Drugs such as cocaine, methylphenidate and antidepressants that block monoamine transport are invariably nitrogen-based. The nitrogen is presumed to be necessary for anchoring the drug to the same aspartic acid residue on the transporter protein that bonds the nitrogen of a monoamine neurotransmitter. We now report a novel series of drugs which possess no nitrogen and bind to the dopamine, serotonin and norepinephrine transporters with relatively high affinity. A lead compound bound to the human dopamine transporter in putamen ( $IC_{50}$ :  $5.01 \pm 1.74$  nM), in cos-7 cells transiently expressing the human dopamine transporter cDNA ( $IC_{50}$ :  $2.1 \pm 0.75$  nM) and blocked [<sup>3</sup>H]dopamine transport in the cells ( $IC_{50}$ :  $7.2 \pm 4.24$  nM). The compounds did not fully [<sup>3</sup>H]WIN 35,428 binding to monkey and human dopamine transporter. These innovative drugs offer unique tools for modeling drug-transporter complexes and highlight the potential for developing a new generation of non-nitrogen drugs targeted to monoamine transporters and receptors. DA06303, DA09462, RR00168, DA 4-8309.

## 207.6

**CHIMERIC HUMAN AND DROSOPHILA SEROTONIN TRANSPORTERS TO PROBE REGIONS INVOLVED IN LIGAND BINDING AND ION DEPENDENCE.** E.L. Barker<sup>\*</sup>, M.A. Gray, E.A. Camp, and R.D. Blakely. Dept. of Pharmacology and Ctr. for Mol. Neuroscience., Vanderbilt Univ. Sch. of Med., Nashville, TN 37232

Pharmacological studies using the cloned human (hSERT) and *Drosophila* (dSERT) serotonin transporter cDNAs have revealed differential sensitivities to substrates and antagonists across species. The tricyclic antidepressants and citalopram were found to be less potent at the dSERT as compared to the human homologue, whereas the antagonist mazindol was significantly more potent at the *Drosophila* transporter. Although cocaine showed no difference in potency across species, the cocaine analog RTI-55 was much less potent at dSERT than hSERT suggesting that cocaine analogs recruit additional sites of interaction that are not present in dSERT. Chimeras between human and *Drosophila* SERTs have localized the region of TMD2 (amino acids 118-136) as playing a major role in mazindol and citalopram recognition. This region does not appear to influence potency for other ligands exhibiting differences between hSERT and dSERT. Using site-directed mutagenesis, the eight amino acids that differ between hSERT and dSERT in the TMD2 region will be explored as potential candidates mediating the species-selectivity of mazindol and citalopram. In addition to identifying ligand binding domains, cross-species chimeras can also track domains responsible for other functional differences observed for the two SERT homologues. For example, serotonin transport by hSERT exhibits absolute dependence upon Na<sup>+</sup> and Cl<sup>-</sup>, whereas dSERT transport activity is also dependent upon Na<sup>+</sup>, but only facilitated by Cl<sup>-</sup> with approximately 20% of uptake activity remaining in the absence of Cl<sup>-</sup>. Functional studies using the wild-type and chimeric SERTs also have implicated the TMD2 region as being involved in Na<sup>+</sup> sensitivity, whereas the region distal to TMD2 appears important for the absolute dependence of hSERT on Cl<sup>-</sup>. Together these studies suggest new opportunities for identification of critical domains and residues involved in SERT function. (This work supported by NIH grants DA07390 and DA05679)

## 207.8

**COCAINE REGULATION OF SEROTONIN TRANSPORTER mRNA AND BINDING SITES IN HUMAN BRAIN**

KY Little<sup>\*</sup>, ZS DelProposto, PR McFinton, DP McLaughlin, CS Livermore, GW Dalack, SJ Watson

Department of Psychiatry, University of Michigan, Ann Arbor, MI

Chronic cocaine exposure in human users appears to increase dopamine transporter binding sites in post mortem brain, as measured with [<sup>3</sup>H]WIN 35428. Although cocaine also binds to and inhibits the serotonin transporter (SERT), there is less information available about the effects of chronic cocaine on the SERT in humans or animals. In this series of experiments, we assessed brainstem SERT mRNA levels employing *in situ* hybridization, and midbrain, hippocampal, and striatal binding sites utilizing [<sup>125</sup>I]RTI-55 and quantitative autoradiography. Brain specimens from 32 cocaine users and age-, sex-, and PMI-matched controls were dissected at autopsy, as authorized by the Medical Examiner. SERT mRNA was labeled using a 920 bp riboprobe and high stringency washes. mRNA OD's were quantified in dorsal raphe, median raphe, and B9 cell groups. [<sup>125</sup>I]RTI-55 binding was quantified at .035, .35, and 3.5 nM (.1 Kd, Kd, and 10xKd) in the presence of 10 nM RTI-121, with specificity defined with citalopram (100 nM). mRNA levels were not different between groups, but binding was significantly increased in caudate (19%), putamen (22%), and accumbens (26%). In contrast, SERT binding was significantly decreased in the midbrain over the substantia nigra, but not linear nucleus or dorsal raphe. An acute conformational change (increasing binding) may have been superimposed on chronic cell loss, especially prominent in substantia nigra where both projecting and terminal neuronal loss would magnify the chronic effect. Supported by NIH award DA09491.

## 207.10

**PHORBOL ESTER INDUCED PHOSPHORYLATION OF DOPAMINE TRANSPORTERS IN RAT STRIATUM.** R.A. Vaughan<sup>1</sup>, R.A. Huff<sup>1</sup>, G.R. Uhl<sup>1</sup>, & M.J. Kuhar<sup>2</sup>. <sup>1</sup>Molec. Neurobiol. Br., NIDA IRP, Balto., MD 21224, Depts of Neurology & Neuroscience, JHUSM, & <sup>2</sup>Neurosci. Div., Yerkes Regional Primate Ctr., Emory Univ., Atlanta, GA 30322

The primary amino acid sequence of dopamine transporters reveals consensus phosphorylation sites for several protein kinases including PKA, PKC, and CaM kinase. Phorbol esters regulate dopamine uptake in synaptosomes and in heterologous expression systems, and direct phosphorylation of DAT has been found in a stably expressing cell line (Huff, et al., Society for Neuroscience Abstract, 1996). We report here the demonstration of DAT phosphorylation in brain. Rat striatal synaptosomes were incubated with [<sup>32</sup>P]-orthophosphate, and radiolabelled of DAT detected by immunoprecipitation, SDS-PAGE, and autoradiography. A phosphorylated protein that co-migrated on gels with [<sup>125</sup>I]DEEP-photoaffinity labeled DAT was extracted using immune but not preimmune serum. Immunoprecipitation was blocked by the addition of the immunizing but not irrelevant peptides, and the protein was not isolated from cerebellum, a brain region devoid of DAT. The level of DAT phosphorylation increased in a dose-dependent manner by the addition of up to 10  $\mu$ M okadaic acid. DAT was phosphorylated at a basal level in the absence of kinase activators, but treatment of synaptosomes with PMA increased DAT phosphorylation 3-4 fold. This effect was dose-dependent with an  $IC_{50}$  of about 300 nM, while the inactive phorbol ester 4 $\alpha$ PDD at 10  $\mu$ M was without effect. Increased phosphorylation was observed within minutes, and was maximum by 20 min. These results provide the first demonstration of neurotransmitter transporter phosphorylation in brain, and raise the possibility that rapid phosphorylation-induced functional regulation of DAT could significantly alter synaptic dopamine dynamics. Supported by the National Institute on Drug Abuse.

## 207.11

**ENHANCEMENT OF DOPAMINE TRANSPORTER PHOSPHORYLATION BY PHORBOL ESTERS: PARALLELS WITH PHORBOL-INDUCED DECREASES IN TRANSPORT.** R.A. Huff<sup>1</sup>, R.A. Vaughan<sup>1</sup>, M.J. Kuhar<sup>2</sup>, & G.R. Uhl<sup>1,3</sup>. <sup>1</sup>Molec. Neurobiol. Branch, NIDA IRP, Balto., MD 21224; <sup>2</sup>Neurosci. Div., Yerkes Regional Primate Ctr., Emory Univ., Atlanta, GA 30322; <sup>3</sup>Depts. Neurol. & Neurosci., JHUSM, Balto., MD 21224.

Dopaminergic neurotransmission is terminated by presynaptic reuptake of dopamine by the dopamine transporter (DAT). The primary sequence of the dopamine transporter contains multiple potential phosphorylation sites, suggesting that the function of the transporter may be regulated by phosphorylation. We have examined DAT phosphorylation *in vivo* by labeling LLC-PK<sub>1</sub> cells expressing DAT with [<sup>32</sup>P]orthophosphate followed by immunoprecipitation and electrophoresis of DAT. We have identified DAT as a phosphoprotein that migrates with the same relative mobility as [<sup>32</sup>P]DEEP-labeled DAT, is immunoprecipitated in the presence of irrelevant peptide but not antigenic peptide, and is absent from nontransfected cells. Activation of protein kinase C with the active phorbol ester PMA enhances modest basal levels of phosphorylation by 3 fold and this enhancement is blocked by the protein kinase inhibitor staurosporine. The inactive phorbol ester 4 $\alpha$ -PDD does not produce this effect. The enhancement of DAT phosphorylation by PMA is concentration- and time-dependent, showing increases as early as 4 min after PMA treatment. The concentration and time dependency of the effect of PMA, as well as its staurosporine-sensitivity, parallel previously documented PMA decreases in dopamine transport  $V_{max}$ . These parallels suggest that phosphorylation of DAT could contribute to rapid down-regulation of transporter function, and thus provide a novel mechanism whereby modulation of protein kinase C activity in dopaminergic neuronal processes could dynamically alter extraneuronal dopamine levels.

## 208.1

**INTRADENTAL RECEPTORS ARE NOT SENSITIZED DURING PULPAL INFLAMMATION IN THE CAT.** D. Andrew and B. Matthews\*. Department of Physiology, University of Bristol, Bristol BS8 1TD, U.K.

We have investigated the effects of inflammation of dental pulp on the properties of intradental receptors in 8 young adult cats. At an initial operation under general anaesthesia, a cavity was cut on the buccal side of each lower canine tooth. To induce pulpitis, dental caries from a human tooth was sealed into the cavity with dental amalgam (Mjör and Tronstad, *Oral Surg.* 34, 102-108, 1972). After 1 week, the animals were anaesthetized with sodium pentobarbitone and recordings were made from single fibres dissected from the inferior alveolar nerve (IAN) during the application to dentine at the tip of the tooth of a range of stimuli that would cause pain in man (mechanical, thermal, osmotic, hydrostatic pressure changes and drying). Pulpal blood flow was recorded with a laser Doppler flow meter during electrical stimulation of the IAN at different intensities. At the end of the experiment the animals were perfused with fixatives and sections of decalcified dentine and pulp from all 4 canines were examined in the light microscope. Some sections were immuno-labelled with antibodies to either substance P (SP) or calcitonin gene-related peptide (CGRP).

Compared with normal teeth studied previously, resting pulpal blood flow was up to 200% greater but it increased less on IAN stimulation. The responses of the 79 single units studied were similar to those of controls, and the same proportion failed to respond to dentine stimulation. There was histological evidence of pulpal inflammation in all the treated teeth but SP and CGRP expression was similar to controls. The cats showed no evidence of pain during the week following insertion of the caries. These results suggest that, in man, the pain of pulpitis may be due to central sensitization in nociceptive pathways.

## 208.3

**A PERIPHERAL FACTOR OF COLD ALLODYNIA AND HYPERALGESIA. HYPOTHESIS AND MODELING.** L. de Medinaceli\*, J.-C. Hurpeau, H. Begorre. IEBM, 54511 Vandoeuvre, & CRAN-INPL, 54516, Vandoeuvre, France.

Allodynia and hyperalgesia are relatively frequent sequelae of peripheral nerve injury. These symptoms are worsened by cold but their mechanism is not well understood. We suggest that incomplete recovery of diameter of regenerated fibers is one of the factors involved in cold intolerance after nerve damage.

Conduction velocity is correlated to fiber diameter, and is slowed down by cold. In normal subjects, cold does not desynchronize the volleys of sensory impulses sufficiently to change the intelligibility of the peripheral "messages." Sensory perception remains accurate although it acquires a characteristic numbness. On the other hand, posttraumatic reduction in fiber diameters causes a permanent distortion of the messages. We considered that when the distortion is severe, the resulting messages may be perceived by the centers as containing nociceptive components. We further hypothesized that, even in cases of moderate permanent distortion, cold acts by increasing the posttraumatic abnormalities of impulse synchronization. In winter, decompensation is observed when a threshold of desynchronization is reached.

We devised a model of peripheral nerve messages, in an attempt to represent the distortion brought about by cold and crush damage. Although our model was quite simple, a great number of parameters could vary. The results of statistical analyses indicated that peripheral desynchronization might explain, at least in part, the painful sensations experienced in winter by many patients after peripheral nerve injury.

## 207.12

**Activation of Purified Inositol Hexakisphosphate Kinase by Protein Kinases.** S. M. Voglmaier\*, C. F. Huang, and S. H. Snyder. Johns Hopkins University School of Medicine, Department of Neuroscience, Baltimore, MD 21205.

Two inositol phosphates which possess pyrophosphate bonds, diphosphoinositol pentakisphosphate (PP-IP<sub>5</sub>) and bisdiphosphoinositol tetrakisphosphate (bis-PP-IP<sub>4</sub>), were recently identified. We have purified an inositol hexakisphosphate (IP<sub>6</sub>) kinase from rat brain supernatants. The purified protein with a molecular weight of 54 kD has high affinity ( $K_m=0.7 \mu M$ ) and specificity for IP<sub>6</sub> as substrate. During the purification process, phosphatase inhibitors were required to maintain the IP<sub>6</sub> kinase activity. This indicates that phosphorylation of IP<sub>6</sub> kinase may be an important regulatory mechanism *in vivo*. We have found that (1) calcium is a necessary cofactor for IP<sub>6</sub> kinase, (2) upon protein kinase C (PKC) phosphorylation, IP<sub>6</sub> kinase activity increases about 500%, (3) in the absence of diacylglycerol and phosphatidylserine, the IP<sub>6</sub> kinase activity cannot be upregulated by PKC, and (4) in the presence of PKC inhibitors, the activation effect is abolished.

## 208.2

**Novel interaction of  $\alpha_2$ -adrenergic with  $\mu$ -opioid and A<sub>1</sub>-adenosine agonists in peripheral antinociception in the rat**

K.O. Alev, P.G. Green\* and J.D. Levine

University of California San Francisco, CA 94143-0452

We evaluated for interactions between the peripheral antinociceptive effect of clonidine, an  $\alpha_2$ -adrenergic agonist, DAMGO ( $\mu$ -opioid agonist), and CPA (A<sub>1</sub>-adenosine agonist) using the Randall-Selitto paw withdrawal test. A rapid (within four hours) development of tolerance and cross-tolerance was observed if any of these agents were administered repeatedly (hourly). Furthermore, the  $\alpha_2$ -adrenergic antagonist yohimbine, produced withdrawal hyperalgesia in paws made tolerant to clonidine, DAMGO or CPA.

In evaluating for cross receptor-specific block of antinociception, naloxone ( $\mu$ -opioid antagonist) and PACPX (A<sub>1</sub>-adenosine antagonist) were found to block clonidine antinociception. Yohimbine ( $\alpha_2$ -adrenergic antagonist) blocked both DAMGO and CPA antinociception. In studies of cross receptor-specific block of withdrawal, naloxone-induced withdrawal hyperalgesia in DAMGO-tolerant paws and PACPX-induced withdrawal hyperalgesia in CPA-tolerant paws was reversed by co-injection of clonidine with naloxone and PACPX, respectively.

Since all three classes of peripherally-acting antinociceptive agents block PGE<sub>2</sub> hyperalgesia, and all three receptors interact in their peripheral antinociceptive effects we suggest that all three receptors are located on the same subpopulation of primary afferent nociceptors. Interactions thought to occur at the level of the second messenger, mediating the development of tolerance, were found to be completely promiscuous. In addition, a novel interaction may also occur at the level of the receptors, centered on an interaction of the  $\alpha_2$ -adrenergic with the  $\mu$ -opioid and A<sub>1</sub>-adenosine receptors.

## 208.4

**ANTI-NGF PREVENTS THERMAL ALLODYNIA IN CHRONIC CENTRAL PAIN FOLLOWING SPINAL CORD INJURY.** M.D. Christensen\*, A. Everhart and C.E. Hulsebosch. Dept. Anat. & Neurosci. and Marine Biomed. Inst., Univ. Texas Med. Br., Galveston, TX 77555-1069.

Spinal cord injury frequently results in dysesthesias. We report that the development of chronic central pain following spinal cord hemisection is prevented by continuous infusion of antibodies to NGF (ANTI-NGF). The spinal cords of male Sprague-Dawley rats were hemisected at T13 and PE 10 tubing was inserted intrathecally to the T12 level. Alzet pumps (2 ml capacity, 10  $\mu l/hr$ , 14 days) containing vehicle (pH 7.2 buffered saline) (N=5), ANTI-NGF (40  $\mu g/hr$ , N=5) or NGF (35  $ng/hr$ , N=5) were connected to the tubing and inserted subcutaneously. The animals were tested both preoperatively and postoperatively for mechanical and thermal thresholds for paw withdrawal and for supraspinal responses. We report the results of the behavioral tests which support the development of mechanical allodynia but the prevention of thermal allodynia in the ANTI-NGF treated group compared to vehicle controls after 14 days. In contrast, the NGF group had heightened mechanical and thermal allodynia and were terminated at 7 days for humane reasons. CGRP peptide is involved in pain transmission, located in A delta and C fibers and upregulated by NGF. Data will be presented to demonstrate that downregulation of CGRP in ANTI-NGF treated rats and inhibition of A delta and C-fiber intraspinal sprouting are two mechanisms that can account for the inhibition of thermal allodynia. (Supported by NS 11255 and the Kent Walder National Paralysis Foundation.)

## 208.5

**EFFECTS OF SUBACUTE INTRAVENOUS SNX-111 INFUSION ON MECHANICAL ALLODYNIA IN A RAT MODEL OF PAINFUL PERIPHERAL NEUROPATHY.** Y.-X. Wang, M. Pettus, T. Singh\*, S. S. Bowersox and R. R. Luther. Neurex Corporation, Menlo Park, CA 94025.

SNX-111, the synthetic version of the naturally occurring  $\omega$ -conopeptide MVIIA, is a selective antagonist of neuronal N-type voltage sensitive calcium channels (VSCC). This compound has been shown to block mechanical allodynia in a rat model of painful peripheral neuropathy when it is administered spinally (Chaplan *et al.* J. Pharmacol. Exp. Ther. 269: 1117, 1994) and is now under clinical evaluation for the treatment of chronic pain. The current study evaluated the effect of subacute (6 days), intravenous SNX-111 infusion on mechanical allodynia thresholds in rats with a painful peripheral neuropathy induced by tight ligation of the L5/L6 spinal nerves at sites distal to the dorsal root ganglia.

Twenty-three rats were divided into four treatment groups: vehicle (0.9% saline, 1  $\mu$ l/hr, n=6), SNX-111 (3  $\mu$ g/kg/hr, n=4), SNX-111 (10  $\mu$ g/kg/hr, n=6) and SNX-111 (100  $\mu$ g/kg/hr, n=7). After confirming the presence of mechanical allodynia, test and control articles were administered by continuous, constant-rate intravenous infusions for 6 days using osmotic minipumps. Hindlimb withdrawal responses to tactile stimuli (mechanical allodynia) were measured daily before, during and after test/control article infusion. Intravenous infusion of vehicle did not significantly alter mechanical allodynia thresholds during or after treatment. SNX-111 delivered at doses of 3 or 10  $\mu$ g/kg/hr was ineffective; however, SNX-111 at 100  $\mu$ g/kg/hr significantly attenuated mechanical allodynia. Analgesia was present 1-2 days after initiating infusion and was maintained for the duration of the treatment period. The anti-allodynic effect of SNX-111 gradually declined after discontinuation of infusion, with mechanical allodynia thresholds returning to pretreatment levels within 3 days of terminating treatment.

These results show that subacute intravenous infusion of the selective N-type VSCC blocker SNX-111 causes a dose-dependent and reversible blockade of mechanical allodynia in rats with an experimentally-induced painful peripheral neuropathy.

## 208.7

**CLONIDINE PREVENTS NEUROTOXIC SIDE EFFECTS WHILE ENHANCING THE NEUROPATHIC PAIN RELIEVING ACTION OF MK-801** J.W. Olney\*, S. Ege, D.E. Wozniak and V. Jevtovic-Todorovic. Depts. of Anesthesiology and Psychiatry, Washington Univ Med School, St. Louis, MO, 63110.

Recent studies show that NMDA glutamate receptor antagonists can alleviate neuropathic pain. However, NMDA antagonists have the liability of causing psychotomimetic reactions in adult humans and adverse effects ranging from memory and locomotor impairment to injury of cerebrocortical neurons in adult rats. Alpha-2-adrenergic agonists prevent the cerebrocortical neurotoxic side effects of NMDA antagonists. For example, clonidine at 0.05 mg/kg sc prevents the neurotoxic side effects of the powerful NMDA antagonist, MK-801 (0.5 mg/kg sc). In the present study we used sciatic nerve ligation and subsequent thermal paw stimulation to elicit a thermal hyperalgesic response (common component of neuropathic pain syndrome) in adult female rats, and studied the ability of clonidine to abolish this response by itself or to modify the analgesic action of MK-801. MK-801 abolished the thermal hyperalgesic response at a dose  $\geq$  0.05 mg/kg sc but not at 0.025 mg/kg sc. The hyperalgesic response was not abolished by clonidine at 0.05 mg/kg sc, but was by combined treatment with MK-801 (0.025 mg/kg sc) and clonidine (0.05 mg/kg sc). The dose of MK-801 required to induce cerebrocortical neuronal injury is approximately 0.2 mg/kg sc. Therefore, MK-801 by itself abolished the hyperalgesic response at a dose lower than that required to produce neurotoxic side effects and when combined with clonidine, which protects against these side effects, the analgesic action of MK-801 is augmented, thereby allowing MK-801 to achieve pain relief at a 50% reduction in dose which further widens its margin of safety. Supported by AG 11355, DA 05072 and RSA MH38894 (JWO).

## 208.9

**CUTANEOUS VASODILATION DUE TO SPINAL CORD STIMULATION (SCS) IS DORSAL ROOT DEPENDENT AND MEDIATED BY CALCITONIN GENE-RELATED PEPTIDE (CGRP).** J.E. Croom\*, R.D. Foreman, M.J. Chandler and K.W. Barron. Dept. of Physiology, Univ. of Oklahoma Health Sciences Center, Oklahoma City, OK 73190

SCS is used clinically to provide pain relief from peripheral vascular disease and has the benefit of increasing cutaneous blood flow to the affected extremities. The purpose of this study was to examine the role of dorsal roots, CGRP, and substance P (SP) in the cutaneous vasodilation induced by SCS. Male rats (280-400 gm) were anesthetized with pentobarbital (60 mg/kg i.p.). A unipolar ball electrode was placed unilaterally on the spinal cord at the L1-L2 spinal segment. Blood flow was recorded in each hindpaw foot pad with laser Doppler flowmeters. Blood flow responses were assessed during 1 min of SCS (either 0.2 mA (subdural) or 0.6 mA (epidural) at 50 Hz, 0.2 msec pulse duration). Dorsal rhizotomy of L3-L5 (n=5) abolished the cutaneous vasodilation to subdural SCS whereas removal of T10-T12 (n=5) and T13-L2 dorsal roots (n=5) did not attenuate the SCS-induced vasodilation. The CGRP antagonist, CGRP(8-37) (2.6 mg/kg i.v., n=7), abolished the epidural SCS-induced vasodilation whereas the substance P receptor antagonist, CP-96,345 (1 mg/kg i.v., n=8), had no effect. In summary, L3-L5 dorsal roots and CGRP are essential for the SCS-induced vasodilation. We propose that SCS antidromically activates afferent fibers in the dorsal roots that causes peripheral release of CGRP producing cutaneous vasodilation. ## 208.6

**EXPERIMENTAL PAINFUL MONONEUROPATHY: INHIBITORS OF TNF- $\alpha$  PRODUCTION INDUCE A DECREASE IN HYPERALGESIA AND AN INCREASE OF SPINAL MET-ENKEPHALIN** C. Sommer\* and M. Marziniak. Neurologische Universitätsklinik Würzburg, Germany

The aim of the present study was to investigate the effects of TNF-inhibiting drugs in experimental painful mononeuropathy. Thalidomide (50 mg/kg) and pentoxifyllin (100 mg/kg), both known to inhibit macrophage production of TNF- $\alpha$ , were administered to rats with a unilateral sciatic nerve chronic constriction injury (CCI). Vehicle treated rats developed heat hyperalgesia and tactile allodynia from postoperative day 3. Both behaviors were consistently present until the end of the experiment on day 14. Pentoxifyllin-treated rats were protected from maximal heat hyperalgesia throughout the course of the experiment, and from tactile allodynia during the first postoperative week. Thalidomide treated rats had decreased heat hyperalgesia on postoperative days 3 and 5 and decreased allodynia during the first postoperative week. Spinal cord tissue harvested on postoperative day 14 was immunostained for neuropeptides. Preliminary results show a moderate increase in met-enkephalin-immunoreactivity in CCI-animals as compared to controls and a significant increase in thalidomide- and pentoxifyllin-treated rats when compared to either controls or to vehicle treated CCI-rats. We conclude that drug-induced attenuation of hyperalgesia and allodynia is paralleled by increased activity of the endogenous pain-modulating system in this model.

## 208.8

**ROLE OF NITRIC OXIDE (NO) IN CUTANEOUS VASODILATION INDUCED BY SPINAL CORD STIMULATION IN THE RAT.** K.W. Barron\*, J.E. Croom, M.J. Chandler, M.C. Koss, and R.D. Foreman. Depts. of Physiology and Pharmacology, Univ. of Oklahoma Health Sciences Center, OKC, OK 73190

Spinal cord stimulation (SCS) increases blood flow to the extremities and may have a limb saving effect in addition to treatment of refractory chronic pain in patients with peripheral vascular disease. The purpose of this study was to examine the importance of NO in cutaneous vasodilation due to SCS. Male rats (300-500 gm) were anesthetized with pentobarbital (60 mg/kg i.p.). A unipolar ball electrode was placed on the left side of the exposed spinal cord at approximately L1-L2. Blood flow responses were concurrently recorded from both hindpaw footpads with laser doppler flowmeters (Vasomedic, 403A). Blood flow responses were assessed during 1 min of SCS (0.6 mA at 50 Hz, 0.2 msec pulse duration). NO synthase was inhibited with i.v. N<sup>G</sup>-Nitro L-arginine methyl ester (L-NAME). L-NAME markedly attenuated the cutaneous vasodilation due to SCS in two separate groups of rats receiving either a 2 mg/kg (n=6) or 10 mg/kg (n=7) dose. The NO synthase inhibitor, N<sup>G</sup>-mono-methyl-L-arginine (L-NMMA, 10 mg/kg, i.v., n=6), also attenuated the SCS response. The ganglionic receptor antagonist, hexamethonium (10 mg/kg, i.v., n=7), did not affect cutaneous vasodilation due to SCS. After hexamethonium, L-NAME administration (10 mg/kg) no longer attenuated the SCS response. Our results demonstrate that NO but not autonomic ganglionic function plays a significant role in the SCS-induced increase in cutaneous hindpaw blood flow in the rat. (Support: NIH Grant HL22732 and the Presbyterian Health Foundation)

## 208.10

**SPINAL NEURONAL RESPONSES TO INNOCUOUS STIMULATION "WIND UP" IN THE PRESENCE OF I.T. STRYCHNINE.** George L. Wilcox\*, Kelley E. Kitto<sup>1</sup> and Christopher Loomis<sup>2</sup>. <sup>1</sup>Dept. of Pharmacology and Graduate Program in Neuroscience, University of Minnesota, Minneapolis MN 55455 and <sup>2</sup>School of Pharmacy, Memorial University, St. Johns, Newfoundland, Canada A1B 3V6. Normally, A-fiber input neither signals nociception nor elicits wind-up (the temporal summation of slow synaptic potentials evoked by repetitive noxious stimulation). However, inappropriate nociception, termed allodynia, accompanies 1) neuropathic states and 2) the acute blockade of spinal glycine receptors with intrathecal (i.t.) strychnine. Thus, light tactile stimulation provokes nocifensive behaviours in conscious rats, and cardiovascular/withdrawal responses in anesthetized rats, comparable to those evoked by noxious thermal, mechanical or chemical stimulation without strychnine. To test the hypothesis that wind-up accompanies these abnormal behavioral and autonomic responses, we characterized the responses of spinal cord neurons to repeated brushing in the peripheral receptive field, before and after the iontophoretic application of strychnine. Extracellular single neuron recordings were made in urethane-anesthetized (1.2 g/kg initial dose, i.p.) male Sprague-Dawley rats (400-500 g). Seven-barreled iontophoretic glass micropipettes were used to record single-unit action potentials through the low impedance (1-3 MW) carbon fiber center barrel and drugs delivered from the surrounding outer barrels: strychnine HCl 10 mM in 190 mM NaCl (pH 4.0), 100 mM N-methyl-D-aspartate Na (NMDA) in 100 mM NaCl (pH 8.0), 10 mM (R,S)- $\alpha$ -amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA) in 190 mM NaCl (pH 8.0). Recordings were made from dorsal horn neurons (L3-L5) responding to noxious and/or innocuous (brush) and noxious (pinch, squeeze) stimuli applied to the ipsilateral hind paw receptive fields. Most low threshold neurons displayed wind-up to repeated A-fiber activation by natural innocuous stimulation. Fewer than half of the wide dynamic range (multireceptive) neurons showed increasing responses to repeated activation. We interpret these results to indicate that the prohibition of wind-up in response to non-noxious stimulation is dependent on glycine. When glycine transmission is blocked, these compensatory changes fail to occur, producing wind-up in the absence of nociceptive primary afferent fiber recruitment. (Supported by NIDA grant R01-DA-04274 to GLW and MRC of Canada to CL.)

**ELECTROPHYSIOLOGICAL EVIDENCE FOR CANNABINOID-MODULATION OF SPINAL NOCICEPTIVE PROCESSING.** A.G. Hohmann, K. Tsou and J.M. Walker. Schnier Research Laboratory, Department of Psychology, Brown University, Providence, RI 02912.

Electrophysiological methods were used to study the role of cannabinoid receptors in spinal nociceptive processing and to determine whether these effects are mediated by direct or indirect actions in the spinal dorsal horn. Extracellular recordings were obtained from the lumbar dorsal horn of urethane anesthetized rats. Noxious thermal stimulation was applied with a Peltier device to regions of the ipsilateral hindpaw corresponding to the receptive field of isolated WDR neurons. Both the classical cannabinoid CP55,940 (125 µg/kg, i.v.) and the non-classical cannabinoid WIN 55,212-2 (125 µg/kg, i.v.) suppressed noxious heat-evoked activity. The suppression of noxious heat-evoked activity was blocked by pretreatment with SR141716A (1 mg/kg, i.v.), a competitive antagonist for the central cannabinoid receptor. Intravenous administration of either vehicle or the receptor-inactive enantiomer WIN55,212-3 (125 µg/kg) failed to alter noxious heat-evoked activity. A subsequent experiment was conducted to determine the site of action for these effects. Intraventricular administration of WIN55,212-2 suppressed noxious heat-evoked activity in lumbar dorsal horn neurons of intact animals. By contrast, intraventricular administration of the enantiomer of the active compound did not differ from treatment with vehicle. These results are consistent with previous work suggesting that cannabinoid-induced suppression of noxious heat-evoked activity is attenuated following spinal transection. The results of these experiments, taken together, suggest that cannabinoids selectively modulate the activity of nociceptive neurons via actions at central cannabinoid receptors. These data also provide converging lines of evidence for a role of descending antinociceptive mechanisms in cannabinoid-modulation of spinal nociceptive processing.

**CP 55,940 PRODUCES ANTINOCICEPTION THROUGH A CANNABINOID RECEPTOR MECHANISM IN THE BRAIN.** A.H. Lichtman\*, K.R. Dimen, L.A. Showalter, and B.R. Martin, P.O. Box 980613, Dept. Pharmacol. & Toxicol., Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

The observation that the potent cannabinoid agonist CP 55,940 injected into the periaqueductal gray (PAG) of the rat elicits an antinociceptive response that is pertussis toxin sensitive and exhibits enantioselectivity suggests a cannabinoid receptor mechanism of action. In the present study, the competitive cannabinoid antagonist SR 141716A was employed to test whether cannabinoid-induced antinociception is mediated through a specific receptor mechanism. Male Sprague Dawley rats, implanted with cannulae aimed at either the lateral ventricle or the ventrolateral PAG, were given microinjections of SR 141716A or DMSO vehicle 10 min before CP 55,940 or DMSO and then assessed in the tail-flick test to radiant heat. As previously reported, CP-55,940 produced antinociception when administered into both the ventricle (ED<sub>50</sub>=50 µg) and the PAG (ED<sub>50</sub>=20 µg). Intracerebroventricular administration of SR 141716A at a dose of 100 µg shifted the ED<sub>50</sub> value of CP 55,940 from 22 to 46 µg and 300 µg of the antagonist completely blocked the antinociceptive effects of CP 55,940. In contrast, SR 141716A failed to attenuate the antinociceptive effects of morphine (10 or 20 µg). In the PAG, SR 141716A (30 µg) antagonized the antinociceptive effects of CP 55,940. These results provide strong evidence that cannabinoids produce antinociception through a receptor mechanism of action. Supported by NIDA grants DA-08387 and DA-03672.

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS

## 209.1

**GDNF KNOCKOUT MICE DIED WITHIN 24 HOURS AFTER BIRTH, DISPLAY RENAL AGENESIS, ABSENCE OF ENTERIC NEURONS, REDUCTION IN MOTONEURON NUMBERS AND NORMAL COMPLEMENT OF MIDBRAIN DOPAMINERGIC NEURONS.** J. Silos-Santiago\*, M. Sánchez\*, J. Frisén\*, B. He\*, M. Barbacid\*. Dept. of Molecular Biology, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08543; \*Centro de Biología Molecular, C.S.I.C., Madrid, Spain.

The glial cell line-derived neurotrophic factor (GDNF), promotes the survival of midbrain dopaminergic neurons *in vivo* and *in vitro*. Furthermore, protects dopaminergic, noradrenergic and motor neurons from degeneration paradigms. And similarly to other growth factors of the neurotrophin family GDNF is also a potent survival factor for embryonic motoneurons, and for sensory and autonomic neurons. These results have suggested that GDNF may be a candidate for the treatment of degenerative diseases. To analyze the role of GDNF during the development and maintenance of the nervous system, we have generated a GDNF null mice. These knockout mice, die within the first 24 hours of life due to renal agenesis. Within the nervous system, there is absence of enteric neurons and a reduction in the number of trigeminal and spinal motoneurons. However, we did not find changes in the number of TH positive neurons in the midbrain. These data indicate that GDNF is a survival factor for enteric neurons and for certain subpopulation of motoneurons, and also suggest that GDNF is not a survival factor for dopaminergic neurons, at least during embryonic development.

## 209.3

**DEMONSTRATION OF NEUROTROPHIN 3 AS A TARGET-DERIVED NEUROTROPHIC FACTOR FOR RAT SYMPATHETIC NEURONS** X.-F. Zhou\*, Z.-W. Oj and R. A. Rush, Department of Physiology and Centre for Neuroscience, Flinders University of South Australia, Australia.

In a previous study using an antiserum specific for neurotrophin 3 (NT3) *in vivo*, we have demonstrated that endogenous NT3 is required for the survival of most sympathetic neurons in postnatal rats (Zhou and Rush, J. Neurosci. 15: 6521-30, 1995). The mechanisms underlying this NT3 action on sympathetic neurons, however, is not known. Whether NT3 is a target-derived factor like NGF or acts in an autocrine fashion is not determined. In the present study in rats, using immunohistochemical and reverse transcription-polymerase chain reaction techniques, we have demonstrated that NT3-mRNA is abundantly expressed in many sympathetic effector tissues including mesenteric arteries, heart, salivary gland and kidney, but it is hardly detectable in adult superior cervical ganglia (SCG). The expression of NT3-mRNA in these tissues is developmentally regulated and increases with age in atrium, salivary gland and mesenteric artery. The levels of NT3-mRNA in effector tissues are highest in densely innervated tissues such as the mesenteric arteries and lowest within the SCG. Almost all sympathetic neurons are immunoreactive for both the NT3 high affinity receptor TrkC and the NGF receptor TrkA. Sympathetic neurons accumulate NT3-immunoreactivity (ir) which is abolished by administration of NT3 antibodies *in vivo* or axotomy of postganglionic neurons. Furthermore, NT3-ir accumulates on the distal but not the proximal side of a lesion on the internal carotid nerve as early as 3 hours post-constriction, indicating endogenous NT3 is retrogradely transported by sympathetic neurons. These studies provide evidence indicating that NT3 acts in parallel with NGF as a target-derived neurotrophic factor for sympathetic neurons both during development and in adult animals.

## 209.2

**PHARMACOLOGICAL STUDIES OF GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) ON ADULT MOTONEURONS IN VIVO.** Q. Yan\*, C.R. Matheson, O.T. Lopez, J.L. Ulrich, A.A. Welcher, and E. Collins. Department of Neuroscience, Amgen Inc., Thousand Oaks, CA 91320.

Motoneurons require neurotrophic factors for their survival and maintenance of function during development and in adulthood. Recent evidence indicates that GDNF is a potent trophic factor for neonatal as well as lesioned adult motoneurons. In this study, we have examined if adult motoneurons can retrogradely transport exogenous GDNF and whether normal un-lesioned adult motoneurons are responsive to GDNF. We found that adult spinal motoneurons readily retrogradely transported <sup>125</sup>I-GDNF in a receptor-mediated fashion after injection into the sciatic nerve. Systemic administration of GDNF resulted in a dose-dependent up-regulation of CGRP mRNA level in both normal and axotomized facial motoneurons. GDNF treatment did not affect the choline acetyltransferase immunoreactivity (ChAT IR) in the normal motoneurons but did attenuate the axotomy-induced decrease of ChAT IR. Using CGRP and ChAT expression levels as endpoints, we compared the effect of varying the frequency or routes of administration of GDNF treatment. We found that a subcutaneous (sc) daily bolus was better than higher but less frequent dose, and sc infusion was better than sc bolus or iv bolus. We also found that intracerebral ventricle infusion, as an approximation of intrathecal delivery of GDNF, was the most effective way to influence adult facial motoneurons.

This study is supported by Amgen Inc.

## 209.4

**OVEREXPRESSION OF NT-3 IN MUSCLE STIMULATES THE FORMATION OF SUPERNUMERARY MUSCLE SPINDLES** D.E. Wright\*, L. Zhou, J. Harding, and W.D. Snider. CNSI, Washington Univ., St. Louis, MO, 63110.

Neurotrophin-3 (NT-3) is required for the survival of primary sensory neurons mediating the sense of proprioception. Remarkably, muscle spindles never develop in NT-3 deficient animals, demonstrating that these sensory end-organs are also directly or indirectly regulated by NT-3. To further examine this issue, we examined neurotrophin receptor expression in developing myotubes and generated transgenic mice that overexpress NT-3 in muscle. We show that trkC, the signaling receptor for NT-3 is not expressed by myotubes or developing spindles, suggesting no direct effect of NT-3 on spindle formation. To overexpress NT-3 in muscle, fertilized mouse embryos were microinjected with a construct containing an NT-3 cDNA under the control of the muscle specific promoter myogenin (Myo/NT-3 mice). In Myo/NT-3 mice, increased levels of NT-3 mRNA expression are apparent in developing muscle by embryonic day (E) 12. The elevated NT-3 expression persists for at least two weeks postnatally and is detectable in both extrafusal and intrafusal muscle fibers. To assess the consequence of increased levels of NT-3 on spindle formation, the number of spindles were counted in two hindlimb muscles. Myo/NT-3 mice have three times the normal number of spindles in hindlimb muscles. The supernumerary spindles have the standard complement of intrafusal fibers and are positioned adjacent to nerves in the hilum region of the muscle. Our results that spindle numbers are altered in response to altered NT-3 levels is consistent with findings in NT-3 heterozygote null mutant mice (+/-) which have 50% of spindles in the soleus muscle (Ernfors et al., 1994). To determine whether the effects of NT-3 on spindle number result from proprioceptive neuron survival and/or axonal branching, the number of proprioceptive neurons were examined. Myo/NT-3 mice have a 65% increase in the number of DRG neurons that express parvalbumin mRNA, a marker for proprioceptive neurons. Conversely, NT-3 (+/-) mice have a 50% loss of parvalbumin (+) DRG neurons. Together, these results reveal that levels of NT-3 in muscle regulate the development and number of muscle spindles. We provide evidence that this regulation is indirect and due in part to effects on proprioceptive neuron survival. Supported by NIH.

## 209.5

**DELETION OF THE  $p75^{\text{NTR}}$  GENE ATTENUATES SEPTAL CHOLINERGIC CELL LOSS IN MICE HETEROZYGOUS FOR A DELETION OF THE NGF GENE.** H. Sauer, M.C. Nishimura, H.S. Phillips\* Dept. of Neuroscience, Genentech, Inc., 390 Point San Bruno Blvd., South San Francisco CA 94080.

Mice heterozygous for a targeted disruption of the *NGF* gene display atrophy and a partial loss of medial septal cholinergic neurons, and a functional impairment in spatial learning tasks. This is consistent with reduced brain tissue levels of NGF and NGF mRNA (Chen *et al.*, Soc. Neurosci. Abstr. 19, 1683). The present study was undertaken in order to investigate the role of the  $p75$  low affinity neurotrophin receptor ( $p75$ ) in mediating septal cholinergic cell loss in mice displaying a partial NGF depletion.

By cross-breeding mice heterozygous for a deletion of the *p75*-gene with mice heterozygous for the disruption of the *NGF* gene, the following genotypes were obtained: ( $p75^{+/+}; NGF^{+/+}$ ), ( $p75^{+/+}; NGF^{-/-}$ ), ( $p75^{-/-}; NGF^{+/+}$ ), ( $p75^{-/-}; NGF^{-/-}$ ). Mice were perfused at 3 months of age and serial sections through the septum were processed for choline acetyltransferase (ChAT) immunocytochemistry.

In  $p75$  wild-type mice we confirmed that the *NGF*<sup>-/-</sup> genotype results in a partial decrease in the total number of ChAT-positive septal neurons ( $866 \pm 36$ ;  $n=14$ ) when compared to *NGF*<sup>+/+</sup> mice ( $1058 \pm 112$ ;  $n=7$ ;  $p<0.05$ ). Disruption of the *p75* gene led to a total attenuation of septal ChAT-positive cell loss in *NGF*<sup>+/+</sup> mice ( $1193 \pm 38$ ;  $n=13$ ;  $p<0.01$  for  $p75^{-/-}; NGF^{+/+}$  vs.  $p75^{+/+}; NGF^{+/+}$ ). In addition, these mice displayed no significant cell loss compared to their *NGF*<sup>+/+</sup> littermates ( $1240 \pm 73$ ;  $n=7$ ). These findings suggest that the  $p75$  receptor plays an important role in mediating septal cholinergic cell loss after partial NGF depletion.

## 209.7

**AMYLOID PRECURSOR PROTEIN POTENTIATES THE NEUROTROPHIC ACTIVITY OF NGF THROUGH THE INSULIN SIGNALING PATHWAY.** WC Wallace\*, CA Akar, HK Kole, JM Egan, and B. Wolozin. GRC/NIA, Baltimore, MD and NIMH, Bethesda, MD.

Cortical amyloid precursor protein (APP) is induced and secreted in response to subcortical lesions of cholinergic innervation. To understand the physiological role of induced APP, we have characterized its neurotrophic activity on PC12 cells. APP (50-1000 pM) induced outgrowth of neurites. At lower concentrations, (10-50 pM), APP also synergistically potentiated the neurotrophic effects of NGF either by simultaneous addition of the two factors or by a priming pretreatment with APP. This neurotrophic activity was reduced by tyrosine kinase inhibitors. Insulin receptor substrate-1 (IRS-1) and mitogen activated kinases (ERKs 1 and 2) were identified among the APP-stimulated tyrosine phosphorylated proteins. In contrast, neither phospholipase- $\gamma$  nor *trkA* exhibited such phosphorylations. In addition, a role for phosphatidylinositol 3-kinase was implicated by wortmannin inhibition. The potentiation of NGF activity was reflected in a corresponding synergistic elevation in the tyrosine phosphorylation of IRS-1. The pattern of tyrosine phosphorylations indicates a signal transduction pathway that is distinct from the NGF/*trkA* and suggests that APP potentiates the responsiveness of neurons to neurotrophins via the insulin signaling pathway. This potentiation may facilitate neuronal recovery following injury. (Supported by IRP, NIA.)

**TRKB FUNCTION IN THE DEVELOPING XENOPUS RETINA.** Z.Z. Liu and F.F. Eide\*. Department of Neurology, University of Chicago, Chicago, IL 60637.

Over-expression of a *trkB* ATP binding mutant receptor in early blastomere-injected *Xenopus* revealed a novel role for this receptor in early retinal development. Severely-affected mutants showed near-complete loss of the laminar organization of the retina, with arrested development of neural and non-neural components of retina. Co-injection of wildtype *trkB* receptors rescued eye abnormalities. *In situ* hybridization demonstrated the precise regulation of *trkB* mRNA in germinal retinal neuroepithelium, differentiating pigment epithelium, and developing photoreceptors. BDNF stimulation of dissociated optic vesicles confirmed roles in early retinal differentiation.

## 209.6

**NEURON-SPECIFIC REGULATION OF EXPRESSION OF THE NGF GENE IN THE BRAIN.** M. Cartwright<sup>1,2</sup>, P. Isackson<sup>3</sup>, and G. Heinrich<sup>2</sup>. <sup>1</sup> Dept. of Pharmacology and <sup>2</sup> Evans Dept. of Clinical and Research Medicine, Boston Univ. Med. Center Hospital, Boston MA., <sup>3</sup> Mayo Clinic, Jacksonville, FL.

The gene encoding nerve growth factor (NGF) is expressed by neurons in the cortex, thalamic nuclei and the hippocampus. In many neurons, NGF mRNA levels are increased by seizure-induced stimulation of neuronal activity. The increase occurs in two distinct patterns. In cortical neurons the induction is slow, with a peak at 12 h. In contrast, in the dentate granule cells the induction is rapid, peaks at 6 h, returns to base line by 12 h, and peaks again at 24 h (Lauterborn *et al.*, Exp. Neuro. 125, p22, 1994).

To identify the regions of the NGF gene that mediate the transcriptional contribution to this induction, we expressed two previously identified promoters. The NGF sequences extended from -5 kb to +8 in exon 1B and were linked to a human growth hormone gene reporter. Northern blot hybridization analyses demonstrated that the transgene was expressed in the brain. *In situ* hybridization studies revealed that transgene mRNA was present in neurons in the cortex, thalamus and the pyramidal cells of Ammon's horn. Interestingly, the transgene mRNA could not be detected in the granule cells of the dentate gyrus even following kainate induced seizure activity. One explanation for the failure to express in these cells could be that the transgene is lacking critical cis regulatory elements. Alternatively, expression in the dentate granule cells may be mediated by another promoter. The unique rapid and biphasic induction of NGF mRNA in the dentate granule cells is also consistent with transcription initiation from a novel promoter. We have identified NGF transcripts whose 5' ends are consistent with this possibility. Related transcripts were previously considered splicing intermediates of the NGF gene primary transcript (Selby *et al.*, Mol. Cell. Biol. 7:9, p3057, 1987). We detected the presence of these transcripts in mouse hippocampus, cortex, and SMG. This suggests that the regulation of NGF gene expression involves multiple promoters. Supported by NIH RO1 AG10565 (GH).

## 209.8

**BRAIN DERIVED NEUROTROPHIC FACTOR (BDNF) REGULATES STRIATAL DARPP-32 AND ARPP-21 *IN VIVO* AND *IN VITRO*.** S.Ivkovic, O.Polonskaia, and M.E.Ehrlich\*. Psychiatry and Cell Biology, NYU Med.Ctr., NY,10016.

DARPP-32 and ARPP-21 are dopamine and cyclic AMP-regulated phosphoproteins and are coordinately expressed in most of the striatal dopaminergic medium size spiny neurons (MSNs). Dopamine regulates the phosphorylation state of DARPP-32 and ARPP-21, but does not regulate their transcription. DARPP-32/ARPP-21 are first detectable in post-migrational neurons, and are phenotypic markers of MSN maturation. BDNF has trophic effects on striatal neurons *in vitro* (Mizuno *et al.*, 1994; Ventimiglia *et al.*, 1995), and a null mutation in the BDNF gene produces a decrease in MSN calbindin expression (Jones *et al.*, 1994). We demonstrate that immunocytochemical levels of DARPP-32 and ARPP-21 are markedly decreased in postnatal day 0 (P0) and P10 BDNF<sup>-/-</sup> animals (provided by Drs. L. Reichardt and I. Farinas). In dissociated, densely plated ( $1 \times 10^6$  cells/ml) cultures derived from embryonic day 13 (E13) and E15 mice, addition of BDNF (50-100 ng/ml) to serum-free media increases the number of DARPP-32-positive cells 5 and 10-fold respectively after one day *in vitro* (DIV). This effect is apparent at 12 hours, and is abolished by actinomycin D (2  $\mu$ g/ml). ARPP-21 is not detectable until 5-7 DIV, at which time the number of immunopositive cells is increased greater than 10-fold as a consequence of the addition of BDNF. These data suggest that BDNF regulates DARPP-32 and ARPP-21 transcription. We are also analyzing proliferative and survival effects of BDNF on DARPP-32/ARPP-21-positive MSNs. (NIMH R29-47028 and K02-00945)

## 209.10

**NEUROTROPHINS PRODUCED IN THE THALAMUS MAY BE NECESSARY FOR THALAMIC GROWTH AND SURVIVAL BEFORE THALAMOCORTICAL AXONS ARE ESTABLISHED.** R.B.Lotto\* and D.J.Price, Dept. of Physiol., Univ. Med. Sch., Teviot Place, Edinburgh EH8 9AG, U.K.

The onset of naturally-occurring cell death in the thalamus coincides with the arrival of thalamocortical axons to the developing cortex, which is around embryonic day 16 (E16) in mice. We showed that, before E16, dissociated thalamic neurons survive and grow in high density, serum free, primary cultures. Immunocytochemistry revealed that they express all the neurotrophins (NT) and their high affinity tyrosine kinase receptors. We added K252a, a selective inhibitor of NT receptors (in the nM range), to these high density cultures. This reduced thalamic growth and survival. In low density cultures, most E16 thalamic neurons die, but their growth and survival increase with the addition of either thalamic conditioned medium or any of the NTs. These data provide the first evidence that a battery of NTs have direct trophic effects on thalamic neurons, suggest that they act in an autocrine fashion early in development, and support the notion of trophic redundancy in the CNS.

Supported by the MRC and The Wellcome Trust

## 209.11

DEPOLARIZATION PROMOTES SPIRAL GANGLION NEURON SURVIVAL VIA MULTIPLE MECHANISMS INCLUDING AN AUTOCRINE NEUROTROPHIC RESPONSE. **M.R. Hansen**, and **S.H. Green\***. Depts. of Biological Sciences & Otolaryngology, University of Iowa, Iowa City, IA 52242.

Previous studies have shown that BDNF, NT-3, and permeant cAMP analogs promote spiral ganglion neuron (SGN) survival *in vitro* in an additive manner; depolarization promotes survival with even greater efficacy. *In situ* hybridization and immunohistochemistry show up-regulation of BDNF and NT-3 synthesis within depolarized neurons *in vitro*. Addition of TrkB-IgG fusion protein abolishes the trophic effect of BDNF and partially inhibits the trophic effect of NT-3; TrkC-IgG has no effect with BDNF but abolishes the trophic effect of NT-3. The Trk-IgG fusion proteins, individually or in combination, inhibit the trophic effect of depolarization by only ~30%. The MEK inhibitor PD098059 abolishes trophic support by neurotrophins but inhibits the trophic effect of depolarization by only ~30%. A combination of PD098059 and Trk-IgG proteins inhibits survival only slightly more than do Trk-IgG proteins or PD098059 alone. The trophic effect of permeant cAMP analogs is unaffected by the MEK inhibitor and by Trk-IgG proteins. These data indicate that neurotrophins promote survival via the Ras-ERK pathway and that depolarization promotes survival, in part, by inducing an autocrine neurotrophic pathway and, in part, by a distinct pathway not involving ERK activation. Trophic signaling by cAMP defines another pathway. This latter pathway also appears to be recruited by depolarization. Rp-cAMPS, a specific PKA inhibitor, abolishes cAMP-dependent survival but has no effect with neurotrophins. Rp-cAMPS inhibits depolarization-dependent survival by ~30%; this inhibition is additive with that of Trk-IgG proteins. Supported by AOS and NIH training grant DC00040.

## 209.12

PARACRINE INTERACTIONS BETWEEN NEURONS AND GLIAL CELLS MEDIATED BY BDNF. **C. Kalcheim\***, **D. Shelton#** and **M. Pruginin**. Dept. of Anat. and Cell Biol.-Hebrew Univ. of Jerusalem-Hadassah Med. School-Jerusalem 91120-P.O.B. 12272. Israel and #Dept. of Neurosciences, Genentech, Inc. 460 Point San Bruno Boulevard, South San Francisco, CA 94080, USA

Avian sensory neurons synthesize primarily BDNF, to a lesser extent NT-3, but no detectable NGF, raising the possibility that specific neurotrophins mediate local activities of paracrine or autocrine type in addition to well known target-derived effects. We have tested the hypothesis that neuron-derived BDNF mediates a neuronal effect on glial differentiation.

Coculturing neurons with developing glial cells of quail DRG stimulates within a day a 2.5-fold increase in the proportion of nonneuronal cells that express the constitutive glial marker SMP when compared to glial cultures devoid of neurons. This effect was found to be mediated by BDNF because incubation of mixed neuron-glia cultures with a specific trkB immunoadhesin that sequesters BDNF, but not with trkA or trkC immunoadhesins, abolishes this stimulation. Furthermore, the effect of the neurons can be mimicked by treatment of glial cultures with soluble BDNF that stimulates the conversion of SMP-negative glial cells into cells that express the SMP phenotype with no effect on their survival or proliferation. That BDNF is the endogenous neuron-derived factor affecting glial development in culture was confirmed by the observation that BDNF immunoreactive protein is expressed by cultured sensory neurons, but not by the ganglionic satellite cells. Preliminary evidence suggests that the p75 receptor is likely to mediate the BDNF-dependent upregulation of SMP, because specific neutralization of p75 abolishes neuronal stimulation of SMP expression. These results show for the first time a local, paracrine role for BDNF in mediating the action of ganglionic neurons on differentiation of adjacent satellite cells.

## LONG-TERM POTENTIATION: PHYSIOLOGY I

## 210.1

HIGH LEVELS OF CALCINEURIN INHIBITED ADENYLYL CYCLASE TYPE 9 (AC9) IN HIPPOCAMPAL PROJECTION NEURONS. **E. A. Antoni\***, **M. Palkovits**, **R. Rosie**, **S. M. Smith**, **J. Simpson**, **G. Fink**, **J. M. Paterson**. MRC Brain Metabolism Unit, Edinburgh, U.K., Lab Cell Biology, NIMH, NIH, Bethesda, MD.

Long-term potentiation in the hippocampus involves cAMP signaling with  $Ca^{2+}$ /calmodulin activated adenylyl cyclases (types 1 and 8) playing a key role. Adenylyl cyclases inhibited by  $Ca^{2+}$  (AC5 and AC6) have not been demonstrated in hippocampal neurons, although AC5 is prominent in rat striatum. Hippocampal long-term depression involves calcineurin, a  $Ca^{2+}$ /calmodulin activated protein phosphatase, that also controls the activity of AC9. In the present study riboprobe and specific antisera raised against the C- and N-terminal portions of AC9 were used to examine the distribution of this cyclase in rodent brain. Northern analysis indicated the presence of a single species of 9kb RNA in mouse striatum and whole brain extracts. Western blots reveal the presence of a single 160K immunoreactive band in hippocampus and hypothalamus, radioimmunoassay suggests that the concentration of adenylyl cyclase in membranes from whole hippocampus is c.190 ng/mg protein. *In situ* hybridization showed a very intensive signal in all hippocampal structures including the anterior hippocampus, induseum griseum, pyramidal layers of CA1, CA2, CA3, the dentate gyrus as well as the subiculum. No clear indication of RNA signal in hippocampal interneurons was found. Hippocampal pyramidal neurons contain high levels of adrenal corticosteroid receptors and AC9 is important for corticosteroid feedback regulation of adenylohypophyseal corticotrope cells. In this respect it is of note that in addition to hippocampus, areas thought to be important for corticosteroid feedback action in the brain such as the hypothalamic paraventricular nucleus, the prefrontal cortex, the cingulate cortex, the amygdala and the anterodorsal thalamic nucleus all contained relatively high levels of AC9 mRNA, although none of these regions matched the hippocampus in intensity. It is proposed that AC9 in hippocampal pyramidal neurons may contribute to long-term changes in neurotransmission and is in all probability co-localized in the same pyramidal neurons that produce AC1 and AC9. Taken together with the functional analysis of pituitary corticotropes, the overall distribution of AC9 in the rodent brain supports the hypothesis that it has an important role in corticosteroid modulation of neurotransmission.

## 210.3

THE ROLE OF CALCIUM IN HOMOSYNAPTIC LTD AND LTP IN HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. **B. R. Christie\***, and **D. Johnston** Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Hippocampal neurons exhibit various forms of synaptic plasticity, including long-term potentiation (LTP) and long-term depression (LTD). The induction of LTD depends, among other things, upon a rise in postsynaptic  $[Ca^{2+}]_i$ . To investigate the changes in  $[Ca^{2+}]_i$  during LTD, we have combined fura-2 imaging with whole-cell recordings of visually identified CA1 neurons.

Hippocampal slices (400  $\mu$ m) were obtained from 2-3 week old rats using standard procedures and maintained at 32°C in a submerged chamber. To measure fluorescence changes in intracellular  $Ca^{2+}$ , fura-2 (100  $\mu$ M) was included in the pipette solution, and relative changes in  $\Delta F/F$  were measured using a cooled CCD camera in sequential frame transfer mode (25 ms frame interval). Whole-cell recordings were made from CA1 neurons located within 50  $\mu$ m of the slice surface. Following a 10-20 min baseline period, cells were synaptically activated at 1-50 Hz for a total of 900 pulses. In all cases, EPSPs subthreshold for action potential generation were paired with somatically generated action potentials and changes in fluorescence were monitored. LTD, which lasted at least 30 min, occurred in neurons that received 1-20 Hz stimuli, while LTP was produced in cells administered 30-50 Hz stimuli. The transition from LTD to LTP was accompanied by increased  $[Ca^{2+}]_i$  in both the soma and dendritic regions of recorded cells. Both the LTD and the LTP were NMDA-dependent, but LTD induction could also be reduced or prevented with L-, R-, and T-subtype voltage-gated  $Ca^{2+}$  channel antagonists. These data suggest that the  $Ca^{2+}$  entry caused by back-propagating action potentials is involved in the induction and maintenance of both hippocampal LTD and LTP (MH44754, MH48432, NS11535, NSERC103103).

## 210.2

POSTSYNAPTIC  $Ca^{2+}$ -DEPENDENT PROTEIN KINASE AND PHOSPHATASE ACTIVITIES DYNAMICALLY CONTROLLING SYNAPTIC STRENGTH THROUGH INTRACELLULAR  $Ca^{2+}$  SIGNALING. **JIN-HUI WANG\*** & **PAUL T. KELLY**, Department of Neurobiology and Anatomy, University of Texas Medical School at Houston, Texas 77030.

The role of protein phosphorylation and dephosphorylation in regulating synaptic transmission and synaptic plasticity was examined by postsynaptic injections of modulators of CaM-KII and PKC or calcineurin (CaN) in area CA1 of adult rat hippocampal slices. Postsynaptic injections of pseudosubstrate inhibitors of PKC plus CaMKII [PKC(19-31)/CaMKII(281-302)] did not affect basal synaptic transmission in naive pathways, but significantly attenuated the maintenance of LTP in pre-tetanized pathways (254±37% vs. 133±22%). Postsynaptic injections of a specific CaN inhibitor (FK-506) induced significant synaptic potentiation in pre-tetanized (239±20% vs. 174±17%) and naive pathways (196±15% vs. baseline values 100%). These results indicate that postsynaptic PKC and CaM-KII activities are essential for LTP maintenance, but CaN activity limits synaptic strength at a stable level during basal and potentiated synaptic transmission (i.e., the dynamic balance among their activities that sets synaptic strength is dominated by CaN). To elucidate the postsynaptic mechanisms responsible for synaptic potentiation induced by CaN inhibitors, a variety of agents including BAPTA, a calmodulin-binding peptide, PKC(19-31)/CaMKII(281-302), or heparin/dantrolene (inhibitors of  $Ca^{2+}$  release from intracellular stores) were co-injected with FK-506. Each agent significantly attenuated FK-506-induced synaptic potentiation. Our results indicate that the down-regulation of synaptic strength by postsynaptic CaN activity is mediated by decreasing intracellular  $Ca^{2+}$  signaling and the activity of downstream components which contribute to the balance among protein kinases and phosphatases.

## 210.4

THE ROLE OF DENDRITIC ACTION POTENTIALS IN THE MODULATION OF SYNAPTIC EFFICACY. **J. Magee\*** and **D. Johnston** Division of Neuroscience, Baylor College of Med., Houston, TX 77030

Neuronal dendrites are the primary site for the coordination and storage of synaptic information. Dendritic voltage-gated  $Na^{+}$  channels allow axonally-generated action potentials to propagate back into the dendrites and activate voltage-gated  $Ca^{2+}$  channels. We have used whole-cell patch-clamp techniques in conjunction with high-speed fluorescence imaging to determine the role of back-propagating action potentials in the induction of long-term changes in synaptic efficacy in CA1 pyramidal neurons. A subthreshold, theta-like, synaptic stimulation was delivered to dendrites > 200  $\mu$ m from soma. When subthreshold trains of EPSPs were delivered, only slight (<3%  $\Delta F/F$ ) increases in dendritic  $[Ca^{2+}]_i$  and no significant changes in synaptic efficacy were observed. When subthreshold EPSP trains were paired with 5-15 action potentials, dendritic  $[Ca^{2+}]_i$  was significantly elevated (>10%  $\Delta F/F$ ) and a long lasting increase in synaptic efficacy observed. The increase in EPSP amplitude (~250%) peaked ~20 mins after theta stimulation and was observed for > 1 hr. Trains of action potentials themselves did not induce any long-term changes in EPSP amplitude. To confirm that dendritic action potentials were required for synaptic plasticity, axonal spikes were blocked from propagating into the dendrites by focal application of 10  $\mu$ M TTX to the proximal dendritic arbor. Large amplitude  $Ca^{2+}$  transients and action potentials could only be recorded in segments of the neuron that are proximal to the TTX block. Small spikes that produce no  $Ca^{2+}$  transients were recorded from the dendritic regions located distal to the block. Pairing of subthreshold EPSP trains and non-backpropagating spikes did not result in any significant change in EPSP amplitude, whereas, subsequent pairing of EPSPs with back-propagating spikes did result in a long lasting increase. These data provide evidence that spike-dependent elevation in dendritic  $[Ca^{2+}]_i$  provides a feedback signal to the synapses that an output of the neuron has occurred.(NS11535,MH48432,MH44754)

## 210.5

## CREB AS A STIMULUS DURATION-DEPENDENT SWITCH FOR SYNAPSE-TO-NUCLEUS SIGNALING.

H. Bito\*, K. Deisseroth, and R. W. Tsien. Dept. of Mol. Cell. Physiology, Stanford University, Stanford, CA 94305-5426.

Using cultured hippocampal neurons, we studied the requirement for synaptic activity in triggering CRE-mediated gene expression. We also investigated in parallel the pattern of nuclear CREB Ser-133 phosphorylation and dephosphorylation at the single cell level. A prolonged (180s), but not a short (18s), train of synaptic stimulation at 5Hz was found to efficiently induce a significant increase in the immunoreactivity of c-Fos and SS-14, two genes with prototypical CRE promoters. Both stimuli, short or long, were equally effective in inducing nuclear CREB phosphorylation, but prolonged stimulation favored slower recovery from phosphorylation. Detailed and quantitative analyses revealed that a CaM kinase kinase/CaMKIV cascade and CaN/PP1 regulated the phosphorylation and dephosphorylation of CREB in a stimulus duration-dependent manner. CRE-regulated gene expression was always associated with the persistence of nuclear pCREB, rather than the induction of pCREB itself. Further experiments suggest that CaN plays an essential role in selecting the signals capable of eliciting CRE-mediated gene expression and in shaping the stimulus duration-dependence of this switch. Supported by NIMH Silvio Conte Research Center, Mathers Foundation (RWT), and fellowships from HFSP (HB) and MSTP (KD).

## 210.7

DIFFERENT  $Ca^{2+}$  SIGNAL AMPLITUDES ARE REQUIRED FOR THE INDUCTION OF LTP AND LTD IN PYRAMIDAL CELLS OF THE RAT VISUAL CORTEX. C. Hansel\*, A. Artola<sup>1</sup> and W. Singer. Max-Planck-Institute for Brain Research, Deutschordenstr. 46, 60496 Frankfurt, FRG. <sup>1</sup>Present address: Dept. of Neurobiology, ETH-Hoenggerberg, CH-8093 Zürich.

Previously, we have shown that in layer II/III pyramidal cells of the rat visual cortex the induction of LTP is associated with higher rises of dendritic  $[Ca^{2+}]_i$  than the induction of LTD (Hansel et al., *Soc. Neurosci. Abstr.* 21: 711.3, 1995). This finding was based on  $Ca^{2+}$  measurements using the fluorescent  $Ca^{2+}$  indicator fura-2. As the  $Ca^{2+}$  buffering capacity of the dye might influence the induction of LTP or LTD we performed the adjustment of LTP and LTD inducing tetanization protocols and the measurements of associated  $Ca^{2+}$  signals in different groups of cells to avoid false correlations. Using  $Ca^{2+}$  chelators we now directly tested the functional significance of the observed difference in the  $Ca^{2+}$  signal amplitude and its potency to determine the direction of synaptic gain change. Neocortical slices (200-250  $\mu$ m) were obtained from rats aged 5-7 weeks. Sharp microelectrodes were used to measure responses to stimulation in either layer IV (conditioned pathway) or lateral layer II (control pathway). As previously reported, LTP was induced in 6 out of 7 cells by pairing of five 50 Hz stimulus trains in layer IV with a postsynaptic 20 mV-depolarization ( $[Mg^{2+}]_o = 1$  mM). The application of the same protocol induced LTD in 3 out of 5 cells when the cells were filled with fura-2 and induced LTD in 4 out of 5 cells when the cells were filled with the non-fluorescent  $Ca^{2+}$  chelator BAPTA (chelator concentration in the electrode tip: 4 mM). In none of the cells LTP was induced. In combination with the previously reported observation that the induction of LTP is associated with stronger  $Ca^{2+}$  elevations than the induction of LTD these results provide compelling evidence for the hypothesis that the amplitude of the postsynaptic  $[Ca^{2+}]_i$  rise is a key factor for the determination of the polarity of synaptic gain changes. This study was supported by the Max-Planck-Society.

## 210.9

## EFFECT OF LONG-TERM POTENTIATION INDUCING STIMULI ON EXPRESSION OF CALCIUM CALMODULIN DEPENDENT KINASE II ISOFORMS, ALPHA AND BETA, AND PROTEIN PHOSPHATASE INHIBITOR 1. L. W. Chiang, K. Deisseroth, R. W. Tsien, and H. Schulman\*. Stanford University School of Medicine, Stanford, CA 94305.

Long-term potentiation (LTP), a stable increase in synaptic strength that can last for days, is sensitive to inhibitors of protein synthesis and RNA transcription. Activity-dependent transcriptional regulation of protein phosphatase inhibitor 1 (INH-1) and calcium/calmodulin-dependent kinase II (CaMKII), signal transduction molecules that modulate postsynaptic responses to presynaptic stimuli, could contribute to long-lasting changes in synaptic transmission. Previously, single-cell PCR experiments demonstrated marked heterogeneity in the relative expression pattern of INH-1,  $\alpha$ - and  $\beta$ -CaMKII isoforms among single CA1 pyramidal neurons in adult rat hippocampal slices. In order to test whether relative transcript levels could have been affected by high frequency stimulation, we measured mRNA levels at various times following LTP-inducing stimuli (3 trains of 18 s at 50 Hz) in cultures of hippocampal neurons. We observed an induction of immediate early genes (*c-fos* and *NGF1a*) by one hour after stimulation that rapidly decays to baseline, and an increase in  $\alpha$ -CaMKII at late times (24 hours). Novel findings were apparent increases in total  $\beta$ -CaMKII transcripts at late times, as well as activity-dependent differential splicing from embryonic ( $\beta_e$  and  $\beta'_e$ ) to adult isoforms ( $\beta$  and  $\beta'$ ). We speculate that differential expression of  $\beta$ -CaMKII could contribute to maintenance of LTP by increasing the affinity of the CaMKII holoenzyme for activation by calcium. This work was funded by a NIMH Silvio Conte Center for Neuroscience Research Grant.

## 210.6

MECHANISMS UNDERLYING THE UNIQUE ROLE OF THE L-TYPE  $Ca^{2+}$  CHANNEL IN SYNAPSE-TO-NUCLEUS SIGNALING.

K. Deisseroth\*, H. Bito, and R. W. Tsien. Department of Molecular and Cellular Physiology, Stanford University Medical School, Stanford, CA 94305-5426.

While many types of voltage-activated  $Ca^{2+}$  channel can be found on the dendrites of mammalian central neurons, we and others have found that L-type  $Ca^{2+}$  channels play a prominent role in signaling leading from the surface membrane to the nucleus. Here we investigate the nature and mechanisms of the involvement of this channel in synaptically-evoked nuclear CREB phosphorylation. L-type blockade with 10  $\mu$ M nimodipine strongly inhibited synaptically-induced CREB phosphorylation while N-type  $Ca^{2+}$  channel inhibition with 1  $\mu$ M  $\omega$ -conotoxin GVIA had no effect, in the presence or absence of additional NMDA receptor blockade with 25  $\mu$ M D-AP5. The comparatively slow activation kinetics of the L-type channel appear to allow the CREB pathway to be selectively responsive to synaptic events. While neither action potentials nor brief (1 ms) voltage-clamp depolarizations could trigger CREB phosphorylation, both synaptic events and slightly longer (5-10 ms) depolarizations succeeded. The brief stimuli failed because insufficient  $Ca^{2+}$  influx occurred through the slowly-activating L-type channels; selectively increasing L-type flux with 5  $\mu$ M S-(+)-Bay K 8644 enabled action potentials to give rise to CREB phosphorylation. On the other hand, the comparatively slow inactivation kinetics of the L-type channel may be important in allowing continued  $Ca^{2+}$  influx and CREB phosphorylation over the long stimulation timescale necessary to give rise to CRE-mediated gene expression. Thus, multiple intrinsic characteristics of the L-type channel appear to make it better suited than the N-type channel to mediate synapse-to-nucleus signalling through CREB. ## 210.8

## KINETICS OF NMDA RECEPTOR ACTIVATION BY CAGED GLUTAMATE IN THE HIPPOCAMPAL SLICE: CONSTRAINING FUNCTIONAL SYNAPTIC GEOMETRY. Z. F. Mainen\* and R. Malinow. Cold Spring Harbor Lab., Cold Spg. Hbr., NY 11724.

The spatiotemporal concentration profile of synaptically released glutamate is central to the physiology of excitatory synapses but is impossible to measure directly. Of particular interest is the possibility that low concentrations of glutamate, sufficient to activate the NMDA receptor but not the lower-affinity AMPA receptor, may "spillover" from one release site to neighboring synapses. To study the non-equilibrium kinetics of glutamate receptor activation at intact synapses, we have used rapid photolysis of caged glutamate during whole-cell recordings from pyramidal neurons in the CA1 region of the hippocampal slice.

Varying the intensity of brief full-field UV light pulses, we find that the decay of the NMDA response (measured at +40 mV in the presence of NBQX and BMI) is sensitive to the amount of glutamate uncaged, with the fastest responses (at the weakest light intensities) being significantly shorter than synaptic responses. Several observations suggest that the decay time reflects primarily a sensitivity of NMDA receptor kinetics to transmitter concentration rather than prolonged activation by slowly-cleared glutamate. The NMDA decay measured at -40 to -60 mV is insensitive to the amount of uncaged glutamate. In addition, the response time course is not affected by the amount of uncaging in the presence of high concentrations of the open channel blocker MK-801, a condition in which the response is expected to approximate the first latency distribution of receptor openings.

These caged glutamate experiments suggest that the decay time of synaptic NMDA responses may be used to quantify the concentration of glutamate by which they were activated. In support, we find that synaptic NMDA responses following a brief tetanus (3-5 pulses, 100 Hz) are slowed compared to single stimuli. However, we find that "silent synapse" responses (responses having NMDA but not AMPA components) have NMDA time courses identical to the NMDA time course for mixed AMPA-NMDA synapses. Furthermore, concentrations of uncaged glutamate large enough to mimic the decay of synaptic NMDA responses are sufficient to activate AMPA receptors. These observations are difficult to reconcile with most scenarios for spillover activation of NMDA receptors.

## 210.10

## CaMKII ACTION ON MICROTUBULES PROMOTES CALCIUM-EVOKED DENDRITIC EXOCYTOSIS. M. Maletic-Savatic\*, T. Koothian and R. Malinow. Cold Spring Harbor Laboratories, Cold Spring Harbor, NY 11724.

We have recently demonstrated that regulated dendritic exocytosis is a  $Ca^{2+}$ - and CaMKII-dependent process which might be involved in long-term potentiation. Here, we wish to test the hypothesis that CaMKII promotes  $Ca^{2+}$ -evoked dendritic exocytosis (CEDE) by action on microtubules. Toward this goal, we have used the quantitative time-lapse imaging of the fluorescent membrane probe FM1-43 to monitor the exocytosis of labeled compartments in cultured hippocampal neurons. Overnight exposure of cultured neurons to 1.5  $\mu$ M FM1-43 preferentially labels dendritic compartments. Exocytosis of these compartments, observed as a robust loss of FM1-43 fluorescence, was induced by a  $Ca^{2+}$  ionophore, A23187. To test the role of microtubules in CEDE, we exposed mature cultured neurons to 2.5  $\mu$ g/mL nocodazole for 30 min at 37°C. A23187-induced exocytosis was completely blocked with nocodazole. To test the association of CaMKII and microtubules in CEDE, we introduced a constitutively active CaMKII into mature cultured neurons via a recombinant vaccinia virus (VV). Spontaneous exocytosis was monitored after overnight culture infection with 10 MOIs of CaMKII-VV. Cultured neurons infected with a  $\beta$ -galactosidase-VV and uninfected cultures served as controls. Spontaneous exocytosis in CaMKII-VV-infected neurons was significantly greater than exocytosis observed in control neurons. This exocytosis was blocked by 2.5  $\mu$ g/mL nocodazole, added to culture medium 30 min before monitoring spontaneous exocytosis. These results indicate that CaMKII activity mediates CEDE via a microtubule-dependent action.

PAIRING-INDUCED LTP IN HIPPOCAMPAL SLICE CULTURES IS NOT STRICTLY INPUT-SPECIFIC. F. Engert and T. Bonhoeffer\*, Max-Planck-Institut für Psychiatrie, 82152 München-Martinsried, FRG.

Several groups have shown that pairing-induced long-term potentiation (LTP) is not specific on the presynaptic fibers: it spreads to neighboring cells which have not participated in the induction procedure (Bonhoeffer et al., '89; Schuman and Madison, '94).

We have now tried to test whether LTP in the Schaffer collateral/CA1 pathway in rat hippocampus is specific on the postsynaptic side, that is whether only the synapses on the stimulated fibers are enhanced or whether other, nearby synapses between other presynaptic elements and the same postsynaptic dendrite are also affected. So far this has mostly been examined by stimulating two separate pathways onto the same postsynaptic cell. However, the spatial resolution of this approach is limited and does not permit rigorous assessment of the specificity of LTP in the tens of micrometer range.

We attempted to achieve our goal as follows: as a first step we blocked voltage activated calcium channels in the entire culture by replacing the standard extracellular solution with a solution containing cadmium and low calcium (0.8 mM) abolishing all normal synaptic transmission. We then re-established synaptic transmission only in a small spot of ~30 µm diameter by using a local superfusion system which applied normal extracellular solution focally to the dendritic tree of an intracellularly recorded postsynaptic neuron. Using this "superfusion spot" like a narrow light beam to search for single groups of synapses we could individually activate small groups of synapses no further apart than 30-40 µm. We then applied the pairing protocol to a first group of synapses (test) while in the neighboring group (control) synaptic transmission was blocked by the cadmium in the extracellular solution.

Moving the superfusion spot - after the pairing procedure - to the control site we observed, to our surprise, that synaptic enhancement at the test-site had also led to substantial enhancement at the control-site. This spread of enhancement occurred only when test and control site were less than 50 µm apart. No increase was observed when the control spot was located more than 100 µm away from the test spot.

These data indicate that there is no strict input-specificity of LTP, at least in hippocampal slice cultures. Rather LTP "spreads" over a relatively short distance to neighboring synapses on the same dendrite even if these synapses were silent during the induction procedure.

## 210.12

ACTIVITY-DEPENDENT ENHANCEMENT AND SUPPRESSION OF LONG-TERM HETEROSYNAPTIC FACILITATION MEDIATES PATHWAY-SPECIFIC PLASTICITY AT CONVERGING INPUTS ON A COMMON TARGET. S. Schacher\*, F. Wu and Z.-Y. Sun, Cntr. Neurobiol. & Behav., Columbia Univ. Coll. of P & S, NYSP, New York, NY 10032.

Activity-dependent modulation of synaptic function with temporal pairing of stimuli is a cellular mechanism for associative conditioning. Although such a mechanism might explain cellular and behavioral changes associated with a single pairing, it is not sufficient to account for pathway-specific plasticity with multiple pairings. To explore the mechanisms associated with cell-specific plasticity at convergent pathways, we examined activity-dependent modulation of 5-HT facilitation of sensorimotor connections of *Aplysia* re-established in cultures that had 2 sensory neurons (SNs) and 1 target L7. Whereas 1X tetanus (20 Hz for 2 sec) or 1X 5-HT evoked only a short-lasting change, a single pairing of the stimuli evoked a significant long-term change only in the SN given the paired stimuli. This change is mediated primarily by a presynaptic mechanism. Repeated (4X) tetanus at 25 min intervals failed to evoke any long-term change, while 4X 5-HT alone evoked a long-term change in both SN connections. By contrast, 4X pairing of tetanus plus 5-HT evoked both a significant increase in the efficacy of the SN connection given the paired stimuli and a significant reduction of the facilitation normally evoked by repeated 5-HT in the other SN connection. These changes involved both an enhancement and a suppression of facilitation; 30 min after the last treatment the efficacy of both unpaired and paired SN connections were enhanced. Moreover, the activity-dependent changes in long-term facilitation appear to be mediated by activity in the motor cell. Both hyperpolarization of L7 and incubation with APV blocked the enhancement and suppression without interfering with long-term facilitation evoked by 5-HT alone. The results suggest that pathway-specific modulation, a feature of long-term synaptic plasticity in many systems, is intrinsic to the neural circuitry that is modified, and requires activity-dependent changes in the postsynaptic target.

SHARP-1,-2: NOVEL HELIX-LOOP-HELIX PROTEINS WITH RAPID INDUCTION BY NGF IN PC12 CELLS

M.J. Rosner, J. Doerr, P. Gass, M. Schwab, and K.-A. Nave\*, Center for Molecular Biology (ZMBH), University of Heidelberg, D-69120 Heidelberg, Germany.

We have amplified the cDNA of a new basic helix-loop-helix protein from the adult rat brain which shows a notable sequence homology to Drosophila neurogenic factors. The search for a full-length cDNA clone of SHARP-1 (enhancer-of-split and hairy related protein-1) yielded a second, closely related gene product, SHARP-2. Both proteins are distinct from mammalian HES proteins and may define a new bHLH subfamily. Both mammalian genes are regulated throughout development and show a highly region-specific expression in the adult central nervous system. By *in situ* hybridization, the 4.5 kb SHARP-1 mRNA is most prominent in the CA1 region of the hippocampus, the dentate gyrus, and the internal granule cell layer of the cerebellum. Neuronal expression increases throughout brain development and is highest in the adult CNS. SHARP-1 and -2 are weakly expressed in exponentially growing PC12 cells but both gene transcripts are rapidly induced by the addition of NGF. In Drosophila, *hairy* and *E(spl)* proteins are transcriptional repressors of neuronal differentiation, and we investigate a similar role of SHARP proteins in mammalian development. Protein kinase raf mediates some of the actions of NGF in PC12 cells, and preliminary data suggest that in cotransfected PC12 cells, SHARP-1 counteracts c-raf effects in the NGF signal transduction pathway.

## 211.3

INDUCIBLE AND CELL TYPE-RESTRICTED GENE KNOCKOUT IN THE CENTRAL NERVOUS SYSTEM OF MICE.

M. T. Hasan, H. Bujard, E. Mercer, D. Anderson, J. Morgan, D. L. King and S. Tonegawa\*, Center for Learning and Memory, Massachusetts Institute of Technology, Cambridge, MA 02139.

We have produced transgenic mice in which cre gene expression in the brain can be induced by oral ingestion of a tetracycline derivative, doxycycline. Our system utilizes the reverse tetracycline transactivator (rtTA) under the control of the brain-specific promoter, L7, and the cre gene under the control of a tetracycline-based minimal promoter. Patterns of cre expression in brain tissues can easily be visualized by utilizing a lacZ reporter system. To accomplish this, these cre-expressing mice were mated to mice carrying copies of lacZ gene under the control of a chicken β-actin promoter. Between the promoter and the lacZ elements was inserted translational STOP sequences flanked by a pair of loxP sites. Progeny mice which carry rtTA, cre and lacZ transgenes were treated for five days with doxycycline in the drinking water. The occurrence of efficient cre/loxP-mediated recombination events in the neocortex and hippocampus was indicated by the presence of blue cells after staining of brain sections with X-gal. In the absence of doxycycline treatment, no blue cells were detectable. These results indicate that cre/loxP-dependent recombination events can occur in postmitotic neuronal cells, and that genes of interest can be knockout in an inducible manner in neuronal cells.

## 211.2

KNOCKOUT OF GPI-LINKED CELL RECOGNITION MOLECULE T-CADHERIN IN MOUSE

M. Garlatti, B. Ferreira and B. Ranscht\*, The Burnham Institute, La Jolla, CA 92037, USA.

T-cadherin, a GPI-linked cell adhesion/ recognition molecule of the cadherin gene family identified in chick, delineates avoided regions in the motor axon pathway and is repulsive to motor axons (Fredette and Ranscht, J. Neurosci. 14:7331-7346 and submitted). To study T-cadherin function in the mouse, we are generating null mutations for T-cadherin by homologous recombination. Using PCR primers, we have isolated mouse T-cadherin cDNA that predicts a protein with 75 % amino acid identity to chick T-cadherin. Expression of the cDNA in COS7 cells results in cell surface expression of a GPI-anchored protein that is immunoreactive with anti-chick T-cadherin antibodies. The gene targeting vector was constructed from mouse genomic DNA by insertion of a neomycin cassette into the exon encoding the amino terminal portion of the first extracellular domain EC1. Herpes simplex thymidine kinase was used as a negative selection marker. The gene targeting vector was electroporated in J1 embryonic stem cells. G418-resistant clones were selected and tested for the mutated allele by Southern blotting. Two targeted ES cell clones were injected into mouse blastocysts and reimplanted in pseudo-pregnant foster mothers. Chimeric founder males mated with Black Swiss females carry the mutation into the germline. Matings for mice homozygous for the T-cadherin null mutation are underway. The mice will be analyzed for developmental defects, including misrouting of motor axons projections. A preliminary assessment of the phenotype will be presented.

DEVELOPMENTAL RESCUE OF DROSOPHILA CEPHALIC DEFECTS BY THE HUMAN OTX GENES.

T. Nagao<sup>1</sup>, S. Leuzinger<sup>2</sup>, D. Acampora<sup>3</sup>, A. Simeone<sup>3</sup>, H. Reichert<sup>2</sup> and K. Furukubo-Tokunaga<sup>1,2\*</sup>. 1) Inst. Biol. Sci., Univ. Tsukuba, Tsukuba 305, Japan. 2) Zoologisches Institut der Universität Basel, CH-4051 Basel, Switzerland. 3) Internat. Inst. Genet. & Biophys. CNR, I-80125 Napoli, Italy.

Recent studies suggest that the fundamental genetic programs for the development of the cephalic structures including the brain might be highly conserved. Seminal to these processes are the evolutionarily conserved homeobox genes, *otd/Otx* and *ems/Emx* genes, which are expressed in segmental patterns in the developing brains in both flies and mice. In order to examine functional conservation of the *otd* and the *Otx* genes, we have introduced the human *Otx* homologs into flies, and examined their developmental control activity in a fly *otd* mutant, *ocelliless*, which fail to develop ocelli and associated vertex structures as well as the protocerebral bridge in the brain. By inducing expression of the transgene via a heat shock promoter, we find that both the human *Otx1* and *Otx2* genes are as potent as the fly *otd* gene in rescue of the epidermal defects in the mutant. We discuss our results in the light of the origin of cephalogenesis and brain formation in evolution (supported by the Swiss NSF and the Univ. Tsukuba).

## 211.5

**Targeted inactivation of the *hoxd-10* gene affects the development of hindlimb innervation.** E. M. Carpenter\*, J. M. Goddard, A. P. Davis, and M. R. Capecchi. Dept. of Human Genetics, University of Utah, Salt Lake City, UT 84112

We have disrupted the mouse *hoxd-10* gene by inserting the neomycin resistance gene into the homeobox using homologous recombination in embryo stem cells. Mice carrying this mutation are viable and survive to weaning and adulthood. Mutant mice show gait defects primarily affecting their hindlimbs. Severely affected mice hyperextend their hindlimbs and drag the dorsal surface of their hindfeet along the ground. The hindlimbs appear stiff, but not spastic. Mutant mice are also unable to use their hindfeet to grip an object positioned along their ventral midline, though control mice can grasp similar objects with ease. Gross morphology of mutant hindlimbs appears normal. There is no evidence of muscle wasting or large bone deformation. Sections of the hindlimb indicate that the major muscle groups of the hindlimb are present, although some disorganization of the muscles near the distal end of the femur is evident. Analysis of skeletons of mutant mice reveals changes in the organization of the knee, particularly in the placement of the patella. We have also examined the nervous systems of these mice. Carbocyanine dye tracing has shown that mutant mice have a slightly smaller complement of lumbar motor neurons and a smaller number of spinal nerves providing hindlimb innervation. Histological sections show that those motor neurons that are present appear normal in size and position. Immunohistochemical labeling of the hindlimbs in embryonic mice using antibodies directed against neurofilament protein indicates that the developing peroneal nerve is absent in some mutants. Anti-neurofilament labeling and carbocyanine dye tracing also indicate that there is decreased arborization of the developing fibularis nerve. These observations document changes in the skeleton, musculature, and nervous system of *hoxd-10* mutant mice and may provide an explanation for the observed gait defects. Supported by the Howard Hughes Medical Institute and the National Institutes of Health.

## 211.7

**B-50/GAP-43, A MARKER OF NEURAL DEVELOPMENT IN *XENOPUS LAEVIS*** L. H. Schramm\*, G. Leppendörfer\*, A. Moritz\*, N. van den Engel\*, A. Marquard\*, A. B. Oestreicher\*, B. J. L. Eggen, W. J. Hage\*, K. Richter\*, and O. H. J. Destrée\*. Lab. Physiol. Chem., Med. Pharmacol. RMI for Neurosciences, Utrecht University, Universiteitsweg 100, 3584 CG Utrecht, \*Hubrecht Laboratory, NIOB, Uppsalalaan 8, 3584 CT Utrecht, The Netherlands. \*Inst. für Genetik und Allgemeine Biologie, Universität Salzburg, Hellbrunnerstraße 34, A-5020 Salzburg, Austria.

To study the regulation and function of the growth-associated protein B-50 in *Xenopus laevis*, B-50 cDNAs were isolated and characterized. The deduced amino acid sequence reveals potential functional domains of *Xenopus* B-50 that may be involved in G-protein interaction, membrane-binding, calmodulin-binding and protein kinase C phosphorylation. The expression of B-50 at the RNA and protein level during development was investigated using the *Xenopus* cDNA and the monoclonal B-50 antibody NM2. The antibody NM2 recognizes the gene product on western blot and in whole-mount immunocytochemistry of *Xenopus* embryos. Moreover, visualization of the developmentally regulated appearance of B-50 immunoreactivity shows that this mode of detection may be used to monitor axonogenesis under various experimental conditions. In adult *Xenopus*, B-50 mRNA was shown to be expressed at high levels in brain, spinal cord and eye using northern blotting. The earliest expression was at developmental stage 13 with poly(A) RNA. By whole-mount immunofluorescence, applying the CSLM, the protein is first detected in embryos from stage 20, where it is expressed in the developing trigeminal ganglion. Also later in development the expression of the B-50 gene is restricted to the nervous system in *Xenopus*.

XB-50/GAP-43 is a good marker to study the development of the nervous system in *Xenopus laevis*. The endogenous expression of B-50 correlates largely with the previously observed neural-preferred expression in vivo of a rat B-50 promoter-reporter construct in *Xenopus*. This indicates that elements that govern B-50 expression in the nervous system are conserved during evolution. Supported by NWO grant 903-42-001.

## 211.9

**SELECTIVE MODULATION OF Sp1 DNA-BINDING BY LEAD** N.H. Zawia\*, T. Crumpton & R. Sharan. Dept. of Pharmacology, Meharry Medical College, Nashville, TN 37208.

Novel studies in our lab have demonstrated that exposure to lead (Pb) *in vitro* alters the DNA binding of zinc finger proteins (ZFP). These transcription factors play key roles during growth/differentiation. Using the gel shift mobility assay, HeLa cells nuclear extracts, the consensus oligonucleotide for Sp1, and similar concentrations of cadmium (Cd) and calcium (Ca), we examined if such perturbations were selective for Pb. We found that low concentrations of Pb (<1.0 mM) produced a dramatic enhancement of Sp1 DNA binding, while higher concentrations of Pb (>5 mM) abolished the DNA binding activity of Sp1. While both high and low concentrations of Ca had no effect on Sp1 DNA-binding, we found that low concentration of Cd inhibited such binding and high concentrations formed unresolved complexes on the gel. These studies suggest that Pb alters Sp1 DNA-binding in a specific dose-dependent manner and thus may partially impact the expression of target genes through such an action. This work was supported by grants from NIH (5 G12RR0303208) and NSF (HRD-9550699).

**TRANSCRIPTIONAL REGULATION OF GAP-43 PROMOTER BY BASIC HELIX-LOOP-HELIX PROTEINS.** M. N. Uittenbogard, D. R. Peavy, T. Neuman and A. Chiaramello\*. Department of Biochemistry and Molecular Biology, Colorado State University, Fort Collins, CO 80523.

The GAP-43 gene is expressed at high level in the growth cones of neurons during axonal growth and synapse formation. The GAP-43 promoter region contains seven E-boxes (E1 to E7) that are organized in two clusters, a distal cluster (E3 to E7) and a proximal cluster (E1 and E2). Deletion analysis and site-directed mutagenesis of the GAP-43 promoter region showed that only the most proximal E1 E-box significantly modulates the GAP-43 promoter activity. This E-box is conserved between the rat and human GAP-43 promoter sequences, in terms of flanking sequence, core sequence, and position. We found that endogenous E-box binding proteins present in neuroblastoma N18 cells recognize the E1 E-box and activate GAP-43 promoter. The transcriptional activity of the GAP-43 promoter was repressed not only by the negative regulator Id2 protein, but also by two non-tissue specific class A bHLH proteins, E12 and ME1a. *In vitro* analyses showed that both ME1a and E12 bind to the E1 E-box as homodimers. By Northern analyses, we established an inverse correlation between the level of E12 and ME1a mRNA and GAP-43 mRNA in various neuronal cell lines as well as in ME1a-overexpressing PC12 cells. Therefore, we have identified a *cis*-acting element, the E1 E-box, located in the GAP-43 promoter region which either modulates positively or negatively the expression of GAP-43 gene depending on which E-box-binding proteins occupy this site.

**LEAD INDUCES GAP-43 mRNA AND ODC ACTIVITY IN THE NEOCORTEX.** A. Hilliard, N.H. Zawia, J.G. Townsel\* and R. Sharan. Dept. of Pharmacology, Meharry Med. College, Nashville, TN 37208.

Studies in our laboratory found a similar ontogenetic pattern of expression for both ornithine decarboxylase (ODC) activity and growth associated protein 43 (GAP-43) mRNA expression in various brain regions. GAP-43 is a marker of neuronal differentiation and axonal elaboration and the polyamines are produced during periods of peak synaptogenesis. In an attempt to examine a possible link between GAP-43 and the ODC/polyamine system, we challenged animals by exposure to the neurotoxicant lead (Pb), a known modulator of both systems. We found that both ODC activity and GAP-43 mRNA were induced in the neocortex of Pb-exposed female rat pups. However, induction of ODC activity (PND 3) preceded that of GAP-43 mRNA (PND 5). This indicates that the ODC/polyamine system may be related to the expression of GAP-43 mRNA. Further studies in our lab are aimed at investigating common signal transduction mechanisms that may mediate the induction of both proteins. This work was supported by NSF grant number HRD-9550699.

## 211.10

**RECEPTOR TYROSINE PHOSPHATASES EXPRESSED BY DEVELOPING NEURONS IN THE LEECH.** T.R. Gershon\*, M. Nitabach, M. Baker, P. Wu and E. R. Macagno. Columbia Univ. Dept. of Biological Sciences, New York, NY, 10027.

In order to better understand how neurons develop different arbors, we searched for cell surface receptors expressed on different subsets of neurons during embryogenesis. Using RT-PCR we cloned fragments of leech homologues of receptor tyrosine phosphatases (rPTPs) and screened them by whole mount *in situ* hybridization. We found 2 leech homologues of the rPTP leukocyte antigen related protein (LAR) that are expressed by different small sets of neurons. We designated these genes HmLAR1 and HmLAR2, obtained the full coding sequences, expressed portions of them in *E. coli*, and raised antisera to the exogenously expressed protein. We are also in the process of expressing the extracellular domains in insect cells using baculovirus in order to obtain bio-active molecules. Here we present the coding sequences, expression patterns, and protein localization patterns of HmLAR1 and HmLAR2. HmLAR1 notably has a shorter extracellular domain than HmLAR2, and is more closely homologous to the rat protein PTP NE-3 than to LAR. HmLAR2, in contrast appears to be the true LAR homologue. We have identified the normal characteristics of the HmLAR expressing neurons and we plan to block HmLAR function through a variety of techniques in order to change their course of development.

## 211.11

ALTERING GENE EXPRESSION IN IDENTIFIED EMBRYONIC NEURONS BY INJECTING mRNAs INTO SINGLE CELLS. L. R. Wolszon\*, G. Aisemberg, V. Wong and E. R. Macagno. Columbia Univ. Dept. of Biological Sciences, New York, NY, 10027.

The use of invertebrate preparations, such as the medicinal leech, are highly advantageous in developmental studies of neuronal outgrowth, morphology and plasticity. However, the inaccessibility of traditional genetic approaches in this system has made it difficult to determine the functions of developmentally relevant genes. We present here a technique that allows us to alter specific gene expression in identified embryonic neurons, using pressure-injection of mRNAs into individual central neurons of live leech embryos.

The skin is opened over a segmental ganglion of an immobilized E8-E13 *H. medicinalis* embryo. A fine-tipped microelectrode, pulled from silanized and baked thin-walled glass, is filled with 0.5  $\mu$ l of the mRNA solution (plus a tracer dye) and beveled. The electrode tip is micromanipulated into the target neuron and 2-3 250-ms pulses of 5-10 psi are applied to the back. The embryo is then allowed to develop for 2-3 more days, and is processed for antibody staining of the relevant protein.

Funded by NIH grant #NS-34545.

## 211.12

DEVELOPMENTAL REGULATION OF GENE EXPRESSION IN THE MURINE CNS. S. Tontsch, O. Zach, G. Lepperdinger, G. Webersinke, H. Bauer, K. Richter and H.C. Bauer. Inst. f. Molekularbiol. Austr. Acad. SCS. A-5020 Salzburg and \*: Inst. f. Genetik, Univ. Salzburg, A-5020 Salzburg, Austria.

Migration and differentiation of neurons in the developing cerebral cortex starts at an advanced gestational stage in the mouse. In order to identify genes which show stage-specific expression during neurogenesis, we subtracted first strand cDNA from E 12 brains with mRNA from brains derived from newborn animals. By subsequent differential screening two full-length cDNA sequences (A13 and C2) were identified, both corresponding to genes which we have found to be highly expressed between E 10 and E17 but not in adult and early embryonic animals. Whole mount in-situ hybridization has revealed that expression of A 13 and C2 is most prominent in the hindbrain and in the spinal cord. These newly identified cDNA sequences have no homology to already known sequences found in the databases. In a second experiment we have cloned and sequenced the mouse homologue of the *C. elegans unc 33* gene, which was previously suggested to be involved in neurite outgrowth. Again, expression of unc 33 was highest during later stages of development and was located in the eyes, the rhombencephalon and in the spinal cord.

EVIDENCE FOR A DELAY IN THE FORMATION OF THE EXTERNAL GRANULE CELL LAYER IN MEANDER TAIL MUTANT EMBRYOS. K.M. Hamre\* and D. Goldowitz, Dept. of Anat. & Neurobiol., Univ. of Tenn. Coll. of Med., Memphis, TN 38163

In homozygous meander tail mutant mice (gene symbol: *mea*), cerebellar granule cells are virtually absent from the anterior lobe due to the gene acting intrinsically in granule cell precursors (Hamre and Goldowitz, 1995). Results of the analysis of chimeric cerebella suggest the hypothesis that this loss is due to a delay in the formation of the external granule cell layer (EGL). We are testing this hypothesis by examining the morphology of the EGL in homozygous *mea* compared to wild-type (C57BLKS/J) embryos at embryonic days (E) E12.5-14.5. In wild-type (+/+) embryos, a clear EGL is present by E13.5. In E13.5 *mea* embryos, the EGL is either not present or, if present, is smaller and more disorganized. In addition, the cells beneath the EGL (largely Purkinje cells) appear more disorganized. A smaller EGL was also observed at E14.5. To determine whether this difference could be due to alterations in the cell cycle of granule cell precursors, the mitotic labeling was examined in the EGL and germinal trigone of embryos at E12.5-E14.5. Dams carrying homozygous *mea* or wild-type embryos were given an injection of 5-bromo-2'-deoxyuridine (BrdU), allowed to survive for 1 hour and processed for the demonstration of BrdU. The number of labeled and unlabeled cells were computed to determine the labeling index (percentage of cells labeled). At E13.5 and E14.5, the labeling indices of cells in the germinal trigone (the source of EGL neuroblasts) are equivalent in +/+ and *mea* cerebella. Further, in both groups, the labeling index within the germinal trigone decreases as the age of the embryo increases. In the EGL, the labeling indices are also similar between +/+ and *mea* cerebella. However, in *mea* cerebella that appear to lack an EGL there are, as expected, no BrdU-positive cells. These results suggest that there is a delay in the development of cells in the EGL which is not due to alterations in mitotic activity. To test this hypothesis, we are studying the expression of molecules that mark EGL development in *mea* cerebella. Support: NS23475.

## 212.3

ANALYSIS OF RETINAL PHENOTYPE IN BF-1 KNOCKOUT MICE. S.O. Huh\*, V. Hatini, R. C. Marcus\*, C. A. Mason\*, and E. Lai. Cell Biology and Genetics Program, Memorial Sloan-Kettering Cancer Center, New York, NY 10021. \*: Dept. of Pathology, Anatomy and Cell Biology, Columbia University, New York, NY 10032

BF-1 winged-helix transcription factor is expressed in the anterior hemiretina and the telencephalon. The BF-1(-/-) embryos develop with reduced telencephalic vesicles, rudimentary basal telencephalon and distorted retinal morphology. Here, we investigated the molecular basis and ontogeny of eye abnormalities in BF-1(-/-) embryos. Morphological analysis at E13.5-16.5 reveals that retinae in homozygotes becomes enlarged and the whole optic cup expresses Pax-6. The optic stalk normally constricts and decreases in diameter and is eventually replaced by retinal ganglion cell axons. In the BF-1 mutant, however, the optic stalk at E10.5 does not constrict and remain open and the retinae are in broad continuation with third ventricle. The timing of retinal cell differentiation is similar between mutant and wild type, suggesting that the enlarged retinal cells did not arise from unchecked proliferation of the retinal precursor cells. We previously hypothesized that BF-1 might specify positional identity of RGC and regulate axonal targeting at the optic chiasm. Dil-labelled nasal RGCs successfully crosses at the chiasm suggesting that BF-1 is not required for proper targeting. At present, we can not distinguish whether BF-1 functions in the retinal field in an autonomous mode or whether BF-1 is required to signal the retinal field non-autonomously. We are currently attempting to distinguish between these two possibilities (supported by NIH grant, EY11124).

## 212.2

LEVELS OF NMDA-R1, GAD $\delta$ , AND GABA-T mRNAs IN PURKINJE NEURONS ARE IDENTICAL IN WILD-TYPE, *pcd* MUTANTS, AND *Hu-Bcl-2* TRANSGENIC MICE.

H. Zanjanli\*, N.J.K. Tillakaratne, J.C. Martinou, N. Delhaye-Bouchaud, J. Mariani, and A.J. Tobin, UCLA, Los Angeles, CA, USA; Institut des Neurosciences, UPMC and CNRS, Paris, France; and Glaxo Imb., Geneva, Switzerland

We have used non-radioactive *in situ* hybridization to study the cerebellar expression patterns of three neuronal mRNAs -- NMDAR1, GAD $\delta$ , and GABA-T -- in wild-type mice, *pcd* (Purkinje cell degeneration) mice, and transgenic mice that express the human *Bcl-2* gene. In *pcd* mice, Purkinje cells are destined to die as a result of a defect intrinsic to the dying cell, with apoptotic death occurring between P20 and P35. At P18, all Purkinje neurons showed indistinguishable patterns of expression of the three mRNAs examined. We found no evidence for a subset of Purkinje neurons in which the pattern of gene expression could predict a distinctive susceptibility to *pcd*-induced cell death. The cerebella of *Bcl-2* transgenic mice contain 40% more Purkinje neurons than wild-type controls. Again, our *in situ* hybridization studies revealed no heterogeneity in the expression of these three neuronal mRNAs, suggesting that the neurons "rescued" by *Bcl-2* are identical to all other Purkinje neurons. Thus, we found no evidence for a subset of Purkinje neurons that might have a distinctive susceptibility to apoptosis. (Supported by FRM, INSERM and NINDS)

## 212.4

MAPPING QUANTITATIVE TRAIT LOCI THAT CONTROL RETINAL GANGLION CELL NUMBER USING F2 INTERCROSS PROGENY. R.C. Strom\*, D. Goldowitz, and R.W. Williams. University of Tennessee, Memphis, Center for Neuroscience, Memphis, TN 38163.

Variation in retinal ganglion cell number is distributed approximately bimodally among 17 standard inbred mouse strains and also among 26 BXD recombinant inbred strains. This bimodal distribution indicates that one or two genes have large effects on retinal ganglion cell number. Using BXD recombinant inbred strains we have mapped a gene (*Rcnc1*) with a major effect on retinal ganglion cell number to chromosome 11, near *Tstap91a* at ~58 cM. To confirm the precise location of *Rcnc1* on Chr 11 and to locate new loci controlling ganglion cell number, we have produced 105 F2 intercross progeny. These progeny were produced by crossing BALB/cJ and CAST/Ei strains. Axons of retinal ganglion cells were counted in optic nerve cross-sections using electron microscopy. The retinal ganglion cell strain averages for BALB/cJ and CAST/Ei are 63,393 and 45,047, respectively. The strain average for 11 BALB/cJ x CAST/Ei F1's is 59,454  $\pm$  3,445 (SD). The phenotypic distribution of the F2s is unimodal, and the average is 57,208  $\pm$  7,644 (SD). Using Wright's equation the number of genes affecting variation in the F2s was estimated to be one. To identify loci affecting ganglion cell number a whole genome-scan was performed by typing microsatellite markers at intervals of ~30 cM throughout the genome. Microsatellites were typed by PCR. To expedite marker analysis, PCR was performed using pooled DNA from the ten highest and lowest cases. Linkage analysis of the pooled DNA indicated linkage with markers located on Chr 11. Individual F2s used in the pools were then genotyped using Chr 11 markers. Linkage probability was calculated using Map Manager QT. Linkage was found between a target gene controlling retinal ganglion cell number and markers on Chr 11 near ~50 cM, (nominal  $P < 0.00001$ ). This region at 50 cM is just proximal to the region identified previously in our analysis of BXD recombinant inbred strains. Supported by RO1 NS 35485.

## 212.5

## MAPPING QUANTITATIVE TRAIT LOCI THAT CONTROL NORMAL VARIATION IN BRAIN WEIGHT IN THE MOUSE

R. W. Williams\*, R. C. Strom, and D. Goldowitz. University of Tennessee, Center for Neuroscience, Memphis, TN 38163

Genes that control natural variation in brain weight are likely to play important roles in the production, survival, and growth of neurons and glial cells. Isolating these polymorphic genes has been difficult because complex traits such as brain weight are influenced by many loci. Here we show that a small number of quantitative trait loci (QTLs) have sufficiently large effects on brain weight to be mapped using recombinant inbred strains (RI) and F2 intercrosses. Fixed brains were bisected behind the cerebellum and weighed ( $n \sim 850$  adults). Inbred strain averages range from  $374 \pm 8$  mg in CAST/Ei to  $516 \pm 11$  mg in BALB/cJ. Differences between sexes are trivial ( $<10$  mg). The coefficient of variation in isogenic strains averages 4.0% ( $\sim 60$  strains), whereas variation in outbred groups averages 6.5%. Heritability ( $h^2$ ) is  $\sim 0.65$ . A comparison of variance between intercross progeny (CAST/Ei  $\times$  BALB/cJ F2) and isogenic groups indicates that no less than three QTLs control normal variation in brain weight. At least one QTL has a major effect, influencing weight by more than 40 mg. Single gene effects of this size can be mapped using fewer than 200 F2 progeny. The weak correlation between body and brain weight in F2 crosses ( $r^2 = 0.14$ ,  $n = 223$ ) suggests that these QTLs do not have notable effects on body size. BXD and BXH recombinant inbred strains ( $n = 38$ ) and F2 progeny were used to map major effect loci. The strongest candidate regions are on chromosome 8 near *Cpe*, Chr 9 near *Xmiv1.5*, and Chr 11 near the centromere (nominal  $P < 0.0006$  in these regions). Supported by RO1 NS 35485 and EY-9586.

## 212.7

## From Genes to Dynamic States: Mapping Spinal Cord Development with the Gene Expression Matrix Reveals Functional Gene Clusters

X. Wen, S. Fuhrman\*, S. Smith, M. Askenazi\*, J. L. Barker, R. Somogyi. LNP, NINDS, NIH, Bethesda, MD; \*Santa Fe Institute, Santa Fe, NM.

Development can be described as an unfolding genetic program, controlling cell proliferation and differentiation. The primary step in this process is gene activation and inactivation, generating mRNA expression patterns. Simplifying the complexity of these processes will require a detailed characterization of these states. We examined mRNA samples from rat cervical spinal cord from embryonic day 11 (E11) to adult, focusing on genes which mediate intercellular communication, the initiators of cell differentiation: peptide and receptor genes for the neurotrophins, insulin-like factors and heparin-binding growth factor family members, as well as neurotransmitter receptors and metabolizing enzymes. To relate these to major phases of CNS development, we examined the expression of early and late markers. Using ratio-metric RTPCR and PAGE product analysis, we analyzed  $>100$  genes, and found distinct expression patterns which were used to create gene expression clusters with PHYLIP software (see graph). Genes highly expressed solely during early embryonic development (E) generally were limited to peptide factors, their receptors, and several markers. Neurotransmitter signaling genes generally followed a progressive activation between E11 and E15 and either gradually increased until adult (N3), or reached maximal expression late in development and declined to medium (N2) or minimally detectable (N1) levels in the adult. Housekeeping genes remained largely constant (C). The patterns suggest that these genes may affect each other's expression. This conjecture should be confirmed by comparative analysis of mutual information levels, allowing us to distinguish potentially interacting genes.

## 212.9

LINKAGE ANALYSIS OF "DOUBLE CORTEX"/ X-LINKED LISSENCEPHALY, A HUMAN MUTATION CAUSING ABNORMAL NEURONAL MIGRATION K.M. Allen<sup>1</sup>\*, J.G. Gleeson<sup>1,2</sup>, M.E. Ross<sup>3</sup>, I. Scheffer<sup>4</sup>, S. Berkovic<sup>5</sup>, M. Berg<sup>6</sup>, J. Motte<sup>7</sup>, W.B. Dobyns<sup>8</sup> and C. Walsh<sup>1</sup>

Beth Israel Hosp., Neurology Dept., Boston, MA<sup>1</sup>; Children's Hosp., Boston, MA<sup>2</sup>; Univ. of Minnesota Med. School, MN<sup>3</sup>; Austin Hosp., Heidelberg, AU<sup>4</sup>; Univ. of Rochester Med. Ctr., Rochester, NY<sup>5</sup>; American Memorial Hosp., Reims, FR<sup>6</sup>.

Analysis of cerebral cortical development is facilitated by studying genetic disorders with abnormal neuronal migration. Two striking examples in humans are "double cortex" and lissencephaly. Double cortex, also known as subcortical band heterotopia, shows an abnormal band of neurons in the white matter underlying an apparently normal cortex, while lissencephaly shows an abnormally thick cortex with decreased or absent surface convolutions. Affected patients have varying degrees of epilepsy and mental retardation. Inheritance of double cortex in daughters and lissencephaly in sons of double cortex females suggested X-linked dominant inheritance (Pinard et al., JNNP 1994;57:914). We analyzed four families with double cortex and/or X-linked lissencephaly with approximately 40 X-linked STS markers and established linkage to Xq21.3-Xq24 with a maximum two-point LOD score of 2.4 ( $\theta=0$ ). Recombination events with the proximal marker DXS1002 and distal marker DXS1001 define the candidate region. This represents a physical distance of about 30 cM but this region is further refined by a girl with classical lissencephaly and a balanced X-autosomal translocation at Xq22.3-Xq23 (see M.E. Ross et al., this meeting). These results suggest that there is a single gene defect on the X chromosome responsible for the abnormal neuronal migration; the difference in phenotype between affected males and females may be due to X-inactivation of the normal gene in the carrier females. Human inherited malformations may provide a means of elucidating genetic mechanisms of normal migration and cortical development. (Supported by HSFP, NIH and Klingenstein Fdn.)

## 212.6

## States, Trajectories and Attractors: Modeling the Complexity of Developmental Genetic Networks using Boolean Networks

R. Somogyi\*, M. Askenazi<sup>1</sup>, A. Wuenschel<sup>2</sup>, B. Sawhill<sup>3</sup>, S. Fuhrman, S. Kauffman<sup>1</sup>. LNP, NINDS, NIH, Bethesda, MD; <sup>2</sup>Santa Fe Institute, Santa Fe, NM.

Understanding the computational principles of genetic networks may become necessary for solving complex problems like brain development. The unfolding of the developmental program is manifested in the interdependent activation and inactivation of networks of genes. The complexity of multiple molecular interactions is captured in Boolean networks by allowing any set of genes within the system to serve as an input to any chosen gene. The state of a gene (on/off) is computed from the state (on/off pattern) of the input elements through a combinatorial Boolean rule. Such networks can be used to calculate state sequences in time, or trajectories. Because a Boolean network has a limited number of states, each trajectory inexorably leads to a single repeating state (point attractor) or a cycle of states (dynamic attractor). Trajectories can be likened to the transient gene expression patterns of development, and attractors to the resulting differentiated cell types. The higher level properties of these systems allow the identification of ordered, chaotic and complex systems' domains, the complex regimen representing an optimum of diversified yet stable behavior. In random Boolean nets, the complex domain is favored through judicious choice of analyzing rules, i.e. rules in which an input element state overrides the input states of other elements in the rule. Profound predictions of this order may be tested on experimental systems today. A comprehensive synthesis of complex network models with experimental data may be achieved through reverse engineering of genetic network architectures from experimentally measurable trajectories, e.g. gene expression transients during CNS development or responses of cells to targeted perturbations. This approach is being successfully applied to model binary trajectories; using the GeneTool algorithm, a minimum number of trajectories generated by a Boolean net allow the extraction of the underlying network wiring and rules.

## 212.8

PHYSICAL MAPPING OF X-LINKED LISSENCEPHALY AND SBH (XLIS): A CNS NEURONAL MIGRATION GENE. ME Ross<sup>1</sup>\*, A K

Strivastava<sup>2</sup>, G.J. Gleeson<sup>3</sup>, K.M. Allen<sup>3</sup>, C.A. Walsh<sup>3</sup>, J.H. Young<sup>1</sup>, W.B. Dobyns<sup>1</sup>. Neurology Dept, Univ of Minnesota, MPLS, MN<sup>1</sup>; Greenwood Genetic Ctr, Greenwood SC<sup>2</sup>; & Neurology Dept, Beth Israel Hosp, HMS, Boston, MA<sup>3</sup>.

The failure of neuronal migration can produce cortical malformations with associated cognitive and motor impairment and epilepsy. Two striking human malformations are subcortical band heterotopia (SBH or double cortex) and lissencephaly (LIS). The coincidence of LIS in males and SBH in females from several families suggests that a single gene mutation on X may be involved in both disorders. We have mapped the gene responsible for this condition to chromosome Xq22.3-q23 by linkage analysis in 4 multiplex families and physical mapping of an X-autosomal translocation in a girl with LIS. Linkage analysis determined a critical region of approximately 30 cM between Xq21.3 and Xq24, flanked by markers DXS1002 and DXS1001 with a maximum 2 point LOD score of 2.4 (K Allen, et al., Soc. Neurosci. Abst. '96). This region contains the Xq breakpoint of a girl (XLI-01) with classical LIS and a de novo X;2 translocation with breakpoints in Xq22.3-q23 and 2p25.1. Multiple STS markers from the critical region on X were used to physically map a somatic cell hybrid, which retains the der(2). Markers DXS87, DXS1105 and COL4A5 were placed centromeric and DXS1072 telomeric to the breakpoint. This was confirmed by fluorescence in situ hybridization (FISH) using genomic probes from the region to examine metaphase chromosomes from XLI-01. These studies reduced the critical region to 1-2 Mb. We conclude that both X-linked lissencephaly and SBH are caused by malfunction of a single gene (XLIS) located in Xq22.3-q23 and that the less severe, SBH phenotype in females is due to random X-inactivation (Lyonization). We propose that mutational heterogeneity contributes to the observed variation in the severity of the XLIS phenotypes. Identification of the XLIS gene will be important for understanding the molecular basis of cortical neuronal migration. (MMF & NIH)

## 212.10

GCM FAMILY: A NOVEL FAMILY OF POTENTIAL TRANSCRIPTIONAL REGULATORS EXPRESSED IN THE DEVELOPING NERVOUS SYSTEM. T.Hosoya<sup>1</sup>, H. Baba<sup>2</sup>, Y. Akiyama<sup>3</sup>, A. M. Poole<sup>2</sup>, K. Ikenaka<sup>4</sup> and Y. Hotta<sup>1,2</sup>

<sup>1</sup>Molec. Genet. Lab., <sup>2</sup>Grad. Sch. of Sci., Univ. of Tokyo, Tokyo 113, <sup>3</sup>National Inst. of Physiology, Okazaki 444.

The *glial cells missing* gene (dGCM1) was identified as a switch gene that controls glial vs. neuronal developmental decision in *Drosophila*. It encodes a novel nuclear protein with no known motif characterized to date. Our search for *gcm* homologues resulted in the isolation of several homologues from human and mouse mRNA, and one from *Drosophila*. These homologues have many common amino acids in the N-terminal 150aa region. We call this conserved amino acid sequence "gcm box". We showed that the *gcm* box is a novel DNA binding motif that specifically binds to an octamer sequence. This *gcm* binding sequence is repeated in the 5'-region of a *Drosophila* gene whose expression is dependent on dGCM1, strongly suggesting that *gcm* proteins bind the upstream regions of their target genes, thereby controlling the gene expression. Thus the group of *gcm* homologues, or "gcm family", is most likely a novel family of transcriptional regulators.

RT-PCR experiments detected expression of the mammalian homologues in the embryonic brain. We performed *in situ* hybridization of a mouse homologue (mGCMb) to find strong expression both in the central and in the peripheral nervous system. The signal profile in the nervous system suggests that mGCMb expression begins when cells become postmitotic and start differentiation. The expression is confined in the developing stages, and can hardly be detected in the adult brain. These results raise the possibility that *gcm* family proteins may regulate cellular differentiation processes in the mammalian nervous system.

This work was supported by grants-in-aid from Ministry of Education, Science and Culture, and from Science and Technology Agency of Japan.

**NEURONATIN- $\alpha$  IN PC12 CELLS: DOWNREGULATION BY NERVE GROWTH FACTOR.** Rajiv Joseph\*, Wayne Tsang, Dexian Dou, Kevin Nelson and Klaus Edvardson. Department of Neurology, K-11, Laboratory of Molecular Neuroscience, Henry Ford Hospital, Detroit, MI.

*Neuronatin*, first cloned from neonatal rat brain (BBRC 1994; 201:1227-1234), is expressed during mammalian neurogenesis (Brain Res 1995; 690:92-98). There are two alternatively spliced forms,  $\alpha$  and  $\beta$ . The  $\alpha$ -form contains all three exons, whereas, the  $\beta$ -form contains only exons 1 and 3. The 81 bp middle exon, encoding 27 amino acids, has been spliced out in *neuronatin- $\beta$* . More recently we have sequenced the human *neuronatin* gene (Genomics, in press), and assigned it to chromosome 20q11.2-12 (Brain Res, in press). In an attempt to understand the function of this gene, its expression in PC12 cells, an established model of neuronal growth and differentiation, was investigated. Of the two spliced forms, only the  $\alpha$ -form was expressed in PC12 cells. Although, *neuronatin- $\alpha$*  mRNA was abundant in undifferentiated PC12 cells, neuronal differentiation induced by NGF resulted in marked downregulation, and removal of NGF was associated with a return of *neuronatin- $\alpha$*  mRNA levels to baseline. These effects were not seen with TGF $\beta$ 1, EGF, TPA and dexamethasone. Although, bFGF also reduced *neuronatin- $\alpha$*  mRNA levels, the effect was less pronounced than with NGF. The NGF-induced decrease in *neuronatin- $\alpha$*  mRNA levels occurred even when protein and RNA syntheses were blocked. The finding that only the  $\alpha$ -form is expressed in proliferating PC12 cells, may implicate the middle exon of *neuronatin* in the mechanisms of cell growth and proliferation. Supported by grants from the NIH (NS-01521) and American Heart Association-National (92-132) (to R.J.).

## 212.13

**ONTOGENY OF TYPE 4 PHOSPHODIESTERASE IN RAT BRAIN.** K. Zhang, S. Farooqui, N. Leidenheimer\* and J. M. O'Donnell. LSU Medical Center, Shreveport, LA 71130. Type 4 Phosphodiesterase (PDE4) is a family of PDEs that have a high affinity for cAMP and are sensitive to a class of selective inhibitors that includes rolipram. Experiments were carried out to determine the development of PDE4 expression and activity. This was accomplished by measuring the kinetics of rolipram-sensitive PDE activity and through the use of immunoblot using an antibody developed against PDE4 (K116). On postnatal day 1 (PND1), the PDE4 activity was about half of that of the adults, and remained so until PND10. On PND15, the PDE4 activity reached adult value and remained so thereafter. This change in PDE4 activity was due to an increase in the Vmax and not a change in Km. Immunoblot of the adult cerebral cortical proteins with K116 showed 4 protein bands at 115, 105, 100 and 93 KD respectively. The expression of 115 and 93 KD protein was low at birth and reached adult value on PND10. The expression of 105 KD protein was much higher at birth when compared with that of the adult and remained so until PND21. An extra band at 103 KD was found in the cerebrocortex from the neonates. This 103 KD protein disappeared on PND21. Other brain regions such as brainstem and cerebellum were also studied.

**CHANGES WITH THE DEVELOPMENT OF NOMIFENSINE-INDUCED c-fos mRNA EXPRESSION IN THE RAT BRAIN.** M. Murata<sup>1,3</sup>, A. Ohima<sup>1</sup>, A. Kashiwa<sup>1</sup>, T. Nishikawa<sup>1</sup>, K. Emori<sup>2\*</sup> and M. Kurachi<sup>2</sup>. <sup>1</sup>Dept. of Mental Disorder Research, National Institute of Neuroscience, NCNP, Kodaira, Tokyo 187, Japan; <sup>2</sup>Dept. of Neuropsychiatry, Toyama Med. & Pharmaceut. Univ., Toyama 930-01, Japan; <sup>3</sup>Tanino Gozan Hospital, Toyama 930-01, Japan.

Using Northern blot analysis, we examined the postnatal development of c-fos mRNA expression in the rat brain induced by systemic administration of nomifensine (NOM). Subcutaneous injection of NOM (40mg/kg) induced after one hour a high level of c-fos mRNA in the neocortex, striatum and cerebellum, but not in the hippocampus and paleocortex as compared with the saline injected control animals. In neocortex and cerebellum, induction of the c-fos mRNA increased gradually from postnatal day 8 to 49 and dramatically increased from day 23 to 49, especially in the cerebellum. In the striatum, c-fos mRNA induction increased dramatically from day 49. Although c-fos mRNA expression increased gradually every period, the induction was smallest in the hippocampus and no significant difference was observed in the paleocortex. The present results suggest that the maturation of certain neuronal circuits might be needed to develop behavioral sensitization to NOM.

## GENESIS OF NEURONS AND GLIA: EGF AND FGF EFFECTS

## 213.1

**ISOLATION OF PROGENITOR CELLS FROM THE OLFACTORY EPITHELIUM WHICH GIVE RISE TO NEURONS, ASTROCYTES, AND OLIGODENDROCYTES.** A. Gloster\* and F.D. Miller. Montreal Neurological Institute, McGill, Quebec, Canada H3A 2B4.

We have isolated proliferating progenitor cells from the olfactory epithelium of neonatal (P1-9) mice. Two days after isolation in F12/DMEM media supplemented with EGF and B27, most cells were dead or dying. However, a small number of large phase bright cells were present, most of which were attached to the flask bottom, and which over the next 2-6 days began dividing to produce a cluster of cells. On day 4 there were approximately 500 of such cell clusters per pup used in the original isolation. Over the next few days, most of these cell clusters began to lift off from the flask surface to form floating balls of cells. These cells were immunoreactive for nestin, a marker of neuronal stem and progenitor cells. They were induced to differentiate into cells with astrocytic, oligodendritic, and neuronal phenotypes. Six days after the original isolation the cell clusters were transferred to polylysine coated dishes with F12/DMEM media containing B27 and 2% fetal bovine serum. The balls of cells plated down, and within a day began to migrate out of the cell clusters and morphologically differentiate. One month after plating the cells were processed for indirect immunohistochemistry. Some cells were still immunoreactive for nestin, while others were immunoreactive for glial fibrillary acidic protein, galactocerebrosidase, neuron specific  $\beta$ 3-tubulin or neurofilament. Recently we have isolated proliferating cells from adult mouse and rat olfactory epithelium and vomeronasal organs which are also nestin positive, and are presently characterizing their phenotype after their differentiation *in vitro*. These results demonstrate the isolation of progenitor cells from the olfactory epithelium, and suggests that these cells are multipotential, and not restricted to becoming olfactory neurons, their normal *in vivo* fate. ## 213.2

**GLIAL GROWTH FACTOR ENHANCES SUPPORTING CELL PROLIFERATION IN RODENT VESTIBULAR EPITHELIA CULTURED IN ISOLATION.** R. Gu\*, M. Marchionni\*, and J.T. Corwin\*. <sup>1</sup>Depts of Otolaryngology-HNS & Neuroscience, Univ. of VA, Charlottesville, VA 22908, <sup>2</sup>Cambridge Neuroscience, Cambridge, MA 02139.

We have investigated the potential of Glial Growth Factor (rhGGF2) to enhance cell proliferation and self-repair in damaged mammalian vestibular sensory epithelia. Sensory epithelia from the utricles of 66 adult female rats were isolated by a one-hour treatment with thermolysin at 500  $\mu$ g/ml. All edges were trimmed away to remove any non-sensory epithelial cells, then each epithelium was bisected transverse to the stria. Each piece initially was cultured in DMEM/F-12 with 10% FBS for 8 days. Then, experimentals were cultured in that medium supplemented with one of the following factors: rhGGF2 at 12.5 ng/ml, 25 ng/ml, 50 ng/ml, or 100 ng/ml, or TGF- $\alpha$  at 50 ng/ml, or FGF2 at 25 ng/ml for 5 days before fixation. BrdU (3  $\mu$ g/ml) was added for the last 2 days. Each condition was tested on 20-37 pieces of epithelium. The average number for BrdU-labeled nuclei per epithelium was 1.4 $\pm$ 0.4 in controls cultured without the test factors. In epithelia cultured in rhGGF2 the number of BrdU-labeled nuclei was 10.2 $\pm$ 2.5 at 12.5 ng/ml; 19.2 $\pm$ 4.3 at 25 ng/ml; 31.3 $\pm$ 5.5 at 50 ng/ml; and 29.8 $\pm$ 6.3 at 100 ng/ml. Epithelia cultured in TGF- $\alpha$  contained 4.9 $\pm$ 1.3 labeled nuclei. Those in FGF2 contained 0.8 $\pm$ 0.3. Additional epithelia were used to assess the effect of FBS concentration on the response to rhGGF2. These were cultured in DMEM/F-12 supplemented with 10% FBS for the first 8 days, then in DMEM/F-12 supplemented with rhGGF2 at 100 ng/ml with different concentrations of FBS (0%, 2.5%, 5% or 10%) for 5 days. BrdU was added for the last two days. BrdU-labeled nuclei averaged 7.7 $\pm$ 2.5 in epithelia cultured with 0% FBS; 48.0 $\pm$ 9.1 in 2.5% FBS; 39.4 $\pm$ 5.5 in 5% FBS; and 29.8 $\pm$ 6.3 in 10% FBS. In medium that contained 10% FBS the most effective concentration of rhGGF2 was 50 ng/ml. In the presence of 100 ng/ml rhGGF2 the optimal level of FBS was 2.5%. The results show that rhGGF2 significantly enhances supporting cell proliferation in sensory epithelia isolated from rat utricles. \*p<0.05 (Supported by NIDCD grant RO1-00200 and the LOVHF.)

## 213.3

LOCAL REGULATION OF ASTROGLIAL PROLIFERATION THROUGH SPECIFIC CELL-CELL INTERACTIONS. Yuji Nakatsuji\* and Robert H. Miller. Department of Neurosci. Case Western Reserve Univ. School of Medicine, Cleveland OH 44106

During development and maturation of the vertebrate CNS, proliferation and survival of distinct populations of neuron and glial precursors is closely regulated. The mechanisms that regulate the proliferation of astroglial precursors are not clearly understood. Using purified populations of neural cells *in vitro*, we have investigated the growth factor requirements for proliferation and the effects of glial/glia and neuron/glia interactions on the proliferation of type-1 astrocytes and their precursors. We show that type-1 astrocytes and its precursors proliferate in response to serum factors, epidermal growth factor and fibroblast growth factor (FGF). Serum driven proliferation of type-1 astrocytes was specifically inhibited by density dependent contact inhibition but unaffected by soluble factors from high density astrocyte cultures. The inhibition of cell proliferation was cells type specific. Co-culture of type-1 astrocytes with smooth muscle cells had no effect on their proliferation. Similarly, the proliferation of O-2A progenitor cells was not inhibited by type-1 astrocytes. In co-cultures of type-1 astrocytes and neurons, local interactions between neurons and astrocytes altered the morphology of the glial cells and promoted their proliferation. Since during development, the majority of astrocyte proliferation occurs after the majority of neurons are born. It may be that the primary inhibitor of astroglial proliferation in the mature CNS is mediated through contact between adjacent astrocytes. Such inhibition is locally lost in pathological conditions such as CNS injury leading to astrocyte proliferation. (Supported by NIH grant 25597)

## 213.5

NEURONAL INDUCTION OF EMBRYONIC STEM CELLS IN SERUM-FREE MEDIUM. M.F.A. Finley\*, S. Devata, and J.E. Huettner. Department of Cell Biology & Physiology, Washington University, St. Louis, MO 63110

Following aggregation and treatment with retinoic acid (RA), embryonic stem (ES) cells differentiate into neurons and glia. Previous work has shown that a variety of cell phenotypes are produced, including both excitatory (glutamatergic), and inhibitory (glycinergic and GABAergic) neurons. In order to learn more about the control of neuronal development, we have begun to study the effect of a variety of growth and differentiation factors on the mature phenotype of ES-derived neurons.

As a prerequisite for this work we have developed appropriate conditions for the efficient induction of neurons in serum-free, defined medium. Initial tests compared Opti-MEM and Neurobasal Medium + B27 supplements (NB + B27) to our standard induction medium: DMEM with nucleosides and 20% calf serum. ES cells survived poorly in Opti-MEM and failed to differentiate. In contrast, ES cells aggregated for 4 days without RA and 4 days with RA (4- / 4+) in NB + B27 yielded a similar proportion of neurons as in complete DMEM (about 40%). Compared to complete DMEM, however, there were roughly half as many cells in total at the end of the induction period in NB + B27.

In the absence of RA, ES aggregates maintained for 8 days in complete DMEM failed to produce neurons; instead, they gave rise to a significant proportion of contractile cells. In contrast, aggregates maintained for 8 days in NB + B27 without RA yielded a small percentage of neurons but no contractile elements. For both 4- / 4- and 4- / 4+ protocols in NB + B27, the addition of 5 ng/ml bFGF and / or TGF $\alpha$  had little effect on either the proportion or total number of neurons obtained.

NON-VIRALLY MEDIATED GENE TRANSFER INTO HUMAN CENTRAL NERVOUS SYSTEM STEM CELLS. A.L. Vescovi\*, L. Conti<sup>5</sup>, P. Frölichsthal, A. Gritti, S. Govoni<sup>6</sup>, and E. Cattaneo<sup>5</sup>. National Neurological Institute "C.Besta", via Celoria 11, 5 Inst. of Pharmacological Sciences, Univ. of Milan, Via Balzaretti 9, 20133 Milan, and <sup>6</sup> Institute of Pharmacology, Univ. of Pavia, Italy.

The introduction of foreign genes into cells of the central nervous system (CNS) is a method of fundamental relevance for studying the events occurring in the brain under physiological or pathological conditions. Thus far, the use of such a technique to study the basic events underlying the proliferation, fate commitment and differentiation of human CNS precursor cells has been hampered by the lack of both a suitable source of human multipotential CNS cells and of a reliable method to deliver genes into these specific cell type. We report here the successful delivery of foreign genes into multipotential human CNS stem cells. By means of lipofectamine-based transfection the bacterial  $\beta$ -galactosidase or the temperature sensitive allele of the SV40 Large T antigen gene were delivered into foetal (10.5 weeks post-conception) forebrain stem cells that had been grown and expanded for over one year *in vitro*. A transfection efficiency of 7.4% was achieved and expression of the foreign genes was detected in both undifferentiated cells and differentiated neuronal and glial cells. Thus, our data show the possibility of targeting exogenous genes to undifferentiated human CNS stem cells and to their progeny, and define an efficient transfer approach alternative to viral-based methodologies. Supported by the Alzheimer's Association/The Hearst Corporation Pilot Research Grant 94-057 to E.C. and by the Ministry of Health, Italy (ICS49.2/RS93.42) to A.L.V.

## 213.4

ONTOGENY OF CYSTEINE STRING PROTEINS IN PRENATAL RAT BRAIN AND STEM CELL CULTURES.

M.L. Cordeiro<sup>1</sup>, S.D. Zürcher<sup>1</sup>, A. Mastrogiacomo<sup>1</sup>, C. Gundersen<sup>1\*</sup>, and H.J. Kornblum<sup>1,2</sup>. Depts. of Molecular and Medical Pharmacology<sup>1</sup> and Pediatrics<sup>2</sup>, UCLA School of Medicine, Los Angeles, CA 90024.

Cysteine string proteins (CSPs) are intrinsic components of synaptic vesicle membranes. These relatively low mass proteins appear to be involved in the interaction of docked synaptic vesicles with presynaptic calcium ion channels. Recently, CSP immunoreactivity was shown to be abundant in synapse rich areas of the adult rat brain. However, little information is available concerning the role of CSPs in developing brain. We therefore have examined the ontogeny of CSP mRNA in embryonic rat brain (ages E11-P0) using *in situ* hybridization with <sup>35</sup>S-labeled CSP cRNA. By E11, CSP mRNA was relatively homogeneously distributed throughout the CNS. This pattern persisted through E15. By E18, hybridization could be seen predominantly in gray matter and germinal zones, with little expression in white matter. This pattern became even more prominent by the day of birth. Particularly high levels of hybridization were present in the developing cortical plate and hippocampus at these later stages of embryonic development. Because CSP expression was observed in germinal epithelia, we investigated CSP expression in neural stem cells generated from embryonic rat (E17-E19) basal ganglia or cerebral cortex in the presence of TGF $\alpha$ . Western blot identified CSPs in these stem cell cultures. These results suggest that CSPs may have an important role in early development of the CNS.

## 213.6

CULTURED SPHERES OF CNS PROGENITOR CELLS FROM THE E13 RAT STRIATUM EXPRESS MEMBERS OF THE JAK-STAT FAMILIES.

C. De Fraja<sup>1</sup>, L. Conti<sup>1</sup>, A. Vescovi<sup>2</sup>, M. Mora<sup>2\*</sup>, S. Govoni<sup>3</sup>, and E. Cattaneo<sup>1</sup>

<sup>1</sup>Inst. of Pharmacol. Sciences, Univ. of Milano, Via Balzaretti 9, Milano; <sup>2</sup>Besta National Neurological Institute, MI; <sup>3</sup>Inst. of Pharmacology, Univ. of Pavia, Pavia-IT

Stem/progenitor cells from the CNS of different mammalian species have been isolated by different laboratories, expanded for several periods in culture and their differentiation potential analyzed. We started from very early rat striatal material (E13) which had been mechanically dissociated and plated at different densities onto untreated culture dishes. Cells were exposed to EGF or bFGF, alone or in combination, in the absence of a coating substrate. Rat cells detached from the plate within 1-3 days from plating and floated in suspension. Round aggregates of cells (spheres) were soon becoming visible. By 6-7 DIV their size had highly increased. After this period single spheres were dissociated and cells plated at very low density in growth factor enriched medium. Single cells could then be identified which were capable of generating secondary clones *in vitro*. Several of these subclones were grown separately and expanded for over two months. It has been shown that similarly derived spheres contain cells that can differentiate into both neurons and glia. By growing these cells we obtained enough material to perform biochemical analyses. We were interested in whether these proliferating CNS progenitor cells expressed members of the JAK-STAT families of proteins, necessary to transduce from the non tyrosine kinase receptors. Western blot analyses and immunoprecipitation studies were performed on lysates obtained from these expanded CNS progenitor cells. Our data show that JAK2 was abundant in these cells. Furthermore, specific expression of some of the Stat molecules has been identified. Selective recruitment of members of the JAK-STAT by specific stimuli may elicit important biological functions in CNS cells. (Funded by Natl.Res.Coun.Italy)

## 213.8

DIFFERENTIATION OF EGF-RESPONSIVE STEM CELL PROGENY: A TIME COURSE ANALYSIS UNDER VARIOUS CULTURE CONDITIONS. A. Gritti, M. Ferrario, L. Cova, R. Galli, E. Parati and A.L. Vescovi. Natl. Neurol. Inst. "C.Besta", Via Celoria 11, 20133 Milan, Italy.

The establishment of a culture technique enabling the continuous and expansive growth of multipotential CNS stem cells, in the presence of EGF, has raised the intriguing possibility of preparing mixed neuronal/ glial cultures avoiding the repeated use of primary brain tissue. Unfortunately, cultures from EGF-generated cells that are induced to differentiate by removal of EGF contain only a small percentage of neuronal cells, as compared to those obtained using traditional techniques. In order to clarify this phenomenon, we studied the time course of expression of antigenic markers specific for neuronal, astroglial or oligodendroglial cells, in cultures of EGF-generated cells differentiating under various conditions. We found that the percentage of neuronal cells increased at day 2, 4 and 6 after EGF removal, reaching a maximum of 10-12% at this later time point. The number of neurons then dropped over time, reaching a minimum (3-5%) at 12 days, regardless of the presence or absence of serum. Conversely, astrocytes were barely detectable at day 2 but their number increased overtime reaching a maximum at 12 days. The presence of 2% serum strongly affected the percentage of astrocytes in the culture. Serum-containing cultures embodied 15-25% more astrocytes (reaching a maximum of 60-70% at 12 days) than serum-free cultures. Our data indicate that culture conditions can strongly affect the differentiation of stem cell progeny and show that a great deal of death occurs in these cultures during early stages of neuronal differentiation. Further investigations are currently underway to confirm preliminary results showing that FGF-2 may antagonise neuronal death in this system. Supported by The Ministry of Health, Italy (ICS49.2/RS93.42).

## 213.9

**INSULIN-LIKE GROWTH FACTOR-I (IGF-I) IS A POTENT DIFFERENTIATION FACTOR FOR NEURONAL PRECURSORS GENERATED BY EGF-RESPONSIVE CNS STEM CELLS**

**Yvan Arsenijevic and Samuel Weiss\***, Neuroscience Research Group, University of Calgary Faculty of Medicine, Calgary, AB, Canada.

Little is known regarding the action of IGF-I on neuronal precursors of the CNS. We examined the actions of IGF-I, IGF-II and insulin on neuronal precursors generated by embryonic EGF-responsive stem cells. When neuronal precursors were plated in the presence of 1% serum, but in the absence of any insulin family member, very few neurons were detected after seven days *in vitro* (DIV). IGF-I induced a dose-dependent ( $EC_{50}$ ,  $5.5 \pm 1.8$  nM) 10-40 fold increase in neuron number. IGF-II and insulin were equieffective, but 7- and 50-fold less potent, respectively. The presence of IGF-I receptor immunoreactivity and IGF-I actions in low density platings suggest a direct action on neuronal cells. Only 10% of the neurons observed in the presence of IGF-I incorporated bromodeoxyuridine, suggesting that its actions are largely not mitogenic *in nature*. In addition, both short term and delayed administration of IGF-I closely mimicked its actions when present during the entire culture period, suggesting that IGF-I promotes differentiation and not survival. Further support for this conclusion was a dose-dependent increase in neurite number by IGF-I, which did, however, require the continued presence of the growth factor. These results suggest that IGF-I is a potent differentiation factor for CNS stem cell-generated neuronal precursors.

## 213.11

**PACAP LIGAND AND RECEPTOR EXPRESSION IN EMBRYONIC CEREBRAL CORTEX** N. Lu\* and E. DiCicco-Bloom, Dept. of Neurosci. & Cell Biol. UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ 08854

While the transition from proliferation to differentiation in cerebral cortex precursors is well-characterized *in vivo*, regulatory signals remain undefined. Previously, we found that the 38 amino acid peptide, PACAP, promoted this ontogenetic switch in cultured E13.5 cortical precursors, inducing mitotic arrest while enhancing differentiation. Further, precursor expression of PACAP and receptor as well as peptide blocking studies indicated a functional autocrine circuit *in vitro*. To define function *in vivo*, we have examined PACAP ligand and receptor expression in developing brain.

To evaluate mRNA expression *in vivo*, 30µg of total RNA from E13.5 cortex was used for Northern analysis. Two bands at 2.8kb and 3.7 kb were detected with a cDNA fragment hybridizing to the full PACAP coding region. In addition, a 7.5kb band for type I receptor mRNA was detected, consistent with previous studies in adult brain. Further, since PACAP type I receptor exhibits 5 splice variants, RT-PCR was employed to define region-specificity: embryonic cortex exhibited the "short" variant, while embryonic sympathetic ganglia expressed the "hop" insert variant. Thus, both ligand and receptor mRNAs are expressed during cortical neurogenesis.

