 induced the formation of large amounts of testicular tissue in addition to ovarian tissue in genetic females (Wade & Arnold 1996). Therefore, we chose the earlier treatment date of day 3 in the hope of completely preventing development of ovarian tissue, in order to determine whether genetic females with completely sex-reversed gonads will develop a masculine song system. We examined the syrinx, gonads and song system nuclei in 100 days-old birds. Treated females possessed significantly larger syringes, a left ovotestis and a right testis. Despite the large amount of testicular tissue, the volumes of song system nuclei (HVC, RA) did not differ from control females. These results suggest that testicular secretions masculinize the syrinx, but are not sufficient to masculinize the song system in Zebra Finches. The results are compatible with the hypothesis that ovarian secretions prevent masculinization of the song system.

## INFLUENCE OF SEX STEROIDS ON THE DEVELOPMENT OF A SEXUALLY DIMORPHIC PROJECTION FROM THE BED NUCLEUS OF THE STRIA TERMINALIS TO THE ANTEROVENTRAL PERIVENTRICULAR NUCLEUS OF THE RAT. L.A. Hutton\*, G. Gu and R.B. Simerly. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006, and Department of Cell and Developmental Biology, Oregon Health Sciences University, Portland, OR 97201.

In addition to modulating the activity of neural circuits in the limbic system and hypothalamus, sex steroid hormones also influence the development of sexually dimorphic pathways. The principal nucleus of the bed nuclei of the stria terminalis (BSTp) is larger in male rats, and contains a high density of neurons that express sex steroid receptors throughout postnatal development. In males, the BSTp provides a massive projection to the anteroventral periventricular nucleus of the hypothalamus (AVPV), which in contrast to most sexually dimorphic nuclei contains more neurons in female rats. Although the sexual differentiation of the BSTp and AVPV has been shown to be dependent on the neonatal hormone environment, little is known about the impact of sex steroids on the development of the sexually dimorphic pathway between these nuclei. Dil was used to study the ontogeny of the projection from the BSTp to the AVPV in fixed tissue derived from rats perfused on postnatal days 0-10 (P0-P10). In male rats the projection from the BSTp to the AVPV is established between P7 and P10 and is maintained during the juvenile period (P22) and into adulthood. A similar connection is not apparent in female rats at any of the ages studied. Surprisingly, treatment of female rats with high doses of testosterone from P0 to P10 did not induce a connection between the BSTp and the AVPV suggesting that this sexual dimorphism is refractory to postnatal steroids, or is determined prenatally. Supported by NIH grants MH49236 and RR00163.

## 302.9

## ESTRADIOL ACTIVATES IMMEDIATE EARLY GENES IN CULTURED RAT HIPPOCAMPAL NEURONS. D.D. Murphy\* and M. Segal. LN, NINDS, NIH, Bethesda MD 20892, and The Weizmann Institute, 76100 Israel

We have previously shown that 17 $\beta$ -estradiol causes a two-fold increase in dendritic spine density in cultured rat hippocampal neurons, which is accompanied by a concomitant increase in synaptophysin immunoreactivity (Murphy and Segal, J. Neurosci. in press, 1996). Presumably, the formation of new spines and synapses requires the addition of new plasma membrane and synaptic proteins. We began studying the chain of events leading from the estrogen receptors to the formation of new spines by examining estradiol-treated hippocampal cultures for indicators of immediate early gene activation, phosphorylated cAMP response element binding protein (pCREB) and CREB binding protein (CBP). Cells were fixed and stained for CBP and p-CREB at various time points during a 24 hour exposure to estradiol. The proportion of stained neurons and glia, as well as the intensity of staining were assessed in confocal-reconstructed cells. Only a low proportion of cells (about 15% of neurons and 30% of glial cells) were stained for CBP in control, non-drugged conditions. Glial cells displayed a significant increase in CBP staining at 16 hours of estradiol treatment (80% of cells stained) while neurons displayed the greatest proportion of staining at 24 hours (83% of the cells stained, staining intensity was 228% of that in control conditions). At this time, only 42% of glial cells stained for CBP. As seen before for the effects of estradiol on spine formation, the N-methyl-D-aspartate antagonist, 2-APV, partially blocked the CBP response to estradiol, while the AMPA/Ka antagonist, DNQX was ineffective. p-CREB staining was similar to that of CBP, although the magnitude of estradiol-induced staining was lower than that of CBP. Taken together, these results indicate that p-CREB and CBP may be intermediate steps in the formation of new spines in response to estradiol.

## 302.6

## IN OVO ANTIANDROGEN OR ANTIESTROGEN DOES NOT ALTER THE DEVELOPMENT OF THE SONG SYSTEM IN MALE ZEBRA FINCHES. W. Grisham\*, &amp; A.P. Arnold. Dept. of Physiological Science &amp; Brain Research Institute, UCLA, Los Angeles, CA 90095-1527.

Although exogenous estrogen has been shown to masculinize the development of the song system when administered to hatching females, few studies have examined which hormones, if any, are responsible for normal masculine development in male zebra finches. In an effort to answer this question, we injected 20 microgram doses of an antiandrogen (flutamide), or an antiestrogen (ICI 182,780-ICI Pharmaceuticals), or the steroid secretion vehicle alone (SSV--10 microg) into eggs on day 10 of incubation and examined these birds in adulthood (94-124 days old).

In all birds, plumage was consistent with gonadal sex, and the gonads appeared to be macroscopically normal. The syringes were dissected and weighed in flutamide-treated (11 male and 7 female), ICI 182,780-treated (17 male and 7 female), and SSV-treated (5 male and 8 female) birds. Males had significantly heavier syringes, but there was no effect of treatment or sex X treatment interaction. The brains of males that were flutamide treated (n=6), ICI 182,780-treated (n=7), or SSV-treated (n=6) were embedded, sectioned at 40 microns, and stained with thionin. There was no effect of treatment on the volumes of Area X, IMAN, HVC, or RA; soma size in IMAN, HVC, or RA; or number of neurons in RA. These results offer no support for the importance of androgen or estrogen in organizing normal male development of gonadal, syringeal, or neural tissue in this species at this time of incubation. Supported by USPHS DC00217 to A.P.A.

## 302.8

## POSTPUBERTAL GONAECTOMY AND HORMONAL TREATMENT ON EEG OF RATS. I. del Rio-Portilla, E. Ugalde, J. Juárez, A. Roldán, C. Arce and M. Corsi-Cabrera\*. Facultad de Psicología, Universidad Nacional Autónoma de México, México, D.F. 04510, Instituto de Neurociencias Universidad de Guadalajara.

When compared to females, males show higher theta relative power (RP), lower delta and beta RP, higher interparietal correlation (IPC) and similar absolute power (AP). These sex differences are dependent on hormonal oscillations during estrous and on organizing actions of testosterone. Fetal androgen exposure masculinize the female EEG abolishing sex differences.

This study was conducted to determine if EEG sex differences are influenced by postpubertal gonadal steroids. EEG was recorded at 100 days of age in males and females gonadectomized (GNX) at 80 days without and with either vehicle, testosterone propionate (TP) or 5 $\alpha$ -DHT in males and vehicle, progesterone (P) or estradiol (E) in females.

Sex differences in RP and IPC were abolished after GNX, however, GNX induced higher AP in females than males. TP induced higher AP abolishing sex differences. Isolated TP, 5 $\alpha$ -DHT, E or P did not reestablish sex differences in RP and IPC. Sexual dimorphism in EEG need, in addition to organizing effects, the activation actions of gonadal steroids.

## 302.10

## NEONATAL ANDROGENS AFFECT ADULT SPATIAL BEHAVIOR AND CA3 PYRAMIDAL CELL MORPHOLOGY IN RATS: A GOLGI STUDY. C. Isgor\* and D.B. Sengelaub. Department of Psychology, Indiana University, Bloomington, IN 47405.

We have previously reported androgen-sensitive sex differences in adult spatial learning and hippocampal (CA3) volume (male>female; androgen-treated female>female; male>castrates), which were partly due to increases in pyramidal soma size and density. In this study we examined changes in spatial learning and dendritic morphology of CA3 pyramidal cells after neonatal hormonal manipulations.

Spatial learning (using a water-maze) and CA3 pyramidal cell morphology were assessed in adulthood (90+ days of age) in normal males and females, androgen-treated females (testosterone propionate, 1 mg/day, postnatal (P) day 3 and 5), gonadectomized males and females (P2), as well as castrated males with replacement androgen (n=6 per group). Consistent with our previous results, acquisition of water-maze performance was observed only in high-androgen groups. After behavioral testing, brains were stained using the Golgi technique, and dendritic morphology of CA3 pyramidal cells was reconstructed in three dimensions (Eutectic NTS). Pyramidal cells of high-androgen groups had significantly greater total dendritic lengths and number of branches. No effects were observed in spine density, but total number of spines per neuron was greater in high-androgen groups due to increases in dendritic length. Similar findings were found in both apical and basilar dendrites. Thus, neonatal androgens establish the sex difference in adult spatial learning and CA3 volume through regulating neuronal soma size, density, and dendritic morphology. Supported by Sigma XI and NSF DIR-901427.

## 302.11

**LOCAL INHIBITORY CIRCUITS UNDERGO AGE- AND SEXUAL HORMONE DEPENDENT CHANGES.** R.W.Greene<sup>1</sup>, D.G.Rainnie<sup>1</sup>, M. Berger<sup>2</sup>, R.W.McCarley<sup>1</sup> and H.C.R. Grunze<sup>1,2</sup>. <sup>1</sup>Harvard Medical School & VAMC Brockton, Brockton MA, <sup>2</sup>Psychiatrische Universitätsklinik, 79104 Freiburg, Germany

We have previously reported an NMDA-dependent modulation of local inhibitory circuits in the rat hippocampal CA1 layer, and its potential impact on information processing (Grunze et al., 1996). As these data were obtained from prepubescent rats, aged 20-30 d, we now compared these results with those obtained from 9-12 month old rats of both gender, and with 9-12 month old rats who were castrated prior to puberty. Whole cell patch clamp recordings were obtained from CA1 pyramidal neurones, manually held at -60 mV, and the IPSP amplitude in response to alvear stimulation was measured. Recordings from prepubescent rats (n=72) showed an IPSP with a mean maximal amplitude ( $\pm$  SE) of  $4.5 \pm 2.8$  mV. In contrast, the IPSP of older rats was observed with a reduced amplitude of  $1.1 \pm 0.9$  mV. All neurones showed an EPSP of equal size compared to prepubescent controls. A statistically significant gender difference was not observed in the old rats, although there was a tendency toward IPSPs with higher amplitudes in females. However, age matched castrated rats (n=14), showed an IPSP with a mean amplitude of  $2.4 \pm 1.3$  mV which was significantly larger than that of the control old rats ( $p < 0.05$ , Mann-Whitney test). Furthermore, the metabotropic glutamate receptor agonist, trans-ACPD ( $5 \mu\text{M}$ , n=12), applied to the superfusate increased the IPSP amplitude in castrated rats by  $35 \pm 27\%$ , an effect not seen in young control animals. On the other hand, the reduction of the IPSP amplitude by APV ( $25 \mu\text{M}$ ) was comparable to young rats, ( $49 \pm 19\%$  vs.  $31 \pm 9\%$ ). Data for these chemical modulations of the IPSP have yet to be obtained from old, non castrated rats. In conclusion, these data suggest that hippocampal inhibitory local circuits undergo age dependent changes, possibly with an important modulatory role of sexual steroids.

## 302.13

**ESTROGEN REGULATION OF FAS/APO-1 mRNA EXPRESSION IN EXPLANT CULTURES OF THE DEVELOPING CEREBRAL CORTEX.** Z.F. Cheema<sup>1</sup> and R.C. Miranda<sup>2</sup>. Dept. Human Anatomy and Medical Neurobiology, Texas A&M University College of Medicine, College Station, TX 77843-1114

The cerebral cortex expresses high levels of the estrogen receptor transiently during development. Estrogen receptor levels peak during the first postnatal week and decline thereafter. Peak estrogen receptor levels correspond to the occurrence of apoptosis in the cerebral cortex. We therefore, examined the role of estrogen in the regulation of a key cell suicide receptor, the Fas/Apo[apoptosis]-1 receptor. Fas initiates apoptotic cell death in lymphoid tissue without *de novo* mRNA or protein synthesis, suggesting that this receptor is mechanistically proximate to the initiation of cell death. Organotypic explants of the peri-septal cerebral cortex, cultured from postnatal day one rats, were maintained in a humidified roller tube assembly for 6 days. Estrogen was administered on days 2, 4 and 6. Fas mRNA-expressing cells were identified by *in situ* hybridization. Estrogen administration significantly ( $p < .05$ ) increased (by 360%) the number of cells expressing Fas mRNA in the cingulate cortex. In contrast, retinoic acid administration did not yield a significant increase in the numbers of Fas mRNA-expressing cells. These results suggest that estrogen may rescue Fas mRNA-expressing cells that ordinarily die in control cultures. Our current research is focused on the elucidation of the intracellular signaling pathways mediated by Fas in the developing cerebral cortex. Supported by funds from Texas A&M Health Science Center.

## 302.15

**DISTRIBUTION AND ONTOGENY OF NADPH-DIAPHORASE POSITIVE NEURONS IN THE RAT BRAINSTEM** J.X. Zhu, L. Lin, M.F. Zhou, H. Zhang, X.T. Zhou and Z.P. Sun\*. Departments of Physiology and Anatomy, Henan Medical University, Zhengzhou 450052, P.R.C

The experiment studied the distribution of NADPH-diaphorase (NADPH-D) positive neurons of brainstem in adult rats and the ontogeny of them in rats of the first postnatal month with NADPH-D histochemistry and computer graphic analysis system. Adult rats of 60 days and rats at the ages of 1, 3, 5, 7, 9, 13, 20 and 30 days were used. The rats were treated with routine method, and the frozen sections of the brainstem were stained for NADPH-D activity. In the adult rats the NADPH-D positive neurons mainly distributed densely in the pedunculopontine tegmental nucleus (PPTg), laterodorsal tegmental nucleus (LDTg), dorsal raphe nucleus (NDR), laterodorsal central gray (LDCG) and superficial gray layer of superior colliculus (SuG). A few of positive neurons were found in the interpeduncular nucleus (NIPG). On the first day after the rats' birth, the NADPH-D positive neurons were found only in the LDTg. From the second day after birth the positive neurons also appeared in the PPTg, NDR, LDCG and SuG. In the first 9 postnatal days the numbers and density of the neurons increased with the age, reaching a peak at the 9th day after birth. There was no obvious difference between the adult rats and the rats at the ages of 9, 13, 20 or 30 days. The results indicated that NO may take part in the functional regulation and developing process of the brainstem.

**Rapid and transient downregulation of a cerebral cortical gene by estrogen identified by differential display PCR.** G.M. Berbari, K.W. Peebles, & F. Sohrabji\*. Dept. of Human Anatomy & Medical Neurobiology, Texas A&M University Health Science Center, College Station, TX 77843.

We are interested in the molecular actions of estrogen on forebrain cholinergic circuits that mediate cognitive functions. Our current strategy is based on the analysis of novel estrogen-responsive genes, with a view to identifying early events in a hormone-stimulated cellular cascade. Here we describe a cerebral cortical gene rapidly and transiently downregulated by estrogen. Adult ovariectomized (OVX) females were exposed to either estradiol (10  $\mu\text{g}$ ) or vehicle (sesame oil) and sacrificed 4 (4h) or 52 (52h) hours later. DNase-treated cerebral cortical RNA was reverse transcribed and amplified using a modification of the differential display technique. Gel autoradiograms revealed a ~650bp cDNA strongly expressed in OVX animals and to a lesser extent in the 52h group. However, this cDNA was conspicuously absent in the 4h group. Northern blot analysis, using this cDNA as probe, revealed hybridization to 18S rRNA as well as a ~4.2 kb transcript. While hybridization to rRNA was unchanged by estrogen treatment, hybridization to the 4.2 kb transcript was almost absent in the 4h group. Restriction mapping of this cDNA based on sequence analysis of a single clone indicated the presence of two separate cDNAs each of 650bp. One cDNA was found to be identical to 18 rRNA. Sequence analysis of the other cDNA (called C650 $\beta$ ) indicated significant (65%) homology to the human gene coding for iduronate sulfatase (IDS). IDS has been linked to Hunter's syndrome, a genetic disorder characterized by short stature, mental retardation and deafness. Cerebral cortex-specific cDNA libraries are currently being screened to identify the full length clone related to C650 $\beta$ , and to determine its relatedness to IDS. Supported by funds from the Texas A&M University Health Science Center.

## 302.14

**SEX STEROID RECEPTORS AND NITRIC OXIDE SYNTHASE IN THE PREMAMMILLARY NUCLEUS OF THE NEWBORN MALE AND FEMALE RAT** Makoto Yokosuka\* and Shinji Hayashi. Dept. Anat. Embryol, Tokyo Metropol. Inst. Neurosci, Tokyo 183.

The distribution of the estrogen- and androgen receptors (ER and AR), aromatase (AROM) and neuronal nitric oxide (NO) synthase (nNOS) was studied in dorsal and ventral premammillary nuclei (PMd and PMv) of the newborn (the day of birth to postnatal day 7) rat by immunohistochemistry. In the intact male, nNOS immunoreactivity (-IR) was present both in the PMd and PMv, while AR-IR was detected only in the PMv. On the other hand, ER-IR and AROM-IR were scarcely encountered in the both PMd and PMv. By double immunostaining of AR and nNOS, all the nNOS-IR cells in the PMv contained AR-IR. In the intact female, the nNOS-IR was also present in the both PMd and PMv, but neither ER-, AR-, nor AROM-IR were detected. When the male pup was castrated neonatally, no AR-IR was detected in the PMv. Subcutaneous injections of 5-alpha-dihydrotestosterone induced strong AR-IR in the castrated male and the intact female pups. On the contrary, the intensity of nNOS-IR stayed unchanged among these animals.

Neonatal androgen and NO has been considered important to brain development. Moreover, in male rodents, involvement of PMv in aggression and mating behavior has been reported. Together with the fact that the AR-IR and nNOS-IR were found in the same neurons in the PMv, involvement of this nucleus in masculinization of the brain by non-aromatizable androgen is suggested.

## 303.1

# **AFFERENT ARRIVAL AND THE ONSET OF FUNCTIONAL ACTIVITY IN THE TRIGEMINOTHALAMIC PATHWAY OF THE RAT**

C.A. Leamey, S.M. Ho and R.F. Mark\*, Developmental Neurobiology, RSBS, ANU, Canberra, 2601, ACT Australia

An *in vitro* slice preparation has been developed which permits the study of the anatomical and functional development of the trigeminothalamic pathway. Wistar rats ranging between embryonic day (E)15 and postnatal day (P)2 were used. The anatomical development of the trigeminothalamic pathway was traced with 3% biocytin. Tracing studies revealed that the most rostral trigeminal fibres had reached the cephalic flexure by E15, and by E16 were in the diencephalon, ventral to the thalamus. By E17 a few fibres had entered the thalamus where they terminated in unbranched growth cones. Fibres had begun branching by E18 and arbors were more elaborate by E19. Functional development was studied by recording evoked potentials from VPM following stimulation of the trigeminal nerve (5n) and principal sensory nucleus (Pr5). Postsynaptic responses to stimulation of 5n and Pr5 could first be recorded at E17. Reliable responses to stimulation of 5n were recorded from E18 onwards. Stimulation of Pr5 permitted both axonal and postsynaptic responses to be recorded in VPM. The postsynaptic response was reversibly blocked by the addition of 3mM cobalt. The addition of 50µM bicuculline increased the amplitude and duration of the response at all ages studied. Much of the excitatory response was blocked by application of 50µM AP5 (NMDA receptor antagonist) in animals P0 and younger. By P1, a significant component of the response was insensitive to AP5. This latter component was blocked with DNQX (10µM; non-NMDA antagonist). In conclusion, these results demonstrate that the capacity for axonal conduction in the trigeminothalamic fibres and synaptic transmission in the thalamus are present from the time when anatomical connections are made at E17.

## 303.3

# **EFFECTS OF GABA<sub>A</sub> AGONIST APPLICATION ON DEVELOPMENT AND PLASTICITY OF RAT BARREL CORTEX**

P. Golshani, H. Truong, S. Akbarian\*, and E.G. Jones, Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Several studies have shown that GABA may play an important role in the development and plasticity of the mammalian CNS, either by modulating synaptic activity as a neurotransmitter, or by acting as a neurotrophin. GABA<sub>A</sub> receptor subunits are expressed at high levels during the early postnatal days in the rodent barrel cortex, indicating that early in development GABA may act to direct and confine thalamic afferents to individual barrels, or through an activity dependent manner modulate the maintenance or elimination of synapses. To examine the role of GABA in the formation of cortical barrels, Elvax loaded with the GABA<sub>A</sub> agonist muscimol was implanted over the left primary somatosensory cortex of P1 rats. Tangential sections of barrel cortex were either processed for cytochrome oxidase histochemistry or for *in situ* hybridization histochemistry using riboprobes directed against the  $\alpha 1$ ,  $\beta 2$ , and  $\gamma 2$  subunits of the GABA<sub>A</sub> receptor. Infusion of muscimol during the first 12 days of life did not alter the morphology of cortical barrels as determined by CO histochemistry or alter the expression of GABA<sub>A</sub> receptor subunits  $\alpha 1$ ,  $\beta 2$ , and  $\gamma 2$ . To examine the effects of GABA on plasticity of barrel cortex, the C row of whiskers of P1 rats was ablated by cauterization and muscimol loaded Elvax was implanted over the corresponding primary somatosensory cortex. In tangential section processed for cytochrome oxidase histochemistry no change was found in the ratio of cortical area representing the ablated whiskers to the cortical area representing the non-ablated whiskers compared with non-Elvax implanted controls. Higher resolution studies of afferent and efferent axon terminal morphology of muscimol treated barrel cortex will be necessary to delineate a role for GABA during cortical development. Supported by NS21377.

## 303.5

# **ORAL SOMATOSENSORY INNERVATION IN *trkA*, *trkB*, OR *trkC* KNOCKOUT MICE. S. Matsuo\*, T.A. Henderson, T.M. Mosconi, I. Silos-Santiago, M. Barbacid & M.F. Jacquin, Neurology and Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110; Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.**

The development of the mammalian peripheral nervous system is dependent upon access to specific neurotrophic factors. Prior studies of spinal systems suggest that nociceptive, tactile and proprioceptive endings fail to develop in mice homozygous for gene deletion of the high-affinity neurotrophin receptors *trkA*, *trkB*, or *trkC*, respectively. Little is known of the neurotrophic requirements of developing oral somatosensory afferents. Innervation patterns were assessed in *trk* knockout mice by immunohistochemistry for CCRP, substance P, and neurofilament protein-200. *trkA* homozygotes lacked stained fibers in the incisor tooth pulp and had only sparse innervation of the periodontal ligament, whereas heterozygotes and wild-type controls displayed many stained fibers in these same structures. Thin fibers in the palate were also diminished. *trkA* deletion had no obvious effect on the Ruffini endings in the periodontal ligament or the Meissner corpuscles in the palate. Thus, the *trkA* receptor may mediate the neurotrophic signal required for the development of dental innervation. Moreover, in every *trk* knockout preparation examined to date, masseter muscles contained spindle-like structures. The presence of jaw muscle spindles in *trkC* knockouts was surprising, given prior reports of a complete absence of skeletal muscle spindles and afferent fibers in these animals. Perhaps muscle spindle afferents in the trigeminal and spinal systems have differing neurotrophic requirements and associated receptors, as suggested by the data presented in the accompanying abstract (Arends et al.).

## 303.2

# **EFFECT OF NITRIC OXIDE INHIBITION ON PLASTICITY IN THE RAT**

FIRST SOMATOSENSORY (S1) CORTEX. N.W. Sohn<sup>3</sup>, P.J. Hand<sup>2</sup>, J.H. Greenberg<sup>1</sup>, <sup>1</sup>Cerebrovascular Research Ctr., School of Medicine, <sup>2</sup>Dept. of Animal Biology, School of Veterinary Medicine, Univ. of Pennsylvania, Phila., PA 19104, & <sup>3</sup>Dept. of Anatomy, College of Oriental Medicine, Kyung Hee Univ., Seoul, Korea

It has been previously shown that deafferentation of the vibrissae, sparing a single whisker, in neonatal rats leads to a significantly larger metabolic representation of the spared vibrissa in the S1 "barrel" cortex. Nitric oxide has been implicated in development of long-term potentiation and in learning. Its possible role in plasticity has not been examined. We chose to examine the effect of chronic nitric oxide inhibition on the deafferentation-spared whisker metabolic representation in S1. Ten Sprague-Dawley rats received vibrissae deafferentation on postnatal day (PND) 1 (birthdate=PND0) sparing C3 (SC3) unilaterally. Half of the animals received daily intraperitoneal injections of the nitric oxide synthase (NOS) inhibitor L-nitroarginine (20 mg/kg), while the remaining animals received saline. Six weeks post deafferentation, the treatment was terminated, and 3 days later the rats underwent bilateral C3 stimulation with a yoked mechanical stimulator (5 Hz). Local glucose utilization was measured with [<sup>14</sup>C]2-deoxyglucose during stimulation. Glucose metabolic activity was localized in S1 barrel field using cytochrome oxidase staining. Treated animals showed a 97% inhibition of NOS catalytic activity within 3 days of treatment, and inhibition greater than 80% at six weeks. In both treated and control animals the metabolic representation of SC3 was significantly enlarged with respect to the contralateral control C3. Animals receiving NOS inhibition exhibited a 23% smaller increase in areal extent of the metabolic representation of SC3 than saline treated animals ( $p < 0.05$ ). Although chronic NOS inhibition does significantly attenuate the metabolic expansion of the representation of SC3 in S1 cortex, the effect is not large, suggesting that nitric oxide does not play a major role in somatosensory functional plasticity. (Supported by NIH grant NS33785)

## 303.4

# **PATTERNS OF 2DG LABELING EVOKED BY SINGLE WHISKER DEFLECTION IN THE TRIGEMINAL SYSTEM OF MICE AT DEFINED POSTNATAL AGES. T.M. Mosconi\*, J.J. Christensen, M.F. Jacquin & T.A. Woolsey, Neurology & Neurological Surgery, Washington University School of Medicine, St. Louis, MO 63110.**

We previously demonstrated that passive whisker stimulation in 7-day old mice evokes functional activation in restricted and somatotopic foci principally in the barrel cortex revealed by high-resolution 2DG autoradiography and cytochrome oxidase histochemistry, respectively (Mosconi et al. '95). These results have been extended caudally along the trigeminal neuraxis and are being further compared to patterns of activation in actively whisking adults. 7-day old Swiss-Webster mice were injected with 0.5 mCi/5g body weight of (<sup>3</sup>H)2DG (for detailed methods see McCasland and Woolsey '88a) and, under gentle restraint, a whisker on the left mystacial pad was repeatedly stroked at ~2 Hz for 35 minutes. There was increased 2DG uptake in the appropriate barrel in the right S1 cortex, in the appropriate barreloid in the right VPM thalamus, and in the appropriate barrelettes in the left trigeminal brainstem subnuclei principalis, interpolaris and caudalis. Elevated levels were noted when the activated barrels, barreloids and barrelettes were compared to representations of adjacent whiskers. These data show that passive whisker stimulation in young mice effectively activates the somatotopically appropriate "cylinder" (Jacquin et al. '93) throughout the rostral-caudal extent of the trigeminal neuraxis. Experiments are in progress to evaluate the pattern resulting from "passive" whisker stimulation in later perinatal life (e.g., when whisking begins, ~P14) and in adults.

Supported by NIH NS 33939 and NS 17763.

# **NEONATAL CAPSAICIN EFFECTS ON INFRAORBITAL NERVE, PLASMA EXTRAVASATION & PRINCIPALIS RECEPTIVE FIELDS. J.W. Hu\*, J.A. DeMaro, C.L. Kwan, B.J. Sessle & M.F. Jacquin, Fac. of Dentistry, Univ. Toronto, Ontario M5G1G6; Neurol. & Center for Study of Nervous System Injury, Washington Univ. Sch. Med., St. Louis, MO 63110.**

Prior reports (Nussbaumer & Wall '85; Kwan et al. '96), based upon capsaicin treatment, suggest that unmyelinated primary afferents contribute to the development of single whisker-dominant receptive fields (RFs) in the barrel cortex and trigeminal nucleus principalis. Insofar as capsaicin toxicity may not be limited to unmyelinated afferents, it is necessary to assess the properties of the whisker afferent nerve in animals displaying higher-order RF alterations. To begin to address this, we assessed neonatal capsaicin effects on the infraorbital nerve (by electron microscopic analysis of fiber spectra) and on plasma extravasation induced in ipsilateral skin by the inflammatory irritant and small fiber excitant mustard oil in adult rats displaying principalis RF changes. Two rats received 50 mg/kg capsaicin (in ethanol, Tween 80, saline) within 48 hr of birth, another vehicle only, and the other was untreated. The untreated and vehicle-treated rats averaged 19,111 myelinated and 9,697 unmyelinated fibers; they also showed 1-whisker principalis RFs, and ipsilateral plasma extravasation that was 5 times that in contralateral control skin. The capsaicin cases averaged 20,373 myelinated and 1,473 unmyelinated fibers and, consistent with our recent data (Kwan et al. '96), showed multi-whisker RFs and much reduced (2.3 times control) plasma extravasation. Thus, unmyelinated fibers were selectively and significantly reduced in the infraorbital nerves of cases with reduced plasma extravasation and higher-order RF alterations. These data add further evidence that unmyelinated fibers may be necessary for normal RF development in the whisker-barrel neuraxis. Supported by NIH DE04786, DE07734, DE07662.

## SEQUENTIAL TIMING OF GAP-43-IR IN DEVELOPING CUTANEOUS INNERVATION OF THE MOUSE MYSTACIAL PAD

E.L. Rice<sup>1</sup>, B.T. Fudin<sup>2</sup> Dept. of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208; Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden S171 77.

Prior studies using reduced silver techniques have shown sequential development of cutaneous endings in mammals. However, recent immunocytochemical techniques have revealed far more innervation than was seen previously. Also, questions about the sequential differentiation of the sensory endings have become increasingly important in light of investigations on the impact of neurotrophins during development. To further assess this issue, the developing innervation in mystacial pads from newborn (P0), P6, P16 and P25 mice was analyzed with antibodies against growth-associated protein GAP-43 that is present in axonal growth cones during development. The total innervation was colabeled with antibodies against a ubiquitous neuronal cytoplasmic protein (PGP 9.5) which labels all known peripheral innervation. Large caliber axons that supply Merkel and lanceolate endings to the whisker follicles showed GAP-43-LIR at all ages studied. However, during the first postnatal week the intensity was high and gradually declined to a fairly low intensity by P25. In contrast, the Merkel terminals showed high intensity GAP-43-LIR at all ages which increased at P25, suggesting that these endings might be undergoing a continuous turnover at least during the first four weeks postnatally. Medium caliber axons that supply reticular and circular lanceolate endings showed a different timing in the expression of GAP-43-LIR. Only a weak GAP-43-LIR was evident at birth in the reticular afferents. GAP-43-LIR increased in intensity within the reticular endings over the next two weeks then declined. Circular lanceolate endings, which terminate in the inner conical body of the whisker follicle were not present until P2. These endings showed intense GAP-43-LIR only at P6. The epidermis receives several types of unmyelinated as well as small caliber myelinated innervation. At birth, the epidermal innervation was intensely labeled with GAP-43. Within a week, the intensity dropped in the epidermis but remained high in the superficial dermis. At P16 and P25, no profiles in the epidermis were GAP-43 positive. These observations indicate the various sensory endings in the mystacial pad have different developmental and maturational dynamics with regards to GAP-43 expression.

## 303.9

TRIGEMINAL GANGLION NEURONAL ACTIVITY AND SATELLITE CELL GFAP RESPONSES, TO INFERIOR ALVEOLAR NERVE CRUSH, E.H. Chudler<sup>1</sup>, L.C. Anderson<sup>2,3</sup> and M.R. Byers<sup>1,2,3\*</sup>, Depts. of Anesthesiology<sup>1</sup>, Oral Biology<sup>2</sup> and Biological Structure<sup>3</sup>, Univ. Washington, Seattle, WA 98195.

Injury to peripheral branches of the trigeminal nerve may cause abnormal sensory phenomena such as paresthesia and pain. The present study investigates the time course of electrophysiological and glial fibrillary acidic protein immunoreactivity (GFAP-IR) alterations within the trigeminal ganglion (TG) after crush injury to the inferior alveolar nerve (IAN). After recovery periods of 3, 10 or 59 days, rats were anesthetized and prepared for acute, extracellular recording from the TG. Following acute recording, the TG were fixed and removed for GFAP-IR processing. By 10d after IAN crush, regenerating neurons responded to mechanical and electrical stimuli of their innervated tissues, but with slower conduction velocities and higher thresholds than normal. These abnormal properties persisted at 59 days. In all groups 3-4% of the neurons had spontaneous activity. There was intense GFAP-IR in satellite cells of almost all neurons in the mandibular division at 3d, 30-50% at 10d, and 10-30% at 59d. At 3 and 10 days GFAP-IR was also found in satellite cells of 2-10% of maxillary neurons despite normal neuronal electrophysiological properties. Although altered neuronal physiology was recorded in the same region as the greatest GFAP-IR response, the satellite cell reaction spread further into areas of apparently normal electrophysiology. (Supported by NIH DE05159 to MRB).

## 303.11

CAN DORSAL ROOT AXONS SURVIVE AFTER BEING DEPRIVED OF CENTRAL AND PERIPHERAL TROPHIC FACTORS. R.E. Coggeshall<sup>1\*</sup>, G. Kendall<sup>2</sup>, and C.J. Woolf<sup>2</sup>, Dept. of Anat. and Neurosci., Univ. Tex. Med. Br., Galveston, Tx. 77555, USA<sup>1</sup> and Dept. of Anat. and Dev. Biol., Univ. College London, WC1E 6BT, UK<sup>2</sup>.

In previous work, we showed no loss of dorsal root (DR) axons within 16 weeks after peripheral nerve section. This raised the question as to whether survival of these axons, as well as the cells that give rise to them, could be due to trophic factors from the spinal cord. Accordingly, we determined mean numbers of L4 and L5 DR axons 4 and 8 weeks following sciatic N (PN) section + L4 and L5 DR lesions or dorsal root lesions alone in adult rats:

	Naive	4 week DR cuts	4 week PN and DR cuts	8 week DR cuts	8 week PN and DR cuts
MY	5048	4702	5317	4735	5385
UN	9756	8517	13099	9779	10925

Thus there is no evidence for loss of dorsal root axons 4 and 8 weeks following either DR section alone or PN + DR section. Our preliminary conclusion is that adult dorsal root axons and presumably the cells that give rise to them do not depend for their survival on either peripheral or central trophic factors within the time frame of this experiment. We have measured BDNF, NGF and NT3 mRNAs in the DRG, and this upregulation induced by the lesions may promote cell survival. Supported by NIH grants NS10161, NS11255 and the Medical Research Council, UK.

## 303.8

CELL SURVIVAL IN TRIGEMINAL BRAINSTEM NUCLEI OF *trkA*, *trkB*, OR *trkC* KNOCKOUT MICE. J.J.A. Arends<sup>\*</sup>, T.A. Henderson, J. Silos-Santiago, M. Barbacid & M.F. Jacquin. Neurology and Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110; Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.

Nociceptive, proprioceptive, and tactile afferents in dorsal root and trigeminal ganglia require NGF, BDNF, NT-3, and/or NT-4 for their survival. In mice homozygous for gene deletion of the high-affinity neurotrophin receptors *trkA*, *trkB*, or *trkC*, corresponding cell losses occur. Perhaps most impressive is the complete absence of proprioceptive afferents innervating stretch and tension receptors in skeletal muscle of *trkC* knockout mice. However, in these preparations, little is known of the fate of jaw muscle afferents whose distinct pseudounipolar cell bodies constitute the mesencephalic trigeminal nucleus (MesV). Nor is there information on the transsynaptic effects of these gene deletions upon trigeminal brainstem neurons. Nissl-stained profiles of cell bodies with nucleoli were counted blind to genotype in complete series of paraffin-embedded "thin" sections from 11 mice. 6 wild-type or heterozygote controls averaged 638 MesV cell profiles (range: 529-813). 1 *trkA* knockout had 612 MesV cells. 1 *trkB* knockout had 424 MesV cells. 3 *trkC* knockouts had 255, 301, and 310 MesV cells. Cell numbers in the principal and spinal trigeminal nuclei will be reported. These preliminary data suggest that while MesV cells are significantly reduced in number by *trkC* deletion, they are certainly not absent. Therefore, unlike skeletal muscle afferents, many jaw muscle afferents survive the *trkC* knockout (see accompanying Matsuo et al. for stained afferent fibers and spindles in the masseter muscles of these mice). Perhaps *trkB* receptors mediate neurotrophic actions on some jaw muscle afferents, as suggested above. Supported by NIH DE07734, DE07662, NS17763.

## 303.10

EXPRESSION OF GUANOSINE 3',5'-CYCLIC MONOPHOSPHATE-DEPENDENT PROTEIN KINASE I $\alpha$  AND NITRIC OXIDE SYNTHASE IN THE DEVELOPING CHICK EMBRYO. Bonnie L. Firestein<sup>\*</sup> and David S. Bredt. Department of Physiology, UCSF, San Francisco, CA 94143-0444.

We have studied the distribution of guanosine 3',5'-cyclic monophosphate-dependent protein kinase type I $\alpha$  (cGKI $\alpha$ ) and nitric oxide synthase (NOS) in the embryonic chick. In order to identify the onset of cGKI $\alpha$  expression, embryonic day 3-12 chicks were fixed with 4% paraformaldehyde for 4 hours and cryoprotected with 20% sucrose in PBS for 16-18 hours. Embryos were sectioned at 20  $\mu$ m (sagittally or horizontally) using a cryostat. Serial sections were stained using an antibody raised against cGKI $\alpha$  (polyclonal rabbit) and were visualized using an avidin-horseradish peroxidase conjugate and diaminobenzidine tetrahydrochloride as a chromagen. These immunohistochemical studies suggest that cGKI $\alpha$  expression is restricted to embryonic chick trigeminal (TG) and dorsal root ganglia (DRG) as early as E5 and expression continues to be present up to E12. Sections were also assayed for the presence of NOS using  $\beta$ -NADPH diaphorase histochemistry. Unlike cGKI $\alpha$ , NOS is absent from TG and DRG E7 and earlier, but it is present on E10. Since sensory ganglia begin to condense at E3, and apoptosis of neurons commences at E4.5 and continues to E12, this pattern of expression may suggest a role for cGKI $\alpha$  and NOS in TG and DRG development. (Supported by grants from NSF, NARSAD)

## 303.12

GALANIN AND GALANIN MESSAGE ASSOCIATED PEPTIDE (GMAP) IN SENSORY GANGLIA DURING RAT EMBRYOGENESIS. Z.-Q. Xu, T.-J. Shi, P. Wallén<sup>\*</sup> and T. Hökfelt, Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

Galanin, a 29 amino acid peptide, has a wide spread distribution in the nervous system. However, little is known about expression of galanin during ontogenesis. In this study the distribution of galanin/GMAP-like immunoreactivities was investigated in the fetal rat at embryonic days 12, 15, 17, 19 and 21 using immunohistochemistry, mainly focusing on sensory ganglia. We found that galanin/GMAP immunoreactivities were expressed in dorsal root ganglia and the trigeminal ganglia at embryonic days 15, 17 and 19. Galanin/GMAP were also present in the intestine, in the retina as well as in several other regions of the central nervous system, in some areas as early as embryonic day 12. Galanin binding sites were observed in the dorsal horn of the spinal cord at embryonic day 19. Our results suggest that galanin/GMAP may exert developmental roles in sensory neurons and other neuronal systems. (Supported by the Swedish MRC 04X-2887.)

THE NERVE REGENERATION OF PIG FREE SKIN GRAFT C.L. He\*, W.R. Kennedy, G. Wendelschafer-Crabb Dept. of Neurology, Sch. of Med., Univ. of Minnesota, Minneapolis, MN 55455.

The regeneration of nerves in free skin flaps with 3 mm in diameter in the pig was investigated by indirect immunohistochemical technique, using antisera to protein gene product 9.5 (panneural), to calcitonin gene-related peptide (sensory neurons), to substance P (sensory neurons), and to vasoactive intestinal peptide (sympathetic neurons). Digitized images were taken with laser scanning confocal microscope (LSCM). Using these techniques, the three-dimensional distribution of regenerating nerves within a thick section was studied. The normal pig skin is innervated with big bundles of nerves in the deep dermis which give out small nerve bundles in the superficial dermis. The nerves in the superficial dermis are running into the epidermis more or less perpendicularly to the surface. Hair follicle, big blood vessels in the deep dermis and erector pili muscles innervated with nerves are observed. No sweat gland is observed in the pig skin. No regenerating nerves in the graft were observed in the first week. However, the nerve have started to regenerate from the normal edge toward the graft at first week. At the second, third and forth week, regenerating nerves are gradually covering more area of the graft. The regenerating nerves around the basement membrane in the epidermis and superficial dermis grow more fast than the nerves in the deep dermis. Most regenerating nerves come from the normal margin. Only a few regenerating nerves are from the base of the graft. At five and six week, some nerves in the epidermis and superficial dermis start to retract but nerves in regenerating are still can be encountered. The architecture of regenerating nerves are much more near normal. But the reinnervation remain patchy and inadequate in some area of the graft. Supported by NS 26348, NS 31397 and Toray Industries Inc..

## 303.15

CALCIUM-BINDING PROTEIN IMMUNOLocalIZATION IN FOETAL AND ADULT HUMAN SPINAL CORD. P. Rizzonelli<sup>1</sup>, P. Liberini<sup>1</sup>, G. Vezzoli<sup>1</sup>, L. Novelli<sup>1</sup>, G. Moretto<sup>2</sup>, M. Memo<sup>1</sup>, and P.F. Spano<sup>2</sup>, <sup>1</sup> Div. of Pharmacol., Dept. Biomed. Sci. and Biotech., Brescia University School of Medicine, 25123 Brescia; <sup>2</sup> Section Neurology, Dept. of Neurol. and Visual Science, Verona University School of Medicine, Verona, Italy.

Calcium-binding proteins are widely distributed in the central nervous system and are considered to play important roles in the modulation of transmembrane and intracellular signaling. Monoclonal antibodies raised against Parvalbumin (PV), Calmodulin (CM) and Calbindin D-28K (CB-D28K) have been used to determine and compare the immunohistochemical expression of these calcium-binding proteins in foetal (6, 10, 12, and 22 weeks of gestation) and adult human spinal cord. In foetal spinal cord PV immunoreactivity was observed in regions containing primary sensory afferents: the dorsal root ganglia neurons, the dorsal and dorsolateral funiculi and restricted regions of dorsal horn. At this stage, immunoreactive fibers with a dorsoventral orientation through the middle of the dorsal horn were observed. In adult spinal cord a pattern of PV fibre immunoreactivity was localized in the superficial layer of dorsal horn (lamina I, II) and lamina X but not in dorsal and dorsolateral funiculi and in the dorsal root ganglion. CM immunoreactivity was found in the dorsal and dorsolateral funiculi in the mantle layer and in ventral horn but not in dorsal root ganglia. In adult spinal cord CM immunoreactivity appeared in lamina II and in neurons of lamina VII. In foetal stages CB-D28K cellular immunoreactivity was localized in subependymal position. In all this areas the maximum level of immunostaining was found at the 12th weeks of gestation. Overall, our data revealed a specific pattern of expression with different distribution and overlappings. The transient selective pattern of PV, CM and CB-D28K immunoreactivity may disclose some relevant functions of these calcium-binding proteins during somatosensory pathway development. This research was supported by the Italian Study Group on Paraplegia.

## 304.1

ALTERED EXPRESSION OF C-FOS IN THE LATERAL GENICULATE NUCLEUS OF RED-LIGHT-REARED TREE SHREWS. J.L. D'Arcy and H.M. Petry. Departments of Psychology and Ophthalmology & Visual Science, University of Louisville, Kentucky 40292

Objectives were to: 1) clarify the functional organization of chromatic and achromatic channels in tree shrew (*T. belangeri*) LGN, and 2) study permanent effects of early post-natal rearing in deep red light that does not stimulate short-wavelength-sensitive (SWS) cone photoreceptors. Due to differential input of the tree shrew's 2 cone types (SWS and LWS) to its chromatic and achromatic channels, red-light-rearing (RLR) produces biased stimulation of the LWS-cone-driven achromatic channel. Prior work showed permanent effects of RLR in retina, cortex and in visual abilities (Petry & Kelly, '91; Petry, '93; Petry & Murphy, '95).

Expression of c-fos is elevated (from basal levels) following novel visual stimulation. We assessed changes in c-fos levels following 1 hr. of alternating blue/yellow (B/Y; 455nm/555nm) stimulation using immunocytochemical methods (c-fos (Ab-2), Oncogene). Brain tissue from 9 adult animals represented 4 groups: WL (normally-reared, white-light housed); RL (normally reared, red-light housed for 4-43 days); RL-B/Y (normally-reared, red-light housed for 4-7 days, B/Y stimulated prior to perfusion); and RLR-B/Y (red-light-reared, B/Y stimulated prior to perfusion). Results in control animals (groups WL & RL) revealed very light and uniform basal c-fos immunoreactivity (c-fos IR) across all layers of the dLGN and vLGN. RL-B/Y shrews showed consistently dark c-fos IR in layers 1, 2, 4, and 5 of the dLGN (and occasional dark cells in layer 6) as well as a band of cells in the parvocellular lamina of vLGN (likely due to rod stimulation). RLR-B/Y shrews revealed light, uniform staining like controls. These results suggest: 1) color-opponent information is likely to be processed in layers 1, 2, 4, 5, and not konio layer 3; and 2) lack of SWS cone stimulation during early post-natal development, and the corresponding competitive advantage of the achromatic channel, permanently changes c-fos expression in central visual structures. Supported by NSF grant #OSR-9452895 and Univ. of Louisville.

## 303.14

GLIAL GROWTH FACTOR RESCUES MECHANORECEPTOR SCHWANN CELLS FROM DENERVATION-INDUCED APOPTOSIS. D.M. Kopp\*, J.T. Trachtenberg and W.J. Thompson. Dept. Zoology, Univ. Texas at Austin, Austin, Texas 78712.

Golgi tendon organs and Pacinian corpuscles are encapsulated mechanoreceptors whose sensory endings are closely associated with S-100 immunoreactive cells presumed to be Schwann cells. Previous studies have shown that both types of receptors disappear and do not reform if denervated during a critical period in early postnatal development. We have investigated the response to denervation of Schwann cells in Golgi tendon organs and Pacinian corpuscles in the lower hindlimb of neonatal rats. Within 24 hours following sciatic nerve resection, the S-100 positive Schwann cells of these mechanoreceptors undergo apoptosis: the cells and their nuclei fragment, as detected by the TUNEL technique. 3 days later the cells have completely disappeared. Subcutaneous administration of the neurotrophic glial growth factor-2 (GGF-2) into the hindlimb after denervation rescues many of these cells from apoptosis. This rescue suggests that neurotrophins derived from the afferent axons are necessary for the survival of these Schwann cells, just as terminal Schwann cells at the neuromuscular junction appear to be dependent on motor axon-derived neurotrophin (Nature, 1996, 379:174). Our studies also suggest that the inability of these mechanoreceptors to reform following neonatal denervation may be related to the death of their associated Schwann cells. Supported by NIH. We acknowledge Cambridge Neuroscience for GGF-2.

## 303.16

MATURATION OF THE BIPHASIC BEHAVIORAL AND HEART RATE RESPONSES IN THE FORMALIN TEST IN THE RAT G.A. Barr\* Hunter College and NY State Psychiatric Institute 722 W. 168th St. New York, NY 10032.

Injection of formalin into the hindpaw of the adult rat produces a biphasic nociceptive response. There is an initial reaction that lasts approximately 10-15 minutes, a subsequent decrease in the response, and a second phase of increased nociceptive behavior. This pattern is seen when either behavior, heart rate or blood pressure is measured. The neural mechanisms that underlie the two phases of nociceptive responding, which have been studied intensively in the adult, are not likely to be fully functional in the infant. We examined the maturation of the nociceptive response, over a 60 minute period, after injection of formalin into the hindpaw of 7, 14 or 21 day old rats. Both behavior and heart acceleration were dependent measures. At all ages formalin injection elicited an initial behavioral response that was constant during development. At 7 and 14 days of age, however, there was no evidence of the second nociceptive stage. At 21 days of age both the early and late phases were present, and the time course of the response was similar to that reported for the adult. Formalin injection also induced a tachycardia that declined linearly with time at all ages; there was no evidence of a biphasic cardiac response at any age. These data are consistent with the known development of excitatory amino acid receptors in the spinal cord, and of the late maturation of autonomic control of phasic heart rate.

Supported by grant DA07646 and funds from PSC-CUNY.

DEVELOPMENTAL CHANGES IN SPONTANEOUS EPSCs DURING ON/OFF SUBLAMINATION IN THE FERRET LATERAL GENICULATE NUCLEUS. C. D. Hohnke\* and M. Sur, Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

In the lateral geniculate nucleus (LGN) of the ferret, retinal afferents segregate into ON and OFF sublaminae during the third and fourth postnatal weeks; this segregation depends on neuronal activity. To better understand the development of synaptic transmission during this period of remodeling, we have recorded spontaneous excitatory post-synaptic currents (sEPSCs) from LGN relay cells (n=15) in animals ranging in age from postnatal day 15 (P15) to P29 using whole-cell patch clamp techniques in slices.

No change was observed in the input resistance (mean ± s.e.m., 161.9 ± 27.1 MΩ; r=0.28, p=0.38) or resting membrane potential (47 ± 1.91 mV; r=-0.45, p=0.09) of these neurons with age. sEPSC frequency did not change significantly during this period (2.2 ± 0.5 Hz; r=-0.17, p=0.55). However, the mean sEPSC amplitude increased (by ~40%; r=0.62, p<0.05) and the mean width decreased (by ~40%; r=-0.52, p<0.05; see figure: each trace is an average of 50 consecutive sEPSCs in 1 cell) with age. Additionally, the standard deviation of sEPSC width decreased (by ~60%; r=-0.54, p<0.05) during this period. These changes may reflect a process of synaptic reorganization accompanying retinogeniculate pattern formation: retinal axon synapses might withdraw from distal locations on LGN cell dendrites and concentrate near the soma, where they are known to cluster in the adult. Supported by EY07023.

## 304.3

ON/OFF SUBLAMINATION IN THE FERRET LGN IS INDEPENDENT OF SYSTEMIC CHANGES IN BLOOD PRESSURE AND REQUIRES NEURONAL NOS. **K. S. Cramer\*** and **M. Sur**, Department of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Blockade of nitric oxide synthase (NOS) with N-Nitro-L-Arginine (L-NOArg) during the third and fourth postnatal weeks in the ferret disrupts the formation of ON/OFF sublaminae (Cramer and Sur, 1994). Because NO is a potent vasodilator, we examined the role of systemic changes in blood pressure on sublamination during systemic treatment with L-NOArg. Mean arterial blood pressure (MAP) was measured during the fourth postnatal week in four animals treated with 40 mg/kg/day i.p. L-NOArg from postnatal day 14 (P14) and in four normal, age-matched controls. MAP ( $\pm$  s.e.m.) increased from  $57.6 \pm 4.6$  mmHg to  $83.1 \pm 4.8$  mmHg following L-NOArg treatment. When animals received the antihypertensive calcium channel blocker verapamil, 5 mg/kg/day i.p., together with L-NOArg, blood pressure was normal ( $60.0 \pm 1.6$ ;  $n = 4$ ). In these animals, sublamination was assessed in sections of LGN contralateral to an intraocular injection of WGA-HRP; disruption of sublamination was similar to that seen in animals treated with L-NOArg alone, suggesting that NOS blockade-induced changes in retinogeniculate projections occur independently of changes in MAP.

Sublamination in the LGN relies at least in part on the neuronal form of NOS. Neuronal NOS immunohistochemistry was similar to NADPH-diaphorase histochemistry in its transient expression during retinogeniculate segregation. In addition, ON/OFF sublamination was disrupted by blockade of the neuronal form of NOS from P14 to P26 with 7-nitroindazole, which appears not to produce hypertension. While systemic changes in blood pressure are not involved in the segregation of sublaminae, further experiments are necessary to examine the role of local changes in cerebral blood flow produced by NO release. Supported by EY07023

## 304.5

POSTNATAL DEVELOPMENT OF SYNAPTIC PLASTICITY IN THE RAT SUPERIOR COLLICULUS: LONG-TERM DEPRESSION IN THE SUPERFICIAL LAYERS. **R. J. Cork\***, **R. S. Lo** and **R. R. Mize**, Anatomy Department and Neuroscience Center of Excellence, LSU Medical Center, New Orleans, LA 70112. We have been studying the development of the synaptic circuitry in the rat superior colliculus (SC) between ages P1 and P10. Using an in-vitro brainstem preparation, we have measured extracellular field potentials, and made whole-cell recordings of postsynaptic potentials, from the superficial layers of SC. We have also used immunocytochemistry and NADPH-histochemistry to map the development of various molecules thought to be involved in modulating synaptic transmission (i.e. NMDAR1, and NOS). Field potentials or post-synaptic potentials were measured following stimulation of optic tract (OT) fibers. Whole cell recordings showed EPSPs with two components. The later component was blocked by APV, suggesting that it was mediated by the NMDA receptor. NMDAR1 antibody also intensely labeled the neuropil of the superficial layers at P1. From P3 some neurons also showed an IPSP following the EPSP. The IPSP could be blocked by bicuculline, an antagonist of GABA<sub>A</sub> receptors. Between ages P1 and P8, tetanic stimulation (50 Hz, 20 s, submaximal intensity) induced a long-term (>90 min) depression (LTD) of the field potential and the EPSP. Neither APV (10  $\mu$ M or 50  $\mu$ M) nor bicuculline (10  $\mu$ M) could prevent LTD, suggesting that it is independent of either NMDA or GABA<sub>A</sub> receptor activation. Nitrendipine (5  $\mu$ M), an L-type Ca<sup>2+</sup>-channel blocker that blocks induction of LTD in the hippocampus, also failed to prevent LTD induction in the SC. The magnitude of the LTD decreased steadily from P1 to P8 and at P9/P10 tetanic OT stimulation induced a mixture of depression and long-term potentiation (LTP). Consistent with the idea that NOS promotes LTP, significant NOS expression was first observed in cells of the superficial layers at P9. Supported by DOD cooperative agreement DAMD 17-93-V-3013, NIH grant EY02973, and the LSU-MC Neuroscience Center.

## 304.7

ROLE OF RETINAL ACTIVITY IN MATURATION OF ELECTROPHYSIOLOGICAL MEMBRANE PROPERTIES AND SYNAPTIC RESPONSES OF FERRET LGN. **A. S. Ramoa\*** and **G. Prusky**, Dept. of Anatomy, Virginia Commonwealth University, Richmond, VA 23298 and Dept. of Psychology, University of Lethbridge, AB T1K3M4.

The adult form and function of the lateral geniculate nucleus (LGN) arise after extensive modifications in circuit organization that, in the ferret, occur during the first postnatal month. We have shown that electrophysiological membrane properties and synaptic responses in LGN neurons of the ferret change markedly during this critical period of development (J. Neurosci. 14:2089, 1994; J. Neurosci. 14:2098, 1994; J. Neurosci. 15:5739, 1995). These changes, which appear to be coordinated to facilitate circuit remodeling of LGN neurons, include: late maturation of low-threshold Ca<sup>2+</sup> spikes and inhibitory potentials as well as developmental switches in the expression of NMDA receptor isoforms. We examined whether these changes are regulated by retinal activity. Our method uses continuous intraocular application of tetrodotoxin starting as early as the day of birth to block spontaneous discharge of retinal ganglion cells. Whole-cell recordings in the LGN slice preparation revealed that maturation of low-threshold calcium spikes and hyperpolarization-activated currents was unaltered by a 3 to 4-week binocular infusion of tetrodotoxin. In contrast, synaptic properties were markedly affected. Treated animals at P40 were found to display long duration NMDA-EPSCs that resembled those present in normal newborn animals rather than the shorter-duration EPSCs seen in normal animals at similar age ( $P < 0.01$ ). Additionally, application of ifenprodil, which binds with higher affinity to heteromeric receptors containing the NR-2B subunit, blocked more potently NMDA-EPSCs in newborn and TTX-treated animals at P40 than in normal P40 animals ( $p < 0.01$ ), suggesting that a developmental switch in the subunit composition of the NMDA receptor is prevented by intraocular TTX. In conclusion, retinal activity may regulate developmental changes in synaptic properties of LGN neurons (NSF IBN-9421983).

## 304.4

ROLE OF SPONTANEOUS RETINAL ACTIVITY IN REORGANIZATION OF RETINOGENICULATE CONNECTIONS DURING DEVELOPMENT. **P. M. Cook\***, **G. Prusky** and **A. S. Ramoa**, Dept. of Anatomy, Virginia Commonwealth Univ., Richmond, VA 23298 and Dept. of Psychology, Univ. of Lethbridge, Lethbridge AB T1K3M4.

The adult form and function of the lateral geniculate nucleus (LGN) arise after extensive modifications in circuit organization that include segregation of axonal arbors from the two eyes into eye-specific layers. Previous studies have shown that intracranial infusion of tetrodotoxin (TTX) in fetal cats prevents segregation (Shatz and Stryker, 1988), suggesting that spontaneous action potential activity contributes to remodeling of the retinogeniculate pathway. We have examined the activity-dependent mechanisms of eye-specific segregation using a technique which allows direct inferences about the role of spontaneous retinal activity. Our method uses continuous intraocular application of TTX to block spontaneous discharge of retinal ganglion cells in newborn ferrets, which display retinogeniculate remodeling during the first 2 weeks of postnatal life. After a 2 week infusion, intraocular injection of horseradish peroxidase (HRP) revealed the projection pattern contralateral and ipsilateral to the HRP injected eye. Eye-specific segregation of retinogeniculate projections was observed at postnatal day 14 in controls as well as in ferrets that received monocular ( $n=3$ ) or binocular ( $n=1$ ) injection of TTX. However, segregation was aberrant in the monocularly injected animals. First, projections from the untreated eye occupied an approximately 50% larger volume of both LGNs than those from the TTX-treated eye. The total size of the LGN, however, remained unaltered and this suggests that the normal eye invaded territory normally occupied by the TTX treated eye. Moreover, a low density of afferents from the contralateral eye were observed to terminate in layer A1, which normally receives only ipsilateral eye input. These results suggest that binocular competition modulates rearrangements in retinogeniculate projections. Additionally, they are consistent with the hypothesis that spontaneous retinal activity may fine-tune segregation of retinal afferents into eye-specific layers. (Supported by NSF IBN-9421983)

INHIBITION OF NITRIC OXIDE SYNTHASE FAILS TO DISRUPT THE DEVELOPMENT OF CHOLINERGIC FIBER PATCHES IN THE RAT SUPERIOR COLLICULUS. **C. A. Scheiner\***, **R. J. Cork** and **R. R. Mize**, Dept. of Anatomy and the Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112.

Nitric oxide (NO) has been proposed to be a retrograde messenger involved in synaptic refinement during development. The patch-cluster system in the intermediate gray layer (IGL) of the superior colliculus (SC) is an excellent model for studying the role of NO because both the clustered neurons and one of the fiber systems (ACh) that form the patches contain NOS during development. We have used N<sup>G</sup>-nitro-L-arginine, an inhibitor of nitric oxide synthase (NOS), to determine if inhibition of NOS disrupts the formation of the ACh patches. Sprague-Dawley rats received 1-100  $\mu$ M of NOArg from birth until sacrifice at P10, P14, P18, P21-22, or P28. Control animals were litter mates of the experimental animals plus other younger and older animals. ACh fibers were identified using choline acetyltransferase (ChAT) immunocytochemistry and NOS containing cells were labeled with nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d) histochemistry. NADPH-d was expressed in cells within the periaqueductal gray (PAG) and the deep gray layer (DGL) of the SC by P4, the earliest age examined. By P9, many cells in the IGL expressed NADPH-d, while few in the superficial layers were labeled. Some of these neurons in the IGL formed obvious clusters, while others were loosely scattered throughout the layer. NADPH-d labeling in IGL cells declined by P14-P18 and virtually absent in the adult. ChAT labeled fibers first appeared in the IGL at P10 and were readily visualized by P14. At this age, the ChAT fibers were fairly uniformly distributed through the IGL, but by P18 they had a patch like distribution with as many as five patches spaced at 250-300  $\mu$ M intervals. Inhibition of NOS from birth produced no qualitative differences in the distribution or density of ChAT labeled fibers at any of the ages examined. We therefore conclude that NO does not contribute to the refinement of cholinergic fiber patches in the rat SC, probably because the fiber system is not glutamatergic. ## 304.8

CHOLINERGIC PROCESSES IN XENOPUS TECTUM. **M. J. Titmus\***, **L. Plehan**, **R. Lima** & **S. B. Udin**, Dept. of Physiology & Biophysics, SUNY, Buffalo, NY 14214.

The ipsilateral visual input to Xenopus tectum comes into register with the contralateral map during development. The major transmitter for the contralateral (retinotectal) input is glutamate, and the major transmitter for ipsilateral input, relayed via the nucleus isthmi, is probably acetylcholine. The role of NMDA receptors in the activity-dependent process of organization of the ipsilateral map is demonstrated by the ability of NMDA receptor blockers to prevent matching of the ipsilateral map to the contralateral map during the critical period, but little is known about the role of acetylcholine.

Immunohistochemistry indicates that nicotinic receptors are located in the layers of the tectum that receive binocular inputs; unilateral eye enucleation indicates that most of those receptors are located on retinotectal axons. Receptor binding using tritiated cytosine also indicates the presence of nicotinic receptors in the tectum. Muscarinic receptors are located on cells and dendrites located appropriately to receive isthmotectal input.

Calcium imaging using Fura-2 in tectal slices demonstrates no measurable response to nicotinic agonists alone, but shows significant synergism when nicotine or cytosine are applied with NMDA. In contrast, muscarinic agonists decrease calcium influxes elicited with NMDA. These results suggest that activity of isthmotectal axons can significantly modulate the effects of glutamate released from retinotectal axons.

**SP-RECEPTOR DISTRIBUTION PATTERNS IN THE SUPERIOR COLLICULUS OF DEVELOPING RATS, WITH SPECIAL REFERENCE TO ENUCLEATION EFFECTS.** R. Meguro and M. Norita. Dept. Neurobiology and Anatomy, Niigata Univ. Sch. Med., Niigata, 951, Japan.

We have reported that many neurons in the superior colliculus (SC) of the adult rat contain substance P-receptor (SPR), and most of those send fibers outside the SC (Meguro et al., 1993). Neurons with SPR in the SC are likely to receive fibers with SP which originate within the SC. Neurons with SPR, as well as those with SP, are also shown to receive retinal fibers, suggesting SPR-containing tectal outputs would be modulated by retinal afferents.

To clarify the influence of retinal afferents on SPR-containing tectal neurons, we examined developmental changes of the distribution patterns of SP and SPR-containing neurons in the SC with special reference to eye opening time or enucleation effects. The SP-containing neural elements began to be detected by postnatal day 8 and there were no marked changes after enucleation. On the other hand, many of the SC neurons containing SPR in their somata appeared around postnatal day 14, when eyes opened. In rats enucleated at birth, the SC neurons with SPR in their somata decreased in number and changed their morphological polarity. Thus, SP-activating/modifying efferent pathways from the SC were influenced by visual stimulation or visual deprivation. ## 304.11

**EFFECTS OF NEONATAL AND ADULT ENUCLEATION ON THE DISTRIBUTION OF NITRIC OXIDE SYNTHASE IN THE SUPERFICIAL LAYERS OF THE RAT SUPERIOR COLLICULUS.** R. Mendez-Otero\*, F. Tenório, A. Giraldo-Guimarães, W. M. Cintra, H. R. Santos, M. S. Soares. Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ 21941-590, Brazil.

Recent results indicate that nitric oxide (NO) can play an important role in neuronal excitability by modifying the strength of activated synapses. We sought to determine whether the level of nitric oxide synthase (NOS) could, in turn, be regulated by neural activity. In this work we have investigated the role of retinotectal projections on the distribution and light-microscopy features of nitric oxide synthase (NOS)-positive cells in the retinoreceptive layers of the rat superior colliculus (SC) using histochemical methods. Newborn and adult Lister rats had one or both eyes removed and perfused after different survival times. Histochemical results from rats enucleated at birth indicate that the expression of NOS, as revealed by the NADPH-diaphorase method, is not dependent on the presence of retinal projections during development. In the early enucleated animals the temporal pattern of NOS expression did not change as compared with normal animals. In both groups, NOS-positive cells were found in the SC starting at postnatal day 7. However, the morphology of NOS-positive cells was greatly disturbed in animals enucleated at early ages as well as in animals enucleated at adulthood when compared to the normal pattern. We concluded that retinotectal projections can regulate the subcellular distribution of NOS in SC cells in developing and adult animals. Supported by: TWAS, FINEP, CNPq, CEPG/UFRJ.

## 304.13

**FAST FOURIER TRANSFORM ANALYSIS (FFT) AND ORIGIN OF ON AND OFF EVOKED FIELD POTENTIALS IN THE RAT SUPERIOR COLLICULUS DURING DEVELOPMENT.** S. Fortin<sup>1</sup>, S. Itaya<sup>\*2</sup>, I. Dumont<sup>1</sup>, S. Chemtob<sup>1</sup>, and S. Molotchnikoff<sup>1</sup>. 1: Dept. Biology, Univ. of Montreal, Que., Canada. 2: Dept. Biomed. Sci., Univ. South Alabama, Mobile, AL 36688.

ON and OFF light evoked field potentials were recorded in the superior colliculus of anesthetized rats during development. The results presented last year (Soc. Neurosci. Abstract 21:816) showed that OFF evoked field potentials exhibited a strong oscillatory pattern.

Recent simultaneous multi-electrode recordings demonstrated that these oscillatory potentials appear at P15 at a frequency of 20 Hz, and as the rats grow older, the oscillatory frequency increases to reach 35-40 Hz in the adult. The form and the amplitude of ON and OFF field potentials vary considerably depending on the position of the electrode tip in the colliculus. Experiments show that OFF oscillatory potentials are circumscribed in a small zone of the superior colliculus. It appears that oscillations are most prominent in the ventral and medial part of the stratum griseum superficiale. Finally, local cobalt injection provided evidence that these oscillations are produced within the superior colliculus itself rather than in an extra-collicular structure. Supp. by C.R.S.N.G. and F.C.A.R.

**IN RAT SUPERIOR COLLICULUS, DARK REARING DELAYS MATURATION OF VISUAL RESPONSES AND MODULATES THE ROLE OF NMDA RECEPTORS IN VISUAL TRANSMISSION.** K.E. Binns\* & T.E. Salt. Institute of Ophthalmology, University College London, Bath Street, London, EC1V 9EL, UK.

The development of visual responses in rat superficial SC extends beyond eye opening (P14). The role of NMDA receptors in visual transmission is age dependent. Thus visual experience may influence late maturation and the role of NMDA receptors. We studied the effects of visual deprivation (by dark rearing) on visual responses and NMDA mediated transmission, by recording extracellularly from single neurones in urethane anaesthetized rats. The responses to visual stimulation and iontophoretically ejected agonists were challenged with NMDA receptor selective currents of AP5.

In normal rats there is a progressive change in the response profile to visual stimuli from bi-phasic to mono-phasic between P14 and P21. At the same time, the proportion of neurones with AP5 sensitive visual responses increased from 33% in P14-19 rats to a peak of 85% (of sample, n=20) at P20-21, and then reduced to 60% in adults. Similar, but delayed, maturational changes occurred in dark reared rats and there was a corresponding time lag in the rise in the proportion of neurones with AP5 sensitive visual responses. A maximum was reached at P22-23, but, the proportion did not decline. Dark rearing also enhanced the degree by which AP5 reduced individual visual responses. The differences between dark reared rats and normal rats were most pronounced in older subjects: In normal P23-P40 rats, NMDA receptors partially mediate 66% [n=9] of the visual responses, whereas in dark reared P25-40 rats, all [n=8] of the visual responses had NMDA mediated components. Also, the mean reduction with AP5 was significantly increased (0.025 < P < 0.05, Mann-Whitney 'U' test) from 45±7 in normal rats to 65±6 in dark reared rats. These data indicate that visual experience influences maturational changes in the profile of the visual responses in SC. In addition, during development, the role of synaptic NMDA receptors in visual transmission is dependent on environmental factors. Supported by the Wellcome Trust.

**CULTURED RAT RETINOCOLLICULAR SYSTEM ON PLANAR ELECTRODE ARRAYS.** A. Kawana\*, H. Kamioka and Y. Jimbo. NTT Basic Research Laboratories, Atsugi-shi, Kanagawa, 243-01 Japan

In order to study the roles of electrical activity in development of the visual system, we have cultured components of the rat visual system on substrates with planar electrode arrays (PEA) (A. Kawana et al.; Soc. for Neurosci., 1995 517.11). However, the retina (RE) formed hardly any functional synaptic connections with lateral geniculate nucleus (LGN). Here we describe the organotypic coculture of rat RE with superior colliculus (SC) which is considered to be the major target region of the RE in rat on the PEA.

Slices (300 µm) of SC, RE and the LGN, which is a major target of RE in other many mammals, were isolated from E16 rat, and fixed by gentle centrifugation onto the substrate. 7 days after initiating the culture, electrical activity was observed from the RE, SC and LGN simultaneously in culture conditions. SC usually showed synchronized bursting and the retina showed tonic firing with long quiescent period. LGN showed long lasting bursting. Electrical stimulation of the retina did not evoke any electrical activity in other areas. Around 14 days in vitro, the spontaneous electrical activity in RE was observed to propagate to SC, but not to LGN. Electrical activity of LGN could not be evoked by electrical stimulation at RE. When crystals of Df were placed into the retinal explant, anterogradely labeled retinal cells followed into both SC and LGN. These results suggest that the major target of the RE is SC in this system as shown *in vivo* and that spontaneous activity of retina which can evoke the electrical activity in SC has the potential to modify the retinocollicular connection.

EARLY EFFECTS OF GONADAL STEROIDS ON NUCLEOLAR MORPHOLOGY IN AXOTOMIZED HAMSTER FACIAL MOTOR NEURONS (FMN). N.B. Kinderman\* and K.J. Jones, Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153, and Rehab. Res. & Dev., Hines VA Hospital, Hines, IL 60141.

Transcriptional activation of the ribosomal gene occurs within 30' after facial nerve transection at the stylomastoid foramen in gonadectomized (gdx) male hamsters, with or without the addition of exogenous testosterone propionate (TP). However, the subsequent processing steps necessary to form mature ribosomes are substantially accelerated by the addition of TP at the time of axotomy. To explore these findings further, we examined nucleolar morphology in axotomized FMN. Gdx male hamsters received right facial nerve axotomies, with the left side serving as internal control. Half the axotomized animals were immediately implanted with 1 TP Silastic capsule, with 3 animals per group. At postoperative (po) times of 12 and 24 h, the animals were killed by intracardiac perfusion-fixation. Right and left facial nuclei were dissected and processed for routine electron microscopy. Fifteen-20 EMs (mag = 15,000x) of FMN from each group were collected for analysis. Stereological analysis using a point counting system was accomplished for the various subcomponents of the nucleolus, including granular region, nucleolonema, vacuolar space, and fibrillar centers. The data were expressed as a ratio of nucleolar subcomponent area/nucleolar area. The results indicate that, at these early po times, only the granular material was affected. The addition of TP at the time of axotomy resulted in an initial mobilization of the granular portion of the nucleolus at 12 h that was not observed with injury alone. By 24 h, however, the effects of axotomy with or without TP were evident, with there being an increase in granular material. The other subcomponents of the nucleolus were unaffected by either axotomy or TP treatment. These data support the idea that gonadal steroids accelerate, or somehow alter, the process of ribosome buildup after axotomy, probably at the level of processing, not transcription activation, of the rRNA gene. Supported by NIH grants NS28238 (KJJ).

## 305.3

ANDROGEN RECEPTOR (AR) REGULATION IN ADULT HAMSTER FACIAL MOTOR NEURONS (FMN): EFFECTS OF AXOTOMY AND/OR TESTOSTERONE PROPIONATE (TP). S.M. Drenth\*<sup>1,2</sup>, R.J. Hanks<sup>1</sup>, J.L. DonCarlos<sup>1</sup>, K.J. Jones<sup>1,2</sup>, <sup>1</sup>Loyola University Chicago, Maywood, IL, 60153 and <sup>2</sup>Hines VA Hospital, Hines, IL, 60141.

Exogenous TP accelerates recovery from facial paralysis induced by facial nerve crush axotomy, through an androgen-receptor mediated mechanism. In this study, we examined the regulatory effects of axotomy, with and without exogenous TP, on AR mRNA levels in FMN of adult, gonadectomized (gdx) male hamsters. Following right facial nerve axotomy, half the axotomized animals were subcutaneously implanted with one 10-mm Silastic capsule containing 100% crystalline TP, with the other half sham implanted. Postoperative times were 1, 2, & 7 d. *In situ* hybridization with an AR riboprobe, encoding the DNA binding domain of the AR, demonstrated a down-regulation of AR mRNA after AX, relative to the uninjured side. Surprisingly, TP treatment did not reverse the axotomy-induced down-regulation of AR mRNA levels, even though TP treatment has been shown to upregulate AR mRNA in FMN of uninjured gdx animals. These findings suggest that axon injury regulates the expression of androgen receptor mRNA in motoneurons. It is concluded that accelerative effects of TP on FMN regeneration are mediated by existing, rather than newly synthesized, AR. We are currently using ICC and the PG-21 antibody (gift of Dr. G. Prins) to AR to test this hypothesis. NIH NS28238 (KJJ), NIMH 48794 LLDC, and NSF IBN 9408890 (RJH).

## 305.5

REVERSE TRANSCRIPTION - POLYMERASE CHAIN REACTION IDENTIFICATION OF GROWTH FACTORS AND GROWTH FACTOR RECEPTORS EXPRESSED BY HUMAN NEUROBLASTOMA SH-SY5Y CELLS. D.L. Hynds, A.A. Rampersaud, D.A. Kniss and A.J. Yates\*, Departments of Cell Biology, Neurobiology and Anatomy and Pathology, The Ohio State University College of Medicine, Columbus, OH 43210.

SH-SY5Y human neuroblastoma cells respond both mitogenically and neuritogenically to some growth factors, such as insulin, insulin-like growth factor-I (IGF-I) and platelet-derived growth factor (PDGF), that signal through protein tyrosine kinase receptors. Our results indicate PDGF increase average neurite length in SH-SY5Y cells by 2.5 fold and over unstimulated controls. Insulin and IGF-I also increase average neurite length by approximately 2.0 fold over controls. PDGF, insulin and IGF-I increase [<sup>3</sup>H]-thymidine incorporation by 2.5, 1.2 and 1.3 fold, respectively. SH-SY5Y cells have a high basal level of mitosis in serum-free conditions. Therefore, it appears that SH-SY5Y cells are stimulated in an autocrine fashion to promote their own proliferation. Using a reverse transcription - polymerase chain reaction (RT-PCR) of the total RNA fraction we identify mRNA expression of growth factors and growth factor receptors. Co-expression of a growth factor and its receptor may indicate routes of autocrine stimulation in these cells. SH-SY5Y cells express the mRNA for insulin receptor, IGF-I receptor, both  $\alpha$  and  $\beta$  type PDGF receptors, insulin-like growth factor-II (IGF-II) and PDGF-A. From these data, it is concluded that PDGF-A and IGF-II may be an autocrine stimulators of mitogenesis or neuritogenesis in SH-SY5Y cells. Supported by NINDS grant NS10165.

## 305.2

DETECTION OF RETROGRADELY TRANSPORTED WGA-HRP IN AXOTOMIZED HAMSTER FACIAL MOTONEURONS (HFMN) OCCURS AFTER INITIATION OF THE CELL BODY RESPONSE. Christopher Humphester<sup>1,2</sup>, Lisa Tanzer<sup>1,2</sup>, Talat Khan<sup>2</sup> and K.J. Jones<sup>1,2</sup>, <sup>1</sup>Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153 and <sup>2</sup>Rehab. Res. & Dev., Hines VA Hospital, Hines, IL 60141.

We have previously demonstrated, in adult male hamsters, that axotomy of the facial nerve at the stylomastoid foramen activates ribosomal RNA transcription within 30' postoperative (po). The signal for initiation of the axon reaction in motoneurons subsequent to a peripheral nerve lesion is unknown. One hypothesis put forth is that a factor at the periphery is retrogradely transported to the cell body and initiates the injury response. To examine this in view of our rapid effects of axotomy on rRNA transcription, male and female hamsters were subjected to right facial axotomies, with the left side serving as internal control. WGA-HRP was applied at the proximal stump. At 30', 2, 3, 4, 6 and 24 h po, the animals were killed by intracardiac perfusion. The brains were removed, blocked to include the facial nuclei, and 25  $\mu$ m cryostat sections collected. The sections were processed for WGA-HRP, using the TMB method. Four stages of labelling intensity, ranging from no labeling to dark labelling, were defined. Quantitative analysis was accomplished and the percentage of sections labeled at the 4 different levels determined for experimental and control groups at all timepoints. No labelling was detected in any of the contralateral control sides. In males, the earliest timepoint at which detection was observed in the axotomized facial nucleus occurred at 3 h. In females, the earliest timepoint occurred at 4 h. Significant labelling was observed in axotomized facial neurons of both sexes by 6h po. These results do not support the hypothesis that a retrogradely transported factor is the signal for the axon reaction, but do support our previous observations of sex differences in facial nerve regeneration in the hamster. Supported by NIH grant NS28238 (KJJ).

## 305.4

GONADAL STEROID ENHANCEMENT OF HAMSTER FACIAL NERVE REGENERATION: EFFECTS OF DIHYDROTESTOSTERONE PROPIONATE (DHTP) AND ESTRADIOL (E). Lisa Tanzer<sup>1,2</sup>, Jane M. Jacob<sup>3</sup> and K.J. Jones<sup>1,2</sup>, <sup>1</sup>Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153, <sup>2</sup>Rehab. Res. & Dev., Hines VA Hospital, Hines, IL 60141, and <sup>3</sup>Dept. of Anat. Sci., Univ. Oklahoma, Oklahoma City, OK 73190.

In adult male hamsters, systemic administration of testosterone propionate (T) at the time of facial nerve crush axotomy of the facial nerve accelerates functional recovery and the rate of axonal regeneration by 30%. While further work indicates that these effects are, at least in part, androgen receptor (AR)-mediated, T is capable of being converted, by aromatase enzymatic activity, into E. Hence, a role for E in the enhancement of facial nerve regeneration could not be ruled out. Given recent reports of synergistic actions of T and E, as well as our findings of a role for E in AR mRNA regulation in hamster facial motoneurons (FMN), we explored the question of estrogenic regulation of facial nerve regeneration in this study. Adult male hamsters were gonadectomized, and subjected to right facial nerve crush axotomies. The axotomized animals were implanted with 1 subcutaneous capsule containing either 100% crystalline DHTP, a nonaromatizable androgen, 100% crystalline E, or nothing. The radioisotopic procedure to label fast axonally transported proteins was used to assess outgrowth distances of the fastest regrowing axons at postoperative times of 4 and 7 days. The results indicate that, as expected, DHTP accelerated the rate of facial nerve regeneration by about 40%. E also accelerated the rate of facial nerve regeneration, albeit to a lesser degree (30%). Interestingly, DHTP prolonged the delay time before sprout formation occurred, whereas E did not. These results indicate that E may also act to affect facial nerve regeneration, but through a different pathway than androgens. This conclusion is further supported by the knowledge that the facial nucleus of the hamster does not appear to contain E receptors, but does contain androgen receptors. Supported by NIH grant NS28238 (KJJ).

## 305.6

TROPHIC EFFECTS ON CULTURES OF IDENTIFIED BRAINSTEM-SPINAL NEURONS. D.M. Pataky\* and J.D. Steeves, Departments of Zoology, Surgery and Anatomy, UBC, Vancouver, Canada.

Damage to brainstem-spinal neurons as a result of spinal cord injury results in sensorimotor deficits. In order to promote effective repair of these projections it is desirable to specifically study these neurons. Using a retrograde pre-labelling paradigm we have developed an *in vitro* system for studying brainstem-spinal projection neurons. This allows the *in vitro* identification of neurons that are typically disrupted after a spinal cord injury. Fertilized eggs from White Leghorn chickens were windowed on embryonic day (E)5 and a small crystal of Dil implanted into the cervical spinal cord. This procedure labeled many of the neurons that are actively extending axons from the brainstem into the spinal cord. Three days later (E8), the hindbrain was dissected from the embryos, the cells dissociated and plated at low density. Previously, we have shown that FGF-2 (10ng/ml) can enhance the survival of identified brainstem-spinal neurons (82% more than serum-free control) using this assay system. We are following up this finding with an examination of FGF receptor expression in the assay system and *in vivo* during the normal development of the chick. We have also begun to address the possibility that non-neuronal cell types present in the culture (i.e. astrocytes) may mediate the FGF-2 survival effect. We prepared astrocyte conditioned medium (ACM) from 99% pure human fetal astrocyte cultures (gift from Dr. Seung Kim, UBC). In a dose-dependent manner, ACM can support the survival of up to 43% more identified brainstem-spinal neurons compared to serum-free control medium (DMEM). This raises the possibility that astrocytes can contribute to the survival of axotomized long projection CNS neurons. Supported by the Canadian Neuroscience Network.

## 305.7

**AXOTOMY-INDUCED GLIAL CELL DEATH IN THE DEVELOPING CHICK SPINAL CORD.** Christopher B. McBride\*, John McGraw and John D. Steeves, Depts of Zoology, Surgery, and Anatomy, UBC, Vancouver, BC.

Studies of programmed cell death (PCD) in the nervous system have focused primarily on central and peripheral neurons. However, the role of glial PCD is becoming recognized as an important feature of nervous system development and perhaps degenerative disorders such as multiple sclerosis. In this study, we investigated the role of one form of PCD, apoptosis, in spinal glia following transection of embryonic day (E) 12, E14 and mature (P2) chick spinal cord. Within 24-72 hrs, TUNEL and Hoechst 33258 staining revealed large numbers of apoptotic cells confined to the white matter tracts over several segments rostral and caudal to the transection site in embryonic chicks. By contrast, few apoptotic cells were detected in sham treated embryonic or transected hatching spinal cords. Determination of the cell type undergoing apoptosis was accomplished by double-labeling spinal cord sections for apoptosis and oligodendrocyte-specific (carbonic anhydrase II, myelin basic protein) or astrocyte-specific (GFAP) markers. Many apoptotic cells were positively labeled for carbonic anhydrase II and MBP, but not GFAP, indicating apoptosis in the spinal white matter was restricted primarily to dying oligodendrocytes as opposed to astrocytes. Previous studies have demonstrated that oligodendrocytes begin to differentiate on E9, with myelination occurring between E13 and E17. This period appears to coincide with an increased susceptibility to injury-induced apoptosis. These results indicate that axotomy-induced PCD of oligodendrocytes is a feature of the injury response following axotomy of the developing CNS. Thus, this model may be useful in elucidating the mechanisms of oligodendrocyte cell death. Supported by Rick Hansen Man in Motion Foundation, Canadian Neuroscience Network and the Medical Research Council of Canada.

## 305.9

**TRANSPLANTS, NEUROTROPHIC FACTORS AND MYELIN-ASSOCIATED NEURITE GROWTH INHIBITORS: EFFECTS ON RECOVERY OF LOCOMOTOR FUNCTION AFTER SPINAL CORD INJURY IN ADULT RATS** B.S. Bregman\*, H.N. Dai, T. Lin, C.V. James, M. McAtee, M.E. Schwab, L. Schnell, Georgetown University Medical Center, Washington, D.C. 20007 and University of Zurich, Zurich, Switzerland.

The extent of axonal growth after CNS injury in the adult rat can be increased by any one of a variety of interventions. Transplants of fetal spinal cord tissue, exogenous neurotrophic support and antibodies to myelin-associated neurite growth inhibitors (IN-1) each lead to an increase in growth of mature CNS axons after injury. We sought to determine whether the anatomical plasticity elicited by these interventions in combination increases the degree of recovery of function after spinal cord injury. Spinal cord over-hemisection lesions were made at T6 in adult rats. Transplants of E14 spinal cord tissue were placed into the lesion site. At the time of the lesion IN-1 was applied intraventricularly and neurotrophin (NT-3) was applied at the site of the transplant. Recovery of locomotor function was examined for 6 weeks after injury in overground and treadmill conditions. Locomotor function was assessed both directly and from videotapes; the Peak Performance System was used for kinematic analysis. There is a dramatic loss of locomotor function in both hindlimbs immediately after the injury. The early recovery (1-7 days after injury) is identical in all treatment groups. By 10-14 days after injury and thereafter, however, the extent of recovery in all of the IN-1 treated groups was significantly better than that in groups receiving control antibodies. In addition, some aspects of accurate locomotion (number of errors on grid runway) show greater recovery in the rats receiving combined treatment (HX+TP+IN-1+NT-3) than any of the individual interventions (HX+TP or HX+IN-1). The greater recovery was accompanied by increases in the anatomical plasticity of corticospinal, raphespinal and coeruleospinal pathways both within the transplant and within the host spinal cord caudal to the lesion. Supported by NIH-NINDS NS 27054; T32 HD07459, ISRT; neurotrophins supplied by Regeneron.

## 305.11

**PROMOTION OF THE SURVIVAL OF DEVELOPING RETINAL GANGLION CELLS AFTER AXOTOMY.** S. Shen\* and B. A. Barres, Stanford University School of Medicine, Department of Neurobiology, Stanford, CA 94305.

We have recently proposed that the signaling mechanisms that promote the survival and growth of developing CNS and PNS neurons may differ: whereas many types of PNS neurons respond to a single peptide trophic factor, CNS neurons require a combination of peptide trophic factors as well as a coincident signal, elevation of intracellular cAMP, that enhances responsiveness to the peptide trophic factors. Could this difference help to explain why CNS and PNS neurons differ in their response to injury?; whereas PNS neurons survive and regenerate their axons after an axotomy, most types of CNS neurons die and do not regenerate. For instance, CNS neurons might die after axotomy not only because they lose their retrograde supply of trophic factors but because their cAMP levels decrease.

We previously showed that highly purified postnatal day 8 (P8) retinal ganglion cells (RGCs) rapidly undergo apoptosis in serum-free medium in vitro; the majority of RGCs survive in culture when the medium also contains the combination of peptide trophic factors BDNF, CNTF, IGF-1, as well as forskolin to activate adenylyl cyclase (Meyer-Franke et al., *Neuron* 15:805-919, 1995). Others have found that P8 RGCs in vivo after an axotomy, but that their survival is not significantly promoted by intraocular injection of BDNF or CNTF. Here we show that the survival of P8 RGCs in vivo is significantly decreased by pharmacological inhibition of protein kinase A and that the survival of axotomized P8 RGCs is significantly increased by intraocular injection of peptide trophic factors (BDNF and CNTF) together with forskolin. These findings demonstrate that axotomized RGCs in vivo have similar survival requirements as RGCs in vitro and raise the question of whether regeneration of their axons can be achieved by activating the same signaling pathways.

This work was funded by the National Eye Institute (1R01-EY11310).

## 305.8

**REGENERATION OF DESCENDING BRAINSTEM-SPINAL & CORTICOSPINAL AXONS AFTER IMMUNOLOGICAL MYELIN DISRUPTION OF THE ADULT RAT SPINAL CORD.** J.K. Dyer\* and J.D. Steeves, Depts. Zoology, Anatomy and Surgery, UBC, 6270 University Boulevard, Vancouver, BC, V6T 1Z4, CANADA.

The regenerative ability of the adult vertebrate CNS is limited. During development the loss of CNS axonal regeneration coincides with the onset of myelination.

Demyelination of the injured nervous system has been postulated as a possible way of overcoming these inhibitory influences. Most demyelination protocols are irreversible, as well as having adverse effects on other CNS cell phenotypes. We have previously described a transient immunological, myelin-specific, antibody-mediated (anti-GalC), complement-dependent protocol that: (1) suppresses the developmental onset of spinal cord myelination, and (2) disrupts myelin structure in the mature avian CNS; promoting some axonal regeneration and functional recovery after complete transection of the avian spinal cord.

We now describe the effects of injection/infusion of the immunological reagents on adult rat CNS myelin and the possible application to facilitate the regeneration of specific brainstem-spinal tracts. Myelin disruption is evident in the adult rat spinal cord shortly (<1d) after infusion. There is a down-regulation of myelin-associated proteins and a concomitant unraveling of the myelin lamellae. Long term infusion results in local demyelination, with distal myelin-disruption.

Our previous studies in the hatching chick indicated that this change in the myelin is sufficient for some axonal regeneration after injury. We are currently investigating whether this approach facilitates regeneration of descending spinal axons (e.g. corticospinal, rubrospinal and vestibulospinal) in the adult rat.

**NT3 ENHANCES DORSAL ROOT REGENERATION INTO SPINAL CORD.** Y. Ito\*, K. Iwaya, F. Mori, T. Sugawara, K. Mineura, M. Kowada, A. Tessler, <sup>1</sup>Dept. of Neurosurg., Akita Univ. Sch. of Med., Akita City, Akita 010, Japan; <sup>2</sup>Dept. of Neurobiol. and Anat., Med. Col. of PA / Hahnemann Univ. Philadelphia, PA 19129, Philadelphia VA Hospital, Philadelphia, PA 19104.

We have shown previously that embryonic CNS transplants allow adult dorsal roots to regenerate into host spinal cord and form permanent synapses with host neurons, suggesting that transplants release factors permissive for dorsal root regeneration. In the present study we examined whether neurotrophin-3 (NT3) is one of these factors. We used immunocytochemical methods to label regenerated dorsal roots that contain calcitonin gene-related peptide (CGRP). Adult Sprague-Dawley rats received NT3 (provided by Regeneron) by release from a fibrin glue ball placed into a dorsal quadrant cavity in the lumbar enlargement. The cut L4 or L5 dorsal root stump was sandwiched between the fibrin glue ball and host spinal cord. One month later the grafts were processed for CGRP immunocytochemistry, and regenerated axons analyzed quantitatively. CGRP-labeled axons regenerated into host spinal cord; some of them extended into the motoneuron pool. The area fraction occupied by regenerated axons in rats that received NT3 was significantly larger than in control rats that did not receive NT3. NT3 is one factor that contributes to regeneration of dorsal root axons into host spinal cord and may therefore promote reconstruction of interrupted spinal reflex arcs.

## 305.12

**Effects of Calcium, Trophic Factors, and Conditioning Lesions on Neuronal Morphogenesis.** K.L. Lankford\*, S.G. Waxman and J.D. Kocsis, Dept. of Neurology, Yale Univ. School of Med., New Haven CT 06510

In order to identify possible contributions of trophic factors and calcium signals to conditioning lesion enhancement of peripheral nerve regeneration we subjected adult rats to a unilateral mid-thigh sciatic nerve crush or ligation and compared the timing of neurite initiation, rate of outgrowth and branching frequency in cultures of conditioning lesioned neurons to control neurons exposed to NGF, BDNF, NT-3, ligated DRG-conditioned media, Schwann cell-conditioned media, 200 nM thapsigargin, 3 mM caffeine or 50 mM KCl. Our results indicate that conditioning lesioned neurons are developmentally advanced compared to controls. Both crushed and ligated neurons initiate processes earlier than controls and branch less, appearing similar to cultures 1-2 days older. However, conditioning lesioned neurons do not extend processes in culture at significantly greater rates than controls. No single factor appeared to account for all of the conditioning lesion-induced effects. KCl and caffeine both mimicked conditioning lesion-induced advancement of neurite initiation, while thapsigargin inhibited initiation, but branching frequency was unaffected by these  $Ca^{2+}$  manipulations. NGF and NT-3 increased neurite lengths in at least some classes of neurons and their production by denervated Schwann cells could account for the greater rate of neurite outgrowth in crushed as compared with ligated neurons, but neither agent affected branching frequency and effects on neurite initiation were marginal. Schwann cell-conditioned media reduced neurite branching and increased outgrowth rates, but had no effect on initiation. Our results suggest that: (1) prior injury promotes subsequent neurite initiation through a possibly  $Ca^{2+}$  dependent mechanism, (2) exposure to neurotrophins during regeneration stimulates faster outgrowth, and (3) an unidentified mechanism reduces neurite branching. Together, these changes result in more rapid recovery after a second nerve injury. Supported by NIH grant NS10174.

## 305.13

ACTIVATION OF THE EGF-RECEPTOR STIMULATES CHONDROITIN SULFATE PROTEOGLYCAN PRODUCTION IN PRIMARY ASTROCYTES. G.M. Smith<sup>1</sup>, Dept. Anesthesiology and Pain Management, U.T. Southwestern Medical Center, Dallas, TX 75235-9068

The up-regulation of chondroitin sulfate proteoglycan (CSPG) after injury may play an important role in regenerative failure. To reduce the deleterious effects of these molecules it is important to understand which factors regulate their expression. ELISA assays of the conditioned medium from astrocytes treated with cytokines and growth factors, known to be expressed after injury, reveal that in the presence of epithelial growth factor (EGF) CSPG is increased 6 to 8 fold. Treatment of astrocytes with other EGF-receptor ligands, such as TGF- $\alpha$  and heparin-binding EGF, produced similar increases in CSPG. In addition, these effects could be reversed by AG 1478, a selective EGF-receptor antagonist. Interestingly, the amount of CSPG bound to the surface of astrocytes remained unchanged with all treatments. Western blot analysis of supernatants pre-digested with chondroitinase ABC indicates the presence of multiple isoforms of both the 4-sulfated and 6-sulfated chondroitin as detected by the antibodies 2B6 and 3B3, respectively. To determine if EGF-induced CSPG inhibits neurite outgrowth, we grew dorsal root ganglion neurons on dishes blotted with EGF-treated or non-treated astrocyte-conditioned medium. Neurites did not grow over the area containing the supernatant from astrocytes treated with EGF. However, they grew well over the area containing the supernatant from control astrocytes (not treated with EGF). The inhibitory effect on neurite growth could also be reduced when the supernatant from EGF-treated astrocytes was incubated with chondroitinase ABC. These data show that EGF-receptor ligands up-regulate CSPG production by astrocytes and that this increase in CSPG inhibits neurite outgrowth. Supported by the Sid W. Richardson Foundation and NIH (NS 33776).

## 305.15

MOLECULAR CLONING AND REGULATION OF RAT AXL TYROSINE KINASE RECEPTOR COMPARED WITH ITS PUTATIVE LIGANDS GAS6 /PROTEIN S IN THE NERVOUS SYSTEM Hiroshi FUAKOSHI<sup>1</sup>, Tomoko YONEMASU<sup>1,2</sup>, and Toshikazu NAKAMURA<sup>1</sup> <sup>1</sup>Division of Biochemistry, Biomedical Research Center, Osaka University Medical School & <sup>2</sup>Protein Research Institute, Osaka University, Osaka 565, Japan

Axl/UFO tyrosine kinase receptor is a member of tyrosine kinase receptor "Sky/Rse/Tyro3" family, which also includes c-Mer. The family exhibits a unique extracellular structure characterized by the immunoglobulin-like (IgL) repeats and fibronectin III (FNIII) repeats with intracellular tyrosine kinase. IgL repeat is observed in the receptor for neurotrophic factor and FNIII repeat is observed in cell adhesion molecule, suggesting that Axl could have important function such as trophic and guidance.

To assess the role of Axl tyrosine kinase receptor, we have cloned a rat axl by PCR. Cloned rat axl had two forms, with and without 27 nucleotides in the juxtamembrane domain. Expression of mRNAs for rat axl, gas6 and proteinS were analyzed quantitatively by RNase protection assay using specific cRNA probes. All these genes were detected in the brain, spinal cord, DRG, and sciatic nerve. Moreover gas6 and proteinS mRNAs were regulated in the lesioned nerve, suggesting that Axl and its putative ligands have an important role during nerve regeneration. axl mRNA was detected in glial cells, C6 / U138MG, but not in neuronal cells, PC12 / GH3, suggesting that Axl mainly works in non-neuronal cells like glial cells in the nervous system.

## 305.17

DO ALL SPINOCEREBELLAR AXONS GROW THROUGH A LESION OF THEIR SPINAL PATHWAY DURING THE SAME CRITICAL PERIOD? J.R. Terman<sup>1</sup>, X.M. Wang, and G.F. Martin. Dept. of Cell Biology, Neurobiology & Anatomy and Neuroscience Program, The Ohio State University, Columbus, OH 43210.