To define protein expression and localization, we performed immunohistochemistry on E13.5 brain sections. PACAP expression was most abundant in cortex and dorsal hippocampus, and was localized to the cytoplasm of ventricular zone precursors. To define relationships of peptide and receptor to proliferation, acutely dissociated cells were plated for 3 hrs, and double-labeled with PACAP/receptor and mitotic marker, BrdU. PACAP and receptor were expressed by >70% of cortical precursors. Further, both mitotic and non-mitotic precursors expressed peptide and receptor, consistent with PACAP inhibition of proliferation and promotion of differentiation. In sum, the expression of PACAP and receptor mRNA and protein in embryonic cortex suggests that the peptide plays a critical autocrine/paracrine role in neurogenetic regulation. (Supported by RO1 NS32401)

## 213.13

**EXPRESSION OF NOTCH AND JAGGED IN TGF $\alpha$ -GENERATED NEUROSPHERES** S.D. Zurcher<sup>1</sup>\*, C.J. Shawber<sup>2</sup>, G. Weinmaster<sup>2</sup>, and H.L. Kornblum<sup>1,3</sup>, Depts. of Molecular and Medical Pharmacology<sup>1</sup>, Biological Chemistry<sup>2</sup> and Pediatrics<sup>3</sup> UCLA, LA, CA 90095

Transforming growth factor alpha (TGF $\alpha$ ) binds and activates the EGF receptor to induce proliferation of neural stem cells to form spheres. These "neurospheres" are composed of cells that can give rise to both neurons and glia. Cell-cell interactions may regulate cell type differentiation of these stem cells. However, the molecular mechanisms that underlie these decisions are not well defined. In *Drosophila*, cell-cell interactions between the receptor *Notch* and its ligand *Delta* have been shown to regulate cell fate choices. In vertebrates, a family of *Notch* receptors, comprised of 4 *Notch* genes, and a family of potential *Notch* ligands (*Jagged*, *Serrate-2* and *ratDelta1*) have also been isolated. To investigate a role for *Notch* and its ligands in the proliferation and differentiation cells within the neurospheres, we have examined the expression of *Notch1*, *Notch2*, *Jagged* and *ratDelta1*. Neurospheres were generated from rat (E17-19) embryonic rat striatum and were stimulated to divide by the addition of TGF $\alpha$  for 2 weeks before processing. Cells from these neurospheres have the property of self-renewal and that they generate neurons and glia. By Northern blot analysis, the neurospheres express *Notch1*, *Notch2*, *Jagged* and *ratDelta1* mRNA. Western blot analysis confirmed the expression of *Jagged* protein in the cells from neurospheres. Cells cultured from dissociated neurospheres revealed that both neurons and Nestin positive undifferentiated cells express *Notch1* and *Jagged* by immunocytochemistry. The expression of *Notch* and its ligands in cells within the neurospheres, as well as those cells derived from the neurospheres, is consistent with the proposed role for these genes in the development of the mammalian brain. (Supported by the Dana Foundation, NIH/NINDS)

## 213.10

**EPIDERMAL GROWTH FACTOR-RESPONSIVE NEURAL STEM CELLS FROM VARIOUS REGIONS OF MURINE EMBRYONIC CNS: DIFFERENCES IN POTENTIAL FOR NEURONAL DIFFERENTIATION.**

**T.J.O'Connor\***, A.L. Vescovi, P. Hettiaratchi, and B.A. Reynolds. NeuroSpheres Ltd., Calgary, Alberta, Canada T2N 4N1

We have previously isolated epidermal growth factor (EGF)-responsive multipotential neural stem cells from embryonic E14 mouse striatum (Reynolds et al, 1992; J. Neurosci. 12:4565-74), and the subependymal layer of adult mouse striatum (Reynolds and Weiss, 1992; Science 255:1707-10). In this study, we investigated the distribution of EGF-responsive stem cells throughout the developing (E14) mouse CNS. EGF-responsive cells could be isolated from murine embryonic cortex, thalamus, ventral mesencephalon, and spinal cord, as well as striatum. Cultures from all regions could be passaged repeatedly to generate large numbers of progeny, which retained the capacity to differentiate into neurons, oligodendrocytes, and astrocytes. Intriguingly, significant differences in the capacity to produce neuronal progeny were found among cultures from the various regions, with stem cells from more rostral regions generating more neuronal progeny. These findings may suggest the presence of distinct populations of EGF-responsive precursor cells in the embryonic CNS.

## 213.12

**SELECTIVE TRANSFER OF BASIC FIBROBLAST GROWTH FACTOR (bFGF) ACROSS THE MATURE BLOOD-BRAIN BARRIER.** J.P. Wagner\*, J.B. Black, & E. DiCicco-Bloom, Dep't of Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ.

Since most polypeptide growth factors do not cross the blood-brain barrier (BBB), their therapeutic utility in neurodegenerative disease has been limited by the development of appropriate delivery systems. Previously, we reported that a small dose of bFGF (5 ng/g body weight) injected subcutaneously (s.c.) into adult rats stimulated mitosis in multiple brain regions, suggesting that bFGF can exert effects across the mature BBB. The current study investigates bFGF transfer and defines molecular selectivity.

To verify entry of bFGF into the brain, 28 day old rats (n=3) were given 5 µCi of <sup>125</sup>I-bFGF s.c. After four hours, cerebrospinal fluid (CSF) and blood were collected, and levels of <sup>125</sup>I radioactivity were quantitated. Approximately 0.06% of the total injected dose was measured in the CSF, while CSF/blood ratio of the factor was 3.5%, values similar to those obtained from other compounds which readily cross the BBB, such as morphine. Furthermore, <sup>125</sup>I-bFGF was localized within the brain parenchyma *per se*, as determined by a capillary depletion assay, suggesting that peripherally administered factor permeates the BBB, gaining access to both the CSF and brain.

To define the molecular selectivity of this transport mechanism, we first assessed the mitogenic capacity of multiple members of the FGF family on cerebellar granule neurons in culture. Six FGF's were equally effective in stimulating mitosis *in vitro* (aFGF, bFGF, and FGF-4-7); we next defined the activity of these six factors *in vivo*. Although all six family members stimulated cerebellar mitosis after s.c. injection, mitogenic activities varied markedly; bFGF and FGF-7 were most effective. However, in the hippocampus, another potentially responsive region, only bFGF stimulated mitosis after s.c. injection. This region-selective activity of peripherally administered FGF's, possibly due to regional differences in uptake and/or FGF-receptor expression, is currently being evaluated to characterize this potentially useful therapeutic strategy. (Support: NICHD23315; Trophix Pharm.)

## 213.14

**BASIC FIBROBLAST GROWTH FACTOR AFFECTS THE PROLIFERATION AND DIFFERENTIATION OF RAT CORTICAL PROGENITOR CELLS IN VITRO, BUT DOES NOT ALTER THEIR CELL CYCLE.** J.F.R. Cavanagh, M.C. Mione\*, and J.G. Parnavelas, Dept. Anatomy & Dev. Biol., University College London, London WC1E 6BT, UK.

We have examined the effect of basic fibroblast growth factor (bFGF) on cortical progenitor cells *in vitro*, using cells prepared from E16 rat embryos. Even after 48 h, bFGF had doubled the rate of proliferation of these cells, as measured using BrdU incorporation. Analysis of cell cycle parameters using the labelled mitosis method revealed that this increase was not due to any alteration of the lengths of either the cell cycle or any of its phases. This growth factor was also found to prolong the mitotic ability of these cells. Retrovirally-labelled clones grew significantly larger in the presence of bFGF, and BrdU labelling further showed that nearly all the cells in these clones were still cycling after 4 DIV. In defined medium, most of the clonally-related cells ceased dividing after 2 DIV, equivalent to only four cell cycles. An additional effect of bFGF on cortical progenitor cells in culture was to stimulate previously quiescent cells to reenter the mitotic cycle. All of those attempting to do so in defined medium instead underwent apoptosis. The extent of neuronal and glial differentiation was studied after 5 DIV. In the presence of bFGF, the percentage of cells immunoreactive for MAP-2 was less than half that of control cultures. Conversely, the percentage of cells immunoreactive for nestin (a marker of progenitor cells) was as high in the presence of bFGF as at the start of the experiment. These experiments show that bFGF, a potent mitogen for cortical progenitor cells, has no effects on the parameters of the cell cycle but extends the proliferative period of these cells, promotes their survival, and delays their differentiation into neurons. Supported by the Wellcome Trust.

## 213.15

**SYNERGISTIC EFFECTS OF EGF AND FGF-2 ON THE EXPANSION OF RAT CNS PRECURSOR CELLS FROM PRIMARY EMBRYONIC TISSUE.** M.G. Terborg, A.E. Rosser, P. Tyres, S.B. Dunnett\* and C.N. Svendsen MRC Cambridge Centre for Brain Repair, University of Cambridge, UK

Both EGF and FGF have been shown to promote the division of CNS precursors from either embryonic or adult rat CNS tissues. Although it has been suggested that EGF may drive a multipotent stem cell while FGF may effect a bi-potent neuronal/glial precursor, the contribution of each to the division of specific cell types remains poorly understood. In this study precursor cells were isolated from the striatal eminencies of E15 rat embryo's and cultured in EGF, FGF-2, or a combination of EGF and FGF-2 for a period of 5 weeks at an initial plating density of 200,000 cells per ml in 20 mls of medium, and subsequent densities of 100,000 cells per ml at each passage (every 7d). No substrate and no serum was used and the cells generally grew as free floating or attached spheres. The number of viable cells plated and the number of viable cells at the end of each week were assessed and an "expansion ratio" generated (number of cells at end divided by number of cells at start) where 1 indicates no change, <1 a decrease in cell number and >1 an expansion in cell number. FGF-2 alone did not result in any expansion of striatal precursors between any of the passages with expansion ratios of approximately 0.5, 0.7, 0.1, 0.0 and 0.0 at 1, 2, 3, 4 and 5 weeks respectively. EGF resulted in expansion ratios of approximately 2.5, 5.6, 3.6, 0.7 and 0.0 at each week suggesting strong initial growth followed by a sharp reduction and cell senescence. Combined application of EGF and FGF-2 resulted in expansion ratios of 5.2, 5.1, 1.7, 0.8 and 0.1 at each week showing a strong synergy over the first week in vitro, a possible reduction in expansion between 2 and 3 weeks and a lack of effect on the late senescence of the rat precursors. These results suggest a strong interaction between EGF and FGF-2 on striatal precursors after plating from primary tissue, but that continued application of both factors may decrease cell expansion thereafter. Supported by the Wellcome Trust and MRC.

## 213.17

**A DIFFERENCE IN GROWTH RATES BETWEEN RAT AND MOUSE EPIDERMAL GROWTH FACTOR RESPONSIVE CNS PRECURSOR CELLS.** C.N. Svendsen\*, A.E. Rosser, M. Terborg, P. Tyres and T. Rykin MRC Cambridge Centre for Brain Repair, University of Cambridge, UK

There are numerous reports where populations of precursor cells have been isolated *in vitro* from both the embryonic and adult rodent CNS which can then be induced to divide using epidermal growth factor (EGF) as a mitogen. In addition, EGF responsive precursor cells within the adult subventricular zone have also been shown to divide, both *in vivo* and *in vitro*, suggesting that similar cells may exist in specific brain regions throughout life. However, many of these studies have focused on the mouse rather than the rat. More specifically, continued expansion of EGF responsive precursors *in vitro* over a period of months has only been described using mouse tissues. We have performed a direct comparison of the growth characteristics of EGF responsive precursors from either the rat or mouse embryonic striatum and shown that while the mouse cells could be continually expanded as spheres of cells for over 50 days, under identical culture conditions rat cells could only be expanded for between 21 and 30 days, after which the cells reduced in number and died. The centre of the rat spheres were full of dying cells while dividing cells could be seen towards the outside based on exclusion of trypan blue, confocal imaging of rhodamine uptake up and electron microscopy. Various additions to the medium including B27, n-acetyl acetate or LIF did not prevent this senescence of the rat cells. Our data suggest that mouse CNS precursor cells have inherent properties which allow them to divide for extended periods of time as free floating spheres of cells in stark contrast to rat cells which have only limited proliferative potential under the conditions described here. Supported by the Wellcome Trust and MRC.

**b-FGF AS CELL CYCLE MODULATOR *IN VITRO* IN THE NEOCORTICAL PROLIFERATIVE EPITHELIUM OF EMBRYONIC MICE.**

T. Goto<sup>1,2\*</sup>, T. Takahashi<sup>1,2</sup>, P.G. Bhidé<sup>1</sup>, S. Miyama<sup>1,2</sup> and Y.S. Caviness, Jr<sup>1</sup>

1. Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA 02124, 2. Department of Pediatrics, Keio University School of Medicine, Tokyo 160.

b-FGF is an established mitogen for the neocortical pseudostratified ventricular epithelium (PVE) (Ghosh and Greenberg, *Neuron* 15:89-103, 1995). Here we examine the effect of b-FGF upon progression of cells of the PVE into S phase in explants of the cerebral wall *in vitro*. Explants of the full width of the cerebral wall at the 13th embryonic day (E13) were "punched out" by glass pipette trocar, immediately implanted in collagen gel, cultured at 37°C for 5 hr in DMEM/F12 media only (control) and in DMEM/F12 containing 100 ng/mL of b-FGF and then for an additional 6 hrs after the addition of 10  $\mu$ M of the S phase marker, BUdR. Cells marked with BUdR were stained immunohistochemically and the labeling indices (LI) within coronal sectors of the PVE, subdivided in its radial dimension into 10  $\mu$ m bins, were determined in the medial cortical (MCZ) and lateral cortical (LCZ) zones, corresponding to distances of approximately 300  $\mu$ m and 1000  $\mu$ m, respectively from the caudopallial angle of the VZ. The overall LI for the full thickness of the PVE after 6 hr exposure to BUdR is 0.6 in the MCZ and 0.4 in the LCZ of both control and b-FGF-exposed PVE. However, in the LCZ, the LI in the outer half of the PVE (S-phase zone, a zone where the PVE cells are undergoing S phase) are higher in the b-FGF-exposed PVE than control. These findings are consistent with an action of b-FGF to accelerate the entry of G1 cells into the next S-phase or, alternatively, to reduce the fraction of cells which leaves the cycle after division. Such an effect of b-FGF is not observed in the MCZ where the duration of G1 is only 60 % of that in the LCZ (Miyama et al., unpublished).

## GENESIS OF NEURONS AND GLIA: MECHANISMS AND KINETICS

## 214.1

**DIFFERENTIAL GENE EXPRESSION IN THE DEVELOPING TELENCEPHALON OF MUTANTS LACKING THE WINGED HELIX TRANSCRIPTION FACTOR BF-1.** C.A. Baptista\*, G. Balas and E. Lai. Cell Biology and Genetics Program, Division of Endocrinology, Cornell University Graduate School of Medical Sciences, Memorial Sloan-Kettering Cancer Center, New York, NY 10021.

We previously reported that the transcription factor Brain Factor-1 (BF-1) is required for the normal development of the cerebral hemispheres after embryonic day 10 (E10; Xuan et al., 1995). In animals homozygous for the BF-1 deletion the ventral telencephalic neuroepithelial cells stop proliferating after E10 causing the complete absence of the basal telencephalon. In contrast, dorsal telencephalic neuroepithelial cells continue to proliferate, however, they originate smaller dorsal structures because of a premature exit from the cell cycle and differentiation into neurons. We postulated that BF-1 normally carries out its function by upregulating genes that promote cell cycle progression and/or downregulating genes that inhibit progression through the cell cycle thus, keeping telencephalic neuroepithelial cells actively proliferating. In order to find BF-1 target genes we initiated a subtractive hybridization procedure. Briefly, directional cDNA libraries were constructed in phagemid vectors from E10 wild type and mutant animals just before the mutant phenotype is apparent. Single stranded DNA and biotinylated RNA, each made from one of the cDNA libraries, were hybridized and the mixture incubated with streptavidin to remove the common sequences. The single stranded DNA in the unbound fraction (enriched for wild type or mutant specific DNA sequences) was collected and used to construct subtracted libraries. We will report the results of the ongoing analysis of differentially expressed clones. These genes will further clarify the molecular mechanisms which control the development of the cerebral hemispheres.

Supported by NIH grant RO1 HD29584.

## 214.2

**THE ROLE OF THE RETINOBLASTOMA PROTEIN IN NEURONAL COMMITMENT AND TERMINAL DIFFERENTIATION.** R.S. Slack, H. El Bizri, J. Wong, D.J. Belliveau, A. Gloster, R. Varma, A. Speelman, F.D. Miller\*, Montreal Neurological Institute, McGill University, Montreal, P.Q. H2A 2B4

We questioned whether the retinoblastoma protein (pRb) is required to make a commitment decision, or do neurons commit to their fate, express neuronal markers, and undergo apoptosis due to failure to undergo terminal mitosis. To distinguish these possibilities we have used pRb nullizygous mice (Jacks et al., 1992) and established a colony expressing the *Tet*  $\alpha$ -tubulin promoter driving a nuclear  $\beta$ -galactosidase transgene. The reporter gene is induced at the point of commitment to a neuronal fate, coincident, or in many cases prior to, terminal mitosis (Gloster et al., 1994).  $\beta$ -galactosidase expression was analyzed throughout the nervous system of these mice at timepoints ranging from E10.5 to E14.5. We detected abnormal neuronal development throughout the nervous system, including the cortex, the retina and the olfactory epithelium, regions which were previously reported to be spared. Our observations support the hypothesis that neuronal commitment occurs prior to terminal mitosis in all regions examined. However, once migration has commenced and cells fail to exit from the cell cycle, apoptosis takes place. This is best exemplified in the developing olfactory epithelium in which the loss of LacZ-positive cells coincides with the appearance of TUNEL-positive cells. Consistent with this interpretation is the fact that nestin staining in Rb<sup>-/-</sup> mice is similar to controls. Cortical progenitor cells in which the pRb family has been ablated with specific deletion mutants of the adenovirus E1A oncoprotein undergo apoptosis concomitant with terminal mitosis. These studies indicate that pRb is not essential for the maintenance of progenitor cells but is essential for terminal mitosis and differentiation of cortical neurons. Supported by the Neuroscience Network and the Medical Research Council of Canada.

## 214.3

**ALTERED CELL PROLIFERATION IN THE SPINAL CORD OF THE MOUSE NEURAL TUBE MUTANT PAX3 SPLITCH-DELAYED.** C.R. Keller-Peck\* and R.J. Mullen. Program in Neuroscience, Dept. of Neurobiology & Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

Homozygous Splitch-delayed mouse embryos develop lumbosacral myeloschisis (an open neural tube) as well as abnormalities in neural crest migration. A single base pair substitution in the *Pax3* gene produces this phenotype. The *Pax3* protein, expressed in the dorsal neural tube and dermomyotome beginning at embryonic day 8 (E8), is likely regulating extracellular matrix and cell adhesion molecules. We have utilized this mutant to investigate the role normal neural tube closure plays in neuronal proliferation. The thymidine analog BrdU was injected intraperitoneally into pregnant *+/-Pax3<sup>Spd</sup>* females between E10 and E15. Embryos were removed 24-48 hours after injection, embedded, serial sectioned transversely through the entire lumbosacral region, and stained immunohistochemically. PCR primers were devised to genotype embryos so that heterozygous embryos could be differentiated from their wild-type littermates. Cell counts were made by focusing through the section and counting heavily labeled nuclei. At E10, the number of BrdU positive cells is decreased relative to controls. In contrast, there are significantly more cells born in affected embryos between E11 and E13. Our results indicate that more total cells are born in the spinal cord of spina bifida embryos (*Pax3<sup>Spd</sup>/Pax3<sup>Spd</sup>*) than are born in the spinal cord of normal (*+/+*) littermates. Closure of the neural tube may have an antimitotic activity on proliferating cells of the nervous system. (Supported by NIH Grant HD28845)

## 214.5

**PROX1 PROTEIN EXPRESSION IN MOUSE CNS DEVELOPMENT**

H. Dou and C. Q. Doe\*, HHMI, Dept. of Cell and Structural Biology, Univ. of Illinois, Urbana, IL 61801.

Cellular diversity within the Drosophila and vertebrate CNS is generated, in part, by the asymmetric division of neural precursor cells. In Drosophila, the prospero (pros) gene encodes a homeodomain transcription factor that is asymmetrically segregated into the daughter cell during mitosis of the neural precursor. Prox1, a murine homolog of pros, is transcribed in the CNS and many other tissues during development. Here we examine the protein distribution of Prox1, the mouse pros homolog, focusing on the PROX1 distribution in dividing ventricular zone (VZ) precursors.

A rabbit polyclonal antibody was made against a C-terminal 30 amino acid peptide shared by all known vertebrate pros homologs (frog, chick, mouse, human; S. Tomarev, pers. comm.; C. Kintner, pers. comm.). Affinity purified PROX1 antibody specifically detects a protein of 75 Kd in adult brain Western blots, although other bands are detected in embryonic extracts. Histochemical staining of tissue sections from embryos (E10, E12, E14) and adult brain shows nuclear localization of PROX1. Confocal immunofluorescent imaging of mitotic VZ precursors shows that VZ precursors with both vertical or horizontal divisions have cytoplasmic PROX1 protein distribution; no evidence for asymmetric cortical localization is observed. PROX1 is detected in an increasing number of spinal cord and brain VZ cells from E10 to E14, and in a subset of differentiated neurons persisting into the adult. PROX1 is detected in both lens and retinal cells in the eye. In the adult, the highest level of PROX1 is in cerebellar Purkinje cells, both in the nucleus and in dendritic processes. Our data suggests that PROX1 is a transcription factor involved in the early CNS development as well as in the function of mature neurons in the adult.

Supported by NIH 27056 and HHMI. C.Q. Doe is an Assistant Investigator of HHMI.

## 214.7

**REGIONAL DIFFERENCES IN COMPOSITION OF RETROVIRALLY LABELED CLONES DURING EARLY DEVELOPMENT OF THE MOUSE NEOCORTEX.** R.S. Nowakowski\*, L. Cai, and N.L. Hayes. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

A lateral-to-medial gradient in maturation of neocortex during development has been well-documented (Smart, 1985). To investigate the relationship between regional maturation and differences in proliferative behavior in the pseudostratified ventricular epithelium (PVE), we injected a replication-incompetent retrovirus into the lateral ventricles of fetal mouse brains on embryonic day 11 (E11); animals were sacrificed 3 days post-injection at E14. AP-labeled clones were evenly distributed across the entire surface of the developing neocortex indicating that there were no regional differences in the likelihood of infection of the retrovirus. However, the clone composition defined by the inclusion of proliferative cells and post-mitotic cells varied regionally. Clones containing only postmitotic cells (Q-clones) were concentrated in the ventrolateral region, whereas clones containing only proliferating cells (P-clones) and clones containing both proliferating and postmitotic cells (PQ-clones) were concentrated in a band extending from rostral-to-caudal across the dorsal region of the neocortex. The differences in clone composition were correlated with the maturity of the cortex as assessed by the thickness of the cortical plate and corresponded to the known lateral-to-medial gradient in maturation. This correlation indicates that clone composition within the developing cortex is determined by the progression in the proportion of PVE cells leaving the cell cycle (Q) vs those re-entering S (P). In addition, since PQ-clones tend to be largest clones, the state of maturation of the PVE in different regions will affect the sizes of retrovirally labeled clones found in different regions of cortex.

**THE ROLE OF NEUROBLAST PROLIFERATION IN THE ABNORMAL DEVELOPMENT OF THE MOUSE TRISOMY 16 CEREBRAL CORTEX.** T.F. Haydar\*, B.K. Krueger, and P.J. Yarowsky#. Depts. of Physiology, and #Pharmacology, University of Maryland School of Medicine, Baltimore, MD 21201.

Neuroblast proliferation subserves two distinct roles during corticogenesis. Initially, dividing neuroblasts in the ventricular zone give rise to daughter cells which re-enter the cell cycle, causing an exponential tangential expansion of the proliferative epithelium. This tangential cortical expansion is followed by radial growth of the pallial layers, beginning around embryonic day 11 in the mouse, as daughter cells become post-mitotic and migrate outward, away from the pool of dividing cells. Previously, we described abnormalities in corticogenesis and neuronal differentiation in the trisomy 16 (Ts16) mouse cortex, a model of Down syndrome [*Soc. Neurosci. Abstr.* 21:30 (1995)]. We found that radial expansion of the cortex was abnormal in Ts16. Here we show that two separate defects are present during morphogenesis of the Ts16 cortex. First, gross brain measurements indicate that the tangential expansion of the Ts16 cortex is persistently retarded compared to normal littermate brains. Second, we confirmed our earlier finding that beginning at E14, Ts16 cortical growth is characterized by a thinner cortical plate and intermediate zone although the ventricular zones appear normal. We now report that this aberrant radial growth is just a delay, as the Ts16 cortex and cortical layers attain normal thickness shortly before birth. We hypothesized that decreased proliferation, of Ts16 neuroblasts could adversely affect the progression of the tangential and radial cortical expansion. To explore this possibility, we used bromodeoxyuridine and <sup>3</sup>H-thymidine to characterize the cell cycle of the cortical progenitor population. We report that cell cycle kinetics in the Ts16 cortex are slower than controls. This may partly explain the observed growth retardation of the cortex. NIH T32GM08181, AG10686, and SRIS, Univ. Maryland.

## 214.6

**TEMPORAL AND SPATIAL EXPRESSION OF P21<sup>Cip1</sup>/WAF1 IN THE DEVELOPING MURINE NEOCORTICAL CEREBRAL WALL.**

L. Delalle\* and V.S. Caviness, Jr. Neurology, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA 02129.

The length of the cell cycle (Tc) in the murine neocortical pseudostratified ventricular epithelium (PVE) increases from ~10 to ~20 hrs during the neurogenetic interval E11-E17. The increase in Tc is due solely to an increase in the length of the G1 phase (Tg1). In the E12-E15 interval Tg1 is distributed as a rostralolateral to caudomedial gradient with values of Tg1 laterally greater than those medially. We have previously determined that the lateral to medial gradient in Tg1 between E12 and E15 is associated with down regulation in the rate of expression of cyclin E, a regulatory subunit of cyclin-dependent kinase 2 (Cdk2) and necessary for the G1 to S phase transition. Here we explore, by means of *in situ* hybridization with S<sup>35</sup>-labeled riboprobe, the lateral to medial expression at E12 and E15 of p21<sup>Cip1</sup>/WAF1, a cell-cycle inhibitor, that binds and inhibits Cdk2. At both E15 and E12, p21 mRNA is present in both the proliferative and nonproliferative populations of the cerebral wall with the density of expression variably 30% to 2 times greater in strata dominated by nonproliferative cells than in the PVE. The average density of p21 expression in the PVE, in contrast to that determined earlier for cyclin E, is indistinguishable at E12 and E15, whether in the medial or lateral cerebral wall. The presence of p21 mRNA in the PVE suggests that this inhibitor plays a role in cell cycle regulation of this proliferative population. Because average expression of p21 mRNA in the PVE is invariant across widely ranging values of Tg1, it is probable that the level of p21 activity is regulated posttranscriptionally as appears to be the case for the cell cycle inhibitor p27<sup>Kip1</sup>. (by NINDS grant NS12005).

## 214.8

**CLONE SIZE DURING NEOCORTICAL DEVELOPMENT: AGREEMENT OF EXPERIMENT AND PREDICTION.** L. Cai\*, N.L. Hayes and R.S. Nowakowski. Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Neuronogenesis in the developing cortex of the mouse occurs in a pseudostratified ventricular epithelium (PVE) over a 6 day period beginning at embryonic day 11 (E11) and ending on early E17. During this period: there are 11 cell cycles that lengthen from about 8 hr to about 20 hr, the proportion of cells that leave the cell cycle to become postmitotic or quiescent (Q) increases monotonically from 0 to 1, and the complementary proportion of cells that continue to proliferate (P) decreases from 1 to 0. To investigate the effects of these dynamic changes in the proliferative behavior on clone size, we injected a replication-incompetent retrovirus encoding human placental alkaline phosphatase (AP) into the lateral ventricle of E11 fetal mouse brains. After survival for 2, 3 and 4 days, AP-labeled clones were evenly distributed across the neocortex. The number of cells in each clone was counted, and the distribution of clone sizes was compared with the distribution of clone sizes calculated from cell cycle lengths, Q and P [as determined using double labeling with bromodeoxyuridine and tritiated thymidine (Takahashi, et al., 1995)] for the corresponding developmental period. The important finding is that the distribution of clone sizes from the retroviral experiments was in substantial agreement with the calculated distribution. This agreement of experimentally determined clone sizes with calculated histograms made from Q and P measurements means that the average behavior of the population (i.e., the S-phase label data) can be used to predict the range of behaviors of the individual members of the population (i.e., the retroviral clone size data). Thus, during early development of the neocortex the major determinant of clone size in retrovirally labeled lineages is the developmental progression of Q and P. (Supported by NIH (NS33443) and NASA (NAG 2-950).)

## 214.9

**THE RATE OF CELL OUTPUT AND THE PATTERN OF CELL MIGRATION IN THE EMBRYONIC MOUSE CORPUS STRIATUM.** P. G. Bhidé\* and A. N. Sheth, Neurology Department, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA 02129.

The rate of cellular output is a major regulator of cyto-genesis because it is vulnerable to the action of a variety of cell-intrinsic and extrinsic factors. We examined this parameter in the mouse striatum on embryonic day 11 (E11; E0=day of conception), the earliest stage of striatal cyto-genesis. Tritiated thymidine and bromodeoxyuridine were used in combination to distinguish between mitotically active and postmitotic progeny. About 30% of the daughter cells "born" on E11 become postmitotic; the remaining re-enter the proliferative pool. The majority (~94%) of the postmitotic cells rapidly exits the proliferative zone in a tight cluster leaving in its trail a slowly migrating minority. As the cells enter the postmitotic zone on E12, they apparently freely intermingle leaving no indication of their previous segregation. Thus, cellular migratory cues in the proliferative zone may differ from those in the postmitotic zone. The daughter cells which re-enter the cell cycle on E11 also partition into 2 spatially distinct cohorts within the proliferative zone: some remain near the ventricular border as a part of the pseudostratified ventricular epithelium while the others migrate away to "seed" a secondary proliferative population. The relatively high rate of cellular output and the partitioning of the proliferative cells into 2 groups by E11 are the earliest signs of the emergence of a cytokinetically distinct striatal proliferative domain within the seemingly homogeneous telencephalic neuroepithelium and this may presage the eventual formation of striatal and neocortical compartments of the forebrain. Supported by NINDS grant #NS-R29-32657.

## 214.11

**DYNAMIC MODELISATION OF CORTICAL NEURON PRODUCTION.** B. Moraillon, F. Polleux, C. Dehay, H. Kennedy\*, INSERM U371, 18 Ave du Doyen Lépine, 69675 BRON (France).

The cerebral cortex is parcelled in distinct areas that are characterised by their cytoarchitectonics which can be defined on the basis of the number of neurons forming each layer. Previously we have shown that individual cortical areas are characterised by differences in the proliferative rates of their progenitor cells (Dehay et al., 1993, Polleux et al., 1995, 1996). We have designed a computational model in order to test whether the known variations in cell-cycle kinetics of cortical precursors influences the numbers of postmitotic neurons in individual areas. We have simulated neuron production in which the following parameters can be modulated independently and in different combinations (i) the number of precursors, (ii) the cell-cycle duration, (iii) the modes of division (proportions of proliferative divisions -where daughter cells remain in the cell cycle, proportions of differentiative divisions -where daughter cells quit the cell cycle and proportions of mixed divisions -where one daughter cell remains in the cell cycle and the other quits the cycle), (iv) cell death. Covariation of these parameters shows that changes in modes of division and duration of cell cycle can have a complex effect on neuron production.

The model reveals how the observed regional variations in the cell cycle kinetics can lead to the observed differences in neuron number of individual layers in the cortical areas. These results show that modulation of the cell cycle almost certainly plays a significant role in establishing the cytoarchitectonics of the cortex.

**PROLIFERATIVE COMPARTMENTS IN THE POSTNATAL SUBVENTRICULAR ZONE.** J.R.L. Menezes and R. Lent\*, Depto. de Anatomia, Inst. de Ciências Biomédicas, UFRJ, Rio de Janeiro, 21941-590, Brazil.

The postnatal subventricular zone (SVZ) is highly proliferative and a site of neurogenesis. It surrounds the lateral ventricle and extends toward the olfactory bulb (OB). We have studied the BrdU incorporation after short survival periods, to determine the number and distribution of the S-phase cells within the postnatal SVZ. BrdU injections (IP) were given to P2 and P4 mice. Animals were allowed to survive for 15, 30, 60 and 120 min., then killed by ether inhalation and perfused with warm HistoChoice. Brains were embedded in paraffin and cut parasagittally at 5-6 µm, then processed immunohistochemically for BrdU and counterstained. The cell distribution was analyzed with the aid of a microscope coupled to a computer with a tracing software. There was a very high number of BrdU+ cells within the SVZ, usually arranged in clusters and distributed in a decreasing gradient towards the OB. In addition, BrdU+ cells were concentrated along the periphery while the core was less densely populated. Moreover, nuclei with heavily labeled uniform chromatin were more numerous along the periphery of the SVZ, while nuclei with non-uniform heterochromatin labeling were predominant within the core. This result suggests a restricted spatial distribution of early and late S-phase cells within the postnatal SVZ, probably reflecting distinct compartments for proliferation and migration within this zone. Financial support: CNPq, FINEP.

## 214.10

**SEX DIFFERENCES IN THE CELL CYCLE PARAMETERS OF THE PROLIFERATIVE VENTRICULAR EPITHELIUM (PVE) IN THE DEVELOPING RAT PREOPTIC AREA.** V.K. Chetverukhin\*, E.V. Chernigovskaya\*, O.A. Danilova\* and B.S. Nowakowski\*, \*Sechenov Institute of Russian Academy of Sciences, 184223 St. Petersburg, Russia, \*Dept. of Neuroscience and Cell Biology, UMDNJ-RWJMS, Piscataway, NJ 08854, USA.

To elucidate developmental mechanisms of the sexual differentiation in the mammalian brain we have investigated possible sex differences in the cytokinetic behavior within the proliferative ventricular epithelium (PVE) of the developing rat preoptic area (POA). Wistar rat embryos ranging in age from embryonic day 13 (E13) through E16 were exposed to a sequential double S-phase labeling first with 3H-thymidine followed 2 hours later with bromodeoxyuridine (BUDR) and sacrificed 0.5 hours after BUDR administration. The sex of each embryo was determined by counting Barr bodies, i.e., the inactivated X-chromosome (Barr & Bertram, 1949, Nature, 163:676-677) in postmitotic neurons of the brains and spinal ganglia. Labeling indices (ratios of the number of nuclei labeled with one or both markers to all nuclei) were used to calculate the duration of the cell cycle (Tc). Within the PVE, we have found sex differences in Tc that vary with the developmental stage. No differences in Tc were found in POA at E13 (Tc=11 hrs). In contrast, at E14 and E15, Tc was much shorter in males (Tc=13 hrs) than in females (Tc=16 hrs). However, these sex differences are reversed at E16, by which time Tc has become longer in males (Tc=23 hrs) than in females (Tc=17 hrs). Thus, our study has provided the first evidence for the existence of sex differences in the proliferative behavior of cells of the embryonic rat POA. We suggest these sex differences in cell cycle regulation may contribute to, and indeed presage, the formation of the sexual dimorphism in the adult mammalian POA. ## 214.12

**BIRTHDATING EXPERIMENTS IN EMBRYONIC MONKEY REVEALS DISTINCT PATTERNS OF CELL PROLIFERATION AND MIGRATION IN PRESUMPTIVE VISUAL AREAS 17 AND 18.** H. Kennedy\*, C. Dehay\*, G. Ziegler, J. Smart\*, P. Giroud and M. Berland, INSERM U371, 18 Ave du Doyen Lépine, 69675 BRON (France), \*Dundee University Dundee, Scotland.

Direct examination of the proliferative activity of the monkey cortical precursors shows that modulation of the cell-cycle kinetics parameters is responsible for the histogenesis of distinct cortical areas in the primate (Dehay et al., Nature, 1993) and that cell-cycle duration was shorter in area 17 precursors than in area 18 precursors (Kennedy et al., 1995) during the generation of supragranular layers. Here we show that after long survival times, labelling patterns in the adult cortex reflect differences in the areal kinetics. Using long survival times, tritiated thymidine (H3-Thy) pulse injection at E65 results in heavily labelled cells being located in layer 6 in area 17 and in layer 5 in area 18 of the mature cortex. Injection at E78 resulted in heavily labelled neurons being located in layers 2/3 in both areas. Computation of the Labelling Index in the mature cortex indicates differences in the relative duration of S phase with respect to the total cell-cycle duration between area 17 and area 18 precursors during the generation of supragranular layers whereas no difference in the cell cycle kinetics can be detected in the two sets of precursors generation of layer 5. The transition from low values of LI in area 18 to higher values in area 17 is abrupt and coincides with the cytoarchitectural boundary.

The germinal zones giving rise to areas 17 and 18 exhibit conspicuous morphological specialisations which are related to neuron production. Pulse injections of H3-THY made at regular intervals between E61 and E94 and combined with short survival times allows the identification of the germinal zones and reveal that the major phase of neuron output in area 17 is provided by the subventricular layer that expands enormously between E61 and E71 while the ventricular layer is regressing. Pulse injection of H3-Thy at E64 followed by a 7 day survival time shows that migration of neuroblasts from the germinal zone to the cortical plate is considerably faster in presumptive area 17 than in presumptive area 18. This increased rate of migration accommodates the higher rates of proliferation characteristics of A17 ventricular zone. This means that complex mechanisms are regulating the migration rate of neuroblasts originating from distinct regions of the ventricular zone and that there is a precise orchestration of the timing of early events of areal histogenesis.

Bibliography: Dehay et al., Nature (1993); Kennedy et al., Neurosci. Abst (1995); Supported by EEC grant SCT\*CTIO622, HFSP grant RG-55/94B and MRE grant 92C0678.

## 214.14

**MITOTIC NEUROBLASTS ENGAGE IN AXONAL OUTGROWTH AND PATHFINDING IN VIVO.** E. Wolf, L. B. Black, and E. DiCicco-Bloom\*, Dept. Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ 08854

Neuroblast proliferation (neurogenesis) is believed to precede axodendritic outgrowth during neuronal development. However, we previously showed that 1) mitotic sympathetic neuroblasts and cerebellar granule cells in culture elaborate neurites before mitosis, 2) the morphology of these "paramitotic" neurites is heritable, and 3) some mitotic sympathoblasts *in vivo* project axons toward targets before dividing. These findings suggested that mitotic neuronal precursors, in addition to postmitotic neurons, initiate pathfinding.

To begin characterizing the role of paramitotic axonal outgrowth in superior cervical ganglion (SCG) development, we examined ganglia from embryonic ages E15.5 and E16.5. Mitotic neuroblasts projecting axons out of the ganglion were identified by combined retrograde tracing of the internal carotid nerve (ICN) and bromodeoxyuridine (BrdU) labeling of S-phase neuroblasts. We found that a substantial fraction of the mitotic population has axons in the ICN during early neurogenesis *in vivo* (12% at E15.5 and 7% at E16.5).

To assess the incidence and topography of this phenomenon, both the ICN and the external carotid nerve (ECN) of E16.5 ganglia were retrograde-traced. With this procedure, the fraction of S-phase, axon-bearing cells nearly doubled (reaching 13%), and these cells were not regionally restricted within the ganglion. Thus, axon elaboration and pathfinding by mitotic neuroblasts is common and occurs throughout the developing ganglion *in vivo*.

These results raise the possibility that neurogenesis and neuronal connectivity are simultaneously orchestrated through direct interaction of proliferative populations with distant targets. As cerebellar granule cells exhibit paramitotic neurites in culture, this principle may apply more generally to nervous system formation. Supported by NIH HD 23315 and Trophix Pharm.

## 215.1

ISOLATION AND CHARACTERIZATION OF ISAS8-INFECTED RAT OLFACTORY EPITHELIAL CELLS *IN VITRO*. A. N. Polzin\* and D. D. Hunter. Depts. of Neurosci. and of Anatomy and Cell Biol., Tufts Univ., Boston, Mass.

The neurons of the olfactory epithelium continue to turn over and differentiate throughout the life span of an animal; however, the molecular mechanisms underlying these phenomena are not entirely clear. Attempts to elucidate the regulation of proliferation and differentiation of the olfactory epithelium have been hampered by technical limitations both *in vivo* and *in vitro*. For example, primary cell culture systems have been characterized with limited success in part due to the difficulty of isolating pure populations of each cell type present in the olfactory epithelium. Consequently, we have begun to develop cell lines derived from the rat olfactory epithelium that would allow for more accessible biochemical manipulation. This may be potentially useful to search for molecules that are involved in the development of the olfactory epithelium, as well as to identify factors that are either intrinsically or environmentally determined.

To construct cell lines from the olfactory epithelium, we infected the epithelium, dissociated from newborn rats, with a replication-incompetent retrovirus carrying an oncogene. We used a temperature-sensitive mutant of SV40 large T antigen that should promote the proliferation of infected cells at 33°C, but lose its effect at 39°C, thereby allowing the infected cells to differentiate. Following selection in geneticin, eighteen colonies were isolated; five of these (AP7, AP8, AP9, AP11 & AP12) have continued to grow well and adhere tenaciously to the substrate. As expected, when grown at 39°C, cells showed morphological characteristics of further differentiated state, including longer processes. As an initial step to analyze the biochemical characteristics of the cell lines, we looked for the presence of two neuronal markers, NCAM and MAP5, by immunocytochemistry. At 33°C, the cells express little NCAM and no MAP5; in contrast, at 39°C, the cells express both NCAM and MAP5, suggesting that they are neuronal.

To further characterize the cells, we are currently determining the expression of other cell type-specific markers. If the lines are biochemically established to be derived from the olfactory receptor neuron (ORN) lineage, we are interested in testing environmental factors that may control the proliferation and differentiation of progenitor cells and ORNs. The establishment of cell lines of the globose basal cell/ORN lineage may provide insight into mechanisms by which the olfactory epithelium regenerates and factors controlling this process. Support: NIH; Grant #NS29785

## 215.3

FGF AND ACTIVIN SIGNALLING PATHWAYS IN THE DETERMINATION OF RETINAL CELL FATES. Kathryn B. Moore and Sally A. Moody\* Department of Anatomy and Cell Biology and Neuroscience Program, The George Washington University, Washington, DC 20037.

In vertebrates, retinal progenitors begin as multipotent cells which undergo a systematic restriction in cell fate, yet the signalling pathways that determine these fates have not been well defined. In *Xenopus*, both cell position and competence determine whether embryonic progenitors will enter the retinal lineage (Huang and Moody, 1993, *J. Neurosci.* 13, 3193-3210). To identify the molecular basis of these events, we have begun to examine which potential signals (position) and signal transduction machinery (competence) are necessary and/or sufficient. Our first step has been to test specific signals involved in the induction of dorsal mesoderm, the first known signalling event in *Xenopus* development. mRNAs encoding functional and dominant-negative forms of FGF receptors mixed with mRNA for Green Fluorescent Protein as a lineage tracer, were targeted to retinal precursor cells (D1.1.1) in the 32-cell embryo. When the FGF pathway was eliminated in D1.1.1 cells by overexpression of the dominant-negative FGF receptor, these blastomeres continued to contribute to the retina. However, a subset of D1.1.1 descendants was blocked from assuming dorsal mesoderm and ventral brain fates. Wild type FGF receptors were ectopically expressed in V2.1.1, a blastomere that does not normally contribute to retina, and is not competent to produce retinal lineages when transplanted to the D1.1.1 "retinogenic" region of the embryo. Regardless of whether the blastomeres were left in situ or transplanted to the D1.1.1 position, descendants of V2.1.1 only populated the gut and lateral mesoderm, as are their normal fates (Moody, 1987 *Develop Biol.* 122 300-319). Together, these results demonstrate that an intact FGF signalling pathway is not sufficient to specify a blastomere contribution to retinal lineages. Results from the genetic manipulation of functional and dominant-negative activin receptors also will be presented. Supported by NIH grants EY10096 (SAM) and EY06649 (KBM).

## 215.5

OTX2 EXPRESSION IS RESTRICTED TO OUTER LAYERS OF THE EMBRYONIC MAMMALIAN RETINA. K. C. Wikler\*, F. M. Vaccarino and D. L. Stull. Section of Neurobiology, Yale Sch. of Medicine, New Haven, CT, 06510.

The homeobox gene *orthodenticle* (*otd*) plays a critical role in photoreceptor cell development in the *Drosophila* eye (Vandenberg et al., *Dev. Biol.*, 173, 243-255). Specifically, *otd* participates in the relative positioning of photoreceptor subtypes within each ommatidium. We are examining the expression of *Otx2*, the vertebrate homologue of *otd*, in the embryonic mouse and monkey retina to determine whether it serves a similar function in the development of the mammalian photoreceptor mosaic.

Mouse retinae from embryonic (E) day E10, E11, E12, E13, E14, E18, and E20, and macaque monkey retinae from E68 and E84 were sectioned and either immunoreacted with a polyclonal antibody to *Otx2* protein or probed for *Otx2* message using digoxigenin-UTP labeled human *Otx2* mRNA. At E11, the onset of cone genesis in central retina, *Otx2*-positive cells were identified in this region near the proliferative neuroepithelium. By E18, when cone genesis is complete, *Otx2* expression extends into the retinal margins, but remains restricted to the outer layers of the retina. This consistent laminar distribution of *Otx2* mRNA and protein is distinct from the uniform expression patterns of other homeobox genes in the embryonic murine retina (e.g. *Dlx-1*). This pattern of *Otx2* expression was observed in the fetal monkey retina as well; at E68 and E84, *Otx2* immunoreactivity is restricted to the outer layers of the retina and appears to label cone photoreceptors.

The restricted expression pattern of *Otx2* is strikingly similar during the development of the mouse and monkey retina, suggesting that its role in generation and differentiation of photoreceptors may be conserved across species. Supported by EY09917 (KCW).

## 215.2

TASTE BUD DEVELOPMENT IS AUTONOMOUS IN ANTERIOR ENDODERM ISOLATED FROM AMPHIBIAN GASTRULAE. L.A. Barlow\* and R.G. Northcutt. Dept. of Neurosciences, UC San Diego, La Jolla, CA 92093.

The predominant model of embryonic taste bud development has held that ingrowing nerve fibers induce the differentiation of taste buds late in embryonic development. However, several recent findings indicate that the differentiation of embryonic taste buds is independent of innervation. Using salamander embryos, we have now also eliminated the potential inductive role of cephalic neural crest. Taste buds will develop *in vitro* in tissue devoid of neural crest (Barlow and Northcutt, 1995). We have further investigated the ability of isolated cephalic endoderm to generate taste buds under culture conditions by pushing our experimental paradigm back in developmental time. We explanted the anterior ventral endoderm of early salamander embryos (stage 13) and placed the tissue in simple culture medium (60% L15 with Gentamycin and Fungibact) for 10-12 days, until intact control embryos had taste buds. The majority of explants survived and developed taste buds which were recognized using several immunocytochemical markers. Based on these results we have formulated a new model of taste bud genesis. We propose that the initial event in taste bud patterning occurs at gastrulation and involves the specification of anterior (head) endoderm. Subsequently, local cell-cell interactions within this cephalic endoderm trigger differentiation of scattered taste cell progenitors which ultimately produce taste buds. We are currently testing the components of this model.

Supported by NIH grants DC00114 to LAB and DC01081 to RGN.

## 215.4

THE PROGENITOR CELLS IN THE *XENOPUS LAEVIS* NEURULA ORIGINATE DIFFERENT RETINAL CELL LINEAGES. Sen Huang\*, Ida Chow and Sally A. Moody. Department of Anatomy and Cell Biology and Neuroscience Program, George Washington University and Department of Biology, American University, Washington D.C.

We previously demonstrated that as early as the 32-cell stage *Xenopus laevis* blastomeres are biased to produce different amacrine neurotransmitter phenotypes in the retina. The present study aims in determining if the neuroectodermal progenitor cells in the neural plate and neural fold are restricted in their production of different retinal cell types. A fluorescent lineage tracer, Texas Red-Dextran Amine, was iontophoretically injected into the stage 14 to 20 embryos' neuroectodermal cells. At stage 44/45 tadpole retinas were serially sectioned (14 µm) and immunostained to show the GABAergic amacrine cells in the lineage labeled clones. On average, stage 14 progenitors produced clones with 11 cells, stage 16 progenitors produced clones with 7 cells, and stage 20 progenitor clones had 6 cells. Normally, half of the retinal cells are interneurons, about a quarter are photoreceptors, another quarter ganglion cells and some glial cells. However, in the labeled clones 80% of the retinal cells were interneurons, 14% photoreceptors, 4% ganglion cells and 2% glial cells. Two types of clones were observed: 1) radial clones (61%) span all layers of the retina and contain almost all retinal cell types; and 2) tangential clones (39%) spread within a single retinal layer and contain only restricted cell types, mostly horizontal and bipolar cells. Among the lineage labeled amacrine cells, GABA-positive and GABA-negative cells could be found in the same clone. These results suggest that the neuroectodermal retinal progenitors in the neurula are not homogeneous; some of them are determined to produce restricted retinal cell types. (Supported by NIH grant EY10096)

## 215.6

EARLY DIVERGENCE OF POSTMITOTIC CELLS INTO MAJOR GANGLION CELL CLASSES IN THE EMBRYONIC MONKEY RETINA. P. Rakic\* and K. C. Wikler. Sect. of Neurobio., Yale Sch. Med., New Haven, CT.

M and P ganglion cells project to magno- and parvocellular laminae of the lateral geniculate nucleus (LGN) respectively, forming separate and parallel pathways within the primate visual system. M and P ganglion cells can be identified in the adult macaque by antibodies that recognize specific POU domain proteins (Brn-3a, Brn-3b) (Xiang et al., 1995, *J. Neurosci.*, 15, 4762). In the present study we mapped the distribution of Brn-3 proteins in the fetal monkey retina to determine the time and mode of emergence of M and P ganglion cells in relation to the development of their connections within the retina and with the LGN.

Retinae from embryonic (E) day E68, E82, E93, E120 and adult macaque monkeys were serially sectioned and immunoreacted with either the Brn-3a antiserum, which labels all M cells lightly and a subset of P cells intensely, or the Brn-3b antiserum, which labels all P cells intensely. Adjacent sections were labeled alternatively with either the Brn-3a or b antiserum. Analysis of these sections indicated that, as early as E68, these antisera identify separate sets of cells in the ganglion cell layer at more mature, central regions of the retina. Strikingly, these antisera label separate sets of migrating cells near the proliferative neuroepithelium in less mature, peripheral regions of the same retina. These data indicate that Brn3 antibodies identify different subsets of cells prior to their arrival in the ganglion cell layer.

Although the final proportion of M and P cells may be sculpted through differential cell death after retinogeniculate connections have been established, our results suggest that M and P ganglion cells diverge into their respective subtypes coincident with their final mitotic division, prior to the formation of any synaptic contacts within the retina or with the LGN. Supported by EY09917 (KCW) and EY02593 (PR).

## 215.7

ASYMMETRIC EXPRESSION OF RETINOID RECEPTORS DIVIDES THE EMBRYONIC MOUSE RETINA INTO DORSAL AND VENTRAL COMPARTMENTS. D.L. Stull\* and K.C. Wikler. Sect. of Neurobiol., Yale Sch. of Med., New Haven, CT.

We are interested in cellular and molecular mechanisms that regionalize the embryonic mouse retina and segregate middle (MWS) and short (SWS) cones into their respective dorsal and ventral fields. We demonstrated a regional heterogeneity in the response of neuroblasts to endogenous retinoids using indicator mice that possess a retinoid dependent *lacZ* reporter transgene (Stull and Wikler, Soc. Neuro. Ab. 21:1529). Transgene activation is restricted to dorsal retina prior to cone genesis and ventral retina coincident with cone genesis. It remains unclear whether this regional response to retinoic acid (RA) is due to local differences in the synthesis of RA and/or the expression pattern of retinoid receptors.

If local availability of RA regulates transgene activation, then augmenting RA levels should alter the pattern of *lacZ* expression. To test this hypothesis, pregnant indicator mice were given either 50 mg/kg all-trans RA in oil or oil alone 14 hours prior to sacrifice at embryonic (E) days E9.5, E10, E11, and E13. Embryos were sectioned, immunoreacted for  $\beta$ -galactosidase ( $\beta$ -gal), and counterstained with bis-Benzidine. Exogenous RA did not alter the pattern of transgene activity:  $\beta$ -gal positive neuroblasts were restricted to dorsal retina between E9.5 and E11 and ventral retina by E13. To determine if differences in the expression patterns of retinoid receptors underlie dorsal/ventral differences in transgene activation, we mapped the distribution of retinoid (RXR) and RA receptor (RAR) mRNAs across the neuroepithelium. RXR $\alpha$ , RXR $\beta$ , and RXR $\gamma$  are ubiquitously expressed in the retina at E11 and E12; RXR $\gamma$  becomes restricted to the ganglion cell layer and the proliferative zone by E14. In striking contrast to these regionally uniform expression patterns, RAR $\beta$  expression is restricted to dorsal retina at E11 and E12 and extends into ventral retina by E13. These results suggest that the asymmetric response of the neuroepithelium is determined by regional differences in the expression of retinoic acid receptors, and not by local differences in RA synthesis. Supported by EY09917 (KCW).

## 215.9

# IN VITRO DIFFERENTIATION OF EMBRYONIC STEM CELLS INTO MOTONEURON-LIKE CELLS

S. Alonso, Y. Renoncourt, P. Filippi, B. Pettmann\*, D. Salaun, V. Arce and P. Carroll. INSERM U382, IBDM, Case 907 Luminy, 13288 Marseille Cedex 09, France.

Our aim is to better understand the mechanisms that control early motoneuron differentiation. *In vitro* studies of motoneuron differentiation from progenitor cells have been hampered by the lack of established cell lines but recently it has been shown that pluripotent embryonic stem cells can differentiate into various cell types including neurons. We show that retinoic acid (RA) alone is able to induce ES cells from cell line D3 to differentiate along a neuronal pathway characterized by the expression of CD24, GAP43 and NF200. Neurotrophin-3 (NT-3) has previously been shown to induce motoneuron differentiation from avian neural tube progenitor cells (Averbuch-Heller et al., 1994). NT-3 alone is unable to induce ES cells from D3 to differentiate into neuron-like cells. Although RA induces neuronal differentiation, it cannot induce the expression of the LIM homeoprotein *Islet1/2* characteristic of motoneurons. We show that NT-3 in combination with RA induces the appearance of a sub-population of neuron-like cells which express the neurofilament subunit NF200 and *Islet*. We also tested bFGF in presence of RA with or without NT-3 and found no *Islet*-positive neurons. Efficient production of motoneurons from ES cells would considerably facilitate the understanding of motoneuron differentiation.

Supported by grants from The Institut pour la Recherche sur la Moelle Epinière (IRME), the Fondation pour la Recherche Médicale (FRM), the Association Française contre les Myopathies (AFM), INSERM, and CNRS.

## 215.11

# ENGRAILED-1 IS EXPRESSED IN A SUBSET OF SPINAL INTERNEURONS DURING MOUSE DEVELOPMENT

Michael P. Matise\* and Alexandra L. Joyner. Skirball Institute, New York University Medical Center, New York, NY 10016.

The homeobox-containing gene *Engrailed-1* (*En-1*) is expressed in the developing nervous system in neuroepithelial cells spanning the mesencephalic-metencephalic junction, as well as in a bilateral stripe of cells in the ventral hindbrain and spinal cord. Targeted deletion of *En-1* in mice results in the loss of midbrain and cerebellar structures derived from *En-1* expressing regions, suggesting that *En-1* is required for the survival of these precursor cells. In contrast, the spinal cord and hindbrain appear to develop normally. In the spinal cord, *En-1* is initially expressed in cells immediately dorsal to motoneurons, at 9.5-10 days post coitum (dpc). Later, *En-1* cells are located dorsally and laterally, with scattered cells within the motor column in limb regions, but throughout the ventrolateral cord in non-limb regions. As the ventral ventricular zone contracts, *En-1* expression persists at its margins. All *En-1* cells express class III  $\beta$ -tubulin and are thus postmitotic neurons. In addition, *En-1* neurons comprise a subpopulation of *Lim-1/2* expressing cells. The earliest *En-1* expression at ~10 days marks the ventral limit of *Lim* expression dorsal to developing motoneurons. Later, *Lim* expression expands ventrally predominantly into the medial portion of the lateral motor column (LMC), but also some expression is seen in more lateral LMC regions. These latter *Lim* + cells also express *En-1*. No *En-1* interneurons express *Islet-1/2* proteins.

To study the fate of *En-1* cells mice were generated in which the reporter gene *lacZ* has been targeted into the first exon of *En-1*, resulting in a loss-of-function of *En-1* while simultaneously providing a marker for *En-1* expressing cells (Hanks et al., 1995). In heterozygote embryos, the pattern of expression of  $\beta$ -galactosidase ( $\beta$ -gal) is similar to *En-1* as assessed by antibody or in-situ analysis. In homozygotes,  $\beta$ -gal activity in the spinal cord is initiated and maintained in a manner virtually indistinguishable from heterozygous littermates, at all stages examined (10-17.5 dpc). This result indicates that *En-1* is not required for the survival of *En-1* expressing cells. The presence of *En-1* interneurons in the knockout will allow us to begin to analyze the effects of the loss of *En-1* on the development of these cells and the spinal cord. M.M. is supported by an NRSA postdoctoral training grant.

## 215.8

# POSTINFLAMMATORY MUSCLE NEOGENESIS, A.B. Drakontides,\*

M.J. Danon, and S. Levine. Depts. of Cell Biology and Anatomy, Neurology, Pathology, New York Medical College, Valhalla, NY 10595, and N.S. Kline Institute, Orangeburg, NY 10962.

Recent studies (Levine & Saltzman, Exp. Mol. Pathol. 60:60, 1994) have demonstrated formation of ectopic skeletal muscle cells at the peritoneal surface of rat diaphragm following a single injection of chemical irritant. Current studies present further observations of this inflammatory-induced myogenesis. Rats (150-300g) were killed 1 to 180 days (ds) after a single IP injection of sodium dodecyl sulfate, 100 mg/kg. Samples of diaphragm were processed for histochemical and EM studies. The peritoneum overlying intrinsic muscle was thickened and subdivided into an outer inflammatory and inner dense connective tissue (ct) layer. At 4 ds, between these two layers, large myoblast-like cells with central nuclei and bundles of myofibrils were seen. Myotubes and mature muscle cells were evident at 7 and 14 ds. Myogenic elements were always oriented perpendicular to intrinsic muscle and separated from it by a layer of dense ct. Ectopic muscle cells were still present after 180 ds; at this time smooth muscle cells were also evident. The source of skeletal muscle cells is unknown. Muscle satellite cells are excluded, as dense ct would create a barrier for migration. Chemical insult and subsequent sequelae may induce resident fibroblasts, mesothelial cells or stem cells to differentiate into muscle.

## 215.10

# LINEAGE ANALYSIS IN THE EARLY CHICK THORACIC SPINAL CORD

E. B. Cornbrooks\* and C. J. Forehand. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405

In the embryonic neural tube, morphologically similar neuroepithelial precursor cells give rise to a variety of cell types, including motor, sensory and glial cells. In an effort to understand the factors influencing development of the different cell phenotypes, we have begun a lineage analysis of precursor cells in the chick thoracic neural tube. Due to our particular interest in sympathetic preganglionic neurons, we have labeled single progenitor cells in the ventral neural tube at stages encompassing the birth of preganglionic and motor neurons. A fluorescent tracer, Texas red labeled dextran amine, was iontophoretically injected into single neuroepithelial cells in the ventral thoracic neural tube of stage 14-22 chicken embryos. Successful injection restricted to a single neuroepithelial cell was confirmed by visual inspection. Embryos were fixed 2-3 days after injection and the thoracic spinal cord was serially sectioned. Clonal analysis revealed labeled cells in the thoracic region grouped closely to the site of injection; a labeled cell in the ventricular zone, presumed to be the progenitor, could be clearly identified in most embryos at these early time points. Clone size ranged from 12-28 cells, dispersed laterally to the progenitor cell. Typically, cells adjacent to the ventricular zone were morphologically undifferentiated, while more laterally positioned cells exhibited numerous processes. In some clones, labeled cells in a ventrolateral position in the spinal cord had rich arbors and an axon extending out the ventral root, clearly identifying these cells as motor neurons. Supported by the VT Affiliate of the AHA (EBC) and NIH R01 NS30062 (CJF).

## 215.12

# NEUROEPITHELIAL STEM CELLS; ISOLATION, CHARACTERIZATION AND CLONAL ANALYSIS. M. S. Rao\*,

A. Kalyani, and K. Hopson. Department of Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

To study rat spinal cord development we have established cultures of E10.5 neuroepithelial cells (NEP cells) from the caudal neural tube. NEP cells require both FGF (fibroblast growth factor) and CEE (chick embryo extract) to proliferate and to maintain an undifferentiated phenotype. Epidermal growth factor (EGF) does not support E10.5 NEP cell survival and NEP cells do not form neurospheres in EGF supplemented medium. NEP cells express nestin and lack all lineage specific markers for neuronal and glial sublineages. Cultured and passaged NEP cells do however, retain their pluripotent character and can differentiate into neurons and oligodendrocytes when plated on laminin in the absence of CEE. In addition, NEP cells differentiate into astrocytes when supplemented with fetal bovine serum. Thus NEP cells can generate all major CNS cell types in culture. NEP cells grown at clonal density generate colonies that vary in size from single cells to several thousand cells. Approximately 40% of the clones are multipotent and contain A2B5 (an oligodendrocyte marker), B-111 tubulin (a neuronal marker) and GFAP (an astrocyte marker) immunoreactive cells. NEP cells also differentiate into ChAT and p75 immunoreactive cells, likely to be motoneurons, in both mass and clonal cultures. Double labeling of clonal cultures shows that ChAT immunoreactive neurons always arise in mixed cultures with other differentiated cells. Thus, motoneurons differentiate from a pluripotent NEP progenitor cell. The relationship of the NEP stem cell with other CNS derived stem cells is discussed. Supported by the Muscular Dystrophy Association and a University of Utah faculty award.

## 215.13

NEUROEPITHELIAL CELLS FROM EMBRYONIC SPINAL CORD CAN GIVE RISE TO GLIAL PRECURSORS. Margot Mayer-Proschel\* and Mahendra S. Rao. \*Department of Oncological Science, University of Utah/Huntsman Cancer Inst., Biopolymers. Res. Bldg. 570, Tel 585-7170, Salt Lake City, Utah 84132

In embryonic rat spinal cord the ventricular zone of neuroepithelial cells differentiates into neurons, astrocytes and oligodendrocytes. We have observed that cultured E10.5 neuroepithelial cells (NEP), which do not express lineage markers for oligodendrocytes, astrocytes or their precursors can be induced to differentiate into A2B5 immunoreactive cells in culture. A2B5 is an antigenic marker which is expressed on Oligodendrocyte-Type-2 astrocyte progenitor cells (O-2A cells) which have been characterized extensively in the postnatal optic nerve. Clonal analysis of the induced A2B5 expressing NEP cells shows that the immunoreactive population arise from multipotent precursor cells. Double-labeling of the A2B5 positive cells in mixed cultures demonstrates that a subset of the cells can give rise to oligodendrocytes (determined by GalC and O4 immunoreactivity) and astrocytes (identified as GFAP expressing cells), depending on the culture conditions. Selecting the A2B5<sup>+</sup> population by appropriate techniques and culturing them in oligodendrocyte and astrocyte promoting medium showed that this population of cells can generate both oligodendrocytes and astrocytes in the absence of the A2B5<sup>+</sup> cell population. Single cell cloning experiments showed that individual cells were capable of generating both astrocytes and oligodendrocytes suggesting that this differentiation does not require cell-cell contact or signals from other cells. Thus, the A2B5 immunoreactive population derived from NEP cells may represent cells similar to the bipotential O-2A progenitor cell. The NEP culture system therefore provides an unique opportunity to study the cellular and molecular mechanisms that regulate commitment of a multipotent precursor cell into a cell with a more limited developmental potential. This system will also allow us to determine the complex relationship between glial cell precursors isolated from various region of the brain during different stages of glial cell development.

Supported by the Muscular Dystrophy association, a University of Utah faculty award and the Huntsman Cancer Institute at the University of Utah.

## 215.15

EXPRESSION OF *Dfd* HOMOLOGUES IN IDENTIFIABLE NEURONS OF LEECH. V.Y. Wong\*, H.-J. Wang, and E. Macagno. Dept. Biol. Sci., Columbia Univ., New York, NY 10027

To further explore the roles of *Antennapedia*-class homeobox genes in the determination of neuronal cell identity, we have isolated two leech *Dfd* homologues from an embryonic cDNA library and have begun to characterize their expression. The deduced amino acid sequences of *Lox6* and *Lox20* suggest that both are homologues of the *Drosophila* gene *Deformed*.

Thus far, we have only analyzed expression patterns of *Lox6*. Northern blot hybridization indicates that it is expressed in juvenile leeches. *In situ* hybridization shows that expression begins in the CNS at about embryonic day 7 (E7), in the subesophageal ganglion as well as in midbody ganglia 1 (MG1) through 21. At E8, the expression is observed in all ganglia. Interestingly, by E12, only a few pairs of neurons continued to express *Lox6*, with the strongest expression detected in MG1.

The unique expression pattern of *Lox6* in the CNS suggests that this gene may have important roles in determining the identities of specific neurons. We are currently trying to identify these cells by *in situ* hybridization coupled with dye-filling techniques. (Supported by NIH grant HD20954).

## 215.17

HPC-7, A NOVEL STAGE SPECIFIC OLIGODENDROCYTE MARKER. D. Baas, R. Hofstein, M.S. Ghandour\* and C.J. Barnstable. Dept. of Ophthalmology and Visual Sciences, Yale School of Medicine, New Haven, CT 06520. \*Centre de Neurochimie, Strasbourg, France

The identification of cell-type specific molecules expressed at different developmental stages can help to elucidate the regulatory mechanisms governing the survival, differentiation and development of cell in the central nervous system (CNS). Oligodendrocytes (OL) form the myelin sheath and are essential for propagation of nerve impulses. In culture, OL arise from bipotential (O-2A) progenitor cells in chemically defined medium. These O-2A cells give rise to type-2 astrocytes in presence of serum.

Mouse monoclonal antibody HPC-7 was secreted from hybridomas produced by fusion of P3-NS1/1-Ag4-1 plasmacytoma cells with spleen cells from BALB/c mice immunized with rat hippocampal membranes. Immunofluorescence on adult rat brain sections showed selective labelling of white matter and other myelinated fibers. Staining of rat secondary cultures of OL, O-2A and type-2 astrocytes (> 90 % pure in each case) showed selective labelling of OL. To determine at what stage in the OL lineage HPC-7 is expressed, cultures of O-2A progenitors and their progeny were examined. O-2A progenitor cells (A2B5 positive) and type-2 astrocytes (GFAP and A2B5 positive) were HPC-7 negative but OL (galactocerebroside positive) cells were HPC-7 positive so this antigen is only expressed in differentiated OL. In order to characterize more fully at which stage of differentiation HPC-7 appears, we performed double labelling with other antibodies including vimentin, Jones, OL-1, O1 and MBP. Supported by grants from NIH and the Kemper fund.

## 215.14

EN-1 AND EN-2 CONTROL MIDBRAIN DEVELOPMENT IN A GENE DOSE-DEPENDENT MANNER. H.H. Simon\*, W. Wurst#, and D.D.M. O'Leary. Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, CA #GSF-Research Center, Oberschleissheim, Germany.

The embryonic expression domains of *En-1* and *En-2* in the murine brain overlap to a large extent. They are expressed in the dorsal aspect of the most rostral hindbrain and throughout the neuroepithelium in the caudal midbrain. These expression domains coincide with the embryonic regions which give rise to the cerebellum, the inferior and superior colliculi, and more ventrally located mesencephalic nuclei. Homozygous mice for the *En-2* mutation are viable and fertile, those deficient for *En-1* die at birth and the entire cerebellum, inferior colliculus and the caudal superior colliculus are absent. The phenotype of the *En-1/En-2* double mutant reflects the early ontogenetic expression of the two genes. In addition to the deficiencies of the *En-1* mutants, the superior colliculus is completely ablated and deeper mesencephalic nuclei are also affected; the noradrenergic locus coeruleus, the mesencephalic dopaminergic cells groups and the serotonergic dorsal raphe nucleus are all absent in these mice.

Here we describe midbrain development within the context of the four engrailed alleles. The phenotype of the P0 mutant mouse heterozygous for *En-1* and homozygous for *En-2* (*En-1*<sup>-/-</sup>;*En-2*<sup>-/-</sup>) is undistinguishable from the wildtype. In contrast *En-1*<sup>-/-</sup>;*En-2*<sup>-/-</sup> mutant mice, their phenotype is stronger than the single mutant (*En-1*<sup>-/-</sup>) but less severe than the double mutant (*En-1*<sup>-/-</sup>;*En-2*<sup>-/-</sup>). Dorsally, the superior colliculus is further truncated in comparison to the *En-1* mutant but not ablated as observed in the double mutant. Ventrally, noradrenergic, dopaminergic and serotonergic cell clusters are all reduced in size but still present. The reduction in size of these chemically defined neuronal cell clusters in the *En-1*<sup>-/-</sup>;*En-2*<sup>-/-</sup> mutant mice is already apparent by the lower number of these neurons in E12 embryos, at which age they can be first defined. The phenotype of the *En-1*<sup>-/-</sup>;*En-2*<sup>-/-</sup> mutant suggests that the engrailed genes control the midbrain formation in a gene dose-dependent manner. Supported by HFSPO LT-526/94 and NS31558

OLIGOSPHERES AS A MODEL TO STUDY MIGRATION *IN VIVO* AND *IN VITRO*. Avellana-Adalid V., Nait-Oumesmar B., Lachapelle F., Aigrot M.S., Baron-Van Evercooren A.

Cell migration is an essential phenomena in plasticity of the developing and lesioned Central Nervous System (CNS). After CNS demyelination, oligodendrocyte progenitors (OP) but also Schwann cells (SC) contribute to the repair of the lesion. However, their contribution to this phenomena is often limited suggesting ineffective migration in the adult CNS environment.

Migration will depend on interactions that cells establish with the surrounding substrates and the soluble factors present around the lesion. We have designed a strategy to produce homotypic aggregates of purified primary rat OP which we have called "oligospheres" and which can be expanded for over one year in culture. When seeded onto an adhesive substrate they serve as focal reservoirs of OP. Within minutes, OPs emerge synchronously and radially from the sphere onto the substrate (e.g. poly-orbitine). They migrate as bipolar cells aligned against each other and with a speed of 50-60µm/h. Seeded onto adult spinal cord sections and organotypic cerebellum slices *in vitro*, oligospheres derived OPs migrate over white matter and the ependymal wall but not over grey matter. Grafted at a distance from a LPC induced lesion of the mouse spinal cord, oligospheres derived OPs followed the same routes of migration before reaching the lesion. Similar data were obtained with the CG4 rat OP cell line (induced to form oligospheres). Oligospheres are, in contrast to dissociated or clumped cell suspensions, easy to handle focal sources (restricted localisation) of OP. Thus oligospheres are a powerful tool to study the mechanisms which are involved in the migration of OP.

ORIGIN OF OLIGODENDROCYTES EXPRESSING FERRITIN IN THE RAT BRAIN. P. Cheepsunthorn\*, S. Levison and J. Connor. Dept. Of Neuroscience & Anatomy, M.S. Hershey Med. Ctr. Penn State College of Medicine, Hershey PA 17033

Ferritin is the intracellular iron storage protein and is expressed in oligodendrocytes. In the white matter, ferritin positive oligodendrocytes occur in discrete patches of cells and not all oligodendrocytes contain ferritin. This observation that subsets of oligodendrocytes express ferritin suggests either that ferritin (and iron) containing oligodendrocytes are programmed (genetically determined) to migrate to specific areas within the white matter or they are influenced by their position (epigenetic factors) to express ferritin. In this study, the subventricular zone of rats at 2 days of age was injected with retrovirus carrying the E. coli beta-galactosidase gene. At 28 days of age the rats were sacrificed and processed for beta-galactosidase and ferritin double-label immunofluorescence. A subpopulation of the SVZ derived oligodendrocytes that migrated to the white matter expressed ferritin. These cells had the morphological appearance of immature oligodendrocytes. These results demonstrate that 1) ferritin positive oligodendrocytes originate from the SVZ and 2) ferritin is expressed in oligodendrocytes before these cells begin to myelinate. Studies are underway to characterize oligodendroglial clones to establish whether ferritin expression is related to a cells' lineage or whether it is induced by microenvironmental cues.

**HEAVY CHAIN FERRITIN BINDS DNA** K. Manges\* and J. Connor.  
Dept. of Neuroscience and Anatomy, Pennsylvania State University, M. S.  
Hershey Medical Center, Hershey, Pa 17033

Ferritin has long been known to be the major iron storage protein. As part of ferritin's regulatory repertoire, the molecule prevents the formation of hydroxyl free radicals by scavenging free ferrous iron and converting the iron to  $Fe^{3+}$  where it is then stored within the core of the molecule. The ferritin molecule (450 kDa) consists of 24 subunits in varying ratios of Heavy (H) and Light (L) subunits. The subunits are genetically and functionally distinct. The L subunit primarily aids in the formation of the iron core within the molecule. The H subunit is also able to form an iron core, however, the H subunit contains the essential ferroxidase center which is responsible to the rapid uptake of the ferrous iron and subsequent conversion to the ferric form. Unique also to the H chain is an increase in the subunit seen during development, differentiation, proliferation, and stress. This paper presents evidence that H ferritin may also function as a DNA binding protein. Immunohistochemical studies in four week porcine old brains revealed that H chain ferritin stained selective neuronal nuclei while the L chain stained only the cytoplasm. Slot blot analysis of isolated nuclear extract from whole porcine brain indicated that the H subunit was present at a concentration of 4.73 ng ferritin/ug protein. Incubation of FITC-rH ferritin with isolated nuclei pre-incubated with wheat germ agglutinin did not block entry of H ferritin into the nucleus suggesting the presence of a ferritin receptor on the nuclear membrane. Heart ferritin, which is H subunit rich, bound isolated genomic DNA from brain in a saturable and reversible manner and the recombinant H ferritin bound a specific DNA sequence on gel shift assays. L chain ferritin did not bind DNA. Poly dIdC:dIdC (1000 ng) was used in each gel shift assay to ensure that binding was specific. These data indicate that H ferritin can and does enter the nucleus and binds DNA. Future studies are directed at determining whether H ferritin is acting as a transcription/repressor factor or if H ferritin is protecting DNA from iron-induced damage. Supported by NS22671 (NIH).

## CELL DIFFERENTIATION AND MIGRATION IV

## 216.1

**PRIMARY NEURON GROWTH ON STABLY-MODIFIED GLASS SURFACES.** W. K. Scholz\* and B. M. Sullivan. Nalge Nunc International, 2000 N. Aurora Rd, Naperville, IL 60563.

Growth substrates are known to affect the adhesion, morphology and differentiation of neurons in culture. For many applications, glass is the preferred substrate, but the glass surface must be adequately modified to support the growth of neurons. This is usually accomplished by the application of polylysine, laminin or fibronectin. We have examined other, more stable surface modifications to soda-lime glass slides to compare their abilities to support the growth of primary neurons. We modified the surface of glass microscope slides by exposing the glass to a corona discharge, by using a newly developed coating procedure, or by coating with diaminopropylsilane as described by Klienfeld, et al. (1988; J. Neurosci. 8, 4098). Surface energies of the modified glass were measured using specific testing solutions graduated from 30-56 dynes/cm (3DT) and the concentration of primary amines on the surface of the glass was measured using an o-phthalaldehyde-based procedure (Pierce). After surface modification, the slides were assembled into Lab-Tek® Chamber Slide™ culture vessels and plated with primary chick brain cells. After 1 day in culture, the culture medium was changed to the defined neuronal medium N2.1 and after four days, the primary neurons were treated with a mitotic inhibitor. Primary neurons did not adhere to any uncoated glass surfaces. Modification of the glass surface by corona discharge, which significantly increased the surface energy, did not improve neuron attachment. In contrast, the diaminopropylsilane coating enhanced neuron attachment and process outgrowth, even though it decreased the surface energy. A newly developed coating procedure improved the attachment and differentiation of neurons and inhibited the proliferation of non-neuronal cells from the brain. Unlike many cell types that prefer highly charged substrates for growth, neurons require specific substrates for differentiation and survival.

## 216.3

**IDENTIFICATION OF THE CELLULAR SOURCE OF  $\beta 2$  LAMININS IN ADULT AND DEVELOPING VERTEBRATE RETINAE.**

R.T. Libby\*<sup>1</sup>, R.L. Cyr<sup>1</sup>, Y. Xu<sup>2</sup>, D.D. Hunter<sup>2</sup> and W.J. Brunken<sup>1</sup>, <sup>1</sup>Dept. of Biology, Boston College, Chestnut Hill, MA 02167; <sup>2</sup>Dept. of Neuroscience, Tufts Univ. Sch. of Med., Boston, MA. 02111.

Molecules of the extracellular matrix, including laminins, are important in directing some aspects of neural development; specifically,  $\beta 2$  laminin ( $\beta 2L$ ) has been implicated in the phenotypic differentiation of rod photoreceptors and rod bipolar cells. Developmentally, the spatial and temporal pattern of  $\beta 2L$  expression is consistent with a role in rod morphogenesis; however, the cellular source of retinal  $\beta 2L$  in the vertebrate retina is unknown. Here we employ several techniques to identify this source. Western blot analysis of proteins isolated from matrix and cytosolic fractions of skate retinae, using two antisera directed against the  $\beta 2$  chain, demonstrate that one antiserum, GP1, recognizes matrix epitopes whereas the other, R49, recognizes cytosolic epitopes. Therefore, R49 may be useful in identifying the source of  $\beta 2L$ . In adult skate retinae, as shown previously, GP1 immunoreactivity (IR) was present in the interphotoreceptor matrix. On the other hand, R49-IR spanned the neural retina from the outer to inner limiting membranes and was co-localized with vimentin, a marker for Müller cells (MCs). In the rat retina,  $\beta 2$  chain RNA was detected in what appears to be MCs by *in situ* hybridization. Together, these data show MCs are likely to be a source of  $\beta 2L$  in the adult retina. However, during development the  $\beta 2$  chain is present prior to the genesis of MCs, suggesting there is an additional source of  $\beta 2L$ . R49-IR in embryonic skate retinae and RNA localization in embryonic rat retinae suggest the neuroepithelial cells are one likely source of this  $\beta 2L$ . In addition, R49-IR in skate suggests that the retinal pigmented epithelium may be another source of  $\beta 2L$ . Supported by: Boston College Research Expense Grant and Foundation for Fighting Blindness (WJB) and NS29785 (DDH).

## 216.2

**POTENTIAL LAMININ HETEROTRIMERS THAT MAY GUIDE RETINAL DEVELOPMENT.** D.D. Hunter\*<sup>1</sup>, Y. Xu<sup>1</sup>, R.T. Libby<sup>2</sup> and W.J. Brunken<sup>2</sup>, <sup>1</sup>Dept. Neurosci., Tufts Univ., Boston; <sup>2</sup>Biology Dept., Boston College, Chestnut Hill, Mass.

Many environmental signals guide the development of the vertebrate nervous system; such signals include components of the extracellular matrix (ECM). We have previously shown that one ECM component, the laminin  $\beta 2$  chain (formerly s-laminin), is expressed in adult and developing retina, and that laminin  $\beta 2$  is likely to be involved in the differentiation of rod photoreceptors and rod bipolar cells. We have also previously shown that the classical laminin, laminin-1 (a complex of the  $\alpha 1$ ,  $\beta 1$ , and  $\gamma 1$  chains), is not expressed in the retina, suggesting that laminin  $\beta 2$  is not complexed with the  $\alpha 1$  or  $\gamma 1$  chains in this tissue. As it is likely that all laminins exist as heterotrimers consisting of an  $\alpha$ , a  $\beta$ , and a  $\gamma$  chain, we have now asked whether other  $\alpha$  and  $\gamma$  chains are present in the neural retina, in order to gain insight into the potential chain composition of retinal laminins containing the  $\beta 2$  chain.

Immunological reagents do not exist for many of the laminin chains in rodents; therefore, we used non-radioactive *in situ* hybridization to detect RNA encoding the  $\alpha 1, 2, 3, 4$ ;  $\beta 1, 2, 3$ ; and  $\gamma 1, 2$  chains in sections of rat retinae. In the adult neural retina, laminin  $\beta 2$  RNA is present in Müller cells (see accompanying poster); of the other chains, RNA was detected most strongly for the  $\alpha 4$  and  $\beta 3$  chains, and less strongly for  $\alpha 3$ . There was no detectable signal for the known  $\gamma$  chains, nor for  $\alpha 1$ ,  $\alpha 2$ , or  $\beta 1$ . In preliminary immunohistochemistry on human tissue (for which there are more immunological reagents), we detected reactivity for the  $\alpha 3$  chain, as well as for laminin-5 ( $\alpha 3/\beta 3/\gamma 2$ ). Together, our immunohistochemical and RNA expression data suggest that the laminins of the neural retina consist of  $\alpha 3$ ,  $\alpha 4$ ,  $\beta 2$ ,  $\beta 3$ , and an unknown  $\gamma$ . As new reagents become available, we will confirm the expression of laminin chain proteins in the rodent retina. In addition, we are in the process of attempting to identify additional  $\gamma$  chains that may be present in heterotrimeric neural laminins. Support: Foundation Fighting Blindness (WJB); NS29785 (DDH).

## 216.4

**MOLECULAR CUES THAT INFLUENCE SEGMENTAL PATTERNING OF TRUNK NEURAL CREST MIGRATION** C.E. Krull\*, A. Collazo, R. Lansford, S.E. Fraser, M. Bronner-Fraser. Division of Biology, California Inst of Technology, Pasadena, Ca 91125

In the avian embryo, trunk neural crest cells migrate in a striking segmental manner through the somites, entering rostral but not caudal sclerotome. Previous studies have shown that cues intrinsic to the somites are responsible for the patterning of neural crest. Attractive/permissive cues present rostrally, inhibitory cues located caudally or a combination of the two influences could establish this remarkable cellular pattern. Recently, we demonstrated that blocking PNA-binding molecules permits neural crest entry into caudal somite. Time-lapse analysis revealed a difference in the cell migratory behavior in rostral versus caudal somite, suggesting that an important cue located rostrally may be necessary to coordinate efficient migration. To this end, we are examining whether other differentially expressed cell-surface and extracellular matrix molecules influence the migratory process. For example, previous studies have suggested that  $\beta 1$  integrin antibodies affect neural crest migration at cranial levels. It is not clear, however, whether  $\beta 1$  integrin plays a role in patterning trunk neural crest. Antibodies against  $\beta 1$  integrin were added to trunk explants and the subsequent effects on neural crest migration were examined using time-lapse videomicroscopy. Neural crest cells migrate in rostral somitic regions in the antibody-treated explants but at rates significantly faster than cells in control explants. The explant paradigm allows cell migration to be followed over time in the presence of various blocking reagents, helping to unravel the mechanisms that guide this critical developmental process. ## 216.5

PLATELET-DERIVED GROWTH FACTOR-INDUCED CHEMOTAXIS OF NEUROEPITHELIAL PROGENITOR CELLS FROM THE EMBRYONIC RAT CORTEX. K. Forsberg-Nilsson<sup>1</sup>3)\*, T. N. Behar<sup>2</sup>, J.L. Barker<sup>2</sup> and B.D.G. McKay<sup>1</sup>). 1) LMB and 2) LNP, NINDS, NIH, Bethesda, MD 20892. 3) Present address Dept of Pathology, University of Uppsala, 75185 Uppsala, Sweden.

The ability of differentiating cells of the neuronal and glial lineages to migrate within the developing central nervous system (CNS) depends on intrinsic guidance signals, some of which are growth factors. We have investigated the chemotactic response to platelet-derived growth factor (PDGF) of progenitor cells from E14-E15 rat cortex. Multipotential cells from the developing CNS can be maintained and expanded *in vitro* under serum-free conditions in the presence of bFGF. Northern blot analysis of PDGF receptor expression revealed both  $\alpha$ - and  $\beta$ -receptors after culture in bFGF whereas on acutely dissociated cells from the E15 cortex, only the  $\alpha$ -receptor could be detected. Both PDGF-AA and PDGF-BB readily induced migration of these cells as measured in a microchemotaxis assay. Complete blocking of the migratory response was achieved by incubation with PDGF isoform-specific antibodies. Immunocytochemical analysis of the migrated cells show more than 90% to be nestin positive. A low proportion possessed markers for oligodendrocyte precursors (O4) or neurons (NFM) but no cells were detected with a glial marker (GFAP). These findings together with reports that PDGF immunoreactivity can be detected in the ventricular zone at this embryonic age suggest a role for PDGF in stem cell migration in the developing cortex.

EXTENSIVE NETWORK OF CHAINS FOR TANGENTIAL MIGRATION OF NEURONAL PRECURSORS. F. Doetsch, J.M. Garcia-Verdugo, D. Vicario\*, A. Alvarez-Buylla. The Rockefeller University, New York, NY 10021.

Proliferating neuronal precursors persist in the subventricular zone of adult mammals. In the postnatal and adult mouse, cells from the most anterior portion of the subventricular zone (SVZ) migrate tangentially along the rostral migratory stream to reach the olfactory bulb where they differentiate into granule and periglomerular neurons. These neuronal precursors migrate in chains, revealed by anti-PSA-NCAM staining, without guidance from radial glia or axons (Lois et al. Science 271:978-981, 1996). The fate of SVZ cells which continue to divide more caudally in the walls of the lateral ventricle is, however, not well understood; it has been suggested that they die or only give rise to glia. Here we report that the SVZ throughout the lateral walls of the lateral ventricle of adult mouse brain is organized as a network of longitudinally oriented PSA-NCAM positive chains. In order to test the fate of the cells in this network, we transplanted SVZ carrying a neuron-specific reporter gene at different A/P levels of caudal SVZ of non-transgenic hosts. These grafts reveal that SVZ cells migrate to the olfactory bulb even from caudal-most SVZ and differentiate into neurons. Microinjection of Dil to label a restricted cohort of endogenous SVZ cells at different rostro-caudal levels also shows this tangential migration of neuronal precursors. Pre-embedding immunocytochemistry and ultra-thin electron microscopy of the SVZ in the lateral wall of the lateral ventricle indicate that the PSA-NCAM-positive chains are composed of migrating neuronal precursors and are ensheathed by GFAP-positive cells. Contrary to previous studies, these findings reveal that the SVZ of the adult mammalian brain is dynamically organized as a network of chains for tangential migration of neuronal precursors. (NIH Grant HD32116)

## 216.9

CHAIN MIGRATION OF NEURONAL PRECURSORS *IN-VITRO*. H. Wichterle and A. Alvarez-Buylla\*. The Rockefeller University, New York, NY 10021.

Neuronal precursors in adult mice migrate from their site of birth in the subventricular zone (SVZ) of lateral ventricle along a restricted tangential pathway, the rostral migratory stream (RMS), into the olfactory bulb. A previous study (Lois, Garcia-Verdugo and Alvarez-Buylla, Science 271:978-981, 1996) showed that these cells do not use glial or axonal processes for guidance and it was suggested that the neuronal precursors migrate along each other organized as chains. To test this possibility, we developed a system to study this novel form of migration *in-vitro*. SVZ dissected from the anterior horn of lateral ventricle of 5 day old mice was explanted into a 3D substrate (Matrigel<sup>TM</sup>) and cultivated in serum free medium. Long chains of cells grew from these explants 5-40 hrs after explantation. The morphology of cells in these chains (size, growth cone, leading and trailing processes) corresponded to the morphology of neuronal precursors found in RMS. Immunocytochemistry demonstrated that all cells in the chains are positive for Tuj1 (early neuronal marker) and PSA-NCAM (embryonic form of NCAM) and negative for Vimentin (early marker for radial glia), GFAP (marker for astrocytes) and MAP2 (marker for differentiated neurons). Time-lapse videomicrography was performed on these chains during the time period between 20 to 50 hrs in culture, when the length of the chains was maximal (100-400  $\mu$ m long and 10-30  $\mu$ m wide). This analysis revealed bipolar cells migrating along each other in both directions with speeds varying from 50 to 150  $\mu$ m/hr. Periods of migration of individual cells were interspersed with stationary periods, during which some cells retracted their leading process and changed direction of movement. Occasionally cells extended their leading process between two parallel chains and moved from one chain to the other. Cell bodies of these "jumping" cells were usually stationary until the highly motile growth cone established connection with cells in the parallel chain. This interaction resulted in pulling and/or pushing the cell body through the leading process. Our study reveals the dynamic properties of SVZ migrating cells and demonstrates that these neuronal precursors migrate bidirectionally crawling along each other without need for processes from other cell types. (NIH Grant HD32116)

## 216.6

DEFECTS IN THE ROSTRAL MIGRATORY STREAM OF NCAM/mCD24 DOUBLE MUTANT MICE. G. Chazal\*, H. Moreau, G. Monti, H. Cremer, and G. Rougon. LGPD, Luminy, 13288 Marseille, France.

PSA-NCAM was shown to be expressed in the adult brain in areas undergoing secondary neurogenesis. Recently, we showed that mCD24, a GPI-anchored molecule transiently expressed during development, is colocalized with PSA-NCAM on newly-generated neuroblasts in adult mice. These cells originate in the ventricular zone of the lateral ventricle and migrate along a well-defined pathway, the rostral migratory stream (RMS), to reach their final destination in the olfactory bulb (Calaora et al., Neurosci., in Press). The participation of these two molecules in the differentiation and migration of neuroblasts was investigated in NCAM (Cremer et al., Nature, 1994) and mCD24 (Wenger et al., Transgenic Res., 1995) mutant knock-out mice. RMS morphology and cellular composition was analyzed by immunohistochemistry and EM. Perturbations in the organization of the chain migration of neuronal precursors were apparent in the single-mutant mice and amplified in the double ones. They consisted essentially in: a) an enlargement all along the tract of the migratory pathway from the subependymal layer of the lateral ventricle to the olfactory bulb, b) an increase of BrdU labelled migrating cells and c) and increase of GFAP positive cells which may indicate that the absence of both molecules influences neuro-glial interactions and possibly generated a reactive gliosis. Several hypothesis concerning how the lack of expression of these cell surface molecules may influence neuroblasts chain migration will be discussed.

## 216.8

MIGRATION OF SUBVENTRICULAR ZONE CELLS AFTER OLFACTORY BULB REMOVAL IN ADULT MOUSE BRAIN. B. Kirschenbaum\* and A. Alvarez-Buylla. The Rockefeller University, New York, NY, 10021.

Interneurons of the adult mouse olfactory bulb are continually generated. The precursors of these new neurons originate in the subventricular zone (SVZ) of the lateral ventricle and migrate along the rostral migratory stream (RMS) to the olfactory bulb where they differentiate. What determines the migration of these precursors towards the olfactory bulb is not known. One possible hypothesis is that the olfactory bulb secretes a diffusible factor that attracts the migrating precursors. In order to test this hypothesis, we have studied the migration of cells along the RMS after unilateral olfactory bulb removal. The right olfactory bulb was removed by suction at the level of the olfactory peduncle. Six weeks later the overall shape and dimensions of the RMS were similar between the operated and unoperated side. The RMS was, however, different close to the site of excision, where an accumulation of cells formed. To confirm that rostral migration of cells from the SVZ of the lateral ventricle occurs in the absence of the bulb, we did the following. Two weeks subsequent to unilateral olfactory bulbectomy, BrdU was microinjected bilaterally into the SVZ, a treatment that labels a restricted cohort of dividing SVZ cells close to the injection site, at the level of the anterior lateral ventricle. One week after BrdU microinjection, BrdU labeled cells had reached the olfactory bulb in the unoperated side. In the bulbectomized side, BrdU labeled cells migrated rostrally to the anterior part of the RMS and amassed at the site of the stump. These results indicate that the removal of the olfactory bulb did not prevent the rostral migration of precursor cells from the SVZ towards the bulb. We suggest that the directional guidance of precursor cells within the RMS is intrinsic to the RMS and the migrating cells therein.

## 216.10

A SEPTUM-DERIVED CHEMOREPULSIVE FACTOR FOR THE MIGRATING OLFACTORY INTERNEURON PRECURSORS. H. Hu and U. Rutishauser\*. Department of Genetics and Neurosciences, Case Western Reserve University School of Medicine, Cleveland, OH 44106

During mammalian brain development immature neurons often migrate considerable distances to reach their final location. A dramatic example is the rostral migration of olfactory interneuron precursors from the vicinity of the septum to the olfactory bulb in the anterior forebrain, via a specific subventricular pathway. Heterotopic transplantation experiments have been carried out to establish that this migration is unidirectional and that guidance cues operate over a considerable distance. The mechanisms that provide guidance cues for this translocation have not been identified. We have carried out cocultures of the explants from the subventricular zone and the surrounding tissue regions. The results showed that the cells migrated away from caudal part of the septum but not influenced by olfactory bulb, cerebral cortex and caudate putamen. The present studies provide the first evidence that a diffusible chemorepulsive factor, in this case secreted by caudal septum but not by other tissue regions surrounding the pathway, may be involved. This activity is functionally distinct from that produced by factors that influence vertebrate axon outgrowth, such as netrins 1 and 2 and collapsin-1/semaphorin-III. The presence of this activity in the floor plate/ventral spinal cord as well as the septum suggests that this mechanism may influence other forms of cell migration during development. (Supported by NIH grants HD18369 and EV06107)

## 216.11

ESTROGEN REGULATES NG2-CAM-DEPENDENT CALCIUM-SIGNALING DURING MIGRATION OF NEW NEURONS INTO THE ADULT SONGBIRD BRAIN. S. Williams, <sup>1</sup>J. Barry, <sup>1</sup>V. Lemmon, <sup>2</sup>M. Nedergaard, <sup>3</sup>S. A. Goldman  
Depts. of <sup>1</sup>Neurology, Cornell U. Med. Col. NYC, 10021, <sup>2</sup>Neuroscience, Case-Western Res. Sch. Med., Cleveland, OH, <sup>3</sup>Cell Biol., NY Med. Col., Valhalla, NY.

The adult avian forebrain continues to generate neurons from subependymal zone (SZ) precursors, whose neuronal progeny then migrate into the neostriatum. In explant cultures of the adult SZ, neuronal migration is disrupted by antibodies against the Ig-adhesion molecule Ng2-CAM, and new neurons respond to Ng2-CAM protein with increments in cytosolic calcium (Neuron 13:567, 1994). The calcium response to Ng2-CAM is developmentally restricted, to bipolar migrants during the period from 6-9 days in vitro (Molec. Cell. Neurosci. 7:29, 1996). This corresponds to the post-mitotic age at which new neurons leave the adult SZ, to traverse a layer of estrogen-receptive "gatekeeper" neurons, whose activity modulates the survival of the new migrants (J. Neurobiol. 27:470, 1995). Since the passage of new neurons through the estrogen-receptive layer coincides with their acquisition of Ng2-CAM-dependent calcium signaling, we asked whether the development of the CAM-driven calcium response depended upon estrogen. Among cultures of adult female zebra finch SZ raised in gonadal steroid-depleted media, those supplemented with estradiol developed calcium increments of  $82 \pm 21\%$  ( $n = 110$  cells) to Ng2-CAM. In contrast, neither their unsupplemented nor testosterone-supplemented controls exhibited such calcium responses to Ng2-CAM ( $13 \pm 8\%$ ,  $n = 222$ , and  $13 \pm 7\%$ ,  $n = 148$ , respectively) ( $p < 0.001$  by ANOVA). The groups exhibited equivalent calcium responses to depolarization, and appeared equally viable to 9 DIV. However, SZ-derived neurons not exposed to estradiol died soon thereafter, significantly more rapidly than their counterparts raised in estrogen. These findings suggest that estrogen, or estrogen-induced paracrine agents, can regulate the coupling of a stably expressed adhesion molecule to calcium-dependent signaling pathways during neuronal migration.

CALCIUM-DEPENDENT REGULATION OF NEURONAL MIGRATION BY THE HETEROTRIMERIC G PROTEIN  $G_{\alpha_q}$ . Angela M. Horgan & P.F. Copenhaver, Dept. Cell & Developmental Biology, L215, Oregon Health Sciences U., Portland, OR, 97201.

During formation of the enteric nervous system (ENS) of the moth *Manduca sexta*, a group of ~300 post-mitotic neurons (the EP cells) migrates onto a specific set of muscle band pathways on the gut surface. Previously, we showed that these neurons commence the expression of the guanyl nucleotide binding protein  $G_{\alpha_q}$  at the onset of migration. Using a semi-intact embryo culture preparation that allows access to the neurons and their pathways during migration, we have manipulated G protein activity in the EP cells to investigate whether this signaling molecule participates in the regulation of EP cell migration. Our results have demonstrated that stimulation of the G proteins in these cells, using AlF<sub>4</sub>, GTP $\gamma$ S, and mastoparan (which selectively activates  $G_o$  and  $G_i$ ), caused a premature termination of EP cell migration. In contrast, inhibition of G proteins with GDP $\beta$ S and pertussis toxin, had no obvious effect. Since  $G_{\alpha_q}$  is associated with the modulation of intracellular  $Ca^{2+}$  in other systems, we have examined whether the effects of  $G_{\alpha_q}$  on EP cell migration involves  $Ca^{2+}$ -dependent processes. While EP cell migration will still proceed in [0]  $Ca^{2+}$  saline, manipulations that elevated intracellular  $Ca^{2+}$  caused a marked inhibition of migration. In addition, the inhibitory effect of mastoparan was prevented in [0]  $Ca^{2+}$ -saline, indicating that regulatory effects of  $G_{\alpha_q}$  on EP cell motility is  $Ca^{2+}$ -dependent. We are presently investigating whether constitutively active mutants of different G proteins can be expressed in the EP cells to modulate neuronal migration *in vivo*. Supported by NIH # NS35369.

## 216.15

TGF- $\beta$ 1 AND MOTILE BEHAVIOUR OF THE OLIGODENDROGLIAL CELL LINE OLI-NEU: EVIDENCE FOR INVOLVEMENT OF DSD-1-PROTEOGLYCAN. O. Schnädelbach and A. Faissner, Dept. of Neurobiology, University of Heidelberg, D-69120 Heidelberg

DSD-1-Proteoglycan (DSD-1-PG) is a chondroitin sulfate proteoglycan which is produced by glial cells *in vitro* and co-localizes with glial cells *in vivo*. It carries the DSD-1-epitope, a particular glycosaminoglycan specifically recognized by monoclonal antibody (mAb) 473HD. *In vitro*, DSD-1-PG is upregulated on the oligodendroglial precursor cell line oli-neu by members of the TGF- $\beta$  superfamily, as shown with mAb 473HD (Soc. Neurosci. Abstr. 21, 1312 (1995)). In the light of these observations we investigated potential roles of DSD-1-PG for glial cell behaviour.

A bioassay for migratory behaviour was designed where oli-neu cells migrate on preformed tracks of defined extracellular matrix (ECM) glycoproteins. When 4 ng/ml TGF- $\beta$ 1 were applied over 48 hrs, the migratory performance on laminin was decreased to 58% of control values. This effect was partially reversed by application of 50  $\mu$ g/ml polyclonal DSD-1-PG antibodies and completely abolished by addition of 20  $\mu$ g/ml mAb 473HD. Consequently, incubation of oli-neu with antibodies in the absence of TGF increased migration speed by 25% on laminin. No significant changes of migratory behaviour were observed on control ECM substrates under these conditions. Analogous results were obtained in a three-dimensional trans-filter migration assay within 8 hrs, rendering unlikely that anti-proliferative effects of TGF- $\beta$  are the cause of decreased migration. Finally, in a short-term adhesion assay, TGF- $\beta$ 1 reduced the number of adherent oli-neu cells on laminin by 46%, while the number of cells adhering to fibronectin was only slightly reduced.

We conclude from these findings that DSD-1-PG might contribute to the control of migratory behaviour of the glial cell line oli-neu on laminin. (Supported by DFG (Fa 159/5-1,2,3), Friedrich-Ebert-Stiftung and H.-L.-Schilling Stiftung)

DEVELOPMENTAL EXPRESSION AND POSSIBLE ROLE OF FASCICLIN II IN THE GUIDANCE OF MIGRATORY ENTERIC NEURONS. P.F. Copenhaver, J. Wright, M. Snyder, and S. Combes, Cell Biology L215, Oregon Health Sciences U., Portland, OR 97201.

During the formation of the enteric nervous system (ENS) in the moth, *Manduca sexta*, a population of ~300 neurons (the EP cells) migrate onto a set of pre-formed pathways on the visceral musculature. In particular, a subset of these cells must contact one of eight longitudinal muscle bands that form on the midgut to differentiate normally. In an investigation of the molecular mechanisms underlying this interaction, we have identified the cell adhesion receptor fasciclin II as a likely guidance cue that supports EP cell migration. Antisera against the moth form of fasciclin II (MFas II; a putative homophilic receptor in the immunoglobulin superfamily) stained both the EP cells and the muscle bands during migration, while blocking antibodies against MFas II inhibited EP cell migration in embryonic culture. Using microsequence data from the MFas II protein, we cloned cDNAs encoding two isoforms of MFas II, a transmembrane form and a GPI-linked form. *In situ* hybridization histochemistry with probes derived from these clones confirmed that one or both forms of this receptor is expressed by the EP cells throughout development, but they only transiently appear in the muscle bands during the migratory period. Removal of GPI-linked receptors from the gut surface with PI-specific phospholipase C caused a substantial loss of MFas II protein from the ENS and inhibited EP cell migration. We are currently using clone-specific probes to determine which isoform of MFas II is expressed by each of these cell types, and we have begun to investigate the intracellular signaling mechanisms by which MFas II may affect neuronal migratory behavior. Supported by NIH # NS35369.

## 216.14

HEPARIN-BINDING GROWTH-ASSOCIATED MOLECULE (HB-GAM) AND N-SYNDÉCAN (SYNDECAN-3) IN DEVELOPING RAT HEART. J.O. Hiltunen, M. Kaksonen, R. Nolo, M. Scheinin, M. Saarna and H. Rauvala, Inst. of Biotechnology, Univ. of Helsinki; Dept. of Pharmacol., Univ. of Turku, Finland

Heparin-binding growth-associated molecule (HB-GAM, pleiotrophin) is a cell surface- and extracellular matrix-associated protein, which has been shown to promote neurite outgrowth and synapse formation. It shares 50% sequence identity with midkine (MK), which promotes the growth of neuronal and PC12 cells. Syndecans are heparan sulfate proteoglycans regulating the biological effects of heparin-binding molecules. N-syndecan (syndecan-3) has been shown to function as a receptor for HB-GAM.

We studied HB-GAM and N-syndecan expression in developing rat heart by non-radioactive *in situ* hybridization using digoxigenin-labeled riboprobes. We also performed anti-HB-GAM and anti-N-syndecan immunohistochemistry to characterize protein localization and used neuron-specific antibodies to identify cells expressing these proteins.

Both HB-GAM and N-syndecan expressions were detected in the atrioventricular and the outflow tract regions at embryonic day 11 (E11). By E13 both messages were localized to regions undergoing epithelial-mesenchymal interactions.

At E16 mesenchyme the base of the heart expressed strongly HB-GAM message and was especially seen in the cells surrounding cardiac ganglion neurons, probably in Schwann cells. At the same time N-syndecan mRNA could be observed in cardiac ganglion neurons (anti-peripherin immunostaining). HB-GAM and N-syndecan expressions were the same at E20, except that the HB-GAM message was already declining. During day 13 N-syndecan expression was still detected in cardiac ganglion neurons.

These results suggest a role for HB-GAM and N-syndecan in development of cardiac ganglion neurons and also for non-neuronal cells in the atrioventricular region. Juselius Foundation, Finnish Academy.

POSTNATAL DEVELOPMENT OF LAMININ- AND FIBRONECTIN-LIKE IMMUNOREACTIVITY IN THE RAT HIPPOCAMPUS *IN VIVO* AND IN ORGANOTYPIC CULTURE. L. Paulman, L.S. Jones, L. Edwards, and M. Welsh, Dev Biol & Anat, Univ So Carolina, Sch of Med, Cola, SC 29208.

We have compared organotypic cultured and acutely prepared slices of rat hippocampus to examine expression of the extracellular matrix proteins laminin (LN) and fibronectin (FN). The sections were prepared using standard immunohistochemical techniques and polyclonal antibodies to FN, LN, and glial fibrillary acidic protein (GFAP). Tissues were fluorescently labeled and viewed by confocal laser microscopy. The viability of the organotypic cultures was determined by standard extracellular field potential recording of random slices at all timepoints. *In vivo*, we found that expression of both FN- and LN-like immunoreactivity was localized mainly in vasculature at the earliest timepoints. By two weeks (in culture and in acute slices), some LN and FN staining was seen in the neuropil of the hippocampus, but was low compared to the vasculature. In the organotypic cultures, intense staining of vasculature, fibers and cells around the periphery of the slice was seen. This staining continued to be present up to 21d in culture, but was maximal at 2 weeks. The GFAP labeling of the acute slices at all ages demonstrated astrocytes with small numbers of processes which were moderately labeled. In the cultures intense labeling of astrocytes and a large number of processes was seen at all times in cultured tissue and on the adjacent membrane. As the expression patterns of LN and FN are similar in the acute and cultured tissues, although possibly higher in the cultures, it appears to be a good model for examining the postnatal expression of extracellular matrix. Support by NINDS NS27903.

ANALYSIS OF ECM FACTORS ON NG108-15 CELL FUNCTION & VIABILITY. H. Bryant\*, V. Kowtha, D. Stenger. Dpt. Physiol. USUHS, Bethesda, MD; CBMSE/NRL, Washington, DC 20375

NG108-15 (neuroblastoma x glioma) cells, cultured in defined, serum-free media (SFM containing N2 supplements) exhibit stable automaticity (the spontaneous occurrence of regenerative action potentials) following transient exposure to extracellular perfusates containing  $\text{NH}_4\text{Cl}$ . In the present study, we examine changes in morphology and electrical activity upon culturing these cells on extracellular matrix (ECM) factors in SFM. Matrigel™, which consists of laminin, entactin, collagen and heparan sulfate proteoglycan was tested first and it promoted cellular proliferation. Three singular ECM components (collagen IV, fibronectin and laminin) were then compared with control polystyrene (PS) and with Matrigel (added to cells after 3 days in vitro (div)). The singular components promoted NG108-15 cell differentiation (3 div). However, cells on laminin and fibronectin did not survive beyond 15 div. Cells on ECM with a final layer of Matrigel had more dividing cells than PS.

Summary of Results:

Proliferation: Fibronectin>Laminin>Matrigel>Collagen IV>PS  
 Neurite Outgrowth: Laminin>Collagen IV>PS>Matrigel>Fibronectin  
 Viability: PS>Collagen IV> Fibronectin>Matrigel>Laminin  
 Mean RP (10div): Collagen IV>PS>Fibronectin>Matrigel  
 Cells on Collagen IV exhibited stable automaticity (periods > 1hr). Moreover, an abundance of flat cells were present under ECM culturing conditions; these cells did not lift off under cellular stress (movement, rapid fluid flow). Overall, NG108-15 cells can be maintained on specific ECM factors which promote enhanced neurite development and increased membrane excitability. Supported by NRL 6.1 funding

## CELL DIFFERENTIATION AND MIGRATION V

## 217.1

ACTIVATED AKT ENABLES SURVIVAL OF DIFFERENTIATED NEURONAL CELLS. E. M. Eves\*, A. Bellacosa<sup>2</sup>, P. N. Tsichlis<sup>2</sup>, N. Hay<sup>1</sup> and M. R. Rosner<sup>1</sup>. <sup>1</sup>Ben May Inst., University of Chicago, Chicago, IL 60637 and <sup>2</sup>Fox Chase Cancer Center, Philadelphia, PA 19111.

PI-3 kinase has been suggested to mediate survival in neuronal cells. The proto-oncogene Akt (PKB, Rac p56) is a serine-threonine protein kinase that is a downstream target of PI-3 kinase. To test whether Akt acts as a survival factor in neuronal cells, we determined the effect of expressing c-Akt or its oncogenic counterpart v-Akt on the survival of conditionally (SV40-T<sup>ts</sup>) immortalized rat hippocampal H19-7 cells. v-Akt enhanced survival of the differentiated H19-7 cells to an extent comparable to that observed with Bcl-2, and a small increase in survival was observed with c-Akt. When v-Akt and Bcl-2 were co-expressed in H19-7 cells, only a slight enhancement of survival beyond that conferred by each factor alone occurred. Furthermore, v-Akt expression did not significantly induce Bcl-2 or Bcl-x<sub>L</sub> expression in these cells. c-Jun NH<sub>2</sub>-terminal kinase (JNK) has been suggested to mediate apoptosis in neuronal cells. Consistent with this possibility, JNK activity increases in differentiated H19-7 cells undergoing apoptosis. However, v-Akt did not suppress the increase in JNK activity. These results indicate that Akt can act as a survival factor for neuronal cells through a mechanism that is independent of induction of Bcl-2 or Bcl-x<sub>L</sub> or inhibition of JNK activity. (Supported by NIH-NS 338-58)

IDENTIFICATION OF MOUSE HOMOLOGUES OF EYES ABSENT (EYA), A DROSOPHILA GENE INVOLVED IN NEURONAL CELL DEATH.

Y. Tanno<sup>1,2</sup>, T. Mori<sup>1</sup>, S. Yokoya<sup>1</sup>, T. Yamamoto<sup>2</sup>, A. Wanaka<sup>1\*</sup>

<sup>1</sup>Dept. of Cell Science, Institute of Biomedical Sciences, <sup>2</sup>Dept. of Neurology, Fukushima Medical College, Fukushima 960-12, Japan

Eyes absent gene (*eya*) was originally identified by enhancer-trapping in the fruit fly. As its name implies, *eya* mutant shows massive cell death anterior to the morphogenetic furrow in the developing neural retina and this cell death occurs in an apoptotic fashion. *eya* activity, therefore, is thought to be required for the survival of eye progenitor cells and to influence the distribution of cells between differentiation and death. The *eya* gene encodes a protein with 760 amino acids which has little homology to known proteins and has no known functional domains. To elucidate the physiological significance of *eya*, we performed PCR on an embryonic mouse brain cDNA with fully-degenerated oligonucleotide primers which correspond to the homologous regions between *Drosophila eya* and human expressed sequence tag clones, and got two independent fragments with significant homology to *eya*. The expression domains of these genes in the developing mouse embryo and the structures of these will be presented and discussed.

This work was partly supported by Grant-in-Aid for Scientific Research on Priority Areas from The Ministry of Education, Science and Culture, Japan and by grant from Uehara Memorial Foundation.

MAH CELL LINES OVEREXPRESSING E1B19K STILL REQUIRE NGF FOR SURVIVAL AS POSTMITOTIC NEURONS. M. Nakagawa, C.P.B. Sampson, G. Swanson\* and A.M. Tolkovsky. Dept. Biochemistry, University of Cambridge, Tennis Court Road, Cambridge, UK & Trends in Neuroscience, Cambridge, UK.

Postmitotic neurons cannot be stably transfected, making it difficult to manipulate signal transduction mechanisms and study their long-term effects on survival and differentiation. MAH cells, HNK<sup>+</sup> sympathoadrenal precursor cells immortalised with *v-myc* (Birren & Anderson (1990) Neuron 4, 189), can be induced to differentiate into post-mitotic, NGF-dependent neurons by CNTF or FGF. However, proliferating MAH cells continually bud off apoptotic cells and their differentiation is not very efficient. Speculating that expression of survival genes might negate these apoptotic events and lead to an abundance of long-lived neurons, we created several stable MAH cell lines expressing *bcl2* or adenoviral E1B19K using retroviral vectors. As predicted, cells expressing *bcl2* (BMAHs) or E1B19K (EMAHs) did not produce apoptotic progeny and became resistant to death induced by cycloheximide, staurosporine or serum withdrawal. However, EMAHs were much more resistant than BMAHs to toxic insults, so we concentrated on their differentiation. No differentiation was obtained (after dexamethasone was withdrawn) unless NGF was added from the first day. Under these conditions, EMAHs were best differentiated into neurons using a combination of CNTF and high potassium. The poorest factor was bFGF, which caused huge colonies of differentiation-resistant cells to appear amongst the newly formed neurons. Interestingly, despite E1B19K expression, the EMAH-derived neurons still required NGF for their survival, neurons being maintained for ~2 months with NGF. Because it has been suggested that cells expressing high *myc* (e.g. neuroblastomas) are incapable of withdrawing from the cell cycle we investigated how EMAHs become post-mitotic. We report on the roles of some cell cycle and anti-cell cycle genes in this process.

## 217.4

MODULATION OF INTRACELLULAR CALCIUM LEVELS OF THE WEAVER GRANULE NEURONS AFFECTS THEIR SURVIVAL.

Päivi Liesi\* and Victor Krauthamer. LMCN, NIAAA, NIH, 12501 Washington Ave, Rockville, MD 20852 and FDA, CDRH 12721 Twinbrook Parkway, MD20852.

The cerebellar granule neurons of the homozygous weaver mutant mouse fail to migrate and die within the first two weeks of postnatal life. The weaver gene is mapped in the chromosome 16 in the mouse, and recent evidence indicates that a point mutation in the GIRK2 potassium channel gene could be the weaver gene. P7-P9 normal and homozygous weaver granule neurons were cultured on a laminin substratum for 24-48 hrs. Within this time period, the normal granule neurons extended long neurites whereas the weaver granule neurons showed impaired neurite outgrowth. 10 nM BABTA-AM and 50-100 mM ethanol rescued the neurite outgrowth potential of the weaver neurons similar to verapamil, and MK-801. Calcium imaging studies were combined with the rescue studies to correlate the effects of different rescue agents with the modulation of calcium levels inside the weaver neurons. The results raise the question of whether reduction of intracytoplasmic calcium levels by calcium channel blockers (verapamil and MK-801), calcium chelators and moderate concentrations of ethanol is associated with the rescue of the neurite outgrowth potential of the weaver granule neurons. This work was supported by NIAAA and FDA.

## Role of Polyunsaturated Fatty Acids in Nervous System

Lisa Edsall, Martha Garcia, R.W. Peoples\* and Hee-Yong Kim, Laboratory of Membrane Biochemistry and Biophysics, LMCN, NIAAA, NIH, Rockville, MD 20852.

Neuronal membranes are enriched with polyunsaturated fatty acids esterified in phospholipids, especially arachidonic (20:4n6) and docosahexaenoic (22:6n3) species. These polyunsaturates are thought to be essential for proper neuronal function. In order to substantiate the role of these polyunsaturates, we investigated the release of these polyunsaturated fatty acids along with their effects on the survival and proliferation of rat pheochromocytoma cells were examined. Upon stimulation with carbachol, neuronal cells preferentially released 20:4n6 in comparison to 22:6n3, suggesting that 22:6n3 as a membrane component rather than as a released free fatty acid may be of more physiological importance in neuronal membranes. When PC12 cells were subjected to serum free conditions to induce apoptosis in the presence of 1 to 25  $\mu$ M 20:4n6 or 22:6n3, DNA fragmentation in cells exposed to 20:4n6 showed significant resistance to fragmentation, while the effect of 22:6n3 under these conditions was minimal. Growth and proliferation of neuronal cells were also influenced by fatty acids as evidenced by the significant inhibition of  $^3$ H-thymidin incorporation by 20:4n6 in both Neuro-2A and PC12 cells. Alternatively, 22:6n3 exhibited a more proliferative effect, in some cases increasing thymidin incorporation by almost 40%. These results may suggest a functional dichotomy in the role of these two prevalent fatty acids in neuronal systems. Ready release of 20:4n6 from neuronal membranes upon stimulation of PLA<sub>2</sub> may be of more importance to the signaling aspects of the cell, while 22:6n3 may be essential for maintaining cell integrity. Supported by the NIH intramural program.

## TISSUE CULTURE FLASKS AS A VARIABLE AFFECTING THE VIABILITY AND INTEGRITY OF CELL LINES, L.M. Konopka, B. Wong, S.M. Delisi, J.W. Crayton, Biological Psychiatry Section, Hines V.A. Hospital, Hines, IL. 60141.

Tissue culture work using well-described cell lines studied under well-characterized experimental conditions provides the advantages of preparation-reproducibility and a well controlled environment. Investigators tend to assume that standard, commercially-available reagents and disposable supplies contribute to the maintenance of highly-reproducible conditions. During the past year, we noticed that two cultured cell lines, AtT-20 pituitary corticotrophs derived from a mouse tumor line and rat derived lactotroph/gonadotroph GH3 lines both showed a progressive marked failure to grow and a lack of adhesion to the flasks. Systematic study of the various reagents involved, including all solutions, reagents, experimental conditions, and media suggested that the failure to grow coincided with a change in the culture flasks used. "Old" flasks were compared with "New" flasks obtained from the same manufacturer. Parallel, controlled studies using the same cell lines and identically-prepared reagents showed that "New" flasks failed to permit adequate adhesion of cells and within 24-72 hours led to distorted, moribund cells. Identically-treated cells grown in parallel with "Old" flasks showed the expected cell adhesion and growth. To date we have been unable to identify the differences in the two flasks that produced such different results. This work suggests that failures of cell lines may be related to subtle differences in materials generally expected to be highly standardized and uniform. Assays of flask characteristics should be undertaken when the lot number or supplier is changed.

This study was supported by POTTS Foundation and Chicago Consortium for Psychiatric Research

## PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING II

## 218.1

## NEUROTROPHIC EFFECTS OF L-DOPA IN POSTNATAL MIDBRAIN DOPAMINE / CORTICAL ASTROCYTE COCULTURE, MA Mena, Johanna Bogulavsky, Irina Ryzak, Viviana Davila, &amp; David Sulzer\*, Dept Neurol &amp; Psych, Columbia U &amp; Dept Neurosci, New York State Psych Inst, NY 10032.

Parkinson's disease patients who receive L-DOPA achieve long-term benefit following treatment cessation (Nutt 1995, Neurology). We found that short-term L-DOPA elevates extracellular dopamine (DA) by increasing quantal size (Pothos et al., this meeting). To study long-term response, we used postnatal ventral midbrain neuron/cortical astrocyte cocultures in serum-free, glial-conditioned medium. L-DOPA (50  $\mu$ M 3 days post-plating) increased surviving TH<sup>+</sup> neurons by 166 $\pm$ 9%. Although increase was attenuated at >100  $\mu$ M, there was no significant neurotoxicity at 400  $\mu$ M. L-DOPA increased TH<sup>+</sup> processes that extended >800  $\mu$ m by 177%, and TH<sup>+</sup> neurons with >3 primary processes by 162%. This contrasts with embryonic glial-free cultures, where 25  $\mu$ M L-DOPA is toxic (Mena 1993, NeuroReport) and glial-conditioned media protective (Mena 1996, NeuroReport). D-OPA was not neurotrophic (50-200  $\mu$ M), implying a role for DA synthesis. Moreover, the D1/D2 agonist apomorphine (10  $\mu$ M) increased survival of TH<sup>+</sup> neurons by 150 $\pm$ 16%. However, the decarboxylase inhibitor carbidopa (25  $\mu$ M) did not block the neurotrophic effect, indicating a DA-independent action. This paradox may be due to promotion of free radical scavengers. Pretreatment with the glutathione peroxidase inhibitor L-buthionine sulfoximine (3  $\mu$ M for 24h) alone had no neurotoxic effect, but blocked the neurotrophic action of L-DOPA. N-acetyl-L-cysteine (250  $\mu$ M for 48h), which promotes glutathione synthesis, was similar to L-DOPA, increasing TH<sup>+</sup> neurons by 183 $\pm$ 13%. Finally, L-DOPA, which upregulates glutathione (Han 1996, J Neurochem), did not induce quinone formation, whereas D-DOPA and apomorphine did. We are currently testing whether free radicals upregulate glutathione synthesis. Funded by the Parkinson's Disease Foundation and NIDA 10154 & 07418.

## PREFERENTIAL BRANCHING OF CORTICAL NEURITES ON MEMBRANE STRIPES FROM APPROPRIATE LEVELS OF THE SPINAL CORD, E.Dent, J. Callaway and K. Kalil\*, Neuroscience Training Program and Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

During development of the hamster corticospinal pathway *in vivo*, axons from both forelimb and hindlimb sensorimotor cortex extend the full length of the corticospinal tract. Nevertheless, interstitial collaterals branch only into targets at topographically appropriate levels of the cord. Previous studies *in vitro* showed that sensorimotor cortical growth cones respond to developmentally regulated membrane bound cues in the spinal cord. Therefore, in the present study we investigated whether membranes from different levels of the spinal cord would selectively influence branching of neurites from different topographic regions of the sensorimotor cortex. Alternating lanes of membranes from 8 day cervical and lumbar spinal cord were applied to filter supports and then transferred to glass coverslips to permit visualization of cortical neurites and their branches with phase microscopy. Explants from newborn hamster forelimb or hindlimb sensorimotor cortex were positioned on the membrane assays and after 48 hours neurite branching was assessed in fixed cultures. Branches were counted only if they grew at right angles from the cortical neurites and were at least 10  $\mu$ m in length. Preliminary results showed that neurites from forelimb cortical explants branched equally well on membrane stripes from cervical and lumbar cord. In contrast, neurites from hindlimb cortical explants showed a marked preference for branching on membrane stripes from the lumbar cord. These results are consistent with the situation *in vivo* where hindlimb cortical axons must bypass cervical targets without branching, perhaps because of inhibitory target cues. Axons from forelimb cortex, on the other hand, may not need to recognize lumbar spinal targets because they regress from lumbar levels before target innervation occurs. To determine whether inhibitory molecules in the cervical cord prevent the growth of inappropriate collaterals from hindlimb axons, we are currently treating the membrane assays with PI-PLC. Supported by NIH Grant NS 14428 to K.K.

## 218.2

## MOSSY FIBER INTERACTIONS WITH PLASMA MEMBRANES FROM TARGET CEREBELLAR GRANULE CELLS

M.S. Ward and C.A. Mason\*, Departments of Pathology, Anatomy and Cell Biology, and Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University, New York, NY 10032.

Cerebellar granule cells purified and grown in monolayer culture inhibit the growth of neurites from explants of basilar pons, a major source of afferent mossy fibers (Baird et al., J. Neurosci. 12:619, 1992). Previous studies have shown this effect to be specific for pontine explants and dependent on NMDA receptor activity (Baird et al., J. Neurobiol. 23:579, 1992 and J. Neurosci. 16:2642, 1996). To investigate the role of target granule cell membranes in the regulation of afferent growth, we have developed a protocol for the preparation of highly enriched plasma membranes from purified granule cells or glia grown in primary culture. Using a two-step ultracentrifugation approach, we are able to prepare a membrane fraction with 30- to 40-fold relative specific activities of the plasma membrane markers 5'-nucleotidase and alkaline phosphatase. This fraction is applied onto a coverslip and used as a substrate for cell culture by the approach of Wizenmann et al. (Neuron 11:975, 1993), permitting the comparison of pontine mossy fiber growth on alternating lanes of membranes and/or laminin. With this approach, we are analyzing pontine axon length, fasciculation pattern, and branch formation on membrane stripes, and the potential role of adhesion molecules in target regulation of afferent growth. Supported by NIH grants NS16951 (C.A.M.) and MSTP 5 T32 GM07367 (M.S.W.).

## POSSIBLE ADHESIVE PROPERTIES OF ACETYLCHOLINESTERASE IN DEVELOPING CEREBRAL CORTEX, K.J. Clayton\*, L.M. Amezcua, J. Yu and R.T. Robertson, Departments of Anatomy and Neurobiology and of Physical Medicine and Rehabilitation, College of Medicine, University of California, Irvine, CA 92717.

Recent work from this laboratory has investigated transiently expressed acetylcholinesterase (AChE) in developing cerebral cortex. AChE is expressed transiently by some thalamocortical axons during the time when the axons are growing into cortex and forming synapses with cortical neurons. The function of the transiently expressed AChE remains unknown. Recent evidence indicates that the AChE molecule includes a sequence homologous with cell adhesion molecules, suggesting that AChE may serve cell adhesion functions. The experiments presented here explored this possibility. Fluorescent microspheres (Covaspheres) were coated with recombinant AChE (kindly provided by Dr. Palmer Taylor of UCSD) and exposed *in vitro* to freshly cut sections of forebrain from early postnatal rat or mouse pups. The fluorescent microspheres coated with AChE bind non-randomly to slices of developing cerebral cortex, with a developmental pattern that mimics the position of AChE positive thalamocortical axon terminals. AChE coated spheres show preferential attachment to deep cortical layers in the first postnatal days, before layer IV differentiates from the cell dense cortical plate, and strong attachment to layer IV after layer IV differentiates. Microspheres coated with bovine serum albumin show only low level and random patterns of attachment. These data suggest that the transiently expressed AChE may serve an adhesive function to aid the developing thalamocortical axons' growth into cortex. Supported by NIH grant NS 30109

## 218.5

**DENDRITIC DEVELOPMENT OF NEWLY-GENERATED GRANULE CELLS IN THE ADULT HIPPOCAMPUS OCCURS UPON CONTACT WITH RADIAL GLIA-LIKE CELLS.** T. Seki<sup>1,2</sup> and Y. Arai<sup>1</sup>. <sup>1</sup>Dept. of Anatomy, Juntendo Univ. Sch. of Med., Tokyo 113, Japan, <sup>2</sup>Dept. of Genetics, Case Western Reserve Univ., Sch. of Med., Cleveland, OH 44106-4955

The granule cell layer of the hippocampal dentate gyrus possesses two immature aspects. Firstly, the granule cells are continue to be produced in the inner most region of the dentate granule cell layer even during adult period. We have found that newly generated granule cells of the adult dentate gyrus specifically express a highly polysialylated neural cell adhesion molecule (NCAM-H) that is known to be essential in neuronal development. Unlike mature granule cells, the NCAM-H expressing dendrites scarcely have dendritic spines, but spike-like or fan-shaped fine processes. Secondly, there are radial glia-like cells which are similar to radial glia in the developing cerebral cortex. The radial glia-like cells are located in the inner most region of the dentate granule cell layer and extends long radial processes which express a glial fibrillary acid protein (GFAP). Here we show that both NCAM-H expressing granule cells and GFAP-expressing radial glia-like cells decreased with aging. Further, the NCAM-H positive dendrites were found to be in close contacts with the radial processes of the glial cells by confocal laser scanning microscopy and immunoelectron microscopy. Occasionally, the NCAM-H expressing fine processes were surrounded by the glial processes. We assume that radial glia-like cells are associated with the development of the dendrites of newly generated granule cells in the adult dentate gyrus

**BASAL FOREBRAIN CHOLINERGIC PROJECTIONS TO CEREBRAL CORTEX: LACK OF TARGET SPECIFICITY IN ORGANOTYPIC SLICE CULTURES.** J. Baratta\*, D.H. Ha, J. Weiss, J. Yu and R.T. Robertson, Depts. of Anatomy and Neurobiology, Neurology, and Physical Medicine and Rehabilitation, College of Medicine, University of California, Irvine, CA 92717.

Previous studies have demonstrated that basal forebrain cholinergic neurons send their axons to the cerebral cortex in a topographically organized projection. At the extremes, cholinergic neurons of the septum send their axons to hippocampus while cholinergic cells in the substantia innominata and medial globus pallidus send their axons to lateral neocortex. Results of experiments presented here tested the hypothesis that this topographic organization results from target preferences of the cholinergic neurons. Tissue slices containing either medial septum or substantia innominata were grown together with slices of lateral neocortex and of hippocampus as organotypic triple cultures. After several days to 2 weeks, cultures were fixed and processed for AChE histochemistry to demonstrate growth of cholinergic axons. Cholinergic neurons from septum and from substantia innominata projected axons into both neocortex and hippocampus in organotypic patterns. The density of axons was greater in hippocampus than in neocortex, irrespective of whether the axons were derived from septal or substantia innominata tissue. Addition of exogenous nerve growth factor increased the number of AChE positive axons, but did not alter their apparent patterns of termination. These data suggest that basal forebrain cholinergic neurons can innervate any portion of the cerebral mantle, and the topographic organization seen in vivo does not result from chemospecificity of targets. *Supported by NIH grant NS 30109*

## 218.6

**DENERVATION IS INSUFFICIENT TO INDUCE COLLATERAL SPROUTING OF MYELINATED PRIMARY AFFERENTS IN THE ADULT SPINAL CORD.** T.P. Doubell, H. Gill and C.J. Woolf. (Spon: Brain Research Association). Dept. of Anatomy & Developmental Biology, University College London, UK.

Using the transganglionic tracer B-HRP to map the central projections of rat sciatic myelinated A-fibres, it has been previously shown that peripheral nerve injury induces the sprouting of the central axons of myelinated primary afferents into lamina II of the dorsal horn, an area which normally only receives input from C-fibres (Woolf et al., Nature 355 (1992) 75-77).

We have found that the C-fibre specific neurotoxin capsaicin applied locally to the sciatic nerve also induces sprouting of A-fibres into lamina II (Mannion et al. (1995) Soc. Neurosci. Abstr. 21.). Since nerve injury and capsaicin both induce transganglionic C-fibre atrophy, the production of vacant synaptic sites in lamina II may be a factor which initiates A-fibre sprouting in the dorsal horn.

The aim of this study was to test whether denervation alone is sufficient to produce A-fibre sprouting. The L4 spinal segment was partially denervated by sectioning the L4 segmental nerve or the L4 dorsal root, and we investigated, using B-HRP labelling, if remaining intact or peripherally axotomized myelinated sciatic afferents sprouted into the denervated areas.

Neither dorsal root nor segmental nerve section resulted in neighbouring intact myelinated fibres sprouting into lamina II and these lesions prevented the central terminals of injured axons from sprouting into the denervated area. We conclude that denervation alone does not produce sprouting and are examining whether a chemotropic factor released by C-fibres may be involved.

Supported by the MRC.

**OBSERVATIONS ON THE MORPHOLOGY OF GROWING THALAMOCORTICAL AXONS IN DEVELOPING RAT.** K. Ishii<sup>1,2</sup>, E.G. Jones<sup>1</sup> and T. Shirai<sup>2</sup>. <sup>1</sup>Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92715 and <sup>2</sup>Dept. of Anatomy, Yamagata Univ. Sch. of Med., Yamagata 990-23, Japan.

We examined the outgrowth of thalamocortical axons in developing rats and their distribution in the cerebral cortex with DiI and Biocytin labeling methods. All animals were anesthetized with sodium pentobarbital (Nembutal, i.p.) or by hypothermia. We placed crystals of DiI into the thalamus in the fixed brains from embryonic day (ED)16 to postnatal day (PD)1, labeled thalamocortical axons with DiI anterogradely, and observed the pathway under a fluorescence microscope. We also injected 5% Biocytin (Sigma) from a posterior direction into the right thalamus of ED19 and PD0 rats. After 12-24 hours, the rats were transcardinally perfused with 4% paraformaldehyde in 0.1M phosphate buffer. Sections were cut in the coronal plane on a freezing microtome and reacted for Biocytin histochemistry. At ED16, thalamocortical axons were found in the intermediate zone laterally in the cerebrum. Their tips showed various growth cones. By ED18, they had arrived at dorsal areas, and formed bundles in the developing white matter. At ED18, their tips began to appear in layer VI of the cerebral cortex in the lateral and dorsal areas. At ED20, they were densely distributed in layer VI. At PD1, they had reached middle layers and had many horizontal branches there. Many of the tips continued to show growth cones and a few of them reached layer I. These findings show the morphology of thalamocortical axons as they arrive at the intermediate zone at ED16, as they enter into the deep layer of the cerebral cortex at ED18, and begin to be distributed in the deep and middle layers of the cerebral cortex at PD1. Supported by fellowship of Ministry of Education, Science and Culture in Japan (KI).

## FORMATION AND SPECIFICITY OF SYNAPSES III

## 219.1

**AGRIN ISOFORM EXPRESSION BY CHICK SPINAL CORD NEURONS IN CULTURE.** L. S. Honig\* and K. Scott. Department of Neurology, University of Texas Southwestern Medical Center at Dallas, Dallas, TX 75235-9036.

Agrin, a ~200kD glycoprotein, is expressed as several isoforms, through developmentally regulated alternative splicing. Only certain isoforms are active in synaptogenesis at the neuromuscular junction. This study examines the regulation of expression of these isoforms by neurons of the E6 embryonic chick spinal cord. Prior studies have shown that motor neurons (MN) in vivo principally synthesize "active" A4B19 and A4B11 (B+) isoforms during synaptogenesis, while other spinal neurons (SN) principally express "inactive" A4B0 (B-) isoform. We have cultured isolated embryonic spinal neurons and examined by PCR studies whether the pattern of isoform expression might be regulated by the presence of neurotrophic factors or by the influence of target tissue, i.e. muscle cells. MN cultured 2-7 days show increasing "active" B+ isoform production, especially A4B19. Surprisingly, cultured SN, which at the time of isolation express almost exclusively B- isoforms, also start expressing B+ isoforms during culture. A variety of neurotrophic factors (CNTF, BDNF, NT3, GDNF), which do not affect MN survival in our cultures, do not have marked effects on the neuronal patterns of agrin expression. Tissue extract (from E10 chick embryos) increases MN survival, as already demonstrated, but it does not alter the relative pattern of isoform expression during culture. Co-culture of motor neurons with myotubes, resulting in muscle AChR aggregation, does not cause apparent alteration of the isoform pattern. Thus, under our conditions, factors other than cell type, developmental stage and culture period that might influence neuronal agrin expression were not identified. The pattern of isoform expression of agrin may be a relatively autonomous cell function. *(Supported in part by an award from the UT President's Research Council.)*

**AGRIN INDUCES PHOSPHORYLATION OF MUSCLE-SPECIFIC KINASE (MuSK) IN MYOTUBE CULTURE.** A. K. Y. Fu\*, K. M. Chan, F. C. F. Ip, D. M. Valenzuela<sup>1</sup>, D. J. Glass<sup>1</sup>, G. D. Yancopoulos<sup>1</sup>, K. W. K. Tsim and N. Y. Ip. Department of Biology, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, and <sup>1</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, New York.

A recently identified muscle-specific kinase, designated MuSK, was found to be highly expressed during muscle development, and localized to the neuromuscular junction in mature muscle, coincident with the distribution of acetylcholine receptor (AChR). The expression of MuSK was low in proliferating myoblasts and was dramatically induced upon fusion into myotubes. In an attempt to identify the ligand that can activate MuSK, we have utilized the neuron-muscle co-culture system, i.e. NG108-15 and C2C12 cells, to examine the ability of various candidates to induce phosphorylation of MuSK. We found that conditioned medium from NG108-15 cells, as well as exogenous addition of agrin could induce phosphorylation of MuSK in C2C12 myotubes within 5 minutes; significant MuSK phosphorylation was still observed at 4 hours. Inactive form of agrin that could not induce AChR aggregates also failed to induce MuSK phosphorylation. The ability of agrin to induce MuSK phosphorylation was similarly observed with primary rat muscle cultures. Co-localization of MuSK and AChR was observed at the neuromuscular junction of the adult rat, but not during embryonic stages when clustering of AChR was evident. Taken together, our findings demonstrated that agrin could activate MuSK and suggest that agrin-MuSK interactions play an important role in the development of the neuromuscular junction.

## 219.3

DEVELOPMENTAL EXPRESSION AND UPREGULATION OF MUSCLE-SPECIFIC KINASE (MuSK) IN DENERVATED SKELETAL MUSCLE OF THE CHICK AND RAT. F. C. F. Ip\*, A. K. Y. Fu, K. W. K. Tsim, J. Cheung, D. M. Valenzuela<sup>1</sup>, D. J. Glass<sup>1</sup>, G. D. Yancopoulos<sup>1</sup> and N. Y. Ip. Department of Biology, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, and <sup>1</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, New York.

A novel receptor tyrosine kinase specific for the skeletal muscle lineage, designated MuSK, was recently identified. The developmental profile of MuSK gene expression in various tissues of the chick and rat was examined by Northern blot analysis. Multiple MuSK transcripts were detected at abundant levels in skeletal muscles of the rat and chick, particularly during the stages of E10 to P2 in chick and E16 to P2 in rat. Whether these multiple transcripts represent different alternatively spliced forms of MuSK remains to be determined. Interestingly, a low level of MuSK expression could also be detected in different brain regions. Similar to that observed in denervated rat skeletal muscle, the expression of MuSK in skeletal muscle of postnatal chick was upregulated after nerve transection or crush. While MuSK expression remained elevated 60 days after nerve transection, it returned to control level 30 days after nerve crush. Similar pattern of MuSK upregulation following nerve injury could be observed in four different skeletal muscles examined. Taken together, our findings revealed similar profiles of expression for MuSK and AChR during development and following nerve injury.

## 219.5

THE DISTRIBUTION OF AGRIN IN THE SYNAPTIC CLEFT AT THE NEUROMUSCULAR JUNCTION IS CORRELATED WITH THE ARRANGEMENT OF ACTIVE ZONES IN THE AXON TERMINAL. M. Schwarz, P. Theodosopoulos, B. Marshall and U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford CA-94305.

Activity dependent exocytosis of ACh-containing vesicles in the axon terminal occurs along the sides of "active zones" in the presynaptic membrane. The muscle fiber's plasma membrane just opposite the active zones is infolded and AChRs in the plasma membrane are concentrated at the mouths and along the upper sides of the folds. Agrin, which is released by the axon terminal and then bound to the basal lamina in the synaptic cleft induces the formation and maintenance of junctional folds and AChR aggregates. As part of a long range study aimed at characterizing the mechanisms involved in the formation and maintenance of the postsynaptic apparatus we studied the distribution of agrin in the synaptic basal lamina and its relation to active zones at the adult frog neuromuscular junction. Agrin was labeled for EM by a gold conjugated antibody which recognized muscle as well as neural agrin, which is also concentrated in the synaptic cleft but has relatively little AChR-aggregating activity. We found that 68% of the gold particles were located in the synaptic cleft directly under the active zone; this area accounted for only 22% of the total area of the synaptic cleft. The distribution of grains at the active zone peaked at its edges, the sites of activity dependent exocytosis. The concentration of gold particles in the junctional folds was greater than in extra-active zone regions of the synaptic cleft, although it gradually diminished with distance from the mouth of the fold. These findings lead to the hypotheses that the release of agrin from axon terminals is activity dependent, that the release occurs at the same sites as the release of ACh, that the sites of action of neural agrin on the muscle fiber are at or near the mouth of the junctional folds and that neural agrin is stably concentrated in the basal lamina near its sites of action. This study was supported by NIH grant NS14506.

## 219.7

ULTRASTRUCTURAL ORGANIZATION OF DEVELOPING ACETYLCHOLINE RECEPTOR AGGREGATES. D. D. Kunkel\* and J. Stollberg. Békésy Laboratory of Neurobiology, University of Hawaii, Honolulu, HI 96822.

Acetylcholine receptor (AChR) aggregation is one of the key events in synaptogenesis at the neuromuscular junction. Aggregation begins shortly after contact by a motoneuron, and can be induced by several experimental manipulations including agrin - an extra-cellular matrix protein synthesized by motor neurons. Observations of AChR aggregation have been limited to the resolution of light microscopy. Thus, very little is known about the molecular structure of AChR aggregates. In order to examine the spatial arrangement of AChRs in developing aggregates we have employed high resolution scanning electron microscopy (SEM) and quantitative image analysis.

Cultured *Xenopus* muscle cells were stimulated with agrin, immunocytochemically labeled for AChRs using 12 nm gold particles, and observed using a field emission SEM. Backscattered electron images of the gold labeled AChRs were collected from random regions of membrane. Images were digitized and gold particle locations were ascertained in order to produce a list of their X-Y coordinates ( $\pm 2$  nm). Using "nearest neighbor analysis" and "three point angle analysis" we have shown 1) that small micro-aggregates of receptors occur within 2 hours of stimulation, and 2) that the receptors in these microaggregates are bound to an inflexible lattice with  $10 (\pm 1)$  nm spacing and hexagonal geometry. The data further indicate that formation of the lattice is the rate limiting step in receptor aggregation, rather than the diffusion rate of the receptor.

## 219.4

FUNCTIONAL INTERACTION WITH THE AChR IN C2 MYOTUBES IMPLIES A ROLE FOR SRC-FAMILY KINASES IN AGRIN'S SIGNALING PATHWAY. C. Fuhrer and Z.W. Hall\*. National Institute of Mental Health, NIH, Bethesda MD.

In cultured mammalian muscle, agrin induces tyrosine phosphorylation of the  $\beta$  subunit of the nicotinic acetylcholine receptor (AChR). The time course and specificity of phosphorylation suggest that it could play a role in agrin-induced AChR clustering. To investigate the mechanism by which the AChR becomes tyrosine-phosphorylated we tested the ability of src-family kinases to interact with peptides derived from the cytoplasmic loop of the  $\beta$  subunit of the AChR. Using bacterial fusion proteins we found that src binds to and phosphorylates the N-terminal half of the  $\beta$  subunit loop containing a tyrosine-phosphorylation site. Immunodepletion of src abolishes phosphorylation, showing that src accounts for most of the  $\beta$  subunit tyrosine-phosphorylating activity in muscle extracts. The interaction of src with the  $\beta$  subunit is specific, as the corresponding peptides from the  $\gamma$  and  $\delta$  subunits did not bind src, and because no binding was observed to the src-family members yes and fyn. To examine the association of endogenous AChR with src, receptors were isolated from C2 myotubes by affinity purification and tested for the presence of src-family kinases. Both fyn and, to a lesser degree, src were associated with the receptor. AChRs were also found to have tyrosine-phosphorylated  $\beta$  subunits. Our results are consistent with previous experiments showing that fyn is associated with tyrosine-phosphorylated Torpedo AChR (Swope and Haganir, 1994, J. Biol. Chem. 269, 29817-29824). We suggest that the AChR of mammalian muscle is initially phosphorylated by src and subsequently interacts with fyn in a phosphorylation-dependent way. These interactions could play a role in agrin's signaling pathway. Supported by NIMH, Muscular Dystrophy Association, and Human Frontier Science Program.

## 219.6

LOCALIZATION OF UTROPHIN mRNA IN SKELETAL MUSCLE FIBERS AND ITS REGULATION BY AGRIN. A.O. Gramolini\*, J.M. Tinsley\*, G.S. Robertson<sup>1</sup>, K.E. Davies<sup>2</sup>, J. Cartaud<sup>3</sup> and B.J. Jasmin<sup>1</sup>. <sup>1</sup>University of Ottawa, Ottawa, Canada; <sup>2</sup>John Radcliffe Hospital, Oxford, UK; <sup>3</sup>Institut Jacques Monod, Paris, France.

In contrast to the sarcolemmal distribution of dystrophin, utrophin accumulates at the postsynaptic membrane of the neuromuscular synapse. To explore the cellular and molecular mechanisms involved in maintaining this synaptic localization, we first performed in situ hybridization experiments. We showed that out of 375 neuromuscular synapses identified by acetylcholinesterase histochemistry, 313 (84%) displayed a precise co-localization between the presence of utrophin mRNAs and that of neuromuscular synapses. Abolition of nerve-derived electrical activity had only a modest effect on utrophin mRNA expression suggesting that the restricted presence of utrophin transcripts within the postsynaptic sarcoplasm is influenced locally by factors released from motor nerve terminals. In separate studies, we examined the developmental regulation of utrophin expression in C2 myotubes. Initially, we observed that utrophin transcripts are rare in myoblasts but that in multinucleated myotubes, levels of utrophin mRNA increase markedly. Through a sequential detergent/salt extraction procedure, we also noted that in myotubes, utrophin mRNAs are enriched within a cytoskeletal-bound polysomal fraction. Next, we treated myotubes with agrin purified from Torpedo electric tissue in attempts to identify putative extracellular cues involved in maintaining the synaptic accumulation of utrophin mRNAs. In addition to inducing acetylcholine receptor clusters which contained utrophin, agrin treatment significantly increased expression of utrophin transcripts. Utrophin mRNAs in myotubes treated with agrin were also found preferentially within the cytoskeletal-bound polysomal fraction. Together, these results show that utrophin transcripts are selectively expressed within the postsynaptic sarcoplasm of adult neuromuscular synapse and further suggest that agrin may contribute to the maintenance of this synaptic accumulation.

INTRACELLULAR CALCIUM FLUXES ARE REQUIRED FOR AGRIN-INDUCED AChR CLUSTERING

L.J. Megeath\* and J.R. Fallon. Worcester Foundation for Biomedical Research, Shrewsbury MA 01545 and Dept. of Neuroscience, Brown University, Providence RI 02912.

Agrin is an extracellular matrix protein that induces the clustering of acetylcholine receptors (AChRs) and other postsynaptic molecules on muscle cell membranes. The signal transduction pathways by which agrin induces the clustering of AChRs are poorly understood, but may involve tyrosine phosphorylation of AChR subunits. We investigated the role of intracellular calcium fluxes in agrin-induced AChR clustering using BAPTA-AM, an agent that clamps intracellular calcium. BAPTA-AM inhibits agrin-induced AChR clustering on embryonic chick myotubes. Inhibition was dose-dependent and was 67% at 50  $\mu$ M BAPTA-AM ( $n=7$ ). BAPTA-AM treatment altered neither agrin binding nor AChR levels, and its effects were reversible. AChRs remained mobile in BAPTA-AM treated myotubes, as determined by their ability to be clustered by anti-AChR antibodies. Interestingly, agrin-induced tyrosine phosphorylation of AChR  $\beta$  subunits was unaffected by BAPTA-AM.

These results indicate that intracellular calcium fluxes are necessary for agrin-induced AChR clustering, and suggest that they are downstream of AChR phosphorylation in agrin's signaling pathway. These findings raise the possibility that the formation and maintenance of postsynaptic structures could be regulated by the interaction of such calcium fluxes with agrin's signal transduction mechanism. ## 219.9

THE ROLE OF LAMININ IN THE ASSOCIATION OF ENDOGENOUS MUSCLE AGRIN WITH DYSTROGLYCAN. I.E. Sugiyama, M.J. Ferns\* and Z.W. Hall. National Institute of Mental Health, NIH, Bethesda, MD 20892.

The development of the postsynaptic specialization during synaptogenesis at the neuromuscular junction is thought to be organized by agrin, an extracellular matrix component produced by both nerve and muscle. Nerve-derived agrin induces acetylcholine receptors to cluster at the neuromuscular junction, but the functional role of muscle-derived agrin, a biologically less-active form, remains unclear. *In vitro* studies have shown that soluble forms of both nerve and muscle agrin bind to alpha-dystroglycan, a member of the dystrophin complex. Here, we show that endogenous agrin in muscle extracts is associated with dystroglycan and that this association is enhanced by the addition of laminin. Extracts of C2 myotubes were treated with EHS laminin and immunoprecipitated with an antibody against agrin. Following dissociation in SDS sample buffer, the proteins were separated by PAGE, transferred to nitrocellulose blots and probed with a beta-dystroglycan antibody. Agrin in the extracts was found to be associated with beta-dystroglycan. Surprisingly, the extent of association was increased in a dose-dependent manner by laminin, which is known to bind alpha-dystroglycan. Both heparin and calcium removal inhibited the enhanced association seen with laminin. These results indicate that laminin may play a role in assembly of the myotube extracellular matrix by enhancing or stabilizing the interaction between muscle agrin and the dystrophin-glycoprotein complex, thereby strengthening the linkage between the extracellular matrix and the cytoskeleton. (This work was supported by grants from NIH and MDA)

## 219.11

EFFECTS OF INHIBITION OF AGRIN SYNTHESIS ON ADHESION, NEURITE OUTGROWTH AND GEPHYRIN CLUSTER FORMATION. G. Escher\*<sup>1</sup>, C. Bechade<sup>2</sup> & A. Triller<sup>2</sup>. <sup>1</sup>Inst. Anat., Univ. of Lausanne, 1005 Lausanne, Switzerland. <sup>2</sup>Biologie Cellulaire de la Synapse (INSERM CJF 94-10) Ecole Normale Supérieure, Paris, France.

Agrin, a synaptic basal lamina protein synthesized by motoneurons is involved in the aggregation of AChRs. Agrin is widely expressed in the CNS and might be involved in the formation of receptor-rich microdomains.

To approach this question, we used rat embryonic dorsal horn neurons kept in culture. These neurons express glycine receptors (GlyR) which form postsynaptic clusters. They are maintained as such by gephyrin, a protein anchoring the GlyR to the cytoskeleton, and necessary to the maintenance of GlyR clusters. We previously showed that agrin is synthesized in these cultures by almost all neurons and is targeted to axons. We now show that gephyrin clusters (present on somata and on dendrites) are almost always in front of agrin positive axons. This is compatible with a role of agrin in the clusterization of the GlyR.

To test this hypothesis, agrin expression was inhibited using two antisense phosphorotriate oligonucleotides; the corresponding shuffled oligonucleotides being used as controls. After 6 days *in vitro*, agrin-like immunoreactivity was markedly reduced by the daily addition of one or the other antisense oligonucleotides given at of 1 or 5  $\mu$ M (agrin transcripts could still be detected by RT-PCR). Important morphological changes were observed: cells grouped together and formed aggregates, neurites started to fasciculate, and cells eventually detached from the bottom of the dish. In contrast, in control or untreated cultures, no such morphological changes were observed. Gephyrin clusters of the membrane however, were similar in treated, control or untreated cultures. As suggested by the recent unraveling of agrin as an heparan sulfate proteoglycan, our results support the idea that agrin plays a role in cell adhesion and neuritic growth.

### NEUROTRANSMITTER SYSTEMS AND CHANNELS: DEVELOPMENT OF INTRINSIC CELLULAR PROPERTIES—IONIC CURRENTS AND SYNAPTOGENESIS

## 220.1

DEVELOPMENT OF CELLULAR PROPERTIES OF NEURONS IN RAT SUPERFICIAL SPINAL DORSAL HORN. M.C. Jiang\* and G. F. Gebhart, Department of Pharmacology, University of Iowa, Iowa City, IA 52242

It is well appreciated that the central nervous system, including the spinal cord, undergoes postnatal maturation. The goal of these experiments was to investigate the maturation of cellular properties of lumbo-sacral spinal neurons in the superficial dorsal horn.

Sprague-Dawley rats (both sexes) were divided into five groups according to age (1 and 20 d old). Transverse slices (400  $\mu$ m) from the lumbo-sacral spinal cord were maintained at 34°C in oxygenated artificial CSF for intracellular recordings of neurons in a current clamp mode. Intrinsic properties were tested by intracellular current injection, 0.5 nA each step, at varying durations. Synaptic input was obtained by electrical stimulation of the attached dorsal root.

Neurons with stable resting membrane potential (at least -55 mV) and greater than 55 mV amplitude action potential were studied. It was found that the threshold for action potential generation required greater depolarization in younger rats. The half-width of the action potential clearly showed an age-dependent decrease from 1.2 ms to 0.6 ms. The majority of dorsal horn neurons showed slow afterhyperpolarizations (AHP). Fast AHP and afterdepolarization (ADP) could also be found in older rats. Regarding spike frequency adaptation (SFA), three types of SFAs, fast, slow and non-SFA, could be seen at all ages. However, non-SFAs were more common in younger rats. The major component of the fast EPSP is NMDA receptor-mediated in younger rats and AMPA receptor-mediated in older rats. These results reveal that the nature of synaptic input and information processing in the superficial dorsal horn is different in young rats. Supported by NS 19912.

## 219.10

$\alpha$ -DYSTROGLYCAN BINDS HEPARIN, M.A. Bowe\* and J.R. Fallon. Worcester Foundation for Biomedical Research, Shrewsbury, MA 10545 and Dept. of Neuroscience, Brown University, Providence, RI 02912

Synaptic function is critically dependent upon the coordinated expression and highly ordered interaction of an ensemble of cytoskeletal, transmembrane and extracellular components.  $\alpha$ -Dystroglycan ( $\alpha$ DG) is an extrinsic peripheral membrane protein found in several tissues, including muscle and brain. It is the major agrin binding protein in postsynaptic membranes from *Torpedo* electric organ.  $\alpha$ DG forms a tight complex with the transmembrane protein  $\beta$ -dystroglycan, which has been shown to bind the cytoskeletal components dystrophin and utrophin. The  $\alpha$ - $\beta$ DG complex is therefore well-poised to form a key link between the cytoskeleton and the extracellular matrix at the synapse.

Proteoglycans have been implicated in regulating synaptic structure. For example, the glycosaminoglycan (GAG) heparin blocks both agrin- and nerve-induced acetylcholine receptor clustering on cultured neurons, and muscle cells lines deficient in GAG synthesis form abnormal post-synaptic specializations. Here, we asked whether the  $\alpha$ - $\beta$ DG complex interacts directly with GAGs. We found that native  $\alpha$ - $\beta$ DG complex solubilized from *Torpedo* electric organ bound to immobilized heparin. To map the heparin binding site, we made expression constructs encoding fragments of  $\alpha$ - and  $\beta$ -dystroglycan. Recombinant  $\alpha$ DG also bound heparin, with the protein sequence responsible for binding located within the c-terminal half of  $\alpha$ DG. Carbohydrate modification of  $\alpha$ DG is not necessary for heparin binding. These findings suggest that GAGs may directly regulate dystroglycan's activity. [Supported by the NIH and ACS.]

## 220.2

DEVELOPMENT OF ELECTRICAL EXCITABILITY IN ANTENNAL-LOBE NEURONS OF THE SPHINX MOTH *MANDUCA SEXTA*. A.R. Mercer<sup>1,2</sup>, P. Kloppenburg\* and J.G. Hildebrand<sup>1</sup>\*, <sup>1</sup>ARL Div. of Neurobiology, Univ. Arizona, Tucson, AZ 85721, and <sup>2</sup>Dept. of Zoology, Univ. Otago, Dunedin, NZ.

Using whole-cell, patch-clamp recordings from antennal-lobe (AL) neurons *in vitro* and in semi-intact brain preparations, we have examined changes in cell membrane properties associated with the development of the AL neuropil. Development of whole-cell current profiles and cell excitability was examined in 2 morphologically distinct subtypes of *Manduca* AL neurons *in vitro*: PB neurons and RR neurons, identified previously as projection (output) neurons and local AL interneurons, respectively (Oland & Hayashi 1993, *J. Neurobiol.* 24:1170). Cells cultured from animals at stage 3 of the 18 stages of metamorphic adult development exhibit whole-cell current profiles that are dominated by large outward ( $K^+$ ) currents. Although calcium spikes can be elicited from cells at this stage, only a small percentage exhibit sodium spikes. In cells taken from animals at progressively later stages of adult development, the percentage of spiking cells increases, and the waveform of sodium-based action potentials becomes shorter in duration and larger in amplitude. From stages 3 to 10, a significantly larger proportion of PB neurons exhibit sodium currents than RR neurons. By stage 14, sodium currents are apparent in almost all neurons, and spontaneous bursts of spiking activity are frequently observed. Although the appearance of sodium-based action potentials coincides temporally with the ingrowth of primary sensory afferent axons and the onset of formation of protoglomeruli in the AL neuropil, deafferentation early (stage 2) in metamorphic adult development does not affect the development of the whole-cell current profiles of RR neurons and PB neurons. Recordings from AL neurons in isolated brain preparations suggest that cells *in vitro* reflect well the membrane properties of same-stage AL neurons *in situ*. Changes in the biophysical properties of PB and RR neurons over time in culture, if they occur, are very slow. [Supported by NIH grants AI-23253 (JGH,PK), NS-28495 (JGH) and ORG MFZB77 (ARM)]

## 220.3

DEVELOPMENTAL TIME-COURSE STUDIES OF CYTOCHROME OXIDASE, NMDAR1, NITRIC OXIDE SYNTHASE AND Na<sup>+</sup>/K<sup>+</sup> ATPASE IN PRIMARY NEURONAL CULTURES OF RAT VISUAL CORTEX. C. Zhang\* and M.T.T. Wong-Riley, Dept. of Cellular Biology and Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226

Our goal was to determine the developmental time-course of metabolic activity of neurons in glucose-free cultures. We also wished to know if such developmental process bore any relationship to possible changes in neurochemicals related to excitatory glutamatergic synapses. We prepared primary neuronal cultures from postnatal rat visual cortex. Cytochrome oxidase (C.O.) histochemistry, nitric oxide synthase (NOS), NMDA receptor subunit R1 (NMDAR1), and Na<sup>+</sup>/K<sup>+</sup> ATPase immunocytochemistry were done, and the intensities of reaction product for these neurochemicals were quantitatively analyzed by optical densitometry. Neurons in cultures showed morphology similar to those *in vivo*. The size of cell bodies visibly increased during the first two weeks in culture, and reached plateau after the third week. Neurites lengthened with time and formed local network after the first week. C.O. activity and immunoreactivity for NOS, NMDAR1 and Na<sup>+</sup>/K<sup>+</sup> ATPase were present in both cell bodies and neurites, and their levels increased progressively from 1 to 21 days in culture. Increases in optical densitometric values for these neurochemicals were not attributable to increases in cell size during development. Our results suggest that the regulation of metabolic activity in neurons may be related, at least in part, to developmental changes in levels of NOS, NMDAR1 and Na<sup>+</sup>/K<sup>+</sup> ATPase, which, in turn, may be associated with excitatory synaptic interactions in this culture system.

## 220.5

WEAVER GRANULE NEURONS EXHIBIT ABNORMAL DIFFERENTIATION OF VOLTAGE-DEPENDENT IONIC CURRENTS. R.R. Stewart\*, J.M. Wright and P. Liesi. Laboratory of Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892-8205.

The properties of voltage-dependent ionic currents were assessed in wv/wv and +/- granule neurons cultured from P7 mice on a laminin substrate for 1 day in RPMI 1640 medium. Both types of granule neurons extended bipolar processes on laminin. With external and internal solutions to measure sodium and potassium currents, it was found that, 11 of 12 +/- and only 1 of 11 wv/wv granule neurons had detectable sodium currents which were blocked reversibly by 300 nM tetrodotoxin. A-type potassium current ( $I_{K(A)}$ ), identified by its steady-state half-inactivation ( $-90 \pm 2$  mV +/- and  $-88 \pm 2$  mV wv/wv; mean  $\pm$  SEM,  $P = 0.6$ ) and rapid recovery from inactivation properties (range 16-34 ms), was present in 21 of 23 +/- and 14 of 24 wv/wv granule neurons. For cells with detectable  $I_{K(A)}$ , the current densities of +/- and wv/wv granule neurons were significantly different ( $31 \pm 4$  pA/pF for +/- ( $n=21$ ) and  $18 \pm 2$  pA/pF for wv/wv ( $n=14$ );  $P=0.02$ ). In addition, the slowly inactivating delayed rectifier potassium current that was blocked reversibly by 20 mM tetraethylammonium was detectable in all granule neurons and had significantly more current density in +/- ( $62 \pm 3$  pA/pF;  $n=34$ ) than in wv/wv ( $42 \pm 5$  pA/pF,  $n=24$ ) granule neurons ( $P<0.001$ ). Thus, wv/wv granule neurons exhibit abnormal development of three types of voltage-dependent ionic currents. This work was supported by an intramural grant from NIAAA, NIH.

## 220.7

DEVELOPMENTAL REGULATION OF INTRINSIC MEMBRANE OSCILLATIONS IN RAT CA3 HIPPOCAMPAL NEURONS. F. Strata\*, M. Atzori, E. Cherubini. Biophys. Lab, Int Sch. Adv. Studies (SISSA), 34014 Trieste, Italy.

Intracellular recordings were used to investigate the mechanisms underlying intrinsic membrane oscillations in CA3 hippocampal neurons in slices obtained from newborn and adult rats. In adult rats, when cells loaded with intracellular cesium were depolarized to a potential ranging from -50 to -43 mV, they exhibited membrane oscillations (0.1-4 Hz). These oscillations were unaffected by tetrodotoxin (TTX, 1  $\mu$ M). In TTX, the frequency of the oscillations was voltage dependent, varying from 0.1 Hz at -58 mV to 7 Hz at -40 mV. Below -58 mV membrane oscillations were blocked. K<sup>+</sup>-channel blockers such as 4-aminopyridine (200-500  $\mu$ M), tetraethylammonium (10 mM) and barium (0.3-1 mM) elicited plateau potentials with superimposed fast (4-7 Hz), small amplitude oscillations. In the absence of external calcium, membrane oscillations were blocked; they reappeared when extracellular calcium was raised to 0.1 mM. The calcium channel antagonist, Cd<sup>2+</sup> (50-100  $\mu$ M) irreversibly blocked membrane oscillations. A similar effect was obtained with nifedipine (1  $\mu$ M) or nickel (20  $\mu$ M); in this case the block was voltage-dependent. Moreover, the intrinsic rhythmic activity was reversibly abolished by carbachol (10  $\mu$ M).

In newborn rats (P1-P5), in the same experimental conditions (intracellular cesium), spontaneously occurring membrane oscillations were not detected. Few oscillatory events however could be triggered by a depolarizing current pulse to a potential more positive than -20 mV. These rapidly faded during the sustained membrane depolarization.

These data suggest that during development the kinetic properties of Ca<sup>2+</sup> channels in the hippocampus are substantially different from adult ones and this may affect information processing in early postnatal life.

## 220.4

EXPRESSION OF AN N-TYPE CALCIUM CHANNEL COMPLEX IN THE DEVELOPING RAT HIPPOCAMPUS. O.T. Jones\*, G.M. Bernstein, J. Francis, D.G.M. Jugloff, W. Wong, J.H. Eubanks, and L.R. Mills. Playfair Neurosci. Unit, TTH Res. Inst. & Dept. Pharmacol., U. of Toronto, Canada M5T 2S8.

The expression of voltage-dependent calcium channels (VDCCs) in neurons is critical for transmitter release, excitability and in establishing the cytoarchitecture of the CNS. However, a molecular and cellular dissection of the interplay between VDCC expression and CNS development is plagued by the diversity of VDCCs in brain. Such diversity arises via multiple genes encoding the structurally dissimilar  $\alpha_1\alpha_2\delta$  and  $\beta$  subunits of the VDCC heteromer and to alternative splicing of many of the RNA transcripts.

We now describe the expression of a major VDCC complex implicated in neuronal migration - the N-channel - from embryonic to adult stages in rat hippocampus. Expression was measured using the following indices: selective ligand binding, the levels of mRNA and protein corresponding to the  $\alpha_1\alpha_2\delta$  and  $\beta$  subunits of this complex, co-immunoprecipitations and fluorescent imaging of cell-surface N-VDCCs. While  $\alpha_1$  and  $\beta$  subunits are already present in the E18 hippocampus, the bulk of their expression occurs in the first two weeks following birth. Initial data suggests that the fraction of  $\alpha_1$  associated with  $\beta$ , rises in the first week of birth. Surprisingly, the expression of N-VDCCs is not even throughout the hippocampus but occurs in subfields CA3 and CA2 prior to dentate gyrus and CA1. In all regions N-VDCCs appear to be first expressed on the soma and only then in the dendrites.

These data have significant implication for the role of N-VDCCs in migration, synaptogenesis and pruning and in the establishment of neurotransmission in the hippocampus.

This work was supported by MRC and NSERC Canada, The Ontario Mental Health, Savoy and Bloorview Epilepsy foundations.

## 220.6

DURING POSTNATAL BRAIN DEVELOPMENT THE OBSERVED CHANGES IN Na<sup>+</sup> CHANNELS GATING PROPERTIES REFLECT CHANGES IN THE CHANNEL'S SIALIDATION LEVEL. D. Balbi, C. Castillo and E. Recio-Pinto\*. Instituto de Estudios Avanzados, Caracas 10154, Venezuela. Anesthesiology and Physiology Depts, Cornell University Medical College, New York 10021.

The gating properties of rat brain Na<sup>+</sup> channels were studied at three postnatal ages, day 0 (P0), 15 (P15) and adult (>P30) by using the planar lipid bilayer system. The midpoint potential of activation of BTX-modified channels changed from -58mV in P0 channels to -76mV in older channels. At negative potentials gating state changes were observed in all channels; at positive potentials they were observed in P0 channels but rarely in older channels. A long nonconductive state was displayed by most P0 channels but rarely by older channels. Previous studies have shown that neuraminidase treatment of Na<sup>+</sup> channels produces a depolarization shift of the activation curve and increases the frequency of long channel closures (Recio-Pinto et al., 1990, Neuron 5:675-684). In order to investigate whether the observed development changes were due to changes in the sialidation level of the sodium channel, Western blots were done using forebrain plasma membrane preparations before and after neuraminidase treatment. Before treatment, the channels' apparent MW was 210kDa for P0 and 240kDa for P15 and adult Na<sup>+</sup> channels. After neuraminidase treatment the apparent MW of Na<sup>+</sup> channels decreased and became similar for P0 and adult channels. Therefore the increase in the Na<sup>+</sup> channel apparent MW during postnatal development could be accounted for by an increase in the channels' sialidation level. Neuraminidase treatment of adult channels resulted in a channel behavior resembling that of P0 channels. Therefore, during postnatal brain development the Na<sup>+</sup> channel function changes and those changes appear to reflect changes in the channels' sialidation level. An increase in the sialidation level of Na<sup>+</sup> channels is an additional *in vivo* cellular mechanism that contributes in defining neuronal excitability during brain development.

## 220.8

TONICALLY ACTIVE DIVALENT CATION ENTRY INTO EMBRYONIC RAT CORTICAL CELLS *IN VITRO*. H. Xian, D. Maric, I. Maric and J. L. Barker\*. Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

Cytosolic calcium (Ca<sup>2+</sup>) is an important intracellular signal that regulates many cellular functions. Ca<sup>2+</sup> is closely regulated by numerous membrane and intracellular mechanisms. We studied Ca<sup>2+</sup> homeostasis in acutely dissociated embryonic cortical cells (E12-E19) using digital fluorescence microscopy and the Ca<sup>2+</sup>-indicator fura-2. We found that the basal Ca<sup>2+</sup> level largely depended on extracellular Ca<sup>2+</sup> (Ca<sup>2+</sup>). Removal of Ca<sup>2+</sup> from perfusing saline decreased Ca<sup>2+</sup> in a rapid and reversible manner. Cells with higher resting Ca<sup>2+</sup> levels showed larger decreases in Ca<sup>2+</sup> in Ca<sup>2+</sup>-free, while cells with lower levels exhibited smaller decreases. Re-perfusion of cells with Ca<sup>2+</sup>-containing medium (Ca<sup>2+</sup>: 1.8mM) elevated Ca<sup>2+</sup>, which rebounded to levels higher than in control. We next examined the effects of Cd<sup>2+</sup> and Mn<sup>2+</sup> on Ca<sup>2+</sup> to elucidate possible Ca<sup>2+</sup> entry pathways. Cd<sup>2+</sup> blocks voltage-dependent Ca<sup>2+</sup> channels and has a higher binding affinity for fura-2 than Ca<sup>2+</sup>. Perfusion of Cd<sup>2+</sup> (>0.1mM) in the presence or absence of Ca<sup>2+</sup> increased the ratio values for fluorescence emission intensities ( $I_{360}/I_{380}$ ), but did not alter the fluorescence emission intensity at 360nm excitation. This effect of Cd<sup>2+</sup> could not be reversed, even with long-term washing with Cd<sup>2+</sup>-free control saline or EGTA-containing medium. Moreover, the L-type Ca<sup>2+</sup> channel blocker nifedipine did not alter Ca<sup>2+</sup>, nor prevent the Cd<sup>2+</sup>-induced effect. Addition of Mn<sup>2+</sup> (0.5mM) in the perfusing saline decreased fura-2 emission intensity excited at 360nm (dye quenching), which was partially recovered following application of Cd<sup>2+</sup>. These results indicate that there are tonically active Ca<sup>2+</sup> entry pathways in plasma membranes of embryonic cortical cells, which are permeable to Cd<sup>2+</sup> and Mn<sup>2+</sup>, and contribute to basal Ca<sup>2+</sup> levels.

## 220.9

TETANUS TOXIN C FRAGMENT IDENTIFIES ANATOMICALLY DISCRETE EMBRYONIC RAT NEOCORTICAL SUBPOPULATIONS IN SUSPENSION.

I. Maric\*, D. Maric, and J.L. Barker. LNP, NINDS, NIH, Bethesda, MD

*In vitro* studies into embryonic (E) neocortical development are often confounded by unavoidable loss of anatomical cytoarchitecture after cell dissociation. Here we show that fluorochrome-conjugated tetanus toxin C fragment (TnTx) relocates suspended cells in their anatomical context. Neocortex of E19 Sprague-Dawley rat embryos was microdissected into ventricular/subventricular zones (VZ/SVZ) and cortical plate/subplate (CP/SP) regions, then dissociated and reacted with TnTx-FITC. FACS analysis revealed two modal values of TnTx expression: TnTx<sup>high</sup> and TnTx<sup>low</sup> cells found predominantly in CP/SP and VZ/SVZ dissociates, respectively. Dissociates fractionated on continuous Percoll gradients according to their natural specific buoyant densities (BD) showed that TnTx<sup>high</sup> cells composed the most buoyant (BD  $\leq 1.04$  g/ml) while TnTx<sup>low</sup> and TnTx<sup>-</sup> cells constituted the least buoyant (BD  $\geq 1.07$  g/ml) populations. Thus, changes in TnTx binding and BD correlate *in vitro*, identifying cells developing in anatomically distinct locations *in vivo*.

## 220.11

THE MECHANISM OF SPONTANEOUS CALCIUM OSCILLATIONS IN A SELF-ORGANIZING NETWORK OF CULTURED CORTICAL NEURONS. Xiaoshu Wang\* and Eric Gruenstein. Dept. of Molecular Genetics, Biochem & Microbiology, and The Neurosciences Graduate Pgm, Univ of Cincinnati Med School, Cincinnati, OH 45267

Rat cortical neurons cultured at high density form synaptically coupled networks in which clusters of cells undergo synchronized calcium oscillations. Although it is known that each calcium spike is the result of a burst of action potentials (APs), neither the underlying mechanism that gives rise to the AP bursts nor the reason the spikes are synchronized is understood. We have found that the calcium spikes are independent of intracellular calcium stores and thus depend solely on the influx of extracellular calcium. This occurs primarily via L-type voltage gated calcium channels (VGCCs) but also involves N- and T-type channels. Calcium spikes are regulated by at least 4 discrete K<sup>+</sup> channels including 3 voltage regulated channels which stimulate spiking and one calcium activated channel which inhibits. Initiation of calcium spikes requires AMPA/K<sup>+</sup> glutamatergic receptors, although NMDA receptors also augment the process. Termination of calcium spikes involves stimulation of inhibitory GABA receptors. Based on these observations we propose a model for the synchronized calcium oscillations in which the process begins with a spontaneous action potential that is triggered by the occurrence of several closely timed mini-EPSPs arising from the normal, release of glutamate at presynaptic membranes. As the synaptic density of the network increases, the likelihood that several APs will occur within a short period of time also increases. In this way the network generates a large number of nearly simultaneous 'secondary EPSPs' constituting a positive feedback loop which gives rise to a prolonged depolarization of the presynaptic membranes and a burst of APs. Each AP burst activates VGCCs and the resulting influx of calcium constitutes the rising phase of the calcium spike. Spikes are terminated by the combined activation of inhibitory GABA synapses and the slowly activating calcium dependent K<sup>+</sup> channels (I<sub>AHP</sub>) which gradually repolarize the neuronal membrane. Since the I<sub>AHP</sub> current inactivates very slowly, there will be a refractory period before the next calcium spike.

## 220.13

ARIA REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTORS IN RAT INTERPUDUNCULAR NEURONS DEVELOPING IN VITRO K. Wietasch and G. D. Fischbach\*, Department of Neurobiology, Harvard Medical School, Boston, MA 02115

ARIA increases the number of nicotinic acetylcholine receptors (nAChRs) at the vertebrate neuromuscular junction. We have studied the effects of ARIA on AChR expression in CNS neurons, using the habenular-interpuduncular system of the rat. Several nAChR subunit transcripts are abundantly expressed in the interpuduncular nucleus (IPN). ARIA transcripts are expressed in all cholinergic nuclei in the CNS, including the medial habenula nuclei that provide the major input to the IPN. ACh-evoked ionic currents were characterized using patch clamp recordings. In neurons cultured from the IPN of newborn rats, three types of nicotinic currents could be distinguished in whole-cell configuration based on their kinetic properties and pharmacology. Type I currents exhibited fast onset and rapid biphasic desensitization ( $t_{10-90} = 2.4$  ms;  $\tau_1 = 6.8$  ms,  $\tau_2 = 168$  ms;  $n=73$ ) and were blocked by methyllycaconitine (1 nM) and  $\alpha$ -bungarotoxin. Type II currents rose and desensitized more slowly ( $t_{10-90} = 8.3$  ms;  $\tau_1 = 96.4$  ms,  $\tau_2 = 554$  ms;  $n=29$ ) and were blocked by dihydro- $\beta$ -erythroidine (10  $\mu$ M), mecamylamine (5  $\mu$ M) and hexamethonium (100  $\mu$ M). Type III currents exhibited the slowest rise and a slow monophasic decay ( $t_{10-90} = 18.03$  ms;  $\tau = 348$  ms;  $n=42$ ) and were completely blocked by mecamylamine (5  $\mu$ M) and partially blocked by hexamethonium (100  $\mu$ M). Some neurons were found to have a mixed fast and slow response. Single channel analyses suggest that at least two different types of AChRs were responsible for type II and III currents. Treatment of IPN cultures with recombinant ARIA (100 pM human ARIA<sub>177-246</sub>) lead to phosphorylation of a 185 kD protein, suggesting that the cells express ARIA receptors. Immunocytochemistry indicated that IPN cells contain several ARIA receptors including erbB2, erbB3, and erbB4. Treatment of IPN cells with 100 pM ARIA in the continued presence of either forskolin or 8-Br-cAMP was found to increase type I current-density. The effect of ARIA on type II and III currents is currently under investigation. NIH RO1-NS8226

ON-LINE RECORDING OF TETANUS TOXIN-IDENTIFIED EMBRYONIC RAT NEOCORTICAL DISSOCIATES REVEALS PHYSIOLOGICAL CORRELATES OF CELL PROLIFERATION AND DIFFERENTIATION.

D. Maric\*, I. Maric, and J.L. Barker. LNP, NINDS, NIH, Bethesda, MD

We used tetanus toxin (TnTx) binding to discriminate and record functional transmitter receptor/ion channel properties among proliferative (TnTx<sup>-</sup>) and differentiating (TnTx<sup>low</sup> and TnTx<sup>high</sup>) subpopulations of rat neocortical cells in ventricular/subventricular zones (VZ/SVZ) and cortical plate/subplate (CP/SP) regions at embryonic day 19 (see I. Maric et al.). Neocortical dissociates were stained with fluorochrome-conjugated tetanus toxin C fragment and loaded with either a voltage-sensitive (oxonol) or Ca<sup>2+</sup>-sensitive (Fluo-3) fluorescent indicator dyes. The physiological properties distributed throughout the entire neocortical dissociate were then profiled in ~2 minutes by randomly recording on-line identified TnTx expressing and non-expressing cells at ~1000 cells/second using a flow cytometer. Baseline recordings at room temperature revealed reproducible resting membrane potentials and Ca<sup>2+</sup> distributions which varied according to TnTx-fluorochrome intensity and FALS (cell size) or SSC (cell complexity) levels. The majority (>85%) of TnTx negative cells, with the lowest FALS or SSC, which we presume to be proliferating elements from VZ/SVZ, depolarized to 40 mM K<sup>+</sup> and veratridine, a Na<sup>+</sup>-channel agonist, but only a fraction ( $\leq 40\%$ ) of them depolarized to GABA and kainate, and none were affected by acetylcholine (ACh). Furthermore, none of the above depolarizing effects was associated with detectable elevations in Ca<sup>2+</sup>. By contrast, the great majority of TnTx<sup>high</sup> cells, which accounted for ~20% of the dissociate and which we presume to be differentiating CP/SP neurons, were hyperpolarized by ACh and depolarized by the rest of above mentioned ligands. All of these agents triggered sizable increases in Ca<sup>2+</sup> in the majority ( $\geq 70\%$ ) of these cells suggesting an expression of multiple transmitter receptors and ion channels on many CP/SP neurons. Interestingly, sequential Ca<sup>2+</sup> elevations to ACh, GABA and kainate could be induced in these cells even when saturating concentrations of the agonists were allowed to accumulate, implying 'multi-plexability' to these Ca<sup>2+</sup> signalling pathways.

## 220.12

STABILITY OF CYCLIC ADP-RIBOSE ANALOGS, J. A. Boland, W. K. Jones and L. M. Yungler\*, Sigma Chemical Company, St. Louis, MO 63118.

Cyclic ADP-Ribose (cADPR) is a recently discovered cyclic nucleotide involved in calcium-induced calcium release in cells. NAD<sup>+</sup> is converted to cADPR by ADP-ribosyl cyclase, an enzyme we have isolated from the ovotestes of *Aplysia californica*. ADP-ribosyl cyclase will also catalyze the cyclization of NAD<sup>+</sup> analogs with purine bases other than adenine, such as guanine, hypoxanthine and adenines modified at C8. We have synthesized several cADPR analogs including cyclic inosine diphosphate ribose (cIDPR), cyclic guanosine diphosphate ribose (cGDPR), and 8-Bromo, 8-Azido and 8-Amino-cADPR. The effect of temperature and pH on shelf-life and solution stability for these various analogs will be shown. The sodium salts of cADPR, cGDPR, and 8-Bromo-cADPR are stable when stored as solids at -20°C, exhibiting little if any degradation in one year. Aqueous solutions (0.5 - 1 mg/ml, pH=7) hydrolyze at rates of 0-5% per week at 0-5°C.

## 220.14

REGULATION OF ACETYLCHOLINESTERASE EXPRESSION IN DEVELOPING RAT THALAMUS. Z. Rakonczay, P. Hammond, R. Rao, and S. Brimijoin\*. Dept Pharmacol., Mayo Clinic, Rochester, MN 55905.

Acetylcholinesterase (AChE) is often expressed on nerve cells before or during synaptogenesis and may play a role in development of the vertebrate nervous system (Layer, 1995). Regulation of AChE during ontogenesis remains poorly understood, however. We used a reverse transcriptase-polymerase chain reaction assay, standardized with reference to cyclophilin mRNA, to investigate transient expression of AChE in newborn rat thalamus. Relative densities of DNA bands were quantitated by computerized video densitometry of ethidium bromide stained gels. AChE activity was also measured biochemically and histochemically. Analysis focused on a non-cholinergic but AChE-rich area, the medial geniculate nucleus of the thalamus (MGN), where transient increases and decreases of AChE expression during postnatal development are especially obvious (Robertson & Yu, 1993; Brimijoin & Hammond, 1996). Whole thalamus was studied at 1, 3, 6, 9, 12, 16, and 22 days of age, and in adult rats; MGN was examined at 8 and 23 days. Levels of AChE mRNA in the thalamus rose steadily for about nine days and then decreased. The MGN showed high levels of AChE mRNA and enzyme activity at day 8 but at day 23 both measures of AChE expression were 55% lower ( $p < 0.001$ ). This result could reflect reduced message stability. *In vivo* experiments were performed to assess that possibility by determining the decay of mRNA levels after treatment with actinomycin D. Overall, our data support the view that AChE up-regulation during neural morphogenesis may be an important feature of brain development. (Supported by grant NS 29646).

## 220.15

REDUCED VACHT mRNA EXPRESSION IN SEPTUM OF POSTNATAL RATS FOLLOWING PERINATAL LOW-LEVEL LEAD EXPOSURE. X. Sun, X. Tian, and J.B. Suszkiw\*. Dept. of Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH 45267-0576.

We previously reported that perinatal Pb exposure reduces the cholineacetyltransferase (ChAT)-mRNA expression in the septum of postnatal rat. In the present report we examined the effect of Pb-exposure on the vesicular Ach transporter (VACHT)-mRNA expression in postnatal rats. Rat pups were maternally Pb-exposed by giving 0.2% lead acetate in drinking water to dams. Septal tissue was homogenized in RNazol™ B (1:20, w/v). Total RNA from both control and Pb-exposed animals was extracted, quantified at OD<sub>260</sub>, loaded at 10, 5, and 2.5 µg onto nylon membrane in Dot-blot manifold apparatus, and hybridized with α-(<sup>32</sup>P)UTP-radiolabeled VACHT RNA riboprobe or 21bp rat 18S rRNA probe, respectively. The blots were scanned and quantified with the aid of a phosphor imager SF (Molecular Dynamics). The VACHT mRNA signal was normalized to the corresponding signal obtained with a probe specific for the 18S ribosomal RNA. Relative to control levels, the VACHT mRNA levels in septa of PN7 and PN21 animals with Pb-exposure were significantly reduced by 32% and 29%, respectively. The results indicate that Pb alters the expression of both ChAT- and VACHT-mRNA. This work was supported by NIEHS grant ES06365.

## 220.17

EXPRESSION OF GLYCINE RECEPTOR SUBUNITS AND GEPHYRIN DURING NEURAL DIFFERENTIATION IN VITRO. S. Heck, R. Enz\*, C. Richter-Landsberg\*, and D. H. Blohm. Univ. of Bremen, Dpt. of Biotechnology and Molecular Genetics, 28359 Bremen, \*Max-Planck-Institute for Brain Res., Dpt. of Neuroanatomy, 69528 Frankfurt, \*Univ. of Oldenburg, Dpt. of Biology, 26111 Oldenburg, Germany

Inhibitory glycine receptors (GlyR) consist of α and β subunits and are anchored by gephyrin, which is spliced extensively in adult rat brain and necessary to form functional receptor microdomains. During rat brain development the predominant embryonic α2 subtype is replaced by α1 and α3 subtypes. Primary cultures of rat spinal cord neurons express only the α2 and β subunits. Retinoic acid induces the mouse EC cell line P19 to differentiate into neuronal and glial cell types. To characterize this process the expression of about 40 genes at various differentiation stages of P19 has been analyzed by RT-PCR, automatic sequencing and in part by non-radioactive *in situ* hybridization. In case of GlyR and gephyrin, results were compared to primary cultures of rat hippocampal neurons, rat brain glial cells, and adult rat and mouse brain. GlyRβ and gephyrin are constitutively expressed in all cell types investigated. Interestingly, mouse GlyRβ contains an additional 48 bp in-frame insert. Gephyrin splicing pattern clearly changes during P19 differentiation. P19 cells express GlyRα1 and α2 subunits but no GlyRα3 transcripts during the 14 day differentiation period. Primary hippocampal neurons express GlyRα2 only while no GlyRα1 subunit transcripts were found in the glial cell types. In summary, P19 cells and primary hippocampal neurons but not primary glial cells express *in vitro* all transcripts known to be necessary for the generation of functional glycine receptors.

## 220.19

QUANTITATIVE ANALYSIS OF 5-HT<sub>1A</sub> RECEPTOR mRNA FROM EMBRYONIC RAT BRAIN BY COMPETITIVE RT-PCR

J. M. Lauder<sup>1</sup>, J. Liu<sup>1</sup> and D. R. Grayson<sup>2</sup>. <sup>1</sup>Dept. of Cell Biology and Anatomy, Univ. of North Carolina School of Medicine, Chapel Hill, NC 27599, <sup>2</sup>Dept. of Psychiatry, Med. Coll. of Penn. and Hahnemann Univ., Pittsburgh, PA 15212

There is growing evidence that serotonin acts as a growth regulatory signal in CNS development and that this action is mediated by specific 5-HT receptors. We have quantified the expression of 5-HT<sub>1A</sub> receptor mRNA in embryonic rat brain using the highly sensitive method of competitive reverse transcriptase-polymerase chain reaction (competitive RT-PCR). Total RNA was prepared from pooled tissue samples from dissected E12, E14, E15, E16, and E18 rat brain regions. Absolute amounts of 5-HT<sub>1A</sub> mRNA transcripts were quantified by RT-PCR using specific primers and internal standards. The 5-HT<sub>1A</sub> cRNA internal standard was identical to the 5-HT<sub>1A</sub> target sequence except for a restriction site midway in the sequence. 5-HT<sub>1A</sub> subunit mRNA was co-transcribed and amplified with varying concentrations of internal standard. The concentration of target mRNA was determined using linear regression to find the "point of equivalence" where the ratio of internal standard to target RNA was equal to 1. Low levels of 5-HT<sub>1A</sub> transcripts were detected as early as E12 in the metencephalon (about 0.1pg/mg total RNA). By E14, levels had increased by 7 fold (about 0.7 pg/mg total RNA), and continued to increase until E16 (about 1.3pg/mg total RNA). At E18 the concentration was similar to E16, suggesting that a plateau had been reached. These results are consistent with expression patterns seen using immunocytochemistry with 5-HT<sub>1A</sub> receptor antibodies (gift of John Raymond). This study demonstrates that 5-HT<sub>1A</sub> receptor mRNA can be accurately measured in regions of embryonic rat brain using competitive RT-PCR. The presence of early prenatal expression of 5-HT<sub>1A</sub> receptors suggests that they may play important roles in prenatal brain development.

## 220.16

DEVELOPMENTALLY REGULATED CHANGES ON THE PROPERTIES OF GLYCINE RECEPTORS IN CULTURED MOUSE SPINAL NEURONS.

Luis G. Aguayo\*, Juan C. Tapia, Felipe A. Albarrañ, Jorge P. Roa. Labs. Neurophysiol. & Immunocytochem., University of Concepcion, Concepcion, Chile.

We studied several neurophysiological properties of maturing glycine receptors in mouse spinal cord neurons cultured for various times: 3-7 days (early), 10-12 days (intermediate) and 17-24 days (mature). The glycine-activated Cl<sup>-</sup> conductance, studied with whole-cell and gramicidin-perforated patch clamp techniques, increased about 6 fold during development and the current density increased about three fold. The sensitivity to glycine increased transiently from 39±2.8 µM in early cells to 29±1 µM in intermediate neurons. In mature neurons, the sensitivity to glycine was similar to that in early cells. The current decayed (desensitized) during the application of 500 µM glycine. The decay was single exponential and the time constant increased from 221±139 ms in early cells to 4580±1071 ms in mature cells. Picrotoxin (10 µM) inhibited the current to a larger extent in early cells (46±6% of control). On the other hand, the current was potentiated by several concentrations of Zn<sup>2+</sup> and ethanol to a larger extent in mature neurons. In addition, higher concentrations of Zn<sup>2+</sup> (>100 µM) inhibited the current in all the neurons. The receptors were sensitive to strychnine even in the early neurons and the sensitivity of the receptors to the alkaloid (IC<sub>50</sub>) increased from 22±3 nM in early neurons to 9±1 nM in mature neurons. In conclusion, several properties of developing spinal glycine receptors changed during neuronal maturation. This indicates that, similar to GABA<sub>A</sub> receptors, the function of these receptors are developmentally regulated. Supported by FONDECYT 1950917 Grant.

## 220.18

ALPHA-2 ADRENERGIC RECEPTOR DEVELOPMENT IN RAT BRAIN: AN AUTORADIOGRAPHIC STUDY. L.C. Murrin\*, C.L. Coulter, H.K. Happe, D.B. Bylund. Dept. of Pharmacology, Univ. Nebraska Med. Ctr., Omaha, NE 68198-6260

Alpha-2 adrenergic receptors (A2AR) play an important role in many CNS processes, including learning and memory and pain perception. There is also evidence they help regulate development of some CNS regions, such as cerebral cortex. Relatively little is known about A2AR development. We initially examined the ontogeny of total A2AR in CNS using quantitative autoradiography. Sections from rat brain from 0, 5, 10, 15, 21 and 28 day old pups and from adults were labeled with 5 nM [<sup>3</sup>H]RX821002, which has near equal affinity for all A2AR subtypes. Buffer was 50 mM sodium phosphate, pH 7.4, room temperature, and blanks contained 100 µM norepinephrine (NE). Sections were exposed to tritium sensitive film for 4-8 weeks. In many brain regions with the most dense labeling, receptor levels were relatively high at birth, ranging from 50-85% of adult levels, indicating a high level of prenatal development. These include the amygdaloid region, olfactory tubercles, striatum, lateral dorsal nucleus of the thalamus and frontal cortex I-III. By contrast receptor number in cerebellum was very high at birth and decreased to 10-20% of neonatal levels by adulthood. Thus there are major differences in receptor development from region to region. We also noted specific labeling of the corpus callosum and anterior commissure in the early postnatal period. This was seen with two radioligands and was inhibited by NE, suggesting specific labeling. This disappeared by adulthood. Development of A2AR in CNS displays several interesting and surprising features, suggesting dynamic involvement in many developmental processes. (Supported by the Ittner Foundation)

## 220.20

DIFFERENTIAL EXPRESSION OF THE α SUBUNIT OF SOLUBLE GUANYLYL CYCLASE IN THE DEVELOPING RAT BRAIN. R. Smigrodzki and P. Levitt\*. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, 675 Hoes Lane, Piscataway, NJ 08854.

In situ hybridization and DNA sequencing have been used to characterize a clone identified during a differential-display screen of the developing rat forebrain. Initial sequencing results indicate that the clone codes for an α subunit of the soluble guanylyl cyclase (sGCY). Its pattern of expression at embryonic days 15 and 18 in the rat forebrain resembles the α1 subunit in the adult, but is in stark contrast to the reported embryonic expression pattern of the β1 subunit. Strong expression is observed in the ganglionic eminence and striatum, developing medial habenula, olfactory tubercle and hippocampus. Somewhat weaker expression is present in the cerebral cortex and parts of thalamus. Broader expression is seen postnatally, but with very high levels in the same regions observed initially during embryonic development. The discrepancy between the expression of the α versus β subunits of sGCY indicates that the α subunit might perform a different function or associate with a different β subunit during development than in the adult animal. Supported by Fogarty Fellowship F05 TW05141-02 and NIMH grant MH45507.

## 220.21

THE SWEAT GLAND INNERVATION OF TH-/- MICE UNDERGOES A CHANGE IN PHENOTYPE. B. Habecker<sup>1</sup>, M. Rios<sup>2</sup>, D. Chikaraishi<sup>3</sup>, S. Roffler-Tarlov<sup>2</sup>, S. Landis<sup>1</sup>. <sup>1</sup> Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106, <sup>2</sup> Dept. of Neuroscience, Tufts Univ., Boston, MA 02111, <sup>3</sup> Dept. of Neurobiology, Duke Univ., Durham, NC 27710.

The sympathetic innervation of rodent sweat glands undergoes a target-induced switch from expression of norepinephrine (NE) to acetylcholine (ACh) and vasoactive intestinal peptide (VIP) during postnatal development. Analysis of footpad extracts from sympathectomized rats indicates that production of the differentiation activity that induces this switch requires sympathetic innervation. Co-culture of sweat gland cells with sympathetic neurons stimulates sweat gland factor production which is blocked by adrenergic antagonists. Treatment of gland cells with forskolin also results in factor production. These findings indicate that NE can stimulate factor expression but do not eliminate the possibility that other nerve-derived molecules which increase cAMP could do the same. To test whether NE is necessary to induce production of the differentiation activity *in vivo*, we analyzed the gland innervation of mice lacking tyrosine hydroxylase (TH), the rate limiting enzyme in NE synthesis. The TH-null mutation was created using homologous recombination in embryonic stem cells and it caused embryonic lethality. TH-null animals were rescued by treating pregnant heterozygous mice with dihydroxyphenylserine from E8.5 until birth. Sweat glands, which develop postnatally, were not exposed to NE. The gland innervation of 3 wk old TH-/- animals contained TH-immunoreactivity (IR), whereas TH-IR was not detected in null animals. The gland innervation of both TH +/- and -/- mice were IR for the vesicular ACh transporter, a cholinergic marker, and VIP. Thus, sweat glands in mice lacking NE release a factor that causes the gland innervation to change phenotype. These results suggest that whereas NE stimulates factor production *in vitro*, it is not essential *in vivo*, and additional nerve-derived molecule(s) contribute to stimulation of factor expression. DEVELOPMENTAL PLASTICITY OF EXCITATORY SYNAPSES ON LUMBOSACRAL PARASYMPATHETIC PREGANGLIONIC NEURONS. I. Araki<sup>\*</sup> and W.C. de Groat. Dept. Of Pharmacol., Univ. Of Pittsburgh, Pittsburgh, PA 15261 and Dept. Of Urology, Univ. Of Kyoto, Kyoto, Japan.

In neonatal animals, micturition is mediated by a segmental somato-parasympathetic (PSYM) reflex activated when the mother licks the perineum. At approximately 3 weeks of age, this reflex is replaced by a spinobulbospinal PSYM reflex as the principal mechanism of excretion. This study was undertaken to examine the developmental changes in synaptic transmission between interneurons (INT) and PSYM preganglionic neurons (PGN) during the first three postnatal weeks in rats. PGNs in the L6-S1 spinal cord were identified by retrograde labeling with fluorescent dyes injected i.p. prior to the experiment. Whole cell patch clamp recordings were obtained from labeled PGNs in 120  $\mu$ m spinal slices. Unitary synaptic currents were elicited in PGN at short latency (2 ms) by stimulating non-labeled single INT dorsal to PGN. The mean peak amplitude of glutamatergic EPSCs recorded at -60 mV was not different during the first and second postnatal weeks (39.5, n=14 and 37.4 pA, n=15, respectively), but was markedly reduced at three weeks of age (19.3 pA, n=14). When the spinal cord was transected at the T-10 segment on postnatal day 14, the reduction of EPSC magnitude did not occur at three weeks of age (38.2 pA, n=15). A quantal analysis showed that this developmental change in synaptic efficacy results from a reduction in the number of quanta released by single INT. The mean quantal size measured at -60 mV was 10.3 pA (n=14) at one to two weeks of age. A similar value was obtained in preparations from three week old rats with an intact or a transected spinal cord (10.1, n=11 or 10.4 pA, n=11, respectively). We conclude that this developmental synaptic modification is dependent upon the maturation of descending projections from the brain and may underlie the reorganization of excretory reflex pathways that occurs a few weeks after birth. Supported by NIH grant DK 49430.

## NEUROTRANSMITTER SYSTEMS AND CHANNELS: DEVELOPMENT OF EXCITATORY AND INHIBITORY RECEPTORS

## 221.1

INTRACELLULAR BLOCKADE OF GABA-A RECEPTORS AS A TOOL TO INVESTIGATE NEURONAL NETWORK ACTIVITY.

I. Khalilov<sup>1</sup>, R. Khazipov<sup>1</sup>, X. Leinekugel<sup>1</sup>, J. Feger<sup>2\*</sup> & Y. Ben-Ari<sup>1</sup>  
<sup>1</sup> INSERM Unite 29, 123, Bd de Port-Royal, Paris, 75674, France; <sup>2</sup> Lab. de Pharmacol., Faculté de Pharmacie, 4, av. de l'Observatoire, 75006 Paris, France

An approach to isolate GABA and glutamate receptors mediated currents in the cell under investigation is proposed to study the neuronal network activity. Complete blockade of GABA-A receptors mediated currents was obtained by dialysis of the neurons recorded in whole-cell mode by internal solution in which Cl<sup>-</sup> was substituted for F<sup>-</sup>, known to be impermeable through GABA-A channels, and Mg-ATP were omitted to induce rundown of GABA-A conductance. After 1-2 hours of such dialysis both GABA-A receptors mediated spontaneous synaptic currents and responses induced by GABA-A receptors agonist isoguvacine (10  $\mu$ M) were completely blocked. AMPA-EPSCs were not affected during dialysis, whereas NMDA-EPSCs were reduced by about 20%. Giant depolarizing potentials (GDPs) which are present in CA3 pyramidal cells of neonatal hippocampus and represent an example of the neuronal network activity were used as a model to assay this technique. GDPs have been shown previously as entirely GABA-A receptors mediated events. Dialysis by F<sup>-</sup> / Mg-ATP-free solution induced reduction of charge passing during GDPs and shift of the reversal potential from -46 to 2 mV. The dialysis-resistant component of GDPs was assumed as glutamate receptors mediated because of (i) about 0 mV reversal potential; (ii) outward rectification at potentials more negative than -20 mV, characteristic to NMDA receptors mediated responses; (iii) kinetics identity of individual events composing this component of GDP to glutamate-receptors mediated currents. It is concluded that in addition to GABA-A receptors synaptically activated glutamate receptors contribute to GDPs in CA3 pyramidal cells. ## 221.3

MORPHOLOGICAL DEVELOPMENT OF STRATA RADIATUM AND ORIENS INTERNEURONS IN THE RAT CA3 HIPPOCAMPAL REGION

J.L. Gaiarsa, V. Tseeb, X. Leinekugel, R. Khazipov, I. Khalilov, M. Esclapez, B. Berger<sup>\*</sup> and Y. Ben-Ari.  
INSERM U29, 123 Bd. de Port Royal, 75014 Paris, FRANCE

Although biochemical and electrophysiological studies support the idea that the GABAergic system is well developed in the neonatal brain, the extent of dendritic and axonal arborization of interneurons has not been examined in detail. In the present study, interneurons of the hippocampal CA3 region were labeled intracellularly using the whole-cell patch clamp recording technique in rat hippocampal slices between postnatal day 2 and 6. The soma of the biocytin-labeled interneurons were located in the strata oriens and radiatum. Most of the labeled interneurons displayed immature features including dendritic as well as somatic thin, elongated spines and axonal growth cones. In spite of these immature features, the dendritic tree of neonatal interneurons was well developed. The axonal arborization appeared to be widely spread, extending relatively long distances from the soma, covering the entire width of the stratum radiatum. Numerous axonal collaterals were found to project along or into the CA3 pyramidal layer, occasionally entering the stratum oriens. A few axon collaterals also entered the stratum radiatum of the CA1 region.

Several studies have reported that the axonal arborization of interneurons exhibit a high degree of regional targeting in adult hippocampus. In contrast, in neonates, axons are widely distributed and do not display any terminal specificity. These observations suggest that axonal arborizations of interneurons undergo remodeling as development progresses. Supported by INSERM

## 221.2

SYNCHRONOUS Ca<sup>2+</sup> OSCILLATIONS CONTROLLED BY THE SYNERGISTIC ACTIONS OF GABA<sub>A</sub> AND NMDA RECEPTORS IN THE NEONATAL RAT HIPPOCAMPUS.

X. Leinekugel, R. Khazipov, I. Medina, I. Khalilov, A. Represa<sup>\*</sup> & Y. Ben-Ari  
INSERM Unite 29, 123, Bd de Port-Royal, Paris, 75674, FRANCE

In the developing brain, GABA and glutamate have trophic actions via changes in Ca<sup>2+</sup> homeostasis. We used confocal microscopy and patch clamp whole cell recordings from hippocampal slices to study how GABA and glutamate affect Ca<sup>2+</sup> homeostasis during physiological patterns of activity. In the neonatal hippocampus, GABA and glutamate have synergistic actions (see abstract Ben-Ari et al.) which generate repetitive giant depolarizing potentials (GDPs) (see abstract Khazipov et al.). P<sub>2</sub> CA<sub>3</sub> pyramidal cells were loaded with the fluorescent dye Fluo-3-AM to monitor spontaneous changes in [Ca<sup>2+</sup>]<sub>i</sub> while an additional neuron was recorded in whole cell configuration to detect GDPs. The loaded neurons had spontaneous [Ca<sup>2+</sup>]<sub>i</sub> oscillations synchronized with GDPs. In another series of experiments, we studied the cellular location of the NMDA component of GDPs. We loaded neurons with the fluorescent dye Fluo-3 via a patch pipette and measured changes in [Ca<sup>2+</sup>]<sub>i</sub> during GDPs in voltage clamp mode. At a potential allowing for expression of NMDA component (-30mV), no Ca<sup>2+</sup> influx could be observed in the soma during GDPs. These results suggest that Ca<sup>2+</sup> influx through NMDA channels may be restricted to dendrites. This was confirmed in preliminary experiments with direct recordings from dendrites loaded with Fluo-3. We propose that the activation of GABA<sub>A</sub> receptors depolarizes different parts of the cell (soma and dendrites), activating voltage dependent Ca<sup>2+</sup> channels and allowing for expression of NMDA receptor mediated responses. This could be a major factor for the induction of the synaptic plasticity controlled by GABA and glutamate in the neonatal hippocampus (see abstract McLean et al.). Supported by INSERM and MRE.

## 221.4

SYNCHRONIZATION OF INTERNEURON NETWORK IN NEONATAL RAT HIPPOCAMPUS.

R. Khazipov<sup>1</sup>, I. Khalilov<sup>1</sup>, X. Leinekugel<sup>1</sup>, R. Miles<sup>2\*</sup> & Y. Ben-Ari<sup>1</sup>

<sup>1</sup>INSERM Unite 29, 123, Bd de Port-Royal, Paris, 75674, FRANCE

<sup>2</sup>INSERM Unite 261, Institut Pasteur, 25, rue du Dr Roux, 75015 Paris, FRANCE

In the neonatal hippocampus, physiological pattern of activity is characterized by GABA-receptors mediated giant depolarizing potentials (GDPs) (Ben-Ari et al., 1989). We found that GDPs result from the synchronous discharges of interneuron network. Dual patch-clamp recordings from pyramidal cells (PC) and stratum radiatum interneurons (IN) revealed that during GDP, INs fire burst of action potentials generated by interneuronal GDP (IN-GDP). IN-GDPs were mediated by GABA-A and glutamate receptors, since (i) reversal potential of IN-GDPs depended on intracellular Cl<sup>-</sup>; (ii) at reversal potential of GABA-PSCs, IN-GDPs were composed of events with kinetics identical to glutamate-EPSCs; (iii) remaining after intracellular blockade of GABA-A receptors component of IN-GDPs reversed near 0 mV and revealed slope of negative conductance at MP < -20 mV, characteristic to Mg-block of NMDA channels. Pharmacology of evoked IN-GDPs revealed that most of excitation of INs is determined by cooperation between GABA-A and NMDA receptors. Thus, synchronous activation of interneurons during GDP implies synaptic mechanisms and is determined by cooperation of activities of (i) excitatory GABAergic connections between interneurons and (ii) recurrent glutamatergic connections to interneurons from the pyramidal cells. This cooperation is largely based on the phenomenon of potentiation of NMDA receptors by depolarizing GABA, which attenuates voltage-dependent Mg<sup>2+</sup> block and permeates the activation of NMDA-channels in neonatal interneurons (see Ben-Ari et al.).

## 221.5

**SPONTANEOUS  $[Ca^{2+}]_i$  INCREASES MEDIATED BY GABA<sub>A</sub> RECEPTOR ACTIVATION IN NEONATAL CORTICAL NEURONS.** D.F. Owens\*, L.H. Boyce, M.B.E. Davis and A.R. Kriegstein. Dept. of Neurology, Columbia P&S, NY, NY 10032.

At early postnatal ages recordings from neocortical neurons demonstrated spontaneous postsynaptic currents (sPSCs) predominantly mediated by the activation of GABA<sub>A</sub> receptors. In recordings from P1-P4 slices, 72% of the cells had sPSCs. The sPSCs were not blocked by CNQX (10  $\mu$ M) or AP-5 (100  $\mu$ M), however, sPSCs were abolished with application of bicuculline methiodide (BMI, 10  $\mu$ M). Furthermore, in individual cells, the reversal potential for averaged sPSCs matched the reversal potential found for muscimol-induced current. TTX also eliminated the sPSCs, indicating that they were action potential dependent. Using laser confocal imaging of cortical slices loaded with the  $Ca^{2+}$  indicator, fluo-3AM, brief spontaneous  $[Ca^{2+}]_i$  increases were also observed at the same ages and were blocked by BMI and TTX. In experiments at P3 we found that 78% of the spontaneously active cells had  $[Ca^{2+}]_i$  fluctuations that were blocked by BMI and 100% of these cells showed  $[Ca^{2+}]_i$  increases in response to muscimol. Muscimol-induced increases were blocked by cadmium (500  $\mu$ M), a voltage-gated  $Ca^{2+}$  channel blocker. These results indicate that GABA<sub>A</sub> receptors can depolarize neonatal cortical neurons and activate  $Ca^{2+}$  entry, and that spontaneous GABA-mediated events (presumably synaptic activity) can lead to  $[Ca^{2+}]_i$  increases. GABA<sub>A</sub> receptor activation may therefore influence early neocortical development through the activation of  $Ca^{2+}$  dependent signal transduction pathways.

## 221.7

**DIFFERENTIAL CHANGING CO-EXPRESSION OF GABA<sub>A</sub> RECEPTOR SUBUNIT mRNAs AND PEPTIDES IN THE DEVELOPING RAT NEOCORTEX.** F.Lahjouji, W.Ma, A.Da Cunha\*,<sup>1</sup> W.Sieghart<sup>2</sup> and J.L.Barker Lab. Neurophysiology, NINDS; <sup>1</sup>Lab Cell Biology, NIMH, Bethesda, MD20892; <sup>2</sup>Dept. Biochemical Psychiatry, University Clinic for Psychiatry, Vienna, Austria.

The prenatal distribution of 8 GABA<sub>A</sub> receptor subunit transcripts and peptides ( $\alpha 1-4$ ,  $\beta 1$ ,  $\beta 3$ ,  $\gamma 1$  and  $\gamma 2$ ) was determined in the cortex with *in situ* hybridization and immunocytochemistry. Our results reveal a close but not complete parallelism between the expression of the GABA<sub>A</sub> receptor subunit mRNAs and their encoded proteins.  $\beta 1$  immunoreactivity was first detected at E12 in cell bodies. By E14,  $\beta 1$  processes emerged from the ventricular zone (vz) and extended perpendicular to the pial surface. These processes were also RC-1' or nestin'. At E15,  $\alpha 4$  and  $\gamma 1$  appeared, co-localizing with  $\beta 1$  in the vz until E19. At E20, this trio was also found together with all the other subunits in the cortical plate and subplate (see figure). The embryonic emergence and changing distributions of these subunits coincide with cellular proliferation, migration and differentiation, suggesting multiple roles of GABA throughout cortical development

## 221.9

**DIFFERENT INTRACELLULAR LOCALIZATION AND GABA RELEASE FROM NEUROBLASTOMA CELLS TRANSFECTED WITH GLUTAMIC ACID DECARBOXYLASE 65 AND 67 GENES.** H. Asada\*, Y. Kawamura, H. Kume, F.Y. Ji, K. Maruyama and K. Obata. Lab. of Neurochemistry, Natl. Inst. for Physiol. Sci., Okazaki 444, Japan.

$\gamma$ -Aminobutyric acid (GABA) is a major inhibitory neurotransmitter in the central nervous system. It is synthesized from glutamic acid by glutamic acid decarboxylase (GAD). GAD has two isoforms, GAD65 and GAD67, which are encoded by two independent genes. Recent investigations have suggested that GAD65 is enriched in axon terminals but GAD67 is distributed throughout GABAergic cells bodies. GAD65 is anchored to Golgi-complex and thus will be transported to axon terminals. On the other hand, GAD67 is not associated with membranous component by itself and will be transported through axon accompanied with GAD65. The different roles of GAD isoforms can be investigated by over expression of each gene in non-GABAergic neuronal cells. In the present study, we used stably transfected neuroblastoma cells with GAD65 or GAD67 cDNA in order to examine intracellular distribution of GADs and release of GABA into the medium. In GAD65-transfected cells, GAD was localized in the cell organelle and in the neurites to their terminals and GABA was released spontaneously and with high potassium stimulation. On the other hand, GAD was distributed diffusely in the cell bodies transfected with GAD67 gene. GABA was contained in a high amount but was not released extracellularly. These results suggest the hypothesis that GAD65 not GAD67 is contributed to GABA release from presynaptic nerve terminals.

## 221.6

**GABA<sub>ERGIC</sub> DEVELOPMENT IN THE EMBRYONIC CHICK TELENCEPHALON.** P. Lundgren\*, A. Sellström\* and M.-O. Mattsson\*, 1) Dept. of Cellular and Developmental Biology, Umeå University, S-90187 Umeå. 2) Natl. Defence Research Establishment, S-90182, Umeå, Sweden.

The GABA<sub>ERGIC</sub> phenotype is characterized by capacity to synthesize GABA (performed by glutamate decarboxylase, GAD), by the presence of the transmitter, and by mechanisms for release and re-uptake of GABA. The latter function is performed by activity of GABA-transporter proteins (GAT) located in the membrane. In order to establish the time-wise appearance of these characteristics, studies were done on material from the parahippocampal area of the developing chick embryo telencephalon.

GABA-immunoreactivity was found from embryonic day (E) 8 onwards. The expression was rapid, and to some degree transient, with a possible peak at E10/E11. mRNA for GAD65 as well as GAD67 was detected by means of *in situ* hybridization from E8. Early on, GAD67 mRNA was more prominent than GAD65 mRNA, with regard both to intensity and anatomical distribution. Immunostaining with 1440 antiserum (recognizing both GAD forms) revealed the same expression pattern as GAD67 mRNA. A homologue to the rat GAT-1 transporter was detected both on mRNA (Northern blots, *in situ* hybridization: from E8) and on protein (immunostaining: from E11) levels.

These data suggest that several GABA<sub>ERGIC</sub> traits appear more or less simultaneously during a critical period from E8. The transient "overexpression" of GABA-immunoreactivity by E10/E11 suggests additional roles for GABA besides the normal inhibitory transmitter action during embryogenesis.

Support: Natural Science Research Council, grant #B-AA/BU 10684-300 to M-OM.

## 221.8

**GABA<sub>A</sub> AND GABA<sub>B</sub> RECEPTOR ACTIVATION AFFECTS CHOLINERGIC NEURONS IN THE DEVELOPING RAT MEDIAL SEPTUM.** Y. Hong\*, I.E. Mazzoni and R.L. Kenigsberg, Centre de Recherche, Hôpital Ste-Justine, Montréal, Québec, Canada H3T 1C5

GABA does not appear to function as an inhibitory neurotransmitter in the immature central nervous system but may play important roles in various other aspects of brain development. The present study was thus designed to examine some of the effects of the activation or blockade of GABA receptors on cholinergic cell development in the basal forebrain. The medial septal area from fetal rat (embryonic day 17) brain was isolated and cells dissociated and cultured in serum-free chemically-defined media. We found that the addition of GABA to these cultures for short periods of time (40 hours) slightly, but significantly increased the activity of choline acetyltransferase (ChAT). When present in the culture for extended periods of time (7 days), GABA markedly decreased ChAT activity. In contrast, bicuculline and picrotoxin significantly increased ChAT. The aforementioned responses were found to be identical in mixed neuronal-glial as well as pure neuronal cultures. Furthermore, muscimol mimicked the effects of GABA while baclofen increased rather than decreased ChAT activity. Interestingly, although muscimol-induced decrease in ChAT was still maintained in pure neuronal cultures, the cholinergic cell response to baclofen was lost. These results provide evidence for a role for GABA in the developing medial septum where GABA, tonically released under normal physiological conditions, may function to facilitate the maturation of GABA<sub>A</sub> receptors on neurons. These preliminary data also suggest that GABA may promote the differentiation of basal forebrain cholinergic neurons, presumably via the activation of GABA<sub>B</sub> receptors on glial cells. (Supported by MRC of Canada)

## 221.10

**GLIAL CONDITIONED MEDIUM INDUCES CHANGES ON ENDOGENOUS AMINOACID NEUROTRANSMITTERS IN NEURAL PROGENITORS** A.S.Herranz\*, M.A.López-Toledano, C.Redondo, M.J.Casarejos, C.L. Paño and E.Bazán. Depto. Investigación, Hospital Ramón y Cajal, INSALUD. 28034-Madrid, SPAIN.

Neural stem cells obtained from embryonic and adult rodent brain can be used as a source of neurons, oligodendrocytes and astrocytes for neural transplantation. Glial cells express neurotrophic and neurite growth promoting factors, including peptide growth factors, extracellular matrix proteins, cell adhesion molecules and neurotransmitters. The expression of these molecules may exert influences on development, neurite extension and survival of specific types of neural cells. The aim of this work is to study the change of endogenous content of free amino acids neurotransmitters in neural progenitors cells in response to glial conditioned medium (GCM). Progenitor cells, obtained from E 15 rat embryo striatal eminence, were cultured in DMEM:F-12 (1:1) supplemented with glucose, N2 components and 20 ng/ml EGF for a minimum of 5 passages, and then plated on poly-L-ornithine coated dishes or coverslips. Glial conditioned medium (GCM) was prepared from mesencephalic glial cells cultured for 24 in serum free defined medium (EF12). After 3 days postplating DMEM:F-12 medium was removed, replaced by GCM and maintained for 7 days. The endogenous amino acids content was analyzed by HPLC (OPA-precolum derivatization and fluorimetric detection). Progenitors cells treated for 7 days with GCM show a significant increase in taurine, a moderate decrease in GABA, glutamine and serine and a decrease in isoleucine and leucine. No changes were found in aspartate and glutamate, as compared with controls. Since taurine is not provided in the culture medium, the increase of this amino acid might indicate that GCM promotes a selective differentiation of a specific type of cells with the biosynthetic machinery to produce taurine. Supported by FIS 93/555 and 94/0490.

## 221.11

**FUNCTIONAL NON-NMDA GLUTAMATE RECEPTORS ARE PRESENT IN THE PREPLATE NEOCORTICAL ANLAGE.** N. König<sup>2</sup>, M.J. Drian, N. Grimaud and M. Bardoul, EPHE Lab. Quantitative Cellular Neurobiology INSERM U336, University Montpellier II, 34095 Montpellier Cedex 5, France.

We have previously found cells bearing functional non-NMDA receptors permeable to divalent cations in the rat neural tube at very early stages of development (by embryonic day 11). These cells were located in the brainstem or the spinal cord. In the present study, we checked with two independent methods the presence of functional receptors in the neopallium at its earliest stage of organization: the preplate stage. First, we exposed slices of embryonic day 14 neopallium to AMPA/kainate receptor agonists and the desensitization blocker cyclothiazide in the presence of cobalt. After silver-intensification, a substantial number of labeled cells could be found in the lateral pallium. Most of these cells were located in a narrow layer above the matrix zone. Second, we dissociated tissue from the lateral and dorso-lateral day 14 neopallium, and analyzed (by dynamic Fluoro-3 imaging) the modulation of cytosolic calcium after agonist application with or without cyclothiazide. Even in cultures examined shortly after plating, we consistently found responses to AMPA and kainate. As expected, the responses to AMPA were in most cells greatly enhanced in the presence of cyclothiazide. Surprisingly, this was also the case, in some cells, for kainate: the response to this agonist alone was in some cases hardly detectable, whereas a strong calcium increase was observed in the presence of cyclothiazide. Sister-cultures were maintained in vitro for up to 8 days. In these cultures, application of receptor antagonists dramatically reduced the number of surviving neurons, depending upon the dose and the timing of the treatment. Our results demonstrate (1) that functional glutamate receptors in the neopallial anlage arise earlier than hitherto reported, and (2) that receptor blockade may profoundly modify the fate of early neocortical cells. ## 221.13

**XENOPUS GLUTAMIC ACID DECARBOXYLASE TRANSCRIPTS ARE DEVELOPMENTALLY UPREGULATED IN THE EMBRYONIC BRAIN AND SPINAL CORD REGION.** S. Watt and N.C. Spitzer\*, Department of Biology and Center for Molecular Genetics, UCSD, La Jolla CA 92093.

GABA is the neurotransmitter in dorsolateral ascending interneurons in the *Xenopus* spinal cord. The developmental expression of GABA is both transcription- and  $Ca^{2+}$ -dependent, raising the possibility that expression of transcripts encoding glutamic acid decarboxylase (GAD), the GABA-synthetic enzyme, may be  $Ca^{2+}$ -dependent. To examine this hypothesis further, we cloned a gene encoding *Xenopus* GAD. Using PCR with degenerate primers to conserved sequences, a 479 bp DNA fragment was generated for screening of a *Xenopus* tadpole brain cDNA library. Following the isolation of a 2420 bp partial clone, a 780 bp 5' region of the gene containing the initiation of translation was amplified by anchored RT-PCR from total RNA of the spinal cord region. The two clones overlap by 263 bp and produce a 3.2 kb clone. From a 100 aa residue sequence in the region of the putative pyridoxal phosphate binding site, 92 are identical with rat GAD67. Appearance of GAD transcripts during development was examined by RT-PCR of total RNA from blastula (E10), and from the dorsal region at neural plate (E13-14), neural fold (E15-16), neural tube (E20-22) and tailbud (E30-34) stages. Expression is first detected at stages 20-22 when spontaneous  $Ca^{2+}$  spikes are first observed and persists at stage 30-34. *In situ* hybridization shows that transcripts are expressed in the brain of stage 32-34 embryos and in the spinal cord; transcripts are not detected at earlier stages of development. The  $Ca^{2+}$ -dependence of expression of these *Xenopus* transcripts is being investigated. Supported by NIH NS15918.

## 221.15

**POSTNATAL MATURATION OF AMPA- AND NMDA-TYPE GLUTAMATE RECEPTORS IN MACAQUE MONKEY STRIATE CORTEX** V. Meskenaite<sup>1</sup>, H. Kennedy<sup>2</sup>, C. Dehay<sup>2</sup> and K.A.C. Martin<sup>1</sup>. <sup>1</sup>Institute of Neuroinformatics, Zuerich Univ/ETH, CH-8006, Switzerland; <sup>2</sup>Cerveau et Vision, INSERM U 371, 69500 Bron, France.

L-glutamate is a major excitatory neurotransmitter that is essential both in development and in many integrative functions of the cerebral cortex. The transmitter actions of glutamate are mediated by different types of receptors. We used subunit specific antibodies to investigate the glutamate receptor localization in V1 in postnatal development.

In neonates (6-21 days), both AMPA (GluR1, GluR2/3) and NMDA (R2A, R2B) receptor-immunoreactivity (IR) were densely present within thalamorecipient layers 4C and 6. In layer 3, only GluR2/3-IR postsynaptic profiles were dense in the cytochrome oxidase blobs.

By 5-6 months postnatal, the laminar densities of labelled synapses changed dramatically, mainly, due to an increase in pyramidal cell layers. In 5-6 month old monkeys, AMPA R-IR was strongest in layers 4B and 5, and denser than the neonate in layers 1-3. NMDAR2B-IR was elevated in superficial layers. NMDAR2A-IR showed a reversed laminar profile when compared to the neonate: all layers showed strong labelling, except thalamorecipient layers 4A and 4C.

Comparison of 5-6 months postnatal animals with adults showed that in general glutamate receptors matured last in layers 5 and 1-3. The increase in the NMDA receptor subunits in the superficial layers may account for the synaptic plasticity seen outside layer 4 in adults.

**DEVELOPMENT OF EXCITATION AND INHIBITION IN THE RAT SUPERIOR COLLICULUS.** J. Shi and M. Constantine-Paton\*, Department of Biology, Yale Univ. New Haven, Ct. 06520

We are studying the cellular and molecular mechanisms through which activity mediates central nervous system synaptogenesis using the visual layers of the rat superior colliculus. In these layers, AMPA and NMDA receptor subunits show a major upregulation between postnatal day (P)6 and P12 (Hofer et al. 1994, J. Neurochem. 62:2300). Retinocollicular map refinement is complete by P12 (Simon & O'Leary, 1992, J. Neurosci. 12:1212-1232) and eyes open at P14. Whole cell patch clamping in SC slices was conducted between P8 and P20 to investigate associated alterations in synaptic function.

Electrically evoked EPSCs were recorded in SC neurons as early as P8 but these decremented rapidly with successive activation. By contrast, TTX sensitive sEPSCs were robust in this early neuropil. sEPSCs from individual neurons held at their resting potential in magnesium free saline were averaged before and after the slice was bathed in 50uM AP5. All averages sEPSCs had rise times <6msec and amplitudes at least three times greater than baseline. The difference in fall time between averages with and without AP5 was taken as an estimate of the NMDA receptor contribution to these spontaneous currents. The data indicate a high NMDA receptor contribution to these events between P8 and P10 with a large and rapid drop at P11. This is followed by a much slower decrement in the NMDA contribution through P20. We also observed an abrupt decrease in the average frequency of these sEPSCs between P17 and P19. This change appears to be due to the onset of GABA<sub>A</sub> receptor mediated inhibition. Bath application of bicuculline has little effect on the frequency of sEPSCs in the second postnatal week. After P17 bicuculline application significantly increases sEPSC frequency. Thus these data suggest that pronounced changes in excitatory transmission in the superficial SC occur prior to eye-opening and in close association with the refinement of the retinocollicular map. Synaptic inhibition develops later during a period where it could be influenced by pattern vision. Supported by NS32290 to MCP.

## 221.14

**CO-LOCALIZATION OF NON-NMDA AND NMDA RECEPTORS AT EXCITATORY SYNAPSES ON EMBRYONIC XENOPUS SPINAL NEURONS.** J. Rohrbough, E. Gleason\* and N.C. Spitzer, Biology Dept., UCSD, La Jolla, CA.

Non-NMDA and NMDA receptors are co-localized at excitatory synapses in mammalian hippocampal (Bekkers & Stevens, 1989) as well as spinal neurons (Hori & Endo, 1992). The proximity of both receptors at individual synapses has important implications for synaptic plasticity. *Xenopus* spinal dorsolateral interneurons (DLIs) receive excitatory input from primary sensory neurons (Sillar & Roberts, 1988, 1991). We made whole cell recordings of miniature excitatory postsynaptic currents (meps) in DLIs to investigate the participation of non-NMDA and NMDA receptors at these synapses. At -70 mV in  $Mg^{++}$ -free solution containing TTX, strychnine, and bicuculline, 3 types of meps are present in most recordings from 4-8 d larvae (stages 42-48). ~70% are dual component meps, with a fast initial component followed by a variable slow decay in which single channel currents of 4-5 pA are occasionally resolvable; ~20% are fast, lacking a slow component; and a few (5-10%) are slow. Fast meps and the fast component of dual meps have rise times and decay time constants of about 400  $\mu$ s and 1 ms, respectively, and are abolished by the selective AMPA receptor antagonist GYKI-53655 (25  $\mu$ M), indicating they are mediated exclusively by AMPA-type non-NMDA receptors. Slow meps, the slow component of dual meps, and the background single channel noise are blocked by 1 mM  $Mg^{++}$  or 100  $\mu$ M APV, indicating they are mediated by NMDA receptors. In 1 mM  $Mg^{++}$ , the NMDA receptor component is increasingly revealed at more positive holding potentials. These results indicate that both NMDA and AMPA receptors are co-localized at the majority of excitatory synapses on DLIs at these developmental stages. These connections are presumed to be present by 30 hr (stage 26), when embryos first are motile in response to touch stimuli. In recordings from stage 27-38 embryos and larvae, all three types of meps are present though they occur with greater variability. However, ~50% are dual, ~50% are fast, and ~5% are slow, suggesting that AMPA receptor expression may precede that of NMDA receptors during development of excitatory synapses in the spinal cord. Supported by NS09603 (JR) and NS15918 (EG, NCS).

**MOLECULAR ANALYSIS OF GLUTAMATE DECARBOXYLASE EXPRESSION IN THE EMBRYONIC CHICK BRAIN.** E. Wäghberg, A.-K. Åhman and M.-O. Mattsson\*, Dept. of Cellular and Developmental Biology, Umeå University, S-90187 Umeå, Sweden.

The aim of the present study was to investigate the expression of glutamate decarboxylases (GAD) in the developing chick embryo telencephalon, and how these correspond to GAD65 and GAD67 in mammals.

GAD enzyme activity is present as early as by embryonic day 3 (E3). However, Northern blot analysis as well as immunoblots can detect GAD mRNAs and proteins from E8. Expression levels are probably very low prior to this developmental stage. Thus, RT-PCR analysis of GAD65 expression revealed a fragment (216 bp; 83% identical to known mammalian sequences) which showed that the GAD65 mRNA is found by E4. The transcript sizes in the chick are 3.9 kb (GAD65) and 5.6 kb (GAD67) respectively, differing in size from the ones reported in mammals.

Immunoblotting confirmed the presence of proteins corresponding in size to the mammalian GAD forms. The expression patterns of these proteins suggest that GAD67 may predominate during early development, whereas the levels of GAD65 are higher during late embryogenesis as well as in the adult brain. Presently we are sequencing cDNA clones (ZAP-II library from chicken E11 telencephalon) corresponding to both GAD isozymes. Our data will be instrumental in elucidating the functional roles for each GAD during development of the nervous system.

A PROTEIN INVOLVED IN INHIBITION IS REGULATED BY NMDA RECEPTOR ACTIVATION IN VIVO. S.M. Aamodt\* and M. Constantine-Paton. Biology Department, Yale University, New Haven, CT 06520.

The topographic visual map in the rat superior colliculus develops postnatally by the elimination of incorrectly positioned retinal ganglion cell arbors. Chronic local blockade of N-methyl-D-aspartate (NMDA) receptors from birth prevents this process. We have proposed that the highly correlated activity associated with map refinement might close the sensitive period by replacing a juvenile subtype of the NMDA receptor with an adult subtype that is less permissive of synaptic plasticity. This hypothesis predicts that chronic receptor activation with the agonist NMDA begun at postnatal day (P)8 should cause premature expression of the adult NMDA receptor subunit pattern. However, previous experiments indicated that this treatment paradoxically increases NR2B subunit mRNA, normally low in mature animals.

One possible explanation for this unexpected finding might be that chronic NMDA receptor activation induces compensatory changes in inhibitory circuitry, causing an overall decrease in activity levels. Therefore, quantitative western blotting was used to evaluate the effects of NMDA receptor activation or blockade on glutamate decarboxylase (GAD) protein, the synthetic enzyme for the major inhibitory transmitter gamma-aminobutyric acid (GABA). In untreated animals, GAD protein levels were undetectable at P0 and P6, increased steadily from P12 to P27, and then declined somewhat to an adult level comparable to that of P19. After chronic treatment from P8 with NMDA, GAD levels at P19 were elevated to  $141 \pm 17\%$  (S.E.) of untreated sibling control GAD protein. That value was significantly different from GAD levels in siblings treated with the NMDA receptor antagonist 2-amino-5-phosphonovaleate (D-APV;  $53 \pm 6\%$  of normal,  $p < .01$  vs. NMDA) or with its inactive isomer L-APV ( $69 \pm 9\%$  of normal,  $p < .02$  vs. NMDA, ns vs. D-APV). These findings suggest that chronic NMDA treatment either induces premature development of inhibitory circuitry or increases overall inhibition levels in the superior colliculus. In either case, the activity-dependent development of inhibitory connections might help close the normal sensitive period for synaptic refinement. CHARACTERIZATION OF LAN-1 CELL-LINE AS A MODEL OF DEVELOPMENTAL DOPAMINE-SEROTONIN INTERACTION. A. Zuddas\*, V. Lilliu, C. Mancosu, C. Cianchetti, Child Neurology and Psychiatry, Dept. Neurosciences, University of Cagliari, Cagliari, Italy.

LAN-1 is a human neuroblastoma cell-line expressing tyrosine hydroxylase (TH), muscarinic M1 and M3 receptors, veratridine-sensitive sodium channels and lacking voltage-sensitive calcium channel. We have shown that LAN-1 is an heterogeneous cell-line with about 10% TH-positive cells; LAN-1 express the cellular machinery for the high affinity dopamine uptake, they are able to synthesize serotonin but not dopamine. Dopamine synthesis could be activated by the presence of high concentrations of tetrahydrobiopterine (THB 10 mM), which also decrease the 5HIAA levels in these cells (Zuddas et al. *Soc. Neuroscience* 21: 1780, 1995). Aim of this study was to further characterize the dopaminergic phenotype of this cell-line. In LAN-1, the high affinity [3H]DA uptake was not modified by the presence of THB: it was partially inhibited by 1  $\mu$ M desipramine (87%), chlorimipramine (71%) or benztropine (68%). The presence in the culture medium of Retinoic acid (RA, 10  $\mu$ M final concentration), a differentiation factor for LAN-1, did not modified DA uptake nor THB-induced dopamine synthesis. No veratridine- nor carbachol-induced [3H]DA release were observed in the different experimental conditions (THB, RA), indicating that LAN-1 cell-line could express both serotonergic and monoaminergic phenotypes but it is only partially differentiated. To verify specificity, THB was also added to the culture medium of two other serotonin- but not dopamine-synthesizing cell-lines: TB, derived from human neuroblastoma, and Mes-c-myc, generated from E 11 mouse mesencephalic primary culture by infecting with a replication defective retrovirus. In both TB and Mes-c-myc, THB did not induced DA synthesis nor modified serotonin turnover. In both these cell-lines, no high affinity [3H]DA was detected with or without THB in the culture medium. Taken together these data indicate that THB-LAN-1 cellular model could be an useful and specific tool for studying dopamine-serotonin interaction during early CNS development.

## 221.21

SPONTANEOUS DOPAMINE RELEASE IN ORGANOTYPIC SLICE CULTURE OF VENTRAL MESENCEPHALON MEASURED IN REAL-TIME. S. J. Cragg\*, C. Holmes, C. R. Hawkey and S. A. Greenfield. University Department of Pharmacology, Oxford, OX1 3QT, UK.

Spontaneous, synchronised neuronal activity is believed to play a part in the formation and refining of connections in the developing nervous system. Using fast-scan cyclic voltammetry (4Hz) at carbon-fibre microelectrodes, we have shown spontaneous pulses of release of dopamine (DA) from developing neurons within organotypic slice cultures of the ventral mesencephalon (VM). VM cultures containing dopaminergic cells of the ventral tegmental area and substantia nigra, were prepared from two-day-old Wistar rats and incubated (roller tube technique) for 20 to 30 days *in vitro*.

Site-specific patterns of pulses of DA efflux were observed, either phasic or more regular, and the inter-pulse intervals ranged from 2 to 122 secs (mean  $\pm$  S.E.M.  $20.8 \pm 2.7$  s), while the concentration of pulses of DA efflux ( $[DA]_0$ ) ranged up to 2.05  $\mu$ M ( $0.48 \pm 0.02$   $\mu$ M).  $[DA]_0$  was proportional to the preceding inter-pulse interval, whereas it was unrelated to the subsequent interval. A single spontaneous release spike could be mimicked in duration and concentration by a single electrical pulse (0.1ms, 18V) applied locally, suggesting synchronisation of release from local release sites during a spontaneous release pulse. Both spontaneous and evoked efflux were strongly  $Ca^{2+}$ -dependent and TTX-sensitive to varying degrees. Spontaneous DA efflux was inhibited by glutamate antagonists, partially by NMDA-receptor antagonism (10-30  $\mu$ M L-APV) and completely by AMPA-receptor antagonism (25  $\mu$ M CNQX); however release was unaffected by metabotropic-receptor modulation (1mM L-APV). In conclusion, spontaneous oscillations of  $[DA]_0$  occur from developing dopaminergic neurons in organotypic slice culture of ventral mesencephalon, but may be extrinsically modulated by ionotropic glutamate receptors. SJC is the 1995 Goodger Scholar and CH holds an MRC studentship.

## 221.18

AMPHETAMINE INDUCED DOPAMINE OVERFLOW IS GREATER IN NEONATAL THAN IN ADULT RATS.

Q. Contreras\* and L. Hernández, Laboratory of Behavioral Physiology, School of Medicine, Universidad de Los Andes, Mérida 5101-A, Venezuela.

The effect of amphetamine on strial dopamine overflow was tested in neonatal and adult anesthetized rats. Ten (5 days old) rats were anesthetized with ether and a microdialysis probe was stereotactically lowered in the striatum. DA, DOPAC and HVA were monitored following a one mg/Kg amphetamine i.p. measured by high pressure liquid chromatography with electrochemical detection (HPLC-ED). The same procedure was repeated with ten adult rats. Dopamine increased ten folds in the neonatal rats whereas it increased only two folds in the adult rats. This results suggest that dopaminergic neurons are not under feed-back inhibition in neonatal rats. They also might be relevant to interpret the paradoxical effects of amphetamine observed in hyperactive children.

## 221.20

DIFFERENT CRITICAL PERIODS FOR AFFECTING D1 AND D2 RECEPTOR EXPRESSION DURING DEVELOPMENT. W.S. Thomas\*<sup>1</sup>, B.S. Neal-Beliveau<sup>2</sup> and J.N. Joyce<sup>1</sup>, Parkinson's Center, Sun Health Research Institute<sup>1</sup>, Sun City, AZ 85372; Dept. of Psychology, Indiana Univ. Purdue Univ. Indianapolis<sup>2</sup>, Indianapolis, IN 46202.

We have previously demonstrated that neonatal lesions of the dopamine (DA) system have different behavioral and neurochemical effects than lesions administered in the adult. P0/P1 lesions result in loss of D1 binding sites, as well as oral dyskinesias in response to the D1 receptor agonist SKF38393. In contrast, D2 binding is unaffected after 6-OHDA administration. Adult 6-OHDA lesions result in no change or a small decrease in D1 receptor number. However, D2 binding sites increase in number and Parkinson-like behavioral changes occur with lesions in the adult.

To determine when D1 and D2 receptors are vulnerable to lesions of the DA system, we lesioned the neostriatum at P0/P1, P7, P15 or P20 and examined DA receptor numbers at P90 with quantitative autoradiography. Using [<sup>3</sup>H]mazinolol to verify the presence of a lesion, we then quantitated D1 binding sites using [<sup>3</sup>H]SCH23390 and D2 sites using [<sup>3</sup>H]spiroperidol. Our results demonstrate a significant reduction in D2 sites in the caudal corpus striatum following lesion at P7. Preliminary results indicate that D1 binding sites increase in number with lesions at P7. The results indicate that there are different critical periods for affecting expression of D1 and D2 receptors. On the basis of our findings to date, we hypothesize that the critical period for D1 receptors occurs earlier in development than that for D2 receptors. Supported by MH51413 (B.S.N.) and MH48813 (J.N.J.).

MEMBRANES FROM THE INTERMEDIATE LOBE OF THE HYPOPHYSIS ENHANCE HYPOTHALAMIC DOPAMINERGIC DIFFERENTIATION IN PRIMARY CULTURE. J. Niquet<sup>1</sup>, A. Faivre-Bauman<sup>2</sup>, C. Loude<sup>3</sup>, R. Ubieta<sup>3</sup>, C. Kordon<sup>3</sup> and J.L. Charli<sup>1\*</sup>. <sup>1</sup>Instituto de Biotecnología, UNAM, Cuernavaca, Mor., Mexico; <sup>2</sup>Centre Paul Broca, INSERM U159, Paris, France and <sup>3</sup>Centro de Ingeniería Genética, La Habana, Cuba.

Coculture of foetal rat hypothalamic cells with adult cells of the intermediate lobe of rat hypophysis (ILH), a target of dopamine (DA) neurons, specifically accelerate both morphological and biochemical dopaminergic differentiation (*Mol. Cell. Neurosci.* 4, 55, 1993). Since soluble components secreted by ILH cells could only partially mimic the effect of intact cells, we determined whether contact of ILH cells with hypothalamic cells contribute to DA differentiation. Crude membranes from  $0.6 \times 10^6$  ILH cells added just after seeding  $6 \times 10^4$  hypothalamic cells (F17) per cm<sup>2</sup> in serum free medium enhanced tyrosine hydroxylase (TH) levels 3 fold at 3-6 days *in vitro* (DIV). The result was preserved with 1M NaCl washed membranes but not if adenohipophyseal membranes were used. Addition of membranes and conditioned medium, both from  $0.6 \times 10^6$  ILH cells, produced an effect similar to that due to coculture with the same number of ILH cells (5 fold). At DIV 6, membrane treatment stimulated total DA neuritic length as efficiently as coculture. The level of neuron specific enolase was not modified. These results suggest that ILH membranes contain a factor which enhances hypothalamic dopaminergic differentiation *in vitro*. Partially supported by grants from EU (CI1\*-CT93-0301) and DGAPA-UNAM (IN205993).

## 222.1

REGULATION OF BDNF AND CNTF AND THEIR SIGNAL TRANSDUCTION PATHWAYS IN THE ADULT RAT HIPPOCAMPUS AFTER EXCITOTOXIC LESION. J.S. Rudge\*, E.M. Pasnikowski, P.E. Mather, N. Cai, R.M. Lindsay, S.J. Wiegand, Regeneron Pharmaceuticals Inc. 777 Old Saw Mill River Road, Tarrytown, New York, 10591

Systemic injection of the excitotoxin kainic acid (KA) results in a well-defined loss of CA1 and CA3 pyramidal neurons in the adult rat hippocampus. We are interested in understanding how the neurotrophic factors - Brain-derived Neurotrophic Factor (BDNF) and Ciliary Neurotrophic Factor (CNTF) are regulated in the hippocampus after KA injection and how their expression impacts upon the evolution of the lesion. Thus, we have used specific antibodies to BDNF (generously provided by Dr. Qiao Yan, Amgen) and CNTF (Regeneron RG0036) in conjunction with Northern blot analysis to follow expression of these factors as the lesion evolves. BDNF-like immunoreactivity is markedly increased in the perikarya of CA1 pyramidal neurons within 6 hours of KA. By 24 hrs staining is also present in stratum oriens and radiatum, where BDNF-lir is transiently apparent on astrocytes. In contrast, increased CNTF immunostaining is not apparent until 3 days after KA and appears to be exclusively restricted to reactive astrocytes. This expression is sustained for up to 1 month after the lesion. Despite the clear, and, in the case of BDNF, rapid increase in trophic factor levels in the hippocampus, the pyramidal neurons subsequently die. To study whether increased expression of these factors initiates signal transduction following KA, we are in the process of quantitating the level of phosphorylation of the BDNF receptor TrkB and the  $\beta$  components of the CNTF receptor LIFR $\beta$ /gp130 by Western blot analysis.

## 222.3

INCREASED GDNF mRNA EXPRESSION FOLLOWING INTRASTRIATAL INFUSION OF QUINOLINIC ACID J.L. Bizon<sup>1</sup>, J.E. Springer<sup>2</sup>, and C.M. Gall<sup>1</sup>, Depts. of <sup>1</sup>Psychobiology, University of California, Irvine CA 92717 & <sup>2</sup>Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536

Glial cell line-derived neurotrophic factor (GDNF) is a dopaminergic survival factor which can be retrogradely transported from the striatum by mesencephalic neurons. GDNF mRNA levels in normal adult striatum are very low. The present study investigates the possible regulation of striatal GDNF by intense activation of the N-methyl-D-aspartate (NMDA) class of glutamate receptors. Quinolinic acid (QUIN), an endogenous NMDA agonist, was infused (1  $\mu$ L, 240 nM) into the right striatum of nine rats. Following sacrifice at 6, 10, or 20 hrs after QUIN administration (n=3 per time point), striatal sections were processed for GDNF mRNA localization using *in situ* hybridization. Dramatic increases in striatal GDNF mRNA were observed on the side of the lesion throughout the entire rostrocaudal extent of striatum, including portions several millimeters away from the lesioned site. Densitometric analyses demonstrated significant increases in striatal GDNF mRNA ipsilateral to the lesion at all time points examined ( $p < .002$  for 6 and 10 hr;  $p < .02$  for 20 hr). Significant differences were not found between time points indicating that comparable levels of GDNF expression persist for at least 20 hr after NMDA receptor activation. The majority of the GDNF labeling after QUIN infusion appears diffuse suggesting expression by glial cells and/or medium sized neurons, although some large, intensely labeled neurons were also observed. The current results indicate that striatal GDNF mRNA is increased by NMDA receptor activation. Moreover, these findings suggest that normal GDNF expression may be regulated by cortical glutamatergic afferents and that upregulation of this factor under conditions of excitotoxicity may afford protection to responsive neurons in the nigrostriatal system. (Supported by AG00538 and MH14599)

## 222.5

CORTICOSTEROID REGULATION OF BDNF, NT-3, TRKB AND TRKC mRNA EXPRESSION IN THE RAT HIPPOCAMPUS. M.J.M. Schaaf, R.W.M. Hoeltmans, E.R. de Kloet and E. Vreugdenhil\*, Leiden/Amsterdam Center for Drug Research, Division of Medical Pharmacology, Sylvius Laboratories, P.O. Box 9503, 2300 RA Leiden, The Netherlands

Chronic high plasma levels of corticosterone are known to decrease the neuronal cell viability in the hippocampus and may therefore be involved in several neurodegenerative disorders. In the hippocampus, corticosterone binds to two receptors: the low affinity glucocorticoid receptor (GR) and the high affinity mineralocorticoid receptor (MR). It is argued that simultaneous MR and GR occupation endangers neurons in the hippocampus, whereas occupation of MR is protective. This may be the result of a regulatory role of MR and GR in the expression of neurotrophic factors. In order to study this role, we administered a low, medium and high dose of corticosterone s.c. to adrenalectomized rats and measured the mRNA levels of BDNF, trkB, NT-3 and trkC six hours after corticosterone administration by *in situ* hybridization. Our results show that BDNF and trkB mRNA levels in CA3 and dentate gyrus are significantly lower after administration of a high dose of corticosterone compared to those after a low dose. Furthermore, trkB mRNA levels in these regions are two-fold higher in the low dose group compared to the vehicle treated. Levels of NT-3 and trkC do not show significant regulation by corticosterone in our study. Taken together, our results indicate that a high dose of corticosterone (and thus simultaneous MR and GR occupation) leads to a decrease in BDNF and trkB mRNA levels. This may be an explanation for the low neuronal viability in these areas at high plasma corticosterone levels.

## 222.2

CHANGES IN AP-1 COMPOSITION CORRESPOND WITH BIPHASIC PROFILE OF NGF mRNA EXPRESSION AFTER HILUS LESION-INDUCED SEIZURES. R.C. Elliott\* and C.M. Gall Dept. of Anatomy and Neurobiology, University of California, Irvine, 92717.

Nerve growth factor (NGF) expression is increased in many brain areas following seizures. Previous work has suggested that NGF transcription is regulated via an AP1 binding site in intron 1 of the NGF gene. To better define the relationship between AP-1 binding and activation of NGF transcription, the present study evaluated NGF mRNA levels, AP-1 binding, and AP-1 composition after hilus lesion (HL)-induced seizures in adult rats. *In situ* hybridization has shown that HL-seizures elicit a biphasic increase in the NGF mRNA content of dentate gyrus neurons (Lauterborn *et al.*, *Exp. Neurol.*, 1994). The present solution hybridization analysis replicated this finding, showing a 5-fold increase in NGF mRNA at 4 h post-HL, a return to control levels at 10 h, and a second increase to 2.5-times control levels at 24 h post-HL. Electrophoretic mobility shift assay (EMSA) experiments determined that AP1 binding is highly elevated at 4 h post-lesion, then declines progressively through 10 and 24 h, but remains higher than control levels at all timepoints. Supershift analyses indicated that JunD is the predominant Jun-family member in the AP-1 complex at 4 and 24 h, while JunB is predominant at 10 h. Thus, while total AP-1 binding does not correspond with the biphasic increase in NGF mRNA after HL-seizures, dynamic changes in AP-1 composition may underlie changes in the capacity of the bound AP-1 complex to activate NGF transcription. (Supported by NS26748)

## 222.4

ADRENAL HORMONES REPRESS SEIZURE ACTIVATION OF BDNF EXPRESSION AT SPECIFIC 5' PROMOTERS.

J.C. Lauterborn<sup>1</sup>, F.B. Poulsen<sup>1</sup>, P.J. Isackson<sup>2</sup>, and C.M. Gall<sup>1</sup>, <sup>1</sup>Dept. of Anatomy and Neurobiology, Univ. of Calif., Irvine CA 92717 & <sup>2</sup>Dept. of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville FL 32224.

Work from this laboratory has shown that adrenal hormones repress seizure-induced increases in brain-derived neurotrophic factor (BDNF) mRNA and that adrenalectomy selectively potentiates the expression of BDNF exons I & II mRNA after a single epileptiform afterdischarge. In the present study, the effect of adrenalectomy on recurrent seizure-induced increases in BDNF expression from the multiple 5' promoters was examined using the hilus lesion (HL) paradigm, *in situ* hybridization, and cRNA probes that distinguish transcripts containing BDNF exons I - IV. Previous work demonstrated that HL-seizures recur from 2-10 h post-lesion and that, in adrenalectomized HL rats, total BDNF mRNA peaks at 6-12 h and returns to control levels by 24 h post-lesion. In agreement with these findings, hybridization to BDNF exon I - IV mRNAs were at control levels in HL rats killed 24 h post-lesion. In contrast, in adrenalectomized (ADX) rats killed at 24 h post-HL, exon I mRNA levels were 2 to 3-fold greater than in ADX-controls within stratum granulosum ( $p < 0.05$ ), CA1 stratum pyramidale ( $p < 0.01$ ) and neocortical layers 2/3 ( $p < 0.05$ ). In HL/ADX rats, exon II mRNA was markedly elevated ( $> 7$ -fold;  $p < 0.01$ ) and exon III mRNA was slightly elevated (1.5-fold;  $p < 0.05$ ) in CA1 stratum pyramidale relative to levels in ADX-controls. Exon IV mRNA was at control levels in most fields but slightly reduced in superficial entorhinal cortex of HL/ADX versus ADX-control rats. These data demonstrate that adrenal hormones inhibit seizure activation of BDNF expression from specific 5' promoters and, thereby, differentially modulate activity-dependent BDNF expression across neuronal fields and cell types. (Supported by NS26748)

## 222.6

KAINIC ACID INCREASES THE EXPRESSION OF THE PROHORMONE CONVERTASES FURIN AND PC1 IN THE MOUSE HIPPOCAMPUS M. Marcinkiewicz\*, A. Meyer, P. Chrétien, G. Massicotte and M. Chrétien, Laboratory of Molecular Neuroendocrinology, Clinical Research Institute of Montreal, 110 Pine Avenue West, Montreal, Quebec, Canada H2W 1R7

Prohormone convertases (PCs) belong to the mammalian family of subtilisin/kexin-like enzymes which have been implicated in the posttranslational processing of precursor proteins. Several PCs are produced in the CNS and PNS, and only a few specific precursor-substrates have been identified *in vivo*. PCs may be involved in intracellular processing of precursors for neuropeptides, hormones and neurotrophic factors, including nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF). To study the interrelationships between the convertases furin, PC1 and PC2, and the neurotrophins NGF, BDNF and NT-3, we compared their mRNA distribution in different tissues. We also examined their expression in the hippocampus of mice undergoing kainic acid-induced seizures. In this experiment, *in situ* hybridization (ISH) demonstrated that the levels of mRNA for furin, PC1 and BDNF increased maximally at 3 hrs after kainic acid administration, followed by a decline to normal levels by 96 hrs. NGF showed small changes, while NT-3 was downregulated with minimal expression levels between 3 to 12 hrs. Double ISH with radioactively-labeled riboprobes and digoxigenin-labeled riboprobes demonstrated colocalization of furin with NGF and BDNF in the mouse submaxillary gland, and of furin and PC1 with BDNF in the trigeminal ganglion. Based on colocalization studies and evidence of coordinate expression with NGF and BDNF, we suggest the involvement of furin in processing of proNGF, and of both furin and PC1 in processing of proBDNF. Supported by the Medical Research Council of Canada (MT12686) to MM.

## 222.7

VIP AND PACAP STIMULATE BDNF EXPRESSION BY POTENTIATING THE EFFECT OF GLUTAMATE. J.-L. Martin\*, P.J. Magistretti and G. Pellegrini. Institut de Physiologie, Université de Lausanne, Switzerland.

The regulation of BDNF expression by VIP was analyzed by Northern blot in primary cultures of neurons and astrocytes originating from the mouse cerebral cortex. VIP stimulates in a concentration- and time-dependent manner BDNF expression both in cortical neurons and astrocytes although the induction is larger in neurons. The neuropeptide PACAP, which shares a high degree of sequence identity with VIP, also stimulates BDNF expression. Similarly to the potentiation by VIP and PACAP of glutamate-induced *c-fos* expression (Martin et al., J. Neurochem. 65, 1-9, 1995), the potentiating effect of both peptides is completely inhibited by the NMDA receptor antagonist MK-801, while MK-801 is ineffective in cortical astrocytes. These results indicate that, in cortical neurons, up-regulation of BDNF expression by VIP and PACAP is indirect, being mediated by low concentrations of endogenous glutamate (~1  $\mu$ M) acting on NMDA receptors. In this context, it is important to note that exogenously added glutamate (100  $\mu$ M) stimulates BDNF expression to a lower extent than VIP or PACAP. These and previous data (Martin et al., J. Neurochem. 65, 1-9, 1995) indicate that, by stimulating cAMP formation, VIP and PACAP increase the "throughput" or "strength" of glutamate-containing circuits in the cerebral cortex.

## 222.9

CHANGES IN CNTF RECEPTOR  $\alpha$  mRNA EXPRESSION FOLLOWING ENTORRHINAL CORTEX LESIONS. H.-D. Hofmann\*, M.-Y. Lee, M. Kirsch, M. Frotscher and T. Deller. Institute of Anatomy I, Freiburg, Germany.

Recently, ciliary neurotrophic factor (CNTF) has been implicated in reactive processes occurring after brain lesion. To further investigate the role of CNTF, we have studied the expression of CNTF receptor  $\alpha$  (CNTFR $\alpha$ ) in a well defined lesion model (unilateral lesions of the entorhinal cortex, EC). Expression of CNTFR $\alpha$  mRNA was determined in EC-lesioned and sham-operated adult rats after survival times of 4 hours, 3, 7, 10, 14 days, 4 weeks and 6 months by *in situ* hybridization using a digoxigenin-labeled RNA probe. In sham-operated, as in normal animals, CNTFR $\alpha$  expression was restricted to neurons (superficial layers of EC, granule cells of dentate gyrus, pyramidal cell layer of the hippocampus proper). At 4 hours postlesion a hybridization signal appeared in the tissue surrounding the lesion site in the EC. At three days postlesion, CNTFR $\alpha$  expression was observed in areas where degenerating terminals of entorhinal axons are located. The response was massive in the ipsilateral outer molecular layer (OML) of the dentate gyrus and less prominent in the contralateral OML and the lateral septum. After 10 days, CNTFR $\alpha$  expression had returned to control levels. The number of labeled cells and their distribution in the OML strongly suggested that receptor expression had been induced in astrocytes. In addition, beginning at 7 days postlesion, a significant reduction of the hybridization signal was observed in granule cells of the ipsilateral dentate gyrus as compared to the contralateral side. Our results demonstrate complex changes in CNTFR $\alpha$  expression at the site of lesion, in areas of terminal degeneration and sprouting, and in deafferented neurons. Thus, CNTF may be involved in the regulation of glial responses related to degenerative processes and may also contribute to sprouting phenomena and transsynaptic effects after neuronal deafferentation. ## 222.11

NEUROTROPHIN mRNA EXPRESSION IS ALTERED IN LOCUS COERULEUS FOLLOWING TRAUMATIC SPINAL CORD INJURY. X. Mu\*, J.E. Springer, K.H. Lundgren, and K.B. Seroogy. Department of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY, 40536-0084.

Traumatic injury to the spinal cord (SCI) results in damage to descending axons whose cell bodies are located in midbrain pontine nuclei. One such population of neurons are the noradrenergic cells of the locus coeruleus, which are thought to influence the control of certain spinal cord systems involved in locomotion. Recent studies have demonstrated that neurons in the locus coeruleus express the mRNAs for the neurotrophin BDNF and NT-3, as well as for their high affinity receptors, trkB and trkC, respectively. In addition, there is evidence that locus coeruleus neurons respond to the neurotrophic actions of some members of the neurotrophin family. In the present study, we used *in situ* hybridization histochemistry to examine the expression of BDNF, NT-3, trkB, and trkC mRNAs in the locus coeruleus at different times following traumatic injury to the spinal cord at level T10. Within 24 hours following SCI, the levels of NT-3 mRNA were significantly down-regulated at several levels of the locus coeruleus. Conversely, BDNF mRNA expression was found to be substantially upregulated in numerous locus coeruleus neurons at the same post-injury time point. Interestingly, the mRNA for trkB and trkC remain unchanged at the 24 hour time point compared to laminectomy control animals. These studies demonstrate that NT-3 and BDNF mRNA expression is dramatically altered in neurons whose axons, but not cell bodies, are directly damaged by traumatic SCI. The pattern of expression suggests that BDNF may function as a neurotrophic factor for neurons that are functionally compromised due to injury to their descending axons. Supported by a grant from the Kentucky Spinal Cord and Head Injury Trust (JES).

## 222.8

CHARACTERIZATION OF THE REGULATION OF DOPAMINERGIC TROPHIC FACTOR AND CYTOKINE GENE EXPRESSION ASSOCIATED WITH NEUROTOXIN-INDUCED PLASTICITY OF DOPAMINE NEURONS IN YOUNG AND AGING MICE. A. Ho\*, and M. Blum. Fishberg Res. Ctr. for Neurobiology. The Mount Sinai School of Medicine, New York, NY 10029.

It has been reported that young mice challenged with the neurotoxin MPTP, show a substantial recovery of striatal dopamine nerve terminals after one month whereas middle-aged mice do not. Also, exogenously applied bFGF and IL-1 $\beta$  can induce sprouting of dopamine neurons after a neurotoxin challenge. We have previously demonstrated that bFGF mRNA can be regulated by IL-1 $\beta$ , thus suggesting bFGF may mediate IL-1 $\beta$  induced dopaminergic sprouting. However, the regulation of dopaminergic trophic factor and cytokine gene expression in response to acute and long term neuronal injury remains to be elucidated in C57BL/6 mice, particularly in aging mice. Since it has been observed that there is an aging-associated decline in compensatory dopaminergic sprouting in response to neurotoxin-induced toxicity, possibly, the regulation of cytokine and trophic factor gene expression becomes altered with age.

In young mice treated with MPTP, we observed that aFGF mRNA in both dorsal and ventral striatum did not change within one week post-lesioned. In contrast, we observed that bFGF mRNA levels increased 2.7 fold in the dorsal striatum and increased a significant 1.4 fold in the ventral striatum within one week post-lesioned in young mice. In the middle-aged mice treated with MPTP, we observed that neither aFGF and bFGF mRNA levels in the dorsal striatum changed within two weeks post-lesion, thus suggesting there may be an aging-associated loss of the induction of trophic factor synthesis in response to neurotoxin-induced injury. Ongoing studies are investigating the long term effects of MPTP on FGF gene expression and whether endogenous cytokine expression in response to neurotoxin-induced injury becomes altered in aging mice. HEPARIN-BINDING EGF: MODULATION OF GENE EXPRESSION *IN VIVO* AND NEUROPROTECTIVE EFFECTS *IN VITRO* FOLLOWING KAINATE TREATMENT. L.A. Opanashuk\*, R.J. Mark<sup>1,2</sup>, M.P. Mattson<sup>1,2</sup> and K.B. Seroogy<sup>1</sup>. <sup>1</sup>Dept. of Anatomy & Neurobiology and <sup>2</sup>Sanders-Brown Ctr. on Aging, Univ. of Kentucky, Lexington, KY 40536.

We have recently identified mRNA for heparin-binding epidermal growth factor (HB-EGF), a newly described EGF receptor ligand, within several brain regions including neocortex, hippocampus, and piriform cortex. Because seizure activity has been associated with modulation of trophic factor expression in these regions, the present study addressed the possibility that HB-EGF mRNA is regulated in a similar manner. Adult rats received either a saline or 12 mg/kg i.p. injection of kainic acid and were monitored for convulsive behavior. Following various survival periods, brain tissue was processed for Northern blot or *in situ* hybridization analyses using cRNA probes for HB-EGF mRNA (cDNA kindly provided by J. Abraham, Scios Nova). An increase in hippocampal HB-EGF mRNA levels was detected at 3 hr and peak expression occurred at 12-24 hr following the injection of kainate. In dentate gyrus, hybridization was maximal in granule cells 3 hr following kainate administration with levels declining below control by 48 hr. Scattered HB-EGF mRNA-expressing somata were evident in the hilar region between 6 and 24 hr. Prominent hybridization was apparent in and around the pyramidal cell layers of CA1 and CA3 after 12 hr; however, by 24 hr labeling was restricted to surrounding cells. By 48 hr hybridization was sparsely distributed in the CA1 region. To determine whether HB-EGF may serve a neuroprotective role, hippocampal cultures were pretreated with 0-100 ng/ml HB-EGF and then challenged with 10 or 50  $\mu$ M kainic acid. Evaluation of neuronal survival indicated that HB-EGF significantly attenuated toxicity in response to kainate. Taken together, these findings indicate that HB-EGF expression is differentially regulated in response to kainate-induced seizure activity and suggest that this molecule is a trophic mediator for cells within hippocampus. Supported by NIH fellowship NS10007 (LAO) and UK Med. Ctr. (KBS).

## 222.12

IMMUNOLocalization OF FGF-2 IN THE RAT OLFACTORY BULB DURING DEVELOPMENT AND SUBSEQUENT TO OLFACTORY NERVE LESION. M. C. Miller, K. R. Hendricks, J. N. Kott\*, R. S. Morrison, M. E. Lee and L. E. Westrum. Dept. of Neurol. Surg., U. of WA, Seattle, WA 98195.

Basic fibroblast growth factor (FGF-2) is thought to play a role in brain development based upon its expression and the expression of its receptor in neural tissue. We are interested in the relationship of FGF-2 to the process of nervous system repair after injury. We have studied FGF-2 in the olfactory bulb (OB). This structure provides an ideal model in which to study the reinnervation process due to the unique regenerative capacity of the olfactory nerve (ON) throughout life. Initially, using immunohistochemistry, we examined the developmental localization of FGF-2 in the OB of embryonic day (E) 15, E19, postnatal day (PN) 1, PN5, PN28 and adult rats. Next, we determined if there were any changes in FGF-2 distribution in the adult OB subsequent to an ON lesion. Results showed that FGF-2 immunoreactivity: 1) was absent in the OB during early development; 2) became moderate in ON layer astrocytes and ensheathing cells at PN28 and 3) was strong in ensheathing cells of the ON layer along with astrocytes throughout the OB in adults. In response to injury, astrocytic immunoreactivity increased in intensity throughout the OB and neurons subjacent to the lesion site become moderately reactive. The increased FGF-2 immunoreactivity in astrocytes and its appearance in neurons supports the hypothesis that FGF-2 may have multiple functions in response to nervous system injury and may act via paracrine and autocrine mechanisms.

Supported by NIH grant NS09678 and UW-CHDD.

## 222.13

**CHANGES IN RETINAL bFGF EXPRESSION FOLLOWING CONTROLLED OPTIC NERVE CRUSH.** J. Weise\*, M.R. Kreutz, T.M. Böckers, C. Seidenbecher and B.A. Sabel. Inst. of Medical Psychology, Otto-v.-Guericke University, Magdeburg, Germany.

Basic Fibroblast Growth Factor (bFGF) is a potent member of the Fibroblast Growth Factor family which comprises nine rather different forms of FGF. Although present in many tissues, bFGF is of particular interest in the mammalian CNS because it acts as a mitogenic and neurotrophic factor on several neuronal populations. In addition, there is evidence that it exerts neuroprotective effects after ischemia and excitotoxicity both *in vitro* and *in vivo*.

In this study we examined the expression of bFGF in the rat retina in response to a controlled crush of the optic nerve (ONC). Changes in bFGF expression were assessed on both mRNA and protein levels at different time points after ONC. Up to 48 hours after ONC we observed a drop in hybridization signals below control levels in all retinal layers. A gradual increase of bFGF mRNA occurred at 72 hours to 1 week after ONC, especially in the inner nuclear layer. Signals were still elevated 4 weeks after optic nerve injury. Immunocytochemistry against bFGF revealed a staining pattern corresponding to the hybridization results. bFGF staining was generally decreased 12 and 48 hours after ONC. However, beginning at 1 week and peaking at 4 weeks after injury, an increase in immunoreactivity was observed, primarily in the inner nuclear layer. Staining for bFGF was still detectable above control levels even at 10 weeks after ONC. These results suggest that long term upregulation of bFGF in Müller glia and astrocytes provides an important trophic support that may be in part responsible for the survival of a substantial number of retinal ganglion cells after traumatic optic nerve injury. ## 222.15

**CHANGES IN NGF PROTEIN LEVELS IN YOUNG BUT NOT AGED RAT BRAIN AFTER TOTAL IMMUNOLESION.** J. Yu\* and J.R. Perez-Polo. Dept. HBC&G, Univ. TX Med. Br., Galveston, TX 77555-0652.

In the present study we compared the effects of cholinergic deafferentation of the hippocampus, neocortex, and olfactory bulb on nerve growth factor (NGF) level and choline acetyltransferase (ChAT) activity in these areas after intraventricular injection of immunotoxin, 192 IgG-saporin which previously has been shown to be able selectively destroy cholinergic neurons in the basal forebrain. We showed that after total immunolesion with 3.4 µg 192 IgG-saporin ChAT activity was dramatically decreased in the basal forebrain and its target areas in both young and aged rats. NGF protein levels were significantly increased in the hippocampus, cortex, and olfactory bulb of young rats (see also J Neurosci Res 43:213-223) whereas no such responses were observed in aged rats at both two weeks and one month postlesion times. In addition, no changes in NGF and BDNF mRNA levels were observed in the hippocampus and cortex in aged rats as have been shown in young ones (Brain Res 705:247-254). Basal forebrain NGF levels were increased in both young and aged rats. These results suggest that aged animals response to cholinergic differently in terms of neurotrophin homeostasis. This is publication 52A from USPHS P01-A610514 awarded by NIA.

## 222.17

**QUANTITATIVE AND QUALITATIVE ANALYSIS OF FGF-2 AND FGF RECEPTOR 1 mRNAs IN THE HYPOGLOSSAL MOTOR SYSTEM: REGULATION AFTER LESION.** K. Huber, C. Meisinger, T. Janet\*, C. Grothe. Institute of Anatomy, University of Freiburg, D-79104 Freiburg, Germany and University of Poitiers, F-86022 Poitiers, France (TJ).

In hypoglossal motor neurons, FGF-2 immunoreactivity (IR) shows a decrease 2 and 5 days after axotomy, after 11 days FGF-2 IR reappears. Iodinated FGF-2 is specifically retrogradely transported via high-affinity receptors (R) after injection into the tongue (Grothe & Unsicker, J. Neurosci. Res. 32, 1992; Grothe & Janet, J. Comp. Neurol. 353, 1995). To characterize physiological functions of FGF-2 in the motor system we have studied the expression and regulation of FGF-2 and FGFR1 mRNAs in the hypoglossal system 1-28 days after lesion using RNase protection assay and *in situ* hybridization.

The FGFR1 mRNA in the hypoglossal nucleus is confined to motoneurons. The level of the FGFR1 mRNA shows no significant alterations 1, 2, 6, 10, 11, 14, 21, and 28 days after axotomy. The FGFR1 transcript level in the tongue, however, is up-regulated between 11 and 14 days after axotomy.

The weakly expressed FGF-2 mRNA is localized to the motoneurons. 10 and 11 days after peripheral nerve transection the FGF-2 transcript level is significantly enhanced. The expression level in the tongue is not altered.

In the hypoglossal nerve, crush lesion results in a significant increase of both transcripts, in a similar time course as we had previously shown for the sciatic nerve.

Together with previously reported data on survival effects of exogenous FGF-2 on hypoglossal neurons *in vitro* and *in vivo* the results strongly support the idea that endogenous FGF-2 is involved during the regeneration events of motoneurons. (Supported by SFB 505/A/2)

## 222.14

**ELEVATED BDNF mRNA EXPRESSION IN RETINAL GANGLION CELLS FOLLOWING OPTIC NERVE INJURY.** H. Gao\*, X. Qiao, F. Hefti, J.G. Hollyfield, and B. Knusel. Andrus Gerontology Center, Univ. Southern California, CA; Div. Ophthalmology, Cleveland Clinic Foundation, Cleveland, OH

BDNF is the most abundant neurotrophic factor in the adult CNS. Recent studies have shown that exogenous BDNF promotes neuronal survival both *in vitro* and *in vivo* in neurodegenerative models. We have previously localized BDNF gene expression to retinal ganglion cells in the mouse. However, little is known about the function of endogenous BDNF in this location. To investigate whether BDNF may play a role in neuronal protection following ganglion cell trauma, BDNF expression was examined following optic nerve injury. The optic nerve in Sprague-Dawley rats was crushed intraorbitally posterior to the optic disc. For the controls, the optic nerve on the opposite side in each animal was similarly exposed but was not crushed. After intervals of 6 hrs to 6 weeks, eyes were processed for *in situ* hybridization using radio-labeled rat cRNA probes. In the normal rat retina, BDNF mRNA expression was present in a subpopulation of ganglion cells. Following the optic nerve crush, BDNF expression was significantly elevated in individual ganglion cells, and more ganglion cells demonstrated expression of BDNF than were observed in the controls, especially in the central retina. Elevated BDNF expression was first observed at 24 hrs, reached peak levels at 48 hrs, and declined to the basal level 2 weeks after crush injury. In control retinas without optic nerve crush, BDNF expression was localized to some ganglion cells, as was observed in normal eyes without surgery. These results indicate that the ganglion cells can up-regulate gene expression of BDNF in response to axonal injury and suggest that endogenous BDNF may contribute to a neuroprotective process following optic nerve injury.

This study was supported by research grants from NIA AG09793, AG10480, NINDS NS22933, Sankyo Co., Ltd, and National Parkinson Foundation.

## 222.16

**APPEARANCE OF FIBROBLAST GROWTH FACTOR (FGF)-9 IMMUNOREACTIVITY IN DAMAGED AXONS AND REACTIVE GLIAL CELLS IN RAT BRAIN FOLLOWING NEEDLE STAB INJURY.** N. Otsuka<sup>1,2</sup>, T. Todo<sup>2</sup>, S. Nakamura<sup>2</sup>, A. Aoyagi<sup>1,3</sup>, R. Machinami<sup>1</sup> and K. Ikeda<sup>2</sup>. <sup>1</sup>Dept. of Pathol., Fac. of Med., Univ. of Tokyo, <sup>2</sup>Dept. of Ultrastruct. and Histochem., Tokyo Inst. of Psychiat., <sup>3</sup>Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., Univ. of Tokyo, Japan.

FGF-9, originally isolated from a culture medium of a human glioma cell line as a growth-promoting factor for glial cells, is a newly identified member of FGF family. Recently, we found by immunohistochemistry that FGF-9 was present in neurons and astrocytes in human and rat brains. In this report, to see whether and how FGF-9 is induced in neural tissue by damage, we immunohistochemically examined brains of the rats, which had received cerebral needle stab injury, by using polyclonal antibodies raised against human recombinant FGF-9 or synthetic peptides of FGF-9 (87-102 and 193-208, respectively). In result, two types of FGF-9 immunoreactivity were observed adjacent to or around the needle tract area; the staining in axons and/or dystrophic axonal swelling and the staining of reactive glial cells. At 15h following needle insertion, immunoreactivity to FGF-9 was discernible in swollen axons adjacent to the lesion. This immunoreactivity became stronger by time. On the other hand, immunostaining of the glial cells first appeared 50h after the injury. The intensity of staining became gradually stronger by time. By morphological criteria, the immunoreactive cells were considered to be mainly astrocytes. The damage-mediated FGF-9 appearance in degenerating axons and reactive astrocytes may have implications in repairs of the brain.

## 222.18

**FURTHER EVIDENCE FOR AUTOCRINE TROPHIC SUPPORT OF RAT FACIAL MOTONEURONS BUT NOT RUBROSPINAL NEURONS AFTER AXOTOMY.** N.R. Kobayashi\*, K.C. Harrington and W. Tetzlaff. Depts. of Zoology and Surgery, University of British Columbia, Vancouver, B.C. V6T 1Z4

We have previously reported that axotomized rat facial motoneurons increase expression of BDNF and its receptor, trkB, after axotomy, suggesting that these neurons receive trophic support in an autocrine manner. We are currently investigating whether other trophic factors known to act on motoneurons play a similar role. Using RT-PCR, we found an increase in FGF-2 mRNA in microdissected facial nuclei as early as 8 hours after facial nerve transection, which reached levels around 4 fold by 24 hours and was sustained throughout the period of investigation (14 days). *In situ* hybridization (ISH) demonstrated that this increase was seen in all axotomized motoneurons. In contrast to facial motoneurons, axotomized rubrospinal neurons undergo severe atrophy, which can be prevented by BDNF application to the red nucleus. Thus, in this study, we have tested the hypothesis that axotomized rubrospinal neurons fail to increase BDNF and trkB expression. ISH results indicate that only a few (less than 5 %) rubrospinal neurons increased BDNF ISH signals 3 days after axotomy. Decreased trkB mRNA expression was observed 7 and 14 days after axotomy. FGF-2 mRNA ISH signal was not detected in axotomized or contralateral rubrospinal neurons. Preliminary RT-PCR amplifications corroborate these findings by revealing a decrease in both BDNF and FGF-2 mRNA levels. These observations further support the hypothesis that rat facial motoneurons provide their own trophic support after disconnection from their target by axotomy. In contrast, axotomized rubrospinal neurons appear to lack autocrine support.

## 222.19

BDNF UP-REGULATION IS LIMITED TO MYELINATING SCHWANN CELLS. H. Hyman Friedman, S.A. Singel, D.E. Playford\*, G.M. Bray, and A.J. Aguayo. The Montreal General Hospital Research Institute, 1650 Cedar Ave., Montreal, P.Q., H3G 1A4.

Transection of a rat sciatic nerve, which contains a mixture of myelinated and nonmyelinated fibers, leads to a forty-fold up-regulation of BDNF mRNA. This increase in expression begins within three days of transection, increasing gradually to reach its peak only after three weeks. To determine if all Schwann cells were potential sources of this neurotrophin, we measured the levels of BDNF mRNA in the largely unmyelinated (>95%) cervical sympathetic trunk (CST) of rats. Both one week after crush and two weeks after transection, the level of BDNF mRNA distal to the site of injury was less than one tenth (0.1% BDNF/GAPDH) the level in transected sciatic nerves (2% BDNF/GAPDH). These results support the hypothesis that contrary to what happens in myelinated fibers, Schwann cells in unmyelinated nerve fibers do not up-regulate BDNF expression after axonal interruption.

Relevant to this observation, we have found that demyelinating nerve fibers of Trembler mice have a deficit in the up-regulation of BDNF mRNA following axotomy. Together, these experiments suggest that up-regulation of this neurotrophic factor may be limited to Schwann cells that have differentiated towards a myelinating phenotype.

## 222.21

INDEPENDENT REGULATION OF IGF-II mRNA ISOTYPES IN MUSCLE DURING DEVELOPMENT AND DENERVATION. D.J. Marsh and D.N. Ishii\*, Dept. of Biochem. and Molec. Biol. and Dept. of Physiol., Colorado State Univ., Fort Collins, CO 80523.

Insulin-like growth factor II (IGF-II) gene expression in muscle has previously been shown to be closely correlated with synaptogenesis and nerve regeneration in rats. This 36 kb gene has three promoters (P1, P2, and P3) that regulate the alternative usage of leader exons E1, E2, and E3. Here, we determined which promoters are likely to be active during development and nerve regeneration by studying the expression of IGF-II mRNA isotypes using exonic probes. All isotypes were developmentally down-regulated between 5-day-old and adult rats, however, E2 isotypes followed a different time course. The E3 isotypes showed the greatest up-regulation following sciatic nerve transection in neonates or crush in adults. By contrast, E1 and E2 mRNAs were up-regulated in adults but not neonates. E3 mRNAs were by far the most abundant IGF-II transcripts in muscle during development as well as denervation. These results show independent isotype regulation, and suggest that the P3 promoter may play a dominant role in regulating IGF-II gene expression during development and nerve regeneration. (Supported by grant RO1 NS24327-08)

NEUROTROPHIC FACTORS: EXPRESSION AND  
REGULATION—PHYSIOLOGIC AND PATHOPHYSIOLOGIC MECHANISMS III

## 223.1

INTRACELLULAR SORTING AND SITES OF DEPOLARIZATION-EVOKED NEUROTROPHIN RELEASE FROM HIPPOCAMPAL NEURONS. I.M. Krivko, D.W. Ethell\*, J. Klose, R. Kolbeck and H. Thoenen. Dept. of Neurochem., MPI for Psychiatry, Am Klopferspitz 18A, 82152 Germany.

There is increasing evidence that neurotrophins (NTs) are not just target-derived trophic factors, but also act in specific aspects of neuronal plasticity. In order to understand the role neurotrophins play as mediators of neuronal plasticity we have employed confocal microscopy and transmission EM techniques to analyse intracellular sorting and sites of depolarisation-evoked NT6 release from CNS neurons. NT6 shares a common structure with other neurotrophins with the addition of a heparin-binding domain that causes the protein to stick to heparan proteoglycans on the neuronal surface. We modified NT6 to include a carboxy-terminal c-myc 9E10 epitope and transiently transfected E17 rat hippocampal neurons. Taking advantage of NT6's adherence to the cell surface, after release, we have been able to specifically localize the sites of activity dependent neurotrophin release from hippocampal neurons, using both anti-NT6 and anti-c-myc antibodies. NT6 release was found to be highly inducible by 50  $\mu$ M glutamate with a patchy surface distribution. Further analysis confirmed the specificity of such release preferentially at neurite contact areas (potential synapses) and dendrite growth cones. Newly translated NT6 was detected in membrane-confined, ER-like structures and sorting was followed through the Golgi apparatus to accumulation centers which directly corresponded with the sites of activity dependent neurotrophin release. Further, preliminary work with a c-myc BDNF construct has shown the same patchy intracellular distribution within hippocampal neurons.

I.M.Krivko was supported by a Max Planck Society post-doctoral fellowship; D.W.Ethell was supported by a HFSP long-term fellowship

## 222.20

DIFFERENTIAL REGULATION OF FGF-2 ISOFORMS IN SPINAL GANGLIA AND SCIATIC NERVE AFTER LESION. C. Grothe, K. Weweler\*, C. Meisinger. Institute of Anatomy, University of Freiburg, D-79104 Freiburg, Germany.

In order to clarify functional roles of the endogenous FGF-2 in the peripheral sensory system we have studied the expression and regulation of the FGF-2 molecular weight isoforms in spinal ganglia (L4-L6) and in the proximal and distal nerve stump of the adult rat after sciatic nerve crush and transection injury using quantitative Western blot analysis. The regulation of FGF-2 at the protein level was correlated with alterations of the FGF-2 mRNA as determined by RNase protection assay.

In untreated dorsal root ganglia (DRGs) and sciatic nerve the 18kD, 21kD, and 24kD FGF-2 isoforms are expressed. The 18kD isoform often appears as a doublet. Seven days after crush or axotomy of the peripheral nerve all three FGF-2 isoforms display a significant increase in DRGs. The 24kD isoform, however, shows the highest increase. Under both experimental conditions (crush, transection), the alterations of the expression level of the different FGF-2 isoforms are very similar. In the proximal and distal nerve stump, all three FGF-2 isoforms are enhanced 7 days after crush, the proximal stump displays a stronger expression compared to the distal stump. The 21kD isoform shows the highest increase. Seven days after nerve transection in the distal nerve stump FGF-2 is not detectable. In the proximal stump the 18kD and 21kD isoforms show an approximately 8-fold increase and the 24kD isoform a 2.5-fold increase. Different expression of FGF-2 in the distal nerve stumps under regenerating and degenerating conditions is also found at the mRNA level.

The differential response of FGF-2 isoforms in DRGs and sciatic nerve suggests distinct physiological functions, a local reaction at the lesion side where neurite growth occurs and a trophic reaction for de-/regenerating neurons. (SFB 505/A2)

## 223.2

DIFFERENTIAL REGULATION OF ADULT AND NEONATAL CORTICAL ASTROCYTE FUNCTION BY DEPOLARIZING SIGNALS. J. Lackland\*, H.Wu, I.B. Black, C.F. Dreyfus. Dept. Neurosci. & Cell Biol., UMDNJ/RWJMS, Piscataway, NJ 08854

To examine the regulation of astrocyte function in adult animals we have begun to grow Type 1 astrocytes from adult rat cerebral cortex for comparison with astrocytes from neonatal (P1) rats. Primary cultures of adult astrocytes were prepared (Schwartz et al, 1994) and grown for 4 weeks, at which time >98% of the cells were GFAP-positive. Cultures of P1 astrocytes were prepared (McCarthy & DeVellis, 1980) and grown for 3 weeks, with > 95% of the cells being GFAP-positive. No significant morphological differences were noted between the two culture types. In serum-free medium approximately 1/3 of the astrocytes were process-bearing while the majority were flat. Both types stained positively for GFAP, with the process-bearing cells staining more intensely. Previous work in our lab has shown that neonatal astrocytes in other brain areas respond to depolarizing signals with changes in morphology and/or neurotrophin mRNA expression. To examine the regulation of adult astrocyte function, confluent cultures were treated with KCl, stained for GFAP, and examined for changes in morphology. Exposure to KCl (6.25mM to 50mM for 4 or 24 hrs) did not significantly change the morphology of GFAP-positive cells in either adult or P1 astrocytes. The effects of depolarizing signals on neurotrophin mRNA expression were investigated. Both adult and P1 astrocytes express BDNF and NT-3 mRNA when grown in culture. In P1 astrocytes the expression of NT-3 mRNA was increased by treatment with KCl for 4 hours. In contrast, in adult astrocytes, the expression of NT-3 mRNA was unaffected, suggesting that adult astrocytes are less sensitive to depolarizing signals than P1 cells. (Supported by NICHD: HD23315)

## 223.3

**DIFFERENTIAL REGULATION OF NEUROTROPHIN EXPRESSION IN BASAL FOREBRAIN ASTROCYTES** H. Wu\*, I. B. Black, C. F. Dreyfus, Dept. Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

Previous studies have demonstrated that neurotrophins are important for developing basal forebrain (BF) cholinergic neurons. NGF increases choline acetyltransferase activity, BDNF increases survival, and NT3 increases both survival and neurite outgrowth. Our initial studies indicated that BF astrocytes express these neurotrophins. To understand the role of neuron-glia interactions in BF development, we evaluated effects of neuroactive agents on neurotrophin expression in astrocytes from P1 rat BF.

Purified BF astrocyte dissociated cultures were prepared and neurotrophin mRNA levels were determined. NGF, BDNF and NT3 mRNAs were expressed by cultured BF astrocytes. To investigate regulation, effects of KCl, glutamate and carbachol were examined. KCl increased BDNF mRNA, but had no effect on NGF. The cholinergic agonist, carbachol, also increased BDNF expression, without changing NGF mRNA levels. Glutamate increased both NGF and BDNF. These stimuli had no significant effect on NT3 expression. However, in the presence of the thyroid hormones, T3 and T4, KCl increased NT3 mRNA 2-fold; glutamate and carbachol also elicited small but significant increases in NT3 mRNA levels.

Our data suggest that neuroactive agents differentially regulate BF astrocytic expression of neurotrophins. Neuron-glia interactions, therefore, may critically underlie the development and function of the BF. (Supp: NICH.D:HD23315)

## 223.5

**CNTF INFLUENCES NGF EXPRESSION IN CULTURED ASTROCYTES**

I. Semkova and J. Kriegstein,\* Institut für Pharmakologie und Toxikologie, FB 16, Philipps-Universität, Ketzlerbach 63, 35032 Marburg, Germany

CNTF and NGF are characterized as neurotrophic substances for different neuronal populations in CNS. However, a functional synergism between NGF and CNTF has been recently demonstrated. The physiological basis of functional relationship between NGF and CNTF is not well understood. Therefore, we investigated whether exogenous CNTF can influence the expression of NGF in cultured rat cortical astrocytes. Exposure to human recombinant CNTF (1 ng/ml to 0.1 µg/ml) increased the level of mRNA for NGF after 3 h of incubation. The increase in NGF message was followed by a corresponding increase in NGF protein (approximately 2-fold) secreted from the cells into the culture medium as determined 6 h later. Additionally, we found that at the same concentrations exogenous CNTF increased the level of mRNA coding for p75, a low affinity receptor for NGF and other neurotrophins. These results show that CNTF can influence the expression of NGF in cultured astrocytes and could alter the response to neurotrophins via upregulation of p75 receptor in these cells. Since CNTF is highly expressed in the lesioned brain the upregulation of NGF, if it occurs in vivo, can contribute to the neuroprotective activity of this cytokine.

## 223.7

**BASIC FIBROBLAST GROWTH FACTOR AND PLATELET DERIVED GROWTH FACTOR INDUCE THE NEURON-SPECIFIC BRAIN DERIVED NEUROTROPHIC FACTOR mRNA IN RAT HIPPOCAMPAL CELL LINE** Y. Kim Kwon\*, C. D. Stiles<sup>1</sup>, and S. Jin, Dept. of Biology, Kyunghee Univ., Seoul 130-701, Korea. <sup>1</sup>Harvard medical school, Boston MA 02115.

Brain derived neurotrophic factor (BDNF) is well known to promote neuronal survival and differentiation in central nervous system. BDNF mRNA is expressed in the highest level and the protein transduce the signal through trkB and MAP kinase in primary hippocampal culture. Basic fibroblast growth factor (bFGF) also facilitates neuronal survival in rat hippocampus but the mechanism is unclear. BDNF gene has 4 promoter which produce 8 alternative spliced transcripts, and 2 promoters are neuron-specific.

In the hippocampal precursor cell line, HiB5 which is immortalized using ts SV40 T antigen, bFGF promotes cell survival and differentiation. We found that the bFGF induced the neuron-specific BDNF transcripts including exon 1 but not exon 2 by using reverse transcription-polymerase chain reaction (RT-PCR) method with exon specific primers. Platelet derived growth factor (PDGF) also induces the neuron-specific BDNF mRNA. PDGF beta receptor mRNA and the protein were expressed when analyzed by northern and western blotting and the receptor protein were phosphorylated by PDGF BB.

These data are the first demonstration that neuronal growth factors such as FGF and PDGF regulate the expression of neuron-specific BDNF mRNA and suggest that they play a role in neuronal survival and differentiation through the action of BDNF.

This study is supported by SRC for Cell Differentiation and BIOTECH 2000 from KOSEF.

## 223.4

**CALCIUM INFLUX THROUGH NMDA RECEPTORS PLAYS AN IMPORTANT ROLE IN THE INTERLEUKIN-6 INDUCED ENHANCEMENT OF CALCIUM RESPONSE TO NMDA IN DEVELOPING CNS NEURONS** Z. Qiu\*, S. M. Conroy and D. L. Gruol, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

Developing granule neurons chronically treated with interleukin-6 (IL-6; 5 ng/ml) show an enhanced calcium response to NMDA that involves an increase in calcium influx and release from intracellular stores (Qiu et al., J. Neurosci., 1995). Excessive extracellular calcium influx through NMDA receptor-gated channels and voltage-gated calcium channels (VSCC) could contribute to the increase in calcium induced calcium release from intracellular calcium stores in the IL-6 treated neurons. To understand the mechanism mediating the enhanced calcium response to NMDA, studies were carried out to differentiate the contribution of calcium through both pathways. IL-6 (5 ng/ml) was added to primary cerebellar granule cultures at 1, 4, 7, 11 days in vitro (DIV), and its effects were assessed using Fura-2 based microscopic calcium imaging and the nystatin perforate-patch technique for electrophysiologic recordings. In IL-6 treated neurons the sensitivity to VSCC blockers of the calcium response to NMDA was altered in that N-type VSCC contributed to the IL-6 induced enhancement of calcium response to NMDA at early development stages, whereas there was no differences in the sensitivity to L- and P-type VSCC blockers. Neither control nor IL-6 treated neurons were sensitive to L-, P- and N-type VSCC blockers at late developmental stages. Current clamp studies showed that the depolarization to NMDA was enhanced in IL-6 treated neurons, which could contribute to the differences in the calcium response to NMDA between control and IL-6 treated neurons. Voltage-clamp studies showed that IL-6 increased the current response to NMDA. These results demonstrated that L-, P- and N-type VSCC were not involved in the enhanced calcium response to NMDA at late development stages. The effect of IL-6 could be due to an increase in the density of NMDA receptors or an increase in the permeability of the receptors to calcium. Supported by MH47680

**Regulation of Neurotrophin Expression By Developing Basal Forebrain Oligodendrocytes** X. Dai\*, L. D. Lercher, P. Qu, H. Wu, I. B. Black and C. F. Dreyfus, Dept. of Neuroscience & Cell Biol., UMDNJ / Robert Wood Johnson Medical school, Piscataway, NJ 08854.