Using the developing opossum, *Didelphis virginiana*, we have shown that axons which originate within Clarke's nucleus (axons of the dorsal spinocerebellar tract [DSCT]) grow through a lesion of their spinal pathway and reach the cerebellum when the lesion is made on postnatal day (PD) 5 but not when it is made on PD12. Spinocerebellar fibers originate throughout the spinal cord, however, and differ in their developmental history, laterality, funicular position, course, and terminal distribution. We have asked, therefore, whether spinocerebellar fibers which do not originate within Clarke's nucleus (CN) also grow through a spinal lesion and, if so, whether the critical period for such growth is the same as that for axons of the DSCT. In the present study, we focused on spinocerebellar axons supported by spinal border cells (SBC), neurons within Stilling's nucleus (SN), and neurons within the sacral/oculocyl ventrolateral nucleus (VLN). Pouch-young opossums were anesthetized and subjected to a right hemisection of the mid-thoracic cord on PD5. One to nine months later, bilateral injections of Fast Blue (FB) or Fluoro-Gold were made into the anterior lobe of the cerebellum, the major target of spinocerebellar axons. After a 7 day survival, the animals were sacrificed so that their spinal cord and brain could be processed for fluorescence photomicroscopy. In all cases, neurons were labeled bilaterally within SBC, SN and VLN. Since the cerebellar projection from each nucleus is contralateral (unpublished results), labeled neurons contralateral to the hemisection must have supported axons which grew past the lesion and reached the cerebellum. When similar lesions were made on PD12, and the animals were allowed to survive for 1-4 months prior to injections of FB, labeled neurons were not present in any of the above mentioned nuclei contralateral to the lesion although they were present ipsilaterally to it. These results suggest that spinocerebellar axons supported by SBC, neurons within SN, and neurons within the VLN grow rostral to a lesion of their spinal pathway during early development and that the critical period for such growth is comparable to that for axons which originate within CN. (Supp. by NS-25095 and 10165).

ANTIBODIES AGAINST BASIC FIBROBLAST GROWTH FACTOR (bFGF) SUPPRESS THE FORMATION OF THE LESION INTERFACE AFTER STAB WOUNDS TO THE ADULT RAT CEREBRAL CORTEX. Xia Wang and Samuel David<sup>1</sup>, Centre for Research in Neuroscience, The MGH Research Institute & McGill University, 1650 Cedar Ave., Montreal, Que., Canada, H3G 1A4.

A lesion interface consisting of a glia limitans, a laminin-rich basal lamina, and a fibrotic scar comprising of leptomeningeal cells, forms within 2-3 weeks after stab wounds to the adult rat cerebral cortex. Such an interface prevents the growth of axons across CNS lesions. The expression of bFGF increases after cortical stab wounds, and peaks at 7 days post-lesion. In this study, we have examined the effects of anti-bFGF in suppressing the formation of this interface. Anti-bFGF (50 $\mu$ g/ml) was infused for 14 days over the site of cortical stab wounds in adult rats using Alzet osmotic mini-pumps. Animals were then perfused with 4% paraformaldehyde in 0.1M phosphate buffer, and cryostat sections through the area of the lesion were double-labeled by immunofluorescence with either anti-laminin/anti-GFAP, or anti-fibronectin/anti-GFAP antibodies. There was a marked reduction in the length of the laminin<sup>+</sup> and fibronectin<sup>+</sup> areas along the lesion, as compared with lesioned controls. The percentage of the total length of the lesion that was laminin<sup>+</sup> was  $7.6 \pm 7.5\%$  as compared with  $69.5 \pm 8.5\%$  for lesioned controls. Similarly, the percentage of the total length of the lesion that was fibronectin<sup>+</sup> was  $22 \pm 6\%$  as compared with  $60 \pm 11\%$  for controls. In addition, the width of the fibronectin<sup>+</sup> areas comprising the fibrotic scar was also markedly thinner and weakly labeled in anti-bFGF treated lesions. These results indicate that the fibrotic scar that forms within the lesion cavity, and the basal lamina that lines the glia limitans after cerebral cortical stab wounds in adult rats, can be diminished by blocking bFGF.

## 305.16

REGENERATION OF CEREBELLAR PURKINJE CELL AXONS IS AN AGE-DEPENDENT PROCESS: AN IN VITRO STUDY AFTER AXOTOMY, L. Dusart<sup>1</sup> and C. Sotelo, INSERM U106, Hôpital de la Salpêtrière, 75013 Paris, France.

*In vivo* adult Purkinje cells are among the most resistant neurons to axotomy but their axons do not regenerate. Either a role of environmental factors or a loss of the program for axonal growth could explain this lack of regeneration. We have developed an *in vitro* set up of axotomy to study age and environment related factors potentially implicated in Purkinje cell axonal regeneration. Purkinje cells from 10 days old rats have been axotomized after one week in culture and have been confronted with slices of sciatic nerves or slices of embryonic cerebellum (from E19 to E22). These Purkinje cells survive *in vitro* axotomy, and their axons, although unretracted, do not regenerate in the presence of slices of sciatic nerves or embryonic cerebellum slices. In contrast, E19 to P0 axons of Purkinje cells are able to regenerate on slices of mature-like cerebellum. Most of the Purkinje cells from 1 to 5 day old rats die when seeded in organotypic culture. Purkinje cells from rats older than 7 days survive but do not regenerate. In all cases, few postnatal deep nuclei neurons, the target neurons of Purkinje cells, survive in organotypic culture. Thus, we demonstrate that between P1 and P5, Purkinje cells depend on their target neurons for their survival. It is interesting to note that this developmental period (P1 to P5) corresponds to the synaptogenic period of these neurons. Furthermore, the failure of Purkinje cell regeneration is age-related since embryonic Purkinje cells regenerate on postnatal cerebellum whereas postnatal Purkinje cells do not.

## 305.18

PLASTICITY OF GALANINERGIC FIBERS FOLLOWING NEUROTOXIC DAMAGE WITHIN THE RAT BASAL FOREBRAIN. S. de Lacalle<sup>1</sup>, R.G. Wiley and E.J. Mufson. Depts. of Neurology, Beth Israel Hosp., Boston, MA 02115; VAMC, Nashville, TN 37212, Rush Med. Ctr, Chicago, IL 60612.

Galanin (GAL)-immunoreactive (-ir) fibers hyperinnervate remaining cholinergic basal forebrain (CBF) neurons within the medial septum (MS) and diagonal band of Broca (DBB) in AD. The present investigation determines whether an hyperinnervation of GAL-ir fibers occur following unilateral intraparenchymal injections of ibotenic acid or 192 IgG-saporin within the MS or DBB in young adult F344 rats. Sections through the MS and DBB were concurrently stained for GAL and the p75 receptor, an excellent marker of CBF neurons. We found a moderate to intense increase in the density of galanin immunoreactivity within the MS on the lesion, as opposed to contralateral side. In contrast, in DBB-lesioned rats the increase was low to moderate as compared to the contralateral side, and also surrounded the lesion site. There was no apparent correlation with the amount of cell loss in either lesion paradigm. GAL hypertrophy occurred independent of lesion type. In both models, GAL-ir fibers appeared coarse and thicker on the lesioned side as compared to the non-lesioned side. Preliminary experiments indicate that the GAL hypertrophy is not triggered by the injection itself since it was not seen in animals surviving less than 7 days. The plastic response was documented in animals surviving 2 weeks post-lesion. Since longer survival (>8 weeks) returned galanin innervation to normal levels, we hypothesize that GAL hyperinnervation of surviving neurons may have a transient protective effect by down-regulating neurotransmitter release. Supported by NIH AG12401, AG10161, AG10668 and AG9466.

## 305.19

**MOTOR AND SENSORY SPECIFICITY OF HOST NERVE AXONS INFLUENCE NERVE ALLOGRAFT REJECTION RESPONSE.** R. Midha\*, C. Munro, S.E. Mackinnon and L. Ang. Sunnybrook Health Sciences Centre, Univ. of Toronto, Toronto, Ontario and Washington University, St. Louis, MO.

Previous studies have shown both demyelination and Wallerian degeneration within nerve allograft segments after withdrawal of Cyclosporin A (CsA) immunosuppression (J Neurosurg 78:90, 1993; Trans Proc 25:532, 1993). We hypothesized that the nature of end-organ reinnervation may influence the response of the axon, with demyelination for appropriate innervation versus degeneration for inappropriate innervation. The Lewis rat femoral nerve model was chosen. Four ACI rat peroneal nerve allografts (2 cm length) were sutured in correct (right leg) or incorrect (left leg) orientation with regard to motor (M) and sensory (S) specificity (see diagram) in each Lewis rat. Rats received 5 mg/kg s.c. CsA daily for 8 weeks to allow end-organ reinnervation and were sacrificed at 8 (n=5), 10 (n=5), 12 (n=20), 14 (n=10) and 20 (n=5) weeks. Wallerian degeneration, then regeneration, predominated in graft segments. At week 12 and 14, demyelination of the axons was a dominant response in at least one graft in 13/30 rats, and was significantly more common in the motor to motor and motor to sensory orientations ( $p < 0.05$ ). We conclude that the nature of the host axon, rather than the end-organ, may influence whether the axon undergoes demyelination or degeneration after immunosuppression cessation.

### A GENE THERAPY MODEL FOR MOTOR NEURON INJURY.

A. Blesch\*, K. Farhoomand and M.H. Tuszynski. Dept. of Neurosciences-0608, Univ. of California at San Diego, La Jolla, CA 92093 and VA Medical Center, San Diego, CA 92165

The hypoglossal nucleus is a useful model for the study of motor neuronal responses to injury. Axotomy of hypoglossal axons results in downregulation of their cholinergic neuronal phenotype, which we and others have previously shown is preventable by intracerebroventricular infusions of the trkB agonists NT-4/5 and BDNF, but not by NT-3 or NGF. To test whether cells genetically modified to produce neurotrophins are also able to prevent this change in phenotype, MLV based retroviral vectors for NT-4/5, GDNF and LIF/CSF were constructed. Bioactivity and secretion rates were tested by survival of E-14 ventral mesencephalon cultures (for NT-4/5 and GDNF), proliferation of TF-1 cells (for LIF/CSF) and ELISA (for GDNF). Autologous transduced neurotrophin-producing fibroblasts were then grafted adjacent to the hypoglossal nucleus after unilateral nerve transection. Size and number of ChAT positive neurons were determined using NIH Image software. Results will be discussed at the meeting. Supported by grants from Veterans Affairs, International Spinal Research Trust, and the Deutsche Forschungsgemeinschaft.

## 306.2

**TREATMENT OF C6 GLIOMA BY IN SITU RETROVIRUS TRANSFER OF A "SUICIDE" GENE USING AN ENCAPSULATED PACKAGING CELL LINE.** Y. Padua\*, I. O. Martinez\*, N. Schreyer\*, J.M. Joseph\*, X.O. Breakfield\*, P. Aebischer\*. <sup>1</sup>Gene Therapy Center, CHUV, Lausanne University, Switzerland, <sup>2</sup>Department of Neurology, Massachusetts General Hospital, Charlestown, MA 02129

The goal of this project is the development of a gene therapy approach for the treatment of glioblastoma based on the introduction of a "suicide" gene in tumor cells that confers a drug sensitivity. The gene is transmitted by replication-incompetent retroviral vectors that will only integrate into dividing cells allowing targeting of the malignant glial cells. The retroviral vectors are continuously produced by a packaging cell line. The use of microporous membrane to encapsulate the packaging cell line should prolong the life span of the xenotransplanted cells therefore enhancing the probability of infecting a large number of tumor cells. In the present study, we investigated the efficacy and dynamics of *in vivo* transduction of growing malignant brain tumors (C6) with the herpes simplex thymidine kinase gene (HSV-tk) followed by administration of the antiviral drug ganciclovir (GCV). Rats inoculated with  $4 \times 10^4$  C6 malignant glioma cells into the striatum were treated 7 days later with an intratumoral stereotaxic injection of encapsulated murine fibroblasts (psi2-VIK) producing retroviral vectors bearing the HSV-tk gene. The capsule was composed of a microporous membrane allowing the diffusion of retroviral particles. Controls received either an empty capsule,  $5 \times 10^5$  unencapsulated psi2-VIK, 50  $\mu$ l of psi2-VIK cells supernatant or 50  $\mu$ l of sterile cell culture medium. The animals were treated 7 days later with GCV 15 mg/kg ip twice daily for 14 days. In the group treated with encapsulated psi2-VIK cells, the amount of tumor necrosis was significantly higher than in the other control groups. No complete tumor regression was however observed. These results suggest the potential use of an encapsulated packaging cell line for infecting dividing cells in the nervous system.

## 306.3

**INTRAVENTRICULAR ENCAPSULATED CAC CELLS: VIABLE FOR AT LEAST 500 DAYS *IN VIVO* WITHOUT DETECTABLE HOST IMMUNE SENSITIZATION OR ADVERSE EFFECTS ON BEHAVIORAL COGNITIVE FUNCTION.** M.D. Lindner\*, M.A. Pione, B. Frydel, F. Kaplan, P.M. Kneger, W.J. Bell, T.J. Blaney, S.R. Winn, S.S. Sherman, E.J. Doherty, and D.F. Emerich. CytoTherapeutics Inc., Two Richmond Sq., Providence, RI, 02908

Numerous studies have reported that adrenal chromaffin cell transplants, including encapsulated xenogeneic adrenal chromaffin cells, have analgesic effects. However, in addition to efficacy, the clinical utility of encapsulated xenogeneic adrenal chromaffin cells for treatment of chronic pain is dependent on the duration of cell viability *in vivo*, and their relative safety. The objectives of the present study in rats were to: (1) examine encapsulated cell adrenal chromaffin (CAC) cells for evidence of viable cells and continued release of analgesic agents after an extended period *in vivo*, (2) determine if intraventricular encapsulated CAC cells produce detectable adverse effects on behavioral/cognitive function, and (3) test for evidence of host immune sensitization after an extended period of exposure to encapsulated xenogeneic adrenal chromaffin cells. Results of the present study suggest that some encapsulated CAC cells remain viable for well over one year *in vivo* and continue to produce catecholamines and mel-enkephalin. Post-implant device NE output was equivalent to amounts previously shown to produce analgesic effects with intrathecal implants. Encapsulated adrenal chromaffin cells also appeared relatively safe, even when implanted in the cerebral ventricles, with a lower side-effect profile than systemic morphine (4 mg/kg). There was no evidence that encapsulated CAC-cells implanted in the ventricles affected body weight, spontaneous activity levels, or performance in the delayed matching to position operant task which is sensitive to deficits in learning, memory, attention, motivation, and motor function. Finally, encapsulated CAC cells produced no detectable evidence of host immune sensitization after 16.7 months *in vivo*, although unencapsulated CAC cells produced a robust immune response even in aged rats. The results of the present study suggest that adrenal chromaffin cells remain viable *in vivo* for long periods of time, and that long-term exposure to encapsulated xenogeneic adrenal chromaffin cell implants appears relatively safe.

### GRAFTING OF FIBROBLASTS IMMORTALIZED WITH THERMOLABILE LARGE T ANTIGEN INTO RAT BRAIN

Timothy C. Ryken\*, Toby G. Bush, Parmjit S. Jai, Michael V. Sofroniew. Department of Neurosurgery, SUNY-HSC, Syracuse, New York. Center for Brain Repair, Cambridge, U.K., Ludwig Institute for Cancer Research, London, U.K.

Conditionally immortalized cells may provide a renewable source of tissue for CNS grafting studies. Cell lines immortalized with the thermolabile large T antigen proliferate at 33°C but cease dividing at 39°C. We investigated the properties of these conditionally immortal fibroblasts grafted syngeneically into rat brain. Clonal cell lines established by transfecting Sprague-Dawley (tsa129) and Fisher (tsa8) embryonic rat fibroblasts with the thermolabile large T antigen encoded by the simian virus 40 early region mutant tsa58 were grafted stereotactically into the forebrain of adult male rats using varying cell concentration (10,000 - 100,000 cells per  $\mu$ l) and volume (0.5 - 10  $\mu$ l). After survival times from 3 days to 3 months, the implant sites were studied histologically. Grafted cells could be identified at all time points studied using cresyl-violet and immunohistochemistry with an antibody to the large T antigen (pab101), indicating that these cells survive grafting for a minimum of three months. No adverse neurological deficits were noted. No evidence of intracranial tumor formation or invasion of the adjacent parenchyma was observed. There was a general retraction of graft size noted over time and some indication of inflammatory response, particularly noted at the three week time point. These findings suggest that thermolabile donor cells may be useful in central nervous system grafting models, allowing unlimited propagation *in vitro* but limited expansion of cell number following implantation.

**MYOBLAST TRANSFER CLINICAL TRIALS.** J.A. Florendo\*, T. Quinley, G. Vastagh, T.G. Goodwin, O. Fang, M.B. Deering, V. Duggirala, C. Larkin, L.M. Li, T.J. Yoo, N. Chase, M.D. Neel, T. Krahn, R.L. Holcomb, and P.K. Law. Cell Therapy Research Foundation, 1770 Moriah Woods Blvd. Suite 18, Memphis, TN 38117

Myoblast Transfer is a potential cell/gene therapy in which normal immature muscle cells repair genetically defective cells by integration of the normal genome through natural cell fusion. Myoblast Transfer Therapy (MTT, U.S. patent #5130141) is completing Phase II clinical trials (IND 5108) on Duchenne muscular dystrophy (DMD). The whole body trial (WBT) consists of injecting 25 billion myoblasts in two MTT procedures separated by 3 to 9 mo. Each procedure delivers up to 200 injections or 12.5 billion myoblasts to either 28 muscles in the upper body (UBT) or to 36 muscles in the lower body (LBT). A randomized double-blind portion of the study is being conducted on the biceps brachii or quadriceps. Subjects take oral cyclosporine for 3 mo after each MTT. One infantile facioscapulohumeral dystrophy and 27 DMD boys aged 6 to 16 have received WBT and 18 more DMD boys have received UBT or LBT in the past 32 mo with no adverse reaction. Nine months after MTT, immunocytochemical evidence of dystrophin has been demonstrated in 18 of the 20 subjects biopsied. Forced vital capacity increases by 33.3%, and maximum voluntary ventilation increases by 28% at 12 months after UBT. Plantar flexion increases by 52% in force in 6 mo and elbow extension increases by 28.6% in 12 mo in the ambulatory subjects. Behavioral improvements in walking, balancing, and climbing stairs have been reported by subjects. Additional analyses comparing myoblast-treated vs placebo muscles will be available upon completion of the trial, FDA review, and removal of blinding. Six years after MTT, the world's first MTT patient continues to show dystrophin in a myoblast-injected muscle with the absence of dystrophin in the contralateral sham-injected muscle. This would indicate donor cell survival, development, and function six years after transplant. MTT also has potential application to treating other genetic diseases. (Supported by public donations with FDA approval to charge for direct costs.)

## 306.7

**TEMPERATURE-SENSITIVE INDUCTION OF P53 AND DIFFERENTIATION BY ANTICANCER AGENTS IN M213-20 CELLS.** C. Concejero\*, R. Wright, C. Tornatore, and W. Freed. \*NIMH Neuroscience Center at St. Elizabeths, Washington, D.C., 20032, and \*Laboratory of Molecular Medicine and Neuroscience, NINDS, Bethesda, Md., 20892.

M213-20 cells, a rat striatal cell line immortalized by the temperature-sensitive tsA58 mutant of SV40 large T, expresses an immortal phenotype at the permissive temperature (33°C). At 39.5°C, T protein is thought to be inactivated, releasing p53. We have studied the temperature-sensitive induction of p53 by adriamycin, cytosine arabinoside (Ara-C), and glutamate, and the relationship between p53 activation and cellular differentiation. P53 activity was measured by a transient transfection assay, using the PG13-Luc reporter plasmid (El-Deiry et al., Cell 75: 817, 1993). The PG13-Luc plasmid contains 13 copies of the p53 binding site upstream from the polyoma promoter and a luciferase reporter construct. Increases in cellular levels of wild-type p53 activate the p53 enhancer, thereby resulting in an increase in luciferase activity. The anticancer drugs, adriamycin and Ara-C, increased p53 at both temperatures. At 33°C p53 activity was increased more markedly than at 39.5°C, showing a peak 8 hr after the initial exposure for both drugs. Glutamate also increased p53 levels, with the increase at 33°C being more sustained, and was more effective in stimulating cellular differentiation, as measured by process extension, at 33°C than at 39.5°C. In contrast, both anticancer agents, adriamycin and Ara-C, were about twice as effective in stimulating process formation at 39.5°C as compared to 33°C. These data are consistent with the possibility that adriamycin and Ara-C compared to glutamate, stimulate cellular differentiation through separate mechanisms. Induction of differentiation by adriamycin and Ara-C may require inactivation of SV40 large T tsA58 at the non-permissive temperature, and activation of p53 may contribute to differentiation under conditions of cellular damage.

**NEW BIOERODIBLE COPOLYMER AS IMPLANTS IN THE RAT BRAIN** S. Lahtivirta, W. Lu, P. Törmälä, J. Seppälä, and A. Hervonen\* Lab of Gerontol. School of Public Health, Univ. of Tampere, Finland, \*Biomaterial Res. Instit. of Plastic Technol., Tampere Univ. of Technology, \*\*Dept. of Chemical Engineering, Helsinki Univ. of Technology, Finland

Extensive research has been carried out into the use of nontoxic and tissue compatible biodegradable polymers in surgery. To develop a new drug delivery system for CNS, we have tested a new soft polymer as implant up to 32 weeks. Cylinders of mixtures of oligo(L-lactate) and caprolactone were placed surgically in rat parietal cortex. The fate of polymer and the tissue compatibility were followed using several histochemical markers. Traces of the polymer could be discovered still after 24-32 weeks. Some degree of surface erosion and degradation of the material was visible after 2-4 weeks and it proceeded with time. The implants showed ingrowth of glial elements but only weak surrounding gliosis. Capillaries were found inside the degrading implants after 4 weeks. Mixing drugs into the polymer did not change the degradation properties essentially.

The new soft copolymer tested in this study may provide a way to introduce neuroactive drugs into the brain. A sustained release may last as long as 8 months. The high tissue compatibility suggests that the polymer may serve as implantable scaffold for living cells as well.

**XENOGRAFTS OF CLONAL MOUSE MULTIPOTENT NEURAL PROGENITORS INTO INTACT & IBOTENIC ACID (IA)-LESIONED RAT BRAIN.** R.A. Fricker\*, C. Winkler\*, E.Y. Snyder\*, A. Bjorklund\*. <sup>1</sup>Lund University, Wallenberg Neuroscience Center, Solvegatan 17, S-223 62 Lund, Sweden; <sup>2</sup>Depts. of Neurology & Pediatrics, Harvard Medical School, Children's Hospital, Boston, MA 02115, USA

It has previously been demonstrated that the C17-2 murine multipotent, clonal, neural progenitor cell line can engraft & differentiate appropriately throughout the neural axis & across developmental stages (from embryo to adult) of intact (Neurosci. Abstr. 19:613, 1993; 20:1672, 1994; Nature 374:367, 1995; Nature Med 4:424, 1996) & injured (Exp. Neurol. 127:9, 1994; Neurosci. Abstr. 21:2028, 1995; 21:2027, 1995) mice. We wished to explore whether these cells would similarly be useful as xenografts in adult rat striatum subjected to an IA lesion, a model for Huntington's Disease. We investigated the engraftment of C17-2 in intact newborn & adult rats in order to compare their behavior in these hosts with that observed in mice. C17-2 cells, which express lacZ, were first transplanted as a suspension into the striatum or lateral ventricles of neonatal rat pups without immunosuppression. Analysis 4 wks. after grafting revealed that lacZ-expressing cells were detectable at a lower frequency in neonatal rats than in murine controls (20% vs. 60%, respectively). In addition, striatal grafts showed limited migration throughout the striatum & cortex, while intraventricular implants yielded more extensive integration in areas such as cortex, cerebellum & hippocampus, as previously reported for mice. Cells with morphologies resembling astrocytes, oligodendrocytes, & neurons were observed in varying proportions, depending on the site of integration. In the 2nd phase of the study, intact adult rat recipients, which were maintained on immunosuppression, were sacrificed 2 wks. after receiving transplants into the striatum. These results were compared, with adult immunosuppressed rats who received similar transplants into an IA-lesioned striatum. There was ~80% survival in all adult rat recipients. In intact adult rats, donor cells were confined to the injection site, whereas in lesioned hosts, the cells showed a greater degree of migration within the striatum, primarily within the lesioned area. Supported by the Wellcome Trust and the Swedish MRC.

## 306.8

**SV40 LARGE T ANTIGEN IMPAIRS DIFFERENTIATION OF N18-RE-105 CELLS.** O. Dillon-Carter\*, C. Concejero, C. Tornatore, and W. Freed. NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032; LMMN, NINDS, NIH, Bethesda, MD 20892

N18-RE-105 cells differentiate in response to adriamycin and glutamate, both of which increase p53 activity. In N18-RE-105 cells, glutamate toxicity is thought to involve inhibition of the glutamate-cystine antiporter and consequent depletion of glutathione (Murphy et al. Neuron 2:1547, 1989). Adriamycin is an anticancer agent which increases p53 activity in many cell types (El-Deiry et al. Cancer Res. 54:1669, 1993). SV40 Large T antigen, which is frequently employed to immortalize cells, has p53 binding activity. The present study tested the possibility that SV40 Large T antigen would impair the ability of N18-RE-105 cells to differentiate. N18-RE-105 cells were incubated with filtered supernatant from Ψ-2 cells which produce defective recombinant retrovirus containing the SV40 Large T tsA58 and neomycin resistance genes. The alkaline phosphatase gene was used as a control. After selection in G418, clones were isolated and examined for differences in growth properties and differentiation. Control clones expressing alkaline phosphatase showed normal growth patterns and differentiation in response to glutamate and adriamycin. In contrast, clones expressing SV40 Large T grew as isolated colonies with a rounded morphology and no processes. In addition to binding p53, SV40 Large T antigen blocks other cellular proteins which are important for growth control. Expression of SV40 Large T antigen may induce a state of continuous growth which is incompatible with differentiation.

## 306.10

**EX VIVO ADENOVIRUS-MEDIATED GENE TRANSFER INTO SUPRACHIASMATIC NUCLEUS (SCN) TRANSPLANTS.** K.E. van Esseveldt, W.T.M.C. Hermans, R. Liu, R.W.H. Verwer\*, J. Verhaagen and G.J. Roer, Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam ZO, The Netherlands.

Solid pieces of fetal anterior hypothalamus tissue containing the SCN were infected with an adenoviral vector containing the marker gene LacZ under control of the CMV promoter (Ad-LacZ). Thereafter, explants were either cultured in vitro or grafted into the third ventricle of adult Wistar rats. Using immunocytochemistry, expression of β-galactosidase (β-gal), the product of the LacZ gene, was evaluated after 8, 21 and 35 days in vitro (DIV) and 8, 21 and 70 days postgrafting (DPG). Infection of the explants for 18 h with 2x10<sup>8</sup> pfu/ml Ad-LacZ resulted in high numbers of β-gal-positive neurons and glial cells at 8, 21 and 35 DIV. Upon transplantation, expression of β-gal persisted up to 70 DPG. In transplants, the number of β-gal-expressing cells was initially high (DPG 8), but at DPG 21 and DPG 70 only a limited number of cells expressing the transgene was present. This decline in β-gal-positive cells is probably not related to an immune response directed towards the viral capsid since immunocytochemical stainings for macrophages (ED-1 positive) and T-lymphocytes (OX-8 positive) revealed a staining pattern as seen in sham-infected transplants. The procedure described for ex-vivo Ad-LacZ-mediated gene transfer will be used in the future to introduce expression of neurotrophic factors in SCN grafts.

This study was supported by a grant from NWO-MW, The Hague, The Netherlands (903-47-006) to K.E. van Esseveldt.

## 306.11

A NOVEL HERPES VIRUS BASED AMPLICON VECTOR FOR GENE DELIVERY INTO THE CNS. S. Di<sup>1</sup>\*, S. Wang<sup>2</sup>, C. D. Jacobson<sup>1</sup> and C. Link<sup>2</sup>  
<sup>1</sup>Dept. of Vet. Anatomy, Iowa State University, Ames, Iowa 50011 & <sup>2</sup>Human Gene Therapy Institute, Iowa Methodist Medical Center, Des Moines, Iowa 50309.

We have developed a Herpes Simplex Virus (HSV) / Epstein Barr Virus (EBV) based amplicon system for high transgene packaging titer and efficient transgene delivery both *in vitro* and *in vivo*. The viral vector can carry at least a 17 kb insert and show stable replication and packaging. Stereotactic injection of this viral vector with a reporter lac Z gene (pHE-lac) into the adult rat brain resulted in limited, transient viral expression. A moderate  $\beta$ -gal expression was present around the injection site within the caudate nucleus, whereas a substantial population of positively stained neurons was detected in the dentate gyrus following hippocampal injection. The facial nucleus showed maximum expression after injection at that site. In addition, the viral vectors appeared to have been transported along the facial nerve to its genu, and also reached the ipsilateral and contralateral locus coeruleus. Our data demonstrate a novel HSV/EBV amplicon vector that can reliably deliver transgenes into the rat CNS. Interestingly, the HSV/EBV viral vector may possess a preference for specific neuronal pathways with distinct expression thresholds and distribution patterns. This study suggests the interaction between viral vectors and target neurons is one of the key factors which may determine the success of transgene delivery and expression.

## 306.12

ADENO-ASSOCIATED (AAV) VIRAL VECTOR-MEDIATED GENE DELIVERY IN NON-HUMAN PRIMATES K.S. Bankiewicz\*, R. Snyder, S.Z. Zhou, M. Morton, J. Conway and D. Nagy, Somatix Therapy Corporation, Alameda, CA 94501.

*In vivo* gene therapy consists of introducing genetic material into dividing and non-dividing cells *in situ*. AAV vectors engineered to express  $\beta$ -galactosidase ( $\beta$ -gal) gene were introduced into monkey brains to determine the extent of infection and the cell types infected by the vector at 2 and 16 weeks. AAV-lacZ vector was infused into the striatum of normal monkeys (n=5) at 5, 10, 30 and 162  $\mu$ l using a bulk flow delivery method. There were no clinical side effects observed at 2 (n=4) or 16 weeks (n=1) post implantation. 40  $\mu$ m whole mount frozen sections were stained with hematoxylin-eosin (H&E), and with antibodies to  $\beta$ -galactosidase ( $\beta$ -gal), neurofilament (NFT) and glial fibrillary acidic protein (GFAP). Injection sites were found in the caudate nucleus, putamen and in one case the midbrain. Moderate infiltration was observed in the needle tracks and in close proximity to the injection site. In one infusion site, where the largest volume (162  $\mu$ l) was injected, some evidence of necrosis in the center was observed.  $\beta$ -gal-IR cells were found at the site of infusion. The spread of the infected cells appear to be volume-dependent reaching 5-7 mm from the needle track in the 162  $\mu$ l infusion sites.  $\beta$ -gal-immunoreactive (IR) cells appear to have neuronal morphology with long processes extending over 2 mm from the cell bodies. Double-labeling technique with NTF/  $\beta$ -gal immunoreactivity confirmed further the neuronal character of the majority of the infected cells. Only a small fraction of the cells presented GFAP/  $\beta$ -gal IR, and were recognized as astrocytes. The number of AAV infected  $\beta$ -gal-IR cells also appeared volume-dependent, and ranged from 1K cells at 5  $\mu$ l infusion to 31K in 162  $\mu$ l at 2 weeks. Some  $\beta$ -gal-IR cells were also present at 16 weeks. These findings suggest that the AAV vector administration is a potential tool for gene delivery in the CNS.

Sex Differences in Aging of the Human Striatum: An *In Vivo* MRI Study.

F.M. Gunning\*, D. Head, J.D. Acker, & N. Raz

Age and gender differences as well as lateral asymmetries have been observed in motor behavior across many species. These differences may be related to the morphology of the different nuclei in the basal ganglia. However, the evidence of morphological asymmetries and sex differences in the basal ganglia of healthy adults is sparse, especially in regards to the paleostriatum. To examine age, sex, and hemispheric differences in the basal ganglia we measured the volumes of these nuclei in healthy right-handed adults (N=144, 18-77 years old) using MRI-based morphometry. Previously (Soc. Neurosci. Abstr. 21, p 1564, 1995) we reported bilateral age-related changes in both the head of the caudate nucleus (Cd) and the putamen (Pt). In this study, we examined the globus pallidus (Gp) and observed bilateral age-related shrinkage of that structure in males but not in females. Leftward asymmetry of the Cd and rightward asymmetry of the Pt were observed; no hemispheric asymmetry was found in the Gp. Supported by the grant AG11230 to N.R.

## 307.2

AGE-RELATED DENDRITIC AND SPINE CHANGES IN HUMAN OCCIPITAL AND PREFRONTAL CORTICES: A QUANTITATIVE GOLGI STUDY. K. Courms<sup>1</sup>, J. Ferguson<sup>1</sup>, L. Larsen<sup>1</sup>, B. Addleson<sup>1</sup>, M. Schall<sup>2</sup>, and B. Jacobs<sup>1\*</sup> <sup>1</sup>Laboratory of Quantitative Neuromorphology, Psychology, The Colorado College, Colorado Springs, CO 80903. <sup>2</sup>Psychology, Tulane University, New Orleans, LA 70130.

The present study quantitatively examines age-related dendritic/spine changes in human prefrontal (area 10) and occipital (area 18) cortices. Tissue was removed from the left hemisphere of 10 neurologically normal subjects, ranging in age from 23 to 81 years. These individuals were grouped into a younger (<50 years) and older (>50 years) age group for subsequent analyses. After staining with a modified rapid Golgi technique, the basilar dendritic systems of 10 supragranular pyramidal cells per tissue block (N=200) were quantified on a NeuroLucida system (MicroBrightfield, Inc.). Dependent measures were total dendritic length (TDL), mean dendritic length (MDL), dendritic segment count (DSC), dendritic spine number (DSN), and dendritic spine density (DSD).

With the exception of DSC, all dependent measures tended to decrease with age. Most pronounced were significant declines of approximately 50% in DSN ( $F(1,2) = 118.15, p < 0.0001$ ) and DSD ( $F(1,2) = 210.12, p < 0.0001$ ) from the younger to the older age group. Dendritic differences in Brodmann's areas tended to be greater in the younger group than in the older group, with area 10 exhibiting higher dependent values than area 18, especially for DSN ( $F(2,36) = 11.11, p < 0.0001$ ) and DSC ( $F(2,36) = 6.81, p < 0.0015$ ). Across the represented adult lifespan, dendritic declines were slightly more pronounced in area 10 than in area 18. The present results quantitatively document the ongoing, dynamic refinement of dendritic neuropil across the human life span, and suggest that higher order cortical areas (e.g., area 10) may be more susceptible to age-related changes than lower order cortical areas (e.g., area 18). AGE-RELATED ALTERATIONS IN NEUROFILAMENT PROTEIN IMMUNOREACTIVITY IN MOTONEURONS IN THE BRAINSTEM AND SPINAL CORD IN CATS. J.-H. Zhang\*, S. Sampogna, F.R. Morales and M.H. Chase, Department of Physiology and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Abnormalities in neurofilament expression occur in a variety of human neurodegenerative diseases that progress with age such as Alzheimer's Disease, Parkinson's Disease and amyotrophic lateral sclerosis. However, little is known about the alteration of neurofilament expression during normal aging. Accordingly, using immunohistochemical techniques, we compared neurofilament protein immunoreactivity in motoneurons of the brainstem and spinal cord in two adult (1-3 years of age) and an old (18 years of age) cat which did not exhibit signs of human neurodegenerative diseases. We examined these neurons because in previous studies we have found age-related changes in the electrophysiological properties and morphological characteristics of motoneurons and their axons (Morales et al., J of Neurophysiology, 58:180-194, 1987; Chase et al., Brain Res., 586:279-288, 1992), which could be the result of alterations of neuronal neurofilament expression. Three kinds of antibodies were used to identify different neurofilament subunits of low-, medium- and high-molecular weight, respectively. In order to compare changes in the immunoreactivity of these three neurofilament subunits, sets of sections from adult and old cats were treated simultaneously under identical conditions. The results demonstrated a dramatic decrease in the density of neurofilament immunoreactivity involving the three different subunits in motoneurons of the 18 year old cat. These data indicate that neurofilament abnormalities occur not only in a variety of human neurodegenerative diseases, but also in another mammal and that they may play a role in the electrophysiological and morphological changes observed in aged cat motoneurons. Supported by USPHS Grant AG 04307.

## 307.4

DECREASED NEUROFILAMENT (NF-L) GENE EXPRESSION IS AN INDEX OF SELECTIVE AXONAL HYPOTROPHY IN AGING.

G.A. Kuchel<sup>1</sup>, T. Poon<sup>1</sup>, K. Irshad<sup>1</sup>, C. Richard<sup>1</sup>, J.-P. Julien<sup>2</sup> and T. Cowen<sup>3</sup> <sup>1</sup>Geriatrics and Neuroscience, Montreal General Hospital, Montreal, Canada H3G 1A4; <sup>2</sup>Royal Free Hospital School of Medicine, London, UK.

The ability of neurons to sustain an innervation to their targets is necessary for the maintenance of normal function in aging. Axonal atrophy and degeneration by vulnerable projection neurons may be earlier and more readily reversible events in neurodegeneration and aging than are regressive somatic changes. Sympathetic innervation to the middle cerebral artery (MCA) and pineal, both targets of the rat superior cervical ganglion (SCG), decreases by over 50% in old age, while sympathetic innervation density to the iris is unchanged.

Young and aged male SD rats underwent retrograde labeling of neurons projecting either to MCA (Fast Blue) or to iris (Fluorogold). A minority of SCG neurons (~2%) exhibited either FB or FG (but never both). *In situ* hybridization for neurofilament light chain (NF-L) mRNA revealed that a moderate 22-25% decrease in the mean grain density for this mRNA was present in many aged SCG neurons. Using retrograde tracers, there was evidence for a 40% decline with aging in the grain density for NFL mRNA in MCA-projecting neurons ( $p < 0.05$ ), while this parameter was unchanged in SCG neurons innervating the iris. Our results suggest that selective regressive changes in the axonal compartment of aged neurons are associated with significant decreases in neurofilament (NF-L) mRNA expression. (funding: MRC Canada; FRSQ Quebec & British Heart Foundation)

## 307.5

Protein Profiling: Use of Immuno-aRNA. Jim Eberwine and Lori Rogers. Depts. of Pharmacology and Neuroscience, University of Pennsylvania Medical School, Philadelphia, PA. 19104.

Information about mRNA levels is critical to understanding the functioning of the cell and provides a molecular fingerprint of physiological state; yet, in general, it is the resultant proteins that are translated from these mRNAs which act as receptors, channels, enzymes and structural proteins which facilitate cellular functioning. Electrophysiological techniques at the single cell level will permit the monitoring of ion channel functioning as well as the functioning of other receptors or proteins which are coupled to channels. It is however difficult to detect the small amounts of other proteins that do not directly couple to ion channels, which the expression profiling and immunohistochemistry show are present and potentially regulated within an individual cell. To make this connection between coordinated mRNA level changes and presence of protein, a new technique called immuno-aRNA has been developed for use in the single cell. This technique permits the detection of small amounts of antigen-antibody complex by taking advantage of the sensitivity of aRNA amplification. Briefly, the technique provides increased sensitivity over standard protein detection methodologies by covalently coupling an T7 promoter-driven cDNA sequence to the secondary antibody so that the nucleotide sequence can be amplified using T7 RNA polymerase. We have generated data showing that we can detect TAU protein (an intermediate filament) utilizing this technology. Currently we are attempting to determine the relative ratios of phosphorylated-Tau to nonphosphorylated Tau in single cells during the ageing process. This work was supported in part by AGC900.

## 307.7

SYNAPTOSOMAL AND MITOCHONDRIAL MEMBRANE ALTERATIONS IN BRAIN AGING. M. Sugawa, G. Schulze, F. Krause, C. Sajak and N.A. Dencher (SPON: European Neuroscience Association). HMI, BENSCH-NE, Glienicke Str. 100, D-14109 Berlin, Germany (M.S.); Neuropsychopharmacology, FU Berlin (G.S.); Physical Biochemistry, TH, D-64287 Darmstadt (F.K, C.S, N.A.D).

Age-associated alterations in the energetic state of the cell as well as in the cAMP and PI signal pathways could be due to changes in the physical and chemical properties of the membranes. To support this hypothesis, age-dependent changes in the physical state and the biochemical composition of synaptosomal and mitochondrial membranes from the cortex, cerebellum, hippocampus, hypothalamus, and striatum of female Wistar rats were examined by measuring the steady-state fluorescence anisotropy of the membrane probes 1,6-diphenyl-1,3,5-hexatriene (DPH) and TMAP-DPH. Significant differences in the properties of the synaptosomal membranes existed between young (3.5 months) and very aged rats, expressed by a higher anisotropy (i.e., decreased membrane "fluidity") and an increase in cholesterol content of the 40-month-old rat brain tissue. For the various brain regions investigated, the magnitude of the age-dependent differences in anisotropy was similar and similar differences were observed in the hydrophobic core of the membranes (DPH) and in the regions closer to the lipid headgroups (TMAP-DPH). Furthermore, protein and lipid oxidative damage in synaptosomal and mitochondrial membranes was analyzed.

## 307.9

Ontogenic changes of GABA<sub>A</sub> function of the rat Meynert neuron. M. Ueki, J. S. Rhee, Y. H. Jin and N. Akaike Department of Physiology, Kyushu University Faculty of Medicine, Fukuoka 812-82, Japan.

The functional change of GABA<sub>A</sub> receptor with aging was studied in the freshly dissociated rat Meynert neurons by using nystatin perforated patch recording configurations under voltage-clamp condition. Kinetic fits of GABA concentration-response relationships revealed clear developmental changes in the potency of GABA response. The current density decreased from 111.1 pA/pF at 0-3 days after birth (p0 - p3 days) to 74 pA/pF at p6 months, indicating that the current amplitude decreased to almost half of immature rats in adult rats. However, the ligand binding affinities increased with aging, where EC<sub>50</sub> values were 3.46x10<sup>-5</sup> M for p0-p3 days rats and 1.16x10<sup>-5</sup> M for p6 months. Study for benzodiazepine (BZ) receptor modulated GABA response using diazepam and zolpidem revealed that BZ action is mediated mainly by BZ1 receptor in p2 weeks and p6 months, whereas in p1 day rat, the most of BZ receptors were BZ2. We obtained spontaneous GABAergic inhibitory post synaptic current (sIPSC) in acutely dissociated neurons attached presynaptic bouton. The 'off' relaxation kinetics of sIPSCs also have fitted biexponential which is  $\tau_1$  and  $\tau_2$  for p0-2 days and p2 weeks rats. The sIPSCs of p2 week rat were faster twice relatively than p0-2 days rat. These changing of GABA response with aging might correspond to functionally distance postsynaptic receptors in inhibitory synapses.

## 307.6

CHARACTERIZATION OF INCREASED TYROSINE HYDROXYLASE mRNA IN AGED SYMPATHETIC NEURONS.

M. Sales-Prato and G.A. Kuchel Geriatric Medicine, Montreal General Hospital, Montreal, Quebec, Canada H3G 1A4

It appears that declines in gene expression in the aging nervous system are not generalized, but rather modest, with considerable specificity in terms of the mRNA species and neuronal populations affected. Examples of increased gene expression in aging have often involved non-neuronal cells. Several studies have reported moderately increased tyrosine hydroxylase (TH) activity and mRNA levels with aging in extracts of rodent sympathetic superior cervical ganglia (SCG). It has been assumed that these changes are due to increased sympathetic nerve activity.

Quantitative *in situ* hybridization studies were performed using sections from mature and aged male F-344 rats mounted on the same slide. We observed no significant difference in the mean Labeling Index (LI) for cyclophilin mRNA. In contrast, the LI for TH mRNA exhibited a mean increase of 74% ( $p < 0.0001$ ) in aged as compared to mature SCG neurons. The majority of neurons demonstrated only modest (~10-20%) increases. Concomitantly, a subset (~11%) of intermediate-sized (300-800  $\mu^2$ ) aged neurons appeared to be responsible for the greatest increase in TH mRNA LI with 4-10 fold increases above the mean found in mature neurons. Glyoxylic acid fluorescence, cell size, numbers and distribution indicate that these are not SIF cells. Tracer studies combined with *in situ* hybridization suggest that these neurons do not overlap with those projecting to the middle cerebral artery, a target exhibiting considerable axonal sympathetic hypotrophy in aging. Further tracer and lesion studies are underway to establish the nature of the anterograde and/or retrograde stimuli underlying this marked increase in neuronal gene expression with aging. (funding: MRC Canada & FRSQ)

## 307.8

DISTRIBUTION OF NEUROPEPTIDE Y-IMMUNOREACTIVE NEURONS IN THE CAUDAL PART OF SPINAL TRIGEMINAL NUCLEUS OF RAT WITH AGE. M. K. Kim, K. S. Paik, S. P. Lee. Dept. of Oral Anatomy, College of Dentistry, Seoul National University, Seoul 110-749.

The purpose of this study was to undertake the distribution of neuropeptide Y(NPY)-immunoreactive (IR) neurons in the caudal part of spinal trigeminal nucleus of rat with age by means of immunohistochemistry. In the medulla oblongata of rat, a large group of NPY-immunoreactive neurons was seen in spinal trigeminal nucleus. (Yamazoe et al., Brain Research, 335: 109-120, 1985). For this study, Sprague-Dawley rats of 3, 12, 24, 36 months of age were used. Animals were perfused transcardially with 4% paraformaldehyde in 0.1M phosphate buffer (PH7.4). Brains were taken out immediately. Serial frozen 30  $\mu$ m thick sections were made in the coronal plane. Sections were incubated in primary rabbit antiserum to NPY with a dilution of 1:2000, placed into goat rabbit IgG with a dilution of 1:500 and incubated in rabbit PAP( Peroxidase- anti-peroxidase). Then, sections were developed for peroxidase reactivity with 3,3'-diaminobenzidine (DAB). After visualization with DAB, sections mounted in a glycerol and coverslipped. The some sections were stained with toluidine blue and cresyl violet for counterstain. The numbers of NPY-IR perikarya and NPY-IR fibers in the caudal part of spinal trigeminal nucleus were gradually decreased with aging. These results indicate that decrease of the NPY-IR neurons and fibers with aging may concerned with their hypofunction.

## 307.10

AGE-RELATED CHANGES IN THE RHESUS MONKEY: MORPHOLOGY OF NEURONS IN SUBSTANTIA NIGRA-PARS COMPACTA. Z. A. Siddiqui, A. Peters, T. L. Kemper and M. L. Feldman. Dept. of Anatomy and Neurobiology, Boston Univ. School of Med., 80 East Concord St., Boston, MA 02118.

Our studies in rhesus monkey have shown that the dopaminergic pars compacta undergoes a significant age-related neuronal loss. This reduction in the total neuronal number is about 30 per cent when the oldest subject is compared to the youngest animal. The aim of present study is to examine the morphological changes that occur in the neurons of this nucleus during the aging process. Three types of neurons, small, medium and large, have been identified in the pars compacta in younger monkeys (<10 years) on the basis of the size and shape of their soma, dendritic pattern and arrangement of rough endoplasmic reticulum. All three types of neurons show age-related degenerative changes in older animals (>25 years), with the small type being most affected. Although most neurons of the pars compacta accumulate lipofuscin with progressing age, it is the small neurons that show the most extensive accumulation of this pigment. In the electron microscope all types of neurons show membrane bound, clear vacuole in their cytoplasm and a variety of inclusions have been observed in the neuronal nuclei of old animals. In the neuropil there is a large number of degenerating dendritic profiles in which the cytoplasm is vacuolated, and frequently these dendrites contain dark inclusions whose origin is not known. In the pars compacta of older monkeys there are round to oval shaped, darkly staining bodies of the same size as small neurons some of which appear to have a process radiating out from them. In the electron microscope these bodies are seen to be membrane bound, have irregular contours and have a pale homogenous matrix in which a dark granular material is embedded. These bodies are surrounded by astrocytic processes. Whether these represent degenerating neurons or large inclusions in astrocytes has yet to be determined. (Supported by NIH grant P01- AG00001)

## 307.11

AGE-RELATED SYNAPTIC CHANGES IN SENSORIMOTOR CORTEX OF THE F344 X BROWN NORWAY RAT. M.C. Linville\*, J.K. Brunso-Bechtold and W.E. Sonntag. Depts. Neurobio/Anat. & Physio/Pharm., Prog. In Neuroscience, Bowman Gray School of Med., Wake Forest Univ., Winston-Salem, NC 27157.

In the present study, the focus was to assess age-related synaptic changes in sensorimotor cortex. Five F344 X Brown Norway rats were cardiac perfused at each of the following ages: young (10 mos), middle age (15 mos), and old (32 mos). The brains were coronally vibratomed at 200  $\mu$ m. The sensorimotor cortex was blocked by examining the sections using a dissecting microscope. The blocks were processed for electron microscopy and embedded in plastic. Three different sensorimotor cortex blocks from each animal were selected and semithin (1  $\mu$ m) sections were cut and collected on glass slides. Thin sections were cut and examined using a Zeiss 10-CA electron microscope. Using the semithin section as a map for locating layers II and IV, twelve electron micrographs were taken in each of these layers. From the electron micrographs, sample area size, percent neuropil, and total number of synapses were determined. Synapses were also characterized by vesicle shape and postsynaptic element. Preliminary analysis shows that synaptic density increases significantly in old compared to young rats in layer II but not in layer IV. Of these synaptic terminals, the number of round vesicle containing terminals per unit volume increases in old compared to young rats in layer II but not in layer IV whereas the number of nonround vesicle containing terminals increases in both layers. Interestingly, the percent of synaptic terminals that contain round vesicles (presumptive excitatory terminals) decreases significantly between young and old in both layers II and IV. Taken together, these data suggest 1) that age-related changes in synaptic input may affect cortical layers differentially and 2) the balance of presumptive excitatory input to cortical layers in relation to presumptive inhibitory input may decrease with age. ## 307.13

SPINAL CORD EXPLANT CULTURES ARE USED TO STUDY NERVE REGENERATION IN MATURE AND OLD F344 RATS. J.M. Jacob, A.L. Aulthouse and D.L. O'Donoghue\*. Dept of Anat Sci., Univ. of Oklahoma HSC, OKC, OK 73190.

The use of tissue and organ cultures to examine growth and repair processes in injured neurons is not new. However, until now, most studies have focused on dissociated cells and tissues derived from embryonic and neonatal animals because they are undifferentiated and still mitotic. To examine the regulatory pathways involved in initiating and sustaining the cell body response to injury in mature and old animals, we have developed an organ culture model that is not subject to the "age limitations" of dissociated cell and tissue culture. Using lumbar spinal cord explants taken from 6 and 24 mo F344 rats, we tested several culture conditions to assess neuronal viability. Here we demonstrate that both poly-L-lysine and laminin permit attachment of the explant to the substratum while an agarose overlay is necessary to secure the organ culture in place. Dulbecco's Modified Eagle's Medium (DMEM) without serum provides sufficient nutrient support for neurite outgrowth, which was observed within 24 hours. Histochemical (H&E, cresyl violet) and immunocytochemical (GFAP, CGRP, NSE) analysis of cultures was used to demonstrate cell viability as well as demonstrate that this model system is, in some respects, comparable to a lesion *in vivo*. Supported in part by a grant from AFAR (JMJ).

## 307.15

AGE-RELATED CRITICAL PERIODS IN MATURATION OF CEREBELLAR PURKINJE CELLS IN MATURE AND ALTRICIAL BORN ANIMALS. R. Grigorian, \*E. Prigara. Institute of Evol. Physiology and Biochemistry, St. Petersburg, Russia.

The maturation of synapses from principal cerebellar afferents - mossy and climbing fibers afferent systems onto Purkinje cells (PC) dendrites in guinea pigs and kittens takes place mainly after birth and goes on irregularly in the early stages of postnatal ontogenesis. The present study aimed to determine age-associated critical periods of functional maturation of cerebellar PC in mature (guinea pig) and altricial (kitten) born animals. Experiments were performed on anaesthetized animals aging from newborn up to 2 months old. Critical periods were evaluated by the significant changes in PC activity and by the animal motor status before the experiment. In guinea pigs which are born capable of standing, only one critical period of change in PC discharge frequency occurred (from  $12.9 \pm 1.8$  to  $23 \pm 2.2$  imp/s at 12-14 days of ontogenesis). Three critical periods were found in kittens, however: 1/ before eye opening time, 7-8 days of postnatal life (PL); 2/ after eye opening time on 18-22 days of PL, when discharge frequency of PC increased dramatically by 10 times; 3/ on the border of the first and second month of postnatal life, when play-like movements begin to elaborate. The received data suggest that critical periods in maturation of PC discharge frequency reflect the development of motor skills.

## 307.12

EVIDENCE FOR DECLINE IN SMOOTH ENDOPLASMIC RETICULUM CALCIUM BUFFERING WITH AGE IN RAT ADRENERGIC NERVES. H. Tsai, B.J. Pottorf, S. Foucart, J. Buchholz\* and S.P. Duckles. Depts. Pharmacology, Coll. Med. Univ. Calif., Irvine, CA 92717 and Loma Linda Univ. Sch. Med. Loma Linda, CA 92350.

Stimulation-evoked norepinephrine (NE) release from tail artery adrenergic nerves increases with advancing age in the Fischer-344 rat with no corresponding changes in function of uptake mechanisms, metabolism or prejunctional  $\alpha$ -2 adrenoceptors. To examine this at the cellular level, intracellular calcium concentration was measured in acutely dissociated superior cervical ganglion neurons using fura-2/AM. When smooth endoplasmic reticulum (SER) calcium uptake was blocked with thapsigargin (1  $\mu$ M), stimulation-evoked NE release from tail arteries and depolarization-evoked calcium transients in isolated cells significantly increased in 6 month-old tissues with no effect in 20 months. The rate of rise of calcium with K<sup>+</sup>-depolarization increased after thapsigargin treatment but only in young cells. In contrast, we have previously shown that blockade of mitochondrial calcium uptake with dinitrophenol increased stimulation-evoked NE release from tail arteries and depolarization-evoked calcium transients in isolated superior cervical ganglion cells in 20 months with no effect in 6 months. Therefore, older nerves appear to be more reliant on mitochondria for intracellular calcium buffering due to a decline in function of SER calcium buffering systems. These data suggest that age-related increases in NE release are due to a decline in SER calcium buffering mechanisms.

## 307.14

DECREASE IN THE CONDUCTION VELOCITY OF PYRAMIDAL TRACT NEURONS IN THE AGED CAT. R.-H. Liu\*, M.-C. Xi, F.R. Morales, J.K. Engelhardt and M.H. Chase. Department of Physiology and the Brain Research Institute, UCLA School of Medicine, University of California, Los Angeles, CA 90024.

In the present study we wished to determine whether age-dependent changes in conduction velocity occur in pyramidal tract neurons. A total of 260 and 254 pyramidal tract cells were recorded extracellularly in the left pericruciate gyrus from 2 adult control and 2 aged cats, respectively. These cells were antidromically activated by stimulation of the medullary pyramidal tract. In order to calculate their conduction velocities, the straight-line distances between stimulating and recording sites were divided by the antidromic conduction times of the spikes. Fast and slow conducting pyramidal tract cells were recorded in both control and aged cats. However, 50% of the pyramidal tract cells recorded in the control cats were fast conducting, while only 26% in the aged cats were fast conducting. As a consequence, there was a 27% decrease in the conduction velocity of pyramidal tract neurons in aged cats when compared with neurons in the control cats ( $22.5 \pm 0.7$  vs.  $16.4 \pm 0.7$  m/s, for control and aged cats, respectively,  $P < 0.0001$ ). The bases for this decrease in conduction velocity remain to be determined; possible contributing factors are demyelination, reduction in axon diameter and/or death of the fast conducting cells. We have previously reported a reduction in the conduction velocity of spinal cord motoneurons in aged cats (Morales *et al.*, *J. Neurophysiol.*, 1987, 58:180); these cells have long axons which are located principally outside the CNS and receive trophic support from Schwann cells and the muscle fibers which they innervate. The finding of a reduction in pyramidal tract conduction velocity in aged cats is noteworthy because it shows that this phenomenon is present in neurons that, in contrast to motoneurons, are contained entirely within the CNS, are supported by different types of glial cells and innervate neuronal targets, not muscle fibers. Therefore, we postulate that during the process of aging there are specific alterations inherent to neurons that do not depend on changes in non-neuronal tissue. Supported by USPHS Grant AG 04307.

## 307.16

NEURON NUMBERS IN THE MYENTERIC PLEXUS OF AGED RATS: EFFECTS OF DIETARY RESTRICTION. R.J.R. Johnson, R.M. Santer\* & T. Cowen\*. Dept. of Anatomy and Developmental Biology, Royal Free Hospital School of Medicine, London NW3 2PF, UK and \*MOMED, University of Wales College of Cardiff, P.O. Box 911, Cardiff CF1 3US, UK.

A reduction in neuronal numbers of up to 60% has been reported in the enteric nervous system of aged rats fed on an *ad lib* diet, offering at least a partial explanation for the age related functional deficits apparent in enteric neuromuscular transmission. Our study has investigated whether this loss occurs when a 60% restriction of diet is imposed from 10 weeks of age, other studies having shown this regime to enhance the longevity and health of laboratory animals. We have evaluated total neuronal numbers within the myenteric plexus of ileal whole mount preparations from Sprague Dawley rats, aged 4 and 24 months, using the NADH-diaphorase method and the pan-neuronal marker, PGP 9.5. Neuronal sub-population numbers were assessed using antibodies to ChAT, SP, ENK, SOM, NPY, VIP and neurofilament, as well as the NADPH-diaphorase method to demonstrate nitergic neurons. Positive cell bodies were counted using light or fluorescence microscopy and corrected for age related growth of the small intestine. Differences between age groups were assessed with student's t-test. Whilst a small decline of 15% ( $p < 0.05$ ) was evident in the numbers of NADH-positive neurons with age, PGP not only stained a substantially larger numbers of neurons in young and old preparations, but showed no evidence of neuronal loss in old age. Neurofilament immunoreactive neuron numbers increased significantly with age ( $p < 0.05$ ), whilst the cholinergic, peptidergic and nitergic markers failed to demonstrate any significant cell loss, confirming that neuron numbers remain relatively unaffected by age. We speculate that dietary restriction may prevent the cell loss apparent in the myenteric plexus of aged *ad lib* fed rats. This work was supported by the Anatomical Society of Great Britain & Ireland.

## 307.17

ALTERATIONS IN MYSTACIAL PAD INNERVATION IN THE AGED RAT  
B.T.Fundin\*, E.Bergman and B.Ulfhake Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden S171 77.

In the aging rat, changes in the content of neuropeptides have been observed in sensory ganglia. Primary sensory neurons in the aged rat showed an increase in the expression of neuropeptide Y (NPY) mRNA and galanin mRNA whereas a decrease was evident in the expression of calcitonin-gene related peptide (CGRP) mRNA and substance P (SP) mRNA. The changes in expression resemble many of those induced by nerve lesions in young adult rats, suggesting that aging-related lesions are involved. Dystrophy and degeneration of axons have been reported to occur in both central and peripheral sensory pathways.

The mystacial pad was used to assess the impact of aging on cutaneous innervation. The mystacial pad has been shown to receive a large variety of sensory nerve endings organized in a highly predictable pattern. Seven aged (30 months old) male Sprague-Dawley rats and six young adult male rats were used. Immunofluorescence analyses were performed using antibodies against human neuronal cytoplasmic protein (PGP 9.5), neurofilaments and several neuropeptides. The Merkel endings and lanceolate endings that emanate from large caliber afferents in the whisker follicles showed signs of degeneration as well as a substantial decrease in number, whereas most medium caliber mechanoreceptors appeared normal. No obvious change in the CGRP, SP or galanin-IR could be determined in terms of intensity and localization. However, NPY was upregulated but only in a specific population of CGRP-IR small caliber axons which also coexpressed galanin-IR. Normally, NPY-IR is not observed in this set of axons. Interestingly, two additional networks of fine caliber axons which are not present normally were located in the outer and inner root sheaths of the whisker follicles. The epidermis was thinner in the aged rat and showed a loss of unmyelinated components that arise from the subepidermal plexus located just under the basement membrane. Perivascular innervation was present but showed a great loss in the centrifugally distributed sensory components.

## BLOOD-BRAIN BARRIER II

## 308.1

COMPARISON OF THE LIGAND BINDING SITES OF THE BLOOD-BRAIN BARRIER, NEURONAL AND ERYTHROCYTE CHOLINE TRANSPORTERS. DD Allen\*, JRS Matharu, PA Crooks, QR Smith. School of Pharmacy, Texas Tech HSC, Amarillo TX; College of Pharmacy, Univ. of Kentucky, Lexington KY; LNS, NIA, Bethesda MD.

Choline uptake into cells is mediated by one or more transport systems that differ in substrate affinity and sodium dependence. In the present study, the substrate specificity of neuronal, erythrocyte and brain capillary choline transporters was assessed to obtain insight into binding site structure and to identify selective ligands. These carriers exhibit similar 'affinity' ratios ( $K_m/K_i$ ) with some differences. Hemicholinium-3 exhibited strong preference for the neuronal high affinity choline transporter, with an inhibition constant ( $K_i$ ) 10-100 times lower than that at the brain capillary or red cell membranes. In contrast, deanol exhibited 6-fold higher affinity for the brain capillary transporter compared to the erythrocyte and *N*-n-butyl choline demonstrated ~25 fold range in affinity ratios among the BBB, neuronal and erythrocyte transporters, suggesting these compounds may have utility in distinguishing the carriers. Two very high affinity analogs were identified for the brain capillary transporter, *N*-n-octyl- and *N*-n-hexyl-choline, which showed 20-fold greater affinity at the brain capillary than choline itself. Using affinity data for a range of compounds, the structure of the binding sites was modeled with the computer program SYBYL. Comparison of highly active, active, and inactive compounds allowed for prediction of ligand available, ligand excluded and ligand high affinity zones of the binding sites. Comparative molecular field analysis (CoMFA) was used to develop a 3-D model which incorporated steric, hydrophobic and electrostatic factors. The models predict different binding sites that may have utility in differentiating affinity and selectivity among these carrier systems. (NIH Intramural Program)

## 308.2

DISTINCT EXPRESSION OF RECEPTORS LINKED TO  $Ca^{2+}$  SIGNALING IN RAT AND HUMAN CEREBROMICROVASCULAR ENDOTHELIAL CELLS. R Monette, D Stanimirovic, R Ball, 'E Hamel, K Chaundy' & P Morley National Research Council, Ottawa & 'Montreal Neurological Institute, Montreal, Canada

Cerebromicrovascular endothelial cells, an *in vitro* model of the blood brain barrier (BBB), express a variety of receptors for neurotransmitters and vasoactive mediators known to regulate local cerebral blood flow and/or BBB permeability *in vivo*. In this study we compare the expression of receptors for vasoactive mediators coupled to  $Ca^{2+}$ -signaling in rat (RBEC) and human (HBEC) cerebromicrovascular endothelial cells. RBEC and HBEC were isolated by cloning capillary endothelium from dissociated microvessels derived from adult rat brain cortex and from samples of human temporal lobe surgically excised for the treatment of idiopathic epilepsy, respectively. Both RBEC and HBEC expressed Factor VIII-related antigen and high activities of alkaline phosphatase. HBEC were highly enriched in the BBB-specific enzyme,  $\gamma$ -glutamyl-transpeptidase ( $\gamma$ -GTP), relative to RBEC. Vasoactive peptides, angiotensin II (200  $\mu$ M), bradykinin (20  $\mu$ M) and endothelin-1 (10 nM) induced simultaneous increases in  $IP_3$  and  $[Ca^{2+}]_i$  (measured by fluorescence techniques) in both RBEC and HBEC. The  $[Ca^{2+}]_i$  responses for all three peptides were due to the release of  $Ca^{2+}$  from internal stores since they were not affected by incubating the cells in  $Ca^{2+}$ -free medium or by pretreating the cells with  $Ca^{2+}$  channel blockers or the phospholipase C inhibitors, neomycin or U-73122. In contrast,  $IP_3$  and  $[Ca^{2+}]_i$  increases were observed in RBEC, but not HBEC, in response to ATP (100  $\mu$ M), and in HBEC only, in response to histamine (100  $\mu$ M). Neither RBEC nor HBEC responded to carbachol (1 mM), serotonin (100  $\mu$ M), or glutamate (1 mM). The distinct profiles of  $\gamma$ -GTP expression and receptor-linked  $IP_3/Ca^{2+}$  signaling in RBEC vs. HBEC, demonstrate significant species differences in the properties of brain endothelial cells, which may translate into dissimilar responses of brain microvasculature to vasoactive mediators in different species *in vivo*. ## 308.3

DIFFERENTIAL AGRIN AND ZO-1 EXPRESSION ON PERMEABLE AND IMPERMEABLE BLOOD VESSELS OF THE RAT RETINA. E. Lieth\*, A.J. Barber\*, S. Khin\* and T.W. Gardner\*. Depts. of 'Neuroscience & Anatomy, and 'Ophthalmology, Penn State University College of Medicine, Hershey, PA 17033.

Agrin is expressed in the basal lamina (BL) of brain capillaries, where it accumulates during the time when the blood-brain barrier forms. The microvascular distribution of agrin is selective to tissues with blood-tissue barriers. We have now looked also at the retina, which has both permeable and impermeable capillaries. We used indirect immunofluorescence to determine the expression of agrin and the tight junction protein ZO-1 on the barrier vessels in the neural retina compared to the relatively permeable choroid vasculature.

ZO-1 expression was determined by immunofluorescence staining either with monoclonal antibody R-40-76 or with a rabbit polyclonal antiserum. R-40-76 selectively stains vessels in the neural retina and choroid vasculature, but not the RPE in a pattern consistent with localization to tight junctions. The antiserum also stains intercellular junctions of the RPE. Agrin immunofluorescence is very bright on vessels of the neural retina, much dimmer on the choroid vessels, and undetectable in the BL of the RPE. In the ciliary body epithelial tight junctions are immunoreactive with anti-ZO-1 and the epithelial BL contains agrin, consistent with our previous findings in the choroid plexus of the brain. These results suggest that high microvascular agrin expression correlates with the presence of blood-retinal barrier in capillaries of the neural retina while tight junctions are present on all vessels. (Funding NIH K11 EY00331 and PA Lions).

## 308.4

DEHYDRATION INCREASES THE GLUT1 GLUCOSE TRANSPORTER BUT NOT CAPILLARY DENSITY OR FILLING IN THE HYPOTHALAMO-PITUITARY AXIS OF THE RAT. R.B. Pace\*, T.M. Rutherford, R.M. Bryan Jr., J.A. Simpson, and S.J. Vannucci. Div. of Neurosurgery, Milton S. Eshelby Medical Center, Hershey, PA 17033.

We investigated the hypothesis that increased delivery of substrate to magnocellular neurons in the *supraoptic* and *paraventricular nuclei* during periods of increased functional demands could be secondary to increased capillary filling or an increase in the glucose transport capacity of microvessels. We measured the capillary volume fraction and the percent capillary filling in the *supraoptic* and *paraventricular nuclei* of adult male rats by the point counting technique under control conditions and following two days of dehydration. The percent capillary filling did not significantly change in either of these neurosecretory nuclei with dehydration. We measured the concentration of the GLUT1 transporter in the same neurosecretory nuclei under the same conditions by *in situ* hybridization and autoradiography. The optical density in the *paraventricular nucleus* increased 18.7% and that in the *supraoptic nucleus* increased by 27.1 % with dehydration. These increases were statistically significant. Capillary volume fraction did not change during this period of dehydration. Because the concentration of capillaries in the *supraoptic nucleus* and in the *paraventricular nucleus* did not increase and the expression of glucose transporters present in capillaries did increase, these results support the hypothesis that the concentration of vascular glucose transporters increases in response to increased regional functional demand.

## 308.5

**ENDONEURIAL HYDROSTATIC PRESSURE IN RAT SCIATIC NERVE DURING DEVELOPMENT.** N.R. Crowley, S.L. Nelson, A. Weerasuriya and A.C. Black\*. Mercer University Schools of Medicine and Engineering, Macon, GA 31207.

In the endoneurial microenvironment of mammalian sciatic nerve, during development, endoneurial water content, endoneurial blood flow, and blood-nerve exchange of solutes decreases. On the other hand, endoneurial albumin content increases. A more comprehensive and quantitative description of endoneurial fluid dynamics during development requires additional information on endoneurial hydrostatic pressure and endoneurial fluid flow. In pursuance of this information, the objective of this study was to monitor endoneurial hydrostatic pressure in the sciatic nerve during ontogenetic development. In anesthetized Sprague-Dawley rats, ranging in age from 1 to 12 weeks, endoneurial hydrostatic pressure (EHP) was measured in the mid-thigh portion of the sciatic nerve with a servo-null micropressure system. The results (body weight in gms, and EHP in mm Hg) are presented as mean  $\pm$  SEM in the following table.

	1 wk	2 wks	3 wks	4 wks	6 wks	8 wks	10 wks	12 wks
n	7	7	5	5	9	9	4	9
weight	16 $\pm$ 1	29 $\pm$ 1	60 $\pm$ 3	78 $\pm$ 3	164 $\pm$ 6	238 $\pm$ 16	352 $\pm$ 7	384 $\pm$ 6
EHP	2.0 $\pm$ 0.1	2.5 $\pm$ 0.1	2.6 $\pm$ 0.2	2.7 $\pm$ 0.2	2.8 $\pm$ 0.2	2.8 $\pm$ 0.2	3.3 $\pm$ 0.4	3.2 $\pm$ 0.3

EHP increases rapidly during the first two weeks of development and then increases slowly over the next ten weeks. Thus, unlike in tissue edema, it is clear that the higher endoneurial water content seen within the first few weeks after birth is not accompanied by an elevated EHP. On the other hand, the ontogenetic increase of EHP parallels a similar increase in cerebrospinal fluid pressure (Deane & Jones, 1984). This supports the hypothesis that CSF is a major contributor to the endoneurial microenvironment. (NIH NS 30197).

## 308.7

**DEVELOPMENT OF A STABLE HUMAN CEREBROMICROVASCULAR ENDOTHELIAL CELL LINE AS AN *IN VITRO* MODEL OF THE HUMAN BLOOD-BRAIN BARRIER.** A. Muruganandam, J. Durkin\*, and D. Stanimirovic. IBS, National Research Council, Ottawa, Canada K1A 0R6

Our objective was to generate an immortal human brain microvascular endothelial cell line which would provide an adequate model for assessing properties of the human blood-brain barrier (BBB) *in vitro*. To this effect, human capillary and microvascular endothelial cell cultures (passage 7), derived from samples of temporal lobe surgically removed for the treatment of idiopathic epilepsy, were transfected with the plasmid pSV3-neo coding for the SV40 large T antigen. The selection of the successful transformants was enabled by the coexpression of the neomycin resistance gene from the same plasmid. SDS-PAGE followed by immunoblot analysis positively identified the presence of SV40 large T antigen. Further immunofluorescence studies confirmed the uniform and predominantly nuclear expression of the SV40 large T antigen in all of the transfected cells. The transfected cells were contact-inhibited, maintained the characteristic cobblestone morphology of primary endothelial cells in culture, and serum- and anchorage-dependent proliferation. The transfected cells also maintained the phenotypic properties of the parental cells, in that they expressed similar levels of the BBB specific enzymes, alkaline phosphatase and  $\gamma$ -glutamyl transpeptidase, and binding profile of fluorescently labelled lectins relative to naive cells. Moreover, the transfected cells responded to IL-1 $\beta$  and TNF $\alpha$  by up-regulating ICAM-1 in a manner similar to that of their naive counterparts. However, the transfected cells overcame proliferative senescence, commonly observed at passage 10-12 in naive cultures, and their life span was extended until they entered crisis (passage 24). Survivors of this crisis were cloned and propagated further. These prospective immortalized endothelial cell lines of the human brain microvasculature may serve as a representative and readily available *in vitro* model for studying the properties of the BBB.

## 308.9

**POTENTIAL ROLE OF PLEIOTROPHIN IN ANGIOGENESIS IN CEREBRAL ENDOTHELIAL CELLS.** T.F. Deuel, J. Xu, H.-J. Yeh, W. Zhang, Y.-L. Lu, R. Hu\*, C.Y. Hsu. Departments of Medicine and Neurology, Washington University School of Medicine, St. Louis, MO 63110.

Pleiotrophin (PTN), a 17 kD heparin-binding cytokine, has been reported to promote mitogenic, transforming, angiogenic and neurite promoting outgrowth activities. We employed bovine cerebral endothelial cells (BCECs) in culture to investigate potential biological functions of PTN. We found that PTN at 50 ng/ml promoted BCEC proliferation which increased by two-fold 48 hours after exposure of BCEC to PTN. PTN increased DNA synthesis by 2.4-fold in BCECs based on measurement of the incorporation of a nuclear analog BrdU. When BCECs were cultured on matrigel, PTN-treated BCECs morphologically mimicked the appearance of the vascular endothelial cells *in vivo*. Treatment of BCEC with PTN also significantly reduced monolayer permeability of macromolecule. Together, these results indicate that PTN promotes a weak mitogenic response in BCECs and may be involved in the regulation of blood brain barrier function. (supported by a NIH grant NS28995 and an Office of Naval Research grant #4114503-01)

## 308.6

**GLYCOPHINGOLIPID COMPOSITION OF BOVINE BRAIN MICROVASCULAR PERICYTES.** T. Iwasaki, M. Yamawaki and T. Kanda\*. Department of Neurology, Tokyo Medical and Dental University, Tokyo 113, Japan.

Although the brain microvascular pericytes (BMPs) are one of the cardinal constituents of blood-brain barrier (BBB), their biological or chemical properties are almost unknown so far. Recently glycosphingolipid (GSL) composition of brain microvascular endothelial cells (BMECs) was determined and sulfoglucuronosyl paragloboside (SGPG) was shown to play important function as a ligand for L-selectin (Kanda *et al.*, Proc. Natl. Acad. Sci., 1995). Here we report GSL composition of BMPs, which may participate in important immunological functions in BBB. BMPs were isolated using a modified method for BMECs (Kanda *et al.*, J. Cell Biol., 1994). BMPs were identified by their polymorphic morphology, immunoreactivity against alpha-smooth muscle actin and the lack of von Willebrand factor. After confluency, cultured BMPs were harvested and GSLs were purified with Sephadex LH20 and DEAE-Toyopeal column, and GSL composition was analyzed using high-performance thin layer chromatography. BMECs and BMPs shared GM3 as major acidic GSL and GM1 as minor species. Differed from BMECs, BMPs did not express SGPG but were shown to contain a substantial amount of some polysialic GSLs (GD1a, GT1b) and sulfoglucuronosyl lactosaminyl paragloboside (SGLPG); this unique, HNK1 epitope-bearing GSL may play a key role in the physiological function of BBB.

## 308.8

**CNS PERICYTES AND INTEGRINS MEDIATE INDUCTION OF ANGIOGENESIS.** R. Balabanov, S. Malek-Hedayat, and P. Dore-Duffy\*. Department of Neurology, Division of Neuroimmunology, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Angiogenesis or neovascularization is the formation of new vessels from established microcirculation. The mechanisms involved in regulation of angiogenesis are not well understood. It is likely that they involve complex fine tuning between the cellular compartments of the endothelium [endothelial cells (EC) and pericytes (PC)] and the structural components (basal lamina). We have established a model of angiogenesis which mimics the multicellular nature of the blood brain barrier (BBB). Primary CNS EC and PC are simultaneously co-cultured on gelatin coated dishes. A second layer containing an integrin ligand is then added. When EC are cultured alone, cells grow to confluency without tube formation. Upon simultaneous co-culture with primary PC, EC form a few elongated tube-like structures after two weeks in culture. However, if collagen I is used in a liquid overlay, EC form true capillary structures classically associated with angiogenesis. Maximum capillary formation is seen by within 24-48 hrs. Addition of collagen I (col-I) to the EC cultures alone had no effect. PC were found to induce EC activation and angiogenesis as well as upregulation of uPAR protein and gene expression. The PC effect on EC is contact dependent. This primes the EC for a second signal mediated by col-I. EC activation also results in increased expression of  $\beta_1$  integrins. Thus engagement of col-I with  $\beta_1$  integrins initiates rapid formation of capillary structures in CNS EC-PC cultures.

## 308.10

**THE PRESENCE OF ARGININE VASOPRESSIN (AVP) AND ITS mRNA IN RAT CHOROID PLEXUS.** A. Chodobska\*, Y.P. Loh\*, L.-P. Pu\*, C.E. Johanson\*, S. Corsetti\*, and J. Szmydynger-Chodobska\*. Prog. Neurosurg., Dept. Clin. Neurosci., Brown Univ./R.I. Hosp., Providence, RI 02903 and \*Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892.

AVP is a potent regulator of secretory function of choroid plexus, the primary site of cerebrospinal fluid (CSF) formation. This AVP action requires, however, high peptide concentrations. In the present experiments, the hypothesis was tested that AVP is produced locally within the choroid plexus, which would result in sufficiently high peptide levels to alter CSF secretion. The presence of AVP in choroidal tissue was demonstrated using rabbit anti-lysine VP antibody (Incstar) that cross-reacts with AVP. AVP-immunopositive product was detected using biotinylated donkey anti-rabbit IgG, streptavidin-biotin-peroxidase complex, and DAB. *In situ* hybridization histochemistry was employed, to show the presence of AVP mRNA in choroid plexus. Plasmid, pGrVP (a gift from Dr. W.S. Young), containing a 232-bp fragment of rat AVP cDNA encoding the C-terminus of proAVP, was used as a probe. To synthesize  $^{35}$ S-labeled antisense or sense cRNA probe, pGrVP was linearized and transcribed *in vitro* with T7 or T3 RNA polymerase in the presence of  $^{35}$ S-UTP. Choroidal tissue sections following hybridization and post-hybridization washes were coated with nuclear track emulsion and developed 3 wk later. AVP-immunoreactive product was predominantly localized close to the apical membrane and silver grains representing AVP mRNA were distributed throughout the cytoplasm of epithelial cells. Our findings indicate that AVP is synthesized in choroid plexus, and may exert autocrine and/or paracrine effects. Supported by RIH RD Grant 7512-01-95 and NIH Grant NS27601.

## 308.11

**THE CHARACTERIZATION OF A UNIQUE FORM OF VASOPRESSIN-NEUROPHYSIN (VP-NP) GENE PRODUCT FOUND IN RAT CHOROID PLEXUS.** D.M. Demers, J. Szmydynger-Chodobska, C.E. Johanson, S.M. Cascio\*, and A. Chodobski. Prog. Neurosurg., Dept. Clin. Neurosci., Brown Univ./R.I. Hosp., Providence, RI 02903.

In an accompanying abstract (by A. Chodobski et al.) we report the presence of VP and its mRNA in choroid plexus epithelium. In the present study, western blot and reverse-transcription polymerase chain reaction (RT-PCR) analyses were employed to characterize NP-immunoreactive products in rat choroid plexus. For western blot analysis, two different polyclonal anti-NP antibodies (ICN and gift of Dr. A.G. Robinson) were used to probe protein extracts of choroid plexus and hypothalamus. As expected, NP was detected as a ~10 kD polypeptide in hypothalamic extracts. This band was absent in choroid plexus; however, a ~19 kD protein was found to cross-react with the antibodies instead. The difference in molecular weight suggests a variance in the primary structure of the choroid plexus-derived VP-NP gene product. To confirm that choroid plexus expresses the VP-NP gene, RT-PCR was performed on RNA extracted from choroid plexus. Primers designed to amplify a 103-bp fragment corresponding to the 3' end of the NP and the first 75 nucleotides of the glycopeptide coding domains were employed for PCR following reverse transcription. RT-PCR products were then fractionated via agarose gel electrophoresis and stained with ethidium bromide. A single PCR product of the predicted size was obtained from choroid plexus RNA samples. DNA sequencing confirmed that this PCR product was derived from VP-NP transcripts. Our observations demonstrate that NP-immunoreactive protein products and their respective mRNAs are present in choroid tissue; however, western blot analysis suggests unique post-translational processing of proAVP in the choroid plexus compared to hypothalamus. Supported by RIH RD Grant 7512-01-95 (A. Chodobski) and NIH Grants NS27601 (C.E. Johanson) and AM16166 (A.G. Robinson).

**PROSTAGLANDIN CATABOLISM IN THE FETAL CHOROID PLEXUS: A SPECIAL ARRANGEMENT.** N. Kronic<sup>1,2</sup>, S.L. Adamson<sup>2</sup>, L. Bishai<sup>1</sup> and E. Coccani<sup>1</sup>. <sup>1</sup>Div. of Neurosciences, Hosp. for Sick Children, Toronto, Ont., Canada M5G 1X8. <sup>2</sup>Samuel Lunenfeld Res. Inst., Mount Sinai Hospital, Toronto, Ont., Canada M5G 1X5.

In the adult, eicosanoids, such as prostaglandin  $F_{2\alpha}$  ( $PGF_{2\alpha}$ ), are actively removed from the cerebrospinal fluid (CSF) by the choroid plexus for catabolism in the periphery. Catabolism to 13,14-dihydro-15-keto- $PGF_{2\alpha}$  (15KD- $PGF_{2\alpha}$ ) occurs primarily in the lung via cytosolic enzymes. We showed previously that the choroid plexus of the fetal sheep catabolizes  $PGF_{2\alpha}$  to 15KD- $PGF_{2\alpha}$ , whereas newborn and adult were unable to do so. In the current study, we determined the functional relationship between transport and catabolism in the choroid plexus. The intact choroid plexus (0.9 gestation) was incubated in Krebs buffer with  $^3H$ - $PGF_{2\alpha}$ . Transport was expressed as the tissue-to-medium ratio for radioactivity (T/M). Catabolism was expressed as the % radioactivity migrating with authentic 15KD- $PGF_{2\alpha}$  on thin-layer radiochromatography (%15KD). Catabolism was also measured in the 2,000g pellet and supernatant from minced choroid plexus, and in the 100,000g supernatant from homogenized choroid plexus. Lung was used as a reference. Probenecid (1 mM) significantly inhibited uptake in the intact choroid plexus (Control T/M:  $5.6 \pm 0.6$ ,  $n=16$ ; Probenecid T/M:  $2.5 \pm 0.2$ ,  $n=10$ ) but did not affect catabolism (Control %15KD:  $55 \pm 4\%$ ,  $n=9$ ; Probenecid %15KD:  $60 \pm 3\%$ ,  $n=10$ ). Catabolism was not detected in the 100,000g supernatant from choroid plexus, while it was high (%15KD about 80%) in the same fraction from lung. Catabolism was not restored by  $NAD^+$  supplementation or treatment with indomethacin. Conversely, there was catabolism (%15KD:  $78 \pm 2\%$ ,  $n=3$ ) in the 2,000g pellet, but not the supernatant, of minced choroid plexus. In conclusion, the fetal choroid plexus may remove PGs from CSF by independent processes of catabolism and transport. Unlike lung, catabolism does not take place when the structural integrity is disrupted by homogenization, suggesting a special arrangement in the fetal choroid plexus. ## 308.15

**CYTOKINES REGULATE PROSTAGLANDIN H SYNTHASE-2 IN CEREBRAL MICROVASCULAR ENDOTHELIUM.** S.A. Moore\*, E.J. Yoder, and G. Rich. Dept. of Pathology, University of Iowa, Iowa City, IA 52242-1181

Arachidonic acid metabolism is important in regulating the cerebral circulation and its response to CNS injury, a response that often involves vascular cell proliferation, inflammatory cell infiltrates, and glial cell reactions. Induction and regulation of prostaglandin H synthase-2 (PGHS-2) may be important in these processes. To study PGHS expression in cerebrovascular cells, murine-derived cerebral endothelial cultures are being incubated for up to 24h with a variety of inflammatory mediators. Over 24h, LPS and IL-1 $\beta$  cause PGE<sub>2</sub> and I<sub>2</sub> to accumulate in the medium to an 8- to 10-fold greater degree than control, but significant increases are not detected until 12h of incubation. IL-6 and IFN have no effect. Restimulation of LPS and IL-1 $\beta$  activated cells with 7.5  $\mu$ M arachidonic acid reveal 3- to 10-fold increases in total PGHS activity, respectively. Levels of PGHS-2 mRNA and protein are rapidly induced by these same two proinflammatory mediators. Peak mRNA levels are seen by 3h and peak protein levels by 6h. Both times precede the maximum effect of these compounds on PG accumulation in the medium. These data indicate that PGHS-2 expression and PGHS activity in cerebral endothelium are regulated by proinflammatory mediators. Differences in the time course of PGHS-2 induction and PG accumulation suggest that phospholipase A<sub>2</sub> may also be induced, but on a slower time course. Collectively the data suggest that cerebrovascular PG production may be modified by regulation of endothelial cell PGHS and/or PLA<sub>2</sub> in disease states such as trauma, stroke, infection, or neoplasia where proinflammatory mediators are produced.

## 308.12

**EFFECT OF CHRONIC FGF-2 INFUSION ON THE CHOROID PLEXUS.** E.G. Stopa\*, M. A. Mittler, M. H. Lebow, P. N. MacMillan, V. Kuo-LeBlanc, A. Chodobski, J. Chodobski, A. Baird, and C. E. Johanson. Brown U. Sch. of Med./RIH, Providence, RI and PRIZM Pharmaceuticals, San Diego, CA.

Growing evidence suggests that the choroid plexus can synthesize various growth factors normally found within the extracellular milieu of the central nervous system (CNS). FGF-2 mRNA, receptor and protein have all been localized within the choroid plexus.

To assess the possible effects of FGF-2 on choroid plexus epithelium, we examined the ultrastructural changes following continuous infusion of FGF-2 into the right lateral ventricle. Sprague-Dawley rats (250 g) received a dose of 41.7 ng/hr of FGF-2 ( $n=6$ ) or sterile saline ( $n=6$ ) for a 2 week period using an Alzet pump. Samples of choroid plexus were then processed for electron microscopy. Separate groups of FGF-2 infused ( $n=3$ ) and control ( $n=3$ ) animals were used for immunocytochemical studies of FGF-2, GFAP, Ki-67 and vimentin.

Rats treated with FGF-2 showed a striking increase in the percentage of dark epithelial cells when compared to controls (20% vs 2%). Villous surface area was also increased. Immunocytochemical stains showed increased FGF-2, GFAP and vimentin within the brain parenchyma of FGF-2 treated animals. The choroid plexus Ki-67 proliferative index was unchanged.

Our findings support the hypothesis that FGF-2 may enhance CSF secretion and influence the osmotic regulation of the extracellular fluid volume within the CNS. (Supported by AG 10682, NS 27601 and the Rhode Island Hospital Research Fund)

## 308.14

**INHIBITION OF CYTOKINE-INDUCED NF- $\kappa$ B BINDING ACTIVITY AND iNOS EXPRESSION IN CEREBRAL ENDOTHELIAL CELLS (CECs) BY AN HAIRPIN NF- $\kappa$ B OLIGONUCLEOTIDE (HR-NF- $\kappa$ B).** L.M. He, J. Xu, Y.Q. Yang, Y.J. Wu and C.Y. Hsu\* Dept. Neurology, Washington Univ Sch Med, St. Louis, MO 63110.

To explore novel mechanisms to modulate iNOS expression in CECs, we designed an HR-NF- $\kappa$ B in an attempt to block NF- $\kappa$ B binding activity and consequently iNOS expression in CECs. In murine CECs, LPS, TNF $\alpha$ , or IL-1 $\beta$  alone does not induce iNOS or increase nitrite/nitrate (NOx) content. TNF $\alpha$ +INF $\gamma$  increased iNOS expression and NOx formation in a time-dependent manner peaking 3 and 15 hr respectively after exposure. L- nitro-arginine completely blocked NOx production as did cycloheximide (CHX), an inhibitor of macromolecule synthesis. CHX, but not L-nitro-arginine, completely inhibited iNOS protein synthesis determined by Western blot analysis. These findings suggest that TNF $\alpha$ +INF $\gamma$  induced increase in NOx formation was through iNOS induction. When CECs were pretreated with HR-NF- $\kappa$ B, NF- $\kappa$ B binding was blocked. This effect of HR-NF- $\kappa$ B was accompanied by a decrease in iNOS mRNA expression and NOx formation induced by TNF $\alpha$ +INF $\gamma$ . Results showed that in CECs, TNF $\alpha$  + INF $\gamma$  induction of iNOS expression and subsequent increase in NOx formation is subject to different mechanisms of regulation. HR-NF- $\kappa$ B offers an alternative and novel means to modulate cytokine-induced iNOS expression in CECs. (supported by an Office of Naval Research grant #4114503-01 and NIH NS28995).

## 308.16

**OXIDATIVE STRESS AND NF- $\kappa$ B IN LIPOPOLYSACCHARIDE (LPS) AND CYCLOHEXIMIDE (CHX) INDUCED APOPTOSIS IN BOVINE CEREBRAL ENDOTHELIAL CELLS (BCECs).** J. Xu\*, A. Wang, Y. Wu, L.M. Canzoniero, S.L. Sensi, C. Csernansky, L. Dugan, D. W. Choi, C.Y. Hsu Dept Neurology & Ctr Study Nervous System Injury, Washington Univ Sch Med, St. Louis, MO 63110

LPS priming (16 hr) followed by CHX exposure (6 hr) consistently induced BCEC apoptosis which was confirmed by characteristic DNA changes with Hoechst staining, immunoenzymatic demonstration of an increase in the cellular content of cytoplasmic histone-associated DNA fragments [DNA fragment enrichment factor (DNA FER): LPS (0.1 mg/ml)  $0.93 \pm 0.07$ ; CHX (50  $\mu$ g/ml)  $1.16 \pm 0.08$ ; LPS+CHX  $2.42 \pm 0.01$ ,  $p<0.01$ ] and the appearance of DNA laddering on agarose gel electrophoresis. N-acetyl-cysteine (NAC), which enhanced glutathione levels [NAC (-)  $88 \pm 10$  nmol/ml; NAC (1 mM)  $890 \pm 30$ ,  $p<0.001$ ], prevented LPS/CHX-induced apoptosis in a dose-dependent manner [DNA fragment enrichment factor (DNA FER): NAC (-)  $2.53 \pm 0.01$ ; NAC (0.01 mM)  $1.92 \pm 0.14$ ; (0.1 mM)  $1.11 \pm 0.06$ ; (1 mM)  $0.64 \pm 0.06$ ,  $p<0.001$ ]. In contrast, both maleic acid diethyl ester (MADE), a glutathione depletor, and DL-buthionine-(S,R)-sulfoximine (BSO), a glutathione synthase inhibitor, lowered glutathione levels [control  $88 \pm 10$  nmol/ml; MADE (0.1 mM) not detectable; BSO (1 mM) not detectable] but enhanced apoptosis (DNA FER: control  $2.39 \pm 0.13$ ; MADE (0.1 mM)  $4.38 \pm 0.52$ ; BSO (1 mM)  $5.54 \pm 0.41$ ,  $p<0.01$ ). LPS/CHX substantially enhanced NF- $\kappa$ B binding activity. LPS or CHX alone had no effect. These results raise the possibility that LPS/CHX-induced apoptosis may involve a nuclear regulatory mechanism mediated by NF- $\kappa$ B which is subject to modulation by oxidative stress. (supported by an Office of Naval Research grant # 4114503-01 and an NIH grant NS 28995).

## 308.17

RMP-7, A BRADYKININ ANALOG, PERMEABILIZES BLOOD VESSELS IN A RAT BRAIN TUMOR. E. Sanovich\*, H. Le, R. Bartus, R. Dean, P. Elliott, M. Brightman. N.I.H. Bethesda, MD 20892 & Alkermes, Inc., Cambridge, MA 02139.

The permeability of blood vessels supplying RG-2 gliomas, implanted in rat striatum, has been assessed with a newly applied probe: biocytin-lucifer yellow-lysine, visualized by fluorescence and electron microscopy. The probe is small (850 Da), to the extent that it does not bind to serum albumin. This probe or another one, horseradish peroxidase (40 kDa), were infused into the jugular vein and circulated for 2 minutes. Both probes are excluded by the barrier vessels of brain but they escaped from a variable number of vessels within the tumors and at the border with normal brain. In both saline infused rats and those given RMP-7 via the internal carotid artery, there were hemorrhages of variable size and number in the tumors and at their border. The hemorrhages were usually not associated with exudates which, therefore, escaped primarily across intact tumor vessels. More parenchymal exudates in the RMP-7 group coalesced into extensive extravascular pools. RMP-7 thus appears to increase the permeability of some vessels within the tumor and at its border with normal brain.

Supported by Alkermes, Inc. and NIH intramural funding.

## 308.19

IMMUNOULTRASTRUCTURAL AND HIGH-VOLTAGE ELECTRON MICROSCOPIC STUDIES OF ENDOTHELIAL CELL TUBULES AND VESICULAR-VACUOLAR ORGANELLES IN HUMAN BRAIN TUMORS. A.S. Lossinsky<sup>1</sup>, K. Butt<sup>2</sup>, M. Marko<sup>2</sup>, R. Pluta<sup>2</sup>, M.J. Mossakowski<sup>3</sup>, and H.M. Wisniewski<sup>1</sup>. <sup>1</sup>Dept. of Pathological Neurobiology, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314; <sup>2</sup>NYS Dept. of Health, Wadsworth Center for Labs. and Research, Albany, NY 12201; <sup>3</sup>Dept. of Neuropathology, Medical Research Center, Polish Academy of Sciences, Warsaw, Poland 00-784.

The vesicular-vacuolar organelle - VVO was recently described in murine ovarian carcinoma endothelial cells (ECs) (Dvorak et al., J. Leukoc. Biol. 59:100-115, 1996), who suggested their important role for macromolecular transport. The EC tubular system presented by us and others in the injured blood-brain barrier (BBB) described structural profiles that were purported to reflect passageways and conduits for macromolecules and inflammatory/tumor cells respectively. In the present study, we asked the question whether or not the VVO functions similar to the EC tubular profiles. Angioma and glioblastoma multiforme specimens were incubated with anti-human ICAM-1 antibodies using a pre-embedding technique and labeled with immunogold or immunogold probes. Electron microscopy demonstrated that both probes labeled the inner delimiting membrane surfaces of EC tubules and VVOs. A three-dimensional distribution of immunogold labeling could be visualized by stereo-pair images of thick-sections by high-voltage electron microscopy. Our data suggest that both ICAM-1-positive VVOs and EC tubular profiles may represent an important mechanism for transendothelial transport of both macromolecules and tumor cells in human brain tumors. Supported by the Office of Mental Retardation and Developmental Disabilities, the BMIR of the Wadsworth Center (RR 01219), and the Medical Research Center of the Polish Academy of Sciences.

PLASMA IN THE VENTRICULAR SYSTEM OF THE BRAIN INCREASES THE PRODUCTION OF CEREBROSPINAL FLUID. M.A. Maidali\* and G.C. Stachovic. University of Iowa College of Medicine, Department of Anesthesia, Iowa City, IA 52242.

Blood in the ventricular system of the brain is a common sequela of head trauma and ruptured intracranial aneurysms. Hydrocephalus and increased intracranial pressure usually follows that complication. The rate of production of cerebrospinal fluid (CSF) is a major factor that influences intracranial pressure. Thus, we tested the hypothesis that presence of plasma in the ventricles of the brain increases the production of CSF. Experiments were performed in New Zealand White rabbits that were anesthetized, normothermic, and mechanically ventilated. The production of CSF was measured with the open ventriculo-cisternal perfusion method using C<sup>14</sup> dextran as a nondiffusible indicator. Under control conditions, the production of CSF averaged  $7.10 \pm 0.99 \mu\text{L}/\text{min}$  (S.D., n=8). Infusion of plasma into the lateral ventricle of the brain at a rate of  $6 \mu\text{L}/\text{min}$ , increased the production of CSF to  $8.6 \pm 1.6 \mu\text{L}/\text{min}$  (n=8). In a third group of animals administration of indomethacin (5 mg/kg, iv) inhibited increases in CSF production that were produced by plasma. In a fourth group of rabbits, administration of PGE<sub>2</sub> did not result in an increase in CSF production (n=5). These results suggest that presence of plasma in the ventricles of the brain increases CSF production via stimulation of prostaglandin synthesis. Since PGE<sub>2</sub>, alone, did not increase CSF production, our results also suggest that this increase in CSF production may be due to an increase in prostacyclin or thromboxane synthesis in the ventricular system of the brain.

## 308.20

ANALYSIS OF TARGET ANTIGENS ON BLOOD-BRAIN BARRIER RECOGNIZED BY ANTI-ENDOTHELIAL CELL ANTIBODIES(AECA)

M.Yamawaki\*, T.Iwasaki, T.Kanda, T.Ariga#, R.K.Yu# Dept.Neurology Tokyo Medical & Dental Univ.,Tokyo, Japan. #Dept.Biochemistry, Medical College of VA, Richmond, VA.