Our previous studies indicated that basal forebrain (BF) oligodendrocytes express neurotrophins during development in culture and in vivo. To define regulatory mechanisms, we treated cultured oligodendrocytes with glutamate or KCl, and monitored morphological maturation and neurotrophin expression. Enriched oligodendrocyte cultures were established from postnatal day 1 BF. 48 hours after replating, cultures were exposed to glutamate (10 µM) or KCl (25mM) for another 48 hrs in the presence of triiodothyronine/thyroxine. Glutamate and KCl significantly increased the percentage of myelin basic protein-positive oligodendrocytes. To define effects on neurotrophin expression, a sensitive solution hybridization technique was used. Glutamate elicited a significant decrease in BDNF mRNA expression but had no effect on NT-3 expression. In contrast KCl elicited a significant increase in BDNF mRNA. These studies suggest that neuroactive molecules may regulate oligodendrocyte maturation and trophic function. (Supp: NICH.D:HD23315)

## 223.8

**NGF TREATMENT INCREASES BDNF EXPRESSION IN TRK A IMMUNOREACTIVE DORSAL ROOT GANGLION CELLS AND IN THEIR CENTRAL TERMINATIONS WITHIN THE SPINAL CORD.**

J.V. Priestley, G.J. Michael, S. Averill, A. Nitkunan, G. Wotherspoon, M. Rattray, D.L.H. Bennett, O. Yan and S.B. McMahon\*, Divisions of Physiology and Biochemistry, UMDS, St. Thomas's Campus, London, SE1 7EH, and Amgen Inc., Thousand Oaks, California

Brain derived neurotrophic factor (BDNF) is present in dorsal root ganglia and increases in level following systemic NGF treatment and/or axotomy. However little is known about the dorsal root ganglion (DRG) cell types that express BDNF. We have combined immunocytochemistry and in situ hybridization to investigate this question.

In rat lumbar ganglia, 30-40% of trkA immunoreactive cells contained BDNF mRNA. 13 and 24 hours after 1 mg/Kg ip NGF, this percentage had risen to 60-75%. At the 13 hour time point, serial section analysis revealed that only 15% of cells expressing BDNF mRNA expressed trkC mRNA. Of these, half were also trkA immunoreactive. Less than 10% of the BDNF expressing cells expressed trkB mRNA. After systemic or chronic intrathecal (6µg/day, 14 days) NGF treatment, BDNF immunoreactivity increased in DRG cells and their central termination sites in the spinal cord. Analysis of the spinal cord staining revealed that the majority of BDNF terminals were also immunoreactive for CGRP, a known marker for trkA containing primary afferents. Ligations of dorsal roots showed accumulation of BDNF protein proximal, but not distal, to the site of ligation.

Our results show that NGF increases BDNF production in trkA expressing cells and that BDNF is anterogradely transported to the dorsal horn of the spinal cord. Supported by the Medical Research Council, UK.

## 223.9

EXAMINATION OF DRG NEURONS AND BEHAVIORAL TESTING IN MICE OVEREXPRESSING BDNF IN THE EPIDERMIS A.M. LeMaster\*, J.E. Johnson, P.H. Kitzman, B.M. Davis and K.M. Albers, Dept. of

Anatomy and Neurobiology and Pathology, Univ of KY Sch of Med., Lexington, KY 40536 and Dept of Neurobiology and Anatomy, Bowman Gray Sch of Med, Winston-Salem, NC 27157-1010

Brain-derived neurotrophic factor (BDNF) is important in the development of sensory neurons comprising the dorsal root ganglia (DRG). BDNF knockout mice have a 30% decrease in the DRG neuronal population. Other studies have shown exogenously applied BDNF promotes survival of DRG neurons. To elucidate the function of BDNF during development and in the maintenance of DRG neurons, we isolated transgenic mice that overexpress BDNF in the epidermis. Transgene expression was driven by promoter/enhancer elements of the human keratin 14 (K14) protein. In the present study, we examined the number of neurons expressing *trk* receptors, tyrosine kinase receptors that mediate the biological activity of neurotrophins. Uncorrected counts show no change in the number of *trkA*, *trkB*, or *trkC* expressing neurons in the DRG of K14-BDNF transgenic mice. However, increased numbers of *trkA* and *trkB* expressing neurons were found in trigeminal ganglia of K14-BDNF transgenic mice. In addition, elevated BDNF protein levels were found in the whisker pad skin, but not in the brain of K14-BDNF transgenic mice.

We also examined whether epidermal overexpression of BDNF coincided with changes in thermoceptive sensitivity. Midbrain infusion of BDNF was found to decrease nociceptive and thermoceptive sensitivity. Using the hot plate test, no change in thermoception was measured between control and K14-BDNF transgenic mice. Supported by NS33730 (KMA) and NS31826 (BMD).

## 223.11

bFGF MODULATES THE EXPRESSION OF NGF, BDNF AND NT3 IN CULTURED HIPPOCAMPAL NEURONS. L. Ferhat, A. Represa, W. Ferhat, D. Zouaoui-Aggoun, Y. Ben-Ari, J. Ortiz\* and M. Khrestchatsky, Université René Descartes, Paris V, INSERM U-29, 123 Bd de Port Royal, 75014 Paris, France. # Fac. Pharmacie, Université Paris V, 4 Av de l'Observatoire, 75270 Paris Cedex 6, France.

Basic fibroblast growth factor (bFGF) is expressed in the hippocampus and has been demonstrated to promote neurotrophic effects on hippocampal neurons *in vitro*. We show that these neurons, even at the embryonic stage, express the mRNAs encoding the FGF receptors, *bek* and *flg*. We have characterized the effects of bFGF on the expression of NGF using RT-PCR, *in situ* hybridization and immunocytochemistry. In hippocampal neurons grown in the absence of serum, bFGF exposure induces an important elevation of NGF mRNA levels followed by a marked increase of NGF immunoreactivity. Combining *in situ* hybridization with a NGF probe and MAP2 immunocytochemistry we show that bFGF induction of NGF mRNA is localized in MAP2 immunoreactive neurons. We also show in primary cultures of hippocampal neurons that bFGF increases the steady state levels of BDNF mRNAs while it decreases those of NT3. These results suggest roles for bFGF in maintenance of connexions in the central nervous system, particularly the septo-hippocampal pathway, via the regulation of neurotrophic factor expression in neurons.

## 223.13

CYTOKINE-INDUCED SELECTIVE INCREASE OF HIGH MOLECULAR WEIGHT-bFGF ISOFORMS AND THEIR SUBCELLULAR KINETICS IN CULTURED RAT HIPPOCAMPAL ASTROCYTES. H. Kamiguchi\*, K. Yoshida, K. Shimazaki, M. Inaba, H. Sasaki, M. Otani and S. Toya, Department of Neurosurgery, School of Medicine, Keio University, Tokyo 160, Japan.

The biological behavior of basic fibroblast growth factor (bFGF)-expressing cells, that is tissue regeneration or tumorigenic activity, seems to depend on the pattern of expression of bFGF isoforms. Previous studies have suggested that the increase of high molecular weight (HMW)-bFGF isoforms favors tissue regeneration, and that the over-expression of 18-kD isoform has tumorigenic potential. Cytokines such as interleukin-1 $\beta$  (IL-1 $\beta$ ), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and epidermal growth factor (EGF), which are considered to be supplied to the brain following injury, are probable factors responsible for up-regulation of bFGF expression in reactive astrocytes in the case of brain damage, however the effect of these cytokines on the expression of each bFGF isoform has not been elucidated. Western blot analysis revealed the expression of 18, 22 and 24-kD bFGF isoforms in cultured rat hippocampal astrocytes, and the expression of HMW-isoforms (22 and 24-kD isoforms) but not of 18-kD isoform was selectively increased by cytokines. Immunofluorescent analysis demonstrated that bFGF content in the cytoplasm of astrocytes is initially increased by cytokines followed by nuclear targeting and localization in agreement with the previous evidence that HMW-isoforms possess a nuclear targeting signal. Cytokine-induced selective increase of HMW-bFGF isoforms in astrocytes elucidated in the present study may be an important process of neuroprotection. Supported by grants from Keio University and The Ministry of Education, Science and Culture (No. 05557066, 05671183, 07771118).

## 223.10

THE EFFECTS OF OVEREXPRESSION OF NT-3 IN THE SKIN ON SENSORY INNERVATION OF THE CENTRAL NERVOUS SYSTEM. P.H. Kitzman\*, B.M. Davis, A.M. LeMaster and K.M. Albers, Depts. of Pathology and Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536

The survival of a specific subpopulation of sensory neurons in both the trigeminal ganglia and the dorsal root ganglia has been shown to be dependent upon the availability of neurotrophin-3 (NT-3). Studies utilizing mice in which the NT-3 gene has been disrupted indicated that Ia projections do not innervate the spinal cord (Kucera et al., 1995). However, systemic application of NT-3 at early developmental stages has been shown to inhibit the axon collateral growth in the gray matter of the dorsal horn (Zhang et al., 1994). These studies indicate NT-3 may play a role in the development of sensory projections into the central nervous system. Our lab has isolated lines of transgenic mice that overexpress NT-3 in the epidermis. The expression of the NT-3 transgene begins at approximately E11 and continues throughout adulthood. The present study was undertaken to determine whether the overexpression of NT-3 in the skin alters the distribution of DRG sensory axons within spinal cord. Immunohistochemistry was performed on adult tissue using antibodies against BS-I-B4 (a marker for unmyelinated axons) and CGRP (a marker for peptidergic axons). At sacral levels there appears to be a decrease in CGRP immunoreactivity in the dorsal horn of the NT-3 mice when compared to control animals. At thoracic levels there was no obvious difference in either CGRP or BS-I-B4 immunoreactivity in the dorsal horn of the NT-3 mice when compared with the control animals. The lipophilic tracers DiI and DiA are also being used to determine overall changes in large-diameter axon distribution within the dorsal horn and to determine potential changes in the innervation between spinal segments. The effects of NT-3 overexpression on innervation of the trigeminal complex is also being studied. Supported by F32-NS09836-01 to PHK.

## 223.12

bFGF MODULATES THE EXPRESSION OF GENES ENCODING CYTOSKELETAL PROTEINS IN CULTURED HIPPOCAMPAL NEURONS: POTENTIAL INVOLVEMENT OF MAP2 VARIANTS IN MICROTUBULE ORGANIZATION AND STABILITY. W. Ferhat, L. Ferhat, A. Represa, D. Zouaoui-Aggoun, G. Charton, Y. Ben-Ari and M. Khrestchatsky, Sponsored by ENA, Université René Descartes, Paris V, INSERM U-29, 123 Bd de Port Royal, 75014 Paris, France.

Basic fibroblast growth factor (bFGF) is expressed in the hippocampus and has been demonstrated to stimulate differentiation of hippocampal neurons *in vitro*. In order to study the effects of bFGF on cytoskeletal organization in hippocampal neurons we used antibodies directed against MAP2, Tubulin and Actin. We show that bFGF altered the organization of microtubules but not microfilaments: the microtubules of neurons treated with bFGF are more fasciculated compared to controls. We also show that the cytoskeleton of neurons exposed to bFGF is more stable in the presence of destabilizing agents such as nocodazole. We have characterized the effects of bFGF on the expression of mRNAs encoding various cytoskeletal proteins using RT-PCR in cultured hippocampal neurons. bFGF does not modify the expression of mRNAs encoding  $\alpha$ -Tubulin,  $\beta$ -Tubulin,  $\alpha$ -Spectrin and Tau. However, bFGF produced a significant decrease of the expression of MAP2b and MAP2c mRNAs associated with a marked increase of NFM and MAP2d mRNA levels. Combining *in situ* hybridization with a MAP2d probe and MAP2 immunocytochemistry we show that MAP2d induction is selectively localized in neurons. Our data, associated with transfection experiments in non neuronal cells (Ferhat et al., J. Cell Science, in Press, 1996) suggests that MAP2d could be involved in stabilizing differentiated neurites. L.F. is a recipient of a fellowship from AFM (Association Française Contre les Myopathies).

## 223.14

REGULATION OF THE GENE EXPRESSION OF NEUROTROPHIC FACTORS AND RECEPTORS BY RETINOIC ACID IN LEUKEMIA CELL LINES. P. Xie\*, W. M. Cheung, F. C. F. Ip, N. Y. Ip and M. F. Leung, Dept. of Biology, Hong Kong Univ. of Science & Technology, Hong Kong.

It has recently been shown that retinoic acid induced the expression of neurotrophin receptors in neuroblastoma and teratocarcinoma cells *in vitro*. To explore the potential involvement of neurotrophic factors in the actions of retinoic acid on leukemia differentiation, we examined the ability of retinoic acid to regulate the gene expression of various neurotrophic factors and their receptors in leukemia cells. We found that the expression of *trkA*, the high affinity receptor for nerve growth factor (NGF), was induced in K562 and KG-1 cells after exposure to retinoic acid. The expression of gp130, the shared receptor component of several cytokines, was moderately induced in K562 and HL-60 cells by retinoic acid treatment, and was dramatically induced in HL-60/S4 cells (a retinoic acid-supersensitive cell line derived from HL-60). In addition, the mRNA expression for NGF, neurotrophin-3 and neurotrophin-4/5 could be detected in some of the leukemia cell lines, but the expression of these neurotrophins was not affected by retinoic acid treatment. In contrast, the profile of the changes in the expression of neurotrophic factors and their receptors induced by retinoic acid in neuroblastoma IMR-32 cells was different from that observed in leukemia cells. Taken together, our observations suggested that in addition to their pivotal roles in neuronal development, neurotrophic factors may also be involved in hematopoietic differentiation.

## 223.15

**CYTOKINES STIMULATE NERVE GROWTH FACTOR SYNTHESIS IN REACTIVE ASTROCYTES, BUT NOT IN NORMAL ADULT ASTROCYTES.** V. W. Wu and J. P. Schwartz\*. Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892

Cultured astrocytes synthesize a series of neuropeptides, transmitters, cytokines and growth factors. Injury to the brain transforms resting astrocytes to a reactive form and many of these same factors have been detected in reactive astrocytes in injured brain. In this study, we investigated whether cytokines can stimulate nerve growth factor (NGF) synthesis in reactive astrocytes. Reactive astrocytes cultured from 6-hydroxydopamine (6-OHDA)-lesioned rat brain display more immunohistochemical reactivity for GFAP than adult astrocytes from control brain. The NGF content of astrocytes cultured from control, saline-injected, and 6-OHDA-injected rat brain was measured by two-site ELISA. 6-OHDA lesion resulted in an increase of both NGF mRNA and protein in reactive astrocytes from both the ipsi- and contralateral side of striatum or cortex, with a larger increase on the ipsilateral side. Cytokines (IL-1 $\beta$ , TGF- $\beta$ , IFN- $\gamma$ ) increased the content of NGF a further 3-4 fold in reactive astrocytes, but there was only a minimal effect in striatal and cortical astrocytes from control adult brain. This result suggests that the receptors for these factors may be turned on in astrocytes following injury, supporting the concept that cytokines play an important role during the process of brain injury.

## 223.17

**DIFFERING EFFECTS OF GLUCOSE ON THE EXPRESSION OF CILIARY NEUROTROPHIC FACTOR AND ITS RECEPTOR.**

D. E. Miskin\*, A. M. Hanash and X.-Q. Shu. Department of Internal Medicine, University of Michigan Medical School, Ann Arbor, Michigan.

Peripheral diabetic neuropathy is a significant and severe complication of diabetes mellitus, involving a multifactorial pathogenesis of functional, morphological and metabolic changes in the affected nerves resulting from hyperglycemia. Ciliary neurotrophic factor (CNTF) and its receptor have been shown to be present in the peripheral nervous system. Moreover, CNTF has been shown to be synthesized in Schwann cells and its function is thought to include the support of normal or injured sympathetic, sensory and motor neurons in the peripheral nervous system. Therefore, we examined the effects of glucose on the expression of CNTF mRNA, using the rat JS1 Schwannoma cell line as a model of Schwann cells, and on CNTF receptor mRNA, using human SH-SY5Y neuroblastoma cells as a model of peripheral cholinergic neurons. A 600 bp rat CNTF probe was generated by BamHI digestion of pCNGEX (a generous gift of Dr. Peter Richardson). This probe hybridized to a 1.2 kb mRNA. Northern blot analysis of total RNA extracted from rat JS1 Schwannoma cells, cultured in the presence of 5 to 50 mM glucose, revealed a maximal dose-dependent decrease of CNTF mRNA of 80% observed in 20 mM glucose after 5 days. However, this decrease in CNTF mRNA was rapid, reaching a 60% decrease within 8 hours after exposure to 20 mM glucose. An 800 bp probe (bases 699-1502) encoding CNTFR was generated by RT-PCR using oligonucleotide primers specific for the human CNTFR. This probe exhibited 100% homology to the human CNTFR, and hybridized to a single 2 kb mRNA. Northern blot analysis of total RNA extracted from SH-SY5Y neuroblastoma cells, cultured in the presence of 5 to 50 mM glucose, revealed a dose-dependent increase of CNTFR mRNA, with a 2.5 fold increase observed in 50 mM glucose after 5 days. However, this increase was rapid, reaching a 2-fold increase in 1 day. These data suggest that expression of both CNTF and its receptor may be altered by hyperglycemia, and may contribute to the functional and morphologic perturbations observed in diabetic neuropathy. Research supported by institutional funding.

## 223.19

**1,25-DIHYDROXYVITAMIN D<sub>3</sub> REGULATES THE EXPRESSION OF P75<sup>NGFR</sup> AND GDNF.**

P. Naveilhan<sup>1,2</sup>, C. Baudel<sup>1</sup>, D. Wion<sup>1</sup>, M. Metsis<sup>2</sup>, P. Brachet<sup>1</sup> and I. Neveu<sup>2,\*</sup>. <sup>1</sup>INSERM U298, CHR d'Angers, 49033 Angers, France; <sup>2</sup>Laboratory of Molecular Neurobiology, Karolinska Institute, S-17177 Stockholm, Sweden.

Altered expression of neurotrophic factors and/or their receptors may contribute to some disorders in the nervous system. In order to characterize the factors that control their expression, we have analysed the effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on the mRNA levels of neurotrophin receptors and glial cell line-derived neurotrophic factor (GDNF). RNase protection assay did not show any significant changes in the levels of *trk* receptor mRNAs, but a marked increase in the expression of low-affinity neurotrophin receptor (P75<sup>NTR</sup>) was observed in C6 glioma cells and not in primary astrocytes. Since long-term treatment of 1,25-(OH)<sub>2</sub>D<sub>3</sub> induces cell death in C6 glioma cells, our findings support a possible role of P75<sup>NTR</sup> in 1,25-(OH)<sub>2</sub>D<sub>3</sub>-induced cell death. *In vivo* studies also indicate that 1,25-(OH)<sub>2</sub>D<sub>3</sub> may contribute to the tissue-specific regulation of P75<sup>NTR</sup> since treatment of rats with 1,25-(OH)<sub>2</sub>D<sub>3</sub> decreases P75<sup>NTR</sup> mRNA level in spinal cord but not in dorsal root ganglion or sciatic nerve. Our results also show that 1,25-(OH)<sub>2</sub>D<sub>3</sub> is a strong inducer of GDNF. Treatment of C6 cells with 10<sup>-7</sup> M 1,25-(OH)<sub>2</sub>D<sub>3</sub> for 48 h elicited an 18.5-fold increase in the level of GDNF mRNA and cotreatment with 1,25-(OH)<sub>2</sub>D<sub>3</sub> and retinoic acid had additive effects. These data which constitute the first evidence of hormonal control of GDNF expression, suggest that 1,25-(OH)<sub>2</sub>D<sub>3</sub> may participate in the regulation of GDNF *in vivo*.

These findings are consistent with a potential role of 1,25-(OH)<sub>2</sub>D<sub>3</sub> in the regulation of neurotrophic factors and their receptors.

## 223.16

**MECHANISM OF VASOACTIVE INTESTINAL PEPTIDE-STIMULATED EMBRYONIC GROWTH: IGF-1, CYCLINS AND FOS.** S. J. Servoss<sup>1</sup>, G. W. Glazner, S. J. Lee, G. Gibney\*, L. Y. Wu, D. E. Brenneman, and L. M. Hill. Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892, <sup>1</sup>HHMI-NIH Research Scholar.

VIP treatment of whole mouse embryos in culture during neural tube closure and early neurogenesis results in dramatic growth with an increased rate of cell division through shortening of G1 and S phases of the cell cycle (Soc. Neuro. Abs. 21: 1546, 1995). These growth-regulating effects have been shown to occur indirectly through VIP-induced release of diffusible agents from the CNS, including activity dependent neurotrophic factor (ADNF). The influence of VIP treatment on gene expression of *fos* and the cell cycle regulators, cyclins D, E, A and B, was assessed in cultured E9.5 embryos, as was the potential role of IGF-1, an important neurotrophic factor and regulator of embryonic development, in VIP-stimulated growth. Competitive RT-PCR, using RNA extracted from cultured embryos, revealed a VIP-induced increase (400%) in *fos* message. Cyclin D and cyclin E mRNAs were increased with VIP treatment (198% and 268% of control, respectively), consistent with VIP-induced shortening of G1. A 232% increase in cyclin A message correlated with the shortening of S phase. Cyclin B transcript was elevated 258%, although the duration of G2 has been shown to be unaffected by VIP. Somite growth, size, and DNA and protein content were measured in embryos treated with IGF-1, anti-IGF-1, and combinations of VIP, ADNF, anti-ADNF, IGF-1 and anti-IGF-1. IGF-1 induced a significant dose-dependent increase in embryonic growth; suppression of endogenous IGF-1 by anti-IGF-1 inhibited growth. Both VIP- and ADNF-stimulated growth were blocked by anti-IGF-1, while anti-ADNF had no detectable effect on IGF-1-induced growth. These data suggest that both increased embryonic growth and shortening of the cell cycle duration associated with VIP treatment may be the result of transcriptional activation of multiple cyclins and *fos*. Furthermore, IGF-1 appears to act downstream from both VIP and ADNF in the regulatory pathway and mediates, at least in part, VIP-stimulation of embryonic growth.

## 223.18

**PROTEASES REGULATE NERVE GROWTH FACTOR SECRETION FROM CULTURED VASCULAR SMOOTH MUSCLE CELLS.** T. B. Sherer, J. M. Spitsbergen, and J. B. Tuttle\*. Departments of Neuroscience and Urology, University of Virginia, Charlottesville, Va 22908

Nerve Growth factor (NGF) production in peripheral organs may play a role in the pathophysiology of hypertension, diabetes and cardiovascular, bowel or bladder obstructive disorders. We have been examining the cellular processes of NGF delivery and secretion in smooth muscle. NGF secretion was assayed via two-site ELISA of culture media. Inhibitors of extracellular proteases (aprotinin 0.7 to 7 TIU/ml) reduce NGF secretion from cells of vascular (VSMCs) and bladder origin. The mechanism of inhibition of NGF secretion was tested in VSMCs cultured from hyperactive (WKHA) and hypertensive (WKHT) inbred rat strains. Thrombin (3  $\mu$ g/ml), a serine protease, increased NGF secretion rate over control by 218  $\pm$  30% in the initial 4 hours and the effect was maintained throughout a 24 hour test period. Thrombin-induced increases in NGF secretion were prevented by actinomycin D and cycloheximide, suggesting RNA transcription and protein synthesis are required. Trypsin and collagenase also increased NGF secretion. Aprotinin blocked thrombin-induced increases in NGF as well as lowered basal secretion rates to between 47  $\pm$  2.2 % and 93  $\pm$  4.5 % of control during a 24 hour period. Aprotinin also reduced the stimulation caused by IL-1 $\beta$ . These results suggest that extracellular protease activity may regulate NGF secretion in smooth muscle. Proteases affect basal NGF production and interact with other endogenous regulators and may be involved in neuron-target dynamics. (Supported by a Research Grant from NIH and a School of Medicine Dean's Fellowship.)

## 223.20

**NICOTINE INTERACTS WITH ESTROGEN IN BRAIN IN REGARDS TO INSULIN-LIKE GROWTH FACTOR I mRNA EXPRESSION.** S. Kito\*, A. S. Shingo, J. Semba, R. Miyoshi<sup>1</sup>, E. Shimizu, C. Kondo. The Univ. of the Air, Chiba, Japan 261, <sup>1</sup>Div. of Basic Med. Sciences, Royal Free Hospital Sch. of Med., London.

Recently it has been noticed that estrogen plays a role in memory and learning, while nicotine activates memory function at a short term level. In this paper we studied the cross talk between estrogen and nicotine from viewpoints of insulin-like growth factor I (IGF-I) mRNA induction in the hippocampus and cerebral cortex. Perfusion of 10<sup>-5</sup> M nicotine caused an elevation of intracellular Ca<sup>2+</sup> concentration in rat cultured fetal hippocampal neurons. It was also observed that subcutaneous injection of 1mg/kg nicotine induced c-fos expression in the rat hippocampus. Furthermore, a single injection of 1mg/kg nicotine induced IGF-I mRNA expression, though less than that observed by single injection of 500  $\mu$ g/kg estradiol. The effects of co-injection of nicotine and estradiol were not additive and the IGF-I mRNA expression was intermediate between single injections of nicotine and estradiol. This means that a single injection of nicotine causes IGF-I mRNA expression, while nicotine inhibits estradiol-induced IGF-I mRNA expression. This mechanism was analyzed from viewpoints of AP-1 binding activity.

This study was partly supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture, Japan.

## 223.21

DIFFERENTIAL EXPRESSION OF FGF-2 ISOFORMS: REGULATION BY EXTRINSIC MOLECULES. C. Meisinger and C. Grothe\*. Institute of Anatomy, University of Freiburg, D-79104 Freiburg

We had previously shown that the synthetic glucocorticoid dexamethasone (Dex) which is known to stabilize the endocrine phenotype of chromaffin cells induces an up-regulation of the FGF-2 mRNA level in PC12 cells and in the rat adrenal medulla *in vivo* (Meisinger et al., J. Biol. Chem., in press). Using quantitative Western blot analysis we studied the Dex effect on FGF-2 at the protein level.

Western blot analysis of PC12 cells and adrenal medulla using a monoclonal FGF-2 antibody revealed immunoreactive bands at 18, 21, and 22.5 kD. After Dex treatment the FGF-2 protein level was significantly increased both *in vitro* and *in vivo*. This increase was confined to the 21 kD FGF-2 isoform. Dex-effects on FGF-2 expression were not found in non-neuronal tissues, e.g. in adrenal cortex, skeletal muscle, and L6 myoblasts.

Neurite outgrowth of PC12 cells can be induced by K<sup>+</sup>-depolarization. Treatment of PC12 cells with KCl revealed a significant elevation of the FGF-2 transcript level. The KCl-induced increase of the FGF-2 protein level was confined to the 22.5 kD isoform.

These results suggest that the differential functions of FGF-2 could be related to the expression of different FGF-2 isoforms. Studies using PC12 cells which specifically over-express the low or high molecular weight forms are in progress to examine this hypothesis. (Supported by DFG Gr 857/8-2)

## 223.23

CHARACTERIZATION OF TROPHIC FACTORS AND GENES WHICH EXPRESSED IN THE DOPAMINE-DEPLETED STRIATUM.

I. Fujimoto\*, K. Nakajima, Y. Shimano, H. Hida, A. Fukuda and H. Nishino. Dept. of Physiol., Nagoya City Univ. Med. Sch., Nagoya 467, Japan.

We have previously reported that the extract from dopamine (DA)-depleted striatal tissue (lesioned extract) had a trophic activity on cultured pheochromocytoma (PC12D) cells and fetal DAergic neurons. The action of the extract on promotion of neurite outgrowth of PC12D cells and fetal DAergic neurons were a concentration-dependent manner. To characterize the trophic activity, the factors were fractionated from lesioned extract using heparin column affinity chromatography and Sephadex G-100 gel filtration chromatography. The active fractions were further separated by ion-exchange HPLC. In other hand, differential display technique was applied to identify novel genes encoding factors associated with trophic activity. Total RNAs from DA-depleted striatum and from the counter part of hemi-Parkinsonian model rats were amplified by RT-PCR using various sets of random primers. The amount of the amplified products were displayed on sequence gel, and compared. Some fragments expressed in lesioned side more than intact side, such as alpha-actinin, creatine kinase, human clone HFBF54, etc. Characteristics of these genes in terms of trophic actions on DAergic neurons are discussed.

Supported by the Grant-in-Aid (Japan) #07780744

## 223.22

EXPRESSION OF TGF- $\beta$ 1, TGF- $\beta$ 3, AND IL-6 IN RAT PINEAL TISSUE: IN VIVO AND IN VITRO STUDIES. S.-Y. Tsai\*, K. S. Schluns, P. T. Le, and J. A. McNulty. Department of Cell Biology, Neurobiology and Anatomy, Loyola University Medical Center, Maywood, IL 60153

Recent studies have demonstrated that pineal microglia alter cultured pinealocyte differentiation. Although the mechanisms responsible for microglial mediation of pinealocyte differentiation are not known, a role for cytokines is postulated. Therefore we determined to study whether: 1) specific cytokines are expressed during development of the pineal gland; and 2) cytokines gene expression is modulated by norepinephrine (NE). The pineal glands were removed from Sprague-Dawley rats of different ages (postnatal day 1, 5, 10, 21, and 3-4 months) 4 hours after lights on (12:12 L:D cycle). The following groups of pineal glands were tested: 1) untreated controls frozen immediately on dry ice; 2) glands placed in organ culture for 3 h and treated with vehicle (10<sup>-5</sup>M ascorbic acid) for 4 h; 3) glands placed in organ culture for 3 h and treated with norepinephrine (10<sup>-5</sup>M NE) for 4 h. In a second experiment, dispersed pineal cells from 1-day-old animals were cultured for 7 days prior to NE (10<sup>-5</sup>M) or vehicle (10<sup>-5</sup>M ascorbic acid) treatment for 4 h. Total RNA was isolated from all tissues and analyzed for expression of IL-6 (rat cDNA, gift from Dr. Jack Gaudille), TGF- $\beta$ 1 and TGF- $\beta$ 3 (mouse cDNA) by RNA blot analysis. TGF- $\beta$ 1 and TGF- $\beta$ 3 mRNA were constitutively expressed in the pineal gland at all ages and in dispersed pineal cell cultures. IL-6 mRNA were expressed at day 21 and adult. NE stimulation enhanced TGF- $\beta$ 1 and IL-6 expression only in adult pineal glands. NE had no detectable effects on TGF- $\beta$ 3 expression in any of the groups studied. Developmental changes of TGF- $\beta$ 1, TGF- $\beta$ 3 and IL-6 genes expression suggests that these cytokines may play roles in pineal gland differentiation under sympathetic neural control. Studies are in progress to determine if microglia are the source of these cytokines.

## 223.24

MODULATION OF HUMAN NERVE GROWTH FACTOR PROMOTER ACTIVITY BY INTERLEUKIN-1 $\beta$  AND INTERFERON- $\gamma$ . P.A. Baecker, R.O. Javid, A.N. Verity, C.J. Emmett, D.C. Solymar, R.M. Eglen and R.M. Johnson\*. Dept. of Neurobiology, Inst. of Pharmacology, Neurobiology Unit, Roche Bioscience, Palo Alto, CA 94304.

We have cloned and sequenced the human nerve growth factor (hNGF) promoter. Consensus binding sites were found for transcription factors NF- $\kappa$ B, STAT1, EGF1 and C/EBP, in addition to the previously described sites for AP1 and SP1 (Cartwright, M. et al (1992). Mol. Brain Res. 15, 67-75). The NF- $\kappa$ B and STAT1 consensus binding sites were found to be in a novel, overlapping arrangement. NF- $\kappa$ B was activated by interleukin-1 $\beta$  (IL-1 $\beta$ ) and the novel cognition enhancing drug, RS-66252, in the human glioblastoma cell line, T98G. Both IL-1 $\beta$  and RS-66252 elevated hNGF mRNA levels and enhanced secretion of hNGF from T98G cells. Interferon- $\gamma$  (IFN- $\gamma$ ) activated STAT1 and inhibited hNGF production at the transcriptional level. Electrophoretic gel mobility shift assays employing an oligonucleotide containing the overlapping NF- $\kappa$ B and STAT1 sites, revealed NF- $\kappa$ B or STAT1 binding. A time course of hNGF promoter activity in response to 0.5 ng/ml IL-1 $\beta$ , showed maximal stimulation of ~65% over vehicle alone after 6 hrs of treatment. IFN- $\gamma$  (500 U/ml) inhibited hNGF promoter activity in a biphasic time course, with an initial 15% decrease within one hour, followed by a further 20% decrease 6 hrs after treatment. Furthermore, IFN- $\gamma$  was shown to partially reverse IL-1 $\beta$  stimulated hNGF transcription. The data suggests that IL-1 $\beta$  stimulates hNGF transcription through activation of NF- $\kappa$ B, while IFN- $\gamma$  inhibits transcription through activation of STAT1. The close proximity of the NF- $\kappa$ B and STAT1 binding sites suggest mutually exclusive binding of these two transcription factors and reciprocal regulation of hNGF gene transcription.

## NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS I

## 224.1

LEVELS OF <sup>125</sup>I-IGF-I, <sup>125</sup>I-IGF-II AND <sup>125</sup>I-INSULIN RECEPTOR BINDING SITES IN THE HIPPOCAMPUS OF AGED MEMORY-IMPAIRED AND MEMORY-UNIMPAIRED RATS. R. Quirion, S. Doré, S. Kar, W. Rowe and J.-G. Chabot\*. Douglas Hosp. Res. Ctr, McGill University, Montréal, Québec, Canada, H4H 1R3.

The insulin-like growth factors and insulin are localized in distinct brain regions and their respective functions are mediated by specific membrane receptors. High densities of binding sites for these growth factors are discretely distributed throughout the brain, including the hippocampal formation. IGFs and insulin, in addition to their growth promoting actions, are considered to play important roles in normal cell functions. We compared the anatomical distribution and levels of IGF receptors in young (6 month) and aged (24-25 month) memory-impaired (AI) and memory-unimpaired (AU) male Long Evans rats as determined in a Morris water maze task. Apparent levels of <sup>125</sup>I-IGF-I, <sup>125</sup>I-IGF-II and <sup>125</sup>I-insulin binding sites were evaluated in selective brain regions of young (n=7), AI (n=7) and AU (n=6) rats using quantitative receptor autoradiography. In the hippocampus, <sup>125</sup>I-IGF-I binding sites are concentrated primarily in the dentate gyrus (DG) and the CA<sub>1</sub>-CA<sub>3</sub> sub-fields while high densities of <sup>125</sup>I-IGF-II binding sites are localized to the pyramidal cell layer, and the granular cell layer of the DG. <sup>125</sup>I-insulin binding sites are mostly found in the molecular layer of the DG and the CA<sub>1</sub> sub-field. No significant differences were found in <sup>125</sup>I-IGF-I, <sup>125</sup>I-IGF-II or <sup>125</sup>I-insulin receptor levels in any region of the hippocampus of young and aged animals. Furthermore, deficits in cognitive performance did not relate to altered level of these receptors in AI compared to AU rats. Other regions, including various cortical areas, were also examined and failed to reveal significant differences. It was very recently reported that the amount of IGF-I receptor mRNA was increased with age and positively correlated with learning deficits in AI rats (Stenvers et al., Neuroscience 72:505,1996). However, IGF-I receptor protein levels are apparently not affected by the increases in mRNA levels. It thus appears that IGF-I, IGF-II and insulin receptor binding sites are not markedly altered during the normal aging process and their contribution to cognitive deficits in the aged rat is likely limited. Supported by the MRCC and The Alzheimer Society of Canada.

## 224.2

HABREC I, A NOVEL SERINE-THREONINE KINASE RECEPTOR WITH SPECIFIC CNS EXPRESSION PATTERNS. M. Lorentzon, L. Olson\*, T. Ebendal\*, A. Tomac. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden; \*Dept. of Developmental Neuroscience, Uppsala University, S-751 23 Uppsala, Sweden.

Known receptors for members of the transforming growth factor superfamily are of three types. Type I and type II are signaling receptors with intrinsic serine-threonine kinase activity. In order to find new members of this receptor family expressed in the CNS, a PCR-based cloning strategy was applied. Using cDNA from an adult rat habenula library and primers coding for highly specific regions of the receptor kinase domain, we found several type I and type II receptors. Partial cloning suggests that two of these receptors correspond to previously unidentified receptors, one type I (Habrec I) and one type II (Habrec II). *In situ* hybridization revealed a highly specific mRNA expression pattern of Habrec I in the rat CNS. mRNA expression was detected at embryonic day 19, persisted in the adult, where it was found e.g. in striatum, cortex, and hippocampus. Habrec I mRNA expression appeared predominantly neuronal. Treatment with kainic acid (12 mg/kg i.p.) led to a dramatic upregulation of Habrec I mRNA expression in gyrus dentatus 6 hr post injection. This upregulation was not diminished in rats co-injected with MK801 (2 mg/kg), suggesting that the upregulation was not NMDA receptor-mediated. Stereotaxic injections of 6-OHDA (8  $\mu$ g/4  $\mu$ l/4 min) were used to unilaterally lesion the dopaminergic nigrostriatal pathway and rats in which apomorphine induced more than 300 contralateral turns/hr were chosen. *In situ* hybridization did not reveal any change of the cellular expression of Habrec I mRNA in the dopamine-denervated striatum 1 day, 3 days, 1 week or 1 year after lesion.

Supported by the Swedish MRC and NRC, and USPHS grants.

## 224.3

IMMUNOHISTOCHEMICAL LOCALIZATION OF INSULIN-LIKE GROWTH FACTOR II RECEPTORS IN MOUSE BRAIN. Y. Konishi<sup>1</sup>, S. Fushimi<sup>1</sup>, D.-H. Chui<sup>2</sup>, K. Takahashi<sup>2</sup>, T. Tabira<sup>2</sup> and T. Shirabe<sup>1</sup>.  
<sup>1</sup>Department of Neuropathology, Kawasaki Medical School, Kurashiki 701-01, Japan. <sup>2</sup>National Institute of Neuroscience, NCNP, Tokyo 187, Japan.

We previously reported that insulin-like growth factor II (IGFII) is one of the neurotrophic factors for central cholinergic neurons in mice (Brain Res. 649:53, 1994). Although at the report we showed IGFII receptor immunoreactivity in primary neurons including cholinergic neurons cultured from the septal regions of embryonic mouse brain, we demonstrate here the precise localization of IGFII receptor immunoreactivity in adult mouse brain to clarify the target cells of IGFII. The immunohistochemical study was performed with indirect immunoperoxidase technique by using a rabbit anti-IGFII/mannose-6-phosphate (M6P) receptor antibody (provided by Dr. M. Himeno, Kyushu University, Fukuoka, Japan).

This antibody labeled cytoplasm of the cell bodies in many neurons throughout the brain, but did not that in astrocytes. The result was consistent with the autoradiographic localization reported by Lesniak et al. (Endocrinol. 123:2089, 1988). The localization of IGFII receptors was also examined with immunoelectron microscopy. Furthermore, to obtain the circumstantial evidence that IGFII acts on cholinergic neurons via its receptors to increase choline acetyltransferase (ChAT) activity, we performed double immunofluorescence staining with the anti-IGFII/M6P receptor antibody and anti-ChAT antibodies provided by Drs. B. Wainer, Emory University, Atlanta, GA and T. Ichikawa, Tokyo Metropolitan Institute of Neuroscience, Tokyo, Japan. The colocalization was imaged by laser scanning confocal microscopy. (Supported partly by the Funds from Kawasaki Medical School Research Project in Japan.)

## 224.5

ACTIVATION OF THROMBIN RECEPTORS INFLUENCES THE MORPHOLOGICAL DIFFERENTIATION OF DOPAMINERGIC NEURONS IN VITRO. Th. DEBEIR, J. BENAVIDES AND X. VIGÉ\* Synthelabo Recherche, CNS Research Department, BP 110, 92225 Bagneux Cédex, France.

Evidence has been provided for the involvement of thrombin receptors in the development and differentiation of the Central and Peripheral Nervous Systems. In situ hybridization studies have revealed high levels of thrombin receptor mRNA in the mesencephalon, suggesting that dopaminergic neurons may be an important target for thrombin's actions. In this work we have evaluated the effects of thrombin receptor activation, either by thrombin or by TRAP-14 (a 14 amino-acid agonist of thrombin receptor), on the differentiation of cultured rat dopaminergic neurons. Pure cultures of embryonic mesencephalic neurons were treated with different concentrations of thrombin or TRAP-14 the day after plating and tyrosine hydroxylase positive neurons (TH<sup>+</sup>) were studied the 5<sup>th</sup> day of culture. TH<sup>+</sup> cell counting, dopamine uptake and morphometric analysis were also performed. Neurotrophin 4, already demonstrated active in such a model, was chosen as a reference compound. NT4 (10 ng/ml) increased the number of TH<sup>+</sup> cells and dopamine uptake by +250% and +145%, respectively, whereas thrombin (0.1 to 10 nM) and TRAP-14 (0.1 to 100 µM) did not affect significantly these two parameters. The results of morphometric studies are summarized in the table.

Treatment * p < 0.05 ** p < 0.01	Neurite lengths (% of control)		Segment lengths (% of control)	
	Primary	Secondary	Proximal	Distal
NT4 (10 ng/ml)	+ 57**	+ 66*	+ 140**	+ 16**
Thrombin : 10 nM	+ 13	- 42**	+ 38**	- 58**
TRAP-14 : 1 µM	+ 33**	- 45**	+ 41**	- 31**

These data demonstrate that thrombin receptor activation initiates a complex remodelling of synaptic organisation in central nervous system. Indeed, both thrombin and TRAP-14, favor the growth of primary neurites increasing proximal segments but reducing, in contrast to NT4, the length of distal elements which represent secondary neurites and primary endings.

## 224.7

ACTIVIN TYPE IIA RECEPTOR mRNA EXPRESSION BY NEURONS OF THE AVIAN DORSAL ROOT GANGLION. K. Kos and J.N. Coulombe\*  
 Dept. of Anatomy and Cell Biology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814

Previous studies have suggested that activin serves as a target-derived neurodifferentiation factor regulating the expression of somatostatin in neurons of the avian ciliary ganglion (CG). Activin signalling in CG neurons appears to be transduced by the activin receptor type IIA (ActR type IIA) since these neurons express mRNA for the ActR type IIA, but not the activin receptor type IIB.

We examined whether dorsal root ganglion (DRG) neurons also express mRNA for the ActR type IIA. Oligonucleotide primers designed to amplify the chicken ActR type IIA were used in reverse transcription polymerase chain reactions (RT-PCR). Total RNA was isolated from embryonic day 16 (E16) and post-hatch day 1 (P1) chicken lumbar DRG. The RNA was reverse transcribed and cDNA used as a template in RT-PCR. ActR type IIA specific primers amplified a PCR product of the appropriate size for the type IIA receptor from both E16 and P1 cDNAs. It thus appears that mRNA for the ActR type IIA is expressed in the embryonic and post-hatch chicken DRG.

To examine what cell types within the DRG contain mRNA for this activin receptor, digoxigenin-labeled riboprobes from a cloned ActR type IIA fragment were used for in situ hybridization on cryostat sections of embryonic chicken DRG. Antisense strand, but not sense strand, ActR type IIA specific riboprobes hybridized to cells within these sections. Hybridization of this probe appeared to be specific for cells with a neuronal morphology. Moreover all of the neurons within the DRG appeared to hybridize with the ActR type IIA probe. These results suggest that activin may play a role in differentiation of DRG neurons.

## 224.4

PHARMACOLOGICAL CHARACTERIZATION OF THROMBIN (PAR-1) RECEPTORS IN RAT ASTROCYTES X. VIGÉ, Th. DEBEIR AND J. BENAVIDES\* Synthelabo Recherche, CNS Research Department, BP 110, 92225 Bagneux Cédex, France.

The proteolytic action of thrombin on its receptor (Protease activated receptor-1 or PAR-1) results in a conformational change in which the new N-terminal sequence self-activates the receptor. Peptide analogs of this N-terminal sequence (TRAPs) are able to mimic the effect of thrombin and an extensive search has led to the definition of the structural requirement for the activation of thrombin receptors in several peripheral systems (platelets, endothelial cells). These studies have demonstrated the existence of species and cell type differences in the pharmacology of PAR-1. We have now characterized pharmacologically thrombin receptors in cultured rat astrocytes by using [<sup>3</sup>H]-thymidine incorporation as an end-point.

Thrombin increases [<sup>3</sup>H]-thymidine incorporation into DNA with an EC<sub>50</sub> of 1 nM (+ 550 % at 100 nM thrombin). This effect is mimicked by TRAP-14 (EC<sub>50</sub> = 3 µM, + 500 % at 100 µM) and a peptide containing non natural amino acids (H-Ala-Phe(p-F)-Arg-Cha-HArg-Tyr-NH<sub>2</sub>), (EC<sub>50</sub> = 0.8 µM, + 300 % at 30 µM). The effect of TRAP-14 (10 µM) on [<sup>3</sup>H]-thymidine incorporation into DNA was significantly prevented (EC<sub>50</sub> = 150 µM, Ki = 34 µM) by a peptide (LVR(D-cys)GKHSR) previously described as an antagonist in human platelet aggregation (IC<sub>50</sub> = 30 µM). Finally, a peptide corresponding to the N-terminal sequence of trypsin-activated PAR-2 (SLIGRL) did not affect DNA synthesis up to a concentration of 100 µM.

These results demonstrate that rat astrocytes express PAR-1 receptors which are pharmacologically similar to those previously characterized in human platelets.

## 224.6

C-RET mRNA IS STRONGLY EXPRESSED IN DOPAMINE NEURONS OF SUBSTANTIA NIGRA AND THE VENTRAL TEGMENTAL AREA IN ADULT RODENTS. A. Tomac, B. Hoffer\*, L. Olson. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden and Dept. of Pharmacology, Univ. of Colorado Health Sciences Center, Denver, CO 80262.

The receptor tyrosine kinase encoded by the c-ret proto-oncogene is expressed in developing nervous and excretory tissues, suggesting a functional role in several ganglia, the enteric nervous system, the central nervous system and the kidney during development (Pachnis et al., Development 119:1005, 1993). C-ret has been implicated in multiple endocrine neoplasias and Hirschprung's disease. Null mutations lead to absence of enteric neurons and renal agenesis (Schuchardt et al., Nature 667:318, 1994). The c-ret expression pattern and knockout effects parallel the distribution of GNF mRNA (Lindqvist et al., Soc. Neurosci. Abstr. 20:1101, 1994; Hellmich et al., Mech. Dev. 54:95, 1996), and effects of GDNF on ganglia (Ebendal et al., J. Neurosci. Res. 40:276, 1995). Here, we have used in situ hybridization to study the cellular expression of c-ret mRNA in further detail. We find a very high c-ret mRNA expression in the dopamine neurons of substantia nigra and the ventral tegmental area of adult mice and rats. In particular, neurons in pars compacta and substantia nigra express very strong signals. We have previously demonstrated potent actions of GDNF on the adult mouse dopamine neurons (Tomac et al., Nature 373:335, 1995). The present results, therefore, are compatible with the view that c-ret might act as a GDNF receptor in the adult nigrostriatal dopamine system. Further mapping of c-ret at the mRNA and protein levels is in progress.

Supported by the Swedish MRC and USPHS.

## 224.8

THE TGF-β TYPE II RECEPTOR IN THE CENTRAL NERVOUS SYSTEM. M. Böttner, K. Unsicker\* and C. Suter-Crazzolara, Dept. of Anat. & Cell Biol., Univ. Heidelberg, INF 307, D-69120 Heidelberg, Germany.

Members of the TGF-β superfamily signal through heteromeric receptor complexes which consist of type I and type II serine-threonine kinases. The recently cloned TGF-β type II receptor is abundant in many peripheral tissues, but attempts to detect expression in the CNS have failed so far. However, the potential ligands (TGF-β2 and -β3) for this receptor are expressed in the CNS and affect neurons and glial cells. To solve this apparent discrepancy, we decided to investigate the possibility that a novel type II receptor specific for these growth factors is expressed in the brain. We performed degenerate lift-off-PCR from rat CNS. Primers were targeted against the amino acid sequence of type II specific serine-threonine kinase domains. The resulting PCR products were cloned and sequenced. Initial experiments with E16 rat brain reveal that the predominant PCR products are the activin type II receptors. This shows the feasibility of our approach and the specificity for the type II receptors. In addition, we were able to amplify the known TGF-β type II receptor. Thus, TGF-β may signal in the CNS through the same receptor as in peripheral tissues. Furthermore, we are generating more RT-PCR products (also with other primer combinations), which may allow purification of novel type II receptors which are different from the ones obtained so far. Supported by DFG.

## 224.9

**Localization of GDNFR $\alpha$ , a Putative Receptor for GDNF Ligand.** Mark Armanini<sup>1</sup>, James Treanor<sup>1</sup>, Arnon Rosenthal<sup>1</sup> and Heidi Phillips<sup>1</sup>, Dept. of Neuroscience, Genentech Inc., 460 Point San Bruno Blvd., SSF, CA.

A high affinity GDNF binding protein (GDNFR $\alpha$ ) was purified by expression cloning. The high affinity binding to GDNF ligand suggests GDNFR $\alpha$  as a putative GDNF receptor in vivo (Treanor, et al., Soc. Neuro. Abs. 1996). We performed in-situ hybridization for the mRNA to GDNFR $\alpha$  in the E15.5 rat embryo, as well as early postnatal and adult rat brain. Localization of expression at these developmental stages suggests cell populations requiring GDNF in development, differentiation, or maintenance. In the E15.5 embryo, mRNA for GDNFR $\alpha$  is widespread in the CNS and in peripheral tissues. Peripheral expression includes developing structures of the urogenital system, smooth and striated muscle, and dorsal root ganglia. In the E15.5 CNS, GDNFR $\alpha$  is expressed in structures known to be responsive to GDNF, including the ventral midbrain, and ventrolateral spinal cord. In the P1 and adult CNS, GDNFR $\alpha$  expression also includes GDNF-responsive structures such as the substantia nigra and spinal cord motoneurons. Other areas positively labeled in the adult nervous system include the dorsal root ganglia. The expression of GDNFR $\alpha$  within all known GDNF-responsive neuronal populations suggests GDNFR $\alpha$  may be a physiological receptor for GDNF.

## 224.11

**SIGNAL-TRANSDUCING SUBUNIT GP130 OF AVIAN NEUROKINE RECEPTORS: CLONING AND FUNCTIONAL STUDIES IN SYMPATHETIC NEURONS.** Geisler, M., Heller, S., Pennica, D. and Rohrer, H., Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46, 60528 Frankfurt, Germany. #Genentech Inc., South San Francisco, California 94080, USA.

The neurokinin ciliary neurotrophic factor (CNTF), growth promoting activity (GPA), cardiotrophin-1 (CT-1) and leukemia inhibitory factor (LIF) display survival and differentiation effects on a variety of developing neuron populations. These effects are mediated through receptor complexes that share a common signal transducing subunit, gp130. Although functional receptors for CNTF/GPA and LIF seem to be widely expressed in the developing and adult nervous system, the physiological role of these receptors remains unclear. Temporal and spatial specific elimination of these receptors in the living chick embryo would provide insights into their physiological role. To this end, the avian equivalent of gp130 was cloned (the full length cDNA shares about 55% identity to its mammalian homologues) and an antisense approach was developed to interfere with its function in neurons. Sympathetic neurons serve as a model system for target derived differentiation events. Upon treatment with neurokinins, sympathetic neurons become cholinergic which is reflected by the induction of Choline acetyl transferase (ChAT) and the neuropeptide VIP.

To interfere with the function of gp130, primary cultures of sympathetic neurons from E7 chick embryos were transfected with antisense expression constructs. Two antisense vectors and the corresponding sense vectors were used. It was found that in neurons expressing gp130 antisense RNA the ability to respond to neurokinins acting through the GPA receptor complex (GPA) or through the LIF receptor (CT-1) were both significantly reduced (by about 40%). This effect was quantified by immunostaining for the neuropeptide VIP.

These results confirm that gp130 function is required to mediate the biological action of GPA and other neurokinins on primary neurons. By the use of retroviral vectors, this approach can now be used to investigate the role of gp130 during development of the nervous system.

## 224.13

**Cyclin B and p34<sup>CDC2</sup> kinase in the striatum of MPTP-treated mice.** V. Parekh, P. Rowell<sup>1</sup> and M. Gupta, Depts. of Pediatrics, Pharmacology and Anatomical Sci. & Neurobiology, U of L Medical School, Louisville, KY.

Cyclin B and CDC2 kinase are key regulators during the proliferative stage of the cell-cycle. Previous studies from this laboratory have shown that MPTP treatment in mice can damage the nigrostriatal dopaminergic system and leads to an increase in the number of GFAP immunoreactive astrocytes in the striatum. Furthermore, young adult mice treated with MPTP show a complete recovery within six months after treatment, unlike aging mice treated in a similar manner. In order to determine if p34<sup>CDC2</sup> kinase and its subunit Cyclin B are altered following MPTP toxicity, young adult and aging mice were given a single i.p. injection of MPTP (30mg/kg body weight), and sacrificed one hr later. Fresh striata were quickly dissected and placed in kinase buffer. Cyclin B and p34<sup>CDC2</sup> kinase was determined using immunoprecipitation and Histone as a substrate. The results show an increase in phosphorylation of Cyclin B activity in the young adult mice compared to vehicle controls. Aging mice treated with MPTP did not show an altered Cyclin B activity. These data suggest age-related changes in cell-cycle regulating cyclins.

## 224.10

**Isolation and characterization of a receptor for Glial Cell Line-Derived Neurotrophic Factor**

James Treanor<sup>1</sup>, Klaus Beck<sup>1</sup>, Laurie Goodman<sup>1</sup>, Christa Gray<sup>2</sup>, Mark Armanini<sup>1</sup>, Heidi Phillips<sup>1</sup>, Franz Hefti<sup>2</sup>, Audrie Goddard<sup>2</sup>, Alun Davies<sup>2</sup>, Chris Henderson<sup>2</sup> and Arnon Rosenthal<sup>1</sup>, Department of Neuroscience and Molecular Biology, Genentech, Inc., 460 Point San Bruno Blvd., South San Francisco, CA 94080; <sup>2</sup>University of St. Andrews, Bute Medical Building, St. Andrews, U.K.; <sup>3</sup>INSERM U.382, IBDM, Campus de Luminy - Case 907, 13288 Marseille, Cedex 09

Glial cell line-derived neurotrophic factor (GDNF) is a potent survival factor for midbrain dopaminergic, spinal motor and noradrenergic neurons which degenerate in Parkinson's disease, amyotrophic lateral sclerosis and Alzheimer's disease respectively. Despite the physiological and clinical importance of GDNF, little is known about its mechanism of action. Here we describe the isolation of a protein (designated GDNFR $\alpha$ ) that binds GDNF with a high affinity and is expressed on GDNF responsive neurons. GDNFR $\alpha$ , like the receptors for CNTF and endotoxin, is anchored to the cell membrane by a glycosyl-phosphatidyl inositol (GPI) linkage. Furthermore, primary neurons lose their response to GDNF (but not to other neurotrophins) following treatment with phosphoinositide-specific phospholipase C (PIPLC) which specifically cleaves GPI-linked proteins. Thus GDNFR $\alpha$  is an essential mediator of GDNF signaling and is likely to be a ligand binding component in a multi-subunit GDNF receptor.

## 224.12

**THE SOMATOSTATIN RECEPTOR SUBTYPES, AND THEIR SIGNAL TRANSDUCTION SYSTEMS, THAT ARE EXPRESSED IN CEREBELLAR GRANULE CELLS.** D.J. Wilson, Y. Sugita\* and J.P. Schwartz, Clinical Neuroscience Branch, NINDS, NIH, Bethesda MD 20892

Somatostatin (SST) has been shown to function as a trophic factor for cerebellar granule cells (CGCs), stimulating neurite outgrowth and differentiation. A previous report suggested that a SST receptor (SSTR) was present for only 2 days in vitro (DIV) on CGCs prepared from postnatal day 8 rats, and that this receptor inhibited adenylate cyclase (AC) (Gonzalez et al., PNAS 1992). Using primers designed to distinguish among the SSTR subtypes, we find that CGCs express mRNA for subtype 1 only on DIV1, but that mRNA for subtypes 2, 4, and 5 is present from DIV1 to DIV 10 in culture, with decreasing expression over this time course. Although SSTR have been primarily associated with inhibition of AC, there is one report of stimulation in brain (Markstein et al., Neurosci. Lett. 1989). In CGCs, both SST-14 and the analog [des-ala<sup>1</sup>, des-gly<sup>2</sup>, his<sup>4,5</sup>, D-trp<sup>8</sup>]-SST stimulate AC over the time course from DIV1 to 12. These results suggest that the trophic effect of SST on CGCs may be mediated by a SSTR, possibly subtype 2, 4, or 5, which is positively coupled to AC.

## 224.14

**GANGLIOSIDES ALTER NEURONAL MORPHOLOGY BY MODULATING THE ASSOCIATION OF MAP2 WITH MICROTUBULES AND ACTIN MICROFILAMENTS.** L.-J. Wang, R. Colella and F.J. Rosen\*, Anatomical Sciences & Neurobiology, University of Louisville Medical School, Louisville, KY 40292.

Gangliosides are glycosphingolipids that are relatively abundant in neurons and are found in the outer leaflet of the plasma membrane. They enhance neurogenesis of primary neurons and established neuronal lines. Our previous studies demonstrated that exposure to the ganglioside GM1 increased the microtubule network and promoted neurogenesis of Neuro-2a neuroblastoma. Furthermore, a redistribution of MAP2 immunoreactivity from the perikaryon to the distal processes occurred following 24 hr GM1 treatment. Immunoelectron microscopy demonstrated that MAP2 was closely associated with the subcortical cytoplasm; more MAP2 label per unit area was found in processes and spines after GM1 treatment. We examined the immunolocalization of MAP2, actin and tubulin with confocal and electron microscopy to determine if GM1 affects the distribution and expression of actin microfilaments in this region. GM1 exposure caused a redistribution of actin from a uniform, subsurface, circumferential layer to specific foci in the processes and spines. These changes paralleled the redistribution of MAP2 from perikaryal regions to spines after ganglioside exposure. Computer-assisted morphological analysis of actin labeled with colloidal gold revealed more label on the GM1 treated cells ( $p < 0.0001$ ), especially in the areas close to the spines. Studies examining the effect of GM1 on actin synthesis demonstrate a dose dependent increase in actin mRNA and protein levels. Our data suggest that gangliosides enhance neurogenesis and determine dendritic or axonal fate by modulating cytoskeletal elements through a collaboration of actin and MAP2 dependent mechanisms.

## 224.15

**CNTFR $\alpha$ -IMMUNOREACTIVITY IN THE PRIMATE CNS.** Yaping Chu, A. John MacLennan\*, Conwell Anderson\*, and Jeffrey H. Kordower. Department of Neurological Sciences, Rush Presbyterian-Luke's Medical Center, Chicago, IL 60612 and \*Department of Neuroscience, University of Florida Brain Institute, University of Florida College of Medicine, Gainesville Florida, 32610.

Ciliary neurotrophic factor (CNTF) sustains the viability and phenotypic expression of a variety of neuronal populations including cranial and spinal motor neurons. The distribution of the ciliary neurotrophic factor receptor  $\alpha$  (CNTFR $\alpha$ ), which is essential for the trophic effects of CNTF to occur, is unknown in any primate species. The present study used a polyclonal antibody directed against CNTFR $\alpha$  to evaluate the distribution of CNTFR $\alpha$ -ir within the brain and spinal cord of Cebus apella monkeys. CNTFR $\alpha$ -ir was found exclusively within neurons. In the anterior horn of the spinal cord, virtually all motor neurons were immunoreactive for CNTFR $\alpha$ . Furthermore, a similar pattern of CNTFR $\alpha$ -ir was seen within all cranial motor nuclei with general somatic efferent function (III, IV, motor V, VI, motor VII, and XII cranial nerves). CNTFR $\alpha$ -ir was also seen on other regions involved with motor function including the Purkinje cells of the cerebellum, substantia nigra pars compacta, red nucleus, dorsal motor nucleus of X cranial nerve, and layer V of sensory motor neocortex. A few CNTFR $\alpha$ -ir were seen within the globus pallidus with concomitant terminal-like staining within the subthalamic nucleus. Autonomic regions such as the mesencephalic nucleus of the trigeminal nerve and the intermedial lateral cell column of the thoracic spinal cord also contained CNTFR $\alpha$ -ir neurons. CNTFR $\alpha$ -ir was observed within both the rostral (sensory) and posterior (autonomic) portions of the nucleus solitarius. Finally, dense CNTFR $\alpha$ -ir was observed within the pyramidal cell layer of the hippocampal formation and the granule cell layer of the dentate gyrus. The dense expression of this CNTFR $\alpha$ -ir within regions subserving motor, autonomic, and sensory functions suggests that CNTFR $\alpha$  supports many CNS regions with diverse functions. **A RAS/RAF REGULATED POTASSIUM CHANNEL CONTROLS MUSCLE GENE ACTIVATION IN 10T1/2 CELLS EXPRESSING THE MUSCLE TRANSCRIPTION FACTOR MRF4.**

T.L. Peña, S.E. Konieczny and S.G. Rane\*. Dept. of Biol. Sci., Purdue Univ., W. Lafayette, IN 47907.

To understand how receptor tyrosine kinase (RTK) signaling controls cell growth and differentiation, we have focused on ion channels, specifically a small conductance Ca<sup>2+</sup> activated K<sup>+</sup> channel, SK, as potential targets and physiological mediators of this signaling. Mitogenic peptide growth factors upregulate SK channel expression in fibroblasts and stimulate proliferation which is inhibited by the SK channel blocker, charybdotoxin (ChTX) (JBC 269:31183, 1994). Since cell proliferation and differentiation are ultimately effected via gene regulation, our goal is to determine how SK activity regulates these processes. We now present evidence, combining patch clamp techniques with ectopic overexpression of MRF4 in the 10T1/2 fibroblast cell line, that implicates SK channel activity in transcriptional regulation. In response to the mitogenic peptide bFGF, 10T1/2-MRF4 cells express high levels of SK. MRF4 is negatively regulated, and the cells proliferate as fibroblasts. When bFGF is withdrawn, SK levels decrease, and a myogenic program is initiated via MRF4, including expression of acetylcholine (ACh) receptor channels observed as ACh activated whole-cell currents. We now report that cells grown in bFGF and ChTX, i.e., high SK levels, and SK functional blockade, also express high levels of ACh receptor channels, consistent with removal of bFGF negative regulation of MRF4. These results suggest that bFGF negative regulation of MRF4 occurs indirectly through upregulation and activity of the SK channel. Thus, these experiments provide the first evidence linking ion channel activity to control of a defined transcriptional regulatory complex.

**DIVERGENT REGULATION OF NEURONAL PHENOTYPE BY NEUROTROPHINS IN SK-N-SH HUMAN NEUROBLASTOMA CELLS.** S.S. Lesser\* and D.C. Lo. Department of Neurobiology, Box 3209, Duke University Medical Center, Durham, NC 27710.

Neurotrophins help shape neuronal phenotype by regulating the development and maintenance of neuronal excitability through the expression of voltage-gated and ligand-gated ion channel expression. We have used the sympathetic-like human neuroblastoma cell line, SK-N-SH, to examine the differential effects of different neurotrophic factors within a single cellular context. SK-N-SH cells are normally responsive to NGF, but when cultures are treated with retinoic acid (RA), these cells become responsive also to BDNF, NT-3, NT-4. Previously, we have described the differential regulation of Na<sup>+</sup>, Ca<sup>2+</sup>, and K<sup>+</sup> currents in SK-N-SH cells by the neurotrophins. NGF and NT-4 upregulate Na<sup>+</sup>, Ca<sup>2+</sup>, and K<sup>+</sup> currents. BDNF regulates Na<sup>+</sup> and Ca<sup>2+</sup> currents only, and NT-3 regulates only K<sup>+</sup> currents.

In this study we examined the initial signaling events which may underlie downstream differences in late gene expression. Using phospho-specific antibodies, we have assayed Trk, CREB, and ERK activation and have found that each signaling intermediate is induced by the neurotrophins. However, each neurotrophin induces phosphorylation of Trk, CREB, and ERK to similar levels and with similar time courses. Additionally we have examined the regulation of other late genes, such as GAP-43, which is also differentially regulated by neurotrophins in a pattern distinct from that for any of the voltage-gated ion channels. Thus, we conclude that no two neurotrophins have the same set of effects on late gene expression in RA-treated SK-N-SH cells, and that this divergence in regulating neuronal phenotype occurs despite similar early transduction events.

We would like to thank Regeneron Pharmaceuticals for their generous gift of neurotrophins. This work was supported in part by an award from the Ruth K. Broad Foundation, the Alfred P. Sloan Foundation, and NIH grant NS32742.

**NOVEL PATHWAY OF NUCLEAR TARGETING OF FGF-RECEPTOR 1 AND ITS ROLE IN CELL CYCLE CONTROL IN HUMAN GLIOMA CELLS.** E. Mordechai<sup>1,2</sup>, J. Moffett<sup>1</sup>, I.N. Ligidakis<sup>1</sup>, C.L. Yee<sup>1</sup>, E.K. Stachowiak<sup>1</sup>, P.A. Maher<sup>2</sup>, M.K. Stachowiak<sup>1</sup>, \*<sup>1</sup>Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013; <sup>2</sup>Immunosciences Lab, Inc., Beverly Hills, CA 90211; <sup>3</sup>The Scripps Research Institute, La Jolla, CA 92037.

Nuclear accumulation of FGFR1 coincides with the proliferation of human glial cells (Stachowiak et al. 1996; Mordechai et al. 1996). To determine how nuclear FGFR1 exerts its pleiotropic mitogenic effects, we have analyzed its structure-function relationship in human glioma cells. We have transfected the full length FGFR1 cDNA and FGFR1 missing the membrane insertion domain (FGFR1/-MID), as well as, FGFR1 missing the leader sequence domain (FGFR1/-LS) into glioma cells (SF-763) that do not express FGFR1. Immunohistochemistry and Western analysis of fractionated, transfected SF-763 cells demonstrate nuclear accumulation of FGFR1, FGFR1/-MID, or FGFR1/-LS with marginal extra nuclear localization. Consistently, nuclear localization coincides with enhanced FGFR1 associated kinase tyrosine kinase activity in the nuclear fractions of FGFR1 and FGFR1/-MID transfected SF-763 cells. Proliferation assays have demonstrated enhanced mitotic activity of SF-763 cells transfected with either FGFR1 or FGFR1/-MID, resulting from enhanced G<sub>1</sub> to S transition. Additionally, SF-763 cells transfected with FGFR1/-LS have the same basal mitotic activity as SF-763 cells transfected with CMV-Neo. In conclusion: (i) FGFR1 can accumulate in the nucleus without prior insertion into the cell membrane (ii) nuclear accumulation of FGFR1 coincide with enhanced mitotic cycle (iii) leader sequence domain is necessary for the mitogenic activity of nuclear FGFR1. **Increased epidermal growth factor-receptor (EGF-R) expression following MPTP treatment in mice.** M. Gupta, M. Demianova, A. Shum-Siu, and F.J. Hendler, Depts. of Anatomical Sci. & Neurobiology, Medicine, and Biochemistry, Henry Vogt Institute of the Brown Cancer Center, U of L Medical School, and the Louisville VAMC, Louisville, KY.

Epidermal growth factor-receptor (EGF-R) has been implicated in neuronal development as well as in mediating neurotrophic and neuromodulatory effects in the nervous system. The present studies were undertaken to examine if EGF-R is expressed in the nigrostriatal dopaminergic system and if its expression is altered following treatment with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Young adult mice were given two injections of MPTP (15 mg/kg body weight s.c.) 24 hr apart and sacrificed 1 hr after the second injection. Mice were anesthetized, and perfused with 4% paraformaldehyde. Brains were removed and 8  $\mu$ m sections were cut through the striatum and substantia nigra (SN). EGF-R mRNA was detected using in situ RT-PCR. Sections were pretreated with trypsinogen and DNase. EGF-R cDNA was synthesized using an antisense oligonucleotide primer. The EGF-R cDNA PCR amplification with digoxigenin-dUTP was carried out in situ for 7 cycles using taq polymerase. EGF-R mRNA synthesis was detected using a monoclonal anti-digoxigenin antibody conjugated with alkaline phosphatase. The results show increased EGF-R expression in the striatum and SN of MPTP-treated mice, suggesting an increased synthesis of EGF-R in response to MPTP toxicity. Since EGF-R has been shown to have a mitogenic effect and to activate other tyrosine kinases, including MAP kinase, these data suggest that MPTP treatment activates the signal transduction pathway. Supported by grants from the Jewish Hospital Foundation and NSF EPSCoR to MG.

**Preparation of a Cell-Free Translation System from PC12 Cells.** M. Shibutani, E. Kim, P. Lazarovici, M. Oshima\*, and G. Guroff. Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892.

Until now, very few studies on translational regulation during neuronal differentiation have appeared. The postmitochondrial fraction (S10) contains the cellular components essential for translation, and a high salt wash (HSW) of the ribosomes is enriched in eukaryotic initiation factors. To investigate the phenomena linked with translational regulation as a possible mechanism during neuronal differentiation, we established a cell-free translation system utilizing an S10 extract from PC12 cells. The products synthesized from either firefly luciferase mRNA or PC12 cell poly(A) RNAs in the PC12-S10 extract were increased by the addition of the HSW from PC12 cells. Increases in the translation of luciferase mRNA by the addition of PC12-HSW were dose-dependent and also dependent on the time of incubation. The translation of human epidermal growth factor receptor mRNA could also be detected in the PC12-S10 extract translation system by immunoprecipitation. N-linked glycosylation of the translation products also was observed. The efficiency of translation was altered by the addition of Mg<sup>2+</sup> or K<sup>+</sup>, and optimization of these ions was necessary for each mRNA. The translation system made from PC12 cells, then, is capable of the synthesis of proteins of relatively high molecular weight and should be useful for analyzing mechanisms of translational control during proliferation and differentiation of cells from a neuronal lineage.

ACTIVATION OF MAP KINASES (ERKS) BY ESTRADIOL IN CEREBRAL CORTICAL EXPLANTS: CROSS-COUPLING OF THE ESTROGEN AND NEUROTROPHIN SIGNALING PATHWAYS. C. D. Toran-Allerand\*, E. Mauri, C. Leung, M. Warren and M. Singh. Dept. of Anatomy & Cell Biology, Columbia Univ. Coll. P&S, New York, NY. 10032.

Estrogen and the neurotrophins have important roles in the developing and adult central nervous system (CNS). Our previous studies have demonstrated estrogen and neurotrophin receptor co-localization throughout the developing forebrain, suggesting a potential substrate for steroid/neurotrophin interactions. We are testing the hypothesis that estrogen/neurotrophin receptor co-expression leads to reciprocal regulation at the level of signal transduction, through cross-coupling of converging estrogen and neurotrophin signaling pathways whose end-points in the nucleus may be the very same genes. Postnatal day 2 cerebral cortex was maintained as organotypic explants in roller tube culture for 7 days. Following 24 hrs. of estrogen and neurotrophin deprivation, we investigated estradiol's activation of ERKs 1 & 2 (Extracellular-signal Regulated Kinase) and found rapid (by 5 min.) tyrosine phosphorylation of the ERKs (maximal at 30 min.) that persisted for at least 4 hrs. Although estrogen-induced phosphorylation implies activation (required for ERK nuclear translocation) in-gel kinase assays confirmed that phosphorylated ERKs were much more active in phosphorylating MBP as a substrate than untreated controls. In starting to define the pathways leading to ERK activation, we found that both estradiol and the neurotrophins (NGF, BDNF and NT-4/5, but not NT-3) induced tyrosine phosphorylation of the estrogen receptor. Conversely, and in keeping with the idea of reciprocal cross-coupling of the signal transduction pathways, we have found that estradiol also induced tyrosine phosphorylation of the *trk* receptors. Our results provide a novel and alternative developmental mechanism for estrogen action that would explain how estrogen and the neurotrophins could each regulate the same broad array of ERE (estrogen response element)- and non-ERE-containing genes. (Supported by grants from NIH (NIA), NIMH, NSF, and an ADAMHA RSA to DT-A).

UP-REGULATION OF A NOVEL GENE TRANSCRIPT IN PC12 CELLS STIMULATED WITH NERVE GROWTH FACTOR AND MAST CELLS STIMULATED WITH STEM CELL FACTOR. S.-Y. Tam\*, M. Tsai, and S.J. Galli. Depts. of Pathology, Beth Israel Hospital & Harvard Medical School, Boston, MA 02215.

We have recently used the technique of mRNA differential display to identify novel genes whose expression is differentially regulated in mast cells activated by IgE and specific antigen. Of the several differentially expressed cDNA probes identified, one clone hybridized to a 2.6 kb mRNA whose expression was rapidly increased in mouse mast cells that had been activated through the FcεRI for 30 min or 1 hr, but which returned to baseline levels after 2 hrs. Sequence analysis of an entire full-length cDNA clone revealed no significant homology to any known gene sequences, suggesting that the cloned cDNA may represent a novel gene transcript. To examine whether the activated expression of this novel gene transcript was specific for the FcεRI-dependent signaling pathway in mast cells, Northern analysis was performed to assess its expression in mouse bone marrow-derived cultured mast cells that had been stimulated with stem cell factor (SCF) and in PC12 cells that had been stimulated with nerve growth factor (NGF). In mouse mast cells stimulated with SCF (50 ng/ml), the mRNA levels of this novel gene were increased with a time course that was essentially identical to that observed with IgE and antigen stimulation. On the other hand, in PC12 cells stimulated with NGF (50 ng/ml), the mRNA expression of the identified gene was not affected 30 min after stimulation; however, its levels were significantly elevated 1 hr after stimulation and remained undiminished at 2 hr. These data thus indicate that the expression of this novel gene transcript can be differentially regulated in mast cells and PC12 cells via different types of ligand-receptor interactions. Experiments are in progress to test the idea that the gene product encoded by this novel transcript may represent a common signaling element mediating diverse functional responses in different cell types. QUANTITATIVE CHANGES IN THE BINDING OF TRANSCRIPTION FACTORS TO RESPONSE ELEMENTS IN AXOTOMIZED AND NGF-TREATED DORSAL ROOT GANGLION NEURONS. J.D. Corness, T.J. Shi, T. Hökfelt\*. Dept. of Neuroscience, Karolinska Institute, 17177 Stockholm, Sweden.

Transaction of an axon is known to cause diverse changes in the protein make-up of the cell body, and it is believed that the axotomy-induced changes in peptide expression may ultimately be due, at least in part, to decreased availability of growth factors in the neuronal cell bodies. In this experiment we studied the influence of axotomy and nerve growth factor (NGF) treatment on the *in vitro* binding of transcription factors extracted from the dorsal root ganglia (DRGs). We have prepared whole-cell protein extracts of DRGs for quantitative binding analysis during electrophoretic mobility shift assays (EMSA). DRGs from spinal cord levels L4 and L5 were taken from rats at various time points following sciatic nerve axotomy and compared to contralateral and unoperated controls. In addition, a group of axotomized rats was given 1 µg NGF with 0.1% BSA through a capsule applied to the proximal nerve ending, and the protein extracts from these ganglia were compared to those of axotomized animals and normal controls. Binding of these extracts was carried out in the presence of labelled oligonucleotides for the response elements AP-1, AP-2, NFκB, Sp-1 and TFIID, as well as for selected elements within the rat galanin gene promoter. Preliminary results show that axotomy caused an increase in specific binding to the AP-1 probe which was counteracted by NGF treatment. For a probe which includes the galanin CRE and the sequence surrounding it, binding did not increase after axotomy; however, a specific complex binding to this probe was seen to be down-regulated by the growth factor treatment. (Supported by Swedish MRC 04X-2887.)

PC12-E<sub>2</sub> Cells: A Novel Model System for the Study of Estrogen and Neurotrophin Interactions. M. Singh\*, E. Mauri, C. Leung, M. Warren and C. D. Toran-Allerand. Dept. of Anatomy & Cell Biology, Columbia Univ. Coll. P&S, New York, NY. 10032.

We have previously reported that wild-type, differentiated PC12 pheochromocytoma cells express very low levels of estrogen receptors. Here we report that a PC12 cell variant, PC12-E<sub>2</sub> (Wu, Bradshaw, J. Cell. Physiol. 164: 1995), is estrogen responsive and expresses high estrogen receptor levels (~50% of the levels observed in estrogen receptor over-expressing MCF-7 cells). Moreover, although tyrosine phosphorylation of the estrogen receptor appeared to be expressed constitutively, these cells responded to added estrogen. PC12-E<sub>2</sub> responsiveness to estrogen was determined morphologically and by measuring estradiol-induced ERK activation. Estradiol phosphorylated ERKs 1 & 2 on tyrosine within 15 min. In contrast, no estradiol-induced ERK stimulation was observed in wild-type, differentiated PC12 cells, suggesting that the estrogen receptor was integral to the response. Morphological studies revealed extensive and rapid NGF induction of neurite outgrowth (within 24 hrs.). While estradiol alone appeared to have little effect on neurite growth, the concurrent addition of estradiol and NGF elicited both a synergistic enhancement of neurite growth and apparent mitogenic activity. We are utilizing these cells to investigate the pathway(s) by which estradiol activates the ERKs. Preliminary co-precipitation experiments show an association between *src* and estrogen receptor, *src* with MEK (MAP Kinase/ERK-activating Kinase), and MEK with B-*raf*, which phosphorylates the ERKs on tyrosine residues, is known to exist as a complex consisting of at least hsp90 and B-*raf*. Since both the unliganded estrogen receptor and *src* are also known to be associated with hsp90, these findings imply a direct association between the estrogen receptor and at least one component of the MAP Kinase cascade (MEK), suggesting a route by which estrogen could activate the ERKs directly. (Supported by Grants from NIH (NIA), NIMH, NSF, and an ADAMHA RSA to DT-A).

**225.4**

DOWN-REGULATION OF CYCLIN F IN NERVE GROWTH FACTOR-TREATED PC12 CELLS. V. Movsesyan, M. Whalin, E. Broude, and G. Guroff\*. Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892

The PC12EY subclone was used to study the influence of nerve growth factor (NGF) on the cyclin F content during neuronal differentiation. Immunoblot analysis showed a marked decrease in cyclin F levels in PC12EY cells treated with NGF. This down-regulation, was prevented by the addition of K-252a. A smaller reduction of cyclin F was observed when cells were treated with fibroblast growth factor, but epidermal growth factor had no comparable effect. Time course studies suggest that the decline in cyclin F expression precedes the changes produced by NGF in the distribution of cells within the cell cycle (increase in cells containing 4C DNA), as shown by flow cytometry. Immunocytochemical staining showed largely perinuclear localization of cyclin F and confirmed the significant decrease of the immunoreactivity in NGF-treated PC12EY cells. These data suggest that cyclin F may be involved in NGF-mediated cell cycle events.

**225.6**

DIFFERENTIAL EFFECTS OF VASOPRESSIN ANALOGS ON GENE EXPRESSION OF NEUROTROPHINS IN RAT BRAIN Y. C. Du, A. W. Zhou, J. Guo and X. L. Yang\*. Shanghai Ins. of Biochemistry, Shanghai Ins. of Physiology, Chin. Acad. of Sci., Shanghai, China 200031.

*In situ* hybridization and Northern blot assay were used to evaluate the effect of arginine-vasopressin (AVP) analogs on the transcription of genes for nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin 3 (NT-3) in the brain of adult Wistar rat (♂) at 12 after injection (s.c. 1.3 µg/kg body weight in 0.5 mL saline). 1) The differential expression of neurotrophins was significantly found. NGF and BDNF, but not NT-3, were enhanced by AVP<sub>4-12</sub> [I] in the cerebral cortex and hippocampus. 2) In the same conditions, behaviour-active AVP [III] resulted in a smaller effect and its behaviour-inactive homologue, oxytocin [III] did not. 3) Furthermore, additional four synthetic analogs of AVP<sub>4-12</sub>, i.e. NLPR [IV], Ac-YQNC(C)PR amide [V], ZDC(C)PR [VI] and (ZNCPR), [VII] were tested and the results showed that the NGF mRNA level increased significantly in the brain after s.c. injection of either [IV] or [V], while the other two had no positive response. 4) The enhancement of the NGF expression of [III] and [IV] was substantially inhibited by [VI] which was known as the most effective antagonist of AVP<sub>4-12</sub>. In general, the neuropeptide potencies in enhancing NGF expression were well consistent with their ligand-receptor binding abilities and learning behavioral activities reported previously. According to the documented data on the differential distributions of NGF, BDNF and NT-3 mRNA in limbic system, the selective enhancement of these gene expressions undoubtedly indicated the involvement of NGF and BDNF, but not NT-3, in learning and memory via strengthening the basal cholinergic projection. It is postulated that these analogs may share with AVP<sub>4-12</sub> the same signalling pathway in adult rat brain.

This study was supported by grants of The National Natural Science Foundation and Shanghai Joint Laboratory of Life Sciences.

**THE AKT PROTO-ONCOGENE IN NGF AND PDGF SIGNAL TRANSDUCTION.** Thomas F. Franke<sup>1,2,\*</sup>, Henryk T. Dudek<sup>3</sup>, Alex Tokar<sup>2</sup>, Lewis C. Cantley<sup>2</sup>, Michael E. Greenberg<sup>3</sup>, and David R. Kaplan<sup>1,4,\*</sup>. <sup>1</sup>ABL-Basic Research Program, NCI-FCRDC, Frederick, MD, 21702; <sup>2</sup>Montreal Neurological Institute, McGill Univ., Montreal, Quebec H3A 2B4; <sup>3</sup>Division of Signal Transduction, Beth Israel Hospital, and Department of Cell Biology, Harvard Medical School, Boston, MA 02215; <sup>4</sup>Division of Neuroscience, Children's Hospital, Boston, MA 02115.

We have previously shown that the kinase activity of the *Akt* proto-oncogene is induced by PDGF in fibroblasts in a manner dependent on the activity of PI 3-kinase (Franke *et al.*, Cell 81, 1995). Our recent results show that only one of the products of PI 3-kinase, PtdIns-3,4-P<sub>2</sub> is able to activate Akt when added to cells. This regulation is mediated by direct interaction of PtdIns-3,4-P<sub>2</sub> with the Akt pleckstrin homology (PH) domain. Thus, PtdIns-3,4-P<sub>2</sub> is sufficient to activate Akt by binding directly to the Akt PH domain. We also extended our previous studies by examining the activity of Akt in biological relevant systems such as PC12 cells and primary neuronal cells. Akt activity in PC12 cells is induced rapidly and specifically by NGF, but not by EGF. Moreover, the tyrosine residue on TrkA regulating the activity of PI 3-kinase *in vivo* is also necessary and sufficient to induce Akt activation by NGF. In addition, we find that Akt activity in primary neuronal cells is regulated by factors inducing the activity of PI 3-kinase. A possible role of Akt as a downstream effector of PI 3-kinase in PI 3-kinase-dependent pathways such as neurite outgrowth and neuronal survival will be discussed.

## 225.9

**mRNAs FOR ONE, TWO OR THREE MEMBERS OF TRK RECEPTOR FAMILY ARE EXPRESSED IN SINGLE RAT TRIGEMINAL GANGLION NEURONS.** M. Moshnyakov, U. Arumäe, M. Reeben\*, and M. Saarna. Program of Molecular Neurobiology, University of Helsinki, Helsinki, FIN-00014, Finland.

trkA, trkB and trkC constitute a family of protein tyrosine kinase receptors that specifically bind neurotrophins with high affinity. We studied the expression of mRNAs for trkA, trkB and trkC in single rat trigeminal ganglion neurons at embryonic days 12 and 16 to determine, whether single trigeminal ganglion neurons express one trk family member or coexpress several of them. For that purpose we elaborated a sensitive technique of reverse transcriptase-polymerase chain reaction to detect all neurotrophin receptors in a single neuron. Expression of neurofilament light chain mRNA was used as a positive marker to confirm the recovery of mRNAs from single neurons. Neurofilament-positive samples were subsequently analyzed for the expression of mRNAs for catalytic trkA, trkB and trkC, and in some cases, low-affinity neurotrophin receptor (p75). We found neurons expressing one, coexpressing two, or even all three trk receptors. In both developmental stages, most of the analyzed neurons coexpressed two or three trk family members with the combination of trkB and trkC being the most often found. In many neurons analyzed, p75 mRNA was coexpressed with trks, but we also found neurons expressing only trks without p75, and a neuron expressing p75 alone. There were also neurons containing neither trk receptors nor p75. In this work, expression pattern of four neurotrophin receptors in single neurons was determined for the first time. Moreover, coexpression of three or even four receptors was demonstrated directly. This work was supported from the grant of the Academy of Finland, from the University of Helsinki, and from the grant of Sigrid Juselius Foundation.

## 225.11

**MAPK IS PHOSPHORYLATED BY BDNF, NT-3, NGF, GDNF AND MIDKINE IN MOTONEURON-HYBRID CELLS.**

Michikawa M.(1)\*, Sanjo N.(2), Ouwada K.(2), Muramatsu H.(3), Muramatsu T.(3) and Cashman N.R.(4) (1)Dept. of Dementia Res., National Institute for Longevity Science, Aichi, Japan. (2)Dept. of Neurol., Tokyo Med. and Dent. Univ., Tokyo Japan. (3)Dept. of Biochem. Nagoya Univ. School of Med. Aichi, Japan. (4)Montreal Neurological Institute and Hospital, Montreal, Quebec, Canada

Neurotrophic factors, such as Midkine, BDNF, NT-3, GDNF, CNTF are known to promote the survival of motoneurons *in vitro* or *in vivo*. However, their intracellular pathways in motoneurons have not been well investigated so far. A neuroblastoma x spinal cord hybrid cell line (NSC19: Cashman, 1992) was used for this study. Several established neurotrophic factors were added to the culture medium for 5 min at various concentrations, cultured cells were harvested and processed for western blot analysis using anti-MAPK antibody (erk2) or anti-phosphotyrosine antibody.

Among the factors tested, BDNF, NT-3, GDNF and Midkine, which are known to have neurotrophic actions on motoneurons, phosphorylated MAPK, but CNTF did not. Unexpectedly, MAPK of NSC19 cells was phosphorylated by NGF treatment, which has no trophic effect on motoneurons: showing motoneurons may have changed some characters by hybridization, however, NSC cell cultures are useful system for investigating the signal transduction systems of motoneurons.

## 225.8

**STUDIES ON THE REGIONAL DISPOSITION OF rhNGF AND RELATED NEUROTROPHINS FOLLOWING ICV ADMINISTRATION IN RODENTS.** E. Escandon\*, L. Rangell, G. Keller, E. Szonyi, and J.L. Mendoza-Ramirez. Department of PK-Metabolism, Genentech, Inc. 460 Point San Bruno Blvd. South San Francisco, CA 94080.

Nerve Growth Factor (NGF), Neurotrophin 3 (NT-3) and Neurotrophin 4/5 (NT-4/5) are critical for the survival and maintenance of several neuronal populations in the peripheral nervous system. In the central nervous system these neurotrophins are also able to attenuate and prevent neuronal degeneration. Multineurotrophin 1 (MNTS-1) was the first neurotrophin mutant designed and produced by recombinant DNA technology with full NGF, NT-3 and NT-4/5 combined biological activities (Urfer *et al.* EMBO J. 13:5896-5909, 1994). Since these molecules do not cross the blood brain barrier, the objective of this study was to compare the specific brain regional disposition of NGF, NT-4/5 and MNTS-1 following a single intracerebroventricular (ICV) administration. Our results indicate that <sup>125</sup>I-rhNGF (100 ng/rat) delivered ICV is specifically incorporated by cholinergic neurons in the medial septum, the nucleus of diagonal band of Broca, and nucleus basalis of Meynert. A time course analysis following ICV administration indicated that <sup>125</sup>I-rhNGF remains in specific brain regions for as long as 72 hrs. The disposition of <sup>125</sup>I-rhNGF to the caudate-putamen, cerebellum, pons and specific uptake by the spinal cord will be discussed, as well as a comparative electron microscopy autoradiographic analysis with radiolabeled NGF, NT-5 and MNTS-1. (Commercial funding: Genentech, Inc.)

## 225.10

**NGF INDUCES NEURITE OUTGROWTH AND NUCLEAR TRANSLOCATION OF ERKS DESPITE INHIBITION OF ERK ACTIVITY.** P. Kahle\*, A. N. Verity\*, A. Meyer-Franke\*, J. L. Twiss\*, and E. M. Shooter\*. Depts. \*Neurobiology and \*Pathology, Stanford Univ. School of Medicine, Stanford, CA 94305-5401, and \*Dept. Neurobiology, Inst. Pharmacology, Roche Bioscience, Palo Alto, CA 94304-9819.

Nerve growth factor (NGF) causes growth arrest and differentiation of responsive neurons. A very prominent NGF signaling event is the activation of mitogen-activated protein kinases (MAPKs). These regulate immediate-early gene (IEG) induction via phosphorylation and activation of transcription factors, but the relative contribution of MAPKs to neuronal differentiation remains unclear. We have investigated effects of the cyclin-dependent kinase/MAPK inhibitor Olomoucine on NGF-mediated IEG induction and neurite outgrowth in PC12 cells. Olomoucine did not affect tyrosine phosphorylation nor nuclear translocation of extracellular signal-regulated kinases (ERKs) in response to NGF. Thus, phosphorylation of ERKs rather than activity determines nuclear import. NGF-stimulated activation of the 90kDa ribosomal S6 kinase was decreased by Olomoucine, revealing ERK-dependent and -independent pathways. Olomoucine abrogated ERK-dependent induction of the  $\beta$ -actin gene, while induction of the more complex IEGs *c-fos*, *NGFI-A*, *NGFI-B*, and *c-jun* was delayed. However, Olomoucine minimally affected *vgf* induction, which depends on activation of Ca<sup>2+</sup>/cAMP response element binding protein (CREB) by phosphorylation on Ser-133. Indeed, NGF-induced CREB phosphorylation was not affected by Olomoucine. Finally, Olomoucine inhibited neither neurite initiation nor regeneration. Thus, ERKs appear to be dispensable for NGF-mediated neuronal differentiation due to the massive redundancy of NGF signaling. (Supported by fellowships from Roche Research Foundation, Swiss Nationalfonds, Ciba-Geigy-Jubiläumsstiftung (to P.K.), Deutsche Forschungsgesellschaft (to A.M.-F.), an NIH Training grant (HD0749, A.N.V.), NIH grants (NS01706 to J.L.T., NS04270 to E.M.S.), and by the State of California, Department of Health Services, under contract 93-18647).

## 225.12

**ELUCIDATION OF SIGNALING PATHWAYS UNDERLYING ION CHANNEL INDUCTION DURING GROWTH FACTOR STIMULATED PC12 CELL DIFFERENTIATION.**

M.D. Hilborn, J.D. Pollock\*, R.R. Vaillancourt<sup>1</sup>, & S.G. Rane. Dept. of Biol. Sci., Purdue Univ., W. Lafayette, IN 47907. <sup>1</sup>Nat. Jewish Cen. Immunol. Resp. Med., Denver, CO 80206.

There is a debate as to whether full neuronal differentiation of PC12 cells can be achieved by sustained Ras/ERK activity alone, or by Ras/ERK complemented by other signals. EGF transiently activates Ras/ERK and acts as a mitogen, but it produces morphological differentiation when combined with KCl or cAMP, the latter of which produces sustained Ras/ERK activity (Mark *et al.*, JCB 130:701, 1995; Yao *et al.*, JBC 270:20748, 1995). We have used whole cell patch clamp to ask if upregulation of calcium and sodium channels, hallmarks of physiological differentiation, can be achieved by sustained ERK activation (EGF+cAMP), or ERK activation with depolarization (EGF+KCl). We find that treatment of PC12 cell cultures for 4-7 days with EGF in combination with 0.5 mM cAMP or 60 mM KCl elicits extensive neurite outgrowth, but fails to upregulate sodium and calcium channel currents. These observations demonstrate that sustained Ras/ERK activity alone or in complement with cAMP is insufficient for ion channel upregulation. To identify the signals that are required for physiological differentiation, we are now examining ion channel upregulation in PC12 cell lines transfected with either wild-type PDGF receptor, or mutant receptors deficient for activation of distinct signaling pathways (Vaillancourt *et al.*, MCB 15:3644, 1995). In response to PDGF, PC12 cells exogenously expressing the PDGF receptor extend neurites and show increased current densities comparable to those observed in NGF treated cells. By assessing the ability of mutant PDGF receptors to upregulate calcium channels, we hope to elucidate which specific signaling pathways, in addition to Ras/ERK, are necessary and/or sufficient for ion channel upregulation during neuronal differentiation. ## 225.13

**Staurosporine induces neurite outgrowth and stimulates pp60<sup>src</sup> by trk- and ras-independent signal transduction pathway(s).** P. Lazarovici\*, M. Whalin, H. Jiang, D. Kaplan, and G. Guroff. Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892 and †Montreal Neurological Institute, Montreal, Quebec, Canada.

Staurosporine, a microbial protein kinase inhibitor, is a potent, partial, NGF-functional agonist inducing rapid neurite outgrowth in PC12 cells, independent of protein kinase C inhibition, and dephosphorylation of tau, microtubule-associated proteins. In contrast to NGF-activated, trkA receptor-mediated signal transduction, the signalling pathways responsible for staurosporine-induced neurite outgrowth are unknown. We have used different PC12 cell lines, overexpressing or lacking trkA and dominant-negative ras or src, as model systems to examine the phosphorylation reactions by which staurosporine induces neurite outgrowth. Staurosporine (50 nM) treatment of PC12 cells resulted in a rapid activation of pp60<sup>src</sup> and pp60<sup>yes</sup>, but not Csk (C-terminal src kinase). Staurosporine does not activate trkA tyrosine kinase activity, ras-MAP kinase pathway, PLC-gamma or src-associated neurotrophic factor-induced tyrosine phosphorylated target (SNT) tyrosine phosphorylations. Staurosporine-induced neurite outgrowth is not blocked by a dominant inhibitory mutation of ras or src. Furthermore, staurosporine inhibits S6 kinase activity in PC12 cells. These findings indicate a ras-independent signalling by staurosporine and suggest that the activation of the src family of kinases and the inhibition of S6 kinases, may reflect combinatorial novel signal transduction cross-talk pathways contributing to neurite outgrowth which are distinct from those emanating from the trkA receptor.

## 225.15

**BIOTINYLATION OF NERVE GROWTH FACTOR (NGF) FOR THE STUDY OF RECEPTOR-MEDIATED RETROGRADE TRANSPORT.** J.U. Choh and J.R. Unnerstall\*. Dept. Anatomy and Cell Biology, University of Illinois at Chicago, College of Medicine, Chicago, IL, 60612-7308.

Receptor-mediated retrograde transport of trophic factors like NGF from the nerve terminal to the soma is essential for neurotrophin-mediated signal transduction. To better study the dynamics of this process at the anatomical level, we have synthesized a biologically active biotinylated derivative of 2.5S NGF. A biotinylated NGF probe that retains biological activity, in conjunction with the appropriate avidin-conjugated markers, can improve the sensitivity and resolution with which the receptor-mediated NGF transport pathway is visualized. A similar strategy was first described by Rosenberg et al. (*J. Neurochem.* 46:641, 1986); however, replication of these procedures have not been reported. In contrast to this previous report, our approach utilized gentler labeling conditions and included a streptavidin affinity purification step. To biotinylate NGF (C-biotinyl-NGF), 2.5S NGF (1mg/ml) was incubated with 1.25 mM biotin hydrazide and 1.25% 1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide (EDC) at 4°C overnight. C-biotinyl-NGF was purified from free-NGF with streptavidin-conjugated affinity chromatography. To remove excess biotin hydrazide and EDC, the eluent from the affinity chromatography was concentrated and exchanged with PBS without crosslinking substances. Biotinylation of NGF was confirmed using an enzyme-linked immunosorbent assay (ELISA) against PC12 cells or a plasma membrane preparation of PC12 cells labeled with C-biotinyl-NGF. Biotinylation of 2.5S NGF was further confirmed using Western blots probed with streptavidin-conjugated horseradish peroxidase. The biological activity and potency of C-biotinyl-NGF was confirmed by assessing its effectiveness in promoting neurite outgrowth from PC12 cells. We propose that the procedures utilized to produce C-biotinyl-NGF provide for the synthesis of useful probes for the study of receptor-mediated NGF transport. (Funded by Campus Research Board, University of Illinois at Chicago.)

**STRUCTURE-FUNCTION ANALYSIS OF THE C-TERMINUS OF NGF.** A. Kruttgen\*, J.V. Heymach, P. Kahle, E.M. Shooter. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305-5401

Nerve growth factor (NGF) is a member of the neurotrophin family and plays an important role in development and maintenance of the nervous system. Previous work has shown that the C-terminus of mNGF is important for its function, because deletion of residues 112-120 abolished its bioactivity. In the present study we performed a detailed structure-function analysis of this region by deleting stepwise each of the nine C-terminal residues as well as constructing 6 point mutants. The constructs were transiently expressed in COS-7 cells and quantified by ELISA as well as Western blotting. Biological activity was assessed by using PC12 cells in a short term response -TrkA autophosphorylation on tyrosine residues- as well as a long term response -neurite outgrowth scored after 3 days. Our results show that deletion of residues 116-120 as well as a double point mutant with Arg118 119 changed to SerSer did not decrease NGF bioactivity. Further deletion of the carboxy-terminus led to strongly decreased stability of the mutant proteins -as measured by an ELISA recognizing only the native NGF- possibly because of approaching too close to cysteine 110 which is involved in the "cystine-knot-motif" providing rigidity to the molecule. Five point mutants covering the region between position 111 and 115 showed normal stability and decreased bioactivity at low ligand concentrations. This supports the idea that the C-terminus plays a role in structure and function of NGF. (supported by NIH and DFG)

## 225.14

**TWO DEFINED INDEPENDENT SITES RESPONSIBLE FOR NGF SPECIFICITY ANALYSED BY PURIFIED MUTANT NEUROTROPHINS.**

Klas Kullander\* and Ted Ebendal. Dept. of Developmental Neuroscience, Box 587, Biomedical Center, Uppsala University, S-751 23 Uppsala, Sweden.

Despite the large sequence similarity (60 %) among the known neurotrophins within the NGF family, they display different activities on different subsets of neurons. Recent studies have shown that the various neurotrophins are ligands with high affinity for different receptors of the Trk family of tyrosine kinase receptors. In earlier studies we have defined five NGF-amino-acid residues giving NGF-like activity when exchanged into NT-3. The most efficient NGF-like transformation was obtained by the exchange of Pro-Val and Leu-Val-Gly in NT-3 to the NGF residues Val-Phe (residue#: 48, 49) and Glu-Ala-Ala (96-98). The mutated sites are situated in two b-loops at one end of the NGF molecule, forming a cleft that could interact specifically and with high affinity with the signalling NGF receptor complex. The other independent site, situated in the N-terminal of NGF, was defined by a series of mutations replacing NT-3 corresponding residues. In this case, the least altered molecule with NGF-like activity was obtained when a one amino acid replacement, from a Lys to a Pro (5) and an extra residue, a Phe (7), was inserted into the corresponding position in NT-3. Two mutants each with alterations in defined independent sites were transfected into CHO cells for production of neurotrophins and their expression amplified using methotrexate. The mutant neurotrophins were then purified by selective precipitation and ion-exchange chromatography and were eluted as single bands as judged on 10-20 % gradient SDS-PAGE gels. The activities of the purified mutant neurotrophins were compared with NT-3 and NGF by measuring survival of chicken sympathetic neurons, fibre outgrowth from sympathetic and Basmal's ganglia and activation of the human TrkA and TrkB receptor. Also, the binding of the purified neurotrophins to PC12 cells alone, PC12 cells overexpressing TrkA and PC12 cells lacking endogenous TrkA (PC12nmf) was analysed.

## 225.16

**NEUROTROPHIC ACTIVITY OF SYNTHETIC NGF PEPTIDE DERIVATIVES.** F.M. Longo<sup>1</sup>\*, M. Manthorpe<sup>2</sup>, Y. Xie<sup>1</sup> and S. Varon<sup>3</sup>.

<sup>1</sup>Dept. of Neurology, UCSF/VAMC, San Francisco, CA 94121, <sup>2</sup>Vical Inc., La Jolla CA 92021 and <sup>3</sup>Dept. of Biology UCSD, La Jolla CA 92093.

Synthetic peptides corresponding to  $\beta$ -hairpin loop regions of NGF were purified by HPLC and assayed for neurotrophic activity using dorsal root ganglion sensory neurons. Peptide conformation was constrained by chemical modifications. A peptide corresponding to one loop region had significantly greater survival-promoting activity than peptides corresponding to other loop regions. Assays of ten additional peptides of varying length corresponding to this region showed that peptide fractions P7 and P9 had 70-80% of NGF's maximum activity at concentrations of 125 and 250  $\mu$ M. One group of derivatives was active in the 10-100  $\mu$ M range. P7 peptides resembled partial agonists rather than non-specific trophic agents in that they were inhibitory instead of additive to NGF. Antiserum directed against the extracellular domain of the p75 NGF receptor (supplied by M. Chao) inhibited activity of NGF, P7 and P9 to a similar extent but had no effect on scrambled P7. The Trk receptor inhibitor K252a inhibited NGF but not P7. Ongoing studies will further elucidate structure-activity relationships. Taken together, these studies raise the possibility that NGF peptide derivatives support neuronal survival via a p75 receptor-mediated, Trk kinase-independent mechanism. These derivatives might contribute to developing agonists or partial agonists of NGF. Supported by NIA AG 09873 (FL) and the VA (FL).

**ROLE OF PI-3 KINASE IN NERVE GROWTH FACTOR-MEDIATED DIFFERENTIATION OF PC12 CELLS.** M. Ashcroft<sup>1</sup>\*, R.M. Stephens<sup>1</sup>, and D.R. Kaplan<sup>1,2</sup>.

(SPON: Brain Research Association). <sup>1</sup>ABL-Basic Research Program, NCI-FCRDC, Frederick, MD 21702, and <sup>2</sup> Montreal Neurological Institute, Montreal, PQ H3A2B4.

Nerve growth factor (NGF) treatment of responsive cells results in the stimulation of the activity of many intracellular signalling proteins and several transduction pathways. One of these proteins, phosphatidylinositol-3 kinase (PI-3K), has been implicated in the regulation of cell survival and neurite elongation processes in NGF-treated PC12 cells. To assess the role of PI-3K in NGF-mediated neuronal differentiation, we developed a system whereby endogenous PI-3K activity could be stimulated in an NGF-inducible manner in the absence of the activity of any other known signalling protein. We initially generated a mutant Trk/NGF receptor (Trk<sup>def</sup>) which lacked sequences Y490, Y785 and KFG responsible for recognizing and activating the major Trk intracellular targets Shc, PLC- $\gamma$ 1, PI-3K and SNT. This receptor was kinase active but defective for NGF-induced responses when expressed in PC12 nmr cells, which lack endogenous Trk. Site-directed mutagenesis was used to introduce a PI-3 kinase binding consensus site (YMDM) originally identified in the PDGFR receptor, into the kinase insert domain of Trk<sup>def</sup>. Trk<sup>def</sup> encoding the PI-3K site (Trk<sup>def</sup>+PI-3K) was transfected into PC12 nmr cells and at least 25 stable clones were isolated and screened for expression levels. NGF treatment of the Trk<sup>def</sup>+PI-3K-expressing cells resulted in the activation of PI-3K, however activation of any of the other known intracellular targets of Trk was not observed. In response to NGF, these cells underwent a rapid rate of neurite outgrowth compared to PC12 control cells. These results suggest that PI-3 kinase activity alone is sufficient for the initiation of stable neurite outgrowth in PC12 cells. We will use this system to examine the role of PI-3K in cell survival as a prelude to studies in primary neuronal culture. ## 225.19

REGULATION OF NEUROTROPHIN SIGNALING PATHWAY PROTEINS IN DOPAMINERGIC NEURONS BY DRUGS OF ABUSE. D.H. Wolf, E.J. Nestler, and D.S. Russell\* Division of Molecular Psychiatry, Depts. of Neurology and Psychiatry and the Interdepartmental Neuroscience Program, Yale University School of Medicine, New Haven, CT 06508

Chronic exposure to drugs of abuse induce a number of persistent biochemical and physiological alterations in the dopaminergic neurons of the ventral tegmental area (VTA). These include increases in tyrosine hydroxylase protein levels, decreases in neurofilament proteins, and a reduction in axoplasmic transport from the VTA.

Neurotrophins (NTs) are important mediators of induction and maintenance of neuronal differentiation in the brain. Expression in the VTA of NTs and Trk receptors persists in the adult. Drugs of abuse may exert part of their persistent effects via perturbation of the NTs, the Trks, or the intracellular signaling pathways they utilize. It has been shown that local infusions of NTs including BDNF, NT-3, and NT-4 can prevent or reverse some of the biochemical changes induced by chronic morphine or cocaine (Berhow, MT, et al., *Neuroscience*, 68:969, 1995). Evaluation of NT pathway signaling proteins in adult rat brain reveals that levels of some of these proteins are substantially enriched in the VTA compared with other brain regions. For instance, PLC- $\gamma$ 1 is nearly 20-fold more abundant in VTA than hippocampus or frontal cortex. Chronic exposure to morphine regulates the levels of some of these proteins. After 6 days of morphine exposure, protein levels of PLC- $\gamma$ 1 increased 30%, while levels of insulin receptor substrate (IRS) proteins decreased 25-35%. No significant changes were seen in levels of TrkB, PI-3-kinase, or proteins in the Ras/Raf/ERK signaling pathway. However, morphine exposure regulates the enzyme activities of proteins within this pathway.

Some of these changes are mimicked in PC12 and SHSY-5Y cell lines, and are useful to assist in elucidating molecular mechanisms. (supported by DA08227 and the Ribicoff Research Facilities, State of CT).

GENE EXPRESSION IN THE SPINAL CORD NEURONS AFTER SCIATIC NERVE INJURY OF THE ADULT ANIMALS. JK Cui\*, YC Pan, ZZ Gu, S Shenag, and PK Liu, Baylor College of Medicine, Houston, TX 77030

To demonstrate a dependence of spinal cord motoneurons on the communication with their targets, the expression of immediate early gene *c-fos* and neurotrophin genes in the lumbar (L3-L6) spinal cord neurons was examined in Sprague-Dawley rats (male  $\geq$  9-week old) with unilateral sciatic nerve transection. Using *in situ* hybridization, we detected the expression of *c-fos* mRNA in the motoneurons of the spinal cord segments within 45-min to 3-hr of peripheral nerve transection ( $n=4$  in each time point). The expression of *c-fos* mRNA was also correlated positively with the expression of Fos antigen using immunohistochemistry, while no change in calbindin and parvalbumin antigens were noted. The expression of BDNF mRNA increased at 90 min after sciatic nerve transection. However, no detectable enhancement in the expression of NGF mRNA was observed. DNA fragmentation in neurons was observed using the incorporation of digoxigenin-dUTP by terminal transferase into 3'-OH terminals of DNA fragments in the ipsilateral section of the spinal cords 48 hr after nerve injury. Nuclei that exhibited DNA fragmentation were not observed in the spinal cord of the control animals. Lastly, we observed that the majority of astrocytes did not have DNA fragmentation. Because the detection of DNA fragmentation using this assay is one of early detections of apoptosis or programmed cell death, the result suggested we could detect early cell death in spinal cord, and indicated a target dependence of the neurons in the spinal cord after transection of sciatic nerve. Smith Foundation for Restorative Neurology, the Kent Waldrep Institutes for Paralysis Research, the American Heart Association (94012700) and from the NIH (NS34810) to PKL].

## HORMONES AND DEVELOPMENT: SEXUAL DIFFERENTIATION

## 226.1

HORMONAL REGULATION OF ANDROGEN RECEPTOR (AR) mRNA EXPRESSION IN THE NEONATAL RAT FOREBRAIN. M. McAbee\* and L.L. DonCarlos, Neuroscience Graduate Prog. & Dept. Cell Biol., Neurobiol., and Anatomy, Loyola University of Chicago, Coll. of Med., Maywood, IL 60153.

Testosterone and its metabolites masculinize the developing forebrain. Estrogen is the primary metabolite responsible for this process; however, there is evidence that androgens, via androgen receptors, also play a role in the organization of male-typical behaviors and neuroendocrine regulation. For that reason, we have studied the sites and regulation of AR in the developing forebrain. Previously, we showed that AR mRNA expression was greater in males than in females by postnatal day 10 (PND-10; PND-0 = day of birth), in the medial preoptic area (MPOA) and caudal bed nucleus of the stria terminalis (cBNST). In contrast, AR mRNA levels were not different in males and females in other regions (lateral septum, arcuate n., ventromedial n. of the hypothalamus, and preammillary n.). Gonadectomy on either PND-0 or PND-5 reduced AR mRNA expression in PND-10 males in the MPOA and cBNST but not in other areas. In the present experiments, male rats were gonadectomized on PND-0 and treated daily with diethylstilbestrol (2 $\mu$ g/day), dihydrotestosterone propionate (10 $\mu$ g/day), testosterone propionate (10 $\mu$ g/day) or oil vehicle. Intact males were treated with flutamide (40 $\mu$ g/day), vehicle, or were untreated. Rats were sacrificed on PND-10, and brains were removed and processed for standard *in situ* hybridization using an 35S-labeled riboprobe for AR mRNA. The results to date confirm our previous findings in neonatal rats and suggest a complex pattern of regulation of AR mRNA by gonadal steroid hormones. Supported by NIMH 48794.

## 226.2

ONTOGENY OF ANDROGEN RECEPTOR IMMUNOREACTIVITY IN RAT BRAIN. C. W. Malsbury\* and D. Babstock, Dept. Psychology, Memorial University, St. John's, NF, Canada, A1B 3X9.

We have used the androgen receptor (AR) antibody, PG21, donated by Dr. Gail Prins, with immunohistochemistry to identify AR-immunoreactive (ARir) neurons in male and female rats of various ages. Apparently, PG21 binds much better to ligand-bound, than to unbound, AR. Because of this, male and female littermate pairs were either given a single ip injection of dihydrotestosterone benzoate (DHTB) 30 minutes before perfusion or left untreated before perfusion.

The results show that different brain regions begin to show ARir staining at different times during development. For example, in males the ventral preammillary nucleus (VPM) contains many ARir neurons with dense nuclear staining as early as postnatal day (PND) 1, even without DHTB treatment. In contrast, the posterior-dorsal medial amygdala (MePD) shows little staining at PND 1 or 4. However, by PND 14, MePD contains many ARir neurons in untreated males. Within the hippocampus, areas CA1 and CA3 contain numerous ARir pyramidal neurons in adult male rats. Although some ARir cells are seen in the hippocampus as early as PND 4, the adult pattern of staining is not seen until much later (after PND 14). For example in CA1, at PND 4 most ARir cells are seen just outside the pyramidal cell layer, while in the adult, most are confined to this layer.

Supported by NSERC Grant OGP0007907 to C.W.M.

## 226.3

ANDROGEN RECEPTOR IMMUNOREACTIVITY IN PUDENDAL MOTONEURONAL SUBPOPULATIONS OF THE ADULT MALE RAT. C. L. Jordan\* Dept. Psych., UC Berkeley, CA 94720-1650.

Pudendal motoneurons (MNs) of the adult male rat are grouped in two distinct motoneuronal pools, the spinal nucleus of the bulbocavernosus (SNB), positioned medially, and the DLN, positioned dorsolaterally. Most SNB MNs innervate the sexually dimorphic bulbocavernosus (BC) and levator ani (LA) muscles, and a small number of SNB MNs innervate the sexually monomorphic anal sphincter (AS) muscle. DLN MNs innervate either the sexually dimorphic ischiocavernosus (IC) or the sexually monomorphic external urethral sphincter (EUS) muscles. Collins et al. (Brain Res., '92) report that BC, LA and IC MNs shrink in size after castration whereas AS and EUS MNs do not. This raises the question of whether AS and EUS pudendal MNs have androgen receptors (ARs). I combined Fluoro-Gold retrograde tracing with AR immunoreactivity to answer this question for normal adult male rats. I find that a large percentage of MNs within each subpopulation have AR+ nuclei, including MNs within AS and EUS subpopulations. However, a lower percentage of AS and EUS MNs have AR+ nuclei compared to the other subpopulations. Because androgen may act directly on pudendal MNs to regulate their size (Watson et al., Soc. Neurosci. Abstr., '96) the apparent androgen-insensitivity of AS and EUS MNs may reflect fewer AR expressing MNs in these groups, leading to smaller, less discernible average response to androgen. Future studies will address whether AS and EUS MNs with AR+ nuclei are androgen sensitive. Supported by IBN-9210229 and IBN-9309856.

## 226.4

SYNERGISTIC EFFECTS OF TESTOSTERONE METABOLITES ON DENDRITIC GROWTH IN A SEXUALLY DIMORPHIC RAT SPINAL NUCLEUS. E.M. Kurz\*, K.A. Burke, M.B. Widows, and D.R. Sengelaub, Program in Neural Science, Indiana University, Bloomington, IN 47405.

Motoneuron dendrites in the spinal nucleus of the bulbocavernosus (SNB) grow exuberantly through postnatal day (P)28. This growth is steroid-dependent: dendrites fail to grow in males castrated at P7, but grow normally in castrates treated with testosterone (T). Treatment with either of the T metabolites dihydrotestosterone (DHT) or estrogen (E) alone supports dendritic growth in castrates, but not to normal male or T-treated castrate levels. Furthermore, in intact males treated with the E antagonist tamoxifen, dendritic growth is reduced to levels seen in DHT-treated castrates, suggesting that E is necessary for normal SNB dendritic growth. In this study, we tested the hypothesis that DHT and E act together to support development of SNB dendrites.

Dendritic morphology was assessed in normal males and males castrated on P7 and treated daily with DHT (dihydrotestosterone propionate, 2 mg/day) combined with low or high doses of E (estradiol benzoate, 5  $\mu$ g or 100  $\mu$ g/day) ( $n=4$  per group). SNB motoneurons were retrogradely labeled with cholera toxin-HRP at P28, when dendritic length is normally maximal, and motoneuron morphology assessed in three dimensions (Eutectic NTS). Dendritic lengths in DHT+high E-treated castrates (mean=5855  $\mu$ m) were like those of normal males (mean=5614  $\mu$ m). In contrast, dendritic lengths of DHT+low E-treated castrates (mean=3836  $\mu$ m) were significantly shorter than those of both normal males and DHT+high E-treated castrates. These results suggest that E and DHT act synergistically to support normal masculine SNB dendritic development. Supported by NIH NS24877.

## 226.5

**Brain-Derived Neurotrophic Factor Regulates Expression of Androgen Receptor in Perineal Motoneurons.** H.A. Al-Shamma\* and A.P. Arnold, Dept. of Physiological Science and Laboratory of Neuroendocrinology, Brain Research Institute, UCLA, Los Angeles, CA 90095-1527.

In adult male rats, axotomy of the spinal nucleus of the bulbocavernosus (SNB) motoneurons causes a reduction in expression of nuclear androgen receptor (AR), which is reversed when the motoneurons reinnervate the target perineal muscles. The present experiments further characterize the role of target-derived factors in the regulation of motoneuronal AR. We studied AR immunoreactivity in SNB motoneurons one week after these motoneurons were either 1) silenced with TTX, 2) treated with an axoplasmic transport blocker, vinblastine, or 3) axotomized and treated with one of several neurotrophic factors. Unilateral activity blockade with TTX did not alter the density of AR immunoreactivity. In contrast, unilateral blockade of axoplasmic transport with vinblastine significantly reduced the number of densely labeled AR-immunoreactive motoneurons to 28% of that on the untreated control side ( $p < 0.0001$ ). These studies suggest that AR expression in the SNB is not dependent on neuromuscular activity, rather it is dependent on factors that are retrogradely transported to the SNB motoneurons. We tested different protein trophic factors as possible regulators of AR expression in the SNB. Unlike other trophic factors (CNTF and NT-4), treatment of severed SNB axons with gel foam soaked in brain-derived neurotrophic factor (BDNF, 2.9mg/ml in PBS) significantly blocked the axotomy-induced down regulation of AR immunoreactivity ( $p < 0.05$ ). These results indicate that protein trophic factors can regulate expression of steroid receptors in neurons.

This work was supported by National Institutes of Health grant MH10839 (H.A.A.).

## 226.7

**NEONATAL DEVELOPMENT OF THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS IN THE MONGOLIAN GERBIL: A LIGHT MICROSCOPIC THIONIN STUDY.** G.S. Fraley\* and C. Ulibarri, Department of Veterinary & Comparative Anatomy, Pharmacology and Physiology, College of Veterinary Medicine, Washington State University, Pullman, WA 99164-6520.

The spinal nucleus of the bulbocavernosus (SNB) of the Mongolian gerbil (*Meriones unguiculatus*) is located in the lumbosacral spinal cord in area X. The SNB innervates perineal musculature and is sexually dimorphic in that male gerbils have more and larger SNB motoneurons than do female gerbils. To examine the normal postnatal development of the gerbil SNB, groups of male and female gerbils were aldehyde perfused at ages from postnatal day 1 (PND1) through PND15 and PND25. Spinal cords were dissected, cryoprotected, and embedded in 5% gelatin. Spinal cords were then sectioned coronally (50  $\mu$ m) on a cryostat, mounted on slides and stained with thionin. SNB motoneurons were counted by an individual unaware of the treatment groups. Statistical analyses were conducted using analysis of variance. At birth male gerbils had more SNB motoneurons than did female gerbils. The number of SNB motoneuron number increased over time. However, at all ages male gerbil pups had significantly more SNB motoneurons than did female gerbil pups (mean  $\pm$  SEM; PND1  $\sigma = 76.8 \pm 7.3$ ,  $\phi = 36.6 \pm 9.6$ ; PND3  $\sigma = 89.5 \pm 16.5$ ,  $\phi = 48.3 \pm 4.3$ ; PND6  $\sigma = 172.8 \pm 9.1$ ,  $\phi = 55.5 \pm 11.3$ ; PND9  $\sigma = 235.3 \pm 25.1$ ,  $\phi = 42.3 \pm 6.8$ ; PND12  $\sigma = 244.5 \pm 19.3$ ,  $\phi = 63.7 \pm 8.3$ ). The maximal number of SNB motoneurons seen in males at PND25 ( $250 \pm 7.5$ ) was lower than that reported previously for adult males. In contrast, the maximal number of SNB motoneurons seen in females on PND15 ( $58.7 \pm 1.3$ ) was equivalent to that reported in adult females. This study suggests that the developmental pattern in the SNB of gerbils is different than the developmental pattern in the rat. This research was supported by NSF (BNS-9112097) to CU.

## 226.9

**INCIDENCE OF PYKNOTIC CELLS IN THE PREOPTIC AREA OF NEONATAL RATS.** L.L. DonCarlos\* & K. Schwenk. Dept. Cell Biol., Neurobiol., & Anat., Loyola Univ. Stritch Sch. Medicine, Maywood, IL 60153.

Exposure to the estrogenic metabolites of testosterone during the early postnatal period has permanent effects on rodent brain development. One effect of estrogen exposure is to alter the number of cells in specific regions of the preoptic area (POA), such as the central portion of the medial preoptic nucleus (MPNc), which is more cell dense in males, and the anteroventral periventricular nucleus, which is more cell dense in females. In the present studies, we examined the number and distribution of pyknotic cells throughout the perinatal period in order to determine both where and when cell death occurs in this region. Sprague-Dawley rat pups (postnatal day 0, 4, 7 and 10; PND 0=day of birth) were anesthetized and perfused with 10% formalin. Brains were embedded in paraffin and cut at 6 microns on a rotary microtome. Sections were stained in toluidine blue, dehydrated, cleared and coverslipped. A subjective analysis showed that the number of pyknotic cells in the medial POA as a whole was highest on PND 0 and 4, and more pyknotic cells were found in the caudal POA than in the rostral POA. Neurons of normal and pyknotic appearance were then counted within the caudal MPNc. The density of total cells decreased in the caudal MPNc with age and was not different in males and females. In contrast, the density of pyknotic cells in the caudal MPNc was highest on PND 7 in both males and females, and higher in females than in males. Further analyses of the distribution and relative abundance of pyknotic cells in the POA are in progress. Supported by NIMH 48794.

**DEVELOPMENT OF SEXUAL DIMORPHISM IN CNTF-RECEPTOR KNOCKOUT MICE.** M.L. Howell<sup>1</sup>, T.M. DeChiara<sup>2</sup>, G.D. Yancopoulos<sup>2</sup> and N.G. Forger<sup>1</sup>. <sup>1</sup>Neuroscience and Behavior, University of Massachusetts, Amherst, MA, and <sup>2</sup>Regeneron Pharmaceuticals, Tarrytown, New York.

The spinal nucleus of the bulbocavernosus (SNB) is a sexually dimorphic neuromuscular system in rodents. Motoneurons of the SNB are located in the lumbar spinal cord and innervate perineal muscles that attach to the base of the penis. During prenatal development, males and females have comparable numbers of SNB cells. Androgen secreted from the testes maintains these motoneurons in males whereas they die in females during the late prenatal and early postnatal period. The administration of testosterone can prevent the death of SNB cells in females. Recently, ciliary neurotrophic factor (CNTF) has been shown to mimic some effects of testosterone in development of the SNB system. Specifically, perinatal CNTF treatment prevents degeneration of SNB motoneurons and their target muscles. To examine whether the CNTF receptor is required for the normal development of sexual dimorphism in the SNB, we counted SNB motoneurons in mice with a null mutation of the alpha component of the CNTF receptor. CNTF receptor knockouts (CNTF<sup>-/-</sup>) exhibit significant motoneuron death and do not survive beyond postnatal day 1 (DeChiara et al., 1995). SNB cell number was reduced in both male and female CNTF<sup>-/-</sup> newborns as compared to their CNTF<sup>+/+</sup> counterparts ( $p < 0.05$ ), as would be expected. However, the percent reduction in the SNB was greater than the reduction in the lateral horn. When expressed relative to motoneuron number in the lateral horn of the same spinal segments (# of SNB motoneurons divided by # of lateral horn motoneurons), CNTF<sup>-/-</sup> males had significantly fewer motoneurons in the SNB than did CNTF<sup>+/+</sup> males ( $p < 0.001$ ), and CNTF<sup>-/-</sup> males did not differ significantly from CNTF<sup>+/+</sup> or CNTF<sup>-/-</sup> females on this measure. Thus, deletion of the CNTF receptor may reduce or eliminate the development of a sex difference in the SNB.

Supported by NIH HD33044 and the Whitehall Foundation.

## 226.8

**POSTNATAL DEVELOPMENT OF 5 $\alpha$ -REDUCTASE-CONTAINING CELLS IN THE RAT FOREBRAIN.** Y. Tsuruo\*, H. Yokoi and K. Ishimura. Dept. of Anatomy, Tokushima Univ. Sch. of Med., Tokushima, 770, Japan

Steroid 5 $\alpha$ -reductase (5 $\alpha$ -R) is the enzyme converting steroids with C-3 ketone and C-4,5 double bond to 5 $\alpha$ -dihydro form. The enzyme is known to be preferentially localized in the white matter rather than the gray matter, and the enzyme activity is shown to be high during the first 1-2 weeks of postnatal life, when the active myelination occurs. To further investigate the localization and characteristics of 5 $\alpha$ -R-containing cells, we raised a rabbit antibody against a rat 5 $\alpha$ -R type-1, and the localization of 5 $\alpha$ -R-containing cells was immunohistochemically examined in the rat brain. During the first week of postnatal life, positive immunoreaction was observed in small cells within the subventricular zone (SVZ) adjoining the lateral ventricle and in the neighboring white matter including the corpus callosum. Some of these cells were shown to be mitotic. Following several weeks, the intensity of immunostaining as well as the number of 5 $\alpha$ -R-positive cells increased in the white matter. These cells appeared to consist of two morphologically different cells: one had a few fine processes and the other showed several radiating processes. By double immunostaining using antibodies against several glial markers, most of these 5 $\alpha$ -R-positive cells were shown to be oligodendrocytes, and some were astrocytes. These results suggest that the cells containing 5 $\alpha$ -R, mostly oligodendrocytes, are primarily generated in the SVZ early in the postnatal life, and gradually distributed to the white matter region in the forebrain during development.

## 226.10

**A REGIONAL SEX DIFFERENCE IN THE SIZE OF THE LOCUS COERULEUS OF THE SPRAGUE-DAWLEY RAT.** D. M. Babstock\*, C. W. Malsbury and C. W. Harley. Dept. Psychology, Memorial Univ. Newfoundland, St. John's, NF, Canada, A1B 3X9.

Previous studies indicate that the locus coeruleus (LC) can be divided into subareas depending upon dominant efferent projection zones. Ascending projections to the forebrain originate within the dorsal half and projections to the spinal cord and the cerebellum course from the ventral half of the LC. Using Sprague-Dawley rats, the present study analyzed sex differences in total LC area and in ascending and descending projection zones. Horizontal sections were stained with cresyl violet or for tyrosine hydroxylase and it was found that the dorsal ascending projection zone is larger in the male. One of the well-defined subareas within the dorsal half of the LC provides noradrenergic innervation of the hippocampus, a structure that exhibits various male-dominated sex differences in the rat, and post hoc analysis localized the sex difference to this area of the LC. No difference was found in total LC area. As well, a sex difference is indicated in the shape of the LC by a longer anterior-posterior extent in males, while females have a greater dorso-ventral extent. UNBIASED STEREOLOGICAL STUDY AND GOLGI ANALYSIS OF THE SEXUALLY DIMORPHIC NUCLEUS OF THE MEDIAL PREOPTIC AREA. L. Xue, J. P. Andrade, M. M. Paula-Barbosa and M. D. Madeira\*. Dept. of Anatomy, Porto Medical School, 4200 Porto, Portugal.

The effects of gonadal steroids on the anatomy of the sexually dimorphic nucleus of the medial preoptic area (SDN) have been much studied, both during development and in the adult rat. However, apart from volume estimations, precise morphometric analyses of this nucleus are still lacking. Thus, we have estimated the total number of SDN neurons, using the fractionator method, and the mean volume of its neurons, by applying the nucleator to vertical sections. In addition, we have performed a metric analysis of the dendritic trees of SDN neurons. We found that in males the total number of neurons was 2.3x higher and the mean cell volume 1.4x greater in males than in females, and that these differences accounted for the male/female differences in the volume of SDN, which we found to be 3x greater in males than in females. Conversely, the total dendritic length, the total number of segments, the dendritic density and the number of spines per unit length of bipolar and multipolar neurons were globally greater in females than in males. However, the differences were significant only for the number of terminal segments of bipolar and multipolar cells and for the dendritic density of the proximal part of the dendritic trees of multipolar cells.

These findings show that the sex differences in neurites are less robust than those present in neuronal numbers and volumes, which demands accurate studies at the ultrastructural level for a further characterization of the influence of gonadal steroids on the structural organization of the SDN.

## 226.13

DIFFERENTIAL EXPRESSION OF GABA<sub>A</sub> RECEPTOR SUBUNITS IN MALE AND FEMALE NEONATAL RAT BRAIN Aline M. Davis\*<sup>1</sup>, Silke Penshuck<sup>2</sup>, Jean-Marc Fritschy<sup>2</sup>, and Margaret M. McCarthy<sup>1</sup>. 1-Dept. of Physiology, University of Maryland, Baltimore MD 21201. 2-Institute of Pharmacology, University of Zurich, CH-8057 Zurich Switzerland.

Sex differentiation of the rat brain is dependent upon the hormonal milieu during pre- and postnatal development. The mechanisms of differentiation are not well understood. We examined the role of the GABAergic system in mediating these differences and in establishing the sex specific phenotypes of the adult rat brain. GABAergic neurotransmission is well established early in development and promotes neurite outgrowth and cell survival in neonatal tissue. It is also regulated by steroid hormones in the adult. Evidence indicates pharmacological properties of the GABA<sub>A</sub> receptor vary with subunit composition, and that there is a developmental change in the ratio of  $\alpha 2$  to  $\alpha 1$  subunits in some brain areas. Therefore, we examined sex differences in subunit expression in neonatal rat brain.

Using an RNase protection assay (RPA), we have evaluated message levels for the  $\alpha 1$  and  $\alpha 2$  subunits in postnatal day 1 (PN1) rat brain. Brain regions were chosen for known content of GABAergic and/or estrogen receptor containing neurons. For both  $\alpha 1$  and  $\alpha 2$  we found sex differences in the ventromedial nucleus (VMN) and the arcuate nucleus (ARC). In the VMN, males had a higher abundance of mRNA for both subunits [ANOVA,  $p < .01$ ]. However, in the ARC, levels were higher in females [ANOVA,  $\alpha 1$   $p < .05$ ;  $\alpha 2$   $p < .01$ ]. No differences were found in the medial preoptic area (mPOA), CA1 region of the hippocampus or the cingulate cortex (CTX). We also examined differences in  $\alpha 1$  protein content by immunocytochemistry (ICC) in PN4 rats. The ICC data correspond with our RPA data, showing a more dense staining for  $\alpha 1$  in the VMN of males [t-test,  $p < .05$ ]. Therefore, we conclude that receptor subunit expression is sex dependent during the critical period, and that GABA plays a significant role in sex differentiation of the brain. This project was supported by NIH grant R29MH52716 to MMM.

## 226.15

DEVELOPMENT OF A SEXUALLY DIMORPHIC POPULATION OF PREPROCHOLECYSTOKININ mRNA CONTAINING NEURONS IN THE MEDIAL AMYGDALA OF THE RAT. D.S. Rising In\* and R.B. Simerly. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006, and Department of Cell and Developmental Biology, Oregon Health Sciences University, Portland, OR 97201.

The posterodorsal part of the medial nucleus of the amygdala (MeApd) relays olfactory information to the hypothalamus and contains a hormonally regulated population of cholecystokinin (CCK)-containing neurons in adult rats. Moreover, the MeApd contains high densities of cells that express gonadal steroid hormone receptors, and both the MeApd and CCK have been implicated in the regulation of reproductive behavior and gonadotropin secretion. Because the MeApd is thought to sexually differentiate during the perinatal period, we used *in situ* hybridization to evaluate the pattern of preprocholecystokinin (PCK) mRNA expression in the MeApd between embryonic day 18 (E18) and postnatal day 28 (P28). Very few PCK mRNA containing neurons were found in the MeApd on E18, but a compact, sexually dimorphic population of cells was identified in the lateral part of the MeApd as early as postnatal day 0. By the second postnatal day (P2) male rats had approximately 4 times as many PCK mRNA containing neurons in this cell group compared with that of females, and this difference was maintained through P28. To test the role of postnatal sex steroids in the regulation of this developmental pattern, newborn female rats were treated with testosterone during the postnatal period and levels of PCK mRNA were measured in the MeApd. The results indicate that sex steroids have a profound influence on PCK expression in the MeApd during the postnatal period, but that prenatal hormone exposure may also affect the number of neurons in the MeApd that can display the CCK phenotype.

## 226.12

SEX DIFFERENCES IN NON-NMDA GLUTAMATE RECEPTOR BINDING IN NEONATAL RAT BRAIN. M.M. McCarthy\*, K.Y.S. Chan and J.G. Pfau. Dept. of Physiology, Univ. of Maryland, Baltimore, MD and Dept. of Psychology, Concordia Univ., Montreal CA.

The perinatal period of the rat constitutes a sensitive developmental window for steroid hormone mediated sexual differentiation of the brain. Changes in neurotransmission may be important regulators of differentiation. On the day of birth (PN 0), rats were divided into four treatment groups: 1) castrated males injected with testosterone propionate (TP, 50µg) or 2) oil vehicle, 3) females injected with TP, or 4) oil. On PN3, brains were collected and prepared for *in vitro* receptor autoradiography. Binding to the non-NMDA glutamate receptor was assessed by incubating fresh frozen slide-mounted tissue sections in [<sup>3</sup>H]-glutamate in the presence of AP5 to block NMDA receptors and AP3 to block metabotropic glutamate receptors. Following appropriate washes, slides were exposed to tritium sensitive film for 8 weeks. Densitometry analysis of the films was performed using NIH Image. Results indicate that in the posterior portion of the ventromedial nucleus (VMN) there is significantly higher binding in males and females treated with TP (2-way ANOVA,  $p < .05$ ). The same effect was seen, but to a lesser degree, in the medial preoptic nucleus ( $p < .05$ ). In the anterior VMN, binding was significantly higher in males than females independent of hormone treatment ( $p < .05$ ). There were no sex or hormone effects in the dorsolateral septal nucleus, cortex or most regions of the hippocampus. In a separate group of animals, immunocytochemistry for glutamate indicated a large number of glutamate immunoreactive neurons in the VMN on PN3, suggesting a population of glutamate interneurons exists in this brain region. By contrast, glutamate immunoreactivity in the preoptic area was broadly distributed. There were no obvious sex differences in the distribution of glutamate immunoreactive cells. In conclusion, steroid modulation of the glutamatergic system in the hypothalamus may be an important mediator of sexual differentiation of brain. ## 226.14

POSTNATAL CHANGES IN ESTROGEN RECEPTOR, SUBSTANCE P AND CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY IN RAT SENSORY NEURONS. S. Sarajeri\* and M.M. Oblinger. Dept. Cell Biol. and Anat., Chicago Medical School, N. Chicago, IL 60064

In adult dorsal root ganglia (DRG), calcitonin gene-related peptide (CGRP), Substance P (SP) and estrogen receptor (ER) appear to be co-expressed in many of the small-sized nociceptive neurons. CGRP immunoreactivity (IR) is also seen in some medium and large-sized DRG neurons while SP-IR, as well as nuclear ER-IR, is largely restricted to the small sensory neurons in the adult. Recently we have found that estrogen treatment affects the levels of SP-IR (reduces) and CGRP-IR (increases) in DRG neurons. In the present study, we were interested in determining how the levels of SP and CGRP change in the DRG relative to ER during postnatal development. Lumbar DRGs were harvested from rat pups at postnatal (P) days 5, 10, 21 and 30; histological sections were stained with a variety of polyclonal and monoclonal antibodies. The results showed that nuclear ER-IR was present at the earliest times examined (P5) and was restricted to only the small neurons at all times examined (rather than being widely expressed at early times and then becoming more restricted in expression). SP-IR followed a largely similar pattern of change as ER. CGRP-IR at early postnatal times was similar to the adult pattern in that small, medium and some larger DRG cells were positive for this peptide. It will be of interest to determine how the establishment of peptide and ER expression in the DRG is related to gonadal steroid status.

## 226.16

SEX DIFFERENCE IN GALANIN IMMUNOREACTIVITY IN THE FERRET PREOPTIC AREA/ANTERIOR HYPOTHALAMUS J.J. Park\*, S.A. Tobet and M.J. Baum. Department of Biology, Boston University, Boston, MA 02215 and Department of Biomedical Sciences, The Shriver Center, Waltham, MA 02254

A sexually dimorphic male nucleus (MN) is seen in Nissl-stained sections of the dorsal preoptic area/anterior hypothalamus (POA/AH) of male ferrets, but not females, beginning as early as embryonic day (E) 37 of a 41-day gestation. In the POA/AH of ferrets we assessed the distribution of several neuropeptides previously reported to be sexually dimorphic in various rodent species, using immunohistochemistry. In males killed on E38, a dense cluster of galanin-immunoreactive (GAL-IR) cell bodies and processes was present in the dorsal POA/AH, beginning rostrally at the level of the diagonal band of Broca and extending caudally to include much of the MN-POA/AH and ending in the ventral bed nucleus of stria terminalis. In E38 females no GAL-IR cell bodies and processes were found in the dorsal POA/AH, although both sexes had a GAL-IR group in the ventral POA/AH. A sexually dimorphic group of GAL-IR cell bodies and processes was also seen in the dorsal POA/AH of adult males. Castration removed this dimorphic GAL-IR elements whereas administration of testosterone propionate (TP) reversed this effect. Administration of TP to ovariectomized adult females augmented the number of GAL-IR cell bodies and processes in the dorsal POA/AH, but not to the degree seen in males. Thyrotropin-releasing hormone, leucine-enkephalin and neurotensin IR elements were present in the POA/AH at E38 and in adulthood; their distribution was not sexually dimorphic. Arginine-vasopressin, oxytocin, vasoactive intestinal polypeptide, calcitonin gene-related peptide and somatostatin IR elements were not seen in the POA/AH of either fetal or adult ferrets. Our findings raise the question of whether galanin neurons in the dorsal POA/AH contribute to sexually allomorphic behavioral or neuroendocrine functions in this carnivore (Supported by HD21094; MH00392 and IBN94-10426).

## 226.17

ESTROGEN STIMULATES CCK AND PREPROENKEPHALIN mRNA IN THE FEMALE RAT LIMBIC-HYPOTHALAMIC CIRCUIT DURING THE PERIPUBERTAL PERIOD. K.L. Holland\*, L. Abelson and P.E. Micevych. Dept. of Neurobiology, Laboratory of Neuroendocrinology, Brain Research Institute, UCLA. Los Angeles, CA 90095.

CCK mRNA and peptide are expressed in regions of the rat central nervous system at neonatal ages. Within the limbic-hypothalamic circuit, however, the expression of CCK is delayed. Our developmental time course shows that during the neonatal period CCK mRNA levels are below the level of detectability in the medial preoptic nucleus (MPN), the principal nucleus of the stria terminalis (BNST) and the posterodorsal medial amygdaloid nucleus (pdMeA). Cells begin expressing elevated levels of CCK mRNA and peptide during the peripubertal period and in the adult, estrogen induces CCK expression within the interconnected cell groups of this circuit. The objective of this study was to determine if exogenous estrogen is able to induce the expression of CCK mRNA in the developing limbic-hypothalamic circuit. On PND 1, 10, 13, 18 and 23, female rats were subcutaneously injected with 25µg estradiol benzoate (EB), EB and 50µg progesterone or were untreated. All rats were sacrificed 48 hours after estrogen treatment and alternate brain sections were processed for CCK and PPE mRNA in situ hybridization histochemistry. EB induced PPE mRNA at all ages, while CCK mRNA expression was not increased by steroids until PND 20. Progesterone did not augment the estrogen effect on CCK or PPE mRNA levels. These results suggest that estrogen receptors are present and functional in the neonatal brain, as evidenced by the induction of PPE mRNA at all ages. Estrogen sensitive transmission within the limbic-hypothalamic circuit have not yet been established, or components of second messenger cascades which regulate estrogenic induction of CCK expression in the adult may not be functional before PND 20. Supported by NS21220 and T32-GM07185.

## 226.19

ORGANIZATIONAL EFFECTS OF ESTRADIOL ON D<sub>2</sub> AND 5-HT<sub>2</sub> RECEPTORS. J. Williams\*, D. Bell, F. Bell, B. Knight, E. Knight, and B. Ludrick. Dept. Biol. Sci., Southeastern Oklahoma State Univ., Durant OK 74701.

Perturbations of perinatal brain sexual differentiation may be contributing factors in some cases of schizophrenia. During development, testosterone exerts organizational effects on brain differentiation. In early adulthood organizational effects of steroids may become manifested in the overt symptoms of schizophrenia. This study examined the organizational effects of gonadal steroids on the dopaminergic and serotonergic systems. Three day old F-344 rats were used. Male pups were castrated or sham operated and female pups were injected s.c. with 1 µg estradiol benzoate or vehicle. At 20 days of age animals were sacrificed. Immediately following sacrifice the brain was removed and the prefrontal cortex, striatum, and hippocampus were dissected out over ice and stored at -80°C until used in membrane preparations. Membrane preparations were used for Scatchard analyses of the D<sub>2</sub> and 5-HT<sub>2</sub> receptors. Organizational effects on receptor binding parameters appeared to be similar for castrated males/control females and for control males/estradiol-treated females. D<sub>2</sub> and 5-HT<sub>2</sub> receptors had a higher affinity (lower K<sub>d</sub>) and greater receptor density (higher B<sub>max</sub>) in the castrated male/control female groups relative to the control male/estradiol-treated female groups.

Funding provided by NIGMS grant number 1 R21 GM54420-01.

## 226.18

IDENTIFICATION OF ESTROGEN RECEPTOR TARGET GENES IN THE NEUROBLASTOMA CELL LINE SK-ER3. M. Garnier, D. Di Lorenzo\*, and A. Maggi\*. Inst. of Pharmacol. Sci., Milan-I 20133. Hormonol. and Toxicol. Lab., Brescia Civic Hosp., Brescia-I 25100.

To study the activity of estrogen receptor (ER) in cells of neural origin, the ER expressing SK-ER3 cell line was obtained by stable transfection of ER in neuroblastoma cells. In these cells, estrogen (E2) causes growth arrest and differentiation. To identify the ER target genes relevant to the effects of E2 on the cell cycle and differentiation, we compared the mRNA patterns from E2-treated versus non treated SK-ER3 cells using the mRNA differential display PCR technique and combining different sets of oligo-(dT)11 (with M = A, G or C) and 10-mer arbitrary primers in the PCR reactions. The analysis of the radiolabeled amplification products on denaturing polyacrylamide gels evidenced 19 bands which were reproducibly differentially expressed. These products were reamplified, directly sequenced by cycle sequencing, labeled with digoxigenin and used as probes for Northern blots analysis to confirm their pattern of regulation following hormonal treatment.

Several genes appeared to be regulated in the neuroblastoma cells in response to E2. Among these genes, one appears to be essential for cell proliferation. Results will be discussed with emphasis on the role of the ER target genes in the effects of E2 on growth and differentiation of neuroblastoma cells.

## 226.20

DISRUPTION OF THE ESTROGEN RECEPTOR GENE INTERFERES WITH SEXUAL DIFFERENTIATION OF DOPAMINE NEURONS IN THE PREOPTIC REGION OF THE MOUSE. R.B. Simerly<sup>1,2</sup>, K.S. Korach<sup>3</sup>, D.B. Lubahn<sup>3</sup> and M. Zee<sup>1</sup>. <sup>1</sup>Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006 and <sup>2</sup>Department of Cell and Developmental Biology, Oregon Health Sciences University, Portland, OR 97201, <sup>3</sup>NIHES, Research Triangle Park, NC 27709.