Serum anti-endothelial cell antibody (AECA) is known to be associated with several inflammatory disease such as systemic vasculitis and systemic lupus erythematosus (SLE). In the present study we investigated the serum AECA activities in multiple sclerosis (MS) and further analyzed the target antigens of AECA on brain microvascular endothelial cells (BMECs). Sera from MS patients were collected according to clinical course (4 to 9 sera from each patients). AECA was detected by cellular enzyme-linked immunosorbent assay (cELISA). Target antigens of AECA were determined by ELISA, Western-blotting, and TLC-immunoblotting methods using cultured bovine BMECs and authentic standards of glycolipids as antigens. BMECs stimulated with interleukin-1(IL-1) beta were also used as antigens. We found that patients showed serum AECA activity of the IgG class against stimulated BMECs, but not against unstimulated cells. AECA reacted with sulfoglucuronosyl glycosphingolipids (SGGLs: a ligand for L-selectin) and a 65kD protein from the stimulated BMECs. Both of the antigens were upregulated with IL-1 beta. We conclude that the target antigens of AECA may play important roles in the course of inflammation on blood-brain barrier (BBB).

## PRESYNAPTIC MECHANISMS: NEUROMUSCULAR JUNCTION

## 309.1

DETERMINANTS OF SYNAPTIC STRENGTH: PHYSIOLOGY MATCHED TO ULTRASTRUCTURE IN IDENTIFIED PHASIC AND TONIC CRAYFISH NEUROMUSCULAR JUNCTIONS. H.L. Atwood<sup>1</sup>\*, M. Moshina<sup>1</sup>, L. Marin<sup>1</sup>, J. Pearce<sup>2</sup>, and C.K. Govind<sup>2</sup>. <sup>1</sup>Dept. of Physiology and <sup>2</sup>Scarborough College, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

In the crayfish leg extensor muscle, two excitatory motor neurons, phasic and tonic, innervate all muscle fibers in parallel. Neuromuscular junctions are readily observed and morphologically distinct. We recorded quantal currents with focal 'macro-patch' electrodes of 10-20  $\mu\text{m}$  diameter, marking the recording sites with fluorescent polystyrene microspheres (5  $\mu\text{m}$  diameter) which are identifiable in both light and electron microscopy (Wojtowicz et al., J. Neurosci. 14:3588, 1994). Preparations were then fixed for electron microscopy and the recorded regions of the neuromuscular junction reconstructed from thin serial sections. Synapses were measured and counted in the reconstructions.

Quantal content of synaptic currents was often 50 to 150-fold greater at low frequencies in recordings at phasic junctions, yet in the recorded area the number of individual synapses per  $\mu\text{m}$  of terminal was in some cases less for phasic than for tonic junctions. As well, contact areas of individual synapses were two-fold smaller on average in phasic junctions. On the other hand, there was a substantially greater percentage of synapses with more than one active zone ('complex' synapses) in phasic (30-50%) than in tonic (5-10%) junctions. Additionally, at these 'complex' synapses, paired active zones were more closely spaced in phasic junctions. While these latter two factors may account for some of the overall difference in synaptic strength (Cooper et al., J. Neurophysiol. 75: 1996), they are not in themselves likely to account for all of the difference. Supported by grants from MRC and NSERC, Canada.

## 309.2

EFFECT OF MELATONIN ON SYNAPTIC TRANSMISSION AT CRAYFISH NEUROMUSCULAR JUNCTIONS. H.Brignull, W.North\* & S.J. Velez. Dept. Biol. Sciences, Dartmouth College, Hanover, NH 03755.

Melatonin has been shown to decrease EPSPs when applied to neuronal populations in the hippocampus and the gastrointestinal wall in vertebrates. The few melatonin studies in invertebrates have not looked at possible effects in synaptic transmission. We use a simple crayfish neuromuscular system to study how synaptic performance is affected by the application of drugs like caffeine (Soc. Neurosci. Abstr. 21:1089) and hormones like serotonin (Soc. Neurosci. Abstr. 20:1338), so we decided to investigate whether our system could be affected by the application of melatonin. We recorded junction potentials (JP's) produced by stimulation of the axons innervating superficial flexor muscle of the crayfish *Procambarus clarkii*. Recordings were made in normal Ringers before exposing preparations to different melatonin concentrations. JP's produced by axon 6, the largest excitator, did not change in the presence of melatonin but those produced by the other axons increased in size within minutes of exposure. The response was dosage dependent: no responses were seen with concentrations lower than 0.1mM, were first observed at 0.5mM, and increased with stronger dosages. Applying 2.3mM melatonin in Ringers of different calcium concentrations gave mixed results: in 30% calcium Ringer melatonin had no effect, but in 200% calcium Ringers the response was larger than controls, suggesting a presynaptic site of action for the hormone.

(Supported by Dartmouth College Research Funds)

## 309.3

**EFFECT OF CAFFEINE ON CALCIUM RESPONSES AT CRAYFISH NEUROMUSCULAR SYNAPSES.** E. Shugert and S. J. Velez\*. Dept. of Biological Sciences, Dartmouth College, Hanover, NH 03755. We had previously reported that caffeine decreased the junction potentials (JP's) recorded from crayfish neuromuscular synapses in Ringers varying in calcium concentrations (Soc. Neurosci. Abstr. 21, 1089), and suggested that caffeine was reducing the amount of presynaptic calcium. To continue this study, we analyzed the responses of crayfish muscle fibers to (1) changes in calcium and to (2) the calcium ionophore A23187, before and after the application of caffeine. JP's elicited by stimulation of excitator axons were recorded in normal Ringers and in 117% calcium Ringers before exposing the fibers to a 5mM, 10mM or 20mM caffeine solution. After caffeine exposure, the JP's were recorded again in normal and 117% calcium Ringers; these JP's were smaller in size than controls and the facilitation observed previously (JP at 10 Hz/Jp at 1 Hz) was reduced or absent, suggesting that caffeine's effects persist after drug removal. A23187 application created an initial enhancement of JP sizes at 1 and 10 Hz, followed within 4 min by a decline until sizes at 10 Hz were smaller than sizes at 1 Hz (i.e. terminals that facilitated now show antifacilitation). 10mM caffeine in A23187 does not eliminate the decline in JP size with time nor the antifacilitation, but slows down the appearance of the initial rise in JP and lowers its final size, suggesting that caffeine's effects do not involve calcium sequestration into internal stores.

(Supported by Dartmouth College Research Funds)

## 309.5

**OSMOTIC ENHANCEMENT OF NEUROTRANSMITTER RELEASE AT NEUROMUSCULAR JUNCTIONS: COMPARISONS WITH STRETCH ENHANCEMENT.** A.H. Kashani, B.M. Chen and A.D. Grinnell\*. Jerry Lewis Neuromuscular Research Center, Department of Physiology, UCLA School of Medicine, LA, CA 90024

Hyperosmotic enhancement (HE) of spontaneous neurotransmitter release is widespread and poorly understood. We have shown that the maintained tonic component of HE at frog (*Rana pipiens*) neuromuscular junctions is mediated, at least in part, by integrins (Chen & Grinnell, Science 269, 1578-1580, 1995). Further experiments directed at elucidating the mechanism of osmotic modulation of release and comparing it with stretch enhancement (SE) show that: (a) both forms of enhancement are reduced 40-60% by the hexapeptide GRGDSP, which blocks integrin binding to natural ligands. Mammalian junctions also show GRGDSP sensitive HE; (b) Although both effects persist in 0 Ca<sup>2+</sup> Ringer, SE is much more strongly suppressed when internal Ca<sup>2+</sup> is buffered by BAPTA; (c) Like SE, HE is inversely proportional to resting mEPP frequency; (d) as mEPP frequency is elevated by stretch, HE decreases and, at high frequencies (>5Hz), reverses and becomes inhibitory to SE; (e) elevation of mEPP frequency by K<sup>+</sup>-depolarization severely inhibits HE, while having no effect on the SE-mEPP frequency relationship. Although there are some striking differences between SE and HE in terms of dynamics and potency, there are sufficient similarities to suggest that at least part of HE may involve the same integrin-dependent mechanism(s) as SE. Supported by NS 30673

## 309.7

**AN ACTIVITY-DEPENDENT ANTIBODY PROBE FOR USE AT THE SNAKE NEUROMUSCULAR JUNCTION.** Y.-J. Son, J. C. Cole and R. S. Wilkinson\*. Department of Cell Biology & Physiology, Washington University School of Medicine, St. Louis, MO 63110.

NMJs in the thin transversus abdominis muscle of the garter snake contain large (2-3  $\mu$ m) terminal boutons which may be studied physiologically and then identified for light microscopic visualization. We have developed an antibody probe for visualization of one bouton component, recently active vesicular membranes, using this method. Our probe putatively recognizes the luminal domain of a vesicular membrane protein, synaptotagmin II, and is thereby taken up from the bath by living boutons undergoing exo- or endocytosis associated with neural activity (Malgareoli et al., Science 268: 1624-28, 1995).

A snake spinal cord cDNA library was constructed and probed with marine ray synaptotagmin II (gift of R. Scheller, Stanford Univ.). A snake homologue was cloned, and the entire luminal domain of the gene utilized to construct a fusion protein for antibody generation. The resulting rabbit polyclonal antiserum recognized a ~50 kD spinal cord membrane fraction in Western blots, but neither brain membrane nor spinal cord cytosolic proteins. Bath-applied antiserum (but not pre-immune serum) stained living KCl-depolarized snake nerve terminal boutons brightly, but did not stain similar boutons bathed in normal reptilian saline (visualized with a fluorescent secondary antibody after fixation). High resolution 3-D confocal imaging revealed that stained regions of the bouton were punctate (<300 nm) and often opposed postsynaptic secondary folds (visualized with the anti-AChR monoclonal mAb 22, gift of J. Lindstrom, Univ. Pennsylvania). Supported by NIH grant NS24752, the McDonnell Center and the Keck Foundation.

## 309.4

**NO SYNTHASE LOCALIZATION AT THE FROG NEUROMUSCULAR JUNCTION.** Laurence Descarries\*, Chantale Marier and Richard Robitaille. Département de physiologie et Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal (Qc) Canada H3C 3J7.

Nitric oxide (NO), a modulator of synaptic function, is produced by many cells of the nervous system including glial cells. This study aimed at determining whether the biosynthetic enzyme of nitric oxide, NO synthase, is present at the frog neuromuscular junction (NMJ), a synapse known to be sensitive to NO (Lindgren and Laird, 1994, Neuroreport 5, 2205). The histochemical technique involving NADPH-diaphorase staining revealed activity in cell body and processes of perisynaptic Schwann cells, glial cells at the NMJ. Muscle fibers were also stained, particularly near end plates, which presence was confirmed by revealing acetylcholinesterase activity. Incubation with NO synthase inhibitor N $\omega$ -Nitro-L-Arginine methyl ester greatly reduced the staining of NADPH-diaphorase, confirming that it was due to NO synthase activity. Omission of calcium did not affect this reaction, suggesting that the activity of the enzyme was not calcium-dependent. Staining was absent after denervation (seven days) and in younger frogs (<20g).

Polyclonal antibodies against different types of NO synthases were used in an attempt to identify the type of enzyme present. Observation with fluorescent confocal microscopy revealed staining with neuronal and epithelial NO synthase antibodies in perisynaptic Schwann cells. Muscle fibers were labeled with epithelial NO synthase antibody only. No staining was observed with anti-induced NO synthase. The presence and functionality of NO synthase at the frog NMJ suggest that endogenous NO may modulate synaptic activity at this synapse. (Supported by MRC of Canada and the Sloan Foundation).

## 309.6

**ADENOSINE FEEDBACK IS NOT THE PRIMARY BASIS FOR TETANIC FADE AT THE MAMMALIAN NEUROMUSCULAR JUNCTION.** M. Malinowski, P.M. Barr, S. Cannady, Schmitz, K.V., and D.E. Wilson\*. Zoo Dept., Miami Univ., Oxford, OH 45056.

It has been suggested that tetanic fade (decline in transmitter release during repetitive stimulation) at the mammalian neuromuscular junction is due to increased negative feedback action of adenosine during repetitive neural stimulation. In the present study, the presynaptic effects of blocking adenosine A<sub>1</sub>-receptors in the rat diaphragm with 1,10 or 100  $\mu$ M 8-cyclopentyl-theophylline (CPT) were examined. Intracellular recording techniques were used to monitor end-plate potentials and miniature end-plate potentials in the isolated cut-muscle and end-plate potentials in the curarized rat diaphragm-phrenic nerve preparation (40 stimuli of 1, 25, and 50 Hz were used). Quantal release and tetanic fade in the presence and absence of the antagonist were examined. CPT enhanced quantal release and end-plate potential amplitudes at the onset of tetanic stimulation in both the curarized and cut muscle preparations, but did not reverse tetanic fade at stimulus frequencies of 25 and 50 Hz. While adenosine may play a role in depressing transmitter release our results suggest that adenosine is not the major mechanism for causing tetanic fade. It is suggested that tetanic fade is due to calcium inactivation of calcium influx.

## 309.8

**FLUORESCENCE IMAGING OF STIMULATION-INDUCED [Ca<sup>2+</sup>] CHANGES IN LIZARD MOTOR NERVE TERMINALS.** G. David\*, J.N. Barrett and E.F. Barrett. Dept. of Physiology & Biophysics, Univ. of Miami Med. Sch., P.O. Box 016430, Miami, FL 33101.

Ca-sensitive dyes were ionophoreed into motor axons innervating the ceratohandibularis muscle of the lizard (*Anolis sagrei*). Fluorescence changes following stimulation were measured for both low-Kd (Fluo-3 and Ca Green-2N) and high-Kd (Ca Green-5N, Fluo-FF) dyes, using a confocal microscope. Most nerve terminals are composed of clusters of small (~1-3  $\mu$ m diameter) interconnected boutons, which connect to the pre-terminal myelinated axon via thin (<0.25  $\mu$ m) heminodal processes.

In boutons bathed in physiological saline, single suprathreshold stimuli to the nerve trunk evoked transient increases in the fluorescence of the low-Kd, but not the high-Kd, dyes. Addition of the K-channel blockers 3,4-DAP (100  $\mu$ M) or TEA (5 mM) increased the amplitude of the fluorescence response of the low-Kd dyes (see Figure) and produced transient fluorescence responses of the high-Kd dyes. These fluorescence changes were blocked by  $\omega$ -conotoxin GVIA (0.3  $\mu$ M). The fluorescence response to a single stimulus started with a delay of ~1.5 ms after nerve stimulation and rose to 1/2 peak amplitude within ~1.5 ms.

Little or no fluorescence increase was observed in the myelinated region and terminal heminode of axons stimulated with single stimuli or short trains (5 @ 50 Hz). Longer trains (50-100 Hz, >500 ms), resulted in some increase in these regions, but this increase was always smaller in amplitude than that in boutons.

RECRUITMENT OF ACTIVE SYNAPSES AT THE CRAYFISH NEUROMUSCULAR JUNCTION VISUALIZED WITH THE FLUORESCENT DYE FM1-43. P.A. Quidley<sup>1</sup>, R.L. Cooper<sup>2</sup>, C.K. Govind<sup>1</sup> and H.L. Atwood<sup>2</sup>. <sup>1</sup>Scarborough College and <sup>2</sup>Dept. of Physiology, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

The crayfish neuromuscular junction consists of a series of varicosities, each of which contains 20-40 individual synapses with variable number of active zones (Cooper *et al.*, 1995, *J. Neurosci.* **15**, 4209-4222). Frequency facilitation is very pronounced at neuromuscular junctions of 'tonic' motor neurons: quantal content of transmission at a varicosity is very low (often less than 1) at low frequencies, and increases dramatically at higher frequencies. We hypothesize that one of the mechanisms underlying the dramatic increase in quantal content with frequency is the recruitment of additional synapses.

An optical method to test this hypothesis is afforded by the fluorescent dye FM1-43, which is sequestered by synaptic vesicles at active synapses (Betz *et al.*, 1992, *J. Neurosci.* **12**, 363-375). We have found that this dye is taken up at the crayfish neuromuscular junction, and that neurons releasing more transmitter take up more of the dye (Moghini *et al.*, 1995, *Soc. Neurosci. Abstr.* **21**, 333). Individual varicosities show a few well-defined bright spots after stimulation in FM1-43. At intermediate frequencies, the number of bright spots is less than the number of individual synapses found on these varicosities by electron microscopy, suggesting that not all synapses are equally active. The staining pattern depends on frequency and duration of stimulation, indicating unequal and progressive synaptic participation linked to frequency facilitation. Supported by grants from MRC and NSERC, Canada.

TETANUS-INDUCED-INTRACELLULAR  $Ca^{2+}$  DYNAMICS IN THE FROG MOTOR NERVE TERMINAL. KUBA, K.<sup>1</sup>, MITSUMOTO, T.<sup>2</sup>, OSANAI, M.<sup>3</sup>, NARITA, K.<sup>4</sup>, SHIRASAKI, T.<sup>2</sup>, SUZUKI, S.<sup>3</sup>, SUZUKI, N.<sup>3</sup>, & KIJIMA, H.<sup>2</sup> Dept. of Physiology, Nagoya Univ. Sch. of Med.<sup>1</sup> Showa-ku, Nagoya 466, Dept. of Physiology, Saga Med. Sch.<sup>2</sup>, Nabeshima, Saga: Dept. of Physics, Sch. of Science, Nagoya Univ.<sup>3</sup>, Chikusa-ku, Nagoya; Dept. of Physiol., Kawasaki Med. Sch.<sup>4</sup>, Kurashiki, Okayama, Japan

Fluorescence of indo-1 loaded in the motor nerve terminals of frog cutaneous pectoris muscles was recorded by line-scanning with a confocal laser-scanning microscope and the ratio of fluorescence in two wavelength ranges ( $F_{412}/F_{475}$ ) was taken. Tetanic nerve stimulation (100 Hz, 0.5-5 sec) produced a rise in intracellular  $Ca^{2+}$  (tetanus-induced  $Ca^{2+}$  transient) which decayed in fast and slow phases (time constants: several 100 msec and more than several seconds). The fast phase was increased in amplitude, but not in time constant, with the number of pulses. Replacement of extracellular  $Na^{+}$  with  $Li^{+}$  increased both the amplitude and time constant of the fast component. Raising pH to 9 (to block the plasma membrane  $Ca^{2+}$  pump) or applying thapsigargin (to block the  $Ca^{2+}$  pump at the organelle membrane) did not affect  $Ca^{2+}$  transients. High pH, however, prolonged the both phases of the decay under the effect of  $Li^{+}$  and increased the amplitude of the slow phase. The decay phase of tetanus-induced  $Ca^{2+}$  transient in the motor nerve terminals is thus determined predominantly by the  $Na/Ca$  exchange and partially by the  $Ca^{2+}$  pump at the cell membrane.

## 309.13

MODULATION OF TRANSMITTER RELEASE BY 5-HT AT PHASIC AND TONIC NEUROMUSCULAR JUNCTIONS IN CRAYFISH: QUANTAL PARAMETERS ASSESSED.

M.E. Crider and R.L. Cooper School of Biological Sciences, Section of Organismal & Integrative Biology, University of Kentucky, Lexington, KY 40506-0225

It is well established that serotonin (5-HT) enhances neurotransmitter release at crustacean neuromuscular junctions (NMJs) and that circulating 5-HT in the blood has a physiological relevance in regulating the animal's behaviour. Since there is synaptic differentiation, both morphologically and physiologically, among high- and low-output motor nerve terminals, we investigated if the neuromodulator, 5-HT, displayed differential effects on these terminals. To better understand the enhanced effects of 5-HT on synaptic release, quantal analysis was performed to determine  $m$  (mean quantal content),  $n$  (number of release sites), and  $p$  (probability of a vesicle releasing at a site). Recordings of synaptic currents were obtained with a focal macropatch electrode placed over terminals made visible with a fluorescent dye (4-Di-2-Asp). We will present the effects 5-HT has on release in high- and low-output tonic terminals as well as high-output phasic motor terminals in the crayfish limbs. (Supported by Univ. of Kentucky start-up funds to RLC).

## 309.10

NERVE ACTIVITY DETERMINES THE TIME COURSE OF ENDOCYTOSIS AND SYNAPTIC DEPRESSION AT FROG NEUROMUSCULAR JUNCTIONS

L.G. Wu<sup>1</sup> and W.J. Betz Department of Physiology, UCHSC, Denver, CO 80262

To measure the time course of endocytosis at frog cutaneous pectoris motor nerve terminals, we stimulated nerves at 30 Hz, then added FM1-43 at various times after the end of the stimulus train, and then washed and imaged terminals to measure the amount of dye taken up by the terminals. The endocytic rate declined exponentially after the end of the stimulus train, and the time constant was approximately equal to the duration of the train (we used trains lasting 10, 60, and 300 s, and the endocytic time constants were 23, 62, and 385 s respectively).

We also recorded end plate potentials (EPPs) and observed that the recovery from synaptic depression was also slowed after prolonged stimulation. To quantify these observations, we developed a three compartment model consisting of a reserve pool of vesicles (measured by nerve terminal brightness after maximum FM1-43 staining), a docked pool of vesicles (measured by EPP amplitude), and an externalized membrane pool (unretrieved vesicle membrane, measured by the post-stimulus dye uptake as described above). Results suggest that the rate constants of both endocytosis and vesicle mobilization determine the depression time course.

We tested the hypothesis that the endocytic time constant increased after long stimulus trains due to a rise in  $[Ca^{2+}]_i$ . Terminals were loaded with the salt form of Fura-2, and calcium concentrations were determined by conventional ratio imaging. Consistent with the hypothesis, we found that the post-stimulus rise in calcium concentration was more prolonged after long stimulus trains. However, calcium concentration during a stimulus train (up to 1  $\mu M$ ) was much higher than after the train, yet endocytosis (FM1-43 uptake) was not inhibited during a stimulus train. Thus, it appears that an increase in calcium concentration is not responsible for the dependence of the endocytosis rate on stimulation duration.

This work was supported by research grants from MDA and NIH(NS23466).

## 309.12

CHANGES IN THE KINETICS OF TRANSMITTER RELEASE DURING FACILITATION AT THE INHIBITORY OF THE CRAYFISH NEUROMUSCULAR JUNCTION. A. Vyshedskiy, Jen-Wei Lin, Dept.

Biology, Boston Univ. Boston, MA 02215.

The inhibitor of the crayfish opener muscle is used to investigate synaptic facilitation. Two electrode voltage clamp is used to control the amplitude and duration of presynaptic depolarizations. Inhibitory postsynaptic potentials (IPSP) are measured from a muscle fiber near the presynaptic voltage electrode. We investigate the F2 component of facilitation with controlled presynaptic pulses. Paired-pulse facilitation, tested by 5 ms presynaptic pulses, reveals an acceleration of neurotransmitter release kinetics. The acceleration is best shown as a reduction of delay measured between the onset of a presynaptic pulse and an IPSP at its 50% peak amplitude (delay<sub>50</sub>). The reduced delay<sub>50</sub> decays with the same time constant as that measured from IPSP amplitudes. As we change the strength of facilitation, by varying the amplitudes of conditioning pulses, the reduction of delay<sub>50</sub> quantitatively correlates with the magnitude of facilitation measured by amplitudes. Similar to facilitations tested by action potentials, short presynaptic pulses, 2 ms pulses depolarized to 0 mV, detect facilitation with no reduction of delay<sub>50</sub>. In contrast, longer presynaptic pulses, 5, 10 or 20 ms pulses depolarized to 0 mV, reveal a clear decrease in delay<sub>50</sub> during facilitation. The change in transmitter release time course has never been reported before and its mechanism is currently under investigation. (Supported by NIHNS31707)

## 309.14

QUANTAL ANALYSIS BASED ON SPECTRAL METHODS OF HIGH-OUTPUT, PHASIC & LOW-OUTPUT, TONIC NEUROMUSCULAR JUNCTIONS IN CRAYFISH. A.E. Dityatev<sup>1</sup> and R.L. Cooper<sup>2</sup> Dept. of Physiology, Univ. of Bern, CH-3012, Bern, Switzerland; <sup>1</sup>Sch. of Biol. Sci., Sect. of Organismal & Integrative Biol., Univ. of Kentucky, Lexington, KY 40506-0225.

Single of the muscle fibers in the leg extensor muscle receive phasic and tonic innervation. As observed by focal macropatch current recordings placed directly over visualized terminals, the phasic endings have a larger (> 50 fold) quantal content than the tonic terminals at a 1 Hz stimulation frequency. Since the phasic output is so high at physiological  $[Ca^{2+}]_i$  the gold standard of counting evoked quanta is not possible as with the low-output, tonic terminals. So, we applied spectral analysis to the distributions of amplitude and charge measures of observed evoked & spontaneous currents to determine if this approach may allow us to evaluate the quantal parameters of the synaptic transmission in the phasic and tonic terminals. This method was chosen because (1) it is effective when quantal content is high; (2) it does not require any parameterisation of quantal size distribution and; (3) it provides an estimate of reliability of peaks in the analyzed distributions. The spectral analysis allowed us to compare the values of quantal size of evoked and spontaneous events and to assess quantal variability among these diverse terminals in order to better correlate quantal parameters to the observed synaptic differentiation. (Funds: Swiss National Funds to AED; Univ. of Kentucky start-up funds to RLC).

## 309.15

**INTRACELLULAR ACIDIFICATION ARRESTS ENDOCYTOSIS AT THE NEUROMUSCULAR JUNCTION.** Clark A. Lindgren\*, Dennis G. Emery, & Philip G. Haydon. Department of Zoology and Genetics, Iowa State University, Ames, Iowa 50011.

We investigated the pH dependence of synaptic vesicle recycling at neuromuscular junctions of the lizard (*Anolis carolinensis*). Endocytosis was assayed by measuring accumulation of the fluorescent dye FM1-43, which becomes trapped in nerve terminals during the retrieval of membrane into synaptic vesicles. Intracellular pH was monitored by loading terminals with the fluorescent pH indicator BCECF. Nerve terminals were acidified by replacing chloride in the external bathing solution with equimolar concentrations of propionate. (Intracellular pH is reduced as some of the propionic acid diffuses across the cell membrane and dissociates inside the nerve terminal, releasing free hydrogen ions.)

Whereas the exocytosis of synaptic vesicles (detected as the loss of fluorescence from terminals preloaded with FM1-43) was unaffected by internal acidification, we found that membrane retrieval stopped if intracellular pH was reduced by at least 0.6 pH units. This degree of acidification was generated by 100 mM propionate. Lower concentrations of propionate did not arrest endocytosis. Furthermore, endocytosis was restored if the change in intracellular pH created by 100 mM propionate was made less than 0.6 units by either raising extracellular pH or by adding ammonium chloride.

The results with FM1-43 were confirmed using electron microscopy (EM). Neuromuscular junctions were depolarized in 60 mM KCl for 15 minutes to induce extensive exocytosis of synaptic vesicles. Junctions were allowed to recover for 15 minutes, either in the presence or absence of propionate, and then prepared immediately for EM. Those junctions which recovered in the absence of propionate contained normal numbers of synaptic vesicles whereas those exposed to 100 mM propionate during the recovery period were nearly depleted of vesicles. (Supported by NIH Grant NS26650.)

**Increased neuronal excitability conferred by a mutation in the *bemused* gene.** K. Walters\*, T. Yoder and M. Stern. Department of Biochemistry and Cell Biology, Rice University, Houston, TX 77251.

We are interested in identifying genes that control neuronal excitability and synaptic transmission at the larval neuromuscular junction. As part of this long term interest, we have isolated a mutation in a novel gene. This mutation, *bemused* (*bem*), is the result of a P element insertion at cytological position 85D. Flies defective in *bem* display uncoordination, inability to fly and female sterility. The phenotype of female sterility is currently undergoing further characterization, though preliminary analysis suggests it may be due to incomplete oogenesis. Furthermore, *bem* mutant larvae display aberrant synaptic transmission at the larval neuromuscular junction, specifically a more rapid onset of augmentation than do wildtype larvae. This increased rate of augmentation is potentiated by application of the potassium channel blocking drug quinidine. This electrophysiological phenotype is conferred by several other mutations that increase neuronal excitability; therefore, we propose that the *bem* mutation causes increased neuronal excitability as well. This hypothesis is supported by the observation that the facilitated transmitter release that occurs in *bem* mutants is the result of prolonged nerve depolarization.

In order to clone *bem*, DNA flanking the P element was obtained by the plasmid rescue technique. The 6 kb fragment was used to isolate additional genomic DNA spanning the P element insertion region. This DNA is currently being used to screen head and ovarian cDNA libraries. This work is supported by NSF predoctoral fellowship to K. Walters and grant aid from the American Heart Association to M. Stern.

## MECHANISMS OF NEUROTRANSMITTER RELEASE I

## 310.1

**CHARACTERIZATION OF N-SEC1 BINDING TO SYNTAXIN SUGGESTS A POSITIVE ROLE IN SECRETION.** L. Frelin and J. Peysner\*. Dept. of Neuroscience, Kennedy Krieger Institute and Johns Hopkins School of Medicine, 707 N. Broadway, Baltimore, MD 21205

N-sec1 (also called Munc-18 or RbSec1) is a soluble 67 kDa protein implicated in synaptic vesicle trafficking in mammalian nerve terminals. N-sec1 is a high affinity ligand for syntaxin 1a, one of a family of 35 kDa plasma membrane proteins that may regulate synaptic vesicle docking and/or fusion. In *Drosophila*, the n-sec1 homolog rop is required for secretion in neuronal and non-neuronal pathways. Four lethal alleles of rop involve single amino acid substitutions (Harrison et al., Neuron 13:555-566, 1994). We generated corresponding mutant proteins in rat n-sec1 by site-directed mutagenesis. We in vitro translated these proteins and quantitated their binding to recombinant syntaxin 1a immobilized on agarose beads. In three of the n-sec1 mutants, binding to syntaxin was reduced >99% relative to wildtype n-sec1. In a fourth mutant, binding to syntaxin was reduced 24%. These results are consistent with the hypothesis that n-sec1 binding to syntaxin is required for secretion. *Drosophila* rop mutants are presumably lethal because of their failure to bind syntaxin.

## 310.2

**MORPHOLOGICAL AND BIOCHEMICAL CHARACTERIZATION OF SYNVEICLIN IN RAT BRAIN.** C.-J. Jeng\*, E. Floor and E. S. Schweitzer. Dept. of Neurobiol., UCLA Med. Sch., LA, CA 90095 and Dept. of Physiol. and Cell Biol., Univ. Kansas, Lawrence, KS 66045.

We have recently identified a novel protein, synvesiclin, which is a 27 kD vesicle-specific integral membrane protein component of both small clear vesicles and large dense-core vesicles in PC12 cells. We have now examined the subcellular and regional distribution of synvesiclin in rat CNS.

Immunohistochemical analysis of CNS reveals a fine punctate staining, similar to that seen for two other synaptic vesicle markers, SV2 and synaptophysin, consistent with synvesiclin's association with synaptic vesicles. It is present throughout the gray matter in the brain and spinal cord, but is absent from white matter. Synvesiclin staining is found in all layers and regions of the cerebral cortex, in the molecular and granule cell layers of cerebellar cortex, in the synaptic layers of the hippocampus, as well and in the inner plexiform and ganglion cell layers of the retina.

We have also demonstrated biochemically that synvesiclin is a component of two distinct populations of synaptic vesicles in brain. Using dot blot analysis, we find that synvesiclin copurifies with rat brain synaptic vesicles through centrifugation, density gradient fractionation, and Sephacryl S-1000 and controlled-pore glass sizing columns. These results confirm the conclusion that synvesiclin is a common component of both small synaptic vesicles and large, dense-core vesicles in brain as well as in PC12 cells, and is likely to play a fundamental role in regulated secretion.

Supported by NIH grants R01 NS23084 and AG12993.

## 310.3

**DISTINCT FEATURES OF SYNAPTIC ENDOCYTOSIS LINKED TO DYNAMIN AND ATP LEVELS.** O. Shupliakov\*, E. Zotova, L. Bakueva, P. Löw, H. Gad, L. Brodin. Dept. of Neuroscience, Karolinska Institute, S-17177 Stockholm, Sweden; <sup>1</sup>Belozersky Inst., Moscow State Univ., Moscow, Russia.

It is still debated which mechanisms underlie synaptic vesicle (SV) recycling. One reason for this uncertainty is the diverse time courses of membrane retrieval reported in different studies, and another is the poor correlation between the level of synaptic activity and the incidence of morphological correlates of membrane retrieval including clathrin-coated (CC) pits (reviewed in Neuron 14:689-96, 1995). Here we test whether the intrinsic properties of a given type of synapse may influence these parameters. Sustained depolarization (30 mM KCl, 30 min) of lamprey axons adapted to low-level activity ("phasic" reticulospinal axons), resulted in a marked depletion of SVs and a massive increase in the number of CCs. In axons adapted to high-level activity ("tonic" dorsal column axons), however, this treatment did not alter the number of SVs or CCs. As the release sites in tonic axons contained a much larger number of mitochondria than phasic synapses, we repeated the depolarization in the presence of mitochondrial inhibitors (3.2 mM dinitrophenol or 40 mM NaN<sub>3</sub>). Now a depletion of SVs also occurred in the tonic axons, and the number of CCs increased significantly. However, the number of CCs did still not approach that in phasic synapses, suggesting additional differences. Immunogold analysis with dynamin antiserum showed that the levels of dynamin were significantly higher in tonic synapses, both over SVs and the plasma membrane around active zones. The results indicate that synapses adapted to tonic activity have a far more efficient recycling machinery (with a shorter life-time of CCs), than those adapted to phasic activity. This differentiation appears to involve the ATP supply as well as the availability of "endocytic" proteins, such as dynamin. (Supported by the Swedish MRC).

## 310.4

**BIOCHEMICAL AND FUNCTIONAL STUDIES OF SYNAPTOBREVIN-MEDIATED PROTEIN INTERACTIONS.** L. Pellegrini, O. El Far, V. O'Connor, W. DeBello\*, D. van Rossum\*, G. Augustine\* and H. Betz. Max-Planck-Institut für Hirnforschung, Frankfurt/M, Germany 60528, and <sup>2</sup>Duke University Medical Centre, Durham, 27710 USA.

Neurotransmitter release (NtR) occurs via the calcium-dependent fusion of a pool of synaptic vesicles (SV) that appear docked at the presynaptic plasmamembrane (PPM). A ternary complex containing the SV protein synaptobrevin (SyB) and the PPM proteins syntaxin and SNAP-25 has been assigned a critical role in both the docking and fusion processes. The clostridial neurotoxin tetanus toxin (TeTx) inhibits NtR by cleaving SyB into two fragments: a soluble N-terminal domain and a smaller C-terminal fragment that remains anchored to the SV. Despite SyB cleavage, SV docking appears unaffected in nerve terminals poisoned with TeTx. Biochemical evidence indicates that both fragments associate to form a ternary complex with the PPM proteins, thus the cleaved protein could still participate in a SyB-dependent mechanism of SV docking. This suggests that TeTx cleavage might define SyB domains with distinct binding sites in the ternary complex and/or distinct roles in exocytosis. Indeed, the small C-terminal domain consistently causes an irreversible inhibition of NtR when introduced into the squid presynaptic terminal. The effects of this peptide on the *in vitro* protein interaction that reflect SyB function and morphological analysis of the terminals inhibited by this peptide should provide further insight into the function of SyB. Supported by the Deutsche Forschungsgemeinschaft (Leibniz-Programm and Be718/11).

## 310.5

**CHARACTERIZATION OF SPECIFIC SITES OF INTERACTION OF THE SYNAPSINS BY USING PHAGE DISPLAY LIBRARIES.** P. Vaccaro, L. Dente, F. Onofri, A. Zucconi, F. Valtorta, P. Greensgard, G. Cesareni, F. Benfenati\* Dept. of Biology and Exp. Medicine, II Roma University and \*Dibit, Dept. of Pharmacology, Milano University, Italy; \*The Rockefeller University, New York.

The synapsins are a family of phosphoproteins that are involved in the short-term regulation of neurotransmitter release and in the formation of synaptic contacts. The synapsins interact with the cytoplasmic surface of synaptic vesicles and with cytoskeletal proteins, namely actin. To identify and localize specific interaction sites of the synapsins, we have analyzed libraries of short peptides of random sequence (about 10<sup>6</sup> peptides), displayed on the surface of a filamentous bacteriophage. Oligonucleotides encoding for nonapeptides of random sequence were inserted by means of a phagemid vector into the gene of the capsid protein pVIII so that the peptides were expressed in multiple copies at the surface of the phage. Affinity selection of specific ligands of synapsin I (Syn I) was performed by screening the phage library on Syn I-coated polystyrene beads (biopanning). After a few cycles of biopanning and phage amplification, phage clones that bound Syn I with high affinity were obtained and sequenced. The amino acid sequences of the exposed peptides were determined and aligned according to their sequence similarity. Families of reactive clones exhibiting common motifs (QNYV, YxxWE, YVxxW; single letter code) could be identified. The most reactive phage clones were used to produce anti-peptide antibodies in mice and to synthesize the corresponding peptides. The resulting peptides and antibodies were then characterized for the ability to affect the binding of Syn I to synaptic vesicles and actin. The identification of the specific sites and sequences of interaction between Syn I and its partners in the nerve terminal may provide peptide tools capable of selectively interfering with the functional activity of Syn I in the regulation of neurotransmitter release and synapse formation. Supported by Telethon, Italy (grant # 753).

## 310.7

**INTRANEURONAL TRAFFICKING AND DIFFERENTIAL DISTRIBUTION OF AMPHIPHYSIN AND SYNAPTOJANIN IN THE RAT PNS AND SPINAL CORD** J.-Y. Li\* and A. Dahlström Dept. of Anat. & Cell Biol., Göteborg University, S-413 90 Göteborg, Sweden

Transmitter release takes place in a very short delay after nerve terminal depolarization, followed by a rapid endocytic reuptake of synaptic vesicle membranes. We investigated intraneuronal dynamics and distribution of two neuronal components, amphiphysin and synaptotagmin, considered to be involved in the endocytosis process. The nerve crush ("stop flow") technique was used in combination with immunofluorescence, cytofluorimetric scanning (CFS), confocal laser scanning microscopy and immuno EM. After crushing, distinct accumulations of immunoreactive amphiphysin and synaptotagmin were detected as early as 1 h post-operation, demonstrating fast axonal transport of these proteins. The proximal accumulations increased linearly between 1 and 8 h. CFS analysis showed that about 30% of anterogradely transported amphiphysin and synaptotagmin was retrogradely transported (recycled), in contrast to the transmembrane vesicle protein, synaptophysin, 80% of which was recycled. The results suggest that amphiphysin and synaptotagmin are predominantly involved in anterograde axonal transport and to a large extent degraded or metabolized in nerve terminals. Immuno-gold EM showed that anti-amphiphysin and anti-synaptotagmin had primarily associated with heterogeneous membrane profiles in crushed sciatic nerves, and with small synaptic vesicles in nerve terminals of the spinal cord. In addition, peroxidase immuno-EM demonstrated that the two proteins were differentially distributed in subsets of nerve terminals, the intensity of immunolabelling of nerve terminals for amphiphysin and synaptotagmin differing from negative to very intense. The study indicates 1) that amphiphysin and synaptotagmin are transported with fast anterograde axonal transport in the sciatic nerve, 2) that only little (30%) is recycling, 3) that the two proteins are associated with heterogeneous membrane structures and 4) they are selectively present in subsets of spinal cord nerve terminals.

Supported by the Swedish MRC (2207) and the Royal Acad. of Sci and Arts in Göteborg. The generous supply of antibodies from Dr. P. De Camilli and Dr. R. Jahn is acknowledged.

## 310.9

**SYNAPSINS, SYNAPTOTAGMIN AND OTHER VESICLE MARKERS IN AXONAL NEUROTRANSMITTER VESICLES** Gabriel Fried\*<sup>1,2</sup>, Andrew Czernik<sup>3</sup>, Andrew Bean<sup>4</sup>

Dept. of <sup>1</sup>Physiology and Pharmacology, <sup>2</sup>Dept. of Woman and Child Health, Karolinska Institute, Stockholm; <sup>3</sup>Molecular and Cellular Neuroscience, Rockefeller University, New York and Dept. of <sup>4</sup>Neuroscience, Stanford University.

We have examined the subcellular distribution of several synaptic vesicle proteins (synapsins, synaptophysin, synaptotagmin, synaptobrevin (VAMP-1/2), rab3a, n-secl and dopamine-β-hydroxylase (DBH)), in density gradients from bovine splenic nerve axons. Nerves were homogenized and centrifuged on linear density gradients (0.25-1.5 M sucrose) at 280,000xg for 90 min in a Beckman L70 using a SW40 rotor. Subcellular fractions were analyzed by immunoblotting. We found that synapsin I and synaptophysin, markers for small synaptic vesicles, peaked in low density fractions. DBH, a marker for large noradrenergic vesicles, showed a distinctly different pattern with a single peak at much higher density. Synaptotagmin was present throughout the gradient, with maximal levels below the DBH peak. VAMP-1/2, rab-3 and n-secl were only seen in low density fractions. The results show that the bulk of synapsin and synaptophysin transported in the bovine splenic nerve is present in fractions containing organelles with different size and density than organelles transporting DBH. Synaptotagmin was localized in both small and large vesicle fractions, which is compatible with its suggested role as a general calcium sensor in exocytosis.

## 310.6

**AXONAL TRANSPORT OF SYNAPTIC VESICLE PROTEINS IN THE RAT OPTIC NERVE** A. Dahlström\* and J.-Y. Li Dept. of Anat. and Cell Biol., Göteborg University, S-413 90 Göteborg, Sweden

The optic nerve, a part of the central nervous system (CNS), has been used to study axonal transport for decades. The present study has concentrated on the fast axonal transport of synaptic vesicle proteins in the optic nerve, as a model of the CNS, using the "stop-flow" (nerve crush) method. After blocking fast axonal transport, distinct accumulations of synaptic vesicle proteins developed during the first hour after crush-operation and marked increases were observed up to 8 hrs post-operation. Semi-quantitative analysis, using cytofluorimetric scanning (CFS) of immuno-incubated sections, revealed that the ratio between distal accumulations (organelles in retrograde transport) and proximal accumulations (organelles in anterograde transport) was much higher (up to 80-90%) for the transmembrane proteins than that for surface adsorbed proteins (only 10-20%). The pattern of axonal transport in the optic nerve was comparable to that in the sciatic nerve. However, immunoreactive clathrin and Rab3a were found to accumulate in much lower amounts than in the sciatic nerve. Most synaptic vesicle proteins were colocalized in the axons proximal to the crush. However, a differential distribution of synaptobrevin I and II was observed in optic nerve axons; synaptobrevin I was present only in large sized axons, while synaptobrevin II immunoreactivity was present in most axons, including the large ones. The two isoforms were, thus, partially colocalized, in the large axons.

The results demonstrate 1) that CFS techniques could be successfully used to study axonal transport not only in peripheral nerves, but also in the CNS, 2) that synaptic vesicles are transported with fast axonal transport in this nerve, and that 3) some quantitative differences were noted compared with the sciatic nerve, especially for Rab3a and clathrin.

Supported by the Swedish MRC (2207), the Royal Acad. of Science and Arts in Göteborg, Gustav V:s 80-årsfond, and by the Swedish Soc. for Med. Res. For a generous supply of antibodies we are grateful to: Dr. R. Jahn, Dr. P. Greensgard, Dr. R. Kelly, Dr. T. Südhof and Dr. K. Haglid.

## 310.8

**Secretory Proteins SNAP-25 and Syntaxin Form Complexes at the Active Zone *in situ*: Evidence from Co-application of Botulinum A and C1.** D.A. Raciborska, W.S. Trimble\*, and M.P. Charlton. <sup>1</sup>Dept. Physiology, Univ. Toronto and <sup>2</sup>Center for Research in Neurodegenerative Diseases, Toronto, Canada, M5S 1A8.

SNAP-25 and syntaxin have been identified as critical participants in exocytosis, associated with membrane and other compartments of the presynaptic cell. *In vitro* studies they form complexes with each other and with other proteins. Cleavage of SNAP-25 and syntaxin by Botulinum A (BoTA) and C1 (BoTC) results in blockade of neurotransmitter release. We used immunocytochemistry and exploited the regularity of active zones at the frog neuromuscular junction to investigate protein distribution before and after poisoning. SNAP-25 and syntaxin were distributed in incomplete bands at 1 μm intervals in register with post-synaptic acetylcholine receptors. BoTA blocked transmitter release and caused a decrease in SNAP-25 C-terminus, but not in SNAP-25 N-terminus or syntaxin immunoreactivity. BoTC blocked transmitter release and reduced syntaxin but not SNAP-25 immunoreactivity. This effect was strongest between active zones, presumably due to sensitivity of the cytoplasmic/vesicular pool of proteins to toxins. When BoTA and BoTC were applied together, both SNAP-25 N- and C-terminal, and syntaxin immunoreactivity were reduced, indicating that retention of cleaved SNAP-25 depended on intact syntaxin. Hence, these molecules form a complex at the active zone *in vivo* in frog nerve terminals, with syntaxin anchoring SNAP-25 and influencing its conformation. Because not all immunoreactivity disappeared upon cleavage of SNAP-25 and syntaxin, distinct pools of these proteins in the nerve terminals may be differentially cleaved by the toxins.

Supported by a grant to M.P.C. from MRC of Canada.

## 310.10

**MgATP-DEPENDENT DISSOCIATION OF A 68-kDa SYNAPTIC PROTEIN FROM SYNTAXIN.** T. Nishiki<sup>1,2</sup>, M. Sekiguchi<sup>1</sup>, S. Kozaki<sup>3</sup>, K. Kumakura<sup>2</sup> and M. Takahashi<sup>1</sup>. <sup>1</sup>Mitsubishi Kasei Inst. of Life Sci., Tokyo, Japan, <sup>2</sup>Sophia Univ., Tokyo, Japan, <sup>3</sup>Osaka Pref. Univ., Osaka, Japan.

Neurons release neurotransmitters at synapses by exocytosis of synaptic vesicles. Syntaxin, a synaptic membrane protein, interacts with various synaptic proteins *in vitro* and is believed to form a core complex required for docking/fusion of synaptic vesicles. However it is still unclear how the protein-protein interactions are regulated. In this study, we have found a 68-kDa protein binding to syntaxin *in situ* and characterized the interaction between syntaxin and the syntaxin-binding protein. Digitonin-permeabilized rat pheochromocytoma cells were incubated with various chemical cross-linkers and the cell proteins were analyzed by immunoblotting with anti-syntaxin antibody. In the presence of 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) a new immunoreactive band with 105 kDa was formed. The molecular mass of the syntaxin-binding protein was 68 kDa, deduced from the difference between the migration in SDS-PAGE of the conjugate and that of syntaxin. Treatment of the permeabilized cells with MgATP prior to cross-linking with EDC largely decrease the amount of cross-linked product. The cross-linked product was also formed when cell proteins were solubilized with Triton X-100 and incubated with EDC, indicating that the interaction between syntaxin and the 68-kDa protein is not influenced by the solubilization. The 105 kDa cross-linked band containing syntaxin was also detected in the detergent extract obtained from rat brain synaptosomes. These results suggest that the 68 kDa protein binds to syntaxin on plasma membranes and the interaction between them is dependent on MgATP. The 68-kDa syntaxin-binding protein may regulate the function of syntaxin in synaptic vesicle exocytosis.

**ISOLATION AND FEATURES OF A  $Ca^{2+}$ -INDEPENDENT  $\alpha$ -LATROTOXIN RECEPTOR.** Yu. Ushkarov\*, B. Davletov, and O. Shamotienko. Biochemistry Department, Imperial College, London SW7 2AY, UK.

$\alpha$ -Latrotoxin (LTX), a neurotoxin from the Black Widow Spider venom, binds to the presynaptic membrane and causes massive neurotransmitter release in all vertebrate synapses both in the presence and in the absence of  $Ca^{2+}$ . Neurexins (Ushkarov, Yu. A., et al. (1992) *Science* 257, 50-56), isolated previously as LTX receptors interact with the toxin only in  $Ca^{2+}$  and, thus, may not represent the  $Ca^{2+}$ -independent receptor. We now report the isolation of a novel neuronal protein that binds LTX in EDTA. This high molecular weight protein, termed here latrophilin, has been purified from detergent-solubilised bovine brain membranes by affinity chromatography on immobilised LTX and wheat germ lectin. Latrophilin binds to LTX, immobilised on a column or immunobeads, with high affinity ( $K_d=0.5-0.7$  nM). Sucrose density gradient centrifugations demonstrated that latrophilin forms with LTX stable complexes composed of one molecule of each protein. Latrophilin consists of a single polypeptide chain that is heavily N-glycosylated. When analyzed by the two-phase partitioning method, latrophilin behaved as a hydrophobic protein, indicating that it is normally membrane-bound. Anti-latrophilin antibodies detected this protein in a glycoprotein-enriched membrane fraction from bovine cerebral cortex and cerebellum but not from non-neuronal tissues. Four times more latrophilin was present in the cortex than in the cerebellum, and the level of expression did not exceed 0.8 pmol latrophilin/mg total membrane protein. Sequences of peptides, purified from protease-digested latrophilin, showed no homology to proteins in the current data bases. All features of latrophilin are in good agreement with known characteristics of the  $Ca^{2+}$ -independent LTX receptor. Our data suggest that latrophilin may represent the presynaptic receptor and/or molecular target for  $\alpha$ -latrotoxin. - This work was supported by a Wellcome Senior European Research Fellowship (to Y.A.U.).

**CHARACTERIZATION OF RAB3A, RAB3B AND RAB3C -DIFFERENT BIOCHEMICAL PROPERTIES AND INTRACELLULAR LOCALIZATION IN BOVINE CHROMAFFIN CELLS** <sup>1</sup>Chong-Gee Lin, <sup>1,4</sup>Yu-Chi Lin, <sup>1,4</sup>Hwan-Wun Liu and <sup>1</sup>Lung-Sen Kao. <sup>1</sup>Institute of Biomedical Sciences, Academia Sinica; <sup>2</sup>Department of Biochemistry, National Yang-Ming University; <sup>3</sup>Department of Anatomy, National Defense Medical Center; <sup>4</sup>Institute of Life Science, National Defense Medical Center, Taipei, Taiwan, R. O. C.

Rab3 proteins are the only group of small G proteins that is thought to be involved in regulated exocytosis. Although amino acid sequences of Rab3 proteins are highly homologous, their functions are distinct. Compartmentation and biochemical characteristics are main determinants for specific functions of small G proteins. In this study, we examined the biochemical properties and subcellular localization of Rab3A, Rab3B and Rab3C in bovine adrenal chromaffin cells. The  $K_d$  for GTPyS of the three Rab3 proteins was 15 nM, 2700 nM and 204 nM for Rab3A, Rab3B and Rab3C, respectively. The intrinsic GTPase activity of the three Rab3 proteins was similar. It appears there are different GAPs for different Rab3 proteins in bovine chromaffin cells. Truncation of C-terminal 31 amino acids decreases the binding affinity for GTPyS of the three Rab3 proteins. When the C-terminal of Rab3C is replaced with that of Rab3A, the binding affinity of Rab3C for GTPyS is decreased, but the replacement does not affect the affinity of Rab3B for GTPyS. Immunostaining and subcellular fractionation experiments show that Rab3A, Rab3B and Rab3C were separately localized within chromaffin cells. Rab3A is predominantly localized in fractions of chromaffin granule, plasma membrane and cytosol. Anti-Rab3B antibody distinctly stained the plasma membrane. Rab3C was rich in fractions of chromaffin granules and mitochondria. In summary, bovine chromaffin cells express the three Rab3 proteins but the subcellular localization and biochemical properties of the three Rab3 proteins are distinct. **NSF IS INVOLVED IN A KINETICALLY IMPORTANT STEP IN NEUROTRANSMITTER RELEASE.** F.E. Schweizer\*, W.M. DeBello, T. Dresbach, V. O'Connor, H. Betz, and G.J. Augustine. Dept. Neurobiology, Duke Univ. Med. Cntr, Durham, NC 27710, MBL, Woods Hole, MA 02543, and Max-Planck Inst., Frankfurt, Germany.

A peptide derived from the N-terminal domain of NSF (NSF-1) alters synaptic transmission when microinjected into the giant presynaptic terminal of squid. This peptide both reduces the amplitude and slows the time course of the postsynaptic potentials evoked by presynaptic action potentials (Soc. Neurosci. Abs. 21, 325). To understand the mechanism of NSF-1 action, we monitored pre- and postsynaptic currents while injecting NSF-1. Control postsynaptic currents (PSCs) evoked by presynaptic action potentials rose with a mean rise time (20% to 80%) of  $0.40 \pm 0.06$  ms. PSC decay could usually be described as the sum of two exponentials with time constants of  $0.58 \pm 0.09$  ms and  $4.09 \pm 1.27$  ms. Presynaptic injection of NSF-1 slowed in a dose dependent manner both the onset and the decay of the PSC. The rapid component of the decay was slowed ~2-fold more than the rise time, whereas the slow component of the decay was not affected by NSF-1. To determine whether the slowing is due to changes in the rate of presynaptic  $Ca^{2+}$  entry we measured voltage-dependent presynaptic  $Ca^{2+}$  currents and monitored PSCs triggered by these currents. The  $Ca^{2+}$  currents were not affected by NSF-1 injections even though the time course of the PSCs was slowed. We conclude that NSF participates in transmitter release by catalyzing a step that influences the kinetics of exocytosis. NSF-1 is thus a valuable tool for understanding both the presynaptic function of NSF and the reactions that determine the speed of transmitter release. Supported by NIH NS-21624.

**CA-DEPENDENT MODULATION OF ASSOCIATION AND DISSOCIATION OF SYNAPTOTAGMIN TO SYNTAXIN.**

A. Yoshida\*, T. Yoshioka. Dept. of Mol. Neurobiol., Waseda Univ., Tokorozawa, 359, Japan.

Synaptotagmin, that has been postulated to act as a  $Ca^{2+}$  sensor for neurotransmitter release,  $Ca^{2+}$ -dependently forms a complex containing syntaxin. In this study, we examined the dynamical interaction of synaptotagmin to syntaxin by BIAcore system based on surface plasmon resonance. A glutathione-S-transferase (GST)-fusion protein of syntaxin amino- or carboxyl-terminal region (GST/Stx-Nt or -Ct) were immobilized by anti-GST antibody crosslinked on the sensor chip surface. The cytoplasmic region of rat synaptotagmin 1 with a maltose binding protein (MBP/Syt) slightly bound to the immobilized GST/Stx-Ct in the absence of  $Ca^{2+}$ . It showed two component of the association and dissociation. In the presence of  $Ca^{2+}$  (0.5 mM), the amount of the fast associated MBP/Syt and the rate of the slow association component were increased. The amount of slowly dissociated MBP/Syt from the complex were increased in the presence of  $Ca^{2+}$ . No binding activity of MBP/Syt to the GST/Stx-Nt nor GST was found. These results suggested that the  $Ca^{2+}$  might modulated the state of the complex of synaptotagmin and syntaxin.

**SEC-1/UNC-18 REGULATES NEUROTRANSMITTER RELEASE AT A STEP THAT FOLLOWS VESICLE DOCKING** M.E. Burns\*, T. Dresbach, V. O'Connor, W.M. DeBello, H. Betz, and G.J. Augustine. Dept. Neurobiology, Duke University Medical Center, Durham, NC USA and Max-Planck Institute for Brain Research, Frankfurt Germany.

Sec-1/unc-18 is a presynaptic protein that regulates SNARE complex assembly *in vitro*. We have cloned the gene for the squid homolog of sec-1/unc-18 and tested the function of this protein in neurotransmitter release. Microinjection of sec-1/unc-18 into the presynaptic terminal of the squid giant synapse produced a reversible inhibition of transmitter release evoked by presynaptic action potentials. This inhibition did not occur when sec-1/unc-18 was co-injected with syntaxin, suggesting that sec-1/unc-18 inhibits release via an association with endogenous syntaxin. A synthetic peptide from a conserved region of sec-1/unc-18 also inhibited release reversibly, while a scrambled version of this peptide, as well as other peptides from other regions of the protein, had no effect. Electron microscopy of terminals injected with the active peptide revealed an accumulation of vesicles located at the plasma membrane of active zones. These results are consistent with the hypothesis that sec-1/unc-18 is a negative regulator of transmitter release and that this regulation is conferred by binding to syntaxin. Because sec-1/unc-18 regulates SNARE complex assembly *in vitro*, our results further suggest that SNARE complex assembly is important for release at a step that follows the docking of vesicles at the plasma membrane. Supported by NIH NS-21624 and Sigma Xi.

**REGULATION OF SNARE COMPLEX ASSEMBLY *IN VIVO* BY THE SNAP-25-BINDING DOMAIN OF SYNTAXIN 1A** C. Heuss, W.M. DeBello, T. Dresbach, V. O'Connor, T. Schäfer\*, M.M. Burger, H. Betz, and G.J. Augustine. Friedrich Miescher Institute, Basel, Switzerland; Dept. Neurobiology, Duke University Medical Center, Durham, NC, U.S.A.; and Max-Planck Institute for Brain Research, Frankfurt, Germany.

Syntaxin, an integral membrane protein found in nerve terminals, interacts *in vitro* with the plasma membrane-associated protein SNAP-25. It has been suggested that both proteins mediate Ca-dependent neurotransmitter release *in vivo*. In order to assess the role of the SNAP-25-syntaxin interaction in transmitter release, we microinjected syntaxin fragments into giant presynaptic terminals of squid. A squid homolog of syntaxin 1A was cloned and two recombinant peptides were prepared: TAX86, corresponding to the 86 C-terminal residues of mammalian syntaxin 1A, a region known to bind SNAP-25, and TAX50, corresponding to the 50 N-terminal residues of TAX86. Gel overlays showed that TAX86, but not TAX50, bound squid SNAP-25. TAX86 also competitively inhibited the binding of syntaxin to SNAP-25. Further, *in vitro* binding measurements showed that TAX86 forms SDS-sensitive trimeric SNARE complexes with recombinant SNAP-25 and synaptobrevin. Microinjection of TAX86 caused a rapid and irreversible inhibition of release evoked by single action potentials. In contrast, comparable injections of TAX50 had no effect on release. Our interpretation is that TAX86 inhibits release by binding to endogenous SNAP-25, and thereby prevents the binding of endogenous syntaxin. The irreversible action of TAX86 on release is consistent with this interpretation, because SNARE complexes formed with TAX86 should be insensitive to ATP hydrolysis by NSF (Neuron 14:991-8). We conclude that the interaction between syntaxin and SNAP-25, and the subsequent NSF-dependent disassembly of the SNARE complex, are critical for neurotransmitter release. Supported by NIH grant NS-21624.

## 310.17

DEVELOPMENTAL EXPRESSION OF BRAIN/KIDNEY (B/K) GENE ENCODING A PROTEIN WITH TWO C2 DOMAINS THAT IS SELECTIVELY EXPRESSED IN THE BRAIN AND KIDNEY. Q.-J. Kwon<sup>1</sup>, H. Kim<sup>2</sup>, and H. Chin<sup>3</sup>. <sup>1</sup>Dept. of Biochemistry, Catholic University Medical College, <sup>2</sup>Dept. of Anatomy, Korea University Medical College, Seoul, Korea, and <sup>3</sup>Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

We have previously isolated and characterized a rat brain cDNA clone that encodes a protein with structural similarity to the synaptotagmins, and called it B/K protein based on its selective expression in the brain and kidney (Kwon, et al., FEBS Letters, 378:135, 1996). We now isolated a human brain cDNA encoding the B/K protein. The 1.5 kb hB/K12 cDNA clone, which exhibited ~90% nucleic acid sequence identity with the rat B/K, contained the entire coding sequence of 474 amino acid B/K protein. On Northern blot analysis, a hB/K cDNA probe hybridized to a 3.0 kb B/K transcript present only in human brain and kidney.

*In situ* hybridization histochemistry analysis of developing and adult rat brains showed that B/K expression gradually increases during development. In the prenatal stage, low levels of B/K transcript was found in the brain and spinal cord. After birth, the B/K expression continually increased, but became restricted to the frontal brain. In the adult rat brain B/K mRNA was highly expressed in the superficial layer of cerebral cortex, cingulate gyrus, dentate gyrus and CA1 area of Ammon's horn. This spatiotemporal pattern of expression suggests that B/K protein may function in membrane trafficking process in this region of the brain. This work is funded by the grants from Korean Science Foundation and by the NINDS, NIH, Intramural Program.

INHIBITION OF NEURONAL NITRIC OXIDE SYNTHASE BY A NOVEL ASSOCIATED PROTEIN, S. R. Jaffrey<sup>1</sup> and S. H. Snyder. Departments of Neuroscience, Pharmacology and Experimental Therapeutics, and Psychiatry, Johns Hopkins University, School of Medicine, Baltimore, MD, 21205.

Neurotransmitter functions of nitric oxide are dependent upon dynamic regulation of its biosynthetic enzyme, neuronal nitric oxide synthase (nNOS). A yeast two-hybrid screen was employed to identify a regulatory protein that binds nNOS. A small, ~10 kD protein was identified which physically interacts with and inhibits the activity of nNOS. This protein inhibitor of nNOS (PIN-1) appears to be one of the most conserved proteins in biology with 92% amino acid identity between *C. elegans* and man. Binding destabilizes the nNOS dimer, a conformation necessary for activity. PIN-1 provides a novel mode of regulation of NOS activity and may regulate numerous biological processes.

METAL SELECTIVITY OF THE INTERACTION BETWEEN SYNAPTOTAGMIN AND PHOSPHOLIPID BILAYERS. J.L. Tomsig<sup>1</sup>, X. Sun and J.B. Suszkiw. Dept. of Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH 45267-0576.

We have previously reported (*J. Neurochem.* 66, 644-650, 1996) the metal selectivity of exocytosis in  $\alpha$ -toxin permeabilized chromaffin cells. Metal cations that activate exocytosis exhibit the following potency sequence:  $Pb^{2+} \gg Cd^{2+} > Ca^{2+} \approx La^{3+} > Ba^{2+} \approx Sr^{2+}$ . We report here the effect of these metals on the interaction between phospholipid bilayers and synaptotagmin, a molecule that has been proposed as the calcium sensor that triggers the mechanism of exocytosis. We studied the association of histidine-tagged synaptotagmin and liposomes labeled with dansyl-phosphatidylethanolamine using a fluorescence resonance energy transfer assay. We found that the interaction between synaptotagmin and phospholipid bilayers is promoted by a metal series that resembles the potency sequence described for activation of exocytosis. The concentrations of metal cations required for half-maximal activation were:  $Pb^{2+}$ ,  $7.2 \times 10^{-9}$  M;  $Cd^{2+}$ ,  $2.1 \times 10^{-7}$  M;  $Ca^{2+}$ ,  $5.2 \times 10^{-7}$  M;  $La^{3+}$ ,  $5.8 \times 10^{-6}$  M;  $Tb^{3+}$ ,  $3.0 \times 10^{-5}$  M;  $Sr^{2+}$ ,  $6.5 \times 10^{-4}$  M;  $Ba^{2+}$ ,  $1.1 \times 10^{-3}$  M. The similarity between these two sequences supports the hypothesis that synaptotagmin or a protein structurally related to synaptotagmin can function in chromaffin cells as the intracellular receptor that promotes exocytosis. Supported by NIEHS grant ES-04090.

## MECHANISMS OF NEUROTRANSMITTER RELEASE II

## 311.1

INSULIN TRIGGERS PEPTIDE SECRETION FROM THE BAG CELL NEURONS OF APLYSIA. C.M. Smith<sup>1</sup>, E.A. Jonas<sup>1</sup>, N.L. Wayne<sup>2</sup>, and L.K. Kaczmarek<sup>1</sup>. Dept. of Pharmacology<sup>1</sup>, Yale Univ. Sch. of Med., New Haven, CT 06520. Dept. of Physiology<sup>2</sup>, Univ. of California Sch. of Med., Los Angeles, CA 90095.

Localized increases in cytoplasmic free  $Ca^{2+}$  levels are critical in regulated exocytosis. Insulin elevates intracellular  $Ca^{2+}$  in both the somata and neurite tips of the peptidergic bag cell neurons of *Aplysia* (Jonas et al., *Neurosci. Abstr.*, 1995). We studied the effect of insulin on the secretion of egg-laying hormone (ELH) from the bag cells. Bag cell clusters were treated with insulin (5  $\mu$ M) dissolved in artificial sea water. In some experiments, the afferent input to the clusters was electrically stimulated to fire a repetitive series of action potentials (afterdischarge; AD). Perfusate from clusters was collected by regular bath exchange, and the amount of ELH in each sample was quantified by radioimmunoassay. Clusters that were not stimulated to AD nor treated with insulin did not secrete ELH. However, control clusters secreted ELH in response to an AD. In the absence of action potential firing, insulin-treated clusters secreted an amount of ELH comparable to the amount secreted by control cells that afterdischarged. The ability of insulin to trigger ELH release contrasts with that of thapsigargin (5  $\mu$ M), which failed to elicit secretion. Calcium imaging of isolated, fura-2-loaded bag cell neurons showed that thapsigargin elevates cytoplasmic free  $Ca^{2+}$  primarily in the somata (Knox et al., *J. Physiol.*, 1996), and less in the neurites of bag cells, where secretion is believed to occur. The results suggest that ELH secretion from the bag cells can be supported at least in part by  $Ca^{2+}$  released from an insulin-sensitive, intracellular  $Ca^{2+}$  store that is localized to the site of exocytosis. Work supported by NIH grants NS18492 (L.K.K.) and NS33548 (N.L.W.).

## 311.2

CHARACTERIZING A NOVEL INTRACELLULAR CALCIUM POOL THAT MAY REGULATE NEURONAL PEPTIDE SECRETION. E.A. Jonas<sup>1</sup>, R.I. Knox, J.A. Connor, L.K. Kaczmarek. Dept. Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06520. Lovelace Institute, Albuquerque, NM 87108.

The bag cell neurons of *Aplysia* are a model system in which to study the regulation of neuronal excitability and secretion. In fura-2 loaded bag cell neurons, activation of the plasma membrane insulin receptor stimulates  $Ca^{2+}$  release from a novel intracellular  $Ca^{2+}$  source (Jonas et al., *Neurosci. Abstr.*, 1995) which is particularly prominent in neurites, where peptides are secreted from these cells. Insulin also stimulates secretion of neuropeptide from bag cell neurons (Smith, et al., *Neurosci. Abstr.*, 1996). We developed a technique to form giga-ohm seals on intracellular membranes, so that we could attempt to measure channel activity associated with the insulin-stimulated  $Ca^{2+}$  release. Following seals on intracellular organelle membranes, we identified three different intracellular membrane conductance levels of 7, 13, and 78 pS with reversal potentials of +70, 0, and -20 mV respectively. The 7 pS conductance may be activated by extracellular insulin application. Further studies of the insulin-sensitive store will attempt to identify the type of organelle responsible for the intracellular  $Ca^{2+}$  release. Peptide-containing vesicles are present in bag cell neurite tips, therefore the novel insulin-sensitive store may be one such vesicle located near the sites of neuropeptide release. Work supported by NIH Grant # NS18492 (L.K.K.).

## 311.3

**LOCAL CALCIUM GRADIENTS GENERATED BY RELEASE FROM INTRACELLULAR CALCIUM STORES REGULATE EXOCYTOSIS IN PITUITARY GONADOTROPHS.** F.W. Tse<sup>1</sup>, A. Tse<sup>1</sup>, B. Hille<sup>2</sup> & W. Almers<sup>3</sup>. <sup>1</sup>Dept. Pharmacol., U. Alberta, Edmonton, Alberta, Canada. <sup>2</sup>Dept. Physiol. & Biophys., U. Washington, Seattle, Washington, USA. <sup>3</sup>Max-Planck-Institut für Medizinische Forschung, Heidelberg, Germany.

In single identified gonadotrophs of male rat, the hormone GnRH induces release of intracellular  $\text{Ca}^{2+}$  from  $\text{IP}_3$ -sensitive stores which in turn stimulates exocytosis (Tse et al., *Science* 260:82). The rate of GnRH-induced exocytosis (increase in membrane capacitance) was >50 vesicles/s when spatially averaged  $[\text{Ca}^{2+}]_i$  was rising from 0.5  $\mu\text{M}$  to 1.5  $\mu\text{M}$ . When  $\text{Ca}^{2+}$  was released from intracellular stores by flash photolysis of caged  $\text{IP}_3$  (either in the presence or absence of extracellular  $\text{Ca}^{2+}$ ), the exocytic rate at  $[\text{Ca}^{2+}]_i$  in between 0.5  $\mu\text{M}$  to 1.5  $\mu\text{M}$  could be as fast as that induced by GnRH; however, the rate of exocytosis was more closely correlated with the rate of rise of  $[\text{Ca}^{2+}]_i$  than with  $[\text{Ca}^{2+}]_i$  itself. In addition, when  $[\text{Ca}^{2+}]_i$  was raised uniformly to comparable levels by flash photolysis of caged-Ca, or by intracellular dialysis of Ca-buffered solutions, the exocytic rate was <1 vesicle/s. These observations suggest that the exocytic sites are selectively localized near  $\text{IP}_3$  receptors and are stimulated by local high elevations of  $[\text{Ca}^{2+}]_i$  around active  $\text{IP}_3$  receptors rather than by the lower average  $[\text{Ca}^{2+}]_i$  measured by photometry. (Supported by Canadian MRC, AHFMR, US NIH HD-12629, AR-17803.)

## 311.5

**THE RELATION BETWEEN CALCIUM INFLOW AND TRANSMITTER RELEASE AT A FAST GLUTAMATERGIC SYNAPSE.** J.G.G. Borst, A. Villarroel\* and B. Sakmann. Max-Planck-Institut für medizinische Forschung, Jahnstraße 29, 69120 Heidelberg, Germany.

Each principal cell in the medial nucleus of the trapezoid body (MNTB) is excited by a single, large synaptic terminal, called the calyx of Held. We measured synaptic currents and presynaptic calcium currents in transversal rat brainstem slices containing the MNTB, to obtain an estimate of the number of calcium ions needed to release a single vesicle. The calcium current flowing into the calyx of Held during a presynaptic action potential was measured by voltage clamping it with an action potential waveform, after blocking the sodium and potassium currents. The calcium current activated shortly after the peak of the action potential and ended before repolarization was complete. It had a peak amplitude of  $2.6 \pm 0.2$  nA and its integral was  $0.89 \pm 0.04$  pC ( $n=12$ ), at 2 mM external calcium.

An estimate for the quantal content of the excitatory postsynaptic currents (EPSCs) was obtained in separate experiments by voltage clamping principal cells during afferent stimulation and taking the ratio of the peak amplitude of the EPSCs, at 2 mM external calcium and the quantal currents ( $43 \pm 5$  pA), measured at low (0.25 mM) calcium concentration. Quantal content was  $151 \pm 14$  ( $n=10$ ), indicating that around 18000 calcium ions enter for each vesicle that is released. Given the low conductance of calcium channels this may mean that the simultaneous opening of many calcium channels is needed to release a single vesicle at this fast excitatory synapse.

J.G.G.B was supported by EMBO and Max-Planck Gesellschaft.

## 311.7

**COUMARINE - BASED FLUORESCENT ION INDICATORS.** H. E. Katerinopoulos, E. Foukaraki, A. K. Moschovakis\*, M. A. Kuhn<sup>2</sup>. Dept. of Chem. and <sup>1</sup>Div. of Basic Sciences, Sch. of Med., Univ. of Crete, 71409 Greece, and <sup>2</sup>Molecular Probes Inc. Eugene, OR, 97402, USA.

A number of cell permeable tetracarboxylate (A) and tricarboxylate (B) fluorescent indicators have been synthesized and tested as probes of intra as well as extra cellular ion concentrations. Coumarins with substituents, causing bathochromic shift, were used as chromophores. Tetracarboxylate dyes (A) were found to be selective for  $\text{Ca}^{2+}$  ions. Tricarboxylate dyes (B) appear to be selective for  $\text{Zn}^{2+}$  ions. In both cases the indicators with the benzothiazolyl substituent gave the longest excitation wavelength and the largest shift upon ion binding. These properties enable the compounds to be used as alternatives to known  $\text{Ca}^{2+}$  and  $\text{Zn}^{2+}$  probes such as fura 2 and TS-Q, respectively.

Y = O, S R = -COMe, -CO<sub>2</sub>Me, -Benzoxazolyl, -Benzothiazolyl

## 311.4

**STIMULUS-SECRETION COUPLING IN PITUITARY CORTICOTROPHS.** A. Tse\*, A.K. Lee & F.W. Tse. Dept. Pharmacology, U. Alberta, Edmonton, Alberta, Canada.

Corticotrophs in the anterior pituitary secrete the stress hormone, adrenocorticotrophic hormone (ACTH) in response to arginine vasopressin (AVP). Single, rat corticotrophs were identified with the reverse hemolytic plaque assay and voltage-clamped at -50 or -70 mV. AVP (100 nM) triggered a "spike and plateau" elevation in  $[\text{Ca}^{2+}]_i$  (monitored by indo-1 fluorescence). Peak  $[\text{Ca}^{2+}]_i$  elevation ranged 1-2  $\mu\text{M}$ . Several lines of evidence suggest that AVP acts via a G-protein coupled phosphoinositide pathway to release  $\text{Ca}^{2+}$  from the  $\text{IP}_3$ -sensitive stores and triggers exocytosis. (1) AVP response was blocked by intracellular dialysis of 2 mM GDP- $\beta$ -S. (2) Dialysis of  $\text{IP}_3$  (10  $\mu\text{M}$ ) or flash photolysis of caged  $\text{IP}_3$  (10  $\mu\text{M}$ ) mimicked the response. (3) Intracellular dialysis of the  $\text{IP}_3$  blocker, heparin (300  $\mu\text{M}$ ) abolished the response. (4) AVP could trigger  $[\text{Ca}^{2+}]_i$  elevation in the absence of extracellular  $\text{Ca}^{2+}$ . (5) Simultaneous measurement of  $[\text{Ca}^{2+}]_i$  and changes in membrane capacitance showed that exocytosis (20-80 fF) was triggered when AVP-induced  $[\text{Ca}^{2+}]_i$  elevation was >1  $\mu\text{M}$ . (6) Flash photolysis of caged  $\text{IP}_3$  raised  $[\text{Ca}^{2+}]_i$  (2-3  $\mu\text{M}$ ) and triggered exocytosis (80 - 120 fF). (Supported by Canadian MRC and AHFMR).

## 311.6

**EXOCYTOSIS AND RE-SUPPLY OF SUBPLASMALEMMAL SECRETORY GRANULES OBSERVED WITH EVANESCENT WAVE FLUORESCENCE MICROSCOPY.** Jürgen Steyer and W. Almers\*. Max-Planck-Institut für Medizin. Forschung, Heidelberg, Germany.

Secretory granules of bovine chromaffin cells (average diameter 340 nm) were stained with the fluorescent dye acridine orange. Cells adhering tightly to a coverslip were viewed. The granules immediately adjacent to the coverslip were selectively illuminated with the evanescent wave (EW) caused by total reflection of light at the glass/ aqueous interface. Photometry with 280 nm fluorescent beads showed that we collect EW fluorescence from a distance of up to 300 nm from the coverslip. Single fluorescent spots (FS) representing subplasmalemmal granules were readily seen. Most dithered randomly around a fixed position, while rare FS's migrated several  $\mu\text{m}$ 's parallel to the plasmalemma within 10 s. When high  $[\text{K}^+]$  triggered Ca entry and exocytosis, single FS's disappeared abruptly as granules exocytosed and lost their dye. Indeed, the loss of FS's was accompanied by exocytic release of epinephrine from single granules, as recorded simultaneously with a carbon fiber. A 2 min exposure to high  $[\text{K}^+]$  caused depletion of FS's. New FS's replaced the old within 20 min, though not at the same position. Since no dye was present externally, the new FS's represent chromaffin granules that entered the EW from regions deeper within the cell. The method allows us to watch single granules as they migrate and exocytose, and to study how they travel the last 300 nm of their way to the plasmalemma. Supported by the Max Planck Society.

**$\text{NH}_4^+$  DECREASES TRANSMITTER RELEASE INDEPENDENT OF  $\text{pH}_i$  AND  $[\text{Ca}^{2+}]_i$ .** W. Raabe\* and R. Nitzan. Departments of Neurology and Physiology, University of Minnesota and VA Medical Ctr., Minneapolis, MN, 55417.

$\text{NH}_4^+$  is involved in the pathogenesis of hyperammonemic encephalopathies such as hepatic encephalopathy. To investigate how  $\text{NH}_4^+$  causes encephalopathy, we studied the effects of  $\text{NH}_4^+$  on transmitter release from cerebellar neurons grown in tissue culture. MiniEPSCs were recorded by whole cell patch clamp in cultures treated with bicuculline and TTX to suppress IPSCs and action potential dependent transmitter release.

$\text{NH}_4^+$  (2.5-5 mM) reversibly decreased the frequency of miniEPSCs without effects on amplitude. The effect of  $\text{NH}_4^+$  did not depend on an increase of  $\text{pH}_i$  since intracellular alkalization with trimethylamine did not affect miniEPSC frequency.  $\text{pH}_i$  measurement with the fluorescent dye BCECF showed that  $\text{NH}_4^+$  (5 mM) and trimethylamine (5 mM) increased  $\text{pH}_i$  to the same extent.  $\text{pH}_i$  changes by  $\text{NH}_4^+$  were transient and followed by an "undershoot" of  $\text{pH}_i$  upon  $\text{NH}_4^+$  washout. In contrast, trimethylamine increased  $\text{pH}_i$  throughout application and without "undershoot" upon washout. The decrease of miniEPSC frequency by  $\text{NH}_4^+$  was not altered by pretreatment of cultures with the  $[\text{Ca}^{2+}]_i$ -buffer BAPTA-AM.

These observations indicate that  $\text{NH}_4^+$  decreases transmitter release by effects independent of changes in  $\text{pH}_i$  and  $[\text{Ca}^{2+}]_i$ , suggesting an effect of  $\text{NH}_4^+$  on synaptic vesicle proteins involved in vesicle fusion and exocytosis of transmitter. Such an effect of  $\text{NH}_4^+$  causes or contributes to the encephalopathy associated with hyperammonemia, e.g. hepatic encephalopathy.

## 311.9

**THE NUMBER OF DOCKED VESICLES DETERMINES THE RELEASE PROBABILITY OF HIPPOCAMPAL NEURONS.** T. Schikorski and C.F. Stevens\* Howard Hughes Medical Institute at the Salk Institute, 10010 N. Torrey Pines Rd., La Jolla, CA 92037

Physiological experiments have indicated that release probability at central synapses are very variable from synapse to synapse, and that the number of docked vesicles is an important determinant of this release probability. For this reason we reconstructed synapses in the CA1 region of adult mice and in rat hippocampal neurons in cell culture from EM serial sections. An average of 7.7 docked vesicles/presynapse was found in mice (std 4.19) and 4.6 docked vesicles in cell cultured neurons (std 3.0). The number of docked vesicles is strongly correlated with the size of the active zone ( $r=0.745$  for mice;  $r=0.934$  for cell cultured neurons), which is in turn strongly correlated with the size of the postsynaptic densities. The distribution of docked vesicles over the active zone appears random.

To determine if the release probability measured for synapses of hippocampal CA1 neurons could be explained by a varying number of release sites, we compared the distribution of release probability in hippocampus with the distribution of docked vesicles/synapse. If every docked vesicle is assigned a constant release probability of .04, both distributions match (Kolmogorov-Smirnov test  $p > 0.1$ ). Therefore, varying the number of docked vesicles at these synapses, seems to correlate with release probability.

## 311.11

**SNAP-25 ANTIBODIES ARE POTENT BLOCKERS OF SYNAPTIC RELEASE IN VIVO.** P. Löw, O. Shupliakov, T. Norlin, C. Risinger, D. Larhammar, V.A. Pieribone<sup>3</sup> and L. Brodin\*. Dept. of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden, <sup>1</sup>Dept. of Molecular & Cell Biology, Berkeley, CA 94720, <sup>2</sup>Dept. of Medical Pharmacology, Uppsala University, S-751 24 Uppsala, Sweden, <sup>3</sup>Dept. of Molecular & Cellular Neuroscience, The Rockefeller University, NY 10021.

SNAP-25 is a plasma membrane-associated protein which can engage in a protein complex (SNAP-25+syntaxin+VAMP) thought to mediate the targeting and/or fusion of synaptic vesicles (Calakos & Scheller, *Physiol. Rev.* 76:1-29, 1996). The C-terminal fragment of SNAP-25 can be selectively cleaved by Botulinum toxin A, which results in a partial inhibition of transmitter release (Dreyer and Schmitt, *Pflügers Arch.* 399:228-234, 1983; Niemann et al. *TIBS* 4:179-185, 1994; Owe-Larsson et al. *Soc. Neurosci. Abstr.* 1996). Here we test the effect of microinjection of a polyclonal antibody raised against the whole SNAP-25 protein into the presynaptic element of the lamprey giant reticulospinal synapse. The reticulospinal neurons were shown by *in situ* hybridization to express high levels of SNAP-25. The antibody was affinity-purified, labeled with CY5, and microinjected presynaptically by pressure. Following injection the antibody accumulated in spots within the axon, with a location corresponding to that of release sites (Pieribone et al., *Nature* 375:493-497, 1995). The synaptic response, monitored by intracellular recording from target cells, showed a rapid decay, which coincided with the occurrence of antibody fluorescence in the synaptic area. Within minutes, no synaptic release could be detected. Neither trains of high-frequency stimulation, nor broadening of the presynaptic spike (by current pulses) were effective in restoring synaptic responses. Our results are consistent with an essential role of SNAP-25 in synaptic exocytosis. (Supported by the Swedish MRC).

## 311.13

**CHARACTERIZATION OF SMALL SYNAPTIC AND LARGE DENSE CORE VESICLE EXOCYTOSIS USING CARBON FIBERS AS ELECTROCHEMICAL DETECTORS.** D. Bruns, S. Engers, A. Jeromin and R. Jahn\*. Howard Hughes Medical Institute, Yale Univ. Sch. of Med., New Haven, CT, 06510

Carbon fiber electrodes were used to measure transmitter discharge from small synaptic (SSV) and large dense core vesicles (LDCV) in cultured serotonergic neurons of the leech (*Hirudo medicinalis*). Transmitter release from individual vesicles was monitored as discrete spike-like oxidation currents. The frequency of oxidation signals was greatly reduced in neurons injected with the neurotoxin Tetanus toxin (TeNT-LC), which blocks transmitter release in other preparations by cleaving the synaptic vesicle protein synaptobrevin. The leech synaptobrevin homologue was cloned and found to be also sensitive to TeNT-LC. Furthermore, western blot analysis of single cell protein demonstrates the successful cleavage of leech synaptobrevin in toxin injected neurons compared with control cells. These results support our hypothesis that the identified signals reflect vesicle mediated exocytosis. At axonal recording sites two types of oxidation signals, small and large events, were observed that likely correspond to exocytosis of SSV and LDCV, respectively. At somatic sites only large events were measured. Electron microscopy demonstrates that both vesicle types are present in the axon stump, whereas solely LDCV were found in the soma of these neurons. SSV and LDCV exocytosis differ with respect to the number of released molecules, the kinetics of transmitter discharge and the time dependent coupling to action potentials. Funding sources: HHMI, NIH-RO1-NS33709-0141.

**RUTHENIUM RED POTENTIATES EXOCYTOSIS AT SINGLE NERVE ENDINGS.** D.R. Giovannucci\* and E.L. Suenkel, Department of Physiology, University of Michigan Medical School, Ann Arbor, MI 48109.

Mitochondria provide low affinity, high capacity  $\text{Ca}^{2+}$  buffering in neurons, and may play a role in  $\text{Ca}^{2+}$  homeostasis under physiological conditions. For example, strong stimulus demand or the generation of local  $\text{Ca}^{2+}$  domains may raise  $[\text{Ca}^{2+}]_i$  to  $\geq 1 \mu\text{M}$ , a level high enough to fully activate mitochondrial  $\text{Ca}^{2+}$  uptake. In the present study, the role that mitochondrial  $\text{Ca}^{2+}$  buffering may play in modulating exocytosis was investigated at the rat single neurohypophyseal nerve ending level using time-resolved membrane capacitance ( $C_m$ ) measurements in combination with fura-2 microfluorometry. Treatment with  $10 \mu\text{M}$  Ruthenium Red (RuR), a blocker of the mitochondrial  $\text{Ca}^{2+}$  uniporter, introduced via patch pipette whole cell dialysis, was shown to have no effect on resting  $[\text{Ca}^{2+}]_i$ ,  $C_m$  or  $\text{Ca}^{2+}$  currents ( $I_{\text{Ca}}$ ). Most nerve endings tested contained mitochondria as shown by EM and fluorescence microscopy, and exhibited a RuR-sensitive  $\text{Ca}^{2+}$  buffering component that limited depolarizing stimulus-induced spatially averaged  $\Delta[\text{Ca}^{2+}]_i$  to  $\sim 500 \text{ nM}$ . RuR treatment enhanced the magnitude of exocytotic response to repetitive depolarizing pulses from a release-ready granule pool (170 granule fusions/pulse train;  $n=7$ ) by  $\sim 5$ -fold over control nerve endings. In addition, the rise in  $C_m$  continued after cessation of the stimulus for a longer period, and the rate of recovery of  $C_m$  to pre-stimulus levels was slowed 4-fold in RuR-treated nerve endings ( $\tau_{1/2} = 44 \text{ s}$ ) compared to control. These effects were abolished by co-treatment with  $5 \text{ mM}$  EGTA ( $n=7$ ) and indicated that the potentiation of exocytosis by RuR was dependent on the reduced rate of  $\text{Ca}^{2+}$  buffering and enhanced rises in  $[\text{Ca}^{2+}]_i$ . These studies suggest a role for mitochondria in modulating secretion in peptidergic nerve endings. (Supported by NIH and NSF grants to ELS and AHAM/MI fellowship to DRG.)

**ACTION OF  $\alpha$ -LATROTOXIN ( $\alpha$ -LT) ON QUANTAL RELEASE FROM EXCITABLE ENDOCRINE CELLS.** J.Liu\*, D.W. Barnett, and S. Misler. Depts. of Medicine and Cell Biology and Program in Neurosciences, Washington Univ., St. Louis MO 63110

$\alpha$ -LT, from the black widow spider, produces rapid and massive "spontaneous" quantal release of neurotransmitters from a variety of vertebrate nerve terminals with small synaptic vesicles. It also has variable effects on evoked transmission and vesicle recycling. Its action at excitable endocrine cells containing dense core granules is controversial. Using capacitance measurements to track granule fusion and/or carbon fiber amperometry to detect epinephrine release, we now report that in rat adrenal chromaffin cells,  $\alpha$ -LT, in the nM range, produces exocytosis, over tens of seconds, of many hundreds to several thousand quanta stored in dense core secretory granules. Isolated cells were maintained in culture for 2-5 days and then exposed to a physiological saline for recording. The onset of release is preceded by the development of a large inward cation current. The time course of the subsequent capacitance increase parallels the cumulative amperometric spike release, where each spike corresponds to the release of at least a million molecules of catecholamine. Termination of the discharge can be followed by delayed endocytosis. After the discharge, the voltage-dependent Na current is intact and, in some cells, the Ca current still supports depolarization-evoked release. In pilot studies with dog pancreatic islet  $\beta$ -cells,  $\alpha$ -LT produced comparable effects on the time course of membrane current and capacitance, and quantal release of serotonin. Since neither endocrine cell is reported to contain neurexin, the putative  $\alpha$ -LT receptor at the nerve terminal surface, these results raise new questions about the mechanism(s) of  $\alpha$ -LT action. Support: NIH (DK37380) and Jewish Hospital Research Fund to S.M.

**EVIDENCE FOR A ROLE OF CALCINEURIN IN  $\text{Ca}^{2+}$ -INDUCED NEUROTRANSMITTER RELEASE: EFFECTS OF ANTI-CALCINEURIN ANTIBODIES AND PHOSPHATASE INHIBITORS IN PERMEATED NERVE TERMINALS.** J.J.H. Hens\*, M. De Wit\*, W.E.J.M. Ghijsen\*, A.G.M. Leenders\*, H.W.G.M. Bokkeke\*, R. Kissmeijer\*, U. Weller\*, W.H. Gispen\* and P.N.E. De Graan\*

<sup>1</sup>Rudolf Magnus Inst. for Neurosciences, Utrecht Univ. and <sup>2</sup>Graduate School for the Neurosciences, Univ. A'dam, NL, <sup>3</sup>Sandoz Pharma, Basle, Switzerland, <sup>4</sup>Biology Dept., Univ. Konstanz and <sup>5</sup>Inst. Med. Microbiology, Univ. Mainz, Germany. (SPON: European Neuroscience Association).

Several proteins that have been implicated in  $\text{Ca}^{2+}$ -induced neurotransmission have been identified as protein kinase substrates, e.g.: the synapsins, synaptotagmin, rabphilin-3A, synaptobrevin, MARCKS, dynamin I and B-50/GAP-43. Recent evidence, however, shows that protein phosphorylation is not a crucial step in  $\text{Ca}^{2+}$ -induced release. Therefore, we investigated the role of  $\text{Ca}^{2+}$ /calmodulin-dependent phosphatase calcineurin (CaN) and protein dephosphorylation in  $\text{Ca}^{2+}$ -induced exocytosis and subsequent vesicle recycling. We introduced CaN-neutralizing antibodies (IgGs) into streptolysin-O-permeated synaptosomes from rat cerebral cortex and measured the release of glutamate (glu), noradrenaline (NA) and neuropeptide cholecystokinin-8 (CCK). The vesicular nature of  $\text{Ca}^{2+}$ -induced glu release (obtained by an elevation of free  $[\text{Ca}^{2+}]_i$  from  $10^{-8}$  to  $10^{-4} \text{ M}$ ) was demonstrated by its complete block by the light chain fragment of tetanus toxin (300 nM). Specific poly- and monoclonal anti-CaN IgGs, that inhibited CaN-mediated dephosphorylation of protein kinase C-substrates B-50 and MARCKS, inhibited  $\text{Ca}^{2+}$ -induced release of glu, NA and CCK. Control IgGs were without effect. Moreover, CaN-inhibitor cyclosporin A ( $10 \mu\text{M}$ ) decreased  $\text{Ca}^{2+}$ -induced glu release from permeated synaptosomes. Okadaic acid ( $\leq 10 \mu\text{M}$ ) did not significantly inhibit  $\text{Ca}^{2+}$ -induced release of glu, NA or CCK, indicating that phosphatase 1 and 2A are not involved in this release process. Altogether, these data identify CaN as a key protein phosphatase involved in the regulation of  $\text{Ca}^{2+}$ -induced exocytosis and/or vesicle recycling of all major neurotransmitter types. **SYNAPTIC PROPERTIES OF BOTULINUM TOXIN A-TREATED RAT HIPPOCAMPAL NEURONS.** B. Owe-Larsson\*, K. Kristensson and L. Brodin. Dept. of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden.

Botulinum toxin A (BoNT/A) cleaves off a C-terminal fragment of SNAP-25, which results in a decreased stability of the "SNARE-complex" (SNAP-25+VAMP+syntaxin). In neuromuscular synapses BoNT/A reduces, but it does not abolish, synaptic transmission. To test the effect of BoNT/A on the properties of a central synapse, we recorded autaptic responses in rat hippocampal neurons, grown at low density in culture, using voltage clamp, whole cell recordings. Control cells showed an autaptic response in 70 % of the cells. The response remained stable during 0.2 Hz stimulation, and showed a gradual depression during 5 Hz stimulation. Cells exposed to high BoNT/A concentrations (40 nM for 4 h) showed virtually no response during 0.2 Hz stimulation. However, when cells were stimulated at 5 Hz, a synchronous response occurred in 30 % of the cells. In contrast to the untreated cells, this autaptic response facilitated markedly during the course of the pulse train. At intermediate concentrations of BoNT/A (10 nM), a good half of the responding cells showed facilitation, while at low concentrations (1 nM) most of the responding cells showed depression. For comparison, in cells treated with high concentrations of Tetanus toxin (6.7 nM), the autaptic response was almost completely abolished. Our results shows that the blocking effect of BoNT/A can be overcome by raising the stimulation frequency, indicating that the C-terminal portion of SNAP-25 is not essential for action potential-induced fusion of synaptic vesicles in central synapses. This may suggest that the threshold for activation of synaptic vesicle fusion is linked to the stability of the "SNARE-complex". Supported by grants from MFR and Stanley Foundation.

## 311.17

**SYNAPTIC ACTIVITY IN PRIMARY POSTNATAL RAT NEOSTRIATAL MICROCULTURES.**

P.B. Senatus and D.D. Potter. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

GABA/peptidergic medium spiny projection neurons comprise the predominant neuronal cell type in the adult rat striatum (e.g., Wilson and Groves [1980] J. Comp. Neurol. 194: 599-615). There is extensive collateral synapse formation among these neurons (e.g., Somogyi et al. [1981] J. Comp. Neurol. 195: 567-584; Kitai et al. [1979] Adv. Neurol. 24: 45-51). To study these synapses *in vitro*, neostriatal microcultures were prepared from postnatal rats and cultured several weeks using methods previously reported (Senatus [1995] Soc. Neurosci. Abstr. 21: 1566); the microcultured neurons contain GABA and leu-Enkephalin immuno-reactivity, and NADPH diaphorase activity in proportions similar to those in adult neurons.

In single, dual and multi-neuron striatal microcultures one to four weeks old, stable perforated patch recordings up to three hours in duration in current clamp were obtained using electrodes containing Gramicidin D. In Tyrode's solution containing 1mM Mg<sup>2+</sup> and 3mM Ca<sup>2+</sup>, conventional spontaneous depolarizing synaptic potentials as well as robust evoked autaptic and synaptic potentials were present; they were sensitive to 10-20  $\mu$ M bicuculline and 10-100  $\mu$ M baclofen. Spontaneous depolarizing shifts (DS's) of varying amplitude and duration occurred occasionally and sometimes rhythmically; action potentials were usually present on their crests. Transitions in striatal neurons between metastable membrane potential states have been reported *in vivo* and in slices (e.g., Wilson and Kawaguchi [1996] J. Neurosci. 16(7): 2397-2410). Supported by 5 F31 GM 14736 to P.B. Senatus, NS02253 to D.D. Potter, and Departmental funds. The authors thank E.J. Furshpan for many helpful conversations.

## 311.19

**STIMULUS-DEPENDENT MOBILIZATION MODEL OF QUANTAL NEUROSECRETION.**

M. Bykhovskaya<sup>1,2</sup>, J.T. Hackett<sup>1</sup> and M.K. Worden<sup>1</sup>. <sup>1</sup>Dept of Physiology, UVa Health Sci. Ctr., Charlottesville, VA 22908, <sup>2</sup>Sechenov IEPH, S-Petersburg 194223, Russia

We have developed a new model of neurosecretion which explains the phenomenon of frequency facilitation in terms of quantal mobilization and demobilization. We propose that each stimulus causes mobilization and docking of a number of quanta ( $n_s$ , see the schematic) independent of frequency of stimulation ( $f$ ). Based on this model we derived and solved the kinetic equations describing quantal mobilization, demobilization and release. This enabled us to predict a linear dependence between  $(1/m)$  and  $(1/fp)$ :

$$1/m = (k_d / \langle n_s \rangle) (1/fp) + 1/\langle n_s \rangle,$$

where  $m$  is the average quantal content,  $p$  is the probability of release and  $k_d$  is the rate constant of quantal demobilization back to cytoplasm. This prediction was tested on lobster dactyl opener muscle with focal extracellular recordings of postsynaptic quantal currents. In each experiment  $m$  and  $p$  were estimated by the statistical analysis of the distribution of the quantal content for several values of  $f$  in the range from 1 to 15 Hz. The relationship between  $(1/m)$  and  $(1/fp)$  was found to be linear, as was predicted by the model, and from its slope and intercept we estimated  $\langle n_s \rangle$  and  $k_d$ . Quantal neurosecretion was simulated by Monte-Carlo method, where the stimulus-dependent quantal mobilization was modeled as a random process with the average  $\langle n_s \rangle$  and variance  $\text{var}(n_s)$ , and quantal demobilization and release were modeled as binomial processes with the probabilities  $(1 - \exp(-k_d/f))$  and  $p$ , respectively. The parameters of the model were obtained by fit of experimental and predicted distributions of quantal content by  $\chi^2$ -minimization. The values of the parameters of the model  $\langle n_s \rangle$ ,  $k_d$  and  $p$  obtained by these two methods, were found to be in a good agreement, as were the simulated and predicted distributions of quantal content. Supported by NIH grant RR10481 to M.K.W.

## 311.16

**BLOCKADE OF ACH RELEASE AT A SYNAPSE IN APLYSIA BY A PEPTIDE THAT MIMICS THE CARBOXY-TERMINAL DOMAIN OF SNAP-25.**

J.P. Aplan<sup>1</sup>, M. Adler<sup>1</sup>, A.V. Farrer-Montiel<sup>2</sup>, M. Monta<sup>2</sup>, and M.G. Filbert<sup>1</sup>. <sup>1</sup>Neurotoxicology Branch, USAMRICD, Aberdeen Proving Ground, MD 21010-5425, and <sup>2</sup>Dept. of Biology, UCSD, La Jolla, CA 92083-0366.