Although it has been known for some time that estrogen exerts a profound influence on brain development and the expression of sexually dimorphic functions, a definitive demonstration of the role of the estrogen receptor (ER) in sexual differentiation has remained elusive. In rats the anteroventral periventricular nucleus (AVPV) plays an essential role in mediating the preovulatory gonadotropin surge and contains a sexually dimorphic population of dopamine neurons that develops under the influence of perinatal sex steroids. This neurochemical sex difference is also present in adult C57BL/6J mice: female animals have a 4-fold greater number of tyrosine hydroxylase (TH) immunoreactive neurons in the AVPV relative to the number found in males. We tested the dependence of this neurochemical sex difference on a functional ER by comparing the number of TH-immunoreactive neurons in the AVPV of male wild type mice (WT) with that of male mice (ERKO) in which the ER had been disrupted by homologous recombination. The number of TH-immunoreactive neurons in the AVPV of ERKO mice was 3 times that of WT littermates suggesting that disruption of the ER gene prevented the hormonally induced loss of TH-immunoreactive neurons that normally occurs in males. Moreover, sexually dimorphic nuclei such as the bed nucleus of the stria terminalis and medial nucleus of the amygdala appear to be demasculinized in ERKO animals. These results indicate that a functional ER is essential for sexual differentiation of dopaminergic neurons in the AVPV, and perhaps plays a role in the development of other sexually dimorphic features of the mouse brain as well. Supported by NIH grants MH49236 and RR00163.

## NEURONAL DEATH: INTRACELLULAR SIGNALS

## 227.1

THE ISOQUINOLINESULFONAMIDE-SENSITIVE PATHWAY IS INVOLVED IN NEURONAL APOPTOSIS INDUCED BY DIVERSE STRESSFUL STIMULI. C.M. Cagnoli\* and H. Maney. ASRI, Medical College of Pennsylvania and Hahnemann University, Allegheny Campus, Pittsburgh, PA. 15212.

We previously reported that a group of isoquinolinesulfonamide kinase inhibitors, IQS (H-7, 1-(5-isoquinolinesulfonyl)-2-methylpiperazine; H-8, N-[2-(methylamino)ethyl]-5-isoquinolinesulfonamide; and H-9, N-2-(aminoethyl)-5-isoquinolinesulfonamide) prevents apoptosis triggered in neurons by the inhibition of phosphatases 1 and 2A with okadaic acid, and by the inhibition of protein kinase C with staurosporine and chelerythrine (*J. Mol. Neurosci.*, 1996, in press). In the present study, we assessed the ability of IQS to prevent apoptosis induced in primary cultures of rat cerebellar granule neurons by diverse stressful stimuli. We selected three groups of stressors: a) treatment with ceramide C-2, a stimulator of stress-activated kinases; b) neurotoxins, i.e., beta-amyloid peptide and lead ion; and c) serum removal and potassium deficiency. Apoptosis was assayed by morphological appearance after nuclear staining with propidium iodide, DNA ladder, and by the in-situ TUNEL assay. Cell death was assessed by quantitative assay of membrane permeability to trypan blue dye. The IQS prevented apoptosis in all the above-noted models. It appears that the IQS-sensitive pathway is a common mechanism in different types of apoptosis. Because the anti-apoptotic action of IQS did not correlate with the known selectivity of these drugs in inhibiting protein kinases, nor could it be attributed to the antioxidative action of IQS, we propose that the IQS-sensitive pathway of neuronal apoptosis might involve the activation of a protein kinase not yet identified. Elucidating this mechanism may provide us with new strategies in the design of novel neuro-protective drugs.

## 227.2

STRESS-ACTIVATED PROTEIN KINASES, c-JUN, AND PROGRAMMED CELL DEATH IN THE DEVELOPING NERVOUS SYSTEM. J.R. Whitfield, A. Eilers, D. Lallemand\*, L.L. Rubin\* and J. Ham. Eisai London Research Laboratories, University College London, Gower Street, London, WC1E 6BT, UK and #Unité des Virus Oncogènes, Institut Pasteur, Paris, France.

When deprived of NGF, sympathetic neurons die by apoptosis and this death requires transcription and protein synthesis. We have studied the role of the Jun and Fos (AP-1) family of transcription factors in this process. We found that the level of c-Jun protein increased after NGF withdrawal and that c-Jun became highly phosphorylated on its transcriptional activation domain. Microinjection into sympathetic neurons of an expression vector for full length, wild-type c-Jun induced apoptosis. Furthermore, overexpression of a c-Jun dominant negative mutant protected sympathetic neurons against cell death after NGF withdrawal. These results suggest that the AP-1 family, and in particular c-Jun, plays a key role in neuronal cell death due to survival factor withdrawal.

We are currently studying the signal transduction pathways that lead to the activation of c-Jun after NGF withdrawal. One candidate for the kinase which activates c-Jun is Jun kinase (JNK, a stress-activated protein kinase), which phosphorylates c-Jun on serines 63 and 73 in the transactivation domain. In immune complex kinase assays we have found that Jun kinase activity increased when sympathetic neurons were deprived of NGF. Consistent with this, an antibody that specifically recognises c-Jun phosphorylated at serine 63 stained the nuclei of sympathetic neurons after NGF withdrawal. JNK is normally activated by SEK1 which in turn is activated by MEKK1. Microinjection of an expression vector for an activated form of MEKK1 induced the expression of c-Jun protein in the presence of NGF, and caused the injected cells to die by apoptosis. Co-injection of a SEK1 dominant negative mutant (SEK AL) inhibited MEKK1-induced cell death. These results indicate that an increase in the level of JNK activity is sufficient in itself to induce the expression of c-Jun protein and cell death. Source of funding: Eisai Co. Ltd. (Japan).

**BRIEF TREATMENT WITH PHORBOL ESTER PROTECTS CORTICAL NEURONS FROM APOPTOSIS INDUCED BY SERUM DEPRIVATION OR OXYGEN-GLUCOSE DEPRIVATION** M.M. Behrens, U. Strasser, B.J. Gwag, J.Y. Koh and D.W. Choi, Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Several lines of evidence suggest a key role of protein kinase C (PKC) in mediating or modulating apoptosis. We examined the effect of the PKC activator, phorbol 12-myristate 13-acetate (PMA) on two forms of neuronal apoptosis in murine cortical cell cultures. Brief exposure to PMA (3-40 nM for 1 hr) produced a concentration-dependent reduction in serum deprivation-induced apoptosis in near pure neuronal cultures. A similar protective effect was also seen with brief exposure to 40 nM PMA against the neuronal apoptosis triggered by oxygen-glucose deprivation in the presence of NMDA and AMPA/kainate antagonists. This protective effect of PMA was selective for apoptosis; no protective effect was seen against the excitotoxic neuronal necrosis induced by oxygen-glucose deprivation in the absence of glutamate antagonists.

Supporting the possibility that PMA neuroprotection may be due to activation of PKC, no gross alteration in PKC  $\alpha$  protein levels was observed at the end of a 1 hr exposure to 40 nM PMA. However, clearly further experiments will be necessary to determine the mechanisms responsible for this observed protective effect of brief PMA exposure.

Supported by a Roche Research Foundation Fellowship (US) and NIH grant 30337 (DWC).

**ANNEXIN V LABELS NEURONS EARLY IN APOPTOSIS.** G. Rimon, C. Bazenot, J. Taylor\* and L.L. Rubin, Eisai Labs, University College, London WC1E 6BT, UK.

Neuronal apoptosis is a complex process that includes changes in nuclear and cytoplasmic structures. ICE-like proteases are thought to mediate at least some of these changes. However, substrates for these proteases have not yet been delineated completely, and the timing of activation of the different proteases has not been resolved, particularly in neurons. In order to address these issues, we have studied apoptosis in several different neuronal systems. For some studies, we have used NGF-differentiated PC12 cells, which die by apoptosis extremely rapidly and synchronously in response to treatment with staurosporine, a non-specific protein kinase inhibitor. One of the earliest changes (1-2 hours) that occurs following staurosporine addition is the appearance of high concentrations of surface phosphatidylserine, as indicated by intense labelling of live cells with fluorescent annexin V, a ligand for this phospholipid. Annexin binding occurs at a time when nuclear fragmentation is just becoming visible, as revealed by Hoechst staining. At this point, the plasma membrane is still intact since cells are not permeable to propidium iodide. Annexin V is a reliable marker of apoptosis since virtually 100% of cells with even mildly fragmented nuclei are labelled. Pretreatment with ZVAD-fmk, a peptide inhibitor of ICE-like proteases, prevents cells from becoming annexin V positive. Thus, an early event in apoptosis is the redistribution of phosphatidylserine to the outer leaflet of the plasma membrane by a mechanism that is dependent upon activation of ICE-like proteases.

**TAU PHOSPHORYLATION OCCURS CONCURRENTLY WITH SELECT ALTERATIONS OF PHOSPHATASES AND KINASES DURING APOPTOSIS OF NEURONAL PC12 CELLS.** P. K. Davis\* and G. V. W. Johnson, Dept. of Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0017.

Neuronal PC12 cells that are deprived of serum and nerve growth factor (NGF) undergo apoptosis. Although apoptosis normally plays an important role during development, it has been implicated in neurodegenerative diseases such as Alzheimer's disease (AD). Apoptotic cells shrink, and exhibit nuclear and chromatin condensation, and membrane blebbing. These events involve significant alterations of the cytoskeleton. Since the microtubule-associated protein tau has been identified *in vitro* as a mediator of microtubule stability, we examined the protein levels and phosphorylation state of tau during PC12 cell apoptosis. After 72 hours of serum and NGF deprivation, the majority of PC12 cells were apoptotic. During this time period, an increase in the phosphorylation of tau Ser/Pro sites within the epitope of the phosphate-dependent Tau-1 antibody was observed. Interestingly, in AD tau is hyperphosphorylated at the Tau-1 epitope, among others.

Although biochemical processes of apoptosis remain largely unknown, the involvement of cell cycle proteins such as cyclin-dependent kinases (cdks) during apoptosis have been reported. During PC12 cell apoptosis, cdc2 kinase levels and histone H1 kinase activity in p13<sup>suc1</sup> precipitates were significantly increased. Additionally, the catalytic subunit of protein phosphatase 2B (PP2B) significantly decreased concomitant with a large decrease in PP2B activity that occurred very early in the apoptotic process. As a consequence of decreased phosphatase and increased kinase activities during PC12 cell apoptosis, the phosphorylation state of several proteins including tau may be altered. Thus, the study of tau phosphorylation in neuronal apoptosis may provide pertinent information as to the mechanisms responsible for tau hyperphosphorylation in AD brain.

**UP-REGULATION OF PROTEIN KINASE C ISOZYMES UPON INDUCTION OF APOPTOSIS IN RAT CEREBELLAR GRANULE NEURONS.** T. Ono, Y. Akita, K. Blomgren, A. Sato\* and S. Kawashima, Department of Molecular Biology, The Tokyo Metropolitan Institute of Medical Science, 3-18-22 Honkomagome, Bunkyo-ku, Tokyo 113, Japan.

The primary culture of cerebellar granule neurons provides an excellent *in vitro* model to study the activity dependent regulation of survival which is a cellular basis of developmental plasticity. The presence of NMDA in the culture medium suppresses the apoptosis and greatly enhances the survival of cerebellar granule neurons. Apoptosis of the granule neurons can be induced by adding AP-5, a specific blocker of NMDA receptor, into the culture medium. Addition of H7 or TPA simultaneously with the induction of the apoptosis partially blocked the apoptosis or enhanced the apoptosis, respectively, suggesting that protein kinase Cs were positively involved in the induction of apoptosis. In order to elucidate which protein kinase C isozymes were responsible for the acceleration of apoptosis, we have employed western blotting analysis. Protein kinase C  $\beta$ 1,  $\beta$ 2, and  $\epsilon$  were up-regulated and translocated from the cytosolic fraction to the membrane fraction upon the induction of apoptosis.

**NEURONAL APOPTOTIC CELL DEATH MEDIATED BY MICROTUBULE NETWORK PERTURBATIONS** B. Chromy, M.P. Lambert\*, and W.L. Klein, Dept. of Neurobiology and Physiology, Northwestern Univ. Evanston, IL 60208.

Both colchicine and taxol can be used in asynchronous populations of proliferating cells to arrest the mitotic cycle. Recent experiments from several non-neuronal cell lines showed that these drugs also induce an apoptotic cascade. We have utilized these compounds in the neuronal CNS derived B103 cell line to study cell death and protein tyrosine phosphorylation. Cell death has been characterized first on the basis of morphological changes. Analysis via phase microscopy showed neurite atrophy and retraction as well as cellular rounding as early as two hours after treatment followed by membrane blebbing at 7-12 hours. Noticeable cell death and disadhesion resulted within 24 hours. Ethidium homodimer-intercalated DNA fluorescence showed the occurrence of chromatin condensation and marginization in the dead cells. DNA fragmentation occurred by 20-24 hours, visualized as a 180-200 bp 'ladder' via DNA gel electrophoresis. The above data demonstrate both colchicine and taxol induce apoptotic B103 cell death. Quantitative measurements of apoptotic death were obtained via flow cytometry. Partial inhibition of apoptosis was caused by the protein synthesis inhibitor, cycloheximide, and by the specific protein tyrosine kinase inhibitor, genistein. Immunoprecipitation with tyrosine phosphorylated monoclonal antibodies revealed a striking increase in the phosphorylation of a ~90 kDa cytoskeletally localized protein, roughly concurrent with the onset of DNA fragmentation. Although cycloheximide and genistein were able to fully block the induction of this ~90 kDa protein, they did not completely block apoptosis. The lack of a complete inhibition could be due to apoptosis of a sub-population of cells in a distinct state of the cell cycle. Cells differentiated with B<sub>1</sub>cAMP or arrested at G<sub>1</sub> through serum deprivation both underwent apoptosis after 24 hours of colchicine and taxol treatment. The G<sub>1</sub>/M block conferred by these drugs thus may not be the only trigger for apoptosis. Since colchicine and taxol have opposite actions on microtubule integrity, yet both caused apoptosis in this system, disruption of the active flux of the microtubule network appears to be a crucial step for the initiation of apoptosis. At least two pathways leading to apoptosis appear to be initiated by the microtubule perturbations, one of which involves the hyperphosphorylation of a 85-90 kDa cytoskeletally localized protein.

**EFFECTS OF TYROSINE KINASE ANTAGONISTS ON NGF-INDUCED SURVIVAL AND ACTIVATION OF TRKA IN SYMPATHETIC NEURONS,** Cesar Sanz-Rodriguez, Eugene M. Johnson, Jr., and James L. Franklin, Dept. of Molecular Biology and Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110

Binding of ligands to tyrosine kinase growth factor receptors causes phosphorylation of the receptors on tyrosine residues. A number of effector molecules then bind to these residues and become activated. In order to study how phosphorylation of the NGF tyrosine kinase receptor TrkA relates to NGF-survival-signaling, we first characterized the ability of four pharmacological agents (K252-a, staurosporine, 5'-S-methyladenosine, and herbimycin A) to cause inhibition of TrkA phosphorylation in sympathetic neurons exposed to NGF in culture. All of these antagonists caused a dose-dependent suppression of TrkA phosphorylation in response to NGF. We then tested the effect of these inhibitors on neuronal survival. Withdrawal of NGF caused complete loss of tyrosine phosphorylated TrkA within 2 hours of deprivation. K252-a, staurosporine, 5'-S-methyladenosine, and herbimycin A at concentrations which reduced tyrosine phosphorylation to levels comparable to NGF deprivation blocked the survival response to NGF. However, block of tyrosine phosphorylation of the receptor by as much as 90% did not suppress survival. These results suggest that only low levels of TrkA receptor phosphorylation are necessary to transduce the survival-promoting action of NGF.

Supported by a grant from the Ronald McDonald Foundation.

IGF-1 PROTECTS NEURONS FROM HYPEROSMOTIC-INDUCED PROGRAMMED CELL DEATH THROUGH THE PI-3 KINASE SIGNALING PATHWAY. C. van Golen\* and E.L. Feldman. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor 48109.

We are interested in the potential therapeutic value of insulin-like growth factor-I (IGF-I) in the treatment of neurological disorders such as diabetic neuropathy. We have used SH-SY5Y neuroblastoma cells, a clonal cell line structurally resembling developing neurons, exposed to hyperosmotic stress as an *in vitro* model of diabetic neuropathy. When these cells are exposed to hyperosmotic stress induced by mannitol, approximately 65% of them die by an apoptotic mechanism by 48 hours. We have previously shown that addition of IGF-I to the media will prevent the death of these cells.

IGF-I is known to activate at least two signaling pathways upon binding to its receptor, the MAP kinase pathway and the PI-3 kinase pathway. The current study was performed to investigate the potential role of the PI-3 kinase pathway in mediating IGF-I's protective effects. SH-SY5Y cells were plated at a  $1 \times 10^5$  cells/cm<sup>2</sup> density in 6 well plates. After 4 hr of serum deprivation, the cells were exposed to 600 mM mannitol  $\pm$  10 nM IGF-I and increasing concentrations of wortmannin, an inhibitor of PI-3 kinase activity. The number of apoptotic cells was then measured after 24 hr by staining the cells with propidium iodide and performing flow cytometry. We found that addition of 100 nM wortmannin reduces the number of IGF-I protected neurons by about half. Therefore, we conclude that the activation of the PI-3 kinase pathway through the IGF type I receptor is in part responsible for IGF-I's neuroprotective effects.

MOLECULAR MECHANISMS OF SURVIVAL AND APOPTOSIS IN CEREBELLAR NEURONS. H. Dudek<sup>1</sup>, S.R. Datta<sup>1</sup>, T.F. Franke<sup>2</sup>, D.R. Kaplan<sup>2</sup>, R.A. Segal<sup>3</sup>, and M.E. Greenberg<sup>1\*</sup>. <sup>1</sup>Div. Neuroscience, Children's Hospital, and Dept. of Neurobiology, Harvard Medical School, Boston, MA; <sup>2</sup>Montreal Neurological Inst., Montreal, Quebec; <sup>3</sup>Dept. Neurology, Harvard Medical School and Beth Israel Hospital, Boston, MA.

Using biochemical and molecular genetic approaches we have examined signal transduction pathways that may regulate survival of cultured cerebellar neurons. Activation of the MAP kinase pathway appears to be insufficient for survival; MAP kinase is strongly activated by agents that are poor survival factors, while insulin (which promotes survival) activates MAP kinase poorly. We have also directly tested the effects on survival of a number of factors in the Ras/MAP kinase pathway by using a modified calcium phosphate/DNA transfection protocol for primary neurons. These experiments indicate, for example, that expression of a constitutively active mutant of Ras is insufficient to prevent death. In contrast to these observations, insulin strongly activates the PI3 kinase pathway in these cells. Wortmannin, a PI3K inhibitor, blocks this activation and also induces death. This suggests that activation of this pathway is important for survival, and preliminary results suggest this effect may involve the protein kinase Akt. funded by NIH grant CA43855 and ACS grant PF4059

## 227.13

INHIBITION OF PI-3 KINASE INDUCES APOPTOSIS IN DRG NEURONS IN AN DEPENDENT MANNER. K.M. Rich\*, J.X. Tong, M.A. Vogelbaum. Department of Neurological Surgery, Washington University School of Medicine, St. Louis, MO 63110

Dorsal root ganglion (DRG) neurons undergo apoptosis after withdrawal of nerve growth factor (NGF). This trophic factor-induced cell death is age dependent. During the first three weeks in culture, embryonic DRG neurons lose their dependence on NGF for survival. This loss of NGF dependence has been correlated with an increase in intracellular calcium levels during this period. NGF stimulates the tyrosine kinase *trk* receptor which in turn stimulates phosphatidylinositol-3 (PI-3) kinase. Inhibition of PI-3 kinase with LY294002 (2-(4-morpholinyl)-8-phenyl-4H-1-benzopyran-4-one) induces apoptosis in sympathetic neurons (communication Dr. Doug Creedon). The ability of LY294002 to induce apoptosis in DRG neurons was examined.

Dissociated DRG neurons from rat embryos were maintained in cell culture for 5, 10, or 21 days at which time they were treated with LY294002. Neurons were stained with crystal violet after 72 hours and cell counts done to assess survival. Massive cell death (99% death) occurred in both 5 and 10 day-old DRG neurons with 25  $\mu$ M LY294002. In contrast, 21 day-old DRG neurons showed only a 54% loss at concentrations of LY294002 up to 50  $\mu$ M. Older DRG neurons (21 days in culture) were placed in medium with low calcium. Their intracellular calcium levels decrease to levels similar to the neurons grown in culture for only 5 days. Older neurons maintained in low calcium medium became very susceptible to treatment with LY294002 (50  $\mu$ M). There was only 50% death in standard Ca<sup>2+</sup> medium group compared with 97% death in neurons with lowered intracellular calcium. DRG neurons grown in cell culture for 10 days were treated with 50  $\mu$ M LY294002 and stained with the fluorescent DNA-binding dye Hoechst 33258 after various time points. DNA condensation was found in 9% at 24 hours and 7.4% at 48 hours.

In conclusion, DRG neurons undergo apoptosis after inhibition of PI-3 kinase with LY294002 in a dose-dependent manner. This apoptotic response has similar characteristics with that found after NGF withdrawal. (Support NS NIH 29407)

## 227.10

INHIBITION OF NEURONAL APOPTOSIS BY PI 3-KINASE DEPENDENT AND INDEPENDENT PATHWAYS. S.R. D'Mello\*, S.P. Soltoff<sup>2</sup>, K. Borodetz<sup>1</sup>. Dept. of Physiology and Neurobiology, University of Connecticut, Storrs, CT 06269<sup>1</sup>, and Div. of Signal Transduction, Harvard Medical School, Boston, MA 02115<sup>2</sup>

Cerebellar granule neurons die by apoptosis when switched from culture medium containing elevated potassium (25mM KCl) to medium with low K<sup>+</sup> (5mM KCl). Death in low K<sup>+</sup> can be prevented by insulin-like growth factor-I (IGF-1). To understand how IGF-1 inhibits apoptosis, we examined the role of phosphatidylinositol-3 kinase (PI 3-kinase), a signaling molecule shown by others to be required for NGF-mediated survival in the PC12 cell-line. In primary granule neurons, IGF-1 treatment leads to a robust activation of PI 3-kinase, as judged by lipid kinase assays and by Western analysis of tyrosine phosphorylated enzyme. Activation of PI 3-kinase occurs via tyrosine phosphorylation of the insulin receptor substrate (IRS-1) protein. PI 3-kinase is necessary for IGF-1 mediated survival. Treatment with two distinct inhibitors of PI 3-kinase, wortmannin and LY294002, reduces PI 3-kinase activation by IGF-1 and inhibits its survival promoting activity. Death resulting from a blockade of PI 3-kinase is accompanied by DNA fragmentation, a hallmark of apoptosis, and can be delayed by transcriptional and translational inhibitors. In sharp contrast to the necessity for PI-3 kinase in IGF-1 signaling, elevated K<sup>+</sup> does not activate PI 3-kinase and can maintain cell survival in the presence of PI 3-kinase inhibitors. Therefore, neuronal survival can be mediated by PI 3-kinase dependent (IGF-1) and independent pathways (elevated K<sup>+</sup>).

Supported by grants from the Whitehall Foundation, the AT Children's Project, and the National Science Foundation to S.R.D.

## 227.12

POTASSIUM-MEDIATED SURVIVAL OF RAT CEREBELLAR GRANULE CELLS MAY DEPEND ON PI-3 KINASE ACTIVITY. T.M. Miller\*, M.G. Tansey, E.M. Johnson, Jr. and D.J. Creedon. Departments of Neurology and Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

Depolarizing concentrations of potassium promote the survival of many neuronal cell types, including cerebellar granule cells. The survival promoting effect of potassium is mediated by calcium entry through L-type calcium channels, which leads to a sustained rise in intracellular calcium. One possible mechanism whereby this increase in intracellular calcium promotes survival is by activating intracellular pathways involved in neurotrophic factor signalling. One such pathway is signalling through PI3-Kinase, which is involved in survival of PC12 cells (Yao and Cooper, *Science*, 267: 2003, 1995). We have tested whether the survival promoting effect of potassium depolarization in cerebellar granule cells is dependent on the activity of PI3-kinase. Cerebellar granule cells maintained in the presence of serum and 25 mM extracellular potassium undergo apoptosis when switched to serum-free, non-depolarizing conditions. After 48 hours only 40% of the neurons remain viable as measured by calcein AM staining. Potassium depolarization blocks this apoptosis. The survival promoting effect of 25 mM potassium was negated by the addition of 30  $\mu$ M LY 294002, an inhibitor of PI3-Kinase activity. The cell death induced by LY 294002 was similar to that caused by non-depolarizing conditions. In both situations the dying cells displayed nuclear condensation and the cell death in both cases was blocked by cycloheximide. This suggests that inhibition of PI3-kinase triggered programmed cell death. Cerebellar granule cells can also be maintained in serum-free media containing either 100 ng/ml IGF-1 or 800  $\mu$ M cAMP. LY 294002 completely blocked the survival promoting activity of IGF-1, but had no effect on cAMP-mediated survival. These results suggest that PI3-Kinase activity is important for neuronal survival mediated by potassium, and IGF-1, but not cAMP. (Supported by NIH grant AG 12947.)

## 227.14

CERAMIDE INDUCES APOPTOSIS IN MURINE CORTICAL NEURONS. C. H. Yeh\* and D. W. Choi. Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Recent studies have suggested that ceramide can serve as an intracellular mediator of mammalian cell apoptosis, for example that induced by tumor necrosis factor alpha, Fas ligand or ionizing radiation. To begin to examine the possibility that ceramide might also be a mediator of central neuronal apoptosis, we tested the hypothesis that addition of exogenous ceramide would induce apoptosis in cultured murine cortical neurons.

Mixed neuronal and astrocyte cultures exposed to 10-200  $\mu$ g/ml ceramide (or 10-200  $\mu$ M concentrations of the C2 synthetic analogue) for 24 hr developed concentration-dependent neuronal apoptosis associated with cell body shrinkage, membrane blebbing, chromatin condensation, DNA fragmentation, and cycloheximide sensitivity. The cell-permeable interleukin-1 $\beta$  converting enzyme (ICE) inhibitor, Z-val-ala-asp-CH<sub>2</sub>F (ZVAD, 100  $\mu$ M), also blocked ceramide-induced neuronal death. Exposure to higher concentrations of C2 ceramide resulted additionally in glia death. Neurons in cultures nearly devoid of glia retained vulnerability to ceramide-induced apoptosis.

Supported by NIH NINDS grant NS 30337 (DWC).

## 227.15

ACTIVATION OF THE CERAMIDE-DEPENDENT SIGNAL TRANSDUCTION PATHWAY INDUCES APOPTOSIS IN CULTURED MESENCEPHALIC NEURONS. B. Brugg<sup>1</sup>, P.P. Michel<sup>1</sup>, Y. Bailly<sup>2</sup>, Y. Agid<sup>1</sup> and M. Ruberg<sup>1</sup>. <sup>1</sup>INSERM U289, Hôpital de la Salpêtrière, 47, Bd de l'Hôpital, 75013 Paris. <sup>2</sup>CNRS UPR 9009, Centre Neurochimie, 5 rue Blaise Pascal, 67084 Strasbourg, France.

Recent evidence from our laboratory indicates that the degeneration of mesencephalic dopaminergic neurons of patients with Parkinson's disease occurs by the genetically programmed process known as apoptosis. These neurons express the low affinity receptor (p55) for the cytokine TNF- $\alpha$ , which, in patients, is synthesized by microglial cells in their vicinity. The recent description of the ceramide-dependent signal transduction pathway leading to apoptosis, in cells of the immune system, when activated by TNF- $\alpha$  suggests a possible mechanism for the death of dopaminergic neurons in parkinsonian patients. To test this hypothesis, primary cultures of rat mesencephalon were treated with cell-permeant ceramide analogs or liposome-delivered native ceramide, that can activate the signalling pathway downstream of the cytokine receptor.

After 7 days of maturation in vitro, ceramide treatment induced activation of the transcription factor NFkB/Rel and provoked dose- and time dependent apoptosis, reflected morphologically by neurite fragmentation, cell body shrinkage, chromatin condensation and fragmentation. Intracellular DNA degradation could also be evidenced by gel electrophoresis. The death program could be antagonized by inhibition of protein synthesis, elevation of cyclic AMP levels, and appropriate concentrations of serum.

The signal transduction pathway which leads to apoptosis in immune cells following cleavage of ceramide from membrane sphingomyelin can be activated in neurons *in vitro* with the same consequence. The degeneration of such neurons in patients with Parkinson's disease could result from activation of this mechanism.

Supported by Bioavenir-France

## 227.17

RESTORATION OF ACID SPHINGOMYELINASE-DEPENDENT CERAMIDE GENERATION AND APOPTOSIS IN CELLS FROM NEURODEGENERATIVE NIEMANN-PICK DISEASE PATIENTS. L.A. Peña<sup>\*</sup>, M.P. Santana, E.H. Schuchman, R.N. Kolesnick. Lab. of Signal Transduction, Memorial Sloan-Kettering Cancer Center, N.Y., N.Y. 10021.

An inherited deficiency of Acid Sphingomyelinase (ASMase) results in Niemann-Pick disease (NPD), a fatal neurodegenerative disorder. Neutral sphingomyelinase (NSMase) and ASMase are types of phospholipase C which cleave sphingomyelin into ceramide and phosphocholine. A novel ceramide-mediated signal transduction system has recently been described. Specific neurotrophic factor/cytokine receptors or irradiation of plasma membranes, activate the hydrolysis of sphingomyelin to generate ceramide. Ceramide serves as a second messenger stimulating specific kinases, phosphatases, and transcription factors that activate a final common pathway of apoptosis or cell growth.

Using EBV-transformed lymphoblasts as a model system, we show that induction of apoptosis is impaired in NPD cells. ASMase activity was restored to NPD cells by transient infection of normal copies of ASMase cDNA packaged in retroviral producing cell lines, or by stable transfection of ASMase cDNA in a mammalian expression vector. Furthermore, ceramide generation was restored, as measured by the DAG-kinase assay. When ASMase activity was restored to NPD cells, the ability of Fas antibody (200 ng/ml) and irradiation (20 Gy) to induce apoptosis was also restored, as quantitated by morphological changes in nuclear chromatin stained with Hoechst-33258. These data suggest (i) ASMase and not NSMase is critical for ceramide mediated apoptosis and (ii) gene transfer of ASMase into NPD cells can restore normal cell function and may be a potential therapy for NPD. (Supported by NIH CA57400 & CA61801.)

## 227.19

*c-jun* IS NOT NECESSARY FOR DEVELOPMENTAL CELL DEATH IN THE MAMMALIAN RETINA. K.H. Herzog<sup>1</sup>, S.-C. Chen<sup>2</sup> and J.I. Morgan<sup>1</sup>. <sup>1</sup>Developmental Neurobiology, St. Jude Children's Research Hospital, 332 N. Lauderdale St., Memphis, TN 38105; <sup>2</sup>Hoffmann-LaRoche, 340 Kingsland St., Nutley, NJ 07110.

Numerous studies have shown a correlation between *c-jun* expression and cell death. In addition, *in vitro* analysis suggest a causal role of *c-Jun* in programmed cell death. However, none of these experiments have assessed the contribution of *c-Jun* in the central nervous system (CNS) *in vivo*. To analyse the contribution of *c-Jun* to neuronal death, we have used mice that lack a functional *c-jun*-allele through homologous recombination. In the retina, a CNS structure, developmental cell death has been described in some detail. Unfortunately, cell death in the retina takes place in the first two postnatal weeks which is after the time at which *c-jun*-null mice die (~13d in utero). Therefore, to analyse neuronal tissue of *c-jun*-null mice a transplantation method was introduced. For the *in vivo* analysis of *c-jun*, retinas of either mutant or wildtype embryos were removed between E11.5 and E13.5 and allowed to develop in host rats until the theoretical stage of the transplanted eye was postnatal (P) days 6, P9 or P11. Analysis of transplanted eyes by TUNEL and examination of pyknotic nuclei revealed dying cells in -/- and +/- retinas indicating that *c-jun* is not necessary for natural occurring cell death in the retina. To further assess the involvement of *c-Jun*, or an interacting factor in development we are currently constructing transgenic mice which either overexpress *c-jun* or a dominant negative form of *c-jun* in defined neuronal populations. These mice will be analysed for cell death and regenerative capacity.

## 227.16

ACTIVATION OF THE SPHINGOMYELIN PATHWAY INHIBITS PROLIFERATION OF IMMORTALIZED HYPOTHALAMIC GT1-7 CELLS. M.A. Sortino<sup>\*</sup>, V. Cardile<sup>1</sup> and P.L. Canonico<sup>2</sup>. Institutes of Pharmacology and <sup>1</sup>Human Physiology, University of Catania School of Medicine and <sup>2</sup>Chair of Pharmacology, University of Pavia School of Dentistry, Italy.

The sphingomyelin pathway, leading to ceramide generation, has been related to cell cycle arrest and/or induction of programmed cell death by either serum deprivation or specific agonist receptor activation. To study this phenomenon we have used immortalized hypothalamic GT1-7 cells which are known to respond to serum starvation with reduced cell division and viability. Treatment of GT1-7 cells for different lengths of time (6-48 h) with reported maximally effective concentrations of C8-ceramide and sphingomyelinase (10  $\mu$ M and 200 mU, respectively) did not produce any change in cell proliferation and survival as assessed by either cell counting, MTT proliferative assay and LDH activity in the extracellular environment. No apparent sign of cell apoptosis was either evident by bisbenzimidazole nuclear staining or immunodetection of oligonucleosomes. However, a longer exposure (72 h) of GT1-7 cells to the same agents induced a significant, marked reduction of cell proliferation (59.2 and 41.5% for C8-ceramide and sphingomyelinase, respectively). Interestingly, the inhibitory effect of C8-ceramide was completely counteracted by the exogenous addition of phorbol ester (TPA, 100 nM, added during the last 24 h-incubation time) suggesting that also in GT1-7 cells a balance exists between the two pathways initiated by sphingomyelinase hydrolysis. Again this inhibitory effect was not accompanied by pronounced signs of apoptotic cell death.

Supported in part by a grant from CNR (95.04431.CT04) to MAS

## 227.18

MATURE, "NGF-INDEPENDENT", AND IMMATURE, "NGF-DEPENDENT", NEURONS SHARE EARLY BUT NOT LATE PATTERNS OF GENE EXPRESSION AFTER NGF DEPRIVATION. C. van Rooyen, H.M. Tucker<sup>\*</sup>, and S. Estus. Dept. of Physiology, Sanders-Brown Center, University of Kentucky, Lexington, KY 40536

We previously identified a temporal cascade of gene induction in a model of developmental apoptosis, i.e., neonatal rat sympathetic neurons undergoing NGF-deprivation. (Freeman, et al., *Neuron* 12: 343 (1994); Estus et al., *J. Cell Biol.* 127: 1717 (1994). In this model, *c-jun*, *cyclin D1*, and *mip-1* were induced beginning within 5 hours of NGF deprivation, while several genes were induced at 15 hours, including *c-fos*, *fos B*, *jun B* and *NGF1-A*. Neuronal death began thereafter and was largely complete by 72 hours. Significantly, the protein product of one of the induced genes, *c-Jun*, was necessary for apoptosis. To gain clarity into the mechanisms rendering neonatal "immature" neurons susceptible to apoptosis, we are evaluating whether similar genetic changes occur in "older", mature sympathetic neurons, wherein NGF-deprivation results in a protracted neuronal atrophy, with death occurring much later than 72 hours. Sympathetic neurons are maintained for up to 5 weeks in culture, then NGF deprived for various intervals, and RNA isolated. Quantitative RT-PCR data indicate that the induction of *c-jun* in immature and mature neurons is indistinguishable, whereas *c-fos* is induced only in immature neurons. These results suggest the existence of an apoptosis regulator that becomes active upon neuronal maturity and that acts temporally after *c-Jun* induction to inhibit apoptosis. Supported by NIH grants T32AG00242 and NS34370.

## 227.20

MOTONEURONS UNDERGOING APOPTOSIS HAVE INCREASED JNK (SAPK) ACTIVITY BUT NOT ERK1 ACTIVITY

M.A. Glicksman<sup>\*</sup>, K. Walton, A. Basma, N.T. Neff, C.A. Dionne, A.C. Maroney. Cephalon, Inc, West Chester, PA 19380

The activation of *c-jun* N-terminal kinase (JNK) is likely to play a critical role in apoptosis (Estus et al. 1994, Ham et al. 1995, Xia et al. 1995). In contrast, ERK1, has been shown to be non-essential for survival of superior cervical ganglion (SCG) neurons (Virdee and Tolkovsky 1995). In order to determine whether the signaling characteristics of apoptotic death in SCG neurons are paralleled in other cell types, JNK and ERK1 activities were examined in motoneurons undergoing apoptosis. Spinal cord cultures were enriched for motoneurons by metrizamide gradient centrifugation, and found to be approximately 75% immunoreactive for the low affinity neurotrophin receptor, a marker for motoneurons. In the absence of growth factors, motoneurons begin to die between 24-48h as measured by a fluorimetric viability assay. Apoptotic nuclei containing condensed chromatin were evident by Hoechst staining 48h after plating. JNK and ERK1 activities were measured in cell lysates by specific immunoprecipitation followed by *in vitro* kinase assays at various times after cell attachment. A 50% increase in JNK activity at 2 h and a 4-fold increase at 22 h was measured. The increase in JNK activity was not accompanied by changes in ERK1 activity suggesting that changes in ERK1 activity were not required for this process of apoptosis. Therefore, there are similar signaling events shared between SCG neurons and motoneurons undergoing apoptosis. In addition, motoneurons provide a relatively homogeneous neuronal population in which signaling and gene regulation during apoptosis can be studied.

## 227.21

CYCLIC AMP IMPROVES THE *IN VITRO* SURVIVAL OF MESENCEPHALIC DOPAMINERGIC NEURONS BY DECREASING APOPTOTIC CELL DEATH. X. Huang, W.M. Zawada, K. Prasad\* and C.R. Freed. Div. Clin. Pharmacol., Dept. Radiology, Univ. Colorado School of Medicine, Denver, CO 80262.

In the search of a transplant cure for Parkinson's disease, agents which can improve midbrain dopamine (DA) neuron survival have received great attention. Although cyclic AMP (cAMP) has been shown to increase DA neuron survival *in vitro*, the mechanism underlying this effect has not been studied. We investigated the *in vitro* effects of dibutyryl cAMP (dbcAMP), a cAMP analog and 2-chloroadenosine (2-CAD), an adenosine agonist which is known to decrease cAMP levels at high micromolar concentrations, on the rate of apoptotic death of embryonic DA neurons from E15 ventral mesencephalon. Dopamine neurons were identified by tyrosine hydroxylase (TH) immunoreactivity and apoptosis was determined by characteristic nuclear chromatin condensation imaged by Hoechst 33258 fluorescent DNA dye. After 5 days in culture, 100  $\mu$ M dbcAMP increased the number of surviving TH<sup>+</sup> neurons by 33%. This treatment also decreased the rate of the apoptosis observed in TH<sup>+</sup> neurons from 6% to 3%. By contrast, 100  $\mu$ M 2-CAD decreased the number of TH<sup>+</sup> neurons 5-fold and increased the rate of apoptosis in these neurons from 7% to 40% on day 5 in culture. Previously, we have shown that a number of neurotrophic factors (IGF-I, bFGF, and GDNF) increase DA neuron survival by decreasing apoptotic cell death. By combining dbcAMP with bFGF and/or IGF-I, or GDNF, dopamine neuron survival was increased above that observed with the growth factor treatment. These results indicate that cAMP increases the survival of DA neurons by decreasing apoptotic cell death. Since cAMP effects on DA neuron survival are additive to those of bFGF and the combination of IGF-I and bFGF, cAMP is likely to act through a signal transduction pathway different from those employed by the growth factors. Supported by NS 18639, GM 07063, and the National Parkinson Foundation.

## NEURONAL DEATH: ICE-RELATED RESPONSES

## 228.1

CHARACTERIZATION OF A cDNA HIGHLY ENRICHED IN CNS THAT SHARES SEQUENCE HOMOLOGY WITH THE ICE/CED-3 FAMILY W. P. Hynicka\* and R. N. Pittman. Dept. of Pharmacology, University of Pennsylvania, Philadelphia PA 19104.

MUD 5 is one of several cDNAs isolated in a differential screen to identify messages upregulated during programmed cell death in terminally differentiated PC 12 cells following removal of NGF. Although the role of MUD 5 in programmed cell death is unclear it remains of interest because it is expressed almost exclusively in brain. MUD 5 is currently being characterized using a variety of biochemical, molecular and cell biological approaches. Northern blots indicate a single transcript of 1.4 kb that is expressed primarily or exclusively in brain. MUD 5 expression begins around postnatal day 4 and increases gradually until it reaches adult levels at postnatal day 25. *In situ* hybridization studies of adult rat brain localize MUD 5 mRNA to neurons in cortical and limbic system structures as well as areas of the cerebellum and brain stem.

The transcript has a high GC content, 62% overall, with some areas as high as 71%. Protein sequence analysis indicates that the N-terminal 210 amino acids of MUD 5 shares 25% sequence homology with Ced-3, ICE, and ICH-1s, including the QACR active site. Studies are currently under way to determine if MUD 5 has cysteine protease activity and whether it is a positive or negative regulator of programmed cell death. This work was supported by grant NS32465 from N.I.H.

## 228.3

ENZYMATIC PROPERTIES OF RECOMBINANT ICH-1L SUPPORT A ROLE IN MEDIATING APOPTOSIS. Sheryl L. Meyer\*, Mark A. Aitor, Stephen P. Trusko, Chrysanthos M. Spais, and Richard W. Scott. Cephalon, Inc., West Chester, PA 19380.

Considerable evidence exists demonstrating that the mammalian cysteine proteases homologous to the Ced-3 cell death protein of *C. elegans* are mediators of apoptosis. Family members can be classified into two subfamilies by amino acid homology; those homologous to the prototypic protease of the class, interleukin-1 $\beta$  converting enzyme (ICE), and those with homology to CPP-32. The substrate preference of the latter class implicates those enzymes in the cleavage of various proteins during apoptosis, including poly(ADP-ribose) polymerase (PARP). Because of the abundant expression of the homolog ICH-1L in the nervous system, we were particularly interested in its enzymatic specificity. Recombinant truncated ICH-1L (a.a. 143-435), CPP-32 and human ICE were expressed using the baculovirus system. All three proteins were processed to active heterodimers and caused premature cell death during expression. Kinetic parameters of partially-purified enzymes were measured with either the ICE-preferred substrate, Suc-YVAD-AMC, or the CPP-32-preferred substrate, Ac-DEAD-AMC, and the behavior of several diagnostic inhibitors was examined. The enzymatic properties of ICH-1L were very similar to CPP-32, suggesting that it belongs to that subfamily. It was also capable of cleaving PARP. These data support the hypothesis that activation of ICH-1L in the nervous system would contribute to apoptotic cell death. Cell-penetrant inhibitors of the CPP-32 subfamily would therefore be expected to ameliorate apoptotic events in neurodegeneration.

## 228.2

MOLECULAR CLONING AND SEQUENCING OF A cDNA FOR RAT *NEDD2/ICH-1*. N. Sato, Y. Uchiyama#, D.M. Prevette\* and R.W. Oppenheim. Dept. of Neurobiol. & Anat., Bowman Gray Sch. of Med., Winston-Salem, NC 27157. #Dept. of Cell Biol. & Anat. I, Osaka Univ. Med. Sch., Suita, Osaka, Japan.

Recent studies demonstrate that inhibition of interleukin-1 $\beta$ -converting enzyme (ICE) activity by expression of *csmA* or peptide inhibitors of the ICE family of cysteine proteases protect neurons from cell death. To further investigate the role of ICE family proteins in neuronal cell death, we have isolated cDNA clones for rat *Nedd2/Ich-1*, which was originally isolated as an mRNA expressed during early mouse embryonic brain development and which encodes a protein similar to ICE and the product of the *C. elegans* cell death gene *ced-3*. By use of primers based on the mouse *Nedd2* DNA sequence, we first generated rat *Nedd2* probes from total RNA of PC12 cells by RT-PCR. Then, a PC12 cell cDNA library (1 $\times$  10<sup>6</sup> clones) was screened using these probes. We isolated several cDNA clones and DNA sequencing of these clones showed these to be the rat homolog of *Nedd2/Ich-1*. Rat *Nedd2/Ich-1* cDNA clones have an open reading frame of 452 amino acids. Predicted amino acid sequence of rat *Nedd2/Ich-1* is highly similar to those of mouse (97.3%) and human (91.3%). The sequence QACRG containing the active Cys residue, which is necessary for the proteolytic activity of ICE family proteases, is also completely conserved in rat *Nedd2/Ich-1*. Rat *Nedd2/Ich-1* also has several Asp residues in the presumptive amino and carboxyl cleavage regions similar to other ICE family proteins. This cDNA clone for *Nedd2/Ich-1* should be useful for the investigation of neuronal cell death in the developing and adult rat.

## 228.4

ACTIVATION OF ICE-LIKE PROTEASES AFTER ISCHEMIA. R. J. DiRocco, V. R. Marcy, D. G. Flood, P. Dobrzanski, R. Siman, R. Scott, P. C. Contreras, M. Miller\* and R. V. Bhat. Cephalon, Inc., Dept. of Pharmacology, West Chester, PA 19380.

Members of the IL-1 $\beta$  converting enzyme (ICE)/CED-3 family of proteins have been implicated in neuronal cell death. The role of specific genes of this family in neuronal cell death, however, remains unclear. To address this issue, we have determined the expression and localization of the cell death genes, *Ice* and *Nedd-2* after seven minutes of global forebrain ischemia in gerbils. Chromatin condensation in the hippocampal CA1 pyramidal neurons was observed within two days, while internucleosomal DNA fragmentation and apoptotic bodies were observed by four days after ischemia. *Ice* mRNA and pro-ICE protein expression increased gradually over the four day period after ischemia. ICE-like immunoreactivity was not altered in neurons, but increased in microglia throughout the hippocampus. On the other hand, *Nedd-2*-like immunoreactivity increased in neurons two days after ischemia, prior to the onset of cell death in CA1 and diminished thereafter, as CA1 neuronal cell death progressed. These results suggest that *Ice* could indirectly contribute to tissue damage after ischemia via an inflammatory response. The role of *Nedd-2* in CA1 neuronal death after ischemia remains to be further evaluated.

## 228.5

**Expression of an ICE-Related Protease (IRP) During Early CNS Development and Following Transient Global Ischemia.** S.M. Paul<sup>1,2\*</sup>, X. Wu<sup>1</sup>, Y. Su<sup>1</sup>, D. Stephenson<sup>1</sup>, B. Smalstig<sup>1</sup>, K. Rash<sup>1</sup>, J. Clemens<sup>1</sup> and B. Ni<sup>1</sup>  
<sup>1</sup>Lilly Research Laboratories, Indianapolis, IN 46285; <sup>2</sup>Departments of Pharmacology, Toxicology & Psychiatry, IU School of Med., Indpls., IN 46285

The death of central neurons is widely recognized as a normal feature of vertebrate CNS development. Although the precise mechanisms underlying the fatal selection of neurons during development remains a mystery, previous studies suggest that their death occurs via apoptosis. We have recently cloned an ICE-like protease from rat brain which is quite homologous to human cysteine protease-P32 (CPP32) and which may represent the rat homologue of this ICE-related protease (IRP). A dramatic upregulation of the IRP mRNA is associated with K<sup>+</sup>-deficiency-mediated apoptosis of cultured cerebellar granule neurons (see abstract by Ni et al.). We now report the developmental expression of this IRP and the selective protracted expression of the IRP transcript in CA1 pyramidal neurons following transient global ischemia. Expression of the IRP mRNA was determined during pre- and postnatal development of the rat CNS using *in situ* hybridization and Northern blot analyses. IRP mRNA in brain is predominately confined to pre- and early postnatal development (from E17 to PND5). IRP mRNA is selectively expressed in neuron-enriched regions of the developing brain, such as the cerebral cortex, hippocampus and cerebellum. IRP mRNA expression is dramatically decreased after PND10, since only trace levels of the IRP mRNA can be detected in most regions of the mature rat brain. Transient forebrain ischemia, which results in the apoptotic death of CA1 hippocampal neurons, induces IRP mRNA expression in hippocampal pyramidal neurons (CA1-4) at 24 hr following ischemia. However, a marked reduction in the expression of the IRP mRNA occurs in CA2-CA4 pyramidal neurons by 72 hr and thus a highly elevated expression of IRP mRNA remains confined to CA1 pyramidal neurons just prior to cell death. Our data suggest that this IRP, closely related to CPP32, may play an important role in the fatal selection of neurons during CNS development and may be responsible for the apoptotic death of CA1 hippocampal neurons following global forebrain ischemia.

## 228.7

**YVAD-CHO, AN ICE SPECIFIC INHIBITOR, CAN PREVENT MOTONEURON DEATH INDUCED BY AXOTOMY IN NEONATAL MICE.** E. de Bilbao and M. Dubois-Dauphin\* Dept. of Physiology, University Medical Center, 1211 Geneva, Switzerland.

When performed during the postnatal period, the lesion of the facial nerve induces death of facial motoneurons. We have previously reported that neonatal mouse lesioned motoneurons die by apoptosis within 72 hours, with a peak observed 28 hours after the lesion (de Bilbao and Dubois-Dauphin, 1996).

Several lines of evidence indicate that *in vitro* the ICE (interleukin 1 $\beta$ -converting enzyme) proteases family, the mammalian homologs of CED-3, are positive effectors of the cell death process. In order to determine if these proteases could be involved in the model of axotomy-induced cell death *in vivo*, we have administered a peptide inhibitor of ICE, YVAD-CHO, on the lesioned facial nerve of two days old mice (four injections of 10  $\mu$ l at 10  $\mu$ M). The effect of YVAD-CHO on motoneuron death was tested 24 hours after the lesion using the TUNEL method which labelled apoptotic DNA breaks *in situ*.

Our results show that YVAD-CHO can significantly prevent motoneuron death since 32% less TUNEL-labelled motoneurons were observed in treated mice when compared to control ( $p < 0.05$ ). These results indicate that ICE or ICE-like proteases may be involved in the cell death processes induced by an axotomy *in vivo*.

## 228.9

**GENETIC AND METABOLIC STATUS OF NGF-DEPRIVED SYMPATHETIC NEURONS SAVED BY AN INHIBITOR OF ICE-FAMILY PROTEASES.** M. Deshmukh<sup>1</sup>, J. Vasilakos<sup>2</sup>, T. L. Deckwerth<sup>1</sup>, P. A. Lampe<sup>1</sup>, B. Shivers<sup>2</sup> and E. M. Johnson, Jr.<sup>1\*</sup>

<sup>1</sup>Dept. of Mol. Bio. and Pharm., Wash. Univ. Sch. of Med., St. Louis, MO 63110. <sup>2</sup>Parke-Davis Pharm. Res. Ann Arbor, MI 48105.

Sympathetic neurons from embryonic rat superior cervical ganglion (SCG) undergo programmed cell death (PCD) when deprived of nerve growth factor (NGF). We have used an ICE-family protease inhibitor to examine the function of ICE-family proteases during SCG neuronal death and to assess the metabolic and genetic status of neurons saved by such inhibition. Boc-aspartyl(OMe)-fluoromethylketone (BAF), a cell-permeable inhibitor of the ICE-family proteases, inhibited ICE and CPP32 *in vitro* (EC50 ~5  $\mu$ M) and blocked Fas-mediated apoptosis in thymocytes (EC50 ~10  $\mu$ M). BAF also blocked the NGF deprivation-induced death of rat SCG neurons in culture (EC50 ~10  $\mu$ M).

Compared to NGF-maintained neurons, BAF-saved neurons were smaller and maintained only basal levels of protein synthesis; readdition of NGF restored growth and metabolism. Although BAF blocked apoptosis in SCG neurons, it did not prevent the fall in protein synthesis or the increases in the expression of *c-jun*, *c-fos* and other mRNAs that occur during neuronal PCD, indeed the induction was augmented. This suggests that the ICE-family proteins function after these events during PCD. Commitment point experiments indicated that NGF and BAF rescue SCG neurons with an identical time-course, suggesting that both block apoptosis at either an identical or an adjacent event during neuronal PCD. Supported by NIH grant AG12947.

## 228.6

**ICE AND CYCLIN D1, BUT NOT BCL-2 mRNA EXPRESSION INCREASE FOLLOWING FACIAL NERVE AXOTOMY.** W. Tetzlaff, J.L. Vanderluit, K.C. Harrington, N.R. Kobayashi, J.D. Steeves\* and J. Rossiter\*  
 Depts. of Zoology and Surgery, U.B.C., Vancouver, B.C., Canada V6T 1Z4, \*Queen's University, Kingston, Ontario, Canada K7L 3N6.

Motoneurons become more vulnerable to insult if previously axotomized. We are therefore examining whether this is reflected by a shift in the balance of death control genes after the initial axotomy. Interleukin-1 $\beta$ -converting enzyme (ICE) and family members (nec-2), *bax*, *bcl-x<sub>s</sub>*, *bad*, *bak* and cyclin D1 have been demonstrated to promote active forms of cell death whereas *bcl-2*, *bcl-x<sub>l</sub>*, and *bag* appear to have protective effects against cell death. In adult rats, the left facial nerve was transected at the stylomastoid foramen. Animals were sacrificed at 1 day (d), 2d, 3d, 7d and 14d following axotomy. The facial nuclei were microdissected for RNA extraction followed by reverse transcription and subsequent semi-quantitative (serial dilutions) polymerase chain reaction (PCR). 2d following axotomy, we found a 2-4 fold increase in ICE mRNA which remained elevated for at least 14 days. Similarly, a 2-4 fold increase in the mRNA of the cell cycle regulator, cyclin D1 was observed between 2 and 14d after axotomy. The level of mRNA expression for *bcl-2*, *bcl-x<sub>l</sub>* and *bcl-x<sub>s</sub>* did not change with axotomy. Thus, *bcl-2* and *bcl-x<sub>l</sub>* do not appear to respond to the increase in death promoting genes in this *in vivo* model. Preliminary data indicate an increase in mRNA, for *bax* and no changes for *bag* and *bad*. These data indicate a shift towards death promoting genes after an initial axotomy, which may explain enhanced susceptibility to a subsequent trauma.

## 228.8

**EXAMINATION OF THE ROLE OF THE ICE FAMILY CYSTEINE PROTEASES AND THEIR PUTATIVE SUBSTRATES IN MOTONEURON CELL DEATH.** L.L. R.W. Oppenheim, and C.E. Milligan\* Dept. Neurobiol. and Anat., Bowman Gray School of Medicine, Winston-Salem, NC 27157

We have previously shown that members of the ICE/Ced-3 family of cysteine proteases are involved in motoneuron(MN) cell death in the chick embryo. We are now attempting to identify the specific protease that mediates cell death. One candidate protease is Cpp-32, which cleaves the nuclear enzyme poly (ADP-ribose) polymerase (PARP) at a tetrapeptide sequence DEVD. We have used a well characterized primary tissue culture system that yields a pure population of MNs that survive in the presence of trophic support (muscle extract, MEX) and die in its absence. The death of MNs requires new gene expression and occurs by apoptosis. When a specific inhibitor of Cpp-32 (DEVD-aldehyde) is added to cultures of MNs deprived of MEX, their death is prevented. Initial western blots of E5.5, E8, E11 lumbar spinal cord show that cleaved PARP is increased at E8, when MN cell death in lumbar spinal cord reaches its peak, and then decreased at E11 when MN death is complete. Experiments are in progress to determine whether naturally occurring MN death can be prevented *in vivo* with the Cpp-32 peptide inhibitor and to determine whether PARP and Cpp-32 are present in dying MNs. These results suggest that Cpp-32 may modulate motoneuron cell death following trophic factor deprivation.

## 228.10

**ICE-RELATED PROTEASES INVOLVED IN GROWTH FACTOR DEPRIVATION-INDUCED NEURONAL APOPTOSIS.** D. Bozyczko-Coyne\*, P. Dobrzanski, S. Meyer, T. O'Kane, S. Carswell, R.W. Scott and R. Siman. Cephalon, Inc., West Chester, PA 19380.

Apoptosis is a well-established mode of neuronal death essential to the development of the nervous system and recently implicated in multiple disorders of the adult CNS. With the identification of interleukin-1 $\beta$  converting enzyme (ICE) and a family of related cysteine proteases (IRPs) as contributors to apoptosis of a variety of non-neuronal cells, there is interest in discerning the role of specific proteases and their protein substrates in neuronal apoptosis. Using NGF-differentiated PC12 cells as a model, we sought to (i) determine whether ICE or particular IRPs are important for NGF deprivation-induced apoptosis, (ii) define the time at which proteolysis becomes crucial for the commitment to apoptosis, (iii) identify proteins degraded during apoptosis, and (iv) develop a potential histochemical marker for apoptotic proteolysis. Immunoblot and rtPCR analyses revealed that the IRPs Ned2/ICH-1 and CPP32 were expressed in NGF-differentiated cells, whereas ICE was not. Following NGF deprivation, each of two active site-directed inhibitors of Ned2/ICH-1 and CPP32 promoted survival of PC12 cells, even when their application was delayed 16 hours after NGF withdrawal. Survival-promoting activity of the protease inhibitors was observed for at least 4 days based on measures of membrane integrity and mitochondrial function. Using an antibody designed to react specifically with a preferred IRP cleavage domain, two protein fragments of ~46 kDa and ~35 kDa were detected by immunoblotting following NGF deprivation. These two fragments co-migrated with products generated when PC12 extracts were incubated with recombinant versions of either ICH-1 or CPP32. When applied to immunohistochemistry, the antibody specifically labelled apoptotic bodies of degenerating PC12 cells. These data implicate either of the IRPs Ned2/ICH-1 or CPP32 in NGF deprivation-induced apoptosis. IRP-mediated proteolysis is a late molecular event in the neuronal death pathway. An antibody specific for IRP-mediated proteolysis detects two substrates of potential importance to neuronal death, and may be a useful histochemical marker for neuronal apoptosis.

## 228.11

ACTIVATION OF A CPP32-LIKE ASPARTASE IN NAIVE AND NEURONAL PC12 CELLS UNDERGOING APOPTOSIS FOLLOWING WITHDRAWAL OF TROPHIC SUPPORT. **L. Stefanis\*, D.S. Park, C.Y.I. Yan, S.E. Farinelli, C.M. Troy, L.A. Greene.** Dept. of Pathology and Neurology and Center for Neurobiology and Behavior, Columbia University College of Physicians and Surgeons, New York, N.Y. 10032.

Inhibitors of ICE (Interleukin-1 $\beta$  Converting Enzyme) and other members of the ICE/ced-3 aspartase family inhibit apoptotic cell death in a variety of models, including naive and neuronal PC12 cells and sympathetic neurons following withdrawal of trophic support. However, the inhibitors used are not specific for individual aspartases and the particular family members that are involved in each paradigm are unknown. In the current study, we used specific substrates to differentially measure ICE-like and CPP32-like activities in lysates of naive and neuronal PC12 cells following withdrawal of trophic support. We detected a substantial increase in CPP32-like, but not ICE-like enzymatic activity. This increase was rapid and occurred well before morphological signs of cell death. A variety of agents that promote survival in this model, including ATA, NAC, bcl-2 and a number of cell cycle blockers, inhibited the induction of the CPP32-like activity, placing their action at a point further upstream in the apoptotic pathway. Actinomycin-D, an inhibitor of transcription, blocked the induction of the CPP32-like activity in neuronal PC12 cells only, raising the possibility that ongoing or novel transcription may be required for the aspartase activation in neuronal cells. Jun kinase activation temporally preceded the aspartase activation. When applied to living cells, zVAD-FMK, a pseudosubstrate aspartase inhibitor, blocked the activity/activation of the aspartase, but at a concentration about one order of magnitude lower than that required to promote survival. This would imply that the CPP32-like aspartase activation correlates with cell death, but is not the main determinant of apoptosis in this model.

## 228.13

ACTIVATION OF THE CED3/ICE-RELATED PROTEASE, CPP32, IN CEREBELLAR GRANULE NEURONS UNDERGOING APOPTOSIS BUT NOT NECROSIS. **R. C. Armstrong, T. J. Aja, S. Gaur, K. D. Hoang, T. Oltersdorf\*, X. Bai, D. S. Karanewsky, L. C. Fritz, and K. J. Tomaselli.** IDUN Pharmaceuticals, La Jolla, CA, 92037.

Neuronal apoptosis occurs during nervous system development and possibly in neurodegenerative diseases and following brain injury. Inhibition of Ced3/ICE-related proteases has been shown to inhibit neuronal apoptosis *in vitro* and *in vivo*, suggesting a pivotal role for these cysteine proteases in neuronal apoptosis. We have studied the activation of the Ced3/ICE-related protease, CPP32, in two *in vitro* models of mouse cerebellar granule (Cb Gr) neuronal cell death: low K<sup>+</sup>/serum deprivation-induced apoptosis and glutamate-induced necrosis. Pretreatment of Cb Gr neurons with an irreversible inhibitor of Ced3/ICE family proteases, ZVAD-fmk, specifically inhibited Cb Gr apoptosis but not necrosis, indicating a selective role for Ced3/ICE proteases in Cb Gr apoptosis. Extracts prepared from apoptotic, but not necrotic, Cb Gr neurons contained a protease activity that cleaved the tetrapeptide substrate DEVD-amc. Affinity labelling of the protease activity with an irreversible Ced3/ICE protease inhibitor (ZVK(biotin)-D-fmk) identified two putative protease subunits, p20 and p18, that were present in apoptotic but not necrotic Cb Gr extracts. Western blotting with antibodies to the C-terminus of the large subunit of mouse CPP32 (anti-CPP32) identified p20 and p18 as processed subunits of the CPP32 proenzyme. Anti-CPP32 specifically inhibited the DEVD-amc cleaving activity, verifying the presence of active CPP32 in the apoptotic Cb Gr extracts. These results demonstrate that the Ced3/ICE homolog, CPP32, is processed and activated during Cb Gr neuron apoptosis. The lack of CPP32 activation during Cb Gr neuron necrosis suggests that proteolytic processing and activation of Ced3/ICE proteases are specific biochemical markers of apoptosis.

Cloning and Expression of a Rat Brain ICE-Related Protease (IRP) and Role in KCl Deficiency-Mediated Apoptosis of Cultured Cerebellar Granule Neurons

**B. Ni<sup>1\*</sup>, X. Wu<sup>1</sup>, Y. Du<sup>1</sup>, E. Hamilton-Byrd<sup>1</sup>, P. K. Rockey<sup>1</sup>, P. Rostock Jr.<sup>1</sup>, G. G. Poirier<sup>2</sup>, Y. Su<sup>1</sup> and S. M. Paul<sup>1,3</sup>.** <sup>1</sup>Lilly Research Laboratories, Lilly Corporate Center, Indianapolis, IN 46285; <sup>2</sup>PARP Metabolism Group, Laboratory of Molecular Endocrinology, Centre Hospitalier de l'Université Laval Research Center and Laval University, Sainte-Foy, Quebec, Canada, G1V 4G2; <sup>3</sup>Departments of Pharmacology, Toxicology and Psychiatry, IU School of Medicine, Indianapolis, IN 46202.

Several members of the ICE (interleukin-1 $\beta$  converting enzyme) family of proteases have recently been implicated in the intracellular cascade mediating the apoptotic death of various cell types. It is unclear, however, whether ICE-like proteases are involved in apoptosis of mammalian neurons and if so, how they are activated. Here we report the cloning of an ICE-related protease (IRP) from rat brain which is almost identical to the previously characterized human cysteine protease - P32 (CPP32). Overexpression of this IRP cDNA in HeLa cells results in cell death accompanied by strong internucleosomal cleavage of DNA, a typical feature of apoptosis. In cultured cerebellar granule neurons, reduction of extracellular K<sup>+</sup> reliably induces apoptosis and stimulates overexpression of this IRP mRNA. The latter is especially prominent 4 hr after switching from high K<sup>+</sup> to low K<sup>+</sup> medium. Expression of IRP mRNA was maintained at this level for at least 8 hr followed by apoptotic cell death and internucleosomal DNA fragmentation. Induction of this IRP mRNA and cell death are completely blocked by adding depolarizing concentrations of KCl  $\leq$  90 min after switching to low K<sup>+</sup> medium (i. e., before the commitment point for apoptosis). Finally, the antibody c-2-10 to poly(ADP-ribose) polymerase (PARP) detected cleavage of this death substrate beginning 8 hr after changing from high K<sup>+</sup> to low K<sup>+</sup> medium, coinciding with the time-course of induced expression of the IRP gene. Our data suggest that overexpression of this IRP, closely related to CPP32, may be involved in the neuronal death cascade in mammalian neurons.

## 228.12

DIFFERENTIAL EFFECTS OF SERUM AND POTASSIUM DEPRIVATION ON APOPTOSIS AND CPP32 mRNA EXPRESSION IN RAT CEREBELLAR GRANULE CELLS. **B.A. Eldadah\*, A.G. Yakovlev, and A.J. Faden,** Georgetown Institute for Cognitive and Computational Sciences, Washington, DC 20007.

Apoptosis appears to contribute to delayed neuronal death after traumatic or ischemic brain injury. One of the mechanisms leading to apoptotic cell death may involve a withdrawal of trophic support from neurons through a reduction in growth factors or transmitter-mediated neuronal activity. Primary cultures of cerebellar granule cells serve as an *in vitro* model of apoptosis that can be induced by the deprivation of serum or potassium ions, which are thought to provide trophic support to these cells.

The progression of cell death in granule cell cultures was examined after deprivation of serum or potassium alone and in combination. DNA fragmentation associated with apoptosis was assayed by agarose gel electrophoresis, using a modified resin-based DNA extraction technique, and *in situ* end labeling. In addition, semi-quantitative RT-PCR was used to measure changes in the mRNA levels of CPP32, an ICE-like cysteine protease known to cleave the DNA repair enzyme poly(ADP-ribose) polymerase.

Our results show that, in cultures deprived of both serum and potassium, DNA fragmentation increased markedly by 12 hours after withdrawal, while in cultures deprived of either serum or potassium alone, fragmentation was increased only moderately at the same time point. Furthermore, RT-PCR showed significantly different profiles of CPP32 mRNA expression for each condition. Serum deprivation caused an early peak in CPP32 mRNA levels, while potassium deprivation led to a delayed rise in expression. Combined serum and potassium deprivation produced a progressively increasing pattern of expression. Taken together, these results show an additive effect of serum and potassium deprivation on apoptotic death in cerebellar granule cells and may suggest two pathways for the mediation of programmed cell death. (Supported by CDC CCR306634)

## 228.14

CASCADE OF POTASSIUM DEPRIVATION-INDUCED APOPTOSIS OF CEREBELLAR GRANULE NEURONS **J. B. Schulz\*, M. Weller, T. Klockgether.** Department of Neurology, University of Tübingen, 72076 Tübingen, Germany

Potassium (K<sup>+</sup>) deprivation-induced apoptosis of cerebellar granule neurons requires new mRNA and protein synthesis. Using a fluorogenic substrate (DABCYL-YVADAPV-EDANS) for interleukin 1 $\beta$ -converting enzyme (ICE) we show that K<sup>+</sup> deprivation of cerebellar granule neurons induces cycloheximide-sensitive ICE-like protease activity. A peptide inhibitor of ICE-like protease activity, Ac-YVAD-chloromethylketone, prevents K<sup>+</sup> deprivation-induced apoptosis as assessed by staining with fluorescein diacetate. Further, reactive oxygen species (ROS) are essential mediators of K<sup>+</sup> deprivation-induced apoptosis of cerebellar granule neurons since neuronal death is also blocked by superoxide dismutase (SOD), N-acetyl-L-cysteine and free radical spin traps. Using fluorescent assays we show that ROS production after K<sup>+</sup> deprivation is blocked by actinomycin D, cycloheximide, and Ac-YVAD-chloromethylketone, suggesting that ROS act downstream of gene transcription, mRNA translation and ICE activation. Taken together, we show that new mRNA and protein synthesis, activation of ICE-like proteases, and ROS production are sequential events in K<sup>+</sup> deprivation-induced apoptosis of cerebellar granule neurons.

## 228.16

INHIBITION OF ICE-RELATED CYSTEINE PROTEASES PREVENTS NEURONAL APOPTOSIS **T. Lynch<sup>1</sup>, J. P. Vasilakos<sup>2</sup>, K. Raser<sup>2</sup>, K. M. Keane<sup>2</sup>, and B. D. Shivers<sup>2\*</sup>.** <sup>1</sup>Dept. of Neurology, University of Michigan, Ann Arbor, MI 48106; <sup>2</sup>Neuroscience Therapeutics, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48105

Members of the interleukin-1 $\beta$  converting enzyme (ICE) family of cysteine proteases have been implicated in the regulation of apoptosis. To determine whether these cysteine proteases play an integral role in the low potassium-induced apoptotic death of cerebellar granule neurons (CGN), we tested the effects of a peptidomimetic (active-site) inhibitor, boc-aspartate-fluoromethylketone (boc-Asp-CH2F), which selectively inhibits ICE and ICE homologs. Primary rat CGN (7 days *in vitro*) were incubated in 5 mM potassium (K<sup>+</sup>) in the presence or absence of boc-Asp-CH2F at selected time intervals of 6, 18, 24 and 48 hours. Apoptosis was assessed by propidium iodide staining, scanning electron microscopy and DNA fragmentation on agarose gels. Expression of ICE/homologs was analyzed by northern blotting. A single, exogenous application of 20-100  $\mu$ M boc-Asp-CH2F blocked apoptosis for up to 48 hours. In addition, neurons treated with boc-Asp-CH2F and subsequently supplemented at 18 hours with 25 mM K<sup>+</sup> remained viable until 48 hours, suggesting that treated cells retain their ability to respond to trophic factors. The control peptidic fluoromethylketone (boc-Thr-CH2F), and inhibitors to calpain I (Ac-Leu-Leu-norleucinal), calpain II (Ac-Leu-Leu-normethioninal), and cathepsin B (Z-Phe-Ala-CH2F) did not prevent apoptotic death at comparable concentrations. Unlike cycloheximide, boc-Asp-CH2F did not inhibit protein synthesis. Although northern blot analysis did not detect ICE expression in CGN, the homologs Nedd2 and CPP32 were found to increase following induction of apoptosis, making these proteases potential mediators of death in these neurons.

Supported by Warner-Lambert.

**POLY(ADP-RIBOSE) POLYMERASE ACTIVATION IS NOT REQUIRED FOR NEURONAL DEATH IN DEVELOPING RAT RETINA.** L. Colombari\*, Istituto di Neurofisiologia del CNR, 56100 Pisa, ITALY.

In neonatal rat retinas, isolated and cultured in defined medium, is possible to induce ganglion cell apoptosis by serum withdrawal (Colombari *Soc. Neurosci. Abstr.* 1994, 1995). Recent studies have demonstrated that in many cellular systems cysteine proteases, closely related to the interleukin converting factor (ICE), are critically involved in apoptosis onset. A potential intracellular substrate for ICE-related proteases is the nuclear enzyme poly(ADP-ribose)polymerase (PARP). This enzyme is involved in DNA repair and, when fully activated, can deplete intracellular energy stores to an extent which leads cell to death. Therefore the possibility exists that the proteolytic activation of PARP by ICE-like proteases is a key step in neuronal apoptosis. In the present study, to evaluate the role of PARP activation in serum-dependent death of retinal ganglion cells, the protective effect of an inhibitor of PARP, the 3-aminobenzamide (3AB), was tested. Retinas from newborn P0-P3 rats were cultured in serum free medium. 3AB, added at concentrations ranging from 0.1 to 1mM, did not prevent ganglion cell death, indicating that apoptosis of these neurons is not determined by a PARP-dependent energy depletion. Supported by Italian National Research Council grant.

**ICE-LIKE PROTEASE INHIBITORS AND CERAMIDE PROMOTE SYMPATHETIC NEURON SURVIVAL FOLLOWING NGF WITHDRAWAL IN VITRO.** Y. Wen, G. DeGuia, Y. Bai, X.-F. Tian, R. P. Hart, and G. M. Jonakait\*, Dept. of Biological Sciences, Rutgers University, Newark, NJ 07102

Cultured neurons derived from neonatal superior cervical (sympathetic) ganglia (SCG) require NGF for survival in vitro. After 10 days in vitro, withdrawal of NGF and addition of antibodies to NGF (Genentech, Inc.) results in the apoptotic death of  $54.4 \pm 3.1\%$  of the neurons as determined by bisbenzimidazole staining of nuclei. Because of the homology of ICE-like proteases to the cell death gene *ced-3* and because adult SCG express mRNA for both ICE and its family member CPP-32, NGF was withdrawn in the presence of a pan-ICE inhibitor, Z-VAD-fmk (50  $\mu$ M). Only  $14.3 \pm 1.56\%$  of neurons died. A cathepsin B inhibitor (Z-FAD-fmk) had little or no protective effect. By contrast, a granzyme B inhibitor (Z-AAD-cmk) enhanced NGF-induced cell death and killed almost 35% of the neurons even in the presence of NGF. Therefore, ICE-like proteases may be involved in mediating the neuronal cell death resulting from NGF withdrawal.

Because of the possible involvement of ceramide signalling in ICE-mediated cell death, we tested soluble C2 and C6 ceramide and found that both protected neurons from NGF withdrawal. A specific inhibitor of phosphatidylcholine-phospholipase C (D609), expected to block ceramide signalling, paradoxically saved neurons from NGF withdrawal. Supported by NINDS and NIMH.

## NEURONAL DEATH: p53 AND Bcl FAMILY

## 229.1

**Expression of p53 and several growth factors in denervated striatum after excitotoxic cortical lesion in rats.** M. Isono\*, Y. Wakabayashi, M. Fujiki, K. Asakuno, T. Mori, S. Hori, Dept. of Neurosurgery, Oita Med. Univ., Oita, Japan 879-55

Ablation of the sensorimotor cortex might induce degenerative changes in the dorso-lateral (DL) striatum. We have been studying the mechanisms of neuronal death underlying these degenerative changes in a surgical cortical ablation model (M. Isono et al, abstract, 25th annual meeting of Society for Neuroscience). In this study, we investigated molecular changes including apoptotic procedure in denervated striatum using animal models of excitotoxic cortical lesion. In this model, degenerative changes might progress relatively slowly compared to those in previous models. In adult male Wistar rats, N-methyl-D-aspartate (5 mg each) was applied extracranially over the sensorimotor cortex. These procedure resulted in progressive degenerative changes of the sensorimotor cortex. Immunoreactivities of p53, bFGF, c-fos protein and GFAP in the denervated ipsilateral DL striatum were examined by ABC method and compared to those of contralateral striatum. Also, DNA fragmentation was investigated by TUNEL method. The observation period ranged from 3 days to 3 months. According to the progression of cortical degeneration, expressions of bFGF, c-fos protein and GFAP became prominent in ipsilateral DL striatum. Interestingly, prominent expressions of p53 were also observed, especially 2 weeks after the operation, quite few cells TUNEL-positive cells were found at the same time. These data suggest not only the potential to regenerate in denervated striatum, but also the possibility that the apoptotic procedure might be involved in denervation-induced degeneration. (partly supported by a grant from the Ministry of Education, Science and Culture of Japan)

## 229.2

**EVIDENCE FOR p53-MEDIATED MODULATION OF NEURONAL VIABILITY.** H. Xiang, D. Hochman, H. Sava, P. Schwartzkroin, R. Morrison\*, Dept. of Neurol Surg, Univ of Washington, Seattle, WA 98195, Dept of Oncology, Kumamoto Univ. Sch. of Med., Kumamoto 860, Japan

A role for p53-related modulation of neuronal viability has been suggested by the finding that p53 expression is increased in damaged neurons in models of ischemia and epilepsy. These findings were recently confirmed with the demonstration that mice deficient in p53 ("knockout" mice) exhibit almost complete protection from seizure-induced brain injury, whereas wild-type mice display significant neuronal cell loss in the hippocampus and other brain regions. Because the p53 "knockout" mice used in the latter study expressed a global p53 deficiency in all cell types, it was not possible to conclude that protection was conferred by the exclusive absence of p53 in neurons. Therefore, in the present study, we determined whether p53 expression in isolated neurons is directly coupled to a loss of viability. Primary cultures of hippocampal or cortical neurons were derived from animals containing p53 (+/+, +/-) or those deficient in p53 (-/-). p53 deficient neurons appeared identical to wild-type neurons with respect to morphology, neurofilament expression and resting levels of intracellular calcium. Neurons containing at least one copy of p53 were severely damaged by treatment with kainic acid or glutamate. Cell damage was assessed by direct cell counting and by nuclear morphology following propidium iodide staining of DNA. In contrast, neurons deficient in p53 (-/-) exhibited little or no damage in response to excitotoxin treatment. Despite their divergent outcomes, both p53 (+/+) and p53 (-/-) neurons demonstrated sustained elevations in intracellular calcium levels triggered by glutamate exposure. Restoring p53 expression to p53 deficient neurons, using adenovirus-mediated transduction, was sufficient to promote neuronal cell death, even in the absence of excitotoxin. These results demonstrate a direct relationship between p53 expression and loss of viability in CNS neurons.

## 229.3

**KAINATE INDUCES RAPID BUT REVERSIBLE NEURONAL DAMAGE IN HIPPOCAMPAL CA1 PYRAMIDAL CELLS IN p53-DEFICIENT MICE.** Y. Kinoshita\*, H. J. Wenzel, M. Klotz, C. Kinoshita, P. A. Schwartzkroin and R. S. Morrison, Department of Neurological Surgery, University of Washington, Seattle, WA 98195-6470.

The tumor suppressor gene, p53, is activated in response to DNA damage and causes growth arrest and/or apoptosis depending on the cellular context of the injury. We previously reported that kainate induces extensive cell loss in hippocampal subregions CA1 and CA3 in wild-type mice; apoptotic cell death was confirmed in CA1 (3-4 days), but not in CA3 degenerating neurons. In contrast, the majority of p53 (-/-) mice displayed no signs of CA1 cell damage at 3-12 days after kainate. However, based on an analysis of much earlier time points, we found that a fraction of p53 (-/-) mice showed clear and extensive morphological damage in CA1 pyramidal neurons 8 hr to 2 days following kainate injection. The peak of damage occurred at day 1 with more than 50% of p53 (-/-) animals showing severe damage. Cresyl violet staining showed that many damaged neurons in p53 (-/-) mice had condensed nuclei, shrunken cell bodies and loss of Nissl substance. They showed light and limited staining with the terminal transferase-based TUNEL method (preferentially stains double-strand breaks) and more intense and frequent staining with the DNA polymerase-based in situ nick translation method (preferentially stains single-strand nicks). The staining pattern of the damaged neurons observed with these methods differed from the typical pattern of delayed neuronal cell death seen in the CA1 region of wild-type mice. Despite the extent of neuronal damage, we did not detect a proportionate degree of neuronal cell loss in p53 (-/-) mice at 4 or 7 days; the number of surviving neurons was similar to that of nontreated control animals, and Fink-Heimer silver impregnation revealed little or no evidence of neuronal degeneration at these time points. Since the recruitment of new-born neurons is highly unlikely in the adult CA1, this observation suggests that the damaged neurons seen at earlier time points in p53 (-/-) mice are not dying but are actually recovering from the initial damage.

## 229.4

**p53 EXPRESSION INDUCES APOPTOSIS IN HIPPOCAMPAL PYRAMIDAL NEURON CULTURES.** J. Jordan\*, M.F. Galindo, R.P. Roos\*, J.M. Leiden\*, G.D. Ghadge\*, and R. J. Miller\*, <sup>1</sup>Pharmacological and Physiological Sciences, <sup>2</sup>Neurology, <sup>3</sup>Medicine, Univ. of Chicago, 947 E. 58th Street, Chicago, IL 60637.

Previous investigations on dividing cells, including neuronal precursors, have demonstrated the importance of p53 in mediating apoptosis caused by irradiation or genotoxic agents. We investigated the effects of p53 on rat hippocampal pyramidal neurons in culture by using an adenovirus that expresses p53 (Adp53; courtesy Schering-Plough Res.Inst.). p53 protein was not detectable in these neurons by Western blot under control conditions, but, 48 h following Adp53 infection, it was clearly detectable. Neuronal death increased greatly during the 72 h period following infection, with death of about 75% after 3 days. 48 h after Adp53 infection about 80% of the neurons were positive for TUNEL staining and displayed chromatin condensation using Hoechst 33348, indicating that p53 causes post-mitotic neurons to undergo apoptosis. We also examined the effect of the cyclin kinase inhibitor p21 and a constitutively active non-phosphorylatable form of retinoblastoma gene product (HApRb) by expressing these proteins following infection with recombinant adenoviruses. The 2 proteins did not have a major effect on neuronal viability. When cultures were exposed to X-rays (500 cGy) at 11 days *in vitro*, some neurons showed immunostaining for p53 5 h following irradiation. We investigated the possibility that p21 or HApRb expression could modify the apoptosis induced by either irradiation or p53 overexpression. Cultures were infected 3 days prior to x-ray irradiation or Adp53 infection. Overexpression of HApRb protected neurons from irradiation induced damage but was unable to prevent death when we reinfected the cultures with Adp53. Under similar conditions, p21 overexpression was unable to protect cells from death due either to irradiation or p53 overexpression. TGF- $\beta$ 1 was ineffective in preventing death due to Adp53 infection but did block irradiation induced death. These results suggest that p53 may mediate some forms of neuronal death, distinct from its actions related to cell cycle arrest, and provide support for its role in neurodegenerative diseases. ## 229.5

**P53 AND BAX ARE INVOLVED IN THE CELL DEATH PATHWAYS OF MOUSE TASTE RECEPTOR CELLS.** Q. ZENG and B. OAKLEY\* Department of Biology, University of Michigan, Ann Arbor, MI 48105

We investigated immunocytochemical expression patterns of the tumor suppressor p53 and BCL-2 family proteins in adult and developing mouse taste buds and gustatory epithelium in vivo. An antibody against p53 reacted with the nucleus and apical cytoplasm in 10-20% of adult mouse taste cells. Bax, known to be an inducer of cell death and a downstream target of p53, was evenly expressed within 10-20% of elongated taste cells of which some had recognizable apoptotic morphology. Double-labeling revealed taste cells with both p53 and Bax. BrdU labeling indicated Bax-positive taste cells were at least 5 days old. These lines of evidence are consistent with p53-promotion of bax and cell death. However, p53 was not essential for Bax-expression in taste cells. Postnatal day 3 mice had 0-2 Bax-positive cells per taste bud, but the first p53-positive taste cell was not evident until postnatal day 4. This suggested some Bax-expression may be independent of p53. Bax-independence was confirmed by the observation of numerous Bax-expressing taste cells in adult p53-gene null mutant mice. Squamous epithelial cells of the tongue did not express p53 or Bax.

## 229.7

**THE DNA DAMAGE-INDUCIBLE GENE GADD45 IS OVEREXPRESSED IN THE RAT BRAIN FOLLOWING KAINIC ACID-INDUCED EPILEPTIC SEIZURES** R.L. Zhu\*, J. Chen, K.L. Jin, R.A. Steller, R.P. Simon, and S.H. Graham, Dept of Neurology, University of Pittsburgh, Pittsburgh, PA 15261

Generation of oxygen free radicals and oxidative DNA-damage have been implicated in the pathogenesis of brain injury due to epileptic seizures and other neurodegenerative diseases. However, the molecular events that are associated with DNA oxidation and repair in these settings remain unclear.

GADD45 is one of the five GADD (growth arrest and DNA damage-inducible) genes that were originally identified by their induction in UV-irradiated Chinese hamster ovarian cells. GADD45 is induced by many DNA-damaging stimuli in a variety of mammalian cells. Recently, it has been found that GADD45 protein can bind to the nuclear protein PCNA and stimulates DNA excision repair. This study has examined the expression of GADD45 mRNA and protein using in situ hybridization, Northern blotting, Western blotting and immunohistochemistry in rat brains after kainic acid (KA)-induced seizures.

Both GADD45 mRNA and protein are expressed at very low levels in control brains. At 2-4h after KA injection, expression of GADD45 mRNA was remarkably increased in a variety of neuronal cell populations including hippocampal CA1-3 pyramidal neurons and dentate granular cells, neurons in the cortex especially the piriform cortex (Pr), caudate putamen (Cpu), and the thalamus (Ti). At 8-16 h, mRNA was mainly increased in CA1-3 neurons and Pr but subsided in other regions. At 24h, mRNA was still moderately increased in CA1 neurons but decreased below control levels in CA3 and Pr. At the protein level, increased GADD45 expression was detected in neurons in CA1-3, DG, Cpu, Ti, and cortex at 4-8 h. At 16-24 h, GADD45 protein was persistently increased in CA1 neurons and dentate gyrus; but decreased in CA3 and Pr. Histology revealed that sustained cell loss occurred in CA3 and Pr.

These results suggest that increased expression of DNA-repair genes such as GADD45 may be an important mechanism by which neurons recover from injury after epileptic seizures.

## 229.9

**UPREGULATION OF BAX PROTEIN IN RETINAL GANGLION CELLS AFTER OPTIC NERVE LESION.** S. Isenmann\*, C. Wahl, S. Krajewski<sup>1</sup>, J. C. Reed<sup>1</sup>, and M. Bähr, Neurologische Universitätsklinik, Hoppe-Seyler-Str. 3, D-72076 Tübingen, La Jolla Cancer Research Foundation, La Jolla, CA, USA.

We have investigated Retinal Ganglion Cell (RGC) death after crush lesion to the rat optic nerve (ON). Retina sections were examined 30 minutes to 105 days after lesion. Morphologic features suggested that at least part of RGC death occurs by apoptosis. Quantitative evaluation of TUNEL staining for DNA cleavage showed TUNEL positive cells between 3 and 8 days after proximal ON crush, with a peak at 6 days. No TUNEL positive RGCs were seen in control retinae and in retinae examined 55 and 105 days after crush lesion.

Bcl-2 is known to be a key regulator of apoptosis and has great potential to suppress cell death. Bax is a Bcl-2 homologue with strong Bcl-2 antagonistic, pro-apoptotic potential. To test whether proteins of the Bcl-2 family are involved in RGC death after lesion, we carried out immunocytochemical stainings using Bcl-2 and Bax antisera. Bcl-2 protein was readily detected in the majority of cells in the RGC layer in control retinae and during the first hours after optic nerve crush. Signal intensity decreased markedly within several days after lesion. In contrast, Bax was expressed at varying levels: while in most RGCs immunoreactivity was faint to moderate, scattered cells were strongly stained even in normal adult retina. The level of Bax expression increased as soon as 30 minutes after lesion, with more RGCs strongly positive for the protein. Increased Bax immunoreactivity was detected for at least two weeks after lesion.

We carried out double labeling studies for TUNEL and Bax in order to examine if RGCs undergoing DNA fragmentation were the ones that had upregulated Bax expression. However, in none of the sections processed, co-localisation of the two signals was detected. Thus, it seems likely that Bax expression precedes DNA fragmentation.

Our results suggest that regulation of Bcl-2 family proteins is involved in the induction of RGC death in response to ON lesion. These findings might bear consequences for future therapeutic strategies to prevent apoptotic cell death by modification of the ratio of anti- and proapoptotic Bcl-2 family proteins.

## 229.6

**INCREASED EXPRESSION OF p53-TARGET GENES, BAX AND GADD-45 IN RAT BRAIN FOLLOWING EXCITOTOXIC LESION.** P.E. Hughes\*, T. Alexi, T. Yoshida, S.S. Schreiber and B. Knusel, Andrus Gerontology Center and Depts of Neurology, Cell and Neurobiology, Univ. of Southern Calif. and Dept. of Physiological Science, UCLA, Los Angeles, CA.

In various cell lines p53, induced by DNA damage, has been shown to function to halt cell cycle progression (perhaps by increasing p21/WAF1 expression) and under certain circumstances to induce programmed cell death or apoptosis. Previously we have shown that excitotoxic lesioning of rat brain with intrastriatal injection of quinolinic acid (QA) increases p53 mRNA and protein in injured brain regions and that the expression of p53 mRNA clearly precedes DNA damage detected by TUNEL. Therefore, rather than being induced as a result of DNA damage it is possible that the expression of p53 may be involved in initiating neuronal apoptosis and therefore DNA fragmentation. Since p53 is a known transcription factor we have examined the expression of two p53-responsive genes, Bax (Bcl-2 associated X protein) and Gadd-45 (growth arrest- and DNA damage-inducible gene-45) in rat brain lesioned by intrastriatal QA. Here we show increased expression of Gadd-45 (preceding p53 expression) and down-regulation then re-expression of Bax (following p53 expression) in rat brain following intrastriatal QA. These results suggest that p53 may initiate neuronal apoptosis perhaps by regulating the ratio of Bax/Bcl-2.

## 229.8

**CELL DEATH INDUCED BY NIGERICIN IS SUPPRESSED BY OVEREXPRESSING BAX IN MN9D CELLS WHEREAS STAUROSPORINE-MEDIATED APOPTOSIS IS ACCELERATED.** Jae H. Oh<sup>1</sup>, Karen L. O'Malley<sup>2</sup>, Stanley Krajewski<sup>3</sup>, John C. Reed<sup>3</sup> and Young J. Oh<sup>1</sup>, <sup>1</sup>Dept. of Biology, Yonsei University, Seoul 120-749, Korea, <sup>2</sup>Dept. of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110, USA, and <sup>3</sup>La Jolla Cancer Research Foundation, Cancer Research Center, La Jolla, CA 92037, USA.

Bax has been shown to heterodimerize with Bcl-2 and counters the protective effects of Bcl-2 in a hematopoietic cell line. Recent studies, however, suggest that Bax may subserve more diverse functions depending on the cell type and/or the apoptotic stimuli. To test the hypothesis that Bax function might vary depending upon the cell death inducing stimuli in a given cell type, we established and characterized a murine dopaminergic neuronal cell line (MN9D) stably expressing murine (MN9D/mBax) or vector alone (MN9D/Neo). Previously, we have shown that both the proton/potassium antipporter blocker, nigericin, and protein kinase inhibitor, staurosporine, induced apoptosis in the MN9D. In either paradigm, cell death could be attenuated by the overexpression of Bcl-2. In these experiments, MN9D/Neo and MN9D/mBax cells were treated with either 1.0 uM staurosporine or 0.1 uM nigericin and subsequently assayed using MTT method. Overexpression of Bax in the MN9D cells suppressed cell death induced by nigericin (86.6 ± 7.8% vs 22.0 ± 7.2% in 24 hrs of incubation) in a manner comparable to that seen with the MN9D/Bcl-2 cell line. In contrast, overexpression of Bax accelerated apoptotic cell death following treatment with staurosporine (27.0 ± 4.6% vs 62.3 ± 5.7% in 12 hrs of incubation). In both experiments, the magnitude of DNA fragmentation corresponded to the extent of cell death. Thus, depending upon the apoptotic stimuli, Bax subserves at least two and opposite functions in MN9D cells: acceleration or repression of apoptosis. (supported in part by grants from Ministry of Education and MH45530)

## 229.10

**Bax is required for naturally-occurring cell death in developing mouse lumbar dorsal root ganglia and motor pools.** F.A. White<sup>1</sup>\*, C.M. Knudson<sup>2</sup>, S.J. Korsmeyer<sup>3</sup>, and W.D. Snider<sup>1</sup>, Dept. of Neurology, CSN<sup>1</sup>, Dept. of Pathology<sup>2</sup>, and Dept. of Medicine<sup>3</sup>, Washington Univ., St. Louis, MO, 63110.

The bcl-2 family of apoptosis regulators contains both death inhibiting and death promoting members. Recent targeted deletion studies have identified bcl-x, a death inhibiting member, as a critical regulator of neuronal survival at early developmental stages. The function of the death promoting members, bax, bad, and bak, in relation to neuronal survival during development is unclear. To clarify the influence of these death promoting proteins in the developing nervous system, we examined the degree of apoptosis occurring in the well-characterized embryonic mouse lumbar spinal cord and dorsal root ganglia (DRG) in mice with a bax null mutation (Knudson et al., Science, 270:90). We compared *bax*(-/-) and *bax*(+/+) mice between embryonic day 13.5-15.5 using the TUNEL method.

In lumbar DRGs of E13.5 *bax*(+/+) animals, 41+/4 cells/section (n=3) exhibited apoptotic figures while *bax*(-/-) mice exhibited virtually no cell death in DRG (n=4). At E14.5, *bax*(+/+) animals had on average 64 cells per DRG section, versus *bax*(-/-) animals which exhibited an average of less than 1 apoptotic figure per DRG section. Similar to the DRG results, the ventral horn of E14.5 *bax*(+/+) mice exhibited 16 apoptotic figures per section while *bax*(-/-) animals exhibited an average of less than 1 apoptotic figure per spinal cord section. Lumbar DRGs of E15.5 *bax*(+/+) and *bax*(-/-) animals exhibited an average of 19+/7 apoptotic figures per section (n=2) and less than 1 apoptotic figure per section (n=5), respectively. In sharp contrast, the occurrence of cell death in the differentiating hindlimb, dermomyotome, and viscera did not appear to be affected in *bax*(-/-) mice, although there appeared to be higher degree of apoptotic figures in the developing gonads. These results show that the expression of bax, a death promoting bcl-2 homologue, is required for programmed cell death of sensory and motor neurons during normal development. Surprisingly, bax functions appear to be essential primarily for the nervous system as death in many other tissues occurs normally. Supported by MDA and NIH.

## 229.11

CHOLINERGIC NEURON-SPECIFIC OVEREXPRESSION OF BAX IN ChAT-BAX TRANSGENIC MICE J.D.Cooper\*, T.M.Michaelidis, G.Tzimogiorgis, M.Sendtner†, M.Meyer and H.Thoenen

Department of Neurochemistry, Max-Planck-Institute for Psychiatry, 82152 Martinsried, Germany and †Neurological Clinic, University of Würzburg, 97080 Würzburg, Germany.

Bax has been shown to promote cell death *in vitro* by antagonizing the anti-apoptotic action of bcl-2. Bax mRNA and protein levels are up-regulated in neurons which are destined to die after various insults. However, the physiological role of bax in the mechanisms which influence neuronal survival remains unclear. To study the effect of overexpressing bax in defined populations of neurons we have generated transgenic mice in which expression of bax is driven by the promoter region of the murine choline acetyltransferase (ChAT) gene. We have previously shown that a 4kb EcoRI/HindIII fragment of the 5' flanking sequences of the murine ChAT gene confers NGF inducible expression of reporter genes in transiently transfected PC12 cells but not NIH 3T3 fibroblasts. This ChAT promoter fragment was linked to a construct containing coding and endogenous intronic sequences of the mouse bax gene. Pronuclear injections of this ChAT-bax construct have generated several lines of transgenic mice. Regional analysis of the CNS of ChAT-bax transgenic mice by RT-PCR and Western blot revealed high levels of transgene mRNA and bax protein in areas which contain large numbers of cholinergic neurons. *In situ* hybridization and immunohistochemical analysis confirmed that bax mRNA and protein are specifically expressed in cholinergic neurons. We observed a rostro-caudal gradient in the level of bax expression with highest levels in the spinal cord and facial nucleus and lower levels of expression in the cholinergic basal forebrain. The *in vivo* effects of increased levels of bax in the cholinergic system will be presented. (JDC Funded by a fellowship of the Human Capital and Mobility Program of the EC).

## 229.13

APOPTOSIS OF BCL-X-DEFICIENT TELENCEPHALIC CELLS IS REDUCED BY INSULIN-LIKE GROWTH FACTOR I (IGF-I) *IN VITRO*. K.S.Shindler\* and K.A.Roth†. Depts. of Pathology and †Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

Targeted disruption of the *bcl-x* gene causes massive cell death in the intermediate zone of the embryonic central nervous system (CNS), suggesting that Bcl-x plays a critical role in the regulation of immature neuron survival. This massive death is recapitulated *in vitro* by dissociated neuroepithelial cells from the embryonic day 12 telencephalon of *bcl-x*-deficient mice grown in basal media for 48 hours. *bcl-x*-deficient cells cultured in chemically-defined serum-free media (ITS), or in media supplemented with fetal calf serum (FCS), however, do survive and differentiate into neurons, indicating that factors present in ITS and FCS may promote *bcl-x*-independent anti-apoptotic pathways. To determine the ability of known trophic factors to stimulate these pathways, telencephalic cells from *bcl-x*-deficient, heterozygous, and wild-type littermates were cultured for 48 hours in basal media in the presence or absence of factor. Neurotrophin-3, neurotrophin-4/5, and brain-derived neurotrophic factor all failed to rescue *bcl-x*-deficient cells from increased cell death. In contrast, IGF-I demonstrated a significant survival effect, as fewer apoptotic cells, identified by clumped nuclear bisbenzidine staining, and more viable neurons, identified by microtubule-associated protein 2 immunoreactivity, were present in IGF-I treated cultures than in untreated cultures. Not all cells were rescued, however, as IGF-I treated *bcl-x*-deficient cultures did not contain as many neurons nor as few apoptotic cells as heterozygote and wild-type cultures. These results indicate that IGF-I can promote the survival of immature telencephalic neurons independent of the cell death inhibitor Bcl-x.

## 229.15

INTRACELLULAR LOCALIZATION OF BCL-2, BCL-XL AND BAX IN PC12 CELLS AND RAT CENTRAL NEURONS. T.Gotow†, S.Waguri†, Y.Ohsawa†, T.Watanabe†, Y.Tsujimoto†, E.Kominami† and Y.Uchiyama†. Dept. of Cell Biology and Anatomy I† and Biomedical Research Center†, Osaka Univ. Med. Sch., Suita, Osaka 565, Japan and †Dept. of Biochemistry, Juntendo Univ. Sch. of Med., Tokyo 113, Japan.

Bcl-2 and its related proteins, Bcl-xL and Bax, play essential roles in the regulation of apoptotic cell death, although it still remains unknown how they control the death process. To elucidate their regulation mechanism, we need to define which cellular components are targets for these proteins, since the Bcl-2 localization has been reported without consensus to be in association with certain organelles. We applied subcellular fractionation and immunocytochemistry including a cryothin-colloidal gold method with various antibodies against human, rat, mouse and chicken Bcl-2, Bcl-xL or Bax to PC12 cells transfected with or without the human *bcl-2* gene and normal rat central nervous tissue. With confocal laser microscopy, immunoreactivities for these three proteins showed the identical distribution, similar to that of Rhodamine 123, being prominent in perikarya and neurite tips in PC12 cells. The immunofluorescence was faint in wild PC12 cell, significantly enhanced in NGF-treated cells and much stronger in *bcl-2*-transfected cells. In the central nervous tissue, immunoreactivity was conspicuous in neuronal perikarya. Fractionation of *bcl-2*-transfected PC12 cells demonstrated that Bcl-2 was almost equivalent in distribution to mitochondria and ER/membrane fractions. With electron microscopic quantification of PC12 cells, immunogold particles were selectively associated with inner mitochondrial and ER/vesicular membranes, and hardly with any other membrane system. Such association of the reactivity to these organelles including synaptic vesicles was also observed in neurons and glial cells. The results suggest that Bcl-2 and other two proteins are preferentially integrated into inner mitochondrial and ER/vesicular membranes, where they contribute to the regulation of dying processes by interacting with each other and also being related with the organelle membrane functions.

## 229.12

CELL DEATH GENE EXPRESSION & BAX KNOCKOUT EFFECTS IN THE DEVELOPING BARREL NEURAXIS. K.E.Good, H.-X.Dong, B.L.Schlaggar, J.J.A.Arends, C.M.Knudson, S.Korsmeyer, F.A.White, W.D.Snider\* & M.F.Jacquin. Neurology & Center for the Study of Nervous System Injury, Washington Univ. Sch. Med., St. Louis, MO 63110.

It has previously been hypothesized that programmed ganglion cell death is necessary for pattern formation in the whisker-barrel neuraxis (Henderson et al., *J. Neurosci.*, '94). The bcl-2 gene family which regulates apoptosis has both death inhibiting (bcl-2, bcl-x) and death promoting (bax, bad, bak) members. Therefore, immunohistochemical patterns of cell death gene expression bear upon the cell death hypothesis as it pertains to pattern formation. In rats on postnatal days (P) 0-5, Bax expression occurred in the cortical plate, subplate and underlying white matter, and it diminished from P7-15. On P7, Bcl-2 was expressed in cells of cortical layers IV, V, VIa, the subplate and underlying white matter. On P0, p53 was expressed in the cortical plate, subplate and underlying white matter, whereas c-jun and c-fos were not. In the rat brainstem, Bax and Bcl-2 staining occurred in the P5-10 trigeminal root/tract, possibly in oligodendrocytes. Nucleus principalis was heavily labeled for Bax prior to birth, for p53 at birth, and for Bcl-2 on P4-5; few if any cells expressed c-jun or c-fos at birth. These staining patterns, in general, support the above-stated cell death hypothesis. However, in 3 adult mice homozygous for Bax gene deletion, whisker-related patterns were normal in the brainstem, thalamus and cortex, as determined by cytochrome oxidase histochemistry. Insofar as other studies suggest that programmed cell death is ameliorated in Bax knockout mice, the apparent normal development of barrel-like patterns fails to support this hypothesis. Ganglion cell numbers are currently being assessed in Bax knockout mice that have normal whisker-related patterns in the CNS. Supported by NIH DE07734, NS17763.

BCL-XL OVEREXPRESSION IN TRANSGENIC MICE PROTECTS FACIAL MOTONEURONS AGAINST AXOTOMY-INDUCED CELL DEATH. A.Sh.Parsadanian\*, C.R.Keller-Peck, J.L.Elliott, J.C.Harding, R.W.Gerfen, W.D.Snider, CSNSI, Dept. of Neurology, Washington Univ. Sch. of Med., St.Louis, MO 63110.

Bcl-x is a death-inhibiting member of the Bcl-2/Ced-9 family and is expressed in a long and short form. Like Bcl-2, *in vitro* the long form (Bcl-xL) is a potent inhibitor of apoptosis after trophic factor deprivation. In contrast to Bcl-2, Bcl-xL is required for neuronal survival during embryonic development. Also unlike Bcl-2, we have shown that Bcl-xL expression is upregulated in the postnatal period. In order to explore further the role of Bcl-xL in neuronal cell death *in vivo* and better understand the mechanisms by which it acts, we generated transgenic mice overexpressing Bcl-xL under the control of the  $\alpha$ -tubulin-1 promoter (A.Gloster et al., *J. Neurosci.*, 1994, 14, 7319-7330). Twelve transgenic founders were obtained and analysed by Southern blot and *in situ* hybridization. The copy numbers and Bcl-xL mRNA expression pattern are varied between different lines. Lines 7194 (60 copies), 7199 (20 copies) and 7193 (80 copies) have been chosen for detailed analysis. Line 7194 shows high expression of the transgene in the cerebral cortex, CA1 and CA2 region of hippocampus, but not in CA3 region or dentate gyrus. It is not expressed in the cerebellum and is expressed in only a few motoneurons in the facial motor nucleus. In the line 7199, Bcl-xL is expressed at intermediate levels in cortex, hippocampus and brainstem including facial nucleus motoneurons. In the line 7193 Bcl-xL is expressed at high level in cerebellar granular cells (but not in Purkinje cells) and in motoneurons in brainstem, and to a lesser extent in hippocampus and cortex. In order to test whether Bcl-xL can prevent neuronal death in the postnatal period *in vivo*, we unilaterally transected facial nerve of neonatal wild-type and transgenic mice. Seven days post-axotomy the number of facial motoneurons were counted. In the line 7199 about 30% of the motoneurons survive in the lesion site vs. 7% in contralateral nucleus. The effect of the Bcl-xL is more dramatic in the line 7193. About 50% of the motoneurons survive 7 days after axotomy, consistent with the prominent expression of Bcl-xL in facial nucleus in this line. Our results show that Bcl-xL, like its homolog Bcl-2, can significantly protect neurons *in vivo* from apoptosis.

CLONING AND EXPRESSION OF THE HUMAN BCL-2 RELATED PROTEIN, BAD W.A.Horne\*, J.L.Diaz, S.Ottile, J.L.Chang, S.Gaur, K.M.Tuffo, L.C.Fritz and T.Oltersdorf. IDUN Pharmaceuticals, La Jolla, CA 92037

Bcl-2 related proteins act upstream of ICE family proteases (Chinnaiyan et al., *JBC* 1996) to regulate a final common pathway for programmed cell death. Some of these proteins are present in neurons and may be involved in the regulation of neuronal survival. In particular, Bcl-x<sub>L</sub> functions as a cell death suppressor (Gonzalez-Garcia et al., *PNAS* 1995), whereas Bad and Bax may act as cell death promoters (Yang et al., *Cell* 1995; Krajewski et al., *J. Neuroscience* 1995). The mechanism by which they act is thought to be related to their ability to form homo- and heterodimers. The pro-apoptotic effect of Bad may arise from its ability to displace bound Bax from Bcl-x<sub>L</sub>.

To characterize the interactions of Bad with other Bcl-2 family members, we chose to clone human Bad. To isolate the human cDNA we searched the EST database (NCBI) with mouse protein sequence using the BLAST network service. This yielded a partial cDNA sequence homologous to mouse sequence which was then used to screen human cDNA libraries. Overlapping cDNAs were isolated from substantia nigra, bone marrow, and placenta. A full length *bad* clone isolated from placenta was used in further studies.

We found that the human *bad* cDNA encodes a 168 a.a. protein (18.4 kDa) that is 77 percent identical to mouse Bad. The N-terminus of the human protein, however, is 42 a.a. shorter. Like mouse Bad, the protein lacks a C-terminal anchor sequence, and is weakly homologous to other Bcl-2 family members in its putative BH1 and BH2 domains. There is a consensus site for A-kinase phosphorylation in the BH1 domain.

To characterize its interactions with other Bcl-2 family members, we expressed human Bad as 6His and GST fusion proteins in bacteria, and as LexA and B42 fusion proteins in yeast. We found that Bad binds with high affinity to Bcl-x<sub>L</sub> (app. Kd = 10 - 20 nM), but weakly to Bcl-2. It does not dimerize with Bax, Bcl-x<sub>S</sub>, or itself. Interestingly, Bad does bind to a mutated version of Bcl-x<sub>L</sub> that doesn't bind Bax. Funded by IDUN Pharmaceuticals.

## 229.17

OVEREXPRESSION OF HUMAN BCL-2 IN MIDBRAIN DOPAMINERGIC CELLS USING A TYROSINE HYDROXYLASE PROMOTER. J. Liu\*, J.P. Merlie, and K.L. O'Malley. Dept. of Anat. & Neurobiol., Dept. of Mol. Biol. & Pharm., Washington Univ., Sch. of Med., St. Louis, MO 63110

Oxidative stress is thought to contribute to several CNS disorders including Parkinson's Disease. For example somatic mitochondrial mutations as well as excess production of reactive oxygen species may be associated with the death of midbrain dopaminergic neurons. Several studies have shown that the cell death repressor protein, Bcl-2 blocks the effects of reactive oxygen species and thus protects cells from oxidative stress. In order to determine whether Bcl-2 could protect these cells in vivo, we used the rat tyrosine hydroxylase (TH) promoter to target Bcl-2 expression to midbrain dopaminergic cells. Previously we have shown that 2.5 kb of the rat TH promoter will direct foreign gene expression in the midbrain (Liu et al., Neurosci. Abs., 1994). In this study, three independent lines were analyzed which all showed cell type-specific bcl-2 gene expression in a sub-population of A8-A10 neurons. Bcl-2 immunoreactivity was found in the cytoplasm at a slightly different focal plane from that of TH probably due to its known association with membrane structures. It was also in the terminals of those A10 or medial A9 neurons which project to the ventral/medial part of the posterior half of the olfactory bulb. During the first three weeks of postnatal development, there are two waves of naturally occurring cell death in the substantia nigra. To determine whether overexpression of Bcl-2 affected the final number of neurons, we compared the A8-A10 cell numbers in control littermates and heterozygous bcl-2 transgenic animals at P21. To date, we have observed a small but consistent increase of dopaminergic neurons in animals that overexpress human Bcl-2. These studies suggest that Bcl-2 may play a developmental role in achieving adult numbers of midbrain dopaminergic neurons. Currently, we are investigating whether overexpression of Bcl-2 can attenuate the effects of midbrain dopaminergic neurotoxins such as MPP<sup>+</sup> or 6-OHDA. (Supported in part by NIH 45330)

## 229.19

IRON INDUCES CELL DEATH IN A CNS-DERIVED DOPAMINERGIC CELL LINE. J. Lotharius\*, A. Uhland-Smith and K. O'Malley. Department of Anatomy and Neurobiology, Washington University, St. Louis, MO, 63110.

Parkinson's disease (PD) is a progressive neurological disorder characterized by a marked degeneration of dopaminergic neurons in the striatum. It has been suggested that environmental factors could be involved in the etiology of the disease. The effect of endogenous as well as exogenous toxins in the aging brain may also be exacerbated by the irreversible accumulation of somatic mitochondrial mutations. Such phenomena may lead to increased oxidative stress in response to toxic insults. Additionally, increased iron deposits have been found in post-mortem brains of afflicted persons. Iron has been shown to stimulate free radical formation and promote the autooxidation of dopamine. Because Bcl-2 has been shown in some systems to protect cells from oxidative stress, we tested whether Bcl-2 could protect a CNS-derived dopaminergic cell line, MN9D, from reagents involved in free radical production. Previously, we have shown that Bcl-2 protects these cells from MPP<sup>+</sup> induced cell death but not 6-OHDA (Oh et al., 1995, Neurobiol. Dis., 2:157-167). In this study we tested the hypothesis that Bcl-2 could protect these cells from iron toxicity. Both MN9D/Neo (control) and MN9D/Bcl-2 cells were treated with increasing concentrations of ferric chloride (50-1000  $\mu$ M). Exposure of MN9D/Neo cells to iron for 24 h led to cell death with a mean lethal dose of 100  $\mu$ M. Morphologically, iron-induced cell death did not resemble apoptosis inasmuch as no condensed nuclei or membrane blebbing was observed. Cells transfected with Bcl-2 were not protected from iron toxicity. In contrast to the previous 6-OHDA studies, the addition of 1  $\mu$ g/ml cycloheximide did not block iron-induced cell death. Thus, in the MN9D cells, Bcl-2 did not block cell death mediated by factors contributing to oxidative stress. Supported by MH45330.

## 229.18

INHIBITION OF BCL-2 TRANSCRIPTION WITH ANTISENSE OLIGONUCLEOTIDES POTENTIATES MPP<sup>+</sup> INDUCED APOPTOSIS. C. P. Fall\* and J. P. Bennett. Department of Neurology, University of Virginia School of Medicine, Charlottesville, VA 22908.

MPP<sup>+</sup>, the active metabolite of the Parkinsonism-inducing neurotoxin MPTP, inhibits complex I of the mitochondrial electron transport chain resulting in an increase in intracellular reactive oxygen species. MPP<sup>+</sup> treatment causes apoptosis in cultures of the catecholamine-like SY5Y neuroblastoma cell. The protein bcl-2 has been shown to protect neurons from apoptosis resulting from endogenous and exogenous free radicals. Bcl-2 seems to function as the negative regulating species in a stoichiometric molecular switch which controls the ability of a cell to enter the apoptosis pathway.

Motivated by the search for a means to rescue nigral neurons from death in Parkinson's disease, we tested whether decreasing the level of bcl-2 would increase susceptibility to MPP<sup>+</sup> induced apoptosis. SY5Y neuroblastoma cells were incubated with phosphorothioated antisense or sense oligonucleotides directed against the translation initiation site for bcl-2 mRNA and then exposed to MPP<sup>+</sup>. Cells treated with antisense oligos and MPP<sup>+</sup> showed an increase in apoptosis over those treated with sense oligos and MPP<sup>+</sup>. Antisense oligos alone caused a slight increase in apoptosis over baseline. These data suggest that bcl-2 may play a role in MPP<sup>+</sup> neurotoxicity.

C. P. Fall is supported by a Dean's Fellowship Grant, Univ. of Virginia.

## 229.20

ORDERING THE EFFECTS OF BCL2, AN ICE-FAMILY PROTEASE INHIBITOR, AND OTHER SURVIVAL AGENTS ON C-JUN KINASE ACTIVATION IN SERUM/NGF DEPRIVED PC12 CELLS. D.S. Park\*, L. Stefanis, C.Y.I. Yan, S.E. Farinelli, and L.A. Greene. Dept. of Pathology and Center for Neurobiology and Behavior, Columbia Univ. College of Physicians and Surgeons, New York, NY, 10032.

Previous studies indicate that activation of c-Jun kinase (JNK) is necessary for apoptosis of trophic-factor-deprived PC12 cells. Here, we determine the order in which known survival agents, including, BCL2, inhibitors of the interleukin-1 converting enzyme (ICE) family of proteases, blockers of transcription, and a variety of small molecules with differing modes of action, block apoptosis relative to JNK activation. Overexpression of BCL2 promotes PC12 cell survival and blocks JNK activation caused by trophic factor withdrawal. Similarly, aurintricarboxylic acid (an endonuclease inhibitor), N-acetylcysteine, the NO generator DETA-NO, 8-bromo-cGMP, and 8-(4-chlorophenylthio)-cAMP promote survival and inhibit JNK activation. In contrast, zVAD-fmk (a permeant ICE-family inhibitor), actinomycin-D, the G1/S cell cycle inhibitor deferoxamine, and the CDK inhibitor flavopiridol, all promote survival after trophic factor withdrawal, but do not attenuate the activation of JNK. These findings indicate that 1) BCL2 and a number of survival-promoting agents act upstream of JNK; 2) ICE-family protease actions, regulated genes required for cell death, and certain cell cycle blockers lie either downstream of JNK or on independent pathways required for apoptotic death. This work was supported in part by grants from the NIH-NINDS, March of Dimes, ALS foundation, and Aaron Diamond foundation. D.S.P. is the recipient of an Aaron Diamond Foundation Fellowship. S.E.F. was supported, in part, by an NRSA from the NIH-NINDS.

NMDA AND METABOTROPIC RECEPTOR mRNA EXPRESSION IN THE RAT STRIATUM FOLLOWING DECORTICATION DURING DEVELOPMENT. C. H. Lam\*, and A. F. Sadikot. Division of Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, Quebec

Glutamate receptors are thought to play an important role in central nervous system development. When the course of growth is altered by deafferentation, glutamate receptor mRNA expression may be altered. We use the striatum as a model due to a stereotypic temporal pattern of excitatory amino acid receptor mRNA expression and because of its major excitatory input from the cortex. In-situ hybridization using 35-S oligonucleotides generated from a published sequence (Wullner et al., 1994) was used to study the expression of two excitatory amino acid receptor families. Sprague-Dawley rats were decorticated at 4 days. At post-natal day 14, 21, and 30, they were sacrificed and hybridized using probes for NMDA and metabotropic receptor mRNAs. R1(ins) and R1(del) isoforms were found to be increased, particularly in the sensorimotor area of the striatum. 2A expression was equivocal while 2B, 2C, and 2D did not increase. The metabotropic receptor subtype M4 increased in a generalized manner throughout the striatum, but M1, M2, M3, and M5 were not increased. Alterations in message expression were seen as early as P21. Changes in subunit composition due to decortication may suggest a role for development of excitatory amino acid receptor mRNA expression in the striatum. (Supported by MRC of Canada).

FEWER AND SMALLER CEREBELLAR PURKINJE CELLS IN OLD SEDENTARY RATS AS COMPARED TO RATS SUBJECTED TO LONG-TERM PHYSICAL EXERCISE. J. O. Larsen\*<sup>1,2,3</sup>, M. Skalicky<sup>4</sup> and A. Viidik<sup>5</sup>

<sup>1</sup>Institute of Pathology, Aalborg Hospital, Denmark. <sup>2</sup>Center for sensory-Motor Interaction, University of Aalborg, Denmark. <sup>3</sup>Stereological Research Laboratory, Bartholin Building, University of Aarhus, DK-8000 Aarhus C, Denmark. <sup>4</sup>Institute of Physiology, University of Veterinary Medicine, Vienna, Austria. <sup>5</sup>Institute of Anatomy, University of Aarhus, Denmark.

The effects of long-term physical exercise on the number and volumes of Purkinje cell perikarya have been evaluated with unbiased stereological methods. Male Sprague-Dawley rats were trained from the age of 5 months to the age of 23 months. The training program consisted of running in a treadmill, with a horizontal floor speed of 20 m/min., for 20 minutes, twice a day for five days a week. The total number of Purkinje cells was estimated with the optical fractionator technique, and the volumes of the Purkinje cell perikarya were estimated with the vertical rotator technique. The runners were found to have 13 % more, and 10 % larger Purkinje cells compared to the sedentary controls,  $2P = 0.02$  and  $2P = 0.02$ , respectively, while the mean weight of the cerebellum was the same in the two groups.

The extent to which neurogenesis occurs after the age of 5 months is not yet known, and it is not clear whether the observed difference of the Purkinje cell population is due to an increased formation of new Purkinje cells or a decreased loss of Purkinje cells in the rats subjected to physical exercise.

This study was supported by grants from The Danish Technical Research Council, The Danish Medical Research Council and The Danish Insurance Industry research project "Aging, Life and Fitness".

CONTROL OF BODY SUPPORT AND TRANSPORT BY THE LUMBAR AND THORACIC APPENDAGES IN LOCOMOTION AND ITS INITIATION BY NORMAL, TRANSECT, AND TRANSPLANT RATS. V. Graziani, M.R. Davies, W. Kargo, M. Shibayama, A. Book\*, M. Murray, A. Tessler, and S.F. Giszter. Department of Neurobiology and Anatomy MCPHU, Philadelphia, PA 19129.

Previous work in our laboratories (Miya et al. 1994, Smeraski et al. 1995) has shown that compared to normal rats, transplant recipient rats show a number of significant differences. Many of these are simplifications of the locomotor pattern. Others are compensatory adjustments due to absence or insufficiency of normal pathways. One such adjustment appears to be a prolonged overlap of stance phases in transplant recipients. During this overlap period there could be significant elastic force compensations occurring through the closed kinematic chains comprised of hindlimb, axial segments and forelimbs. It was unclear to what extent such mechanisms could form a basis for the initiation of locomotion, and for the fore-limb to hind-limb coupling in the transplant animals recovered locomotory function.

Previous work examined kinematics and muscle activation patterns. In this study we focused on the ground forces and center of pressure variations in rats as they initiated locomotion or locomoted steadily over two six axis force transducers instrumenting either wide or narrow runway platforms. We predicted that if initiation pathways have reached the lumbar spinal cord in transplant recipients the parasagittal or axial components of the initiating ground force vectors of both forelimbs and hindlimbs should be of the same direction and approximate magnitude as in normals. In contrast, if initiation is a result of lumbar motion driven by forelimbs dragging the hindlimbs (rather like a treadmill) then ground force vectors will be of opposing signs. We observed that transplant recipient rats which showed good locomotion may show nearly normal ground forces during initiation. Initiation in the poorest walkers showed opposing ground force vectors in the forelimbs and hindlimbs. Support: ASRI grant to SFG, NIH HD01127-02 to VG and NIH 5P01 NS24707.

A SIMPLE TECHNIQUE FOR ORGANOTYPIC CULTURE OF 'THIN' SLICES: SPINAL CORD AND BRAINSTEM. C.P. Parsley\*, K.W. Cheng, E.S.S. Ling, and S. Hochman. Dept. of Physiology, University of Manitoba, Winnipeg, MB., CANADA, R3E 0W3.

Existing approaches used for explant culture are the 'roller tube' (Gähwiler et al. *TINS* 11:484, 1988) or 'interface' methods (Stoppini et al. *J. Neurosci. Methods* 37:173, 1991). While powerful, both approaches have limitations. For example, the roller tube method is technically demanding, and although the interface method is a simpler approach, the membrane inserts are expensive with electrophysiological and imaging studies being difficult to perform. We have found that a reduced slice thickness provides sufficient oxygenation to allow explants to be cultured directly on the bottom of collagen-coated petri dishes.

Under sterile conditions, the dissected brainstem-spinal cords from E-15 rat fetuses were cut into transverse slices (100-200  $\mu$ m thick), transferred to 35 mm petri dishes, coated with collagen, and then incubated at 37°C in 5% CO<sub>2</sub> - 95% O<sub>2</sub> atmosphere in 600  $\mu$ l media. Viable explant cultures have been obtained for at least 21 days *in vitro*. Live/dead cell indicators revealed predominantly living cells within the slices and in regions of cell migration. Neurons and astrocytes could be identified immunohistochemically and explants were observed to extend many processes. In order to test the usefulness of this approach, we incubated spinal cord explant cultures in serum-free Neurobasal™ Media and assessed the actions of various trophic factors on process outgrowth. Initial results with trophic factors suggest that CNTF, BDNF, and NT-4/5 enhance neuritic extensions whereas outgrowth in the presence of NT-3 or NGF were not statistically different from controls. Future studies will capitalize on this approach for electrophysiological studies in regeneration. Supported by the Canadian Neuroscience Network. Trophic factors were generously supplied by Regeneron Pharmaceuticals, Inc.

TRANS-NEURONALLY INDUCED MUSCLE ATROPHY: HISTOLOGICAL AND PHYSIOLOGICAL CHANGES. K.E. Personius, R.F. Chapman\* and the late E.A. Arbas. ARL, Div. of Neurobio., Univ. of Arizona, Tucson AZ 85721.

When the grasshopper, *Barrytettix psolus*, sheds a hind-limb certain thoracic muscles, which are neither damaged nor denervated, exhibit severe atrophy. Previous studies indicate that muscle atrophy is triggered trans-neuronally by the severing of the leg nerve (which does not supply the thoracic muscles) during autotomy (Arbas & Weidner, 1991). We use this system to study changes induced in healthy muscle following remote nerve damage. This study used histochemical fiber typing and intracellular recordings to study changes in tergotrochanteral muscle #133b,c.

Muscle #133b,c contains only "fast" muscle fibers. 1 day post-autotomy no atrophy is seen; however, the percentage of fibers showing spontaneous miniature potentials (mEJP) is increased compared with controls. Atrophy is evident by day 3 and other physiological changes begin to occur. Some muscle fibers are depolarized compared with controls and membrane excitability is increased, with muscle fibers supporting post-inhibitory rebound spikes. By 10 days, atrophy is severe, but the number of fibers is the same. Muscle fibers are further depolarized and the percentage of fibers showing enhanced membrane excitability continues to increase. The frequency of mEJP is increased compared to control, indicating a pre-synaptic change at the neuromuscular junction. 15 days post-autotomy only a few atrophied fibers continue to stain for myosin ATPase. Interestingly, in the remaining fibers, resting membrane potential and the percentage of fibers showing mEJP are restored towards control values.

The rate of muscle atrophy is not constant. By day 15, a gradation of fibers exists: some which atrophy more slowly and others which are highly depolarized and have lost all contractile apparatus. Supported by NSF IBN 9210394 and APTA Post-Professional Scholarship.

ORGANIZATION OF CORTICAL MOTOR REPRESENTATIONS IN NORMAL, TRANSECT AND TRANSPLANT RATS. W. Kargo, M.R. Davis, M. Murray\* and S.F. Giszter. Dept Neurobiology and Anatomy, MCPHU, Philadelphia, PA 19129.

The rat neonatal transplant model uses transplants of fetal tissue or cell lines into fully transected neonatal spinal cord. Operated rats can show considerable motor function as adults (Miya et al. 1995, Smeraski et al. 1995). It has also been reported that corticospinal tract (CST) neurons cross transplants and enter lumbar cord in the rat neonatal transplant model (Bregman et al. 1996). The targets of the CST neurons, their cortical origins, and their relative role in recovery has not been established physiologically. In this study we examined cortical motor representations in normal, transect and transplant recipient rats as revealed by focal microstimulation. We also related features of the maps to a previously established data base of kinematic and muscle activity patterning during locomotion on a variety of tasks.

Animals were anaesthetized, the skull immobilized in a stereotaxic apparatus and the skull and dura opened to reveal the cortical surface. Mapping was performed with 50uA trains of 200uSec pulses at 333Hz in the manner described by Wise and Donoghue, and Donoghue and Sanes. 16 pairs of electromyogram wires were used together with observation and muscle palpation to examine the organization of motor output. Mapping was performed across both granular and agranular cortex. Maps in normal rats closely matched published findings. We also found: (1) transplant and transect rats possessed no motor representation of the legs or tail i.e. we were unable to elicit any motor responses in these structures. (2) The trunk axial representation was greatly enlarged in transplant and transect rats as might be expected from published work. (3) Transplant rats which were considered 'good' walkers could have richer and more finely grained axial motor responses. (4) Some bilateral forelimb responses were observed in transplant rats. We thus believe that CST projections that enter transplants and project caudal to the transplant region terminate predominantly on axial motor structures. Supported by ASRI grant to SFG and NIH 5P01 NS24707.

CORRELATES OF MUSCLE ATROPHY IN GRASSHOPPERS. A.S. Clinton\* and the late E.A. Arbas. ARL, Division of Neurobiology, University of Arizona, Tucson AZ 85721.

In the grasshopper *Barytettix psolus*, hind-limb autotomy induces atrophy in a group of proximal metathoracic leg muscles that are neither damaged nor denervated during the loss of the more distal leg segments. Damage to the leg nerve triggers the process trans-neuronally. This system provides a model for the study of regulatory interactions between identified neurons and their synaptic partners.

Within the group of 16 affected muscles, extent of atrophy varies both between muscles and between fibers within a single muscle. For example, discrete bundles of fibers in both muscle (M) #120 and M. #121 exhibit a pronounced resistance to atrophy, while remaining fibers degenerate completely. In contrast, M. #119 uniformly degenerates. In these 3 muscles as well as the remaining 13, differences in muscle atrophy are correlated with both innervation pattern and histochemical fiber type. Immunohistochemical staining reveals the presence of a protolin-like substance associated only with muscle regions that exhibit resistance to atrophy. These same regions also receive inhibitory innervation, as demonstrated by the presence of GABA-like immunoreactivity. An additional correlate of muscle atrophy is derived from the histochemical staining of several of these muscles for myosin ATPase activity. In all muscles examined to date (7 out of 16), regions that are resistant to autotomy-induced atrophy contain slow type fibers. In contrast, the staining pattern in those muscle regions that degenerate severely is characteristic of fast/intermediate type fibers. Histochemical analysis of myosin ATPase activity in M. #120-124 from *B. psolus*, 5 weeks following autotomy, reveals that slow type fibers are maintained, while many of the fast/intermediate fibers degenerate. (Supported by NIH T32 NS07363 and NSF IBN 9210394).

OVEREXPRESSION OF MYOGENIN INDUCES A SHIFT FROM GLYCOLYTIC TO OXIDATIVE METABOLISM IN SKELETAL MUSCLE OF TRANSGENIC MICE. K. Gunderson\*, M.M. Chi<sup>2</sup>, Simon M. Hughes<sup>3</sup> and O.H. Lowry<sup>2</sup>.

<sup>1</sup>Departments of Biology and Neurophysiology, Univ. of Oslo, NORWAY. <sup>2</sup>Dept. of Pharmacology and Mol. Biol., Washington Univ., St Louis MO. <sup>3</sup>The Randall Institute, King's College London, UK.

Myogenin is a member of a group of transcription factors that has been implicated in the initial differentiation of muscle cells in the developing embryo, but myogenin has also been implicated as a mediator of changes that occur in permanent, fully differentiated muscle cells. Thus, myogenin is thought to be involved in acetylcholine receptor up-regulation after paralysis, and recent data has indicated that the level of myogenin expression parallels changes in contractile properties.

We ligated myogenin cDNA to the myosin light chain 1/3 promoter and enhancer and inserted this construct into the genome of transgenic mice. This transgene confers tissue specific expression of myogenin in post mitotic fast muscle cells, and the expression apparently did not interfere with muscle differentiation. In fast muscles the levels of oxidative enzymes (acetoacetyl-CoA thiolase,  $\beta$ -hydroxyacyl-CoA dehydrogenase, citrate synthase and malate dehydrogenase) were increased 2-6 fold, while the levels of glycolytic enzymes (glycogen phosphorylase, glycerol-3-phosphate dehydrogenase, pyruvate kinase and lactate dehydrogenase) were reduced to 40-90 % compared to the levels in wild type animals. Preliminary fibertype analysis with specific antibodies against myosin heavy chain indicated that the changes in enzyme levels came about without major changes in fibertype composition.

It is well known that changes in activity, either experimentally, by electrical stimulation, or by physical training, can alter muscle properties. Thus, extreme changes in the pattern of activity can induce complete changes in fibertype, defined as a complete substitution of the myosin iso-enzyme. Milder forms of training lead to changes in the composition of metabolic enzymes not accompanied by change in fibertype. Our data suggest that myogenin could be a mediator of this type of activity dependent muscle plasticity. Sup. by the Norwegian Research Council and the MRC.

**SATELLITE CELLS AND MUSCLE FIBER PROLIFERATION IN TOADFISH SONIC MUSCLE.** K. E. Loesser and M. L. Fine\*. Depts. of Biology, Mary Washington Col., Fredricksburg, VA 22401 and Virginia Commonwealth Univ., Richmond, VA 23284-2012.

Sonic muscle fibers on the oyster toadfish *Opsanus tau* swimbladder proliferate throughout adult life and have an unusual radial morphology: alternating ribbons of sarcoplasmic reticulum (SR) and myofibrils surround a central core of sarcoplasm. Large fibers in adults form multiple cores, fragment and appear to divide into smaller, more energy efficient units. In this study we examined the embryonic formation of sonic muscle and used electron and light microscopy to describe the morphology and incidence of satellite cells (SC) developmentally. Muscles fibers form late in the larval period from myoblasts with a heterochromatic nucleus. The cells do not appear to fuse into myotubes but enlarge and differentiate myofibrils in a single circular patch. The SR differentiates from the outside inward, separating the myofilaments which are variable in number and often exceed the 8 layers of thick filaments in adults. The % SC decreases from a high of 80% in larvae to a low of 1% in adults although the adult average is 10%. No embryonic type fibers in the process of differentiating myofibrils were seen in adults. Small immature fibers, which had not yet formed the central core, had a complete radially organized contractile cylinder, suggesting that splitting rather than SCs is the major source of new fibers in adults. Supported by NIH DCO 1083.

## 230.11

**THYMOCYTE WINGED HELIX GENE IS ESSENTIAL FOR THE NORMAL DEVELOPMENT OF SPINAL MOTOR COLUMNS.** C.-L. Dou<sup>1</sup>, X. Ye<sup>2</sup>, G. Balas<sup>1</sup>, D. Hirsh<sup>3</sup>, and E. Lai<sup>1</sup>, S. C. Li<sup>2</sup>. <sup>1</sup> Cell Biology Program, Memorial Sloan-Kettering Cancer Center, New York, NY 10021; <sup>2</sup> Dept. of Pediatrics and <sup>3</sup> Dept. of Biochemistry, Columbia University, New York, NY 10032.

Winged-helix (WH) transcription factors play important roles during embryogenesis. Thymocyte winged-helix (TWH) gene is a new member of this rapidly growing gene family. During neurogenesis, TWH is highly expressed in the neuroepithelial cells and in a subset of differentiated neurons. Its unique pattern of expression in the developing central nervous system suggesting a function in neural development. To learn the function of TWH, we have generated mice containing null mutation of TWH and analyzed the mutant phenotype.

About 80% of homozygous mutants die within the first postnatal week. Those surviving show retarded postnatal growth. Mutants also display motor deficits as indicated by muscle weakness and a clutching reflex characteristic of mice with motor neuron disease. In situ hybridization studies show that TWH is expressed in subpopulations of spinal motor neurons. The mutant animals have about same total number of Islet-1 positive motor neurons as their heterozygous littermates at E13.5, however, the number in the medial motor column (MMC) is reduced by birth. Interestingly, the number of neurons expressing TWH in the lateral motor column (LMC) is increased in mutants indicating a shift of TWH-expressing neurons from MMC to LMC. These results suggest that TWH plays an important role in the normal migration and/or segregation of motor neurons and the deficit in motor function may be due to a failure of misplaced motor neurons to make synaptic connections with their correct peripheral targets. **GLYCINE- AND GABA-MEDIATED SPONTANEOUS MOTOR ACTIVITY IN THE RAT FETUS IN VITRO.**

H. Nishimaru, M. Iizuka, S. Ozaki, & N. Kudo\*. Department of Physiology, Institute of Basic Medical Sciences, University of Tsukuba, Tsukuba, Ibaraki 305, Japan.

Spontaneous motor activity in the fetal period are widely observed in various kinds of mammalian species. However, the neuronal mechanism mediating these early motor activity remain unknown. To examine this issue, we recorded motoneuronal activity from the lumbar ventral roots in an isolated spinal cord preparation from rat fetuses. Spontaneous bursts that were synchronized in the corresponding ventral roots on each side were observed periodically (0.5-5.0 min intervals) between embryonic day (E) 14.5-E17.5. Kynurenate (4 mM), a glutamate receptor blocker, failed to block spontaneous bursts at E14.5-E15.5, while it completely abolished them at E17.5. On the other hand, glycine receptor antagonist strychnine (10  $\mu$ M) completely blocked spontaneous bursts at E14.5-E15.5. At these stages, Bicuculline (10-40  $\mu$ M), a GABA<sub>A</sub> receptor antagonist, reduced the amplitude of the spontaneous burst. Brief glycine (250  $\mu$ M-2 mM) applications evoked excitatory responses that resembled the spontaneous bursts in their time course and amplitude at E15.5. These glycine-induced responses were not observed under Ca<sup>2+</sup>-free saline, suggesting that they were synaptically evoked. These synaptic responses were not blocked by kynurenate (4 mM), but they were abolished by strychnine (10  $\mu$ M). These results indicate that glycine receptors and GABA<sub>A</sub> receptors mediate the earliest spontaneous motor activity in the embryonic spinal cord.

**HINDBRAIN SEGMENTATION: ONTOGENY OF PERMANENT RHYTHMIC MOTOR ACTIVITIES IN THE CHICK EMBRYO.**

G. Fortin, A. Le Métayer and M. Denavit-Saubié\*. Institut Alfred Fessard, C.N.R.S., Gif/Yvette 91198, France.

Respiration in vertebrates, is a permanent rhythmic motor behaviour generated centrally within hindbrain neuronal networks. During embryogenesis, the hindbrain (rhombencephalon) neuroepithelium becomes partitioned into a series of 8 reiterated compartments (rhombomeres) along the antero-posterior axis. We have shown, using an isolated hindbrain preparation, that this segmentation process whereby cells are given positional information and neural fates determined, is accompanied in its latest stage (E4) by the appearance of permanent rhythmic motor activities coactive on all branchiomotor nerves. These activities between E4 and E8 consist of short (10-40s) episodes of cyclical burst discharges separated by long (1-4min) periods of silence.

On the same preparation, a single electrical shock applied to the ventral aspect of the neural tube can evoke a full episode only when the stimulus falls within a 10-20s permissive time window preceding the normal occurrence of an episode.

Whole cell recordings combined to biocytin labeling indicate that 100% of the neurones so far recorded (n=40) are rhythmically modulated independent of their axial position. Distinct functional phenotypes are present: « motoneuron-like » cells discharging in phase with the motor nerve, « inhibited » cells discharging in phase opposition with the motor nerve, « pre-active » cells discharging prior to the motor nerve. All these neurons remain silent throughout the period separating episodes. One cell category however, fires bursts of action potentials throughout the silent period of the nerve. Given the permissive period of excitability preceding episodes, such cells could initiate the discharge of « pre-active » cells and in turn the onset of episodes.

Ubiquitary rhythmic patterns of activity in the hindbrain could rely on the early specification of gating properties within neuronal assemblies. (Supported by C.N.R.S. and Fondation pour la Recherche Médicale).

**Anatomy of the Dorsal-Ventral Motor Neurons of *Drosophila***

Yi-an Sun,\* James Nagy and R. J. Wyman

Department of Biology, Yale University, New Haven, CT 06511

Flight in *Drosophila* is powered by one large wing depressor muscle (the dorsal-longitudinal muscle, DLM) and three large wing elevator muscles, the dorsal-ventral muscles. The location and morphology of the motor neurons innervating the DLM is described in Sun and Wyman (1996, J. Comp. Neurol. In Press).

The three muscles are arrayed DVM I, II & III from anterior to posterior; they are composed of 3, 2 and 2 muscle fibers respectively. HRP was injected into each muscle fiber separately and the motor neuron was back-filled. Each of the seven muscle fibers is innervated by a single and separate motor neuron. Surprisingly, the anterior-posterior location of the motor neuron cell bodies does not correlate with the position of the muscles.

The cell bodies of the motoneurons (DVMNs) to DVM I sit anterior, ventral and lateral in the T2 hemiganglion. Their primary neurites fasciculate and run straight dorsally to the surface. Here they loop postero-medially and then run anteriorly again to arborize near the midline, mostly ipsilaterally. The somas of DVMn II lie at the posterior edge of the T2 neuromere about midway in the D-V plane. Its primary neurite runs anteriorly. The cell bodies of DVMn III lie on the dorsal surface and anterior to those of DVM I. The primary neurite runs posteriorly. The dendrites of all 7 MNs ramify in the same dorsal-anterior region, which is slightly posterior to, but overlaps with, the ramification of the DLM dendrites.

TAU mRNA ISOFORM EXPRESSION FOLLOWING SCIATIC NERVE INJURY IN THE ADULT RAT. Christopher B Chambers\* and Nancy A Muma, Dept. of Pharmacology, Loyola University Chicago, Maywood, IL 60153.

Microtubule-associated proteins (MAPs) play a key role in regulating neuronal microtubule assembly/disassembly and therefore provide a balance between two opposing forces in neuronal processes: stability and plasticity. Regenerating axons display a high level of plasticity, similar to that seen during development. The expression of tau proteins, one of the major MAPs present in axons, developmentally regulated such that only one tau isoform containing 3 microtubule-binding domains is expressed during development. This isoform has a lower ability to bind microtubules than do the adult tau isoforms which have 4 microtubule-binding domains, consistent with the high degree of plasticity in the developing nervous system.

We hypothesized that following sciatic nerve injury in the adult rat, tau gene expression would be altered to reflect that seen during development. We have used both regenerative permissive (nerve crush) and non-permissive (nerve transection) conditions and the reverse transcription-polymerase chain reaction (RT-PCR) to detect and quantitate alterations in tau isoform expression in the lumbar spinal cord (L4/L5 region) at various time points following nerve injury. The tau primers were designed to span exon 10 to allow amplification of fetal and adult tau isoforms. Primers specific for H3.3 histone gene were included in the amplification step to allow simultaneous amplification of a constitutively expressed gene as an internal control for amplification. Southern blot analysis of the PCR products with oligonucleotide probes specific for either the 3 or 4 repeat isoforms indicate that the tau primers generate both isoforms using cDNAs generated by reverse transcription of total RNA extracted from rat lumbar spinal cord as the template. Data will be presented indicating what alterations in tau gene expression occur following sciatic nerve injuries which either do or do not allow for successful regeneration. (Supported by NS30460)

IDENTIFICATION OF GENES ASSOCIATED WITH NEURONAL REGENERATION BY DIFFERENTIAL DISPLAY PCR

E.M.Hol\*, F.-W. Schwaiger, A. Schmitt and G.W. Kreutzberg

Max-Planck-Institute for Psychiatry, Dept. of Neuromorphology, D-82152 Martinsried, Germany

Peripheral nerve injury leads to morphological, metabolic and molecular changes in the severed neurons and the surrounding glial cells. Neuron-glia interactions and changes in gene expression in these cells take part in the program that controls nerve regeneration. In search for novel genes associated with neuronal regeneration, changes in gene expression were analyzed in rat spinal cord 72h after sciatic nerve crush and in rat facial nucleus 72h after facial nerve axotomy.

The DNA fragments obtained with the differential display PCR (dd-PCR), were cloned, sequenced and their expression pattern was screened by *in situ* hybridization. Up to now we have isolated and sequenced 63 DNA fragments from spinal cord and facial nucleus. About 70% of these gene fragments showed no homology at all with sequences in the gene bank. Other gene fragments isolated showed a moderate to high homology with genes like stearyl CoA desaturase, S3 ribosomal protein, 12S rRNA, human pBX2 gene, chicken c-maf, hox4.4/4.5, NADH ubiquinone oxidoreductase, non-muscular myosin light chain, connexin 43, mouse elongation factor 2, human colon mucosa protein, ribosomal protein L7, homeobox protein R1a and pyruvate kinase. *In situ* hybridization revealed that 20% of the novel gene fragments were differentially expressed. We found neuron specific as well as glial specific genes.

In conclusion, we successfully identified novel regeneration associated genes by means of the dd-PCR technique.

ENHANCED EXPRESSION OF 14-3-3 FAMILY MEMBERS DURING PERIPHERAL NERVE REGENERATION. K.NAMIKAWA, Q.N.SU, H.TOKI, and H.KIYAMA\*, Dept. of Neuroanatomy, Biomed. Res. Center, Osaka Univ. Med. Sch., 2-2, Yamadaoka, Suita, Osaka, 565 Japan

Differential display-PCR (DD-PCR) was used to isolate cDNA fragments whose mRNA expression are increased or decreased in mouse hypoglossal motoneurons after axotomy. *In situ* hybridization (ISH) confirmed that the expression of some fragments derived in DD-PCR have been up-regulated following nerve injury, and one of them was found to be highly homologous to rat  $\gamma$  subtype of 14-3-3 protein which is a Raf-1 kinase activator. To examine which subtypes of 14-3-3 members are involved in nerve regeneration, we used rat  $\beta$ ,  $\gamma$ ,  $\eta$ ,  $\theta$ , and  $\zeta$  subtype of cDNA which have been already cloned in rat. Among this family members,  $\beta$ ,  $\gamma$ ,  $\theta$ , and  $\zeta$  subtypes were up-regulated. Especially, dramatic increase of  $\theta$  and  $\zeta$  subtype mRNA expression were detected within a few days after nerve transection and continued until 4 and 3 weeks, respectively. Recently some studies demonstrated that  $\beta$  and  $\zeta$  subtype of 14-3-3 have been found to bind Raf-1 and function as Raf-1 kinase activators *in vivo*. Taking these findings into consideration, enhanced expression of 14-3-3 family members after nerve injury suggests that Raf-1 is likely to be activated during nerve regeneration. The present results together with our previous finding (MEK and ERK up-regulation after axotomy) suggest that enhancement of Raf-ERK signaling pathway machinery is probably crucial for nerve regeneration.