Neurotransmitter exocytosis is preceded by docking of synaptic vesicles at active sites on the presynaptic membrane. SNAP-25 (synaptosomal-associated membrane protein of 25 kDa) is one of several proteins forming the fusion complex at the active sites. Botulinum neurotoxins serotypes A and E cleave SNAP-25. This is presumed to be the mechanism by which they block neurotransmitter release. The SNAP-25 C-terminal 20-amino acid peptide (named ESUP, for excitation-secretion uncoupling peptide) was recently shown by Gutierrez et al. (FEBS Lett. 372:39,1995) to inhibit transmitter release from permeabilized bovine chromaffin cells. The effect of this peptide on acetylcholine (ACh) release at an identified cholinergic synapse of *Aplysia* neurons was investigated.

Recordings were obtained from isolated buccal ganglia of *Aplysia*. The presynaptic neuron was current-clamped and stimulated electrically at 0.1 Hz to elicit action potentials. The postsynaptic neuron was voltage-clamped, and evoked inhibitory postsynaptic currents (IPSCs) were recorded. ESUP was pressure-injected into the presynaptic neuron, and its effect on the amplitude of the IPSCs was studied. ACh release from presynaptic cells, as measured by the amplitudes of IPSCs, was consistently inhibited by the peptide. The inhibition was gradual, requiring 2-3 hr to produce a 50-60% reduction of IPSC amplitude. A random-sequence peptide of the same amino acid composition had no effect. These results suggest that ESUP competes with the intact SNAP-25 for binding with other fusion proteins, thus inhibiting exocytosis of neurotransmitter. This effect may account, in part, for botulinum toxin-induced inhibition of transmitter release. Supported by DoD.

## 311.18

**QUANTAL DEMOBILIZATION DETERMINES FREQUENCY FACILITATION**

M.K. Worden<sup>1</sup>, M. Bykhovskaya<sup>1,2</sup> and J.T. Hackett<sup>1</sup>. <sup>1</sup>Dept Physiology, UVa Health Sci. Ctr., Charlottesville, VA 22908, <sup>2</sup>Sechenov IEPH, S-Petersburg 194223, Russia

In the lobster dactyl opener muscle, the proximal synapses of the excitatory motoneuron have a larger quantal content ( $m$ ) but less frequency facilitation than central synapses. We compared proximal and central synapses using focal extracellular recordings of postsynaptic quantal currents at frequencies of stimulation in the range from 1 to 10 Hz. The number of quanta released in response to each stimulus was counted, and from a statistical analysis of the distribution of quantal content the number of releasable quanta ( $n$ ) and the probability of quantal release ( $p$ ) were estimated. At low frequencies both  $n$  and  $p$  were found to be higher at proximal synapses. At high frequencies ( $f > 5$  Hz) the value of  $p$  saturated at the same level for both central and proximal synapses. All central synapses had a statistically significant increase in  $n$  as  $f$  increased, whereas at proximal synapses  $n$  did not increase. We interpreted this result in terms of stimulus-dependent mobilization model, which predicts that the relationship between  $(1/m)$  and  $(1/fp)$  should be linear, with a slope and intercept equal to  $(k_d / \langle n_s \rangle)$  and  $(1/\langle n_s \rangle)$  respectively, where  $\langle n_s \rangle$  is the average number of quanta newly mobilized with each stimulus, and  $k_d$  is a rate constant of demobilization of docked quanta back to cytoplasm. The relationship between  $(1/m)$  and  $(1/fp)$  was linear both for proximal and central synapses with similar intercepts (see plot). However the slopes of this relation for central synapses are steep, whereas for proximal synapses the slopes were nearly zero. These results indicate that central synapses differ from proximal synapses by higher rates of demobilization of docked quanta. At central synapses quantal demobilization between sequential stimuli decreases as  $f$  increases, therefore more quanta are released. In contrast, quantal demobilization for proximal synapses is always low resulting in more releasable quanta independent of  $f$ . Supported by NIH grant RR10481 to M.K.W.

## 311.20

**A MODEL OF TRANSMITTER RELEASE THAT ACCOUNTS FOR FAST FACILITATION AND AUGMENTATION.**

R. Bertram<sup>1</sup> and A. Sherman<sup>2</sup>. <sup>1</sup>Division of Science, Penn State Erie, Erie, PA 16563 and <sup>2</sup>Mathematical Research Branch, NIDDK, NIH, Bethesda, MD 20892.

We describe a simple mathematical model of transmitter release that can account for F1 and F2 fast facilitation as well as longer-lasting augmentation. This model reconciles two recent experimental findings, one which showed that exogenous buffers reduce fast facilitation (Kamiya and Zucker, Nature, 371:603), and one which showed that they did not (Winslow et al., J. Neurophysiol., 72:1769). We show that these apparently contradictory findings are due to the different experimental protocols, and are both consistent with our model. The model we present is a modification of an earlier one based on the colocalization of Ca<sup>2+</sup> channels and transmitter release sites, each release site having four Ca<sup>2+</sup> binding sites with different affinities and kinetic rates (Stanley et al., Soc. Neurosci. Abstr., 21:24). The modification consists of placing one of the binding sites away from the Ca<sup>2+</sup> channel, so that it senses the bulk cytosolic Ca<sup>2+</sup>, but not the domain Ca<sup>2+</sup> surrounding an open channel. Augmentation is due to the accumulation of Ca<sup>2+</sup> bound to this distant site, while F1 and F2 facilitation are due to the accumulation of Ca<sup>2+</sup> bound to two of the three sites adjacent to the Ca<sup>2+</sup> channel. In addition to these features, the model preserves features of the earlier version including fourth power cooperativity with respect to external Ca<sup>2+</sup>, a release time course that is independent of an increase in quantal content, an inverse relation between external Ca<sup>2+</sup> and the degree of facilitation, and frequency-dependent steps in synaptic enhancement.

## 312.1

MORPHOLOGICAL PLASTICITY OF DENDRITIC SPINES: CHANGES IN SPINE NUMBER AND SHAPE AFTER DEAFFERENTATION OR APPLICATION OF GLUTAMATE RECEPTOR ANTAGONISTS IN HIPPOCAMPAL SLICE CULTURES.

R.A. McKinney, R. Dürr, M. Müller\*, B.H. Gähwiler and S.M. Thompson.  
Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland

Changes in synaptic structure may represent a mechanism underlying lasting changes in synaptic strength. The determinants of the number and shape of dendritic spines on CA1 pyramidal cells in hippocampal slice cultures were investigated with confocal microscopy of cells that had been filled with Lucifer Yellow. In control cultures, the average spine density was  $\sim 1/\mu\text{m}$  and spine length was up to  $1.5\mu\text{m}$ . Transection of Schaffer collateral afferents in mature cultures resulted in a transient increase in spine length (up to  $\sim 2.5\mu\text{m}$ ) at 3 days post-lesion, followed at 7 days by a marked decrease in spine length to  $<0.5\mu\text{m}$  and massive decreases in density. By times  $>14$  days post-lesion, spine density and length had returned to almost control values, due to reinnervation from area CA3 (as seen immunohistochemically and electrophysiologically). Do these morphological changes result from the absence of glutamatergic excitation after axonal degeneration? In contrast to axonal transection, 'chemical deafferentation', by incubation of mature cultures with the AMPA receptor antagonist NBQX for 3 days, produced only modest decreases in spine length and number. Blocking NMDA receptors with MK-801 for 3 days, in contrast, led to striking decreases in spine density and a dramatic increase in the proportion of mushroom-shaped or caliciform spines having long spine necks ( $\sim 2.5\mu\text{m}$ ) and enlarged heads. NBQX or MK-801 applied for 14 days after axonal transection reduced, but did not prevent, the re-establishment of spines upon reinnervation.

Supported by the Swiss National Science Foundation (31-41829.94).

## 312.3

GLYCINE RECEPTOR  $\alpha$  SUBUNIT mRNAs IN DENDRITES OF RAT SPINAL CORD NEURONES. C. Racca\*, A. Gardiol and A. Triller, Lab. Biologie Cellulaire de la Synapse, INSERM CEF 94-10, ENS, Paris, France.

The presence of neurotransmitter receptor mRNAs in dendrites, close to synapses, may be relevant for local modifications of the responsiveness of the postsynaptic membrane. The glycine receptor (GlyR) is the only ligand-gated channel to be present exclusively at the postsynaptic differentiations on both neuronal somata and dendrites (Triller et al., 1985, JCB 101: 683). We have therefore investigated the subcellular distribution of the mRNAs encoding for the various GlyR subunits in adult rat spinal cord neurones.

The transcripts were detected using light and electron microscopic nonisotopic *in situ* hybridization (ISH) with specific complementary oligonucleotide and cRNA probes for  $\alpha 1$ ,  $\alpha 2$ , and  $\beta$  GlyR subunits and gephyrin. With digoxigenin-labeled probes and the alkaline phosphatase reaction we found that  $\alpha 1$  and  $\alpha 2$  subunit transcripts were present in somata and neurites of most neurones. In contrast, those for  $\beta$  and gephyrin were detected in somata only. Fluorescent double-labeling experiments (ISH for all GlyR complex mRNAs and immunodetection for  $\alpha 1$ , gephyrin, or GlyR) showed that  $\alpha 1$  and  $\alpha 2$  transcripts aggregate in particles and tend to predominate at the periphery of the dendrites. Nanogold silver-enhanced labeling confirmed that  $\alpha 1$  and  $\alpha 2$  transcripts were within the dendroplasm and revealed their frequent localization near synaptic sites in association with submembranous cisternae.

GlyR  $\alpha$  subunit transcripts are the first mRNAs for neurotransmitter receptors which are shown to be localized in dendrites *in situ*. The presence in dendrites of organelles involved in protein synthesis (the RER: Peters et al., 1991, 3rd ed.; polyribosomes: Steward & Reeves, 1988, J. Neurosci. 8: 176; components of the Golgi apparatus: Triller, unpublished results), and of mRNA suggests a local synthesis of GlyRs.

In conclusion, mRNA targeting and localized protein synthesis might contribute to a fine regulation at postsynaptic sites of the expression of GlyR subunits. This work was supported by grants from AFM and AC-SV 11, France.

## 312.5

GLUTAMATE-INDUCED ACTIVATION OF PRE- AND POSTSYNAPTIC PKC INVOLVES DISTINCT METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES. G.M.J. Ramakers, P. Pasinelli, W.H. Gispen and P.N.E. De Graan. Rudolf Magnus Institute for Neurosciences, P.O. Box 80040, 3508 TA Utrecht, The Netherlands (SPON: European Neuroscience Association).

Activation of protein kinase C (PKC) is thought to be an important step in long-term potentiation (LTP) of glutamatergic transmission in the hippocampus of the rat. Both pre- and postsynaptic PKC is implicated, because LTP induction in the CA1 field of the hippocampus increased the phosphorylation state of presynaptic protein B-50 (a.k.a. GAP-43, F1) as well as that of postsynaptic protein RC3 (a.k.a. neurogranin, BICKS), effects that could be prevented by the NMDA receptor antagonist AP5. In this study we investigated the effect of glutamate receptor (GluR) activation on pre- and postsynaptic PKC activity, as monitored by B-50 and RC3 phosphorylation. Hippocampal slices ( $450\mu\text{m}$ ) were labelled with  $^{32}\text{P}$  (100  $\mu\text{Ci/ml}$ ) for 90 min at  $30^\circ\text{C}$ , treated with L-Glutamate (Glu), and *in situ* B-50 and RC3 phosphorylation was determined using quantitative immunoprecipitation and phosphorimaging. Glu treatment induced a time- and concentration dependent increase in the phosphorylation state of both RC3 and B-50, which could be blocked by PKC inhibitors. Antagonists for the ionotropic GluRs, CNQX (100  $\mu\text{M}$ ) and AP5 (100  $\mu\text{M}$ ) did not affect the Glu induced increase in RC3 and B-50 phosphorylation. Pretreatment with MCPG (500  $\mu\text{M}$ ), an antagonist for the metabotropic glutamate receptor (mGluR) prevented the increase in RC3 and B-50 phosphorylation. In addition, ACPD (100  $\mu\text{M}$ ), a broad spectrum mGluR agonist mimicked the Glu effect. mGluRs have been classified into three major classes (group I, II and III) based on their second messenger coupling and pharmacological profile. DHPG (500  $\mu\text{M}$ ), a specific group I agonist, only affected RC3 phosphorylation, whereas L-AP4, a group III and presynaptic mGluR agonist (50  $\mu\text{M}$ ) specifically increased B-50 phosphorylation. In addition, the Glu-induced increase in RC3 phosphorylation could be prevented by pretreatment of slices with thapsigargin (10  $\mu\text{M}$ ), showing that  $\text{IP}_3$  sensitive Ca-stores were essential in this process. Our results show that Glu increased the *in situ* phosphorylation of PKC substrates B-50 and RC3 in a concentration- and time-dependent manner. This activation of pre- and postsynaptic PKC involves distinct mGluR subtypes, coupled to different second messenger pathways. (This work was supported by an ENP grant of the ESR)

## 312.2

REGIONAL DIFFERENCES IN THE SUBCELLULAR LOCALIZATION OF GLYCINE RECEPTOR  $\alpha 1$  AND  $\alpha 2$  mRNAs IN RAT CNS. A. Triller\*, A. Gardiol and C. Racca, Laboratoire de Biologie Cellulaire de la Synapse, INSERM CEF 94-10, Ecole Normale Supérieure, Paris, France.

We have shown previously that neurones in the ventral horn of adult rat spinal cord express  $\alpha 1$  and  $\alpha 2$  glycine receptor (GlyR) subunit mRNAs in somata and dendrites, whereas those for  $\beta$  and gephyrin are in the somata only. We have studied here the subcellular distribution of GlyR complex mRNAs with respect to the regional localization of neurones in the adult rat CNS. Nonradioactive *in situ* hybridization with digoxigenin-labeled oligonucleotide and cRNA probes specific for the GlyR subunits and gephyrin was used to detect these mRNAs.

As seen by others (refs in Kirsch et al., 1993, EJM 5: 1109), we observed that  $\beta$  subunit and gephyrin mRNAs had similar regional and subcellular distributions in the whole CNS. Although,  $\alpha 1$  and  $\alpha 2$  subunit mRNAs predominated in the diencephalon, mesencephalon, medulla, and spinal cord, their regional distributions were comparable to that of  $\beta$  and gephyrin transcripts. However, in the neocortex and thalamus,  $\alpha 1$  and  $\alpha 2$  subunit mRNA hybridization signals were restricted to cortical layers II-III, V, and VI, and certain thalamic nuclei, whereas  $\beta$  subunit and gephyrin transcripts were widely present all over these regions. The transcripts for  $\alpha 1$  and  $\alpha 2$  subunits were found in dendrites only in the globus pallidus, amygdaloid complex, substantia innominata, substantia nigra, deep cerebellar nuclei, medulla, and spinal cord.

These data provide further support for a role of GlyR inhibition in higher structures of the brain. The main result of this study was that the dendritic localization of  $\alpha 1$  and  $\alpha 2$  GlyR subunit mRNAs depended on the brain region. This finding suggests that different regulatory mechanisms for the localization of  $\alpha 1$  and  $\alpha 2$  subunit transcripts are used by distinct populations of neurones.

## 312.4

DEVELOPMENTAL EXPRESSION OF THE BIDIRECTIONAL CONTROL OF MAP2 PHOSPHORYLATION AT GLUTAMATE SYNAPSES

E.M. Quinlan and S. Halpain\* Department of Neuroscience and The Center for Cell Signalling, University of Virginia, Charlottesville, VA 22908

Although profound changes in neuronal morphology occur as synapses mature, little is known about how synaptic transmission regulates the developing neuronal cytoskeleton. Previously we showed that the postsynaptic microtubule-associated protein MAP2 is a target of bidirectional, calcium-dependent pathways stimulated by glutamate receptor activation in the hippocampus. To examine the regulation of MAP2 phosphorylation by synaptic transmission over development, slices of adult and neonatal hippocampus were depolarized with 40mM KCl. Depolarization produced a time-dependent bidirectional change in MAP2 phosphorylation in adult (postnatal day 42-44) and P21-23 hippocampus: a large transient increase was observed within 30 sec, followed by a pronounced decrease that persisted for  $\geq 10$  min. In contrast, in P17-18 and P7-8 hippocampus, depolarization induced only a net increase in MAP2 phosphorylation, which remained elevated relative to baseline for  $\geq 10$  min of depolarization. The depolarization-induced increase in MAP2 phosphorylation was mimicked by the glutamate receptor agonist 1S,3R-ACPD; however, the magnitude of the MAP2 phosphorylation observed after 5 min of ACPD was 2-fold higher in P7-8 versus P42-44. The depolarization-induced decrease in MAP2 phosphorylation was mimicked by NMDA; however, the magnitude of the dephosphorylation was significantly less at P7-8 than P42-44. Thus, early in neonatal development, signalling pathways that stimulate a net increase in MAP2 phosphorylation are favored. Because phosphorylation reduces the affinity of MAP2 for F-actin and microtubules, glutamate-induced increases in MAP2 phosphorylation may reduce cytoskeletal stability and promote morphological plasticity early in postnatal development. Supported by NIMH.

## 312.6

AFFERENT STIMULATION CAUSES DEPOSITION OF SOMATICALLY SYNTHESIZED PROTEIN AT DENDRITIC SPINES IN THE GUINEA-PIG HIPPOCAMPUS SLICE. S. Feig and P. Lipton\*. Depts. Anatomy and Physiology and Center For Neuroscience, University of Wisconsin Medical School, Madison, WI, 53706.

Local synthesis of protein is activated in CA1 pyramidal cell dendrites and spines by pairing Schaffer collateral stimulation with carbachol (J. Neuroscience 13: 1010). The possibility that the newly synthesized protein might enhance deposition of protein arriving via dendritic transport (dendritic flow) from the cell somata, was tested. This would allow appropriate stimulation to cause long-term synaptic change.

Rapid dendritic transport was characterized in control slices by L.M. autoradiography. Nocodazole-inhibitable protein accumulation in the dendrites peaked at 30' and reached a plateau after 2 hours.

Effects of paired Schaffer collateral stimulation and carbachol on dendritic transport was tested using E.M. autoradiography to localize transported protein. 90' after stimulation, when local synthesis, but not the newly synthesized protein, had disappeared, slices were pulse-labeled with  $^3\text{H}$ -leucine; flow was allowed to occur for 2 hours.

Accumulation of  $^3\text{H}$ -leucine at dendritic spines of the CA1 pyramidal cells was 2-fold greater ( $p < .01$ ) in slices which had been stimulated than in control (exposed to carbachol but not stimulated) slices. There was no enhancement of accumulation over other portions of the dendrite. Thus the same stimulation that induces local synthesis of protein, causes deposition of somatically synthesized protein at dendritic spines.

Studies are in progress to determine whether the deposition is dependent on increased local protein synthesis or on other aspects of the stimulation. Support: American Heart Association, Wisconsin.

**PEPTIDE SUBSTRATES FOR IN VITRO ASSAY OF ERK (MAP KINASE) ACTIVITY.** John W. Haycock\*. Dept. Biochemistry and Molecular Biology, Louisiana State University Medical Center, New Orleans, LA 70119.

Extracellular signal-regulated protein kinases (ERKs) are a family of proline-directed Ser/Thr kinases. ERK1 (44 kDa) and ERK2 (42 kDa) phosphorylate both microtubule-associated protein 2 and myelin basic protein (MBP) avidly in vitro (high V/Km). Pelech and coworkers developed a synthetic peptide substrate (APRTGPGRR) for the ERKs, modeled after the phosphorylation site in MBP. Although this peptide contains the -P-X-S/T-P- motif thought to represent the consensus substrate recognition sequence for the ERKs, several other ERK substrates do not contain the Pro residue in the -2 position. For example, this is absent from the ERK phosphorylation site (rat: -EAVTS<sup>31</sup>PRF-; human, -EAIMS<sup>31</sup>PRF-) in tyrosine hydroxylase (TH), one of the first physiological substrates of ERK1/ERK2 described. In the present studies, several synthetic peptides modeled after S<sup>31</sup> in TH were evaluated as in vitro substrates for the ERKs. The phosphorylation of a S<sup>31</sup>-containing peptide from type 1 human TH by activated, recombinant ERK2 was found to exhibit a V/Km approximately 50% higher than that for the MBP peptide. In extracts from untreated PC12 cells, the phosphorylation of MBP peptide was higher than that of the Ser31-TH peptide. However, the relative increase in extracts of NGF-treated PC12 cells was much greater for the Ser31 peptide, suggesting that the latter peptide may be a more specific substrate for the ERKs. ## 312.9

**CALCIUM OSCILLATION FREQUENCY DEPENDENCE OF MULTIFUNCTIONAL CaM KINASE II ACTIVATION.** P. De Koninck\* and H. Schulman. Dept. of Neurobiology, Stanford Univ. School of Medicine, Stanford, CA 94305-5401.

Most external stimuli produce intracellular Ca<sup>2+</sup> oscillations of various durations and frequencies; these oscillations may encode specific signals within cell compartments, such as the nucleus or dendrites. Specialized molecules in these compartments could serve as decoders and translators of Ca<sup>2+</sup> signals. The cellular localization and biochemical properties of multifunctional CaM kinase II (CaMKII) make this enzyme a good candidate for such role. To determine the dependence of CaMKII activation on the duration and frequency of Ca<sup>2+</sup> oscillations (or spikes), we developed a rapid perfusion technique: Recombinant  $\alpha$ -CaMKII is immobilized via antibody onto plastic tubing connected to pressurized chambers and manifold valves. This setup is used to exchange the solution to which the enzyme is exposed (high/low Ca<sup>2+</sup>, EGTA, calmodulin or ATP) within  $\leq 20$  ms. Preliminary results indicate that application of 20-30 Ca<sup>2+</sup>/CaM spikes ( $\leq 200$  ms each) at frequencies  $\geq 3$  Hz induces high levels of CaMKII autonomy (Ca<sup>2+</sup>/CaM-independent activity). In contrast, the same number of spikes given at frequencies  $\leq 1$  Hz produce little CaMKII autonomy. These results support the notion that CaMKII serves as a Ca<sup>2+</sup> spike frequency decoder, a role that may underlie the involvement of CaMKII in synaptic plasticity.

## 312.11

**IDENTIFICATION OF FYN SUBSTRATES IN THE POSTSYNAPTIC DENSITY FRACTION PREPARED FROM THE RAT FOREBRAIN.** T. Suzuki<sup>1</sup>, K. Okumura-Noi<sup>2</sup>. <sup>1</sup>Department of Neuroplasticity, Research Center for Aging and Adaptation, Shinshu University School of Medicine, 3-1-1 Asahi, Matsumoto 390, Japan. <sup>2</sup>Department of Biochemistry, Nagoya City University Medical School, Mizuho-ku, Nagoya 467, Japan

The efficacy of neuronal signal transmission can be augmented or diminished according to the synaptic input into neurons, and the experimental models for these synaptic plasticities are long-term potentiation (LTP) and long-term depression (LTD), respectively. Various kinases control synaptic strength. Besides CaMKII and protein kinase C, some tyrosine kinases can modulate synaptic strength. The involvement of protein tyrosine kinase(s) has been suggested by experiments using specific inhibitors for tyrosine kinases. Furthermore, *fyn*-deficient mice have an impairment in LTP and in spatial learning. In this report, we investigated the synapse-specific substrates for Fyn. Fyn, protein tyrosine kinase, and its substrates were highly concentrated in the postsynaptic density (PSD) fraction prepared from the rat forebrain (Wistar, male). There were a number of Fyn substrates unique to the PSD fraction. One of the major substrates in the PSD fraction was found to be a concanavalin A-binding glycoprotein, PSD-gp180, which is the N-methyl-D-aspartate (NMDA) receptor subunit  $\epsilon 2$  (NR2B). Western blotting and immunoprecipitation supported the phosphorylation of  $\epsilon 2$  by Fyn. NMDA receptor subunit  $\epsilon 1$  (NR2A) was also a substrate for Fyn. These results suggest that Fyn is involved in the modulation of synaptic efficacy through the phosphorylation of synapse-specific substrates such as the NMDA receptor/channel. Supported by a Grant-in-Aid for Scientific Research from the Japanese Ministry of Education, Science and Culture.

**CO-LOCALIZATION OF PROTEINS FROM THE POSTSYNAPTIC DENSITY FRACTION AT GLUTAMATERGIC SYNAPSES IN HIPPOCAMPAL NEURONS IN CULTURE.** M.L. Apperson<sup>1</sup>, L. Jia<sup>1</sup>, J.C. Lee<sup>1</sup>, M.J. Kiehl<sup>1</sup>, T. Schenker<sup>1</sup>, and M.B. Kennedy<sup>2</sup>. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

We have recently identified several abundant proteins associated with the postsynaptic density fraction prepared from homogenates of rat forebrain. One of these proteins is the 2B subunit of the NMDA-type glutamate receptor (NR2B) <sup>1</sup>. A second is PSD-95, a homologue of discs-large which is a component of *D. melanogaster* septate junctions and ZO-1 which is a component of mammalian tight junctions <sup>2</sup>. PSD-95 binds tightly to the terminal seven amino acids of the type 2 subunits of NMDA receptors, including NR2B, via the second of three PDZ motifs located in its amino terminal half. <sup>3</sup> A third PSD component is densin-180, a brain specific transmembrane protein that appears to belong to the family of O-sialoglycoprotein adhesion molecules <sup>4</sup>. To determine whether these proteins are all present in most excitatory synapses, or are present in distinct subsets of synapses, we have carried out pairwise double-label immunohistochemical labeling of dissociated, 3-4 week cultured hippocampal neurons with antibodies specific for each of these proteins and for the  $\alpha$  subunit of CaM kinase II, which is also associated with the PSD fraction. We find that all four molecules are present in the vast majority of excitatory synapses in the cultures. Thus, we conclude that several of the most abundant proteins purified from the PSD fraction are present together in vivo, perhaps in an organized complex, in glutamatergic synapses in the forebrain.

## 312.10

**CHANGES IN PSD-ASSOCIATED CAMKII ACTIVITY IN ANIMALS CHARACTERIZED BY ALTERED SYNAPTIC PLASTICITY.** A. Caputi, F. Gardoni, L. Pastorino, M. Cimino, F. Cattabeni\* and M. Di Luca. Inst. of Pharmacol. Sci., Univ. of Milano, V. Balzaretto 9, Milano 20133 Italy

To investigate the function of the autophosphorylated form of CaM Kinase II in synaptic plasticity we generated a rat characterized by lack of LTP in the CA1 region of the hippocampus (Ramakers et al, Neurosci., 1993). This animal model has been achieved by administering an antiproliferative agent selective for neuroepithelial cells (Methylazoxymethanol, MAM-rats; Cattabeni and Di Luca, Physiol. Rev., in press) during development, inducing a targeted neuronal ablation in hippocampus. At presynaptic level, these animals show molecular alterations, i. e. increased translocation of PKC, leading to facilitation of glutamate release in hippocampal synapses (Di Luca et al., Eur. J. Neurosci., 1995). We now show that at postsynaptic site the Ca<sup>2+</sup> dependent component of Post Synaptic Densities (PSD)-associated CaMKII autophosphorylation is decreased in MAM-rats to 35% of control levels, although concentration of the enzyme is not altered. In addition the Ca<sup>2+</sup>/Calmodulin dependent phosphorylation of NR2A/B NMDA receptor subunits is decreased to a similar extent in MAM rats when compared to controls, as revealed in back-phosphorylation experiments. The alteration in CaMKII activity appears to be confined to PSD-associated CaMKII, since cytosolic enzyme activity is unchanged in MAM-rats. These data design a framework in which "in vivo" an enhanced presynaptic release of glutamate coexists with down-regulation of PSD associated CaM-Kinase activity. Endogenous autophosphorylation of the kinase might thus regulate the synaptic events that couple presynaptic activity and production of postsynaptic responses, such as LTP.

**ALTERNATION OF GTP BINDING PROTEINS IN THE POSTMORTEM BRAINS OF HEROIN ADDICTS.** S. Shichinohe<sup>1</sup>, E. Hashimoto<sup>1</sup>, H. Ozawa<sup>1</sup>, S. Toki<sup>1</sup>, M. Yamamoto<sup>1</sup>, T. Saito<sup>1</sup>, L. Frölich<sup>2</sup>, P. Riederer<sup>3</sup> and N. Takahata<sup>1</sup>

<sup>1</sup>Dept. of Neuropsychiatry, School of Medicine, Sapporo Medical University Sapporo, Japan. <sup>2</sup>Dept. of Psychiatry, University of Frankfurt am Main, Frankfurt, Germany. <sup>3</sup>Dept. of Psychiatry, University of Würzburg, Würzburg, Germany.

Opioid receptors couple to GTP binding (G) proteins which play an obligatory role in the transduction of extracellular, receptor-detected signals across cell membranes to intracellular effectors. It is found that G proteins are modulated by various psychotropic drugs such as antidepressants and opiates. However, there are few direct information on the status of G proteins in the human brain during chronic opiate addiction. In the present study we examined the alternations of G proteins in membrane preparations in postmortem human brains obtained from heroin addicts and control subjects without a history of drug abuse. The quantity of G proteins (G $\alpha$ s, G $\alpha$ i-1,2, G $\alpha$ i-3, G $\alpha$ o, G $\alpha$ q, G $\beta$ ) were investigated by immunoblotting with polyclonal antibodies (RM/1, AS/7, EC/2, GC/2, QL, SW/1, respectively). The immunoreactivities of G $\beta$  subunit in temporal cortex were significantly increased in heroin addicts compared with controls. Recently it has been demonstrated that  $\beta$  subunit of G proteins play an important role in the regulation of post-receptor signal transduction as well as  $\alpha$  subunit.

The present findings suggest that alterations in the density of G proteins may be involved in pathophysiology of opiate tolerance and dependence.

## 312.13

MECHANISMS INVOLVED IN THE ANTIDOPAMINERGIC ACTION OF CLONAZEPAM AND MELATONIN IN RAT STRIATUM. L.P. Niles\* and C.C. Tenn. Biomedical Sciences, McMaster Univ., Hamilton, ON, Canada L8N 3Z5.

The GABA<sub>A</sub> receptor antagonist, bicuculline (2.5 mg/kg, i.p.), causes a significant inhibition (~ 65%) of the antidopaminergic effect of clonazepam or melatonin in 6-hydroxydopamine-lesioned rats, indicating that this effect is mediated primarily by a GABAergic mechanism (1). To examine the extent of GABAergic involvement, direct intrastriatal injection of bicuculline was utilized in order to circumvent the convulsant effect of high doses of this antagonist. In addition, the intrastriatal effect of the peripheral-type BZ antagonist, PK11195, was examined since this agent caused a modest but significant attenuation of the above effect, when administered peripherally (1).

The intrastriatal injection of bicuculline (1-10 nmoles), was more effective than peripheral treatment, but did not completely block the antidopaminergic effect of clonazepam or melatonin. However, the intrastriatal infusion of bicuculline (5 nmoles) together with PK11195 (20 nmoles) completely abolished this effect. These findings confirm the predominant role of a GABAergic mechanism in the antidopaminergic action of clonazepam and melatonin. Moreover, since PK11195 can block the inhibitory effect of BZs and melatonin on cyclic AMP production in the striatum (2), it appears that suppression of this pathway is also involved in the antidopaminergic action of these drugs. 1. Tenn, C.C. and Niles, L.P.: J. Pharmacol. Exp. Ther. 274, 84-89 (1995). 2. Tenn, C.C. Neu, J.M. and Niles, L.P.: Soc. Neurosci. Abstr. Vol 21, Part 3, p. 2069 (1995). (Supported by NSERC, Canada).

## 312.14

SENSITIZATION OF DIAZEPAM INHIBITORY EFFECT ON ADENYLATE CYCLASE ACTIVITY IN 6-HYDROXYDOPAMINE LESIONED ANIMALS. C.C. Tenn, L.P. Niles and L.J. Smith. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Recent studies indicate that benzodiazepines, such as diazepam and Ro5-4864, inhibit adenylyl cyclase activity (AC) via a pertussis toxin-sensitive G protein-coupled benzodiazepine (BZ) receptor. Since the inhibition of cAMP production is involved in the antidopaminergic effect of BZs in lesioned animals, the effects of diazepam on AC activity was investigated in these animals. Unilateral lesioning of the nigrostriatal pathway with 6-hydroxydopamine was carried out in male Sprague Dawley rats (200-250g). Functional studies revealed a biphasic inhibition of forskolin-stimulated AC activity by diazepam for both the denervated and intact striatum. While there was no difference in the enzyme activity between striata from sham-operated animals, there was a significant difference in AC activity between the intact and denervated striata of lesioned rats. For the receptor-mediated (first) phase of diazepam-induced inhibition, the EC<sub>50</sub>'s were 10.2 nM and 4.2 nM, for intact and lesioned striata respectively. The second phase of inhibition, which involves a direct action on AC, showed no significant differences. The EC<sub>50</sub>'s were 70.3 μM and 68.2 μM for intact and lesioned striata, respectively. These results indicate a sensitization of the receptor-mediated inhibitory effect of diazepam on AC activity in lesioned animals.

In addition, we have observed a significant increase in [<sup>3</sup>H] diazepam binding in denervated striatal tissue as compared to the controls, with no change in the dissociation constant. The possibility that enhanced receptor G-protein coupling is involved in this sensitization, is currently being investigated (Supported by a NSERC (Canada) Strategic grant).

## POSTSYNAPTIC MECHANISMS Ach, ATP AND PEPTIDE SIGNAL

## 313.1

POSTSYNAPTIC ACTIONS OF CHOLINERGIC RECEPTOR ACTIVATION ON MULTIPLE TYPES OF INTERNEURONS IN CA1 REGION OF THE RAT HIPPOCAMPUS. A.R. McQuiston and D.V. Madison. Department of Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA 94306.

Previous studies have shown cholinergic receptor activation have several diverse modulatory actions on the electrophysiological properties of the mammalian hippocampus. Investigations have demonstrated that the mixed muscarinic and nicotinic agonist carbachol has excitatory actions on interneurons in area CA1 of the mammalian hippocampus. Indirect studies have shown an increase in the spontaneous inhibitory postsynaptic currents in pyramidal cells whereas direct studies have demonstrated that carbachol can depolarize some interneurons in stratum oriens (SO) of area CA1. We have further investigated the postsynaptic actions of cholinergic receptor activation in 109 interneurons of strata oriens, radiatum and lacunosum moleculare in area CA1 of the rat hippocampus. Consistent with previous findings, 38 of these cells depolarized (13.7 ± 0.9 mV) in response to the activation of muscarinic receptors with no significant effect on the input resistance of the cell (percent change 0.24 ± 3.32 %). A further four cells depolarized (14.0 ± 2.9 mV) as a result of the activation of nicotinic receptors which was accompanied by a decrease in input resistance (-23.7 ± 9.3 %). These depolarizations were often enough to bring a quiescent cell to the threshold for action potential firing. In contrast to previous studies, a subpopulation of interneurons hyperpolarize in response to muscarinic receptor agonists. Seventeen cells from the 3 regions investigated hyperpolarized (-12.8 ± 1.0 mV) with a concomitant decrease in input resistance (-33.9 ± 7.4 %). Furthermore, the outward current generated by carbachol or muscarine on these hyperpolarizing cells reverses at the expected reversal potential for the activation of a selective potassium conductance. Perhaps more interesting, some interneurons produced an afterdepolarization (ADP) in response to muscarinic agonist application following the injection of a depolarizing current pulse. This ADP was often sufficient to evoke bursts of action potentials following the depolarizing pulse. The ADP was insensitive to tetrodotoxin and inhibition of calcium influx. Supported by NIH grant NS1451.

## 313.3

CARBACHOL-INDUCED OSCILLATIONS IN AREA CA1 OF THE HIPPOCAMPAL SLICE. J.H. Williams\* and J.A. Kauer. Dept. of Neurobiology, Duke University Medical Center, Durham NC27710.

Brief applications of carbachol (CCH), a cholinergic receptor agonist, have been reported to generate oscillatory behavior in all regions of the hippocampus *in vitro* (Bland et al, 1988). CCH-induced oscillations may provide a convenient *in vitro* model for studying the synaptic processes that contribute to the behaviorally important type 2 theta observed *in vivo*.

We have examined the pharmacology of CCH-induced oscillations in CA1. Slices were maintained at 33° C in a submersion bath perfused with ACSF containing 2.5mM KCl. Extracellular EPSP's were recorded in s.radiatum; in some experiments an intracellular microelectrode was also used to record from s.pyramidale. CCH (50μM, 7-10 mins) induced oscillations in both the field (34-41 slices) and intracellular records (5-5 slices). The oscillations were sustained for the duration of the CCH application and were comprised of discrete bursts that were remarkably regular in terms of burst length (1.5±0.1secs n=20) and inter-burst interval (14±0.8 secs n=16) both within and across slices. The peak frequency of the oscillations was 7.2± 0.4Hz, well within the range of frequencies reported for theta *in vivo*.

The CCH-induced oscillations were blocked by atropine (5 μM, n=2) or DNQX (10 μM, n=2) but were largely unaffected by DL-AP5 (100 μM, n=4). Simultaneous recording in CA3 and CA1 suggested that the CCH-induced oscillation was initiated in CA3. Intriguingly while removal of CA3 (n=6) markedly attenuated the CCH-induced oscillations recorded in CA1 it failed to abolish it completely. Surprisingly bicuculline (10 μM, n=4) reversibly desynchronized the CCH-induced oscillations. These data are consistent with interneurons playing a role in determining the temporal properties of the CCH-induced oscillations. Bland et al, 1988. Brain Res. 447: 364-368. Supported by: NINDS NS30500.

## 313.2

CARBACHOL-INDUCED OSCILLATIONS IN INTERNEURONS IN AREA CA1 OF THE RAT HIPPOCAMPAL SLICE. L.L. McMahon\*, J.H. Williams, and J.A. Kauer. Department of Neurobiology, Duke Univ. Med. Cntr., Durham, NC 27710.

The septal cholinergic system plays an important role in the generation of hippocampal theta activity. *In vitro*, bath application of the muscarinic agonist, carbachol, produces oscillatory behavior in extracellular and intracellular recordings of CA1 pyramidal cells (Bland et al., 1988). We are testing the idea that interneurons in the CA1 region of the hippocampal slice undergo carbachol-induced oscillatory behavior as well. Whole-cell current clamp recordings were obtained from visually identified s. oriens and s. radiatum interneurons in 400 μm thick slices from 24-28 day old rats. Slices were submerged in a recording chamber and perfused with ACSF containing 5 mM KCl at 32°C. Upon carbachol application (50 μM), s. oriens interneurons were depolarized 5-15 mV from RMP (-60±3 mV; n=3). After 1-2 min in the continued presence of carbachol, rhythmic oscillations, 10-20s in duration, occurred at 5-10s intervals and continued for the duration of drug application. The oscillations consisted of a 6-8 mV depolarization to threshold, with a spike frequency of 10-12 Hz at the peak. Stratum radiatum interneurons were also depolarized by carbachol (3-40mV, n=5), however, consistent oscillatory behavior was not observed. In some cases (n=2), the carbachol-induced depolarization elicited tonic firing (3-6 Hz) which was interrupted by random 5-20s quiet periods. These data suggest that oscillatory behavior in interneurons may contribute to the rhythmic behavior observed in pyramidal cells. NIH NINDS NS30500 to J.A.K. and NIH NRSA NS09734 to L.L.M.

CHOLINERGIC-DEPENDENT PLATEAU POTENTIALS SYNAPTICALLY EVOKED IN HIPPOCAMPAL PYRAMIDAL NEURONS. D. Doll, D.D. Fraser and B.A. MacVicar\*, Neuroscience Research Group, University of Calgary, Calgary, AB, Canada T2N 4N1

The intrinsic activation of cholinergic-dependent plateau potentials (PP) involves the interplay between calcium entry and the Ca<sup>2+</sup>-activated non-selective cation conductance (Fraser and MacVicar, *J. Neurosci.* In press). We have examined the response of pyramidal neurons to synaptic activation following muscarinic stimulation to determine if similar PPs could be synaptically evoked. Whole cell current clamp recordings were obtained from CA1 pyramidal neurons in 450 μm slices and synaptic responses were elicited from Schaeffer collateral stimulation. In oxotremorine (OXO; 15 μM; muscarinic agonist) PPs could be evoked intrinsically with intracellular current injection but not by synaptic stimulation even at 100 Hz for 800 ms. However when GABAergic receptors were inhibited with bicuculline (GABA<sub>A</sub> antagonist; 30 μM) and CGP35348 (GABA<sub>B</sub> antagonist; 50 μM) synaptically evoked PPs were recorded in OXO that were identical in duration, amplitude and waveform to intrinsically evoked PPs. These results indicate that synaptic inputs can trigger the generation of PPs within pyramidal neurons following muscarinic receptor activation when GABA receptors are also inhibited. Supported by MRC Canada.

## 313.5

**PURINERGIC RECEPTORS INVOLVED IN VOLUME RECOVERY IN SPREADING DEPRESSION.** B. Hampel\*, S. Duffy and B.A. MacVicar, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1

The role of ATP-activated purinergic receptors in the various phases of spreading depression was investigated using receptor antagonists and imaging of intrinsic optical signals. Spreading depression was induced in rat hippocampal slices (400  $\mu$ m) by superfusion of ouabain (100  $\mu$ M) and was monitored by imaging changes in light transmittance at 700 $\pm$ 10 nm. As we have previously shown spreading depression is associated with a propagating wave-like increase in light transmittance that is followed in dendritic regions by a rapid decrease below resting levels. The decrease in light transmittance following spreading depression was attenuated reversibly by the purinergic antagonist suramin (100  $\mu$ M to 1 mM). These results suggest that activation of purinergic receptors plays an important role in regulatory volume decrease following spreading depression. Furthermore the propagation of spreading depression and the inhibition of the dendritic transmittance decrease by suramin was still observed in 0 external  $\text{Ca}^{2+}$  indicating that these effects are independent of  $\text{Ca}^{2+}$  influx.

## 313.7

**EXPRESSION OF CHOLINERGIC-DEPENDENT PLATEAU POTENTIALS REQUIRES PHOSPHATASE-INDUCED DEPHOSPHORYLATION.** D.D. Fraser\* and B.A. MacVicar, Neuroscience Research Group, University of Calgary, Alberta, Canada. T2N 4N1.

We have previously identified a novel cholinergic-dependent plateau potential (PP) in CA1 pyramidal neurons that relies on the interplay between HVA  $\text{Ca}^{2+}$  channels and the  $\text{Ca}^{2+}$ -activated non-selective cation conductance (Fraser and MacVicar, *J. Neurosci.* in press). In the presence of carbachol, the PP was elicited by action potential firing and is reminiscent of ictal depolarizations. The PP was depressed by the non-selective muscarinic antagonist atropine (1  $\mu$ M; n=7) or individual  $\text{M}_1/\text{M}_2$  receptor antagonists (4-DAMP > pirenzepine > > p-F-HHSID; n=3 at 1  $\mu$ M for each), and completely inhibited by intracellular perfusion with 2 mM GDP- $\beta$ -S (n=3). Surprisingly, the PP was still evoked in the presence of a PLC inhibitor [either 3  $\mu$ M U-73122 (n=6) or 10  $\mu$ M manoolide (n=3)] or following disruption of  $[\text{Ca}^{2+}]_i$  stores [either 1  $\mu$ M thapsigargin (n=4) or 400  $\mu$ M IP<sub>3</sub> (n=4)]. PPs were also observed following intracellular perfusion with a non-selective protein kinase inhibitor (300  $\mu$ M H-7; n=4) or a phosphorylation-inhibiting cocktail (0  $\text{Mg}^{2+}$ , 5 mM ADP- $\beta$ -S, 50  $\mu$ M dinitrophenol, 0.1 mg/ml alkaline phosphatase; n=4). In contrast, the PP could not be generated following incubation of the slices in 1-2  $\mu$ M calyculin-A, an inhibitor of protein phosphatases (PP-1, PP-2A; n=3), or following a 20 min intracellular perfusion with 5 mM ATP- $\gamma$ -S (n=6). These data indicate that  $\text{M}_1/\text{M}_2$  receptors are coupled to protein phosphatases, either directly or indirectly, via G-proteins. Furthermore, the expression of cholinergic-dependent PPs requires phosphatase-induced dephosphorylation.

## 313.9

**CHARACTERISTICS OF SYNAPTIC TRANSMISSION IN RAT OTIC GANGLION CELLS.** R.J. Callister\* & P. Sah, The Neuroscience Group, Faculty of Medicine & Health Sciences, University of Newcastle, NSW 2308, AUSTRALIA

Neurons in the otic ganglion (OG) innervate several important structures in the head, including the parotid salivary gland and cerebral blood vessels. In this report we describe the physiological properties of OG neurons and their synaptic connections. Ganglia were removed from halothane-anesthetized adult rats and pinned out in a perfusion chamber. Recordings were made at room temperature (20-23°C) with KCl-filled microelectrodes (50-140 M $\Omega$ ) using standard intracellular techniques. Neurons (n=32) had resting potentials of  $-56 \pm 6.6$  mV (mean  $\pm$  SD), input resistances of  $119 \pm 60$  M $\Omega$ , and membrane time constants of  $12.8 \pm 5.7$  ms. Action potentials had amplitudes of  $83 \pm 8.3$  mV and were followed by an afterhyperpolarization lasting  $331 \pm 97$  ms (time to 90% decay). Most neurons (70%, n=52) were innervated by a single preganglionic axon. Stimulation of preganglionic afferents generated a suprathreshold synaptic input which was markedly reduced by the nicotinic antagonists mecamylamine (20-100  $\mu$ M) and d-tubocurarine (100  $\mu$ M). In the presence of eserine (10-20  $\mu$ M), low frequency synaptic stimulation (1-2 Hz) resulted in a sustained depolarization ( $9.5 \pm 4.5$  mV, n=10) which persisted throughout the period of stimulation (up to 180 s). This depolarization was accompanied by an increase (58  $\pm$  16%) in conductance, was insensitive to atropine (1  $\mu$ M) and was blocked by d-tubocurarine (100  $\mu$ M). Upon cessation of stimulation, membrane potential slowly ( $16.6 \pm 6.7$  s recovery time constant) recovered to a level below ( $4.5 \pm 2.9$  mV) that of control. This hyperpolarization was accompanied by a decrease (21  $\pm$  11 %) in conductance. Together, these results show that fast synaptic transmission is mediated by nicotinic acetylcholine receptors in OG neurons. Furthermore, our data suggests that when acetylcholinesterase is blocked, diffusion of acetylcholine away from the synaptic cleft may proceed slowly. ## 313.6

**REGULATION OF VOLUME RESPONSES DURING SPREADING DEPRESSION IN HIPPOCAMPAL SLICES.** T.A. Basarsky\*, B.A. MacVicar, Neuroscience Research Group, University of Calgary, Calgary, AB, Canada, T2N 4N1.

Previously our lab has examined the dynamics of intrinsic optical signals in hippocampal slices during ouabain induced spreading depression. Intrinsic optical signals (light transmittance) at 700  $\pm$  10 nm were imaged from 15-25 day old (400  $\mu$ m) hippocampal slices. At these wavelengths changes in the intrinsic signals are largely dominated by changes in cell volume. During spreading depression there is a transient increase in light transmittance that undergoes a wave-like propagation across the entire hippocampal slice, which is followed by a rapid decrease in dendritic regions to below control levels, indicating extensive cellular volume changes during spreading depression. Since volume-sensitive organic osmolyte-anion channels are present in a number of cells we have examined the involvement of these channels in spreading depression. The anion channel inhibitors NPPB (5-nitro-2-(3-phenylpropylamino) benzoic acid) (100  $\mu$ M) or niflumic acid (100  $\mu$ M) did not significantly affect the onset of spreading depression, whereas the subsequent decrease in light transmittance was attenuated. This raises the possibility that these channels mediate flux of ions or other compounds, such as amino acids, that play an active role in spreading depression.

Supported by the MRC of Canada (BAM) and an AHFMR Post-doctoral Fellowship (TAB).

**INHIBITORY SYNAPTIC CURRENTS AND AGONIST-INDUCED RESPONSES IN GANGLION CELLS FROM RAT RETINAL SLICES.**

D.A. Protti<sup>1</sup>, H.M. Gerschenfeld<sup>2</sup> and J. Llano<sup>1</sup>, <sup>1</sup>Arbeitsgruppe Zelluläre Neurobiologie, Max-Planck-Institut für Biophysikalische Chemie, Göttingen, 37077, FRG and <sup>2</sup>Ecole Normale Supérieure, Paris, France.

Ganglion cells in 200  $\mu$ m thick retinal slices from rats aged 4 to 7 weeks were studied using tight-seal whole cell recordings (wcr). Ganglion cells, selected by their position in the ganglion cell layer, were characterized by the presence of extracellularly recorded action potentials in the cell-attached configuration and of TTX-sensitive, voltage dependent sodium currents in wcr. In all cells studied, the prevalent spontaneous postsynaptic currents were inhibitory (IPSCs). Two different types of IPSCs were found. The first was sensitive to bicuculline (2-10  $\mu$ M) and SR95531 (1-3  $\mu$ M) while the second was sensitive to strychnine (0.3-2  $\mu$ M) and insensitive to GABA<sub>A</sub> receptor antagonists. They were respectively identified as GABAergic and glycinergic. GABAergic IPSCs occurred in a higher proportion of cells and their frequency was usually diminished in the presence of TTX. Glycinergic IPSCs often had a slow decay phase with discrete single channel closings and reopenings having a prevalent conductance level of 45-50 pS. Bath applications and puffs of GABA and glycine elicited responses in all ganglion cells tested. In symmetrical  $\text{Cl}^-$  solutions, GABA-activated currents had outwardly rectifying I-V relations, while currents elicited by glycine had linear I-V relations. In cells dialyzed with low internal  $\text{Cl}^-$ , IPSCs and agonist-induced currents reversed at membrane potentials close to  $\text{E}_{\text{Cl}^-}$ , indicating that the underlying channels were  $\text{Cl}^-$  selective. These data provide a first characterization of IPSCs in ganglion cells from mammalian retinal slices. D.P. holds an A. von Humboldt fellowship.

**THE MUSCARINIC POSTSYNAPTIC EFFECT OF DEXMEDETOMIDINE (DMT) ON SYMPATHETIC GANGLIONIC TRANSMISSION.** J.B. McCallum, Q. Hogan, and Z. J. Bosnjak\*, Department of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226.

The present study provides direct evidence for a muscarinic rather than nicotinic site of action for the  $\alpha_2$  agonist DMT. Twelve stellate ganglia were removed from adult mongrel dogs after halothane anesthesia, desheathed and superfused with Krebs' solution equilibrated with a mixture of 97%  $\text{O}_2$  and 3%  $\text{CO}_2$  and maintained in a tissue chamber at pH of  $7.4 \pm 0.05$  and  $37 \pm 0.5^\circ\text{C}$ . Fast and slow excitatory postsynaptic potentials (EPSP) were generated by subthreshold stimulations of the preganglionic T3-ramus at a frequency of 0.4 Hz to reduce the number of postsynaptic receptors occupied by acetylcholine. Nicotinic stimulation was elicited with 1,1-dimethyl-4-phenylpiperazinium (DMPP, 10  $\mu$ M) in the presence of atropine sulfate (20  $\mu$ M), and muscarinic stimulation was evoked by (+)-cis-dioxolane (CD, 10  $\mu$ M) in the presence of hexamethonium (20  $\mu$ M). Nicotinic and muscarinic stimulations were given before and after application of 70  $\mu$ M DMT. DMT abolished the increase in fast (550%) and slow (275%) EPSP after muscarinic stimulation, while DMT did not reduce the increase (42%) in fast EPSP after DMPP application. These results indicate that the inhibitory action of DMT resides in the late portion of the action potential, possibly via cellular hyperpolarization due to potassium channel activation.

## 313.11

ELECTRICAL PROPERTIES AND SYNAPTIC CURRENTS OF RAT CHROMAFFIN CELLS IN SITU. R. Kaijawa<sup>1</sup>, Q. Sand<sup>2</sup>, Y. Kikokoro<sup>3</sup>, M. Barish<sup>4</sup> and T. Iijima<sup>1</sup> Electrotechnical Lab., Japan, 2 Univ. Oslo, Norway, 3 Univ. Gunma, Japan, 4 Beckman Res. Inst., USA

Adrenal chromaffin cells originate from the neural crest and are innervated by terminals from the splanchnic nerve. The cells have neuron-like electrical properties and have been extensively used as a model system for studies of voltage-gated ion channels and non-muscle-type nicotinic acetylcholine receptors. Most of these studies have been performed on cultured cells, and only data obtained using traditional microelectrodes have previously been reported from chromaffin cells in situ. We have performed whole-cell "tight seal" voltage clamp recordings from chromaffin cells in 300  $\mu$ m slices of rat adrenal medulla. The general electrophysiological properties of the cells in situ were in agreement with previous reports on cultured cells. In particular, the input resistance was usually larger than 1 Gohm, a result not consistent with previous suggestions of electrical coupling between chromaffin cells in situ. The peak inward current evoked by depolarizing voltage steps reached a maximum value of 4-6 nA at about 0 mV, and displayed an IV-relation and inactivation properties characteristic of voltage-gated  $\text{Na}^+$ -current. The outward current showed the bell-shaped IV-curve characteristic of  $\text{Ca}^{2+}$ -activated  $\text{K}^+$ -current. Although preparation of the slices is likely to disconnect superficial chromaffin cells from their nerve input, about 10% of the cells studied displayed excitatory postsynaptic currents (EPSC) of 200 pA-1 nA upon direct electrical stimulation of sympathetic nerve branches in the slice. An EPSC of this magnitude will provide a cell exhibiting Gohm input resistance with a large safety factor for spike initiation. The EPSCs recorded from a particular cell frequently showed several discrete amplitudes, suggesting the presence of multiple active synaptic sites. The EPSC was completely and reversibly blocked by 100  $\mu$ M hexamethonium, an indication that only nicotinic ACh receptors contributed to the observed EPSCs. This is the first reported description of the EPSCs of chromaffin cells.

## 313.13

ATP-RECEPTOR MEDIATED SYNAPTIC TRANSMISSION IN THE DORSAL HORN OF THE RAT SPINAL CORD. P. A. Goldstein\*, C. J. Lee, R. Bardon, J. G. Gu & A. B. MacDermott. Depts. of Physiology and Cellular Biophysics and Anesthesiology and the Center for Neurobiology & Behavior, Columbia Univ New York, NY 10032.

ATP-receptor mediated synaptic transmission has been demonstrated in only one area of the CNS, the habenula (Edwards *et al.* 1992). While ATP excites a subpopulation of rat dorsal horn (DH) neurons (Jahr & Jessell 1983), direct evidence of ATP-receptor mediated synaptic transmission in the spinal cord has been elusive. Using Fura-2  $\text{Ca}^{2+}$ -imaging we have demonstrated that exogenously applied ATP elevates intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) by  $\text{P}_{2\text{U}}$  receptor activation and direct electrophysiological measurements of evoked EPSCs have demonstrated that these receptors are synaptically activated.  $\text{Ca}^{2+}$  measurements were made on acutely dissociated DH neurons prepared from young (P7-10) animals. ATP, but not  $\alpha, \beta$ -Me-ATP, evoked large increases in  $[\text{Ca}^{2+}]_i$ , and this increase could be completely or partially blocked by the  $\text{P}_{2\text{U}}$  receptor antagonist, suramin ( $n=4$ ). This pharmacological profile suggests that these neurons express the  $\text{P}_{2\text{U}}$ ,  $\text{P}_{2\text{X}_1}$ ,  $\text{P}_{2\text{X}_2}$ , and/or  $\text{P}_{2\text{X}_3}$  subunits, although the distribution of cRNA coding for those subunit excludes  $\text{P}_{2\text{X}_3}$  (Collo *et al.* 1996). Synaptic recordings were made on lamina II DH neurons in acutely prepared transverse sections of cervical spinal cord. In the presence of CNQX, APV, bicuculline, and strychnine, a small (-10 to -30 pA at -70 mV) EPSC was detected in some cells. This synaptic current was completely blocked by suramin in 3 cells, partially blocked ( $63.9 \pm 8.9\%$ ) in 12 cells, and minimally blocked in 3 cells ( $12.8 \pm 4.2\%$ ). These data indicate that  $\text{P}_{2\text{U}}$  receptors contribute to synaptic transmission in the spinal cord dorsal horn. Supported by Whitehall Foundation, NIH and a HFSP Fellowship to R.B.

EXPERIMENTAL AND MODELING ANALYSIS OF MINIATURE ENDPLATE CURRENT VARIABILITY: EFFECTS OF TEMPERATURE AND CHOLINESTERASE INHIBITION. J.R. Stiles\*, I.V. Kovyazina, E.E. Salpeter and M.M. Salpeter. Section of Neurobiology & Behavior, Cornell University, Ithaca, NY 14853-2702.

We investigated synaptic current variability at endplates, where acetylcholine receptors (AChRs) are present at high density and in great excess over released ACh. Acetylcholinesterase (AChE) density is species dependent and varies widely, predicting that miniature endplate current (mEPC) fall time ( $t_f$ ) is critically dependent over a very narrow range (Anglistter *et al.*, 1994, *Neuron* 12:783). The mEPC shape and short rise time ( $t_r$ , 20-80% -80  $\mu$ s) can be measured accurately using extracellular (EC) recording, and can be modeled using passive diffusion of ACh through a rapidly expanding vesicular fusion pore (Stiles *et al.*, 1996, *PNAS*, in press). In the present study, we examined the dependence of  $t_r$  and  $t_f$  on temperature and AChE inhibition using EC recording and lizard intercostal muscle. We used a wide range of AChE inhibition conditions, all of which gave complete (>98%) block by biochemical and histochemical criteria. Increased mean  $t_r$  and  $t_f$  variability (up to 3-4 fold) nevertheless showed a marked dose response to inhibition conditions, while  $t_r$  increases were less sensitive. These findings are consistent with 3D Monte Carlo modeling predictions, and indicate that cleft geometry and sparsely packed transmitter removal sites can profoundly influence current decay times. Temperature changes from 40°C down to -12°C increased  $t_r$  and its variability by only ~60%. However, at lower temperatures (down to 3°C), 2-3 fold increases were seen. Similar results were obtained for  $t_f$ . We hypothesize that a change in membrane fluidity underlies this temperature sensitivity, and from modeling studies suggest that the primary effect is on AChR gating rather than on ACh release. Additional studies utilizing partial AChR blockade and quantitative voltage clamp may help to further define pre- and postsynaptic factors contributing to mEPC variability. Supported by NIH K08NS01776 (JRS) and NS09315 (MMS).

OXYTOCIN-EVOKED CURRENT IN VAGAL NEURONS: NEGATIVE MODULATION BY cAMP. S. Albrici\* and M. Roesenbass. Department of Physiology, University Medical Center, CH-1211 Geneva 4, Switzerland

The nonapeptide oxytocin can increase the excitability of vagal neurons in brainstem slices of the rat by generating a sustained inward current which is sodium-dependent and TTX-insensitive. This action is  $n$ -modulated by G protein activation and is independent of an increase in the intracellular calcium concentration (Soc. Neurosci. Abstr., 21, 591, 1995). We have used whole-cell recordings to investigate a possible interaction between the cAMP-dependent pathway and the peptide-induced current. We found that whereas in control neurons the current generated by oxytocin at 0.2  $\mu$ M was on average  $55 \pm 5$  pA, in neurons loaded with 100 to 500  $\mu$ M Br-cAMP, this current was reduced to  $25 \pm 5$  pA ( $n = 36$ ). A similar decrease in the amplitude of the peptide-specific current was also observed following inclusion into the patch pipette of forskolin, an activator of adenylyl cyclase, at 10  $\mu$ M and 20  $\mu$ M. By contrast, loading neurons with Br-cGMP, at 100 to 500  $\mu$ M, had no significant effect on the oxytocin response. The action of Br-cAMP was probably direct, rather than mediated by protein kinase A (PKA). Indeed, Rp-cAMPS and Sp-cAMPS, an inhibitor and an activator of PKA respectively, when included into the patch pipette at 500  $\mu$ M, did not modify the average amplitude of the oxytocin-induced current. These results suggest that part of this current could be mediated by cAMP. Alternatively, cAMP could negatively regulate the peptide-evoked current without being a second messenger by itself.

## POSTSYNAPTIC MECHANISMS: GABA SIGNALS

## 314.1

ROLE OF BICARBONATE IN THE GENERATION OF GABAERGIC SPONTANEOUS ACTIVITY IN THE INHIBITORY NETWORK OF THE RAT HIPPOCAMPAL SLICE. K. Lamsa\* and K. Kaila. Department of Biosciences, Division of Animal Physiology, P.O. Box 17, 00014 University of Helsinki, Finland.

4-aminopyridine (4-AP) is an interesting convulsant agent in that it can evoke epileptiform activity in the hippocampus despite its potentiating effect on GABAergic transmission. In brain slices exposed to blockers of ionotropic glutamate antagonists, 4-AP has been shown to induce a bicuculline-sensitive wave of activity that spreads through the preparation (e.g. Perreault & Avoli 1992; J. Neurosci. 12:104). This is associated with a GABA<sub>A</sub> receptor-mediated long-lasting depolarization (LLD) in pyramidal neurons and with an increase in the extracellular  $\text{K}^+$  concentration ( $[\text{K}^+]_o$ ). The present work was done on rat hippocampal slices in an interface chamber to examine the ionic basis of the generation of the LLDs. We employed conventional intra- and extracellular microelectrodes, as well as ion-selective electrodes to measure changes in  $[\text{K}^+]_o$  and extracellular pH ( $\text{pH}_o$ ). The LLDs were linked to an alkaline  $\text{pH}_o$  transient and to a transient rise in  $[\text{K}^+]_o$  with a time course similar to the depolarization. All these responses were inhibited in the nominal absence of  $\text{CO}_2/\text{HCO}_3^-$  and following application of a membrane-permeant inhibitor of carbonic anhydrase (ethoxycarbonyl, 50  $\mu$ M). Inhibition of extracellular carbonic anhydrase with benzolamide (10  $\mu$ M) blocked the alkaline  $\text{pH}_o$  transients but had no significant effect on the LLDs or on the  $[\text{K}^+]_o$  shifts. Application of pentobarbiturate (100  $\mu$ M), a positive allosteric modulator of GABA<sub>A</sub> receptors, enhanced the amplitude and frequency of the LLDs and of the  $[\text{K}^+]_o$  and  $\text{pH}_o$  transients. These results suggest that depolarizing bicarbonate currents mediated by GABA<sub>A</sub> receptors play a critical role in the excitatory coupling of interneurons within the inhibitory network, and hence (see abstract by Voipio *et al.*) in the generation of the LLDs in principal neurons. Supported by the Academy of Finland and by the Sigrid Juselius Foundation.

## 314.2

RISE IN EXTRACELLULAR  $\text{K}^+$  AND FALL IN  $\text{Ca}^{2+}$  INDUCED BY TETANIC STIMULATION OF INHIBITORY INTERNEURONS IN AREA CA1 OF RAT HIPPOCAMPAL SLICES. J. Voipio\*, K. Lamsa, A.-M. Autero, S. Smirnov, T. Taira, K. Kaila. Department of Biosciences, Division of Animal Physiology, P. O. Box 17, 00014 University of Helsinki, Finland.

Brief tetanic stimulation (40 or 100 pulses applied at 100 or 200 Hz) induced fast rise in the interstitial  $\text{K}^+$  concentration ( $[\text{K}^+]_o$ ) from 3 to 8 mM, as measured with  $\text{K}^+$ -selective microelectrodes placed at a distance of 0.5 mm from the site of stimulation in the CA1 stratum radiatum of rat hippocampal slices in an interface recording chamber. Application of ionotropic glutamate antagonists (10  $\mu$ M NBQX + 80  $\mu$ M AP5) had a negligible effect on the  $\text{K}^+$  shift, but it was fully blocked by the GABA<sub>A</sub> receptor antagonist, picrotoxin (100  $\mu$ M). The rise in  $[\text{K}^+]_o$  was associated with a fall in free extracellular  $\text{Ca}^{2+}$  from 1.6 mM to 1.4 mM, which indicates that synaptic activation of GABA<sub>A</sub> receptors can lead to neuronal uptake of calcium in the adult hippocampus. Both ionic shifts were inhibited in the presence of a membrane-permeant inhibitor of carbonic anhydrase (ethoxycarbonyl, 50  $\mu$ M), or in the nominal absence of  $\text{CO}_2/\text{HCO}_3^-$ . The GABA<sub>A</sub> receptor-mediated  $\text{K}^+$  transient had a latency of 100 ms and a time-to-peak of 900-1200 ms, which closely paralleled the time course of the depolarizing phase of the biphasic hyperpolarizing/depolarizing postsynaptic potential that was simultaneously recorded in pyramidal neurons. Experiments with intracellular inhibitors of  $\text{K}^+$ - $\text{Cl}^-$  cotransport (such as 100  $\mu$ M DIOA), applied via whole-cell recording electrodes, suggested that the change from hyperpolarizing to depolarizing of the postsynaptic voltage response is due to a carrier-mediated influx of  $\text{Cl}^-$ , driven by the rise in  $[\text{K}^+]_o$ , that appeared to originate from the activity of inhibitory interneurons. Taken together, the present data suggest that ionic shifts evoked upon activation of the inhibitory network play an important role both in the generation and modulation of neuronal activity evoked by tetanic stimulation in area CA1. Supported by the Academy of Finland and by the Sigrid Juselius Foundation.

## 314.3

GABA<sub>A</sub> RECEPTORS MEDIATE A POST-TETANIC EXCITATION IN CA1 AREA IN RAT HIPPOCAMPAL SLICES. T. Taira\*, K. Lamsa and K. Kaila, Department of Biociences, Division of Animal Physiology, P.O. Box 17, 00014 University of Helsinki, Finland. Email: Taira@katk.helsinki.fi.

The main excitatory drive in the adult hippocampus is thought to be provided by glutamate. However, in the absence of glutamatergic transmission GABA<sub>A</sub> receptor-mediated depolarizing postsynaptic potentials can be evoked in CA1 pyramidal neurons of rat hippocampal slices upon high-frequency stimulation of interneurons. To elucidate the role of GABA as an excitatory transmitter we studied the contributions of glutamatergic and GABAergic synaptic inputs to excitation of CA1 pyramidal neurons. The experiments were done with conventional intracellular microelectrodes in an interface chamber. Under control conditions, tetanic (100-200 Hz/0.5 s) stimulation applied to a radiatum typically resulted in a triphasic depolarization/hyperpolarization/sustained depolarization sequence. The late depolarization gave rise to a prolonged train of spikes. Antagonists of ionotropic glutamate receptors (10  $\mu$ M NBQX, 80  $\mu$ M AP5, 50  $\mu$ M tetrodotoxin) blocked the initial fast depolarization, but they had little effect on the late depolarization and the associated spiking. In contrast to this, the late depolarization and spike firing were selectively blocked (within a time window of 3-6 minutes) following exposure to the GABA<sub>A</sub> receptor antagonist, picrotoxin (PITX, 100  $\mu$ M). Paradoxically, at this early stage of PITX application, overall neuronal excitability was attenuated to a higher degree than what was achieved by the glutamate antagonists. The present results suggest that intense activation of GABAergic interneurons may accentuate neuronal excitation under physiological and pathophysiological conditions. Supported by the Academy of Finland and by the Sigrid Juselius Foundation.

## 314.5

NEURONAL PROPERTIES IN ORGANOTYPIC RAT HIPPOCAMPAL SLICE CULTURES. R.J. Holland, N. Best, J. Mitchell, J.E. Chad\* & H.V. Wheal, Neuroscience Research Group, University of Southampton, SO16 7PX, UK.

The ability to maintain neuronal architecture and connectivity in a long-term culture permits detailed investigations into the effects of neuroprotective agents. We are using the method of Stoppini *et al.* (1991) to produce cultures derived from 400  $\mu$ m hippocampal slices from P8 rats. Experiments were conducted after 10-15 days in culture. Neurons in control slices were shown to be viable due to their fluorescent dye exclusion, maintenance of Ca<sup>2+</sup> homeostasis and electrophysiological properties. We are investigating the role of synaptic inhibition in controlling inhibitory neurons. Within these cultures we routinely observe non-pyramidal neurons lying at the CA1/2 stratum pyramidale/radiatum boundary. We have compared the electrophysiological properties of these neurons to pyramidal cells were recorded from in current clamp and set to -60 mV. Preliminary data indicates that the number of action potentials induced by a 300ms 0.2 nA current pulse was greater in the pyramidal cells (7.0  $\pm$  0.82, n=4) compared to non-pyramidal cells (3.25  $\pm$  0.96, n=4). Accommodation was greater in the non-pyramidal cells and the latency of the first spike was larger (40ms  $\pm$  40) than the pyramidal neurons (15ms  $\pm$  4).

From EM analysis of morphologically identified interneurons filled with neurobiotin there is evidence for the presence of inhibitory synaptic inputs. Local (200  $\mu$ m) monopolar stimulation appears to induce IPSCs, as well as EPSCs. We are presently investigating the source of inputs to these neurons and tracing their outputs in order to determine their role in hippocampal function.

ANALYSIS OF INHIBITORY SYNAPTIC CURRENTS IN PYRAMIDAL AND NONPYRAMIDAL NEURONS OF THE RAT VISUAL CORTEX.

Mario Galarreta\* and Shaul Hestrin, University of Tennessee, Dept. of Anatomy & Neurobiology, TN 38163.

To characterize the properties of the GABA<sub>A</sub> receptors that mediate the inhibitory synaptic currents in the visual cortex, we have analyzed the miniature GABA<sub>A</sub> receptor-mediated inhibitory synaptic currents (mIPSCs), and the currents elicited by rapid application of GABA on somatic outside-out membrane patches, from excitatory pyramidal and inhibitory nonpyramidal neurons. Whole-cell recordings (20-25 °C) were made from visually identified cells, in slices of the visual cortex of 14-18 day-old rats.

mIPSCs (in the presence of CNQX, 10  $\mu$ M and TTX, 0.5  $\mu$ M) recorded from pyramidal and nonpyramidal cells were similar. Their decay time course was described by a biexponential function with the following parameters:  $\tau$  fast = 6.2  $\pm$  1 ms (68.6  $\pm$  14 %) and  $\tau$  slow = 22.0  $\pm$  7 ms for pyramidal cells in layer V (n = 17, mean  $\pm$  SD); and  $\tau$  fast = 5.0  $\pm$  2 ms (61.7  $\pm$  12 %) and  $\tau$  slow = 24.7  $\pm$  12ms, for 10 nonpyramidal cells (4 in layer V and 6 in layer I).

Decay of currents elicited by a brief (1ms) pulse of GABA (1 or 10mM) in outside-out patches from both types of cells, also required a biexponential fitting. The responses obtained in patches excised from pyramidal neurons (n=29) were described with a  $\tau$  fast = 4.8  $\pm$  3 ms (49.0  $\pm$  9 %) and a  $\tau$  slow = 48.3  $\pm$  15, and those from nonpyramidal cells (n=7) with a  $\tau$  fast = 4.6  $\pm$  2 ms (52.4  $\pm$  12 %), and a  $\tau$  slow = 34.1  $\pm$  8 ms.

The patch responses under these conditions did not accurately mimic the mIPSCs. However, the general resemblance we observed suggests that the kinetics of synaptic currents in these cells, primarily reflects receptor properties.

SPATIO-TEMPORAL MATURATION OF INHIBITORY SYNAPTIC TRANSMISSION IN GRANULE CELLS OF THE RAT DENTATE GYRUS.

G.S. Hollrigel\* and I. Soltesz, Department of Anatomy and Neurobiology, University of California Irvine, Irvine, CA 92717.

Granule cells in the adult dentate gyrus receive tonic inhibitory input from GABAergic synapses located near the soma (Soltesz *et al.*, 1995). A higher concentration of GAD-containing cells can be found slightly above the outer border of the developing granule cell layer (Dupuy and Houser, 1995), and the first synapses onto granule cells appear on proximal dendrites (Löbbers and Frotscher, 1988). We determined whether these early synaptic contacts were functional, and to what extent their location influences the kinetics of the synaptic currents.

Miniature IPSCs (mIPSCs) were recorded from granule cells in the dentate gyrus in brain slices from neonatal and adult rats. Slices were perfused with 36°C artificial cerebral spinal fluid containing glutamate receptor antagonists and tetrodotoxin.

Miniature IPSCs were detected within the first 24 hours after birth. Between P0 and P4 the mean frequency of the mIPSCs was 0.59  $\pm$  0.21 Hz, and it increased with age to the adult value of 6.04  $\pm$  1.62 Hz. The rise time constants were slower for mIPSCs recorded from P0-P4 rats (0.32  $\pm$  0.04 ms) and attained adult values by P21 (0.18  $\pm$  0.01 ms). Similarly, the mean decay time constant for P0-P4 granule cells equaled 10.63  $\pm$  0.96 ms, and by P21, it was similar to that of adult granule cells (4.91  $\pm$  0.09 ms). In contrast, the peak amplitude of the averaged mIPSCs was not significantly different from the adult value (64.75  $\pm$  3.19 pA).

These data indicate that immediately after birth, IPSCs are slower rising and slower decaying than in adult granule cells. The slower kinetics of IPSCs in young granule cells may be due to both electrotonic filtering and differential GABA<sub>A</sub> subunit expression patterns.

## 314.6

DELTA-RHYTHM OSCILLATIONS IN THE ENTORHINAL CORTEX MEDIATED BY INHIBITORY INTERNEURON ACTIVITY. V. Lopantsev\* and M. Avoli, Montreal Neurological Institute and Dept. of Neurology & Neurosurgery, McGill University, Montreal, QC, H3A 2B4, Canada

Spontaneous rhythmic, oscillatory potentials were recorded extra- and intracellularly in adult rat entorhinal cortex slices in the presence of 4-aminopyridine (4AP, 50  $\mu$ M). Field potential oscillations occurred at a frequency of 1.2  $\pm$  0.3/s (mean  $\pm$  SD; n=30 slices) either continuously or following GABA-mediated synchronous events. Simultaneous intracellular recordings showed corresponding rhythmic membrane depolarizations that had amplitude of 11.4  $\pm$  4.3 mV (n=24) and lasted 319  $\pm$  124.9 ms (n=16). These depolarizations gave rise to occasional single action potentials and were associated with a decrease (up to 86 %) of the input membrane resistance. The rhythmic depolarization amplitude varied linearly during steady changes of the membrane potential and had reversal potentials of -66.7  $\pm$  5.7 mV (n=13). These depolarizations increased in amplitude (up to 31.0  $\pm$  5.5 mV, n=3) after intracellular Cl<sup>-</sup> injection, were blocked by a non-NMDA receptor antagonist, but were not influenced by antagonists of the NMDA receptor. The amplitude of the rhythmic field potentials was larger at depths 700-900  $\mu$ m, corresponding to entorhinal cortex layers IV-V. Intracellular recordings from presumably inhibitory interneurons revealed rhythmic depolarizations which gave rise to regular action potential discharge, and did not increase in amplitude during intracellular Cl<sup>-</sup> injection. Thus these depolarizations may represent large, synchronous EPSPs generated by inhibitory interneurons. Our findings indicate that entorhinal cortex neurons can generate in the presence of 4AP delta-rhythm oscillations representing Cl<sup>-</sup>-dependent, depolarizing IPSPs, that are driven by inhibitory interneurons via excitatory, non-NMDA-mediated circuits. Supported by the MRC of Canada.

## 314.8

SPONTANEOUS IPSCs IN RAT NEOCORTICAL LAYER I NEURONS. F.-M. Zhou\* and J. J. Hablitz, Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294

The properties of inhibitory postsynaptic currents (IPSCs) in neocortical interneurons are not well described. Since layer I neurons of the rat neocortex are fast-spiking GABAergic interneurons, we have used these cells as model interneurons to study spontaneous (s) and miniature (m) IPSCs. Whole-cell patch clamp techniques were used in brain slice preparations. All recordings were made at -22 °C, in the presence of 20  $\mu$ M D-APV and 10  $\mu$ M CNQX to block EPSCs. At a holding potential of -60 mV, using symmetrical Cl<sup>-</sup> concentrations, amplitudes of sIPSCs ranged from 5 to 500 pA. mIPSC amplitudes were less than 80 pA at -60 mV. Both s- and mIPSCs reversed polarity at +5 mV, near the Cl<sup>-</sup> equilibrium potential. Bicuculline (10  $\mu$ M) reversibly blocked sIPSCs and mIPSCs, indicating mediation by GABA<sub>A</sub> receptors. At -60 mV, the 10-90% rise time was -1.3 ms for averaged sIPSCs (13 cells) and -1.2 ms for averaged mIPSCs (10 cells). The majority of individual sIPSCs and mIPSCs had double exponential decays with time constants of ~1-10 ms and ~20-70 ms. The decay was slower at more positive potentials. The slow component contributed 30-70% to the total amplitude. Dendritic filtering was not solely responsible for the observed variability. Differences in subunit composition and/or gating schemes for the GABA<sub>A</sub> receptors at different synapses may also be responsible. sIPSCs and mIPSCs were also recorded from 6 pyramidal neurons and the kinetics of sIPSCs and mIPSCs from layer I and pyramidal neurons were similar, suggesting that GABA<sub>A</sub> receptors were similar between the two cell types. Supported by NIH grant NS18145.

GABA-INDUCED MEMBRANE CONDUCTANCE AND THE INTEGRATIVE PROPERTIES OF NEOCORTICAL PYRAMIDAL CELLS. Christian Schmidt\*, Peter König, and Ronald B. Langdon. The Neurosciences Institute, San Diego, CA 92121.

Total somatic input conductance ( $G_m$ ) and cable response properties must play a critical role in determining (1) the number of synchronous inputs needed to drive cortical neurons to fire and (2) the time interval over which asynchronous inputs are effectively summed. We have studied the ability of GABA to modify membrane potential excursions ( $\Delta V_m$ ) induced by current injection and synaptic input, since summation of excitatory inputs must occur against a background of inhibitory, GABA-induced shunting conductance during normal cortical function. Most GABA receptors are located proximally, so GABA-gated conductance could hypothetically alter  $\Delta V_m$  amplitudes at the soma more than  $\Delta V_m$  time-course.

Our data were obtained by whole-cell, current-clamp recording from pyramidal cells ( $n = 7$ ) in layer 3 of slices of occipital cortex from adult (130 to 235 g) rat. Under control conditions, cells exhibited a mean resting  $G_m$  of 20.5 nS, a mean principal response time-constant ( $\tau_p$ ) of 14.2 msec, and resting  $V_m$  between -65 and -83 mV. Current step and synaptic input levels were adjusted to have  $-10 < \Delta V_m < +5$  mV. GABA (applied by dropping into the bath, 0.10 < final bath [GABA] < 7.5 mM) increased  $G_m$  by up to 500 nS (the upper limit observable) in a concentration-dependent manner (apparent  $EC_{50} = 0.2$  mM).  $G_m$  and EPSP amplitudes were somewhat more sensitive to GABA than was  $\tau_p$ . At 0.25 mM, GABA increased the mean  $G_m$  2.7-fold and reduced the mean peak EPSP amplitude by 58%, while reducing  $\tau_p$  by only 38%. These data imply that GABA action *in vivo* would strengthen the requirement for spatial summation at the soma while shortening, to a lesser extent, the interval of effective temporal integration. IMPACT OF SPONTANEOUS NETWORK ACTIVITY AND MINIATURE PYRAMIDAL POTENTIALS ON MEMBRANE PROPERTIES OF CORTICAL PYRAMIDAL NEURONS: AN *IN VIVO* INTRACELLULAR STUDY H. Gaudreau\*, E. J. Lang, A. Destexhe and D. Paré. Dept. of Physiol., Sch. of Med., Laval Univ., Quebec, Canada G1K 7P4.

*In vivo* intracellular recordings were obtained from area 5-7 cortical pyramidal neurons with pipettes containing KCl. TTX was applied locally to the recording area to block all network activity as shown by the lack of evoked responses to local stimuli and by the loss of Na spikes. Under these conditions cells had  $R_{IN}$  of 40-60 M $\Omega$ , whereas in the absence of TTX the  $R_{IN}$  ranged between 20-30 M $\Omega$ . Cells recorded with pipettes containing KCl and QX314, had intermediate  $R_{IN}$  values of 30-40 M $\Omega$  (no TTX present). TTX increased the time constants  $\sim 2$ -fold. Thus, spontaneous network activity significantly influences the membrane properties of pyramidal neurons.

After TTX application, we observed frequent (5-20/sec), low amplitude (0.5-2 mV) depolarizing events, which were interpreted as miniature synaptic potentials (minis) independent of Na spikes. The amplitude of the minis was correlated with the  $R_{IN}$  of the cell, suggesting the presence of additional unobserved events occurring at more distant sites. Larger potentials were also seen, and appeared to result from summing minis. Presumably, the minis were generated at sites electrotonically close to the soma where most synapses are GABAergic. Consistent with the idea that the minis were reversed GABA<sub>A</sub> IPSPs, membrane depolarization reduced their amplitude. Experiments are currently underway to identify the involved transmitter. The minis produced transient drops in  $R_{IN}$ , suggesting that ongoing action potential-independent transmitter release is a major determinant of the membrane properties of pyramidal neurons in intact networks. Support: MRC, NINDS and FRSQ.

#### MODULATION OF EVOKED HIPPOCAMPAL FIELD POTENTIALS *IN VIVO* BY STRESS AND NEUROSTEROIDS

H.J.A. Beldhuis\*, I.M. Nijholt, E. Dijkstra, T. Suzuki, S.E. de Boer and B. Bohus. Center for Behavioral and Cognitive Neurosciences, Dep. Animal Physiology, University of Groningen, PO Box 14, NL-9750 AA Haren, The Netherlands.

Neurosteroids (NSs) can rapidly alter the excitability of neurons by nongenomic mechanisms. Because the physiological significance of neurosteroids in intact organisms is still poorly understood, the main goal of this study was to examine the effects of NSs on transmission in the Schaffer collateral pathway to pyramidal cells in CA1 hippocampus in freely moving rats. In addition, since the hippocampal formation is implicated in stress responses and levels of certain NSs are increased during stress, we investigated the effect of stressful stimuli in the same neuronal network.

Animals were chronically implanted with electrodes in the dorsal hippocampus to stimulate the Schaffer collaterals (SC), and recording electrodes to record dendritic pEPSPs in the CA1 stratum radiatum. Pharmacological manipulation of NS levels was performed by *ip* application of synthetic neurosteroids, i.e. dehydroepiandrosterone (DHEAS), allopregnanolone (ALLO) and 5 $\alpha$ -dihydroprogesterone (5 $\alpha$ -DHP). Social interactions with dominant conspecifics were used to induce stressful situations. Single and double pulse responses were evoked before and after experimental treatment.

Application of 5 $\alpha$ -DHP, the main progesterone metabolite, had no effect on evoked responses. DHEAS increased pEPSP amplitude and suppressed paired-pulse inhibition, whereas ALLO and a conflict situation had the opposite effects. Together, these data suggest a role for NSs in modulating neuronal excitability at the SC-CA1 synapse *in vivo*.

These investigations are supported by the Dutch National Epilepsy Foundation.

INFLUENCE OF CORTICAL HYPERSYNCHRONISATION ON POSTSYNAPTIC ACTIVITY OF THE RAT NEOSTRIATUM *IN VITRO*. B. Schlösser, F. Rucker and G. ten Bruggenqate. Department of Physiology, University of Munich, D-80336 Munich, Germany. Spon: EBBS.

Neuronal activity within the neostriatum is mainly determined by cortical afferents. In the present study, we investigated the influence of cortical hypersynchronisation on synaptic activity in the striatum *in vitro* using intracellular recordings.

Experiments were performed on rat neostriatal slices with preserved inputs from the medial agranular cortex. In the recording chamber the slices were kept submerged in artificial cerebrospinal fluid. Synaptic activity was evoked by intracortical electrical stimulation.

Focal application of the GABA<sub>A</sub> receptor antagonist bicuculline into the neocortex induced transient paroxysmal depolarisations in cortical neurons associated with large epileptiform field potentials indicating hypersynchronous activity. During the state of hypersynchronisation, the cortically evoked synaptic activity in the striatum was strongly potentiated as indicated by the marked increase in amplitude and duration of synaptic responses. The potentiated synaptic potentials were composed of an EPSP and a depolarizing GABA<sub>A</sub> receptor-mediated IPSP. The contribution of the GABA<sub>A</sub> receptor-mediated IPSP to the synaptic response increased from 14% under control conditions to 41% during hypersynchronisation of the neocortex.

The results demonstrate that hypersynchronous activity in neocortical neurons potentiates both excitatory and inhibitory synaptic transmission in striatal neurons. The pronounced increase of striatal inhibition can be attributed to a more than proportional activation of inhibitory striatal interneurons and/or to the activation of recurrent inhibitory mechanisms within the striatum. Supported by the German Research Ministry.

## 314.12

SYNAPTIC AND SYNAPTICALLY-ACTIVATED HYPERPOLARIZING CONDUCTANCES REGULATE THE RESPONSIVENESS OF LATERAL AMYGDALOID (LAT) PROJECTION NEURONS. E. J. Lang\* and D. Paré. Dept. of Physiol., Sch. of Med., Laval Univ., Quebec, Canada G1K 7P4.

The inhibitory processes controlling LAT projection neurons ( $n=174$ ) were studied with *in vivo* intracellular recordings. In contrast to *in vitro* results, spontaneous and synaptic potentials evoked by stimulation of major input and output structures of the LAT nucleus always consisted of an early EPSP truncated by a large monophasic hyperpolarization, which reversed at  $-84.7 \pm 1.3$  mV when recorded with K-acetate (K-ac). The monophasic IPSPs probably resulted from divergent activity through intact cortical and LAT networks that smeared the activation of interneurons in time. Supporting this, convergence from widespread perirhinal cortical regions onto LAT neurons was demonstrated by evoking responses whose amplitudes and durations varied with stimulation site. At each site, the responses were intensity-dependent: low intensities evoked depolarizing responses and higher intensities hyperpolarizing ones. Orthodromic spikes could only be evoked in a narrow range of stimulus intensities.

The underlying conductances were investigated using K-ac, KCl, Cs-ac, and BAPTA filled pipettes. The hyperpolarization was demonstrated to be mainly comprised of a short latency Cl IPSP (presumably GABA<sub>A</sub> mediated) and Ca-dependent K conductance. A slowly activating K conductance (presumably a GABAB IPSP) also made a small contribution.

These results suggest that information processing in the LAT nucleus may be based primarily on quantitative differences in activation of intra-LAT circuitry and intrinsic conductances. Therefore, inputs from relatively small cortical ensembles may be the most effective stimulus for activating LAT neurons. Support: NINDS: 1F32NS1000601, MRC: MT-11562.

## 315.1

CONDUCTION OF POSTSYNAPTIC POTENTIALS IN THE DENDRITES OF CULTURED HIPPOCAMPAL NEURONS AS MEASURED BY HIGH-SPEED LASER-SCANNING MICROSCOPY. A. Bullen\* and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The conduction and integration of postsynaptic potentials in the dendrites of cultured hippocampal neurons was investigated using a high-speed laser-scanning microscope. Postsynaptic potentials were elicited at one or more presynaptic sites by focal stimulation (Bekkers & Stevens, 1995). A random-access laser-scanning microscope developed in our lab was used to acquire signals from fluorescent voltage-sensitive membrane probes (Patel et al., 1995). Transients in membrane potential were derived from the fractional change in fluorescence ( $\Delta F/F$ ). Typically, recordings were made at 2 kHz sampling rate (per scanning spot) and digitally filtered at 300 Hz. Spatial resolution was limited by spot size at the level of the preparation (2  $\mu$ m). Hippocampal neurons were harvested from E19 rat pups and plated at a density of  $10^4$  cells/cm<sup>2</sup>. These cells were stained by bath application of voltage-sensitive dye (VSD; Di-8-ANEPPS, 100  $\mu$ M). A DIC image was used to interactively select multiple locations for optical recording. Focal stimulation was accomplished by the application of hyperosmotic solution (bath solution + 500 mM sucrose) applied through a patch pipette positioned at strategic locations in the dendrites. Both EPSPs and IPSPs could be elicited depending on the nature of synapses present. Optical transients recorded from the soma with VSDs were highly correlated with corresponding current-clamp records. After noise reduction procedures (oversampling, ratioing and digital filtering) a signal-to-noise ratio of 5-10 could be achieved (detector bandwidth = 15 kHz) for postsynaptic potentials in small dendritic structures. The conduction and summation of postsynaptic potentials were examined in small dendritic processes and at branch points, up to 150  $\mu$ m from the soma. Dendritic recordings were compared to electrical recordings made concurrently from the soma via a patch pipette. The conduction and integration of postsynaptic potentials elicited at different points throughout the dendritic tree of hippocampal neurons will be described. *Supported by NSF BIR-9521685.*

## 315.3

A DECREASE IN Na<sup>+</sup> CURRENT CONTRIBUTES TO LOSS OF ACTION POTENTIAL AMPLITUDE IN DENDRITIC SPIKE TRAINS. C. M. Colbert\* and D. Johnston. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Action potentials initiated in the axon of central pyramidal neurons propagate "backwards" through the soma and dendrites. When the neuron fires trains of action potentials, the amplitude of action potentials recorded in the apical dendrites decreases toward a steady-state value in a frequency dependent manner (Spruston et al., Science 268:297-300, 1995; Callaway and Ross., J. Neurophysiol. 74:1395-1403, 1995). The mechanisms of the decrease in dendritic action potential amplitude are unknown. To test the hypothesis that a decrease in available Na<sup>+</sup> current contributes to the loss of action potential amplitude in the dendrites, we measured Na<sup>+</sup> currents in cell-attached patches on apical dendrites (20-200  $\mu$ m from the soma) of pyramidal neurons in layer V neocortex, CA1 of the hippocampus, and the subiculum. K<sup>+</sup> currents were blocked by 4AP and TEA in the patch pipette. Action potentials were simulated by a step to a command potential of -10 mV for 2 ms from a holding potential near rest. Trains of action potentials were simulated by 7 steps at an interval of 20 ms. Ensemble averages were computed from at least 25 trains. A ratio of the ensemble current elicited by the last step to that elicited by the first step in a train was computed for each patch. When holding the patches at rest (~ -65 mV) between simulated action potentials, the ratio was  $0.49 \pm 0.04$  (mean  $\pm$  SEM,  $n = 8$ ) (i.e. Na<sup>+</sup> current decreased during the train). When holding at 20 mV hyperpolarized to rest (~ -85 mV), the ratio was  $0.72 \pm 0.06$  ( $n = 6$ ). Thus, the voltage-dependence of the loss of Na<sup>+</sup> current is consistent with mechanisms such as slow Na<sup>+</sup> channel inactivation and voltage-dependent return from inactivation, but inconsistent with Na<sup>+</sup> accumulation. These results suggest that a decrease in Na<sup>+</sup> current contributes to the loss of action potential amplitude seen in the apical dendrites of pyramidal neurons. (NS11535, MH44754, MH48432 and MH10896).

## 315.5

ACTIVATION OF PERSISTENT SODIUM CURRENT IN NEOCORTICAL LAYER V NEURONS CORRELATES WITH INCREASED INTRADENDRITIC SODIUM CONCENTRATION. T. Mittmann\*, S.M. Linton, P.C. Schwindt and W.E. Crill. Dept. Physiol. & Biophys., Univ. Washington, Sch. of Med., Seattle, WA 98195.

In neocortical layer V neurons fluorescence imaging technique and intracellular recordings were combined to study changes in the intracellular sodium concentration ([Na<sup>+</sup>]<sub>i</sub>) due to activation of persistent sodium current ( $I_{NaP}$ ). Brain slices (200-250  $\mu$ m) were prepared from ketamine anaesthetized 15-36 day old rats. Neurons were loaded through the intracellular electrode with the sodium sensitive dye SBFI (8-12 mM). Images were recorded with a cooled CCD-camera system at 380 nm illumination.  $I_{NaP}$  was activated by both current clamp and voltage clamp methods. In current clamp a short depolarizing current pulse (20 ms) in Ca<sup>2+</sup>-free ACSF containing Mn<sup>2+</sup> (2 mM) and TEA (20 mM) evoked a single action potential (AP) following by a plateau depolarization (PD) lasting >1s. The TTX-sensitive PD is caused by  $I_{NaP}$  activation (Stafrstrom et al., 1985). The PDs are associated with SBFI-fluorescence changes in the soma and apical dendrite, indicating an increased [Na<sup>+</sup>]<sub>i</sub>. The SBFI changes ( $\Delta F$  and  $\Delta F/F$ ) reached into the dendrites as far as dye could be visualized (50-300  $\mu$ m) ( $n=10$ ). Single APs induced no detectable SBFI fluorescence changes ( $n=3$ ). During voltage clamp in normal ACSF a depolarizing voltage ramp (40mV/s) evoked persistent inward current and associated increase in somatic and dendritic [Na<sup>+</sup>]<sub>i</sub> that was blocked by TTX (1  $\mu$ M). We conclude that both somatic and dendritic membrane generate  $I_{NaP}$ . Supported by NIH Grant NS16792, the Keck Foundation & an Alexander v. Humboldt fellowship to T. Mittmann.

## 315.2

EFFECTS OF DENDRITIC MEMBRANE CURRENTS ON THE SHAPE OF EPSPs IN PYRAMIDAL NEURONS. Paul A. Rhodes\* and Alex M. Thomson. Mathematical Research Branch, NIDDK, National Institutes of Health, Bethesda, MD and Dept. of Physiology, Royal Free Hospital School of Medicine, London.

Measurements of the EPSPs produced in neocortical pyramidal neurons by the firing of a single presynaptic pyramid reveal a wide variety of EPSP shapes, as well as a pattern of shape change as postsynaptic membrane potential is increased. In an effort to understand the generation of these features, in vitro measurements from connected pairs of layer V pyramidal neurons were simulated using compartment model methods, with reconstruction of the presynaptic axon (Deuchars et al. 1994) guiding the placement of presumed synaptic contacts at appropriate locations on the postsynaptic dendritic tree. Simulations were constrained both to match EPSP shape parameters measured under control conditions, and to account for the changes in EPSP shape observed in vitro as membrane potential of the postsynaptic neuron was varied, or NMDA antagonist added. The results indicate that for the first spike in a train much of the EPSP broadening seen with postsynaptic depolarization could be reproduced in the model by inactivation of the transient potassium (A) current, along with increased activation of the low threshold calcium (T) current, suggesting that dendritic voltage-gated currents could play an unexpectedly large role in controlling the shape of subthreshold EPSPs. Further, in these simulations dendritic Ca(T) (but not Na) current enhanced the broadening effect of synaptic NMDA current. These predicted consequences of dendritic voltage-gated channels draw attention to the local depolarization in the dendritic branches receiving input, and call into question approaches to the analysis of EPSPs which neglect currents in the dendritic membrane. We conclude that the dendritic currents activated by subthreshold synaptic conductance may considerably transform the impact of synaptic input.

## 315.4

PHARMACOLOGICAL MODULATION OF SPIKE PROPAGATION IN THE APICAL DENDRITES OF HIPPOCAMPAL PYRAMIDAL CELLS. H. Tsubokawa and W.N. Ross\*. Dept. of Physiology, New York Medical College, Valhalla, NY 10595.

Na<sup>+</sup> dependent action potentials backpropagate over the apical dendrites of CA1 pyramidal neurons in an activity dependent manner (Jaffe et al., 1992; Spruston et al., 1995; Callaway and Ross, 1995). When recorded in the middle dendrites, the amplitudes of each spike in a train gradually decrease, but propagation of all spikes appears to be regenerative. In the distal dendrites the fall in amplitude after the first spike is more dramatic, and only the first spikes propagate actively to the end of the cell. Using whole cell recording from the middle dendrites we studied the gradual reduction in amplitude in trains of action potentials antidromically activated at 10 ms to 2 s intervals. The bath contained 50  $\mu$ M DL-APV, 10  $\mu$ M CNQX, and 10  $\mu$ M bicuculline methiodide to block fast synaptic responses. Their presence had no effect on spike propagation. The recording pipette contained (in mM): 130 K-glu, 10 Na-glu, 4 NaCl, 4 Mg-ATP, 0.3 GTP, 4 Na<sub>2</sub>-phosphocreatine, 10 Hepes (pH=7.2). Under these conditions addition of 50  $\mu$ M carbachol reduced the amplitude modulation, making the spike heights almost equal. 10  $\mu$ M carbachol or 20  $\mu$ M norepinephrine had little or no effect on the amplitude profile. 500  $\mu$ M Cs<sup>+</sup>, 200  $\mu$ M Ni<sup>2+</sup> or 200  $\mu$ M Cd<sup>2+</sup> also reduced the amplitude modulation, but were often irreversible. These results suggest that the M-current, Q-current, and possibly the current underlying the slow AHP regulate spike propagation into the dendrites. However, changes in the resting potential and the composition of the intracellular solution complicate this interpretation.

Supported in part by NIH grant NS-16295 and the Naito Foundation.

## 315.6

THE MONOSYNAPTIC PERFORANT PATH INPUT TO CA3 PYRAMIDAL NEURONS: II. THE ROLE OF VOLTAGE-DEPENDENT CONDUCTANCES IN PROPAGATION OF EPSPs. N.N. Urban\* and G. Barriomeu. Department of Neuroscience and Center for the Neural Basis of Cognition, University of Pittsburgh, Pittsburgh, PA 15260.

Models of CA3 pyramidal cells based on passive cable theory predict that perforant path (PP) EPSPs reaching the soma will be reduced in amplitude by ~95% and will have very slow rise times. In contrast with these predictions, we have found that in whole-cell recordings from CA3 pyramidal cells, PP stimulation results in large (>25 mV peak amplitude), and fast (<8 msec rise time) EPSPs. These observations suggest that voltage dependent (VD) conductances in CA3 neurons influence the propagation of perforant path synaptic responses to CA3 cell somas. To test this hypothesis we examined the effect of blockers of VD channels on the somatic depolarization observed following stimulation of distal dendrites.

Distal dendrites of CA3 cells were stimulated either by PP synaptic activation or by direct depolarization using an extracellular stimulating electrode placed in *s. lacunosum moleculare* of CA3. When direct depolarization was used, synaptic transmission was blocked using either 500  $\mu$ M CdCl<sub>2</sub> or a combination of glutamatergic antagonists. Local application of 1  $\mu$ M TTX to the CA3 cell dendrites in *s. radiatum* blocked action potentials evoked by distal stimulation (N=5). This same application of TTX did not affect the amplitude of action potentials induced by somatic depolarization. In other experiments, subthreshold responses to synaptic and direct stimulation of distal dendrites were significantly attenuated by TTX as well as by low concentrations (10-30  $\mu$ M) of NiCl<sub>2</sub> (average reduction by NiCl<sub>2</sub> 32%; N=6). These data suggest that VD sodium channels and T-type calcium channels may play a role in the amplification of perforant path inputs to CA3 cells.

This work was supported by NS24288 and a Howard Hughes Medical Institute predoctoral fellowship (to NNU).

## 315.7

## THE MONOSYNAPTIC PERFORANT PATH INPUT TO CA3 PYRAMIDAL NEURONS: I. PHARMACOLOGICAL CHARACTERIZATION.

Julia Berzhanskaya, N.N. Urban and G. Barrioune Department of Neuroscience and Center for the Neural Basis of Cognition, University of Pittsburgh, Pittsburgh, PA 15260.

Much of our current understanding of hippocampal function is based on the classical view of the hippocampus as a "trisynaptic circuit". This view ignored the direct projection from the entorhinal cortex to CA3 and CA1 via the direct perforant path (PP). However, *in vivo* experiments have demonstrated that PP stimulation can elicit monosynaptically population spikes in CA1 and CA3 cells. In our experiments on CA3 pyramidal cells we have observed isolated PP-evoked EPSPs as large as 25 mV. These observations suggest that perforant path may provide an important excitatory input to CA3 pyramidal cells.

PP-evoked EPSCs in CA3 pyramidal cells were studied using whole-cell recording techniques. EPSCs were evoked by stimulation of PP fibers as they travel in the subiculum. Selectivity of PP stimulation was confirmed by laminar profile analysis showing a single current sink in the apical dendrites of CA3 cells at about 450  $\mu$ m from pyramidal cell layer. A series of cuts was made to exclude polysynaptic contamination produced by possible activation of the mossy fibers.

Monosynaptic EPSCs were studied following blockade of inhibition. Application of D-APV (25  $\mu$ M) and CNQX (10  $\mu$ M) revealed that PP-evoked EPSCs have both AMPA and NMDA receptor mediated components. The NMDA component accounted for 30%  $\pm$  7% of the peak EPSC (at -50 mV, N=6).

When inhibition was intact, PP stimulation elicited both EPSCs and IPSCs. Both fast and slow IPSCs were observed. The fast component of the IPSC reversed at the chloride equilibrium potential and was blocked by bicuculline (10  $\mu$ M). The slow component of the IPSC reversed at K<sup>+</sup> equilibrium potential and was partially blocked by CGP3548 (50-100  $\mu$ M). Supported by NS24288 and Howard Hughes Medical Institute Predoctoral Fellowship (to NNU).

ACTIVITY-DEPENDENT EXTRACELLULAR ALKALINE SHIFTS IN RAT HIPPOCAMPUS ARE SUPPORTED BY EXTERNAL Ba<sup>2+</sup>. SE Smith, II Grichtchenko & M Chesler.

Depts. Physiol./Neurosurg. NYU Med. Ctr., 550 1st Ave., NY, NY 10016.

Activity-dependent alkaline shifts in area CA1 are blocked in 0 Ca<sup>2+</sup> [1,2], suggesting involvement of plasmalemmal Ca<sup>2+</sup>-H<sup>+</sup> exchange (Ca<sup>2+</sup> ATPase) [3]. We therefore studied whether external Ba<sup>2+</sup> could support agonist- and electrically-evoked alkaline shifts. In s. radiatum, AMPA-evoked alkalizations were blocked in 0 Ca<sup>2+</sup>, but recovered after addition of 50-500  $\mu$ M Ba<sup>2+</sup>. Adding 300  $\mu$ M Cd<sup>2+</sup>/100  $\mu$ M Ni<sup>2+</sup> reduced both control and Ba<sup>2+</sup>-dependent alkaline shifts by ~50%. Activation of pyramidal cells (by 10-100 Hz current pulses along the soma-dendritic axis) in 20  $\mu$ M CNQX/50  $\mu$ M APV elicited alkalizations of 0.1-0.2 unit pH in s. radiatum that were blocked by TTX, Cd<sup>2+</sup>/Ni<sup>2+</sup> or 0 Ca<sup>2+</sup>. In 0 Ca<sup>2+</sup> media, addition of 1-10 mM Ba<sup>2+</sup> restored the alkaline shifts which could again be blocked by TTX or 300  $\mu$ M Cd<sup>2+</sup>/100  $\mu$ M Ni<sup>2+</sup>. Both the AMPA and the electrically-evoked Ba<sup>2+</sup> responses were increased by benzolamide and persisted in HEPES-buffered media. These data demonstrate that Ca<sup>2+</sup> entry is not an absolute requirement for the alkaline shift. If Ca<sup>2+</sup>-H<sup>+</sup> exchange mediates these responses, the data suggest that either (a) Ba<sup>2+</sup> is transported by the exchanger, or (b) electrical activity induces sufficient release of Ca<sup>2+</sup> from internal stores. SUMMATION OF SYNAPTIC POTENTIALS IN LAYER V PYRAMIDAL NEURONS. A.D. Reyes and B. Sakmann, Max-Planck-Institut für Medizinische Forschung, D-69028 Heidelberg, Germany

The firing of cortical neurons depends on the amplitude of the composite synaptic potential reaching the soma and initial axon segment. The manner in which individual synaptic potentials originating in dendrites summate at the soma is yet unclear.

To examine how unitary excitatory postsynaptic potentials (EPSPs) summate, we performed simultaneous whole-cell recordings from three layer V pyramidal neurons wherein two neurons have a common input to a third neuron. Slices were made from P14 rats and maintained at 34°C. The presynaptic neurons were stimulated individually and simultaneously and the resulting EPSPs recorded in the soma of the third neuron. In most cases (15/20 triplets), the EPSPs summated linearly. Summation was linear: 1) at different subthreshold membrane potentials (-70 to -50 mV); 2) when the EPSPs were evoked at different delays; and 3) when the EPSPs were evoked in trains (10-66 Hz). In 3 cases, summation was supralinear and in 2 cases, sublinear.

To examine how inputs from different dendritic branches summate at the soma, simultaneous recordings were made from the soma, basal dendrites, and apical dendrites of individual neurons. Preliminary results indicate that current injection at either the apical and a basal dendrite or two basal dendrites produce voltage deflections that summate linearly at the soma.

These data suggest that in the subthreshold range, unitary EPSPs of layer V neurons summate linearly at the soma.

PLATEAU POTENTIALS IN AMBIGUOUS NEURONS IN NEWBORN MOUSE BRAIN STEM *IN VITRO*. J.C. Reikling and J.L. Feldman, Departments of Physiological Science and Neurobiology, UCLA, Box 951527, Los Angeles, CA, 90095-1527.

Whole-cell patch recordings from neurons located in the rostral part of the nucleus ambiguus were performed in rhythmic brain stem slices of newborn (1-3 day) mice (Funk et. al, *J. Neurophys.* '94). Neurons were visualized using IR video microscopy. Some neurons were weakly respiratory-modulated, showing trains of IPSPs in synchrony with inspiratory bursts of the XII nerve. Following suprathreshold depolarizing pulses or strong hyperpolarizing pulses, neurons displayed long-lasting depolarizing plateau potentials. A two-pulse stimulation paradigm revealed that the plateau potential was voltage-dependent, increasing in amplitude and duration more positive potentials. At more positive potentials the plateau potential lead to sustained repetitive firing that could be terminated by ~5 s hyperpolarizing pulses. The plateau potential was linked to a rise in intracellular Ca<sup>2+</sup> because it was blocked by high pipette BAPTA concentrations. When the plateau potential was blocked with BAPTA a number of active properties resembling that of adult ambiguous neurons were uncovered, such as delayed excitation and postinhibitory rebound responses.

We conclude that ambiguous neurons in newborn mice have bistable properties leading to long-lasting firing after both excitatory and inhibitory input. Supported by NIH grant HL40959.

VOLTAGE ATTENUATION AND INTRACELLULAR RESISTIVITY IN NEOCORTICAL PYRAMIDAL NEURONS. N. Spruston and G. Stuart.

Dept. Neurobiology & Physiology, Institute for Neuroscience, Northwestern University, Evanston, IL 60208-3520. Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, ACT 0200 Australia.

Direct measurements of voltage attenuation in response to small somatic hyperpolarizing current pulses were obtained with simultaneous patch-pipette recordings from the soma and primary apical dendrite of layer V pyramidal neurons in slices of rat neocortex. Steady-state voltage decayed approximately linearly, with 50% attenuation 333  $\mu$ m from the soma in control conditions. Addition of 3-5 mM CsCl to the bathing solution blocked the "sag" in voltage responses, presumably due to a block of a hyperpolarization activated conductance (I<sub>h</sub>). Attenuation in the presence of CsCl was considerably less than in control, with 50% attenuation at 545  $\mu$ m.

Neurons were routinely filled with biocytin, and three neurons fully reconstructed and modeled with NEURON. Using the membrane time constant determined from somatic and dendritic voltage responses in the presence of CsCl to constrain the passive membrane properties, an intracellular resistivity of about 150  $\Omega$ cm best described the observed voltage attenuation in CsCl.

A hyperpolarization-activated sag conductance (with kinetics modified slightly from Budde et al. *J. Neurophysiol.* 72:2737-2742, 1994) incorporated into the passive models revealed that the voltage attenuation observed in control conditions could only be reproduced if a large portion of the total I<sub>h</sub> conductance was concentrated in the apical dendrites. Consistent with this observation, sag in dendritic voltage responses was greater than at the soma. These data suggest that a nonuniform distribution of I<sub>h</sub> channels plays an important role in determining voltage attenuation in layer V pyramidal neurons and that its density is substantially higher in the distal apical dendrites than in the soma or basal dendrites.

RESONANCE PROPERTIES MEASURED FROM SOMA AND DENDRITES OF LAYER 5 NEOCORTICAL NEURONS. B. Huitcheon, J. Segev, P. Carlen, Y. Yarom, Department of Neurobiology, The Hebrew University, Jerusalem, Israel, 91904

Previous studies of the frequency responses of central neurons have shown that their subthreshold voltage-dependent conductances can generate electrical membrane resonances. These resonances confer band-limited frequency preferences on these neurons which may underlie spontaneous oscillations of the membrane potential or affect the coupling of periodic synaptic inputs to firing. Recording sites on the somata and apical dendrites of layer 5 pyramidal neurons in neocortical slices from young rats were identified visually under infrared illumination with the aid of Nomarski optics and a video system. Low-frequency subthreshold resonances were observed from the cell body and also from the apical dendrite at distances greater than 100  $\mu$ m from the soma. Recordings from the soma and dendrite of the same neuron showed that the resonant frequency was almost unchanged by position along the dendrite. In contrast, the results of simulations using a compartmental model of an idealized neuron with a resonance-generating current in the soma and a single passive dendrite showed that the resonant frequency measured from the dendrite is expected to be up to 30% lower than that measured from the soma depending on the electrotonic length of the dendrite. The discrepancies between our observations and the predictions from the model suggest that the currents generating resonance in neocortical neurons are distributed over both the soma and dendrites. This distribution of resonant properties may contribute to the efficient conduction of resonant-band signals along dendrites and attenuate or amplify post-synaptic potentials depending on their frequency compositions.

**Roles of Negative Feedback by Potassium Currents and Recurrent Inhibition**

Jonghan Shin\*, Div. of Biology, Caltech 139-74, Pasadena, CA 91125.

This abstract describes precision improvement of neural coding by internal negative feedback currents such as the delayed potassium current, etc. and external recurrent inhibition. The negative feedback by the delayed potassium current can reduce errors induced in transforming analog potential of soma into nerve pulses. The errors related on neural coding are filtered by high pass filter which result from the negative feedback mechanism. Thus signal-to-noise ratio of neural coding is increased at low frequency band in which important informations exist. Moreover additional negative feedback via recurrent inhibition, etc. could make the high pass filter higher order, which result in more signal-to-noise ratio than without it. Also this could explain internal biophysical mechanism about power spectral shapes observed from many experimental preparations, which has a dip at low frequencies and a positive slope between the low frequency band and high frequency band. In general, we know that the signal-to-noise ratio of neural coding would increase with increasing maximum mean firing frequency. But we cannot explain efficient neural coding of nerve cell completely, using this kind of oversampling and averaging concepts only. As a result, a kind of noise spectral shaping via negative feedback mechanism could address hidden secrets of the efficient neural coding. **ELECTROTONIC PROPERTIES OF NON-PYRAMIDAL NEURONS IN THE HIPPOCAMPAL CA3 REGION, Raymond A. Chitwood\* and David B. Jaffe, Div. of Life Sci., Univ. of Texas at San Antonio, San Antonio, TX 78249.**

Inhibitory neurons control firing activity in biological neural networks. We have been studying the properties of non-pyramidal neurons in the four extra-pyramidal subregions, *s. lacunosum-moleculare*, *s. radiatum*, *s. lucidum* and *s. oriens*, of hippocampal area CA3.

Whole-cell current-clamp recordings were made from non-pyramidal neurons in 14-28 day-old rat hippocampal slices. For cells in all four regions, the mean input resistance ( $R_N$ ) was  $521 \text{ M}\Omega \pm 218$  and the mean slowest membrane time constant, measured within the linear range of the membrane, was  $68 \text{ ms} \pm 35$  (mean  $\pm$  S.D.,  $n=96$ ). All though there was large variance between neurons in each sub-field, there was no significant difference in passive membrane properties between the four subregions.

A subset of cells were labeled with biocytin or Neurobiotin for morphometric analysis. Electrotonic analysis of compartmental models constructed from these data was performed using NEURON.  $R_N$  of the modeled neurons were within 20% of measured values in 12 of 24 cells. Electrotonic analysis suggests that, in spite of their relatively shorter and more limited branching dendritic trees, there is significant voltage attenuation from most dendritic locations to the soma.

## 315.14

**CHARACTERIZATION OF VOLTAGE-GATED K<sup>+</sup> CHANNELS IN THE SOMA AND DENDRITES OF HIPPOCAMPAL CA1 PYRAMIDAL NEURONS Dax Hoffman\*, J. Magee, and D. Johnston**

Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Single potassium channel recordings using cell-attached and outside-out patches were carried out on the somatic and dendritic membranes of CA1 pyramidal neurons from rat hippocampal slices. The three most frequently encountered types of potassium channels were a transient, A-type channel, a delayed-rectifier channel, and a large conductance, calcium-dependent channel. The transient, A-type channel is activated by moderate depolarization from the resting potential and has a single-channel conductance of 7–10 pS. Micromolar concentrations of 4-aminopyridine inhibit the current. The number of channels per patch has ranged from 2 to greater than 100. Inactivation is mostly voltage-independent with time constants of inactivation between 15 and 20 ms. A second, commonly observed potassium channel is a delayed-rectifier type. The delayed-rectifier is not encountered as frequently as the A-type channel. This delayed onset channel has a single-channel conductance of approximately 20 pS and is activated at potentials positive to -40 mV, more depolarized than the A-type channel. Another frequently observed outward current channel is inferred to be a calcium-dependent potassium channel from its range of activation and single-channel conductance. This channel exhibited large unitary currents and single-channel conductance (90–140 pS) reminiscent of the BK or maxi-K channels. At potentials greater than +60 mV the single-channel conductance saturates, most likely due to magnesium block. (MH44754, MH48432, N511535).

**Focal photolysis of caged Ca using two-photon excitation**

Christian Lüscher\*, Peter Lipp, Hans-R. Lüscher &amp; Ernst Niggli.

Department of Physiology, University of Bern, Switzerland

Subcellular Ca signals are a common feature of many cell types including neurons and myocytes. Here we describe the use of a Ti-sapphire laser yielding two photon photolysis (TPP) of caged Ca, in a very small volume (sub-femtoliter). The energy of the Ti-sapphire laser (wave length 700 nm, pulse duration 75 fs, repetition rate 80 MHz, output energy 150 mW) was reduced by a polarizing filter to 8–70 mW and parafocally, coaxially combined with an argon laser (514 nm, 2 mW) of a confocal laser scanning microscope (CLSM) to detect the released Ca. Cultured hippocampal neurons of the rat and guinea pig cardiac myocytes were dialyzed with Fluo-3 (0.1 mM, 0.25 Ca) and DM nitrophen (1 mM) in the whole-cell configuration of the patch clamp technique. High temporal resolution (500 Hz) was obtained in the line scan mode of the CLSM. The three-dimensional point spread function was determined in the reflection mode or using fluorescein. *In vitro* full width at half maximum (FWHM) in the two photon mode was 0.6  $\mu\text{m}$  for x-y and 1  $\mu\text{m}$  for z-axes. Photolysis of caged Ca led to an increase of up to 100% of the baseline fluorescence. Diffusion of uncaged Ca could be observed (decay  $\tau = 20 \text{ ms}$ ,  $\lambda = 6.2 \text{ }\mu\text{m}$ ). *In vivo*, in both cell types DM nitrophen could be uncaged without damaging the cell ( $\Delta F/F$  up to 2). In hippocampal neurons Ca spreading in the cytoplasm was slow (decay  $\tau = 90 \text{ ms}$ ,  $\lambda = 8.7 \text{ }\mu\text{m}$ ). In contrast TPP led to a more confined ( $\lambda = 3.2 \text{ }\mu\text{m}$ ), rapidly reversible ( $\tau = 25 \text{ ms}$ ) Ca spreading in cardiac myocytes, and occasionally triggered propagating Ca waves. These findings suggest that uncaged Ca is sufficient to activate Ca-induced Ca release and subject to an active reuptake of Ca in cardiac myocytes, whereas in the neurons investigated uncaged Ca mainly spreads by diffusion only.

## 316.2

**LOCAL DENDRITIC CALCIUM TRANSIENTS CAUSED BY UNITARY SYNAPTIC EVENTS IN HIPPOCAMPAL NEURONS. V. N. Murthy\*, T.J. Sejnowski and C.F. Stevens. Computational Neurobiology, and Molecular Neurobiology Laboratories, Salk Institute, 10010 N. Torrey Pines Rd., La Jolla, CA 92037.**

Spontaneous, action potential-independent calcium transients have been observed in dendrites of cortical neurons, and are presumed to be caused by spontaneous transmitter release (Science, 263:529). To determine the mechanisms involved in these presumed miniature synaptic calcium transients (MSCTs), we performed high-temporal resolution confocal imaging of cultured hippocampal neurons filled with 50  $\mu\text{M}$  fluo-3 through a patch pipette. MSCTs were observed at resting membrane potentials in the presence of TTX and no added  $\text{Mg}^{2+}$ , and 100 mosM sucrose to increase spontaneous vesicle release. MSCTs persisted when AMPA receptors were blocked by 10  $\mu\text{M}$  DNQX, and calcium channels were blocked by 50  $\mu\text{M}$  cadmium. MSCTs were blocked reversibly by 100  $\mu\text{M}$  D-APV, an NMDA receptor antagonist. In the presence of 3 mM external  $\text{Mg}^{2+}$ , MSCTs could be suppressed by voltage-clamping the soma at -70 mV; transients reappeared when the membrane was depolarized to -30 mV to remove the  $\text{Mg}^{2+}$  block of NMDA receptors. Taken together, these findings indicate that MSCTs are caused by calcium entry through NMDA receptors when spontaneous vesicle release occurs. MSCTs originate at sites 1–2  $\mu\text{m}$  along the dendritic axis, and can spread to 10  $\mu\text{m}$  axially. Preliminary analysis of multiple occurrences of MSCTs at a single site indicates that they can vary considerably in amplitude and duration. These experiments could further the understanding of the causes of response variability at single synapses. Support: HHMI and NIH (TJS and CFS); HHWhitney Fellowship (VNM).

## 316.3

**TWO-PHOTON CONFOCAL IMAGING OF CALCIUM SIGNALS IN HIPPOCAMPAL SLICES AND CEREBELLAR GRANULE CELLS.** A.C. Hargreaves, B.G. Frenquelli\* & G.L. Collingridge. Dept. of Anatomy, University of Bristol, Bristol, UK BS8 1TD.

We have used two-photon laser scanning confocal microscopy (TP-LSCM) to visualise calcium dynamics in acutely-prepared hippocampal slices and in 3-10 day old cultures of cerebellar granule cells. Hippocampal slices were prepared using standard techniques from 3-17 day old rat pups and maintained, submerged, in 4 ml of standard aCSF containing indo-1 AM (10  $\mu\text{M}$ ) and pluronic F-127 (0.2-0.4 %) at room temperature. Loading of CA1 pyramidal cells with indo-1 was only obtained in young slices (3-6 days). Older slices showed loading of putative interneurons and superficial dendrites only. Cerebellar granule cells were prepared from 7 day old rats by dissociation in  $\text{Ca}^{2+}$ -free medium and were loaded with 5  $\mu\text{M}$  indo-1 AM with 0.2 % pluronic F-127. TP-excitation was provided by a Spectra Physics Tsunami Ti-Sapphire laser coupled to a BioRad MRC 1024 LSCM. Excitation of indo-1 was achieved by 50-130 fs pulses of red light ( $\lambda=700-750$  nm) at 82 MHz. Emission was collected via a 405 nm bandpass filter and a 460 longpass filter. Under TP excitation, the isosbestic wavelength for indo-1, usually around 450 nm, shifted to a shorter wavelength (~410 nm).

CA1 neurones in hippocampal slices from young (~4 day old) rats showed increases in intracellular calcium in response to L-glutamate (L-Glu) (1-10 mM), AMPA (100  $\mu\text{M}$ ) and NMDA (100  $\mu\text{M}$ ). Stimulation of the Schaffer collateral/commissural pathway caused a rise in intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) in a few neurones, although the size of the responses and the number of responding cells was greatly increased in medium lacking  $\text{Mg}^{2+}$ . In cultured cerebellar granule cells, AMPA, NMDA and L-Glu evoked increases in  $[\text{Ca}^{2+}]_i$ . In addition, both acutely-prepared slices and cerebellar cultures showed evidence of spontaneous  $\text{Ca}^{2+}$  activity.

The financial support of the Wellcome Trust (UK) is gratefully acknowledged.

## 316.5

**CALCIUM ACTION POTENTIALS IN APICAL DENDRITES OF NEOCORTICAL PYRAMIDAL NEURONS IN RAT BRAIN SLICES.** J. Schiller\*, Y. Schiller and B. Sakmann. Max-Planck-Institut für Medizinische Forschung, Heidelberg, Germany, D-69120.

To explore synaptic integration in mature neocortical layer 5 pyramidal neurons in rat brain slices we performed double whole-cell voltage recordings from an apical dendrite and the soma of the same neuron combined with high speed calcium imaging measurements. Synaptic stimulation or dendritic current injection initiated dendritic action potentials in the distal apical dendrites, which in turn evoked a large calcium influx into these dendrites. Initiation of dendritic action potentials resulted from co-activation of dendritic voltage dependent calcium and sodium channels. Dendritic action potentials evoked by current injection were eliminated altogether by the addition of Cadmium, and their initiation threshold markedly increased after the addition of TTX. Initiation of dendritic action potentials by synaptic stimulation was blocked by addition of AMPA and NMDA receptor blockers. We conclude that apical dendrites of neocortical pyramidal neurons contain active conductances, which can support initiation of dendritic action potentials, and thus possibly are important in synaptic integration and amplification of synaptic potentials.

## 316.7

**SPATIALLY LOCALIZED CALCIUM TRANSIENTS IN HIPPOCAMPAL CA3 NEURONS PRODUCED BY MOSSY FIBER SYNAPTIC TRANSMISSION.** David B. Jaffe\*, Div. of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX 78249.

The hippocampal mossy fiber (MF) terminal field contains a lower density of NMDA receptors compared to other areas of the hippocampus. High-time resolution fluorescent imaging was used to test the hypothesis that MF synaptic transmission could produce localized increases  $\text{Ca}^{2+}$  in CA3 pyramidal neurons that is NMDA receptor-independent.

CA3 neurons in rat hippocampal slices were filled via patch pipettes with the  $\text{Ca}^{2+}$ -sensitive dye Fura-2. In addition, pipettes contained  $\text{Cs}^+$  and QX-314 to block  $\text{K}^+$  and  $\text{Na}^+$  currents. High-frequency stimulation (100 Hz, 1 second duration) of the MFs produced increases in  $\text{Ca}^{2+}$  in proximal dendrites. Distal dendritic signals were not detected. These transients were not blocked by the NMDA receptor antagonist D,L-APV (100  $\mu\text{M}$ , n=5). Furthermore, signals were detected when the membrane potential was raised above the reversal potential for ionotropic glutamate receptors (> 0 mV). Finally, in some cases MF-stimulated  $\text{Ca}^{2+}$  signals propagated approximately 5-15  $\mu\text{m}$  from initial sites of origin. The shape of the delayed transients along the dendrite was not consistent with diffusion of  $\text{Ca}^{2+}$  or the indicator dye.

These data suggest that tetanus of the MFs can trigger localized increases in  $\text{Ca}^{2+}$  independent of NMDA receptor activation.

This work was supported by the NSF-IBN 9511309.

## 316.4

**CONFOCAL RATIOMETRIC CALCIUM IMAGING IN HIPPOCAMPAL SLICE NEURONS DURING SYNAPTIC FREQUENCY POTENTIATION.** O. Thibault\*, R.W. Hadley and P.W. Landfield. Dept. Pharmacology, College of Medicine, Univ. Kentucky, Lexington, KY 40536.

Synaptic activation has been shown to induce calcium ( $\text{Ca}$ ) transients in dendritic and somatic compartments of CA1 hippocampal neurons. Both voltage-gated  $\text{Ca}$  channels and receptor-operated  $\text{Ca}$  channels contribute to this  $\text{Ca}$  influx. Although the frequency-dependence of postsynaptic  $\text{Ca}$  influx has been investigated in several studies, its relation to short-term synaptic plasticity (e.g. EPSP facilitation) has not been assessed in detail. Thus, it is not clear whether the magnitude of the EPSP facilitation determines the degree of  $\text{Ca}$  influx or conversely, whether large  $\text{Ca}$  transients in dendrites reduce EPSP conduction to the soma (by activating shunting conductances).

In the present study, we combined whole cell patch clamp recording and  $\text{Ca}$  imaging to determine the relationship of  $\text{Ca}$  influx to the magnitude of frequency potentiation (facilitation) of the EPSP during repetitive synaptic activation in adult (3-5 month-old) rat hippocampal slice CA1 neurons. We used the ratiometric dye Indo-1 (potassium salt) to monitor calcium entry with a rapid acquisition, UV-compatible confocal laser scanning microscope (Nikon RCM 8000). The neurons showed characteristic electrophysiological responses in the presence of Indo-1 in the recording pipette, including significant afterhyperpolarizations and large facilitation of the EPSPs during 7-10 Hz stimulation of stratum radiatum. Stimulation of the Schaffer-commissural pathway yielded large and sustained calcium transients in somatic and dendritic compartments, which appear to be related in a complex manner to the degree of frequency potentiation of the EPSP. (Supported by NIH AG04542, AG10836)

## 316.6

**ACTION POTENTIAL INITIATION IN NEOCORTICAL PYRAMIDAL NEURONS - REVISITED.** Greg Stuart\* and Bert Sakmann.

Abt. Zellphysiologie, MPI für medizinische Forschung, Heidelberg, Germany.

\* Present address: Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, Australia.

Simultaneous patch pipette recordings were made from the soma and main apical dendrite of neocortical layer V pyramidal neurons in brain slices from 28 day old rats at 35 °C. Synaptic stimulation of the distal apical dendrites at an intensity threshold for somatic action potential initiation usually evoked action potentials first at the soma, whereas high intensity synaptic stimulation often evoked dendritic regenerative responses prior to somatic action potentials (n=23). This apparent shift in the site of action potential initiation was observed with both whole-cell and cell-attached recordings (n=8). Dendritic electrogenesis was not observed during proximal synaptic stimulation and its time to onset relative to that of the somatic action potential was greater the more distal the dendritic recording site from the soma, indicating that this dendritic electrogenesis was generated in the distal apical dendrites. The occurrence of this dendritic electrogenesis could be modulated by changes in resting membrane potential following current injection via the somatic or dendritic recording pipettes. To investigate if this dendritic electrogenesis propagates faithfully to the soma and axon, simultaneous patch pipette recordings were made from the soma, dendrite and axon of the same cell. These experiments showed that action potentials were always initiated in the axon before the soma with the same onset latency and time to peak, independent of whether a dendritic regenerative response occurred or not (n=5). In conclusion, these findings suggest that synaptic stimulation can initiate dendritic regenerative responses in the distal apical dendrites of neocortical pyramidal neurons. These regenerative events, however, do not appear to propagate faithfully to the soma and axon, indicating that the final site of synaptic integration and action potential initiation in neocortical pyramidal neurons is always in the axon, even during dendritic electrogenesis.

**OMEGA-AGATOXIN-IVA-INSENSITIVE CALCIUM CHANNELS IN RAT CEREBELLAR PURKINJE NEURONS.** S. WATANABE<sup>1,2</sup>, T. MIYASHOU<sup>1,3</sup>, H. TAKAGI<sup>1</sup>, Y. KIRINO<sup>2</sup>, H. SUZUKI<sup>3</sup>, H. MIYAKAWA<sup>1\*</sup> and Y. KUDO<sup>1</sup>. <sup>1</sup>Tokyo Univ. of Pharmacy & Life Science, Tokyo 192-03; <sup>2</sup>Faculty of Pharmaceutical Sciences, The Univ. of Tokyo, Tokyo 113; <sup>3</sup>School of Science & Engineering, Waseda University, Tokyo 169, Japan.

Voltage-activated  $\text{Ca}^{2+}$  channels in mammalian neurons govern many physiological processes, such as transmitter release and neuronal dendritic integration. In rat cerebellar Purkinje neuron,  $\text{Ca}^{2+}$  influx is largely dependent on the activation of the voltage dependent  $\text{Ca}^{2+}$  channels induced by the firing of the action potentials. But the spatial distribution of  $\text{Ca}^{2+}$  channels and their contribution to physiological activity is not well understood. To help delineate the contribution of different channel types to somatic and dendritic functioning, we imaged  $\text{Ca}^{2+}$  increase in response to the depolarized voltage pulse and studied the effect of several specific  $\text{Ca}^{2+}$  channel antagonists on  $\text{Ca}^{2+}$  increase in the soma and dendrites of Purkinje neurons.  $\omega$ -Agatoxin-IVA (200 nM) blocked  $\text{Ca}^{2+}$  increase in Purkinje cell somata but did not show significant effect in dendrites, whereas  $\text{Ni}^{2+}$  (50  $\mu\text{M}$ ) reduced  $\text{Ca}^{2+}$  increase in dendrites. Blockers for other types of  $\text{Ca}^{2+}$  channels did not show significant effect on  $\text{Ca}^{2+}$  increase. These data indicate that  $\omega$ -Agatoxin-IVA-sensitive  $\text{Ca}^{2+}$  channels (P) are dominant in cell body and  $\text{Ni}^{2+}$ -sensitive  $\text{Ca}^{2+}$  channels (T or R?) are localized in dendritic region. These conclusions suggest that the different  $\text{Ca}^{2+}$  channel types participate in distinct physiological functions:  $\text{Ni}^{2+}$ -sensitive  $\text{Ca}^{2+}$  channels likely play a greater role in dendritic integration, whereas  $\omega$ -Agatoxin-IVA-sensitive  $\text{Ca}^{2+}$  channels are more important for somatic  $\text{Ca}^{2+}$ -dependent process.

Calcium Signals in the Zebrafish Mauthner Cell: Large Size and Potentiation with Repetitive Sensory Stimulation. D.M. O'Malley\* and J.R. Fetcho, Department of Neurobiology & Behavior, SUNY @ Stony Brook, NY 11794.

The Mauthner cell, a large reticulospinal neuron found in fish and amphibians, integrates an array of sensory inputs (auditory, visual and lateral line), and triggers a robust escape behavior. Mauthner cells in the hindbrain of intact larval zebrafish were retrogradely labeled with the fluorescent indicator calcium green dextran (CGD) to visualize *in vivo* the cells' activity during escape behaviors (Fetcho & O'Malley, 1995). In response to single sensory stimuli, the Mauthner cell soma often exhibited a large calcium signal (20% to 100% increase in CGD fluorescence). These large signals were evoked repetitively over hours or days, and consistently recovered rapidly and completely. The size of the calcium signals was surprising because the Mauthner cell is known to fire only a single action potential each time it triggers the escape behavior. Antidromic stimulation of the Mauthner cell with single shocks produced just the small fluorescence increases (5 to 10%) typically observed after single action potentials in other neuronal somata (e.g. rat thalamus, Zhou et al., '95; and bullfrog sympathetic neurons, O'Malley, '94). As a rough estimate, a 50% increase in CGD fluorescence corresponds to about a 145 nM calcium increase, while a 5% increase equates to about a 10 nM change. In many fish, the fluorescence increases were initially small, but with periodic stimulation, increased dramatically to the higher levels seen at the outset in other fish. Also, providing 3 sensory stimuli in succession (at 2.5 sec intervals within a trial), often produced one enhanced response, together with smaller responses in that trial. 1 mM caffeine also enhanced the calcium responses, suggesting a role for internal calcium stores. These potentiated calcium signals may represent a novel form of plasticity. Because calcium has powerful influences on cellular activities in the nucleus, soma, and dendrites, including the enhancement of auditory inputs to the Mauthner cell [Wolszon & Faber, 1988], these calcium signals are likely to have physiological consequences. LOCAL CALCIUM RELEASE BY  $\text{IP}_3$  IN PURKINJE CELL DENDRITES. E.A. Finch\* and G.J. Augustine, Dept. Neurobiology, Duke University Medical Center, Durham, NC 27710.

To characterize the spatial and temporal properties of  $\text{IP}_3$ -induced Ca release in dendrites, local photolysis of caged  $\text{IP}_3$  was used to generate rapid and focal increases in  $\text{IP}_3$  within Purkinje cells (PCs) in cerebellar slices. Localized photolysis of caged  $\text{IP}_3$  (2-10  $\mu\text{m}$  spots) evoked Ca release, which was monitored with Ca Green using confocal laser-scanning microscopy. In all regions of the dendritic arbor the Ca signals evoked by  $\text{IP}_3$  were highly restricted, in no case spreading more than 20  $\mu\text{m}$ , and were thus confined to one or a few dendritic branches. The time course of the Ca signal depended on the amount of  $\text{IP}_3$  generated, with the highest  $[\text{IP}_3]$  producing increases in  $[\text{Ca}]$  with a short latency (< 10 ms), fast rate of rise (< 10 ms), and  $[\text{Ca}]$  in the micromolar range. Brief pulses of  $\text{IP}_3$  produced transient Ca increases that declined to baseline levels within several seconds, whereas sustained or repetitive generation of  $\text{IP}_3$  produced longer-lasting increases in Ca. To further assess the effective range of released Ca, we used whole-cell recording to monitor the activation of dendritic Ca-activated K channels, which have a low affinity for Ca. K currents were activated only by  $\text{IP}_3$  concentrations that produced near-maximal Ca signals, indicating that Ca released from intracellular stores by  $\text{IP}_3$  can reach micromolar levels at the plasma membrane. Thus, in PC dendrites  $\text{IP}_3$  can produce large Ca signals that are restricted to small dendritic compartments. These findings are consistent with the idea that rises in postsynaptic  $\text{IP}_3$  can locally influence dendritic physiology during synaptic transmission. Supported by NS-09586 and NS-34045.

## POSTSYNAPTIC MECHANISMS: GLUTAMATE SIGNALS

PHARMACOLOGY OF CA1 PYRAMID TO ORIENTS ALVEUS INTERNEURONE CONNECTIONS IN HIPPOCAMPUS. Afia Ali and Alex M. Thomson\*, Dept. Physiology, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF, UK

CA1 pyramid to oriens alveus (O/A) interneurone connections were studied with dual intracellular recordings and biocytin-filling in slices of rat hippocampus. O/A interneurone somata were located at the O/A border with horizontally orientated spiny dendrites. Their axons ramified extensively in stratum lacunosum moleculare. In 3 pairs, trains of 4 presynaptic spikes elicited EPSPs showing strong paired pulse facilitation. To determine whether NMDA receptors contributed to EPSPs and to this facilitation, D-AP5 was applied in one pair. In control conditions the first 3 EPSPs in the train were larger and broader at -72 than at -78 mV (half widths 113, 110 and 112.5 %). However at -69 mV, the EPSPs were also smaller and narrower than at -72mV. Responses to brief current pulses showed a similar sensitivity to membrane potential. D-AP5 (62 $\mu\text{M}$ ) caused a more rapid decay of the EPSPs, which were up to 10% smaller and significantly narrower than under control conditions (half widths of the 4 EPSPs reduced by <10, 15, 20 and 15 % respectively). Prolonged application of D-AP5 lead to only a small change in membrane time constant (10.8 cf. 11.8msec). Subsequent addition of DNQX (20 $\mu\text{M}$ ) reduced the EPSP amplitude to <10% of control within 20 minutes. This work was supported by Sandoz Pharma, Basel.

## 316.10

IMPROVED SPATIAL RESOLUTION IN GLUTAMATE RECEPTOR MAPPING WITH A NOVEL AND INEXPENSIVE METHOD FOR TWO-PHOTON EXCITATION OF CAGED COMPOUNDS. D.L. Pettit\*, S.S.-H. Wang, K.R. Gee\* & G.J. Augustine, Dept. Neurobiology, Duke Medical Center, Durham, NC & \*Molecular Probes, Eugene OR.

'Caged' glutamate has been used to map the distribution of receptors and synaptic connections in brain slices. However, unfocused light causes photolysis of glutamate throughout the slice, limiting spatial resolution (Neuron 15:755). We have devised a simple solution to this problem using a glutamate derivative that has two caging groups, requiring absorption of two UV photons before conversion to active glutamate. Spatial resolution will be improved because the probability of generating active glutamate is high only near the focal point of the light beam. This is similar to two-photon excitation with a pulsed laser (PNAS 91:6629), but has the advantage that it can be performed with an inexpensive arc lamp. We tested the method via whole-cell patch clamp recordings from pyramidal neurons in rat hippocampal slices. Photolysis of either singly- or doubly-caged glutamate was accomplished by varying the focal point of a UV light beam positioned over the dendrites of the neurons. Glutamate-induced currents varied according to the z-axis position of the beam, with maximal responses evoked when the beam was focused on the dendrite. The relationship between axial position and current was well fit by a gaussian function, with a half-width that was significantly smaller for doubly-caged glutamate than for the singly-caged compound. Thus, doubly-caged compounds offer a simple and inexpensive way to improve spatial resolution in experiments requiring local photolysis of caged compounds. Supported by NH15177, NS17771, 09586 and 34045.

## 317.2

SYNAPTIC FACILITATION IN THE DENTATE GYRUS OF THE RAT: EFFECT OF STIMULATION SITE, TARGET SITE, AND MEASUREMENT PROTOCOL. J.Ferbinteanu, B.Srebro\* and N.W. Milgram University of Toronto-Scarborough Campus, 1265 Military Trail, Scarborough, Ontario M1C-1A4, and Department of Physiology, University of Bergen, Norway.

Although synaptic facilitation has been reported in the dentate gyrus, this is not true in all cases. Such inconsistencies could reflect differences in pathway tested, recording site, or possibly in parameter used to measure facilitation. To examine this problem, we studied synaptic facilitation of field excitatory postsynaptic potentials (fEPSPs) evoked by stimulation of either the lateral (LPP) or medial (MPP) perforant path. A three-pulse test procedure was used with a reference pulse followed by a conditioning test pulse pair. To avoid contamination of fEPSP, the intensity of the reference and test pulses were identical and were set at stimulation levels below threshold for triggering population spikes. We studied recording sites in both the molecular and granular cell layers and measured both the slope and amplitude of the fEPSP.

Consistent with previous literature, we found differences in parametric properties of fEPSPs evoked by LPP and MPP stimulation. In addition, stimulation of the LPP produced more robust facilitation than MPP. Facilitation also varied as a function of the recording site; greater facilitation was recorded in the molecular layer. The results varied as a function of the parameter used to estimate fEPSP, more consistent facilitation was obtained with the amplitude measure. Further analysis confirmed that for the fEPSP the slope and amplitude parameters are not interchangeable. A regression analysis revealed a low correlation between the slope and amplitude measurements. This low correlation was a reflection of non-linearity of the slope function, which contrasts with the assumption commonly made. This non-linearity is probably a reflection of co-activation of excitatory and inhibitory postsynaptic potentials.

POST-SYNAPTIC CONDUCTANCES CAUSE NON-LINEAR SUMMATION OF AMPA-MEDIATED EPSPs IN RAT NEOCORTICAL LAYER V PYRAMIDAL NEURONS. J.S. Nettleton\* and W.J. Spain. Depts. of Neurology and Physiology and Biophysics, Univ. of Washington and The VA Puget Sound Health Care System, Seattle, WA 98108.

It is hypothesized that voltage sensitive conductances present on the soma and dendrites of neurons, cause non-linear summation of EPSPs. We tested this hypothesis in layer V pyramidal neurons using intracellular recording with sharp electrodes in the presence of 100  $\mu$ M AP-5 (NMDA blocker) and 3  $\mu$ M Bicuculline (GABA<sub>A</sub> blocker). This isolates the AMPA response but does not completely disinhibit the slice. Subthreshold AMPA EPSPs (1-10mV) were induced by a stimulating electrode in layer I (E1), and another one in the layers II-V (E2). The areas of stimulation were isolated from each other by a cut just below layer I. To block post-synaptic conductances, 50 mM QX-314 was included in the recording electrode in some experiments. We quantified the summation as an area ratio (area of experimentally measured response to area of the mathematical sum of the individual stimulus responses, E1+E2). In approximately 50% of the cells, the response to the two stimuli temporally spaced 5-10 ms apart was >10% larger than the mathematical sum and 20% of all cells had > 25% increase. In contrast, ~90% of the QX-314 loaded cells summed linearly. The average area ratio was statistically different in the QX-314 vs. non QX-314 loaded cells (two-tailed Student's T-test,  $P < 0.05$ ). These results demonstrate that post-synaptic conductances can alter EPSP summation. Preliminary data in which current pulses applied at the soma were summed with a layer I evoked EPSP, suggest that the non-linear boosting occurs in the apical dendrite.

## 317.5

KAINATE-INDUCED CURRENTS IN CA3 HIPPOCAMPAL NEURONS. M. Vignes\*, C. Mathiesen and G.L. Collingridge. Dept. of Anatomy, University of Bristol, Bristol BS8 1TD, UK.

We have investigated the postsynaptic effects of kainate receptor activation in CA3 hippocampal neurons. Whole-cell patch clamp recordings were performed on hippocampal slices, prepared from 12-15 day old rats, perfused with a standard medium  $Mg^{2+}$ -containing medium at room temperature. GABA receptor-mediated responses, i.e. GABA<sub>A</sub> and GABA<sub>B</sub>, were inhibited respectively by applying picrotoxin (50  $\mu$ M) in the perfusion and by Cs<sup>+</sup> in the recording electrode. The perfusate also included GYKI 52466 (100  $\mu$ M) and AP5 (50  $\mu$ M), in order to block AMPA and NMDA receptors, respectively.

Under these conditions, the application of 200nM kainate evoked inward currents ( $-81 \pm 8$  pA,  $n=11$ ) accompanied by a decrease in the input resistance. These effects were reversible and antagonized by the non-NMDA receptor antagonist CNQX ( $83 \pm 6\%$  reversal, 10  $\mu$ M,  $n=5$ ). In contrast, AMPA was much weaker under these conditions ( $-30 \pm 6$  pA, 10  $\mu$ M,  $n=7$ ). Thus, kainate is a potent excitant of CA3 neurons via the activation of kainate receptors. In comparison, kainate is a weaker excitant in area CA1 under similar conditions. For example, inward currents of 10-30 pA were induced by 1  $\mu$ M kainate (Chittajallu et al., *Nature*, 379, 78-81, 1996).

## 317.7

REUPTAKE CONTRIBUTES TO THE REMOVAL OF GLUTAMATE FROM THE SYNAPTIC CLEFT OF RAT CEREBELLAR GRANULE AND UNIPOLAR BRUSH CELLS. N.T. Slater\* and G.A. Kinney. Department of Physiology, Northwestern University Medical School, Chicago, IL, 60611 U.S.A.

The contribution of transporters to the removal of glutamate from the synaptic cleft during transmission has been controversial; inhibitors of glutamate transport have been observed to prolong the AMPA receptor-mediated synaptic current evoked by single stimuli at some synapses, but are without effect at others. However, the contribution of reuptake to the removal of glutamate following single EPSCs may be masked by rapid receptor desensitization. Moreover, many of the pathways examined normally fire at high frequencies, during which glutamate transport may play a more prominent role. To examine this issue further we have studied the actions of the glutamate transport inhibitor L-trans-PDC on the time course of the AMPA receptor-mediated synaptic current in cerebellar granule (GC) and unipolar brush cells (UBCs; D.J. Rossi et al. *J Neurophysiol* 74:24, 1995) using whole-cell recording in thin slices of rat vestibular cerebellum (nodulus). In GCs, the decay of single, pharmacologically-isolated AMPA EPSCs were best fit as the sum of two exponentials ( $\tau_1=3.8$  ms;  $\tau_2=53.1$  ms,  $n=6$ ); the slow component was prolonged by 100  $\mu$ M L-trans-PDC ( $\tau_2=99.7$  ms,  $n=6$ ) and the EPSC peak was reduced (25%). In the presence of 100  $\mu$ M cyclothiazide (to block desensitization), a similar enhancement of the slow component was observed (cyclothiazide alone:  $\tau_1=13.8$  ms;  $\tau_2=139.5$  ms; cyclothiazide + L-trans-PDC:  $\tau_1=15.7$  ms;  $\tau_2=388.4$  ms,  $n=8$ ). With repetitive stimulation (7 stimuli at 40 Hz) a significant enhancement in the net charge was observed ( $39 \pm 17\%$ ,  $n=4$ ) in the presence of L-trans-PDC alone. In UBCs the peak amplitude of the fast EPSC was reduced and the net charge enhanced by L-trans-PDC. The data are consistent with the notion that reuptake contributes to the removal of glutamate from the synaptic cleft at both small (GC) and large (UBC) diameter contacts. This process primarily shapes the synaptic current when glutamate is present within the cleft for prolonged periods, during repetitive activity at small synapses and the prolonged entrapment of glutamate at the giant UBC synapse. ## 317.4

NON-NMDA RECEPTOR OCCUPANCY AND OPEN PROBABILITY DURING TRANSMISSION AT SYNAPSES WITH ONE RELEASE SITE.

R. Angus Silver\*, Stuart G. Cull-Candy and Tomoyuki Takahashi. Pharmacology, University College London, London WC1E 6BT, UK.

Neurophysiology, Institute for Brain Research, University of Tokyo, Japan.

The fraction of postsynaptic receptors occupied following the release of a quantum of transmitter is a fundamental synaptic parameter. At the neuromuscular junction receptors are not saturated. However, at central synapses receptor saturation has been widely postulated. We have investigated non-NMDA receptor occupancy and open probability ( $P_o$ ) during transmission at rat cerebellar mossy fibre-granule cell synapses with one functional release site. EPSCs from single site synapses were identified on the basis of their lack of dependence of amplitude on release probability. Release probability was altered by changing the  $[Ca^{2+}]/[Mg^{2+}]$  ratio in the external solution, and the mean EPSC amplitude (excluding failures) was measured. We have modelled transmitter release at synapses with different numbers of release sites and have developed a criterion for identifying synapses with one release site. Although synapses identified with this method are likely to have only one release site, the presence of additional release sites with low release probabilities cannot be ruled out. Postsynaptic receptor open probability was calculated in two ways. A lower limit was estimated from the coefficient of variation of the single-site EPSCs, and an upper limit was calculated from the ratio of the mean EPSC amplitude and the largest EPSC amplitude. Postsynaptic receptor occupancy was estimated from  $P_o$  by dividing by the maximal open probability. These limits for occupancy (0.45-0.6) suggest that release of a quantum of transmitter does not saturate non-NMDA receptors at the cerebellar mossy fibre-granule cell synapse.

ACTIVATION OF A SINGLE PYRAMIDAL NEURON SUPPRESSES EXCITATORY TRANSMISSION IN CA1 STRATUM RADIATUM OF RODENT HIPPOCAMPUS. Y. Yanovsky<sup>1</sup>, D. Stevens<sup>1</sup>, J.T. Sanz<sup>2</sup>, E.H. Buhl<sup>2</sup> and H.L. Haas<sup>1</sup>. <sup>1</sup>Institute of Physiology, Heinrich-Heine-University, Düsseldorf, Germany and <sup>2</sup>MRC Anatomical Neuropharmacology Unit, University of Oxford, Oxford, UK

Pyramidal cells in the CA1 area of the rodent hippocampus target with their recurrent collaterals both neighboring pyramidal cells and GABAergic interneurons. We studied the efferent target selectivity of biocytin labeled pyramidal cells ( $n=2$ ) employing random electron microscopic sampling of pyramidal cell synaptic boutons. We found the recurrent output of CA1 pyramidal cells heavily biased towards GABAergic local-circuit neurons, since 50% ( $n=10$ ) of the pyramidal cell terminals were found in synaptic contact with dendritic shafts displaying the characteristic electron microscopic features of non-principal cells. Strong intracellular stimulation of single pyramids (10 bursts, 0.5 s, 0.5 nA at 0.1 Hz) but not an equal number of dissipated action potentials, reduced excitatory transmission in the apical dendritic region in slices from mouse hippocampus by  $19 \pm 7\%$  (SE,  $n=36$ ) with a delayed onset and for prolonged periods in two phases. The first phase had a duration of ca. 20 min, the second lasted usually longer than 1 hour. EPSPs in the stimulated pyramids were increased for equally long periods but this was not the cause of the field EPSP reduction. Paired pulse facilitation of the field EPSPs was unchanged indicating a postsynaptic effect. At least part of the effect may be mediated by metabotropic glutamate receptor activation.

## 317.8

THE SLOW TIME COURSE OF AMPA RECEPTOR-MEDIATED SYNAPTIC CURRENTS IN RAT CEREBELLAR UNIPOLAR BRUSH CELLS REFLECTS AN ENTRAPMENT OF GLUTAMATE IN THE SYNAPTIC CLEFT.

G.A. Kinney\*, L.S. Overstreet and N.T. Slater. Department of Physiology, Northwestern University Medical School, Chicago, IL, 60611 U.S.A.

Activation of glutamatergic mossy fibers afferents to unipolar brush cells (UBCs) of mammalian vestibular cerebellum evokes a long-lasting synaptic current (>2 s) with a biphasic AMPA receptor-mediated component displaying a late peak at ~300 ms (D.J. Rossi et al. *J Neurophysiol* 74:24, 1995). It was proposed that this reflects an entrapment of glutamate in the synaptic cleft, and the slow EPSC results from a steady-state current. To further examine this proposal, AMPA receptor-mediated synaptic currents in UBCs were recorded using whole-cell recording in thin slices of rat cerebellar nodulus at 22°C. In double-pulse experiments, the peak of the fast EPSC, which will probe for the fraction of available receptors, was depressed in amplitude compared to the peak of the first stimulus, and recovered with a slow time course ( $t_{1/2} = 200$  ms) which mirrored the time course of synaptic currents in the presence of cyclothiazide. The steady-state dose-response curve for glutamate acting at AMPA receptors, measured in excised patches from both UBCs and granule cells, was biphasic, peaking at 50  $\mu$ M, and declining to 50-70% of this value at 1 mM. When glutamate was slowly washed from patches to simulate the slow decline of [glutamate] in the synaptic cleft, the steady-state current displayed a marked hump in patches from both cell types. In UBCs displaying slow EPSCs, reduction of release probability by lowering extracellular  $[Ca^{2+}]$  from 2.5 to 1.0 mM eliminated the slow EPSC, and it was restored at 1 mM  $[Ca^{2+}]$  by a brief repetitive stimulus (2-5 stim at 40 Hz). Similarly, slow EPSCs were revealed or enhanced in UBCs by repetitive stimuli. Taken together, these results support the hypothesis that the slow AMPA receptor-mediated EPSC in UBCs reflects a long-lasting entrapment of glutamate in the synaptic cleft, and the time course of this current is sculpted by the kinetic properties of the postsynaptic receptor. Supported by the NIH (NS34840 to N.T.S.).

## 317.9

**CROSS TALK BETWEEN EXCITATORY SYNAPSES IN THE HIPPOCAMPUS.** D.E. Bergles\* and C.E. Jahr. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Diffusion of transmitter to adjacent synapses has been suggested as a mechanism for heterosynaptic depression at both excitatory and inhibitory synapses. Despite this evidence that transmitters can diffuse for some distance, evidence for the activation of postsynaptic receptors by transmitter diffusing from neighboring release sites, or cross talk, is equivocal (Diamond and Jahr, 1995; Mennerick and Zorumski, 1995), except at calyceal synapses (Trussell et al., 1993) or when transmitter reuptake is reduced (e.g. Isaacson et al., 1993). We investigated whether the concentration profile of glutamate is prolonged at excitatory synapses in acute hippocampal slices when the probability that neighboring sites are releasing glutamate is increased.

The time course of glutamate in the synaptic cleft has been estimated in culture by measuring the non-equilibrium inhibition of NMDA EPSCs by the rapidly-dissociating antagonist D-aminoadipate (D-AA) (Clements et al., 1992). We recorded NMDA EPSCs ( $V_h = +40$  mV) from CA1 pyramidal neurons in acute slices prepared from 11-15 day old rats, and compared the inhibition obtained with DL- $\alpha$ -aminopropionate (DL-APA), an antagonist with a  $\sim 5$ x faster unbinding rate than D-AA, under low and high stimulus intensities (a manipulation which changes the number of active fibers, but does not change release probability). At elevated release probability, the amount of inhibition of NMDA EPSCs by DL-APA was less at high stimulus intensity ( $73 \pm 6\%$ ) than at low stimulus intensity ( $82 \pm 5\%$ ). In contrast, NMDA EPSCs evoked at high and low stimulus intensities were reduced the same amount with D-carboxypiperazin-propyl-phosphonate (D-CPP) (low:  $85 \pm 4\%$ ; high:  $84 \pm 3\%$ ), an antagonist with a  $\sim 1000$ x slower unbinding rate. These data suggest that increasing the density of active synapses increases the concentration profile of glutamate seen by NMDA receptors at some synaptic sites through intersynaptic diffusion.

Supported by NIH NS21419.

## 317.11

**MAGNESIUM SENSITIVITY OF SYNAPTIC NMDA RECEPTORS IN RAT SPINAL CORD LAMINA I AND II NEURONS DURING POSTNATAL DEVELOPMENT.** R. Bardoni\*, P.C. Magherini & A.B. MacDermott. Dept. of Biomedical Sciences, Univ. of Modena, Modena (Italy), I-41100 and Dept. of Physiology and Cellular Biophysics, Columbia Univ., New York, NY 10032.

NMDA receptors have been shown to mediate activity-dependent developmental changes in motoneurons during a critical time in early postnatal development (Kalb & Hockfield 1992) but there is little information concerning the possible roles of NMDA receptors in synaptic transmission and synaptic maturation during postnatal development in the spinal cord dorsal horn. The first two postnatal weeks are the most active time of synaptic maturation in rat dorsal horn (Fitzgerald 1985). Therefore, we have tested for developmental changes in one of the most physiologically important properties of the NMDA receptors, voltage-dependent  $Mg^{2+}$  block, as a first step towards understanding the developmental role of NMDA receptor in the dorsal horn. NMDA EPSCs were recorded in spinal cord slices from postnatal rats (P2-P15). Whole cell patch clamp recordings were made from lamina I and II neurons. The neurons were visually identified, using a modification of the infrared video imaging system (Bardoni et al. 1995). EPSCs were evoked by focal stimulation in the proximity of the patch-clamped cell. During the first 2 postnatal weeks, as in the adult (Yoshimura & Jessell 1990), the EPSCs evoked at  $-70$  mV in normal Krebs (1 mM  $Mg^{2+}$ ) were mediated predominantly by non-NMDA receptors (blocked by  $10 \mu M$  CNQX). However, a large NMDA receptor-mediated component, monitored at  $+50$  mV, was present in cells from P2-P15. These NMDA EPSCs were strongly blocked at  $-70$  mV in a  $Mg^{2+}$ -dependent manner. For example, at  $-70$  mV, current amplitude increases by 18 times in  $0$   $Mg^{2+}$  bath in neurons from P3-P4 rats. These results indicate that NMDA receptors are expressed postsynaptically as early as P2 in lamina I and II neurons in rat dorsal horn and that they are strongly  $Mg^{2+}$ -sensitive throughout the main period of synaptic maturation. This work was supported by MURST, NSF, NIH and Whitehall Foundation.

**DEVELOPMENTAL CHANGES IN NMDA RECEPTOR-MEDIATED SYNAPTIC TRANSMISSION TO RAT MOTONEURONS.** J.H. Singer, M.C. Bellingham\*, and A.J. Berger. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195-7290.

We examined the development of the NMDA receptor (NMDA-R) component of glutamatergic excitatory postsynaptic currents (EPSCs) recorded in visualized hypoglossal motoneurons (HMs) in transverse brainstem slices from rats in three age groups: P1-2 (group 1), P8-11 (group 2), P16-26 (group 3). Monosynaptic NMDA-R mediated EPSCs were evoked by extracellular stimulation in the reticular formation just ventrolateral to the hypoglossal motor nucleus (n.XII) in the presence of strychnine ( $10 \mu M$ ), bicuculline ( $10 \mu M$ ), and DNQX ( $20 \mu M$ ) to block glycine, GABA $_A$ , and AMPA/kainate receptor mediated currents, respectively. The remaining current displayed a region of negative slope conductance at depolarized holding potentials ( $-30$  mV) and was blocked by APV ( $50 \mu M$ ), indicating that it was, indeed, NMDA-R mediated. At  $-30$  mV, the peak current in group 1 HMs was  $-316.7 \pm 72$  pA ( $n=4$ ). This decreased to  $-149.9 \pm 27$  pA in group 2 HMs ( $n=4$ ) and to  $-77.1 \pm 35$  pA in group 3 HMs ( $n=3$ ). These data support the hypothesis that NMDA-R mediated synaptic transmission decreases dramatically over the first four weeks of postnatal development.

**MIDDLE TERM POTENTIATION OF MINIATURE EXCITATORY POSTSYNAPTIC CURRENTS IN CULTURED RAT SUPERIOR CERVICAL GANGLION NEURONS.** Shirasaki, T.\*<sup>1</sup>, Liu, C.<sup>1</sup>, Lu, F.<sup>2</sup>, Kuba, K.<sup>2</sup> <sup>1</sup>Dept. of Physiol. Saga Med. Sch., Saga 849; <sup>2</sup>Dept. of Physiol., Nagoya Univ. Sch. of Med, Showa-Ku, Nagoya 466, Japan

The amplitude of nicotinic miniature excitatory postsynaptic currents (MEPSC) grows during a high  $K^+$  ( $40$  mM) treatment and it lasts for more than 20 min after the treatment in rat cultured superior cervical ganglion neurons. The potentiation of MEPSC was seen in about one third of neurons studied and accompanied by the potentiation of acetylcholine (ACh)-induced currents. These middle term potentiation of MEPSC and ACh-induced current were produced in similar time course by the conditioning application of a nicotinic agonist, dimethylphenylpiperazinium (DMPP) or ACh in the presence of atropine. Intracellular application of BAPTA  $5$  mM abolished the increases in both intracellular free  $Ca^{2+}$  concentration and high  $K^+$ -induced MEPSC potentiation. Calmodulin dependent kinase II (CaMKII) inhibitor, KN62, blocked the generation of MEPSC potentiation. However, an inactive analog, KN04, had not such effects. The magnitude of potentiation of ACh-induced currents induced by a high  $K^+$  or ACh treatment was smaller as the test ACh responses became greater. These results suggest that  $Ca^{2+}$  entered through nicotinic ACh receptor channels enhances its activation via activation of CaMKII, leading to the middle term potentiation of MEPSC in rat sympathetic neurons.

## 317.12

**ATTENUATION OF EPSPS IN THE DENDRITES OF MOTONEURONS FROM ORGANOTYPIC RAT SPINAL CORD CULTURES.** M. Larkum, T. Launey, A. Dityatev and H.-R. Lüscher\*. Dept. of Physiol., Univ. of Bern, Switzerland CH-3012.

Motoneurons *in vivo* receive a large number of synaptic inputs. To understand how they process this input to generate action potentials, it is necessary to determine the influence of dendritic properties on the integration of synaptic input. Recently we have shown that it is possible to simultaneously record excitatory postsynaptic potentials (EPSPs) in the dendrites and somata of motoneurons from organotypic rat spinal cord slice cultures (Larkum et al. *J. Neurophysiol.* **75**:154-170, 1996). Here we present the results of experiments with two electrodes patched either on the soma and a dendrite or on two different dendrites allowing us to measure the attenuation of subthreshold signals in the dendritic tree.

Spontaneous signals were detected using a modified version of an algorithm devised by Ankri et al. (*J. Neurosci. Meth.* **52**:87-100, 1994). With two electrodes, the location of the synaptic input could be placed into one of three categories: distal to electrode 1, distal to electrode 2 or between the two electrodes. Regression lines could be fitted through clusters of points representing these different populations by comparing the amplitudes of events at both electrodes. The likelihood that there were one, two or three populations was calculated using Wilks statistics. This method applied to simulated data was found to accurately predict both the number of populations and the attenuation of signals. The data recorded from motoneurons in organotypic cultures indicate that the somato-dendritic trees were quite compact electrically but suggest that the soma can greatly affect the spreading of EPSPs from one dendrite to another.

**DIRECT MEASUREMENT OF COUPLING BETWEEN DENDRITIC SPINES AND SHAFTS MEASURED USING TWO-PHOTON EXCITATION PHOTOBLEACHING AND PHOTOACTIVATION.** W. Denk, K. Svoboda\*, and D.W. Tank. Lucent Technologies, Bell Laboratories, Murray Hill, NJ 07974.

Dendritic spines are attached to their parent dendrite via a thin neck. Speculation regarding the functional significance of spines has centered on the presumably large diffusional and electrical resistance of the spine neck. We measured the time-course of diffusional exchange between spines and their parent dendrite. CA1 pyramidal cells in slices of rat hippocampus were dialyzed and voltage clamped using whole-cell electrodes containing  $200 \mu M$  fluorescein dextran ( $MW = 3$  kD) at  $22-24^\circ C$ . Single spine heads were photobleached using two-photon excitation of fluorescence and the fluorescence recovery due to diffusional exchange with the parent dendrite was characterized with two-photon microscopy (line-scan mode,  $2$  ms temporal resolution). Fluorescence recovered completely with an exponential time course with time constants in the range  $\tau = 20 - 100$  ms. Experiments using two-photon uncaging of fluorescein dextran gave consistent results. Spine heads are therefore diffusively isolated on this time scale. The time constant of fluorescence recovery by diffusion can be expressed as  $\tau = lV_h / AD$ , where  $l$  and  $A$  are the length and cross sectional area of the spine neck respectively,  $V_h$  is the spine head volume, and  $D$  is the dextran diffusion coefficient. The spine neck resistance is then  $R_n = \tau D_p / V_h$ . Comparing spine head fluorescence intensity distributions to published electron microscopy data provided an estimate of  $V_h$ .  $D = 1.0 \times 10^{-6} \text{ cm}^2/\text{s}$  was measured *in vitro* using photo-release techniques. Using a cytoplasmic resistivity of  $\rho_i \sim 250 \Omega \text{ cm}$ , we estimate  $R_n = 4 - 50 \text{ M}\Omega$ . The spine neck conductance ( $G_n = 5-30 \text{ nS}$ ) is large compared to unitary synaptic conductances ( $< 500 \text{ pS}$ ), implying that the neck does not attenuate synaptic current, and therefore cannot be used to control synaptic weight. We estimate that during synaptic activation the spine head potential is elevated by at most  $3$  mV with respect to the dendrite.

**DEMONSTRATION OF N-METHYL-D-ASPARTATE (NMDA) MINIATURE EXCITATORY POSTSYNAPTIC CURRENTS IN RAT MOTONEURONS.** J.A. O'Brien and A.J. Berger. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195-7290.

Whole-cell patch-clamp recordings were used to study NMDA miniature excitatory postsynaptic currents (mEPSCs) in hypoglossal motoneurons (HMs) from neonatal rats 1-8 days old. HMs were identified using Normarski optics and infrared transillumination of transverse brainstem slices, 300  $\mu$ m thick. NMDA mEPSCs were recorded from HMs bathed in nominally  $Mg^{2+}$  free extracellular solution containing TTX (1  $\mu$ M), bicuculline (20  $\mu$ M), strychnine (20  $\mu$ M), and DNQX (10  $\mu$ M) while voltage clamping the cells at -80 mV (n=4). NMDA mEPSCs were completely abolished by addition of  $Mg^{2+}$  (3 mM, n=3) to the bathing solution. Additionally, NMDA mEPSCs were also abolished by the addition of APV (50  $\mu$ M, n=3) to the bathing solution.

The global mean amplitude and interevent interval of NMDA mEPSCs were  $-13.0 \pm 2.4$  pA and  $1.37 \pm .91$  seconds, respectively. NMDA mEPSC kinetics were studied by fitting a single exponential to the decay phase of each mEPSC. The global average  $\tau$  was  $11.9 \pm 4.6$  ms. Addition of 50 mM sucrose to the bathing solution increased the frequency of mEPSCs without changing the mEPSC amplitude (n=3), suggesting that the NMDA mEPSCs were due to presynaptic release of glutamate. We conclude that it is possible to identify NMDA mEPSCs, based on their pharmacological properties, in HMs from neonatal rats. (Supported by NS 14857)

**THE PHYSIOLOGY OF EXCITATORY SYNAPSES IN THE LATERAL AND BASOLATERAL AMYGDALA.** N.K. Mahanty\* and P. Sah. The Neuroscience Group, Department of Physiology, Faculty of Medicine, University of Newcastle, Newcastle, NSW 2308, AUSTRALIA.

The amygdala is a part of the limbic system which has been implicated in the acquisition of fear conditioning. Little is known about the synaptic physiology in the various subregions of the amygdala. We investigated the excitatory synaptic physiology of the input from the external capsule (e.c.) to the lateral (LA) and basolateral (BLA) amygdala. Experiments were performed on coronal or horizontal slices of the amygdala from 18-22 day old rats at room temperature. Recordings were made from neurones in the amygdala using the "blind" whole cell technique using biocytin containing electrodes. Cells were classified as pyramidal or interneurons, based on their morphology, capacitive transient, and their ability to elicit an AHP.

Synaptic inputs were stimulated using bipolar stimulating electrodes placed over the e.c. Inhibitory inputs were blocked with picrotoxin (50  $\mu$ M). At a holding potential of -60 mV stimulation of the e.c. elicited short latency inward currents. Depolarisation of the cell revealed an additional slow component to the synaptic current. The fast component had a linear current-voltage relation while the slow component exhibited a region of negative slope conductance. The fast component was selectively blocked by the non-NMDA receptor antagonist CNQX (10  $\mu$ M). In contrast, the slower component was selectively blocked by the NMDA receptor antagonist d-AP5 (50  $\mu$ M). Spontaneous synaptic potentials (minis) recorded in the presence of tetrodotoxin (1  $\mu$ M) at -70 mV had a fast rise time and monophasic decay. At +50 mV a second slower component was seen which was blocked by d-AP5 (50  $\mu$ M). These results demonstrate that synaptic transmission between the e.c. and the lateral, and basolateral, amygdala is glutamatergic, and that the NMDA and AMPA receptors are co-localised in the post synaptic membrane. **Cytokine-activated microglia enhance the neurotoxicity of glutamate in primary culture of rat cerebellar granule cells.** W.K. Kim\* and Y.S. Pae. Dept. of Pharmacol., College of Medicine; Div. of Neurosci., Medical Research Center, Ewha Womans University, Seoul, Korea.

Microglia have been shown to be activated by inflammatory cytokines and produce a number of toxic mediators. Here we report that activated microglia can enhance the glutamate-mediated neurotoxicity in rat cerebellar granule cells in culture. Neurotoxicity was assessed by measuring the leakage of lactate dehydrogenase and/or by counting the cells stained with trypan blue during the 18-24 hour incubation following exposure to glutamate. Cultured microglia were activated by lipopolysaccharides (LPS, 1.0  $\mu$ g/ml for 2 hour) and  $\gamma$ -interferon ( $\gamma$ -IFN, 1000 U/ml for 2 hour) and 2 days later were used for co-culture with cerebellar granule cells. Activated microglia induced cerebellar granule cell damage less than 20%. In pure culture of cerebellar granule cells, a 2-min exposure to glutamate (100  $\mu$ M) resulted in neuronal cell death less than 20%. However, glutamate-mediated neurotoxicity was synergistically potentiated in co-cultures of cerebellar granule cells and activated microglia: over 80% of neuronal cells were killed by the 2-min exposure to 100  $\mu$ M glutamate. Similar potentiation of glutamate action was also found when cerebellar granule cells were briefly exposed to glutamate and then co-cultured with activated microglia. These observations suggest that during ischemic brain injury cytokine-activated microglia may be implicated in the inflammatory reaction and potentiate the glutamate-mediated neurotoxicity as well. (This work was partially supported by U.Research Grant (for W.K. Kim)).

## 318.2

**IMAGING SWELLING OF THE NEOCORTEX DURING ACUTE EXCITOTOXICITY.** Nicole G. Rolfe\* and R. David Andrew. Department of Anatomy and Cell Biology, Queen's University, Kingston, Ontario K7L 3N6.

Neuronal swelling is considered an early excitotoxic event, the result of excessive release of glutamate that leads to receptor mediated  $Na^+$  influx followed by  $Cl^-$  and water. Until recently, studies of excitotoxicity have investigated cell body swelling in culture or in histological sections that are sampled hours or days post-trauma. Swelling of CA1 dendritic regions in the hippocampal slice is inducible within minutes by glutamate agonists or ischemia as measured by real time increases in light transmittance (LT) (Andrew and colleagues, this meeting). Regional elevation of LT is an indirect measure of increased cell volume in the hippocampal slice (Andrew and MacVicar, 1994). Because swelling of the cerebral cortex can be a lethal consequence of trauma/ischemia, we hypothesized that frontal and parietal neocortical slices from the rat might display swelling, detectable as elevated LT, in response to glutamate agonists. Bath application of 100  $\mu$ M NMDA for 1 min at 35°C increased LT in layers I-V by 40 to 60% but not in underlying white matter (n=6). The NMDA response was completely blocked by pre-application of 100  $\mu$ M of the NMDA antagonist AP-5 (n=4). A 1 min exposure to 100  $\mu$ M kainate evoked a temporally and regionally similar response that was blocked by 10  $\mu$ M of the non-NMDA antagonist CNQX. Preliminary spectrometry revealed that the LT increased across the 400 to 800 nm spectrum which further supports cell swelling rather than narrow band activation of chromophores (e.g. cytochromes).

We conclude that a 1 min application of a NMDA or non-NMDA glutamate agonist evokes pronounced and reversible swelling in neocortex similar to that seen in dendritic regions of the hippocampal CA1 region. Whether longer exposure times lead to neuronal death (as in CA1) is currently being examined. Supported by the Heart & Stroke Foundation of Ontario and the Canadian MRC

## 318.3

**THIOPENTAL REDUCES NMDA AND AMPA INDUCED NEURONAL DAMAGE IN THE RAT HIPPOCAMPAL SLICE.** Heshen Zhu, Jia S. Kass\* and James E. Cottrell. Departments of Anesthesiology and Pharmacology, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203

Thiopental is a common anesthetic agent that shows protection against cerebral anoxia. To examine whether such protection involves the attenuation of glutamate excitotoxicity, the effect of thiopental on NMDA and AMPA induced neuronal damage was investigated. Extracellular responses in CA1 pyramidal cells due to Schaffer collateral stimulation were quantified by measuring the amplitude of the post-synaptic evoked population spike (P.S.). The percentage recovery after thiopental and/or NMDA/AMPA was calculated by dividing the amplitude of the P.S. after the treatment by its pre-treatment value. The duration of NMDA (25 $\mu$ M) or AMPA (15 $\mu$ M) application was 10 minutes. Thiopental (600 $\mu$ M) was present 15 min before, during and 10 min after the NMDA or AMPA treatment. The recovery of the P.S. in both thiopental groups is significantly better than that with NMDA or AMPA alone (see Table). This demonstrates that thiopental can improve recovery of rat hippocampal slices from NMDA and AMPA induced neuronal damage, if it is present before, during and shortly after the insult. Hence, blockade of the NMDA and AMPA mediated glutamate excitotoxicity may be one mechanism by which thiopental protects against anoxic damage. (Supported by funding: NIGMS GM38866)

Table Effect of thiopental on the percentage recovery of the P.S.

	1 hr	2 hr	3 hr	4 hr	5 hr

**LOW-AFFINITY INDICATORS DISTINGUISH LETHAL CALCIUM ENTRY DURING GLUTAMATE RECEPTOR ACTIVATION IN CULTURED NEURONS.** K.L. Hyc\* S.D. Handran, S.M. Rothman, and M.P. Goldberg. Center for the Study of Nervous System Injury, Washington Univ. School of Med., St. Louis, MO 63110.

Although abundant evidence suggests that calcium entry participates in excitotoxic neuronal death, studies using fluorescent calcium indicators have failed to show a relationship between intracellular free calcium concentrations ( $[Ca^{2+}]_i$ ) and subsequent neuronal injury. One explanation may be that conventional indicators, such as fura-2, are limited by their high affinity for  $Ca^{2+}$  ( $K_d = 0.2 \mu$ M) and can not assess potentially toxic  $[Ca^{2+}]_i$  levels above 1-2  $\mu$ M. We examined this hypothesis using fluorescence videomicroscopy with the ratiometric, low-affinity  $Ca^{2+}$  indicator, benzothiazole coumarin (BTC;  $K_d = 7-14 \mu$ M; Iatridou et al., *Cell Calcium*, 15:190, 1994).

Murine cortical neuronal cultures were loaded with either fura-2/AM or BTC/AM (6  $\mu$ M). Confocal microscopy showed that labeling with BTC/AM or BTC free acid (microinjected by patch electrode) was uniformly distributed throughout the neuronal cytoplasm. Cultures were exposed for 10-15 min to 100-300  $\mu$ M NMDA, 100-300  $\mu$ M glutamate, 300-500  $\mu$ M AMPA, or 50 mM KCl (the latter two with MK-801). Each treatment produced a large rise in  $[Ca^{2+}]_i$ , detected by fura-2. However, only the NMDA and glutamate exposures resulted in neuronal death one day later. When  $[Ca^{2+}]_i$  was measured by BTC (400 nm/480 nm ratio), AMPA and K<sup>+</sup> depolarization elicited only a small transient rise in  $[Ca^{2+}]_i$ , whereas NMDA and glutamate induced much larger, sustained elevations in  $[Ca^{2+}]_i$ . There was a positive correlation between  $[Ca^{2+}]_i$ , determined by BTC ratio, and increasing toxicity with NMDA exposure (50-300 mM). Other low-affinity indicators, including mag-fura-5 and calcium green-5N, also demonstrated  $[Ca^{2+}]_i$  elevation after NMDA application; however, BTC may be especially useful because of its selectivity for  $Ca^{2+}$  over  $Mg^{2+}$ , and ability to provide ratiometric data. These data support the hypothesis that micromolar elevations of intracellular calcium may be critical for glutamate receptor-mediated cell death. Supported by NIH NINDS grants NS32140 (MPG), NS19988 (SMR), and T32NS07071 (SDH).

## 318.5

**INHIBITION OF TUMOR NECROSIS FACTOR- $\alpha$  (TNF- $\alpha$ ) ATTENUATES NMDA-INDUCED STRIATAL NEUROTOXICITY IN PERINATAL RATS.** L.M. Galasso, P. Wang, D. Martin, and E.S. Silverstein\*. Neuroscience Program and Depts. of Pediatrics and Neurology, Univ. of Michigan, Ann Arbor, MI 48109 and Dept. of Inflammation, Amgen Boulder Inc., Boulder, CO 80301.

Recent observations implicate pro-inflammatory cytokines including TNF- $\alpha$  and IL- $\beta$  as mediators of acute brain injury. In 7 day old (P7) rats, direct intra-cerebral administration of NMDA elicits a rapid increase in TNF- $\alpha$  gene expression (Stroke 26:1093); however, the pathogenic role of TNF- $\alpha$  is unknown. To test the hypothesis that TNF- $\alpha$  production contributes to the severity of excitotoxic injury *in vivo*, we sought to determine the efficacy of a TNF- $\alpha$  inhibitor, a dimeric polyethylene glycol linked form of the type I soluble receptor of TNF [TNF binding protein (bp)] in protecting against NMDA neurotoxicity. Methoxyfluorane-anesthetized P7 rats received a right intra-striatal co-injection of 10 nmol of NMDA and 3.75  $\mu$ g of TNFbp (volume:1  $\mu$ l), followed 15 min later with an i.p. injection of 50  $\mu$ g of TNFbp (n=13). Litter-mate controls received heat-treated (100°C, 30 min) TNFbp (n=11). Severity of brain injury was quantified on P12 by measuring intact Nissl staining in the striatum bilaterally in 20  $\mu$ m cresyl-violet-stained coronal sections ( $\geq 14$ /brain), using NIH Image; a summation formula was used to estimate striatal volumes and lesion volumes were calculated as the inter-striatal volume differences. Treatment with the active form of TNFbp attenuated NMDA-induced damage by 26% in comparison with controls [lesion volume (mean $\pm$ SEM) 12.3 $\pm$ 5 vs 16.7 $\pm$ 3,  $p < 0.012$ , t-test]. These results suggest that TNF- $\alpha$  may be an important mediator of NMDA receptor-induced neurotoxicity *in vivo*. Thus, pharmacological antagonism of endogenous TNF- $\alpha$  may represent an effective neuroprotective strategy against acute brain injury.

## 318.7

**AChE Reactivity in the Basal Lateral Amygdala: A Post-Mortem Index of Seizure Severity Following Soman** J. Forster, F. Cann, G. Ballough, B. Hackley\*, M. Filbert. U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground 21010. LaSalle University Philadelphia, PA 19141

The possibility that the loss of AChE reactivity in discrete brain regions may have differential importance for induction of status epilepticus was investigated. Rats were infused with monosialoganglioside, GM1, through a permanent cannula implanted intracerebroventricularly (i.c.v.) and connected to an osmotic minipump. Controls received saline infusions or were sham operated. Rats received soman or saline injections 4.0  $\pm$  0.5 days following GM1 infusions. ECoG recordings were monitored via indwelling cortical electrodes. Twenty-seven hours after soman administration, rats were euthanized via transcardial perfusions with brains removed and processed for AChE histochemistry. An Image Analysis System assessed optical densities of AChE staining in the piriform cortex (Pir), basal lateral amygdaloid nucleus (BL) and caudate putamen (CPu). All soman rats showed evidence of seizure initiation within 10 min. However, 6 out of 11 rats infused with GM1 did not develop status epilepticus. All animals receiving soman showed statistically significant reductions in staining for AChE. However, in those rats infused with GM1 that did not develop status epilepticus, the AChE staining in the BL was significantly higher than in rats not receiving GM1. These observations suggest that the loss of AChE reactivity in the BL may be a postmortem index of seizure severity following soman administration.

## 318.9

**RESISTANCE OF NEONATAL CA1 NEURONS TO GLUTAMATE-INDUCED INJURY IN VITRO IS ASSOCIATED WITH MINIMAL INCREASES IN  $[Ca^{2+}]_i$ .** J.D. Marks\*. Department of Pediatrics, University of Chicago, Chicago, IL 60637.

Glutamate receptor activation can increase free intracellular calcium ( $[Ca^{2+}]_i$ ), alter neuronal morphology, and cause cell death. In the rat, glutamate receptor subtype expression changes markedly during the first 3 weeks postnatal life. We have shown that CA1 neurons from 3 week old rats respond to glutamate stimulation with somal swelling, dendrite retraction, and loss of membrane integrity, whereas neurons from newborn animals show none of these effects. We hypothesized that this neonatal resistance occurs because glutamate increases  $[Ca^{2+}]_i$  to lower levels in neurons from newborns compared with neurons from older animals. We measured  $[Ca^{2+}]_i$  and changes in neuronal morphology by obtaining alternating differential interference contrast and epifluorescence images of single, Fura-2 loaded, hippocampal CA1 neurons that had been acutely dissociated from mature (P21-P25) and newborn (P0-P5) Sprague-Dawley rats. Images were obtained every 20 s at baseline, during glutamate perfusion (100  $\mu$ M), and during washout. Mean somal  $[Ca^{2+}]_i$  at baseline was significantly lower in neonatal neurons (80  $\pm$  9 nM, mean  $\pm$  SEM, n=10) than in mature neurons (120  $\pm$  9 nM, n=12;  $p < 0.01$ ). Glutamate increased  $[Ca^{2+}]_i$  abruptly in all neurons. However, mean peak  $[Ca^{2+}]_i$  attained during glutamate stimulation was significantly lower in neonatal neurons (343  $\pm$  53 nM) compared with mature neurons (2066  $\pm$  338 nM,  $p < 0.0001$ ). Following glutamate stimulation, mature neurons demonstrated marked swelling and dendrite retraction, followed by sudden loss of dye and cell death. Morphology of neonatal cells did not change. We conclude that glutamate causes smaller  $[Ca^{2+}]_i$  increases in neonatal neurons than in mature neurons. This decreased  $[Ca^{2+}]_i$  response may underlie the lack of morphologic change and subsequent death seen in newborn neurons.

## 318.6

**ANALYSIS OF ACUTE RESPONSES TO IBOGAINE AND A PRIMARY METABOLITE IN CEREBELLAR PURKINJE CELLS.** L.J. Larson-Prior\* and P.L. Hawkins. Dept. of Neuroscience & Anatomy, Penn State University College of Medicine, Hershey, PA 17033.

Ibogaine, an indole alkaloid under investigation as an anti-addictive agent, has been shown to be neurotoxic in the cerebellar cortex at high doses (>100 mg/kg i.p.). Ibogaine may exert its anti-addictive effects via a recently identified long-lasting metabolite, 12-hydroxyibogamine (noribogaine). The acute toxicity (1 - 48 hr) of these agents on cerebellar Purkinje cells was investigated using immunocytochemical markers for glial activation (GFAP), Purkinje cell (PC) morphology (calbindin-28), and cell stress (HSP-70).

Adult male Sprague-Dawley rats were injected with ibogaine or noribogaine (5 mg/ml in distilled water) at a final dose of 40 mg/kg i.p. Injections were given in 4 equal doses at 15 minute intervals over the course of an hour. One, 6 and 48 hrs after administration of the final dose, animals were sacrificed and the brain immunostained using antibodies to GFAP, calbindin-28 (C-28) or HSP-70.

No differences from controls were seen in staining for C-28 or GFAP at any of the time points examined for either treatment group. PCs continued to stain strongly and completely for C-28 and no changes in the astroglial population were noted. Increased synchrony of firing in the inferior olivary nuclei has been suggested as a mechanism mediating ibogaine cytotoxicity in the cerebellum. No changes in C-28 or GFAP staining, and no differences between drug treated animals and controls were noted in these cells. However, 48 hrs after ibogaine treatment, cerebellar Purkinje cells were strongly stained for HSP-70 while animals treated with noribogaine showed no staining for this marker. Immunostained PCs were found only in the vermal cortex. The inferior olivary nuclei were equally immunoreactive for HSP-70 protein in both ibogaine and noribogaine treated animals, while control animals showed no immunoreactivity for this marker. Thus, ibogaine produces a stress reaction in cerebellar vermal PCs within 48 hrs of application. Noribogaine, which does not mirror this potentially toxic stress reaction may thus prove a more useful antiaddictive agent. Supported in part by NS 30759 and IBN-9514844 (LLP).

## 318.8

**EFFECT OF BCL-2 EXPRESSION ON GLUTAMATE EXCITOTOXICITY AND APOPTOSIS IN IMMORTALIZED RAT HIPPOCAMPAL CELLS.** C. A. Sherman, E. M. Eves†, M. R. Rosner†, J. A. Izzo\*, J. W. Kusiak. Molecular Neurobiology Unit, NIA, Baltimore, MD 21224; †The University of Chicago, Chicago, IL 60637.

Excitotoxicity plays a role in neuronal death seen after acute neurological insults (ischemia, stroke) and may be involved in neurological disorders such as Parkinson's disease and Alzheimer's disease. Whether or not this phenomenon leads to a necrotic or apoptotic cell death pathway is controversial. In order to study the molecular mechanisms involved in glutamate excitotoxicity, two SV-40<sup>+</sup> immortalized rat embryonic hippocampal cell lines were utilized. These were a parent line, H19-7, and a Bcl-2 transfected line, H19-7/Bcl-2. These cells were differentiated by a temperature shift to 39°C with 10ng/ml bFGF, N2 supplements in serum free media. By RT-PCR, they were found to express the GluR-3, GluR-6 and KA-2 glutamate receptor subunit mRNAs. The H19-7 and H19-7/Bcl-2 cell cultures were differentiated and treated with 1 mM glutamic acid for 24 hours. H19-7 cultures exhibited a 30% cell loss determined by cell counts and MTS assay while the H19-7/Bcl-2 cultures did not. LDH release was not increased in either line compared to untreated cells. Glutamate treatment of H19-7 cultures led to increased DNA laddering which did not occur in the similarly treated H19-7/Bcl-2 cultures. Based on the lack of LDH release, DNA laddering and the protection from cell loss by Bcl-2, we conclude that the glutamate excitotoxicity and cell loss exhibited in the H19-7 cell line is apoptotic in nature. This work was supported by the NIH and the Aluminum Association.

**NEUROPROTECTIVE ROLE OF *c-fos* ANTISENSE OLIGONUCLEOTIDE AGAINST GLUTAMATE/NMDA INDUCED NEUROTOXICITY IN THE RAT HIPPOCAMPUS.** X.-C. M. Li\*, J. R. Dave, M. Laskosky, H. S. Ved and F. C. Tortella. Div. of Neurosci., Walter Reed Army Inst. Res., Washington, DC 20307

Excitatory amino acids (EEA) have been shown to stimulate the expression of *c-fos* proto-oncogene through the glutamate/NMDA receptor complex. Previous studies in our lab showed that treatment of hippocampal cultures with 5  $\mu$ M *c-fos* antisense oligonucleotide (ASO) partially blocked glutamate-induced neurotoxicity (Dave, et al., Neurosci Abst, 1993). To further understand the role of the *c-fos* oncogene in the mechanisms of neuronal death, we investigated the dose-response and the time-course of *c-fos* ASO after *in vitro* and *in vivo* glutamate or NMDA treatments. Primary cultures enriched in neurons dissociated from embryonic rat hippocampus were treated in serum-free media with vehicle or 80  $\mu$ M glutamate. Addition of 10 or 25  $\mu$ M *c-fos* ASO to the culture for 4 hr promoted the survival of hippocampal neurons in a dose-dependent manner; 23% survival at 10  $\mu$ M and 97% survival at 25  $\mu$ M. *In vivo*, rats received stereotaxic bilateral injections of either 25 nM NMDA alone (n=3) aimed at CA1 of the hippocampus or injections of 25  $\mu$ M (n=6) or 125  $\mu$ M (n=6) *c-fos* ASO 30 min or 4 hr prior to the NMDA injection at the same hippocampal site. During the next 24 hr, NMDA treatment alone produced extensive neuronal degeneration along the CA1 axis rostral and caudal to the injection site. Cell density measurements revealed that 30 min pretreatment with either 25  $\mu$ M or 125  $\mu$ M *c-fos* ASO resulted in significant survival of CA1 neurons. However, no significant effect was observed with 4 hr pretreatment at both doses. Collectively, these *in vitro* and *in vivo* results demonstrate a protective role of *c-fos* ASO against glutamate or NMDA induced neurotoxicity in a dose- and time-dependent manner and suggest a causative role of the expression of *c-fos* proto-oncogene during EEA induced neuronal death. (Research was funded by the U.S. Army Medical Research and Materiel Command.)

Neuroprotective effect of ocular hypotensive  $\alpha_2$  adrenoceptor agonists in primary rat hippocampal cultured neurons. **R.K. Lai\*, D. Hasson and L.A. Wheeler.** Dept. of Biological Sciences, Allergan, INC., Irvine, CA 92715.

$\alpha_2$  adrenoceptor agonists are a class of compounds that have shown promising therapeutic efficacy for the treatment of ocular hypertension associated with glaucoma and post-ocular surgical procedures. These compounds effectively lower intraocular pressure in rabbits, monkeys and humans. Recent studies suggest that this class of compounds are also neuroprotective in the focal ischemia and the optic nerve crush models. We examined the effect of novel Allergan  $\alpha_2$  adrenoceptor agonists, brimonidine and AGN 191103, on NMDA and kainic acid induced toxicity in primary rat hippocampal cultured neurons. By monitoring the lactate dehydrogenase release and number of cell death, we found that these  $\alpha_2$  compounds are neuroprotective against the kainic acid ( $10^{-4}$ M) induced cytotoxicity but not the NMDA ( $10^{-4}$ M) induced cytotoxicity. Radioligand binding studies demonstrated no significant interaction by these compounds at the NMDA, kainate, glycine or PCP sites of the glutamate receptor, suggesting that the neuroprotective effect is probably downstream. Exposure to these compounds for 24 hr upregulated the expression of bFGF 2-fold in these hippocampal neurons. We further found that mRNA expression of bFGF increased 3-fold in retina obtained from rats that were i.p. injected with brimonidine or AGN 191103 24 hours earlier at 1 mg/kg dose using both RT-PCR and Northern analyses. The combined data suggest a mechanism by which  $\alpha_2$  adrenoceptor agonists brimonidine and AGN 191103 are effective ocular hypotensive agents with neuroprotective properties.

GLUTAMATE RELEASE DURING GLOBAL CEREBRAL ISCHEMIA IS ATTENUATED BY THE Na<sup>+</sup>-CHANNEL BLOCKER LAMOTRIGINE. **A. Bacher and M.H. Zornow\*.** Department of Anesthesiology, University of Texas Medical Branch, Galveston, TX 77555-0830

The excitatory amino acid glutamate is known to play an important role in ischemia-induced neuronal injury (1). Recently, it was demonstrated that Na<sup>+</sup>-channel blockers can improve neuronal survival rate after ischemia (2,3). The present study was performed to investigate the effects of the Na<sup>+</sup>-channel blocker lamotrigine on glutamate release during transient cerebral ischemia.

After IRB approval, 28 New Zealand white rabbits were randomly assigned to 4 groups: control (n=8), 30°C hypothermia (n=7), and lamotrigine 20 mg/kg (n=8) or 50 mg/kg (n=5). Animals were anesthetized (1% halothane), intubated, and mechanically ventilated to maintain normocarbida. Microdialysis catheters were stereotactically placed in the dorsal hippocampal region and perfused with synthetic cerebrospinal fluid. Two 10 minute-periods of global cerebral ischemia were produced by systemic hypotension (trimethaphan 5 mg i.v.) and inflation of a neck tourniquet to obtain an isoelectric EEG. Lamotrigine was intravenously administered 90 minutes before the onset of the first ischemic period. Glutamate concentrations in the microdialysate were determined by HPLC. Levels after ischemia and reperfusion were compared by ANOVA and Dunnett's test. Data are presented as mean $\pm$ SD.

Increases in glutamate concentration were minimal during the first ischemia and reperfusion. During the second ischemia, there was an approximately five-fold increase in glutamate concentration compared to baseline in the control group (peak=5.48 $\pm$ 2.11  $\mu$ M). Significantly lower values (p<0.008) were found in the hypothermia (0.97 $\pm$ 0.94  $\mu$ M) and the lamotrigine 50 mg/kg (2.16 $\pm$ 1.49  $\mu$ M) groups. Values of the lamotrigine 20 mg/kg group (3.51 $\pm$ 1.03  $\mu$ M) were significantly lower (p<0.008) than those of the control group (5.92 $\pm$ 1.98  $\mu$ M) during second reperfusion.

We conclude that lamotrigine is comparable to hypothermia in attenuating hippocampal glutamate increases associated with transient global ischemia.

ON THE NEUROPROTECTIVE AND NEUROTOXIC POTENTIAL OF INTRACELLULAR CALCIUM CHELATION IN ORGANOTYPIC HIPPOCAMPAL SLICES EXPOSED TO OXYGEN/GLUCOSE DEPRIVATION (OGD). **Khaled M. Abdel-Hamid\* and Michael Tymianski.** Playfair Neuroscience Unit, University of Toronto, Ontario, Canada, M5T 2S8.

Excessive endogenous glutamate release has been implicated in ischemia-induced central neuronal injury, mainly by derangement of intraneuronal Ca<sup>2+</sup> homeostasis. An attractive neuroprotective strategy is to enhance neuronal capacity to buffer excess Ca<sup>2+</sup> influx associated with ischemic events, thus reducing Ca<sup>2+</sup> mediated neurotoxicity. Here we present evidence that neuronal pre-loading with the artificial Ca<sup>2+</sup> buffer, BAPTA, is associated with early partial protection of cultured organotypic hippocampal slices against OGD (*in vitro* ischemia). Hippocampal slices from 7d postnatal rat pups were maintained *in vitro* (Stoppini *et al.*, 1991) for 12 days prior to 60 minutes of OGD at 37°C (>90% neuronal loss at 24 hours). NMDA antagonists (MK801 and APV) produced a sustained protection (60-70% protection at 3 hours, 40-50% protection at 24 hours). Pre-treatment with BAPTA-AM (60 min) was associated with neuroprotection at 3 and 5 hours after OGD (50%, 40% for 10  $\mu$ M BAPTA-AM, and 60%, 50% for 100  $\mu$ M BAPTA-AM pre-treatments) which did not persist at 24 hours. Analogous effects were observed with the low affinity Ca<sup>2+</sup> chelator APTRA-AM. The protection time-course of BAPTA was paralleled exactly by the time-course of BAPTA retention in the slice tissue as measured by <sup>14</sup>C-BAPTA autoradiography. Neuroprotection was absent when 100  $\mu$ M BAPTA-AM was used prior to injury with 100  $\mu$ M NMDA, suggesting that protection from OGD may be mediated at the pre-synaptic level, possibly by attenuating transmitter release. Furthermore, with submaximal neuronal injury using 40  $\mu$ M NMDA, 100  $\mu$ M BAPTA-AM pretreatment caused severe neuronal loss. These results illustrate the complexity of the role of Ca<sup>2+</sup> in neuronal damage, and that chelation of intraneuronal Ca<sup>2+</sup> may have both a protective and neurotoxic potential. (Supported by an Ontario Technology Fund grant with Allelix Biopharmaceuticals to MT).

## 318.12

NEUROPROTECTIVE EFFECTS OF 1,25(OH)<sub>2</sub> VITAMIN D<sub>3</sub> IN HIPPOCAMPAL NEURONS SUBJECTED TO NMDA INSULT. **N.M. Porter\*, V. Thibault and P.W. Landfield.** Dept. Pharmacology, Coll. Medicine, Univ. Kentucky, Lexington, KY 40536.

It is well established that vitamin D (VitD) plays an important role in Ca<sup>2+</sup> homeostasis in the periphery. Although VitD receptors are present in hippocampal neurons, much less is known regarding the function of VitD in the CNS. Because VitD regulates Ca<sup>2+</sup> homeostasis in the periphery, we hypothesized that it may play a similar role in the CNS. The present study was undertaken to examine the effects of VitD in an experimental paradigm of neuronal injury involving Ca<sup>2+</sup> influx, NMDA-induced excitotoxicity.

Primary rat hippocampal neurons, maintained in serum, were chronically treated (days 3, 6 and 8) with the active metabolite of VitD, 1,25(OH)<sub>2</sub> vitamin D<sub>3</sub> (0.1-1000 nM). Moderate insults were induced on day 8 by treatment of cultures with NMDA (100-300  $\mu$ M). Cell survival was quantitated 24 and 96 hr later by counting viable cells using phase-contrast microscopy.