**231.2**

TIMING OF C-JUN PROTEIN INDUCTION IN RAT DORSAL ROOT GANGLIA AFTER SCIATIC NERVE TRANSECTION IS DEPENDENT ON LESION DISTANCE: SUPPORT FOR THE INVOLVEMENT OF RETROGRADE TRANSPORT IN C-JUN REGULATION. A.M. Kenney and J.D. Kocsis\*, Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT 06510 and Neuroscience Res. Ctr., VA Medical Center, West Haven, CT 06516

One of the earliest detectable molecular indicators of response to sciatic nerve crush or transection is the up-regulation of the immediate early gene c-jun mRNA and protein in L4/L5 DRG neuronal cell bodies. The lesion-induced signal which upregulates c-jun is not known, although studies using capsaicin, vinblastine, and colchicine suggest that a retrogradely transported molecule is involved. However, these compounds may have injurious effects which could independently influence c-jun regulation. We have used a surgical method to determine whether a transported molecule or another kind of signal, such as electrical discharge or cessation of ambient electrical activity, underlies the upregulation of c-jun protein. The sciatic nerve was transected 1 cm from the L4/L5 DRGs, at the convergence of the L4 and L5 spinal nerves, or 5 cm from the L4/L5 DRGs, at the midhigh level. We used western blotting to study the relative levels of c-jun protein in transected and sham operated contralateral DRGs during the first 24 hours after injury. Immunostaining of frozen sections was used to localize c-jun protein to neurons. Elevated levels of c-jun protein were detectable 2-3 hours after the more proximal nerve transection, whereas increased c-jun protein was not apparent until 12 hours after the distal transection. The different rate of c-jun induction after proximal transection as compared to distal transection supports the hypothesis that a retrogradely transported molecule is responsible for c-jun induction after injury, as an instantaneous signal would lead to c-jun upregulation within a similar time frame regardless of injury site.

CLONING OF AN AXOTOMY-INDUCED GENE WHICH IS SPECIFICALLY EXPRESSED IN INJURED MOTONEURONS. S. Kiryu\*, N. Morita, H. Kiyama, Dept. of Neuroanatomy, Biomedical Research Center, Osaka Univ. Med. Sch., Suita, Osaka, 565 JAPAN.

To gain an insight into the molecular events during peripheral nerve regeneration, we compared differences in expression of mRNAs between axotomized and normal hypoglossal nuclei by means of differential display PCR (DD-PCR) coupled with *in situ* display. DD-PCR and subsequent *in situ* hybridization gave us several candidate gene fragments.

Among them, one clone showed unique expression pattern of the mRNA. A slight increase in the mRNA was detected initially on the injured hypoglossal nucleus 1 day after the nerve cut. The hybridization signal markedly increased to a peak level during the following 3 days and gradually decreased to control level over the following 4 weeks. However, no expression of the mRNA was observed in any other region of the rat brain. Searching of the nucleotide database, DDBJ, revealed that it had no similarity with other known genes. It is therefore suggested that this novel gene is highly implicated in nerve injury or regeneration event.

**231.6**

P53 INDEPENDENT CYCLIN G EXPRESSION IN MOTOR NEURONS AFTER NERVE INJURY. N. Morita\*, S. Kiryu and H. Kiyama, Dept. of Neuroanatomy, Biomed. Res. Center, Osaka Univ. Med. Sch., Suita, Osaka 565 Japan.

An increase in cyclin G expression after nerve injury was demonstrated by differential display PCR (DD-PCR), carried out to compare differences in expression of mRNAs between axotomized and normal hypoglossal motoneurons in the rat. The nerve injury dramatically upregulated the expression of cyclin G mRNA in the motoneurons during nerve regeneration.

Since cyclin G has been shown to be a transcription target of p53, we further examined the cyclin G expression in p53 deficient mouse. Cyclin G was upregulated in motoneurons of p53 deficient mouse after nerve injury, and constant expression of cyclin G was also observed in some regions of the brain and in some other non-neuronal tissue of p53 deficient mouse. These results suggest that the expression of cyclin G, at least in the nervous system, is not regulated by p53 predominantly, and that there may be an alternative regulatory factors or pathways for cyclin G expression in the nervous system.

## 231.7

## CHANGES IN GENE EXPRESSION IN DORSAL ROOT GANGLION CELLS FOLLOWING SCIATIC NERVE LESION OR DORSAL RHIZOTOMY

M. E. Rott<sup>1</sup>, M. Bähr<sup>1</sup> and J. D. Steeves<sup>2</sup>. <sup>1</sup>Dept. of Neurology, Univ. Tübingen, Germany and <sup>2</sup>Dept. of Zoology, UBC, Canada.

We have used the differential display reverse transcriptase polymerase chain reaction technique (DDRT-PCR) to screen for differentially expressed genes following axonal injury which may be critical for regeneration of injured axons. It is thought that altered expression of intrinsic neuronal factors may be important determinants for axonal regeneration. In order to identify such genes, we compared gene expression following regenerative and non regenerative axonal injury in hatchling chicks subjected to either a sciatic nerve lesion or a dorsal rhizotomy, respectively. Total RNA was purified from lesioned DRGs as well as contra lateral control DRGs and analyzed by DDRT-PCR. Several hundred differentially expressed cDNA bands were detected, eluted from the gels, re-amplified and cloned. Sequence analysis of these cDNAs identified both known and unknown genes. To confirm the differential expression of cDNA clones chosen for further analysis, sequences were used as probes against total amplified cDNA from lesioned and control DRG RNA. A wide range of gene expression was observed for these clones in terms of magnitude and pattern of expression, up-regulation after sciatic lesion and/or dorsal rhizotomy as well as down regulation after one or both lesion paradigms. We have now selected a few of these clones for further analysis by developmental Northern blots as well as in situ hybridizations. Those cDNAs that give an expression pattern consistent with that expected for a regeneration associated neuronal factor, will be candidates for continuing cloning and sequence analysis studies.

AXOTOMY-INDUCED ALTERATIONS IN HEAT SHOCK PROTEIN (HSP) 70 PROTEIN LEVELS IN HAMSTER FACIAL MOTOR NUCLEI (FMN). G.A. Newfry<sup>1,2</sup> and K.J. Jones<sup>1,3</sup> <sup>1</sup>Dept. of Cell Biol. & Anatomy, Chicago Medical School, North Chicago, IL 60064, <sup>2</sup>Dept. of Physical Therapy, Univ. IL at Chicago, Chicago, IL 60612, and <sup>3</sup>Dept. of Cell Biol., Neurobiol., & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153.

In the adult hamster, facial nerve axotomy at the stylomastoid foramen induces a reactive sequence of events in the FMN that is geared toward neuronal survival and regeneration. Both axotomy and heat shock result in alterations in nucleolar morphology. General trauma has been found to induce hsp in mammalian brain. Based on evidence that the experimental overproduction of hsp accelerates nucleolar recovery after heat shock, hsp may be important in the recovery from axotomy-induced nucleolar alterations in neurons. Previous work has shown that axotomy induces hsp 70 mRNA within 30' in FMN of adult hamsters, with a return to control values by 12h. In this study, the ability of facial nerve transection to induce hsp 70 in FMN of hamsters of varying ages, which have attained differential nucleolar development and post-trauma survival capacities, was analyzed by western blotting. Postoperative (po) times were 2-24h. Each group had at least 3 animals. Ten µg of protein, from control and injured FMN, were electrophoresed. Paired gels were run for each experiment; one was Coomassie stained, the other transferred to Nytran membrane. Studies used a 1:1000 dilution of a rat antibody which recognizes denatured constitutive and induced members of the eukaryotic hsp 70 family (gift of Dr. S. Lindquist). Blots were developed with the Elite ABC kit (Vector Labs), and DAB/H<sub>2</sub>O<sub>2</sub>. In the adult FMN, in which 100% of the neurons survive axotomy, increased levels of hsp 70 protein were observed by 12h po. In the young FMN, in which the neurons are unsuccessful in post-trauma survival, decreased levels of hsp 70 protein were observed after injury. The results provide the first evidence that survival and regeneration after peripheral axotomy are correlated with hsp 70 protein levels. Supported by an APA grant (KJJ).

## 231.11

## ISOLATION OF A NOVEL REGENERATION SPECIFIC GENE BY MODIFIED DIFFERENTIAL DISPLAY. Holly D. Soares\* and James I. Morgan. Department of Developmental Neurobiology. St. Jude Children's Research Hospital, Memphis, TN 38101.

Outcome following sciatic nerve axotomy is dependent upon developmental age. For example, axotomy performed during the neonatal period results in cell death of axotomized neurons. However, primary motor and sensory neurons can survive sciatic nerve transection when axotomy is performed during adulthood. The present study utilizes neonatal and adult sciatic nerve axotomy as a model to examine the molecular mechanisms underlying a neuron's commitment to either a cell death or survival/regeneration program. Utilizing a modified version of differential display we have isolated a novel 5kb transcript which we have termed Reg1 for regeneration specific gene 1. Northern and *in situ* analysis show that Reg1 is up-regulated in axotomized regenerating adult motor neurons, but not in axotomized degenerating neonatal motor neurons. Further *in situ* analysis shows that Reg1 is not expressed in muscle, kidney, lung, pancreas or small intestine, but is constitutively present in granule cells of the hippocampus and cerebellum. Finally, in chronically transected neurons, Reg1 is still up-regulated at two weeks after axotomy. However two weeks following sciatic nerve crush, Reg1 gene expression has returned to normal levels. These data suggest that Reg1 is regulated by neuronal regeneration. In summary, Reg1 is a novel regeneration specific gene whose expression is localized to the nervous system. This work was supported by ALSAC institutional funding.

## DIFFERENTIAL REGULATION OF A NOVEL FABP (DA11) IN AXOTOMIZED NEURONS FOLLOWING SCIATIC NERVE CRUSH. C.A. Molinari, Y. Liu\*, A.A. Welcher\*, M. De Leon\*†

† Center for Molecular Biology and Gene Therapy and Dept of Physiology, Loma Linda, CA, 93350; \*Amgen Inc., Amgen Center, Thousand Oaks, CA 91320; Department of Anatomy and Human Pathology, Loma Linda CA 92350.

We previously reported the cloning and characterization of DA11, a novel Fatty Acid Binding Protein (FABP) isolated from rat dorsal root ganglia (DRG) cDNA Library (De Leon, et al 1994). In addition we have demonstrated the expression and localization of DA11 protein in the DRG after Sciatic nerve transection (Molina et al 1995). The present study used immunocytochemistry (ICC), *in situ* hybridization (ISH), Western and Northern blots to examine the expression and localization of DA11 protein in the DRG and spinal cord after sciatic nerve crush. Adult male Sprague-Dawley rats received a left ipsilateral (I) sciatic nerve crush and right contralateral (C) sham manipulation at the mid thigh region of the sciatic nerve. Lumbar (L<sub>4</sub>-L<sub>5</sub>) spinal cord segments and respective I and C DRG were harvested and their proteins and total RNA extracted for analysis. Western blot results showed a significant increase in DA11 protein peaking 7 days following crush in the I DRG as compared to the C or naive controls. Subsequently, DA 11 protein in the I DRG decreased to control levels 35 days after injury. Northern blot analysis showed an up-regulation of DA11 mRNA in the I DRG as compared to naive control. The increase was apparent 3 days after the crush peaking at 7 days, and further after returned to normal levels by 28 days after nerve crush. Additional animals were surgically manipulated as above, perfused after 7 days, and processed for ICC with DA11 antisera. Results from the ICC demonstrated mostly cytoplasmic localization of DA11-like immunoreactivity in the C DRG neurons, with very few neurons exhibiting any nuclear staining. In contrast, the immunoreactive pattern of the I DRG showed a marked elevation of DA11 protein in the nucleus of DRG neurons as well as the large motor neurons of the ventral horn of the spinal cord. Our data suggest that DA11 is regulated during nerve repair and regeneration. This work was supported by NIH grant HD3807-Supplement.

## 231.10

## REGULATION OF LIM-TYPE HOMEBOX GENES AFTER PERIPHERAL NERVE INJURY

F.-W. Schwaiger, E.M. Hol, A. Schmitt, and G.W. Kreutzberg\*

Max-Planck-Institute for Psychiatry, Department of Neuro-morphology, D-82152 Martinsried, Germany

LIM-type homeobox genes are believed to play an important role in motoneuron differentiation. The fate of motoneuronal projections depends on the LIM code, a combination of several LIM-type homeobox proteins characterising a given motoneuron. Injury (e.g. axotomy or nerve crush) of peripheral nerves prevents normal nerve cell function, possibly leading to changes in the expression of some LIM genes or reactivation of the embryonic LIM code.

We investigated two models of peripheral nerve injury (facial nerve transection and sciatic nerve crush) in rat. mRNA was isolated from facial nucleus and from spinal cord (T12-L1). After reverse transcription to cDNA the amount of Cyclophilin A as an internal standard was determined to estimate the amount of cDNA. A semiquantitative PCR for GAP-43 was used to validate the PCR conditions and showed GAP-43 to be upregulated by 560% in the facial nucleus and 340% in the spinal cord after nerve injury. Using primers for the semiquantitative PCR of the five known LIM-type homeobox genes (LIM-1, LIM-2, LIM-3, ISLET-1 and ISLET-2), we found a significant downregulation of ISLET-1 and possibly other LIM-type homeobox genes in both peripheral nerve injury models. This might indicate a "growth state" of regenerating motoneurons.

## 231.12

STEROID HORMONE AUTORADIOGRAPHIC LOCALIZATION OF ESTROGEN RECEPTORS IN HAMSTER BRAINSTEM AFTER FACIAL NERVE AXOTOMY. D.R. Sengelaub\*<sup>1</sup> and K.J. Jones<sup>2,3</sup>

<sup>1</sup>Program in Neural Science, Indiana Univ., Bloomington, IN 47405, <sup>2</sup>Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153 and <sup>3</sup>Rehab. Res. & Dev., Hines VA Hospital, Hines IL 60141.

We have demonstrated that administration of testosterone propionate (TP) to hamsters at the time of facial nerve crush axotomy at the stylomastoid foramen will accelerate both functional recovery from facial paralysis and the rate at which facial nerve regeneration occurs. Further work has shown that these effects appear to be androgen receptor-mediated. However, we have recently discovered that estrogen (E) may play a role in the steroid-mediated augmentation of peripheral nerve regeneration. While the presence of estrogen receptors (ER) in the facial motor nucleus (FMN) has been seen transiently in the developing rodent, ER have not been shown to be present in the adult FMN. In this study, we used steroid autoradiography to examine the hypothesis that E influences facial nerve regeneration via classically mediated steroid hormone action. Three groups of adult hamsters were used: normal males, castrated males + unilateral facial nerve axotomy, and castrated males + unilateral facial nerve axotomy + TP (1 s.c. capsule). Postaxotomy survival time was 10 days. Two days prior to sacrifice, normal males were castrated and T capsules were removed from implanted, castrated + axotomy animals. Hamsters were injected with tritiated E (s.c.; 1.5 mCi/g body weight) and killed 1.5 hrs later. Preliminary results (11 weeks exposure) revealed that while E accumulation was apparent in positive control nuclei (e.g., hypothalamus), no labeling was detected in the FMN. Thus, E effects on facial nerve regeneration do not appear to involve classically mediated steroid action at the FMN. Supported by NIH NS28238 (KJJ).

## 231.13

TNF- $\alpha$  AND IL-1 ACTIVATE MAP AND SAP KINASE IN HUMAN NEUROMA FIBROBLASTS. G. Lu, R.W. Beuerman\*, S. Zhao, G. Sun, D.H. Nguyen, S. Ma, D.G. Kline LSU Eye Center and Dept. of Neurosurgery (DGK, SZ), LSU Medical Center, New Orleans, LA 70112

Tumor necrosis factor alpha (TNF- $\alpha$ ) and interleukin-1 (IL-1) induce activation of mitogen-activated protein kinase (MAPK) and stress-activated protein kinase (SAPK), which locate at parallel signal transduction pathways and are involved in cell cycle G<sub>0</sub>/G<sub>1</sub> transition and cellular proliferation in human fibroblasts. These cytokines are released by macrophages during the early inflammatory phase of nerve injury. In our study, fibroblasts cultured from surgically removed human neuromas were serum starved and stimulated with TNF- $\alpha$ , IL-1 (a and b), phorbol 12-myristate 13-acetate (PMA), or platelet-derived growth factor-AB (PDGF-AB), a potent activator for MAPK, individually or in combination. Myelin basic protein (MBP) and human *c-jun* (1-169) glutathione S-agarose transferase (GST) fusion protein were used as substrates in the protein kinase assay. The results showed that TNF- $\alpha$  and IL-1 produced a rapid activation of MAPK, with a peak at 15 minutes for TNF- $\alpha$  stimulation, and a peak at 30 minutes for IL-1 (a and b) stimulation. Increases in MAPK induced by TNF- $\alpha$  and IL-1 were similar to those induced by PMA and PDGF-AB. TNF- $\alpha$  and either IL-1a or IL-1b were synergistic in the activation of MAPK. In addition, TNF- $\alpha$  and IL-1 markedly increased activation of SAPK, whereas PMA and PDGF-AB were much less effective. The results of our study suggest that TNF- $\alpha$  and IL-1 may promote fibroblast proliferation by strongly stimulating these kinases after nerve injury and that this mechanism may play a role in forming the incipient neuroma. *Support: DAMD17-93-V-3013; EY04074, EY02377, NEI*

## 231.15

CHANGES IN UBIQUITIN IMMUNOREACTIVITY IN THE QUAIL CILIARY GANGLION AFTER POSTGANGLIONIC NERVE CRUSH. M.E. De Stefano\*, R. Squitti and G. Toschi. Dip. Biologia Cellulare e Sviluppo, Università "La Sapienza", P.le A. Moro 5, 00185-Roma, Italy.

Ubiquitin (Ub) is a highly conserved eukaryotic protein involved in several cell processes, such as the intracellular breakdown of damaged proteins in stress conditions. We studied, by light microscopy, the immunocytochemical localization of Ub in the quail normal ciliary ganglion, and measured the changes in immunolabelling intensity, after postganglionic nerve crush, in experimental and contralateral ganglia. The numerical values represent an arbitrary absorbance unit (gray scale value from 1 to 260) obtained using an image analyzer. In normal ganglia, both neuronal populations -ciliary and choroid neurons- show Ub immunoreactivity (Ub-ir). The immunoreaction product is evenly distributed in the cell cytoplasm and labels the nucleus intensely. Six hours after crushing the postganglionic ciliary nerves, we observed a slight, but significant increase ( $3.61 \pm 0.26$ ) of Ub-ir in the cytoplasm of the ciliary neurons compared with normal ganglia ( $1.94 \pm 0.07$ ). The immunopositivity reaches a peak 1 day after surgery ( $11.17 \pm 0.66$ ), and then decreases after 3 ( $5.50 \pm 0.17$ ) and 6 ( $4.51 \pm 1.11$ ) days, when the nuclei appear strongly immunolabeled and highly eccentric. In the contralateral ganglia, Ub-ir is always significantly lower than in the corresponding treated ganglia. Our data suggest that the early increase in cytoplasmic Ub-ir in ciliary neurons, subjected to a reversible chromatolytic process after postganglionic nerve crush (De Stefano *et al.*, 1994), is related to the targeting and degradation of damaged proteins. The strong nuclear positivity observed 6 days after crushing may, on the other hand, be related to high histone ubiquitination, involved in maintaining the structure of transcriptionally active chromatin. *Supported by Fondazione Cenci Bolognietti to MEDS and by MURST.*

GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) EXPRESSION IN THE HAMSTER FACIAL MOTOR NUCLEUS (FMN): EFFECTS OF AXOTOMY AND STEROIDS. K.J. Jones<sup>1,2</sup>, N.B. Kinderman<sup>1,2</sup>, and M.M. Oblinger<sup>3</sup>.

<sup>1</sup>Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Chicago, Maywood, IL 60153, <sup>2</sup>Rehab. Res. & Dev., Hines VA Hospital, Hines, IL 60141, <sup>3</sup>Dept. of Cell Biology & Anatomy, Chicago Med. Sch., North Chicago, IL 60064. It has been shown that GFAP, the astrocyte-specific intermediate filament, increases in response to neural injury and that gonadal steroids regulate GFAP expression in the brain. Work in our laboratory has established that gonadal steroids accelerate recovery from facial paralysis following facial nerve injury in adult male hamsters. In this study, we examined the expression of GFAP mRNA levels in hamster FMN following facial nerve severance at the stylomastoid foramen. Adult gonadectomized male hamsters received right facial nerve axotomies, with the left side serving as internal control. Half the animals were also given TP at the time of injury. At 6h, 1, 2, 4, 7 or 14 d postoperative (dpo), the animals were killed and the brains quickly removed and frozen. *In situ* hybridization was performed with a <sup>33</sup>P-labeled GFAP cDNA probe. Slides were processed for autoradiography and quantitative analysis was performed using a computerized image analysis system. The results indicate that GFAP mRNA levels are significantly increased in the axotomized FMN of both TP-treated and nonTP-treated animals, relative to controls, by 2 dpo and remain elevated throughout the 2-week time period analyzed. However, between 2-7 dpo, GFAP mRNA levels were significantly reduced on both the injured and the control sides in the TP-treated animals, relative to the levels in the corresponding FMN from the nonTP-treated animals. These results are consistent with previous work identifying a preservation of synaptic input to the FMN after injury plus TP and suggest that a component of the mechanism by which steroids accelerate axonal regrowth after injury may involve GFAP. *Supported by NIH grants NS28238 (KJJ) and AG13338 (MMO).*

INCREASE IN GAP43 PROTEIN IN SCIATIC NERVE INJURY AND NEUROMA FORMATION. S. Zhao, Q. Ma, R. W. Beuerman, G. Lu, D.G. Kline\*. Departments of Neurosurgery (SZ, DGK) and Ophthalmology, LSU Medical School, New Orleans, LA 70112.

The current study was designed to determine the expression of the neuronal growth-related protein GAP43 after sciatic nerve lesion and early stage of neuroma development. Sciatic nerves of adult rats were severed below the sciatic nerve notch and the severed ends were treated in one of three ways: (1) perineurium and endoneurium were sealed by a bipolar coagulator and buried in the muscles; (2) perineurium was tied with #6 suture; and (3) no treatment. The nerves were harvested at 2 days, 4 days, 14 days, and 1 month post surgery. Specimens of nerve (0.5 cm) were removed from the severed ends and total proteins were extracted. The results of Western blot showed that beginning 2 days post surgery, GAP43 protein was expressed in all the severed nerves. At 14 days after surgery, the nerves that were tied with suture tended to yield more GAP43 than the nerves in the other two groups. Further study is needed to determine the roles of GAP43 in nerve regeneration and neuroma development in the early stages after nerve repair or injury.

## 231.16

EXPRESSION OF NEUREGULINS AND THEIR PUTATIVE RECEPTORS, ERBB2 AND ERBB3, IS INDUCED DURING WALLERIAN DEGENERATION. S.L. Carroll\*, M.L. Miller, P.W. Frohner, S.S. Kim, and J.A. Corbett Div. of Neuropathology, Washington U. Sch. of Med., St. Louis, MO 63110.

Schwann cell dedifferentiation and proliferation is a prerequisite to axonal regeneration in the injured peripheral nervous system. The neuregulin (NRG) family of growth and differentiation factors may play a particularly important role in this process as these axon-associated molecules are potent Schwann cell mitogens and differentiation factors *in vitro*. We have examined Schwann cell DNA synthesis and the expression of NRGs and their receptors, the erbB membrane tyrosine kinases, in rat sciatic nerve, sensory ganglia and spinal cord 0-30 days post-axotomy. Analysis of NRG cDNAs from these tissues revealed several novel splice variants and showed that cells endogenous to injured nerve express NRG mRNAs. A selective induction of mRNAs encoding the GGF subfamily of NRGs occurs in Schwann cells, beginning 3 days post-axotomy. The onset of GGF mRNA accumulation and Schwann cell DNA synthesis coincide precisely. In later stages of Wallerian degeneration, however, Schwann cell mitogenesis markedly decreases while elevated GGF expression persists. Of the four known erbB kinases, Schwann cells express both erbB2 and erbB3 receptors over the entire interval studied. Expression of erbB2 and erbB3 is coordinately induced in response to axotomy, indicating that Schwann cell responses to NRGs may be modulated by changes in receptor density. Thus, in contrast to the concept of NRGs as axon-associated mitogens, our findings argue that NRGs produced by Schwann cells within the adult nerve itself induce Schwann cell proliferation during Wallerian degeneration, probably acting via autocrine or paracrine mechanisms.

## 231.18

GONADAL STEROID REGULATION OF CYTOSKELETAL GENE EXPRESSION IN AXOTOMIZED HAMSTER FACIAL MOTONEURONS (FMN). P.D. Storer\*, S.M. Drengler<sup>1</sup>, M.M. Oblinger<sup>2</sup>, and K.J. Jones<sup>1,3</sup>.

<sup>1</sup>Dept. of Cell Biol., Neurobiol., and Anat., Loyola University, Chicago, Maywood, IL 60153, <sup>2</sup>Dept. of Cell Biol. and Anat., Chicago Med. Sch., North Chicago, IL 60064, <sup>3</sup>Rehab. Res. and Dev., Hines VA Hospital, Hines, IL 60141.

Axotomy of facial motoneurons (FMN) induces cytoskeletal mRNA expression as a component of the neuronal regenerative response. Testosterone propionate (TP) can act as a trophic factor by augmenting select elements of the injury response, leading to accelerated nerve regeneration. In this study, we tested the hypothesis that TP treatment can affect the mRNA levels of  $\alpha_1$ -tubulin and  $\beta_1$ -tubulin, two key cytoskeletal proteins involved in neuronal regeneration. Previous findings from northern hybridization studies showed that TP treatment differentially augments tubulin gene expression in axotomized FMN. Here, adult, gonadectomized male hamsters received right facial nerve axotomy, with the left side serving as internal control. Half the animals received TP implants at the time of injury. At 0.25, 2, 4, 7, or 14 days postoperative (dpo), animals were killed and the brains quickly removed and frozen. *In situ* hybridization was performed using <sup>33</sup>P-labeled cDNA probes to  $\alpha_1$ -tubulin and  $\beta_1$ -tubulin. Slides were processed for autoradiography and quantitative analysis was performed. Results demonstrate that  $\alpha_1$ -tubulin and  $\beta_1$ -tubulin mRNA levels increase significantly in axotomized FMN by 2 dpo relative to controls, and remain elevated through 14 dpo. In the TP treated animals, the induction of both cytoskeletal mRNAs by axotomy was enhanced, relative to axotomized non-TP animals. With TP, mRNA levels increased as early as 0.25 dpo, and remained significantly higher than non-TP levels through 14 dpo. The ability of TP to modulate these cytoskeletal mRNA levels confirms that TP can influence the cell response to injury, and further supports a role for TP in recovery from peripheral nerve damage. *Supported by NIH grant NS28238 (KJJ) and AG13338 (MMO).*

## 231.19

**CYTOSKELETAL PROTEIN EXPRESSION IN LONG-TERM AXOTOMISED FACIAL AND SCIATIC MOTONEURONS.** T. Petrov\*, S. You, S.L. Cassar, W. Tetzlaff, T. Gordon, Div. Neurosci. Univ. of Alberta, Edmonton, Canada T6G, 2S2 and Dept. Zool. & Surgery, UBC, Vancouver, B.C. V6T 1Z4

This comparative study of the expression of cytoskeletal proteins in axotomized rat facial and sciatic motoneurons determines whether reduced regenerative success after prolonged axotomy is due to a reduced capacity to maintain expression of regeneration associated genes and/or to respond to a refreshment axotomy. Facial or sciatic nerves were transected unilaterally and 1 to 12 months later, the contralateral nerves were transected 7 days prior to sacrifice and the experimental nerves cut a second time. There were four clear differences in the effect of prolonged axotomy on facial and sciatic motoneurons: 1) a 2.5 fold increase in actin mRNA at 7 days declined rapidly to control levels within 1 month of axotomy (facial) but more gradually within 6 months after sciatic axotomy, 2) increase in actin and alpha-tubulin mRNA in response to a second axotomy reached the levels of acutely axotomized sciatic but not facial motoneurons, 3) downregulation of neurofilament after the first axotomy was further enhanced by second axotomy in facial but not in sciatic motoneurons and 4) many facial but not sciatic motoneurons showed dramatic atrophy 1 year after axonal injury which was reversed by the second axotomy. Thus injury-induced upregulation of tubulin and actin is not maintained in long term axotomized motoneurons but can be induced again by a second injury. The second axotomy also compromises axonal size in facial motoneurons by a further downregulation of neurofilament. Both types of motoneurons respond to the second axotomy, but the weaker response of chronically injured facial motoneurons might indicate that their regenerative capacity is compromised as early as 6 months following chronic disconnection from their targets. It remains to be determined whether sciatic motoneurons show a weaker response with more prolonged axotomy or whether the differences are due to different distance between the cell body and the injury site in the two models. **CHANGES IN MAP1B PHOSPHORYLATION DURING REGENERATION OF AXOTOMIZED SCIATIC NERVE IN ADULT RAT**

D. Ma, T. Connors and I. Fischer\*

Department of Neurobiology and Anatomy, The Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129

MAP1B is a major component of the neuronal cytoskeleton during early stages of development particularly in growing axons. In normal adult rat the phosphorylated MAP1B isoform, recognized by the monoclonal antibody IBP (Boyne et al., J. Neurosci. Res. 40:439, 1995), was present in axons of DRG neurons, but not in their cell bodies. In contrast polyclonal antibodies that recognize all isoforms of MAP1B detected the protein in DRG neurons as well as their central and peripheral branches. Changes in MAP1B and its mRNA were analyzed in DRGs and their axonal projections using Western blots and RNase protection assays. The analysis showed that after axotomy there were no significant change in the levels of MAP1B and its mRNA in DRGs, their central branches and the proximal parts of peripheral branches. However, in the distal parts of sciatic nerve phosphorylated MAP1B was reduced as early as 3 days after sciatic nerve injury probably due to the Wallerian degeneration of axons. The levels of phosphorylated MAP1B in the distal sciatic nerve increased between 1-3 months after the injury concurrent with the arrival of regenerating axons to this region. We reasoned that MAP1B, which is transported into the growing distal-end of the axons with the slow axonal transport fraction, is phosphorylated in axons and may be required in facilitating axonal growth both during development and nerve regeneration. We propose that the relatively high levels of MAP1B and its mRNA in adult DRGs (Ma et al., J. Neurochem. 66:s64, 1996) provide structural plasticity to peripheral neurons and may correlate with their ability to regenerate without inducing this protein. Supported by NIH grant NS24725, NS 24707 and a fellowship from AHERF neuroscience center.

## TRANSPLANTATION: FUNCTIONAL

## 232.1

**HYPERTROPHY OF BRANCHING IN AXONS REGENERATED FROM ALLOTRANSPLANTED NEURONS IN THE CRAYFISH.**

KM Krause\* and B Arietta, Department of Natural Sciences, St Thomas Aquinas College, Sparkill, NY 10976.

The branching pattern of transplanted neurons which reinnervate the superficial flexor muscle (SFM) of the crayfish *Procambarus clarkii* was examined using scanning electron microscopy (SEM). The 3rd and 4th abdominal ganglia, with attached SFM nerve, were isolated from one animal and transferred to the denervated field of another individual. Earlier electrophysiological work had shown that these transplanted neurons were able to accurately reform specific connections, yet only 65% of host muscle fibers displayed functional synapses suggesting feeble regrowth. (Krause and Velez, J. Neurobiol. 27:154-171, 1995) However SEM micrographs made 8-15 weeks after surgery reveal that the SFM axons from transplanted ganglia in fact exhibit robust regrowth with extensive branching. The fact that specificity remains intact despite hypertrophy suggests that the morphological alterations observed do not represent a failure to eliminate inappropriate connections, but a failure to coordinate the release of the proper signaling molecules from the pre- and post synaptic cells. Axons which were allowed to regenerate following simple axotomy did not show abnormal amounts of sprouting. Thus extensive sprouting is not a normal part of the regeneration response, but results from exogenous influences unique to transplanted neurons. *Funded by St. Thomas Aquinas College Fund*

## 232.2

**PRENATAL ENGRAFTMENT OF CNS STEM-LIKE CELLS: AN APPROACH TO THERAPY FOR CAPRINE  $\beta$ -MANNOSIDOSIS.** K.L. Lovell\*, C. Mitchell-Herpolzheimer, N.K. Ames, E.Y. Snyder, Depts. Pathol. & Large Animal Clin. Sci., Mich. State Univ., E. Lansing, MI; Depts. Neurol. & Pediatr., Children's Hosp., Harvard Med. School, Boston, MA.

In caprine  $\beta$ -mannosidosis, inherited deficiency of the lysosomal enzyme  $\beta$ -mannosidase is associated with severe clinical manifestations at birth, cytoplasmic vacuolation and dysmyelination. However, a goat homozygous for the  $\beta$ -mannosidosis mutation, recently documented as a natural hematopoietic chimera, showed late postnatal onset of mild neurological symptoms and normal myelination. Studies demonstrated that a small amount of normal enzyme supplied prenatally significantly ameliorated the disease (Jones et al., J. Inher. Metab. Dis. 16:1012, 1993). The present report describes studies targeted toward prenatal intracerebral therapy using two types of normal CNS cells: caprine fetal primary cells and the C17-2 murine neural stem-like cell line transduced with the lacZ gene (Snyder et al., Cell 68:33, 1992; Snyder et al., Nature 374:367, 1995; Lacorazza et al., Nature Med. 2:424, 1996). Cells were injected intracranially into two 60-day-gestation fetuses, during the immunotolerant period. Animals were sacrificed 8 days post-injection for analysis of transplanted cells, either by fluorescence to detect fast blue-labelled cells, or by incubation for 16 hours in X-gal. Donor cells were visualized in brain sections of both recipients. The activities of  $\beta$ -mannosidase and  $\beta$ -hexosaminidase were measured in media from cultured cells. Both cell types secreted lysosomal enzymes into the media. To our knowledge, this is the first report of a prenatal intracerebral xenograft (mouse to goat) of CNS stem-like cells during the immunotolerant period. These results reinforce the potential efficacy of prenatal therapy for lysosomal storage diseases characterized by early neurodegeneration. Support: NS33911 to M.Z. ## 232.3

**INTRINSICALLY LABELED RELAY NEURONS OF HOMOTOPIC OLFACTORY BULB TRANSPLANTS ESTABLISH ORGANOTYPIC SYNAPSES WITH HOST NEURONS.** G. Sekerková<sup>1,2</sup>, Z. Katarová<sup>1</sup>, E. Mugnaini<sup>2\*</sup>, E. Joó<sup>3</sup>, J.R. Wolff<sup>4</sup> and G. Szabó<sup>1</sup>. Biological Research Centre, Institute of <sup>1</sup>Biochemistry and <sup>2</sup>Biophysics, 6701 Szeged, Hungary, <sup>3</sup>Northwestern University, Institute of Neuroscience, Chicago, IL, 60611 and <sup>4</sup>University of Göttingen, Dept. Anatomy, 37075 Göttingen, Germany.

Embryonic olfactory bulb (OB) of transgenic mouse line Tg(GAD67lacZ.5.1), in which the glutamic acid decarboxylase/lacZ transgene is strongly expressed in nearly all the mitral and tufted cells, was transplanted into unilaterally bulbectomized neonatal non-transgenic mice. Transplants were evaluated by  $\beta$ -galactosidase enzyme- and immunohistochemistry at the light and electron microscopic level. After 2 months survival the transplant developed into a bulb-like structure that occupied the space between lamina cribrosa and forebrain. The typical laminar organization of the OB was not present in this newly formed bulbar structure. The OMP-positive glomeruli were found irregularly distributed throughout the transplant. The grafted relay neurons, identified by the presence of blue reaction product filling their whole cytoplasm, were scattered in the neuropil of the transplant individually or in small groups. They showed long-term postoperative survival, received afferent axodendritic synapses from regenerated host olfactory terminals within newly formed glomerular arrays, established typical local circuits with unlabeled granule cells, and extended their axons into the piriform cortex where they synapse onto dendrites of host neurons. Our data show that homotopically transplanted relay neurons of the OB are able to integrate into the host olfactory pathway and indicate possible functional recovery. (Supported by OTKA T016971, OTKA T020638, NS09904 and Volkswagen Stiftung #1-7-777)

## 232.4

**Transplantation of EGF-responsive neural stem cells derived from GFAP-hNGF transgenic mice attenuates excitotoxic striatal lesions.** M.K. Carpenter<sup>1</sup>, C. Winkler<sup>2</sup>, R. Fricker<sup>2</sup>, S.C. Wong<sup>1</sup>, C. Greco<sup>1</sup>, D. Emerich<sup>1</sup>, E. Y. Chen<sup>3</sup>, Y. Chu<sup>3</sup>, J. Kordower<sup>4</sup>, A. Messing<sup>4</sup>, A. Björklund<sup>2</sup>, J. P. Hammang<sup>1</sup>. 1) Cell and Molecular Neurobiology, CytoTherapeutics, Inc., Providence, RI 02906; 2) University of Lund, Sweden; 3) Rush Presbyterian Medical Center, Chicago, Illinois; 4) School of Veterinary Medicine, Madison, Wisconsin, 53706.

EGF-responsive neural stem cells isolated from the adult and embryonic striatum propagated in vitro, have the capacity to differentiate into both neurons and glia. Current strategies for the genetic modification of neural stem cells must overcome a number of problems including toxicity, long-term gene stability, transfection or infection efficiency and specificity. The use of transgenic mice in which promoter elements direct the expression of various genes may be an improved method for the genetic modification of these stem cells. We have generated transgenic mice in which the human GFAP promoter directs the expression of human NGF. EGF-responsive stem cells generated from these transgenic animals proliferate and form neurospheres, which appear identical to stem cells generated from control (non-transgenic littermate) animals. Upon differentiation, the transgenic stem cell-derived astrocytes express hNGF as indicated by ELISA. Previous studies have shown that local cell-based delivery of NGF will protect against QA lesions. We transplanted approximately 250,000-500,000 undifferentiated GFAP-hNGF or littermate control stem cells into the striatum of adult rats. One week after transplantation the rats received a striatal QA lesion (225 nmol). Two weeks post-lesion the animals were sacrificed and the brains were evaluated. Animals which received control cells showed comprehensive lesions of the striatum, whereas animals which received GFAP-hNGF stem cells show much smaller lesions. Qualitative histological assessment further demonstrated a sparing of ChAT, GAD and NAPH-d-positive neurons within the striatum of rats receiving GFAP-hNGF stem cells. These data suggest that transplanted GFAP-hNGF stem cells survive, differentiate, secrete NGF and can protect against excitotoxic lesions.

## 232.5

XENOGENEIC ENGRAFTMENT OF PORCINE FETAL LATERAL GANGLIONIC EMINENCE CELLS INTO THE RAT HIPPOCAMPUS: A POTENTIAL THERAPY FOR EPILEPSY. D.B. Jacoby, C. Lindberg, J. Ralliff, J. Dinsmore,\* Diacrin, Inc., Charlestown, MA 02129.

Considerable research has demonstrated that intracerebral engraftment of fetal neural cells can potentiate the severity of epileptic seizures in animal models. Noradrenergic locus ceruleus neurons have been used to reinnervate the hippocampus and normalize basal and seizure-induced noradrenaline levels in the host brain. However, while some reports are promising, others have demonstrated only mild anticonvulsant effects. Recently, the inhibitory neurotransmitter gamma aminobutyric acid (GABA) has been shown to suppress seizures, thus raising the possibility that GABAergic tissues such as fetal lateral ganglionic eminence (LGE) cells may provide a regulated source of GABA. Porcine fetal LGE cells have previously been shown to survive and integrate in the adult rat striatum, but work by others has shown poor survival of fetal striatal cells outside of the striatum. We now address whether ectopically placed porcine LGE cells can survive and integrate in the hippocampus, a central regulator of epileptic activity. Porcine LGE cells were stereotactically transplanted into the hippocampus of adult rats. To enhance graft survival, animals received immunosuppression with cyclosporine A (10 mg/kg/day, s.c.), or cells were treated with F(ab')<sub>2</sub> antibody fragments directed against MHC class I antigen prior to engraftment. Our preliminary data demonstrate that fetal pig striatal grafts survive long term within the hippocampus.

These studies were supported by Diacrin, Inc.

## 232.7

IMPROVEMENT OF CHOLINERGIC EXPRESSION IN SEPTAL TRANSPLANTS BY PURIFYING CHOLINERGIC FETAL NEURONS. J. Cadusseau, L. Vermeil and M. Peschanski\* INSERM U 421 Faculté de Médecine Créteil FRANCE

Transplants of fetal septal-diagonal band tissue have been reported to supply neurons which mature and grow when implanted into a denervated host parenchyma. However the ability to reinnervate the target is limited, due to the presence of heterogeneous cell populations and a low number of cholinergic neurons. Attempts to enrich septal transplants in cholinergic neurons have used immunopanning. At developmental age E17 the septal areas of rat embryos contain many neurons expressing the low affinity NGF receptor (LNGFR) and in the adult septum nearly all the LNGFR positive neurons are choline acetyltransferase (ChAT) positive. We used antibodies against the LNGFR to purify the cholinergic neurons of the E17 septal area. The enrichment of cell suspensions in cholinergic neurons was assessed by analyzing the purified fraction and its complement by acetylcholine esterase (AChE) histochemistry, LNGFR and gamma-aminobutyric (GABA) immunohistochemistry. A highly enriched population of viable cholinergic neurons was isolated. The cholinergic fetal cell suspension was then transplanted into the neuron depleted parenchyma of an adult host and the cholinergic expression of the transplanted tissue was compared with the cholinergic expression of transplants obtained from non-purified suspensions. After 40 days survival, grafts obtained from purified transplants were darkly stained by AChE histochemistry, with nearly all the neurons being LNGFR immunoreactive. More than half the grafted neurons were also ChAT positive, while only a very few were GABA positive. By contrast, grafts obtained from non purified cell suspensions contained very few LNGFR and ChAT immunoreactive neurons but a majority of GABA positive neurons. These results indicate that LNGFR positive neurons can be selected from fetal septal cell suspensions, and the majority of the selected neurons mature into cholinergic neurons when transplanted into an adult parenchyma.

Supported by a grant from INSERM.

## 232.9

TRANSPLANTATION OF HUMAN TERATOCARCINOMA NEURONAL (hNT) CELLS INTO ISCHEMIC RATS PRODUCES RECOVERY OF MOTOR FUNCTION AND PASSIVE AVOIDANCE BEHAVIOR. P.R. Sanberg\* and C.V. Borlongan, Div. Neurol. Surgery, Depts. Surgery, Neurology, Psychiatry, and Pharmacology, Univ. South Florida Coll. Med., Tampa, FL 33612.

Transplantation of fetal striatal tissue into ischemic rats introduced to occlusion of the middle cerebral artery (MCAo) has been shown by Nishino and colleagues (1993) to reverse profound deficits in passive avoidance learning and memory. The present study was designed to replicate this and to determine if transplantation of human hNT cells into ischemic rats can produce recovery of function. Eight-week old rats initially received MCAo ischemic lesions or sham lesions. One month following surgery, animals were tested for asymmetric motor behavior (EBST) and passive avoidance behavior, then assigned to one of the following groups: Normal animals, Sham-surgery/with medium infusion, Stroke-surgery/with medium infusion, Sham-surgery/with striatal cell transplant, Stroke-surgery/with striatal cell transplant, Stroke-surgery/with fresh hNT cell transplant and adjacent Cyclosporine (CsA) treatment, Stroke-surgery/with cyropreserved hNT cell transplant and CsA treatment, Stroke-surgery/with fresh hNT cell transplant and no CsA treatment, Stroke-surgery/with CsA treatment only. At 1, 2, and 3 months post-transplant, animals were evaluated again on the behavioral tests. After completion of these tests, approximately half of the animals were sacrificed for histological immunohistochemistry. At 1 month post-transplantation there was significant recovery in both EBST and passive avoidance task in all three groups given hNT cells or fetal striatal tissue. This behavioral recovery continued for all three months post-transplant, except in the hNT fresh group without CsA which showed a significant decreasing trend of behavioral recovery for two and three months post-transplant. Control animals showed no behavioral recovery. Histological analysis will be reported by Trojanowski and colleagues. Transplantation of hNT cells into the infarcted striatum of rats introduced to transient focal ischemia has been demonstrated to ameliorate motor and cognitive deficits associated with such ischemia. The observed recovery following transplantation of hNT cells paralleled that of the transplantation of fetal striatal cells which has been the primary graft source for a number of neurodegenerative disorders such as Huntington's disease and recently with cerebral ischemia. (This study was supported by Layton Bioscience, Inc., Atherthon, CA.)

## 232.6

COMPETITIVE INTERACTIONS FOR ADULT OLFACTORY BULB FOLLOWING ALLOGRAFTING INTO ADULT RAT STRIATUM: IMPLICATIONS FOR BRAIN DYNAMICS. N.H. Lion\*, J.J. Yu, J.C. Liu and F.W. Chang. Departments of Biology and Anatomy, National Defense Medical Center, P.O. Box 90048-502, Taipei, Taiwan, Republic of China.

Allografts derived from donor adult organ had long been used to overcome chronic abnormalities in human. Besides that, embryonic central nervous system (CNS) tissue such as substantia nigra (SN) have proven to be feasible as graft secreting dopamine and exhibited promising effect on the functional recovery from rat or human model of Parkinson's disease. However, various issues concerning practical use for allografting embryonic tissue still remained to be determined. Based upon those studies, instead use fetus tissue and/or cells we raise an issue expanding the avenue of allografts to explore fundamental biological issues and applications through the use of adult CNS tissue implanted in the adult host CNS. Documented evidence indicated that striatum is the area integrating as well as coordinating input information originated from general and special sensation. Adult olfactory bulb (AOB) that organized in the extent of less laminated structure and connected with outside in a relatively simple circuits. Under normal situation, there is no direct connection between these two structures. Hence, AOB is chosen from donor to determine whether its allografted adult tissue can survive robustly with increasing time after transplantation in the adult host striatum. Consequently, patterns of nerve innervation following grafting in the striatum and cell-cell interactions between graft and host tissue are necessary to examine if the well-integrated phenomenon can be achieved. Under this rational process, functional evaluation such as rotational behavior was also being tested. Results suggest that neurons of AOB still survive at the time tested four months after grafting. Striatal nerve innervation under retrograde tracing studies display increasingly isolated phenomenon following grafting compared to that pattern exhibited before grafting. EM observations reveal apparently consecutive characteristics of reorganization surrounding graft area. Further experiments are underway to extend the notion of brain dynamics in the adult mammalian CNS. (Funded by grant from Taiwan government; NSC 85-2331-B-016-091)

## 232.8

BEHAVIORAL EFFECTS OF AF64A STRIATAL LESIONS AND REVERSAL OF LEARNING DEFICITS BY NEURAL TRANSPLANTS. M. Giordano\*, M. Sánchez-Alavez, R. Salado-Castillo and R. Prado-Alcalá. Centro de Neurobiología-UNAM, Departamento de Fisiología, Facultad de Medicina-UNAM, México D.F.

Ethylcholine mustard aziridinium ion (AF64A) is an irreversible ligand for high affinity choline transport system, a cholinotoxin and an inhibitor of choline acetyltransferase. Intrastriatal and i.c.v. injections of AF64A have been shown to disrupt the acquisition and retention of learning tasks. Neural transplants can reverse behavioral abnormalities and establish anatomical connections with the host brain. In the present study, the effects of striatal AF64A lesions and fetal striatal grafts on a passive avoidance task and on spontaneous locomotor behavior were evaluated. Male Wistar rats (250-300 g) were habituated to activity chambers and their spontaneous activity was recorded for 15 min before and after each experimental manipulation. Animals received bilateral infusions of AF64A (11 nmol/ $\mu$ l, 0.2  $\mu$ l/min) into the striatum. One week after the lesion, group 1 received bilateral solid fetal striatal transplants, group 2 received bilateral dissociated fetal striatal transplants, group 3 received bilateral solid cerebellar transplants, group 4 received only bilateral vehicle infusions, group 5 was a naive group. Six weeks after the transplant, animals were trained and tested (30 min and 24 h later) in a passive avoidance task. After the lesion 6/54 animals showed self-injurious behavior and were excluded. The results showed that locomotor activity was at its highest one week after AF64A lesions and for most groups it returned to baseline levels six weeks after the transplant. In the passive avoidance task, sham and cerebellar transplanted groups were significantly different from naive animals in their retention scores 24 hours after training ( $t=2.13$ ,  $t=2.25$  respectively,  $p<0.05$ ). There were no significant differences between naive and striatal transplant groups. These results show that striatal transplants can reverse the retention impairment induced by the cholinergic lesion, and that this effect appears to be selective. Support provided by UNAM-DGAPA to R. Prado-Alcalá.

## 232.10

XENOTRANSPLANTED CHOLINERGIC NEURONS INTO ANIMAL MODELS OF COGNITIVE DYSFUNCTION. C. Le Blanc<sup>1</sup>, L. Burns<sup>1\*</sup>, P. Borghesani<sup>1</sup>, T. Deacon<sup>1,3</sup>, J. Dinsmore<sup>2</sup>, O. Isacson<sup>1</sup>. Neuroregeneration Laboratory, McLean Hospital, Belmont, MA 02178 and Program in Neuroscience, Harvard Medical School<sup>1</sup>, Diacrin, Inc., Charlestown, MA 02129<sup>2</sup> Boston University, Boston, MA 02115<sup>3</sup>

Recent clinical observations and specific use of immunotoxins selective for the forebrain cholinergic system support the notion of cholinergic synaptic function in cognitive processes such as those disrupted in Alzheimer's disease. We have produced cholinergic dysfunction in rats either by lesions of the nucleus basalis using excitotoxins or by infusions of saporin conjugated antibodies to the rat p75NGF-receptor into the lateral ventricle. IgG saporin lesions were found to deplete 75-98% of cholinergic neurons in the septum diagonal band region and basal forebrain. We compared cholinergic neuron production from different regions of pig fetal brains. Medial ganglionic eminence, fronto-medial telencephalon, and fronto-basal telencephalon were selectively dissected from fetal pigs (E30-E35) and cell suspensions from these tissues were transplanted into the nucleus basalis of immune suppressed lesioned animals. After 2-3 months survival, histological analysis with a second p75NGF-receptor antibody and a 70kd neurofilament antibody, both reactive with pig but not rat neurons, demonstrated cholinergic cells from all three graft types. Both p75NGF- and NF70-immunoreactive axons could be traced long distances within the host brain. Behavioral recovery by porcine grafts is currently being tested in a Morris water maze. This study demonstrates the capacity of transplanted xenogeneic cholinergic neurons to survive and replace neurons previously lost in an animal model of a cholinergic neurodegenerative process. (Supported by funds from Diacrin Inc. and McLean Hospital.)

**RESTORATION OF MNEMONIC FUNCTIONS WITH TRANSPLANTS OF FETAL ENTORHINAL CORTEX.** L.A. Rothblat<sup>1,2</sup>, T.C. Gleason<sup>1</sup>, R.M. Torrisi<sup>1</sup>, S.M. Matzke<sup>1</sup>, N. Vnec<sup>1</sup>, and J.M. Rosenstein<sup>1</sup>. <sup>1</sup>Dept. of Psychology; <sup>2</sup>Dept. of Anatomy & Cell Biology, The George Washington Univ., Washington, DC 20052.

It has been shown that bilateral transections of the angular bundle (AB) impairs retention, but not acquisition of visual object discriminations (Vnec et al., *J. Neurosci.*, 1995). This lesion (1) removes entorhinal cortex (EC) inputs to the hippocampus and (2) results in degeneration of layer II EC cells. In this study we wanted to see if the memory impairment that results from AB transections can be reversed with fetal transplants. Seventeen rats received bilateral knife cuts intended to partially transect the perforant pathway. Seven to 10 days later, 7 of the lesioned rats received embryonic EC grafts placed bilaterally into the dentate gyrus (DGT). Ten rats had lesions with no transplants (AB) and 6 served as normal controls (NC). After two weeks, rats began behavioral testing on a spatial alternation task and then were trained on a series of object discriminations. For the discrimination task, animals learned 3 problems simultaneously. Following a 3 week interval, they were tested for retention (RT1), then tested again two weeks later (RT2).

While DGT and AB rats were impaired on the spatial task, rats in all 3 groups learned the object discriminations normally. On retention, only the AB group was significantly impaired. DGT scores were somewhat elevated on RT1, but were normal on RT2. These results suggest that fetal EC grafts placed directly into the dentate gyrus can ameliorate some of the deficits that result from EC-hippocampal disconnection. The EC transplants could improve nonspatial mnemonic function either by restoring perforant path inputs to the hippocampus (Woodhams et al., *Neurosci.*, 1992) or by providing trophic factors that prevent axotomy-induced degeneration in entorhinal cortex (Peterson et al., *J. Neurosci.*, 1994). Supported by Alzheimer's Association Grant PRG-94-172.

**NEURONAL RESCUE BY EMBRYONIC NEURAL CELL GRAFTS IN LURCHER MUTANT MICE.** J.A. Heckroth<sup>1</sup>, Department of Anatomy and Neurobiology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Lurcher mutant mice ten days of age received embryonic day 12 cerebellar cell suspension grafts in the cerebellar hemisphere. The donor embryos were obtained from a transgenic mouse line (provided by Dr. J. G. Sutcliffe of the Scripps Research Institute) which carries a neuron specific enolase promoter-LacZ construct. Host mice received grafts of between 500,000 and 1,000,000 live cells as determined by Trypan blue staining of the cell suspensions. The cells were injected at 2-4 sites in the right cerebellar hemisphere. Host mice were euthanized at 90 days of age, and the brains processed for: 1) visualization of beta-galactosidase activity, 2) immunohistochemical localization of 28K calcium binding protein (antiserum provided by Dr. Anthony Norman, UC Riverside), or 3) Nissl staining. Olivary neuron numbers were estimated in the right and left olivary complex of ten graft hosts and five 90 day old lurcher mice. Analysis of variance indicates no left-right asymmetry in lurcher mice and shows that the right olivary complex of the graft hosts is identical in cell number to ungrafted lurcher mice. The left inferior olivary complex of the graft hosts, however, contains statistically more neurons than the right, and more neurons than ungrafted lurcher mice. When analyzed by olivary subdivision only the caudal medial accessory olive and dorsal accessory olive exhibit significant neuronal rescue. Given that the grafted neurons undergo a period of differentiation after grafting which may delay their potential therapeutic effects for 5-10 days and considering that olivary degeneration has already begun at the time of grafting, it appears that the grafts are highly efficient in their rescue of olivary neurons. These results prove that neural cell grafts can function to reduce transneuronal degeneration in a progressive neurodegenerative disease. Research supported by NINDS grant #NS33969

**IMPLANTATION OF ENCAPSULATED CNTF-PRODUCING CELLS PREVENTS THE BEHAVIORAL DEFICITS AND STRIATAL DEGENERATION IN A RODENT MODEL OF HUNTINGTON'S DISEASE.** D.E. Emerich<sup>1</sup>, M.D. Lindner<sup>1</sup>, S.R. Winn<sup>1</sup>, E-Y. Chen<sup>1</sup>, B.R. Frydel<sup>1</sup>, J.H. Kordower<sup>1</sup>, CytoTherapeutics, Inc., 21 Richmond Square Providence, RI 02906 and Research Center for Brain Repair and Department of Neurological Sciences, Rush Presbyterian Medical Center, Chicago Illinois 60612<sup>1</sup>.

Delivery of neurotrophic molecules to the central nervous system has gained considerable attention as a potential treatment strategy for neurological disorders. In the present study, a DHFR-based expression vector containing the human ciliary neurotrophic factor (hCNTF) was transfected into a baby hamster kidney fibroblast cell line (BHK). Using a polymeric device, encapsulated BHK-control cells and those secreting hCNTF (BHK-hCNTF) were transplanted unilaterally into the rat lateral ventricle. Twelve days later, the same animals received unilateral injections of quinolinic acid (QA, 225 nmol) into the ipsilateral striatum. Following surgery, animals were behaviorally tested for apomorphine-induced rotation behavior and for skilled forelimb function using the staircase test. Rats receiving BHK-hCNTF cells rotated significantly less than animals receiving BHK-control cells. No behavioral effects of hCNTF were observed on the staircase test. Nissl-stained sections demonstrated that BHK-hCNTF cells significantly reduced (approximately 50%) the extent of striatal damage produced by QA. Quantitative analysis of striatal neurons further demonstrated that both CHAT and GAD-immunoreactive neurons were protected by BHK-hCNTF implants. In contrast, a similar loss of NADPH-diaphorase-positive cells was observed in the striatum of both implant groups. Analysis of retrieved capsules revealed numerous viable and mitotically active BHK cells that continued to secrete hCNTF. These results support the concepts that implants of polymer-encapsulated hCNTF-releasing cells can be used to protect striatal neurons from excitotoxic damage and that this strategy may ultimately prove relevant for the treatment of Huntington's disease.

## 232.12

**PHENOTYPIC EXPRESSION OF HUMAN FETAL CEREBELLAR CELLS FOLLOWING TRANSPLANTATION INTO NUDE MOUSE CEREBELLUM.** L. L. Pundt<sup>1</sup>, E. A. Jörn<sup>1</sup>, J. A. Conrad<sup>1</sup>, W. C. Low<sup>2</sup>. Depts. of Neurosurgery, and Physiology, and Program in Neuroscience, Lions Research Bldg., University of Minnesota Medical School, Minneapolis, MN, 55455.

Previous rodent studies have demonstrated the capacity of grafted cerebellar cells to organize into the trilaminar cell layers typical of the normal cerebellum. Utilizing Purkinje cell deficient hosts, transplanted Purkinje cells originating from fetal cerebellum of wild-type donors have been shown to migrate from the graft site to the location of the missing neurons, and form synaptic contacts. In addition, it has been demonstrated that fetal grafts of normal cerebellar tissue transplanted into the Purkinje cell degeneration (PCD) mutant mouse results in an improvement of motor behaviors in open field and balance rod tests. These studies indicate the potential therapeutic use of neural transplantation in patients with cerebellar ataxia. In the present study, human fetal cerebellar tissue (8.5 weeks post conception; n=2) was dissociated and transplanted into the cerebellum of normal nude mice (n=10). Six months following transplantation, histological analysis revealed donor cells within the host cerebellum of nine animals. Calbindin staining revealed the presence of donor Purkinje cells which were organized in discrete cellular layers within the transplant neuropil, and in most cases, demonstrated dendritic processes orientated in the same direction (in the "molecular layer"). Human neurofilament immunostaining revealed donor fibers within the transplant neuropil. Human astrocytes were located within the transplant region and adjacent host tissue. These results demonstrate the capacity of human fetal cerebellar cell suspension to develop into Purkinje cells following transplantation into the rodent cerebellum. Supported by PHS grant RO1-NS-24464 and the Bobby Allison Ataxia Center.

## 232.14

**AUTORADIOGRAPHIC STUDIES OF AMINO ACID RECEPTOR BINDING IN CEREBELLAR GRAFTS.** K. Stasi<sup>1</sup>, A. Mitsacos<sup>1</sup>, E.D. Kouvoulas<sup>1</sup> and L.C. Triarhou<sup>2</sup>. Dept. of Physiology, Univ. of Patras Med. Sch., 265 00 Patras, Greece and Dept. of Pathology and Lab. Medicine, Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

We used quantitative autoradiography of [<sup>3</sup>H]CNQX (200 nM), [<sup>3</sup>H]muscimol (13 nM) and [<sup>3</sup>H]flunitrazepam (10 nM) binding to study the distribution of non-NMDA and GABA<sub>A</sub> receptors in the cerebellum of *pcd* mutant mice with unilateral cerebellar grafts. Non-specific binding was determined by incubation with 1 mM Glu, 200 μM GABA or 1 μM clonazepam, respectively. Saturation parameters were defined in wild-type and mutant cerebella. In mutants, non-NMDA receptors were reduced by 35% in molecular layer (ML), by 36% in granular layer and by 33% in deep cerebellar nuclei (DCN). [<sup>3</sup>H]CNQX binding sites were visualized at higher density in grafts that had migrated to the cerebellar cortex (11 and 23 pmol/mg prot. at 23 and 37 days after grafting), and at lower density in grafts arrested intraparenchymally (8 and 12 pmol/mg prot.). The reduction of non-NMDA receptors in *pcd* ML supports their localization on Purkinje dendrites. The pattern of expression of non-NMDA receptors in cortical vs. parenchymal grafts suggests a possible regulation of their levels by transacting elements from host parallel fibers. GABA<sub>A</sub> binding levels in the grafts for both ligands used were similar to normal ML. Binding was increased in DCN of mutants: the increase in [<sup>3</sup>H]muscimol binding over normal was 271% in the non-grafted and 198% in the grafted side; for [<sup>3</sup>H]flunitrazepam, the increase was 134% in the non-grafted and 112% in the transplanted side over normal. Such increases in the *pcd* DCN reflect denervation-induced supersensitivity subsequent to loss of Purkinje axon terminals. The relatively smaller increase of GABA<sub>A</sub> receptors in the transplanted side compared to the contralateral side indicates a partial normalizing effect of the grafts on postsynaptic supersensitivity in the reinnervated DCN, possibly mediated through the synapses established by donor Purkinje cells. (Supported in part by USPHS R29-NS29283 and EU Biomedicine Programme Contract No. BMH1-CT94-1378).

## 232.16

**STRIATAL GRAFT GROWTH DEPENDS ON STRIATAL LESION SIZE IN A RAT MODEL OF HUNTINGTON'S DISEASE.** C. Watts<sup>1</sup>, E. Torres<sup>1</sup> and S.B. Dunnett<sup>1</sup>, MRC Cambridge Centre for Brain Repair, University of Cambridge, Cambridge CB2 2PY, UK.

The effect of lesion size on the growth and development of intrastriatal striatal transplants was evaluated in the rat model of Huntington's disease.

Thirty female Sprague Dawley rats weighing between 180 - 200g were randomly allocated to 4 groups. 3 groups received unilateral striatal lesions involving stereotaxic injection of 2 x 0.5ul of either 20nM, 40nM, or 90nM quinolinic acid (quin) into the striatum (n=8 per group). The 4th group remained unlesioned (n=6). Seven days after lesioning, 6 rats from each lesion group and all 6 unlesioned rats received a cell suspension graft of 2.3million cells in a volume of 2 ul. The cells were obtained from the whole striatal anlage of E16 (CRL 15mm) rat embryos. Ten weeks after grafting the rats were perfused with 10% formalin and 60 micrometer frozen sections were processed for Tyrosine Hydroxylase (TH) and Dopamine and Cyclic Adenosine 3:5 monophosphate Regulated Phosphoprotein of 32 kdaltons (DARPP-32) immunoreactivity.

Lesions of increasing severity were obtained with increasing concentrations of quin. Graft survival was good in all the lesioned rats. Striatum-like tissue, as defined by DARPP-32, was present in all grafts in localised patches (P-zones). TH staining within the grafts was confined to these P-zones which received TH positive fiber ingrowth from the host neuropil. In contrast, graft survival in intact animals was poor with no P-zones present and little TH fibre ingrowth within the parts of the grafts localised within the host striatum.

These results suggest that grafts will grow and develop areas of striatal tissue in both partial and complete lesions but growth of striatum-like tissue in the intact striatum is inhibited by the intact striatal neuropil. Supported by the Wellcome Trust and MRC.

## 232.17

THE EFFECT OF INTERVAL BETWEEN LESION AND TRANSPLANTATION ON STRIATAL GRAFT SURVIVAL AND INTEGRATION IN THE QUINOLINIC ACID-LESIONED NEOSTRIATUM OF RATS. S.Thian, C.Watts, E.M.Torres, B.J.Everitt, W.F.Blakemore and S.B.Dunnett (SPON: European Brain and Behaviour Society). MRC Cambridge Centre for Brain Repair, Forvie Site, Robinson Way, Cambridge CB2 2PY, UK.

In order to examine factors influencing neuronal graft survival and integration in an animal model of Huntington's disease, excitotoxic lesions were produced at specific timepoints prior to transplantation. Quinolinic acid (45nmol in 0.5µl) was slowly injected into the neostriatum of five groups of rats, 6 hours, 24 hours, 2 days, 7 days and 6 weeks prior to the transplantation of cell suspensions prepared from E14 rat striatal primordium. The grafts were placed in the same site as the lesion. Survival and integration were assessed histologically after 6 weeks, with immunocytochemical and enzyme stains. The grafts survived well in all groups, even in that with excitotoxin injection only 6 hours prior to transplantation. However the grafts differed in their extent of growth, which was least in the 1 day and 2 day groups. There was also a difference in the shape of the grafts, which was more cylindrical at the 6 hour interval, and more spherical at all longer intervals. The proportion of striatal patch to non-patch compartments within the graft did not differ significantly between groups. Tyrosine hydroxylase immunohistochemistry revealed somewhat greater fibre ingrowth into the non-patch as well as patch areas of grafts implanted at shorter intervals after lesioning. This may point to an interaction between a declining plasticity of host nigrostriatal terminals following loss of their intrinsic target, and the trophic properties of patch and non-patch neuronal compartments within the striatal graft.

Supported by the Wellcome Trust and the Medical Research Council.

## 232.18

BILATERAL INTRASTRIATAL TRANSPLANTATION OF RAT FETAL STRIATAL TISSUE INTO THE 3-NITROPROPIONIC ACID RAT MODEL OF HUNTINGTON'S DISEASE. C.V.Borlongan, T.K.Koutouzis, S.G.Poulos, S.Saporita, R.A.Hauser, D.W.Cahill\*, T.B.Freeman and P.R.Sanberg. Div. Neurol. Surgery, Depts. Surgery, Neurology, Psychiatry, and Pharmacology, Univ. South Florida Coll. Med., Tampa, FL 33612.

The promising results in clinical neural transplantation for Parkinson's disease coupled with the demonstration of positive effects of fetal neural transplantation in ameliorating neurobehavioral deficits in animal models of Huntington's disease (HD) have prompted several researchers to propose clinical trials for HD. Accordingly, the implications of the evidence accumulated from HD animal models should be closely evaluated. To date, excitotoxic (e.g. kainic, ibotenic or quinolinic acids) animal models of HD have reproduced only the hyperactive stage of HD. Recently, we showed that chronic low dose injection of 3-nitropropionic acid (3-NP, a mitochondrial toxin) in mature rats leads to hypoactivity. Most, if not all, fetal tissue transplantation in animal models of HD have been carried out using the excitotoxic-induced hyperactive model of HD. In the present study, we used the 3-NP-induced hypoactive model of HD to demonstrate whether fetal tissue transplantation can ameliorate the behavioral deficits associated with the advanced stage of HD. Twelve-week old Sprague-Dawley rats were introduced to the 3-NP dosing regimen (10 mg/kg, i.p., once every 4 days for 28 consecutive days). At the end of this injection period, the rats were tested for general spontaneous locomotor activity using the Digiscan locomotor apparatus. All rats displayed significant hypoactivity compared to their pre-3-NP injection locomotor activity. Randomly selected rats then received bilateral intrastratial solid grafts of fetal striatal (lateral ganglionic eminence) tissues from embryonic day 14 rat fetuses. Approximately 1/3 of each striatal tissue in hibernation medium was infused into each lesioned host striatum (AP: +1.2, ML: ±2.6, DV: -4.7). In control 3-NP-induced hypoactive rats, medium alone was infused intrastratially. A 3-month posttransplant maturation period was allowed prior to locomotor activity test. Animals receiving fetal striatal grafts exhibited a significant increase in locomotor activity compared to their or to controls' post-3-NP injection activity or to the controls' posttransplant activity. Histological characterization of host-graft interaction will be reported. This observation supports the use of fetal striatal transplants to correct the akinetic stage of HD. To the best of our knowledge, this is the first study that has directly investigated the effects of fetal striatal transplantation in a hypoactive model of HD.

## 233.1

DOES ULTRASOUND IRRADIATION AMPLIFY IMMUNOHISTOCHEMICAL LOCALIZATION? N.Havkaj-Coates, K.M.Crofton\* and S.Barone Jr. Neurotoxicology Division, National Health & Environmental Effects Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711

Ultrasound irradiation has been used to enhance electron microscopic procedures (Robb *et al.*, 1991), and in amplifying immunohistochemistry (Podkletnova *et al.*, 1993). Since ultrasound irradiation is still regarded as a novel tool and is suggested as a method for amplifying immunohistochemical staining, we tested its usefulness and reproducibility with different antisera on sections from perfusion fixed adult rat brains. Immunohistochemistry was performed on 40 µm free-floating sagittal sections collected using a freezing-stage microtome. The sections were incubated for 30 minutes at room temperature on a shaker in 10% normal goat serum to block the nonspecific binding sites of the proteins. The sections were then transferred to polystyrene scintillation vials with one of 3 polyclonal antisera: TH (Tyrosine Hydroxylase), PKC γ diluted 1:10,000, or glial fibrillary acidic protein (GFAP) diluted 1:40,000. Using a conventional ultrasound bath, the sections were briefly exposed to 30 seconds of irradiation then incubated for 30 min or 18 hrs at 4°C in primary antisera. Immunohistochemical staining was carried out using routine immunoperoxidase techniques. Ultrasound irradiation increased TH immunoreactivity (IR) considerably at both time points but the longer incubation had the greatest increase in cellular and fiber staining. PKC-IR at short incubation times was poor regardless of ultrasound treatment. Ultrasound treatment increased PKC-IR only at the longer incubation time. Ultrasound treatment improved GFAP-IR only at the earlier incubation time, with no significant difference in IR at the longer incubation time. There was no significant increase in the temperature of the incubation medium and no increase in the background staining. Our results show that ultrasound irradiation could be used as an option to improve immunohistochemical techniques while reducing the incubation time in primary antisera and increasing the dilution of primary antisera. This method may have great utility; however, its usefulness in non-neural tissues and with different antisera must be determined empirically.

## 233.3

ANTIBODY-BASED TECHNIQUES ARE SUPERIOR TO ROUTINE HISTOCHEMICAL METHODS FOR THE EVALUATION OF MYELIN. K.M.Weidenheim\* and W.D.Lyman. Department of Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

The evaluation of myelin in biopsy and autopsy CNS tissue is limited because of formalin fixation, paraffin embedding and hematoxylin-based or copper-thiocyanate dyes. However, because immunohistochemical methods employing antibodies that recognize myelin-specific proteins have become available, we have evaluated the relative utility of immunologic techniques using antibodies which recognize myelin basic protein (MBP), proteolipid protein (PLP) and myelin associated glycoprotein (MAG) for the evaluation of myelin in sections of 17 formalin-fixed human spinal cords obtained at autopsy from patients without significant neurologic disease. These results were compared to those obtained using the Luxol fast blue technique (LFB). Staining intensity was evaluated by light microscopy and graded as +3 (uniform staining in all funiculi); +2 (mild variability in staining); +1 (marked variability in staining intensity); and 0 (no staining). Methods for MBP and PLP revealed uniform, +3 staining of myelinated tracts in 16/17 cases. The LFB technique revealed variability in myelin staining with 11/17 cases staining +2 and 6/17, +3. MAG immunohistochemistry produced inconsistent results. These results suggest that visualization of MBP and PLP myelin epitopes provide a sensitive and specific method for assessing myelin integrity in autopsy material obtained and fixed by widely available methods. (Supported in part by USPHS grants MH 47667 and MH 46815)

## 233.2

USE OF PEROXIDASE SUBSTRATE VIP™ FOR MULTIPLE STAINING IN LIGHT MICROSCOPY. J.L.Lanciego, P.H.Goede, F.G.Wouterlood, and M.P.Witter. (SPON: European Neuroscience Association). Research Institute Neurosciences Amsterdam. Department of Anatomy and Embryology. Vrije Universiteit. 7 van der Boechorststraat, 1081 BT Amsterdam. The Netherlands.

Study of the distribution of a fiber input in a particular brain area and the anatomical relationships in this area with both projection- and interneurons requires a triple-staining that allows the unequivocal distinction of each of the three involved components in one and the same histological section. We investigated in this respect the properties of a recently introduced peroxidase substrate, VIP (Vector Labs; forms a purple precipitate) in combination with two traditional substrates, standard diaminobenzidine (DAB; brown precipitate) and nickel-enhanced DAB (black). In rats, the tracers biotinylated dextran amine (BDA, anterograde tracer) and fluorogold (FG, retrograde tracer) were injected in the perirhinal cortex and hippocampus, respectively. Transported BDA was detected with an avidin-biotin-peroxidase complex (Veenman *et al.*, 1992) whereas the transported FG was detected via PAP method (antisera kindly provided by Dr. H. Chang, Dept. Anat. Neurobiol. Univ. of Tennessee). Tracing with BDA and FG was combined with immunocytochemistry with antibodies against the calcium-binding proteins parvalbumin or calbindin. We report on various combinations and staining sequences. Best results were obtained with a staining sequence that comprises first a BDA stain with DAB-Ni, second a FG protocol with DAB and then parvalbumin- or calbindin immunocytochemistry with VIP. The sequence in which chromogens were applied appeared critical. The first stain should be done using DAB-Ni, the second using DAB and the third using VIP. Color separation is excellent, and the sensitivity is good. Sections are mounted on slides and dried. The only specific caution to be exerted is to dehydrate in alcohol rapidly before coverslipping in order to prevent fading of the VIP reaction product. For dehydration, toluene can be used as an alternative to ethanol.

## 233.4

AN ANTISERUM TO CALRETININ FIXED IN THE CALCIUM-FREE FORM REVEALS CEREBELLAR GRANULE CELL IMMUNOREACTIVITY. L.Winsky\* Lab. of Clinical Science, NIMH, Bethesda, MD 20892.

Results of a previous report (Winsky and Kuznicki, 1996, J. Neurochem.) indicated that commonly used antibodies to calretinin (CR), calbindin D28k and parvalbumin preferentially recognize calcium bound proteins. The present studies extend these earlier findings in an attempt to produce an antiserum to CR that is suitable for immunohistochemistry and which preferentially recognizes the calcium free conformation of CR. Recombinant CR was cross-linked with formalin following incubation with low calcium buffer and injected into a rabbit for the production of a polyclonal antiserum. Tests for immunoreactivity were made of pre-immune serum and sera obtained at various times after injection of the CR solutions. These tests included the examination of CR immunoreactivity on brain sections of rats and guinea pigs, on western blots and on dot blots containing serial dilutions of unfixed or formalin fixed recombinant CR. Results revealed similar overall patterns of immunoreactivity to that seen with a previous CR antiserum in most brain regions. However, granule cells of the cerebellum, which contain CR mRNA but have previously only shown low immunoreactivity where intensely immunoreactive in some lobules. No cross-reacting proteins were seen on western blots of cerebellum but the new antiserum preferentially recognized CR cross-linked in a calcium free form on dot blots. These preliminary results suggest that it may be possible to develop calcium binding protein antisera for studying the calcium binding status of these proteins in cells. (Supported by NIMH DIRP)

## 233.5

**IMMUNOHISTOCHEMICAL LOCALIZATION OF THE MULTICATALYTIC PROTEINASE (PROTEASOME) IN THE RAT CENTRAL NERVOUS SYSTEM.** <sup>1</sup>E. Mengual\*, <sup>2</sup>P. Arizti, <sup>3</sup>J. Rodrigo, <sup>1</sup>J.M. Giménez-Amaya and <sup>2</sup>J.G. Castaño. <sup>1</sup>Departamento de Morfología and <sup>2</sup>Departamento de Bioquímica, Facultad de Medicina, U.A.M., 28029 Madrid and <sup>3</sup>Departamento de Neuroanatomía Comparada, Instituto Cajal, C.S.I.C., 28002 Madrid, Spain.

The multicatalytic proteinase (MCP, proteasome or prosome) is a 20S complex which plays a major role in non-lysosomal pathways of intracellular protein degradation. In this study, a polyclonal antibody against rat liver MCP was used to investigate the distribution of MCP in the central nervous system (CNS) of the rat and its subcellular localization within the neurons. As expected, MCP-immunoreactivity (MCP-ir) is ubiquitously distributed in the rat CNS, but its distribution is not homogeneous. At the subcellular level, MCP-ir is primarily localized in the nuclei of neurons and glial cells. The most intensely stained neurons were the pyramidal cortical neurons of layer 5 and the motor neurons of the ventral horn in the spinal cord. These cells displayed an intense nuclear and cytoplasmic MCP-ir and clearly stained processes. Additionally, some populations of large neurons in the mesencephalon and brainstem also displayed a moderate MCP-ir in their perikarya. The vast majority of neurons in the remaining structures did not show a strong cytoplasmic MCP-ir, but their nuclei displayed an intense MCP-ir. The ubiquitous distribution of MCP in the rat CNS and its subcellular localization are discussed in relation to: (1) the brain distribution of calpain, the other major non-lysosomal cellular protease, that has been implicated in neuronal vulnerability to ischemia; and, (2) the possible role of MCP in the degradation of key transcription factors which are essential in many neuronal responses (e.g., in short-term and long-term memory processes). Supported by FIS 93/0337, SAF 94-0685 and Fundación Ramón Areces.

## 233.7

**IMMUNOHISTOCHEMICAL LOCALIZATION OF LIPOCORTIN 1.** M-Z Zhang\* and JA McKanna. Dept. of Cell Biology, Vanderbilt University School of Medicine, Nashville, TN 37232.

Lipocortin 1 (LC1) has received considerable attention as a substrate for protein kinases, as a  $Ca^{2+}$ - and phosphatidylserine-binding protein, and as a mediator of glucocorticoid anti-inflammatory effects. However, progress in this field has been confused by contradictory immunohistochemical localizations; e.g., according to various reports, LC1-ir localizes in rat brain exclusively to either neurons or astrocytes or microglia. Hypothesizing that the contradictory data may arise from unusual properties of the antigen, we developed a novel brain slice model to test hundreds of fixation and staining variables. The results show that several commonly used immunohistochemical procedures have profound but unexpected effects on LC1-ir. As defined by (a) sensitivity to pre-absorption of 1<sup>st</sup> sera with LC1 purified from either human placenta or recombinant yeast and (b) staining with 1<sup>st</sup> antibodies affinity purified with immobilized recombinant LC1, "true" LC1-ir was readily apparent in microglia of brains fixed with acidified aldehydes and embedded in paraffin. However, LC1-ir was eliminated either by fixation with neutral/alkaline aldehydes, or by freezing prior to strong acid fixation, or by staining prior to partial dehydration. We suggest that the sensitivity of LC1 epitopes to [proton] and [water] activities may reflect molecular properties important to LC1's roles *in vivo*, and also suggest the similar sensitivities may influence immunolocalization of other proteins with phospholipid affinity. Regardless of methodological variables tested to date, true LC1-ir is never detected in neurons or astrocytes. The specific expression of LC1 in microglia supports the hypothesis that the anti-inflammatory and immuno-suppressive properties of LC1 may play important roles as these cells respond to damage and disease in the mammalian central nervous system.

Supported by DOD Medical FEL program and NS-32660HD15052.

## 233.9

**USE AND INTERPRETATION OF DI1 IN ELECTRON MICROSCOPY.**

L.L. Bruce\*, M.A. Christensen, M. Khachab, and B. Fritzsche. Dept. Biomedical Sciences, Creighton Univ., Omaha, NE 68178.

The fluorescent neuronal tracer, DiI, will diffuse through aldehyde-fixed tissue, and can then be photoconverted and processed for analysis with electron microscopy. We obtained optimal results using the parameters below. Furthermore, transneuronal and directly labeled DiI profiles can be easily and clearly differentiated with electron microscopy. **EM fixative:** 4% paraformaldehyde, 0.25% glutaraldehyde, 4% dextrose, and 0.005% calcium chloride in 0.05 M phosphate buffer. Keep tissue in this solution during diffusion. **DiI application:** Dissolve crystals of DiI in a drop of dimethylformamide. Immerse a nylon filter strip in this solution, air dry. Place strip in a cut through the application site. **Time vs. temperature:** DiI will diffuse approximately 3 mm in 2 days at 37°C, or 3 mm in 12 days at 25°C. Similar labeling patterns are achieved under both conditions. **Photoconversion of DiI:** After sectioning tissue, soak section to be photoconverted in DAB solution (1 mg/ml DAB in 0.1 M phosphate buffer, pH 8.3) for at least 1 hr. Place in fluorescent light, using 20X or 10X objectives for 15-40 min, until axons are lightly but definitively labeled. **Direct vs. transneuronal labeling:** Spiral ganglion cells labeled directly by applying DiI to a severed eighth nerve contained very dense labeling throughout the cytoplasm and along all membranes, but not within the mitochondrial matrix. Spiral ganglia labeled transneuronally by applying DiI to a cut olivocochlear efferent bundle contained labeling in some endoplasmic reticulum membranes, but never in the plasma membranes, mitochondrial membranes, Golgi apparatus, or in the cytoplasm. This differential labeling, together with the methods described above, make DiI easy to use in amniote embryos and neonates yielding a quality superior to biotin-based electron-microscopic tracing techniques.

Supported by NIH grant DC00215-09.

## 233.6

**ISOFORMS OF DYSTROPHIN PROTEIN Dp71 IN RAT BRAIN: IDENTIFICATION, CELLULAR AND SUBCELLULAR LOCALIZATION.** V. Alemán\*, D. Martínez, O. Chávez, B. Osorio, D. Mornet and A. Rendón. Dept. of Physiology, CINVESTAV, México, D.F. 07300. México.

Dp71 a C-terminals isoform of dystrophin has been identified as the major DMD gene product in CNS. It has been reported the existence of four different isoforms of Dp71 originated by alternative splicing for exons 71 and for 78 (Human Mol. Gen. 4, 1475-1483, 1995). MW of Dp71 isoforms ranged from 71-75 kD. Here we analyzed by Western blot (Wb) the Dp71 isoforms expression in extracts from whole brain, hippocampus and cultured hippocampal neurons (HN) and brain astroblasts. Three distincts monoclonal antibodies were used: Dys2 and H5A3 detect isoforms retaining the C-terminal sequence of dystrophin and 5F3 the Dp71 isoform containing the alternative 31 amino acid C-terminus. Using Dys2 antibody a single isoform of Dp71 was detected in cultured neurons. Immunofluorescent observations revealed neurite and cytoplasmic staining which appears as a fine reticulum of filaments. Comparative Wb analysis with H5A3 detects a full length dystrophin in whole brain, HN and glial cells. Furthermore, in brain extracts two Dp71 isoforms were detected, which migrate as a doublet 71-73 kD. In neurons but not in glia a single reactive band was observed. Immunofluorescent analysis of neurons showed a similar stain than Dys2. Wb of neurons and astroblasts were shown to contain a single Dp71 band revealed by 5F3 antibody, which appears to label the endoplasmic reticulum in both type of cells.

**SECRETION AND RETENTION OF CHROMOGRANIN A IN FIBROBLASTS: A BIOCHEMICAL AND EM STUDY.** J-H. Tao-Cheng\*, A. Iacangelo, and L. E. Eiden. Sec. Molec. Neurosci., Lab. of Cell Biology, NIMH & Lab. of Neurobiology, NINDS, Bethesda, MD 20892.

Chromogranin A (CGA), an acidic glycoprotein expressed in neuronal and endocrine cells, is a prohormone for pancreastatin and other bioactive peptides, and has also been suggested to participate in the formation of secretory granules. To investigate the latter properties of CGA, this protein was expressed in CV-1 fibroblasts using the vaccinia virus/bacteriophage T7 hybrid system. Secreted and retained CGA was measured by Western blot analysis. The subcellular localization of CGA was examined via EM immunocytochemistry (ICC) with an anti-CGA (anti-WE-14) antibody.

The majority of CGA produced by CV-1 cells over a 2-24 hr period after initiation of expression was secreted into the medium. A portion of the CGA immunoreactivity was retained in the cells. EM ICC revealed copious staining for CGA within structures consistent with constitutive vesicles and endoplasmic reticulum. Compared to mock-transfected or untransfected cells, CGA-expressing CV-1 cells formed many more secretory granule-like structures, with the appearance of both immature and mature granules. Only the 'immature' (less electron dense) ones were markedly stained for the WE-14 CGA epitope. This pattern is consistent with WE-14 staining in bovine adrenal chromaffin cells where WE-14 was exclusively in granules and preferentially in immature granules.

Expression of CGA in CV-1 fibroblasts results in its sorting to both a constitutive secretory pathway and, to a lesser extent, to secretory granule-like structures which are absent in untransfected cells. These findings suggest that CGA is involved in secretory granule formation and that additional factor(s) are required for efficient formation of secretory granules in these non-neuroendocrine cells. (NIH intramural funding)

**QUANTIFYING IMMUNOGOLD LABELLED NEUROTRANSMITTERS AND RECEPTORS BY ELECTRON MICROSCOPY AND IMAGE ANALYSIS.**

F.M.S. Haug\*, V. Desai<sup>1</sup>, P.O. Nergaard<sup>2</sup> and O.P. Ottersen. Dep. anat., Inst. bas. med. sci., Univ. of Oslo, Norway. Soft Imaging Software GmbH<sup>1</sup>, Münster, Germany and Norsk Philips AS<sup>2</sup>, Oslo, Norway.

We have optimised an image analysis system for rapid evaluation of immunogold labelled ultrathin sections. Video images are seamlessly fused into high-resolution images of 1280 x 1024 pixels and analysed on the monitor. Relative average concentrations of glutaraldehyde fixed neuroactive amino acids in different types of tissue structures are estimated as relative average numbers of particles per unit area. Profiles are outlined and classified interactively. Gold particles are detected by thresholding and classified by size for double or triple labelled sections.

Relative average densities of receptors or transporters in membranes are estimated as relative numbers of particles per unit length. Binding to a membrane antigen is suggested for particles within a distance of the membrane that depends on the antibody-gold particle complex, the epitope's position in the membrane (usually unknown) and other factors. The centres of 15 nm particles coupled to membrane antigens via secondary and primary antibodies should theoretically be within 23.5 nm of the epitope. An adequate electron optical magnification is carefully calibrated. Membrane segments are drawn and classified. Particle-to-membrane distances are measured interactively. Alternatively, thresholded particles are superimposed on a "map" that holds each pixel's distance from the membrane. The value corresponding to a particle's centre of gravity is then obtained automatically, but the accuracy of the latter method remains to be evaluated. Number of particles per unit length is calculated directly, or after subtracting background particle density.

Particle densities are tabulated per profile, or per membrane segment, and exported to external statistical and graphical software for further analysis.

Sponsored by the Norwegian Research Council and EU Biomed (PL 950815).

## 233.11

A RAPID METHOD FOR COMBINED CONFOCAL MICROSCOPIC AND EM VISUALIZATION OF BIOCYTIN- OR NEUROBIOTIN-LABELED NEURONS.

X.J. Sun<sup>1</sup>, L.P. Tolbert<sup>2</sup>, J.G. Hildebrand<sup>2</sup>, and J.A. Meinertzhagen<sup>1</sup>. <sup>1</sup>Life Sciences Centre, Dalhousie University, Halifax, NS, B3H 4J1, Canada; <sup>2</sup>ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721, USA.

The combination of intracellular recording and staining is still one of the most powerful and heavily used techniques for correlating the morphology and physiology of neurons. The recent widespread application of laser scanning confocal microscopy (LSCM) offers a particularly useful tool in neuroanatomy because of its capacity to reconstruct rapidly the complex shapes of neurons in three dimensions (3D). Light microscopic investigation of a neuron, however, often raises the question of whether synaptic connections exist at a particular site on the neuron's surface, for which electron microscopy (EM) is needed. The combination of intracellular staining with LSCM and EM is difficult, however, because of incompatibility of the staining protocols for the two types of microscopy. We have reported previously an immuno-gold method for rendering intracellularly injected neurons simultaneously fluorescent and electron-dense (Sun et al., J. Histochem. Cytochem. 43:329-335, 1995); but this method is sufficiently time-consuming to be worthwhile pursuing on only a small number of preparations. Here, we report a technique that quickly and easily converts a fluorescent label into a more stable and electron-dense stain, a method less flexible but more suitable for routine use. With this technique, a Neurobiotin or biocytin-labeled neuron can be imaged with LSCM after reacting with fluorophore-conjugated avidin. Then the fluorescent label is converted to an electron-dense material which will permit long-term storage or EM study. This single-step conversion uses the commercially available ABC kit (Vector Labs) with DAB as a substrate for the peroxidase. We find the current method to be more sensitive and allowing greater penetration for EM staining compared with our previous immuno-gold method, and faster and less labor-intensive than the photoxidation procedure in common use. At the same time, it retains the opportunity to examine interesting areas of the stained neuron and localize these easily for thin-sectioning prior to EM study, by using the 3-D information obtained with LSCM. Supported by award from Univ. of Arizona, Center for Insect Science, to XJS, and grants to I.A.M. (NIH EY-03592, NSERC A 0065), to LPT and JGH (NIH NS-28495) and to JGH (NIH AI-23253).

## 233.13

FAST METHOD FOR SCREENING CONNEXIN-IDENTITY USING RT-PCR ASSAYS. M. Urban, R. Rozental, F.-C. Chiu<sup>1</sup>, M. Kremer, R. Dermietzel and D.C. Spray. Dept. of Neurosci., A. Einstein Coll. Med., Bronx, NY 10461; Inst. Anat., U. Regensburg, Germany; Inst. Biophys., Fed. Univ. Rio de Janeiro, Brazil.

Gap junctions are large aggregates of transmembrane channels, composed of connexin proteins (Cx), that interconnect neighboring cells. Cloning of connexin cDNAs has revealed at least twelve distinct isoforms in mammalian tissues. Since the same Cx-type can be expressed in different tissues and more than one Cx-type can be expressed by the same cell, identification of which Cx-type is expressed has become quite laborious. The Cx family exhibits both conserved (extracellular and transmembrane regions) and divergent (cytoplasmic domains) regions. Based on their cDNA sequences, Cxs have been divided in Groups I ( $\beta$ ; Cx26→Cx32) and II ( $\alpha$ ; Cx33→Cx50). We have now used "Universal Primers" (*sense primer* "B", degenerate oligo corresponding to a region of the 1<sup>st</sup> extracellular domain; *antisense primer* "C", degenerate oligo complementary to the 2<sup>nd</sup> extracellular domain) for RT-PCR assays to amplify unknown DNA sequences starting from total RNA; Cxs belonging to Groups I and II present band sizes of 360-380 and 420-520 bp, respectively. Subsequently, we perform second generation of PCR products to identify which Cxs have been amplified within a certain group by using specific restriction endonuclease enzymes. This method thus provides a simple and rapid procedure for identifying Cx-types expressed in a variety of tissues.

## 233.15

GFP-SYNAPTOBREVIN CHIMERIC PROTEIN AS A MARKER FOR SYNAPTIC VESICLES IN DEVELOPING NEURONS. X.-h. Wang\* and M.-m. Poo. Dept. Biol., UCSD, La Jolla, CA 92093.

Several cDNA clones coding for synaptobrevin II (SybII) were obtained from brain cDNA library of *Xenopus laevis*. The *Xenopus* protein (XsybII) shows 89.5% identical with the amino acid sequence of rat SybII and 78.1% identical with rat SybI. A chimeric gene (GFP-XsybII) coding green fluorescence protein (GFP) and XsybII was constructed. Synthesized cRNA of the fusion protein was obtained by *in vitro* transcription and microinjected into one of the blastomeres of early *Xenopus* embryos. Expression of the chimeric protein was shown by the green fluorescence in cultured nerve and muscle cells prepared from injected embryos. In neurons, a large green spot was usually observed in the soma and small punctuate fluorescence spots of varying sizes were observed in the neurite, growth cone, and presynaptic terminals. Immunostaining with synaptophysin antibodies showed that these small green spots colocalize with synaptophysin staining, suggesting that they represent clusters of synaptic vesicles. Electrophysiological recordings of spontaneous and evoked synaptic currents showed that expression of GFP-XsybII in these neurons does not affect the synaptic activity. Thus GFP-XsybII may be useful as a marker to study the biogenesis, trafficking and recycling of synaptic vesicles in developing neurons. Supported by NIH grant NS 31923.

## 233.12

MAPPING REGIONAL BOUNDARIES AND MODELING THE COMPRESSION OF ULTRASTRUCTURAL THIN SECTIONS THROUGH THE USE OF VIDEO IMAGERY. J.P. Pierce\* and T.A. Milner, Dept. of Neurology and Neuroscience, Cornell Univ. Med. Coll., NYC, NY 10021

The increasing availability of video cameras that are used in conjunction with both light and electron microscopes has allowed the development of precise mapping procedures that can aid the electron microscopist. By capturing a light level *enface* image of a blockface, and comparing the dimensions of this image to a captured low magnification electron microscopic image of a thin section from the block, the extent of compression produced by sectioning can be determined, and then used to compress a map of tissue boundaries and locations, generating a template that can be overlaid on an image of any section from that block. Specifically, *enface* blockface images are captured after thin sectioning (using a x4 light level objective and NIH Image 1.5 software), and thin section images are captured (using x18 mag. on the electron microscope and the MCID package). The scale of the two images is then matched (by comparing the length of the images, and making adjustments with zeroes), and the extent of compression determined (by comparing the widths of the images). A map of the blockface, with boundaries and locations marked, is then traced into Image using a drawing tablet, and saved as a Pict file. The Pict file is imported into Adobe Illustrator as a template and autotraced. The lines are then linked, and the Free Distort function is applied, to model the precise extent of compression, along a ruler. Finally, the compressed map is printed, and the scale again adjusted, so that it can serve as an overlay for an image of any section from that block, that needs to be examined. This approach has been useful both in studies that involve the random sampling of specific subregions, and the localization of specific labeled elements that can be seen at the light level. Additionally, determining the extent of compression provides feedback on the quality of sectioning, and allows for the correction of density measurements taken at the ultrastructural level. Supported by DA08259 and MH42834.

## 233.14

QUANTIFICATION OF CYCLIC AMP IN SINGLE DEVELOPING GLIAL CELLS. A.P. Wiemelt, M.J. Engleka, and F.A. McMorris\*. The Wistar Institute, 3601 Spruce Street, Philadelphia, PA 19104.

Previous findings in our lab have demonstrated that either the application of cyclic AMP (cAMP) analogs, or the stimulated increase of endogenous cAMP levels cause an acceleration in the rate of differentiation of glial precursor cells into mature oligodendrocytes. We seek to determine what changes in endogenous cAMP levels occur during the normal course of oligodendrocyte development, and what role such changes have in regulation of development. We have used a novel fixation procedure employing the aldehyde acrolein to cross-link cAMP to proteins and fix cells in a single step. We have generated polyclonal antibodies to cAMP by injecting rabbits with cAMP linked to carrier proteins by acrolein fixation. The resulting antibodies recognize acrolein-fixed cAMP-protein conjugates at dilutions of 32,000 and greater in ELISA assays, and indirect FITC immunofluorescence microscopy shows elevated cAMP levels in C6 glioma cells in response to isoproterenol (IPTN) treatment. Competition studies indicate that this reactivity is specific for cAMP, when other nucleotides were tested. cGMP did exhibit some cross reactivity, but this did not interfere in cell staining. Primary glial cultures show increased cAMP following activation of adenylyl cyclase with forskolin (FSK) and cholera toxin (CTX). Double staining with antibodies that recognize different stages of oligodendrocyte development and cAMP antibodies indicate that cAMP is inducible during a critical developmental window, when cells express the O4 antigen, as the cells are committing to a fully differentiated phenotype. Early A2B5 expressing (immature) or late O1 expressing (mature) cells do not induce cAMP in response to FSK/CTX. Supported by 5T32CA09171, NS32394, NS32122, NS26119.

## 234.1

**DISTINGUISHING NEURONS FROM GLIA IN REPLICAS OF HIPPOCAMPUS AND SPINAL CORD: REASSIGNMENT OF CELLS WITH GAP JUNCTIONS**  
J. E. Rash\*, T. Yasumura, H. S. Duffy, R. K. Dillman, B. Bilhartz, and F. E. Dudek  
Dept. of Anatomy and Neurobiology, Colorado State Univ., Ft. Collins, CO 80523

In previous studies of gap junctions between neurons in adult rat spinal cord, we used confocal "grid-mapped" freeze-fracture to develop affirmative criteria for distinguishing neurons from glia. Criteria developed in that study are now applied to analyses of the dentate gyrus and CA1-3 regions of adult and developing rat hippocampus. Defining criteria for neurons are described elsewhere (Rash, et al., *Proc. Nat. Acad. Sci.*, 1996). In hippocampus and spinal cord, oligodendrocytes are exclusively identified by: 1) their continuity with myelin; 2) presence of tight junctions in the outer layers of myelin; 3) presence of abundant gap junctions on their somata and dendrites, one type having irregular arrays of connexons (i.e., heterologous gap junctions to astrocytes), and a less-abundant type having regular arrays of connexons (i.e., homologous gap junctions, primarily at nodes of Ranvier and in the internodal myelin); 4) a single-strand "necklace" of IMPs surrounding E-face images of heterologous gap junctions; 5) "moth-eaten appearance" of somatic and dendritic plasma membranes where they contact myelin; 6) numerous grooves and furrows in their somatic and dendritic plasma membranes, representing the impressions of glial and neuronal processes; and less definitively, 7) by their small nuclei and thin rim of cytoplasm that is devoid of the widely-spaced (i.e., 4-5  $\mu$ m) parallel stacks of Nissl substance that are found only in neurons. Astrocytes and ciliated ependymal cells are identified by square arrays in their plasma membranes and GFAP filaments in their cytoplasm. By these criteria, previous freeze-fracture images purported to represent neurons with gap junctions are now reclassified as oligodendrocytes, or less commonly, as astrocytes or ependymal cells.

## 234.3

**INGROWTH OF ACTIVATED ASTROCYTES INTO GELATIN SPONGE AFTER STAB INJURY OF ADULT RAT BRAIN** P.R. Perillan, C.C. Park, M. Gorospe, J.M. Simard\*. Division of Neurological Surgery, University of Maryland School of Medicine, 22 South Greene Street, Baltimore, MD 21201.

The response of the central nervous system to traumatic injury involves activation of astrocytes, with proliferation, hypertrophy and an increase in expression of glial fibrillary acidic protein (GFAP). Western blot analysis and *in vitro* recovery of activated astrocytes from implanted gelatin sponge were used to assess ingrowth of these cells during the gliotic response to injury. Adult rat brains were subjected to a stab injury followed by implantation of pieces of gelatin sponge. After 8 d *in vivo*, the sponge pieces were harvested and cultured. When the sponge pieces were left in the culture dishes, cell counts performed at 8 d revealed a homogeneous population of cells that became confluent after 3 wk *in vitro*. More than 90% of cells were identified as astrocytes based on their immunohistochemical profile, including positive staining for GFAP, S-100 and vimentin, and western blot analysis for GFAP, as well as negative staining for  $\alpha$ -actin and MAC-1. By comparison, when sponge pieces were removed from the culture dishes at 24 hr, cell counts performed at 8 d revealed no cells. Also, culture for 8 d of pieces of gelatin sponge that had been implanted for less than 3 d, of pieces of previously injured brain, or of pieces of freshly isolated but otherwise uninjured brain, invariably failed to yield reproducible cellular outgrowth. We conclude that astrocytes recovered in primary culture originated from the gelatin sponge, rather than from adherent tissue, that migration of cells into the sponge pieces required >3 d *in vivo*, and that migration of cells out of the sponge pieces required >24 hr *in vitro*.

**RAT SPINAL CORD ASTROCYTE RESPONSES TO LYSOPHOSPHATIDIC ACID**

T. Manning\* and H. Sontheimer, Neurobiology Research Center and Dept. of Physiology and Biophysics, University of Alabama at Birmingham, Birmingham, AL 35294

Lysophosphatidic acid (LPA) is a biological signaling molecule that is produced by activated platelets and is bound to serum albumin. It can have a wide variety of effects in different cell types. LPA stimulates stress fiber formation and DNA synthesis in fibroblasts, promotes platelet aggregation, and inhibits gap junction coupling in hepatocytes. During pathological situations where the blood brain barrier is disrupted, the brain is exposed to blood constituents including LPA. We examined the effects of LPA on primary cultures of rat spinal cord astrocytes using fluorescent  $\text{Ca}^{2+}$  imaging, proliferation assays, and time-lapse video microscopy. At nanomolar concentrations of LPA, astrocytes responded with long trains of  $[\text{Ca}^{2+}]_i$  oscillations that were dependent on release from intracellular stores. Low micromolar concentrations of LPA also produced oscillations, but often with a sustained rise that was dependent on  $[\text{Ca}^{2+}]_o$ . The response to LPA showed little desensitization and transients could be observed for periods of up to 45 minutes.  $^3\text{H}$ -thymidine incorporation was monitored to examine mitogenic effects of LPA. Treatment with nanomolar concentrations of LPA increased DNA synthesis by ~90% as compared to untreated controls. It has previously been shown that in serum free media, flat, protoplasmic astrocytes round up and adopt a more stellate morphology following increases in intracellular cAMP. This process can be initiated by the application of the cAMP analogue dibutyryl cAMP or the adenylate cyclase activator forskolin. The presence of LPA in defined medium inhibited the morphological changes induced by these compounds. Time-lapse video microscopy showed that the stellation could be completely reverted if LPA was added after the change in morphology. It remains to be seen whether LPA can affect some of the known astrocytic functions such as buffering of  $\text{K}^+$  and clearance of neurotransmitters. (Supported by RO1-NS-31234 and P50-HD-32901)

## 234.2

**EXPRESSION OF SYNAPTIC PROTEINS IN PRIMARY CULTURED ASTROCYTES** R. P. Sanzgiri\*, L. E. Trudeau and P. G. Haydon. Lab. of Cellular Signaling, Department of Zoology and Genetics, Iowa State University, Ames, IA 50011.

Astrocytes, a subtype of glial cells, have been shown to release the neurotransmitter, glutamate, which can cause a subsequent excitation of neurons (Papura et al. (1993), *Nature*, 369, 744-747). A possible mechanism of release is vesicular exocytosis. Consistent with this idea, it was found that a subset of neuronal synaptic proteins including synaptobrevin and syntaxin but not SNAP-25, are expressed in astrocytes (Papura et al. (1996), *FEBS Lett.*, 77, 489-492). Given that astrocytes can release neurotransmitter yet only express a sub-set of synaptic proteins, they may act as a convenient cellular expression system for studying synaptic protein interactions and their functional roles.

Towards this end, we have demonstrated that primary astrocyte cultures are effective expression systems by performing direct nuclear microinjections. By coinjecting a fluorescent dye, fluoruby, with either CMV or RSV promoter driven plasmids, we determined that 80% of microinjected cells express the desired protein. Expression is detected as early as three hours after microinjection. Microinjection of two constructs results in reliable co-expression. Overexpressed proteins appear to be correctly localized as synaptotagmin showed a punctate staining pattern consistent with its expression in intracellular organelles while synapsin and SNAP-25 are more diffusely expressed. Preliminary experiments suggest that overexpression of SNAP-25 together with synaptotagmin reduces the accumulation of synaptotagmin within perinuclear golglike structures, compatible with a role of SNAP-25 in regulating the export of synaptic proteins to the synapse.

Supported by the NIH (NS26650, NS24233).

## 234.4

**IDENTIFICATION AND CHARACTERIZATION OF NINJURIN, AN ADHESION MOLECULE EXPRESSED IN SCHWANN CELLS AFTER NERVE INJURY**

T. Araki\* and J. Milbrandt. Department of Pathology, Washington University Medical School, MO 63110

After injury to a peripheral nerve, the axons and myelin sheath distal to the site of injury degenerate by a process known as Wallerian degeneration. During this process Schwann cells undergo a number of phenotypic changes, including alterations in patterns of gene expression, that are important for axonal regeneration. Using differential screening strategies, we identified a novel protein, termed *ninjurin* (Nerve Injury Induced protein), that is up-regulated after axotomy in Schwann cells in the distal nerve segment which contains the degenerate axons. Ninjurin is expressed in embryos and adult animals in a number of tissues including liver, thymus, bone, and kidney. Interestingly, it is expressed predominantly in epithelial cells in each of these tissues. Sequence analysis revealed that ninjurin is a 16 kD protein that is predicted to contain two membrane spanning domains, but has no homology to other characterized proteins. Immunohistochemical and cell surface labeling demonstrated that ninjurin is located on the cell surface. Aggregation assays using transfected cells expressing ninjurin indicated that ninjurin functions as an adhesion molecule, although it does not have any previously identified adhesion motifs. Our data suggest that ninjurin may play an important role in nerve regeneration as well as in the formation and function of other tissues.

**THE MICROTUBULE ARRAY OF THE OLIGODENDROCYTE IN VITRO** K.F. Lunn\*, P.W. Baas, and I.D. Duncan. Departments of Medical Sciences and Anatomy, University of Wisconsin, Madison, WI 53706.

Glial cell cultures were prepared from the spinal cords of 10 day old rats, and the microtubule (MT) arrays of oligodendrocytes (OLs) were studied by electron microscopy (EM), immunofluorescent antibody labeling and confocal microscopy after 4 days *in vitro*. EM and confocal microscopy showed that MTs form a network throughout the OL cell body with no discrete organizing centers detected. A hooking protocol was used to show that the MTs which form parallel arrays in OL processes have a mixed polarity orientation, but the majority (70-80%) of MTs have plus ends distal to the cell body. Labeling with an antibody to tyrosinated tubulin showed that recently polymerized tubulin was present throughout the OL cytoskeleton, and extended to the ends of the processes. An antibody to acetylated tubulin showed that this more stable isoform was not present at the distal tips of the OL processes. The sensitivity of OL MTs to the MT-depolymerizing drug nocodazole was assessed by quantifying the total MT polymer in OLs after exposure to drug for times ranging from 15 minutes to 6 hours. Total fluorescence of cells labeled with an anti- $\beta$  tubulin antibody was used as a measurement of MT polymer mass, and in OLs this showed 2 distinct phases of loss in nocodazole, indicating the existence of both drug-labile and drug-stable polymer in these cells. A separate analysis of OL cell bodies and processes showed that while both types of polymer are present in both regions, relatively more of the total MT polymer in the processes consists of the drug-labile form. (Supported by NIH grant NS32361)

## 234.7

**ASTROCYTES PROMOTE PROCESS OUTGROWTH BY ADULT HUMAN OLIGODENDROCYTES THROUGH INTERACTIONS OF bFGF AND ASTROCYTE MATRIX.** Oh Y.S., & Yong, V.W.\*  
Montreal Neurological Institute, Department of Neurology and Neurosurgery, McGill University, Montreal, Canada H3A 2B4.

An early event in myelin formation is process outgrowth by oligodendrocytes (OLs). We demonstrate that process outgrowth by adult human OLs is enhanced in co-culture with human astrocytes. To investigate the mechanism by which astrocytes promote oligodendroglial process outgrowth, we exposed adult human OLs to growth factors known to be produced by astrocytes. Of a variety tested, only bFGF exerted significant promoting effects on process extension by OLs; in concordance, a neutralizing antibody to bFGF retarded the ability of astrocytes to promote oligodendroglial process outgrowth. The effects of bFGF was less potent than that of live astrocytes, and no synergistic effects of bFGF with other soluble growth factors were observed. Further investigations on the role of astrocytes revealed that the astrocyte extracellular matrix (ECM) could also promote process extension. Significantly, the co-treatment of OLs with bFGF and astrocyte ECM reproduced the potent effects of live astrocytes. To identify the astrocyte ECM involved in process extension, purified ECM molecules known to be produced by astrocytes (laminin, vitronectin, fibronectin, HSPG & CSPG) were tested. None of these by themselves promoted process outgrowth by OLs, but laminin and fibronectin augmented the effects of bFGF. We conclude that bFGF and astrocyte matrix are important factors that enhance process extension by adult human OLs.

## 234.9

**MIGRATION OF SCHWANN CELLS ON THE POLYESTER FIBERS IN VITRO AND THE EFFECT OF LAMININ** X.Y. Shen\* and J. Yang, Department of Anatomy, Shanghai Medical University, Shanghai 200032, P.R.China

It has been reported about the purification and migration of the Schwann Cell (SC) in vitro. However, what will happen if the SC co-culture with the artificial materials, the Polyester fiber (PF). Sciatic nerves from 30 mice aged P 3-7 were cut into small pieces (1mm) and cultured on the collagen-coated round coverslip with the PF (diameter 10  $\mu$ m). Living observations under reversed phase contrast microscopy in the 2, 4, 6, 8 and 10 d.i.v., and Sudan black staining, S-100 protein immunocytochemical labelling and electron microscopies (SEM/TEM) were also made. Results showed that the cultured SC migrated along the PF in a good compatibility. The SC showed in typical fusiform shape and connected together one by one and their process always made plexus wrapping onto the PF. No any myelin-like structures were ever seen. The experimental group in which Laminin was added to the medium showed its obvious effect in promoting migration as well as proliferation of the SC in comparing to the control ones.

## 234.11

**DYSTROGLYCAN IS A DUAL RECEPTOR FOR AGRIN AND LAMININ-2 IN SCHWANN CELL MEMBRANE.** K. Matsumura<sup>1</sup>, H. Yamada<sup>1</sup>, A. J. Denzer<sup>2</sup>, M. A. Ruegg<sup>2</sup> and T. Shimizu<sup>1</sup> <sup>1</sup>Dept. of Neurology & Neuroscience, Teikyo Univ. Sch. of Med., Tokyo 173, Japan and <sup>2</sup>Dept. of Pharmacology, Biozentrum, Univ. of Basel, CH-4056 Basel, Switzerland

We have shown previously that  $\alpha$ -dystroglycan with a molecular mass of 120 kDa is a Schwann cell receptor of laminin-2, the endoneurial isoform of laminin comprised of the  $\alpha 2$ ,  $\beta 1$  and  $\gamma 1$  chains. Here we show that Schwann cell  $\alpha$ -dystroglycan is also a receptor of agrin, an acetylcholine receptor-aggregating molecule having partial homology to laminin  $\alpha$  chains in the C-terminus. Immunochemical analysis demonstrates that the peripheral nerve isoform of agrin is a 400 kDa component of the endoneurial basal lamina and is co-localized with  $\alpha$ -dystroglycan surrounding the outermost layer of myelin sheath of peripheral nerve fibers. Blot overlay analysis demonstrates that both endogenous peripheral nerve agrin and laminin-2 bind to Schwann cell  $\alpha$ -dystroglycan. Recombinant C-terminal fragment of the peripheral nerve isoform of agrin also binds to Schwann cell  $\alpha$ -dystroglycan, confirming that the binding site for Schwann cell  $\alpha$ -dystroglycan resides in the C-terminus of agrin molecule. The binding of recombinant agrin C-terminal fragment to Schwann cell  $\alpha$ -dystroglycan competes with that of laminin-2. These results indicate that  $\alpha$ -dystroglycan is a dual receptor for agrin and laminin-2 in the Schwann cell membrane.

## 234.8

**SELECTIVE ATTACHMENT OF ASTROCYTES TO VARIOUS BASEMENT MEMBRANE AND EXTRACELLULAR MATRIX PROTEINS.** L. Kam<sup>1</sup>, R. Bizios<sup>1</sup>, W. Shain<sup>2</sup>, J.N. Turner<sup>1,2</sup>, <sup>1</sup>Rensselaer Polytechnic Institute, Troy, NY 12180, <sup>2</sup>Wadsworth Center and School of Public Health, Albany NY 12201-0509

Selective attachment of astrocytes to substrates in vitro may improve methods of cell preparation and biocompatibility of prosthetic devices designed for brain insertion. Fluorescently labeled cells were used to characterize astrocyte attachment and identify portions of proteins that mediate attachment. Astrocytes were prepared from 3-day old rat-pup cortices and maintained in DMEM containing 5% FBS and antibiotics. After 14 days in culture, cells were labeled with Hoechst-33342 (2  $\mu$ g/mL; overnight incubation at 37°C), enzymatically dissociated, pelleted, and resuspended (1x10<sup>5</sup> cells/mL). Collagens I and IV, laminin, and vitronectin (10-0.04  $\mu$ g/mL) were adsorbed to 96-well microtiter plates (Dynatech; overnight incubations at 4°C), blocked with 1% bovine serum albumin (BSA; 3 hr at 37°C), and washed 2X with HEPES-buffered Hanks' saline (HH). Cell suspensions (100  $\mu$ L) were placed in each well and incubated for 2 hr—a period of time sufficient for maximum attachment. Wells were aspirated and washed 2X with HH and cells lysed (200  $\mu$ L of HH containing 2.5% triton). The fluorescence signal of each well was read using a plate reader on a Perkin-Elmer fluorescence spectrophotometer. Cell attachment to substrates was presented as % corrected maximal binding (fluorescence signal from untreated polystyrene wells containing cells - signal from wells containing no cells). Treatment of blank wells with BSA blocked cell attachment. Cells attached to substrates in a concentration-dependent fashion. Maximum binding and apparent affinity were determined using Michaelis-Menton kinetics. Maximal attachment was different for each of the proteins, 0.95 (collagen IV), 0.80 (collagen I), 0.3 (laminin) and 0.16 (vitronectin). Cells showed highest affinity to collagen IV (0.05  $\mu$ g/mL) and lower affinity to collagen I (0.44  $\mu$ g/mL). Cells bound with intermediate affinity to vitronectin (0.31  $\mu$ g/mL) and very low affinity to laminin (2.28  $\mu$ g/mL). Assessment of attachment to collagen IV is being made with hydrolytic peptides of native collagen and synthetic peptides. (This work is partially supported by NIH RR-10957.)

**IN VIVO EVIDENCE SUPPORTING A ROLE FOR MYELIN-ASSOCIATED GLYCOPROTEIN AS A CELL RECOGNITION-ADHESION MOLECULE** C. Li<sup>1</sup>, A. Peterson<sup>2</sup>, J. Roder<sup>3</sup>, <sup>1</sup>Dept. Physiol., Univ. Toronto, Canada, <sup>2</sup>Neurosciences, Montreal General Hospital, Canada, <sup>3</sup>Dept. Med. Genet., Univ. Toronto, Canada.

MAG (myelin-associated glycoprotein) has been postulated to play an important role in initiating myelination *in vivo* based on several lines of *in vitro* evidence: 1) MAG-containing liposomes bind specifically to neurons; 2) MAG is the first myelin protein to be detected upon myelinogenesis; 3) MAG belongs to the immunoglobulin supergene family; 4) MAG is primarily found in the periaxonal region of a myelinated fiber; and 5) up or down regulation of MAG resulted in accelerated or diminished myelination, respectively. We tested this hypothesis by targeted disruption of the *mag* locus in mice and showed previously that the mutant mice had no gross perturbations of myelination as judged by X-ray diffraction, immunohistochemistry, Western blotting and light microscopy. Ultrastructural studies by electron microscopy, however, revealed subtle impairment of periaxonal organization, indicating a role for MAG in the normal formation and maintenance of periaxonal structures. Here we show that MAG mutants exhibit an increase in the proportion of unmyelinated axons and a reciprocal decrease in myelinated axons in optic nerves. Aberrant forms of myelination, such as redundant myelin, multiple myelin and myelination of multiple axons are also occasionally encountered. In addition, axons of MAG null optic nerves appear less densely packed. Taken together, these lines of evidence support a role for MAG as an axon-glia cell recognition and adhesion molecule. Compromised cell recognition and adhesion in the absence of MAG might underlie the abnormalities observed.

**ANALYSIS OF L1/MAG DOUBLE KNOCKOUT MICE.** C. A. Haney<sup>1,2</sup>, C. Li<sup>3</sup>, X. Yin<sup>4</sup>, P. Soriano<sup>4</sup>, J. Roder<sup>3</sup>, and B.D. Trapp<sup>1,2</sup>, <sup>1</sup>Department of Neuroscience, Case Western Reserve University, Cleveland, OH 44106 <sup>2</sup>Department of Neuroscience, Cleveland Clinic Foundation, Cleveland, OH 44195, <sup>3</sup>Mt Sinai Hospital, Neurobiology, Toronto, Canada, <sup>4</sup>Fred Hutchinson Cancer Research Center, Seattle, WA 98194

Molecules of the Immunoglobulin (IgG) gene superfamily mediate cell-cell interactions in the developing nervous system. The myelin-associated glycoprotein (MAG), is an IgG superfamily member which is expressed exclusively by myelinating cells and enriched in the adaxonal membrane of the myelin internode. MAG knockout mice are myelinated but have compromised periaxonal spaces. L1, another member of the IgG superfamily, is expressed during initial stages of Schwann cell ensheathment of axons and by Schwann cells of unmyelinated fibers. To test if L1 could be compensating for MAG during myelin formation in the MAG knockout animals, we generated L1/MAG knockout mice. Affected male animals (MAG<sup>-/-</sup>, L1<sup>-/-</sup>) are runted and display delayed muscle mass development of the hind limbs. Morphological analysis of 28 day sciatic nerve demonstrated comparable numbers of myelinated axons in both knockout and control animals. These observations fail to support a compensatory role for L1 in MAG knockout mice, and raise the possibility that growth of long axons or formation of neuromuscular junctions is compromised. Currently, we are looking at younger mice to identify initial changes in myelination, axonal growth or muscle innervation that could account for the runted phenotype. This work was supported by NIH grant NS 29818 and the MRC.

## REVERSIBLE CHANGES IN BASAL LAMINA SUBJACENT TO THE SUPRAOPTIC NUCLEUS.

J.B. Bobak\*, N. Hawrylak and A.K. Salm. Departments of Anatomy and Physical Therapy, West Virginia University, Morgantown, WV, 26505

Previous studies have suggested that astrocytes associated with the supraoptic nucleus participate in the plasticity of this system. We recently demonstrated reversible morphological changes in astrocytes forming the glial limitans subjacent to this nucleus. In the present study we investigate potential changes in basal lamina associated with these astrocytes within, and ventral to, the glial limitans. The supraoptic nucleus was stimulated in adult male rats by replacing drinking water with 2% saline for 2 (n=5) or 9 (n=5) days. Control (n=5) animals received free access to tap water. A rehydrated group (n=5) was given 2% saline for 9 days, then returned to tap water for 9 days. Animals were sacrificed and their brain tissue was processed for electron microscopy. Electron micrograph montages of astrocytes (3,887X) in the glial limitans were constructed and the total volume fraction of basal lamina was estimated by means of an unbiased stereological point counting method. Group differences were assessed by an ANOVA. A post-hoc Tukey's t-test showed a significant decrease in the volume fraction of basal lamina by 28% from control levels with 2-days of dehydration. A 31% decrease was observed with 9-days of dehydration when compared with control animals. Upon rehydration, the volume fraction of basal lamina reversed to control levels. From these data we conclude that the basal lamina reversibly changes in association with dehydration. Since basement membranes, of which the basal lamina is a component, can act as barriers to the movement of cells and macromolecules, we suggest these changes contribute to an alteration in the barrier function of the glial limitans. Supported by NSF-9109827.

GROWTH AND FATE OF NEONATAL PSA-NCAM+ RAT PRECURSOR CELLS. T. Ben Hur<sup>1</sup>, G. Rougon and M. Dubois-Dalcq<sup>2</sup>. Institut Pasteur, Paris and Institut de Biologie du développement, Marseille, France

Oligodendrocytes, the myelin forming cells of the CNS, are derived from neural stem cells in the developing brain. Oligodendrocyte differentiation from O-2A progenitor cells has been well characterized, yet it is unclear how early precursors become committed to the oligodendrocyte lineage (OL). Pre-O-2A progenitor cells are small round cells that express the embryonic, polysialylated form of neural cell adhesion molecule (PSA-NCAM, Greenspan et al, JNR 41:540, 1995). The aim of this study was to characterize OL pre-progenitors and to identify factors controlling their fate. OL cells were shaken off from primary cultures of 1 day old rat cerebral hemispheres, immunopanned with PSA-NCAM antibody and grown on poly-ornithine coated dishes. Addition of bFGF to defined medium induced proliferation of PSA-NCAM+ cells which formed clusters of round and unipolar cells. BrdU incorporation increased from 4% at 1 day to 18% at day 4 in the presence of bFGF while in its absence, extensive cell death occurred. After 1 week in bFGF, the clusters of PSA-NCAM+ cells were surrounded by multipolar OL cells stained by O4 antibody. Such differentiation of PSA-NCAM+ cells was blocked by growing them on uncoated dishes where cell clusters progressively evolved into spheres. After 1 week, clusters of PSA-NCAM+/O4- cells were dissociated in single cells which grew new clusters in response to bFGF. The effects of bFGF on growth and survival of PSA-NCAM+ cells was dependent on the presence of thyroid hormone in defined medium. Therefore these factors permit sustained growth of OL pre-progenitors on non adhesive substrate. We are currently studying whether these PSA-NCAM+ cells still have the potential to differentiate along other neural lineages.

Glutamic acid decarboxylase (GAD), the GABA synthetic enzyme is localized in 20-30% of all CNS neurons found in all regions of the brain.

To study the mechanisms underlying the transcriptional control and the region-specific expression of the gene encoding the 67 kDa form of GAD, we have characterized the promoter and the 5'-upstream regulatory region of the mouse gene. Within 400 bp of the flanking region, three tandemly arranged promoters of two different classes were identified. The most proximal promoter (P1) with multiple transcription start sites contains several GC boxes and is devoid of TATA and CAAT boxes, similar to the promoters of housekeeping genes. It is embedded in a CpG island, which spans P1, the first exon, and the first intron. Distally to the CpG island, two additional closely spaced tissue specific like promoters with TATA and CAAT boxes were found. In the multiple promoter region, we have identified several putative transcription factor binding sites and neuronal specific regulatory elements including *egr-1*, NFκB, and the neuronal restrictive silencer element (NRSE).

As revealed by using transgenic mice, neuron-specific and cell type-specific expression of GAD67 is mediated through the combination of silencers identified in the basic promoter region and/or the first intron, and upstream region-specific enhancers.

## 235.2

## REGULATION OF SODIUM CHANNEL GENE EXPRESSION BY TRANSCRIPTIONAL SILENCING. B.J.L. Eggen\*, J. Tapia-Ramirez and G. Mandel. Department of Neurobiology and Behavior, State Univ. of New York at Stony Brook, Stony Brook, NY 11794-5230.

In the central nervous system (CNS), fast electrical signaling is often mediated through sodium-based action potentials. A predominant Na channel in rat brain is the type II CNS-specific sodium channel. The presence of a 28 bp DNA element in the promoter region of the type II gene is likely required for restricting the expression of this gene to the CNS. The transcription factor (REST<sup>1</sup>/NRSF<sup>2</sup>) that binds to this silencer element in the type II gene and mediates its neuron-specific expression has been identified. Cotransfection assays of PC12 cells with type II reporter genes and a recombinant REST cDNA results in silencing of the type II promoter. The domains of REST responsible for the transcriptional silencing of the type II promoter were studied using deletion mutants and GAL4 DNA binding domain fusion genes introduced into PC12 cells with type II reporter genes. The results from these studies suggest that specific domains in REST can function as autonomous silencer domains. This may have implications for future studies directed at perturbing expression of genes in vivo.

## 235.3

## SILENCING THE GAP-43 GENE. J.R. Weber and J.H.P. Skene\*. Dept. of Neurobiology, Duke Univ., Durham, NC 27710.

Expression of the gene for the growth cone protein GAP-43 is highly restricted to the developing or regenerating nervous system, and its 5' flanking region can confer a substantial degree of neural specific expression to a reporter gene. In order to identify tissue specific regulatory elements, we have used mutational analysis of the most neuronal specific subdivision of the 5' flanking region, a 386 bp promoter located distally to the coding region. We showed previously that this region contains several positive acting elements used in neurons, including two CCAAT boxes, a TATA box, an AP-1 site, and two apparently novel transcription factor binding sites, Cx1 and Cx2. However, these positive elements cannot account for the high degree of neuronal specificity displayed by this promoter. Rather, we now show that a novel 29 bp negative element located in the transcription start region is primarily responsible for controlling tissue specificity. Transferring this silencer element to heterologous promoters blocks expression in non-neuronal cells. Conversely, mutations in this element permit strong expression of the 386 bp GAP-43 promoter in non-neuronal cells. Considering that silencer elements have been found in several other neuron specific genes, the control of tissue specificity by negative elements may turn out to be a common theme in neuronal differentiation. This mechanism offers the advantage of being able to use many widely expressed, non-tissue specific transcriptional activators to modulate and fine tune the activity of neuronal genes, yet still keep expression confined to the nervous system. Supported by NIH grant EY07397.

## 235.4

FUNCTIONAL ANALYSIS OF THE 5'-UPSTREAM PROMOTER REGION OF THE MURINE TRYPTOPHAN HYDROXYLASE GENE USING THE IMMORTALIZED PINEAL CELL LINE FROM TRANSGENIC MICE. S.V.Yim<sup>1</sup>, J.H.Chung<sup>1</sup>, S.J.Park<sup>1</sup>, S.O.Huh<sup>2</sup>, J.H.Son<sup>2</sup> and T.H. Joh<sup>2</sup>. <sup>1</sup>Department of Pharmacology, KyungHee University Medical College, Seoul, Korea. <sup>2</sup>Cornell University Medical College at The W.M. Burke Medical Research Institute, White Plains, NY, 10605.

Tryptophan hydroxylase (TPH) catalyzes the initial step of serotonin and melatonin biosynthetic pathway in neuroendocrine cells of the pineal gland. TPH gene expression is differentially regulated in the pineal gland during circadian rhythm. Previously, we have identified putative cis-acting motifs such as CRE, CTF/NF1, SP1, AP2, AP1 and OCT in the first 1 kb of the mouse TPH upstream region. We also established the immortalized neuroendocrine pineal cell lines, PGT-811 and PGT-β, by targeted tumorigenesis using the TPH promoter. PGT-β cells express the pineal marker enzymes, TPH and N-acetyltransferase. The pharmacological study demonstrated the utility of PGT-β cells as *in vitro* model system for the investigation of TPH gene expression by circadian regulation (Son et al. Mol. Brain Res. in press). To localize important cis-acting elements for the cell type-specific and/or inducible TPH expression in the pineal gland, a series of plasmids containing different lengths of the TPH upstream region fused to the luciferase as a reporter gene were constructed. The lipofection method reproducibly provided high transfection efficiency. In conjunction with the gel mobility shift assay, the DNA sequence analysis of further upstream promoter region revealed both positive and negative cis-acting elements in the 5' proximal region of the murine TPH promoter, which can be crucial to the cell type-specific and/or inducible regulation of TPH expression in the pineal gland. Supported by KyungHee University Foundation.

## 235.5

## NEURAL SPECIFIC EXPRESSION OF THE PNMT GENE.

M.J. Evinger\*, E. Mathew, J. Egan†, Y. Ughrini†, W. Rosenberg, and Y.-S.E. Lee.  
Depts. Pediatrics, Pharmacology† and Neurobiology†, SUNY, Stony Brook, NY, 11794.

Expression of the PNMT gene is restricted to cells of neural lineage. Previously, we identified two sequences in the 5' upstream region of the rat PNMT gene which repress expression of PNMT promoter-reporter constructs transfected into non-neuronal cell lines and which share sequence similarity with neural-specific elements in the Type II Na<sup>+</sup> channel and SCG-10 genes.

We sought to resolve whether neural-specific silencing of the PNMT gene is mediated in the same manner as that characterized for the Na<sup>+</sup>(II) and SCG-10 genes. Electrophoretic mobility shift assays resolve two complexes of L6 nuclear proteins binding <sup>32</sup>P- oligonucleotides representing the PNMT Mid (-603 bp) and Proximal (-557 bp) putative silencers. The faster complex shares the migration pattern observed with Na<sup>+</sup>(II) and SCG-10 RE-1 oligos. Excess Na<sup>+</sup>(II) or SCG-10 oligo competes with binding to the lower band produced with PNMT Mid and Proximal oligos. The upper band is competed only by PNMT oligos. Antisera to REST silencer protein (from G. Mandel) supershifts material from the lower PNMT and from the Na<sup>+</sup>(II) oligo bands.

Cotransfection of plasmids expressing either wild type or dominant negative REST (G. Mandel) into L6, PC12, BE-2C, and primary chromaffin cells produces elevated expression of PNMT promoter constructs. In contrast, cotransfection of Na<sup>+</sup>(II) RE-1-CAT with wild-type REST suppresses CAT expression in PC12s while dominant negative REST produces elevated CAT expression in L6 cells. Thus, structural and functional properties of the PNMT Mid and Proximal silencers differ from those in the Na<sup>+</sup>(II) and SCG-10 genes and indicate a distinctive silencing mechanism is responsible for neural-specific expression of the PNMT gene. (Sponsored by NIH grant GM 46588 to MJE.)

## 235.7

## DIFFERENTIAL EFFECT OF THE NEURON-SPECIFIC SILENCING FACTOR (REST) ON THE TRANSCRIPTIONAL ACTIVITY OF THE TYROSINE HYDROXYLASE (TH) AND DOPAMINE β-HYDROXYLASE (DBH) PROMOTERS.

C.Y. Yang\* and K.-S. Kim Dept of Neurology, University of Tennessee, Memphis, TN38163.

The human DBH gene contains a negative regulatory element (termed DNRE) in the 5' upstream sequence. The DNRE shows a sequence homology and shares binding affinity with the neuron-specific silencer motifs identified in type II sodium channel, SCG10 and synapsin I genes. Recent isolation of the cognate transcription factor which binds to these silencer motifs, termed RE1 silencing transcription factor (REST; Chong et al., Cell (1995) 80, 949-957) or neural restrictive silencing factor (NRSF; Schoenfeld and Anderson, Science (1995) 267, 1360-1363) made it possible to test whether the same factor can regulate the activity of the DNRE and/or DBH promoter. Here, we report that neither the 2.6 kb DBH upstream sequence nor the DNRE is subject to repression by REST using a cotransfection assay. In contrast, the promoter activity of the tyrosine hydroxylase (TH) upstream sequence was suppressed by REST in a dose-responsive manner. Strikingly, the dominant negative form (p73) of REST also suppressed the TH promoter activity with a similar efficiency. Taken together, these results dispel the possibility that REST may regulate the silencer activity of the DNRE, but are consistent with the hypothesis that REST may suppress the promoter function of certain genes (e.g., TH) via protein-protein interactions.

## 235.9

## CRE IS INVOLVED IN THE TRANSCRIPTIONAL UPREGULATION OF HUMAN DOPAMINE β-HYDROXYLASE GENE BY TPA. H. Ishiguro\*, K. Yamada, N. Ichino, T. Nagatsu. Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi 470-11, Japan.

Protein kinase A (PKA) and protein kinase C (PKC) upregulate the transcriptional level of human dopamine β-hydroxylase (DBH) gene in neuroblastoma SK-N-SH cells. Although functional CRE of human DBH gene (TGACGTC) has 1-nucleotide change of consensus CRE sequence (TGACGTC), PKA upregulates the transcription of the gene. Previous studies showed that YY-1 binding to the promoter was important to the induction of human DBH gene transcription by the treatment of TPA. To identify the TPA response region (TRR) in human DBH gene promoter, deletion mutant constructs from -604bp to -171bp were prepared and these luciferase reporter genes (Luc) were transfected to SK-N-SH cells. TRR resided in the upstream of CRE between -223bp and -175bp of human DBH gene, and there were no similar sequences in other known TRE sequences. When the sequences of TRRs (-223bp to -199bp or -206bp to -181bp) was placed in the 5'-position of the tk promoter (tkLuc), there were no transcriptional induction by the addition of TPA. To analyze the mechanism of TRRs, CRE sequences were inserted between TRRs and tk promoter in these reporter genes. Region from -206bp to -181bp in TRRs enhanced the transcriptional level of this reporter gene by the addition of TPA. These data define the TRR, residing at -206bp to -181bp upstream of the transcription initiation site, as an essential DNA region for the induction of DBH gene transcription by TPA. (Supported by MESC Japan)

## 235.6

## CHARACTERIZATION OF THE CELL-SPECIFIC SILENCER REGION OF THE DOPAMINE β-HYDROXYLASE GENE.

H.-S. Kim\* and K.-S. Kim Dept of Neurology, University of Tennessee, Memphis, TN38163.

Previous transient expression assays identified a cell type-specific silencer domain which resides between -486 bp and -262 bp from the transcription start site of the human DBH gene. This upstream domain encompasses a nucleotide fragment (termed DNRE) with a significant homology to the neuron-specific silencer motif found in several neuronal genes, suggesting that the DNRE is responsible for the cell specific silencer function of that domain. The DNRE exhibited repressive activity when placed in front of the homologous DBH or heterologous thymidine kinase promoter. However, site-directed mutation of the DNRE did not significantly diminish the repressive activity of the silencer domain, indicating that additional cis-regulatory motifs may reside within that silencer region, and coordinately regulate cell-specific silencer function. To address this possibility, that silencer domain was further analyzed by DNase I footprint analysis using nuclear proteins prepared from DBH-expressing SK-N-BE(2)C and DBH-nonexpressing HeLa cell lines. Three potential cis-regulatory elements, residing at -254 to 267 bp (domain I), at -295 to -316 bp (domain II), and at -324 to -348 bp (domain III) appeared to interact with nuclear extracts. While domain II was protected by both nuclear extracts, domain I and III were protected only by HeLa extracts in a cell-specific manner. In support of this, the electrophoretic mobility shift assay showed a similar pattern of cell-specific DNA-binding activities. Taken together, these results support our hypothesis that multiple cis-regulatory elements are involved in the cell type-specific silencer function of the upstream region between -486 bp and -262 bp of the human DBH gene.

NIH grant MH48866 and Gerwin Neurodegenerative Grant to KSK

## 235.8

## MULTIPLE FACTORS INTERACT WITH CIS-REGULATORY ELEMENTS OF THE PROXIMAL PROMOTER IN A CELL-SPECIFIC MANNER AND REGULATE TRANSCRIPTION OF THE DOPAMINE β-HYDROXYLASE GENE.

H. Seo\* and K.-S. Kim Dept of Neurology and Anatomy & Neurobiology, University of Tennessee, Memphis, TN38163.

A cAMP response element (CRE) residing at -181 to -174 bp from the transcription start site of the human dopamine β-hydroxylase (DBH) gene appears to be essential for DBH transcription. Potential cis-regulatory motifs such as AP1 and YY1 occur proximal to and overlap this CRE, endowing the area with a composite promoter structure. Using the DBH-expressing human neuroblastoma SK-N-BE(2)C and DBH-negative HeLa cell lines as model systems, we here report that this CRE/YY1/AP1 area interacts with multiple nuclear proteins including CRE-binding protein (CREB) and transcription factor YY1 in a cell-specific manner. In support of the notion that multiple proteins bind to the CRE/YY1/AP1 area, DNase I footprinting analysis demonstrated that nuclear extracts protected an extended region (from -186 bp to -150 bp), relative to that protected by purified CREB (from -186 bp to -171 bp). Site-directed mutational analysis revealed differential roles of potential cis-regulatory motifs in regulation of DBH transcription. Furthermore, three additional DNA-binding sites were identified by DNase I footprint analysis in the upstream 260 bp promoter region of the human DBH gene, of which two sites were cell-specific. These results support a model whereby multiple proteins bind to the 5' proximal area in a cell-specific manner and coordinately regulate the cell type-specific transcriptional activation of the DBH gene.

NIH grant MH48866 and Gerwin Neurodegenerative Grant to KSK

## 235.10

## ANALYSIS OF CELL TYPE SPECIFIC EXPRESSION BY THE RAT TYROSINE HYDROXYLASE PROMOTER USING TWO DIFFERENT TRANSGENIC APPROACHES. K.L. O'Malley\*, J.P. Merlie\*, R.D. Todd\*, and J. Liu. Dept. of Anat. &amp; Neurobiol., Dept. of Mol. Biol. &amp; Pharm., Depts. of Psychiatry &amp; Gen., Washington Univ., Sch. of Med., St. Louis, MO 63110

As the rate-limiting enzyme in the biosynthetic pathway of catecholamines, tyrosine hydroxylase (TH) is regulated both spatially and temporally in its pattern of gene expression. In order to study cell type specific gene expression, we examined different lengths of the rat TH promoter directing the LacZ gene in founder transgenic animals without establishing transgenic lines. In contrast to the usual practice of establishing inbred lines, this approach allowed us to economically analyze a large number of animals and constructs in a relatively short period of time. Fragments encompassing 6.0 kb, 3.4 kb, 2.5 kb and 0.8 kb of the rat TH promoter were used for this analysis. Descriptively as well as statistically, our results showed that cell type specific enhancer elements for adrenergic/noradrenergic cells in the brain stem and locus coeruleus and dopaminergic cells in midbrain, hypothalamic and olfactory periglomeruli were all located within 6.0 kb of the promoter sequence. Cell type specific elements for peripheral tissue such as adrenal chromaffin cells were located within 2.5 kb of the promoter sequence. In contrast to studies by others, we also found that a mesencephalic cell type specific element was located within 2.5 kb of the TH promoter sequence, which seemed to be negatively regulated by the addition of upstream sequences. We have also established independent transgenic lines using the 6.0 kb construct. Comparison of the variance in cell type specific gene expression between the "kill the founder" approach (n=9) and an analysis of gene expression within one transgenic line (n=6) showed no significant differences. These studies demonstrate the feasibility and reliability of using founder transgenic animals for promoter analysis. (Supported in part by NIH 45330)

## 235.11

INDUCIBLE cAMP EARLY REPRESSOR (ICER) CAN MODULATE TYROSINE HYDROXYLASE (TH) GENE EXPRESSION AFTER STIMULATION OF cAMP SYNTHESIS. C. Tinti\*, B. Conti, J.E. Cubells, K.-S. Kim, H. Baker and T.H. Joh. Cornell Univ. Med. Coll. at Burke Med. Res. Inst., White Plains, NY, 10605.

The forskolin-induced activation of the cAMP pathway regulates transcription of TH, the rate-limiting catecholamine biosynthetic enzyme, through a CRE sequence located in the proximal 5' promoter of the gene. To identify specific nuclear factors that modify TH transcription through the TH-CRE, gel mobility shifts were performed with nuclear extracts derived from untreated or forskolin-treated PC12 cells. Retardation patterns, supershift analysis, as well as Western- and Northern blots showed induction by forskolin of a small protein corresponding to inducible cAMP early repressor (ICER). ICER, a strong transcriptional repressor, belongs to the family of CRE binding proteins and is derived by alternative promoter usage in the CREM gene. Transient transfection experiments in PC12 cells combining a previously-characterized TH2400CAT plasmid with the expression vector CMV-ICER-Ib, showed that ICER can repress transcription driven by the proximal 2.4 kb of the rat TH promoter. ICER also repressed protein kinase A-stimulated transcription of the TH2400CAT construct. Finally reserpine, which profoundly stimulates TH transcription, induced ICER in the rat adrenal gland. These results suggest that ICER can modulate cAMP-stimulated transcription of the TH gene and may, therefore, mediate rapid reversal of increased TH transcription following elevations in cAMP. (Supported by NIH grant MH24285)

## 235.13

NEURON-SPECIFIC EXPRESSION IN TRANSFECTED RETINAL ORGAN CULTURES USING THE CR16 PROMOTER. W.H. Ashman, Y.-C. Li, A.P. Young, J.N. Masters\*, Department of Cell Biology, Neurobiology and Anatomy and the Neurobiotechnology Center, The Ohio State University, Columbus, OH 43210

CR16 is a novel glucocorticoid-regulated gene expressed in subpopulations of rat brain neurons. In order to characterize the cis-acting DNA elements mediating the neuron-specific expression, we have determined the structure of the CR16 gene and assayed promoter function in HeLa cells and retinal organ cultures. Primer extension and RACE cloning suggest that a single promoter is responsible for transcription initiation in hippocampal neurons. The CR16 promoter sequence lacks TATA and CAAT boxes, but is contained in a possible GC island with multiple SP-1, AP-2 and E-box elements. Cell type specific expression was determined by electroporation of chicken E12 retina with  $\beta$ -gal reporter constructs followed by primary culture and immunocytochemistry as described (Li et al., J. Mol. Neurosci. 6:169 1995). Reporter constructs containing the RSV or SV40 promoters were relatively non-selective in terms of neuronal vs glial expression (65% neurons, 35% glia) while the glutamine synthetase promoter was relatively glial selective (20% neurons, 80% glia). The CR16 promoter from -492 to +71 (relative to the transcription initiation site) is predominantly expressed in neurons (95% neuron) and this specificity is maintained in deletion clones containing as little as 101 bp of upstream sequence. Future studies will further localize and identify the neural-specific enhancer and/or glial suppressor elements. The identification of these elements may be useful in preparing neuron-targeting vectors. Supported by NIH AG09425 (JNM) and EY05063 (APY).

## 235.15

EXPRESSION PATTERNS OF MURINE ALDOLASE C (ZEBRIN II) TRANSGENES. S. M. Maricich, E. Walther, M. Dichgans, S. Dziennis, E. Denen\*, S. Zackson, R. Hawkes and K. Herrup. Case Western Reserve Univ., Cleveland, and University of Calgary.

Although many genes with compartmentalized patterns of expression in cerebellum have been identified, the specific cis-acting elements responsible for these expression patterns have remained elusive. Aldolase C (zebrin II), expressed in Purkinje cells, is one such gene product. To study its regulation, we designed three different reporter-gene constructs containing bacterial  $\beta$ -galactosidase (*lacZ*). Multiple independent transgenic lines were created using each of the constructs. Expression was CNS-specific in all lines which showed reporter activity. Those with *lacZ* in the final exon, exon 9, (MAC29) showed glial expression throughout the brain. A deletion construct lacking all structural gene sequence between the second and ninth exons (MAC22A9) showed more restricted and sporadic expression. Finally, a construct with the reporter in exon 2 (MAC22) showed no expression. None of the constructs reproduced the pattern of expression of the endogenous gene. Copy number analysis, Northern blots of transgene expression, and in situ hybridization using specific probes for aldolase A and aldolase C were also performed. We propose a model where elements 5' to those in our constructs as well as the spacing of various cis-acting elements, some present within the body of the gene, are important for achieving normal patterns of aldolase C expression.