The number of surviving hippocampal neurons was significantly greater in cultures pretreated with VitD, particularly at the lower concentrations of VitD. NMDA induced 70% cell death in cultures pretreated with ethanol vehicle (0.05%) but only a 37% reduction in cells pretreated with VitD. The results suggest that as in the periphery, VitD may regulate Ca<sup>2+</sup> homeostasis in the CNS, and exert protective effects against certain (Ca<sup>2+</sup>-dependent) types of neuronal insults. (Supported by NIH AG10836)

## 318.14

NEUROPROTECTIVE EFFECTS OF DEEP HYPOTHERMIA ON EXCITOTOXIC INJURY IN CULTURED CORTICAL NEURONS. **M. Tymianski\*, R. Sattler\*, R.F. Spetzler\* and J.M. Zabramski\*.** Playfair Neuroscience Unit, University of Toronto and \*Barrow Neurological Institute, Phoenix, AZ 85013.

Temperature reductions to 10-20°C are used clinically to protect brain tissue against ischemic injury. However, the mechanisms by which deep hypothermia protects neurons are unknown. We therefore investigated the survival of cultured cortical neurons under a range of combinations of temperature (12-37°C), excitatory amino acid (EAA) receptor agonists (glutamate, NMDA, AMPA, kainate and tACPD, each at 0.30, 100, 300 and 1000  $\mu$ M) and antagonists (APV 50, 100  $\mu$ M, MK-801 50  $\mu$ M, CNQX 10  $\mu$ M). The time-course and extent of excitotoxicity was gauged in a multiwell fluorescence scanner as described by Sattler *et al.*, (abstract, this meeting). All temperatures were well tolerated by control cultures. Neuroprotective efficacy of hypothermia against EAA insults was U-shaped, with maximal protection achieved at 20°C and 30°C, but less so at 12°C. Equimolar insults with glutamate and NMDA were equally toxic at 37°C, but glutamate toxicity was temperature resistant- while NMDA toxicity was considerably lessened by the temperature reduction. The temperature-insensitive component of glutamate toxicity was still due to NMDA receptor activation as it was abolished by NMDA antagonists, and was not reproduced by non-NMDA agonists or the mGluR agonist tACPD. Although hypothermia may protect neurons by attenuating endogenous EAA release (Bruno *et al.*, J Neurochem 63, 1398), the present data show that a significant component of neuroprotection by deep hypothermia can also occur postsynaptically, though these postsynaptic effects are sensitive to the specific agonist used. (Supported by an MRC clinician-scientist award to MT, a National Centers of Excellence of Canada Studentship to RS, and an Ontario Technology Fund grant with Allelix Biopharmaceuticals to MT).

## 318.16

PREGNENOLONE SULFATE MODULATES EXCITOTOXIC AND APOPTOTIC NEURONAL INJURY IN CELL CULTURE. **J.K. Muir\*, L.M.T. Canzoniero, S.L. Sensi and D.W. Choi.** Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

The neurosteroid pregnenolone sulfate (PS) enhances NMDA receptor-gated current while reducing AMPA, kainate and GABA receptor-gated currents (Wu *et al.*, Mol. Pharmacol. 40:33, 1991). Thus, we hypothesized that PS would enhance NMDA-induced, and reduce AMPA/kainate-induced, excitotoxic neuronal injury.

As predicted by the electrophysiology, neuronal death in mixed murine cortical cell cultures (DIV 14-16) exposed to 10  $\mu$ M AMPA or 40-50  $\mu$ M kainate for 20-24 hr was reduced by concurrent addition of 50-100  $\mu$ M PS. Further, the submaximal injury induced by 3-12  $\mu$ M NMDA was potentiated. Application of 100  $\mu$ M PS alone for 24 hr was not toxic. Interestingly, the apoptotic neuronal injury induced by exposure of cultures to 100 nM staurosporine for 24-48 hr (Koh *et al.*, Exp. Neurol. 135:153, 1995) was concentration-dependently reduced by 1-100  $\mu$ M PS. This protective effect was blocked by the NMDA antagonist MK-801.

Cycloheximide (1  $\mu$ g/ml) also attenuated staurosporine-induced neuronal death, however the protective effect of cycloheximide was unaffected by MK-801. We hypothesize that the ability of PS to reduce neuronal apoptosis may be mediated by elevations of intracellular free calcium, due to enhancement of NMDA receptor-gated current as well as perhaps reduction in GABA receptor-mediated current.

PREGNENOLONE SULFATE NEUROTOXICITY IN CULTURED CHICK CORTICAL NEURONS. J.M. Fahey\* and D.G. Lindquist, Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Pregnenolone sulfate (PS) has been reported to selectively augment glutamate-induced depolarizations mediated by the N-methyl-D-aspartate (NMDA) subtype of the glutamate receptor. Previously, this laboratory has demonstrated that NMDA-mediated increases in intracellular calcium in primary cortical neurons are potentiated in the presence of PS. The present study examines the effect of this neurosteroid on neuronal cell death alone and in combination with NMDA/glycine. Primary cortical chick neurons were exposed to PS and subsequently assayed for [<sup>3</sup>H]ouabain binding to quantify cell loss. Neuronal survival was significantly decreased in the presence of PS at 24 h (500  $\mu$ M), 48 h (500  $\mu$ M) and 72 h (250  $\mu$ M and 500  $\mu$ M) relative to controls. In a second study, co-application of non-toxic concentrations of NMDA/glycine (500  $\mu$ M/50  $\mu$ M) and PS (250  $\mu$ M) for 48 h significantly reduced neuronal survival in these neurons relative to either compound alone. These data indicate that higher concentrations of the neurosteroid PS alone are toxic to cortical neurons *in vitro*. In addition, this study demonstrates a synergistic toxic effect of PS and NMDA/glycine, providing additional evidence of the possible involvement of PS in excitotoxicity and cell death.

ELEVATION OF ENDOGENOUS BRAIN KYNURENIC ACID LEVELS BY NOVEL ANALOGUES OF NICOTINYLALANINE. A.F. Miranda\*, K. Jhamandas, R. Beninger and R.J. Boegman, Departments of Pharmacology & Toxicology, Psychology, and Medicine, Queen's University, Kingston, Ontario, Canada K7L 3N6.

Endogenous excitotoxins have been implicated in several neurodegenerative disorders. One such agent quinolinic acid (QUIN) is derived from the kynurenine pathway which also yields kynurenine acid (KYNA), an endogenous excitatory receptor antagonist. Previously, we have demonstrated that nicotinylalanine (NICALA), an inhibitor of kynureninase and kynurenine hydroxylase, in combination with probenecid, an inhibitor of organic acid transport, and kynurenine, the precursor of KYNA, elevates brain KYNA and protects against QUIN toxicity *in vivo* (*Soc. Neurosci. Abstract* 21:74, 1995). NICALA however, is not a potent inhibitor of kynureninase or kynurenine hydroxylase. This study examined the ability of novel analogues of NICALA to increase endogenous brain KYNA levels. Male Sprague-Dawley rats (125-150 g) received equivalent doses (5.6 nmol/5  $\mu$ l i.c.v.) of An#1 (2-amino-4-hydroxy-4-(3-pyridyl) butyric acid), An#2 (2-amino-1,4-dihydroxy-4-(3-pyridyl) butane dihydrochloride salt), NICALA or saline in combination with probenecid (200 mg/kg, i.p.) and kynurenine (450 mg/kg, i.p.). Brain KYNA levels were measured at 1.5, 3, 6 and 9hr following treatment. NICALA, An#1 and An#2 produced elevations of brain KYNA that were at least 3-fold greater than those produced by saline 3hrs post treatment. An#1 produced elevations of brain KYNA levels that were approximately 1.5-fold greater than those produced by NICALA 3hrs post treatment. KYNA levels following administration of An#2 were not significantly different than those produced by NICALA at all time points. This study demonstrates that An#1 and An#2 elevate endogenous brain KYNA levels and thus, have the potential to be effective neuroprotective agents. Gene Transfer of Calbindin D28k cDNA by HSV Amplicon Vector Decreases Calcium Ion Mobilization Following Hypoglycemic Challenge And Enhances Neuronal Survival. T. J. Meier\*, D. Y. Ho and R. M. Sapolsky, Dept. of Biological Sciences, Stanford University, Stanford, CA 94305-5020.

Maintenance of intracellular calcium ion homeostasis plays an important role in the cellular well-being of hippocampal neurons. Disruption of that homeostasis often leads to cell death. In recent years the function of calcium-binding proteins as calcium ion (Ca<sup>2+</sup>) buffers has been proposed. We hypothesized that calbindin D28k (CB) may function as an intracellular Ca<sup>2+</sup> buffer and constructed herpes simplex virus vectors to deliver rat CB cDNA to hippocampal neurons *in vitro*. These vectors co-express bacterial *lacZ* as a reporter gene. Cells were infected with vectors delivering the CB cDNA, or the CB gene inactivated by insertion of stop codons in all three reading frames near the 5' end of the cDNA (*cbs*). Infected cells were subjected to 12 or 24 hours of hypoglycemia (0.5 mM glucose), and then examined by calcium ratiometric imaging utilizing the fluorescent calcium indicator fura-2. Following hypoglycemic incubation, cells infected with vectors carrying the CB gene exhibited lower overall amounts of Ca<sup>2+</sup> mobilized in response to aglycemic challenge, as compared to uninfected cells. Cells infected with the *cbs* vector exhibited significantly higher Ca<sup>2+</sup>. Cells infected with these constructs were assayed for survivorship after 12- or 24-hour hypoglycemic challenge *in vitro*. Infected neurons which survived the treatment were visualized using the chromogenic substrate X-gal. Cells receiving the CB gene gained a significant survivorship advantage over cells receiving the *cbs* vector at 12 but not at 24 hours post hypoglycemic challenge. Our work previously indicated that decreased Ca<sup>2+</sup> mobilization via CB overexpression did not enhance neuronal survival following glutamate exposure. In contrast, we demonstrate here, in response to hypoglycemia, both decreased Ca<sup>2+</sup> mobilization and increased survivorship of neurons infected with CB vectors.

NEUROPROTECTIVE INTERACTION EFFECTS OF NMDA AND AMPA RECEPTOR ANTAGONISTS IN AN IN VITRO MODEL OF CEREBRAL ISCHEMIA. R.L. Arias\* and J.R.P. Tasse, CNS Disorders Division, Wyeth-Ayerst Research, CN-8000, Princeton, NJ 08543-8000.

An *in vitro* model of ischemia was developed in the rat hippocampal slice preparation. Ischemia was defined as a thirty minute aglycemic period ending in five minutes of concurrent anoxia. Slice viability was determined before and after ischemia by testing for the presence of a population spike in CA1 upon electrical stimulation of the Schaffer collaterals. Exposure of slices to an ischemic period resulted in a nearly complete loss of viability. This effect was prevented by withholding calcium from the buffer during ischemia. The glutamate subtype antagonists, MK-801 (NMDA noncompetitive), CGS-19755 (NMDA competitive), GYKI-52466 (AMPA noncompetitive) and YM90K (AMPA competitive) were bath applied to slices, alone and in combination, during ischemia. AMPA antagonists applied alone had no neuroprotective effect in this model. NMDA antagonists applied alone had a modest neuroprotective effect. Co-application of MK-801 and GYKI-52466 resulted in complete neuroprotection, comparable to that obtained with calcium withholding. The effect of this combination treatment on slice survival rate was synergistic, that is greater than the sum of the individual drug effects. Results indicate that neuroprotection against ischemia may require a combination therapy approach.

## EXCITATORY AMINO ACIDS: EXCITOTOXICITY II

## 319.1

THE MAPK/ERK KINASE (MEK) INHIBITOR PD-98059 REDUCES NEURONAL CELL DEATH FOLLOWING COMBINED OXYGEN AND GLUCOSE DEPRIVATION IN PRIMARY NEOCORTICAL CULTURES. A.W. Probert\*, P.A. Boxer, S.S. Basu, T.K. Brabham and R.G. MacKenzie, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48105.

The neuroprotective effect of the MAPK/ERK kinase (MEK) inhibitor, PD-98059, was evaluated in primary neocortical neuronal cultures exposed to increasing intervals of combined oxygen (1%) and glucose (1 mM) deprivation (COGD). Neuronal injury (increased lactate dehydrogenase levels in culture supernate), which first appears following 135-150 minutes of COGD and peaks after 240-255 minutes of deprivation, is preceded by a similar pattern of <sup>45</sup>Ca<sup>2+</sup> uptake approximately 15 minutes prior to injury onset. This initial injury sequence is primarily driven by glutamatergic mechanisms, since it can be abolished in the presence of 100  $\mu$ M R(-)-3-(2-Carboxypiperazine-4-yl)-propyl-1-phosphonic acid (CPP), a competitive NMDA antagonist. Treatment with PD-98059 [30  $\mu$ M] prolonged deprivation intervals required to initiate both neuronal injury and <sup>45</sup>Ca<sup>2+</sup> uptake by 45-60 minutes, but failed to inhibit either parameter following excitotoxic challenges with either NMDA [30-500  $\mu$ M], glutamate [100  $\mu$ M] or AMPA [200  $\mu$ M]. MAP kinase activation was found to be maximized in both normoxic and hypoxic control samples but was decreased by approximately 75% in cultures treated with PD-98059. Present data suggests PD-98059 may affect injury outcome through presynaptic influences on MAP kinase activity.

## 319.2

INDUCTION OF HEME OXYGENASE-1 (HO-1) IN RAT BRAIN FOLLOWING ACUTE PHENCYCLIDINE ADMINISTRATION. S. Rajdev\* and F.R. Sharp, Department of Neurology, V A Medical Center (127) and University of California, San Francisco, CA 94121.

Acute administration of NMDA receptor antagonist phencyclidine induces neuronal necrosis in cingulate and retrosplenial cortices in adult rats. However, the exact cellular mechanism of this toxicity is not completely understood. In this study we show that doses of PCP which produce pathomorphological changes in neurons, also significantly increase the expression of HO-1, a small heat shock protein (HSP32) known to be induced by oxidant stress, in rat brain. Since previous studies have shown heat shock protein 70 (HSP70) induction in brain regions vulnerable to PCP, we also studied the relationship between HO-1 and HSP70 expression. Unlike HSP70 which is primarily induced in pyramidal neurons, HO-1 increase was mainly observed in microglia and astrocytes. The increase in HO-1 protein was dose-dependent (5-50 mg/kg, PCP, i.p.) and was found to be maximum at 24 hrs during time course studies. HO-1 positive cells could be detected within 7 hrs and were still present at 5 days following a single dose of PCP. Interestingly, these HO-1 positive cells mostly presented themselves as a layer surrounding the HSP70 positive neurons in cingulate and retrosplenial cortices, though considerable staining was observed throughout the cortex especially piriform cortex and hippocampus. The increase in HO-1 was also observed in striatum, an area where no HSP70 positive neurons have been detected. These results suggest that HO-1 may be a sensitive indicator of neuronal stress and injury. Treatment of animals with 1,3-dimethylthiourea, an antioxidant, significantly blocked the increase in both HO-1 and HSP70 positive cells, suggesting an involvement of oxidative stress in PCP toxicity. Whether this dramatic increase in HO-1 levels in response to PCP *in vivo* is a protective mechanism or plays a role in PCP toxicity is being investigated.

## 319.3

EXCITOTOXIC STRIATAL LESIONS INDUCED BY THE ANTIOXIDANT ENZYME INHIBITOR MERCAPTOSUCCINATE. W.F. Maragos\*, R.A. Fox, O. Ben-Joseph and B. Ross. Dept. Neurology, Univ. Kentucky, Lexington, KY, 40536 and Dept. Radiology and Biol. Chem., Univ. Michigan, Ann Arbor, MI 48109

Reactive oxygen species (ROS) such as superoxide and hydrogen peroxide have been implicated in the pathogenesis of a number of neurodegenerative disorders. The accumulation of ROS beyond antioxidant defenses (i.e., oxidative stress) stimulates a number of processes including lipid peroxidation, enzyme inactivation and damage to DNA. ROS also increases glutamate release and impairs glutamate uptake, however it is not known whether this is functionally significant. In this study, we have used the antioxidant enzyme inhibitor mercaptosuccinate (MS) as a novel method by which to examine *in vivo* oxidative toxicity. MS is a competitive inhibitor of glutathione peroxidase (GPx). The GPx pathway is the principle route for the degradation of hydrogen peroxide. Although not highly toxic itself,  $H_2O_2$  can react with transition metals such as iron and undergo the Fenton reaction to produce hydroxyl radicals, which are among the most highly toxic ROS. A total of 24 rats received intrastriatal injections of 2  $\mu$ mol of MS. Twelve of the animals were pretreated with 3 mg/kg of the NMDA antagonist MK-801 and 12 with saline. Five days following surgery, brains were processed for histopathological assessment. Although somewhat variable in size ( $17.6 \pm 4.5$  mm<sup>3</sup>), lesions in the control group demonstrated a necrotic core surrounded by a region of neuronal loss and gliosis. In the MK-801 group, lesion volumes were markedly attenuated ( $1.3 \pm 0.35$  mm<sup>3</sup>,  $p < 0.01$ ) and the morphology of the striatum preserved. Six animals injected with mercaptoethanol displayed almost no tissue damage ( $0.38 \pm 0.11$  mm<sup>3</sup>). The results of this study indicate 1) that inhibition of antioxidant enzymes may provide a method by which to create oxidative tissue damage and 2) ROS toxicity may, in part, be mediated by activation of NMDA receptors.

## 319.5

INCREASED EXTRACELLULAR CYSTEINE DURING ANOXIA/AGLYCEMIA *IN VITRO* IS REDUCED BY  $\gamma$ -GLUTAMYL TRANSEPTIDASE INHIBITION Li, X., Revesjö, C., and Sandberg, M.\* Inst. of Anatomy and Cellbiology, Univ. of Göteborg, S-413 90 Göteborg, SWEDEN and Weber S.G. Dept of Chem., Univ. of Pittsburgh, PA 152 60, USA

Anoxia/aglycemia ( $N_2/CO_2$ ; 0 mM glucose; 10 min) evoked efflux of amino acids and  $\gamma$ -glutamyl peptides was studied from incubated rat hippocampal slices. Determination of amino acids and peptides was performed by reversed phase HPLC of OPA-derivatives and fluorescence detection. Anoxia/aglycemia for 10 min increased the net efflux of glutamate,  $\gamma$ -glutamyl glutamate, cysteine and cysteine sulfinic acid. Preincubation with acivicin, an enzyme blocker of  $\gamma$ -glutamyl transpeptidase, increased the net efflux of glutamate (GSH) while the apparent efflux of cysteine, cysteine sulfinic acid and  $\gamma$ -glutamyl glutamate were reduced. The net efflux of glutamate was not affected by acivicin. The results implicate that cysteine, a neurotoxic amino acid, increase extracellularly during anoxia/aglycemia as a result of transpeptidation of GSH and extracellular amino acids by  $\gamma$ -glutamyl transpeptidase.

## 319.7

REDUCED NMDA TOXICITY IN TYPE I NITRIC OXIDE SYNTHASE GENE KNOCKOUT MICE, *IN VIVO*. C. Ayata, G. Ayata, H. Hara, R. Christie, P.L. Huang, M.C. Fishman\*, M.A. Moskowitz. Stroke and Neurovascular Regulation, Depts. Neurosurgery and Neurology; Cardiovascular Res. Center, Dept. of Medicine, Massachusetts General Hosp., Harvard Medical School, Charlestown, MA, 02129

We investigated the lesions produced by intrastriatal NMDA microinjection in wild type and type I NOS<sup>-/-</sup> mice. Littermate wild type (nNOS<sup>+/+</sup>, n=8), heterozygote (nNOS<sup>+/-</sup>, n=12) and homozygote (nNOS<sup>-/-</sup>, n=7) knockout mice (20-28g) were anesthetized by halothane (2.5% for induction and 1-1.5% for maintenance). NMDA (67 mM in 0.1M phosphate buffered saline, 0.3  $\mu$ L, over 2 min) or vehicle was injected stereotactically into the striatum 0.7 mm anterior, 1.7 mm lateral and 3 mm ventral from bregma. The needle was kept in place for an additional 8 min. Mice were sacrificed after 48 hr and frozen sections (20  $\mu$ m thick, every 200  $\mu$ m) were stained by H&E. The volume of the lesion was measured by an image analysis system and expressed as percent of wild type ( $\pm$ SEM). NMDA caused reproducible and well delineated lesions. Morphological changes (e.g., pyknosis, eosinophilic cytoplasm, TUNNEL positive) suggestive of apoptosis were observed in all strains. The volume of the NMDA lesion was significantly smaller in nNOS<sup>-/-</sup> (53 $\pm$ 10%) than both nNOS<sup>+/+</sup> (100 $\pm$ 8%) and nNOS<sup>+/-</sup> (101 $\pm$ 15%). A delayed increase in [3H]-L-NA binding was observed in the lesion by autoradiography. This increased binding reached a peak 24 hr after NMDA injection and was absent in nNOS<sup>-/-</sup> mice. Our results suggest that NO synthesized by nNOS plays a role in NMDA toxicity *in vivo*, and that targeted disruption of type I NOS confers resistance to excitotoxicity.

## 319.4

EFFECTS OF PYRROLOQUINOLINE QUINONE ON GLUTAMATE INDUCED PRODUCTION OF REACTIVE OXYGEN SPECIES IN RAT FOREBRAIN NEURONS J. Scanlon\*, E. Aizenman, and I.J. Reynolds. Depts. of Pharmacology and Neurobiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Pyrrroloquinoline quinone (PQQ), a water soluble redox cofactor and essential vitamin, may act as a free radical scavenger and also as a modulator of the N-methyl-D-aspartate (NMDA) receptor associated redox modulatory site. With the use of the oxidation sensitive dye dihydroethidium (DHE), we examined the effects of PQQ on free radical production in cultured forebrain neurons following glutamate receptor activation. Both glutamate (100  $\mu$ M) and hydrogen peroxide (30 mM) produced a rapid increase in DHE fluorescence indicating dye oxidation. PQQ (5-200  $\mu$ M) effectively inhibited DHE fluorescence induced by glutamate but not by hydrogen peroxide. To determine if this effect of PQQ was due to free radical scavenging or to modulation of the redox site, we examined the effects of various reductants and oxidants of the NMDA redox site in combination with PQQ. Glutamate induced DHE fluorescence was enhanced by the thiol reductant dithiothreitol (5 mM DTT) and was inhibited by the thiol oxidant dithionitrobenzoic acid (100  $\mu$ M DTNB). PQQ (50  $\mu$ M) was capable of significantly ( $p < .001$ ) reversing the effects of DTT. However, PQQ did not further decrease the response to glutamate in DTNB treated neurons. These results suggest that PQQ was indeed inhibiting the response to glutamate by oxidizing the NMDA receptor redox site and not by free radical scavenging. Thus, the previously reported neuroprotective action of PQQ may be solely mediated by an action of this drug on the NMDA receptor.

DEPLETION OF BRAIN GLUTATHIONE ASSOCIATED WITH BLOCKADE OF GLUTAMATE-INDUCED HIPPOCAMPAL APOPTOSIS IN MICE. R. S. Bitner\* and G. E. Isom. Dept. of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN 47907

*In vitro* studies show that glutamate-induced apoptosis involves the depletion of glutathione (GSH), which leads to oxidative stress (Ratan *et al.*, J. Neurochem. 62:376, 1994). The purpose of the present study was to determine if GSH depletion would exacerbate apoptosis *in vivo* in the hippocampus following intracerebroventricular (i.c.v.) administration of glutamate. TUNEL (TdT dUTP nick end labeling) staining, characteristic of apoptosis, was seen in the CA1 region of the hippocampus of mice that received 48 hrs earlier a single i.c.v. injection of glutamate (3.2  $\mu$ mol). However, in mice that also received the GSH synthesis inhibitor L-buthionine sulfoximine (BSO) (13.4  $\mu$ mol i.c.v.) 24 hrs earlier, glutamate was completely ineffective in producing any type of hippocampal damage. Contrary to our initial hypothesis, these results indicate that *in vivo* GSH depletion is neuroprotective against glutamate-induced hippocampal apoptosis. It is possible that BSO excitotoxic blockade involves an unknown mechanism independent of GSH depletion. But, this unexpected finding may also suggest that depleting GSH triggers compensatory systems, absent from *in vitro* preparations, that offer protection against subsequent excitotoxic insults. (Supported in part by NIEHS grant 04140)

## 319.8

STRIATAL NEURONAL NITRIC OXIDE SYNTHASE POSITIVE NEURONS INCREASE AFTER CEREBRAL HYPOXIC-ISCHEMIC DAMAGE IN IMMATURE RAT. S. Ishiwa, M.E. Blue, W.H. Trescher and M.V. Johnston\*. Neuroscience Laboratory, Kennedy Krieger Research Institute and Johns Hopkins Medical Institutions., Baltimore, MD 21205

Nitric oxide has been implicated as a mediator of glutamate excitotoxicity in response to cerebral ischemia. In the present study, we investigated the sequential changes of neuronal nitric oxide synthase (nNOS) expression in immature rat striatum after hypoxic-ischemic damage. Postnatal day 7 rats underwent unilateral carotid artery ligation, followed by exposure to hypoxia in 8% oxygen for 75 minutes at 37°C. At time points 6 hours (n=5), 3 days (n=9), 7 days (n=7) and 30 days (n=6) after hypoxic-ischemic injury, brains were perfused and processed for immunocytochemistry using nNOS specific antibodies (Transduction Labs). The cross-sectional areas of ipsilateral hypoxic-ischemic and contralateral non-ischemic sides of the striatum were measured in coronal sections. nNOS positive neurons were counted in a standard area comprising 36% of the striatal area within a section. Measurements were made automatically with a microcomputer-based video image analysis system (Imaging Research Inc.) and the average counts from the ipsilateral hypoxic-ischemic side were compared to the contralateral non-ischemic side and to that of untreated controls (n=5). The results showed that the number of nNOS positive neurons declined with age. At each timepoint after injury studied, the number of nNOS positive neurons on the side ipsilateral to the hypoxic-ischemic damage was significantly increased ( $p < 0.05$ ) compared with the contralateral non-ischemic side. These results suggest that in the immature brain, hypoxic-ischemic damage produces a long-term induction of nNOS activity. Supported by N.I.H. grants NS-28208 and NS-29167.

## 319.9

POTENTIATION OF GLUTAMATE NEUROTOXICITY BY SERUM ALBUMIN. ROLE OF FREE RADICALS. E.G. Sorokina, V.P. Reutov, N.P. Vinskaya, B.I. Khodorov, and V.G. Pinelis. Lab. of Membranology, Inst. of Pediatrics, RAMS, Moscow, 117963, Russia, Lab. of Gen. Pathology of Nervous System, Inst. of Gen. Pathology and Pathophysiology, RAMS, Moscow, 125315, Russia.

S. Eimerl and M. Schram (Brain Research, 1991, 560, 282-290) found that serum albumin (SA) when applied simultaneously with glutamate (GLU) greatly potentiates delayed neuronal death (DND) in rat cerebellar granule cell cultures. The objective of the present work was to clarify the origin of this SA effect. Experiments were performed with cultured rat cerebellar granule cells. Cytoplasmic  $Ca^{2+}$  concentration was measured in individual fura-2-loaded neurons. DND was evaluated by counting of cerebellar granule cells containing and excluding trypan blue 4hr after the termination of the neurotoxic treatment. The principal findings of the study are as follows. (1) The bovine SA (4mg/ml) does not enhance  $Ca^{2+}$  influx through GLU-activated channels. (2) SA caused no toxicity in absence of GLU. (3) DND enhanced by a combined 15-min application of SA (4 mg/ml) and GLU (100  $\mu$ M, 10  $\mu$ M glycine,  $Mg^{2+}$ -free solution) to nerve cells can be effectively prevented by the NO synthase inhibitor N $\omega$ -nitro-L-arginine methyl ester (100  $\mu$ M) applied to the medium prior to and during a neurotoxic challenge. (4) Along with GLU neurotoxicity SA also greatly enhances DND induced by a 15-min exposure of cell cultures to NO donors NaNO<sub>2</sub> (10  $\mu$ M) or sodium nitroprusside (10  $\mu$ M) as well as of the prooxidant FeCl<sub>2</sub> (10  $\mu$ M). The results obtained suggest that SA-induced potentiation of GLU neurotoxicity results from exacerbation of the toxic effects of NO and oxygen free radicals on the neuronal membranes. NITRIC OXIDE AND AMPA-INDUCED EXCITOTOXICITY IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURE. J. Chan\* Dept. of Neurology, SUNY Health Science Center, Brooklyn, NY 11203.

Brief (30 minute) exposure of organotypic cultured rat hippocampal slices to 5  $\mu$ M AMPA results in  $Ca^{2+}$ -dependent toxicity 24 hours later, preferentially in CA1 of the pyramidal cell layer. Slices were exposed to AMPA in sucrose buffer containing 10 mM Na<sup>+</sup>, 2 mM CaCl<sub>2</sub>, 5  $\mu$ M MK-801 (to block NMDA receptors) and 3  $\mu$ M cyclothiazide (to inhibit desensitization of AMPA receptors), with or without antagonist. Twenty four hours later, toxicity was quantified by propidium iodide fluorescent microscopy within fixed areas of each slice pre-defined as CA1 or CA3. N=6 for each condition.

Delayed pyramidal cell death was prevented (dose-dependently) by the selective AMPA receptor antagonists 6-nitro-7-sulphamoylbenzo[f] quinoxaline-2,3-dione (NBQX; 10  $\mu$ M), LY293558 (Lilly; 10  $\mu$ M) and Joro spider toxin (10  $\mu$ M), but not by the NMDA receptor antagonist MK-801 or the free radical scavenger  $\alpha$ -tocopherol. The nitric oxide synthase (NOS) inhibitor L-Nitro-arginine methyl ester (L-NAME) and the nitric oxide scavenger oxyhemoglobin and attenuated up to 80% of the delayed damage to CA1. Differing inhibition of toxicity by NOS inhibitors selective for neuronal (7-nitroindazole and S-methyl-L-thiocitrulline), inducible (S,S'-1,3-phenylene-bis[1,2-ethanediy]bis-isothiourea and S-ethylisothiourea) and endothelial (Tannin) isoforms of NOS will be presented.

## 319.10

SOD2 MAY ACCOUNT FOR THE RESISTANCE OF nNOS NEURONS TO EXCITOTOXICITY. M. Gonzalez-Zulueta<sup>1</sup>, L.M. Ensz<sup>1</sup>, V.L. Dawson<sup>1,2,3</sup>, and T.M. Dawson<sup>1,2</sup>. Departments of Neurology<sup>1</sup>, Neuroscience<sup>2</sup> and Physiology<sup>3</sup>, The Johns Hopkins University School of Medicine, Baltimore, MD 21287.

Neurons containing neuronal nitric oxide synthase (nNOS) activity liberate nitric oxide (NO) and mediate, in part, the toxicity associated with derangements of glutamate neurotransmission via the NMDA subtype of glutamate receptors. These neurons have the remarkable ability to preferentially survive in Huntington's Disease as well as the neurotoxicity induced by ischemia or exposure to excessive concentrations of glutamate. The mechanisms of neuroprotection in these nNOS neurons are unknown.

We have obtained PC12 cells which differ from the parental cell line in that they are resistant to NO-induced toxicity. We have used this *in vitro* model of resistance to NO toxicity and an antisense approach to investigate the role that manganese superoxide dismutase (SOD2) may play in neuroprotection. Exposure of NO-resistant PC12 cells to specific SOD2 antisense oligonucleotide restored sensitivity to sodium nitroprusside (SNP), a NO releasing agent, with SNP-induced cell death equivalent to that seen in the parental cell line. This effect was not observed in cells exposed to control sense oligonucleotide and was not due to bare antisense oligonucleotide-associated toxicity. These results suggest that SOD2 downregulation potentiates NO-induced cell death. Our findings may be relevant to the mechanisms of neuroprotection of nNOS neurons in neuronal degenerative disorders caused by impaired regulation of cellular levels of NO and superoxide.

## EXCITATORY AMINO ACIDS: EXCITOTOXICITY III

## 320.1

DOMOIC ACID-STIMULATED RELEASE OF GLUTAMATE AND ASPARTATE FROM CULTURED RAT CEREBELLAR GRANULE NEURONS OCCURS VIA THREE ROUTES: SWELLING-INDUCED EFFLUX, REVERSAL OF SODIUM-DEPENDENT TRANSPORT AND VESICULAR RELEASE. F.W. Berman and T.F. Murray\* College of Pharmacy and Toxicology Program, Oregon State University, Corvallis Oregon, U.S.A.

We have shown that domoate causes cerebellar granule neuron toxicity by stimulating the release of excitatory amino acids (EAAs) into the exposure buffer, thereby indirectly activating NMDA receptors. Domoate-stimulated EAA release was characterized by exposing cerebellar granule neurons (3.5 - 4.0  $\times$  10<sup>6</sup> neurons per 35 mm culture dish) to 10  $\mu$ M domoate in a 1 ml volume and assaying for glutamate and aspartate at specific timepoints by HPLC analysis. Glutamate and aspartate concentrations increased rapidly between 2 and 5 minutes, reaching a maximum of 10.0  $\pm$  0.9 and 5.3  $\pm$  0.8  $\mu$ M, respectively (N = 5), at 15 minutes. When neurons were pre-incubated for 1 hr with 200  $\mu$ M L-trans-2,4-pyrrolidine dicarboxylate, a competitive and transportable inhibitor of the high affinity glutamate transporter, glutamate and aspartate efflux were reduced by 47  $\pm$  10 and 55  $\pm$  15 %, respectively. EAA efflux was reduced further, by 89.6  $\pm$  4.1 and 94.3  $\pm$  5.0 % for glutamate and aspartate, respectively, when swelling of PDA pre-exposed neurons was prevented with 100 mM sucrose. Cyclopentyl-adenosine had no further effect on EAA release, whereas the adenosine receptor antagonist 8-p-sulpho-phenyl-theophylline (8-pSPT) facilitated glutamate efflux, to 136  $\pm$  4 % of domoate-stimulated controls, suggesting that vesicular release is inhibited by the tonic activation of adenosine receptors. 8-pSPT had no effect on aspartate release. Tetrodotoxin reduced the rapid phase of EAA release and completely prevented 8-pSPT-induced increases in glutamate efflux. These results suggest that cultured cerebellar granule neurons exposed to domoate release EAAs by two primary routes, reversal of the sodium-dependent glutamate transporter and via osmotically driven swelling with attendant EAA efflux, while vesicular release of EAAs is largely prevented by the tonic activation of adenosine receptors.

## 320.2

CHRONIC ADMINISTRATION OF THE GLUTAMATE UPTAKE INHIBITOR L-TRANS-PYRROLIDINE-2,4-DICARBOXYLATE PRODUCES STRIATAL EXCITOTOXIC LESION. J.-C. Lievens, M. Duterre, C. Forni, P. Salin\* and L. Kerkerian-Le Goff. Laboratoire de Neurobiologie Cellulaire et Fonctionnelle, CNRS, 31 chemin Joseph Aiguier, 13402 Marseille Cedex 20.

This study examined the morphological effects of chronic intrastratial infusion of L-trans-pyrrolidine-2,4-dicarboxylate (PDC) via osmotic minipumps. PDC was found to induce dose- and time-dependent striatal lesion. Administration of PDC at 5 10-2M (25 nmoles/0.5 $\mu$ l/hr) for 3 or 14 days produced neuronal damage of quite similar extent. Histological evaluation on frontal sections at the injection site showed that the primary neuronal loss was circumscribed to a circular area of about 0.6 mm radius and represented 25-30% of the striatal surface; anteroposterior examination showed that the lesion extended over 2.5-3mm. The lesion area shared a total loss of glutamate decarboxylase, enkephalin and substance P mRNA hybridization signals, suggesting degeneration of the two populations of striatal efferent neurons. In the surrounding apparently spared striatal areas, the levels of glutamate decarboxylase or substance P mRNAs did not differ from control values, whereas enkephalin mRNA expression decreased by an average 28%, suggesting a higher sensitivity of enkephalin neurons to glutamate-uptake-mediated alterations. Combined systemic treatment with dizocilpine maleate (0.25mg/kg/i.p.) did not prevent the PDC-mediated neuronal injury, suggesting that this neurodegenerative process may not primarily involve NMDA receptors. PDC at 10-2M did not produce neuronal damage when administered over 14 days (5nmoles/0.5 $\mu$ l/hr), but elicited restricted degeneration when administered over 27 days (25 nmoles/2.5 $\mu$ l/hr).

This study provides the first *in vivo* evidence that chronic inhibition of glutamate uptake is sufficient for inducing neuronal damage, and supports the view that defective transport is one of the critical condition that may give rise to delayed toxicity of an endogenous transmitter system in the striatum.

## 320.3

**POTENTIATION OF L-GLUTAMATE-INDUCED NEUROTOXICITY IN VITRO BY INHIBITION OF GLUTAMATE UPTAKE.** C.L. Willis\*, C.S. Esslinger, A.R. Chamberlin\*, R.J. Bridges, Pharm. Sci., Univ. of Montana, Missoula, MT 59812, Chemistry, Univ. of California\*, Irvine, CA 92717

Transport of glutamate is thought to be a key step in the regulation of extracellular glutamate levels and prevention of excitotoxic damage. Previous studies have identified L-trans-2,4-pyrrolidine dicarboxylate (L-trans-2,4-PDC), L-anti-endo-3,4-methanopyrrolidine dicarboxylate (L-anti-endo-MPDC), meso-2,4-MPDC and DL-threo- $\beta$ -hydroxyaspartate ( $\beta$ -THA) as potent competitive inhibitors of the Na-dependent synaptosomal glutamate transporter. In the present study we have used neuronal cortical cultures to assess the excitotoxic properties of these compounds in the presence and absence of added glutamate. L-Glutamate and transport inhibitors were added to 19 day old cultures prepared from fetal (E16) rats. Neuronal lysis was quantified 24 hr later by measuring the levels of extracellular lactate dehydrogenase and expressed as a percentage of total neuronal lysis induced by addition of NMDA (100 $\mu$ M) and kainate (100 $\mu$ M). L-trans-2,4-PDC, L-anti-endo-MPDC, meso-MPDC or  $\beta$ -THA alone, induced little or no neuronal lysis at 100 $\mu$ M. At 200 $\mu$ M significant neuronal lysis was observed with both L-trans-2,4-PDC (30%) and  $\beta$ -THA (45%). When 50 $\mu$ M L-glutamate was co-applied with L-trans-2,4-PDC and L-anti-endo-MPDC, neuronal lysis was increased in a concentration-dependent manner to 100%. In contrast, co-application of meso-MPDC had no effect on glutamate toxicity. This lack of effect may reflect its activity as an excellent substrate of the transporter. The potentiated neuronal damage induced by transport inhibition mimicked the injury induced by high levels of glutamate (200 $\mu$ M) in that the neuronal loss could be almost completely prevented by MK-801 (10 $\mu$ M). These studies identify a series of conformationally constrained transport inhibitors and should prove useful in elucidating the neuropathological consequences of impaired glutamate uptake. This work was supported in part by NIH NS30570, NS27600 and RR10169.

## 320.5

**CAPILLARY ELECTROPHORESIS DETERMINATION OF GLUTAMATE IN RAT BRAIN DIALYSATE - IMPROVEMENTS IN DETECTION AND ANALYSIS TIME USING CYCLODEXTRINS** - W. H. Church\* and K. Dranchak, Dept. of Chemistry/Neuroscience Prog., Trinity College, Hartford, CT 06106, C. S. Lee, Dept. of Chemistry, East Carolina Univ., Greenville, NC 27858

Glutamic acid and aspartic acid were derivatized to fluorescent products using naphthalene-2,3-dicarboxaldehyde (NDA) in the presence of cyanide and separated using capillary zone electrophoresis (CZE). Quantitation and separation performance was evaluated using separation buffers containing  $\alpha$ ,  $\beta$ ,  $\gamma$ , and hydroxypropyl  $\beta$ -cyclodextrins (CD),  $\beta$ - and hydroxypropyl  $\beta$ -cyclodextrin enhanced the fluorescent signal of standard 5  $\mu$ M CBI-GLU by factors of 1.73 and 1.69 and CBI-ASP by factors of 1.72 and 1.53, respectively. A CD-concentration dependent decrease in resolution was observed. Separation times were dependent on CD concentration. CD:CBI-amino acid binding constants calculated using changes in migration time were compared to those calculated by the steady-state fluorescence enhancement technique. Analysis of 10  $\mu$ L of rat brain dialysate by CZE using 4 mM  $\beta$ -cyclodextrin in borate buffer resulted in base-line resolution of CBI-GLU and CBI-ASP in 3.6 minutes with signal enhancement of 1.11 and 1.23, respectively. Preliminary studies of rats subjected to isolation stress illustrate the usefulness of this method in quantifying the effects of stress on striatal and hippocampal glutamate levels.

## 320.7

**Glutamate Monitoring with Enzyme-Modified Electrochemical Probe**

Mark A. Hayest and Werner G. Kuhr\*, University of California, Riverside, CA 92521-0403, Arizona State University, Tempe, AZ 85287

The monitoring of glutamate in a biologically relevant time-course, sample size and sensitivity is a very difficult task. Enzyme-modified microelectrodes (with glutamate dehydrogenase) have been developed to accomplish this goal. Quality of fast scan voltammetry of  $\beta$ -nicotinamide adenine dinucleotide- reduced form (NADH) is critical for sensitivity of enzyme-modified electrodes based on dehydrogenases. While NADH voltammetry is sluggish at solid electrode surfaces, several schemes have been developed to minimize overpotential at carbon fiber electrodes. Unfortunately, this improved voltammetry is reduced upon covalent modification of the carbon fiber surface with enzyme attachment schemes. In this study, strategies for improved pretreatment of carbon fiber electrodes and identification of factors which lead to a reduction of voltammetric quality were investigated. An improved electrochemical pretreatment was developed for 32  $\mu$ m carbon fiber electrodes. Manufacture techniques for enzyme-modified electrodes were investigated which minimize solution exposure time and provide alternative attachment sites. These attachment schemes include a direct electrochemical amine reaction and an electrochemically reductive hydrazide reaction to form a bond to the surface. Fluorescence and electrochemical evidence is presented confirming surface attachment and improved retention in voltammetric quality, respectively. These probes are presently capable of 1  $\mu$ M detection limits with DC detection and 50  $\mu$ M by cyclic voltammetric measurements.

## 320.4

**BARBITURATES CAN IMPAIR GLUTAMATE UPTAKE AND POTENTIATE EXCITOTOXIC NEURONAL DEATH** R.A. Swanson\*, L.L. Seid, K. Farrell, and R.G. Giffard Dept. of Neurology, Univ. of California and VAMC, San Francisco, CA 94121.

Barbiturates can reduce brain metabolic rate and antagonize neuronal depolarization induced by excitatory amino acids. Barbiturates have failed, however, to produce consistent reductions in brain injury resulting from stroke or trauma. In this study, rat cortical astrocyte cultures exposed to  $\geq 200\mu$ M second showed increased glucose utilization and slowing of glutamate uptake. These findings were accentuated at low medium glucose and mimicked by azide, suggesting a barbiturate effect on oxidative ATP production (Chance and Hollunger, 1963). Barbiturates had a biphasic effect on the sensitivity of rat cortical neurons to 5 minute NMDA exposures: toxicity was markedly potentiated at barbiturate concentrations between 50 $\mu$ M and 300 $\mu$ M, but antagonized at levels above 1mM. These findings suggest that neurons are particularly sensitive to the cyanide-like effect of barbiturates. The cyanide-like effect of barbiturates may counter or outweigh NMDA antagonistic effects at barbiturate concentrations employed *in vivo*. Supported by NIH R01 NS31914

## 320.6

**On-line Monitoring of Extracellular Glutamate: a Novel Capillary Biosensor**

Rebecca J. Olson Cosford\* and Werner G. Kuhr, University of California, Riverside, CA 92521-0403.

We have developed a novel flow-injection based biosensor for glutamate. The characteristics of this sensor, including low micromolar sensitivity and sub-second time response, make its application to *in vivo* neurochemical measurements particularly attractive. The biosensor exploits the biological selectivity of glutamate dehydrogenase (GDH) to convert glutamate to a detectable signal. In the presence of nicotinamide adenine dinucleotide (NAD<sup>+</sup>), GDH converts glutamate to  $\alpha$ -ketoglutarate while simultaneously reducing NAD<sup>+</sup> to NADH. Detection of NADH may be accomplished using laser induced fluorescence (325 nm excitation wavelength) or by electrochemistry. By attaching GDH to the inner surface of a small diameter fused silica capillary (40  $\mu$ m i.d.; 150  $\mu$ m o.d.) and including NAD<sup>+</sup> in the perfusion buffer, it is possible to transduce glutamate to a detectable signal during transport from the sampling site to the detection window of the capillary.

Response time for the biosensor is 450 milliseconds with detection limits of 3  $\mu$ M ( $s/n = 3$ ). However, improvements in sensitivity are expected with higher laser power and optimization of enzyme efficiency within the capillary. Efficiency varies between 2% and 92% with optimal performance at low perfusion rates and high glutamate concentrations. The biosensor has been successfully applied to the measurement of extracellular glutamate at the neuromuscular junction of the *musca domestica* demonstrating the feasibility of use *in vivo*. Future work will involve the incorporation of this enzyme-based sensor as the outlet line for a microdialysis probe to allow on-line monitoring of dialysate glutamate. Also, efforts have been initiated to use this sensor on-line with capillary electrophoresis allowing the separation of NADH from other potentially fluorescent components in the cerebrospinal fluid

**IMAGING EXCITOTOXIC CELL SWELLING AND NEURONAL DEATH IN THE HIPPOCAMPAL SLICE: CONFIRMATION WITH SPECTROMETRY AND ELECTROPHYSIOLOGY.** Trevor M. Polischuk\* and R. David Andrew, Department of Anatomy & Cell Biology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Excitotoxicity involves an acute, early phase of neuronal swelling which may presage cell death. Increased light transmittance (LT) through the brain slice indirectly measures cell swelling. We imaged changes in LT across hippocampal slices induced by three distinct glutamate agonists. At 37°C, a 1 min superfusion of 100  $\mu$ M NMDA, 10  $\mu$ M domoate (DOM), or 10  $\mu$ M AMPA induced a reversible increase in LT, primarily in the dendritic regions of area CA1 (strata radiatum and oriens, i.e. RAD and OR). The peak response measured in the CA1 RAD ( $n \geq 5$  slices each) was not significantly different among agonists ( $p < 0.01$ ). Spectrometry revealed that the increased LT occurred across 400-800 nm spectrum for each agonist ( $n = 5$  slices each), confirming generalized swelling rather than narrow band activation of chromophores (e.g. cytochromes). Agonist exposures at 37°C for 1 min resulted in immediate loss of the orthodromically evoked field potential recorded in the CA1 cell body region (PYR) but the response returned to pre-exposure levels once swelling in the dendritic area dissipated. In contrast, increasing exposure times resulted in irreversible changes in LT. A 4 min application of 100  $\mu$ M NMDA ( $n = 7$ ) or a 10 min application of 10  $\mu$ M DOM ( $n = 12$ ) or 10  $\mu$ M AMPA ( $n = 6$ ) each caused a characteristic "swell/shrink" event in the CA1 RAD where the LT increase was followed by a pronounced irreversible decrease in LT below baseline levels. At the same time, LT irreversibly increased in the cell body layer of CA1 (PYR). Again, spectral analyses of RAD and PYR revealed wide band increases in LT indicative of cell swelling. However, the evoked field potential was irretrievably lost following 4 min of 100  $\mu$ M NMDA ( $n = 7$ ) or 10 min of 10  $\mu$ M DOM ( $n = 3$ ) coinciding with the irreversible dendritic shrinkage and cell body swelling. We conclude that glutamate-induced excitotoxicity involves dynamic volume changes in both the cell body and dendritic regions which coincide with electrophysiological cell death.

## USE OF A MULTIWELL FLUORESCENCE SCANNER WITH PROPIDIUM IODIDE TO ASSESS NMDA MEDIATED EXCITOTOXICITY IN CORTICAL NEURONAL CULTURES

J.G. Rudolph\*, J.J. LeMasters, and F.T. Crews. Center for Alcohol Studies and Department of Cell Biology, University of North Carolina, College of Medicine, Chapel Hill, NC 27599.

Previous studies using cortical neuronal cultures have used LDH release as a measure of cell death due to NMDA excitotoxicity. This method is labor intensive and therefore does not easily allow for detailed time course experiments. We have adapted the use of propidium iodide fluorescence in microtiter plates read by a multiwell fluorescence scanner. Propidium iodide (PI) intercalates itself into cell DNA once the plasma membrane becomes permeant due to cell death. Primary cortical neuronal cultures 10-15 days post ARA-C treatment were used. To study NMDA excitotoxicity cells were incubated with glutamine free DMEM media and 30  $\mu$ M PI for 10 minutes after which a baseline reading was taken. The PI containing media was removed and replaced with 25 mM HEPES buffer with or without various NMDA agonists and antagonists. Cells were washed once with 25 mM HEPES and replaced with glutamine free DMEM media containing 30  $\mu$ M PI. Fluorescent readings were then taken at specified intervals to assess cell death over 24 hours. Following NMDA exposure, when glutamine was present in the DMEM media a more rapid increase of PI fluorescence as well as greater  $t_{max}$  values were seen, compared to media without glutamine. Using either a 25 minute or continuous NMDA exposure, maximum fluorescence was reached within 6-9 hours. The  $ED_{50}$  for NMDA induced excitotoxicity was 48  $\mu$ M. This excitotoxicity could be blocked with 1  $\mu$ M MK-801, 10  $\mu$ M Ifenprodil, and Ethanol ( $IC_{50}$  = 37.1  $\mu$ M). Cell death elicited by 25 minute Glutamate exposure was blocked by the NMDA antagonists MK-801 and Ifenprodil, but not the non-NMDA antagonist CNQX. Results seen with PI fluorescence following 25 minute exposure to 100  $\mu$ M NMDA were replicated using the LDH release assay. (Funded by AA06069)

EFFECTS OF ACUTE ISCHEMIA ON THE MODULATION OF  $K^+$  CURRENTS BY METABOTROPIC GLUTAMATE RECEPTORS IN CA3 CELLS IN RAT HIPPOCAMPAL SLICE CULTURES.

M. Tanabe, B. H. Gähwiler and U. Gerber

Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland

We were interested whether metabotropic glutamate receptors (mGluRs) are activated as a result of the excessive release of glutamate during cerebral ischemia. Intracellular recordings were made from CA3 pyramidal cells in organotypic hippocampal slice cultures. Brief chemical ischemia (2 mM 2-deoxyglucose and 3 mM  $NaNO_3$  for 4 min) reversibly induced outward currents and reduced the slow calcium-dependent afterhyperpolarization current  $I_{AHP}$ . Since the activation of mGluRs is also known to reduce  $I_{AHP}$ , we examined whether mGluRs mediate the inhibition of this current during ischemia. The reduction in  $I_{AHP}$  induced by 1S,3R-ACPD (10  $\mu$ M), a selective mGluR agonist, was antagonized by the specific mGluR antagonist MCPG. In contrast, MCPG did not modify the effect of ischemia on the  $I_{AHP}$  response. Furthermore, MCPG did not alter the ischemia-induced outward current. We have previously shown that the activation of mGluRs by 1S,3R-ACPD, or synaptic stimulation in the presence of ionotropic blockers, induces a slow inward current due to the suppression of membrane  $K^+$  conductance. Interestingly, this response was potentiated following the ischemic period (for up to 10 min). Thus the enhancement of mGluR responses after acute ischemia may contribute to glutamate excitotoxicity. Supported by the Swiss National Science Foundation and Sankyo.

## 321.3

MECHANISMS UNDERLYING THE PROTECTIVE EFFECT OF GROUP-II METABOTROPIC GLUTAMATE RECEPTORS (mGluRs) IN CULTURED CORTICAL NEURONS. V. Bruno<sup>1,2\*</sup>, M. Storto<sup>1</sup> and F. Nicoletti<sup>1,3</sup>. <sup>1</sup>I.M.N. "Neuromed", Pozzilli, Italy; Institute of Pharmacology, <sup>2</sup>School of Medicine or <sup>3</sup>Pharmacy, Catania University, Italy.

Activation of group-II mGluRs by DCG-IV protects mouse cultured cortical neurons grown over a monolayer of astrocytes against NMDA toxicity. The neuroprotective action of DCG-IV has been ascribed to multiple mechanisms, which include the inhibition of (i) cAMP formation, (ii) voltage-sensitive  $Ca^{2+}$  channels, and (iii) glutamate release. All these mechanisms should efficiently reduce neuronal excitability and synaptic transmission only during the exposure time to DCG-IV. Surprisingly, however, DCG-IV was neuroprotective when transiently applied to the cultures 6 hours before the NMDA pulse. This effect of DCG-IV could be prevented by applying the protein synthesis inhibitor, cycloheximide (CHX) either in combination with DCG-IV or during the interval between the DCG-IV- and the NMDA pulse. A delayed exposure to CHX also prevented the neuroprotective activity of DCG-IV applied in combination with NMDA. We suggest that activation of group-II mGluRs induces the expression of "neuroprotective genes", which oppose to NMDA toxicity during the progression of neuronal damage.

## 321.2

ANTISENSE OLIGODEOXYNUCLEOTIDES DIRECTED AGAINST mGluR5 METABOTROPIC GLUTAMATE RECEPTOR PROTECT AGAINST MALONIC ACID LESIONS IN RAT STRIATUM. J.J. Cha\*, A. Talati, J. A. Kerner, and A. B. Young. Dept. Neurology, Massachusetts General Hospital, Boston, MA 02114.

Glutamate receptors linked to phosphoinositide metabolism may play a permissive role in excitotoxicity (Beal et al., *Neurodegeneration* 2:81-91, 1993). We have explored the role of the mGluR5 subtype of metabotropic glutamate receptors in striatal toxicity using antisense oligodeoxynucleotides (ODN's). Phosphorothioate-modified antisense ODN's, scrambled ODN controls, or saline were injected into the right lateral ventricle of rat brain at various intervals prior to receiving a left intrastriatal injection of the mitochondrial toxin malonic acid. Rats were sacrificed 48h later, and the lesion sizes were determined by 2,3,5-triphenyltetrazolium chloride (TTC) staining of brain slices.

Pretreatment of rats with i.c.v. injection of antisense ODN directed against mGluR5 protected against malonic acid-induced striatal lesions in a time- and dose-dependent manner. Maximal protection was achieved when antisense ODN was injected 30h prior to the malonic acid injection. With single dose injections of antisense ODN, protection was dose dependent, with doses of 12 and 24 nmols being more protective than doses of 1 and 4 nmols.

Analysis of mGluR5 mRNA expression by *in situ* hybridization revealed no change in expression following treatment with antisense ODN directed against mGluR5. However, a measure of protein function, [ $^3H$ ]glutamate receptor binding under metabotropic receptor preferring conditions, showed a dose dependent decrease with pretreatment with antisense ODN.

These data argue that mGluR5 plays a permissive role in certain types of striatal toxicity. Further, in this system, the mechanism by which antisense ODN's exert their action appear to be at the level of translation into protein.

## 321.4

INDUCTION OF LIMBIC SEIZURES BY INTRACEREBRAL INJECTIONS OF 3,5-DIHYDROXYPHENYLGLYCINE (DHPG), A SELECTIVE METABOTROPIC GLUTAMATE RECEPTOR AGONIST, PRODUCES NEURONAL INJURY IN MICE. W. H. Jordan\*, J. A. Johnson, and J. P. Tizzano, Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN 46140.

Metabotropic glutamate receptors (mGluRs) are a heterogeneous family of receptors coupled to multiple second messenger systems via G-proteins. We have previously described that the mGluR selective agonist 1S,3R-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD) induces limbic seizures and selective neuronal injury in mice. In the present study we further evaluate the potential for limbic seizures and neuronal injury of the highly selective mGluR agonist 3,5-dihydroxyphenylglycine (DHPG), which like ACPD activates phosphoinositide (PI) coupled mGluRs (mGluR1 and/or mGluR5), however, is devoid of cAMP formation when expressed in non-neuronal cells. DHPG (800 nmol; 5ul) injected into the thalamus of mice induced limbic seizures that were similar to ACPD injections. At two days post-injection, neuronal necrosis and increased staining of glial fibrillary acidic protein occurred in the hippocampus. Necrosis was observed in the subiculum and in CA1-3, but not in the dentate gyrus. These data suggest that induction of mGluR mediated limbic seizures and neuronal injury in mice are a result of activating PI linked *in situ* mGluRs.

## 321.5

**METABOTROPIC GLUTAMATE RECEPTOR AGONIST 1S,3R-ACPD INDUCES INTERNUCLEOSOMAL DNA FRAGMENTATION AND CELL DEATH IN RAT STRIATUM.** Y. Wang, Z.-H. Qin, Streicher Eugene \*and T. N. Chase. ETB, NINDS, NIH, Bethesda, MD 20892.

To characterize some biochemical features of 1S,3R-ACPD-induced neurotoxicity, DNA fragmentation and striatal cell death were assessed after the acute unilateral administration of this drug into rat striatum. 1S,3R-ACPD induced internucleosomal DNA fragmentation in a dose-dependent manner. TUNEL and propidium iodide staining showed DNA fragmentation and profound nuclear condensation in striatal cells. Internucleosomal DNA fragmentation induced by 1S,3R-ACPD was attenuated by a protein synthesis inhibitor and was partially blocked by non-selective and selective metabotropic glutamate receptor antagonists. Receptor autoradiography showed that 1S,3R-ACPD (900 nmol) caused a loss of about 20%, 10% and 13% of striatal D<sub>1</sub> and D<sub>2</sub> dopamine receptors and NMDA receptors, respectively. 1S,3R-ACPD-induced striatal cell death was confirmed by *in situ* hybridization histochemistry which revealed significant decreases in GAD and proenkephalin mRNAs. Somatostatin mRNA was also decreased, indicating some associated interneuron degeneration. These results indicate that apoptotic mechanisms may contribute, at least in part, to the cellular neurotoxicity of 1S,3R-ACPD. Cell death caused by 1S,3R-ACPD may include GABAergic projection as well as interneurons.

## 321.7

**METABOTROPIC GLUTAMATE RECEPTORS MODULATE STRIATAL QUINOLINIC ACID TOXICITY** L.R. Orlando\*, D.G. Standaert, J.B. Penney, Jr., and A.B. Young. Program in Neuroscience, Harvard University and Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Metabotropic glutamate receptors (mGluRs) appear to play a role in excitotoxicity. We have found that two mGluR agents, (S)-4-carboxy-3-hydroxyphenylglycine ((S)-4C3HPG) and (RS)-3,5-dihydroxyphenylglycine acid, protect the rat striatum against quinolinic acid lesions. Both of these compounds are group 1 mGluR antagonists, while (S)-4C3HPG is also a group 2 mGluR agonist.

Another way of examining the effects of mGluRs on excitotoxicity is via restoration of striatal lesions after decortication, which has been shown to block toxicity of not only quinolinic acid but also NMDA, AMPA, and kainate. We have tried a number of mGluR agents, including (±)-1-aminocyclopentane-trans-1,3-dicarboxylic acid (*t*-ACPD) and the more selective group 1 agonists *trans*-azetidine-2,4-dicarboxylic acid (*t*-ADA) and (RS)-3,5-dihydroxyphenylglycine (DHPG), none of which were toxic alone in sham or decorticated animals. These agents were co-injected with quinolinic acid into the striatum of male rats that had been decorticated two weeks prior, and 2,3,5-triphenyltetrazolium chloride (TTC) was used for lesion analysis. None of these agonists restored toxicity at doses of 1000 nmoles co-injected with either 100 or 200 nmoles quinolinic acid. Only at extremely high doses of quinolinic acid (400 nmoles) and mGluR agonist (2000 nmoles) is toxicity partially restored (average lesion by TTC = 11.78 mm<sup>3</sup>).

Interestingly, DCG-IV, an NMDA receptor and group 2 mGluR agonist, restores toxicity in decorticated animals at a more moderate dose of 100 nmoles (average lesion by TTC = 13.81 mm<sup>3</sup>). The same dose in normal animals creates a very large lesion extending beyond the striatum into the cortex. We are investigating whether this is due to the NMDAR or mGluR actions of this compound.

## 321.9

**EFFECT OF NITRIC OXIDE SYNTHASE (NOS) INHIBITORS-ON QUINOLINATE-INDUCED NEUROTOXICITY.** D. Santamaria, F. Pérez, A. Santamaria, B. Escalante and C. Ríos\*. Dept. of Neurochemistry, I.N.N.N. and Dept of Pharmacology and Toxicology, CINVESTAV, MEXICO 14269.

Quinolinic acid (QUIN), a potent excitotoxin acting on NMDA receptors, is able to increase circling behavior (CB) and lipid peroxidation (LP) in rats, two expressions of neurotoxicity. It has been recently proposed a role of nitric oxide as a mediator of QUIN injury. Both *in vivo* and *in vitro* QUIN toxicity was tested in the presence of inhibitors of NOS activity, such as L-nitro arginine methyl ester (L-NAME). QUIN-induced CB (observed after apomorphine challenge) and LP (evaluated by lipid fluorescent products) were measured in striatally-lesioned rats and brain synaptosomes, respectively. QUIN (240 nmol/μL)-mediated CB (265 turns/hr) was blocked by 5, 10 and 15 mg/kg of i.p. L-NAME (-25, -49 and -52 %, respectively, as compared vs QUIN-treated rats). QUIN (10 mM)-induced LP was 156 % vs control and L-NAME (10, 20 and 40 mM) prevented LP by -52, -42 and -51 % vs QUIN, respectively. Similar results were obtained with other NOS inhibitors. These findings suggest a contribution of NOS activity on QUIN induced brain injury.

## 321.6

**DIFFERENTIAL ALTERATIONS in TRANSCRIPTION FACTOR BINDING ACTIVITIES DURING EXCITOTOXIN-INDUCED APOPTOSIS in RAT STRIATUM.** Z.-H. Qin, Y. Wang and T. N. Chase\*. ETB, NINDS, NIH, Bethesda, MD 20892.

To understand cellular mechanisms contributing to neuronal death, we measured changes in transcription factor binding activities during apoptosis induced by the NMDA receptor agonist quinolinic acid (QA). QA (120 nmol) induced rapid and robust increases in AP-1 and NFκB binding activities. The increase in AP-1 binding activity was relatively transient. NFκB binding dramatically increased from 2-12 h and then declined but remained elevated 24 h after QA injection. E2F-1 binding activity was only increased 6 h after QA injection. OCT-1 and SP-1 binding gradually decreased following QA injection. Myc-Max and CREB were not significantly altered. Increasing intensity of internucleosomal DNA fragmentation was detected from 12 h to 24 h after QA injection. Alterations in AP-1, NFκB, E2F-1, OCT-1 and SP-1 binding activities were blocked by the NMDA receptor antagonist MK-801. The increases in AP-1 and NFκB binding activities were also attenuated by the protein synthesis inhibitor cycloheximide. These studies demonstrated a complex pattern of changes in transcription factor binding activities during QA-induced apoptosis and a temporal correlation of these alterations with the appearance of internucleosomal DNA fragmentation, suggesting that some genes may be turned on while others may be turned off during apoptosis.

## 321.8

**ZINC CHELATING AGENTS INHIBIT EXCITOTOXIC ACTION OF QUINOLINIC ACID ON BASAL FOREBRAIN CHOLINERGIC NEURONS.** P.J. Lee, K. Jhamandas, R.J. Boegman\*, and R.J. Beninger<sup>1</sup>. Dept. of Pharmacology and Toxicology and <sup>1</sup>Psychiatry, Queen's Univ. Kingston, Ontario, Canada K7L 3N6.

Picolinic acid, which chelates zinc, attenuates the excitotoxic action of quinolinic acid (QUIN). To determine if zinc chelation underlies picolinate action, we evaluated potential of two known zinc chelators to inhibit the neurotoxic action of QUIN on cholinergic neurons of the rat nucleus basalis magnocellularis (nbM). The neurotoxicity was assessed by measuring loss of choline acetyl-transferase (ChAT) activity in the cortex or amygdala 6 days after an intra-nbM injection of QUIN (60, 120 nmol) with or without the zinc chelators - diethyldithiocarbamate (DCA; 120-480 nmol) or N-N'-N'-tetrakis (2-pyridylmethyl) ethylene-diamine (TPEN; 120 nmol). Injection of QUIN (60, 120 nmol) reduced ChAT activity in both regions. Combination of DCA or TPEN with QUIN partially prevented this reduction of ChAT activity. DCA failed to influence the reduction in ChAT activity produced by injections of NMDA (30 nmol) or AMPA (1 nmol). The results show that known zinc chelators produce a selective attenuation of cholinergic neurotoxicity produced by QUIN and mimic the action of picolinic acid. [Supported by MRC Canada].

## 321.10

**THE NMDA RECEPTOR AGONIST, QUINOLINIC ACID, INDUCES *hsp70* GENE EXPRESSION AND APOPTOSIS IN THE DENTATE GYRUS.**

J.W. Sharp\*. Dept Anatomy & Physiology, College of Veterinary Medicine, Kansas State University, Manhattan, KS 66506-5602.

The NMDA receptor agonist, quinolinic acid, was hypothesized to generate apoptosis in the rat brain. Quinolinic acid should induce apoptosis in the same hippocampal areas with heat shock gene, *hsp70*, induction.

Female Sprague-Dawley rats (200-250gm) were placed under halothane anesthesia and stereotactically injected with 5μl of 4mg/ml quinolinic acid into the right lateral cerebral ventricle. After 72 hours survival, rats were anesthetized with halothane and perfused. Alternate frozen brain sections (40μm) were processed for evidence of apoptosis or heat shock protein, HSP70, induction. For apoptosis, DNA fragmentation was determined by binding digoxigenin-11-dUTP to 3'-OH ends of DNA using the terminal deoxynucleotidyl transferase enzyme (TdT). An anti-digoxigenin antibody conjugated with a peroxidase enzyme was then used to detect the digoxigenin complexed to DNA fragments. HSP70 induction was determined by the avidin-biotin/horseradish-peroxidase immunocytochemical technique utilizing a monoclonal antibody (Amersham).

Quinolinic acid HSP70 induction was found predominantly in CA3 pyramidal cells, and cells of the polymorph and granule cell layer of the dentate gyrus. Evidence of apoptosis was seen only in dentate granule cells. There was no evidence of apoptosis in areas where HSP70 was not induced. 5μl of 4mg/ml quinolinic acid induced HSP70 in more than 90% of dosed rats. Rats without HSP70 induction did not show evidence of apoptosis.

Results suggest that apoptotic-like cell death may be an important consequence of NMDA receptor mediated excitotoxicity. This however, may not be as widespread as necrosis or heat shock induction.

RECOVERY OF HYPOTHALAMIC NMDA-INDUCED C-FOS EXPRESSION FOLLOWING NEONATAL MSG LESIONS. M. Natarajan and M. Wilkinson\* Depts. of Obst. and Gynaecol., Physiol. and Biophys., Dalhousie U., Halifax, N.S., Canada.

We have previously reported that a single, neonatal injection of MSG (4mg/g; day 2) induces precocious puberty in female rats (Neuroendocr. 52 143, 1990). At this dose MSG exerts neurotoxic damage to the ARC nucleus. We hypothesize that some degree of recovery or reorganization must occur to sustain the emergence of normal ovulatory function approximately 4 weeks later. To test this we have used c-fos expression as a developmental marker of ARC response to GLUR stimulation with NMDA (Dev. Br. Res. 73 193, 1993). Neonatal (d2) female pups were injected with MSG (4mg/g, s.c.). Controls received saline. Groups of pups (n = 4) were given injections of NMDA, known to stimulate ARC c-fos (d3 - d29). Pups were sacrificed 2hr after NMDA injection. Control (saline) pups responded to NMDA with a robust age-dependent induction of FOS-like immunoreactivity (FLI). MSG treatment severely attenuated the FLI response immediately following the lesion (d2 - d10). Subsequently, FLI recovered up to 75% of control values by d16. Full recovery was seen by 29 days. In contrast, pups given chronic MSG treatment (d2,4,6,8; 4mg/g s.c., known to delay puberty and induce severe endocrinopathies) followed by NMDA as above (d16 - d29), revealed only a 50% recovery of FLI by d29. In both treatment groups, the zone of recovery (i.e. re-appearance of FLI) began close to the third ventricle and with time, radiated outwards towards the periphery of the ARC. FLI-positive neurons which reappeared in the ARC following MSG lesions presented a highly irregular nuclear morphology. Nissl staining indicated both condensed nuclear and cytoplasmic areas. We conclude that recovery of ARC function (i.e. onset of puberty) after a neonatal MSG lesion is coincident with the reappearance of a normal FLI response to NMDA. ## 321.13

LOW DOSE ADMINISTRATION OF DOMOIC ACID IN THE NEONATAL RAT: C-FOS EXPRESSION AND SPATIAL LEARNING. S.M. Strain, G.V. Allen\* and R.A.R. Tasker\* Dept. Anat. & Physiol. Atlantic Vet College, UPEI, Charlottetown PEI, C1A 4P3 and Dept. Anat. and Neurobiology, Dalhousie Univ., Halifax, NS, B3H 4H7, Canada.

Our objective was to assess the effects of administration of equitoxic but subconvulsive doses of domoic acid (DOM) on central patterns of C-Fos expression and spatial learning in developing female Sprague Dawley rats. Injections (i.p.) of various doses of DOM or saline (n=6) were administered to different groups on postnatal days 0, 5, 14, 22 and 30. Dose response curves for behavioural toxicity were generated to determine equitoxic doses of DOM for each age. C-Fos experiments were conducted in groups of rats (n= 3-5) from P5 to adult receiving either saline or an equitoxic but subconvulsive dose of DOM. Assessment of spatial learning in the Morris water maze began at postnatal day 60 (n=8 per dose). Two hours post-injection animals were euthanized, perfused transcardially with 4% paraformaldehyde and coronal sections (40µm) of whole brain were incubated in the presence of C-fos antibody. Image analysis revealed widespread cellular C-Fos expression that intensified with age following subconvulsive doses of DOM, although, little or no label was detected in P5 pups. The most pronounced elevations in FOS-LIR occurred in the nucleus gracilis, area postrema, NTS of the medulla, the parabrachial nucleus, central hypothalamic nuclei, the amygdala, and various cortical regions. Preliminary analysis of the maze data imply alterations between groups in spatial learning although full analysis is incomplete at time of submission. We conclude that there are differences in both C-Fos expression and spatial learning following exposure to DOM at different ages. (Supported in part by New Brunswick Heart & Stroke Foundation)

## 321.12

RAPID INDUCTION OF NF-κB IN ADULT BUT NOT JUVENILE RAT LIMBIC STRUCTURES FOLLOWING SEIZURE ACTIVITY. Y. Rong, M. Baudry\* Neuroscience Program, Univ. of Southern California, Los Angeles, CA 90089

Previous studies have indicated that increased formation of oxygen free radicals is likely to participate in the cascade of events leading to neuronal damage following kainate (KA)-induced seizure activity. As reactive oxygen species are involved in signal transduction pathways leading to nuclear factor kappa B (NF-κB) activation, we examined the effects of KA treatment on the activation of NF-κB in adult and juvenile rat brain. For comparison, changes in two other transcription factors, activator protein-1 (AP-1) and Sp1, were also determined. In adult rat piriform cortex and hippocampus, significant induction of NF-κB was observed at 4 h after KA injection, and maximal increase was reached at 8-16 h post-treatment. NF-κB binding activities returned to control levels by 5 days after injection. NF-κB binding activities were slightly decreased in adult rat cerebellum at 8 and 16 h after KA treatment. In the juvenile rat, no significant changes in NF-κB binding activity were observed in piriform cortex, hippocampus and cerebellum after KA injection. Changes in AP-1 binding activity were qualitatively similar to those observed with NF-κB in adult but not juvenile rat brain, as AP-1 was significantly induced in juvenile piriform cortex and hippocampus following KA injection. On the other hand, little or no changes in Sp1 activity were detected in adult and juvenile rat brain. Our results provide further evidence that oxidative stress participates in neuronal damage resulting from KA-induced seizure activity.

## 321.14

PRIMING OF CULTURED NEURONS WITH SABELUZOLE RESULTED IN LONG LASTING INHIBITION OF NEUROTOXIN-INDUCED TAU EXPRESSION AND CELL DEATH. Rizzini D, Uberti F, Sinelli M, Pizzi M, Grilli P.F., Spano and M. Memo\* Div. Pharmacol., Dep. Biomed. Sci. & Biotechnol., Brescia University, School of Medicine, 25123 Brescia, Italy

Sabeluzole is an experimental drug originally developed for its anti-ischemic, anti-epileptic and cognitive enhancing properties. Recently, it has been reported that repeated treatments with sabeluzole protect cultured rat hippocampal neurons against NMDA and glutamate-induced neurotoxicity. We evaluated the possibility that Sabeluzole may elicit neuroprotection by acting, either directly or indirectly, on tau proteins in primary neurons from rat brain and in differentiated human neuroblastoma cell line. The repeated treatments of primary cultures of cerebellar granule cells with nanomolar concentration of sabeluzole result in mature cells that are resistant to the excitotoxicity induced by glutamate. Sabeluzole treatment prevents glutamate elicited increase of tau expression, as determined at two hours after the neurotoxic pulse by immunocytochemistry analysis. Moreover, sabeluzole treatment did not modify the pattern of expression of tau proteins, as shown by measurement of the mRNA levels during the cell maturation by PCR analysis and of tau proteins at DIV 12 by western blot analysis. We then performed a second set of experiments using the human neuroblastoma cell line SH-SY5Y differentiated in neuron-like cells after treatment with retinoic acid. Since these cells do not express functional glutamate receptors doxorubicin exposure was chosen to induce cell degeneration. Doxorubicin was neurotoxic and, like glutamate, increased tau immunoreactivity two hours after the treatment. Sabeluzole prevents cell death and the increase of tau induced by doxorubicin. Sabeluzole was indeed able to prevent neurotoxicity induced by agents acting with different mechanisms and at different cellular levels.

### EXCITATORY AMINO ACID RECEPTORS: PHYSIOLOGY, PHARMACOLOGY, AND MODULATION—mGluR II

## 322.1

A NOVEL SELECTIVE ANTAGONIST OF METABOTROPIC GLUTAMATE RECEPTORS COUPLED TO PHOSPHOLIPASE D. D.E. Pellegrini-Giamprini\*, S. Albani Torregrossa, R. Pellicciari, M. Marinuzzi† and F. Moroni. Dipartimento di Farmacologia Preclinica e Clinica, Università di Firenze, 50134 Firenze, and †Istituto di Chimica e Tecnologia del Farmaco, Università di Perugia, 06123 Perugia, Italy.

Activation of phospholipase D (PLD) represents an important mechanism leading to a long-lasting and abundant formation of diacylglycerol in brain tissue. Metabotropic glutamate receptors (mGluR) coupled to PLD appear to be distinct from any known mGluR subtype linked to phospholipase C or adenylyl cyclase (Pellegrini-Giamprini et al., *Br. J. Pharmacol.*, in press). Unfortunately, selective ligands for these receptors have not yet been identified. mGluR agonists activate PLD with the following rank order of potencies: quisqualate > ibotenate > L-CCG-I > (1S,3R)-ACPD > L-cysteinyl sulfinate > L-AP3 > L-aspartate > L-glutamate. (+)MCPG (at 1 mM) and DHPG (IC<sub>50</sub> = 60 µM) inhibit the PLD response induced by agonists, but their antagonist effect is not selective for PLD-coupled mGluRs. With this in mind, we examined the effects of a series of sixteen stereoisomers of phenylcarboxycyclopropylglycine (PCCGs, Pellicciari et al., *J. Med. Chem.*, in press) on the PLD-specific transphosphatidyl transfer reaction resulting in the formation of [<sup>3</sup>H]phosphatidyl-ethanol ([<sup>3</sup>H]PEt) in rat hippocampal slices. The most interesting compound appeared to be the (2S,1'S,2'R,3'S)-PCCG stereoisomer (PCCG-16), which antagonized the formation of [<sup>3</sup>H]PEt induced by (1S,3R)-ACPD in a concentration-dependent manner (IC<sub>50</sub> = 1 µM) and was unable to elicit a PLD response up to 1 mM. PCCG-16 had no effect (up to 300 µM) on phosphoinositide hydrolysis or adenylyl cyclase activity in BHK cells expressing mGluR1a, mGluR2 or mGluR4. Moreover, PCCG-16 failed to displace (up to 200 µM) radioligand binding to AMPA, NMDA, and kainate receptors, as well as to mGluR1 and mGluR4 in rat cortical homogenates. Selective antagonists of PLD-coupled mGluRs may be of help in elucidating their physiological and pathological functions in the CNS. Supported by the European Commission (Biomed I BMH1-CT93-1033 project)

## 322.2

SELECTIVITY OF THE EFFECTS OF N-ACETYLSPARTYLGLUTAMATE (NAAG) ON mGluR3 METABOTROPIC GLUTAMATE RECEPTORS.

B. Wroblewska\*, A. Surin\*, S. Pshenichkin\*, J.T. Wroblewski\*, J.H. Neale†, Dept. Biology†, and Pharmacology\*, Georgetown University, Washington, DC 20057.

We have shown previously that in cerebellar granule and glial cells NAAG, like glutamate, trans-ACPD, and AP4, decreases forskolin-stimulated cAMP levels in a dose-dependent manner. This inhibition is blocked by pertussis toxin, and is not due to the activation of phosphodiesterase. These data strongly suggested that NAAG interacts with metabotropic glutamate receptor(s). Using clones of metabotropic glutamate receptors, we developed lines of Chinese hamster ovary cells expressing different mGluRs. Our results indicated that only in the cells expressing mGluR3 receptor, NAAG had an inhibitory effect on forskolin-stimulated cAMP formation. NAAG did not inhibit cAMP in the cells expressing mGluR2, mGluR4, mGluR6, and mGluR7, and did not affect PI hydrolysis in the cells expressing mGluR1, and mGluR5. To further investigate this selectivity of NAAG on subtypes of metabotropic glutamate receptors we constructed chimeric receptor molecules in both CHO and A293 cells. Replacement of the extracellular N-terminus of mGluR1a with the corresponding portion of mGluR2 or mGluR3 preserved signal transduction mechanism characteristic for mGluR1a receptor, while generated agonist selectivity characteristic for mGluR2 or mGluR3. In the cells expressing chimeric receptors glutamate, trans-ACPD, and L-CCG-I increased intracellular Ca (measured by Fura-2 fluorescence). However, NAAG caused increase in [Ca<sup>2+</sup>]<sub>i</sub> only in the cells expressing chimeric receptor mGluR3/mGluR1a, but not in mGluR2/mGluR1a, and had no effect on mGluR1a receptor. Our results support the hypothesis that NAAG is a very highly selective, endogenous agonist of type 3 metabotropic glutamate receptor, and interacts with the N-terminal binding domain of the receptor. (Supported by NIH grants NS28130 and NS01720.)

## 322.3

## PHARMACOLOGICAL CHARACTERIZATION OF mGluR6 METABOTROPIC GLUTAMATE RECEPTORS EXPRESSED IN CHO CELLS

J.T. Wroblewski<sup>1</sup>, S. Pshenichkin<sup>1</sup> and B. Wroblewska<sup>2</sup>, <sup>1</sup>Dept. of Pharmacology and <sup>2</sup>Dept. of Biology, Georgetown University, Washington D.C. 20007

The metabotropic glutamate receptor mGluR6 belongs to group III mGluRs (together with mGluR4, 7 and 8) characterized by high sensitivity to L-2-amino-4-phosphonobutyric acid (AP4) and has been shown by RNA blot hybridization and *in situ* hybridization to be localized exclusively in the retina. In our studies, using PCR amplification we detected the message for mGluR6 in whole rat brain, in the retina, cerebellum, as well as in the spinal cord and in primary cultures of cerebellar granule neurons and cerebellar astrocytes. To study its pharmacological properties we prepared Chinese hamster ovary (CHO) cells stably transfected with mGluR6 cDNA. This cell line showed a high level of receptor expression and the maximal inhibition of forskolin-stimulated cAMP formation induced by AP4 reached 95%. Dose-response studies performed with several putative agonists indicated that the most potent were serine-O-phosphate (SOP, EC<sub>50</sub> = 0.1  $\mu$ M), AP4 (0.5  $\mu$ M) and glutamate (3  $\mu$ M), but also (2S,1'S,2'S)-2-(carboxycyclopropyl)glycine (L-CCG-I, 0.5  $\mu$ M) and less potent transACPD (50  $\mu$ M), quisqualate (100  $\mu$ M) and 4-carboxyphenylglycine (4CPG, 100  $\mu$ M). The action of 1  $\mu$ M AP4 was not antagonized by the following compounds (at 1 mM concentration): 4-carboxy-3-hydroxyphenylglycine (4C3HPG),  $\alpha$ -methyl-4-carboxyphenylglycine (MCPG),  $\alpha$ -methyl-cyclopropylglycine (MCCG), and  $\alpha$ -methyl-aminophosphonobutyrate (MAP4). A 50% inhibition of the AP4 effect was observed with 1 mM  $\alpha$ -methyl-4-phosphonophenylglycine (MPPG). These results indicate that in addition to the retina mGluR6 may be significantly expressed in other brain structures and that its pharmacological profile, as determined in transfected CHO cells, may be distinct from that of other group III metabotropic glutamate receptors. (Supported by NIH grants NS28130 and NS01720.)

## 322.5

PHARMACOLOGICAL CHARACTERIZATION OF hmGluR2 AND hmGluR4 EXPRESSED IN CHINESE HAMSTER OVARY (CHO) CELLS USING [<sup>35</sup>S]GTP $\gamma$ S BINDING. D.M. Kowal, C. Hsiao<sup>1</sup>, S. Leinbach<sup>1</sup>, A. Ge, J. Wardwell-Swanson, and J.R. Tasse<sup>2</sup>. Wyeth-Ayerst Research, CNS Disorders, CN 8000, Princeton, NJ 08552 and <sup>1</sup>Wyeth-Ayerst Research, Core Biotechnology, Radnor, PA 19087.

To date, the functional assessment of cloned human metabotropic glutamate receptor (hmGluR) subtypes negatively coupled to adenylate cyclase has been identified by use of agonist inhibition of forskolin-stimulated cAMP accumulation. In the present study, mGluR agonists have been evaluated in at least two cell lines expressing hmGluRs using a functional [<sup>35</sup>S]GTP $\gamma$ S binding assay. Comparison of mGluR agonist rank order of potency of EC<sub>50</sub> values in the hmGluR2 clone showed good correlation with published results for the inhibition of forskolin-stimulated cAMP formation assay (Flor *et al.*, Eur. J. Neurosci. 7:622, 1995). Interestingly, it appeared that both L-quisqualate and L-AP4 possessed weak partial agonist effects in the [<sup>35</sup>S]GTP $\gamma$ S binding assay which were not observed in the cAMP accumulation assay. Evaluation of agonist activity with the hmGluR4 clone in [<sup>35</sup>S]GTP $\gamma$ S binding also correlated well with published cAMP EC<sub>50</sub> determinations (Flor *et al.*, Neuropharmacol. 34:149, 1995). Unexpectedly, L-quisqualate exhibited weak partial agonism at concentrations >10  $\mu$ M in [<sup>35</sup>S]GTP $\gamma$ S binding which was not detected in the forskolin-stimulated cAMP assay. The hmGluR7 is presently being expressed in a CHO cell line for evaluation in the [<sup>35</sup>S]GTP $\gamma$ S binding assay. The results of the present study suggest that [<sup>35</sup>S]GTP $\gamma$ S binding could be used as a functional assay for hmGluRs expressed in CHO cells. In the case of the determination of partial agonist activity, it appears that the [<sup>35</sup>S]GTP $\gamma$ S binding assay could be more sensitive than the forskolin-stimulated cAMP assay.

## 322.7

METABOTROPIC GLUTAMATE RECEPTORS MODULATE TRANSMITTER OUTPUT: A MICRODIALYSIS STUDY IN THE RAT CORTEX AND CAUDATE. A. Cozzi, G. Lombardi<sup>1</sup>, P. Leonardi, M. Carli, F. Moroni. Dept. of Pharmacology, Univ. of Florence, Viale Morgagni, 65, 50134 Firenze, Italy.

A number of *in vitro* studies have shown that mGluR1 agonists potentiate transmitter release from cortical slices or synaptosomes, and that mGluR2/3 agonists reduce the depolarization-induced transmitter output from striatal slices (see: Br. J. Pharmacol. 110: 1407; 1993, Neurochem. Int. 24: 525; 1994 and Br. J. Pharmacol. 117: 189; 1996). Thus, the stimulation of mGluRs may either decrease or increase transmitter release depending on which receptor subtype is present. In the present study, utilizing microdialysis in freely moving rats, we tested the effects of 1S,3R-ACPD, (RS)-3,5-dihydroxyphenylglycine (DHPG) a selective agonist of mGluRs of the first group) and (2S,3S,4S)- $\alpha$ -(carboxycyclopropyl)glycine (L-CCG-I as a preferential agonist of mGluRs of the second group) on the extracellular concentration of L-Glu and L-ASP in the cortex and in the caudate. In the cortex, the addition of 1S,3R-ACPD (100  $\mu$ M-1 mM) to the microdialysis fluid caused a concentration-dependent increase of L-Glu in the dialysate. The maximum increase was approximately 4 fold; reached within 5 min of 1S,3R-ACPD application and rapidly returning to basal level. Similarly, DHPG (300  $\mu$ M - 1 mM) caused a significant increase of L-Glu concentration in the dialysate. L-CCG-I did not change L-Glu output up to a concentration of 100  $\mu$ M, but slightly increased this output when its concentration was 1 mM. The potentiating effect of 1S,3R-ACPD (300  $\mu$ M) on glutamate output was reduced by (S)-4-carboxyphenylglycine (4-CPG, 300  $\mu$ M), a mGluR1 antagonist. When the dialysis probe was placed in the caudate, 1S,3R-ACPD (100  $\mu$ M-1 mM) or L-CCG-I (3-10  $\mu$ M) significantly decreased the appearance of L-Glu in the dialysate. In conclusion, these experiments support the idea that mGluR agents modulate the function of the glutamatergic synapses by increasing or decreasing transmitter release depending on the subtype of the receptor that prevails in the neurons under study.

DESENSITIZATION OF HUMAN mGluR1 $\alpha$  INVOLVES BOTH TRANSCRIPTIONAL AND TRANSLATIONAL MECHANISMS. M.A. Desai<sup>1</sup>, N.G. Mayne, J.P. Burnett, and D.D. Schoepp. Central Nervous System Research, Eli Lilly & Co., Indianapolis, IN 46285.

We have studied desensitization of a human mGluR1 $\alpha$  (HmGluR1 $\alpha$ ) receptor coexpressed with a rat glutamate/aspartate transporter (GLAST) in a novel cell line (AV12-664; ATCC CRL 9595). Desensitization of HmGluR1 $\alpha$ -mediated phosphoinositide (PI) hydrolysis is maximal after 12 hour pretreatment with the mGluR agonist, 3,5-dihydroxyphenylglycine (DHPG). This desensitization was blocked in a concentration-dependent manner upon pretreatment with increasing concentrations of the protein synthesis inhibitors, cycloheximide (CHX) or puromycin (PUR). Concentrations of CHX that maximally blocked desensitization inhibited protein synthesis by  $88 \pm 1.3\%$ , as determined by measurement of [<sup>3</sup>H]leucine incorporation. DHPG-induced desensitization of HmGluR1 $\alpha$ -mediated PI hydrolysis was also fully blocked by the transcription inhibitor, actinomycin D (ActD). Reversal of DHPG-induced desensitization required washout of agonist from the culture medium for 12 hours before subsequent measurement of glutamate-stimulated PI hydrolysis. CHX, at a concentration that maximally inhibited protein synthesis, had no effect on reversal of HmGluR1 $\alpha$  desensitization. These data suggest that desensitization of HmGluR1 $\alpha$  involves synthesis of an inducible protein. In contrast, reversal of agonist-induced desensitization does not appear to require synthesis of new HmGluR1 $\alpha$  protein. Funded by Eli Lilly & Co.

pA<sub>2</sub> DETERMINATIONS OF THE COMPETITIVE hmGluR4 ANTAGONIST MAP4: A DIRECT COMPARISON OF [<sup>35</sup>S]GTP $\gamma$ S BINDING AND FORSKOLIN-STIMULATED cAMP ACCUMULATION ASSAYS. J.R. Tasse, E.A. Muth<sup>1</sup>, C. Hsiao<sup>1</sup>, A. Ge, J. Wardwell-Swanson and D.M. Kowal. Wyeth-Ayerst Research, CNS Disorders, CN 8000, Princeton, NJ 08543 and <sup>1</sup>Wyeth-Ayerst Research, Core Biotechnology, Radnor, PA 19087.

To validate use of the [<sup>35</sup>S]GTP $\gamma$ S binding assay as a means of assessing functional hmGluR activity, the pA<sub>2</sub> of the selective mGluR4 antagonist MAP4 was determined using a CHO cell line stably expressing cloned hmGluR4. Agonist mediated responses evoked by the Group III mGluR selective agonist L-AP4 were determined in the absence and presence of MAP4 in both the [<sup>35</sup>S]GTP $\gamma$ S binding assay and the forskolin-stimulated cAMP accumulation assay. L-AP4 produced concentration-related effects in each assay both in the absence and presence of MAP4. L-AP4 responses were shifted to the right in a parallel manner in the presence of increasing concentrations of MAP4. Schild analysis of the dose ratio versus the concentration of MAP4 revealed a linear regression in both assays whose slopes did not differ statistically from unity, indicative of a competitive antagonism. pA<sub>2</sub> values determined for MAP4 between assays were not statistically different. The results of the present study correlate with *in vitro* electrophysiological experiments using the neonatal rat spinal cord preparation (Jane *et al.*, Br. J. Pharmacol. 112:809, 1994) and confirm the suggestion by Johansen and Robinson (Eur. J. Pharmacol.- Mol. Pharmacol. Sect. 290, R1, 1995) that MAP4 is a competitive antagonist of hmGluR4 agonist mediated responses. Furthermore, the finding of similar MAP4 pA<sub>2</sub> values in the [<sup>35</sup>S]GTP $\gamma$ S binding and the forskolin-stimulated cAMP accumulation assays suggests that the activity in these assays is mediated via a common receptor and that the pharmacological activities of mGluR4 ligands, when determined in these assays, are likely to be equivalent.

## 322.8

ASTROCYTE INTRACELLULAR pH IS INCREASED BY ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS. B. Amos, A. Mathie<sup>1</sup>, C.D. Richards<sup>2</sup> and M. Chesler<sup>2</sup>. Depts. Physiol./Neurosurg. NYU Med. Ctr., 550 1st Ave., NY, NY 10016, Depts. Physiol./Pharmacol. RFHSM, Rowland Hill St. London NW3 2PF. <sup>1</sup>† <sup>2</sup>‡

We studied the effect of metabotropic glutamate receptor (mGluR) activation upon the intracellular pH (pH<sub>i</sub>) of primary cultured (7-21d) rat astrocytes using BCECF fluorescence. Application of the mGluR agonist 1s,3R-ACPD (25-100  $\mu$ M) evoked a rapid pH<sub>i</sub> increase of up to 0.3 unit pH [1]. This response could be evoked by s-3HPG but not by i-CCG-I or L-AP4 suggesting involvement of a group-I receptor (mGluR1 or mGluR5). The alkalinization was only seen in solutions buffered by CO<sub>2</sub>/HCO<sub>3</sub><sup>-</sup> and was not blocked by SITS (500  $\mu$ M), DIDS (750  $\mu$ M) or EIPA (200  $\mu$ M). The response persisted in the absence of Na<sup>+</sup>, whereas depolarization-induced alkaline shifts (40 mM K<sup>+</sup>) were blocked, indicating that the metabotropic pH shift was not due to electrogenic Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport. The mGluR-evoked response was reduced in 0 Ca<sup>2+</sup> media and abolished by BAPTA-AM pretreatment, suggesting a Ca<sup>2+</sup>-dependent mechanism of activation. Our data suggest that *in vivo* alkalinization of astrocytes [2] can have a mGluR-mediated component. Supported by the NIH (NS32123), BBSRC† <sup>1</sup> and the Wellcome Trust‡. ## 322.9

STRIATAL METABOTROPIC GLUTAMATE RECEPTORS REGULATE ACUTE AMPHETAMINE-STIMULATED NEUROPEPTIDE GENE EXPRESSION IN THE RAT STRIATUM. J. Q. Wang\* and J. F. McGinty. Dept. of Anatomy and Cell Biology, East Carolina Univ. Sch. of Med., Greenville, NC 27858-4354, USA.

Metabotropic glutamate receptors (mGluR) are expressed by medium spiny neurons in the rat striatum. In order to detect possible involvement of mGluRs in regulation of tonic and phasic expression of neuropeptide genes contained by these neurons, a competitive mGluR receptor antagonist, (+)- $\alpha$ -methyl-4-carboxyphenylglycine [(+)-MCPG], was unilaterally injected into the right dorsal striatum (caudoputamen). The effects of pharmacological blockade of striatal mGluRs by (+)-MCPG on basal and amphetamine-stimulated neuropeptide mRNA expression in the striatum on the injection side were evaluated with quantitative *in situ* hybridization. Intrastriatal injection of (+)-MCPG at doses of 0.4, 2 and 10  $\mu\text{g}/1\ \mu\text{l}$  had no influence on basal levels of preprodynorphin, substance P and preproenkephalin mRNA in the dorsal striatum. However, (+)-MCPG, at doses of 0.4 and 2  $\mu\text{g}/1\ \mu\text{l}$ , significantly attenuated induction of striatal preprodynorphin and substance P mRNA induced by acute injection of amphetamine (2 mg/kg). Moderate induction of preproenkephalin mRNA by acute amphetamine was also attenuated by intrastriatal pretreatment with (+)-MCPG at doses of 0.4 and 2  $\mu\text{g}/1\ \mu\text{l}$ , although the effect did not reach significance. Intrastriatal vehicle infusion had no effect on basal or amphetamine-stimulated neuropeptide mRNA expression. These results indicate that activation of (+)-MCPG-sensitive mGluRs is necessary for preprodynorphin and substance P and, to a lesser extent, preproenkephalin mRNA induction in striatal projection neurons in response to indirect dopamine agonist administration. However, activity of (+)-MCPG-sensitive mGluRs may not be important for maintaining constitutive expression of these mRNAs in the striatum (supported by N.C. Governor's Institute).

## 322.11

4-HYDROXYNONENAL, A PRODUCT OF LIPID PEROXIDATION, IMPAIRS SIGNAL TRANSDUCTION OF METABOTROPIC RECEPTORS IN HIPPOCAMPAL NEURONS. E. M. Blanc\*, J. F. Kelly, R. J. Mark, and M. P. Mattson Sanders-Brown Center on Aging and Dept. of Anatomy & Neurobiology, Univ. Kentucky, Lexington KY 40536. Gerontology Research Center, NIA, Baltimore, MD 21224.

Amyloid  $\beta$ -peptide (A $\beta$ ) can disrupt ion transport systems and kill neurons. We recently showed that subtoxic levels of A $\beta$  can impair muscarinic cholinergic signal transduction, apparently by "uncoupling" the receptor from its GTP-binding (G) protein (Kelly et al, PNAS, in press). Neurotoxic actions of A $\beta$  are mediated by generation of oxyradicals and lipid peroxidation. 4-hydroxynonenal (HNE) is a prominent aldehydic product of lipid peroxidation that may play a key role in the mechanism of A $\beta$  neurotoxicity (Mark et al, this meeting). HNE conjugates to cysteine, lysine and histidine residues of proteins and can impair their function. We now show that HNE can impair coupling of metabotropic acetylcholine and glutamate receptors to their G proteins in cultured rat hippocampal neurons. Carbachol and 3,5-dihydroxyphenylglycine (DHPG) were employed to selectively activate metabotropic receptors for acetylcholine and glutamate, respectively. HNE caused a concentration-dependent suppression of carbachol- and DHPG-induced accumulation of inositol phosphates. Antioxidants, (vitamine E and propyl gallate) were unable to reverse the impairment of metabotropic receptor signaling induced by HNE consistent with HNE's action being downstream of lipid peroxidation. Calcium imaging studies indicated that HNE abolished metabotropic agonist-induced calcium responses. The molecular target of HNE-induced metabotropic signal transduction disruption may be the G protein because GTPase activity induced by metabotropic agonists was abolished in membranes isolated from neurons treated with HNE. Our data indicate that HNE is a mediator of oxidative stress-induced disruption of signaling via GTP binding protein-linked receptors. Oxyradical-induced alteration of metabotropic receptors could contribute to neuronal dysfunction and death in an array of neurodegenerative disorders including Alzheimer's disease. INTRACELLULAR CALCIUM RESPONSES TO mGluR-ACTIVATION IN GUINEA-PIG HIPPOCAMPAL SLICES. S.R. Young\*, R. Bianchi, and R.K.S. Wong. Dept. of Pharmacology, SUNY-HSCB, Brooklyn, NY 11203.