TRIPLEX FORMING OLIGONUCLEOTIDE TARGETED TO THE AP-1 SITE OF THE RAT TYROSINE HYDROXYLASE PROMOTER. N.A. Papanicolaou, B. Nankova and E.L. Sabban. Dept. of Biochemistry and Molecular Biology, New York Medical College, Valhalla, N.Y. 10595.

The rat tyrosine hydroxylase (TH) gene is regulated by a variety of pharmacological and physiological signals. Sequences between -205 and -182 contain an AP-1-like motif which regulates the rat TH gene expression in tissue culture cells in response to NGF and phorbol esters. Moreover, nuclear extracts isolated from the adrenal medulla of rats subjected to immobilization and cold stress, exhibit increased binding of fos/jun complexes to the AP-1 site of the rat TH promoter. Triplex forming oligonucleotides (TFOs) may be used to modulate gene transcription in a sequence specific manner. In an effort to specifically inhibit transcriptional activators acting at the AP-1 site, a 22 nucleotide TFO (Thap-1) was synthesized. Thap-1 (1-100  $\mu$ M) was found to bind to two rat promoter fragments (32 bp and 128 bp) containing the AP-1 site and to reduce their electrophoretic mobility. Competition experiments showed that Thap-1 binds specifically the AP-1-containing oligonucleotides and prevents the interaction of fos/jun complexes in nuclear extracts from the adrenal medulla of immobilized rats. These results suggest that TFOs may be useful in modulating transcriptional activation at the AP-1 site of the TH promoter (Supported by NIH grant NS28869).

## 235.14

TRANSCRIPTIONAL REGULATION OF THE NEURONAL GLUCOSE TRANSPORTER (GLUT 3). R.A. Rajakumar, R.K. Menon, K. D. Ryan\*, and S.U. Devaskar. Department of Pediatrics, University of Pittsburgh, Magee-Womens Research Institute, Pittsburgh, PA 15213.

The glucose transporter, Glut 3, is targeted specifically to the axonal processes of mature neurons. Glut 3 expression is developmentally regulated with low amounts being noted in the fetal and early postnatal brain and peak amounts being observed at postnatal day 21 in both the rat and mouse. To examine the role of transcription in the developmental regulation of Glut 3 we undertook the present investigation. Employing a mouse Glut 3 genomic clone containing -1884 bp 5'-to the translation start site (J. Takeda & Bell; Genebank no. U11844), 5'-deletional constructs were made by PCR and subcloned into a promoterless, enhancerless luciferase vector. Following transient transfection of cultured immortalized embryonic fetal rat neural cells which exhibit a neuronal phenotype (Eves et al., PNAS 1992) and N2A mouse neuroblastoma cells (ATCC), the luciferase activity (reporter) was assayed and standardized to  $\beta$ -galactosidase activity (n=3 each). The results of these studies focused the Glut 3 promoter activity to -149 to -124 bp of the 5'-sequence. Subsequent competitive gel shift and super shift assays have demonstrated Sp1, the ubiquitous nuclear protein to bind this domain. The Sp1-Glut 3 DNA binding activity increases from the 1d to the 21d postnatal age. We conclude: 1) the GC rich region of a CAAT box domain forms the cis-element and Sp1 a trans-activating factor regulating neuronal transcription of mouse Glut 3; 2) the Sp1 DNA-binding activity increases with development. [Supported by NIH-HD-33997]

## 235.16

TISSUE-SPECIFIC, 5' TRANSCRIPTIONAL CONTROL OF THE MOUSE ACETYLCHOLINESTERASE GENE. E. Atanasova\*, S. Chiappa, and S. Brimijoin. Mayo Clinic, Rochester, MN 55905.

A previously uncharacterized portion of the gene for mouse acetylcholinesterase (AChE), extending from position -1267 to -493 in the 5' untranslated region, was obtained by RAGE-PCR (Rapid Amplification of Genomic Ends). The RAGE-DNA co-hybridized with coding-sequence cDNA in a mouse genomic library and was 61.5% identical to the human AChE promoter region. Analysis revealed a CCAAT box and consensus sequences for transcription factors including SP1, ATF/CREB, and AP2, as well as clustered MyoD and NFkB sites. To investigate possible promoter activity, RAGE-DNA linked to the open reading frame of a luciferase reporter-gene was transfected into neural (N1E.115 mouse neuroblastoma) and skeletal muscle cells (L6P rat myoblastoma). At 48 hr, lysate luciferase was compared with activity produced by two other reporter-constructs: 1) with the recognized minimal promoter and 2) with a 1.2 kb DNA extending from the 5' end of the RAGE sequence to position -75. In L6P, the 1.2 kb construct and the minimal promoter were, respectively 10 and 7 times as effective as the RAGE-construct. In N1E.115, the 1.2 kb construct was 6 times as effective as the RAGE-construct (p < 0.001 by Mann Whitney Test), but the RAGE DNA was just as effective as the minimal promoter. These data suggest that the RAGE sequence might play a biological role in neural tissue. Further evidence for this idea was derived by applying 5' RAGE-PCR (Rapid Amplification of cDNA Ends) to mouse brain cDNA. Thus, DNA products cloned into TA vector and transformed into INVaF<sup>+</sup> cells yielded colonies hybridizing with both RAGE-DNA and cDNA from the AChE coding sequence. (Supported by NS28646).

## 235.17

MOLECULAR COMPONENTS OF DEVELOPMENTALLY REGULATED FAR-DISTANT REPRESSION OF THE ENKEPHALIN GENE. A. Dobi, M. Palkovits, A. Eitel, M. Mahan, F. Lim, M. Ring, C.G. Palkovits, and D.V. Agoston\*, MCN, Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892

The peptide neurotransmitter enkephalin is primarily expressed in neurons of the caudate nucleus, whereas the thalamus and the cortex contain 10 to 100-fold less neurons that express the ENK gene. We previously identified an AT-rich region [(ATT)19 repeat] (at -2450 bp) which specifically interacts with the proximal promoter region in a development- and brain region-specific manner through a complex of DNA binding proteins. The DNA-protein complex binds with high affinity to cationic lipids. Competitive mobility shift assays with various mutants of the ATT motif indicate that the protein complex requires a specific DNA structure characterized by AT rich sequences. The protein complex binds to the DNA in an all-or-nothing fashion suggesting cooperative binding between proteins or protein subunits. Based on UV crosslinking, the complex is composed of four proteins of MW ~200 kD, ~90 kD, and 43 kD. The 43 kD protein is a novel protein characterized by very high proline content. Decoying the binding of the endogenous protein complex to the ATT repeat in developing primary cortical neurons resulted in a 3-5-fold increase in ENK mRNA expression further supporting the hypothesized repressor role for this element. Also, distamycin, which specifically binds to the minor groove and thereby perturbs minor groove-protein interactions, induced a several-fold increase in ENK mRNA in primary cortical neuronal cultures. Our results suggest that the major regulatory mechanism in the mammalian brain is likely selective gene repression.

## 235.19

CHARACTERIZATION OF THE PROMOTER ELEMENTS AND TRANS-ACTING FACTORS INVOLVED IN THE REGULATION OF FGF-2 EXPRESSION BY GROWTH FACTORS AND SECOND MESSENGERS IN HUMAN ASTROCYTES. J. Moffett, E. Mordechai, E. Kratz, A. Schwartz\*, M.K. Stachowiak, Barrow Neurological Institute, Phoenix AZ 85013.

Mitogenic FGF-2 is involved in the transition of astrocytes from the quiescent to the reactive, proliferating state. We utilized cultures of human astrocytes to examine whether soluble growth factors and second messenger systems may also control expression of FGF-2. Astrocytes express the 18 kDa and high molecular weight (HMW; 21/22, 24 kDa) FGF-2 isoforms. Treatment of serum-free cultures with cytokine IL-1 $\beta$  increases the intracellular content of predominantly the 24 kDa FGF-2 isoform. Growth factors EGF and PDGF increased predominantly the levels of the 18 kDa FGF-2 isoform. Incubation with 18 kDa recombinant FGF-2 increased the content of the 18 kDa as well as the HMW FGF-2 isoforms. The induction of FGF-2 was accompanied by an increase in FGF-2 mRNA levels. Transfection of FGF-2 promoter-luciferase constructs showed that IL-1 $\beta$  and growth factors stimulate transcription of the FGF-2 gene by acting through a -550/-512 bp promoter region. Forskolin or PMA increase FGF-2 mRNA and FGF-2 promoter activity from the promoter region -650/-555 indicating that adenylate cyclase or PKC signaling pathways are not involved in FGF-2 gene stimulation by growth factors. In vitro DNA-protein binding experiments indicate that stimulation of FGF-2 gene results from increased binding of trans-activating factors to the growth factor-responsive and cAMP/PKC promoter regions, respectively. DNase I footprinting of the -650/-512 region revealed several sequences within this region that may bind trans-acting factors involved in FGF-2 regulation. UV-crosslinking identified at least 3 proteins that may be involved in trans-activation of the FGF-2 promoter. The data indicates that the FGF-2 promoter is regulated by trans-acting factors binding to novel cis-elements in the FGF-2 promoter (supported by NSF, ADRC, Univ. of Arizona Biomed. Res. Prog.).

### EXCITATORY AMINO ACID RECEPTORS: STRUCTURE, FUNCTION, AND EXPRESSION—FUNCTIONAL PROPERTIES

## 236.1

CHARACTERIZATION OF THE pH SENSITIVITY OF NMDA RECEPTOR GLYCINE SITE LIGAND BINDING AND DEVELOPMENT OF A MOLECULAR MODEL IMPLICATING NR1 SUBUNIT HISTIDINE RESIDUES B.M. Baron\*, B.W. Siegel, R. Vaz, and B.L. Harrison, Hoechst Marion Roussel, Cincinnati, OH, 45215

The effect of pH on NMDA receptor glycine site ligand affinity was studied using the radiolabeled antagonist [<sup>3</sup>H]MDL 105,519. The pH optimum for binding to rat brain membranes was pH 6.0. Similar results were obtained using stably expressed NMDA NR1 subunits indicating that the molecular substrate is the NR1 protein. In brain membranes, acidification increased the affinity of the radioligand without changing the total number of binding sites. The K<sub>d</sub> values were determined at pH 6.0 and 7.4 for a panel of unlabeled agonists and antagonists. Three distinct effects were noted which were correlated with ligand structure. Agonists possess a charged nitrogen atom and showed a 5-fold reduction in affinity at the more acidic pH. Antagonists possessing a distally-located carboxylic acid moiety (e.g. MDL 105,519 and related structures) exhibited a 3-5-fold increase in affinity at the acidic pH. Antagonists lacking this side chain (e.g. ACEA 1021 and amide derivatives of MDL 105,519) were unaffected by these pH changes.

We hypothesized that the effect of pH on ligand affinity results from coulombic interactions with charged histidine residues (pK<sub>a</sub> = 6.1) in the binding pocket. A molecular model of the putative glycine recognition site on the NMDA NR1 subunit was generated using the crystal structure of the homologous bacterial protein LAOBP with a loop-search technique to map non-homologous regions. Docking MDL 105,519 into the NR1 model using coordinates defined by LAOBP-bound lysine, revealed a potential ionic interaction with two histidine residues. As brain ischemia is associated with acidosis, the combination of decreased agonist affinity and increased antagonist affinity may make glycine antagonism a distinctly efficacious approach or provide selectivity for the ischemic zone. Future work should be directed to testing the hypotheses concerning the amino acids responsible for these effects.

## 235.18

CONTRIBUTIONS OF MULTIPLE CIS-ACTING ELEMENTS TO BASAL CELL-SPECIFIC AND SECOND MESSENGER-STIMULATED TRANSCRIPTION OF THE VIP GENE. S. H. Hahm and L. E. Eiden\*, Sec. Molec. Neurosci., Lab. of Cell Biol., NIMH, NIH, Bethesda, MD 20892.

A construct containing five kb of 5' flanking sequence, and extending through the second exon of the VIP gene, fused to a sequence encoding luciferase, was used to demonstrate that an upstream region (-5.2-2.5 kb) previously shown to be important for cell-specific regulation of the VIP gene (PNAS 85:9547, 1988) is absolutely required for cell-specific expression in EP and SK-N-SH neuroblastoma cells. The proximal VIP CRE (cyclic AMP response element) is also required for full cell-specific constitutive expression in the context of the 5.2 kb VIP-luc construct. Cyclic AMP (forskolin) responsiveness absolutely requires the CRE sequence. Contrary to previous reports using heterologous promoters to assay the activity of the VIP-CRE, responsiveness to phorbol esters is independent of the CRE and dependent on the presence of a region upstream of the CRE containing a consensus AP-1 site.

Multiple cis-acting sequences of the VIP gene act combinatorially to affect full basal and stimulated expression of VIP. The VIP-CRE functions only as a cyclic AMP response element, and not as a TPA-response element (TRE), in the context of the VIP gene. An additional TRE exists in the VIP gene, probably at the TGACTCA sequence approximately 2.3 kb upstream of the start of transcription of the VIP gene.

## 235.20

REGULATION OF THE CHICKEN OVALBUMIN UPSTREAM PROMOTER TRANSCRIPTION FACTOR (COUP-TF I) PROMOTER. K. Brubaker, H. O. Nomes\*, and T. Neuman, Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

The gene for COUP-TF I codes for a transcription factor that belongs to the Steroid/Thyroid nuclear hormone receptor superfamily. Receptors in this family transduce hormone signals involved in development and cellular processes through molecules such as the retinoids and thyroxine. One function of the COUP-TF subfamily is to repress the receptor function of other superfamily members. In this way the responsiveness of cells to hormone signals is inhibited. Identification of the regulatory elements of the COUP-TF I promoter may allow for the expression to be blocked, thereby enhancing cellular response to hormone signals.

The promoter region for COUP-TF I was sequenced and the start site identified. Transgenic mice containing the reporter gene (CAT) under the control of the COUP-TF I 4kb regulatory region were generated. Comparison of COUP-TF I and reporter gene expression using *in situ* hybridization demonstrate that the 4kb regulatory region is sufficient for proper expression in the developing and adult CNS. Transient CAT assays were performed to characterize regulatory elements contained within the promoter region using PCC7, 3T3, and C3A cell lines.

This research was funded by the Spinal Cord Society.

## 236.2

ASPARAGINE<sub>616</sub> IN THE NR1 SUBUNIT CONTROLS SPERMINE BLOCK, SPERMINE POTENTIATION, AND pH SENSITIVITY. M.F. Burgess\*, J. Powers and S.F. Traynelis, Dept. of Pharmacology, Emory University, Atlanta, GA 30322 and Dept. of Chemistry, Kennesaw State College, Marietta, GA 30061

Our previous studies have demonstrated that inclusion of exon5 in the NR1 subunit of the NMDA receptor leads to a voltage-independent relief of the tonic inhibition exerted by physiological pH. The polyamine spermine appears to mimic the effects of exon5 by reducing pH inhibition for NR1 splice variants that lack exon5. To further explore the structural basis of spermine and pH effects on NMDA function, we have used site-directed mutagenesis to investigate the role of residues that are suggested to line the channel pore, because these residues may control other pH-independent effects of spermine. We found that a single amino acid (Asn<sub>616</sub>) controls voltage-dependent block of the channel by 100 and 1000  $\mu$ M spermine. Substitution of arginine for the asparagine removes spermine-induced outward rectification of recombinant NR1( $\pm$ exon5)/NR2 receptor responses in the *Xenopus* oocytes (n=35 oocytes). Interestingly, this mutation also decreased both the pH sensitivity (n=50) and spermine (100  $\mu$ M) relief of tonic proton block (n=6). We conclude that either the Asn<sub>616</sub> contributes to a complex interaction that involves exon5, spermine, and the pH-sensor, or Asn<sub>616</sub> controls the gating of the channel in a pH-sensitive fashion.

PERMEATION PROPERTIES OF WILD TYPE (NR1/NR2A) AND MUTANT (NR1-E603K/NR2A) NMDA CHANNELS J.Kupper, R. Schneggenburger, J.Neyton and P. Ascher\* Laboratoire de Neurobiologie, CNRS URA 1857, Ecole Normale Supérieure, 75005 Paris, France.

In the primary sequence of NMDA channels composed of the NR1 and NR2A subunits the glutamate (E) in position 603 of the NR1 subunit is the only negative charge near the Q/R/N site. We have compared the permeation properties of wild type NR1/NR2A channels to those of mutant NR1 E603K/NR2A channels in which the glutamate is replaced with a positively charged lysine (K). The channels were expressed in *Xenopus* oocytes or HEK cells. In outside out patches with symmetrical 150mM CsCl the single channel *i/v* relation of NR1 E603K mutant channels shows a much more pronounced inward rectification than what is observed for wild type channels. Increasing the CsCl concentration from 150 mM to 500mM increases only marginally the single channel conductance of the wild type channel, indicating that this channel operates near apparent saturation under physiological conditions. In contrast, the same change of ionic concentrations increases the single channel conductance of the NR1 E603K mutant from  $\approx 35$  pS to  $\approx 53$  pS (at -80mV) and reduces the inward rectification. Reversal potential measurements of macroscopic currents in HEK cells show that the calcium permeability of the NR1-E603K/NR2A channel is reduced by  $\approx 50\%$  as compared to the wild type channel. Measurements of fractional calcium currents ( $P_i$ ) in the voltage range between 0mV and -60mV indicate that close to 0mV  $P_i$  has the value predicted from reversal potentials but with hyperpolarization the  $P_i$  value of the mutant channel increases up to the value of the wild type. Taken together these observations are consistent with the idea that the E603K mutation introduces a positive surface charge in or close to the inner mouth of NMDA channels. Supported in part by a HFSP fellowship to J.K., an EC fellowship to R.S. and EC grant (BIO2-CT93-0243).

#### MOLECULAR DETERMINANTS OF CA-DEPENDENT INACTIVATION IN RECOMBINANT NMDA RECEPTORS

J. Krupp\*, B. Vissel†, S. Heinemann† & G. L. Westbrook, Vollum Institute, Oregon Health Sciences University, Portland OR and † Salk Institute, La Jolla CA.

Ca-dependent inactivation of the NMDA receptor regulates transmission at hippocampal synapses. We have previously shown that Ca-dependent inactivation in NR1-1a/2A heteromers is similar to hippocampal neurons, but does not occur in NR1-1a/2C heteromers. To determine the molecular basis of Ca-dependent inactivation, we first tested whether differences in Ca influx could explain the apparent subunit specificity using combined calcium-imaging and whole-cell patch-clamp measurements in HEK293 cells (Vh: -50). The intracellular solution contained 200  $\mu$ M fluo-3, 100  $\mu$ M EGTA, and no added Ca. In NR1-1a/2A heteromers 10  $\mu$ M NMDA ( $\text{Ca}_o = 2$  mM) induced inward currents with prominent Ca-dependent inactivation ( $43.8 \pm 8.2\%$ ,  $n = 4$ ) concomitant with a calcium transient ( $F/F_0 = 1.3$ -5.2). Similar calcium transients were evoked in NR1-1a/2C, but there was no Ca-dependent inactivation of the whole-cell current. Thus the slightly lower Ca influx of 1a/2C receptors (Burnashev et al., J. Physiol. 1995) does not explain the subunit specificity of inactivation.

The C-terminus of NR1 has been shown to bind Ca-CaM, resulting in reduced channel activity in inside-out patches of NR1/2A receptors (Ehlers et al., Cell 1996). We tested whether Ca-dependent inactivation simply reflects CaM binding by cotransfecting NR2A with a splice variant of NR1 (NR1-4a) that lacks the C-terminal inserts containing a PKC site and one of the CaM sites. We also constructed two deletion mutants (NR1-stop838 and NR1-stop863), terminating 5 and 30 aa after the putative TMIV. Ca-dependent inactivation was retained with NR1-4a ( $54.3 \pm 13.0\%$ ,  $n = 7$ ) as well as NR1-stop863 ( $32.8 \pm 18.0\%$ ,  $n = 5$ ), but was absent with NR1-stop838 ( $5.5 \pm 27.1\%$ ,  $n = 8$ ). Thus, Ca-dependent inactivation requires the first 30 aa after TMIV of NR1 that contains one calmodulin binding site. However, calmodulin inhibitors have no effect on Ca-dependent inactivation in native receptors, suggesting that Ca-dependent inactivation involves additional receptor domains.

NMDA RECEPTOR SUBTYPES STABLY EXPRESSED IN HUMAN KIDNEY 293 CELL-LINES. F. Besnard, S. Renard, M. Partiseti, C. Drouet-Petre, S.Z. Langer\* and D.Graham, Synthelabo Recherche, 92500 Rueil Malmaison, France

NMDA receptors are composed of many different subunits subdivided in two families: NR1 (8 splice variants) and NR2 (4 related subunits A-D). They are involved in a number of important CNS functions such as motor coordination and delayed neuronal cell death. As subtype-selective drugs could help determine the composition and role of the different native NMDA subtypes we developed a novel strategy to establish stable cell lines expressing various NMDA receptor subunit combinations in order to identify such drugs. These cell lines were established using a tetracycline inducible promoter in order to protect the cells against cytotoxicity induced by NMDA receptor expression. The NR1A subunit was subcloned downstream of the tetracycline regulated promoter and after transfection and selection, clones were screened by Western-blot with a NR1 specific antibody. Several clones showed expression patterns that could be modulated from background to high levels by removing tetracycline for 24 hours. One clone was selected for surtransfection with different NR2 subunits. After a second round of selection two cell-lines expressing binary combinations of NR1A/NR2A and NR1A/NR2D were obtained and characterized. Expression of NR1/NR2 subunits in these cells upon tetracycline removal was confirmed by Western-blot analysis with subunit-selective antibodies as well as by induction of cytotoxicity. The pharmacological and electrophysiological properties of these cell-lines will be presented.

Ca<sup>2+</sup> SELECTIVITY AND PERMEATION IN NMDAR CHANNELS. L.P. Wollmuth\*, T. Kuner\*, D.-S. Koh, P.H. Seeburg\*, and B. Sakmann. MPI für med. Forschung, Abt. Zellphysiologie, Jahnstr. 29, \*Center for Mol. Biology (ZMBH), Heidelberg Univ., Im Neuenheimer Feld 282, Heidelberg, Germany.

The critical contribution of the *N*-methyl-D-aspartate receptors (NMDAR) to synaptic physiology and plasticity arises in part because its channel is more selective for Ca<sup>2+</sup> than for monovalent cations. The mechanism of Ca<sup>2+</sup> selectivity and transport in NMDAR channels is unknown. A GHK formalism which assumes ions permeate independently seems inappropriate: (i) the addition of 1.8 mM Ca<sup>2+</sup> externally (to 120 mM NaCl) shifts the reversal potential of currents rightward as expected for a more permeant ion but reduces the current amplitude over the entire potential range indicating that Na<sup>+</sup> and Ca<sup>2+</sup> ions do not cross the channel independently; (ii) channels with substitutions of the NR1 N-site asparagine have an attenuated  $P_{Ca}/P_{Cs}$  but surprisingly invert relative to wild type the voltage dependence of fractional Ca<sup>2+</sup> currents ( $P_i$ ); (iii) channels with substitutions of the NR2 N+1 site asparagine also attenuate  $P_{Ca}/P_{Cs}$  without affecting  $P_i$ , indicating along with (ii) that the magnitude and voltage dependence of fractional Ca<sup>2+</sup> currents are not strictly determined by Ca<sup>2+</sup> selectivity. The deviation from GHK reflects in part that Ca<sup>2+</sup> permeation in NMDAR channels depends on Ca<sup>2+</sup> interacting with two sites: the NR1 N-site positioned at the narrow constriction (50-60% across the transmembrane electric field) as well as a site positioned less than 10% across the field.

Supported in part by a Alexander von Humboldt fellowship to LPW.

IDENTIFICATION OF RESIDUES LINING THE EXTRACELLULAR VESTIBULE OF THE NMDA RECEPTOR CHANNEL. C. Beck, P.H. Seeburg, T. Kuner\* Center for Molecular Biology (ZMBH), University of Heidelberg, and MPI für Medizinische Forschung, 69120 Heidelberg, Germany

The current model of glutamate receptor topology depicts three membrane spanning segments, M1, M3, and M4, and a membrane reentrant segment, M2. The M2 segment forms a channel-lining loop which originates and ends at the cytoplasmic side of the membrane. The selectivity filter is formed by a cluster of hydrophilic residues at the tip of the loop. The ascending,  $\alpha$ -helical segment, and the descending, extended segment of the loop form part of the cytoplasmic channel wall. Such a structure of M2 (Kuner et al., Soc. Neurosci. Abstr. 21,85) suggests, that other domains form the external vestibule of the channel.

We used the substituted-cysteine-accessibility method (SCAM, Akabas et al., 1992 & 1994) to identify channel-lining residues within, and flanking, the membrane spanning segments (M1, M3, M4) of the NR1 subunit. NR1(mut)-NR2C channels expressed in *Xenopus* oocytes were probed from the extracellular side of the membrane with differently sized methanethiosulfonate reagents. From the irreversible current reduction in mutants P539C (preM1), L544C (M1), N632C (M3) and G797C (M4) we infer that these positions are exposed to the channel lumen. No current reduction was found in mutants W545 to V552 of the M1 segment. We propose that the region preceding M1, the M3 segment and the M4 segment of the NR1 subunit cooperate to form the outer vestibule of the NMDA receptor channel.

Supported by SFB 317 grant B9 to P.H.S. and a VCI doctoral fellowship to C.B.

EFFECTS OF A MONOCLONAL ANTIBODY TO THE GLUTAMATE BINDING PROTEIN ON NMDA AND L-GLUTAMATE- ACTIVATED ION CHANNELS. R. E. Ragan\*, G.L. Aistrup, K.N. Kumar, R.D. Schowen, E.K. Michaelis, M.L. Michaelis. Dept. of Pharmacol. & Toxicol. and Ctr. Neurobiol. & Immunol. Res., Univ. of Kansas, Lawrence, KS 66045

Excess activation of the *N*-methyl-D-Aspartate (NMDA) subtype of brain glutamate receptors has been implicated in neurodegeneration occurring as a result of massive Ca<sup>2+</sup> influx. A group of proteins has recently been isolated from rat brain synaptic membranes that have binding characteristics consistent with those reported for the NMDA receptors (JBC 269:27384, 1994). This complex does not contain the NMDAR1 protein or any other glutamate receptors that have been sequenced to date. Monoclonal antibodies (mAb's) were raised against the glutamate binding protein (GBP) subunit of this complex. The studies reported here were undertaken to determine whether these mAb's inhibited the glutamate/glycine-activated ion currents detected when this protein complex was reconstituted into planar lipid bilayers and whether these same mAb's decreased NMDA-activated Ca<sup>2+</sup> influx into primary hippocampal neurons. The protein complex reconstituted in lipid bilayers exhibited a glutamate/glycine activated ion current which was inhibited by the NMDA receptor blockers 2-AP5 and MK-801. Addition of 10ng/ml of the purified  $\alpha$ -GBP mAb's inhibited nearly 100% of glutamate/glycine- activated ionic current. The same mAb's also decreased the NMDA-activated Ca<sup>2+</sup> influx into primary hippocampal neurons by approximately 50%, suggesting that a portion of the NMDA-activated Ca<sup>2+</sup> influx is regulated by this protein complex. This mAb should serve as an important tool for probing the physiological relevance of this group of proteins in the function of neuronal NMDA receptors. (Funded in part by PHS grants GM07775, AA04732, and by a KTEC grant to the Center for Neurobiol. & Immunol. Res.)

## 236.9

**SUPEROXIDE INDUCED INHIBITION OF L-[<sup>3</sup>H]GLUTAMATE BINDING TO NMDA RECEPTORS IN BRAIN SYNAPTIC MEMBRANES, TO A PURIFIED PROTEIN COMPLEX AND TO ONE OF ITS SUBUNITS.**

X. Chen\*, N. S. Ranciat, M.L. Michaelis, and E. K. Michaelis. Dept. Pharmacol. Toxicol., Cntr. Neurobiol. & Immunol. Res., Univ. of Kansas, Lawrence, KS 66045

Oxidative stress in neurons may be triggered by hyper-activation of NMDA receptors (NMDARs) and may be the cause of NMDA-induced neuronal degeneration. Superoxide ( $O_2^{\bullet-}$ ) and nitric oxide ( $NO^{\bullet}$ ) are rapidly formed and may modify the structures of proteins, DNA and cell membrane lipids. The NMDARs may themselves be among the proteins modified by reactive oxygen species (ROS). This may either alter the rate of formation of ROS. In the present studies, rat brain synaptic membranes were treated with 5  $\mu$ M xanthine (X) and 0.02 U/ml of xanthine oxidase (XO) to generate  $O_2^{\bullet-}$ . The NMDA-sensitive L-[<sup>3</sup>H]-glutamate (Glu) binding to the membranes following treatment was less than 20% of control. The X+XO treatment primarily reduced the  $B_{max}$  and had only a modest effect on the  $K_d$ . The purification of the NMDA R1/R2 complex in a functional state is difficult to achieve. Therefore, a further molecular definition of the targets of  $O_2^{\bullet-}$  action was pursued by purifying a complex of proteins with ligand-binding characteristics similar to those of NMDARs. Treatment of this complex with X + XO produced nearly identical results to those for the synaptic membranes. Furthermore X + XO treatment decreased the  $B_{max}$  for L-[<sup>3</sup>H]-Glu binding to the glutamate-binding protein (GBP) subunit of the complex: Treatment of with X, XO, or  $H_2O_2$  (10  $\mu$ M) alone did not alter the binding of L-[<sup>3</sup>H]-Glu to any of these preparations. The effect of  $O_2^{\bullet-}$  formation on the function of NMDARs in intact cells is currently being explored in cerebellar granule cells and cortical neurons in culture. **FUNCTIONAL CHARACTERIZATION OF TWO ISOFORMS OF THE HUMAN GLUR6 RECEPTOR AND DISTRIBUTION OF GLUR6 RNA EDITING SITES.** L.P. Daggett\*, C. Jachec, F.F. Lin, C. Deal, M.A. Varney, S.D. Hess, G. Velicelebi, and E.C. Johnson. SIBIA Neurosciences Inc., La Jolla, CA 92037

Overlapping cDNA fragments isolated from a human fetal brain cDNA library were used to construct cDNAs encoding human GluR6a-1YQ and an alternatively-spliced carboxyl-terminal isoform, hGluR6b-1YQ. The deduced amino acid sequences of the hGluR6a and hGluR6b receptors contain 908 and 870 residues, respectively. PCR techniques were used to obtain four additional hGluR6a cDNAs that contained various combinations of RNA edits encoding I/V, Y/C or Q/R. The distribution and extent of editing at the three GluR6 RNA editing sites were analyzed by PCR techniques with cDNAs isolated from 12 different human brain regions. The expected hGluR6 PCR product (387 bp), which spanned the three editing sites, was identified in each of the 12 brain regions investigated. Restriction enzyme and DNA sequence analyses of the PCR fragments were performed and the composition of the editing events was determined for each region. In addition, [ $Ca^{2+}$ ]<sub>i</sub> measurements were performed in HEK293 cells transiently transfected with cDNAs encoding hGluR6a-1YQ, 6a-VQC, 6a-1YR, 6a-1CR, and 6a-VCR and hGluR6b-1YQ. Kainate-induced [ $Ca^{2+}$ ]<sub>i</sub> responses (100-300 nM above basal) were observed in hGluR6a-1YQ, hGluR6a-VQC- and hGluR6b-1YQ-expressing cells. [ $Ca^{2+}$ ]<sub>i</sub> responses to kainate were not observed in cells expressing hGluR6a containing an arginine (R) at the TM2 editing site. A 125-kDa protein was detected in membranes isolated from hGluR6a-1YQ and hGluR6a-VQC-transfected cells and probed with anti-GluR6/7 antibody in Western blots. The immunoreactive protein was reduced to ~103 and ~120 kDa following digestion with N-glycosidase F and endoglycosidase H, respectively. In response to application of 100  $\mu$ M kainate, in the presence of ConA, inward currents with a mean amplitude of  $6.3 \pm 3.1$  nA were recorded from hGluR6a-1YQ-transfected cells held at -60 mV.

## 236.13

**POLYAMINES PERMEATE & BLOCK GLUTAMATE RECEPTOR CHANNELS.** R. Bähring\*, D. Bowie and M.L. Mayer. LCMN, NICHD, National Institutes of Health, Bethesda, MD 20892.

Intracellular polyamines cause inward rectification of both voltage-activated  $K^+$  and glutamate receptor channels. Voltage ramp experiments in the outside-out patch configuration on homomeric GluR6(Q) channels expressed in HEK 293 cells showed voltage-dependent block by 30  $\mu$ M internal spermine ( $G_{50-100} = 0.03$ ). Shifting the reversal potential, by lowering [ $Na^+$ ]<sub>i</sub>, was accompanied by a hyperpolarizing shift in the voltage dependence of block, indicating interactions within the pore between permeant ions and polyamines. Relief of block with extreme depolarization ( $G_{100-100} = 0.51$ ) suggests spermine itself is permeant. The structurally related but larger toxin, PhTx 343, produces a similar voltage-dependent block but with no relief at positive potentials ( $G_{50-100}$  and  $G_{100-100} = 0.01$ ). We suggest that relief with depolarization of block by spermine is due to permeation and that PhTx 343 cannot permeate because of its larger size.

Given the ability of polyamines to cross the channel we tested the action of externally applied spermine. Using voltage ramps (-100 to +150 mV) we observed strongly voltage dependent block with an unusually high affinity ( $K_{app,0mV} = 100$  nM) which was not confirmed in steady state experiments with different spermine concentrations ( $IC_{50} = 65$   $\mu$ M at both +40 and -40 mV). However, with 30  $\mu$ M external spermine inducing inward currents by transiently hyperpolarizing the membrane potential resulted in a fast ( $\tau = 1$  ms) onset block at +40 mV which showed slow recovery to the steady state level ( $G_{trans} = 0.05$ ,  $G_{SS} = 0.6$ ). Both the rate of onset and the amount of block were dependent on the membrane potential, the duration of the prepulse, and external spermine concentration. This suggests that with inward current flow spermine permeates the channel from the outside to cause block from an internal high affinity binding site when the membrane potential is reversed. In addition there is an external site of polyamine action which shows lower affinity and much weaker voltage dependence.

## 236.10

**SUBUNIT-SPECIFIC PROPERTIES OF HUMAN RECOMBINANT NMDA RECEPTORS.** C. Deal, S.D. Hess\*, M. Washburn, G. Velicelebi and E.C. Johnson. SIBIA Neurosciences, Inc., La Jolla, CA 92037.

Recombinant receptors formed from combinations of cDNAs encoding human NMDAR1A and NMDAR2A-D expressed in *Xenopus* oocytes or HEK293 cells were studied using voltage-clamp techniques. In HEK293 cells transiently expressing hNMDAR1A/2D receptors, there was an approximate 10 mV shift in the reversal potential upon changing the bath from Ringer containing 135 mM  $Na^+$  to 110 mM  $Ca^{2+}$ , suggesting an appreciable fractional calcium conductance for this receptor. For hNMDAR1A/2C receptors, we determined  $EC_{50}$  values of 22.6  $\mu$ M for NMDA and 0.67  $\mu$ M for glycine, and an  $IC_{50}$  of 1.8  $\mu$ M for CGS 19755. For agonists, NMDA and glycine were most potent on hNMDAR1A/2D receptors, and can discriminate this combination from hNMDAR1A/2A, 1A/2B, or 1A/2C receptors. The glycine-site competitive antagonist 5,7-DCKA was more potent against hNMDAR1A/2A than 1A/2B or 1A/2D receptors, but CGS 19755 did not distinguish between the pairwise combinations. Ifenprodil displayed a high affinity for hNMDAR1A/2B receptors ( $IC_{50}$  of 114 nM) and low affinity for hNMDAR1A/2A, hNMDAR1A/2C and hNMDAR1A/2D receptors (39.5, 55.4 and 75.9  $\mu$ M, respectively). We compared the ifenprodil sensitivities of NMDA receptors formed by injecting into oocytes transcripts encoding NMDAR1A and different ratios of 2A and 2B subunits. At a 1:1 2A:2B ratio, the resulting receptors were pharmacologically indistinguishable from hNMDAR1A/2B receptors in terms of sensitivity to NMDA, glycine, D-serine, and CGS 19755. The receptors expressed from a 10:1 2A:2B transcript ratio displayed an ifenprodil sensitivity that would be predicted for a population in which 51% was represented by hNMDAR(1A)<sub>2</sub>(2A)<sub>1</sub> complexes. Our results underscore the need for subtype-selective compounds acting at novel sites in order to sufficiently probe the pharmacological differences between NMDA receptor subtypes formed by different subunit combinations.

## 236.12

**STABLE EXPRESSION AND CHARACTERIZATION OF THE RECOMBINANT HUMAN AMPA RECEPTOR SUBTYPE GLUR3-FLIP IN MAMMALIAN CELLS.** S. Rao, M.A. Varney\*, F.F. Lin, C. Jachec, R. Skvoretz, L.P. Daggett, C. Deal, S. Hess, G. Velicelebi, E.C. Johnson. SIBIA Neurosciences, Inc., La Jolla, CA 92037.

A stable cell line expressing the human AMPA receptor GluR3-flip (hGluR3i) was established in HEK293 cells. Functional expression was demonstrated by glutamate-induced [ $Ca^{2+}$ ]<sub>i</sub> signals in fluo-3-loaded cells, and glutamate-evoked currents in whole-cell patch-clamp recordings. The presence of hGluR3i protein was confirmed by immunoblot analysis.

The pharmacology of recombinant hGluR3i was investigated by measuring [ $Ca^{2+}$ ]<sub>i</sub> signals and [<sup>3</sup>H]-AMPA binding. The rank order of potency for agonists in the [ $Ca^{2+}$ ]<sub>i</sub> assay, in the presence of cyclothiazide, was quisqualate > AMPA = glutamate > kainate. Kainate was not a fully efficacious agonist, as compared to glutamate. These potency results differed from those obtained with [<sup>3</sup>H]-AMPA displacement curves, where the rank order of potency was kainate > AMPA > quisqualate > glutamate.

Total [<sup>3</sup>H]-AMPA binding was reduced by cyclothiazide, and in some cases the Hill coefficients for the displacement curves were lower than unity. However, the rank order of potency for displacement of bound [<sup>3</sup>H]-AMPA was the same as that obtained in the absence of cyclothiazide. GYKI-52466, a non-competitive AMPA-receptor antagonist, inhibited AMPA-stimulated [ $Ca^{2+}$ ]<sub>i</sub> signals in the presence of cyclothiazide. However, in binding studies GYKI-52466 did not displace [<sup>3</sup>H]-AMPA binding, or reverse the cyclothiazide-mediated reduction in [<sup>3</sup>H]-AMPA binding. These results suggest that cyclothiazide and GYKI-52466 act at different binding sites on hGluR3i.

## 236.14

**DUAL BLOCKADE OF GLUTAMATE RECEPTORS BY EXTERNAL DIVALENT CATIONS AND INTERNAL POLYAMINES.** Derek Bowie\* and Mark L. Mayer. Laboratory of Cellular & Molecular Neurophysiology, NICHD, National Institutes of Health, Bethesda, MD 20892.

We have previously reported that the complex rectification of kainate and AMPA receptors expressed from cDNAs for GluR6(Q) and GluR-A<sub>flip</sub> results from ion-channel block mediated by the endogenous cytoplasmic polyamines, spermine and spermidine (*Neuron*, 15, 453-462, 1995). In the absence of internal polyamines the current-voltage relationship for both AMPA and kainate receptors exhibited weak outward rectification. In each case, voltage-dependent block by external divalent cations contributed to this rectification. With symmetrical sodium (120mM) solutions block at -60 mV by  $Ca^{2+}$  (30  $\mu$ M - 30 mM) for GluR6(Q),  $IC_{50} = 0.72 \pm 0.1$  mM (n=10) was stronger than block by  $Mg^{2+}$ ,  $IC_{50} = 1.34 \pm 0.1$  mM (n=7). For both ions block was incomplete even at high concentrations; extrapolated  $G_{min}$  values for  $Ca^{2+}$  and  $Mg^{2+}$  were  $4.0 \pm 0.74$  % (n=10) and  $9.97 \pm 1.49$  % (n=7) of the maximum response, respectively. AMPA receptors generated from GluR-A<sub>flip</sub> exhibited weaker block and a lower affinity for  $Ca^{2+}$  ( $IC_{50} = 2.56 \pm 0.38$  mM at -60 mV;  $G_{min} = 26.43 \pm 2.59$ , n=5). For GluR6(Q) inclusion of 30  $\mu$ M spermine in the internal solution generated strong inward rectification but did not measurably alter block by external  $Ca^{2+}$  ( $IC_{50}$  at -60 mV =  $0.78 \pm 0.1$  mM;  $G_{min} = 4.2 \pm 1.7$  %, n=4). In addition, the extent of block by 30  $\mu$ M internal spermine was similar in divalent-free solution and in the presence of 1mM external  $Ca^{2+}$  suggesting that block by divalent cations and by polyamines occurs through independent mechanisms. Our data suggest that physiological concentrations of intracellular polyamines and extracellular divalent cations will jointly control the amplitude of synaptic responses as well as the complex rectification properties of unedited versions of glutamate receptors. MODULATION OF GLUR1, GLUR2 AND GLUR3 EXPRESSED IN OOCYTES BY HYDROGEN ION AND CHEMICAL MODIFICATION. B. Yu<sup>1</sup>, C. Brechtel<sup>1</sup>, S. C. King<sup>1</sup>, J. Sims<sup>1</sup>, S. Alagarsamy<sup>1</sup> and B. N. Christensen<sup>2</sup>. Dept. Physiology and Biophysics and Dept. Pharmacology, Univ. Tx. Med. Branch, Galveston, TX 77555.

Protons titrate non-NMDA receptor activity with a pK of 6.5, a value similar to that of free histidine. We have investigated the role of hydrogen ion and chemical agents that modify histidine residues on GLUR1-3 expressed in *Xenopus* oocytes in an attempt to identify the pH sensor. GLUR1-3 cRNA was injected into oocytes and responses to kainic acid recorded 1 week later. Both homomeric as well as combinations of GLUR1-3 were expressed. Membrane current was recorded using the two-electrode voltage clamp. Decreasing pH reduced the membrane current for both homomeric and heteromeric receptors. This is similar to the effect of pH on native mammalian and teleost non-NMDA receptors. Increasing pH increased the membrane current relative to the current measured at pH 7.5. This effect is not seen either on native mammalian or teleost non-NMDA receptors. The pK obtained from a titration curve ranged from 6.1 to 6.4 and the Hill coefficient obtained by using the Hill equation to fit the data was near 1.2. Similar to the effect of increasing pH, diethylpyrocarbonate (DEPC) a histidine modifying agent also increased the current in a concentration-dependent manner. This is similar to the reported action of DEPC on the native mammalian NMDA receptor but opposite the effect seen on native non-NMDA receptors in teleost retina. DEPC also potentiated the KA-induced membrane current in cultured cortical neurons. The pH dependence of the expressed receptors was altered following DEPC modification. At increased pH, the current was reduced compared to pH 7.5. In addition, the pK was shifted to the left near 5.8. These results indicate multiple pH sensors on GLURs and that DEPC can modify at least one. Supported by grant NEI-01897 from the NIH. cDNA for GLUR1-3 was a kind gift from the Salk Institute, La Jolla, CA.

## 236.17

MUTATIONAL ANALYSIS OF A SITE REGULATING MODULATION OF AMPA RECEPTOR DEACTIVATION AND DESENSITIZATION. M.W. Fleck, K.M. Partin\* and M.J. Mayer. Lab Cellular & Molecular Neurophysiology, NICHD, NIH, Bethesda, MD 20892.

AMPA receptor subunits express an alternatively spliced exon, known as the flip/flop domain, located within the extracellular M2-M3 loop. Amino acid mutations within this 38-residue domain affect desensitization and allosteric modulation by cognition-enhancing drugs such as aniracetam and cyclothiazide. We had previously shown that a single residue, SER750 in *Aflip* or ASN750 in *Aflop*, underlies differential modulation of desensitization by cyclothiazide.

To further examine the role of residue 750 in regulating deactivation, desensitization and allosteric modulation, we constructed and tested a series of *Aflip* point mutants converting SER750 to ASN, GLN, ALA, ASP, GLU, VAL, LEU, MET, CYS, THR and TYR. The mutated receptors were transiently expressed in transfected 293 cells, then analyzed in whole-cell and outside-out patch configurations. Different phenotypes of these mutations included nonfunctional receptors, receptors with altered control responses, and receptors with altered kinetics of modulation. In whole-cell experiments, modulation of desensitization by 100  $\mu$ M cyclothiazide followed a rank order of SER > ALA > ASN  $\geq$  GLY > GLN  $\geq$  MET, whereas modulation by 5 mM aniracetam followed a rank order of ASN > SER > ALA  $\geq$  GLY  $\geq$  GLN  $\geq$  MET. To examine modulation of deactivation kinetics, 1 ms pulses of glutamate were applied to outside-out patches. Cyclothiazide slowed deactivation of *Aflip* ( $\tau_{\text{control}} 0.86 \pm 0.08$  ms;  $\tau_{\text{cyclo}} 2.34 \pm 0.19$  ms) but did not affect deactivation of *Aflop* ( $\tau_{\text{control}} 0.82 \pm 0.05$  ms;  $\tau_{\text{cyclo}} 0.76 \pm 0.07$  ms). In contrast, aniracetam slowed deactivation of *Aflop* ( $\tau_{\text{control}} 0.84 \pm 0.08$  ms;  $\tau_{\text{anir}} 3.42 \pm 0.32$  ms) to a greater extent than *Aflip* ( $\tau_{\text{control}} 0.86 \pm 0.08$  ms;  $\tau_{\text{anir}} 1.75 \pm 0.13$  ms). These experiments characterize molecular determinants at position 750 that regulate control kinetics, modulation of desensitization, and modulation of deactivation. SUPPORTED BY THE NIH.

FUNCTIONAL EXPRESSION OF GluR1 AND GluR2 AMPA RECEPTOR SUBUNITS IN PC12 CELLS USING ADENOVIRAL VECTORS. K. Tsuzuki<sup>1</sup>, M. Sudo<sup>1</sup>, H. Okado<sup>2</sup>, A. Miwa<sup>2</sup> and S. Ozawa<sup>1\*</sup>. <sup>1</sup>Dept. of Physiol., Sch. of Med., Gunma Univ., Maebashi 371, <sup>2</sup>Dept. of Neurobiol., Tokyo Metropolitan Inst. Neurosci., Fuchu 183, Japan

Adenoviral vectors are promising means for in vivo transfer of therapeutic genes into the central nervous system. To examine the possibility of expression of functional receptor channels by adenoviral vectors, we have constructed recombinant adenoviruses encoding rat AMPA receptor subunit genes, GluR1 (AxCAR1) and GluR2 (AxCAR2X) with modified chicken  $\beta$ -actin promoter and cytomegalovirus immediate-early enhancer. PC12 cells, intrinsically lacking the expression of AMPA receptor channels, were infected with these adenoviruses. Expression of transferred genes in PC12 cells was confirmed by reverse transcription followed by polymerase chain reaction (RT-PCR) and immunoblotting. AxCAR1 infected cells were intensely stained by anti-GluR1 antibodies (Chemicon). Expression of AMPA receptor channels was analyzed electrophysiologically using the whole-cell patch-clamp technique. In infected cells, current responses were induced by iontophoretic application of kainate. These current responses were completely blocked by 2.5  $\mu$ M 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). Inwardly rectifying current-voltage relations of responses to kainate in these cells indicated the assembly of functional homomeric channels. On the other hand, in AxCAR1 / AxCAR2X doubly infected cells, formation of heteromeric GluR1 / R2 channels was indicated by the outwardly rectifying current-voltage relations. This work was supported by the Human Frontier Science Program and the Ministry of Education, Science, Sports and Culture of Japan.

## 236.16

MOLECULAR DETERMINANTS OF LIGAND SPECIFICITY AT FUNCTIONAL AMPA-TYPE GLUTAMATE RECEPTORS. J. S. Sessoms<sup>1</sup>, M. Sturgess<sup>1</sup>, and T. A. Verdoorn<sup>1</sup>. Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600.

To determine the role of S1 and S2 domains in ligand-specific responses at functional AMPA-type glutamate receptors, site-directed mutagenesis and molecular modelling were used to examine amino acid residues predicted to line the binding pocket. Mutant receptors were examined functionally by two-electrode voltage-clamp in *Xenopus* oocytes and fast-application patch-clamp in HEK293 cells. Lysine 755, a positively charged S2 residue conserved among members of the iGluRs, KBPs, and LAOBPs, has been mutated to a glutamate. The resulting mutant receptor altered the apparent affinity of glutamate as detected by dose-response experiments in *Xenopus* oocytes. The dose-response curve for mutant homomers did not plateau even at 1mM glutamate measured in the presence of 30 $\mu$ M cyclothiazide. The EC50 for glutamate was higher in oocytes coexpressed with Aflip755E/wtBflip from wild-type AB(A755E: 1.38mM (95% CI .0047-396mM), ABwt: 9.12 $\mu$ M (4.17-19.5 $\mu$ M)). In addition to a change in the apparent affinity of glutamate, the shape of macroscopic currents in oocytes injected with K755E dna were different from wild-type. K755E is currently being examined in HEK293 cells. Ongoing experiments will examine the role of charge at the K755 residue by measuring the effects of both glutamine and arginine substitutions at this residue. These studies are anticipated to reveal residues of the AMPA binding pocket which are critical for functional ligand recognition and specificity. Source of Funding: NS30945

## 236.18

THE SENSITIVITY TO JORO SPIDER TOXIN OF RECOMBINANT AMPA RECEPTORS. Olimpia Meucci\*, Dongjun Ren and Richard J. Miller Dept. of Pharm.Phys., Univ. of Chicago, Chicago 60637 IL.

We showed that AMPA receptors in cells of the O-2A lineage may contain variable amounts of the edited GluRB subunit (GluRB(R)) and that the subunit composition of the receptor is developmentally regulated. The inhibition of kainate-induced  $\text{Ca}^{2+}$  entry and  $\text{Na}^{+}$  currents by joro spider toxin (JSTx) was found to be lower when the cells expressed high levels of GluRB(R). To further investigate the role of this subunit on the properties of AMPA receptor we have studied the toxin sensitivity and  $\text{Ca}^{2+}$  permeability of recombinant receptors in HEK 293 cells. The cells were transiently transfected with different ratios of cDNAs for GluRA and GluRB(R). Fura 2-based video imaging and simultaneous recording of  $\text{Ca}^{2+}$  entry and  $\text{Na}^{+}$  currents were used to measure kainate-induced responses in the presence of cyclothiazide. The expression of the different subunits was assessed by Western blot analysis and immuno cytochemistry. Imaging studies showed that 85% of recombinant homomeric GluRA receptors responsive to kainate were inhibited 42 $\pm$ 3% by JSTx. Cotransfection of GluRA+ GluRB(R) subunits in a 10:1 ratio did not change the toxin sensitivity significantly. However, reducing the ratio GluRA/GluRB(R) to 4:1 or to 1:1 caused a reduction in the number of responsive cells which were inhibited by JSTx (55-60%). Only 40% of cells were inhibited by the toxin when the ratio of transfection was 1:4. We also noted a difference in the magnitude of the  $[\text{Ca}^{2+}]_i$  rise evoked by kainate in the different conditions, the highest response being noted in cells cotransfected with the two subunits at a ratio 4:1 (465 $\pm$ 93 nM) and the lowest one at a ratio 1:4 (234 $\pm$ 39 nM). Homomeric GluRA receptors showed a fast  $\text{Ca}^{2+}$  response (280 $\pm$ 56 nM). Homomeric GluRB(R) receptors were generally impermeable to  $\text{Ca}^{2+}$  and only 1 out of 30 cells showed a low  $\text{Ca}^{2+}$  response (205 nM). These results show that the toxin sensitivity and the  $\text{Ca}^{2+}$  influx of heteromeric recombinant AMPA receptors depends on the relative amount of GluRB(R). **X-1 and X-2, MEMBERS OF A NOVEL CLASS OF THE GLUTAMATE RECEPTOR SUPERFAMILY.** K.A. Sevarino\*, A.M. Ciabarra, and M.S. Forcina. Division of Molecular Psychiatry, Departments of Pharmacology and Psychiatry, Yale University School of Medicine, 34 Park Street, New Haven, CT 06508.

Ionotropic glutamate receptors mediate the majority of rapid excitatory neurotransmission in the CNS. We previously identified a novel member of the rat glutamate receptor superfamily, x-1, that has 27% homology to NMDA receptor subunits (Ciabarra et al., J. Neurosci. 15: 6498). Co-expression of x-1 with other NMDA receptor subunits strongly inhibits agonist-induced currents. Ligand binding studies were performed in HEK-293 cells transiently transfected with NMDA R1 and 2A in combination with x-1. Binding of [<sup>3</sup>H]-CGP39653, a glutamate site antagonist, was upregulated nearly two fold, and binding of the glycine site antagonist [<sup>3</sup>H]-DCKA was increased several fold, by co-expression of x-1 with NMDA R1/2A hetero-oligomers. These data support a post-translational mechanism for x-1 attenuation of NMDA receptor currents, but attempts to demonstrate co-assembly of x-1 with NMDA subunits using C-terminally directed antisera have been unsuccessful. We have now isolated and cloned to near completion x-2, a second member of the x class with structural similarity to x-1. Northern blot studies reveal that x-2 mRNA is enriched in the dorsal and ventral striatum, in contrast to x-1. Isolation of the full length clone, and *in situ* studies, are in progress. These studies were supported by the Scottish Rite Schizophrenia Research Program, the Theodore and Vada Stanley Research Foundation, and the Abraham Ribicoff Research Facilities, Connecticut Mental Health Center. Special thanks to the DNA Sequencing Facility, Pfizer Central Research, Groton, CT for nucleic acid sequencing.

## 237.3

**MOST CORTICAL NMDA RECEPTORS CONTAIN THREE SUBUNITS (NR1/NR2A/NR2B).** J.H. Luo, Y.H. Wang, R.P. Yasuda and B.B. Wolfe\*. Department of Pharmacology, Georgetown University School of Medicine, Washington, DC 20007

A monoclonal antibody recognizing the NR1 subunit of the NMDA receptor was developed using a fusion protein corresponding to the N-terminal amino acids 341-561 (a common region for all NR1 splice variants). Using membranes from NR1 transfected cells and from rat brain tissue, this monoclonal antibody recognized a fuzzy band at 115 kDa in immunoblots. No crossreactivity with any NR2 subunit was seen. The NR1 subunit was selectively immunoprecipitated under conditions where the subunits have been solubilized under denaturing conditions. On the other hand, if the receptors are initially solubilized using non-denaturing conditions this antibody immunoprecipitated other NMDA receptor subunits indicating an interaction *in vivo*. Using the monoclonal antibody and polyclonal antibodies against the NR2A and NR2B subunits, immunoprecipitation and immunoblot experiments using rat cortical membranes were performed to determine the subunit composition of cortical NMDA receptors. We found: 1) The dominant complex comprising the NMDA receptor in rat cortex contains three subunits, NR1/NR2A/NR2B; 2) A small fraction of NMDA receptors is composed of only two subunits, NR1/NR2A or NR1/NR2B; 3) No complexes exist that are composed of NR2A/NR2B without NR1; and 4) A small fraction of each subunit exists as 'free' and is not associated with any of the other subunits measured. These results suggest that functional studies with recombinant receptors composed of at least three subunits may be the most physiologically meaningful. (Supported by NS28130, AG09973, and AHAF)

## 237.5

**INCREASED CONTRIBUTION TO SYNAPTIC NMDA RECEPTORS OF NR2A SUBUNIT IN DEVELOPING VISUAL CORTICAL NEURONS.** G.Stocca\* and S. Vicini. Dept. of Physiology, Georgetown Univ. Med. Cntr. Washington DC 20007.

*In situ* hybridization studies showed the selective increase of mRNA for the NMDA receptor subunit 2A (NR2A) as compared to NR2B during postnatal development in rat neocortex. We investigate whether synaptic NMDA receptor underlying spontaneous excitatory synaptic currents (NMDA-sEPSCs) were sensitive to inhibition by haloperidol and ifenprodil, selective antagonists of recombinant receptors containing NR1 and NR2B subunits. Visual cortical neurons in brain slices of rats at different age (P7-9 and P13-16) were used. NMDA-sEPSCs from voltage-clamped (-60 mV) stellate and pyramidal neurons in layer IV/V were studied in Mg<sup>2+</sup> free solution containing NBQX (5 μM) with Kgluconate or CsMeSO<sub>4</sub> filled pipettes. 4-aminopyridine (2 mM) was added to bath perfusion to increase the low frequency of occurrence of NMDA-sEPSCs and in most cell induced paroxysmal bursts of synaptic events. Haloperidol and ifenprodil were surprisingly poorly effective in blocking both NMDA-sEPSCs and paroxysmal bursts. In the younger group only 20% of neurons investigated (n=11) showed a clear reduction of the averaged NMDA-sEPSCs with haloperidol (100 μM) while cells in the older group (n=27) were dramatically less affected. Fast applications of L-glutamate (1 mM, 4 msec) activated rapid inward currents in nucleated patches excised from small layer IV neurons. Haloperidol (50 μM) reversibly inhibited the inward current in all four patches from a P16 rat by more than 50%. These data indicate that an increasing proportion of synaptic NMDA receptors may comprise NR1/NR2A/NR2B subunit heteromers, insensitive to "NR2B selective blockers" with distinct pharmacological properties as compared to NMDA receptors in excised nucleated patches. Supported by NINDS grants NS28130 and NS01680.

## 237.2

**DIFFERENTIAL SURFACE EXPRESSION AND REGULATION OF NR1 AND NR2B SUBUNITS IN CULTURED HIPPOCAMPAL NEURONS**

R.A. Hall\* and T.R. Soderling. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

The surface expression of the NR1 and NR2B subunits of the NMDA-type glutamate receptor was studied in cultured hippocampal neurons by exposing intact cultures to extracellular treatments (either the protease chymotrypsin or the membrane-impermeant cross-linking reagent BS<sup>3</sup>) which modify surface-exposed proteins and shift their mobility on SDS-PAGE gels. It was found that less than half of the total NR1 subunits are located in the plasma membrane, whereas almost all of the NR2B subunits in the hippocampal neurons are located at the cell surface. These data suggest that NR2 subunits are critical for the targeting of NMDA receptors to the neuronal plasma membrane, an idea which finds support in recent studies on the surface expression of NMDA receptor subunits expressed in fibroblasts (McIlhinney et al., *Neuroscience* 70:989, 1996). We are currently studying the effects of different types of neuronal stimulation on both the surface expression and the total level of protein for the various NMDA receptor subunits (supported by NIH grant NS27037).

**REGIONAL AND DEVELOPMENTAL EXPRESSION OF NMDA SUBUNIT NR2D PROTEIN IN RAT BRAIN USING A SUBUNIT-SPECIFIC ANTIBODY.**

A. W. Dunah<sup>1,2\*</sup>, R. P. Yasuda<sup>1,2</sup>, J. Luo<sup>1</sup>, Y.-H. Wang<sup>1</sup>, M. I. Davila-Garcia<sup>1</sup>, M. Gbadegesin<sup>2</sup>, S. Vicini<sup>2,3</sup> and B. B. Wolfe<sup>1,2</sup>. Department of Pharmacology, Interdisciplinary Program in Neuroscience<sup>1</sup>, and Department of Physiology and Biophysics<sup>2</sup>, Georgetown University School of Medicine, Washington, DC 20007.

A subunit-specific polyclonal antibody for the NMDA receptor subunit NR2D has been developed using peptides from the carboxyl terminus of the rat NR2D protein. The affinity purified antibody recognizes the free peptides on ELISA and a dominant ~160 kDa band on immunoblots of membrane fractions from transfected cells as well as from CNS tissues. This antibody shows no cross-reactivity with other NMDA receptor subunits. Enzymatic deglycosylation with PNGase F shows that the NR2D receptor subunit in both brain and transfected cells is N-glycosylated. Using this antibody, the relative densities of the NR2D subunit in nine areas of postnatal day seven (P7) and adult rat brains have been determined by quantitative immunoblotting. The NR2D subunit was found to be expressed at highest levels in the thalamus, midbrain, medulla and spinal cord, while intermediate levels of this receptor were seen in the cortex and hippocampus. More complete ontogenic profiles of the NR2D subunit have been determined in the telencephalon, diencephalon, and spinal cord of rats. The data showed that high levels of NR2D protein were present at embryonic stages of development, which rose to a peak at P7 and decreased but remained quantifiable during late postnatal life. These results suggest that native NMDA receptors containing the NR2D subunit may play functional roles not only in the developing brain but also in adult brain. (Supported by NS28130, AG09973 and the AHAF).

**PROPERTIES OF NMDA RESPONSES IN HEK293 CELLS EXPRESSING HETEROMERS OF NR1/NR2A/NR2B SUBUNITS.** JH.Li, JF.Wang, JH.Luo

YH.Wang, BB.Wolfe and S.Vicini\* Depts. of Physiology & Pharmacology, Georgetown Univ. Med. Cntr. Washington D.C. 20007

Individual plasmid cDNAs encoding the NR1a, NR2A and NR2B NMDA receptor subunits were transiently transfected in mammalian HEK293 cells using the Ca phosphate precipitation technique. Successful transfection was evaluated with the use of specific immunopurified antibodies raised in mice and rabbits against NMDA receptor subunits NR1, NR2A and NR2B. Confocal microscope analysis of immunostained transfected cells revealed that most cells expressing NR1 subunit also expressed NR2A and NR2B subunits. A small but consistent population of cells expressed individual NR1/NR2A or NR1/NR2B heteromers. The subcellular staining pattern for the NR2A subunit in confocal optical sections well matched that for the NR2B subunit. Rapid application of L-glutamate (1 mM, 4 msec) by a piezoelectric translator, activated whole-cell currents in small lifted transfected cells expressing recombinant NMDA receptor heteromers. Our previous results indicated that currents produced by rapid pulse application on NR1/NR2A transfected cells had faster deactivation kinetics compared to those containing NR1/NR2B subunits and were insensitive to haloperidol blockade. We now report that currents recorded from cells transfected with NR1/NR2A/NR2B cDNAs were characterized by a slow deactivation (range 170-300 ms) and they were insensitive to haloperidol (50 μM). However, a small population of NR1/NR2A/NR2B transfected cells had deactivation kinetic and haloperidol sensitivity characteristics of individual NR1/NR2A or NR1/NR2B heteromers, consistent with what was observed in immunocytochemical staining. Our results indicate that the formation of NR1/NR2A/NR2B heteromers produce receptors with kinetic dominated by the NR2B subunit and haloperidol sensitivity dominated by the NR2A subunit. Supported by NINDS grants NS28130 and NS01680.

**Evidence for a significant pool of unassembled NR1 subunit of the NMDA receptor in the adult mouse forebrain.**

Paul L. Chazot and F. Anne Stephenson\* School of Pharmacy, University of London, 29/39 Brunswick Square, London. WC1N 1AX UK  
The N-methyl-D-aspartate (NMDA) receptors of the mammalian brain are a pharmacological subclass of fast-acting excitatory glutamate receptors. There are five NMDA receptor genes, encoding the subunits, NR1 and NR2A-2D. The NR1 gene undergoes alternative splicing to yield eight different forms of the NR1 subunit, NR1-1 to -4a/b, which differ by the presence or absence of a 21 amino acid insert in the N-terminal region and the differential use of exons 21 and 22 which yield distinct C-termini. We have raised two anti-NR1 antibodies which distinguish between the different splice forms of the NR1 subunit; an anti-NR1 17-35 antibody which recognises all splice forms and an anti-NR1 911-920 antibody which recognises NR1-1a, 1b, 2a, 2b. These antibodies and others have been used to characterise the native NMDA receptors of adult mouse forebrain. Thus, optimal solubilisation was achieved with 1% Triton X100 and 1M NaCl which extracted maximally 15% of the total NR1 subunits. Gel filtration of this soluble extract yielded a major anti-NR1 immunoreactive peak with Mr 710 000 and a minor peak with Mr 125 000 (40% of the total NR1 immunoreactivity). Purification of the NMDA receptors from the detergent extract by anti-NR1 911-920 immunoaffinity chromatography resulted in the isolation of the cognate subunit. No NR2A or NR2B subunit immunoreactivity was detectable. Similarly, NR2A or NR2B immunoreactivity was not detectable following immunoprecipitation from soluble forebrain extracts with anti-NR1 911-920 antibodies. This is in contrast to precipitation with anti-NR1 17-35 antibodies where NR1, NR2A and NR2B immunoreactivities were present in the immune pellets. Overall, these results demonstrate the presence in adult mouse forebrain of a significant pool of unassembled NR1 subunit comprising the NR1-1a, 1b, 2a, 2b splice forms i.e. those containing the C2 exon. This work was funded by the BBSRC

**LIKELY CO-ASSEMBLY OF THREE NR2 SUBUNITS IN FUNCTIONAL NMDA RECEPTOR CHANNELS.** J.C. Brimacombe\*, F.A. Boeckman and E. Aizenman. Dept. Neurobiol., Univ. Pittsburgh Sch. Med. Pittsburgh, PA 15261.

A recent study suggested that NMDA receptors most likely contain two NR1 subunits in a functional channel (Bébé et al., *Proc. Roy. Soc. Lond.* 262:205; 1995). However, the number of NR2 subunits which co-assemble with NR1 has yet to be determined. We have utilized an expression system to develop a profile that can distinguish between various possible functional combinations of NR1 and NR2 subunits. Single-channel recordings were performed from outside-out patches excised from Chinese hamster ovary cells transfected with NR1 in combination with either NR2A, NR2B or both. NMDA (10  $\mu$ M)-activated unitary currents were recorded under basal conditions or in the presence of either the reducing agent DTT (1 mM), the oxidizing substance DTNB (100  $\mu$ M), or the ifenprodil analog CP 101,606-27 (CP; 1  $\mu$ M). Channels obtained from NR1/NR2A-transfected cells (n=10) exhibited a large (1.7 ms) difference in mean open time between reduced and oxidized conditions, and were completely insensitive to CP. NR1/NR2B channels (n=7) showed a much smaller difference in open time between redox states (0.5 ms), while CP dramatically reduced both their open time and nPo. Of 12 patches obtained from cells transfected with NR1/NR2A/NR2B, 2 had channels with virtually identical properties to NR1/NR2A, while 4 were indistinguishable from NR1/NR2B. Interestingly, the remaining 6 patches could be grouped into two new additional categories. Four of these had channels with little redox sensitivity in their open time (like NR1/NR2B), but were totally insensitive to CP (like NR1/NR2A). The remaining two patches were also NR1/NR2B-like in their redox sensitivity, but CP decreased only their nPo without altering open time. These four distinct categories suggest that three NR2 subunits likely co-assemble with NR1 to form pentameric structures. Supported by NIH grant NS29365.

## 237.11

**INTERACTION OF THE NMDA RECEPTOR WITH A NOVEL SYNAPSE ASSOCIATED PROTEIN, SAPI02.** L.F. Lau\*, A. Mammen, M. D. Ehlers, S. Kindler, W. J. Chung, C. C. Garner and R. L. Huganir. HHMI, Dept of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205 and The Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Recently, *in vitro* studies have shown that members of the NMDA class of glutamate receptors interact with a synapse associated protein, SAP90 (PSD-95). However, evidence for the *in vivo* interaction of NMDA receptors with SAP family members is still lacking. In the present study, we demonstrate a specific interaction between SAPI02, a novel synapse associated protein, and the NMDA receptor complex from the rat cortical synaptic plasma membranes using co-immunoprecipitation techniques. No association was observed between SAPI02 and GluR1, a member of the AMPA class of glutamate receptors. To identify the domain on the NMDA receptor responsible for this interaction, we constructed hexahistidine fusion proteins from different regions of the NR1a and NR2 subunits of the NMDA receptor. Immunoblot overlay experiments showed that while the C-terminal domain of the NR2 subunit displayed strong binding, the NR1a intracellular C-terminal tail did not interact with SAPI02. The site of interaction was more precisely located to the last 20 amino acids of the NR2 subunit. In summary, we demonstrate here for the first time an *in vivo* interaction between the native NMDA receptor complex and a synapse associated protein. These results suggest that SAPI02 may play an important role in NMDA receptor clustering and immobilization at excitatory synapses. (This work was supported by HHMI and DDRG)

## 237.8

**STOICHIOMETRY OF RECOMBINANT NMDA RECEPTOR CHANNELS.** L. S. Premkumar\* and A. Auerbach. Department of Biophysics, SUNY at Buffalo, Buffalo NY 14214.

Single channel currents were recorded using outside out patches from *Xenopus* oocytes injected with mouse cRNA for wild type and mutant NMDAR subunits. Wild type  $\zeta_1$  and  $\epsilon_2$  subunits have an asparagine (N) at position 598 and 589, respectively. Wild type receptors ( $\zeta$ N/ $\epsilon$ N) had one predominant conductance level of 86 pS in  $\text{Ca}^{++}$  and  $\text{Mg}^{++}$  free extracellular solution. Injection of oocytes with subunits having a glutamine (Q) mutation formed channels having specific conductance and kinetic fingerprints because they occupied a subconductance level with a high relative probability (p). Channels with mutations in both subunits ( $\zeta$ Q/ $\epsilon$ Q) had a main conductance level of 95 pS (p=0.52) and a subconductance level of 62 pS (p=0.48). Channels with a mutation only in  $\epsilon$  subunit ( $\zeta$ N/ $\epsilon$ Q) had a main conductance level of 59 pS (p=0.67) and a subconductance level of 24 pS (p=0.33). Channels with a mutation only in the  $\zeta$  subunit ( $\zeta$ Q/ $\epsilon$ N) had a main conductance level of 69 pS (p=0.15) and a subconductance level of 12 pS (p=0.85). When oocytes were injected with a  $\zeta$ Q/ $\epsilon$ Q+ $\epsilon$ N subunit combination, there were exactly three classes of current. Two correspond to  $\zeta$ Q/ $\epsilon$ Q and  $\zeta$ Q/ $\epsilon$ N receptors. The third class had a main conductance level of 85 pS (p=0.32) and a subconductance level of 38 pS (p=0.68). When oocytes were injected with a ( $\zeta$ Q+ $\zeta$ N)/ $\epsilon$ Q subunit combination, there were four common classes of current. Two correspond to  $\zeta$ Q/ $\epsilon$ Q and  $\zeta$ N/ $\epsilon$ Q receptors. The third class had a main conductance of 97 pS (p=0.2) and a subconductance of 69 pS (p=0.8), and the fourth had a main conductance of 59 pS (p=0.47) and a subconductance of 42 pS (p=0.53). These results suggest that there are exactly two  $\epsilon_2$  subunits and at least three  $\zeta_1$  subunits forming the NMDAR channel complex (supported by NS-23513)

## 237.10

**APPARENT CYTOPROTECTIVE ACTIONS OF NMDAR1(N616Q) MUTANT IN TRANSFECTED CELLS IS DUE TO HIGH RESIDUAL CALCIUM.** E. Aizenman\*, K.A. Hartnett and F.A. Boeckman. Department of Neurobiology, University of Pittsburgh Sch. of Medicine, Pittsburgh, PA 15261.

Two recent studies (Cik et al., *E. J. Pharmacol.* 266:R1, 1994; Aneqawa et al., *J. Neurochem.* 64:2004, 1995) reported that the cytotoxicity which ensues following the functional expression of NMDA receptors in transfected HEK-293 cells could be partially averted with the use of a NMDA receptor subunit which has decreased calcium permeability, NR1(N616Q). Liposome-transfected Chinese hamster ovary (CHO) cells perish following expression of NR1/NR2A and NR1/NR2B-containing NMDA receptors (Boeckman and Aizenman, *Soc. Neurosci. Abstr.* 21:86, 1995), regardless of whether or not the NR1(N616Q) mutant is used. In contrast, the use of an NR1(N616R) mutant in CHO cells substantially increases cell survival by 40% and 70% when co-expressed with either NR2A or NR2B, respectively. It came to our attention that the well-established actions of extracellular calcium in decreasing NMDA single-channel conductance (Ascher and Nowak, *J. Physiol.* 399:247, 1988) were dramatically reduced in recombinant channels containing the NR1(N616Q) mutation (Ruppersberg et al., *Biochem. Pharmacol.* 46:1877, 1993). We thus sought to test whether the high residual  $\text{Ca}^{2+}$  (4.4 mM) that results from the calcium phosphate precipitation transfection technique normally utilized with HEK-293 cells (Aneqawa et al., *ibid*) could be sufficient to account for the observed discrepancies. High calcium conditions (4.5 mM) were observed to increase cell viability by 17  $\pm$  7% (n=4) in NR1/NR2A-transfected CHO cells and by 31  $\pm$  5% (n=4) in NR1(N616Q)/NR2A-expressing cells. These results suggest that the previously reported cytoprotective effects of the glutamine mutation may have been partly artifactual. Supported by NIH grant NS29365.

**NMDA RECEPTORS IN CULTURED CEREBELLAR GRANULE CELLS: SUBUNIT EXPRESSION AND METABOLIC TURNOVER.** K.H. Huh\* and R.J. Wenthold. Laboratory of Neurochemistry, NIDCD, NIH, Bethesda 20892.

We used cultured cerebellar granule cells to characterize the expression of NMDA receptor subunits and to investigate the metabolic turnover rate of the receptors. Cultures were established from 7-8 day-old rat cerebella, and all analysis were done after 7-8 days *in vitro*. By Western blot using various subunit-specific and NR1 splice variant-specific antibodies (C1, C2, C2' and N-cassettes), we have identified the expression of NR2A, 2B subunits and of at least two different NR1 splice variants. NR2C subunits do not appear to be expressed at a detectable level at this developmental stage. Also, splice variants containing C1 and/or C2 cassettes are expressed more abundantly than those with the N-terminal cassette, although the reverse is true for adult cerebellum. Cells were pulse labeled with  $^{35}\text{S}$ -methionine/cysteine and radioactive NR1 subunits were identified by fluorography after immunoprecipitation. N-deglycosidase F treatment of receptors obtained immediately after a 10 min pulse produced a deglycosylated form of NR1 subunits with a MW of 100-105 kDa, instead of 120 kDa for the glycosylated form. Complete deglycosylation is confirmed by tunicamycin treatment of cells before and during the pulse chase experiment. Based on the MW difference between glycosylated and non-glycosylated forms of subunits, it appears that, after 10 min of pulse, newly synthesized NR1 subunits are already present in the Golgi or post-Golgi compartments. Pulse labeling followed by immunoprecipitation of NR1 subunits at various chase periods indicates that  $t_{1/2}$  of the NR1 subunit is about 3-5 hr, indicating a relatively rapid turnover of the NMDA receptor. (Supported by the NIDCD Intramural Program)

## 237.13

**ADHESION MOLECULES & SYNAPTIC FUNCTION: EVIDENCE THAT ALTERATIONS IN NEURAL CELL ADHESION MOLECULE (NCAM) AFFECT THE BINDING AFFINITY OF AMPA RECEPTORS.** K.B. Hoffman, M. Kessler & G. Lynch, CNLM, Univ. of Calif., Irvine, CA 92717-3800.

The 180 and 140 kDa isoforms of NCAM are enriched in postsynaptic densities (Persohn et al., 1989) and synaptosomal membranes (Bahr et al., 1993). Interactions between NCAM isoforms and other extracellular components have been implicated in memory consolidation (Doyle et al., 1992), LTP stabilization (Lüthi et al., 1994), and LTP induction (Rønn et al., 1995). The strength of NCAM-mediated adhesion can be altered by removing its polysialic acid moieties with the enzyme neuraminidase. The present study examined whether such a treatment alters the binding characteristics of glutamate responsive receptors. Rat brain membranes were incubated for 15 min at 37°C with neuraminidase and then tested for binding of radiolabeled agonists to three glutamate receptor subtypes. [<sup>3</sup>H]Glutamate binding to the NMDA receptor and [<sup>3</sup>H]kainate binding were unaffected, but binding of [<sup>3</sup>H]AMPA (50 nM) was increased by 20-25 % ( $p < .0001$ ;  $n=18$ ; paired  $t$ -test). Scatchard analysis (5 to 1500 nM) suggested that the binding sites most affected by the enzyme treatment were of the low-affinity variety. To determine if the neuraminidase treatment was directly affecting AMPA receptors, membranes were solubilized with 1% TX-100 and then exposed to the enzyme; no change in AMPA binding was observed. Treatment with neuraminidase at 0°C caused no change in AMPA binding. Western blot analysis revealed that the molecular weights of the 180 and 140 kDa isoforms of NCAM were decreased by ~10 % post-enzyme treatment (with and without membrane solubilization), while those of AMPA receptor subunits GluR1 and GluR2/3, and the NMDA receptor subunit NR-1, were unchanged. Such results suggest that modulations of NCAM-mediated adhesion directly affect the endogenous binding affinity of agonist to AMPA receptors, and hence further suggest that adhesion dynamics within the synaptic zone may play a role in transformations of synaptic functioning (supported by AFOSR 95-1-0304 and Cortex Pharm).

## 237.15

**DISTRIBUTION AND MOLECULAR INTERACTIONS OF NON-NMDA GLUTAMATE RECEPTORS PRESENT IN DEVELOPING RAT CEREBELLUM AND CULTURED CEREBELLAR GRANULE CELLS.** J.A. Ripellino\* and J.R. Howe, Yale University, School of Medicine, New Haven, CT 06520-8066.

We characterized the cellular distribution and molecular interactions of ionotropic glutamate receptors present in the developing and adult cerebellum and in cerebellar granule cell cultures. Analysis of non-NMDA GluR subunits were performed using antibodies selective for GluR1, GluR2/3/4c, GluR4, GluR6/7 and KA2. At the light microscopic level, immunostaining was detected to varying degrees in each region of the cerebellar cortex at all ages studied. From P1 to P7, the distribution of immunoreactivity in the molecular and internal granule cell layers was similar with each antibody. However, at P10 to adult, a more distinct staining pattern for each subunit was observed. The GluR1 subunit was predominantly associated with the molecular layer with weak staining of the internal granule cell layer. Only the GluR2/3/4c antibody gave significant staining of Purkinje cells with intense immunoreactivity present in both the soma and dendrites. KA2 immunoreactivity was found associated with a population of cells distributed throughout the molecular layer and also with a layer of cells which reside at the level of the Purkinje cell soma, possibly consistent with basket cell staining. After 7 DIV, primary cultures of granule cells demonstrated varying degrees of immunoreactivity for all of the above GluR subunits.

Immunoprecipitation of detergent extracts prepared from postnatal days 1, 10, 18 and adult rat cerebella with anti-GluR6 resulted in the complete removal of KA2 subunit immunostaining on Western blots, indicating that all of the KA2 protein is associated with GluR6 as a heteromeric complex. In contrast, only a small proportion of GluR6 protein is depleted by immunoprecipitation with the anti-KA2 antibody. Similarly, GluR1 antibodies quantitatively immunoprecipitated GluR4 from cerebellar extracts, but all of GluR1 was not immunoprecipitated by anti-GluR4. These results were qualitatively the same at all ages studied. (Supported by NS 30996).

\*Significantly different by  $t$ -test, ( $p < 0.003$ ). <sup>1</sup>N- & C-terminal halves of GluR1<sub>0</sub> (G1) or GluR3<sub>0</sub> (G3).

The formation of heteromeric receptor complexes was demonstrated by cross-immunoprecipitation of both subunits from solubilized oocyte membranes. The AMPA analogue ACPA (2-amino-3-(3-carboxy-5-methyl-4-isoxazol-5-yl) propionic acid) was the most potent and selective agonist tested at GluR1<sub>0</sub> and GluR3<sub>0</sub>, the least potent being kainate. These experiments suggest that for activation, an interaction occurs between N-terminal and C-terminal domains of the receptor. Also, it seems that electronegative group substitutions on the isoxazole ring and decreasing the  $pK_a$  of the substituent at position 3 play a major role in determining the degree of receptor activation under steady-state conditions. Future studies will examine the effects of single amino acid mutations in these receptors, giving a more precise localization of the agonist binding site. (Supported by a research grant from the Alfred Benzon Foundation).

## 237.14

**TYPES AND SUBUNITS OF GLUTAMATE RECEPTORS CAN DIFFER IN THEIR DISTRIBUTION IN NEURONS.** M.E. Rubio\*, #P.B. Manis, R.J. Wenthold NIDCD, NIH, Bethesda, MD 20892, #Johns Hopkins University, Baltimore, MD 21205.

In this study we addressed the fundamental question of whether or not all glutamate receptors that are expressed in a neuron are targeted to the same synaptic populations or if subsets are targeted to specific synaptic populations. Glutamate receptors are one of the more complex families of receptors which includes eight metabotropic receptors, and 17 subunits of ionotropic receptors that form four receptor subtypes (AMPA, kainate, NMDA and delta). The metabotropic glutamate receptors (linked to G-proteins) may exert long-lasting actions in neurons. Among the ionotropic glutamate receptors, AMPA and kainate subunits gate fast ionic currents, and the NMDA receptors mediate slower currents subject to voltage dependent  $Mg^{2+}$  block. The physiological function of the delta receptors is still unknown. It has been demonstrated that the physiological properties of the receptor are related to the subunits and subtypes expressed. As our model system, we chose the fusiform cell (FC) of the dorsal cochlear nucleus. This is a bipolar neuron with an apical and a basal dendritic tree which receive two different excitatory inputs. A direct auditory nerve input synapses on the basal dendrites, whereas parallel fibers of the granule cells synapse on the apical dendrites of FC. Studies indicate that the AMPA receptors of the ascending auditory synapses have the fastest constant of desensitization compared to other synapses of the CNS (Raman et al., 1994; Geiger et al., 1995), whereas parallel fibers may produce slower synaptic response. In order to study the distribution of these subunits in FC, we combined retrograde tracer labeling (horseradish peroxidase) with pre-embedding glutamate receptor immunocytochemistry using DAB as chromogen in P15 day old Sprague Dawley rats. Antibodies selective for the following subunits were used: (AMPA: GluR 1,2/3,4; kainate: GluR 6/7, KA2; NMDA: NR1, NR2A/B; metabotropic: mGluR1, mGluR2/3; delta 1/2). Our results show that while both populations of synapses contain multiple glutamate receptors on their postsynaptic membranes, there are critical differences. The results suggest that some receptor subunits are selectively targeted to the two synaptic populations. (Supported by NIDCD Intramural Program)

## 237.16

**SUBUNIT STOICHIOMETRY AND PROPERTIES OF HETEROMERIC GLUR6/KA2 CHANNELS.** K.E. Pemberton\*, J.A. Ripellino and J.R. Howe, Yale University, New Haven, CT 06520-8066.

Two stable HEK 293 cell lines were identified that express different relative amounts of the kainate-type subunits GluR6(R) and KA2. In each line, virtually all of each subunit protein was immunoprecipitated with antibody directed against the other subunit, indicating that the stoichiometry of heteromeric GluR6/KA2 channels is not fixed. Average GluR6/KA2 stoichiometries of 3/2 and 4/1 were determined for the two cell lines from Western analysis (assuming the channels are pentamers).

Homomeric GluR6(R) and GluR6(Q) channels differ in their  $Ca^{2+}$  permeability,  $I-V$  behavior, and unitary conductance. KA2 contains glutamine at the site corresponding to the Q/R site in GluR6. Patch-clamp experiments were done to determine to what extent the properties of GluR6(R)/KA2 channels are intermediate between homomeric GluR6(R) and GluR6(Q) channels. In cells where the GluR6(R)/KA2 ratio was 3/2, the reversal potential of kainate-evoked currents shifted  $-16 \pm 3$  mV when  $Ca^{2+}$  replaced  $Na^{+}$  as the only cation in the external solution. This value is closer to that reported for GluR6(Q) channels ( $-24$  mV; Köhler et al., 1993) than to the value ( $-3 \pm 1$  mV) we obtained for GluR6(R) channels. In contrast to results for GluR6(Q) channels (Köhler et al., 1993),  $I-V$  curves for both GluR6(R) and GluR6(R)/KA2 channels showed outward rectification at positive potentials. The unitary conductance of GluR6(R)/KA2 channels (3/2 cells) was 0.60 pS, whereas values for homomeric GluR6(R) and GluR6(Q) channels of 0.23 and 5.4 pS have been reported (Swanson et al., 1996; Howe, 1996). The extent to which co-expressing KA2 with GluR6(R) confers a "Q-like" phenotype appears to differ for different channel properties. (Supported by NS 30996).

**BINDING PROPERTIES OF RECOMBINANTLY EXPRESSED AMPA RECEPTOR SUBUNITS EXHIBIT AFFINITY PROFILES SIMILAR TO THOSE OF NATIVE AMPA RECEPTORS.** Martin Hennegriff\*, Amy Araki<sup>1</sup>, Markus Kessler<sup>1</sup>, Peter Vanderklish<sup>1</sup>, Manpreet Singh Mutneja<sup>1</sup>, Gary Rogers<sup>1</sup>, Rachael L. Neve<sup>2</sup>, and Gary Lynch<sup>1</sup>. <sup>1</sup>Ctr. for the Neurobiology of Learning & Memory, Univ. California, Irvine, CA 92717-3800. <sup>2</sup>Cortex Pharmaceuticals, Inc., Irvine CA 92718. <sup>3</sup>Dept. of Genetics, Harvard Medical School & McLean Hospital, Belmont, MA 02178.

Homomeric AMPA receptors were stably expressed in kidney cells from cDNAs encoding GluR1<sub>0</sub>, GluR2<sub>0</sub>, GluR2<sub>0</sub>, GluR3<sub>0</sub>, and GluR4<sub>0</sub> subunits. The recombinant receptors were of the expected size and were functional as evidenced by whole-cell recording. Scatchard plots for [<sup>3</sup>H]AMPA binding to GluR1<sub>0</sub>, 3, and 4 receptors were linear, but those for GluR2<sub>0</sub> receptors showed a marked curvature, indicating the presence of two components. Upon solubilization of the GluR2<sub>0</sub> receptors, a major fraction of the lower affinity component was converted into the high affinity form. PCMBs increased [<sup>3</sup>H]AMPA binding to GluR2<sub>0</sub>, but had only minor effects on the other receptors. These results suggest that several characteristic features of brain AMPA receptors reflect at least in part an influence of specific subunits such as GluR2. [<sup>3</sup>H]AMPA binding was inhibited in a non-competitive manner by two classes of drugs known to change the desensitization kinetics of the AMPA receptor. In agreement with physiological observations, the apparent affinity of cyclothiazide for GluR2<sub>0</sub> was approximately ten times higher than for receptors made of flop subunits. In contrast, BDP-37, a rigid benzamide drug related to the benzoylpiperidine family, exhibited a three times higher potency for the flop vs. the flip isoform of the GluR2 subunit, suggesting that the action of centrally active drugs may vary across brain regions expressing receptors with different subunit compositions (supported by AFOSR 95-1-0304).

**A Novel Excitatory Amino Acid Response in Purkinje Cells: Selective Activation by Aspartate and High Calcium Permeability.** M. Yuzaki\*, D. Forrest†, T. Curran and J. A. Connor‡. St. Jude Children's Res. Hosp., Memphis, TN38105, †Mount Sinai Sch. of Med., New York, NY 10029, ‡Lovelace Inst., Albuquerque, NM 87108.

An endogenous excitatory amino acid (EAA) neurotransmitter L-aspartate (Asp) is widely distributed in the mammalian central nervous system. In the cerebellum, Asp has been suggested to be a transmitter at climbing fiber-Purkinje cell synapses. However, the Asp responses of Purkinje cells have puzzled physiologists and pharmacologists for almost 20 years. In this study, we aimed at solving this enigma by taking advantage of mice with a disrupted NMDA receptor 1 gene (NR1), which lack functional NMDA receptors, to exclude the involvement of a classical NMDA receptor. Hippocampal neurons, cerebellar granule cells, and Purkinje cells were prepared from newborn wild type (NR1+/+) and homozygous mutant (NR1-/-) mice and maintained for 7-18 days *in vitro*. Asp induced a large inward current in Purkinje cells from NR1-/- mice (EC<sub>50</sub> = 90  $\mu$ M), in Mg<sup>2+</sup>-free, glycine-, picrotoxin-, and TTX-containing solution. This current was sensitive to both NMDA and non-NMDA receptor antagonists. In contrast, no current was induced by Asp in hippocampal neurons and cerebellar granule cells from these same NR1-/- mice. Other known glutamate receptor agonists such as glutamate, homocysteate, AMPA and kainate did not evoke this response. NMDA acted only as a partial agonist and competitively inhibited the Asp-induced current with IC<sub>50</sub> of 265  $\mu$ M. In contrast to glutamate, Asp induced a large Ca<sup>2+</sup> influx (P<sub>Ca</sub>/P<sub>Ca</sub> = 13.2) into Purkinje cells. These results suggest that in Purkinje cells, Asp activates a novel type of EAA receptor that could contribute to synaptic plasticity through its high Ca<sup>2+</sup> permeability.

EXCITATORY AMINO ACID RECEPTORS: STRUCTURE, FUNCTION, AND  
EXPRESSION—REGULATION OF EXPRESSION

**MOLECULAR DIVERSITY OF NMDA RECEPTORS: NR2B C-TERMINAL DOMAIN DELETION MICE** C. Amico, R. Brusa, U. Krueth, G. Köhr\*, P. H. Seeburg, R. Sprengel. Center for Molecular Biology (ZMBH), University of Heidelberg, 69120 Heidelberg, Germany.

The NMDA receptor channel is formed by the subunit NR1 expressed in different combinations of the four NR2 (2A, 2B, 2C, 2D) subunits. Considering the functional significance of the molecular diversity of NMDA receptor channels, we generated mutant mice with the NR2B c-terminal domain deletion by homologous recombination. The NR2B subunit occurs early in development (mRNA is already detectable at E13). The long c-terminal domain interacts with the postsynaptic density protein PSD95 and is the most prominently tyrosine-phosphorylated segment. Our proposal is that the long c-terminal segment plays a role anchoring the subunit from the membrane to the cytoplasm and the resulting deletion could alter both distribution and developmental pattern. To investigate the physiological role of this we transfected embryonic stem cells with a NR2B gene construct in which a translational stop codon is introduced immediately downstream from the M4 coding region. Three positive clones were identified by PCR nested primers and Southern blots analyses of 210 G-418 resistant clones. Two independent clones were injected into host mouse blastocysts and germline chimeras were obtained at high rate.

## 238.3

**SUBUNIT-SPECIFIC REGULATION OF NMDA RECEPTOR EXPRESSION IN CULTURED RAT CEREBELLAR GRANULE CELLS.** M. Villa, O. Weinmann, S. Haller, H. Mohler\*, J.-M. Fritschy. Institute of Pharmacology, ETH and University of Zurich, 8057 Zurich, Switzerland.

The developmental expression of the NMDA receptor subunits NR1, NR2A and NR2B was monitored immunocytochemically in cerebellar granule cell cultures obtained from 5-day old rat pups. A gradual increase in NR1 and NR2A subunit staining was observed, while the NR2B subunit immunoreactivity was intense initially and decreased after 6-8 days *in vitro* (DIV) to reach very low levels by 14 DIV. These changes parallel the maturation of NMDA receptors *in vivo*. Further, we observed a frequent colocalization of synaptophysin-immunoreactive puncta with neurites positive for the NR2A subunit, but not for the NR2B subunit, suggesting that receptors containing the NR2A subunit are preferentially engaged in synaptic transmission. Incubation of 5 DIV-cultures with 100  $\mu$ M NMDA for 24-48 h, a treatment known to induce a down-regulation of functional NMDA receptors, resulted in a selective decrease in NR2A subunit staining, most pronounced in neurites. In contrast, 24 h treatment with KN93, a specific inhibitor of the Ca<sup>2+</sup>/calmodulin-dependent kinases II and IV, dramatically increased the NR2B-subunit staining, suggesting that the expression of these NMDA receptors is controlled by phosphorylation mechanisms involving these kinases. Our results indicate that the NR2A and NR2B subunits represent distinct populations of NMDA receptors in cerebellar granule cells, differing in developmental regulation and subcellular distribution. Support: Swiss National Science Foundation, grant 31-36327.92.

## 238.2

**IMPAIRED KINDLING DEVELOPMENT IN NMDA RECEPTOR NR2A C-TERMINAL MUTANT MICE** Jianying Li\*, Rolf Sprengel, Linda Butler, Rosella Brusa, Peter H. Seeburg, James O. McNamara. Department of Medicine, Duke University, Durham, NC27710. Center for Molecular Biology University of Heidelberg, D-69120 Heidelberg, Germany.

Kindling, an animal model of epilepsy, is a form of activity-determined plasticity of the mature nervous system. The activity consists of a focal electrical seizure or afterdischarge. Periodic elicitation of afterdischarges in an otherwise normal animal induces a lifelong seizure-prone state accompanied by diverse synaptic modifications. Activation of NMDA receptors is a key component of the activity, because NMDA receptor antagonists markedly inhibit development of kindling. The subunit composition of the NMDA receptors underlying kindling development, as well as the mechanism by which activation of these receptors contributes to kindling development are unknown. To begin to address these questions, we examined kindling development in mutant mice in which the carboxyterminal intracellular domain of NR2A subunit had been eliminated by gene targeting (Brusa et al, Neurosci Abstr 20:726, 1994).

Wild type (WT) and mutant (MT) mice underwent stereotaxic implantation of a stimulating/recording electrode in the right amygdala. The rate of kindling development was measured by the number of stimulation-induced afterdischarges required to trigger three consecutive clonic motor seizures. The rate of kindling development was markedly impaired in MT (27.4 $\pm$ 4.2 stimulations [n=8]) compared to WT (12.9 $\pm$ 1.2 stimulations [n=10]) mice (p<0.01). These findings implicate the NR2A subunit as a key component of the NMDA receptors underlying kindling development. Current investigations are aimed at determining whether this mutation interferes with synaptic activation of NMDA receptors or somehow uncouples the receptor from intracellular signaling events. Supported by NS32334 from NINDS.

## 238.4

**CHRONIC TREATMENT WITH NMDA RECEPTOR LIGANDS AND CHANNEL BLOCKERS MODULATES NR1 PROTEIN EXPRESSION** T.M. Thiesen, O. Jeyifous and M.C. Curras\* Dept. of Neuroscience, University of California, Riverside.

The NR1 subunit is required for the function of recombinant NMDA receptors, is found throughout the brain and is probably a component of all functional native NMDA receptors. In order to examine the plasticity of the NR1 subunit and to identify putative extracellular regulatory signals, we exposed ED 17-19 cortical cultures to general NMDA receptor/channel ligands and blockers. After 1-3 days of treatment, tissue from test and control groups was harvested, assayed for protein and subjected to SDS-PAGE and Western blotting. Immunodetection of NR1 protein was carried out with a polyclonal anti-NR1 primary antibody (Petralia et al, 1994; Chemicon), a goat anti-rabbit IgG conjugated with HRP (BioRad) and ECL. With progressive days *in vitro* (DIV) the NR1 immunoreactive band (100-120 kDa) increased in intensity: NR1 expression in cultures with 7 DIV > 5 DIV > 4 DIV. We used 7-day-old cultures for the present study. Chronic treatment with glutamate produced a dose-dependent (0.1 - 10  $\mu$ M) decrease in NR1 expression suggesting a regulatory role of glutamate on NR1. In some experiments, however, low doses of glutamate increased NR1 expression. Prolonged treatment of cultures with D-APV (100  $\mu$ M) produced a marked upregulation in NR1. Cultures treated with NMDA (15 - 60  $\mu$ M) and D-APV showed less NR1 expression than those treated with D-APV alone suggesting that prolonged agonist binding may downregulate NR1. Mg<sup>2+</sup> (1 mM) treatment provoked a dramatic upregulation of NR1 possibly due to prolonged channel blockade. Treatment with NMDA and Mg<sup>2+</sup> resulted in lower levels of NR1 protein expression compared with Mg<sup>2+</sup> alone. In the presence of Ca<sup>2+</sup> (2 mM), Mg<sup>2+</sup> failed to produce increased NR1 levels. These results suggest that expression of NR1 is plastic and may be regulated by extracellular levels of glutamate, divalent cations and drugs acting at NMDA receptors.

## 238.5

**CHRONIC ADMINISTRATION OF A GLYCINE PARTIAL AGONIST (1-AMINOCYCLOPROPANECARBOXYLIC ACID, ACPC) ALTERS EXPRESSION OF NMDA RECEPTOR mRNAs.** S. Bovetto<sup>1</sup>, P. Skolnick and L.H. Fossom<sup>1</sup>, Laboratory of Neuroscience, NIH/NIDDK, Bethesda, MD 20892

The glycine partial agonist ACPC is neuroprotective in animal models of focal, global and spinal ischemia. Converging lines of evidence indicate that different mechanisms are responsible for this neuroprotection following acute and chronic treatments. To investigate the possibility that chronic treatment affects NMDA receptor composition, the levels of  $\epsilon 1$ ,  $\epsilon 2$  and  $\epsilon 3$  mRNAs were quantified by *in situ* hybridization histochemistry using <sup>35</sup>S-labeled riboprobes in 15  $\mu$ m brain sections taken from NIH-Swiss mice 24 hr after chronic treatment (14 daily injections) with ACPC (200 mg/kg) or saline. Chronic ACPC increased  $\epsilon 1$  subunit mRNA levels in the hippocampus (especially CA1 and CA2), dentate gyrus, cerebral cortex (frontal, parietal and occipital) and cerebellum. In contrast, chronic ACPC decreased  $\epsilon 3$  subunit mRNA levels in the hippocampus (especially CA1), dentate gyrus, and frontal and occipital cortices, but did not alter levels in cerebellum. Chronic ACPC also decreased  $\epsilon 2$  subunit mRNA in cerebral cortex (especially frontal and parietal), but did not alter levels in cerebellum, hippocampus or dentate gyrus. From studies using recombinant NMDA receptors, it may be hypothesized that an alteration in subunit composition of NMDA receptors (to a larger proportion of receptors containing  $\epsilon 1$  relative to  $\epsilon 2$  and  $\epsilon 3$  subunits) within specific brain areas would decrease the affinity of glutamate and glycine, resulting in the observed neuroprotective actions of chronic ACPC.

**ANALYSIS OF THE NMDAR1 GENE PROMOTER IN TRANSGENIC MICE.** T. Storck, R. Kolhekar, J. Jeretic, R. Sprengel and P. H. Seeburg<sup>\*</sup>, Center for Molecular Biology, ZMBH, Univ. Heidelberg, and MPI für medizinische Forschung, 69120 Heidelberg, Germany.

The NMDAR1 receptor subunit is the essential subunit of N-methyl-D-aspartate receptors which play crucial roles in synaptic plasticity, memory formation and neurotoxicity. Targeted disruption of the NMDAR1 gene in mice results in neonatal death, precluding the analysis of its consequences in adult animals. In order to circumvent this problem we are employing the tetracycline (tet) system to produce tet-inducible NMDAR1-knockouts. Our first approach was aimed at expressing the tet-transactivator (tTA) under the control of the NMDAR1 promoter. Several lacZ reporter constructs containing different regions of the murine NMDAR1 gene were analyzed in transgenic mice. A DNA fragment encompassing 4kb of upstream sequence and the transcribed region including part of exon IV gave rise to an expression pattern resembling that of the endogenous NMDAR1 gene in three out of four transgenic animals, but the level of expression was low. Thus, an important enhancer element might be missing from this construct.

In order to recruit all cis-elements necessary for NMDAR1-specific expression, we introduced the tTA gene into the promoter region of the NMDAR1 gene via homologous recombination in murine embryonic stem cells. We are currently evaluating the regulatable expression from the engineered allele in differentiated stem cells.

Supported by Sonderforschungsbereich grant 317.

## 238.9

**MOLECULAR ANALYSIS OF NMDA RECEPTOR 2 SUBUNIT EXPRESSION DURING DEVELOPMENT.** M. Sasner<sup>\*</sup> and A. Buonanno LDN, NICHD, NIH, Bethesda, MD 20892-4480

The refinement of synaptic inputs and neural plasticity during development are partly controlled by the activation of NMDA receptors (NR), which are composed of a NR1 subunit and at least one of the four different NR2 (A-D) subunits. The NR2 subunits are differentially expressed in various brain regions during development and the NR2 composition of the receptor influences the characteristics of the channel. The NR2B subunit is expressed in the forebrain throughout life. In the cerebellum, the NR2B subunit is expressed at high levels early in development, then replaced by the NR2C subunit during the second week of postnatal life. The down-regulation of the NR2B gene has been suggested to be activity-dependent, but activity is not sufficient to activate the NR2C gene. We are studying the molecular mechanisms that control the neural specificity of NR2 expression and the switch from the NR2B to NR2C subunit during development. We have identified the murine NR2B promoter region sufficient for neural specificity and a downstream region necessary for down-regulation in the cerebellum during development. Sequence motifs in these regions that are conserved with other neural genes include the neuron-restrictive silencer element (NRSE), the BSF1 element and two N boxes. We are currently mapping the elements that mediate the developmental down-regulation of NR2B transcription. In addition, we are developing transgenic lines that express reporter genes driven by the NR2C promoter that will be useful tools to study the molecular mechanisms that drive the NR2B to NR2C switch during cerebellar development.

Supported by the NIH intramural program.

**REGULATION OF THE NMDAR1 GENE PROMOTER BY SERUM DEPRIVATION STRESS IN PC12 CELLS.** Q. Bai<sup>\*</sup>, M. Prenger and J.W. Kusiak. Mol. Neurobiol. Unit, Gerontology Research Center, NIA, NIH, Baltimore, MD 21224.

The expression of NMDAR1 gene is increased during neuronal development and may be differentially regulated in ischemia and epileptogenesis. We are interested in studying the role of trophic factors in regulating the NMDAR1 gene. We measured the activity of a 3 kb NMDAR1 promoter-luciferase reporter stably transfected into PC12 cells under conditions of serum deprivation and re-addition. We compared the serum effects with the effects of different trophic factors. The results showed that serum deprivation for 4 hr caused a down-regulation of the NMDAR1 promoter activity to about 33% of untreated cells and re-addition of serum for two hr increased the NMDAR1 promoter activity over serum-deprived cells by 13 fold. This serum-induced activity partially resides in the proximal 356 bp promoter. In the absence of serum, NGF, bFGF and EGF individually up-regulated the activity of serum-deprived cells by more than 8 fold. NGF and serum had an additive effect. NGF also had an additive effect with EGF on serum-deprived cells. But, the kinetic effects of serum re-addition and growth factors on the promoter were different: Serum re-addition caused a robust increase within 15 min while NGF induced a significant up-regulation only after one hr treatment. Pretreatment with actinomycin D prevented the serum- and NGF-induced increase in the luciferase activity. The NGF effect was sensitive to K-252a blockade. Our studies suggest that a lack of trophic support causes a down-regulation of NMDAR1 promoter and both serum and trophic factors like NGF can up-regulate the activity of this promoter but through different mechanisms. Supported by NIH and the Aluminum Association.

## 238.8

**NMDAR-1 IS A POTENTIAL TARGET GENE FOR THE EGR FAMILY OF TRANSCRIPTION FACTORS** Penny Jensen<sup>1,2</sup>, Noemi Milán<sup>2</sup>, and Kenneth J. Mack<sup>2</sup>

Departments of Physiology<sup>1</sup> and Neurology<sup>2</sup>, University of Wisconsin-Madison, Madison, WI 53706

The EGR family of transcription factors has been implicated in synaptic plasticity including complex functions such as LTP and seizures. Yet no specific downstream target gene has been identified in orchestrating these events. The promoter region of the glutamate receptor NMDAR-1 contains the EGR cis-regulatory element (Bai and Kusiak, 1994) therefore we asked if NMDAR-1 is transcriptionally regulated by the EGR family of transcription factors. Since previous results from this lab have shown highly dissimilar levels of NGF1-A/ZIF268 following either a physiological (whisker stimulation) or pathological (seizure) stimulus in rat brain, levels of NMDAR-1 were examined following the same paradigms. RT-PCR investigation displays that in the somatosensory cortex there is relatively no change in NMDAR-1 mRNA expression following sensory stimulus, and a 50% (n=5) reduction subsequent to a PTZ (50 mg/kg) induced seizure. In contrast, RT-PCR, *in-situ*, and western analysis indicate that both mRNA and protein levels appear to increase following a seizure in the motor cortex. *In vitro* gel shift and supershift analysis shows that all EGR family members have the capability of binding to the promoter region of NMDAR-1 either alone or within nuclear homogenates. *In-vivo*, transfection analysis in PC12 cells using a luciferase reporter plasmid under control of the NMDAR-1 promoter (bps -1024 to 1) shows an increase in luciferase expression following addition of NGF. Two constructs containing sequences flanking but excluding the cis-regulatory element exhibit a significant decrease in expression 86% (n=6) and 91% (n=5) respectively for regions 5' (bp -1024 to -362) and 3' (bp -302 to 1) to the gsg-box. Within the missing region also resides an SP1 binding site, co-transfection analysis with SP1 demonstrates no increase in expression of the reporter plasmid. Co-transfection assays depict a biphasic relationship for both NGF1-A and Krox20, low levels increase expression, whereas high levels provoke a decrease. These data reveal that the EGR family may play an influential role in NMDAR-1 expression. Supported by NIHNS33913.

**ANALYSIS OF CHANGES IN GLUTAMATE RECEPTOR mRNAs IN EPILEPSY MODELS USING A REVERSE NORTHERN BLOT ASSAY.**

K. Borges<sup>\*</sup>, J. Doherty, P.J. Conn and R. Dingledine.

Dept. of Pharmacology, Emory Univ., Atlanta GA 30322.

The properties of glutamate receptors are largely determined by their subunit composition. To assess changes in the glutamate receptor subunit composition that might play a role in the development of epileptic seizures we developed a reverse Northern blot assay that permits measurement of the relative abundance of many specific mRNAs in a single, small (~20 mg) tissue sample. PolyA<sup>+</sup> RNA from epileptic and control tissue was isolated and reverse transcribed with random primers in the presence of a <sup>32</sup>PdCTP to obtain a mixture of radiolabeled cDNA probes. After hybridizing each probe to cationic nylon filters containing dots of denatured plasmid DNA of glutamate receptor subunits (400 ng), cyclophilin (25 ng) and vector (200 ng), the signals of bound probe were quantified and normalized to cyclophilin. We compared these signal ratios from tissue of amygdala-kindled rats 24 hrs after the 10th stage 5 seizure (N=10) to ratios obtained from sham-operated rats (N=10). The signal for the NR2A subunit was significantly decreased by 29% and 21% in the kindled piriform cortex and the kindled "area tempestas" implicating a change in NMDA receptor properties. No changes were found for the NMDAR1, -2B and the GluR1, -2, -3 and -4c subunits, which contrasts to the reported downregulation of GluR2 protein found in piriform cortex by Western blotting (Prince et al., 1995. J. Neurochem. 64, 462-465). These data suggest that 24 hr after the last kindled seizure only the NR2A mRNA is decreased.

## 238.11

IDENTIFICATION OF TRANSCRIPTIONAL CONTROL ELEMENTS IN THE NEURON-SELECTIVE RAT GLUR2 PROMOTER. S.J. Myers\*, J. Peters, and R. Dingledine. Dept. of Pharmacol., Emory Univ. Sch. of Med., Atlanta, GA 30322.

Glur2 is the key subunit controlling calcium permeability and rectification properties of native hetero-oligomeric AMPA receptors in neurons. A fall in Glur2 expression, relative to Glur1, R3, and R4, could lead to increased calcium entry into these cells and would have important consequences on synaptic physiology and neuronal health. For these reasons, we conducted a mutational deletion scan of the proximal Glur2 promoter (-175 to +372, relative to transcription initiation) to identify key promoter regions that regulate transcriptional expression of Glur2 in transfected cultured cortical neurons, primary glia, and C6 gliomas. Anti-luciferase staining of the neuronal cultures revealed that expression was restricted to cells with neuronal morphology. Two main regions of control were identified that together confer neuron-selective expression of the Glur2 gene: (1) Deletion of the domain harboring a silencer element (RE1 consensus) resulted in a 2- to 3-fold increase in Glur2 promoter-driven luciferase expression (Glur2pro-Luc) in non-neuronal cells. This same deletion construct had no effect in neurons. Further analysis showed that function of the Glur2 silencer was sensitive to as few as 1- or 6-bp mutations. When Glur2pro-Luc constructs were cotransfected with a repressor that recognizes RE1 (REST), luciferase expression was reduced in neurons in a silencer-dependent manner, suggesting that REST or a repressor similar to REST may regulate Glur2 expression. (2) Three additional contiguous, independent deletion constructs (~25 bps each) resulted in sequential and strong attenuation (35, 56, and 65% reduction) of Glur2pro-Luc expression in neurons. This 75-bp region was found to exhibit a high density of transcription factor consensus sequences, including four Sp1/Sp4 sites. By analysis of a combination of these deletion constructs, 35 to 56% of the Glur2 promoter activity mapped to these Sp1/Sp4 sites. Coexpression of Sp1 or Sp4 with WT Glur2pro-Luc increased luciferase expression 3- to 5-fold in neurons, glia, and C6 gliomas, consistent with the hypothesis that Sp1/Sp4 transcription factors are involved in Glur2 gene expression. In sum, we have identified a repressor and an activator domain in the Glur2 promoter that, in part, governs neuron-selective expression of the rat Glur2 gene. Supported by NS27452.

## 238.13

CHARACTERIZATION OF AMPA RECEPTOR SUBUNIT (GluR-B) RNA EDITING IN RAT BRAIN NUCLEAR EXTRACTS. S.M. Rueter\*, C.M. Burns and R.B. Emeson. Department of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600.

Site-specific editing of pre-mRNA encoding the B-subunit of the AMPA subtype of glutamate receptor (GluR-B) alters a codon in the second hydrophobic region (TMII) of the receptor subunit, leading to alterations in both the Ca<sup>2+</sup> permeability and electrophysiological properties of the resultant ion channel. The identification of an RNA duplex formed by exonic and intronic sequences surrounding the editing site (Q/R site), in conjunction with *in vitro* observations that this post-transcriptional modification occurs by creation of an inosine moiety in the substrate RNA, has indicated that this editing reaction is catalyzed by a double-stranded RNA-specific adenosine deaminase.

Unlike nuclear extracts prepared from HeLa cells, which edit GluR-B transcripts *in vitro* at both the Q/R site and intronic position +60, crude rat brain nuclear extracts did not efficiently edit GluR-B RNA substrates at the +60 site, although editing at the Q/R site was substantially higher than that observed in HeLa nuclear extracts (75% vs. 30%). To isolate and characterize the enzymatic activity responsible for catalyzing the modification of GluR-B RNA transcripts, we have fractionated rat brain nuclear extracts by anion-exchange, cation-exchange, and gel-filtration chromatography. Analyses of fractions eluting from the cation-exchange and gel-filtration columns revealed that editing at position +60 could now be observed to almost the same extent as at the Q/R site. In addition, enzymatic activity mediating the editing of the +60 adenosine residue was resolved from the activity responsible for Q/R site modification. Both peaks of activity contained a generic double-stranded RNA (dsRNA)-specific adenosine deaminase activity as assessed by thin-layer chromatographic analyses of inosine production from a radiolabeled dsRNA substrate. The apparent molecular weights of these distinct editing activities corresponded to those of two previously characterized adenosine deaminases that act on dsRNA (DRADA/dsRAD and RED1), suggesting that both of these activities may be responsible for mediating the post-transcriptional modification of GluR-B transcripts. Supported by NIH grant NS33323.

## 238.15

CALPAIN-MEDIATED REGULATION OF AMPA RECEPTORS IN ORGANOTYPIC HIPPOCAMPAL CULTURES. X. Bi\*, G. Tocco, and M. Baudry. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Calpains, calcium-activated neutral proteases, have been implicated in a variety of physiological and pathological processes. We have recently demonstrated that *in situ* activation of calpains in frozen-thawed rat brains sections results in a partial proteolysis of GluR1 subunits of AMPA receptors. Further studies using antibodies directed towards peptide sequences in the N-terminal (N-Ab) and C-terminal (C-Ab) domains of the subunit indicated that the cleavage of GluR1 subunit by calpain-mediated proteolysis occurs in the C-terminal domain, resulting in the formation of a new species with a molecular weight approximately 7 kD lighter than the native protein. The present study examined changes in GluR1 subunits after kainic acid (KA) treatment of organotypic hippocampal cultures. Hippocampal slices were processed for Western blots immediately (3 hr) or 3 hr (6 hr) after KA (50  $\mu$ M) treatment. Immunoblots labeled with the C-Ab revealed a decrease in GluR1 immunoreactivity that appeared at 3 hr and was further enhanced by 6 hr. However, immunoblots labeled with the N-Ab indicated that KA-induced changes in GluR1 were due to alterations in the mobility rather than to a decreased amount of the protein. At 3 hr, GluR1 immunopositive bands shifted towards a slightly lower molecular weight while a second band with a 7 kD lighter molecular weight was evident by 6 hr. These changes in GluR1 subunits were significantly reduced by the application of 100  $\mu$ M calpain, a cell membrane permeable calpain inhibitor. These results indicate that 1) changes in GluR1 properties elicited by KA treatment are mediated by calpain activation, 2) at least two cleavage sites for calpain-mediated proteolysis exist in the C-terminal domain of GluR1 subunits (possibly at residues 885-886 and residues 833-834 or 837-838 respectively), and 3) the temporal specificity of the two cleavages indicates a diverse regulation of GluR1 by calpain-mediated proteolysis, suggesting that calpains participate in different stages of neurophysiological or neuropathological processes. Supported by Grants from the Human Brain Project and NINDS.

## 238.12

RNA EDITING OF GLUTAMATE RECEPTOR SUBUNIT 2 (GluR-B) AFTER MAXIMAL ELECTROSHOCK AND KAINIC ACID-INDUCED SEIZURES.

Ruo Q. Hu\*, Jang-Ho J. Cha, and Andrew J. Cole, Epilepsy Research Laboratory, Neurology Service, Massachusetts General Hospital, Harvard Medical School, Fruit St., Boston, MA 02114.

**Introduction:** RNA editing at a single nucleotide results in a Gln to Arg substitution in the second transmembrane domain of GluR-2. This critical residue determines the calcium permeability of AMPA-sensitive glutamate receptors. Disruption of the editing process in mice results in an epileptic phenotype that is lethal by day 20 (Brusa *et al.*, *Science*, 270, 1995). Because seizures themselves may be epileptogenic, we hypothesize that certain epileptic conditions may be the result of acquired defects in the editing process. In the present study, we examined the editing status at the Q/R site of GluR-2 after seizures induced by both maximal electroshock (MES) stimulation and kainic acid (KA) administration.

**Methods:** Male Sprague Dawley rats were studied after single MES (85mA, 100Hz, 1s), 10 daily MES, or seizures induced by systemic KA (15 mg/kg i.p.). Rats were sacrificed 24 h after last MES and 72 h after KA treatment. Cortex, cerebellum and hippocampus were dissected for isolation of DNA and RNA. Following reverse transcription, PCR was carried out to amplify a portion of the GluR-2 coding sequence containing the Q/R editing site. Products were analyzed to determine the sensitivity *Bbv* I hydrolysis, which is abolished by the A to G conversion produced by editing.

**Results:** Rat genomic DNA was cleaved by *Bbv* I, while cDNA produced from cortex, cerebellum and hippocampus of control animals was resistant to hydrolysis. Neither acute MES, chronic MES, nor KA induced seizures resulted in the appearance of unedited cDNA as determined by this assay. These findings indicate that neither acute nor repeated seizures significantly affect the GluR-2 RNA editing process in these models of epilepsy. Support: Whitehall Foundation

AMPA RECEPTOR EXPRESSION IN CULTURED RAT HIPPOCAMPAL NEURONS FOLLOWING SUBLETHAL OXYGEN-GLUCOSE DEPRIVATION. H.S. Ying\*, J. Weishaup\*, M. Grabb, L.M.T. Canzoniero, S.L. Sensi, H. Monyer, and D.W. Choi. Center for the Study of Nervous System Injury and Dept of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110. \*Center for Molecular Biology (ZMBH), Univ. of Heidelberg, 69120 Heidelberg, Germany.

We used single cell RT-PCR to examine the effect of a sublethal preconditioning oxygen-glucose deprivation (OGD) insult on AMPA receptor gene expression in hippocampal neurons. DIV 18-22 dissociated rat hippocampal cultures were exposed to OGD for 30-45 min. 24-48 hrs later, neurons were randomly selected for RNA harvesting through a patch pipette. Reverse transcription and two rounds of PCR (40 and 35 cycles) were performed using hemi-nested degenerate oligonucleotide primers to detect the four major AMPA receptor subunits. PCR products were probed with subunit-specific oligonucleotides and quantitated using a phosphorimager. Average percent of total AMPA receptor abundance  $\pm$  S.E.M. for 42 cells are given below:

CONDITION	GLUR-A	GLUR-B	GLUR-C	GLUR-D
CONTROL (n=19)	35.1 $\pm$ 4.3	34.0 $\pm$ 4.8	17.4 $\pm$ 3.7	13.5 $\pm$ 3.7
OGD (n=23)	26.0 $\pm$ 3.5*	28.6 $\pm$ 3.8	18.0 $\pm$ 3.3	28.0 $\pm$ 4.3*

\* indicates difference from control using repeated-measures ANOVA,  $P < 0.01$ .

Thus sublethal OGD produced a relative increase in GluR-D expression at the expense of GluR-A expression. The decrease in GluR-B expression previously reported in hippocampal CA1 neurons *in vivo* exposed to severe ischemia was not observed here, although a non-significant trend towards reduction was noted. Since desensitization and deactivation time constants are negatively correlated with GluR-D abundance, decreased GluR-D gene expression -- if reflected in receptor composition -- might act as a protective mechanism to reduce AMPA receptor-mediated currents and consequent excitotoxic injury. Supported by NIH NINDS grant NS 32636 (DWC).

GROWTH FACTOR-INDUCED TRANSCRIPTION OF GLUR-1 INCREASES FUNCTIONAL AMPA RECEPTOR DENSITY IN GLIAL PROGENITOR CELLS. L.J. Chew, M.W. Fleck\*, P. Wright, S.E. Scherer, M.L. Mayer and V. Gallo. Lab. of Cell. and Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892.

We have previously demonstrated that platelet-derived growth factor (PDGF) and basic FGF (bFGF) regulate the expression of glutamate receptor (GluR) subunits in cultured oligodendrocyte progenitor (O-2A) cells (Wright *et al.*, *Soc. Neurosci. Abstr.* 1994, 20, 214.11). Untreated cortical O-2A cells express GluR1 mRNA at levels lower than that of the other AMPA receptor subunits. bFGF treatment caused a 2-3 fold increase in steady-state mRNA levels for GluR1, 2, 3 and 4. PDGF did not significantly modify the mRNA levels for any of the AMPA subunits, but selectively potentiated the effects of bFGF on GluR1 mRNA (5-6 fold increase over untreated). We analyzed if: i) the changes in GluR1 RNA levels triggered by PDGF+bFGF were due to modifications of GluR1 gene transcription; ii) changes in GluR1 gene expression also modified expression of functional AMPA receptors. Nuclear run-on assays demonstrated that PDGF+bFGF caused a 2.5 fold increase in the rate of GluR1 gene transcription, while having no effect on GluR2. Western analysis showed that PDGF+bFGF caused a 10-fold increase in GluR1 protein levels, but did not modify GluR2,3 and 4 protein levels. Functional receptor expression was assessed by rapid application of AMPA (500  $\mu$ M) to cultured cells in the whole-cell recording configuration. AMPA receptor densities were quantified from peak current amplitudes relative to whole-cell capacitance (pA/pF) and were increased nearly 5-fold in cells treated with PDGF+bFGF, as compared to untreated cells. Further, AMPA receptor channels in cells treated with PDGF+bFGF were more sensitive to voltage-dependent block by intracellular polyamines, as expected from the robust and selective enhancement of GluR-1 expression. Our combined molecular and electrophysiological analyses indicate that GluR function can be regulated by changes in the rate of GluR subunit gene transcription. Supported by NIH.

CATALYTIC RNA-DIRECTED CLEAVAGE OF THE NMDA RECEPTOR SUBUNIT NR1 mRNA. L. Yen\* and R. G. Kalb. Dept. of Neurology, Yale University, School of Medicine, New Haven, CT 06510

The NMDA subtype of glutamate receptor is believed to play important roles in the brain development, learning, memory, and neurotoxicity of many neurodegenerative diseases. The presence of NR1 subunit is required to form a functional NMDA receptor. We are working on a new strategy for regulating the expression of NR1 subunit that involves the selective destruction of its mRNA mediated by a small catalytic RNA. A small RNA can be designed (the external guide sequence or EGS) that will bind in a sequence-specific manner to NR1 mRNA and this complex becomes a substrate for the RNase P (an enzyme present in all cells). RNase P will cleave the substrate, efficiently and selectively eliminating the target mRNA from the cell.

RNase T1 mapping of a minigene of the NR1 mRNA has led us to the identification of a site highly sensitive to RNase digestion. This accessible site is within a region common to all isoforms of NR1 mRNA. Hybridization of a custom-designed EGS to this accessible site of the NR1 mRNA leads to the efficient and selective destruction of NR1 mRNA *in vitro*. Sequencing the cleaved NR1 mRNA fragments confirms that cleavage occurred at the expected location. Furthermore, control experiments indicates that the designed EGS interacts with NR1 mRNA in a sequence-specific manner and does not affect other glutamate receptor related genes *in vitro*.

We have engineered the EGS into a vector under the control of the U6 promoter. This constructed vector leads to high level expressions of EGS both in human embryonic kidney HEK 293 cells, and in rat neuronal-like PC12 cells. The expression of EGS is strictly confined to cell nucleus where RNase P is concentrated. A critical next step is to examine the efficacy of this EGS to direct cleavage of NR1 RNA in cells. We believe that this system could have important applications for the study of NMDA receptor-mediated development and neurotoxicity. (Supported by NIH NS 29837).

PHARMACOLOGICAL CHARACTERIZATION IN OOCYTES OF AMPA-RECEPTORS EXPRESSED FROM RAT AND HUMAN WHOLE BRAIN mRNA. D.A. Gurley<sup>1</sup>, S.D. Donevan<sup>2</sup> and E.W. Harris<sup>1\*</sup>. <sup>1</sup>Biology Dept., Astra Arcus USA, Rochester, NY 14602 and <sup>2</sup>Dept. Neurology, Univ. Utah, Salt Lake City, UT 84112.

Studies of cloned AMPA-receptors (AMPA-Rs) have identified toxins that selectively block Ca<sup>2+</sup>-permeable AMPA-R channels, and compounds that differentially potentiate AMPA-R splice-variants. These new pharmacological insights have been applied to AMPA-Rs expressed in injected oocytes injected with whole brain polyA<sup>+</sup> mRNA.

AMPA and glutamate yielded small currents that were potentiated >50-fold by 50μM cyclothiazide (CYZ); CYZ increased kainate currents only 2-3-fold, for adult rat and human mRNA, suggesting mostly "flop" variants, and ~6-fold for human fetal RNA, suggesting mostly "flip" variants. AMPA and Iodo-Willardiine were antagonized ~50% by 3mM SCN<sup>-</sup>, which slightly potentiated kainate currents.

Although JSTX-sensitive (Ca<sup>2+</sup>-permeable) AMPA-Rs are sparse in adult brain, 1μM JSTX blocked 75% of adult brain mRNA AMPA-R current. The remaining current was blocked by 1mM pentobarbital.

A published study of human epileptic mRNA concluded that Ca<sup>2+</sup>-permeable AMPA-Rs had increased, since ~75% were Ca<sup>2+</sup>-permeable. Our results suggest that control mRNA may have a similar profile.

ALTERATION OF GLUR5 mRNA EDITING USING GENE TARGETING. Andreas Sailer, Geoffrey T. Swanson, D. K. Smetters<sup>+</sup>, Robert E. Petroski<sup>\*</sup>, Charles F. Stevens<sup>+</sup>, Stephen O'Gorman<sup>#</sup>, and Stephen F. Heinemann. Molecular Neurobiology Laboratory, <sup>+</sup>Howard Hughes Medical Institute, <sup>#</sup>Gene Expression Laboratory. The Salk Institute for Biological Studies, La Jolla, CA 92037, USA.

Editing of mRNAs coding for subunits of the glutamate-gated ion channels at the Q/R site in the membrane domain 2 (MD2) has been shown to alter the channel properties in terms of Ca<sup>2+</sup>-permeability, rectification, and single channel conductance. Analysis of total brain mRNA for the kainate receptor subunit GluR5 showed that about 40% of the mRNA transcripts are edited at the Q/R site in MD2. To address the physiological role of glutamate receptor mRNA editing in the brain, we have made mutant mice which express 100% edited GluR5 mRNA using ES-cell-mediated transgenesis. In the first step a targeting vector carrying a point mutation (CGG = R) at the Q/R site in MD2 and a neomycin resistance gene (flanked by loxP sites) located in the adjacent intron was transfected into ES cells. In a second step the resistance marker was excised by the transient expression of the Cre recombinase. Subsequently, recombined clones were injected into blastocysts to generate chimeric animals which upon breeding with wild type animals transmitted the mutant allele to the next generation.

EXCITATORY AMINO ACID RECEPTORS: PHYSIOLOGY,  
PHARMACOLOGY, AND MODULATION—mGluR I

## 239.1

DIFFERENTIAL INVOLVEMENT OF GROUP II AND GROUP III mGLURS AS AUTORECEPTORS AT LATERAL AND MEDIAL PERFORANT PATH SYNAPSES. T.A. Macek<sup>\*</sup>, D.G. Winder, R.W. Gereau IV, C.O. Ladd, and P.J. Conn. Dept. of Pharmacology, Emory Univ. School of Med., Atlanta, GA 30322.

Previous reports have shown that group III metabotropic glutamate receptors (mGluRs) serve as autoreceptors at the dentate gyrus lateral perforant path (LPP) synapse. However, the possible roles of other mGluR subtypes at this synapse have not been examined. Furthermore, it is not known whether specific mGluR subtypes serve as autoreceptors at the medial perforant path (MPP) synapse. Utilizing whole cell patch clamp and field excitatory post-synaptic potential (fEPSP) recordings, we have examined the effects of group-selective mGluR agonists on transmission at lateral and medial perforant path synapses in adult rat hippocampal slices. Micromolar concentrations of the group III-selective mGluR agonist L-2-amino-4-phosphonobutyric acid (L-AP4) reduced transmission at the LPP but not the MPP synapse. In contrast, the group II selective agonist (2S,1'R,2'R,3'R)-2-(2,3-dicarboxycyclopropyl) glycine (DCG-IV) reduced transmission at the MPP but not the LPP synapse. The group I-selective agonist 3,5-dihydroxyphenylglycine (DHPG) had no effect on transmission at either synapse. (2S,3S,4S)-2-methyl-2-(carboxycyclopropyl)glycine (MCCG), a group II selective antagonist blocked the inhibitory action of DCG-IV at MPP but not that of L-AP4 at the LPP. In contrast, the group III-selective antagonist α-methyl-L-AP4 (MAP4) blocked the effect of L-AP4 but not that of DCG-IV. DCG-IV had no effect on kainate evoked currents at a concentration that maximally reduced transmission at the MPP synapse. Taken together, these data suggest that group II and group III mGluRs serve as autoreceptors at MPP and LPP synapses respectively. Supported by NIH NINDS grant NS31373 (PJC).

## 239.2

ROLE AND MECHANISM OF ENDOGENOUSLY ACTIVATED mGluR1 IN MODULATING SYNAPTIC TRANSMISSION TO PHRENIC MOTONEURONS. X-W. Dong\* & J.L. Feldman. Depts. of Physiological Science & Neurobiology, UCLA, Los Angeles, CA 90095-1527

Activation of metabotropic glutamate receptors (mGluRs) by 1S,3R-ACPD exerts multiple actions on phrenic motoneurons (PMNs), including reduction of inspiratory-modulated synaptic currents and increase of cell excitability. These actions are mediated by different receptor subtypes: mGluR1 increases excitability and mGluR2/3 depresses synaptic transmission. We determined their functional roles by examining whether these receptors are endogenously activated and investigated the underlying mechanisms. PMN activity was recorded under whole-cell patch-clamp conditions or from C4 root in the brainstem-spinal cord preparation of neonatal rat. Drugs were applied via pipettes over the PMN pool. To determine endogenous activity of mGluR1, the effect of the antagonist (RS)-1-Aminoindan-1,5-dicarboxylic acid (AIDCA; 200 μM) was examined. AIDCA significantly reduced C4 inspiratory discharges to 89±8% (n=5) of control, indicating that mGluR1 is endogenously activated, enhancing PMN inspiratory activity. The mGluR1 agonist (RS)-3,5-dihydroxyphenylglycine (DHPG) induced an inward current (I<sub>DHPG</sub>) associated with a decrease of membrane conductance (G<sub>m</sub>). The I<sub>DHPG</sub> had a reversal potential (E<sub>rev</sub>) of ~-100 mV, close to the estimated E<sub>K</sub> (-95 mV). Elevating [K<sup>+</sup>]<sub>o</sub> to 9 mM reduced I<sub>DHPG</sub> E<sub>rev</sub> to -73 mV. The K<sup>+</sup> channel blocker Ba<sup>2+</sup> occluded DHPG effects by diminishing I<sub>DHPG</sub> and the associated decrease of G<sub>m</sub>. The Ba<sup>2+</sup>-sensitive component of I<sub>DHPG</sub> had similar I-V relationship to Ba<sup>2+</sup>-induced current with E<sub>rev</sub> at ~-95 mV. Our data indicate that the major component of I<sub>DHPG</sub> results from blockade of a Ba<sup>2+</sup>-sensitive resting K<sup>+</sup> conductance. We conclude that mGluR1s are endogenously activated to enhance inspiratory drive to PMNs. Supported by NIH Grant NS 24742.

## 239.3

**ROLE OF METABOTROPIC GLUTAMATE RECEPTORS IN ACTIVITY-DEPENDENT INHIBITION OF EXCITATORY SYNAPTIC TRANSMISSION IN LOCUS COERULEUS NEURONS.** G. R. Dubé\*, and K. C. Marshall, Dept. of Physiology, University of Ottawa, Ottawa, On, Canada, K1H 8M5.

Regulation of excitatory synaptic transmission in the locus coeruleus (LC) was investigated in an adult rat brain slice preparation. Evoked excitatory postsynaptic potentials (EPSPs) resulting from stimulation of LC afferents were measured intracellularly in LC neurons in the presence of bicuculline (10  $\mu$ M). When two single stimulations were delivered to the afferents with a 600ms interval, the amplitude of the second [test (T)] EPSP was identical to the first [control (C)]. However, when a 300ms, 70 Hz train of stimulation was delivered 500 ms prior to T, the amplitude of the latter EPSP was consistently smaller than C ( $p < 0.001$ ,  $n = 20$ ). We proceeded to characterize the mechanisms involved in this activity-dependent EPSP inhibition. Perfusion of the slice with cyclothiazide (100  $\mu$ M), an AMPA receptor desensitization blocker, resulted in a significant increase in amplitude of both C and T ( $142 \pm 14$  and  $163 \pm 16$ , respectively,  $p < 0.01$ ,  $n = 5$ ). This resulted in a significant increase in the ratio of EPSP amplitude of T over C (T/C), from  $0.57 \pm 0.08$  in regular perfusate to  $0.67 \pm 0.08$  in cyclothiazide ( $p = 0.002$ ). In a second set of experiments, the effects of mGluR antagonists were investigated. Bath applied MAP4 (500  $\mu$ M), an mGluR group III antagonist, caused a significant increase in T/C from  $0.60 \pm 0.06$  to  $0.67 \pm 0.06$  ( $n = 7$ ,  $p = 0.01$ ). Conversely, (+)MCPG (500  $\mu$ M), a broad spectrum mGluR antagonist, failed to significantly alter EPSP inhibition ( $0.73 \pm 0.05$  vs  $0.77 \pm 0.05$ ,  $p = 0.3$ ). Finally, we are presently investigating the effects of GABA<sub>A</sub> and adenosine A<sub>1</sub>/A<sub>2</sub> receptor agonists and antagonists. However, preliminary results provide little evidence that these were involved in activity-dependent inhibition of EPSPs. Hence, in our preparation, desensitization of the AMPA receptor following a train of stimulation can account for up to 25% of the inhibition of EPSP amplitude, while approximately 20% of this inhibition in mGluR group III-dependent. The present study thus demonstrates that presynaptic mGluR (group III) activation and AMPA receptor desensitization are two mechanisms by which excitatory synaptic transmission can be reduced during high frequency activity of LC afferents. Supported by the MRC, Canada.

## 239.5

**A ROLE FOR METABOTROPIC GLUTAMATE RECEPTORS IN PAIRED PULSE DEPRESSION IN SLICES OF RAT DENTATE GYRUS**

Deirdre O'Leary & John O'Connor\*, Department of Human Anatomy & Physiology, University College, Earlsfort Terrace, Dublin 2, Ireland.

There is now evidence that metabotropic glutamate receptors (mGluRs) modulate perforant path responses, via both pre- and post-synaptic mechanisms in the hippocampus. In the present study we have investigated the effect of a number of mGluR agonists and antagonists on paired pulse depression (PPD) in the medial perforant pathway of the rat dentate gyrus *in vitro*. Transverse hippocampal slices were prepared from male Wistar rats (50-150g) by standard methods. Field excitatory post-synaptic potentials (epSPs) were evoked in the medial perforant pathway every 20s. Paired pulses were applied at inter stimulus intervals (ISIs) of 10, 50, 100 and 500ms. In control slices the second synaptic response was consistently smaller than the first at all ISIs tested (e.g. by  $18.7 \pm 1.4\%$  at 100ms ISI,  $n = 16$ ). The mGluR agonists, ACPD (10  $\mu$ M) and L-2-amino-4-phosphonobutyric acid (L-AP4; 20  $\mu$ M) reduced PPD at all ISIs less than 500ms (e.g. by  $8.0 \pm 1.7\%$  &  $5.1 \pm 1.5\%$  at 50ms ISI respectively;  $p < 0.01$ ;  $n = 5$ ; Students *t* test). Application of the mGluR antagonist,  $\alpha$ -methyl carboxy-phenylglycine (MCPG; 100  $\mu$ M) inhibited the ACPD-induced reduction in PPD at all ISIs ( $n = 7$ ). The mGluR antagonists  $\alpha$ -methyl-L-AP4 (MAP4; 200  $\mu$ M) and  $\alpha$ -methylserine-*o*-phosphate (MSOP; 200  $\mu$ M) did not block the L-AP4-induced reduction in PPD at ISIs less than 20ms. However both agents did inhibit the effects of L-AP4 at intermediate ISIs (50-500ms). These results further demonstrate the involvement of mGluRs in the modulation of PPD in the medial perforant pathway. (Supported by Forbairt, Ireland).

**ACPD INCREASES SPONTANEOUS IPSC FREQUENCY IN NEOCORTICAL NEURONS.** Z. G. Chu, F.-M. Zhou and J. J. Hablitz\*.

Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294

Spontaneous (s) and miniature (m) IPSCs were recorded in pyramidal cells and GABAergic interneurons using whole-cell patch clamp techniques. All recordings were made at  $\sim 22^\circ\text{C}$  in slices of rat neocortex maintained *in vitro*. Excitatory postsynaptic currents were blocked with 20  $\mu$ M D-APV and 10  $\mu$ M CNQX. IPSCs were recorded at a holding potential of -60 mV. Under the recording conditions used, the Cl<sup>-</sup> equilibrium potential was near 0 mV. Amplitudes of spontaneous IPSCs ranged from 5 to 500 pA. sIPSCs were reversibly blocked by bicuculline (10  $\mu$ M) indicating mediation by GABA<sub>A</sub> receptors. Bath application of the metabotropic glutamate receptor (mGluR) agonist ACPD induced an increase in the frequency of sIPSCs in layer II/III pyramidal neurons which was reversible upon washing. The amplitude of AP-dependent sIPSCs was not significantly increased. Decay kinetics of sIPSCs were unaffected. mIPSCs recorded in the presence of TTX were not affected by ACPD. Recordings from layer I interneurons showed an ACPD-induced increase in sIPSC, but not mIPSC frequency. ACPD-evoked inward currents were occasionally observed in layer I but not layer II/III neurons. These results suggest that the potentiating effect of ACPD on IPSCs may be mediated by mGluR receptors on a subset of interneurons. Supported by NIH grant NS18145.

## 239.4

**REGULATION OF SYNAPTIC TRANSMISSION IN OLFACTORY MITRAL CELLS THROUGH MULTIPLE METABOTROPIC GLUTAMATE RECEPTORS.** N. E. Schoppa\* and G. L. Westbrook, Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201.

Several mGluRs (mGluR1, 2, 7 and 8) are expressed in mitral cells of the olfactory bulb, but their specific roles in regulating excitatory synaptic transmission are unclear. We evaluated the effects of different mGluR agonists and antagonists on miniature excitatory post-synaptic currents (mEPSCs) in whole-cell patch recordings of cultured rat mitral cells. Experiments (at  $V_h = -60$  mV) were conducted using a CsCl or KCl-based pipette solution containing 1 mM EGTA and 0  $\text{Ca}^{2+}$ , and a bath solution containing 2 mM  $\text{Ca}^{2+}$  and TTX (1  $\mu$ M). Picrotoxin (50  $\mu$ M) and APV (100  $\mu$ M) were added to isolate AMPA mEPSCs. The group I and II mGluR selective agonist 1S,3R-ACPD (100  $\mu$ M) had two effects on mEPSCs. In 8 of 24 cells, ACPD caused a dramatic increase in the mEPSC frequency. This effect was apparently an indirect result of depolarization of surrounding mitral cells because it was blocked by Cd (100  $\mu$ M), and ACPD reduced a resting  $\text{K}^+$  current in the test mitral cell. In the majority of mitral cells, and in all recordings made in the presence of Cd, ACPD caused a reduction in the mEPSCs frequency ( $37 \pm 8\%$  in 13 recordings made in Cd). The ACPD-induced increase in mEPSC frequency was mimicked by the Group I selective agonist DHPG (100  $\mu$ M), whereas the ACPD-induced decrease was mimicked by the purported Group II selective agonist CCG-I (2  $\mu$ M). The Group III selective agonist L-AP4 (100  $\mu$ M) also caused a Cd-insensitive  $34 \pm 4\%$  ( $n = 16$ ) reduction in the mEPSCs frequency. 5  $\mu$ M L-AP4 caused a similar magnitude mEPSCs inhibition, that was blocked by the Group III selective antagonist MAP4 (500  $\mu$ M;  $n = 3$ ). These results suggest that multiple mGluRs can regulate synaptic transmission in mitral cells. Although mGluRs can inhibit calcium influx, the Cd-insensitivity of mEPSCs inhibition suggests that mGluRs can regulate neurotransmitter release by altering step(s) in the release process downstream of calcium influx. Supported by ST32-DK07680-05 (NES) and NS26494 (GLW).

## 239.6

**THE MIXED MGLUR AGONIST / ANTAGONIST, 4C3HPG, INHIBITS EVOKED BURSTING IN BASOLATERAL AMYGDALA NEURONS FROM KINDLED RATS.** N. B. KEELE\* AND P. SHINNICK-GALLAGHER, DEPT. OF PHARMACOLOGY, UNIV. OF TEXAS MEDICAL BRANCH, GALVESTON, TX 77555.

Whole-cell current and voltage clamp recordings in a slice preparation were obtained from single basolateral amygdala neurons of control and kindled rats. Previously, this laboratory has demonstrated that kindling-induced epileptogenesis produces bursting in response to both the mGluR agonist 1S,3R-ACPD and electrical synaptic stimulation. The purpose of this study is to define the pharmacology of mGluR agonist-induced bursting and to evaluate the effects of phenylglycine compounds on agonist-induced and synaptic-evoked bursting in kindled animals.

In kindled rats, application of either 1S,3R-ACPD (100  $\mu$ M;  $n = 8$ ), or the group I agonist DHPG (20  $\mu$ M;  $n = 9$ ), induced bursting. Neither group II nor group III agonists [L-CCG-I (10  $\mu$ M) and L-AP4 (100  $\mu$ M)] produced bursting in any neuron tested ( $n = 4$ ), suggesting group I receptors participate in bursting. Superfusing either MCPG (500  $\mu$ M;  $n = 3$ ) or 4C3HPG (100-300  $\mu$ M;  $n = 5$ ) inhibited agonist-induced bursting. We also tested MCPG and 4C3HPG on bursting evoked by lateral amygdala (LA) stimulation. MCPG had no discernible effect on synaptic-evoked bursts ( $n = 3$ ). In contrast, 4C3HPG showed anticonvulsant efficacy in neurons from kindled animals: (i) The threshold stimulus intensity for bursting ( $7 \pm 0.6$  V) produces only EPSP ( $4 \pm 0.2$  mV) in the presence of 4C3HPG (300  $\mu$ M;  $n = 5$ ). Increasing stimulus intensity evokes spiking, similar to control neurons, but not bursting. (ii) Burst threshold is increased dose-dependently ( $\text{EC}_{50} \approx 350 \mu\text{M}$ ) by 4C3HPG [ $F(3,16) = 3.95$ ;  $P < 0.05$ ; ANOVA; control:  $7 \pm 0.5$  V; 300  $\mu$ M 4C3HPG:  $13 \pm 3$  V;  $p < 0.05$ ]. These data may suggest that the combined agonist/antagonist properties of 4C3HPG may be necessary to inhibit ictal-like burst activity. [Supported by NS24643].

## 239.8

**ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS IN THE RAT NUCLEUS ACCUMBENS INCREASES LOCOMOTOR ACTIVITY.**

L.-H. Kim\* and P. Vezina, Department of Psychiatry, The University of Chicago, Chicago, IL 60637.