Activation of metabotropic glutamate receptors (mGluRs) has been reported to have multiple effects in hippocampal pyramidal cells including suppression of  $\text{K}^+$  currents,  $\text{Ca}^{2+}$  release from intracellular stores, and modulation of calcium channels (Pin & Duvoisin, *Neuropharmacology* 34: 1, 1995).

We studied the effects of the specific mGluR agonist 1S,3R-1-aminocyclopentane-1,3-dicarboxylate (ACPD) on the electrical activity and intracellular calcium ( $[\text{Ca}^{2+}]_i$ ) of pyramidal cells in hippocampal slices. Calcium Green-1 was injected into neurons with intracellular electrodes. Cell membrane potentials together with fluorescence of the  $\text{Ca}^{2+}$ -sensitive dye were recorded. At resting membrane potentials (-59/-73 mV), bolus application of ACPD (estimated concentration 100-200  $\mu\text{M}$ ) induced depolarization (6-18 mV) and firing associated with  $[\text{Ca}^{2+}]_i$  increase of similar duration. In tetrodotoxin (0.4  $\mu\text{M}$ ) the spike firing was abolished, but the ACPD-induced depolarization (5-22 mV) and the concomitant  $[\text{Ca}^{2+}]_i$  increase persisted. Hyperpolarizing current pulses showed that the depolarization was associated with a conductance increase. Furthermore, the hyperpolarization reduced the  $[\text{Ca}^{2+}]_i$  increase caused by ACPD.

The data suggest that mGluR activation induces prolonged depolarization associated with a  $[\text{Ca}^{2+}]_i$  rise. The  $[\text{Ca}^{2+}]_i$  rise is, at least in part, caused by an influx through voltage-sensitive channels.

GROUP III mGLURS MODULATE CALCIUM CURRENTS IN THE ADULT RAT NEOCORTEX. A. Stefani\*, F. Spadoni and G. Bernardi, IRCCS Ospedale S.Lucia and Uni. Tor Vergata, Via Ardeatina 306 00139 Rome, Italy

The contribution of 1-AP4-sensitive mGluRs to the physiology of the corticostriatal projection is a crucial matter with regard to the potential capability of group III agonists to act as neuroprotective agents, to modify the seizure threshold, to influence both short- and long-term changes of synaptic transmission. We have studied, with standard whole-cell techniques, 1-AP4- and 1-SOP-mediated modulation of HVA  $\text{Ca}^{2+}$  currents of pyramidal neurons freshly isolated from the adult rat neocortex.

Ba $^{2+}$  was the charge carrier, 180 mM and 150 TEA were the main ion species of internal and external solutions. Group III agonists reduced HVA  $\text{Ca}^{2+}$  currents in 80% of the recorded cells; significantly, 1-SOP was active at nanomolar concentrations. A reliable dose-response curve was hard to define because of the extreme variability of the response. The modulation was partially voltage-dependent (about 1/3rd was relieved by facilitation protocols). Interestingly, MAP4 antagonised the 1-AP4-induced inhibition. Each of the calcium channel blockers we have tested (conotoxin GVIA, Agatoxin and nifedipine) blocked part of the responses, supporting the interaction of agonists at group III mGluRs with multiple channel subtypes. Finally, the observed modulation was strictly age-dependent, being negligible in the first 3 postnatal weeks. Funding source: IRCCS Ospedale S.Lucia

## 322.12

METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED G-PROTEIN ACTIVATION IN RAT CEREBRAL CORTICAL MEMBRANES.

N. Nishi\*, Y. Odagaki, T. Koyama. Department of Psychiatry, Hokkaido University School of Medicine, North 15 West 7, Sapporo 060, Japan.

Glutamate receptors are widely distributed in neurons and glia of the CNS. They are divided into two major classes; ionotropic and metabotropic glutamate receptors (mGluRs). The mGluRs are G-protein coupled receptors which can be further subdivided into three subgroups, namely, Group I (mGluR $_1$ , mGluR $_3$ ), Group II (mGluR $_2$ , mGluR $_4$ ) and Group III (others).

In the present study, we measured high-affinity GTPase activity of G-proteins activated through mGluRs in rat cerebral cortical membranes. The following mGluR-related compounds elevated the high-affinity GTPase activity in a concentration-dependent manner with the mean  $\text{EC}_{50}$  values indicated in the respective parentheses ( $\mu\text{M}$ ): (2S,1S,2S)-2-(carboxycyclopropyl)glycine (L-CCG-I) (0.90), L-glutamate (4.8), trans-(1S,3R)-1-amino-cyclopentane-1,3-dicarboxylate (L-ACPD) (11), (±)-ibotenate (390). On the other hand, none of the ionotropic glutamate receptor agonists, N-methyl-D-aspartate (NMDA), kainate and  $\alpha$ -amino-3-hydroxy-5-methyl-isoxazole-4-propionate (AMPA) elevated the activity. In addition, quisqualate, (2S,1R,2'R)-2-(carboxycyclopropyl)glycine (L-CCG-II), L-2-amino-4-phosphonobutylate (L-AP4) and L-serine-O-phosphate (L-SOP) were also ineffective. Some of the phenylglycine derivatives with agonistic and antagonistic properties for mGluR $_2$  and mGluR $_3$ , respectively, such as (S)-4-carboxy-3-hydroxyphenylglycine ((S)4C3HPG) and (S)-3-carboxy-4-hydroxy-phenylglycine ((S)3C4HPG), activated GTP hydrolysis with  $\text{EC}_{50}$  value of ca. 30-200  $\mu\text{M}$ . These pharmacological profile indicates that the Group II mGluRs, especially mGluR $_2$  receptors, are responsible for the agonist-induced high-affinity GTPase activity in rat cerebral cortical membranes. This method provides a useful strategy for investigation of functional coupling between Group II mGluRs and their coupled G-proteins in native brain membranes. Supported in part by a grant from the Ministry of Education, Science and Culture of Japan.

## 322.14

METABOTROPIC GLUTAMATE RECEPTOR AGONISTS EVOKE A HYPERPOLARISING RESPONSE IN LABELLED, ACUTELY DISSOCIATED RAT TRIGEMINAL MOTONEURONES. S.J. Harris, K. Appenteng and T.F.C. Batten. Department of Physiology, University of Leeds, Leeds, LS2 9NQ, UK.

We have developed a preparation to make patch clamp recordings from acutely dissociated, identified, rat V motoneurons. Following dissociation of a block of tissue from the area containing the motornucleus it is difficult to identify V motoneurons on the grounds of morphology or electrophysiology. Therefore motoneurons are prelabelled by retrograde transport of fluorescent latex beads (FluoSpheres 0.04  $\mu\text{M}$ , Molecular Probes). Latex beads were injected into the left masseter muscle of Wistar rats on postnatal day 4 (10  $\mu\text{l}$ /muscle). Neurons were acutely dissociated from a tissue block taken from the area of the V motornucleus on postnatal day 8. Following an enzymatic incubation period of one hour in 0.5% protease (Sigma type XIV) the neurons were dissociated and plated out in a recording chamber. Bright fluorescence was observed in a population of the neurons and recordings were made directly from labelled neurons. Whole cell patch clamp recordings were made at room temperature (18-20 °C) in oxygenated ACSF containing (mM): NaCl 140, KCl 3,  $\text{CaCl}_2$  1.5,  $\text{MgCl}_2$  1, Glucose 25, HEPES 10. Drugs were applied locally from micropipettes using pressure pulses. The metabotropic glutamate receptor agonists 1S, 3R-ACPD (aminocyclopentane dicarboxylic acid) and L-CCG-I ((carboxycyclopropyl)glycine) (both 100  $\mu\text{M}$  in pipette) evoked a hyperpolarising response with an associated increase in neurone input resistance in labelled neurons (n=5). We have previously reported this response on unlabelled brainstem neurons. These results confirm its presence on trigeminal motoneurons.

**INWARD CURRENT IN MICE CEREBELLAR PURKINJE CELLS INDUCED BY 1S,3R-ACPD.** M. Hirono<sup>1</sup>, S. Konishi<sup>2</sup>, M. Sakakibara<sup>2</sup> and T. Yoshioka<sup>1</sup>. <sup>1</sup>Dept. of Mol. Neurobiol. Waseda Univ. Tokyo, JAPAN. <sup>2</sup>Mitubishi Kasei Inst. Life Sci. Tokyo, JAPAN. <sup>3</sup>Tokai Univ. Sch. of High-technology for human welfare, Numazu, JAPAN.

Inward current induced by the application of 1S,3R-ACPD to cerebellar Purkinje cells were studied mainly by Knöpfel et al. The tentative conclusion proposed by them is that the inward current seen after application of 1S,3R-ACPD may be generated by Ca<sup>2+</sup>-activated non specific cation channel or an electrogenic Na<sup>+</sup>/Ca<sup>2+</sup> exchanger, where Ca<sup>2+</sup> may be mobilized by IP<sub>3</sub>.

We examined these hypothesis by combination of patch clamp and Ca<sup>2+</sup> imaging recording and eventually we reached to the different conclusions never proposed yet on the basis of experimental results.

(1) Injection of neomycin, spermin and spermin, selective inhibitors of PIP<sub>2</sub>-specific phospholipase C, demonstrated no effect on the production of inward current.

(2) Extracellular application of MCPG, non-specific antagonist of metabotropic glutamate receptor, diminished the response, while specific inhibitor (L-AP3) did not.

(3) Purkinje cells of cerebellar of mice lacking mGluR1 induced no inward current by the application of 1S,3R-ACPD (Conquet et al. 1994).

Therefore it is reasonable to assume that the inward current can be induced by the activation of mGluR1 receptor without hydrolysis of PIP<sub>2</sub> by phospholipase C. In this case mGluR1 receptor can function as ionotropic receptor.

GABA<sub>A</sub> RECEPTORS: NATIVE FUNCTIONS

## 323.1

**OPTICAL ANALYSIS OF SPATIO-TEMPORAL PATTERNING OF GABA RESPONSES INVOLVING A POSSIBLE NOVEL RECEPTOR IN EARLY EMBRYONIC AVIAN BRAINSTEM.** Y. Momose-Sato, K. Sato, A. Hirota, T. Sakai & K. Kamino\*. Dept. Physiol., Tokyo. Med. & Dent. Univ. Sch. Med., Tokyo 113, Japan

To examine the embryonic functional expression of  $\gamma$  aminobutyric acid (GABA) receptors, we studied the inhibitory effects of GABA on the EPSPs evoked by vagal stimulus in 7- to 10-day old embryonic chick brainstem slice preparations, applying a multiple-site optical recording technique with a voltage-sensitive merocyanine-rhodanine dye (NK2761). First, in the GABA response, we pharmacologically identified three components: (1) component 1 related to GABA<sub>A</sub> receptors; (2) component 2 related to GABA<sub>B</sub> receptors; and (3) component 3 which is insensitive to GABA<sub>A</sub> and GABA<sub>B</sub> antagonists, but is stimulated by both GABA<sub>A</sub> and GABA<sub>B</sub> agonists. Subsequently, we investigated the embryogenesis and early development of the three components, and we have constructed developmental maps of regional distribution patterns of the three components. Components 1 and 3 have already emerged in the 7-day old embryo, and subsequently, component 2 appeared in the 8-day old preparations. No component related to GABA<sub>C</sub> receptors was observed, during the 7- to 10-day old embryonic stages. From the pharmacological properties of component 3, we suggest that component 3 is related to a new subtype, GABA<sub>p</sub> receptor.

## 323.3

## FAST AND SLOW SPONTANEOUS IPSCs IN CA1 PYRAMIDAL CELLS.

MI Banks<sup>1</sup> and RA Pearce. Dept. Anesthesiology, Univ. Wisconsin-Madison 53706.

Two kinetically distinct GABA<sub>A</sub> IPSCs evoked in rat hippocampal CA1 neurons (GABA<sub>A,fast</sub> and GABA<sub>A,slow</sub>) are differentially modulated by anesthetics and may have distinct functional roles. However, the synaptic basis of GABA<sub>A,slow</sub> is unclear, since only a single population of rapidly decaying spontaneous IPSCs (fast sIPSCs) has been described. We investigated the kinetics of sIPSCs in CA1, and studied the modulation of IPSCs by the benzodiazepine 4'-Chlorodiazepam (CIDZ). CIDZ is known to differentially modulate GABA receptors with different subunit compositions, but its effect on IPSCs in CA1 has not been reported previously.

Whole-cell recordings were obtained from pyramidal cells at 35°C in slices prepared from 2 to 5 week old rats. >90% of sIPSCs recorded in CNQX and APV decayed rapidly as measured by the mean time to 63% decay ( $t_{0.63}$ ). The best Gaussian fit to the  $t_{0.63}$  histogram had  $\mu=5.4$  ms and  $\sigma=2.93$  ms ( $n=5129$  events, 6 cells), but 3% of the events decayed with  $t_{0.63}>20$  ms ( $\mu=4.5\sigma$ ) and as long as 103 ms. The kinetics of these slow sIPSCs were strikingly similar to GABA<sub>A,slow</sub> ( $t_{0.63}=41.7\pm 4.8$  ms;  $n=9$  cells), evoked by stimulating in *s. lacunosum-moleculare*, while the fast sIPSCs were similar to GABA<sub>A,fast</sub> ( $t_{0.63}=10.5\pm 1.1$  ms), elicited by stimulation in *s. pyramidale*, implying that these spontaneous events arise from the same two groups of synapses giving rise to GABA<sub>A,fast</sub> and GABA<sub>A,slow</sub>. Consistent with this hypothesis, CIDZ reversibly reduced peak amplitude of evoked GABA<sub>A,fast</sub> (-75±2%;  $n=4$ ) and fast sIPSCs (-58±10%;  $n=3367$  events from 3 cells) with little effect on the amplitude of evoked GABA<sub>A,slow</sub> (+14 ± 43%) or slow sIPSCs (-6±10%; control  $n=31$ , CIDZ  $n=51$  events, 3 cells). Thus, we have found that slow sIPSCs are present in CA1 neurons, and that CIDZ is a selective blocker of GABA<sub>A,fast</sub>. These data suggest that GABA<sub>A,fast</sub> and GABA<sub>A,slow</sub> arise from different groups of synapses apposed by receptors with distinct properties.

## 322.16

**CROSS-TALK BETWEEN TRANSDUCTION SYSTEMS COUPLED TO PHOSPHOINOSITIDE (PI) HYDROLYSIS AND ADENYL CYCLASE (AC)** S. Miller<sup>1</sup>, R. Balazs<sup>2</sup>, Y. Chun<sup>2</sup> and C.W. Cotman<sup>1</sup>, Inst. Brain Aging, UCI, CA 92717

Astrocytes express mGluRs which mediate PI hydrolysis (group I) or are negatively coupled to AC (group II/III). Culturing cells in a chemically defined medium (with EGF and bFGF) results in a marked increase in the amount and function of mGluR5, which is the only group I receptor detectable in these cells. Concurrently, mGluR agonists (one of the exceptions, L-AP4), potentiate rather than attenuate cAMP formation evoked by stimulation of  $\beta$ -adrenergic receptors (isoproterenol, Iso) or directly activating AC (forskoline, FK). It seems that the potentiating effect is due to the influence of some product of the mGluR5-coupled transduction system. 1) mGluR5 agonists had only a marginal effect, if any, on basal cAMP generation. 2) The rank order of agonist potencies for augmenting the evoked cAMP accumulation was similar to that for activating mGluR5. In particular, the most potent agonist was quis, a weak mGluRII/III agonist, followed by DHPG, a selective group I mGluR agonist. 3) L-SOP, which inhibits in other systems ACPD-induced potentiation of evoked cAMP accumulation, had no effect in astrocytes. 4) Potentiation, as mGluR5 function, was PTX-sensitive. mGluR5 stimulation leads via IP<sub>3</sub> to the release of stored Ca<sup>2+</sup>, which may activate Ca<sup>2+</sup>-dependent AC isoforms. However, chelating Ca<sup>2+</sup> with BAPTA-AM did not abolish DHPG potentiation of cAMP accumulation. In fact, 'Ca<sup>2+</sup>-free' conditions resulted in a substantial increase in the Iso/FK-evoked cAMP formation, that was further augmented by the mGluR5 agonists. Finally, mGluR5 inhibition abolished DHPG-potentiation of the cAMP response. MCPG, a group I/II inhibitor, attenuated and TPA, which severely depresses mGluR5 activity, abolished the DHPG-evoked potentiation of the cAMP response. It seems, therefore, that the mGluR agonist-induced potentiation of evoked cAMP accumulation is mediated through mGluR5 activation. In astrocytes, similar potentiating effect was exerted by agonists (CCh and methoxamine) activating other PI hydrolysis-coupled receptors. The potentiation through different receptors may involve AC isoenzymes, which are activated by the  $\beta$ ,  $\gamma$  subunits of G protein.

## 323.2

**DEVELOPMENTAL DIFFERENCES IN SYNAPTIC GABAERGIC CURRENTS IN HIPPOCAMPAL AND CEREBELLAR CELLS OF MALE RATS.** E. J. Cooper, G. A. R. Johnston\* and F. A. Edwards. Dept. of Pharmacology, University of Sydney, NSW 2006, Australia.

Whole-cell patch-clamp electrophysiology was used to record inhibitory synaptic currents (IPSCs) in dentate granule cells (HG) and cerebellar Purkinje cells (CP) in brain slices of male rats. These cell types exhibit IPSCs with different kinetics [1,2] and also feature different GABA<sub>A</sub> receptor subunits [3]. Miniature IPSCs (mIPSCs) from HG and CP cells were compared from rats of two age groups (denoted as 10 and 20 postnatal days). The inhibitory neuroactive steroid, 5 $\alpha$ -pregane-3 $\alpha$ ,21-diol-20-one (THDOC) selectively increased the decay rate constant of IPSCs. This effect was stereo-specific and not voltage-dependent. Developmental differences in IPSC sensitivity to low concentrations (0.05 and 0.1  $\mu$ M) of THDOC were found in HG cells as those of 10 day group were prolonged by 24.3%  $\pm$  8.4% ( $n=9$ ) in response to 0.05  $\mu$ M whereas those of the 20 day group were unaffected by concentrations less than 1  $\mu$ M. In contrast, both age groups of CP cells were sensitive to low concentrations of THDOC. However, there were developmental differences in the amplitude and frequency of control mIPSCs of CP cells. A further effect of THDOC was noted in that the degree of potentiation of IPSCs often covered a broad range within the same cell. These differences are most likely due to developmental changes in GABA<sub>A</sub> receptor subunits expressed synaptically in these cell types.

**KINETIC PROPERTIES OF EXCISED GABA<sub>A</sub> RECEPTORS AND SPONTANEOUS IPSCs IN CA1 HIPPOCAMPAL PYRAMIDAL NEURONS.** T-B Li, MI Banks and RA Pearce\*. Dept. Anesthesiology and Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

Although a single population of receptors can generate currents with multiexponential decay kinetics, there is evidence that fast and slow components of evoked inhibitory currents in CA1 neurons reflect the kinetic properties of distinct and segregated receptor populations. We have used rapid agonist application methods to study GABA<sub>A</sub> receptors in outside-out patches excised from somata of CA1 pyramidal cells in brain slices that were prepared from 16-30 day old rats, and compared their kinetics at room temperature with spontaneous IPSCs.

Outside-out patches were exposed to 1 mM GABA for 1-2.5 ms using a "liquid filament" technique. Currents elicited by 7 to 70 pulses of GABA were obtained from six patches with stable properties. In all cases, averaged currents were fit well by biexponential functions, with time constants of 15.5  $\pm$  4.9 ms and 92.6  $\pm$  24.0 ms (mean  $\pm$  s.d.). The absolute amplitude of the currents varied considerably between patches, from 3.1 to 78.7 pA, but the proportion of fast and slow components was similar in different patches (42.8  $\pm$  4.4% fast), suggesting that these kinetic properties reflect gating characteristics of a single receptor population.

In contrast to rapid application responses, spontaneous IPSCs recorded from the same population of CA1 pyramidal cells were optimally fit by monoexponential functions. The average decay rate of 8 isolated sIPSCs from a cell with too high a spontaneous rate to analyze all events was 22.1 ms, and of 1062 events from a cell with a low spontaneous rate (17.7 Hz) was 17.4 ms. This decay rate is similar to the fast component of excised receptors.

We have found that differences exist between kinetic responses of receptors excised from somata of pyramidal neurons and IPSCs that are somatic in origin. These results may reflect a change in receptor properties caused by excision of the membrane patch, or differences between subsynaptic and extrasynaptic receptors. Supported by NIH NS01548 and UW Dept. Anesthesiology.

GABA CURRENTS IN DEVELOPING RAT DENTATE GYRUS. Y.-B. Liu\*, J. F. Pasternak, B.L. Trommer. Division of Pediatric Neurology, Evanston Hospital, Evanston, IL 60201 and Dept. of Pediatrics and Neurology, Northwestern University Medical School, Chicago, IL 60611

Granule cells (GC) at different stages of maturation defined by cell properties and morphologic criteria co-exist in rat dentate gyrus during the first postnatal month. We studied GABA neurotransmission in GC in response to medial perforant path stimulation using whole cell patch clamp recordings in hippocampal slices from 8-32 d rats. GABA postsynaptic currents (PSCs) consist of both monosynaptic (from direct activation of interneurons) and polysynaptic (requiring an intervening glutamatergic synapse) components in GC of all maturities. Monosynaptic GABA PSCs (evoked in 50  $\mu$ M AP5 and 10  $\mu$ M CNQX) were >96% antagonized by 10  $\mu$ M bicuculline (BMI), reversed at -69 mV, and had slight outward rectification, as expected for GABA<sub>A</sub> current. When PSCs were evoked in AP5 (50  $\mu$ M) and BMI (10  $\mu$ M), we detected a late current with marked outward rectification that followed the AMPA current. We concluded that this, too, was a GABA current because: it reversed at -61 mV with standard internal solution but near 0 mV when  $[Cl^-]_{int}$  and  $[Cl^-]_{ext}$  were equimolar; was blocked by picrotoxin 100  $\mu$ M, but was unchanged by strychnine (5  $\mu$ M), BAPTA (10 mM), and saclofen (500  $\mu$ M). This was a polysynaptically evoked GABA, since the monosynaptic GABA was blocked by 10  $\mu$ M BMI. When the combined mono- and polysynaptic GABA PSC was evoked in AP5 (50  $\mu$ M) at  $V_{holding} = 0$ , the portion resistant to 10  $\mu$ M BMI (i.e., polysynaptic) was significantly higher in immature (31 $\pm$ 14%, n=6) than mature (8 $\pm$ 5%, n=7) GC ( $p < 0.003$ ). These data suggest the existence of a unique GABA current that is developmentally regulated, mediated predominantly by polysynaptic pathways, and less sensitive to BMI than the monosynaptic GABA<sub>A</sub>.

## 323.7

SUBUNIT COMPOSITION AND FUNCTIONAL PROPERTIES OF ZOLPIDEM-INSENSITIVE GABA<sub>A</sub> RECEPTOR CHANNELS OF EMBRYONIC RAT HIPPOCAMPAL CELLS. R. Serafini\*, I. Maric, X.L. Wen, R. Somogyi, J.L. Barker and D. Maric. Lab. Neurophysiology, NINDS, NIH, Bethesda MD 20892. Studies on recombinant GABA<sub>A</sub> receptors demonstrate that the presence of  $\alpha_4$  and  $\gamma_3$  subunits confers low affinity to the allosteric modulator zolpidem. A flow-cytometry assay with the voltage-sensitive dye oxonol was performed to identify and sort a population of cells with low zolpidem-induced potentiation of GABA-evoked depolarization. When 5  $\mu$ M zolpidem was added to a threshold GABA concentration, cells exhibited heterogeneous membrane potential changes ranging from no effect to nearly 0 mV. Cells with no voltage response and cells with the most depolarized membrane potential value were then sorted. PCR analysis demonstrated the mRNA encoding a wide variety of subunits in the zolpidem-sensitive cells, whilst, in the zolpidem-insensitive cells only the transcripts for the  $\alpha_3$ ,  $\alpha_4$ ,  $\beta_3$ ,  $\gamma_3$  subunits could be shown. In both populations, analysis of the current fluctuations induced by GABA and recorded whole-cell yielded spectral density plots composed of three components. In the zolpidem-insensitive population, the longest-lasting component exhibited a longer  $\tau$  value (98 $\pm$ 9 msec vs 76 $\pm$ 7 msec;  $p < 0.05$ ) and a lower contribution to the overall power in the fluctuating signal (47 $\pm$ 4 % vs 62 $\pm$ 3 %;  $p < 0.01$ ). The data illustrate a novel strategy to sort distinct subpopulations of cells and demonstrate properties of native GABA<sub>A</sub> receptor channels which are likely related to the presence of  $\alpha_4$  or  $\gamma_3$  subunits.

## 323.9

PROPERTIES OF GABA<sub>A</sub> RECEPTOR-MEDIATED CHLORIDE CURRENTS IN RAT NEOCORTICAL PYRAMIDAL CELLS. J.F.M. van Brederode\* and W. J. Spain. VA Puget Sound Health Care System, Seattle, WA 98108 and Depts. of Neurology, and Physiology & Biophysics, University of Washington, Seattle, WA 98195.

Previously we described a post-synaptic mechanism as underlying some of the observed differences between evoked GABA<sub>A</sub> mediated IPSPs recorded from layer 2/3 (L2/3) vs. large layer 5 (L5) pyramidal cells. Here we compare GABA<sub>A</sub> receptor-mediated currents recorded in outside-out patches excised from the somata of visually identified pyramidal cells located in those layers (fronto-parietal cortex; 2-4 week old rats). Cells were identified in 300  $\mu$ m thick slices using infrared videomicroscopy. In layer 5 we targeted only pyramidal cells with the largest cell bodies, which was confirmed in a few cells by including biocytin (0.5%) in the patch electrode. The patch solution contained (in mM): 140 CsCl, 1 CaCl<sub>2</sub>, 3.45 BAPTA, 10 HEPES and 5 Mg<sub>2</sub>ATP and pipettes had resistances between 10 and 20 M $\Omega$  when filled with this solution. The bath contained CNQX (10  $\mu$ M), AP5 (50  $\mu$ M) and TTX (1  $\mu$ M). After seal formation and patch rupture the pipette was slowly withdrawn from the cell to form an outside-out patch and exposed to long pulses of GABA (10-20  $\mu$ M), pressure-ejected from a nearby pipette. In the absence of GABA, channel openings were infrequent and brief. In the presence of GABA longer, burst-like openings were observed. Both spontaneous and GABA-induced openings were sensitive to blockade by bath-applied bicuculline (100  $\mu$ M). Single channel currents reversed near the calculated chloride equilibrium potential. Current-amplitude histograms suggest a main channel conductance of about 30 pS. Supported by a VA Merit Review (W.S.) and NIH EY 01208 (J.v.B.)

## 323.6

"COLD SHOCK" INCUBATION INCREASES ZOLPIDEM SENSITIVITY OF GABA<sub>A</sub> IPSCs IN RAT HIPPOCAMPAL CA1 NEURONS. C. Gu\*, J.L. Weiner, and T.V. Dunwiddie. University of Colorado Health Sciences Center, Depts. of Pharmacology & Neuroscience and VA Medical Center, Denver, CO 80262.

We previously identified a slice incubation protocol (COLD SHOCK) that decreased extracellular GABA<sub>A</sub> IPSPs and increased ethanol, but not flunitrazepam or pentobarbital, sensitivity of GABA<sub>A</sub> IPSCs in rat hippocampal CA1 neurons. To further understand the mechanism(s) mediating the effect of COLD SHOCK incubation on ethanol potentiation of GABA<sub>A</sub> IPSCs, we characterized the effects of zolpidem, a selective type I benzodiazepine (BZ I) agonist that has been postulated to share the same GABA<sub>A</sub> receptor subunit requirements as ethanol. In control slices, zolpidem had no effect on GABA<sub>A</sub> IPSCs at 200 nM (5  $\pm$  1%), but did produce significant potentiation at concentrations of 1  $\mu$ M and higher. In contrast, GABA<sub>A</sub> IPSCs evoked from COLD SHOCK slices were significantly potentiated by zolpidem at concentrations as low as 200 nM (53  $\pm$  10 %) ( $p < 0.001$  vs control). These results suggest that COLD SHOCK incubation may result in an increase in the contribution of BZ I receptors at GABAergic synapses in hippocampal CA1 neurons or alternatively, that zolpidem enhancement of GABA<sub>A</sub> IPSCs, like that observed with ethanol, can be regulated by PKC. Supported by NS 29173 and the VA Medical Research Service.

## 323.8

CALCINEURIN REGULATES DESENSITIZATION OF GABA<sub>A</sub> RECEPTORS IN ACUTELY DISSOCIATED RAT HIPPOCAMPAL NEURONS. J.W. Morzymas\*, M. Martina, F. Ruzsics, and E. Cherubini. Biophys Lab, Int Sch Adv Studies (SISSA), 34013 Trieste, Italy.

GABA-evoked currents were recorded in the whole-cell configuration of the patch-clamp technique in acutely dissociated hippocampal neurons obtained from postnatal (P) days P2-P7 old rats. In control conditions, the decay of the currents evoked by GABA (100  $\mu$ M) could be fitted with a biexponential function having time constants of 0.65  $\pm$  0.24 s and 3.75  $\pm$  2 s, for the fast and slow component, respectively. The plateau to peak ratio was 0.087  $\pm$  0.034 (n=13). A complete recovery from desensitization could be obtained after at least 150 s. When the cells were dialysed with the cyclosporin A-cyclophilin A complex (CC complex, 50 nM cyclosporin and 20 nM cyclophilin, gift of Dr. H. Boddeke, SANDOZ, Basel), a potent and highly selective calcineurin inhibitor, the decay of GABA-evoked currents could be fitted with a biexponential function having time constant values similar to those obtained in control conditions (0.81  $\pm$  0.47 and 3.62  $\pm$  2.1 for the fast and slow component, respectively). However the area of the fast component was significantly ( $p < 0.05$ , n=8) smaller. Moreover, the plateau to peak ratio was significantly ( $p < 0.05$ ) larger than controls, being 0.185  $\pm$  0.07. With CC complex in the patch pipette, recovery from desensitization was faster, being completed in about 40 s. In order to ascertain the specificity of action of CC complex, in five experiments, a cyclosporin A derivative PSC 833 (which does not affect calcineurin) was used instead of cyclosporin A. In these conditions the desensitization and recovery kinetics were indistinguishable from those seen in controls. We conclude that, in acutely dissociated hippocampal neurons, desensitization processes of GABA<sub>A</sub> receptors are strongly regulated by calcineurin. Supported by grants from CNR (95.01664.CT04) and HCMP.

## 323.10

N-ETHYLMALIMIDE ALTERS THE INTRINSIC MEMBRANE PROPERTIES AND INHIBITORY SYNAPTIC POTENTIALS OF NEURONS IN A RAT SEPTAL SLICE PREPARATION. K.D. Phelan\* and H.R. Mahler. Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205.

N-ethylmaleimide (NEM) has long been used to investigate receptor coupling to G-proteins in membrane preparations. Although it has recently been applied to cultured neurons and brain slice preparations, the effects of NEM on neurons have not been well characterized. In the present study, intracellular recordings were used to determine the effects of NEM on intrinsic membrane properties and synaptic potentials of rat dorsolateral septal nucleus neurons using a submerged slice preparation.

Superfusion of NEM (100  $\mu$ M, 10-30 minutes) consistently produced an irreversible decrease in neuronal input resistance. It also blocked the low threshold calcium spikes that occur during rebound depolarization, calcium spikes evoked during depolarizing current steps, and slow calcium-dependent afterhyperpolarizations. Cells typically displayed a marked increase in spontaneous excitatory synaptic events and less consistent changes in the frequency of action potential firing. NEM pretreatment selectively reduced the amplitude of GABA<sub>B</sub> IPSPs, while increasing the amplitude of GABA<sub>A</sub> IPSPs. NEM completely blocked low intensity stimulus evoked GABA<sub>B</sub> IPSPs and baclofen (<30  $\mu$ M) induced membrane hyperpolarizations. However, a low amplitude, slow component of GABA<sub>B</sub> IPSPs evoked at high stimulus intensity and a small amplitude baclofen (100  $\mu$ M) induced membrane hyperpolarization was more resistant to NEM. At the same time, baclofen activation of presynaptic GABA<sub>B</sub> receptors was blocked by NEM pretreatment suggesting a differential sensitivity of presynaptic and postsynaptic GABA<sub>B</sub> receptors to NEM alkylation. These findings indicate that although NEM can be used in slice preparations to investigate the presumed G-protein coupling of receptors in single neurons, it can also produce significant changes in the intrinsic membrane properties and excitability of neurons. Supported by NIH 533959.

## 323.11

**INFLUENCE OF HIGH FREQUENCY STIMULATION ON INHIBITORY POSTSYNAPTIC POTENTIALS RECORDED FROM NEURONS OF THE ROSTRAL NUCLEUS OF THE SOLITARY TRACT.** G. Grubauskas and R. M. Bradley\*. Sch. of Dentistry, Univ. Michigan, Ann Arbor, MI 48109-1078.

During gustatory stimulation of the tongue afferent taste fibers are capable of responding with impulses frequencies up to 100 Hz. We have examined the consequence of this high frequency afferent stimulation (HFS) on IPSPs elicited in 58 neurons of the rostral nucleus of the solitary tract (rNST) in a brain slice preparation. IPSPs were evoked by stimulation of the solitary tract (ST) after elimination of excitatory synaptic activity with blockers of NMDA and AMPA/kainate glutamate receptors. Whole cell recordings were made from second order rNST neurons and the solitary tract was stimulated at frequencies that mimic the *in vivo* firing rate of afferent taste fibers (5 - 50 Hz). We found that HFS induced membrane hyperpolarization and increased conductance that could be blocked by bicuculline indicating involvement of GABA. When compared to single shock stimuli HFS altered the characteristics of the evoked IPSPs. In most neurons ( $n = 42$ ) HFS prolonged the decay time of the IPSP. Depending on the frequency, duration and magnitude of the ST stimulation, the decay time of the IPSP was lengthened several hundred orders of magnitude compared to single shock stimuli. Thus, HFS can potentiate the IPSPs thereby increasing the time of inhibition. In some neurons ( $n = 10$ ) HFS elicited a biphasic response with an initial hyperpolarization which then became depolarizing and elicited action potentials. The depolarizing amplitude and the number of action potentials was dependent on the frequency, duration and magnitude of the stimulus. Thus GABA activation which is normally inhibitory can become excitatory at these high stimulation frequencies. For a few neurons ( $n = 6$ ) there was no difference between the IPSPs initiated by HFS and a single shock. This short-term change in synaptic activity induced by afferent frequencies normally resulting from taste stimulation can alter the transmission of taste information in rNST and illustrates the importance of inhibitory activity in the gustatory relay nucleus. Supported by NIDCD, NIH Grant DC 00288 to RMB.

## 323.13

**BIDIRECTIONAL REGULATION OF GABA<sub>A</sub> RECEPTOR  $\alpha 1$  AND  $\alpha 6$  SUBUNIT EXPRESSION BY A cAMP-MEDIATED SIGNALLING MECHANISM IN CEREBELLAR GRANULE CELLS IN PRIMARY CULTURE**

Christopher L. Thompson, Simon Pollard and F. Anne Stephenson (SPON: Brain Research Association). Department of Pharmaceutical and Biological Chemistry, School of Pharmacy, University of London, London, UK.

Forskolin treatment of rat cerebellar granule cells in culture resulted in bidirectional regulation of the expression of GABA<sub>A</sub> receptor  $\alpha 1$  and  $\alpha 6$  subunits. Thus, forskolin applied at 2 days *in vitro* (2 DIV) increased expression of the  $\alpha 1$  subunit but decreased the expression of the  $\alpha 6$  subunit. Values with respect to vehicle-treated control cultures, both assayed at 9 DIV by immunoblotting, were  $310 \pm 48\%$  for  $\alpha 1$ , and  $25 \pm 16\%$  for the  $\alpha 6$  subunit. Similar effects were evoked following chronic treatment with both dibutyryl cAMP (1 mM) and 3-isobutyl-1-methylxanthine (IBMX, 250  $\mu$ M). Dideoxyforskolin (10  $\mu$ M) had no effect on the level of expression of either the  $\alpha 1$  or the  $\alpha 6$  GABA<sub>A</sub> receptor subunits. The changes in subunit expression were accompanied by a 1.7-fold increase in total specific [<sup>3</sup>H]Ro15-4513 binding sites expressed by intact cerebellar granule cells. This increase in total binding sites was accommodated by a 2.7-fold increase in diazepam-sensitive (DZ-S) [<sup>3</sup>H]Ro15-4513 binding sites in accordance with the observed increase in  $\alpha 1$  subunit expression. The diazepam-insensitive (DZ-IS) subtype of binding sites were not significantly changed. These results suggest that GABA<sub>A</sub> receptor subtype expression can be differentially regulated by intracellular cAMP concentration.

This work was supported by the MRC (UK).

## 323.15

**GABA<sub>A</sub> RECEPTORS IN DOPAMINERGIC NEURONS OF RAT SUBSTANTIA NIGRA PARS COMPACTA.**

D. Eugène, L. Cathala and D. Paupardin-Tritsch\*. Neurobiologie Cellulaire, Institut des Neurosciences, CNRS - Université Pierre et Marie Curie, 9 Quai Saint Bernard, 75005 Paris, France.

We have studied the effect of isoguvacine, a specific agonist of  $\gamma$ -aminobutyric acid<sub>A</sub> (GABA<sub>A</sub>) receptors, on dopaminergic (DA) neurons. These neurons were acutely dissociated according to I. Mintz's procedure (J. Neurosci. 1994, 14, 2844-53) from slices containing only substantia nigra pars compacta of 7-12 day old rats. Seventy-five percent of the neurons with neurites ( $n = 114$ ) showed positive staining for tyrosine hydroxylase determined by immunocytochemistry.

Using the whole cell patch-clamp configuration, bath application of isoguvacine (1-200  $\mu$ M) induced a Cl<sup>-</sup> current in these DA-containing neurons. Concentration-response curves of peak current amplitude could not be fitted by a single exponential but display two components.

Since molecular biological and binding studies have demonstrated that GABA<sub>A</sub> receptors with different subunit composition may coexist in the same cell, single channel patch-clamp currents were recorded from outside-out patches of DA neurons. At a holding potential of -70 mV, 1  $\mu$ M isoguvacine evoked single channel currents of small amplitude, brief duration openings that usually occurred as single events. The amplitude histogram showed that this channel had a main conductance level of about 8 pS. In addition, 2-5  $\mu$ M isoguvacine produced single channel openings that were longer in duration and larger in conductance (22 pS) and occurred in bursts of opening and closing. Both single channel currents reversed at E<sub>Cl</sub> and were blocked by bicuculline (10  $\mu$ M). These results might account for the two components of the concentration-response curve and suggest that DA neurons contain two types of GABA<sub>A</sub> receptors.

## 323.12

**REGULATION OF GABA<sub>A</sub> RECEPTOR  $\delta$  SUBUNIT mRNA EXPRESSION IN CULTURED RAT CEREBELLAR GRANULE NEURONS.** L.M. Gault and R.E. Siegel\*. Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106-4965.

The distribution of GABA<sub>A</sub> receptor subunit mRNAs in the cerebellum has been well-characterized, but the factors regulating their expression are largely unknown. Previous studies in cultured rat cerebellar granule neurons have shown that the  $\delta$  subunit mRNA is barely detectable in neurons maintained in a defined nondepolarizing medium (5 mM KCl). In contrast, the  $\delta$  transcript increases six-fold between 2-4 days in neurons maintained in a depolarizing medium (25 mM KCl). When calcium influx through L-type channels is reduced by the addition of 1  $\mu$ M nifedipine, levels of the  $\delta$  transcript decrease by 75%. The possibility that gene expression can similarly be altered by calcium entry through the NMDA receptor was also investigated. Although HPLC measurements indicate that comparable amounts of glutamate, the neurotransmitter of granule neurons, are present in the medium of neurons maintained in nondepolarizing or depolarizing conditions, activation of NMDA receptors in nondepolarizing medium may be less effective due to a magnesium block. In fact, addition of 50  $\mu$ M NMDA to increase activation of this receptor subtype results in a significant rise in the level of the  $\delta$  transcript to about 40% of that attained in neurons maintained in depolarizing medium. These results suggest that activation of NMDA receptors plays a role in initiating  $\delta$  subunit mRNA expression and raise the possibility that synaptic contact between glutamatergic mossy fibers and granule neurons *in vivo* regulates levels of this subunit mRNA. Supported by NIH grant NS 31266.

## 323.14

**EXPOSURE OF PRIMARY GRANULE CELLS TO POTASSIUM DEPOLARIZATION OR TO N-METHYL-D-ASPARTATE ALTERS THE STABILITY OF THE  $\alpha 1$  GABA<sub>A</sub> RECEPTOR SUBUNIT mRNA.** Snezana Ikonovic\*, William Paljug, and Dennis R. Grayson. Neurosciences Research Center and Department of Psychiatry, Medical College of Pennsylvania and Hahnemann University, Pittsburgh, PA 15212.

K<sup>+</sup>-induced depolarization or NMDA treatment promotes the survival and maturation of cultured cerebellar granule cells *in vitro* and increases the amount of functional NMDA receptors present. We have previously shown that NMDA and K<sup>+</sup> depolarization of primary cultures of cerebellar granule cells increases the mRNA levels of the  $\alpha 1$  and  $\alpha 5$ , but not the  $\alpha 6$  GABA<sub>A</sub> receptor subunits as compared to cultures maintained in low KCl. These alterations are accompanied by increases in the  $\alpha 1$  and  $\alpha 5$  receptor subunit proteins, and increases in the Bmax associated with [<sup>3</sup>H] flunitrazepam binding. Whole cell voltage clamp recordings show that the NMDA treatment increases the affinity of the receptors for GABA and increases flunitrazepam potentiation of GABA-mediated Cl<sup>-</sup> currents. We have also shown that the mRNA increases occur with a concomitant increase in the transcription rates of the corresponding genes. In the present study, we have used the transcriptional inhibitor actinomycin D (Act-D) to block mRNA synthesis 24 hr after adding NMDA to granule cell cultures maintained in low KCl containing media. Total RNA was isolated from control and treated cultures at various times (0, 1, 2 and 3 hrs) after adding Act-D (10  $\mu$ g/ml) and steady state levels of mRNA were examined. Absolute amounts of  $\alpha 1$  and  $\alpha 6$  mRNAs were quantitated using an RT-PCR based assay with subunit specific primer pairs and internal standards. The half life of both the  $\alpha 1$  and  $\alpha 6$  mRNAs was comparable and longest in granule cells maintained in high KCl. The stability of the  $\alpha 1$  mRNA decreased in granule cells treated with NMDA for 24 hr. The half life ( $t_{1/2}$ ) of this mRNA decreased from 13 hr to 2.7 hr after the addition. In contrast, no change was observed in the stability of the  $\alpha 6$  mRNA in cells maintained in treated cultures as compared to the low K<sup>+</sup> maintained controls. This suggests that NMDA alters patterns of GABA<sub>A</sub> receptor subunit expression at multiple levels. Supported by NIH grants NS 30537 and K04 NS01647 to D.R.G.

## 323.16

**GABA MEDIATED DENDRITIC PLATEAU POTENTIALS IN RAT NEOCORTICAL PYRAMIDAL NEURONS.** R. Cerne\* and W. J. Spain. Depts. of Neurology and Physiology & Biophysics, Univ. of Washington, and The VA Puget Sound Health Care System, Seattle, WA 98108

Last year we reported that continuous intense activation of GABA<sub>A</sub> receptors in slices of rat somatosensory cortex resulted in a plateau potential (PP) following repetitive firing of action potentials. Whole-cell current-clamp recordings were made from somata of visually identified layer V pyramidal cells in slices of from 3-5 week-old rats. Internal solution contained Cl<sup>-</sup> = 9 mM. Slices were superfused with ACSF containing APV, CNQX and CGP-35348 ([Cl<sup>-</sup>]<sub>o</sub> = 141 mM). Somatic Nernst equilibrium potential for Cl<sup>-</sup> = -73 mV. In the presence of GABA (>50  $\mu$ M) or muscimol (100  $\mu$ M) an evoked train of action potentials was followed by a voltage and time dependent PP that does not depend on calcium entry. The PP was associated with low amplitude sodium dependent spikes which continued and arose directly from the baseline even after the soma was repolarized by means of constant current injection to -70 mV suggesting a dendritic origin. In addition, in neurons with surgically amputated apical dendrites the PP was absent. The PP was enhanced with increased intracellular Cl<sup>-</sup> but was blocked by furosemide (1 mM) or bumetanide (100  $\mu$ M) but not by acetazolamide (100  $\mu$ M) suggesting that it depends on a high dendrite to low soma [Cl<sup>-</sup>]<sub>i</sub> gradient. Supported by a VA Merit Review.

## 324.1

DEHYDRO-PIRLINDOLE IS A CLOZAPINE-LIKE PARTIAL GABA<sub>A</sub> RECEPTOR BLOCKER AS WELL AS A POTENT SELECTIVE INHIBITOR OF MONOAMINE OXIDASE-A. A.E. Medvedev<sup>1</sup>, V.I. Shvedov<sup>2</sup>, T.M. Chulkova<sup>1</sup>, O.A. Fedotova<sup>3</sup>, E. Saederup<sup>3</sup> and R.F. Squires<sup>3</sup>. <sup>1</sup>Institute of Biomedical Chemistry, Russian Academy of Medical Science, Moscow, Russia, <sup>2</sup>Centre of Drug Chemistry-Institute of Pharmaceutical Chemistry, Moscow, Russia, <sup>3</sup>Nathan Kline Institute, Orangeburg, NY 10962.

Pirlindole is clinically effective in the treatment of depression as well as some forms of schizophrenia. Dehydro-pirlindole (DHP) is an active metabolite possibly formed by the action of MAO on pirlindole. DHP, but not pirlindole, partially reversed the inhibitory effect of 1  $\mu$ M GABA on <sup>35</sup>S-TBPS binding ( $\Delta B_{\text{DHP}} = 42\%$ ,  $EC_{50} = 12 \mu\text{M}$ ). DMCM (methyl 6,7-dimethoxy-4 ethyl- $\beta$ -carboline-3-carboxylate) and Ro5-4864, acting on largely separate populations of benzodiazepine binding sites, both partially reverse the inhibitory effect of 1  $\mu$ M GABA ( $\Delta B_{\text{DHP}}$  40% and 49%,  $EC_{50}$  9 and 710 nM, respectively) and together they reverse ~75%, with 14% overlap. Like clozapine, the reversing effect of DHP was partially additive to the reversing effects of DMCM (100 nM) and Ro5-4864 (5  $\mu$ M). Thus, clozapine and DHP both preferentially block a population of GABA<sub>A</sub> receptors (~25%) that does not appear to be coupled to benzodiazepine binding sites. In addition, DHP selectively inhibits MAO-A from rat brain and human placenta with  $IC_{50}$  values of 6.4 and 4.5 nM, respectively, in a slowly reversible way. Pirlindole is also a selective, but weaker, inhibitor of MAO-A with  $IC_{50}$  values of 320 and 90 nM, respectively. The MAO-A inhibitory and GABA antagonistic effects of DHP may be involved in the clinical antipsychotic/antidepressant effects of long term treatment with pirlindole. Funding: Russian State Program "Design of New Drugs" (Grant No. 040103) and New York State, OMH.

## 324.3

CAM KINASE II-DEPENDENT PHOSPHORYLATION OF SYNAPTIC PLASMA MEMBRANE INCREASES MUSCIMOL BINDING. S.B. Chum<sup>\*</sup>, and R.J. DeLorenzo. Department of Neurology, Medical College of Virginia. Richmond, VA 23298.

Calcium/calmodulin-dependent kinase II (CaMKII) is an important, neuronally enriched calcium effector enzyme. However, many pathological states such as seizure activity and stroke result in decreased CaMKII activity. CaMKII-dependent phosphorylation has been shown to increase Cl<sup>-</sup> currents in rat spinal dorsal horn neurons (J. Neurophys. 1995. 73:2099). In addition, GABA receptor subunits have been shown to be substrates for CaMKII (J. Neurochem. 1993. 61:375). Since CaMKII activity may alter GABAergic function, this study was designed to determine the effects of phosphorylation on muscimol binding on synaptic plasma membrane fractions isolated from rat whole brain homogenates. P-2 fractions were isolated by standard techniques, lysed in hypotonic buffer, washed 3X and the resultant synaptic plasma membrane (SPM) resuspended into buffer (50 mM Tris-HCl, pH = 7.4). The SPM fractions were subjected to CaMKII-dependent phosphorylation (J. Neurosci. 1995. 15:3200), and then tested for muscimol binding. For muscimol binding, samples were equilibrated with <sup>3</sup>H-muscimol (100 nM)  $\pm$  100  $\mu$ M GABA for 1 hr on ice. Binding reactions were terminated by rapid filtration under vacuum and washing with ice-cold buffer. Addition of CaMKII enriched from rat brain resulted in 60% increase in muscimol binding when compared to sham-treated P-2 fractions (CaMKII reactions without addition of kinase). The significant increase in muscimol binding was observed in 3 different SPM preparations ( $p < 0.01$ , Student's *t* test,  $n = 16$ ). In addition, the increase in muscimol binding could be reversed by co-incubation with W-7, H-7, KN-93 and peptide inhibitors specific for CaMKII. The results demonstrate CaMKII-dependent regulation of muscimol binding in SPM. R01-NS23350, P01-NS25630.

## 324.5

IONIC DEPENDENCE OF THE ENDOGENOUS PHOSPHORYLATION AND DEPHOSPHORYLATION OF GABA<sub>A</sub> RECEPTOR PROTEIN. Jacques Laschet<sup>1,2\*</sup>, Frédéric Minier<sup>1</sup>, Bertrand Evrard<sup>1</sup>, Guy Dandifosse<sup>2</sup>, Patrick Chauvel<sup>1</sup> and Michel Bureau<sup>1</sup>. Lab. of Biochemistry, Univ. of Rennes I, Rennes, France, F-35043 and Lab. of Biochemistry and Physiology, ULg, Liège, Belgium, B-4000.

GABA<sub>A</sub> receptors are ligand gated ion channels that mediate most inhibitory synaptic transmission in the central nervous system. Recently we have identified an endogenous phosphorylation on distinct purified polypeptides by Ser/Thr and Tyr kinase activities (Bureau and Laschet, *J. Biol. Chem.* 270, 26482-26487, 1995). We studied the ionic modulations of this phosphorylation that predominates on the 51 kDa-polypeptide corresponding to  $\alpha 1$  subunit. Each ion alone produced a dose-dependent activation with different efficiencies ( $\text{Zn}^{2+} > \text{Mn}^{2+}$ ,  $\text{Ca}^{2+} > \text{Mg}^{2+} > \text{Spermine}$ ). However, in the presence of low concentrations of  $\text{Mg}^{2+}$  (30  $\mu$ M) or  $\text{Zn}^{2+}$  (10  $\mu$ M), the dose-dependent activation of the other ions (except  $\text{Ca}^{2+}$ ) was replaced by a biphasic modulation i.e. an activation followed by a inhibition. In the case of calcium, a dose-dependent inhibition was directly observed ( $IC_{50} = 100 \mu\text{M}$ ), suggesting that the inhibition of endogenous phosphorylation, or the activation of phosphatase activity by  $\text{Ca}^{2+}$  requires the presence of another divalent cation. By increasing the temperature of incubation from 30°C to 40°C, the activations by  $\text{Zn}^{2+}$  and  $\text{Ca}^{2+}$  were specifically lost whereas the modulations by  $\text{Mn}^{2+}$ ,  $\text{Mg}^{2+}$  and Spermine were thermoresistant. These results suggest not only the presence of multiple binding sites for these ions with possible competition, but are also consistent with the modulation of multiple kinase and phosphatase activities associated with the purified receptor.

## 324.2

ANTIDEPRESSANT AND BICUCULLINE ACTION AT THE GABA<sub>A</sub> RECEPTOR CHLORIDE-IONOPHORE COMPLEX; SCHILD REGRESSION ANALYSIS. E. Malatynska<sup>\*</sup>. Evansville Center for Medical Education, University of Indiana, Evansville, IN 47712

It was shown that antidepressants inhibit GABA-stimulated <sup>36</sup>Cl<sup>-</sup> uptake in rat cerebral cortex. The site of antidepressant action at the benzodiazepine-GABA<sub>A</sub> receptor chloride ionophore complex was subjected to study. The allosteric modulation of the GABA<sub>A</sub> receptor mediated chloride flux by antidepressants through the benzodiazepine receptor site was previously excluded. However, it is still not clear whether antidepressants are competitive antagonists or non-competitive (allosteric modulators) of the GABA<sub>A</sub> receptors. To study this problem the Schild regression analysis was used. The GABA concentration-response curves for <sup>36</sup>Cl<sup>-</sup> uptake in rat cerebral cortex were generated in the absence and presence of increasing concentrations of antidepressants: amitriptyline (AMI), amoxapine (AMX) mianserine (MIA) and known GABA<sub>A</sub> receptor antagonist, bicuculline (BIC). The concentrations of inhibitors were 2  $\mu$ M, 8  $\mu$ M, 32  $\mu$ M 128  $\mu$ M and 512  $\mu$ M. The  $E_{\text{max}}$  value of GABA for stimulation of <sup>36</sup>Cl<sup>-</sup> uptake was reduced only by the highest antidepressant concentration used while it was reduced by all BIC concentrations. Dose ratios were calculated at the GABA  $EC_{50}$  values at each concentration of drug. The  $pA_2$  values for AMI, MIA, AMX and BIC were 3.9, 4.4, 5.4 and 6.2 respectively. Respective slope values were 0.7, 0.6, 0.7 and 1.0. The slopes for antidepressants were significantly different from unity. It is concluded from our study that neither antidepressants nor BIC are pure competitive antagonists of GABA at the GABA<sub>A</sub> receptors in the rat cerebral cortex. Supported by NARSAD

## 324.4

KINETICS OF ENDOGENOUS PHOSPHATE INCORPORATION INTO THE GABA<sub>A</sub> RECEPTOR SUGGESTS A CASCADE OF KINASES AND A RECEPTOR ASSOCIATED PHOSPHATASE ACTIVITY. Michel Bureau<sup>\*</sup>, Jacques Laschet, Frédéric Minier, Bertrand Evrard and Patrick Chauvel. Laboratory of Biochemistry, School of Pharmacy and Medicine, University of Rennes I, Rennes, France, F-35043.

The phosphorylation of either the GABA<sub>A</sub> receptor itself or of a closely associated protein may be required to maintain receptor function (Stelzer et al., *Science*, 241: 339-341, 1988). The receptor « run down » is accelerated by alkaline phosphatase. The molecular identification of the phosphatase and kinase protein(s) involved in these mechanisms is presently unknown, although we recently showed that endogenous kinase activities are associated with the purified receptor (Bureau and Laschet, *J. Biol. Chem.* 270, 26482-26487, 1995). We have studied the effects of incubation time on endogenous phosphorylation in the presence of several activators, i.e.  $\text{Mg}^{2+}$ ,  $\text{Mn}^{2+}$  and  $\text{Zn}^{2+}$ . At short incubation time we observed the phosphorylation of two copurified bands of about 38 and 16 kDa: this occurred before any incorporation of phosphate into the receptor. Phosphorylation and dephosphorylation of the 38 kDa band took place within the first few minutes of incubation. The 16 kDa band was phosphorylated in the following minutes. The dephosphorylation rate of the latter was coincident with the phosphorylation of an upper band of 19 kDa and of the receptor itself. At longer incubation time, a slow dephosphorylation took place after one hour. Taken together these results suggest 1) that the endogenous phosphorylation of the GABA<sub>A</sub> receptor could be under the dependence of a cascade of copurified kinases 2) the presence of an endogenous phosphatase activity.

## 324.6

MODULATION OF GABA<sub>A</sub> RECEPTORS BY ALUMINUM. PAUL Q. TROMBLEY<sup>\*</sup> Dept. of Bio. Science, Florida State Univ., Tallahassee, FL 32306.

The effects of aluminum ( $\text{Al}^{3+}$ ) on several classes and subtypes of amino acid receptors were examined using whole-cell voltage-clamp electrophysiology on rat olfactory bulb mitral/tufted (M/T) cells in primary culture. Elevated  $\text{Al}^{3+}$  in the CNS has been associated with cognitive impairment and implicated in Alzheimer's disease. Several laboratories have demonstrated that inhaled  $\text{Al}^{3+}$  results in uptake into the brain and distribution along olfactory pathways. The effects of  $\text{Al}^{3+}$  on amino acid receptors were examined because synaptic pathways that use amino acid transmitters are often involved in neuropathology associated with  $\text{Al}^{3+}$ . Under voltage-clamp at -60 mV, 100  $\mu$ M  $\text{Al}^{3+}$  was co-applied during the middle of the current evoked by amino acid receptor agonists.  $\text{Al}^{3+}$  had no effect on membrane currents evoked by 500  $\mu$ M glutamate, 100  $\mu$ M kainate, 100  $\mu$ M NMDA, or 100  $\mu$ M glycine. In contrast, 10-100  $\mu$ M  $\text{Al}^{3+}$  potentiated GABA (30  $\mu$ M) mediated currents by as much as several hundred percent. However, in most M/T neurons, at concentrations  $\geq 300 \mu\text{M}$ ,  $\text{Al}^{3+}$  blocked the GABA-evoked current. In a subpopulation of neurons,  $\text{Al}^{3+}$  inhibited the current and potentiation was never observed. These results may indicate that GABA receptors express two binding sites for  $\text{Al}^{3+}$ : one potentiates the response to GABA, and one inhibits the response. GABA receptors in some cells may only express the inhibitory site. Neither effect of  $\text{Al}^{3+}$  was voltage-dependent, suggesting an allosteric binding site(s). Zinc and copper are endogenous to the olfactory bulb and can alter the function of amino acid receptors. Carnosine is a dipeptide contained in and released by olfactory sensory neurons. Whereas carnosine can reduce or eliminate the modulatory effects of zinc and copper on amino acid receptors, carnosine dramatically potentiated the effects of  $\text{Al}^{3+}$  on GABA mediated currents. These results suggest that  $\text{Al}^{3+}$  may contribute to neuropathology by affecting GABAergic pathways. This research was supported in part by the NIH.

## 324.7

**ORGANOCHLORINE PESTICIDES REGULATE PRENATAL EXPRESSION OF GABA<sub>A</sub> RECEPTOR SUBUNITS IN VITRO AND IN VIVO.** J. Liu<sup>1</sup>, A. L. Morrow<sup>2</sup>, L. Devaud<sup>3</sup>, D. R. Grayson<sup>3</sup> and J. M. Lauder<sup>1</sup>. <sup>1</sup>Dept. of Cell Biology and Anatomy and <sup>2</sup>Psychiatry and Center for Alcohol Studies, Univ. of North Carolina School of Medicine, Chapel Hill, NC 27599, <sup>3</sup>Dept. of Psychiatry, Med. Coll. of Penn. and Hahnemann Univ., Pittsburgh, PA 15212

In order to test the hypothesis that the ability of organochlorine pesticides to specifically target GABA<sub>A</sub> receptor may make the developing nervous system especially vulnerable to these neurotoxins, we used *in vitro* and *in vivo* models to determine whether exposure to these pesticides alters developmental expression of GABA<sub>A</sub> receptor subunits. For the *in vitro* model, dissociated cultures were prepared from embryonic day 14 (E14) brainstem and cultured in BME + 10% NuSerum for 1 day *in vitro* (DIV), then treated for 48 hrs with 10  $\mu$ M of the pesticide dieldrin in serum-free medium. For the *in vivo* model, timed pregnant rats were injected i.p. with 2.5 mg/kg dieldrin or with vehicle beginning on day 12 of gestation (E12) and injections continued until E17. After pregnant rats were sacrificed by rapid decapitation under ether anesthesia, fetuses were rapidly removed and their brainstems dissected. Absolute amounts of  $\alpha$ 1,  $\beta$ 3,  $\gamma$ 1 mRNA transcripts were quantified in cultured and fetal brainstem by competitive RT/PCR using internal standards. Expression of  $\alpha$ 1 and  $\beta$ 3 mRNA were up-regulated, but  $\gamma$ 1 mRNA was down-regulated by dieldrin *in vitro*, whereas  $\alpha$ 1,  $\beta$ 3,  $\gamma$ 1 mRNAs were down-regulated by dieldrin *in vivo*. These results suggest that *in utero* exposure to organochlorine pesticides may pose a risk to the developing brain by virtue of their ability to alter expression of GABA<sub>A</sub> receptor subunits. Supported by NIEHS grant to JML.

**LOW LEVEL HYPERBARIC EXPOSURE: SELECTIVE UNCOUPLER OF ALLOSTERICALLY MODULATED RECEPTORS.** R.L. Alkana<sup>1</sup>, M.B. Bolger, R.D. Brinton and D.L. Davies, Dept. of Molecular Pharmacology and Toxicology, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

Exposure to helium-oxygen (heliox) gas, at 12 times normal atmospheric pressure (ATA), antagonized the behavioral effects of diazepam and pentobarbital, but not those of THIP, a GABA prodrug, and picrotoxin in C57 mice. These findings suggest that pressure acts selectively by uncoupling allosteric modulation of GABA<sub>A</sub> receptor function. We tested this hypothesis further by investigating the effects of pressure versus GABA<sub>A</sub> receptor drugs in LS mice. Exposure to 12 ATA heliox antagonized the anticonvulsant effects of the allosteric modulators diazepam and pentobarbital. Pressure also antagonized flunitrazepam- and pentobarbital-potential of GABA-activated <sup>36</sup>Cl uptake in LS mouse brain microsacs. In contrast, pressure did not alter GABA stimulation or picrotoxin blockade in this system. Further, pressure did not alter the behavioral or *in vitro* effects of the neuroactive steroid 3 $\alpha$ ,5 $\beta$ -P. These results support the hypothesis that pressure selectively antagonizes drugs by uncoupling allosteric modulation of receptor function. Moreover, the lack of pressure antagonism versus 3 $\alpha$ ,5 $\beta$ -P suggests that there is heterogeneity among allosteric coupling mechanisms that can be identified by pressure. Since pressure is a physical manipulation, this selectivity among allosteric modulators cannot derive from pressure's chemical or molecular structure. Rather, sensitivity to pressure antagonism likely reflects pressure acting on similar physico-chemical changes that underlie a subset of coupling mechanisms among allosteric modulators. Further studies are necessary to test this hypothesis and to determine whether pressure can be used as a tool to link coupling mechanisms within and across allosterically modulated receptor systems (e.g., GABA<sub>A</sub> and NMDA). (Supported by NIAAA, NIH grants R01AA03972, AA05234, F31AA05436 and the USC School of Pharmacy).

## 324.11

**SUBSTANCE P DOWN-REGULATES THE FUNCTION OF GABA<sub>A</sub> RECEPTORS VIA PROTEIN KINASE C IN BULLFROG SENSORY NEURONS.** K. Yamada<sup>1</sup>, T. Tokimasa<sup>2,3</sup>, J. P. Gallagher<sup>3</sup> and T. Akana<sup>1</sup>. <sup>1</sup>Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, <sup>2</sup>Dept. Physiol., Tokai Univ. Sch. Med., Isehara 259-11, Japan and <sup>3</sup>Dept. Pharm. & Tox., Univ. of Texas Med. Br., Galveston, TX 77555, U.S.A.

Effects of substance P (SP) and related tachykinins on the function of  $\gamma$ -aminobutyric acid-A (GABA<sub>A</sub>) receptors were examined in acutely dissociated neurons of bullfrog dorsal root ganglia (DRG) by using whole-cell voltage-clamp techniques. Application of SP (10 nM-1  $\mu$ M) depressed inward currents produced by GABA<sub>A</sub> receptor activation (I<sub>GABA</sub>) in a non-competitive manner. Neurokinin A (NKA) and neurokinin B (NKB) also depressed the I<sub>GABA</sub>; the rank order of agonist potency was SP > NKA > NKB. [D-Arg<sup>1</sup>, D-Trp<sup>7,9</sup>, Leu<sup>11</sup>]SP (spantide, 1  $\mu$ M) and L-703,606 (1  $\mu$ M), antagonists for NK<sub>1</sub> receptors, blocked the SP-induced depression of the I<sub>GABA</sub>. SP irreversibly depressed the I<sub>GABA</sub> when DRG neurons were intracellularly dialyzed with GTP $\gamma$ S (200  $\mu$ M). Intracellular GTP $\gamma$ S (500  $\mu$ M) prevented the SP-induced depression of the I<sub>GABA</sub>. The SP-induced depression of the I<sub>GABA</sub> was blocked by H-7 and PKC(19-36), protein kinase C (PKC) inhibitors but not by H-9 and HA-1004, PKA inhibitors. The I<sub>GABA</sub> was blocked by 1,2-sn-di-octanoylglycerol (DOG, 10-50  $\mu$ M), a PKC activator, but not by inositol trisphosphate (IP<sub>3</sub>, 50  $\mu$ M). Okadaic acid (2  $\mu$ M) and adenosine 5'-O-3-thiotriphosphate (ATP $\gamma$ S, 5 mM) prolonged the SP-induced inhibition of the I<sub>GABA</sub>. It is concluded that SP down-regulates the function of GABA<sub>A</sub> receptor in bullfrog DRG neurons through an NK<sub>1</sub> receptor that links to a G-protein-PKC pathway. (Glant-In-Aid (A) 07308054, Japan)

## 324.8

**THE INTERACTION OF ORGANOCHLORINE INSECTICIDES WITH RECOMBINANT HUMAN GABA<sub>A</sub> RECEPTORS.** L.S. ASPINWALL<sup>1</sup>, K.A. WAFFORD<sup>2</sup>, I. BERMUDEZ<sup>1</sup> AND L.A. KING<sup>1</sup>. <sup>1</sup>Oxford Brookes University, Oxford, OX3 0BP, <sup>2</sup>MSD Research Laboratories, Harlow, Essex CM20 2PT, UK.

The effect of convulsant and non-convulsant hexachlorocyclohexane (HCH) isomers on recombinant gamma-aminobutyric acid (GABA<sub>A</sub>) receptors were studied, using a variety of expression systems, the baculovirus system, stably expressing mammalian cells and *Xenopus oocytes*. Using human  $\alpha$ 1,  $\beta$ 3 and  $\gamma$ 2 subunits, all three systems were shown, by ligand binding assays and electrophysiological studies, to produce functional, triple subunit receptors that bound both [<sup>3</sup>H]GABA and [<sup>3</sup>H]flunitrazepam (FNZ). It was observed that the mammalian cell system produced four-fold higher levels of the GABA<sub>A</sub> receptor, than the baculovirus system, and was therefore more practical, for use in the radioligand binding studies.

$\gamma$ -lindane and two of its isomers, the  $\alpha$  and  $\delta$  forms, were applied to recombinant GABA<sub>A</sub> receptors, in the presence of [<sup>3</sup>H]muscimol, an analogue of GABA, in an optimised radioligand binding assay. The three insecticides produced no displacement of [<sup>3</sup>H]muscimol suggesting that they do not interact with the GABA binding site on the GABA<sub>A</sub> receptor. Similar binding assays were performed using [<sup>3</sup>H]FNZ, showing no displacement, demonstrating no interaction with the benzodiazepine binding site. Chloride [<sup>36</sup>Cl] flux experiments on this cell line, in the presence and absence of the three insecticides, clearly showed that  $\gamma$ -lindane inhibited the influx of chloride ions through the channel, while the  $\alpha$  and  $\delta$  isomers potentiated the influx, the  $\delta$  isomer exhibiting the largest effect. This phenomenon was substantiated by electrophysiological studies on the stably expressing mammalian cells, using the whole cell patch clamp technique. Further studies involving [<sup>35</sup>S]-butylbicyclophosphorothionate (TBPS) binding, a known chloride channel blocker, and expression of different combinations of the human GABA<sub>A</sub> receptor subunits in *Xenopus oocytes* should enable identification of the site of binding and which subunit(s) influence this interaction.

Supported by the BBSRC and Merck Sharp & Dohme.

## 324.10

**NAAG modulates expression of the GABA-A  $\alpha$  6 subunit mRNA via activation of a mGluR in cultured cerebellar granule cells.** S. Ghose<sup>1</sup>, B. Wroblewska, D.R. Grayson<sup>2</sup>, J.H. Neale, Dept. of Biology, Georgetown University, Washington D.C. and <sup>2</sup>Neuroscience Research Center, Department of Psychiatry, Medical College of Pennsylvania and Hahnemann University, Pittsburgh, PA.

We have demonstrated that treatment of cultured cerebellar granule cells with N-acetylaspartylglutamate (NAAG) transiently alters the expression of the GABA-A  $\alpha$  6 subunit mRNA. Using a quantitative PCR, we determined the increase to be up to 170% of control levels. The first increase in expression is seen within 30 minutes of addition of NAAG returning towards control levels after two hours before showing a second peak at 4 hours. Similar effects of equal potency are seen on treatment with trans-ACPD and glutamate. In addition, the response is pertussis-toxin sensitive, implying the involvement of a metabotropic glutamate receptor. L-AP 4, a group III mGluR agonist, had no effect. Stimulating the muscarinic and alpha adrenergic receptors (negatively linked to adenylate cyclase) in these cells reproduced the effects seen with NAAG. Forskolin abolished the response. This suggests that the effect of NAAG is mediated via a decrease in intracellular cAMP. This is in accordance with previous data (Wroblewska et al. 1995) that NAAG activates mGluR3. We measured the effect of NAAG on GABA-A  $\alpha$  6 mRNA stability by treating the cells with D-actinomycin. We found that NAAG decreases the half-life of the message which could explain the rapid return of the mRNA levels to the baseline levels. These data indicate that short-term treatment with NAAG stimulates a group II mGluR inducing transient increases in GABA-A  $\alpha$  6 mRNA of a shorter half-life. (Supported by NIDA)

## 324.12

**GABA-STIMULATED CHLORIDE UPTAKE TO RAT BRAIN SYNAPTONEUROSOMES IS INHIBITED BY THYROID HORMONE.** D. B. Williams, K. Lee, D. M. Azzarano, H. Lee, and J. V. Martin<sup>2</sup>. Biology Department, Rutgers University, Camden, NJ 08102.

We recently showed that submicromolar concentrations of triiodothyronine (T<sub>3</sub>) and thyroxine (T<sub>4</sub>) stereospecifically stimulate the binding of [<sup>35</sup>S]-butylbicyclophosphorothionate (a convulsant ligand for the GABA<sub>A</sub> receptor complex) to highly washed rat brain membranes, while higher concentrations of the hormones inhibited radioligand binding. Further studies investigated the effect of L-T<sub>3</sub> on GABA-stimulated uptake of <sup>36</sup>Cl into synaptoneurosomes. Whole forebrains from male Sprague-Dawley rats were homogenized in 7 volumes (w/v) of ice-cold buffer (118 mM NaCl, 4.7 mM KCl, 1.18 mM MgSO<sub>4</sub>, 2.5 mM CaCl<sub>2</sub>, and 20 mM HEPES-Tris, pH 7.4), diluted with 30 more ml of buffer, and gravity-filtered through three layers of nylon mesh. The filtrate was gently pushed through a 10  $\mu$ m filter and centrifuged at 1,000 x g for 15 minutes. The final pellet was resuspended and used as the synaptoneurosomal preparation. An aliquot of the preparation was preincubated at 30°C for 20 minutes. GABA and/or various doses of L-T<sub>3</sub> were added with 0.5  $\mu$ Ci of <sup>36</sup>Cl. In five seconds, 5.0 ml of ice-cold buffer including 100  $\mu$ M picrotoxin was added, and the suspension was filtered under vacuum. After the filters were washed twice, the retained radioactivity was determined. L-T<sub>3</sub> inhibited GABA-stimulated flux of <sup>36</sup>Cl into synaptoneurosomes in a dose-dependent fashion, with a half-maximally effective dose of 100 nM. Recent estimates of the concentrations of thyroid hormones in the synaptic cleft of the CNS (Mason et al., *Neuropsychopharmacology* 8, 253-258, 1993) are within the range which should exert the effects on GABA<sub>A</sub> receptor binding and activity found in our studies. Our observations of the effects of thyroid hormones on the GABA<sub>A</sub> receptor complex therefore suggest a potential non-genomic mechanism for thyroid hormone actions in adult brain. This study was supported by grants from the Rutgers University Busch Fund and the National Science Foundation (IBN 94-12109).

## 324.13

CONFOCAL IMAGING OF INTRACELLULAR CHLORIDE ( $[Cl^-]_i$ ) IN ACUTELY PREPARED SLICES: MEASUREMENT OF GABA<sub>A</sub> RECEPTOR ACTIVITY. **Jon R. Ingelfield\*** and **Rochelle D. Schwartz-Bloom**. Dept. Pharmacol., Duke Univ. Med. Ctr., Durham, 27710

We have developed an optical recording technique, using UV laser-scanning confocal microscopy (LSCM) and the fluorescent  $Cl^-$  ion indicator, 6-methoxy-N-ethylquinolinium chloride (MEQ), to image changes in  $[Cl^-]_i$  in individual neurons of acute brain slices (12-21 d.o. rats). MEQ is quenched collisionally by increased  $[Cl^-]_i$ . After bath-loading slices (27°C) with the cell-permeant form (reduced) of MEQ, there was intense fluorescence (F) within numerous neurons in the hippocampus, neocortex and cerebellum. MEQ fluorescence was localized to the cytosol of both the somata and dendrites of neurons but was typically lower (higher  $[Cl^-]_i$ ) in dendrites compared with the soma, suggestive of an intraneuronal  $[Cl^-]_i$  gradient. There was no autofluorescence. When MEQ-loaded neurons were exposed to the UV laser continuously (> 1200 sec), photobleaching proceeded with a rate constant of  $k = 0.0041 \pm 0.0007 \text{ sec}^{-1}$  and a  $t_{1/2} = 173.8 \pm 24.6 \text{ sec}$ . Thus, illumination time never exceeded 20 sec in all experiments to minimize the photobleaching to ~6%. In hippocampal pyramidal cells, superfusion of GABA produced a time- and concentration-dependent increase in  $[Cl^-]_i$  ( $EC_{50} = 40 \mu\text{M}$ ) that was blocked by picrotoxin (1 mM). Pentobarbital (1 mM) and diazepam (50  $\mu\text{M}$ ) in the perfusate each enhanced the GABA-mediated relative change in MEQ fluorescence (ΔF). Also, the GABA (40  $\mu\text{M}$ )-induced ΔF varied ( $P < 0.05$ ) among cell types and brain regions: cerebellar Purkinje cells (70.6 ± 4.7%) > cerebellar granule cells (38.5 ± 7.5%) > pyramidal neurons of the hippocampus (30 ± 1.7%) and neocortex (19.5 ± 2.1%) = hippocampal interneurons (20.7 ± 3.6%). Local application (via picrospritzer) of the GABA<sub>A</sub> agonist, muscimol (10  $\mu\text{M}$ ), to hippocampal neurons led to a rapid (2-5 seconds) ΔF of 25%. This response was fully reversible and was blocked by the GABA<sub>A</sub> antagonist, bicuculline (100  $\mu\text{M}$ ). Optical imaging of  $[Cl^-]_i$  using MEQ and UV-LSCM is a useful new method to assess GABA<sub>A</sub> responses in neurons of defined morphology within living brain slices. Supported by NS28791 and American Heart Assoc., NC Affiliate, Inc.

## 324.14

BIOCHEMICAL AND IN VIVO EFFECTS OF A SELECTIVE INVERSE AGONIST FOR  $\alpha_5$  SUBUNIT-CONTAINING GABA<sub>A</sub> RECEPTORS. **J.R. Atack, R. McKernan, K. Wafford and G.R. Dawson\*** Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Harlow, CM20 2QR, U.K.

The GABA<sub>A</sub> receptor is now generally accepted to be a pentameric chloride ion channel composed of a combination of the 14 GABA<sub>A</sub> receptor subunits ( $\alpha 1-6$ ,  $\beta 1-3$ ,  $\gamma 1-3$ ,  $\delta$  and  $\rho$ ). It contains a benzodiazepine binding site, the pharmacology of which is dictated by the combination of  $\alpha$  and  $\gamma$ -subunits within the receptor. Radioligand binding studies of recombinant GABA<sub>A</sub> receptors have identified FG8094 as being 50 fold selective for  $\alpha_5$ -compared to  $\alpha_2$ - or  $\alpha_3$ -containing GABA<sub>A</sub> receptors whilst electrophysiological studies in oocytes expressing  $\alpha_5\beta_3\gamma_2$  receptors showed that FG8094 is an inverse agonist. Displacement of *in vivo* binding of [<sup>3</sup>H]FG8094 or [<sup>3</sup>H]Ro15-1788 was used to establish doses of FG8094 which occupy  $\alpha_5$  and  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$ -containing GABA<sub>A</sub> receptors, respectively. Doses of FG8094 that were relatively selective for  $\alpha_5$ -containing GABA<sub>A</sub> receptors did not induce seizures in mice nor did they potentiate pentylenetetrazole-induced seizures. However, at higher doses, which gave appreciable occupancy of  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$ -, as well as  $\alpha_5$ -containing GABA<sub>A</sub> receptors, FG8094 blocked the anticonvulsant effects of benzodiazepine agonists. These data suggest that  $\alpha_5$ -containing GABA<sub>A</sub> receptors do not mediate the anticonvulsant effects of benzodiazepine agonists nor do they appear to be involved in GABA<sub>A</sub> receptor-mediated seizures.

MSD Ltd.

GABA<sub>A</sub> RECEPTORS: MICROANATOMY

## 325.1

CLATHRIN-COATED VESICLES FROM BOVINE BRAIN CONTAIN UNCOUPLED AND PARTIALLY DEGRADED GABA<sub>A</sub> RECEPTORS. **M.H. Jajili Tehrani\*** and **E.M. Barnes, Jr.** Dept. of Biochem., Baylor Col. of Med., Houston, TX 77030.

Both sequestration and uncoupling of GABA<sub>A</sub> receptors are thought to represent early events in use-dependent receptor down-regulation. We have examined a possible relationship between these processes using clathrin-coated vesicles (CCVs), a preparation which may include vehicles important for GABA<sub>A</sub> receptor sequestration (Tehrani and Barnes, 1993). The level of <sup>3</sup>H-muscimol and <sup>3</sup>H-flunitrazepam (<sup>3</sup>H-flu) binding to CCVs represents 12.3 ± 1.8% and 7.9 ± 1%, respectively, of that in crude synaptic membranes. The parameters of <sup>3</sup>H-flu binding for CCVs ( $K_D = 12.2 \pm 3.5 \text{ nM}$ ;  $B_{max} = 225 \pm 45 \text{ fmol/mg}$ ) also differ from those for synaptic membranes ( $K_D = 1.38 \pm 0.2 \text{ nM}$ ;  $B_{max} = 1060 \pm 30 \text{ fmol/mg}$ ). As expected, addition of GABA ( $EC_{50} = 2.2 \mu\text{M}$ ) to synaptic membranes enhanced <sup>3</sup>H-flu binding ( $E_{max} = 122\%$ ), an effect completely blocked by SR95531. In contrast, neither GABA nor SR95531 had any significant effect on <sup>3</sup>H-flu binding to CCVs. Immunoblotting of synaptic membranes with an antibody against a GABA<sub>A</sub> receptor  $\beta 2S$  (317-428) fusion protein revealed major a 59-kDa and a minor 53-kDa polypeptide. For CCVs, in addition to these proteins, a range of smaller peptides (32-45 kDa) was also detected. Our results indicate that, during transit from the surface to coated vesicles, GABA<sub>A</sub> receptors undergo both structural and pharmacological modifications. These may reflect a common proteolytic step which occurs early in the process of GABA<sub>A</sub> receptor down-regulation.

## 325.2

VARIABILITY IN SYNAPTIC GABA<sub>A</sub> RECEPTOR CONCENTRATION IN CEREBELLAR NEURONS. **Z. Nusser<sup>1</sup>, W. Sieghart<sup>2\*</sup> and P. Somogyi<sup>1</sup>**. <sup>1</sup>MRC Anatomical Neuropharmacology Unit, Mansfield Road, Oxford, OX1 3TH; <sup>2</sup>Dep. of Biochemical Psychiatry, Psychiatrische Universitätsklinik, Vienna, Austria

The postsynaptic response to the release of a single quantum of GABA varies greatly in central neurons. There is also a large variability in postsynaptic responses to GABA in a single cell as revealed by the skewed amplitude distribution of miniature GABA<sub>A</sub> receptor mediated inhibitory postsynaptic currents (IPSCs). Our aim was to test whether these variabilities can be explained by quantitative differences in postsynaptic GABA<sub>A</sub> receptor concentration in synapses of different types of neurons. To address this question a postembedding immunogold method was employed on ultrathin sections from freeze-substituted and Lowicryl-embedded rat cerebellar tissue. The  $\alpha 1$  subunit of the GABA<sub>A</sub> receptor was visualised using a subunit-specific polyclonal antibody and silver intensified immunogold as marker. Quantitative comparison of immunolabeling at different synapses is possible under postembedding conditions, because there is no difference between different synapses in their access to antibodies. Golgi cell to granule cell synapses contain the lowest level of synaptic immunolabel followed by GABAergic synapses on Purkinje cells. The highest level of immunolabeling is observed in GABAergic synapses on interneurons in the molecular layer. Similarly to our previous observation of variability in  $\alpha 1$  subunit content between different Golgi cell to granule cell synapses, we have found that GABAergic synapses on Purkinje cell somata contain much lower immunolabeling than those on Purkinje cell dendrites. These results show that the differences in postsynaptic GABA<sub>A</sub> receptor concentration may underlie the variability of postsynaptic responses to synaptically released GABA.

## 325.3

EXPRESSION OF GABA<sub>A</sub> RECEPTOR (GABA-R)  $\beta 2$  SUBUNIT mRNA AND [<sup>3</sup>H]MUSCIMOL BINDING IN THALAMUS DO NOT CHANGE DURING THE COURSE OF ABSENCE-LIKE SEIZURES INDUCED BY  $\gamma$ -HYDROXYBUTYRATE (GHB). **P.K. Banerjee<sup>1</sup>, N.J.K. Tillakaratne<sup>4</sup>, S. Brailowsky<sup>7</sup>, R.W. Olsen<sup>3,5,6</sup>, Q.C. Sneed<sup>1</sup> and A.L. Tobin<sup>2,3,4,5,6</sup>** <sup>1</sup>Dept. of Neurology, Hosp. for Sick Children, Toronto; <sup>2</sup>Depts. of <sup>3</sup>Neurology, <sup>4</sup>Pharmacology and <sup>5</sup>Physiol. Sci., <sup>6</sup>Mol. Biol. Inst. and <sup>7</sup>Brain Res. Inst., UCLA; <sup>8</sup>Inst. de Fisiol., U.N.A.M., Mexico.

In thalamic relay nuclei neurosteroids fail to modulate GABA-R binding during the course of GHB-induced absence seizures, and as the seizures terminate GABA-R  $\alpha 4$  subunit mRNA levels in relay nuclei decrease and the effect of neurosteroids is restored (Banerjee et al., Soc. Neurosci. Abstr. 1995). GABA-R  $\beta 2$  subunit is abundant in the thalamus and  $\beta$  subunits possess binding sites for [<sup>3</sup>H]muscimol which are prevalent in the thalamus. In the present study we compared the expression of GABA-R  $\beta 2$  mRNA and [<sup>3</sup>H]muscimol binding in thalamus during GHB-seizures. We used *in situ* hybridization with <sup>35</sup>S-labeled cRNAs to determine the expression of mRNAs for rat  $\beta 2$  and GAD67 form of glutamate decarboxylase (as control). [<sup>3</sup>H]muscimol (5 nM) binding was performed to specifically label the high affinity sites. GABA-R  $\beta 2$  subunit mRNA was highly expressed in thalamus and its distribution in relay nuclei correlated with that of high affinity [<sup>3</sup>H]muscimol sites. In contrast, GAD67 cRNA hybridized strongly to reticular nucleus of thalamus (nRT) but not to relay nuclei. During GHB-seizures [<sup>3</sup>H]muscimol binding in the thalamus did not change. Likewise neither  $\beta 2$  nor GAD67 mRNA levels in relay nuclei or in nRT changed during GHB-seizures. These results suggest that the loss of neurosteroid modulation of GABA-R binding in thalamus during GHB-seizures and/or restoration of neurosteroid effect with the cessation of GHB-seizures is not influenced by GABA-R  $\beta 2$  subunits.

## 325.4

GABA<sub>A</sub> RECEPTOR SUBUNIT mRNA EXPRESSION IN SINGLE CULTURED HIPPOCAMPAL NEURONS. **A.R. Brooks-Kayal, D.E. Pleasure\* and H. Jin**. Depts. of Pediatrics and Neurology, Univ of Pennsylvania School of Medicine and Children's Hospital of Philadelphia, Philadelphia, PA 19104.

GABA is the major inhibitory neurotransmitter in the vertebrate forebrain. Alterations in GABAergic transmission have been implicated in some forms of epilepsy, and developmental changes in GABA<sub>A</sub> receptor expression may play an important role in both normal development and certain developmental neurological disorders. The relative abundances of mRNAs encoding 12 different GABA<sub>A</sub> receptor subunits were examined in cultured embryonic rat hippocampal neurons using the technique of single-cell mRNA amplification. Hippocampal neurons from embryonic day 17 rat pups grown in dissociated neuronal culture were analyzed on days 2, 7, 14 and 28 *in vitro* (DIV2-28). To determine the variability of GABA<sub>A</sub> receptor subunit expression between neurons of similar age in culture, eight individual neurons were examined at DIV 28. Prominent expression of  $\alpha 2$ ,  $\alpha 5$ ,  $\alpha 6$ ,  $\beta 1$  and  $\gamma 2$  mRNAs were detected, and the results demonstrate a high degree of consistency in levels of subunit expression between these same-age neurons. Preliminary studies examining a single neuron each at DIV 2, 7, and 14 suggest that levels of expression of several GABA<sub>A</sub> receptor subunit mRNAs undergo an increase in relative expression as cultured rat embryonic hippocampal neurons differentiate *in vitro*. To ascertain that GABA<sub>A</sub> receptor subunit expression changes in a consistent fashion during *in vitro* development, multiple neurons will be evaluated at each timepoint. ## 325.5

THE ANATOMICAL LOCALISATION OF THE mRNAs FOR THE  $\alpha 1$ - $\alpha 6$  SUBUNITS OF THE GABA<sub>A</sub> RECEPTOR IN POST-MORTEM HUMAN BRAIN. DJS. Sirinathsinghji\*, M. Rigby, R.P. Heavens, B. LeBourdelle, P. Wingrove, R. McKernan, G. Dawson, R. Hill, I. Ragan, J.H. Xue, and P. Whiting. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Harlow, Essex CM20 2QR, UK; Department of Psychiatry, University of Cambridge and MRC Brain Bank Laboratory, Cambridge CB2 2QR, UK

cDNAs encoding the  $\alpha 1$ - $\alpha 6$  subunits of the human GABA<sub>A</sub> receptor have been isolated in our laboratories. These sequences were used to generate specific oligonucleotide probes (<sup>32</sup>S-labelled) for the localisation of the mRNA transcripts in normal human brain. The  $\alpha 1$  mRNA was widely expressed with high levels in frontal, occipital and temporal cortex, hippocampus, caudate, putamen and cerebellum (granule, molecular and Purkinje layers). The  $\alpha 2$  and  $\alpha 4$  mRNAs were also present in these areas but expression in the cerebellum was restricted to the Bergmann glia for  $\alpha 2$  and to the granule cell layer for  $\alpha 4$ . The  $\alpha 3$  mRNA was less widely distributed with expression mainly in the cortical areas and hippocampus. The  $\alpha 5$  mRNA was strongly expressed in the frontal cortex, nucleus accumbens and medial temporal lobe (hippocampus, entorhinal, perirhinal and temporal cortex). The  $\alpha 6$  mRNA was expressed exclusively in the granule cell layer of the cerebellum. None of these subunits were detectable in brain stem nuclei. Studies are in progress to map in greater detail the distribution of the above mRNAs as well as those for the  $\beta$ ,  $\gamma$  and  $\delta$  subunits in human brain. (Supported by Merck).

## 325.7

AUTORADIOGRAPHIC LOCALIZATION OF  $\alpha 5$ -SUBUNIT CONTAINING GABA<sub>A</sub> RECEPTORS. S.M. Cook, K. Quirk, R. McKernan and J.R. Atack\* Merck Sharp & Dohme Research Labs., Neuroscience Research Centre, Harlow, CM20 2QR, U.K.

The pharmacology of the benzodiazepine binding site of the GABA<sub>A</sub> receptor is a function of the  $\alpha$  and  $\gamma$ -subunits contained within the receptor. Non-selective radioligands, such as [<sup>3</sup>H]Ro 15-1788, label a combination of  $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 3$  and  $\alpha 5$  subunit-containing receptors. Recently, however, FG 8094 has been identified as a benzodiazepine possessing greater than 50-fold selectivity for  $\alpha 5$ -over  $\alpha 1$ -,  $\alpha 2$ - or  $\alpha 3$ -containing receptors. In the present study, [<sup>3</sup>H]FG 8094, which was found to have an affinity for post-mortem human cortical  $\alpha 5$ -containing receptors of 1.5 nM, has been used as a radioligand to identify  $\alpha 5$ -containing receptors in sections of human and monkey brain. For autoradiographic studies, 30  $\mu$ M sections of human and monkey brain were incubated with 1 nM [<sup>3</sup>H]FG 8094 (in the presence of 1  $\mu$ M zolpidem to block  $\alpha 1$ -,  $\alpha 2$ - and  $\alpha 3$ -containing receptors) for 1 hr. at room temp. with non-specific binding defined using 1  $\mu$ M flunitrazepam. Specific binding was greater than 95% of total binding and showed marked regional variations in the distribution of binding sites. Thus, there was negligible binding in cerebellum whereas binding was most pronounced in the hippocampus and lower layers of the cortex, particularly the temporal cortex. Moreover, there were distinct variations within the hippocampus with, for example, a particularly high abundance of  $\alpha 5$  binding sites in the dentate gyrus whereas there was low expression of binding sites in the subiculum.

## 325.9

Temporal and Laminar-Specific Expression of 10 GABA<sub>A</sub> Receptor Subunit mRNAs in Fetal Monkey Visual and Sensorimotor Cortex. M. M. Huntsman\*, T. Tran and E. G. Jones, Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

The GABA<sub>A</sub> receptor is the primary target for fast inhibitory neurotransmission in the adult mammalian brain and functions as a ligand-gated chloride-ion selective channel. Thirteen subunit genes have been cloned and appear to co-exist in preferred combinations or subtypes consisting of at least one subunit from each of the three major classes, known as alpha, beta and gamma. The identified subunit genes are subclass variants of these classes grouped by their sequence identity and likely assembling into heteromeric combinations of five where it is presumed the subtype determines the physiological and pharmacological functions of GABA<sub>A</sub> receptors in vivo. In the adult monkey cerebral cortex, the major receptor subtype likely contains the  $\alpha 1$ ,  $\beta 2$  and  $\gamma 2$  subunits as the transcripts which encode these subunits are expressed at extremely high levels that exceed levels observed for other subunits like  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 4$ ,  $\alpha 5$ ,  $\beta 1$ ,  $\beta 3$  and  $\gamma 1$  transcripts. Subcloned cDNAs for the  $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 4$ ,  $\alpha 5$ ,  $\beta 1$ ,  $\beta 2$ ,  $\beta 3$ ,  $\gamma 1$  and  $\gamma 2$  subunits were transcribed and localized in fetal and neonatal monkey visual and sensorimotor cortex in order to determine the likely predominant GABA<sub>A</sub> receptor subtype in cortical development. In situ hybridization histochemistry of these labeled transcripts identify a completely different aggregation of potential GABA<sub>A</sub> receptor subtypes in comparison with adults, with dramatic increases in levels, especially for  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 5$ ,  $\beta 1$ ,  $\beta 3$  and  $\gamma 2$  transcripts. The laminar specification of  $\alpha 5$  transcripts reaches peak levels at embryonic day 137 and resolves the unique distribution pattern of adult animals after postnatal day 125. The presence of subunit mRNAs in regions of the developing cortex probably before the likely onset of inhibition raises the possibility that specific GABA<sub>A</sub> receptor subtypes may be involved in synaptogenesis and the establishment of topographic maps in pre- and early post-natal development. Supported by NIH grant 5-T32-NS07357.

## 325.6

GABA<sub>A</sub> RECEPTOR SUBUNIT MESSENGER RNA DETECTION IN SUPERIOR CERVICAL GANGLIA. Z. F. Liu\* and D. R. Burt. Department of Pharmacology and Experimental Therapeutics, University of Maryland School of Medicine, Baltimore, MD 21201.

Gamma-aminobutyric acid (GABA), the major inhibitory neurotransmitter in the brain, mediates fast synaptic inhibition by opening the chloride channel intrinsic to the GABA<sub>A</sub> receptor. GABA<sub>A</sub> receptors are composed of subunits belonging to different families ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\rho$ ) according to degree of sequence homology. At present, the subunit composition of native GABA<sub>A</sub> receptors in the central nervous system is not known and there are relatively few reports of GABA<sub>A</sub> receptors in peripheral tissues, where the subunit composition may be simpler and easier to determine. Considerable functional data indicates the presence of GABA<sub>A</sub> receptors in superior cervical sympathetic ganglia (SCG). We studied GABA<sub>A</sub> receptor subunit mRNA levels in rat SCG, using subunit-specific oligonucleotide primers and reverse transcriptase-polymerase chain reaction (RT-PCR) amplification. Qualitative data indicated that, of those tested, GABA<sub>A</sub> receptor  $\alpha 4$ ,  $\alpha 6$ ,  $\beta 1$ ,  $\beta 3$ , and  $\gamma 2$  subunit mRNAs were found in rat SCG; only the  $\beta 2$  subunit was negative. This result differs from the adrenal medulla, which reportedly contains  $\beta 2$  subunit mRNA as well as  $\beta 1$  and  $\beta 3$  (Ymer et al., 1989, EMBO J. 8:1665). Quantitative RT-PCR was performed to determine actual GABA<sub>A</sub> receptor subunit mRNA levels in rat SCG by using mouse GABA<sub>A</sub> receptor subunit clones as internal standards. We started quantitative measurements with the  $\alpha 4$  subunit, reportedly very low in brain.

The  $\alpha 4$  mRNA levels in SCG correspond to about 2000  $\alpha 4$  mRNA molecules per SCG (or only about one molecule per twenty principal neurons). The very low messenger level of the  $\alpha 4$  subunit may correspond to "leakage" of transcription in the rat SCG. This shows the importance of quantitative measurements in interpreting positive PCR results. (Supported in part by NIH grant HD16596 to DRB)

## 325.8

DISTRIBUTION IN THE RABBIT CENTRAL NERVOUS SYSTEM OF A mRNA ENCODING A PORTION OF THE  $\alpha 1$  GABA<sub>A</sub> RECEPTOR SUBUNIT. Yunxing Wu\*, Adam A. Book\*, E. Hazel Murphy\* and Dennis R. Grayson<sup>1,2</sup>. Neuroscience Research Center and Department of Psychiatry<sup>1,2</sup>, Medical College of Pennsylvania and Hahnemann University (MCPHU), Pittsburgh, PA 15212 and Department of Anatomy and Neurobiology<sup>2</sup>, MCPHU, Philadelphia, PA 19129.

A rabbit subfragment of the  $\alpha 1$  receptor subunit was generated using primers corresponding to the intracellular loop region of the rat sequence (positions 1091 bp to 1321 bp). We used RT-PCR under reduced stringency annealing conditions (55°C) to isolate a homologous region of the rabbit mRNA. The amplification product was sequenced and over the 230 bp subclone, the rat and rabbit DNA sequences were 95% identical. However, all sequence substitutions were in third bp positions with respect to the coding frame resulting in a 100% amino acid concordance. This subclone was used to assess the distribution of the  $\alpha 1$  mRNA in sections prepared from adult and developing rabbit brain using *in situ* hybridization with an <sup>35</sup>S-cRNA labeled riboprobe. Hybridized brain sections were exposed to film, emulsion coated and counterstained. Both film exposure optical density and silver grain distribution were analyzed to determine localization. Analysis of coronal sections showed that at P20, the  $\alpha 1$  receptor subunit mRNA was most abundantly expressed in large neurons at the border of the stratum oriens and the hippocampal pyramidal cell layers and within the polymorphic layer of the olfactory tubercle.  $\alpha 1$  mRNA was moderately abundant in layers II and V/VI of the frontal cortex, layers II and V of the anterior cingulate cortex (ACC), pyramidal cells of the CA1 and CA2 hippocampal fields, pyramidal layer of the olfactory tubercle, dentate gyrus granule cells, medial septum and diagonal band. Silver grain density was lower in layer IV of the neocortex, layers III and VI of the ACC, hippocampal CA3 field, lateral septum, and caudate-putamen. Analysis of adult sections indicates that many of these patterns are maintained once the brain is fully developed. Supported by NIH grants DA06871 P01 to E.H.M., NIH Training Grant NS07287, and K04 NS01647 to D.R.G.

## 325.10

DISTRIBUTION OF THE GABA<sub>A</sub> RECEPTOR COMPLEX, BETA SUBUNIT IN THE ENCEPHALON OF FROG (*Rana pipiens*). M. I. Aller\*, S. Januszonis\*, K. V. Fitts\* and A. Fernández-López\*. Dpt. Biología Celular y Anatomía, Universidad de León, León, 24071, Spain. <sup>2</sup>Dpt. Psychology, University of Massachusetts at Amherst, MA 01003, USA.

This work reports an immunocytochemical, semi-quantitative distribution of the beta subunit GABA<sub>A</sub> receptor complex throughout the encephalon of frog (*Rana pipiens*) by using a specific monoclonal antibody against this subunit (Boehringer, clone bd 17). Several different fixatives (4% paraformaldehyde, 4% paraformaldehyde-0.1% glutaraldehyde and 4% paraformaldehyde-0.1M L-lysine-0.01M sodium m-periodate) were used. Results obtained with all fixatives were consistent both with regard to the labelled structures and their relative densities of labelling.

The highest labelling with this antibody was found in striatum and cerebellum and was defined as 100%. Very high densities of labelling (>75%) were found in the olfactory tubercle, lateral pallidum, torus semicircularis and some nuclei of the medulla. Regions of the thalamus, some tegmental nuclei and some strata of tectum opticum show intermediate levels of labelling (50-75%) while structures as septum, medial pallidum or nucleus isthmi appeared to have little immunoreactivity for this antibody.

These data are consistent with those obtained from autoradiographic binding of 3H flunitrazepam receptor complex in frog. These findings indicate that this monoclonal antibody raised against the mammalian beta subunit of the GABA<sub>A</sub> complex permits characterization of this subunit in the frog.

Acknowledgement: This work has been financed by DGICYT P82-883. M.I. Aller is a fellowship of the University of León.

## 325.11

THE GABA<sub>A</sub> RECEPTOR SUBUNITS IN THE MAMMALIAN RETINA. A.K. Mehta\*, A. Gutiérrez, Z.U. Khan, C.P. Miralles and A.L. De Blas, Div. Mol. Biol. and Biochem., Univ. Missouri, Kansas City, MO 64110.

Subunit-specific antibodies ( $\alpha_{1,4}$ ,  $\beta_{1,3}$  and  $\gamma_2$ ) were used to immunoprecipitate detergent-solubilized [<sup>3</sup>H]muscimol (<sup>3</sup>H-MUS) and [<sup>3</sup>H]flunitrazepam (<sup>3</sup>H-FNZ) binding sites from bovine retina. The <sup>3</sup>H-MUS and <sup>3</sup>H-FNZ immunoprecipitation values obtained with each anti-subunit antibody were  $\alpha_1$  (56% and 58%),  $\alpha_2$  (24% and 37%),  $\alpha_3$  (28% and 15%),  $\alpha_4$  (13% and 0%),  $\alpha_5$  (16% and 3%),  $\alpha_6$  (8% and 0%),  $\beta_1$  (9% and 1%),  $\beta_2$  (75% and 49%),  $\beta_3$  (19% and 20%) and  $\gamma_2$  (76% and 60%) respectively. Therefore  $\alpha_1$ ,  $\beta_2$  and  $\gamma_2$  are the most abundant GABA<sub>A</sub> receptor subunits in retina and II) a relatively high proportion of GABA<sub>A</sub> receptors have benzodiazepine binding site(s). The <sup>3</sup>H-FNZ immunoprecipitation values obtained with the various anti-subunit antibodies were similar to the diazepam-sensitive (DS) [<sup>3</sup>H]Ro15-4513 immunoprecipitation values. In addition, the bovine retina has about 13% of the [<sup>3</sup>H]Ro15-4513 binding sites that are diazepam-insensitive (DI). However, the DI binding sites from bovine retina could not be precipitated by either anti- $\alpha_6$  or anti- $\alpha_4$  antibodies, which contrasts with the high proportion of cerebellar DI binding sites that could be precipitated with anti- $\alpha_6$ . The cellular localization of some of these subunits has been revealed by immunocytochemistry in rat retina. Supported by grant NS17708 from NINDS.

## 325.12

THE  $\alpha_6$  SUBUNIT OF THE GABA<sub>A</sub> RECEPTORS FROM RAT BRAIN AND RETINA. Z.U. Khan, A. Gutiérrez, A.K. Mehta, C.P. Miralles and A.L. De Blas, Div. Mol. Biol. and Biochem. Univ. Missouri, Kansas City, MO 64110.

A novel anti- $\alpha_6$  antibody has been used for the purification and characterization of the  $\alpha_6$ -containing GABA<sub>A</sub> receptors in the rat brain and for studying the immunocytochemical distribution of the  $\alpha_6$  subunit peptide in rat brain and retina. The anti- $\alpha_6$  antibody recognized a 66 KDa peptide in brain membranes and immunoprecipitated 10-28% of the brain GABA<sub>A</sub> receptors in various brain regions as determined by [<sup>3</sup>H]muscimol binding. The highest immunoprecipitation values were obtained in the thalamus and the lowest in the cerebellum. Surprisingly, the receptors immunoprecipitated by anti- $\alpha_6$  showed little or no diazepam-insensitive or diazepam-sensitive [<sup>3</sup>H]Ro15-4513 binding sites in any brain region. In the cerebellum, where 25% of the [<sup>3</sup>H]Ro15-4513 binding is diazepam-insensitive, much of the latter was immunoprecipitated by an anti- $\alpha_6$  antibody but not by the anti- $\alpha_6$  antibody. Immunoblots of immunoaffinity-purified GABA<sub>A</sub> receptors from the cerebral cortex on immobilized anti- $\alpha_6$  revealed molecular colocalization of  $\alpha_6$  and  $\gamma_2$ . However, the absence of significant benzodiazepine binding in these GABA<sub>A</sub> receptors suggests that the assembly of the  $\alpha_6$  and  $\gamma_2$  subunits in the cerebral cortex and in other brain regions is such that they do not normally form diazepam-insensitive [<sup>3</sup>H]Ro15-4513 binding sites. This result contrasts with the presence of diazepam-insensitive [<sup>3</sup>H]Ro15-4513 binding sites in the GABA<sub>A</sub> receptors expressed in heterologous systems resulting from the combination of  $\alpha_6$ ,  $\gamma_2$  and  $\delta$  subunits. Immunocytochemistry has revealed the abundance of  $\alpha_6$  peptide immunoreactivity in the thalamus and dentate gyrus (mainly in the hilar neurons and the inner 1/3 of the granule cell layer). The  $\alpha_6$  immunoreactivity is also present in the external plexiform layer of the olfactory bulb and in all layers of the neocortex and pyriform cortex. In the retina,  $\alpha_6$  is concentrated on ganglion cells (including some giant ganglion cells), the inner plexiform layer and to a lesser extent in the outer plexiform layer. Supported by grant NS17708 from NINDS.

GABA<sub>A</sub> RECEPTORS: RECOMBINANT STUDIES AND MOLECULAR MAPPING

## 326.1

THE GABA<sub>A</sub> RECEPTOR  $\alpha_6$  SUBUNIT GENE IS TIGHTLY LINKED TO THE  $\alpha_1$ - $\gamma_2$  SUBUNIT CLUSTER IN MOUSE CHROMOSOME 11.

K.M. Garrett\*, A. Rotter, J. Gan and T.W. Seale, Departments of Physiology and Pediatrics, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

The GABA<sub>A</sub> receptor is a ligand-gated channel and is the site of action for several sedative-hypnotic drug classes. This receptor is a multimeric complex composed of varying combinations of  $\alpha$ ,  $\beta$ ,  $\gamma$  and  $\delta$  subunits. The subunits are found in clusters in both the human and mouse genome. We have identified RFLPs for the  $\alpha_1$  (Hind III) and  $\alpha_6$  (BstE II) subunit genes in C57BL/6J and DBA/2J inbred mice. We have determined that these two genes are tightly linked on mouse chromosome 11 by analyzing the strain distribution patterns of the two RFLPs and microsatellite markers flanking these genes in 26 BXD recombinant inbred lines. These results further demonstrate clustering of the GABA<sub>A</sub> receptor subunit genes on mouse chromosomes and the synteny between the mouse and human genome. The physiological and pharmacological functions of the GABA<sub>A</sub> receptor  $\alpha_6$  subunit are not well understood. Mapping of the murine *Gabra6* gene and identification of an RFLP for the  $\alpha_6$  subunit in the mouse provides a means for quantitative trait loci analysis for probing behavioral functions of the  $\alpha_6$  subunit. Supported by grants from Presbyterian Health Foundation to KMG and TWS, NIMH (MH49791) to TWS and NINDS (NS18089) to AR.

## 326.3

COMPARISON OF THE DECAY KINETICS OF RECOMBINANT GABA<sub>A</sub> RECEPTOR CURRENTS FOLLOWING TRANSIENT AGONIST APPLICATION

K. F. Haas\*, E. C. Burgard<sup>1</sup> and R. L. Macdonald<sup>1,2</sup>, Departments of Neurology<sup>1</sup> and Physiology<sup>2</sup>, University of Michigan, Ann Arbor, MI 48104-1687.

Synaptic GABA<sub>A</sub> receptor (GABAR) currents likely reflect a response to high GABA concentrations available in the synaptic cleft for at most a few msec, yet IPSCs decay over a much longer period of time. Studies from native GABARs now suggest that entry into and out of multiple desensitized states can explain the prolongation of current following brief GABA application. We have addressed the mechanisms underlying desensitization with rapid GABA application to outside-out patches containing recombinant GABARs of known subunit composition. cDNAs encoding rat  $\alpha X$  ( $X = 1, 5$  or  $6$ ),  $\beta 3$ , and  $\gamma 2L$  subunits were individually subcloned into the plasmid vector pCMVNeo. L929 fibroblasts were transiently transfected with various combinations (1:1:1) of each, resulting in expression of functional  $\alpha X\beta 3\gamma 2L$  GABARs. Outside-out patch-clamp recordings ( $E_{Cl} = 0$  mV) were obtained from positively transfected cells. GABA (1 mM) was applied to the patch using a piezo-driven application system. Prolonged (200 msec) GABA application to patches ( $V_m = -75$  mV) produced multiple-channel ensemble currents that exhibited both rapid ( $\tau = 5-20$  msec) and prolonged ( $\tau = 50-200$  msec) components of desensitization. Brief (5 msec) applications produced ensemble currents that deactivated with two time constants similar to those of desensitization. Single-channel responses to brief applications were characterized by instantaneous channel opening followed by multiple bursts of openings lasting 20 - 100 msec. Although different GABAR isoforms exhibited characteristic burst patterns, all isoforms eventually entered prolonged (50-100 msec) closed (desensitized) states prior to reopening. These data suggest that similar to native receptors, recombinant GABARs enter desensitized states which prolong GABAR current decay following brief agonist applications. R01-NS33300 (RLM).

## 326.2

GABA<sub>A</sub> RECEPTOR DESENSITISATION: THE ROLE OF THE  $\gamma_2$  SUBUNIT AND ITS PHYSIOLOGICAL SIGNIFICANCE. C. Domínguez-Perrot\*, P. Feltz, M. O. Poulter, Laboratoire de physiologie générale, Université Louis Pasteur, 67084 Strasbourg, France.

To examine the role of the  $\gamma_2$  subunit in GABA<sub>A</sub> receptor desensitisation, the relaxation of GABA-induced whole cell currents was compared for two different recombinant GABA<sub>A</sub> receptors ( $\alpha 1\beta 3$  and  $\alpha 1\beta 3\gamma 2$ ). The  $\alpha 1\beta 3\gamma 2$  receptor desensitized faster ( $\tau_1 = 41.6 \pm 8.3$  ms,  $\tau_2 = 2.4 \pm 0.6$  s; two exponential model at EC100) than  $\alpha 1\beta 3$  ( $\tau_1 = 145 \pm 12$  ms,  $\tau_2 = 6.3 \pm 2.1$  s). For both receptors, the Hill slopes  $\geq 1$ , implying two steps in the activation. For  $\alpha 1\beta 3$  receptor, the fast desensitisation rate of GABA current were unaltered in range from EC50 to EC100 (10-20  $\mu$ M) and the slow desensitisation was observed above  $\sim$ EC20 whose rate was dependent on GABA concentration (maximum at  $\sim$ EC80). Voltage-dependency of the desensitisation rate was only seen for  $\alpha 1\beta 3\gamma 2$  receptor ( $\tau_2$  increased by  $\sim$ 15-20 fold when the holding potential was elevated from -80 to +40 mV). This indicates that the  $\gamma_2$  subunit is responsible for the voltage-dependency of GABA<sub>A</sub> receptor desensitisation. Recovery from desensitisation was also biphasic: the first phase was faster for  $\alpha 1\beta 3\gamma 2$  receptor, the rate of the second phase being the same. Isoquinoline (EC50  $\sim$ 10  $\mu$ M) induced biphasic relaxation and taurine (EC50  $\sim$ 7 mM) induced monophasic relaxations for both. The computer simulation of receptor state kinetics showed that  $\gamma_2$  subunit prolongs the time course of a synaptic potential by fastening the desensitisation. The physiological role of the  $\gamma_2$  subunit might be to prolong the time course of synaptic current through modifying desensitisation kinetics and its voltage-dependency. Supported by MRT grant.

A POINT MUTATION OF THE GABA<sub>A</sub> RECEPTOR DESTABILIZES ITS CLOSED AND DESENSITIZED STATES.

J. D. Clements\*, L. Tierney, B. Birnir, P. Pillai, P. Gage and C. Cox, Australian National University, Canberra, ACT 0200, Australia.

The hypothetical structure of the GABA<sub>A</sub> receptor has the M2 membrane spanning region lining the channel pore. Consistent with its critical location, the M2 region is highly conserved across the ACh receptor family, and a leucine residue near the center of this region is 100% conserved. In the ACh channel, substituting this leucine with a more hydrophilic residue dramatically slows and decreases desensitization (Revah et al., Nature 353:846, 1991). In the present study, the homologous leucine residue in the GABA<sub>A</sub> receptor alpha subunit was substituted with a hydrophilic threonine. Alpha and beta subunits were co-expressed in Sf9 cells and formed functional heteromeric GABA<sub>A</sub> receptors. Drugs were applied using a fast solution exchange system. A step into GABA (10 mM) produced a strongly desensitizing response from wild type, but not from mutant channels. Intriguingly, the mutant's slow activation rate was very similar to the fast desensitization rate of the wild-type response. Mutant channels exhibited a tonic leak current in the absence of GABA that was selectively blocked by picrotoxin (500  $\mu$ M). These findings suggest that the mutation enables the channel to open in the absence of agonist, and converts the desensitized state into a conducting state. The highly conserved leucine residue plays a crucial role in closing the GABA<sub>A</sub> channel. (Dept. of Health, Australia)

## 326.5

POINT MUTATIONS OF THE GABA<sub>A</sub> RECEPTOR AFFECTING MODULATION BY AND BINDING AFFINITIES OF BENZODIAZEPINE SITE LIGANDS. **A. Buhr, R. Baur, P. Malherbe\* and E. Sigel.** Dept. of Pharmacology, Univ. Bern, 3010 Bern, Switzerland; \*Pharma Division, Preclinical Research, F. Hoffmann-La Roche Ltd. 4002 Basel, Switzerland.

Mutants of the GABA<sub>A</sub> receptor have been described in the  $\alpha$  and  $\gamma$  subunits which increase modulation by diazepam (Buhr *et al.*, 1996, Mol. Pharmacol. 49, in press). Rat wild type or mutated  $\alpha 1$ ,  $\beta 2$ , and  $\gamma 2$  subunits were coexpressed in *Xenopus* oocytes and investigated with electrophysiological techniques. The response to zolpidem was increased in receptors containing the  $\alpha 206A$  mutation but was nearly absent in channels containing  $\gamma F77L$ . Competition experiments indicated that Ro 15-1788 similarly to diazepam still interacts with the mutated  $\gamma$  subunit, while zolpidem lost this ability. To quantify these data, radioligand binding experiments were performed using membranes of transiently transfected HEK 293 cells. Receptors containing  $\gamma F77L$  displayed an 8 to 28-fold reduced affinity for diazepam and [<sup>3</sup>H]Ro 15-1788 and a 130-, 290- and 920-fold reduced affinity for Cl 218872, zolpidem and DMCM, respectively.  $\alpha 206A$  resulted in a 4 to 5-fold decreased affinity for diazepam and zolpidem. Interestingly, for the same mutant receptors the affinities for Cl 218872 and DMCM were 16- and 5-fold increased. Results on double mutants will also be discussed. The residues  $\alpha 206$  and  $\gamma F77$  are directly homologous to residues involved in GABA binding. Therefore, our results support the postulate that the benzodiazepine site is located in a homologous position to the agonist binding site. ## 326.7

FUNCTIONAL CHARACTERISTICS AND ALLOSTERIC MODULATION OF HUMAN  $\gamma$ -AMINOBUTYRIC ACID TYPE A RECEPTORS CONTAINING THE  $\alpha 4$  SUBUNIT. **K.A. Wafford, S.A. Thompson, D. Thomas, S. Pollack\* & P.J. Whiting.** Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR.

Recombinant human  $\alpha 4\beta 1\gamma 2$ s and  $\alpha 4\beta 3\gamma 2$ s GABA<sub>A</sub> receptors were expressed in *Xenopus* oocytes and the pharmacology of these receptors investigated using the two-electrode voltage clamp method. The GABA EC<sub>50</sub> for  $\alpha 4\beta 1\gamma 2$  was similar to  $\alpha 1\beta 1\gamma 2$  (33.1  $\mu$ M), but slightly lower than  $\alpha 6\beta 1\gamma 2$  (14.4  $\mu$ M). The efficacy of the GABA partial agonists THIP and P4S were markedly reduced on  $\alpha 4\beta 1\gamma 2$  compared to  $\alpha 1\beta 1\gamma 2$  and  $\alpha 6\beta 1\gamma 2$ . GABA responses on human  $\alpha 4\beta 1\gamma 2$  receptors were sensitive to the competitive antagonists, bicuculline (100  $\mu$ M) and SR95531 (1  $\mu$ M), and the non-competitive antagonist picrotoxin (100  $\mu$ M). Several compounds, which act via the benzodiazepine site, were examined at a concentration of 1  $\mu$ M. The effects of these compounds on  $\alpha 4\beta 1\gamma 2$  when compared to  $\alpha 1\beta 1\gamma 2$  and  $\alpha 6\beta 1\gamma 2$  revealed a unique profile, showing most similarity to  $\alpha 6\beta 1\gamma 2$ . Similar to  $\alpha 1$  and  $\alpha 6$  containing receptors,  $\alpha 4\beta 1\gamma 2$  receptors were potentiated by the steroid, 5 $\alpha$ -pregnan-3 $\alpha$ -ol-20-one, (367  $\pm$  26%). Marked potentiation of the GABA response (706  $\pm$  82%) was observed with pentobarbital (100  $\mu$ M). This compared to 288  $\pm$  32% on  $\alpha 1\beta 1\gamma 2$ s and 719  $\pm$  52% on  $\alpha 6\beta 1\gamma 2$ . The direct activation by pentobarbital on  $\alpha 4\beta 1\gamma 2$ s receptors was extremely small (6% of maximum GABA at 1mM) compared to 31% and 147% on  $\alpha 1\beta 1\gamma 2$  and  $\alpha 6\beta 1\gamma 2$  respectively.  $\alpha 4\beta 1\gamma 2$  also showed no direct activation by propofol, unlike the other combinations studied. The receptor was potentiated by propofol to a greater degree on  $\alpha 4\beta 1\gamma 2$  and  $\alpha 1\beta 1\gamma 2$  than  $\alpha 6\beta 1\gamma 2$ . Flurosemide, which shows selectivity for the  $\alpha 6\beta 3\gamma 2$  subtype, also showed some selectivity for the  $\alpha 4\beta 1\gamma 2$  subtype over  $\alpha 1\beta 3\gamma 2$ . These experiments reveal a unique pharmacology for  $\alpha 4$  containing receptors with similarities to both  $\alpha 6$  and  $\alpha 1$ . Funded by M.S.D. Research Laboratories.

## 326.9

IDENTIFICATION A SINGLE AMINO ACID ON THE GAMMA SUBUNIT OF THE GABA-A RECEPTOR REQUIRED FOR HIGH AFFINITY BINDING OF [3H]Ro15-1788. **P.B. Wingrove, K.A. Wafford and P.J. Whiting\***, Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR.

It is known that both an  $\alpha$  and a  $\gamma$  subunit are required for the formation of a benzodiazepine binding site on the GABA-A receptor; the pharmacology being dependent on the subunit isoforms present. When expressed transiently in HEK293 cells in combination with  $\alpha 1$  and  $\beta 1$  subunits, GABA-A receptors containing a  $\gamma 2$  (or  $\gamma 3$ ) subunit have a much higher affinity for [3H]Ro15-1788 than receptors containing  $\gamma 1$ . This criterion was used to assay chimeric  $\gamma 1/\gamma 2$  subunits and subsequently  $\gamma 1$  subunit mutants to identify a single amino acid,  $\gamma 2Phe77$ , which conferred a high affinity binding site for [3H]Ro15-1788.

Saturation curves for the binding of [3H]Ro15-1788 were constructed for the recombinant receptors  $\alpha 1\beta 1\gamma 2$  and  $\alpha 1\beta 1\gamma 1\Delta Leu79Phe$  and the K<sub>d</sub> values calculated by Scatchard analysis to be 0.91  $\pm$  0.22 nM and 3.13  $\pm$  0.20 nM respectively (mean  $\pm$  s.e.mean). Displacement of this [3H]Ro15-1788 binding by  $\beta$ -CCM and CL218-872 indicated that they also have a high affinity for  $\alpha 1\beta 1\gamma 1\Delta Leu79Phe$ . The affinities for flunitrazepam and zolpidem, however, were unaffected by this mutation.

Thus, Phe77 of  $\gamma 2$  (numbering of mature peptide) is necessary for high affinity binding of [3H]Ro15-1788, CL218-872 and  $\beta$ -CCM to the GABA-A receptor but is either not necessary or not sufficient for binding flunitrazepam and zolpidem. It is of interest to note that Phe77 is at a homologous position to Phe92 of the  $\alpha 1$  subunit which has been implicated as a critical residue at the GABA binding site suggesting some structural homology between binding sites for different ligands.

GABA<sub>A</sub> RECEPTOR HETEROGENEITY IN THE IMR-32 CELL LINE. **D.W. Sapp\* and H.H. Yeh.** Dept. Pharmacology & Program in Neuroscience, Univ. of Conn. Health Center, Farmington, CT 06030.

An analysis of GABA<sub>A</sub> receptors expressed in a variety of neuronal and non-neuronal cell lines may provide insight into the relationship between functional assembly of the receptor and subunit composition. Here, we employed whole-cell patch clamp electrophysiology to examine the modulatory effects of zinc (Zn) and diazepam (DZ) on GABA responses elicited in a human neuroblastoma cell line, IMR-32. Preliminary PCR-based expression profiling of GABA<sub>A</sub> receptor subunit mRNAs from IMR-32 cultures revealed prominent expression of the  $\alpha 3$ ,  $\beta 3$ ,  $\gamma 3$  subunit transcripts with comparatively low levels of  $\alpha 5$  and  $\gamma 2$ . Electrophysiologically, 3 profiles of GABA responses emerged from recordings of >70 IMR-32 cells. <20% displayed a GABA response that was potentiated by DZ but was insensitive to Zn, similar to that found in WSS-1 cells stably transfected with the  $\alpha 1\beta 1\gamma 2$  subunit combination. In the remaining cases, an approximately equal proportion of cells showed GABA responses that either were completely blocked by Zn and resistant to potentiation by DZ or were "mixed", with Zn partially blocking the GABA response that could be shown to be potentiated by DZ.

That clear-cut reciprocal sensitivity to DZ and Zn can be observed in individual IMR-32 cells suggests heterogeneity in functional GABA<sub>A</sub> receptors within this cell line and that some IMR-32 cells may express a  $\gamma$ -less GABA<sub>A</sub> receptor. Other IMR-32 cells may express both  $\gamma$ -containing and  $\gamma$ -less receptors, as reflected by a "mixed" sensitivity to Zn and DZ. Ongoing studies are addressing these issues using combined patch clamp recording and single-cell RT-PCR.

## 326.8

LOCATING THE ANION-SELECTIVITY FILTER IN THE GABA<sub>A</sub> RECEPTOR CHANNEL. **M. Xu, J. Horenstein, and M. H. Akabas\***. Ctr for Mol. Recog., Columbia Univ., NY, NY 10032.

We previously identified 9 residues in the M2 segment of the  $\alpha 1$  subunit that are exposed in the channel lumen of the GABA<sub>A</sub> receptor using the scanning-cysteine-accessibility method (J. Gen. Physiol. 107:195-205). In this anion-selective channel, cationic sulfhydryl reagents, applied extracellularly, reacted with the mutant  $\alpha 1T261C$  but not with the more cytoplasmic mutant  $\alpha 1V257C$ , whereas, anionic reagents reacted with both mutants. In the gene superfamily of ligand-gated ion channels, there is an alanine at the position aligned with the intermediate ring of charge ( $\alpha 1A254$ ) in the anion-selective channels and an anionic residue in the cation-selective channels. To probe the role of the charge at position 254 on the ability of cationic sulfhydryl reagents to penetrate into the channel, we made a double mutant  $\alpha 1A254E/V257C$ . The cationic reagent, MTSET, reacts with this mutant but the rate at which the anionic reagent, MTSES, reacts is markedly reduced. This suggests that the residue at the intermediate ring position may be an important determinant of charge selectivity. Support NIH NS30808, Klingenstein Foundation., AHA, NYHA.

## 326.10

MEASUREMENT OF FUNCTIONAL EFFICACY OF COMPOUNDS ACTING AT THE BENZODIAZEPINE SITE OF  $\alpha 1$  SUBUNIT-CONTAINING GABA<sub>A</sub> RECEPTORS STABLY EXPRESSED IN LTK CELLS, USING THE MICROPHYSIOMETER. **A.J. Smith, R. McKernan\* & J.R. Atack.** Merck, Sharp and Dohme Research Laboratories, Terlings Park, Eastwick Rd., Harlow, UK.

The Cytosensor Microphysiometer measures changes in extracellular acidification rates resulting from alterations in energy demand made on cells in response to receptor or ion channel activation or from alterations in Na<sup>+</sup>/H<sup>+</sup> exchange across the membrane during homeostatic control of intracellular pH.

Chloride conductance through GABA<sub>A</sub> receptors can be modulated by compounds acting at the benzodiazepine site. Cells expressing receptors with subunit composition  $\alpha 1\beta 3\gamma 2$  were seeded at 10<sup>5</sup> cells per cup, with 4-5 days induction and experiments conducted in DMEM containing 44mM NaCl, pH 7.4. Responses to GABA, which were specifically blocked by bicuculline and picrotoxin and were maximal at 30  $\mu$ M, were characterized by an initial alkalisation followed by a peak of acidification, typically from 100% up to a maximum of 140-150% after normalization with respect to baseline. The alkalisation was more evident at low agonist doses and became progressively masked at higher concentrations. Agonist time-courses were performed to optimise the acidification response. Increasing agonist exposure times from 15 to 25 secs prior to rate determination eliminated the initial alkalisation and maximised the acidification component.

From the GABA dose-response curve, a dose of GABA was selected which produced an increase equivalent to 20% of the maximum response (10  $\mu$ M; 11  $\pm$  0.7% increase over baseline, n=13) and the modulatory effects of benzodiazepine agonists were examined. The benzodiazepine full agonist flunitrazepam (1  $\mu$ M) significantly potentiated the response to 10  $\mu$ M GABA by 125  $\pm$  11% (n=12). Benzodiazepine partial agonists with varying efficacy could also be detected. The weak partial agonist bretazenil, for example, produced a significant potentiation (32  $\pm$  4%) of the response to 10  $\mu$ M GABA. In addition, the benzodiazepine full inverse agonist DMCM (10  $\mu$ M) inhibited the response to 20  $\mu$ M GABA up to a maximum of 50%. In summary, the Microphysiometer can be used to determine functional efficacy at the benzodiazepine site of the GABA<sub>A</sub> receptor for both agonists and inverse agonists and the degree of resolution is sufficient for detection of weak partial agonists.

## 326.11

INFLUENCE OF THE  $\alpha$  SUBUNIT ON INTERACTION OF PICROTOXIN-SITE LIGANDS WITH RECOMBINANT GABA<sub>A</sub> RECEPTORS. G.H. Dillon and Cathy Bell-Horner. Dept. of Pharmacology, Univ. of North Texas Health Science Center at Fort Worth, Fort Worth, TX 76107.

We have defined previously the kinetic interactions of picrotoxin-site ligands with the  $\alpha 1\beta 2\gamma 2$  configuration of recombinant GABA<sub>A</sub> receptors, and the influence of GABA on these interactions. Here we report the influence of the  $\alpha$  subunit on the interactions of picrotoxin (PX) and U-93631 [4-dimethyl-3-t-butylcarboxyl-4,5-dihydro (1,5-a) quinoxaline], a novel ligand to the picrotoxin site, with recombinant GABA<sub>A</sub> receptors. Whole-cell patch clamp recordings were obtained from HEK293 cells stably expressing  $\alpha 6\beta 2\gamma 2$  or  $\alpha 3\beta 2\gamma 2$  receptors. Concentration-response curves yielded EC<sub>50</sub> and Hill coefficient values of 1.6  $\mu$ M and 1.5 respectively, for  $\alpha 6\beta 2\gamma 2$  receptors, and 20  $\mu$ M and 1.3, respectively, for  $\alpha 3\beta 2\gamma 2$  receptors. EC<sub>25</sub> concentrations of GABA were applied to  $\alpha 6\beta 2\gamma 2$  or  $\alpha 3\beta 2\gamma 2$  configurations in the presence of varying [U-93631] or [PX]. The IC<sub>50</sub> for current inhibition by U-93631 on  $\alpha 6\beta 2\gamma 2$  receptors in the absence of GABA, determined from its effect on initial peak current, was 42  $\mu$ M. The presence of GABA for 10 sec. shifted the IC<sub>50</sub> for U-93631 approximately 10-fold (to 3.5  $\mu$ M). GABA similarly influenced the interaction of PX with the  $\alpha 6\beta 2\gamma 2$  receptor (IC<sub>50</sub> shifted from 99 to 8.5  $\mu$ M). These results are comparable to those seen in  $\alpha 1\beta 2\gamma 2$  receptors. In  $\alpha 3\beta 2\gamma 2$  receptors, shifts in IC<sub>50</sub> values due to GABA were significantly smaller (2-fold) for both U-93631 and PX. This effect was due to a more marked inhibition of initial peak current by both compounds, and is at least partly attributable to slower GABA binding/channel gating in the  $\alpha 3\beta 2\gamma 2$  configuration. This may permit faster U-93631 and PX binding, relative to GABA binding, in  $\alpha 3$ -containing receptors, compared to  $\alpha 1$ - or  $\alpha 6$ -containing receptors. (Support: NIH R29 ES07904 and TX Advanced Research Program # 009768-027).

## 326.13

EXPRESSION OF ENDOGENOUS GABA TYPE A RECEPTOR IN HEK293 CELLS. S. Ueno<sup>a,c</sup>, C. Zorumski<sup>b</sup>, J. Bracamontes<sup>a</sup> and J.H. Steinbach<sup>a</sup>. <sup>a</sup>Dept. Anesthesiology and <sup>b</sup>Dept. Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO 63110. <sup>c</sup>Present address, Div. of Pharmacol. National Institute of Health Sciences, Tokyo, Japan 158.

The human embryonic kidney cell line (HEK293) has been utilized for the expression studies of GABA-A receptors. We have compared the properties of GABA-A receptor subunits expressed in HEK293 and quail fibroblast (QT6) cell lines. cDNAs of GABA receptor subunits were transfected and expressed in the HEK293 and QT6 cells with the expression vector pcDNA3 (Invitrogen). Recordings of GABA-activated responses were made using standard whole cell methods, 24-72hr. after transfection. The properties of the GABA-elicited responses in transfected HEK293 cells differ from expectations from previous work. In addition, some untransfected HEK 293 cells respond to applications of GABA and transfection of cells with  $\alpha 1$  or  $\gamma 2$  subunits alone can result in the expression of GABA-elicited currents. Further, expression of a mutated  $\beta 2$  subunit ( $\beta 2Y205S$ ) in combination with  $\alpha 1$  and  $\gamma 2$  results in cells showing appreciable responses to GABA. Finally, transfection of HEK293 cells with  $\alpha 1$  plus  $\gamma 2$  subunits results in responses to GABA which are potentiated by the drug loreclezole, suggesting that a subunit resembling the  $\beta 2$  or  $\beta 3$  subunit had assembled with the  $\alpha 1\gamma 2$  subunits. On the contrary, when QT6 cells are used as the expression system, no responses are seen in untransfected cells, or in cells transfected with  $\alpha 1$  or  $\gamma 2$  subunits alone, or with  $\alpha 1\gamma 2$  subunits. In addition, no response to GABA is seen from QT6 cells transfected with  $\alpha 1\beta 2\gamma 2$  subunits. These observations indicate that caution should be taken in interpreting the results of studies of the properties of GABA-A receptors transfected in HEK293 cells, most likely because HEK293 cells express low levels of endogenous GABA-A subunits. Grant NIH P01 GM47969, RSDA MH00964 and Funds from the Anesthesiology Dept. of Washington Univ.

## 326.15

PROTEINS COPRECIPIATING WITH GABA<sub>A</sub> RECEPTORS FROM CALF BRAIN. K. Kannenberg, R. Baur and E. Sigel. Department of Pharmacology, University of Bern, CH-3010 Bern, Switzerland.

GABA<sub>A</sub> receptors are nonrandomly distributed over the neuronal membrane, with a high density at postsynaptic sites. How such GABA<sub>A</sub> receptor clusters are generated and maintained is unknown. By analogy to the anchoring of other ion channels it seems likely that specific proteins are associated with GABA<sub>A</sub> receptors. In an attempt to isolate these linker proteins, we precipitated GABA<sub>A</sub> receptors from Triton X-100 solubilised calf brain membranes with the mAb bd24 coupled to Protein A-Sepharose. This antibody recognizes the human and bovine, but not the rat  $\alpha 1$ -subunit. The precipitates were analysed for the presence of additional proteins. Apart from considerable amounts of tubulin and somewhat lower amounts of actin other proteins have been observed. The cellular prion protein, that was speculated to interact with GABA<sub>A</sub> receptors, and the molecular chaperonin GRP78 could not be detected in the immunoprecipitate. Specific association of proteins with GABA<sub>A</sub> receptor complexes was shown in several negative controls, including immunoprecipitation from SDS solubilised membranes and use of unmodified Protein A-Sepharose or a nonspecific mAb. Furthermore, these proteins were also lacking in bd24-precipitates from rat brain membranes. Analysis of peptides generated from trypsin cleavage of the different proteins by microsequencing is under way. Supported by Grant 31-37192.93 from the Swiss National Science Foundation.

## 326.12

DO GABA<sub>A</sub> RECEPTORS IN WSS-1 CELLS USE AN HEK-293  $\beta 3$  SUBUNIT? P. A. Davies\*, E. Hoffmann\*, H. J. Carlisle, R. F. Tyndale\* and T.G. Hales. Dept. Anesthesiology, UCLA, LA, CA 90025 and \*Addiction Research Foundation and Dept. Pharmacology, University of Toronto, Ontario M5S1A8, Canada.

WSS-1 cells, produced by transfecting human embryonic kidney (HEK) cells with rat GABA<sub>A</sub> receptor  $\alpha 1$ ,  $\beta 2$  and  $\gamma 2$  subunit cDNAs, bind [<sup>3</sup>H]flunitrazepam (Wong *et al.*, Mol. Pharmacol., 42, 996, 1992). However,  $\beta 2$  mRNA is undetectable in Northern and Southern blots. This implies that  $\alpha 1$  and  $\gamma 2$  subunits combine to form receptors in WSS-1 cells. However, HEK cells transiently transfected with  $\alpha 1$  and  $\gamma 2$  cDNAs do not have functional GABA<sub>A</sub> receptors. We used patch-clamp and RT-PCR analyses to study the pharmacology and subunit composition of GABA<sub>A</sub> receptors in WSS-1 cells.

GABA activated currents recorded from WSS-1 cells reversed at the Cl<sup>-</sup> equilibrium potential. The anesthetics propofol (3  $\mu$ M) and pentobarbital (100  $\mu$ M), the anxiolytic diazepam (1  $\mu$ M) and the neurosteroid 5 $\alpha$ -pregnan-3 $\alpha$ -ol-20-one (100nM) all potentiated submaximal GABA-activated (100  $\mu$ M) currents by 310% (n=3), 278% (n=2), 296% (n=7) and 247% (n=7) of control, respectively. GABA-evoked currents were inhibited to 8% (n=2) of control by picrotoxin (10  $\mu$ M). Interestingly, the  $\beta 2/3$  subunit selective anticonvulsant loreclezole (10  $\mu$ M) also transiently potentiated GABA-evoked currents by 255% (n=6) of control. In the absence of GABA, both propofol (100  $\mu$ M) and loreclezole (100  $\mu$ M) activated currents in WSS-1 cells. RT-PCR analysis revealed that WSS-1 cells have both  $\alpha 1$  and  $\gamma 2$  mRNAs, HEK cells have neither. The  $\beta 2$  RT-PCR product was barely detectable in WSS-1 cells only, and was smaller than the expected band size. However, both WSS-1 and untransfected HEK cells had detectable levels of human  $\beta 3$  mRNA.

Our data suggest the presence of human  $\beta 3$  and/or rat  $\beta 2$  subunits in GABA<sub>A</sub> receptors of WSS-1 cells. Antisense knock out of native HEK  $\beta 3$  subunit may identify its role, if any, in the function of these receptors. (Supported by NIH grant GM48456).

## 326.14

STUDY OF THE GABA<sub>A</sub> RECEPTOR ASSEMBLY PATTERNS IN XENOPUS OOCYTES. M.L. Gorder\* and R.W. Olsen. Department of Molecular and Medical Pharmacology, UCLA Sch. of Med., Los Angeles, CA 90095.

Both  $\gamma 2S$  and  $\beta 2$  subunits are capable of "rescuing" intermediate GABA<sub>A</sub> receptor combinations from endoplasmic reticulum (ER) and thus promote the expression of the full ( $\alpha 1\beta 2\gamma 2S$ ) heteropentameric receptors on the cell surface. We used the Xenopus oocytes expression system to study patterns of the GABA<sub>A</sub> receptor assembly, as these cells maintain their vitality long enough during expression of the GABA<sub>A</sub> receptors to allow injections of cRNAs for subunits separately at different time points. Mixture of  $\alpha 1$  and  $\gamma 2S$  cRNAs produced no detectable Cl<sup>-</sup> currents upon application of 1 mM GABA after 6 days of expression. When the same cells were coinjected with  $\beta 2$  cRNA, 24 hr later we recorded GABA (10 mM)-evoked Cl<sup>-</sup> currents; these were not inhibited by 100  $\mu$ M ZnCl<sub>2</sub> and were enhanced by flurazepam (10  $\mu$ M) by approx. 69%. The same paradigm was used to express ( $\alpha 1\beta 2$ ) and ( $\alpha 1\beta 2$ ) combinations for 6 days and then coinject  $\gamma 2S$  cRNA. GABA (100  $\mu$ M)-evoked Cl<sup>-</sup> currents recorded 24 hr later were increased 6 times over that of ( $\alpha 1\beta 2$ ) alone and 50 times for ( $\alpha 1\beta 2$ ). In both cases the currents were inhibited by 100  $\mu$ M ZnCl<sub>2</sub> (20% for ( $\alpha 1\beta 2$ ) and 50% for ( $\alpha 1\beta 2$ )). ( $\alpha 1\beta 2$ )  $\gamma 2S$  currents were increased by 10  $\mu$ M flurazepam by 50%. The zinc inhibition of the Cl<sup>-</sup> currents was not observed 48 hr after  $\gamma 2S$  cRNA coinjection. The increase in the currents could not be accounted for expression of  $\beta 2$ ,  $\alpha 1\gamma 2S$  or  $\beta 2\gamma 2S$  subunit combinations on the cell surface. We propose that both  $\gamma 2S$  and  $\beta 2$  subunits can "rescue" intermediate GABA<sub>A</sub> receptor combinations trapped in the ER and thus produce full heteropentamer receptor on the cell surface. Moreover changes in zinc sensitivity during this "rescue" may be ascribed to different stoichiometry of the pentamers. We are now testing  $\alpha 1$  and  $\alpha 4$  subunits of the GABA<sub>A</sub> receptor in the same paradigm as well as involvement of the cytoskeleton in the "rescue" mechanism. Funded by NS 28772.

## 326.16

PROTEASE MAPPING AS A METHOD FOR STUDYING LIGAND-INDUCED STRUCTURAL ALTERATIONS OF THE GABA<sub>A</sub> RECEPTOR AND MAPPING THE GABA BINDING SITE. C. A. E. Hauser, F. Gerner, and F. Holsboer\*. Max Planck Institute of Psychiatry, Clinical Institute, 80804 Munich, Germany.

The  $\gamma$ -aminobutyric acid (GABA) type A receptor complex interacts with GABA at the large extracellular region of the protein. This region contains the N-terminus and what is termed the cysteine loop, an important structural feature of several binding sites. We utilized limited proteolysis of rat GABA<sub>A</sub> receptor  $\alpha 1$ ,  $\beta 2$  or  $\gamma 2$  subunits synthesized by *in vitro* translation with microsomes from canine pancreas to detect structural alterations induced by GABA. GABA binding changes receptor conformation, giving rise to a fragment resistant to proteolysis. Digestion of  $\beta 2$  without ligand was complete, whereas digestion of the GABA-occupied subunit with subtilisin yielded a 31-kDa fragment and with trypsin a slightly larger fragment of approximately 38 kDa. For  $\alpha 1$  and  $\gamma 2$  GABA provided weak protection. This finding might explain the postulated location of the two GABA binding sites on the receptor pentameric complex, thought to be situated at the interface of the  $\beta 2$  subunit. Thus, protease mapping is a suitable method for determining alterations in receptor configuration.

IDENTIFICATION OF CELLULAR COMPONENTS ASSOCIATED WITH GABA<sub>A</sub> RECEPTORS BY THE YEAST TWO HYBRID SCREEN. H. Wang and R.W. Olsen\*. Molecular Biology Institute, and Department of Pharmacology, UCLA, Los Angeles, CA 90095.

By using the modified yeast two hybrid system, Interaction Trap, we have identified several cellular proteins interacting with GABA<sub>A</sub> receptor  $\alpha 1$  subunit and  $\gamma 2$  subunit. Binding sites for agonists and antagonists as well as other modulatory ligands are located on the N-terminal extracellular domain of GABA<sub>A</sub> receptor proteins. In addition to this extracellular regulation, a large body of evidence suggests that the GABA<sub>A</sub> receptors can be regulated by cellular components presumably through its intracellular loop between TM3 and TM4. In this work, we used Interaction Trap to screen for cellular proteins which can physically associate with GABA<sub>A</sub> receptors. We generated two yeast strains. One harbors the intracellular loop of  $\alpha 1$  subunit as bait. Another contains the intracellular loop of  $\gamma 2$  subunit as bait. Then a human fetal brain cDNA library was transformed into these two strains. Candidate prey were selected on the basis of reporter gene expression requiring bait and prey protein interaction. The prey plasmids in the positive yeast clones were rescued and tested for their specificity. The prey screened for  $\alpha 1$  subunit interaction only interact with  $\alpha 1$  but not  $\gamma 2$  and vice versa. The sequence information of the positives suggests relationship to interesting known proteins. Their ability to interact with GABA<sub>A</sub> receptors in vitro is under investigation.

This work is supported by NIH grant NS28772(RWO) and training grant GM07185(HW).

## 326.19

SUBCELLULAR LOCALISATION OF GABA<sub>A</sub> RECEPTORS IS DETERMINED BY RECEPTOR B SUBUNITS. C.N. Connolly<sup>1</sup>, J.R.A. Woolferton<sup>2</sup>, T.G. Smart<sup>2</sup> and S.J. Moss<sup>1</sup>. <sup>1</sup>MRC LMCB, Dept. of Pharmacology, University College London, London WC1E 6BT, England. <sup>2</sup>Dept. of Pharmacology, The School of Pharmacy, London WC1N 1AX, England.

$\gamma$ -aminobutyric acid type A (GABA<sub>A</sub>) receptors are the major sites of fast synaptic inhibition in the CNS. They are constructed from 4 subunit classes with multiple members:  $\alpha(1-6)$ ,  $\beta(1-4)$ ,  $\gamma(1-4)$ , and  $\delta(1)$ . The contribution of subunit diversity in determining receptor subcellular targeting was examined in HEK293 and polarised Madin-Darby canine kidney (MDCK) cells using  $\alpha 1$ ,  $\gamma 2S$ ,  $\beta 1$ ,  $\beta 2$  and  $\beta 3$ . Significant detection of cell surface homomeric receptors was found only for the  $\beta 3$  subunit in both cell types. Expression of all  $\alpha/\beta$  binary combinations resulted in cell surface staining in both cell types. However, a non-polarised distribution was evident for  $\alpha 1\beta 1$  complexes with specific basolateral targeting of both  $\alpha 1\beta 2$  and  $\alpha 1\beta 3$  complexes. The distribution of these receptors were unaffected by the presence of the  $\gamma 2S$  subunit. Interestingly, delivery of receptors containing the  $\beta 3$  subunit ( $\beta 3$ ,  $\alpha 1\beta 3$  and  $\alpha 1\beta 3\gamma 2S$ ) to the basolateral domain occurs via the apical surface. These results demonstrate that  $\beta$  subunits can selectively target GABA<sub>A</sub> receptors to distinct cellular locations. Changes in the spatial and temporal expression of  $\beta$  subunit isoforms may therefore provide a mechanism for relocating GABA<sub>A</sub> receptor function between distinct neuronal domains. Given the critical role of these receptors in mediating synaptic inhibition this process may provide a novel means of generating synaptic plasticity. This work was supported by the MRC.

## 326.21

GABA<sub>A</sub>-RECEPTOR  $\beta 2$  SUBUNIT IS SUFFICIENT FOR MODULATION OF THE RECEPTOR BY TYROSINE PHOSPHORYLATION. Q. Wan, H.Y. Man, J.L. Brauton, G.M. Brown\* and Y.T. Wang\*. Hosp. Sick Children and Clark Inst., Univ. Toronto, Toronto, M5G 1X8 Canada

GABA<sub>A</sub> receptors are the major receptor mediating fast inhibitory synaptic transmission in the brain. We have previously demonstrated that in cultured CNS neurons the  $\beta 2$  subunit of the GABA<sub>A</sub> receptor is tyrosine phosphorylated and that the function of GABA<sub>A</sub> receptors is modulated by changes in tyrosine phosphorylation states within the cells. In the present study, we have investigated the contribution of  $\beta 2$  subunit to the functional modulation of GABA<sub>A</sub> receptors by protein tyrosine kinases (PTKs) in human embryonic kidney cells (HEK 293) expressing recombinant GABA<sub>A</sub> receptors. GABA<sub>A</sub> receptor-mediated currents were induced by pressure-ejection of GABA (100  $\mu$ M) and recorded with a CsCl-filled pipette under whole-cell patch-clamp configuration. In cells transiently transfected with cDNAs encoding  $\alpha 1$ ,  $\beta 2$  and  $\gamma 2$  subunits, the amplitude of GABA currents was reversibly reduced by extracellular application of genistein (100  $\mu$ M), a membrane-permeable inhibitor of PTK, whereas the currents were unaffected by daidzein (100  $\mu$ M), an inactive analogue of genistein, consistent with an ongoing modulation of the receptor function by basal activity of endogenous PTKs observed in the cultured CNS neurons. As the  $\gamma 2$ , but not the  $\alpha 1$  subunit has previously been shown to be tyrosine-phosphorylated by co-transfection of a constitutive PTK, we next examined the modulation in cells transiently expressing only  $\alpha 1$  and  $\beta 2$ , and lacking the  $\gamma 2$  subunit. In these cells, we observed similar inhibitory effects of genistein on the GABA-induced response. Thus, our results suggest that the  $\beta 2$  subunit of GABA<sub>A</sub> receptor is sufficient for supporting modulation of the receptor function by protein tyrosine phosphorylation and consequently tyrosine phosphorylation of this subunit may be an important mechanism for regulating GABA<sub>A</sub>-receptor function in the CNS. (Supported by Canadian MRC)

## 326.18

EXPRESSION OF AN EXTRACELLULAR DOMAIN OF GABA<sub>A</sub> RECEPTOR. H. Xue\*, H. Zheng, X.L. Zhong, P. Lee and J.T. Wong. Department of Biochemistry, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong.

A 16 Kd fragment of the extracellular part of bovine GABA<sub>A</sub> receptor  $\alpha 1$  subunit has been expressed in *E. coli* as a GST-fusion protein. With a single anion exchange column (Sephacrose Cl<sup>-</sup> 6B, Pharmacia), the fusion product has been purified to near 90% purity. After thrombin digestion, the 16 Kd product is being characterized for stability and secondary structure by calorimetry and circular dichroism, respectively. It will then be subjected to NMR solution structure investigation. Previous mutational studies have identified this part of the receptor as the binding sites of ligands, GABA and Benzodiazapine. The success of structural characterization of the protein produced in this study will eventually facilitate structure-based drug design for GABA<sub>A</sub> receptors.

## 326.20

STOICHIOMETRY OF RECOMBINANT  $\alpha 1\beta 2\gamma 2$  GABA<sub>A</sub> RECEPTORS. D. S. Weiss\*, Y. Chang, R. Wang, and S. Barot. Neurobiology Research Center and the Department of Physiology and Biophysics, University of Alabama at Birmingham, Birmingham AL 35294-0021.

The GABA<sub>A</sub> receptor is presumed to be a pentamer comprised of  $\alpha$ ,  $\beta$ , and  $\gamma$  subunits, although the stoichiometry remains controversial. We have addressed the stoichiometry of the GABA receptor by site-directed mutagenesis of a conserved leucine (to serine) in the putative second membrane-spanning domain of the  $\alpha 1$ ,  $\beta 2$ , and  $\gamma 2$  subunits. This point mutation increased the GABA sensitivity of the receptor in proportion to the number of incorporated mutant subunits. Coexpression of both wild type (e.g.  $\alpha$ ) and mutant (e.g.  $\alpha_m$ ) subunits, along with their wild type counterparts (e.g.  $\beta$  and  $\gamma$ ) in *Xenopus* oocytes, resulted in a mixed population of receptors with distinct GABA sensitivities. We determined the number of each subunit type from the number of components comprising these compound GABA dose-response relationships. We conclude that the  $\alpha 1\beta 2\gamma 2$  GABA receptor is a pentamer comprised of two  $\alpha$  subunits, two  $\beta$  subunits, and one  $\gamma$  subunit. (Grant # NS35291.)

## 327.1

LOSS OF SPECIFIC GABA<sub>A</sub>-RECEPTOR SUBPOPULATIONS IN MICE LACKING THE  $\alpha 5$ -SUBUNIT GENE. J.-M. Fritschy<sup>1</sup>, D. Benke<sup>2</sup>, D.K. Johnson<sup>2</sup>, H. Mohler<sup>1</sup>, U. Rudolph<sup>1</sup>. <sup>1</sup>Inst. of Pharmacology, Univ. of Zurich, 8057 Zurich, Switzerland; <sup>2</sup>Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA.

The mechanisms governing the assembly of functional GABA<sub>A</sub>-receptors remain unresolved. In mutant mice lacking the  $\gamma 2$ -subunit, GABA<sub>A</sub>-receptors are present in unchanged numbers and distribution, being comprised of  $\alpha$ - and  $\beta$ -subunits. The lack of  $\gamma 2$ -subunit does thus not appear to interfere with receptor assembly. To determine whether the presence of an  $\alpha$ -subunit is required for the formation of GABA<sub>A</sub>-receptors, we analysed mutant mice carrying a chromosomal deletion encompassing both the  $\alpha 5$ - and  $\gamma 3$ -subunit genes, or the  $\gamma 3$ -subunit gene only (Culiat et al., 1994, Proc. Natl. Acad. Sci. USA 91:2815). The latter mice served as controls. Autoradiographic analysis in  $\alpha 5/\gamma 3$  mutant mice revealed a nearly complete loss of zolpidem-insensitive benzodiazepine-binding sites, corresponding to GABA<sub>A</sub>-receptors containing the  $\alpha 5$ -subunit. Likewise, a 20% decrease in the number benzodiazepine-binding sites was measured in the hippocampus, in line with the prevalence of receptors containing the  $\alpha 5$ -subunit. Immunofluorescence with subunit-specific antibodies confirmed the absence of  $\alpha 5$ -subunit staining in  $\alpha 5/\gamma 3$  mutant mice. In addition, a decreased  $\beta 2,3$ - and  $\gamma 2$ -subunit staining was apparent in neurons which normally express the  $\alpha 5$ -subunit (e.g., olfactory bulb granule cells, hippocampus pyramidal cells), but not in other brain regions (e.g., thalamus, inferior colliculus, cerebellum). These results indicate that the absence of the  $\alpha 5$ -subunit gene results in the disappearance of a subpopulation of GABA<sub>A</sub>-receptors in the adult mouse brain, thereby suggesting that the  $\alpha 5$ -subunit is required for the formation of these receptor complexes. Thus, the  $\alpha$ -subunit, unlike the  $\gamma 2$ -subunit, might play a major role in assembly or targeting of GABA<sub>A</sub>-receptors. Support: Swiss National Science Foundation, grant 31-32624.91.

## 327.3

IN VIVO ALTERATION OF GABA RECEPTOR COMPOSITION AND FUNCTION USING ADENO-ASSOCIATED VIRUS (AAV) VECTOR GENE TRANSFER. T.J. McCown\*, H.E. Criswell, X. Xiao, G.R. Bresse, A.L. Morrow and R.J. Samulski, UNC Neuroscience Center, Gene Therapy Center and Center for Alcohol Studies, University of North Carolina, Chapel Hill, NC 27599 and Somatix Therapy Corp, Alameda, CA 94501

Because AAV vectors are capable of gene transfer and expression in the CNS (McCown et al., Brain Res. 713:99, 1996), we sought to alter composition and function of an important therapeutic target, the GABA<sub>A</sub> receptor. Seven days after AAV vectors containing a CMV promoter and a truncated human GABA<sub>A</sub>  $\alpha 1$  cDNA were microinjected into the rat inferior colliculus, GABA  $\alpha$ -like immunoreactivity was localized to neurons, far exceeding endogenous levels. The glomerular layer of the olfactory bulb is an area devoid of GABA  $\alpha 1$  protein, and patch clamp recordings on cells acutely dissociated from this brain region do not exhibit zolpidem enhancement of GABA-induced chloride currents. However, 7 days after infusion of the AAV vector, 2 cells dissociated from this brain region exhibited high affinity zolpidem facilitation of GABA responses, and single cell RT-PCR demonstrated the presence of the AAV vector. Thus, it may be possible to alter the composition and function of receptors *in vivo* using AAV vector-mediated gene transfer. (supported by AA09122 and HL51818, HL48347 and AA-09013)

## 327.5

INCREASED NEUROPEPTIDE Y (NPY) IMMUNOREACTIVITY FOLLOWING ANTISENSE KNOCK-DOWN OF GABA<sub>A</sub> RECEPTOR  $\gamma 2$  SUBUNIT IN RAT HIPPOCAMPUS. J. Karle<sup>1</sup>, J. D. Mikkelsen<sup>2</sup> and M. Nielsen<sup>1</sup>. 1. The Research Institute of Biological Psychiatry, St. Hans Hospital, DK-4000 Roskilde, 2. Department of Neurobiology, H. Lundbeck A/S, Denmark.

Antisense oligodeoxynucleotides (ODNs) can be used as selective inhibitors of gene expression in the central nervous system of rodents *in vivo*. Antisense ODNs are short strands of synthetic DNA which presumably work via a nucleotide specific action at the level of mRNA. We have previously shown that continuous intrahippocampal infusion of a phosphorothioate ODN antisense to the rat GABA<sub>A</sub> receptor  $\gamma 2$  subunit mRNA induces a substantial decrease in benzodiazepine receptor binding in rat hippocampus. This effect is paralleled by a decrease in the number of GABA<sub>A</sub> receptors and by an extensive loss of hippocampal neurones. Control experiments with sense and mismatch ODNs have demonstrated the specificity of the effect. Immunocytochemical analyses have been carried out in order to further characterize the effect induced by the antisense ODN. Following unilateral infusion of antisense ODN, but not mismatch control ODN, a marked increase in NPY-immunoreactivity (NPY-ir) in hilar neurones of the fascia dentata was observed bilaterally. Also, intense NPY-ir was visualized bilaterally in the mossy fibers and in perikarya of the entorhinal cortex. The findings are reminiscent of reported changes following seizures induced by e.g. kainic acid and support the hypothesis that blocked synthesis of GABA<sub>A</sub> receptors in the hippocampus leads to selective neuronal cell death via diminished GABAergic inhibitory neurotransmission.

## 327.2

IMPAIRMENT OF GABA<sub>A</sub> RECEPTOR FUNCTION BY SUBUNIT GENE TARGETING IN MICE RESULTS IN NEOPHOBIA. E. Crestani, D. Benke, G. Reyes, J.-M. Fritschy, B. Lüscher\* and H. Mohler, Institute of Pharmacology, University of Zurich, CH-8057 Zurich.

Clinical and experimental observations support the hypothesis of functional alterations in the GABA<sub>A</sub> receptor complex in anxiety-related disorders. Using gene targeting, the GABA<sub>A</sub> receptor  $\gamma 2$  subunit was shown to be necessary for the formation of benzodiazepine (BZ) sites and normal single channel conductance of GABA<sub>A</sub> receptors (Gunther et al., PNAS 92, 7749, 1995). In heterozygous ( $\gamma 2/+0$ ) mice, the  $\gamma 2$  subunit protein was reduced by about 50%. The structure of a small population of GABA<sub>A</sub> receptors were affected, as evidenced by a reduction of the number of BZ sites (25%). The impairment of GABA<sub>A</sub>-receptor function manifested itself behaviorally. The  $\gamma 2/+0$  mice exhibited neophobia in a free-choice exploratory paradigm and novelty-dependent hypolocomotion in an openfield in contrast to wildtype littermates. These behavioral changes were specific since spontaneous locomotion, rearing behavior, learning capacity (Morris test) and neuronal plasticity (LTP) were unaltered. A pretreatment with flumazenil before exposure to novelty prevented neophobia in  $\gamma 2/+0$  mice. Thus, emotional reactivity toward novelty appears to be under stringent GABA-ergic control. Support: Swiss National Science Foundation.

## 327.4

AN ANTISENSE OLIGODEOXYNUCLEOTIDE TO THE GABA-A RECEPTOR  $\gamma 2$  SUBUNIT DECREASES BENZODIAZEPINE BINDING WITH LITTLE EFFECT ON GABA BINDING. T.-J. Zhao, H.C. Rosenberg, M. Li and T.H. Chiu\*. Dept. of Pharmacology, Medical College of Ohio, Toledo, OH 43699.

The presence of a  $\gamma 2$  subunit in the GABA-A receptor is important for optimal binding of benzodiazepines. Previously, we found a significant increase in convulsive threshold for  $\beta$ -CCM, a benzodiazepine "inverse agonist", but no change in picrotoxin threshold, following unilateral intracerebroventricular (ICV) infusion of  $\gamma 2$  antisense oligo in rats. In the present study we have evaluated the effect of this treatment on GABA-A and benzodiazepine receptor binding. Unilateral ICV infusion of the 17-base phosphorothioate-modified antisense oligo (18  $\mu$ g in 2  $\mu$ l saline) was performed every 12 hr for 3 days. Control rats were treated the same way with a sense oligo. Brains were frozen and para-sagittal sections used for quantitative autoradiographic analysis of the binding of 5 nM [<sup>3</sup>H]flunitrazepam (FNP) and 50 nM [<sup>3</sup>H]GABA (in the presence of baclofen). Compared to rats treated with a sense oligo, the rats that had received  $\gamma 2$  antisense oligo had a 15-25% decrease of specific [<sup>3</sup>H]FNP binding in most brain areas, and this was significant in several brain regions including frontal cortex, cerebellum molecular layer, zona reticulata of substantia nigra, and CA 3 of hippocampus (n=5). In contrast, [<sup>3</sup>H]GABA binding was not changed, except for a significant 10% decrease in cerebellar granule cell layer (n=5). The results show that the antisense oligo to the GABA-A receptor  $\gamma 2$  subunit reduced benzodiazepine binding with little effect on GABA-A receptor binding *in vivo*. This may indicate a change in the subunit composition of GABA-A receptors in this experiment. Supported by DA02194.

## 327.6

ANTISENSE INHIBITION OF STRIATAL GABA<sub>A</sub> RECEPTOR PROTEINS DECREASES GABA-STIMULATED CHLORIDE UPTAKE AND INCREASES COCAINE SENSITIVITY IN RATS. J. Peris\*, B. J. Jung, P. Walker, O. Malakhova, Y. Bokrand and D. Wielbo, Depts. Pharmacodynamics and Pharmaceutics, Univ. Florida, Gainesville FL 32610.

The functional status of GABA<sub>A</sub> receptors in striatum is inversely related to behavioral sensitivity to cocaine. Exposure of striatum to antisense oligodeoxynucleotides (ASODNs) targeted to the mRNAs for the  $\alpha 2$  and the  $\beta 3$  subunits of the GABA<sub>A</sub> receptor should decrease expression of receptor proteins. A combination of these ASODNs (25  $\mu$ g each), scrambled ODNs or saline was injected into right lateral ventricle of rats and striatal GABA<sub>A</sub> receptor function was measured 24 hrs later. There was significantly less GABA-stimulated Cl uptake in right striatum compared to left striatum of ASODN treated rats with no significant difference between sides in control animals. ASODN injection increased behavioral stereotypy and contraversive turning caused by cocaine when tested 18-20 hrs after ODN treatment (F(2,26) = 3.8; p < 0.05). Nissl staining indicated there was no difference between the density of stained cells in the left and right edges of striatum in control rats (left: 63±7, right: 65±8) or in ASODN treated rats (left: 69±4, right: 67±5). When fluorescein-conjugated ASODNs were injected and rats were killed 24 hrs later, fluorescence signal was present up to 1.5 mm from the cannula tract and was densest near the most ventral portion of right lateral ventricle. There was penetration into both striatum and lateral septum with evidence of uptake into individual cells. Thus, ASODN is present in striatum at times during which behavioral and neurochemical indices of GABA receptor function are decreased without causing obvious neurotoxicity. Supported by the Alcoholic Beverage Medical Research Foundation.

## 328.1

DIFFERENTIAL AGONIST REGULATION OF  $\mu$  OPIOID RECEPTOR IN HEK 293 CELLS.

A. D. Blake\*, G. Bot, J. C. Freeman and T. Reisine

Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

Mu opioid receptors mediate the analgesia induced by morphine.

Prolonged use of morphine causes tolerance development and dependence. To explore the molecular basis of tolerance and dependence, the cloned mouse  $\mu$  receptor with an N-terminal epitope tag, was stably expressed in human embryonic kidney cells (HEK 293 cells) and the effects of prolonged agonist treatment on receptor regulation were examined. In HEK 293 cells, the expressed  $\mu$  receptor showed high affinity, specific, saturable binding of radioligands and a pertussis toxin sensitive inhibition of adenylyl cyclase. Pretreatment of cells with 1  $\mu$ M morphine or DAMGO resulted in no apparent receptor desensitization, as assessed by opioid inhibition of forskolin-stimulated cAMP levels. However, the morphine and DAMGO pretreatments resulted in a 3-4 fold compensatory increase in forskolin-stimulated cAMP. The opioid agonists, methadone and buprenorphine, are used in the treatment of addiction, due to a markedly lower abuse potential. Pretreatment of  $\mu$  expressing HEK 293 cells with methadone or buprenorphine abolished the ability of opioids to inhibit adenylyl cyclase. No compensatory increase in forskolin-stimulated cAMP accumulation was found with methadone or buprenorphine, however these opioids blocked the compensatory effects observed with morphine and DAMGO. These results indicate that methadone and buprenorphine interact differently with the mouse  $\mu$  receptor than either morphine or DAMGO. The ability of methadone and buprenorphine to desensitize the  $\mu$  receptor and block the compensatory rise in forskolin-stimulated cAMP accumulation may be an underlying mechanism for the therapeutic efficacy of these agents in treating addiction. Supported by DA08951 and DA05636.

## 328.3

## CYCLIC AMP DEPENDENT PROTEIN KINASE INDUCES PHOSPHORYLATION OF MORPHINE STIMULATED BUT NOT DAMGO STIMULATED MU OPIOID RECEPTORS S. Chakrabarti, A. M. Babey\*, P. Y. Law, and H. H. Loh. Department of Pharmacology, University of Minnesota Medical School, MN 55455, USA.

Receptor phosphorylation was examined using a functional, hemagglutinin epitope-tagged  $\mu$ -opioid receptor stably expressed in murine neuroblastoma Neuro2a cells. Receptor density and affinity were 1.87 pmoles/mg, and 0.3 nM respectively for [<sup>3</sup>H]Diprenorphine binding. In a cell-free system, catalytic subunits of cAMP-dependent protein kinase (PKA) profoundly increased  $\mu$ -opioid receptor phosphorylation in the presence of morphine. This effect of morphine was dose-dependent from 1-1000 nM, and was completely blocked in the presence of naloxone, suggesting a receptor mediated effect. Further, morphine analogs or other alkaloids similarly stimulated *in vitro* receptor phosphorylation induced by PKA. However, it was interesting to observe that a potent  $\mu$ -opioid selective peptide [D-Ala<sup>2</sup>, MePhe<sup>4</sup>, Glyol<sup>5</sup>]enkephalin (DAMGO) was incapable of stimulating this PKA-induced *in vitro* phosphorylation of  $\mu$ -opioid receptors. Moreover, following chronic morphine pretreatment, morphine stimulation of PKA-induced phosphorylation of the receptor decreased drastically. In contrast, chronic DAMGO pretreatment did not affect morphine stimulation of PKA-induced receptor phosphorylation. Furthermore, this *in vitro* phosphorylation of  $\mu$ -opioid receptors induced by PKA in presence of morphine, was completely abolished in pertussis toxin pretreated cell membrane suggesting effective receptor G-protein coupling was essential for this phosphorylation. Taken together all these results suggest that PKA-induced phosphorylation of  $\mu$ -opioid receptors *in vitro* demonstrated a distinct difference between morphine and DAMGO occupied forms of the receptor. It is therefore possible to speculate that this *in vitro* receptor phosphorylation induced by catalytic subunits of PKA in the presence of morphine may be useful for future studies of agonist-receptor interactions and determination of agonist-induced desensitization. (Supported by NIH grants DA-01583, DA-00564, DA-08131, DA-05695, DA-07339 and KO5-DA 70554).

## 328.5

A CONSTITUTIVELY RECYCLING MUTANT OF THE  $\mu$  OPIOID RECEPTOR

Veronica Segredo\*, Neil T. Burford, Jelveh Lameh, Wolfgang Sadée, University of California, San Francisco, CA 94143-0446

To determine the domains of the  $\mu$  opioid receptor involved in internalization we constructed two C-tail truncation mutants bracketing a 4-residue domain (354TSST357). An epitope tag (EE) was added to the extracellular N-tail of the wild-type and the two mutant receptors ( $\mu$ EE, T354EE and T358EE, respectively). The three  $\mu$  receptor constructs stably expressed in HEK cells did not markedly differ in ligand binding affinities or G-protein coupling. Both  $\mu$ EE and T358EE resided largely at the plasma membrane and internalized upon DAMGO, but not morphine, stimulation. In contrast, T354EE was already concentrated in intracellular vesicles before agonist exposure, and recycled to the plasma membrane following treatments to block endocytosis through clathrin-coated vesicles. T354EE therefore internalized and recycled constitutively. Despite agonist-independent internalization of T354EE, there was no evidence of elevated basal G-protein coupling. Colocalization of  $\mu$ EE and T354EE with the transferrin receptor in intracellular vesicles indicated that the cellular pathway of  $\mu$  receptor internalization is similar to that of the transferrin receptor. These results strongly suggest that the TSST domain in the C-tail suppresses receptor internalization, and that suppression can be reversed either by stimulation with a permissive agonist (*i.e.*, DAMGO) or by selective truncation of the inhibitory region.

This work has been supported by the NIH Grant DA04166

## 328.2

## TYR-W-MIF-1 ATTENUATES MORPHINE-INDUCED DOWN-REGULATION OF MU AND DELTA OPIATE RECEPTORS IN SH-SY5Y CELLS. L. M. Harrison\*, A. J. Kastin and J. E. Zadina. VA Medical Center and Dept. of Medicine and Neuroscience Training Program, Tulane University Sch. of Med., New Orleans, LA 70146.

SH-SY5Y cells have been used as a model system for studying acute and chronic opiate effects. Morphine down-regulates, and naloxone up-regulates, both  $\mu$  and  $\delta$  receptors after chronic exposure (JPET265:254; 270:1086). We tested the ability of Tyr-W-MIF-1 (Tyr-Pro-Trp-Gly-NH<sub>2</sub>), a peptide from brain (Peptides 13:632) that binds to the  $\mu$  opiate receptor (Life Sci 55:461), to antagonize morphine down-regulation of receptors. SH-SY5Y cells were initially cultured in serum-containing medium and switched to serum-free medium to avoid peptide metabolism. The change decreased  $\mu$  receptors and increased  $\delta$  receptors such that their ratio approached 1:1, but morphine and naloxone retained their abilities to down- and up-regulate receptors in the serum-free medium. Met-enkephalin at 10  $\mu$ M decreased  $\mu$  (32%) and  $\delta$  (60%) receptors, but Tyr-W-MIF-1 at doses of 30  $\mu$ M and 100  $\mu$ M did not affect the number of either  $\mu$  or  $\delta$  receptors. Tyr-W-MIF-1 remained intact after 24h in the serum-free medium. In combination with 3  $\mu$ M morphine, Tyr-W-MIF-1 attenuated morphine-induced down-regulation of receptors in a dose-dependent manner. Morphine-induced down-regulation of  $\mu$  receptors was significantly attenuated by 30  $\mu$ M ( $p < 0.05$ ) and 100  $\mu$ M ( $p < 0.01$ ) doses of Tyr-W-MIF-1. Down-regulation of  $\delta$  receptors was significantly attenuated by 30  $\mu$ M Tyr-W-MIF-1 ( $p < 0.05$ ), with a statistical tendency at the 100  $\mu$ M dose. These results indicate that the endogenous peptide Tyr-W-MIF-1 can attenuate morphine-induced changes in receptor number and thus may be part of a compensatory opiate-modulating system activated during tolerance.

Supported by the VA and NIDA predoctoral training grant DA05645.

## 328.4

TRAFFICKING OF MU OPIOID RECEPTOR (MOR) IN ENTERIC NEURONS *IN VIVO*. C. Sternini\*, M. Spann, B. Anton, D.E. Keith Jr., N.W. Bunnett, M. Von Zastrow, C. Evans, and N.C. Brecha. CURE, Opioid Res. Ctr. & Depts. of Med., Neurobiol. & Psych., UCLA, & WLA VAMC, Los Angeles, CA 90073; & Depts. Surg., Physiol., & Psych., UCSF, San Francisco, CA 94143.

Opioids influence multiple functions in the nervous system by activating G protein-coupled receptors. We examined the trafficking of MOR in enteric neurons of the guinea pig ileum, which naturally express this receptor, in response to opiate alkaloids that are used for pain control using an affinity-purified antibody to rat MOR C-terminus and confocal microscopy. MOR immunoreactive (IR) neurons are located in the myenteric plexus and have the morphology of motor neurons with broad dendrites and a long axonal process. In control animals, MOR-IR is primarily confined to surface membrane. After 30 min of exposure to the opiate agonist, etorphine (Et) (0.06-0.1 mg/kg), MOR-IR is present in cytoplasmic and perinuclear vesicles. MOR internalization occurs by 15 min and persists up to 120 min. By 180 min, MOR recycles to the cell surface. The antagonist, naloxone (10 mg/kg), inhibits Et-induced MOR endocytosis. Morphine (5-20 mg/kg), a high affinity MOR agonist, does not cause detectable endocytosis, and it partially inhibits Et-induced MOR internalization. This study provides evidence that enteric motor neurons have functional MOR. The occurrence of agonist-induced endocytosis of MOR in enteric motor neurons *in vivo* at the soma, dendrites and axons, suggests pre- and post-synaptic regulation of intestinal motility by opioids and alkaloids. Supported by DK41301, DA 05010, & VA Res. Funds.

## 328.6

## AGONIST-INDUCED FUNCTIONAL DESENSITIZATION OF THE MU OPIOID RECEPTOR IS MEDIATED BY LOSS OF MEMBRANE RECEPTORS RATHER THAN UNCOUPLING FROM G-PROTEIN. Y.S. Pak, A. Kouvelas, M.A. Scheideler, J. Rasmussen, B.F. O'Dowd and S.R. George\*. Dept. Pharm. and Med, Univ. of Toronto, Add. Res. Fdn, Toronto, ONT, Canada, Novo Nordisk A/S, Denmark.

The effects of acute exposure of the opioid peptide, [D-Ala<sup>2</sup>, N-Me-Phe<sup>4</sup>, Glyol<sup>5</sup>]enkephalin (DAMGO) on the mu opioid receptor were examined in CHO K-1 and BHK stable transfectants. In the CHO cell line, acute 1 hour treatment with DAMGO decreased the density of receptors without affecting the affinity or proportion of agonist-detected sites and attenuated the agonist ability to inhibit forskolin-stimulated cAMP accumulation. In contrast, acute treatment of BHK cells did not affect receptor density or agonist ability to inhibit cAMP accumulation but longer duration of agonist exposure resulted in a reduction of membrane receptor, identical to the CHO cells. These results suggested that for the mu opioid receptor, alteration in receptor density was the major determinant for the observed agonist-induced desensitization. Consistent with this notion, the ratio of the DAMGO concentration yielding half-maximal occupation of the mu receptor to that yielding half-maximal functional response was less than 1. This suggests the necessity for a high mu receptor occupancy rate for maximal functional response, so that loss of cell surface opioid binding sites was a critical determinant in reducing the functional response. This hypothesis was further supported by the observation that irreversible inactivation of fixed proportions of mu opioid receptors using  $\beta$ -chloralalrexamine demonstrated that there were few spare receptors, in contrast to what had been reported for other G-protein coupled receptors, including the delta opioid receptor. Taken together, these data suggest that the opioid agonist, DAMGO has a high affinity for the mu receptor but has to occupy more than 70 percent of the available receptors to generate the maximal second messenger-linked response. (Supported by the Addiction Research Fdn, Medical Research Council of Canada & National Institute of Drug Abuse).

**NITRIC OXIDE IS INVOLVED IN DESENSITIZATION OF MU OPIOID INHIBITION OF ADENYLYL CYCLASE ACTIVITY BUT NOT DOWN-REGULATION OF MU RECEPTORS AFTER CHRONIC MORPHINE EXPOSURE IN SH-SY5Y CELLS.** J.Y. Xu\* and J.M. Bidlack. University of Rochester, Rochester, NY 14642.

Co-administration of nitric oxide (NO) synthase inhibitors, such as N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME), along with morphine prevents morphine tolerance (Babey et al., 1994; Elliot et al., 1994). The cellular mechanisms of this prevention were investigated using the human neuroblastoma SH-SY5Y cell line differentiated with retinoic acid. This cell line expresses both  $\mu$  and  $\delta$  opioid receptors in a ratio of 5:1, respectively. Culturing of cells with 1  $\mu$ M morphine for 18 hours, followed by extensive washing, produced a significant reduction in the B<sub>max</sub> value for the binding of  $\mu$ -selective peptide [<sup>3</sup>H]DAMGO. Incubation of cells with 100  $\mu$ M L-NAME, together with 1  $\mu$ M morphine for 18 hours did not affect this down-regulation caused by the chronic morphine treatment. Culturing of cells with 10  $\mu$ M morphine for 18 hours, followed by extensive washing, also produced a desensitization of DAMGO induced-inhibition of forskolin-stimulated adenylyl cyclase activity. In contrast to the ineffectiveness in the binding assay, 100  $\mu$ M L-NAME, when given along with chronic morphine treatment, prevented the desensitization to DAMGO in the inhibition of forskolin-stimulated adenylyl cyclase activity. Culturing of cells with 100  $\mu$ M L-NAME alone for 18 hours, followed by extensive washing, neither affected the B<sub>max</sub> value for [<sup>3</sup>H]DAMGO binding, nor DAMGO-induced inhibition of adenylyl cyclase activity. Our results suggest that NO is involved in the desensitization of  $\mu$  opioid inhibition of adenylyl cyclase activity, but not down-regulation of  $\mu$  opioid receptors during chronic morphine exposure in SH-SY5Y cells. (Supported by USPHS grant DA03742 and DA07232.)

## 328.9

**SELECTIVE DOWN-REGULATION OF DELTA OPIOID RECEPTOR SUBTYPES IN MOUSE CORTICAL NEURONS IN VITRO AND IN NG108-15 CELLS.** A. Ambrosini, L. Bresciani, C. Manzoni, P. Pettrillo, G. Dondio, F. Fidone, A. Barassi, G. Racagni\* and G.D. Clarke\*. Center of Neuropharmacology, Univ. of Milan; \*SmithKline Beecham, Baranzate, Milan (Italy).

The effects of preferential agonists and antagonists for  $\delta$ 1 (DPDPE/BNTX) and  $\delta$ 2 (deltorphin II/NTB) opioid receptors on cAMP formation have been studied in various cell systems, namely: CHO cells stably expressing the cloned mouse  $\delta$ 1 opioid receptor cDNA, NG108-15 cell line, and mouse cerebrocortical neurons *in vitro*. In CHO cells the responses to DPDPE and deltorphin II were similarly blocked by BNTX or NTB, and to a lesser extent, by the general antagonist naloxone. In contrast, in NG-108-15 cells and in cortical neurons a distinct  $\delta$ 1 and  $\delta$ 2 pharmacology was observed, the rank order of potency of the antagonists on the DPDPE effect being BNTX > naloxone > NTB, and on the deltorphin II effect NTB > BNTX > naloxone. A chronic (48 h) treatment of cortical neurons with DPDPE or deltorphin II (both 100 nM) lowered basal cAMP levels by 15% and completely abolished deltorphin II (100 nM) but not DPDPE (0.1-1  $\mu$ M) acute response, suggesting that in cortical neurons  $\delta$ 2 subtype is more susceptible to down-regulation than  $\delta$ 1 subtype. A 48 h pretreatment of NG108-15 cells with DPDPE (1 nM) selectively reduced acute DPDPE (10 nM) but not acute deltorphin II (10 nM) effect. Chronic treatment with deltorphin II (1 nM) abolished almost completely both responses; lower acute and chronic concentrations of deltorphin II are now being tested. Overall, our data strongly support the evidence for  $\delta$ 1 opioid receptor subtypes both in NG108-15 cells and in cortical neurons.

**REGULATION OF DELTA OPIATE RECEPTOR INTERNALIZATION AND DOWN-REGULATION.** S. Cysic, N. Trapaidze, C. Cyr and L. A. Davi\*. Dept. of Pharmacology, NYU Medical Center, New York, NY 10016 and ‡ Dept. of Pharmacology, Univ. of Washington School of Medicine, Seattle, WA 98195

It is well known that prolonged exposure to opiates causes reduction in the number of opiate receptors. To study internalization and down-regulation of delta opiate receptor (DOR), we generated Chinese Hamster Ovary (CHO) cell lines that stably express "flag" epitope tagged wild type DOR or mutant DOR with deletion or point mutations of the C-terminal tail. Both wild type and mutated receptor exhibit similar binding and functional coupling properties. Short time treatment (2-30 minutes) of CHO cells with wild type DOR with 100 nM DADLE causes rapid internalization of the receptors as determined by the reduction in mean surface receptor fluorescence intensity measured by flow cytometry. Long term exposure (1 - 48 hours) to 100 nM DADLE causes loss of diprenorphine binding both in the whole cell binding assay and in cell homogenates indicating down-regulation of the receptor. Unlike wild type DOR, mutant receptors with deletions of C-terminal tail or with point mutations within the C-terminal tail show impaired internalization and/or down-regulation. These results suggest that C-terminal tail has an important role in regulation of internalization and down-regulation of DOR. A possibility that regulation of internalization and down-regulation is mediated through interaction with other protein(s), is supported by specific coimmunoprecipitation of proteins with DOR from the CHO cell lysates using anti "flag" antibody.

**BASAL  $\mu$  OPIOID RECEPTOR PHOSPHORYLATION: MODULATION BY RECEPTOR LIGANDS AND KINASE INHIBITORS.** Z. Wang, M. Kassack, N. Burford, & W. Sadée\*. Departments of Biopharm.Sci. and Pharmac.Chem., University of California San Francisco, CA 94142-0446.

We have proposed the hypothesis that agonist stimulation of the  $\mu$  opioid receptor enhances  $\mu$  phosphorylation, and thereby, causes sensitization or constitutive activation, rather than desensitization. Moreover, the kinase inhibitor H7 prevented naloxone induced withdrawal jumping and antinociceptive tolerance in morphine treated mice (Z. Wang, E.J. Bilsky, F. Porreca, & W. Sadée, Life Sci. PL. 54, 339-350, 1994). We studied  $\mu$  receptor phosphorylation in HEK293 cells transfected with a rat  $\mu$  opioid receptor (Y. Chen, A. Mestek, J. Liu, J.A. Hurlley, & L. Yu, Mol.Pharmacol. 44, 8-12, 1993), epitope tagged at the C-terminus. The  $\mu$  receptor was found to be phosphorylated at a basal rate which was further enhanced by acute stimulation with morphine (J.R. Arden, V. Segredo, Z. Wang, J. Lameh, & W. Sadée, J.Neurochem. 65, 1636-1641, 1995). The kinase inhibitor H7 indeed suppressed basal and morphine-stimulated  $\mu$  phosphorylation (Z. Wang, J.R. Arden, & W. Sadée, FEBS Let., in press). We therefore studied the regulation of basal  $\mu$  receptor phosphorylation by kinase inhibitors and  $\mu$  receptor ligands. Basal  $\mu$  receptor phosphorylation was mediated by a unique kinase activity, and it was slowly modulated by an apparent positive feedback loop between receptor and kinase. The ability of  $\mu$  agonist and antagonist ligands to affect  $\mu$  phosphorylation did not correlate with their ability to stimulate G protein coupling. Our results support the hypothesis that basal  $\mu$  receptor phosphorylation plays a role in narcotic tolerance and dependence. Supported by NIDA, DA 04166.

**PROTEIN KINASE A REGULATION OF DELTA OPIOID RECEPTOR GENE EXPRESSION IN NG108-15 CELLS** Beata Buzas, and Brian M. Cox\*. Dept. of Pharmacology, Uniformed Services University, Bethesda, MD, 20814.

The effects of activation of adenylyl cyclase-protein kinase A pathway on delta opioid receptor (DOR) gene expression has been investigated. Competitive polymerase chain reaction assays were used to compare the relative levels of DOR transcripts in treated and control cells. Activation of prostaglandin E1 (PGE1) receptors, which stimulate adenylyl cyclase, resulted in a reduction in DOR mRNA levels in NG108-15 cells. Direct stimulation of adenylyl cyclase by forskolin or treatment of cells with dibutyryl-cAMP (db-cAMP) mimicked the effect of PGE1. Receptor protein levels underwent a similar degree of downregulation, as measured by loss of radioligand binding sites. D-Ser2-Leu-enkephalin-Thr6 inhibition of adenylyl cyclase was also diminished after db-cAMP treatment. Protein kinase A inhibitors partially reversed the transcriptional repression by PGE1 or db-cAMP. Cycloheximide, a protein synthesis inhibitor, did not prevent cAMP mediated DOR mRNA downregulation, suggesting modification of preexisting transcription factors in this process.

Supported by a grant from the National Institute on Drug Abuse.

**CEREBROCORTICAL  $\delta$ -OPIOID RECEPTOR mRNA EXPRESSION IN MORPHINE-ADDICTS.** P. Schmidt<sup>1,2\*</sup>, A. Wevers<sup>1</sup>, K. Maderspach<sup>1</sup>, E. Cserpán<sup>1</sup>, I. Cserpán<sup>1</sup>, M. Staak<sup>2</sup>, H. Käferstein<sup>2</sup>, G. Sticht<sup>2</sup>, H. Schröder<sup>2</sup>, <sup>1</sup>Inst. f. Rechtsmed., Univ. Bonn, 53111 Bonn, FRG, <sup>2</sup>Inst. f. Rechtsmed. u. <sup>3</sup>Inst. II f. Anat., Univ. zu Köln, 50823 Köln, FRG, <sup>4</sup>Inst. of Biochem. and <sup>5</sup>Genetics, BRC, Hung. Acad. Sci., 6701 Szeged, H.

Animal experiments have shown a simultaneous "up"- and "down" regulation of different opiate receptor types following chronic agonist/antagonist treatment. By means of non-isotopic *in situ* hybridization we had shown the localization of the  $\delta$ -OR mRNA in the human frontal cortex. The present postmortem study of the morphine-related fatalities of drug addicts versus a non-addicted control group is intended to elucidate whether chronic opiate exposure affects the distribution of  $\delta$ -OR mRNA expressing neurons in the human neocortex (area 10). Morphine-related fatalities (n=7, 21 to 33 yrs with blood unconjugated morphine levels from 0.15 to 2.49 mg/kg and a total morphine from 0.15 to 3.21 mg/kg) were compared to non-addicted controls (n=7, 19 to 42 yrs). For non-isotopic *in situ* hybridization digoxigenin 3'end labeled oligonucleotide probes were applied. Hybrids were visualized by alkaline phosphatase coupled anti-digoxigenin antibodies and incubation with NBT/BCIP. Numerical densities of mRNA containing and Nissl-stained neurons were assessed morphometrically. In the drug related fatalities 28815  $\pm$  1642 / mm<sup>2</sup> expressing  $\delta$ -OR mRNA were found, in the control group 30741  $\pm$  1905 / mm<sup>2</sup>, accompanied by an increase of Nissl-stained neurons. The differences did not reach statistical significance. These findings go along with the binding behavior of opiate ligands in postmortem brains of heroine addicts (Gabilondo et al., Psychopharmacol 115:135, 1994) revealing similar receptor densities and affinities in the control subjects and addicts.

**IN UTERO EFFECTS OF BUPRENORPHINE ON OPIOID RECEPTORS.** L. B. Jefcoat<sup>1</sup>, M. M. Belcheva<sup>1</sup>, M. T. Ho<sup>1</sup>, F. E. Johnson<sup>2</sup>, J. Yanai<sup>3</sup>, S. Barron<sup>4</sup>, and C. J. Coscia<sup>1</sup>, Depts. <sup>1</sup>Biochem. & Mol. Biol. and <sup>2</sup>Surg., St. Louis Univ. Sch. Med., St. Louis, MO, <sup>3</sup>Dept. Anat. & Emb., Hebrew Univ.-Hadassah Sch. Med., Jerusalem, Israel. <sup>4</sup>Dept. Psychol., Univ. of Kentucky, Lexington, KY.

Previous *in vivo* studies revealed that buprenorphine can down-regulate  $\mu$  and up-regulate  $\delta_2$  and  $\kappa_1$  opioid receptors in rat brain. In order to assess gestational effects of buprenorphine on offspring, pregnant rats were administered buprenorphine by i.p. injection. Opioid receptor binding parameters ( $K_d$  and  $B_{max}$ ) were measured in P1 brain membranes. At 2.5 mg/kg, buprenorphine evoked an up-regulation of  $\kappa_1$  opioid receptors (98% > controls) as assessed with the agonist [<sup>3</sup>H]-U69593. Homologous binding assays with the  $\mu$ -selective agonist [D-al<sup>2</sup>,mephe<sup>3</sup>,gly<sup>5</sup>-ol<sup>1</sup>] enkephalin revealed a buprenorphine-induced decrease in receptor density at 0.3, 0.6 and 2.5 mg/kg drug treatments. A greater down-regulation of  $\mu$  receptors for males (85%, 73% resp.) than for their female counterparts (43%, 57%, resp.) was observed. These data provide evidence for an opioid response to buprenorphine in pup brains treated prenatally wherein  $\mu$  receptors were down-regulated and  $\kappa_1$  receptors were up-regulated. Since buprenorphine is being evaluated in clinical trials for the treatment of heroin abuse, the *in utero* actions of the drug have ramifications for its use in maternal drug abuse. Supported by NIDA grant DA 05412 and NIH training grant H207050.

**EXPRESSION OF BRAIN OPIOID RECEPTORS IN MICE WITH TARGETED ABLATION OF PITUITARY POMC CELLS.** E. M. Unterwald<sup>1,2</sup>, J. Kreuter<sup>1</sup>, M. J. Sirianni<sup>3</sup>, R. G. Allen<sup>3</sup>, and M. J. Kreek<sup>1</sup>. <sup>1</sup>The Rockefeller University, New York, NY 10021; <sup>2</sup>New York University Medical Center, New York, NY 10016; <sup>3</sup>Oregon Health Sciences University, Portland, OR 97201.

Proopiomelanocortin (POMC) is a peptide precursor that gives rise to ACTH,  $\alpha$ -,  $\beta$ -, and  $\gamma$ -MSH, and  $\beta$ -endorphin. The role of POMC-derived peptides in the regulation of opioid receptors was investigated using a line of transgenic mice that express a fusion gene composed of the pituitary expression-specific promoter region of the POMC gene, driving the herpes simplex viral-1 thymidine kinase (Allen et al., *Mol Endo* 9:1005, 1995). Three week old mice were treated with the antihelminthic agent ganciclovir, 90 mg/kg daily for 14 days. One day following the treatment, 98% of the pituitary intermediate lobe melanotrope and anterior lobe corticotrope were ablated and greater than 98% of ACTH,  $\beta$ -endorphin, and  $\alpha$ -MSH was lost. Binding of [<sup>3</sup>H]DAMGO to  $\mu$  opioid receptors as measured by quantitative autoradiography was significantly reduced in several brain regions of the mice with POMC cell ablations including the central grey (-37%), superficial grey layer of the superior colliculus (-33%), and median raphe (-23%). No significant differences were found in the binding of [<sup>3</sup>H]bremazocine (in the presence of DAMGO and DPDPE) to  $\kappa$  opioid receptors or in the binding of [<sup>3</sup>H]naltrindole to  $\delta$  opioid receptors. These results suggest that POMC-derived peptides play a role in the regulation of central  $\mu$  opioid receptor expression, possibly mediated through glucocorticoid receptors. (Supported by P50-DA05130 & K05-DA00049 (MJK), DA08267 (EMU), and NSF 9108426 (RGA).)

## 328.17

**DIFFERENTIAL REGULATION OF  $\mu$  RECEPTORS BY METHAMPHETAMINE IN p53 KNOCK-OUT MICE.**

Bruce Ladenheim<sup>1</sup>, Hiroshi Hirata, and Jean Lud Cadet, Molecular Neuropsychiatry Section, NIH/NIDA, IRP, Baltimore, MD 21224

p53 is an important regulator of cell death and neuro-degeneration. We have shown recently that p53 is a mediator of methamphetamine (METH)-induced degeneration of striatal dopamine (DA) terminals since p53 knock-out mice are protected against the toxic effects of the drug. We showed, in addition, that METH caused increases in p53 in the striata of wild-type mice. Because p53 is a known transcription factor, we reasoned that absence of or overexpression of p53 might alter the expression of some striatal proteins after administration of METH. As a first step towards testing this idea, we have used quantitative autoradiographic techniques to measure striatal  $\mu$  opioid receptor density after METH in wild-type as well as in heterozygous and homozygous p53 knock-out mice. In wild-type mice, METH caused no changes in striatal  $\mu$  receptors at either 1, 3 or 15 days post-treatment. However, in both heterozygous and homozygous mice METH caused marked time-dependent decreases in striatal  $\mu$  receptors. These results suggest that p53 might participate in maintaining the steady state levels of opiate receptor after METH administration. These data identify yet another role for p53 in the central nervous system.

## 328.14

**MULTIPLE MECHANISMS ACCOUNT FOR CHRONIC MORPHINE INDUCED RECEPTOR REGULATION IN RAT CNS.** M. Szűcs, B. Bozó, B. Tombor, G. Fábán, M. Szikszay. Biol. Res. Center Hung. Acad. Sci., Szeged, Hungary (SPON: European Neuroscience Association)

Analgesic tolerance was induced by s.c. injections of increasing doses of morphine-HCl twice daily for 5 days in Wistar rats. Neither the  $K_d$  nor the  $B_{max}$  values of the  $\mu$  opioid agonist [<sup>3</sup>H]DAMGO binding were changed in whole brain P<sub>2</sub> or highly purified synaptic plasmamembrane fractions upon chronic morphine treatment. Affinity labeling with [<sup>3</sup>H]DAMGO-chloromethyl ketone followed by SDS-PAGE and fluorography revealed specific incorporation of the label into the  $\approx$ 50 kDa binding subunit to a similar extent in tolerant and naive rat brain membranes. Measuring Gpp(NH)p inhibition of [<sup>3</sup>H]DAMGO binding, or opioid agonist stimulation of [<sup>35</sup>S]GTP- $\gamma$ -S binding revealed no significant alterations in the coupling of  $\mu$  opioid receptors to G-proteins. Thus, desensitization and down-regulation are not evident in rat whole brain membranes. In spinal cord P<sub>2</sub> membranes [<sup>3</sup>H]DAMGO binding site number decreased in female, but was up-regulated by 164% in male rats after morphine tolerance developed. We conclude that chronic morphine *in vivo* induces diverse molecular events which are influenced by several factors such as those shown in the present study.

Supported by OTKA T-016084 research grant.

## 328.16

**MU OPIOID RECEPTOR GENE KNOCKOUT STRATEGIES.** L. Sora\*, N. Takahashi, H.F. Liu, R. Revay, N. Goodman, D.M. Donovan, J. Sharp, J.L. Miner, & G.R. Uhl #. Mol. Neurobiology, NIH/NIDA, IRP; #Neurol. Neurosci. JHUSM, Balto., MD 21224

The mu opioid receptor is thought to be the opiate receptor subtype that is important for morphine mechanism, analgesia, reward, tolerance and dependence, cardiovascular and respiratory functions, and several neuro-endocrine-immune effects. The endogenous opioid peptides as well as morphine and other opioid alkaloids, are known to bind the mu-receptor to produce many physiological effects, including the modulation of neurotransmitter release and the alteration of ionic conductance and cell firing. To investigate the function of the mu-receptor, we have identified an  $\approx$ 16.5kb clone from a murine 129SvJ genomic library that contained the first exon and  $\approx$ 8kb of 5' and  $\approx$ 8kb of 3' flanking sequence. Targeting vectors replaced a putative promoter region and the first exon with the pgk neomycin resistance gene cassette. 800 Neo resistant embryonic stem (ES) cell lines were screened by Southern blotting, and eight ES cell lines showed homologous recombination at the mu-receptor locus. Heterozygous and homozygous knockout mice is helping to define mu receptor specific feature of normal and morphine-modulated behavior and neurochemistry.

## 328.18

**EXPRESSION OF OPIOID RECEPTOR PROTEIN IMMUNOREACTIVITY IN THE DEVELOPING HUMAN FOREBRAIN.** C. R. Neal, Jr., MD, PhD\* and S. J. Watson, Jr., MD, PhD. Mental Health Research Institute, University of Michigan Medical School, Ann Arbor, Michigan 48109.

In the extremely premature neonate, a large proportion of CNS development is undertaken *ex utero*, while exposed to several environmental and pharmacological stressors. Although there is a wealth of clinical information concerning long-term outcomes of premature survivors, there is little knowledge regarding the effects of environmental influences on their developing brain. Of particular interest to us is the developing opioid receptor system. Although some data has been acquired pertaining to the ontogeny of opioid receptors in the developing rat brain, such information is virtually non-existent regarding the human brain. Premature neonates are exposed to exogenous opiates (e.g., morphine, fentanyl) on a regular basis when critically ill and this may permanently alter their opioid receptor profile as adults. In order to better study this, it is important to first learn the expression of opioid receptors during normal human CNS development. Fresh post-mortem brain specimens were obtained at various gestational ages (16 to 36 wk). Tissue was blocked, immersed in Zamboni's fixative for 90-120 days, soaked in 10% sucrose for 96 hours, fast frozen at -40°C in isopentane, then cryostat cut into 15  $\mu$ m sections. Tissue was incubated in primary rabbit antiserum directed against the C-terminal sequence of the rat mu receptor protein then, using a tyramine-enhanced avidin-biotin-peroxidase complex, visualized with nickel chloride and diaminobenzidine. Pre-absorption controls were performed using 2  $\mu$ M protein absorption of primary antiserum prior to tissue incubation. Immunostaining in regions similar to those described previously in rat was observed in corpus striatum, entorhinal and cerebral cortex, and several additional forebrain and brainstem nuclei. Comparisons to distribution of mu receptor in rat brain and between gestational ages is discussed. Supported by NIDA Grant T32DA07268.