The effect on locomotor activity of *in vivo* activation of metabotropic glutamate receptors in the nucleus accumbens (NAcc) was investigated in the rat. The selective metabotropic glutamate receptor agonist, (1S,3R)-1-aminocyclopentane-1,3-dicarboxylate (1S,3R-ACPD), was microinjected into the NAcc via chronically implanted bilateral guide cannula and locomotor activity was measured for two hours. Different groups of rats injected with one of four doses of (1S,3R)-ACPD (0.005, 0.05, 0.5, or 2.5 nmol/0.5  $\mu$ l/site) showed significant dose-dependent increases in both horizontal locomotion and rearing relative to control rats that received injections of the saline vehicle. In a manner similar to the locomotor effects produced by injection of amphetamine into the NAcc, increases in locomotor activity were observed predominantly in the initial 30 min of testing. During this period, the magnitude of the increases in horizontal locomotion and rearing produced by (1S,3R)-ACPD ranged from 15-40% and 34-73% above saline control levels, respectively. By comparison, injection into the NAcc of a 6.8 nmol (2.5  $\mu$ g)/side dose of amphetamine produced increases in horizontal locomotion and rearing that were 113% and 167% above saline control levels, respectively. These findings are consistent with microdialysis data reported by others indicating that (1S,3R)-ACPD given into the NAcc increases extracellular levels of dopamine in this site and suggest a potentially important role for metabotropic glutamate receptors in the NAcc in the production of locomotor activity. Supported by a grant to P.V. from The Brain Research Foundation.

## 239.9

METABOTROPIC GLUTAMATE AGONIST-INDUCED ROTATION MEDIATED BY GROUP I mGluRs. J. Feeley Kearney\* and R.L. Albin. Department of Neurology and Neuroscience Program, University of Michigan, and Ann Arbor VAMC GRECC, Ann Arbor, MI 48104-1687.

Metabotropic glutamate receptors (mGluRs) are a major class of excitatory amino acid receptors. Eight mGluR subtypes, coupled to a variety of effector systems, have been cloned. These receptors have been sub-classified into three groups based on amino acid sequence homology, pharmacology and effector systems.

The striatum possesses a high density of mGluR binding sites (Albin et al, 1992, Neurosci, 46: 35) and several mGluR mRNAs are expressed by basal ganglia neurons (Testa et al, 1994, J Neurosci, 14: 3005). In rats, unilateral intrastratial administration of the mGluR agonist 1-aminocyclopentane-1S,3R-dicarboxylic acid (ACPD) results in vigorous contralateral rotation with delayed onset (Sacaan et al, 1992, J Neurochem, 59: 245). We sought to determine the mGluR subtype(s) mediating this behavioral effect.

In rats, the group I mGluR agonist 3,5-dihydroxyphenylglycine (DHPG) induces contralateral rotation in a dose-dependent manner. In addition, it has greater potency than the non-selective mGluR agonist ACPD. Selective agonists for group II ((2S,3S,4S)-a-carboxycyclopropylglycine (L-CCG-III)) and group III (L-2-amino-4-phosphonobutyric acid (L-AP4)) mGluRs do not elicit any significant level of rotation at any of the doses administered.

Contralateral rotation induced by ACPD or DHPG was attenuated by the group I mGluR antagonists 1-aminoadant-1,5-dicarboxylic acid (AIDA) and a-methyl-4-carboxyphenylglycine (MCPG) (group I > group II) in a dose-dependent manner. Antagonists at group II ((R,S)-a-methyl-4-tetrazolylphenylglycine (MTPG)) and group III ((R,S)-a-methyl-4-phosphonophenylglycine (MPPG)) mGluRs had no effect on ACPD- or DHPG-induced rotation. Additionally, preliminary data indicates identical modulation of ACPD- or DHPG-induced rotation by dopaminergic and purinergic agents. These results suggest that mGluR-induced contralateral rotation is mediated by group I mGluRs.

METABOTROPIC GLUTAMATE RECEPTORS HAVE DIFFERENT EFFECTS IN DIFFERENT LAYERS OF CAT VISUAL CORTEX. N.W. Daw\* and S.N.M. Reid. Dept. of Ophthalmology, Yale Univ. Sch. of Med., New Haven, CT 06510.

A group of glutamate receptors, metabotropic glutamate receptors (mGluRs) are present in the visual cortex (Reid et al., J. Comp. Neurol. 355:470, 1995). In this study, single neurons were recorded in cat primary visual cortex, and the effect of iontophoresis of the mGluR agonist trans-(1S,3R)-1-amino-1,3-cyclopentenedicarboxylic acid (ACPD) was observed. In nearly all cases, ACPD reduced the visual response. The effect of ACPD on spontaneous activity, however, was variable. Increases were generally seen in infragranular layers (V and VI), and decreases in supragranular layers (II and III). The reduction in the visual response was also largest in supragranular layers. In a number of cases in layers II and III, both visual response and spontaneous activity were almost totally abolished. In a number of cases in layers V and VI, spontaneous activity was increased and visual response was reduced to provide a large decrease in signal/noise ratio. Thus, metabotropic glutamate receptors have both facilitatory and depressive effects in visual cortex, the effect depends on the layer of the cell recorded, and the effect on the visual response and spontaneous activity are sometimes opposite to each other. Supported by RO1 EY 00053.

DENDRITIC INTERACTIONS IN PERICOERULEAR REGIONS CONTRIBUTE THE SYNCHRONOUS ACTIVITY IN ADULT RAT LOCUS COERULEUS.

M. ISHIMATSU and J. T. WILLIAMS\* Vollum Institute, Oregon Health Sciences University, Portland, OR 97201-3098

The synchronous activity was studied in the locus coeruleus (LC) of the adult rat using an intracellular and extracellular recordings from horizontal brain slices. In tetraethylammonium chloride (TEA, 10 mM), BaCl<sub>2</sub> (1 mM) and tetrodotoxin (1 µM) containing krebs solution oscillations in membrane potential and spontaneous field potentials were synchronous throughout the nucleus. This activity was not dependent on synaptic transmission, but was abolished by carbenoxolone (100 µM) or intracellular acidification. These results suggest synchronous activity is due to the electrotonic coupling.

LC cells were labeled with the water soluble dye (Cy5) using microelectrodes and the slices were prepared for catecholamine fluorescence. The cell body region of the LC was indicated as catecholamine fluorescent area. Confocal microscopic studies showed Cy5 filled dendrites that extended in the rostral and caudal directions beyond the cell body region. Other slices were sectioned both at the rostral and the caudal poles of the LC in order to isolate cell body region. In sectioned slices synchronous activity was abolished or remarkably reduced. In addition, [Met<sup>5</sup>]-enkephalin (10 µM) induced current reversed the polarity at -116±4 mV (n=7) in these sectioned slices which was less negative than observed in normal slices (-140 mV). The results suggest the dendritic interactions in pericoerulear regions are the site at which electrotonic coupling occurs in adult rat LC. (Supported by NIH DA08163.)

## 240.3

RELATIONSHIP BETWEEN LOCUS COERULEUS NEURONAL ACTIVITY AND NOREPINEPHRINE RELEASE IN NEOCORTEX. C.W. Berridge\*, E.A. Abercrombie\*, R.T. Kuczenski\* and S.L. Foote\*. <sup>1</sup>Univ. Wisconsin, Madison, WI 53706; <sup>2</sup>Rutgers University, Newark, NJ 07102; <sup>3</sup>UCSD, La Jolla, CA 92093.

A major lacuna in understanding the neurobiology of the locus coeruleus (LC)-norepinephrine (NE) system is a lack of information concerning the relationship between LC discharge activity and rates of NE release. We have begun to examine this relationship utilizing a probe that combines electrophysiological recordings of LC neurons and local infusions of drugs to increase/decrease LC activity in halothane-anesthetized rat. *In vivo* microdialysis is used to assess NE release in the ipsilateral frontal cortex. The day following dialysis probe implant, animals are anesthetized and the recording/infusion assembly positioned with the electrode 200-300 µm below the dorsal border of LC and the infusion needle 200-500 µm lateral to LC. 90-120 min later, collection of 15-min baseline dialysis samples (approx. 2.5 pg/20 µl) and LC neuronal recordings are initiated. Initial observations are: 150nl infusions of the cholinergic agonist, bethanechol (0.5-2.0 ng/nl), increased LC discharge rates to a maximum of 100-1000% above basal levels (approx. 1.5Hz), recovering to baseline within 10-20 min. LC activation 60-200% above basal rates elicited approximately linear increases in NE in the first of two 5-min samples. Increases in LC activity beyond 200% did not elicit further NE increases. In the second 5-min sample, NE concentrations were proportional to the level of LC activation, except at extreme LC activation (800-1000%). This suggests that brief depletion of releasable NE does not contribute to the asymptotic NE response observed with moderate LC activation. Conversely, complete suppression of LC activity by local infusion of clonidine (150 nl; 0.1-1.0ng/nl) decreased NE levels to about 15%-30% of basal levels (approaching the 0.3-0.5 pg limit of detection). During the return of LC activity from clonidine-induced suppression, NE returned to basal levels at a faster rate than did LC activity, occasionally exceeding preinfusion levels. Supported by NSF (CWB).

ANALYSIS OF DISCHARGE CHARACTERISTICS OF LOCUS COERULEUS NEURONS DURING ACTIVATION BY DIVERSE NEUROCHEMICAL INPUTS. M.E. Page\* and E.D. Abercrombie. Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark, NJ 07102

Noradrenergic locus coeruleus (LC) neurons are activated by a wide variety of stimuli: from non-noxious sensory stimuli which elicit orienting responses, to intense stressors that can lead to depletion of norepinephrine in terminal fields. Activation of the LC occurs via multiple, neurochemically diverse afferents. Selective activation of distinct inputs to the LC may serve to confer response specificity as a function of the nature of the activating stimulus. For example, activation by an excitatory amino acid may result in a different profile of firing activity and biochemical responses of LC neurons as compared to activation by corticotropin-releasing factor (CRF). The present studies examined the effects of CRF and the  $\alpha_2$  antagonist, idazoxan on the discharge rate and pattern of LC neurons. Extracellular levels of norepinephrine (NE) also were monitored with *in vivo* microdialysis techniques. CRF administered locally in the LC (30 ng/60 nl) by pressure ejection resulted in a 105% increase in LC discharge rate and was associated with a 24% increase in the percentage of spikes occurring in burst-like mode. Activation of the LC by CRF was accompanied by a significant increase (70%) in extracellular NE efflux. Intravenous administration of idazoxan (1 µg/kg) resulted in a similar magnitude of increase (94%) in LC discharge rate. This activation was associated with a slight increase in burst-like firing of LC neurons (from 3% to 9%). Similarly, a 10 µM dose of idazoxan administered directly onto LC neurons increased firing rate by 34%, whereas no change in the percent of spikes occurring in bursts was detected with this level of activation. Studies are underway to determine if differences in the amount of NE released at the nerve terminal result from differing patterns of activation of LC neurons. Work supported by PHS MH10969 (mep) and a Charles and Joanna Busch research grant (eda).

## 240.4

PREFRONTAL CORTEX ACTIVATION POTENTLY EXCITES LOCUS COERULEUS (LC) NEURONS IN ANESTHETIZED RATS. E. Jodo<sup>1</sup> and G. Aston-Jones\*. Dept. of Psychiatry, Med Coll PA & Hahnemann Univ, Phila., PA 19102; <sup>1</sup>Dept. of Physiology, Fukushima Medical College, Fukushima, Japan.

We found that the medial prefrontal cortex (mPFC) projects to rostral ventromedial peri-LC zone densely populated with LC dendrites (Zhu & Aston-Jones, this meeting). To examine the possible influence of the mPFC on LC activity, electrical or chemical stimulation was applied to either the infralimbic/prelimbic area (PL) or the dorsolaterally adjacent anterior cingulate/rostromedial agranular field (Cg1/Pr2) of Paxinos & Watson) while recording impulse activity of individual LC neurons in anesthetized rats. Most electrical stimulation experiments were conducted in rats (N=32) with 6-hydroxydopamine-induced lesions of the ascending dorsal bundle (DB) of noradrenergic LC fibers to eliminate the possible influence of antidromically activated LC collaterals. Single pulse stimulation (1 mA, 0.3-0.5 msec) synaptically activated 16/56 LC cells for the PL region, and 12/15 LC neurons for the Cg1/Pr2 region. The median onset latency was 32 msec for PL stimulation, and 40 msec for Cg1/Pr2 stimulation. Train stimulation (20 Hz) synaptically activated more LC cells, 41/50 for the PL and 11/12 for the Cg1/Pr2. Weak inhibitory responses were found for 9/56 LC neurons with PL stimulation; no purely inhibitory responses were detected with Cg1/Pr2 stimulation. Chemical stimulation of the mPFC with L-glutamate (10-100 mM) or D,L-homocysteic acid (10 mM) typically produced phasic excitation, sometimes followed by long-lasting oscillatory activity (15/68 LC cells with PL stimulation, and 15/26 LC neurons with Fr2 stimulation). No LC cells exhibited purely inhibitory responses with chemical stimulation of any mPFC site. Lidocaine microinjection (2%, 180 or 300 nl) into the mPFC reduced LC firing rates in 7/19 cells for the PL, and 6/10 neurons for the Fr2; in no case did lidocaine in any the mPFC site activate an LC neuron. Though most of these experiments were conducted in halothane anesthetized rats, similar results were obtained in pentobarbital anesthetized rats. These results indicate that activation of the mPFC potentially excites LC neurons. Supported by PHS grants NS 24698 and DA 06214.

## 240.5

**THE MEDIAL PREFRONTAL CORTEX PROMINENTLY INNERVATES A PERI-LOCUS COERULEUS (LC) DENDRITIC ZONE IN RAT.** Y. Zhu\* and G. Aston-Jones, Dept. Psychiatry, Med Coll PA & Hahnemann Univ, Philadelphia, PA 19102.

We previously found that injections of retrograde tracer into the LC that incorporated peri-LC areas often yielded retrogradely labeled neurons in the medial prefrontal cortex (mPFC), whereas injections restricted to the LC nucleus proper did not produce labeled cortical cells. Here, we examined whether the mPFC innervates the rostral ventromedial peri-LC (pLCrvm) region that contains numerous dendrites of LC neurons. Focal injections of cholera toxin b subunit (CTb) into the pLCrvm produced numerous retrogradely labeled neurons throughout the mPFC. Topography was apparent in these connections: injections centered in the dorsal pLCrvm (focused between the LC and the IVth ventricle) produced neurons most numerous in the infralimbic/prelimbic and anterior cingulate cortices, whereas more ventral pLCrvm injections also produced marked labeling in the dorsolaterally adjacent rostromedial agranular field (rostral FR2 of Paxinos & Watson). Large injections into the pLCrvm also produced many labeled neurons in the orbital cortex. Injections of phaseolus vulgaris leucoagglutinin (PHA-L), biotinylated dextran amine (BDA) or wheat germ agglutinin-conjugated horseradish peroxidase into these mPFC sites confirmed these connections by yielding prominent retrogradely labeled fibers in the pLCrvm. Notably, these cortical injections also confirmed the near absence of innervation to the LC nucleus proper. Physiological experiments in a companion study (Jodo and Aston-Jones, this meeting) reveal that electrical or chemical activation of these mPFC areas potentially excite LC neurons, whereas lidocaine inactivation of these areas decreases LC activity. These results indicate that projections to the pLCrvm may contact distal LC dendrites and have strong functional effects on LC neurons; ultrastructural studies are needed to confirm this hypothesis. The potent influence of the mPFC on LC activity is compatible with the complex discharge properties that we observe in LC neurons in animals performing cognitive behavioral tasks (see Rajkowski et al., Kubiak et al., and Ivanova et al., this meeting). Supported by PHS grants NS 24698 and MH 55309.

## 240.7

**ALTERATIONS IN pH MAY MODULATE SUBTHRESHOLD RHYTHMIC OSCILLATIONS (SROs) AND SPONTANEOUS DISCHARGE IN LOCUS COERULEUS (LC) NEURONS.** A.Y. Iyanov\* and G. Aston-Jones, Dept. Psychiatry, Med. Coll. PA. & Hahnemann Univ., Philadelphia, PA 19102.

SROs are a prominent feature of LC neurons. We found that these oscillations (best observed in TTX plus Ba++) depend upon low-voltage activated Ca++ currents (Soc. Neurosci. Abstr., 1995, p. 633). Here, we report that [Na+]o and pH are also important determinants of SROs and spontaneous discharge in LC cells. Intracellular recordings were obtained from LC neurons in slices using sharp microelectrodes. Superfusion with low [Na+]o (25-50 mM) suppressed spontaneous discharge, hyperpolarized membrane potential and eliminated SROs (n=7 neurons). TTX also eliminated spontaneous discharge but did not hyperpolarize or eliminate SROs, nor did it prevent these effects of low Na+. We investigated whether TTX-independent actions of low Na+ may be due to changes in Na+/H+ exchanger activity with altered pH in LC neurons. Sodium propionate (10 or 25 mM; to decrease intracellular pH) suppressed spontaneous discharge and hyperpolarized LC neurons (n=5); Na+ propionate treatment also suppressed SROs and HVA (high-voltage activated) Ca++ spikes in TTX (1 µM) plus Ba++ (2 mM; n=3). This indicates that superfusion with low Na+ (which may decrease Na+/H+ exchanger activity) produces changes in LC neurons similar to intracellular acidification. In addition, NH4Cl (10 mM; to increase intracellular pH) increased spontaneous discharge and the frequency of SROs observed in TTX plus Ba++. The amplitude and frequency of SROs and HVA Ca++ spikes (in TTX plus Ba++) were also increased in 60 mM NaHCO3 (pH adjusted to 7.3; to increase intracellular pH; n=3). However, the same solution with pH 7.9 (intracellular alkalization also expected; n=4) hyperpolarized LC neurons and blocked spontaneous discharge and SROs. The hyperpolarization evoked in LC neurons by raising extracellular pH was substantially suppressed in the presence of TTX plus Ba++ but HVA Ca++ spikes and SROs were not restored (n=4). These data indicate that SROs and spontaneous discharge in LC neurons may be modulated by Na+/H+ exchanger activity and pH. Supported by PHS grants NS 24698 and DA 06214.

## 240.9

**NEURONAL RESPONSE TO NOREPINEPHRINE IS DETERMINED BY CELL'S LOCATION RELATIVE TO BARREL COLUMN WITHIN RAT SOMATOSENSORY CORTEX.** D.T. Fleischer\* and B.D. Waterhouse, Dept. of Neurobiology & Anatomy, MCP/Hahnemann University, Philadelphia, PA 19102-1102.

Norepinephrine (NE)-containing axons from locus coeruleus innervate multiple sensory circuits throughout the mammalian CNS. It has been proposed that this widespread projection system facilitates sensory signal transmission during arousal and vigilance. Previous studies from this laboratory and elsewhere have examined the effects of NE on extracellularly recorded response properties of cells in primary sensory circuits. The goal of the present study was to categorize NE's effects on intrinsic membrane properties of electrophysiologically and morphologically identified pyramidal neurons in layer II/III of the barrel field of rat somatosensory cortex. Intracellular recordings were obtained from neurons in cortical tissue slices maintained *in vitro*. Intrinsic membrane properties of individual cells were measured under current clamp conditions using glass microelectrodes filled with 2M KAc plus 1% neurobiotin. NE was bath applied at doses up to 10 µM. After each experiment recorded cells were labeled with neurobiotin for morphologic identification. The tissue was then stained using cytochrome oxidase histochemistry to confirm each cell's location within a barrel column. Based upon previously established criteria all recorded layer II/III neurons were identified as regular spiking with pyramidal morphology. In the presence of NE at 1-10 µM, neurons which were located at the periphery of a barrel column showed an increase in input resistance and decrease in rheobase, whereas cells located within the center of a barrel column showed a decrease in input resistance and an increase in rheobase. Thus, NE appears capable of eliciting distinctly different changes in neuronal excitability depending upon the cell's location with respect to the center or periphery of a barrel column. These findings raise the possibility that the manner in which NE modulates neuronal excitability is correlated with the location of a cell relative to well defined, functionally-related cytoarchitectonic landmarks. Finally, our data support an emerging concept that endogenously released NE can selectively modulate specific neural components of sensory cortical networks.

## 240.6

**ELECTRICAL STIMULATION OF THE LOCUS COERULEUS (LC): EFFECT OF FREQUENCY AND PATTERN OF DISCHARGE ON EXTRACELLULAR NOREPINEPHRINE (NE) RELEASE IN THE PREFRONTAL CORTEX (PFC).** S.M. Florin-Lechner\*, J.P. Druhan, G. Aston-Jones and R.J. Valentino, Dept. Psychiatry, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19102.

Evidence suggests that stimuli that activate the brain noradrenergic nucleus locus coeruleus (LC) will facilitate cortical processing of stimulus-related information by targets via synaptically-released norepinephrine (NE). The present study was designed to examine the relationship between frequency and pattern of LC activation and NE release in the medial prefrontal cortex (PFC), a target of LC projections. The LC was electrically stimulated (700 µA, 0.2 ms pulses) at varying frequencies for 20 min and extracellular NE levels were measured in the medial PFC of halothane-anesthetized rats using *in vivo* microdialysis. Tonic electrical stimulation of the LC increased cortical NE levels in a frequency-dependent manner, with 3 Hz stimulation having little effect and 5 and 10 Hz stimulation increasing NE levels by  $48 \pm 4\%$  and  $66 \pm 22\%$ , respectively. The LC was also phasically stimulated with bursts of pulses every 4 s designed to deliver the same number of stimuli in a 20 min period as delivered by tonic stimulation at 3 Hz (12 pulses at 24 Hz) or 10 Hz (40 pulses at 80 Hz). Norepinephrine levels were significantly higher with 24 Hz burst stimulation compared to 3 Hz tonic stimulation. In contrast, 80 Hz burst stimulation was no more effective than 10 Hz stimulation. The present results indicate that both frequency and pattern of LC discharge are determinants of NE terminal release. Additionally, bursts of LC activity may be more effective in increasing terminal NE release than tonic increases in activity. Supported by the Human Frontiers Science Program (RG-16-93) and PHS Grants MH40008, MH00840 and DA06214.

## 240.8

**OPIATE WITHDRAWAL-INDUCED HYPERACTIVITY IN LOCUS COERULEUS (LC): MEDIATION BY SUBREGIONS OF THE ROSTRAL VENTRAL MEDULLA.** H. Hirata\* and G. Aston-Jones, Dept. Psychiatry, Hahnemann Univ., Philadelphia, PA 19102.

LC neuronal hyperactivity during opiate withdrawal (OW) is thought to underlie many withdrawal symptoms. Previous work indicates that this LC hyperactivity is in large part mediated by excitatory amino acid inputs to the LC from the nucleus paragigantocellularis lateralis (PGi) in the rostral ventral medulla. We have previously found that neurons projecting to the LC are widely scattered throughout the PGi region. The purpose of this study was to identify subregions of the PGi that are responsible for OW-induced LC hyperactivity. Extracellular recordings were obtained from individual LC neurons in halothane-anesthetized rats that were chronically pretreated with morphine (osmotic minipump; ~34 mg/kg/day s.c., 6 days). OW precipitated by intravenous naloxone HCl (NLX; 0.1 mg/kg) produced strong activation in all LC neurons recorded (~4-fold increase in firing rate). When the discharge rate stabilized (~3-5 min after NLX), lidocaine (2%; 250-300 nL) was microinfused over 1-2 min into a PGi region from a glass micropipette (~20 µm tip) using pneumatic pressure (Picospritzer). Of 10 cells examined, 4 exhibited ~20-40% reduction of OW-induced activity after lidocaine infusion into the PGi. Preliminary histological results indicate that PGi areas where lidocaine attenuated OW-induced hyperactivity in LC are more rostral than those where lidocaine yielded little or no change in LC hyperactivity. We have also previously reported that lidocaine in the PGi can attenuate LC response to footshock stimulation (Chiang and Aston-Jones, Neuroscience, 1993). Here, we found in 2 cases that lidocaine microinfused into caudal PGi sites attenuated footshock responses of LC neurons but did not appreciably decrease OW-induced hyperactivity in LC cells. The present results indicate that specific subregions of the PGi may be responsible for OW-induced vs. footshock-induced activation of LC neurons. Supported by PHS grants DA 06214 and NS 24698.

## 240.10

**EFFECT OF INCREASING TONIC LEVELS OF NOREPINEPHRINE ON GLUTAMATE EVOKED DISCHARGE OF SINGLE NEURONS IN LAYERS II/III AND V OF RAT BARREL FIELD CORTEX.** D. M. Devilbiss and B. D. Waterhouse\*, Dept. Neurobiology and Anatomy, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19102

Recent microdialysis studies support the widely accepted view that forebrain levels of norepinephrine (NE) fluctuate as tonic output from the nucleus locus coeruleus changes. Previous studies from our laboratory and elsewhere have employed a variety of strategies to assess the potential impact of synaptically released NE on the responsiveness of target neurons to synaptic inputs. The goal of the present study was twofold: (1) to assess the effects of different tonic levels of NE on glutamate (GLU) evoked discharge of cortical neurons and (2) to clarify the results of earlier studies which showed, that depending on the neuron recorded and the dose of NE, both facilitation and suppression of stimulus evoked discharge could be observed. To this end we utilized an *in vitro* cortical tissue slice preparation to identify possible laminar differences, pre- versus postsynaptic effects, and iontophoretic dose dependence of NE's modulatory influence on GLU evoked discharge in rat barrel field somatosensory cortical neurons. Extracellular responses to iontophoretically applied GLU were recorded from neurons in layers II/III and V of the barrel field cortex before, during and after incremental microiontophoretic doses of NE (1-50nA). For each neuron recorded peri-event histograms were quantitatively analyzed in order to determine iontophoretic dose response relationships. Our results showed that for neurons in both layers II/III and V there were two possible modes of interaction between NE and GLU evoked discharge: (1) suppression of GLU evoked response at all doses of NE tested and (2) an "inverted U" dose response relationship, such that GLU evoked responses were progressively facilitated to an optimum as NE levels were increased and then progressively suppressed as NE levels were increased further. We also noted that in the same cell minimal responses to GLU were modulated (ie. facilitated or suppressed) by NE more than maximal responses. A similar set of findings were observed in aCSF containing low Ca<sup>2+</sup> and high Mg<sup>2+</sup>. This latter result suggests that neither the facilitating nor the suppressant effects of NE on GLU evoked discharge rely upon presynaptic mechanisms. In summary, the demonstration that NE can either facilitate or suppress cortical neuron responsiveness emphasizes the intrinsic heterogeneity of cortical neurons with respect to noradrenergic modulatory actions. More importantly, these results suggest that under ideal conditions modulatory interactions between NE and GLU can be optimized. Finally, we believe it is particularly significant that our finding of an "inverted U" dose response relationship between NE and GLU evoked discharge parallels the results of Aston-Jones and colleagues who have described an "inverted U" relationship between tonic rates of locus coeruleus neuron discharge and primate performance on a sustained attention task. Supported by NINDS NS32461 and DA05117 to BDW.

## 240.11

**INNERVATION OF THE NUCLEUS ACCUMBENS SHELL AND VENTRAL TEGMENTAL AREA BY DOPAMINE BETA-HYDROXYLASE-POSITIVE FIBERS: POSSIBLE SITES FOR NOREPINEPHRINE-DOPAMINE INTERACTIONS.** A. Saleem\*, Y. Zhu, J. Druhan and G. Aston-Jones. Dept. Psychiatry, Med Coll PA & Hahnemann Univ., Phila, PA 19102.

Several lines of evidence indicate that norepinephrine (NE) brain systems may influence functions associated with nucleus accumbens dopamine (DA). However, the site(s) for such interactions have not been identified. We undertook anatomical studies to determine whether NE fibers innervate the nucleus accumbens or the ventral tegmental area (VTA) which contains DA neurons that innervate the accumbens. Sections of rat VTA and nucleus accumbens were stained with an antibody to dopamine beta-hydroxylase (DBH) to identify NE-containing fibers. Using dual immunohistochemistry, the VTA sections were also stained for tyrosine hydroxylase (TH) to identify DA neurons and processes, and the sections through the nucleus accumbens were also stained with an antibody against substance P to identify accumbal boundaries. In the VTA, we found moderate densities of DBH+ fibers in dorsocaudal regions that also contained DA somata and dendrites. Numerous DBH+ fibers were also present in the medial shell of the nucleus accumbens. Large injections of Fluoro-Gold into the shell of the accumbens produced retrogradely labeled NE neurons in the locus coeruleus; more focal injections with other tracers are needed to confirm this result. Injections of the anterograde tracers Phaseolus vulgaris leucoagglutinin (PHA-L) or biotinylated dextran amine (BDA) into the LC produced anterogradely labeled fibers in the same VTA regions as contained DBH+ fibers; source(s) of DBH in the accumbens are less certain. These findings indicate that both the VTA and nucleus accumbens shell are possible sites for NE-DA interactions. Such interactions could be important for regulation of motivated behaviors and in drug abuse. Supported by PHS grants DA 06214 and DA 10088.

## 240.13

**Localization of  $\beta$ -Adrenergic Receptor Responses and Tyrosine Hydroxylase Positive Fibers in the Deep Cerebellar Nuclei of F344 Rats.** Thomas J. Gould<sup>1</sup>, Cathy E. Adams<sup>2</sup> & Paula C. Bickford<sup>1,3</sup>. <sup>1</sup>Dept. of Vet. Affairs Med. Ctr., Denver CO; <sup>2</sup>Dept of Psychiatry; <sup>3</sup>Dept of Pharm. Univ. Colorado, Health Sciences Center, Denver, Colorado 80262.

Norepinephrine (NE) is a neurotransmitter that also acts as a neuromodulator. At levels subthreshold for producing depression of spontaneous firing, NE can facilitate excitatory or inhibitory neurotransmission. Whereas a significant body of work has examined cerebellar cortex and noradrenergic function (Bloom, 1979), little work has examined NE pharmacological function in the deep cerebellar nuclei (DCN). The presence of norepinephrine (NE) and NE activated cells in the deep cerebellar nuclei (DCN) of male F344 rats was investigated using electrophysiology during iontophoresis of the  $\beta$ -adrenergic agonist isoproterenol (ISO) and using immunohistochemistry. During extracellular electrophysiology, GABA was iontophoretically applied to the cell and ISO was then co-applied to in an attempt to modulate the GABAergic inhibition of cell firing in the DCN. Immunohistochemistry was used to detect tyrosine hydroxylase (TH) positive fibers in the DCN. Isoproterenol modulated GABAergic inhibition in 51% of the DCN tested. In addition, TH-positive fibers that appeared to make contact with DCN cells were found. Thus, this study demonstrated that functional NE receptors exist in the DCN and NE appears to be present in fibers in the DCN. This work was supported by USPHS grant AG04418, grant AG05686-01 and the VAMRS.

## 240.15

**AN ELECTROPHYSIOLOGIC APPROACH TO THE STUDY OF THYROID HORMONE (TH) ACTION IN BRAIN: MEASUREMENTS OF UNIT ACTIVITY IN BRAIN SLICES.** M.B. Dratman\*, D. W. Pfaff, and L.-M. Kow. Laboratory of Neurobiology and Behavior, Rockefeller University, New York, NY 10021

Previous studies (Rozanov and Dratman, Neuroscience, IN PRESS) have demonstrated that triiodothyronine (T<sub>3</sub>) is strongly localized in locus coeruleus and its projection sites, including molecular and pyramidal cell layers (PC) of hippocampus (Hi). To search for functional correlates of the morphologic observations in Hi, unit activities (basal firing rates and responses to test substances) recorded from PC-CA1 of euthyroid (EU) or hypothyroid (HYPO) rats were measured during perfusion of brain slices with ACSF  $\pm$  norepinephrine (NE), TH, NE+TH or their diluents. TH-induced effects were small and, as observed against the dynamic background of unit activity, were subtle. These preliminary results were graded and subjected to analysis by the ordered chi-square test for trend. Firing rate changes after NE, judged as +4 to -2, were significantly greater ( $p=0.002$ ) in EU (median=4) than in HYPO (median=1). Surprisingly, the effects of T<sub>3</sub> and thyroxine (T<sub>4</sub>) were different; T<sub>3</sub> increased and T<sub>4</sub> decreased both basal and NE-induced firing rates ( $p=0.05$  and  $0.002$  respectively). Dampened PC-CA1 unit activity after NE in HYPO, may reflect down-regulation of adrenergic receptors during low TH states. While opposite effects of T<sub>3</sub> and T<sub>4</sub> were unexpected, they conform with known homeostatic adjustments of TH metabolism in brain (Dratman, et al, Am. J. Physiol., E185-193, 1983). The rapid time course of response to TH makes it unlikely that genomic mechanisms account for its effects on basal and NE-induced firing rates. Instead, both functional and morphologic observations are consistent with mediation through synaptic (adrenergic?) membrane receptors. Support from MH45252 and Pat Kind Fund for Thyroid Research

## 240.12

**DISTRIBUTION OF DOPAMINE- $\beta$ -HYDROXYLASE (DBH)-LIKE IMMUNOREACTIVE FIBERS WITHIN THE NUCLEUS ACCUMBENS SHELL.** A.E. Kelley<sup>1</sup>, T.R. Stratford<sup>1</sup>, S.L. Foote<sup>2</sup>, and C.W. Berridge<sup>3</sup>. <sup>1</sup>Psychiatry Dept., <sup>2</sup>Psychology Dept., Univ. Wisconsin, Madison, WI 53706, <sup>3</sup>Psychiatry Dept., Univ. California, San Diego, La Jolla, CA 92093.

The nucleus accumbens can be divided into distinct subfields, delineated on the basis of afferent and efferent projections, as well as on histochemical markers. Much attention has been focused on the functions of the "shell" subregion, which has reciprocal relationships with a variety of limbic regions and brainstem autonomic structures, and has been suggested to participate in the modulation of stress- and arousal-related processes. The locus coeruleus-noradrenergic system has also been implicated in stress and arousal. Previous tracing studies suggest that the locus coeruleus projects to the accumbens shell. To better understand the anatomical substrate through which LC could influence activity of the accumbens shell, the extent and distribution of noradrenergic innervation within this structure was examined. Sections of rat brain from the rostral accumbens through the bed nucleus of the stria terminalis were processed for DBH immunoreactivity, to visualize noradrenergic axons. In some animals, alternate sections were processed for immunohistochemical localization of substance-P, in order to delineate core, shell, and pallidal compartments. Moderate to dense DBH-like immunoreactivity (DBHir) was found in the approximately posterior one-third of the shell, particularly in the septal pole and ventral shell. The innervation of the septal pole was contiguous with a dense innervation of the bed nucleus of the stria terminalis. Very few fibers were observed in the rostral accumbens, core, or caudate-putamen. Many DBHir fibers were of small caliber with numerous varicosities, features indicative of terminal fields. These observations suggest noradrenergic systems might modulate processes associated with stress, behavioral state, or reinforcement via actions within the accumbens shell. **FISCHER AND LEWIS RATS EXHIBIT DIFFERENTIAL BEHAVIORAL AND NORADRENERGIC RESPONSES TO STRESS AND AMPHETAMINE CHALLENGE.** L.A. Rosario\* and E.D. Abercrombie. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Fischer (F344) and Lewis (LEW) rats show differential behavioral and physiological responses to stress, i.e., F344 rats are hyper-responsive while LEW rats are hypo-responsive in their locomotor activity (LA), ACTH, and corticosterone responses to stressful stimuli. The locus coeruleus (LC), which may underlie differences in behavioral reactivity, plays a role in stress and arousal. This study investigates the locomotor and noradrenergic responses to stress or amphetamine (AMPH) in these strains and examines the LC as a substrate underlying differential behavioral reactivity. LA was measured in the home cage during the light/dark cycle, in response to tail pinch stress (TP), AMPH (1 mg/kg or 5 mg/kg) challenge and novelty stress. LA increases with the onset of the dark phase in F344 and LEW rats ( $p<0.0001$ ); this increase is greater in F344 rats ( $p<0.006$ ). Similarly, the initial LA in response to novelty is greater in F344 rats ( $p<0.0003$ ). TP-induced LA is not different between the groups. Administration of AMPH increases LA in both strains. Low dose AMPH (1.0 mg/kg) induces greater LA in F344 rats ( $p<0.0011$ ) whereas at the higher dose (AMPH 5.0 mg/kg) there is no statistical difference between the groups. *In vivo* microdialysis was used to measure hippocampal NE and DOPAC efflux in F344 and LEW rats in response to TP or AMPH (1.0 mg/kg). Extracellular NE levels are an indicator of the evoked responsiveness of the LC-NE system whereas DOPAC efflux serves as an indirect index of tyrosine hydroxylation. TP increases NE release in both strains ( $p<0.03$ ); this increase is greater in the F344 rats ( $p<0.0006$ ). Similarly, AMPH-induced NE release is greater in F344 rats ( $p<0.002$ ). TP or AMPH injection increases DOPAC efflux only in the F344 rats ( $p<0.0003$ ). In summary, LA in F344 rats is greater than LEW rats during arousal and/or mild stress. Also, F344 rats exhibit a potentiated noradrenergic response to TP stress and AMPH challenge compared to LEW rats. Increased hippocampal DOPAC efflux in F344 rats suggest differences in tyrosine hydroxylation may contribute to the differential noradrenergic profile observed in these rats. **EFFECTS OF 2 WEEK AND 8 WEEK HIGH SALT DIET ON NOREPINEPHRINE CONTENT IN DISCRETE BRAIN NUCLEI OF BORDERLINE HYPERTENSIVE RATS (BHR).** I.P. Edgemon, R. Finkel, G.-P. Zheng, N.E. Dobson, and J.E. Lawler\*. Department of Psychology, University of Tennessee, Knoxville, TN 37996-0900.

The BHR has a mixed genetic history for developing hypertension when exposed to environmental stressors. Previous research in our laboratory has established that chronic stress alone or combined with salt or exercise affects norepinephrine (NE) content of hypothalamic and brainstem nuclei associated with cardiovascular regulation in BHR. While varying durations of high salt diet have been shown to alter blood pressure levels in animals with genetic histories for hypertension, less is known about the effects of salt alone on the NE content of discrete brain centers. The purpose of this study was to investigate the effects of varying durations of high salt diet on NE content of brainstem (A2, A1, C1, LC) and hypothalamic (PH, Arc, DMH, LH, VMH, PVH, Ant, SO) nuclei of BHR and their normotensive parent strain, Wistar-Kyoto rats (WKY). Male BHR and WKY remained on either normal (1%) or high (8%) salt chow for 2 or 8 weeks such that the diets were completed at 12 weeks of age. Following sacrifice, the brains were removed and sliced, and nuclei were extracted using the Palkovits technique. NE content was later determined using liquid chromatography and electrochemical detection. Results indicated that: 1) both high salt diets elevated NE content in many brainstem and hypothalamic nuclei of BHR and WKY; 2) the distribution of nuclei affected within rat strains was different based on the brain region and diet duration; and 3) 2 week high salt diets produced elevations, while 8 week diets produced reductions, in NE content of BHR nuclei compared to WKY. Data are consistent with the hypothesis that BHR lack sufficient central noradrenergic inhibition to counteract the hypertensive effects of a chronic high salt diet. (AHA-TN Affiliate)

$\alpha_2$  ADRENERGIC RECEPTORS (ARS) REDUCE AND  $\beta$  ARS POTENTIATE SYNAPTIC TRANSMISSION BETWEEN THE ENTORHINAL CORTEX AND THE RAT BASOLATERAL AMYGDALA. E. Pralong, M. Kiraly\*, P.J. Magistretti and B. Ferry. Laboratoire de recherche neurologique, CHUV et Institut de Physiologie, Université de Lausanne, Suisse.

Horizontal rat brain slices preserving the synaptic connections between the basolateral amygdala (BLA), the external capsule (eca) and the entorhinal cortex (EC) were used to record synaptic responses in 156 (BLA) neurones to either EC, eca or direct BLA stimulations. Comparison of the time-to-peak latencies for the fast excitatory postsynaptic potentials (EPSPs) evoked by stimulation of the EC, eca or BLA (13.3, 7.9 or 7.2 ms respectively) suggests that the EC-BLA connections are mostly mono or oligosynaptic. Individual components of the post-synaptic potentials evoked by direct BLA stimulation were pharmacologically isolated using CNQX, d-AP5 and bicuculline methiodide. NA reduced the fast EPSPs by ~40 % and the slow EPSP by ~50 %. A similar effect was obtained with the  $\alpha_2$  agonist UK 14,304. In contrast, the  $\beta$  agonist isoproterenol increased the fast EPSP by ~40 % and the slow EPSP by ~20 %. Accordingly, the effect of NA on the EPSPs was blocked only by the  $\alpha_2$  antagonist yohimbine. NA was ineffective on the isolated IPSPs, the fast and slow IPSPs being reduced by ~5 and ~10 % respectively. These results suggest NA action on the excitatory transmission can be dissected into a predominant  $\alpha_2$  AR-mediated inhibition and a  $\beta$  AR-mediated excitation.

REGULATION OF [ $^3$ H]NOREPINEPHRINE ([ $^3$ H]NE) RELEASE FROM GUINEA PIG HIPPOCAMPAL SLICES BY SIGMA $_2$  ( $\sigma_2$ ) RECEPTORS. J.K. Weatherspoon\*, T.I. Netoff, G.M. Gonzalez-Alvarez and L.L. Werling. Dept. of Pharmacology, The George Washington University Medical Center, Washington, DC 20037.

We have shown that  $\sigma$  receptors regulate NMDA-stimulated [ $^3$ H]NE release from slices of rat hippocampus (HIPP) (Gonzalez-Alvarez and Werling, Brain Res. 673: 61-69, 1995). Although a significant portion of regulation of release appeared to be via a  $\sigma_2$  receptor, we had no  $\sigma_2$ -selective drugs with which to confirm this hypothesis. In the current study, we tested  $\sigma$  regulation of NE release in slices of guinea pig HIPP, a tissue in which a larger percentage of inhibition appeared to be via  $\sigma_2$  receptors. We employed the  $\sigma_2$  ligand BIMU-8, whose binding profile had been determined, but whose agonist/antagonist status at  $\sigma_2$  receptors had not been identified. We tested the  $\sigma$  agonists (+)pentazocine (500 nM - 5  $\mu$ M) and BD737 (0.1 nM - 100 nM), both alone and in the presence of the  $\sigma_1$ -selective antagonist Dup734 (100 nM), or BIMU-8 (100 nM). (+)Pentazocine (500 nM - 5  $\mu$ M) alone inhibited NMDA-stimulated release. When the  $\sigma_1$  component of (+)pentazocine inhibition was blocked by inclusion of Dup734, BIMU-8 fully reversed the remaining inhibition produced by (+)pentazocine. BIMU-8 alone had no effect on basal or NMDA-stimulated release. The inhibition mediated by BD737 was not significantly reversed by Dup734, suggesting the inhibition mediated by BD737 in HIPP includes another component. BIMU-8 did not reverse inhibition of release by low concentrations of BD737 (chosen to selectively activate  $\sigma_1$  receptors). We are currently testing BIMU-8 against higher concentrations of BD737 that should also activate  $\sigma_2$  receptors. Our results suggest that (1) BIMU-8 is an antagonist at  $\sigma_2$  receptors and that (2)  $\sigma_2$  receptors contribute to regulation of NE release in HIPP. Supported by NIDA.

## SEROTONIN: TRYPTOPHAN HYDROXYLASE

## 241.1

CELLULAR LOCALIZATION OF TRYPTOPHAN HYDROXYLASE mRNA IN POSTMORTEM HUMAN BRAINSTEM AND PINEAL GLAND. M.C. Austin\*, S.M. O'Donnell, J.L. Rhodes. Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA 15213.

Tryptophan hydroxylase (TPH) is the rate-limiting enzyme involved in the biosynthesis of serotonin. Recent studies have documented that the human TPH gene exhibits an unusual splicing complexity in the 5'-untranslated region which produces four distinct mRNA transcripts (Boularand et al. 1995). Although TPH mRNA has been visualized in raphe neurons in the rodent and monkey brain (Kim et al. 1991; Pecins-Thompson et al. 1995), there have been no reports documenting the cellular localization of TPH mRNA in postmortem human brain. The present study was designed to characterize the cellular distribution of TPH mRNA in the human brainstem and to compare the level of mRNA expression to that in the pineal gland. Postmortem human brain tissue (N=5) was obtained at autopsy, dissected and frozen. All cases had negative toxicological results and no known neurologic or psychiatric disorders. A 345 bp TPH cDNA fragment was amplified from human pineal RNA using oligo primers and RT-PCR. The cDNA fragment was then inserted into a pDIRECT vector (Clontech). Coronal tissue sections (20  $\mu$ m) of the brainstem and pineal were thaw-mounted on gelatin-coated slides and processed for *in situ* hybridization using  $^{35}$ S-labeled cRNA probes. Abundant hybridization signal corresponding to TPH mRNA was localized to neurons in the median and dorsal raphe as well as in the oral pontine and supramedian nuclei. Hybridized sections of the human pineal gland revealed very high levels of TPH mRNA in pinealocytes. It was evident from both the film and emulsion autoradiograms that TPH mRNA levels were much higher in the pineal tissue compared to the raphe, an observation which has been previously documented in rodents. These findings reveal the cellular localization of TPH mRNA in the human pineal gland and in serotonergic neurons of the brainstem. Understanding the nature of TPH gene expression in the human brain may provide new insights into the pathophysiological mechanisms underlying serotonergic dysfunction in neuropsychiatric disorders. ## 241.3

AMINO TERMINAL PHOSPHORYLATION OF TRYPTOPHAN HYDROXYLASE S.C. Kumer\*, S.M. Mockus, and K.E. Vrana. Dept. Of Physiology and Pharmacology, Bowman Gray Sch. of Med., Medical Center Blvd., Winston-Salem, NC 27157-1083.

Tryptophan hydroxylase (TPH) catalyzes the rate-limiting and committed step in serotonin biosynthesis. Within this enzyme, two distinct domains have been hypothesized to exist: an amino terminal regulatory domain and a carboxyl terminal catalytic domain. In the present experiments, the functional boundary between the putative domains was defined utilizing deletion mutagenesis. A full-length cDNA clone for rabbit TPH was engineered for expression in bacteria. Amino terminal deletions were constructed using polymerase chain reaction (PCR). Five amino terminal deletions were created:  $\Delta$ N50,  $\Delta$ N60,  $\Delta$ N90,  $\Delta$ N106, and  $\Delta$ N116 (referring to the number of amino acids deleted from the amino terminus). Enzymatic activity was determined for each mutant following expression in bacteria. Specific activities for  $\Delta$ N50,  $\Delta$ N60,  $\Delta$ N90, and  $\Delta$ N106 were comparable to the wild type recombinant TPH enzyme. Deletion of 116 amino acids, however, abolished activity. As a corollary, the ability to phosphorylate TPH using cAMP-dependent protein kinase (PKA) was also examined. Deletion of the first 60 amino terminal residues abolished the ability of the enzyme to serve as a substrate for PKA, yet the unmodified and the  $\Delta$ N50 constructs maintained phosphorylation. In conclusion, we believe that the first 106 amino acids compose a regulatory domain which is modified at a consensus sequence for phosphorylation by PKA between amino acids 50 and 60. Moreover, this postulated regulatory-catalytic domain boundary is analogous to the similar domain structure in the related enzyme tyrosine hydroxylase. ## 241.2

INCREASED LEVELS OF AROMATIC-L-AMINO ACID DECARBOXYLASE PROTEIN AND mRNA IN HUMAN CARCINOID TUMORS. J.A. Gilbert\*, L.M. Frederick, and M.M. Ames. Div. of Oncology Res., Mayo Clinic & Foundation, Rochester, MN 55905

The carcinoid tumor is an uncommon neuroendocrine malignancy whose primary characteristic is excessive production of serotonin (5-HT), synthesized by conversion of tryptophan (trp) to 5-OH-tryptophan (5-OH-trp) by trp hydroxylase (TPH) and decarboxylation of 5-OH-trp to 5-HT by aromatic-L-amino acid decarboxylase (AAAD). As a preliminary step to developing mechanism-based agents selective against carcinoid tumors, we characterized these enzymes in patient sets of carcinoid hepatic metastases and surrounding normal liver. Carcinoid AAAD, while similar in substrate affinity to AAAD from normal liver, had a 50-fold higher maximal activity. Western immunoblot analyses of the same matched sets indicated that the AAAD polypeptide content of carcinoid tumor was >20-fold that of normal liver. Preliminary Western analyses of patient sets of primary ileal carcinoid tumors and adjacent normal ileum samples indicated a similarly high ratio of carcinoid:normal AAAD protein. Northern blot analyses were performed on total RNA or mRNA isolated from matching carcinoid hepatic metastases and normal liver samples. Blots were sequentially probed with a synthetic 40-mer complementary to the mRNA coding region of human AAAD and a commercially available, 1.0-kb human glyceraldehyde-3-phosphate dehydrogenase cDNA fragment. A higher level of AAAD mRNA was detected in carcinoid tumor than in normal liver. These results suggested that increased levels of carcinoid AAAD protein existed in both primary and metastatic lesions, and that increased levels of carcinoid AAAD mRNA, as determined in matched sets of hepatic carcinoid and normal samples, may be a primary contributing factor. Supported in part by grant CA 58450, NCI, DHHS.

## 241.4

SALT-INDUCED ACTIVATION OF MIDBRAIN SEROTONERGIC NEURONS: ASSESSMENT OF cFOS, TPH, 5HT, AND 5HIAA CONTENTS BY QUANTITATIVE RADIOIMMUNOCYTOCHEMISTRY, IMMUNOBLOT, AND HPLC. S.D. Doughman, J.A. Saydoff\*, J. Spangenberg, and M.S. Brownfield. Dept. of Comp Biosci, Univ of Wisconsin, Madison, WI 53706 and INCSTAR Corp, Stillwater, MN 55082.

Brain serotonin (5HT) stimulates the secretion of vasopressin (VP) and oxytocin (OT) and plays a role in the osmoregulation of these neurohormones in conscious rats. These studies were designed to determine the location of salt activated 5HT neurons. Rats were given 2% sodium chloride to drink for 2 days as an osmotic stimulus. Control rats drank tap water. Single and dual label immunocytochemical (ICC) and radioimmunochemical (RICC) studies were done on brains fixed by perfusion with 4% paraformaldehyde. RICC studies employed antisera against tryptophan hydroxylase (TPH, rate limiting enzyme in the synthesis of 5HT), and 5HT and 5HIAA (serotonin metabolite). Serial cryostat sections were incubated with appropriately diluted antibodies, washed and incubated with 125-I labeled recombinant protein A/G (Pierce), washed and exposed to 3H-Ultrafilim. Immunoblots (using chemiluminescent detection) and high performance liquid chromatography were done on extracts of unfixed brains. Labeled section and immunoblot images on film were quantified by computer densitometry (MCID).

Routine ICC revealed salt-induction of cFOS immunoreactivity in VP and OT cells and in the dorsal (DR) and median (MR) raphe nuclei. Hindbrain 5HT cell groups were not labeled. Dual label ICC studies verified that most cFOS labeled cells were 5HT positive. RICC studies showed significant reductions of TPH and 5HT and an increase in 5HIAA content in the DR and MR, but no change in raphe pontis (RP). Quantitative immunoblots for TPH and HPLC for 5HT and 5HIAA showed similar changes in the midbrain and no change in pontine or medullary hindbrain content of these substances.

These studies show that salt loading induces a selective activation of midbrain 5HT nuclei, but does not affect pontine or medullary serotonergic sites. These studies also show the utility of these approaches for establishing sites of activation of the serotonergic system. Supported by American Heart Association Grant No 94016290 to MSB.

## 241.5

**CHANGES IN TRYPTOPHAN HYDROXYLASE (TPH) mRNA EXPRESSION IN THE DORSAL RAPHE NUCLEUS FOLLOWING LESION OF THE DORSOLATERAL HYPOTHALAMUS (DLH) IN THE RAT.** V. Ljubic-Thibault, A.J. Morin\*, M. Diksic and E. Hamel. Montreal Neurological Institute, McGill University, Montreal, QC, Canada H3A 2B4.

Recent retrograde tracing studies with Cholera toxin  $\beta$  subunit coupled to immunocytochemistry of TPH, the synthesizing enzyme for serotonin (5-HT), suggest that the major serotonergic innervation of the DLH originates from neurons in the lateral aspect of the ipsilateral dorsal raphe nucleus (DRN)(Soc. Neurosci. Abst. 21, #540.5, 1995). As well, 5,7-dihydroxytryptamine (5,7-DHT) lesion of the DLH induces significant increases in TPH levels in 5-HT neurons of the DRN with a similar lateral location (Ljubic-Thibault et al., Brain Res. 1996, in press). In the present study, we investigated whether the local compensatory changes in TPH activity and content, apparently limited to the DLH projecting neurons, also involve changes at the TPH gene transcriptional level. We examined TPH mRNA expression in the rat brainstem raphe nuclei 5 days after a unilateral stereotaxic 5,7-DHT lesion (3  $\mu$ g in 0.25  $\mu$ l) of the DLH (Bregma, -3.0; 1.0 lateral; 8.1 from brain surface). Rat brains were perfusion-fixed, cryostat-cut (10  $\mu$ m) and processed for cellular *in situ* hybridization using a sense or antisense 800 bp  $^{32}$ S-labelled TPH cDNA probe (cDNA fragment generously provided by Drs. KS Kim and TH Joh). Sham (injected with 0.25  $\mu$ l of vehicle) and control brain sections were run in parallel. The distribution of TPH-expressing neurons in the DRN was similar between lesioned, sham and control rats. However, cells expressing very high levels of TPH mRNA, determined by silver grain density, were only detected in the lesioned rats and primarily so, in the lateral aspects of the ipsilateral DRN. On average, the number of cells expressing high levels of TPH mRNAs was  $6.95 \pm 0.55$  on the ipsilateral side as compared to  $1.41 \pm 0.18$  (d.f.=8,  $p < 0.001$ ), on the midline or contralateral side. These results show that DLH lesion results in changes in TPH mRNA levels in a small population of 5-HT neurons in the ipsilateral DRN, most likely corresponding to those projecting to the DLH. They suggest that, following a local damage in the DLH, there is a feedback regulation of the TPH gene transcription in order to provide sufficient amount of TPH protein for the *de novo* synthesis of 5-HT. Supported by the NIH and the HSF of Québec.

## 241.6

**EXPRESSION AND DELETION MUTAGENESIS OF TRYPTOPHAN HYDROXYLASE FUSION PROTEINS: ROLE OF HISTIDINE RESIDUES IN ENZYME FUNCTION.** C.M. D'Sa, R.A. Arthur, Jr., and D.M. Kuhn\*. Dept. Psychiatry & Beh. Neurosci., Wayne State Univ. Sch. Of Med., Detroit, MI 48201

Tryptophan hydroxylase (TPH) is the initial and rate limiting enzyme in the synthesis of the neurotransmitter serotonin. Complementary DNAs encoding the full length enzyme and deletion mutants comprising the catalytic core of TPH (amino acids 99-444) were cloned and expressed in *E. coli* as GST-fusion proteins. Both full length TPH and the catalytic core were expressed as inactive apoenzymes which were converted to holoenzymes by the addition of ferrous iron. It is not known which amino acid residues in TPH are involved in the coordination of iron to determine enzyme stability and catalytic activity. The TPH sequence contains a highly conserved His-X4-His motif within the catalytic core, representing a putative iron binding site. Treatment of purified GST-TPH fusion proteins with diethyl pyrocarbonate (DEPC), a highly specific histidine carbethoxylating reagent, significantly reduced TPH activity in a concentration- and time-dependent manner. The effect of DEPC was prevented by free histidine but not by lysine or tyrosine. DEPC inhibition of TPH was reversed by hydroxylamine. Putative iron binding sites in the catalytic core were studied for their role in catalysis by site-directed mutagenesis. Conserved His residues 272 and 277 were mutated to lysine residues as were the non-conserved His residues 258 and 343. Mutations of His 272 or 277 produced dramatic effects on TPH activity whereas mutations of the latter histidine residues did not. Taken together, these data indicate that histidine residues 272 and 277 form an important iron coordinating center within the catalytic core of TPH and are essential for the expression of catalytic activity.

## SEROTONIN: GENERAL

## 242.1

**IDENTIFICATION AND QUANTITATION OF SEROTONIN IN THE CROP OF THE COCKROACH PERIPLANETA AMERICANA BY HPLC WITH ELECTROCHEMICAL DETECTION.** Z.A. Abdullah, S.L. Myracle, T.D. Kimbrough, P. Archer\* and N. Narasimhachari. Dept. of Biology, Virginia Commonwealth University, Richmond, VA 23284.

Some previous reports have indicated no serotonin (5-HT) in the gut of the cockroach. In this study crop tissues of the cockroach *Periplaneta americana* were examined for serotonin by high performance liquid chromatography with electrochemical detection (HPLC-ECD). The cockroaches were either sham treated or treated with phenelzine sulphate (20  $\mu$ l, 5mg, phenelzine sulfate in 100 ml of saline) for 3 days. The denervated and untreated specimens were harvested, homogenized with 250  $\mu$ l of mobile phase. After centrifugation the supernate was filtered and the clear filtrate (5  $\mu$ l) was injected into hplc system. A Supelco C18, 3  $\mu$ m column with a Waters guard column was used. Phosphate buffer (0.01M pH 4.0 or pH 3.16) with 10.0% acetonitrile was the mobile phase and the flow rate was 1.2 ml/min. The oxidation potential was set at 0.9 volts. The serotonin level in the sham treated crop was 10.8 ng/mg and in the phenelzine treated one was 44.5 ng/mg. We also found N-acetyl serotonin in the crop 0.81 ng/mg tissue. The homogenates were extracted into ethylacetate at pH 9.0, and the extracts evaporated under nitrogen, the residue redissolved in mobile phase and injected into hplc. Both 5-HT and N-acetyl 5-HT were identified in the extracts, thus confirming their identification.

## 242.3

**SEROTONERGIC AND DOPAMINERGIC OPTIC NERVE PATHWAYS IN RAT AND GOLDFISH.** M. Urbina and L. Lima\*. Lab. Neurochemistry, CBB, IVIC, Apdo. 21827, Caracas 1020-A

Serotonin (5HT)-amacrine cells occur in the fish retina, but not in rodents, the latter possess a raphe-retinal pathway non-demonstrated for the fish. The aim of this work was to correlate the concentration of 5HT, dopamine (DA) and their metabolites (ng/mg prot) determined by HPLC-ED in the retina and the optic nerve of rats and goldfish. The concentration of DA, homovanillic acid (HVA) and 3,4-dihydroxyphenylacetic acid (DOPAC) were 3.8, 1.2 and 1.8 for rat, and 5.3, 0.5 and 0.8 for goldfish retina. For 5HT and 5-hydroxy-indoleacetic acid (5HTAA) the values were 0.3 and 0.09 in the rat, and 1.2 and 0.5 in the goldfish. DA, HVA and DOPAC were 0.4, 0.9 and 0.3 in the optic nerve of rat. In the goldfish DA was 0.3 5HT and 5HTAA levels were 0.4 and 0.3 in rat and 0.2 and 0.08 in goldfish. The ratio 5HT in retina/5HT in optic nerve were 0.7 and 6.2 in rat and goldfish, reflecting the *in situ* neuronal production for the goldfish. For DA, produced in both retinas, these ratios were 10.0 and 21.3. The effect of 5,7-dihydroxytryptamine icv or io has been evaluated. Rat ganglion cells contain DA, which might be its source in the optic nerve.

## 242.2

**MONOCLONAL ANTIBODIES TO BUFOTENINE** Naokuni Takeda \*  
Department of Biotechnology, Research and Development center, COSMO Research Institute, Saito, Saitama, 340-01, Japan

There are no chemical indicators that can be used to diagnose the psychiatric abnormalities. We suggested that the presence and levels of bufotenine might be useful and important markers of some kind of psychiatric disorders (Neuro-Report 6: 2378-2380, 1995). Bufotenine (5-hydroxy-N, N-dimethylserotonin) is a dimethylated derivative of serotonin via N-methylserotonin. For the detection of bufotenine by the immunochemical method, monoclonal antibodies to bufotenine were made. Among three kind of hapten antigens, formylated antigen conjugating to BSA showed higher immunoreactivity than the others. By using spleen cells of immuno-Mice (Balb/c:female), cell fusions and clonings were performed repeatedly. The specificity of antisera was tested by the ELISA method with competition experiments. Among 14 strains, ten antibodies showed large cross-reactivity with both serotonin and N-methylserotonin and two antibodies with N-methylserotonin. However, we can get two kind of antibodies to bufotenine which is possible for the sample analysis with small cross-reactivity.

## 242.4

**DIURNAL VARIATION IN CEREBRAL SPINAL FLUID (CSF) SEROTONIN CONCENTRATIONS IN HEALTHY HUMANS.** P. D. Kirwin, C. J. McDougle\*, G. M. Anderson, G. R. Heninger, T. D. Geraciotti, P. B. Chappell, J. F. Leckman, L. H. Price. Clinical Neuroscience Research Unit, Yale Univ. Sch. of Med., New Haven, CT 06519.

The role of serotonin (5-HT) in the pathogenesis and treatment of depression continues to be the subject of extensive research. Previous studies examining central 5-HT functioning measured CSF levels of 5-hydroxyindoleacetic acid (5-HIAA) by using single or multiple lumbar punctures. Recently several groups have demonstrated the feasibility of continuous CSF sampling via an indwelling lumbar catheter. **Methods:** Four healthy female volunteers, aged 21-34 years, underwent continuous CSF sampling. CSF was collected at a constant rate of 1 ml every 10 minutes over a 30-hour period, with levels of tryptophan (TRP) and 5-HIAA, measured every hour. Plasma was also obtained hourly for TRP determination. **Results:** The results of this study indicate a trend toward significant diurnal variation in CSF 5-HIAA levels. CSF TRP and plasma TRP levels showed variation over time, but failed to show diurnal fluctuation. **Conclusion:** Continuous CSF sampling is safe and feasible in humans, and may prove useful for studies of central neurochemicals in neuropsychiatric illness.

**Funding Source:** National Institute of Mental Health

## 242.5

DISTRIBUTION OF 5-HT TERMINALS AND ASCENDING PROJECTIONS OF THE DORSAL AND MEDIAN RAPHE NUCLEI IN THE HAMSTER. LP Morin\* and E Meyer-Bernstein. Dept. Psychiatry, HSC, Stony Brook Univ., NY 11794.

5-HT neurons in the dorsal (DR) and median (MR) raphe differentially innervate nuclei of the circadian rhythm system (*J. Neurosci.* 10, '96). However, other targets of the DR and MR have not been described in the hamster. Therefore, we used iontophoretic injections of *Phaseolus vulgaris* leucoagglutinin to trace the ascending DR and MR projections. Those patterns are compared to the normal distribution of 5-HT fibers and terminals, also not previously described in the hamster.

The DR projects in a moderately robust fashion to most areas. Regions which receive little, if any, innervation include several layers of the hippocampus, olfactory tubercle, medial habenula, arcuate n., suprachiasmatic n., medial geniculate (ventral), reticular n., oculomotor n. and medial terminal n. MR projections are not found in many areas including much of the basal ganglia and ventral telencephalon, bed nucleus of the stria terminalis, arcuate n., supraoptic n., ventromedial n., medial habenula, non-midline thalamic nuclei, most of the pretectum, the accessory optic n. and outer layers of the superior colliculus. Normal 5-HT innervation is generally quite robust, although there is great variation in detail. E.g., cortical layer 1, unlike the inner layers, is very densely innervated. The pattern of 5-HT innervation is more similar to the distribution of DR than MR efferents. However, because the raphe nuclei have non-5-HT efferents as well, it is not presently possible to determine the extent to which either the MR, DR or both contribute to normal 5-HT innervation.

Supported by NS22168 to LPM.

## 242.7

IMPAIRED DEVELOPMENTAL ELIMINATION OF CALLOSAL AND CLAUSTRAL PROJECTIONS TO CORTICAL AREAS 17 AND 18 IN CATS NEONATALLY DEPLETED OF SEROTONIN. K. Turlejski\*, R. Diavadian. Nencki Institute of Experimental Biology, 3 Pasteur st., 02-093 Warsaw, Poland.

Some projections to areas 17 and 18 in the newborn cat are broad and are later limited by the process of axon elimination. We studied the influence of serotonin depletion on this process. Three experimental and one normal kitten were injected on the first two postnatal days with desipramine (0.02 mg/g) and then with 5,7-dihydroxytryptamine (5,7-DHT, 0.075 mg/g). At the age of three months several injections of Fast Blue were done into the cortical areas 17 and 18 of one hemisphere in each cat under Rompun and ketamine anesthesia. After one week survival the animals were killed with an overdose of pentobarbital and perfused with 4% paraformaldehyde. The brains were freeze-cut for 40  $\mu$ m. Immunolabelling of spare sections for serotonin showed that serotonergic axons were scarce in the areas 17 and 18 of the lesioned animals. In the normal kitten callosally projecting neurons were limited to the transient zone of areas 17/18 (representation of the vertical meridian) and the part of area 18 representing the visual field 10-15 deg from the vertical meridian. In the 5,7-DHT injected kittens far periphery of the area 17 was also void of callosal projection, but the retrogradely labelled neurons were found in its part representing 5-10 deg from the vertical meridian. Callosally projecting neurons were also found in almost all of the area 18. Another structure that showed a significantly changed pattern of cortical projections was claustrum. In the ipsilateral claustrum of the 5,7-DHT injected cats the number of the labelled neurons was increased by 30-50%, while in the contralateral claustrum the labelled neurons were 2-3 times more numerous. These results show that depletion of serotonin disturbs the developmental process of partial elimination of excessive projections that finally shapes the cortical connections.

## 242.9

LEVELS OF 5-HT IN THE HIPPOCAMPAL FORMATION OF THE RAT FOLLOWING ELECTRICAL STIMULATION OF THE DORSAL OR MEDIAN RAPHE NUCLEI D.J. Mokler\*, D. LaRiviere, S. Sinclair, E. Housner, D. W. Johnson, J. Bronzino\*, and P. Morgane. Depts. Pharmacol. & Physiol., University of New England, Biddeford, Me. and (1) Trinity College, Hartford, Ct..

Sprague-Dawley rats were surgically implanted with stainless steel bipolar electrodes into either the dorsal raphe nucleus (DRN) or the median raphe nucleus (MRN); and guide cannula into the dorsal hippocampus (DH) or the ventral hippocampus (VH), respectively. Probes were inserted into the hippocampus on the day of the experiment without anesthesia and perfused with artificial CSF containing 1  $\mu$ M sertraline. Following three hours for stabilization, electrical stimulation (ES) was given for twenty minutes (200  $\mu$ A, 1-5 msec, 10-20Hz). Twenty min samples were collected over an additional two hours. At the completion of the experiments electrode and probe placements were verified histologically. Basal levels of 5-HT were 2 fmole/sample in the DRN-DH and 6 fmole/sample in the MRN-VH in the presence of sertraline. ES of the dorsal raphe nucleus at 20 Hz resulted in an increased release in 5-HT in a stimulus-bound manner. ES of the MRN at 0.5 msec, however, led to a decrease in 5-HT release. Changes in 5-HT release following ES may affect 5-HT terminal autoreceptor activation, thus decreasing release following MRN stimulation. ES may also enhance synaptic release following DRN stimulation. (Supported, in part, by grant HD 22539.)

## 242.6

MORPHINE-INDUCED INCREASE IN EXTRACELLULAR SEROTONIN (5-HT) RELEASE IS ATTENUATED DURING PROLONGED TREATMENT. R. Tao\*, Z. Ma, S.B. Auerbach. Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

The aim of this study was to determine if tolerance to morphine-induced increases in 5-HT release develop during prolonged treatment. 5-HT was measured by *in vivo* dialysis in the dorsal raphe nucleus (DRN) of freely behaving rats. After subcutaneous implantation of 2 morphine pellets (75 mg size), 5-HT was increased by  $46.0 \pm 5.6\%$  ( $n=5$ ;  $P<0.05$ ) above levels in the DRN of rats implanted with placebo pellets. Morphine pellets also induced analgesia as measured by a  $11.7 \pm 3.1$  sec increase ( $n=5$ ;  $P<0.05$ ) in hot plate latencies. In contrast, with 2 pellets in place for 7 days, extracellular 5-HT in both treatment groups were no longer significantly different: morphine,  $4.5 \pm 1.0$  pg ( $n=6$ ); placebo,  $5.0 \pm 1.5$  pg ( $n=6$ ). Furthermore, implantation of 2 more morphine pellets at this time produced no significant increase in extracellular 5-HT ( $9.4 \pm 7.1\%$ ,  $n=6$ ;  $P>0.05$ ) or hot plate latencies ( $0.8 \pm 0.4$  sec,  $n=6$ ;  $P>0.05$ ). As a further test, rats were exposed to morphine or placebo pellets for 14 days. One day after removal of these pellets, challenge with morphine (20 mg/kg, sc) produced no significant increase in DRN 5-HT in the morphine treatment group ( $4.4 \pm 1.9\%$ ,  $n=6$ ), compared with a significant increase in placebo rats ( $55.5 \pm 16.4\%$ ,  $n=4$ ). These results suggest that tolerance to the 5-HT-enhancing and analgesic effects of morphine develop in parallel. Supported by NIMH grant #51080.

## 242.8

HYPOTHALAMIC SEROTONERGIC ACTIVITY AND BRAIN TEMPERATURE ACROSS THE SLEEP-WAKE CYCLE. L. Imeri\*, C. Gemma, M.G. De Simoni\*, M.R. Opp\* and M. Mancia. Istituto di Fisiologia Umana II, Università degli Studi, 20133 Milano, Italy; \*Ist. Mario Negri, 20157 Milano, Italy; §Dep. of Psychiatry & Behavioral Sciences, UTMB, Galveston TX 77555-0428, USA.

Recordings of serotonergic raphe cells discharge rates or of 5-HT release indicate that the activity of these cells varies in phase with the sleep-wake cycle. Sleep and waking are associated with changes in several physiological functions, including EEG activity, brain temperature, and locomotion. The aim of the present study was to clarify which of these parameters better correlates with serotonergic activity.

To this purpose, voltammetric recordings of 5-HT metabolism in the Medial Preoptic Area and polygraphic recordings of fronto-parietal EEG, nuchal EMG activity and of brain cortical temperature ( $T_{\text{cort}}$ ) were simultaneously performed in freely moving rats. Correlations between 5-HT metabolism and the variables under investigation (sleep-wake activity, power in the EEG delta band,  $T_{\text{cort}}$  and EMG activity) were estimated.

Univariate analyses of variance revealed that each variable was statistically correlated with 5-HT metabolism. When the variables were entered into the model simultaneously, both partial correlation and stepwise multiple regression analyses indicated that the highest correlation exists between 5-HT metabolism and  $T_{\text{cort}}$ .

Since  $T_{\text{cort}}$  could be regarded as a parameter representing the integral of different physiological variables, the data in this study are in agreement with the hypothesis that serotonergic activity is reflective of the general behavioral state of the organisms (Jacobs, B.L. and Azmitia, E.C., *Physiol. Rev.*, 1992, 72:165-229).

## 242.10

INCREASED DAILY TURNOVER OF NORADRENALINE AND SEROTONIN IN VENTRAL MEDIAL HYPOTHALAMUS (VMH) OF OBESE VERSUS LEAN ZUCKER RATS ASSESSED BY *IN VIVO* MICRODIALYSIS. S. Luo\*, J. Luo, S. Hodge and A. H. Cincotta. Ergo Sci. Dev. Corp., Charlestown, MA 02129.

Noradrenergic activation of the VMH is known to increase feeding, hepatic glucose output, and adipose lipolysis while inducing obesity in mammals. Moreover, serotonin agonists have been shown to potentiate noradrenergic release within the hypothalamus. Recently, we showed that improvements in body composition and insulin sensitivity are strongly associated with decreases in 24 hr VMH turnover of noradrenaline and serotonin in naturally obese Syrian hamsters. The present study employed *in vivo* microdialysis to investigate the temporal changes of monoamine profile in the VMH of freely moving lean and obese Zucker rats. Rats (9 weeks old) held on 12 hr daily photoperiods were cannulated at the right VMH. Dialysate samples were collected every hour for 24 hr through the microdialysis probe (perfused with Ringer's solution at 0.12  $\mu$ l/min), and analyzed by HPLC with electrochemical detection. Blood samples were obtained from the tail vein before microdialysis to measure blood glucose, insulin and free fatty acid (FFA) levels. Plasma insulin and FFA levels in obese rats were dramatically higher than in lean rats ( $407 \pm 28$  vs  $49 \pm 8$   $\mu$ U/ml and  $2.1 \pm 0.4$  vs  $0.6 \pm 0.1$  mmol/L respectively,  $p<0.01$ ), while plasma glucose levels were also higher than in lean rats ( $198 \pm 8$  vs  $169 \pm 5$  mg/dl,  $p<0.01$ ). Extracellular levels of metabolites of serotonin (5-hydroxyindoleacetic acid) and norepinephrine (3-Methoxy-4-hydroxy-phenylglycol) within the VMH were 40% higher ( $p<0.05$ ) in the obese relative to lean counterparts throughout a day. These findings, along with other available evidence, suggest that increased noradrenergic and serotonergic activity within the VMH of obese Zucker rats is associated with and may contribute to the development of hyperinsulinemia and obesity.

## 242.11

SEROTONERGIC AND CHOLINERGIC MODULATION OF VISUALLY-IDENTIFIED INTERNEURONS IN SLICES OF IMMATURE RAT SENSORIMOTOR CORTEX. Eochring, R.C., van Brederode, J.F.M., and Spain, W.J., Dept. of Anatomy & Neurobiology, Univ. of Tenn., Memphis, TN 38163 and Dept. of Neurology, VA Medical Center, Seattle, WA 98108.

Very little is known concerning the effects of modulatory neurotransmitters on neocortical interneurons. We therefore tested the effects of serotonin (5HT: 30-60  $\mu$ M) and the cholinergic agonist carbachol (10  $\mu$ M) by recording from visually-identified interneurons in layers I-III using infrared video-microscopy in brain slices (300  $\mu$ M) from rats aged P9-P21. Whole-cell recordings were made in current-clamp mode at 30°C using a K-methylsulphate internal (0.1mM EGTA, 0.5% Biocytin). Cell type was confirmed in all cases by histological analysis after recording. Neurons accepted for study had resting potentials (RPs) of at least -60 mV, fired repetitively in response to long current injections and had overshooting action potentials. Of the first 16 cells tested, 13 were confirmed by histology to be interneurons. 11 of these were in layer I and 2 in layer II. In addition, we recorded from 3 pyramidal cells. Seven of 13 interneurons were hyperpolarized (2-9 mV) and the remaining 6 were depolarized (4-15 mV) by 5HT. Variable changes in input resistance accompanied these membrane potential changes. In the pyramidal neurons, 5HT hyperpolarized 1 cell and depolarized 2 cells, and all 3 cells fired more rapidly in response to long current injections (at original RP). This increased firing was accompanied by decreased sAHPs and the induction of an afterdepolarization (ADP) after repetitive firing. Carbachol caused a depolarization (2-15 mV) in 4/4 interneurons tested and in 3/4 cells, an ADP followed repetitive firing in carbachol. We have not found a clear correlation between morphological cell type and response to 5HT or carbachol. Supported by NINDS grant NS33579 (R.C.F.) and a VA Merit award (W.J.S.).

## 242.13

CENTRAL SEROTONIN METABOLISM CORRELATES WITH AUTONOMIC CONTROL AND THYROID STATUS. W.N. Henley\*, P.I. Harness, T.J. Koehnle, and L.L. Bellush. Dpts. of Biol. Sci. and Psychol., Ohio U., Athens, OH 45701.

Adult male, Sprague-Dawley rats were placed on either 0.02% methimazole/water (HYPO; n=8) or were maintained on tap water. After 2 wks, HYPO and 8 euthyroid rats (EUTH; n=8) had placebo implants while 3 additional groups of euthyroid rats had either 2.5, 5.0, or 7.5mg triiodothyronine ( $T_3$ ) pellets implanted (s.c.; n=8/group). Overnight urine collections were obtained 5d post-implant and rats were killed by decapitation 7d post-implant. Neurochemical analysis (HPLC-EC) indicated significant ( $p<0.05$ ) increases in serotonin metabolism ([5HIAA], 5HIAA/5HT, or both) in brainstem and spinal cord regions (T1-T5, T6-T10, T11-L2) from hypothyroid rats. Decreased 5HT metabolism was observed in all 3 spinal cord regions in rats with  $T_3$  implants when compared to EUTH or HYPO. Similar significant increases in urinary norepinephrine excretion with HYPO and decreases with  $T_3$  implants were also seen. Statistical analysis indicated that a significant correlation existed between central 5HT metabolism and urinary NE excretion with changes in thyroid status. Preliminary findings indicate that selective brain stem replacement of  $T_3$  in HYPO may elicit cardiovascular responses predicted by the neurochemical changes reported here. Supported by the Ohio U. Coll. of Osteopath. Med.

## 242.15

MORPHOLOGICAL STUDIES OF MICE OVEREXPRESSING THE SEROTONERGIC GROWTH FACTOR S-100 $\beta$ . P.M. Whitaker-Azmitia, R. Gerlai, M. Wingate and A. Borella. Dept. of Psychiatry, SUNY, Stony Brook, New York, 11794-8101.

S-100 $\beta$  is a neurotrophic factor released by astroglial cells in response to stimulation of the serotonergic 5-HT $_{1A}$  receptor. Once released, S-100 $\beta$  acts as a serotonergic and cortical trophic factor. Thus, animals overexpressing this trophic factor would be expected to show significant changes in the development of cortex and the serotonergic system. Moreover, since the gene for S-100 $\beta$  is within the oligate region for Down's Syndrome (DS), and high levels of S-100 $\beta$  are found in DS patients, animals overexpressing S-100 $\beta$  may serve as a model for DS.

Mice overexpressing S-100 $\beta$ , a gift from Dr. John Roder, Mt. Sinai Research Institute in Toronto, Canada, were produced by insertion of a human genomic fragment containing the three exons and the transcription control elements of the S-100 $\beta$  gene. The resultant animals express S-100 $\beta$  levels approximately 5X that of control animals and have learning deficits.

Control CD1 and transgenic mice were perfused at one year and immunohistochemically stained for the dendritic marker MAP-2. Tissue was analyzed densitometrically and morphologically using the Optima system. One year old transgenic animals showed a statistically significant 38% increase in thickness of cortical layers I-4, a 23% decrease in layer 5 and no change in layer 6. In hippocampus, thickness of the granule cell layer of the dentate gyrus showed a 25% increase with no change in the molecular layer.

Finally, transgenic animals showed pronounced somatic staining of MAP-2 in hippocampus, while normals showed MAP-2 staining confined to dendrites, as expected. (Funding through National Institute on Aging).

## 242.12

COLD INCREASES SYMPATHETIC ACTIVITY AND SEROTONIN IN SPINAL CORD MICRODIALYSATES. A.M. Passerin\* and W.N. Henley. Dpt. of Biol. Sci., Ohio U., Athens, OH 45701.

We have previously reported increases in serotonin (5HT) metabolism in spinal cord following 2, 8, 24, 48, and 96hr of cold exposure (3°C). Additionally, increased synthesis of 5HT was found after 24 hr at 3°C. To further investigate the importance of 5HT for cold-induced sympathoexcitation, microdialysates were obtained from spinal cords of urethane-anesthetized, temperature controlled, adult, male Sprague-Dawley rats (L1 or L2; intermediolateral region; CSF, 1.2  $\mu$ l/min). Dialysates were analyzed for [5HT] using HPLC-EC. Blood pressure and HR were also measured. [5HT] was stable 2.5hr. after probes were implanted; recovery averaged 28.1%. An ice pack was placed on the caudal half of the rat's body. When rectal temperature fell below 33.5°C, increases ( $p<0.05$ ) in [5HT] in dialysates were noted. These cold-induced increases in 5HT were accompanied by significant ( $p<0.05$ ) increases and decreases in MAP and HR, respectively; cold effects were reversible. In a second experiment the activity of sympathetic nerves innervating brown adipose tissue was recorded during application of a similar cold stimulus. It was found that when rectal temperature was dropped below 33.5°C, nerve activity increased in a reversible manner. Together, these data suggest that 5HT release may be an important mechanism associated with cold-induced sympathoexcitation. Supported by the Ohio U. College of Osteopath. Med.

## 242.14

IN VIVO ELECTROCHEMICAL MEASUREMENTS OF EXTRACELLULAR SEROTONIN CLEARANCE IN RAT DORSAL HIPPOCAMPUS. L.C. Daws\*, G.M. Toney\*, G.A. Gerhardt\*, and A. Frazer\* <sup>1</sup>Dept. of Pharmacology, University of Texas, HSC, San Antonio, TX 78284. <sup>2</sup>Dept. of Psychiatry, University of Colorado, HSC, Denver CO, 80262.

The regulation of 5-HT transporter function has been studied by several techniques. However, few have used rapid (5-10 Hz) *in vivo* electrochemical detection techniques to measure uptake and clearance of exogenously applied serotonin (5-HT). Male Sprague-Dawley rats were anaesthetized with chloralose/urethane and a Nafion-coated, carbon fiber electrode, attached to a multibarrel micropipette, was positioned in the CA1 region or dentate gyrus (DG) of the hippocampus. Serotonin (10 to 75 nM, 2 to 15 pmol), the selective 5-HT reuptake inhibitor fluvoxamine (FLUV), the selective norepinephrine reuptake inhibitor desipramine (DMI), or vehicle, were pressure ejected (50 to 200 nM, 2.5 to 200 pmol), 150-200  $\mu$ m from the recording electrode. Serotonin signals were reproducible and dependent on the volume delivered. Vehicle injection produced no detectable effect alone and did not alter the 5-HT signal. FLUV had no effect at doses lower than 10 pmol, but increased the total time course of the 5-HT signal by 90  $\pm$  18 % (n=7 rats) at 25 pmol, and by 200  $\pm$  40 % (n=6) at 55 pmol. Surprisingly, DMI produced comparable dose-dependent increases in the time course of the 5-HT signal. Responses were similar in the CA1 region and DG. By contrast, in the corpus callosum, a fiber tract devoid of transporter, neither drug altered the 5-HT response. In rats treated 3-4 weeks previously with 6-hydroxydopamine (6-OHDA, 200  $\mu$ g i.c.v. with citalopram pretreatment), FLUV produced similar results to those observed in intact rats; however, DMI was without effect. Further, for a given amount of applied 5-HT, the signal amplitude was increased 2-fold in 6-OHDA treated rats. Taken together, the data support the hypothesis that both serotonergic and noradrenergic systems are involved in regulating the clearance of exogenously applied 5-HT. (Supported by funds from USPHS (MH29094), NSF (BIR913392) the VA and The Upjohn Co.).

## 242.16

DIFFERENTIAL VULNERABILITY TO AGING IN THE RAT SEROTONERGIC SYSTEM. A. Nishimura<sup>1,2\*</sup>, S. Ueda<sup>3</sup>, Y. Takeuchi<sup>2</sup>, T. Sawada<sup>3</sup>, M. Kawata<sup>1</sup>. <sup>1</sup>Dept. of Anatomy and Neurobiol., and <sup>2</sup>Dept. of Pediatrics, Kyoto Pref. Univ. of Med., Kyoto 602, Japan., and <sup>3</sup>Dept. of Histology and Neurobiol., Dokkyo Univ. Sch. of Med., Tochigi 321-02, Japan.

During the process of aging, the structure and the distributional pattern of many chemically identified neuronal systems in the central nervous system are altered. Morphological aberrations of serotonergic (5-HT) fibers have also been reported previously (Van Luijckelaar et al., 1992, Nishimura et al., 1995). The present study examines immunohistochemically the distributional changes associated with aging of the 5-HT neuron system. Wistar rats ranging from 3 months old (young adult) to 3 years old (aged) were used. In the aged rat brain, abnormal morphology of the 5-HT processes was noted. Aberrant-shaped 5-HT fibers observed in the aged rat were classified into two groups: One was thin fibers with a large number of varicosities outgrowing like bunches of grapes, and the other was thick fibers with smooth-surfaced varicosities distorting and clustering like a ball of worsted. The former type of fibers was observed in the regions projecting from the dorsal raphe nucleus, whereas the latter existed in the restricted areas projecting from the median raphe nucleus. These findings suggest that the vulnerability to aging in these two types of aberrant 5-HT fibers may be different.

## 242.17

ELECTROCONVULSIVE SHOCK INCREASES INTRANEURONAL STAINING OF THE SEROTONERGIC GROWTH FACTOR, S-100 $\beta$ . J. Bell 3rd\*, M. Halasz, A. Borella, E. Azmitia and P.M. Whitaker-Azmitia Dept. Psychiatry, SUNY, Stony Brook, New York, 11794-8101.

Work from our lab has shown that serotonergic 5-HT<sub>1A</sub> receptor agonists can release S-100 $\beta$  and that once released S-100 $\beta$  can act as a trophic molecule both for serotonergic and cortical neurons. Once released, the molecule influences phosphorylation states of neuronal proteins such as MAP-2 and GAP-43.

Electroconvulsive shock (ECS) in animals has been shown to release high amounts of serotonin and animals lesioned with the serotonergic neurotoxin, 5,7-DHT, do not show the usual neurochemical changes associated with ECS. Thus, serotonin appears to be involved in the response to ECS. The current study was therefore undertaken to determine if serotonin-released S-100 $\beta$  might be increased by ECS.

Adult male Sprague-Dawley rats were treated with unmodified ECS every other day for ten days. On Day 11, control and treated rats were perfused and immunocytochemically stained for S-100 $\beta$  and the dendritic marker MAP-2. S-100 $\beta$  immunostaining is generally confined to astroglial cells of the adult rat brain, however the ECS animals showed high levels of intraneuronal staining. As well, there was an increase in MAP-2 staining principally due to increased dendritic size, rather than number.

Our results suggest that ECS may have its therapeutic effects through serotonergic mediated release of the trophic factor, S-100 $\beta$ . (Funding through National Institute on Aging).

## SEROTONIN: BEHAVIOR

## 243.1

IDENTIFICATION OF NOVEL GENES REGULATING BRAIN SEROTONERGIC HYPERINNERVATION BY DIFFERENTIAL DISPLAY RT-PCR IN MURINE ANOREXIA (ANX) MUTANT. C.H. PENG, B. CONTI, J.W. JAHNG, T.H. JOH, S.J. KIM\* AND J.H. SON. Cornell University Medical College at The W.M. Burke Medical Research Institute, White Plains NY, 10605.

The central serotonergic system modulates many important physiological functions including appetite, sleep, motor activity, endocrine secretion, sex activity, learning and memory. The developmental and functional alterations in serotonergic systems have been implicated in human neuropsychiatric disorders. The serotonergic system matures postnatally and the target innervation density seems to depend on unknown factors present in the mature target tissues. Previous work from this laboratory has demonstrated extensive serotonergic hyperinnervation in target fields such as hippocampus, cortex and cerebellum, but no serotonergic hyperinnervation in nontarget fields, in the brain of an *anorexia* (*anx*) mutant (Son et al. *Mol. Brain Res.*, 25, 129 '94). In order to identify novel mRNAs which are specifically regulated by or contribute to the serotonergic hyperinnervation in the brain of *anx* mutant, PCR differential display was employed. Total RNAs from both hippocampus and cortex of either *anx* mutant or normal littermate were isolated and used for RT-PCR at postnatal day 16. By comparing the mRNAs from both *anx* and normal littermate brains, a total of 25 differentially displayed bands between 150 to 400 bp were identified. Of these, 5 clones were selected based upon their brain region-specific expression pattern determined by *in situ* hybridization. Each differentially displayed band is being further examined in order to elucidate the molecular nature of serotonergic hyperinnervation in the brain of *anx* mutant. (Supported in part by NIH grant MH24285)

## 243.3

ANTI-AGGRESSIVE EFFECTS OF S-15535, A NOVEL AND SELECTIVE ANTAGONIST AT POSTSYNAPTIC 5-HT<sub>1A</sub> RECEPTORS AND AGONIST AT 5-HT<sub>1A</sub> AUTORECEPTORS. E. Mocaer<sup>1</sup>, M. Lesourd<sup>1</sup>, S.F. de Boer<sup>2</sup>, B. Bohus<sup>2</sup> and J.M. Koolhaas<sup>3</sup>. <sup>1</sup>Institut de Recherches Internationales Servier, 6 place des Pléiades, 92400 Courbevoie, France; <sup>2</sup>Department of Animal Physiology, University of Groningen, P.O. Box 14, 9750 AA Haren, The Netherlands.

The novel benzodioxopiperazine S-15535 potentially acts as a competitive antagonist at postsynaptic 5-HT<sub>1A</sub> receptors and as an agonist at 5-HT<sub>1A</sub> autoreceptors. This unique pharmacological profile makes S-15535 a useful tool for assessing presynaptic and/or postsynaptic mediation of 5-HT<sub>1A</sub>-induced responses. Recently, we convincingly demonstrated that selective 5-HT<sub>1A</sub>-receptor agonists specifically suppresses offensive aggression. It is not known, however, whether this anti-aggressive effect is pre- or postsynaptically mediated. Therefore, the present experiments investigated the effects of S-15535 (0.5, 1, 2.5 and 10 mg/kg), given either alone or in combination with the selective 5-HT<sub>1A</sub> receptor antagonist WAY 100635 (0.1 mg/kg) on offensive and defensive aggression in wild-type rats using a resident-intruder paradigm. Commencing at 45 min (WAY-100635) and 30 min (S-15535) after SC injection of drugs or vehicle, behavior of drugged resident rats (offensive aggression test) or drugged intruder rats (defensive aggression test) was examined during a 10 min social encounter. S-15535 exerted a potent dose-dependent decrease in offensive aggressive behavior in resident rats (ED<sub>50</sub>=1.34 mg/kg), which was completely antagonized by WAY-100635. Other non-social behavioral elements, i.e., exploration, grooming and inactivity, as well as defensive aggression were not significantly affected by S-15535. No anti-aggressive effects were seen after WAY-100635 treatment alone. The data shows that S-15535, similar to other selective 5-HT<sub>1A</sub> agonists i.e., alnespirone, effectively and specifically suppresses offensive aggression. Given the pharmacological properties of S-15535, these data provide evidence that the anti-aggressive effects of 5HT<sub>1A</sub> receptor agonists are mediated via their action on 5-HT<sub>1A</sub> autoreceptors.

## 243.2

S 15535-3, A 5-HT<sub>1A</sub> RECEPTOR PARTIAL AGONIST, INCREASES RATES OF PUNISHED RESPONDING IN RATS: COMPARISON WITH CHLORDIAZEPOXIDE, IPSAPIRONE AND WAY 100635. R. Samanin<sup>1</sup>, C. Bonvicini<sup>1</sup>, M. J. Millan<sup>2</sup>, E. Mocaer<sup>3</sup>, M. T. Tacconi<sup>4</sup> and L. Cervo<sup>5</sup>. <sup>1</sup>Istituto di Ricerche Farmacologiche "M. Negri", Milano, Italy; <sup>2</sup>Institut de Recherches Internationales Servier, France.

The effect of S 15535-3, a highly selective agonist and antagonist (weak partial agonist) at pre- and post-synaptic 5-HT<sub>1A</sub> receptors respectively, was compared with that of chlordiazepoxide, ipsapirone and the 5-HT<sub>1A</sub> receptor antagonist WAY 100635 in a Geller-Seifter conflict test. Administered orally 1 h before testing, S-15535-3 at 10 and 30 mg/kg selectively increased punished responses. The same effect was found with 3-30 mg/kg chlordiazepoxide administered orally 1 h before testing. Administered subcutaneously 30 minutes before testing, S-15535-3 significantly increased punished responses and reduced unpunished responding at 3 (but not 0.3 and 1) mg/kg. Ipsapirone administered subcutaneously at 5 and 10 mg/kg 30 minutes before testing significantly increased punished responses. The higher dose of ipsapirone reduced unpunished responding. At subcutaneous doses ranging from 0.1 to 1 mg/kg administered 1 h before testing WAY-100635 had no effect on punished and unpunished responses. The results have shown that S 15535-3 has benzodiazepine-like effects in a conflict test, whereas WAY-100635 causes no effects in this test. The results suggest that S 15535-3 may have favourable effects in the treatment of anxiety disorders.

The study was supported by Servier, Courbevoie, France.

## 243.4

ANTI-AGGRESSIVE EFFECTS OF ALNESPIRONE (S-20499), A POTENT 5-HT<sub>1A</sub> RECEPTOR AGONIST, IN WILD-TYPE RATS. M. Lesourd<sup>1</sup>, S.F. de Boer<sup>2</sup> and J.M. Koolhaas<sup>3</sup>. <sup>1</sup>Institut de Recherches Internationales Servier, 6 place des Pléiades, 92400 Courbevoie, France; <sup>2</sup>Department of Animal Physiology, University of Groningen, P.O. Box 14, 9750 AA Haren, The Netherlands

Alnespirone (S-20499) is a novel selective and potent 5-HT<sub>1A</sub> receptor agonist. Since the 5-HT<sub>1A</sub> receptor is known to play an important role in anxiety, S-20499 has reliably been reported to possess potent anxiolytic activity in a variety of animal behavioral models of anxiety. Besides the involvement in anxiety, 5-HT<sub>1A</sub>-receptors are reported to be involved in aggressive behavior as well. Therefore, the present experiments investigated the effects of S-20499 (1, 5, 10 mg/kg) on offensive and defensive aggression in wild-type rats using a resident-intruder paradigm, in comparison to 8-OHDPAT (0.05, 0.1, 0.25, 1.0 mg/kg), eltopazine (1 mg/kg) and ipsapirone (5 mg/kg). Thirty min after SC injection of drugs or vehicle, behavior of drugged resident rats (offensive aggression test) or drugged intruder rats (defensive aggression test) was examined during a 10 min social encounter. S-20499, like 8-OHDPAT, eltopazine and ipsapirone, exerted a potent dose-dependent decrease in offensive aggressive behavior in resident rats. Other non-social behavioral elements, i.e., exploration, grooming and inactivity, were not significantly affected by S-20499. In contrast, the anti-aggressive profile of eltopazine and especially ipsapirone and 8-OHDPAT was paralleled by a strong increase in behavioral inactivity. Pretreatment with the selective 5HT<sub>1A</sub> receptor antagonist WAY 100635 (0.1 mg/kg) completely antagonized the anti-aggressive effects of S-20499 as well as the behavioral effects of 8-OHDPAT, eltopazine and ipsapirone. In the defensive aggression test, S-20499 did not significantly change any behavioral element of the intruder rats. The data indicate that S-20499 effectively and specifically suppresses offensive aggression without interfering with adequate defensive aggressive behavior. Furthermore, these data provide convincing evidence for the involvement of 5HT<sub>1A</sub> receptors alone in the modulation of aggressive behavior.

## 243.5

**B-20991, A NOVEL SELECTIVE 5HT<sub>1A</sub> RECEPTOR AGONIST WITH A POTENTIAL ANXIOLYTIC PROFILE.** Beneytez, M.E.<sup>1</sup>, López Rodríguez, M.L., Morcillo, M.J., Rosado, M., Orensanz, L., Fuentes, J.A.<sup>2</sup> and Manzanares, J.<sup>1</sup>. <sup>1</sup>Department of Pharmacology, School of Pharmacy, <sup>2</sup>Department of Organic Chemistry, School of Chemistry, Complutense University, and <sup>3</sup>Department of Research, Ramon y Cajal Hospital, Madrid 28040, Spain

The purpose of this study was to characterize the effects of 2-[4-(*o*-methoxyphenyl)piperazin-1-ylmethyl]-1,3-dioxo-*pyrido*[1,5-*a*]pyridine (B-20991) on several biochemical and behavioral assays. Rat brain membranes were used to carry out binding affinity receptor studies for the following receptors: 5HT<sub>1A</sub>, 5HT<sub>2</sub>, D<sub>2</sub> and  $\alpha_1$ -adrenoceptor. The pharmacological activity of B-20991 was estimated performing the following assays after s.c. administration: 1) hypothermia in mice, 2) 5HT syndrome (flat body posture, FBP; lower lip retraction, LLR) in rat, 3) 5HT and DA neuronal activity in mice hypothalamus by HPLC-EC, 4) open-field locomotor activity (LA) in mice. The anxiolytic activity of B-20991 was assessed by using the social interaction (SI) and light/dark box (LDB) tests.

Results of binding studies showed that B-20991 binds with high affinity to the 5HT<sub>1A</sub> receptor ( $K_i = 31.7 \pm 1.7$  nM) and low affinity ( $K_i > 1000$ ) to 5HT<sub>2</sub>, D<sub>2</sub> and  $\alpha_1$ -adrenoceptor. B-20991 caused a dose- and time-related decrease in rectal temperature, increased FBP and LLR, decreased 5HIAA/5HT ratio in hypothalamus, did not alter LA and increased SI and LDB scores.

Taken together, these results suggest that B-20991 is a selective 5HT<sub>1A</sub> receptor agonist with anxiolytic activity.

## 243.7

**DOI, A 5-HT<sub>2</sub> AGONIST, NORMALIZES AUDITORY GATING IN ISOLATION-REARED RATS.** R.G. Johnson<sup>1</sup>\*, K.E. Stevens<sup>2,3</sup> and G.M. Rose<sup>1,3</sup>. Depts. of <sup>1</sup>Pharmacology and <sup>2</sup>Psychiatry, UCHSC and <sup>3</sup>Medical Research, VAMC, Denver, CO 80220

Auditory gating is a form of sensory processing which is impaired in schizophrenia. We have previously shown that rats which are reared from weaning in social isolation also show gating deficits. In such rats, as with schizophrenics, gating is not improved after administration of the neuroleptic, haloperidol. However, gating in schizophrenics is normalized by clozapine, an atypical neuroleptic with actions at serotonin receptors. The goal of the present study was to determine whether DOI (2,5-dimethoxy-4-iodoamphetamine), a selective agonist for 5-HT<sub>2</sub> receptors, would restore gating in isolation-reared rats. The animals were prepared for recording by implanting a skull screw at vertex (-4.0 from bregma, on midline). After recovery, auditory evoked potentials were recorded in response to paired clicks (87 dB, 0.5 sec between clicks). Isolation-reared rats consistently showed impaired gating in this paradigm. However, administration of DOI (2.5 mg/kg, i.p.) normalized gating for a period lasting 2-3 hours. These data suggest a role for the 5-HT<sub>2</sub> receptor in the modulation of auditory gating, and may have implications for future therapeutic interventions for schizophrenia. Supported by MH-44212 and the VAMRS.

## 243.9

**ESTROGEN MODULATES 5-HT<sub>1A</sub> RECEPTORS.** A. Jackson\*, L. Sinclair-Worley, M. Caldarola-Pastuszka, H. Conrad-Webb, M. Rudick, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Treatment of ovariectomized rats with 25  $\mu$ g of estradiol benzoate (EB) reduces the ability of the 5-HT<sub>1A</sub> agonist, 8-OH-DPAT, to inhibit lordosis behavior. The effect of EB requires 3-4 days to develop and results in a reduced potency of the 5-HT<sub>1A</sub> agonist. It is not known if estrogen's modulation occurs on a shorter time scale. Ovariectomized rats were injected with 2.5, 7.5, or 25  $\mu$ g EB (s.c.) followed 48 hrs later with 500  $\mu$ g progesterone. Four to six hrs later, rats were infused bilaterally into the ventromedial nucleus of the hypothalamus (VMN) with 8-OH-DPAT (50 to 200 ng). The effects of 8-OH-DPAT varied with the dose of EB. The mechanisms responsible for estrogen's attenuation of the effects of 8-OH-DPAT are not known. Studies are in progress to examine the effects of estrogen on 5-HT<sub>1A</sub> receptor mRNA. Supported by NIH RO1 HD28419 and NIGMS 08256.

## 243.6

**EQUIVALENT EFFECTS OF STIMULATION OR BLOCKADE OF 5-HT<sub>1A</sub> RECEPTORS UPON AMPHETAMINE-INDUCED LOSS OF AUDITORY GATING.** K.E. Stevens\*, R.G. Johnson, J. Luthman and G.M. Rose. Dept. Psychiatry, Pharmacology, and Neuroscience, Univ. Colorado Health Sci. Ctr; VA Medical Center, Denver, CO and the Karolinska Institute, Stockholm, Sweden.

Deficient sensory filtering or "gating", which is a hallmark of schizophrenia, can be demonstrated as an inability to inhibit the response to the second of a pair of identical click stimuli given at a 0.5 sec interval. This deficit can be mimicked in rats by administration of the psychotomimetic, amphetamine. Clinical success with the atypical neuroleptic clozapine, which also improves gating in schizophrenics, has focused attention on the serotonergic system. The 5-HT<sub>1A</sub> receptor is of specific interest since it is localized almost exclusively in limbic structures, certain of which have been implicated in schizophrenia and the concomitant sensory filtering deficit. Administration of a 5-HT<sub>1A</sub> antagonist, (-)UH-301 (5,2,0.5 mg/kg, s.c.), produced a normalization of amphetamine-induced loss of gating while a lower dose (0.1 mg/kg, s.c.) was not effective. (-)UH-301 alone had no significant effect upon gating. Interestingly, administration of a 5-HT<sub>1A</sub> agonist, 8-OH-DPAT (0.1 mg/kg, s.c.) also normalized amphetamine-induced loss of gating. Again, a low dose (0.05 mg/kg, s.c.) was not effective. These data suggest an important function for the 5-HT<sub>1A</sub> receptor in the modulation of auditory gating and, further, suggest that both pre- and post-synaptic receptors are involved. The present studies may have implications for the use of serotonergic compounds in the clinical treatment of schizophrenia. Supported by NIMH R29 MH51931-02.

## 273.8

**INVOLVEMENT OF SEROTONERGIC NEURON SYSTEM IN THE RAT AGGRESSIVE BEHAVIOR (MURICIDE).** S.Ueda\*, M.Aikawa,

A.Nishimura, K.Yoshimoto. Dept. of Histology and Neurobiology, Dokkyo Univ. Sch. of Med., Tochigi 321-02, Japan, Dep. of Pediatrics and Legal Medicine, Kyoto Pref. Univ. of Med., Kyoto 602, Japan.

Transplantation of fetal serotonergic neurons into the hypothalamus restored mouse killing behavior (muricide) in the rat with raphe lesion induced by serotonergic neurotoxin 5,7-dihydroxytryptamine. Immunohistochemical and neurochemical analyses demonstrate that recovery of serotonergic innervation in the lateral hypothalamic area by the graft is brought about the inhibition of muricide. The grafted serotonergic neurons are strongly related to the inhibitory action on the muricide. Transplanted serotonergic neuron system can result in a reinnervation of the host, and leads to a reestablishment of the aggressive behavior.

## 243.10

**8-OH-DPAT DESENSITIZATION OF 5-HT<sub>1A</sub> RECEPTORS.** S. Maingano, J. Hines\*, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Several investigators have suggested that agonist-induced modulation of somatodendritic 5-HT<sub>1A</sub> receptors occurs more rapidly and/or with less agonist activation that is evident for postsynaptic 5-HT<sub>1A</sub> receptors. To further evaluate the dose-dependency of the agonist-induced modulation, we pretreated ovariectomized rats (60 to 90 days) with varying doses of the 5-HT<sub>1A</sub> receptor agonist, 8-OH-DPAT (0.15, 0.25, or 0.5 mg/kg; s.c.). A second 8-OH-DPAT injection (0.15, 0.25, or 0.5 mg/kg; s.c.) was given 24 hrs later; the effects of the drug on flat body posture and hypothermia (evidence of postsynaptic 5-HT<sub>1A</sub> receptor activation) and hyperphagia (evidence of somatodendritic 5-HT<sub>1A</sub> receptor activation) were monitored for 30 min after injection. For all the parameters examined, prior treatment attenuated the response to the second treatment. Relative to the dose required to attenuate hypothermia and flat body posture, a lower dose of 8-OH-DPAT was required to reduce drug-induced hyperphagia. These data are consistent with previous suggestions that a higher dose of the 5-HT<sub>1A</sub> agonist is required to modulate postsynaptic than presynaptic 5-HT<sub>1A</sub> receptor function. Supported by NIH RO1 HD 28419

## 243.11

MEDIOBASAL HYPOTHALAMIC SEROTONIN DURING THE RAT ESTROUS CYCLE AND FOLLOWING GONADAL HORMONES. S. Maswood\*, B. Truitt, M. Caldarola-Pastuszka, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204 and Department of Psychology, University of Colorado, Boulder, Co. 80309.

Serotonin inhibits lordosis behavior by activating 5-HT<sub>1A</sub> receptors while a facilitatory role for 5-HT<sub>2</sub> receptors has been postulated. Tissue concentrations of serotonin fluctuate in response to estrogen and progesterone and during the female rat estrous cycle, but the degree to which variations in tissue levels reflect changes in synaptic concentration of the neurotransmitter are still unclear. A more direct examination of extracellular changes in the biogenic amine is possible with microdialysis procedures. In the following studies, extracellular serotonin in the mediobasal hypothalamus was examined in diestrous, proestrous, and estrous rats and in hormonally-primed, ovariectomized rats. Microdialysate serotonin was significantly lower during proestrus and estrus than during diestrus. Since estrogen increased serotonin in the microdialysate, the relatively low concentration of the neurotransmitter on proestrus and estrus may reflect a progesterone-mediated attenuation of the effects of estrogen. ## 243.13

5-HT<sub>3</sub> RECEPTORS IN THE VMN AND FEMALE LORDOSIS BEHAVIOR. N. Maswood\* and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Within the ventromedial nucleus of the hypothalamus (VMN), serotonin exerts a dual role in the control of female lordosis behavior. Most emphasis has been placed on the 5-HT<sub>1A</sub> and 5-HT<sub>2</sub> receptors, which inhibit and facilitate the behavior, respectively. In the current experiment, a potential role for the 5-HT<sub>3</sub> receptor was examined. Ovariectomized rats, hormonally primed with 25 µg estradiol benzoate and 500 µg progesterone, received VMN infusions with 100 ng, 250 ng or 500 ng of the 5-HT<sub>3</sub> receptor antagonist, tropisetron. Lordosis behavior was inhibited within 10 min of the 500 ng infusion. The 5-HT<sub>3</sub> receptor agonist, m-chlorophenylbiguanide (mCPBG), dose-dependently protected against tropisetron. The 5-HT<sub>3</sub> receptor agonist, alone, had no effect on the lordosis to mount (L/M) ratio, but it slightly reduced lordosis quality. These observations extend prior evidence for the complexity of serotonin's regulation of lordosis behavior. To our knowledge, this is the first evidence for a functional role of VMN 5-HT<sub>3</sub> receptors in the control of lordosis behavior. Supported by NIH RO1 HD28419

## 243.15

ESTROGEN REDUCES 8-OH-DPAT'S LORDOSIS-INHIBITING POTENCY IN THE VMN. T. Price, A. Trevino, A. Wolf, M. Caldarola-Pastuszka, and L. Uphouse\*. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Serotonin (5-HT) inhibits lordosis behavior by acting on 5-HT<sub>1A</sub> receptors; the ventromedial nucleus of the hypothalamus (VMN) was identified as an effective site for the inhibition. However, when ovariectomized rats received two weeks of treatment with estradiol benzoate (EB), infusion with 200 ng 8-OH-DPAT inhibited lordosis behavior on the first, but not the second week of treatment. In the present experiment, ovariectomized rats, with VMN cannulae, were injected s.c. with 25 µg of EB. Seven days later, rats received a second injection of EB followed 48 hrs later with 500 µg progesterone (s.c.). A second group of rats received a single EB treatment followed 48 hrs later by progesterone. Four to six hrs after progesterone, rats were pretested for sexual behavior and were infused into the VMN with 200 ng, 1000 ng, or 2000 ng 8-OH-DPAT. Lordosis behavior of rats receiving a single EB treatment was rapidly inhibited following all doses of 8-OH-DPAT. However, in animals that had received two EB treatments, the potency of the drug was reduced. Supported by NIH RO1 HD28419 and NIGMS 08256.

## 243.12

THE 5-HT<sub>1A</sub> ANTAGONIST S-(-)UH 301 BY ITSELF INDUCES THE HEAD-TWITCH RESPONSE (HTR) AND POTENTIATES THE EFFECTS OF COCAINE AND SERTRALINE ON THE 5-HTP-INDUCED HTR IN MICE. N.A. Darmani\*, Dept. of Pharmacol., KCOM, Kirksville, MO 63501.

5-HT<sub>1A</sub> receptor antagonists appear to increase the basal firing rate of raphe neurons by antagonizing the inhibitory endogenous serotonin tone operating on the somatodendritic 5-HT<sub>1A</sub> autoreceptors. This effect should enhance the concentration of 5-HT in serotonergic terminal fields which may then activate other postsynaptic 5-HT receptors. However, microdialysis studies show that generally 5-HT<sub>1A</sub> antagonists do not increase the basal 5-HT release but potentiate the ability of serotonin reuptake blockers to increase the neuronal serotonin output. In this study we determined whether antagonism of the endogenous serotonin tone can potentiate the activity of other postsynaptic serotonin receptors. We utilized the head-twitch response (HTR) in mice as a model of postsynaptic 5-HT<sub>2A</sub> receptor function. The selective 5-HT<sub>1A</sub> antagonist S-(-)UH 301 produced the HTR in normal but not in reserpinized animals. The 5-HT<sub>2A</sub> antagonist, SR 46349B, completely prevented S-(-)UH 301-induced HTR. Pretreatment with S-(-)UH 301 potentiated 5-HTP-induced HTR both in normal and in reserpinized mice. The 5-HT<sub>1A</sub> selective agonist, 8-OH DPAT, significantly but partially inhibited 5-HTP-induced HTR. S-(-)UH 301 pretreatment not only antagonized but also broke through the inhibitory effect of 8-OH DPAT on 5-HTP-induced HTR. The selective (sertraline) and nonselective (cocaine) serotonin reuptake blockers potentiated the ability of 5-HTP to induce the HTR. Pretreatment with S-(-)UH 301 enhanced the potentiating effect of serotonin reuptake blockers on the 5-HTP-induced HTR. These results suggest that an endogenous 5-HT tone via the discussed mechanism controls the terminal field synaptic activity of serotonergic neurons. This study was supported by NIDA grant DA 07627.

## 243.14

LORDOSIS BEHAVIOR AFTER CO-INFUSION OF KETANSERIN AND DOI INTO THE VMN. A. Wolf\* and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

We have reported that the 5-HT<sub>2</sub> antagonist, ketanserin, inhibited lordosis behavior after infusion into the VMN; similarly, the 5-HT<sub>2</sub> agonist, DOI, facilitated lordosis behavior. The present studies were designed to evaluate the ability of (a) ketanserin to reduce the 5-HT<sub>2</sub> agonist-induced facilitation or (b) DOI to attenuate the inhibitory effects of the 5-HT<sub>2</sub> antagonist. Ovariectomized rats with VMN cannulae were injected s.c. with 0.5 µg estradiol benzoate followed 48 hrs later with 500 µg progesterone. Four to six hrs later, rats were infused with DOI (2000 or 3000 ng) and/or ketanserin (3000 ng). Rats with preinfusion lordosis to mount (L/M) ratios > 0.5 were inhibited by ketanserin; co-infusion with DOI completely prevented the inhibition. L/M ratios of rats with preinfusion L/M ratios ≤ 0.5 were facilitated following the DOI infusion. Although co-infusion with ketanserin failed to prevent the facilitation, prior treatment with ketanserin attenuated the response to DOI. These findings lend further support to the hypothesis that 5-HT<sub>2</sub> receptors in the VMN facilitate lordosis behavior.

Supported by NIH RO1 HD28419 and NIGMS 08256.

## 243.16

5-HT1B KNOCK-OUT MICE DISPLAY IMPULSIVE BEHAVIOR IN A FOOD REWARD CHOICE TASK. <sup>1</sup>D. Brunner, <sup>2</sup>M. A. Hofer\*, <sup>3</sup>R. Hen and <sup>4</sup>M.-C. Buhot. <sup>1</sup>Unit 50-NYSP, <sup>2</sup>Unit 40-NYSP, <sup>3</sup>Center for Neurobiology & Behavior, Columbia University, New York NY 10032, <sup>4</sup>Lab. Neurosci. Comportementales & Cognitives, CNRS-URA 339, Univ. Bordeaux I, Talence, France.

Impulsiveness has been associated with aggression, addiction and OCD, psychopathologies which are likely to be linked to a dysfunctioning of the central serotonergic system. We studied impulsiveness in knock-out mice lacking the 5-HT1B receptor because previous studies demonstrated that these mice displayed a reduced latency to attack in an aggression test and acquired self-administration of cocaine faster than wild-type mice.

Since impulsiveness can be described as a lack of self-control of waiting capacities, we first examined possible learning and time perception deficiencies in these mutant mice in an operant learning. Both wild-type and mutant mice were able to learn and showed no difference in timing accuracy, with a shorter latency to respond in mutants.

Our second experiment involved a 2-arm maze with a choice between a small reward or a larger one. Again, both genotypes discriminated equally. A behavior consisting in switching to the alternative arm within the consumption time of the large reward decreased progressively as training advanced in wild type mice, but was significantly higher and persistent in mutants.

The shorter response latencies found in the operant experiment suggest that switching within a reward may not be due to a decreased motivation but to a lowered threshold for responding. Our results may be relevant for the understanding of impulsiveness in childhood hyperactivity, which results in an inability to wait, and support the involvement of the serotonergic system in behavioral inhibition.

## 243.17

ON THE MECHANISM OF ACTION OF THE PUTATIVE ANTIPSYCHOTIC MDL 100,907 IN RELATION TO MK-801 INDUCED PERTURBATIONS IN MICE. P. Martin\*, N.W. Waters<sup>1</sup>, C.J. Schmidt<sup>2</sup>, A. Carlsson<sup>1</sup> and M.L. Carlsson<sup>1</sup> Dept. of Pharmacology<sup>1</sup>, Gothenburg University, Sweden and Hoechst Marion Roussel Inc.<sup>2</sup>, Cincinnati, Ohio.

MK-801 is an un-competitive N-methyl-D-aspartate (NMDA) receptor antagonist which induces a behavioral syndrome in mice that includes hyperlocomotion (HLMA). The potent and selective 5-HT<sub>2A</sub>-receptor antagonist MDL 100,907 efficiently counteracted the MK-801 (0.3 mg/kg ip.) induced HLMA (cf. Abstract 809.7, 1995), a dose-dependent effect that was abolished when endogenous serotonin stores were depleted by pretreatment with para-chlorophenylalanine (pCPA).

pCPA pretreatment by itself reduced the MK-801 induced HLMA to 75% of MK-801 treated controls. This reduction of HLMA was not affected by replenishment of 5-HT with (+)-5-HTP (2.5-10-40 mg/kg). However, during concomitant treatment with MDL 100,907 (0.1 mg/kg), (+)-5-HTP given in the same doses elicited a marked, dose-dependent reduction of the MK-801 induced HLMA in pCPA treated animals.

These results suggest that MK-801 induced HLMA is accompanied by an activation of, but is not fully dependent upon, CNS serotonergic systems. MDL 100,907, by blocking the 5-HT<sub>2A</sub>-receptors unveils the anti-hyperlocomotor effects of (an)other serotonin receptor(s).

## 243.19

REGULATION OF 5-HT<sub>2</sub> RECEPTORS BY CHRONIC DOM, DOI, RITANSERIN OR DOM PLUS RITANSERIN: BEHAVIORAL EVIDENCE. K.R. Bonson\*, and D.L. Murphy. 10/3D41, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892-1264.

Regulation of the 5-HT<sub>2</sub> receptor is unusual in that chronic exposure to 5-HT<sub>2</sub> agonists as well as 5-HT<sub>2</sub> antagonists reduces receptor numbers. The present study used changes in behavioral responses of rats to a challenge dose of the 5-HT<sub>2</sub> agonist, DOM (2.5 mg/kg sc), as an index of 5-HT<sub>2</sub> receptor sensitivity after chronic exposure to 5-HT<sub>2</sub> agonists, an antagonist or their combination. In treatment groups receiving either DOM or DOI (2.5 mg/kg, sc) for 1-4 d, the head shake response induced on Day 1 was reduced. When rats in these two groups received a challenge dose of DOM 24 or 48 hrs after final agonist injection, the head shake response was reduced compared to saline-treated rats. In contrast, DOM or DOI (2.5 mg/kg) administered by osmotic minipump did not induce head shakes on Day 1, and the head shake response to DOM challenge after 4 d DOM or DOI was equal to that of saline-treated rats 24 hrs after the minipumps were removed. Although 14 d exposure to both ritanserin (5 mg/kg, sc) and ritanserin (5 mg/kg) + DOM (2.5 mg/kg, sc) reduced the head shake responses to DOM challenge compared to DMSO-treated rats 24 hrs after final injection, ritanserin itself induced head shake responses as well as hyperthermia after 10 d administration. No drug treatment altered the 0.5°C increase in temperature upon DOM challenge. Changes in ACTH, corticosterone and prolactin responses to DOM challenge varied between treatment groups. These data offer evidence that certain 5-HT<sub>2</sub> agonist-induced behavioral responses can be altered by chronic exposure to 5-HT<sub>2</sub> agonists, dependent on route of administration, and that the treatment effects of chronic agonist exposure are not blocked or potentiated by concurrent administration with an antagonist.

## 243.18

FUNCTIONAL SUPERSENSITIVITY OF 5-HT<sub>2A</sub> AND 5-HT<sub>2C</sub> RECEPTORS MEDIATING ACTH SECRETION FOLLOWING 5-HT DEPLETION PRODUCED BY PCPA BUT NOT PCA TREATMENT IN RATS. G. Hahn, P. Mazzola-Pomietto\*, C. S. Aulakh, Christine Wichems, and D. L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892-1264.

Systemic administration of both the phenylisopropylamine hallucinogen 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) and m-chlorophenylpiperazine (m-CPP) produce dose-related increases in plasma adrenocorticotrophic hormone (ACTH) concentrations, most likely by stimulation of 5-HT<sub>2A</sub> and 5-HT<sub>2C</sub> receptors, respectively. In the present study, we investigated the effects of 5-HT depletion produced either by inhibition of 5-HT synthesis following intraperitoneal administration of parachlorophenylalanine (PCPA, 150 mg/kg x3 days) or by degeneration of 5-HT nerve terminals following subcutaneous parachloroamphetamine (PCA, 10 mg/kg x2 days) treatment to male Wistar rats. In the PCPA study, separate groups of animals were challenged with various doses of either DOI or m-CPP 72 hrs after the last dose of PCPA. In the PCA study, separate groups of animals were challenged with various doses of DOI or m-CPP 9 days after the last dose of PCA. The animals were sacrificed by decapitation 30 min after m-CPP or DOI administration. Depletion of 5-HT produced by PCPA treatment accentuated both DOI-induced and m-CPP-induced increases in ACTH concentrations. On the other hand, depletion of 5-HT produced by PCA treatment did not modify either DOI-induced or m-CPP-induced ACTH secretion. These findings demonstrate functional supersensitivity of both 5-HT<sub>2A</sub> and 5-HT<sub>2C</sub> receptors mediating ACTH secretion following inhibition of 5-HT synthesis but not following degeneration of nerve terminals.

## 243.20

ATTENUATION OF FOOD INTAKE SUPPRESSANT EFFECT OF THE 5-HT<sub>2</sub> ANTAGONIST MDL-72222 BY DEXAMETHASONE PRE-TREATMENT IN RATS. C. S. Aulakh, P. Mazzola-Pomietto, N. Garrick\*, and D. L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892-1264.

We have recently demonstrated that systemic administration of the 5-HT<sub>2</sub> receptor antagonist MDL-72222 but not ondansetron produced dose-related decreases in food intake and locomotor activity in rats (Psychopharmacology 121:488-493, 1995). Unlike ondansetron, MDL-72222 has been shown to inhibit 5-HT uptake into guinea pig hippocampal synaptosomes (Drug Dev. Res. 23:27-33, 1991) as well as interact with GABA-A receptors (Alcoholism 18:410-414, 1994). In an attempt to understand the mechanism of its anorectic effect, we studied the effects of various serotonergic, noradrenergic, cholinergic, opiate and GABAergic receptor antagonists on MDL-72222 (10 mg/kg)-induced suppression of food intake in male Wistar rats. Pretreatment with metergoline (0.01-1.0 mg/kg), mesulergine (1.0 mg/kg), mianserin (1.0 mg/kg), ritanserin (1.0 mg/kg), spiperone (0.1 mg/kg), ondansetron (2.0 mg/kg), propranolol (20 mg/kg), scopolamine (0.1-1.0 mg/kg), naloxone (4.0 mg/kg), phenoxylbenzamine (1.0 mg/kg), picrotoxin (1.0 mg/kg) or muscimol (1.0 mg/kg) did not affect MDL-72222-induced suppression of food intake. On the other hand, pretreatment with dexamethasone (0.1-1.0 mg/kg) significantly attenuated MDL-72222-induced suppression of food intake but not locomotor activity. Daily administration of MDL-72222 (10 mg/kg/day) for 9 days failed to produce tolerance to its suppressant effect on food intake. These findings suggest that glucocorticoids may be involved in mediating the food intake suppressant effect of MDL-72222.

## SEROTONIN: UPTAKE AND RELEASE

## 244.1

ORAL ADMINISTRATION OF FLUVOXAMINE INDUCES FOS-IR IN THE MALE RAT BRAIN J.G. Veening, L.M. Coolen, W.J.P.M. Spooren, J. Mos, E. Ronken\* and B. Olivier\*, Dept. of Anat. & Embryol., Fac. Med. Sci., Univ. of Nijmegen, the Netherlands; \*Dept. of CNS Pharmacology, Solvay Duphar B.V., Weesp, the Netherlands. (SPON: European Neuroscience Association).

Fluvoxamine is a specific 5-HT reuptake inhibitor with antidepressant effects. To detect the brain areas possibly involved in these effects, the distribution of Fos-IR neurons was studied in the male rat brain after acute and chronic oral administration.

90 min. after acute administration (30 mg/kg) increased numbers of activated neurons were observed in the nucleus of the solitary tract, medial part (NTSm); the lateral parabrachial nucleus, external part (PBlE); the bed nucleus of the stria terminalis, dorsolateral part (BSTdl); and the central amygdaloid nucleus, lateral part (ACl). After chronic administration (14 days, 30 mg/kg/day) the location of the Fos-IR neurons did not appear to be different, but the numbers were much lower, and no longer significantly different from control values. Using double immuno-stained sections, no Fos-IR could be observed in the 5-HT-IR neurons of the raphe nuclei, but a clear topographical relationship was observed with the GAL-IR fibers in the NTSm and PBlE, and with the VIP- and CRH-IR fibers in the BSTdl and ACl.

Treatment by a 5-HT<sub>1A</sub>-receptor-antagonist (WAY 100,635) or a 5-HT<sub>2</sub> antagonist (ondansetron) before acute oral administration of fluvoxamine did not prevent the induction of Fos-IR in the four brain areas, mentioned above.

We hypothesize that the Fos-IR induced in these areas, as an acute effect of Fluvoxamine, may be the result of an emesis-like activation of the NTSm, probably of peripheral origin.

## 244.2

DEXFENFLURAMINE PRODUCES DOSE-DEPENDENT BIOCHEMICAL AND FUNCTIONAL IMPAIRMENT OF BRAIN 5-HT SYSTEMS

W. Pinto\*, F. Garcia, Q. Li, A. Vicentic, L.D. Van de Kar, W. A. Wolf and G. Battaglia Neuroscience Grad. Prog. and Dept. of Pharmacology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

This study investigated the biochemical and functional consequences of short-term, repeated dexfenfluramine (d-FEN) treatment on brain 5-HT nerve terminals. Adult, male Sprague-Dawley rats (300-350g) were treated with either saline or d-FEN (0.5, 2.0 and 12.0 mg/kg, s.c., b.i.d., 4 days). Based on our previous studies with d,l-fenfluramine, the doses chosen represent a low, moderate and a maximally effective dose. 14 days post-treatment, rats were challenged with a single dose of the pre-synaptic 5-HT releaser, d-fen (5.0 mg/kg, i.p.), 15 minutes prior to decapitation. Pre-treatment with low-dose d-FEN (0.5 mg/kg) did not alter 5-HT levels in frontal cortex (FCX) or 5-HT uptake sites in FCX and hypothalamus (HYPO). Consequently, no functional alterations were observed in plasma ACTH or oxytocin responses to a d-FEN challenge. In contrast, pre-treatment with a moderate dose of d-FEN (2.0 mg/kg) significantly reduced cortical 5-HT levels (-22%) as well as 5-HT uptake sites in FCX (-30%) and HYPO (-26%). Consistent with these biochemical reductions, significant functional deficits were observed in the d-FEN challenge induced elevation of plasma ACTH (-42%) and oxytocin (-49%). The maximally effective dose of d-FEN (12.0 mg/kg) produced significantly greater reductions in cortical 5-HT (-77%) and 5-HT uptake sites in FCX (-87%) and HYPO (-59%) with correspondingly greater functional reductions in oxytocin (-80%) and ACTH (-73%) responses to a d-FEN challenge. Together, these data indicate that short-term, repeated dexfenfluramine treatment produces dose-dependent, biochemical and functional impairment of brain 5-HT nerve terminals, which is persistent for at least 2 weeks post-treatment. ## 244.3

COMBINED ADMINISTRATION ENHANCES NEUROTOXICITY OF PHENTERMINE AND FENFLURAMINE ON 5-HT NEURONS: AN AUTORADIOGRAPHIC ANALYSIS. R. Lew\* and L.S. Seiden, Department of Pharmacol & Physiol Sciences, Univ of Chicago, 947 E58th St Chicago IL 60637.

Using 3H-Citalopram autoradiography, we present further evidence demonstrating combined administration enhances the neurotoxicity of phentermine (Phen) and (+) fenfluramine (Fen) on 5-HT neurons. Recently, we reported combined Phen/Fen administration causes significantly greater depletion of serotonin (5-HT) than either drug alone. In the present study, 3H-Citalopram autoradiography was used to measure 5-HT transporters after Phen/Fen treatment. Male Holtzman Sprague-Dawley rats (275-300 g) were injected i.p. on a 4 x 1 hr regimen with either saline, Phen (20 mg/kg), Lo-Fen (3.125 mg/kg), Hi-Fen (12.5 mg/kg) or Phen/Fen (20 mg/kg/3.125 mg/kg). One week after cessation of treatment, rat brains were perfused and processed for autoradiography. On the day of experiment, brain sections (20 µm) were incubated in incubation buffer (50mM Tris HCl pH 7.4, 22 °C, 120 mM NaCl) containing 3H-Citalopram (2nM) for 60 min. Non-specific binding was defined by 0.5 µM fluoxetine. After incubation, sections were washed in cold incubation buffer, rinsed in ddH<sub>2</sub>O and air dried. Sections were apposed to Biomax film in 4-5 wks before photoprocessing autoradiograms. In preliminary studies, fluoxetine>RTI-121> nisoxetine in competing with 3H-Citalopram binding, indicating binding was to the 5-HT transporter. In autoradiography studies, combined Phen/Fen reduced 3H-Citalopram binding in cingulate, frontal, frontal-parietal and occipital-temporal cortex, nucleus accumbens, olfactory tubercle, striatum, hippocampus and ventromedial hypothalamus. The reduction in binding by Phen/Fen was greater than that observed with either Phen or Lo-Fen. The present study suggests that caution should be exercised in the prescription of Phen and Fen. ## 244.5

EFFECTS OF DEXFENFLURAMINE ON THE RELEASE OF SEROTONIN AND DOPAMINE IN THE RAT STRIATUM. A. Balcioglu\* and R.J. Wurtman, Massachusetts Institute of Technology, Brain and Cognitive Sciences, Cambridge MA 02139

D-fenfluramine (DF), when given to animals in doses that produce brain levels more than 10-fold greater than those occurring in obese patients taking therapeutic doses, can cause a prolonged but reversible decrease in brain serotonin (5HT) unassociated with behavioral changes. Since this decrease reportedly is enhanced by L-dopa but not by 5HTP, it might be mediated by dopamine (DA) release occurring at these high brain levels.

We examined the dose relationships of DF's release of brain 5HT and DA, using *in vivo* microdialysis. Rats given 0.5, 1.0 or 2.5 mg/kg of DF i.p. exhibited significant increases in ECF 5HT by 20-40 minutes after DF administration; peak increases were 123%, 150% and 433%, respectively. Small increases in ECF DA occurred 80-100 minutes after the 0.5 mg/kg dose, and 80-100 or 60-80 min after the other doses. Peak increases are 115%, 118% and 150%, respectively.

Methiothepin, a serotonin 5HT receptor antagonist, largely blocked the increase in ECF DA caused by DF.

These data are compatible with the hypothesis that DF increases DA release via a trans-synaptic action mediated by 5HT.

## 244.7

FENFLURAMINE-INDUCED SEROTONIN NEUROTOXICITY IN BABOON BRAIN DETECTED WITH PET. U. Scheffel, Z. Szabo, W. Mathews, P. Finley, R. Dannals, H. Ravert, B. Callahan, J. Yuan, and G. Ricaurte\*. Departments of Radiology and Neurology, Johns Hopkins Medical Institutions, Baltimore, Maryland 21205.

Fenfluramine is a widely prescribed appetite suppressant that has the potential to damage brain serotonin (5-HT) neurons in animals. While fenfluramine's 5-HT neurotoxic effects in rodents and nonhuman primates are well documented, fenfluramine's neurotoxic potential in humans has not been investigated, largely because of difficulties inherent in evaluating 5-HT neuronal integrity in the living brain. The present studies sought to determine whether PET imaging with the newly developed 5-HT transporter ligand, [<sup>11</sup>C](+)-McN-5652, could be used to detect fenfluramine-induced 5-HT neurotoxicity in the brain of living primates. A 22.3 kg male baboon (*Papio anubis*) underwent 6 PET studies: 3 before and 3 after treatment with fenfluramine (5 mg/kg, s.c., twice daily for 4 days). The 5 mg/kg dose is known to produce a profound loss of 5-HT axon markers, and is approximately two times higher than a dose of fenfluramine reported to produce small and inconsistent weight loss in baboons. In each PET study, 25-32 mCi of [<sup>11</sup>C](+)-McN 5652 (the active enantiomer) and [<sup>11</sup>C](-)-McN 5652 (the inactive enantiomer) were injected, followed by dynamic PET acquisition over 115 min. PET studies 18, 45 and 81 days after fenfluramine revealed marked reductions in regional brain specific binding of [<sup>11</sup>C](+)-McN-5652. Findings with PET corresponded well with post-mortem results indicative of 5-HT neurotoxicity. These results suggest that PET imaging with [<sup>11</sup>C]McN-5652 will be useful for evaluating the 5-HT neurotoxic potential of fenfluramine and related drugs in living humans. SUPEROXIDE-MEDIATED OXIDATION OF SEROTONIN: POTENTIAL ROLE IN NEURODEGENERATIVE DISEASES. M.Z. Wrona and G. Dryhurst\*. Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK 73019.

There is a general consensus that oxygen free radicals contribute to degeneration observed in many neurodegenerative disorders, including Alzheimer's (AD) and Parkinson's (PD) diseases, transient cerebral ischemia, and alcohol and amphetamine abuse. There is also a widely accepted assumption that their deleterious effects are caused by damage to proteins, nucleic acids and lipids. However, many other biomolecules, including neurotransmitters, may be targets for free radicals and these types of reactions may lead to formation of endogenous neurotoxins(s). Recent studies from this laboratory have demonstrated that the serotonergic transmitter 5-hydroxytryptamine (5-HT) is an easily oxidized compound. It is also well known that degeneration of serotonergic pathways contributes to the overall neuropathology observed in AD, cerebral ischemia and methamphetamine abuse. Recently, we demonstrated that 5-HT is readily oxidized at physiological pH by hydroxyl radicals (HO<sup>•</sup>), generated by Fenton chemistry, to give, initially, a mixture of 2,5- and 4,5- and 5,6-dihydroxytryptamine (DHT). Two of these compounds 2,5- and 5,6-DHT, are unique products of the HO<sup>•</sup>-mediated oxidation, whereas 4,5-DHT is also formed in electrochemical or enzyme-mediated oxidations. The neurotoxic properties of 5,6-DHT are well established while those of 2,5- and 4,5-DHT are under current investigation. In the present study, it has been established that 5-HT is very rapidly oxidized by superoxide radicals (O<sub>2</sub><sup>•-</sup>), generated by the xanthine-xanthine oxidase system. Two products of this reaction, 4,5-DHT and 5,5'-dihydroxy-4,4'-bityryptamine (DHT'), could be detected by HPLC with electrochemical detection. Yields of both products increase rapidly with enzyme concentration and incubation times shorter than 9 min., reaching after that steady levels. DTPA has no effect on the overall reaction, whereas catalase inhibits formation of DHT with only a small decrease in 4,5-DHT formation. The effects of glutathione and other antioxidants on the rate and mechanism of O<sub>2</sub><sup>•-</sup>-mediated oxidation of 5-HT as well as the mechanism of this reaction and its potential biological consequences will be discussed.

## 244.6

NEUROTOXICITY OF METHAMPHETAMINE: DEGENERATION VERSUS DEPLETION, A STUDY USING SEROTONIN TRANSPORTER AS A MARKER.

S. B. Bledsoe\* and F. C. Zhou. Indiana University, School of Medicine, Department of Anatomy, Indianapolis, IN 46202.

It is not conclusive whether the neurotoxicity of hallucinogenic drugs of the amphetamine analogue, e.g. methamphetamine (METH), causes depletion or degeneration of serotonin (5-HT) in the brain. This vital difference is not distinguishable since detection markers are subject to the 5-HT level. In this study, using immunocytochemistry against serotonin transporter, we report that METH caused definitive damage to 5-HT fibers at the dosage of 12.5-50mg/kg i.p., within hours. Immunocytochemical 5-HTT staining detected that 5-HTT-immunostained (5-HTT-im) fibers became vesicular along the axons within minutes to hours after METH injection, not normally detectable by anti-5-HT antibodies. The blebs enlarged from 2 to 20µm and eventually perforated when exceeding 15µm-20µm. The perforation of the blebs caused fragmentation which in turn resulted in degeneration of 5-HT fibers. Reduction of 5-HTT-im and 5-HT-im fibers in cortical and hippocampal regions was observed within hours. This rapid damage of 5-HT fibers preceded the normal course of degeneration which takes place over several days. Four days after METH injection, the 5-HTT-im fibers were greatly reduced in many regions of the brain, particularly in frontal, parietal, and occipital cortices, hippocampus, striatum, and thalamus. The sparse thick 5-HTT-im and 5-HT-im fibers that were scattered in the temporal cortex, septal nucleus, nucleus accumbens, hypothalamus and brainstem are more resistant to the METH insult. The damage of 5-HTT-im and 5-HT-im cell bodies in the raphe, if it exists is largely unnoticeable with the current method. In summary, we reported that there are two phases of 5-HT fiber damage by METH: the initial physical damage-vesiculation and perforation; second, the degeneration due to fragmentation and lack of further supply of nutrients and vital proteins occurs within days.

## 244.8

SELECTIVE INCREMENTS OF 5-HT RELEASE IN THE MEDIAN AND DORSAL RAPHE NUCLEI BY MILD STRESS. A. Adell\*, J.M. Casanovas, F. Artigas. Dept. of Neurochemistry, C.S.I.C. Barcelona, Spain.

The serotonergic system participates in the neurobiological adaptations to aversive stimuli. Severe stressful situations increment the turnover of 5-HT and its release in forebrain structures. Less attention has been paid to the response of 5-HT neurons to mild aversive situations. Using microdialysis in conscious rats, we have examined the effects of mild stress on 5-HT release in the dorsal and median raphe nuclei (DRN and MRN, respectively) and in forebrain areas with selective innervation from both (striatum, frontal cortex, hippocampus). The release of 5-HT in the MRN doubled that in the DRN (45 ± 5 vs 22 ± 2 fmol/20-min in presence of 1 µM citalopram, probe length 1.5 mm) and both were markedly superior to that in various forebrain areas (8-13 fmol/fraction). A saline injection increased 5-HT release only in the DRN and MRN (160 % and 210 % of basal, respectively). Also, 5-HT release in the MRN increased to 195 % of basal in rats handled for 30 sec and to 140 % in rats subjected to a mild stress procedure (noise, water spill) within their cages for 5 min. These procedures attenuated or reversed the spontaneous decline of 5-HIAA output in the MRN but not in forebrain. Rats subjected to forced swimming for 5 min experienced a moderate increment of 5-HT release in the midbrain which was accompanied by a reduction in medial prefrontal cortex and hippocampus. These results indicate that the release of 5-HT in the DRN and MRN is very sensitive to mild aversive situations. Given the presence of somatodendritic 5-HT<sub>1A</sub> autoreceptors, the enhanced 5-HT release in these midbrain nuclei may be a physiological mechanism by which 5-HT neurons could attenuate unwanted increments of activity during stressful situations. ## 244.9

ESTROGEN INCREASES SEROTONIN TRANSPORTER (SERT) BINDING SITES AND SERT mRNA EXPRESSION IN FEMALE RAT BRAIN. J.K. McQueen, H. Wilson and G. Fink\*. MRC Brain Metabolism Unit, University Department of Pharmacology, 1 George Square, Edinburgh, UK.

In the rat, estrogen stimulates a massive increase in the expression of 5-HT<sub>2A</sub> receptor mRNA in the dorsal raphe nucleus<sup>1</sup>, and significant increases in the density of 5-HT<sub>2A</sub> receptors in several forebrain areas<sup>2</sup>. The key regulator of serotonergic transmission in brain is the reuptake of extracellular 5-HT by the 5-HT transporter (SERT). We have investigated the possible effects of estradiol-17 $\beta$  on the expression of SERT mRNA and the density of SERT binding sites in female rat brain. Adult female rats were ovariectomized under halothane anaesthesia between 09.00 and 12.00 h on di-estrus, and immediately injected s.c. with either 10  $\mu$ g estradiol benzoate (EB) in 0.1 ml arachis oil (n = 7) or with oil alone (n = 7). The rats were killed between 16.30 and 18.00 h on the following day and the brains removed. SERT mRNA levels were determined by *in situ* hybridization using a 45 base oligonucleotide probe labelled at the 3' end with <sup>35</sup>S- $\gamma$ -ATP and SERT binding sites were measured by quantitative autoradiography using <sup>3</sup>H-paroxetine as ligand. EB increased (~50%) the numbers of cells expressing SERT mRNA in the dorsal raphe nucleus and the density of SERT binding sites in lateral septum (90%), basolateral amygdala (20%), ventromedial nucleus of hypothalamus (250%) and ventral thalamus (250%). Sites in periaqueductal central gray were decreased (by 15%). These results show that estrogen has potent effects on the serotonin transporter as well as 5-HT<sub>2A</sub> receptors, suggesting that effects of estrogen on mood and mental state may be mediated through both of these central serotonergic mechanisms.

## 244.11

BEHAVIORAL EVIDENCE OF SEROTONERGIC TRANSMISSION IN THE SUBSTANTIA NIGRA PARS COMPACTA OF FREELY MOVING RATS. J.L. Góngora-Alfaro\*, F. Heredia-López, F. Alvarez-Cervera and J.L. Bata-García. Centro de Investigaciones Regionales, Universidad Autónoma de Yucatán, Mérida, Yuc., México, 97000.

The substantia nigra pars compacta (SNc) receives serotonergic innervation from the raphe nuclei. Here we investigated the behavioral effect of duloxetine, a serotonin (5-HT) reuptake inhibitor, microinjected into the SNc. Drugs were applied through a cannula aimed at the SNc of the right cerebral hemisphere of male rats. Each rat received two consecutive injections 60 min apart. Circling was counted with an automated rotometer at 5 min intervals. PBS (0.5  $\mu$ l) had no effect. Duloxetine elicited a modest contralateral circling: 2  $\mu$ g, 18.4  $\pm$  5.5 turns/60 min; 4  $\mu$ g, 19.8  $\pm$  5.2 turns/60 min. 5-HT applied alone induced a weak effect. However, an intense contralateral circling developed when 5-HT (8  $\mu$ g) was co-injected with duloxetine. The potentiating effect of duloxetine was dose-dependent: 2  $\mu$ g, 53.6  $\pm$  9.1 turns 60/min (n=7); 4  $\mu$ g, 110.4  $\pm$  16.8 turns/60 min (n=8). It is concluded that 5-HT spontaneously released at the SNc modulates motor behavior. (Supported by grant 1831-M9211 from CONACyT, México.)

## 244.13

IN VIVO CRITERIA TO DIFFERENTIATE MONOAMINE UPTAKE INHIBITORS (MARIs) FROM SEROTONIN RELEASING DRUGS: SIBUTRAMINE IS A MARI. C. Gundlach, K.F. Martin<sup>1</sup>, D.J. Heal<sup>1</sup>, J. Schjott, S.B. Auerbach\*, Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855 & <sup>1</sup>Knoll Pharmaceuticals, Nottingham G.B.

Monoamine reuptake inhibitors (MARIs) and releasers increase extracellular serotonin (5-HT), and it can be difficult to differentiate these two mechanisms *in vivo*. The MARIs, fluoxetine, paroxetine and sibutramine (1-10 mg/kg i.p.) dose-dependently increased 5-HT levels in rat hypothalamus by 2-3 fold. By contrast, the 5-HT releaser fenfluramine (10 mg/kg i.p.), also increased dialysate 5-HT but to a much greater extent (12-fold). The effects of the MARIs, but not fenfluramine, were attenuated by administration of 8-OH-DPAT. All drugs increased extracellular 5-HT when infused into the hypothalamus via the dialysis probe and the effect of the MARIs was attenuated by subsequent systemic administration. In contrast, systemic fenfluramine did not attenuate the increase produced by prior local infusion of fenfluramine into the hypothalamus. Therefore, MARIs can be distinguished from 5-HT releasers by (1) magnitude of their effect, (2) susceptibility to inhibition of neuron firing and (3) blockade of local MARI action by systemic MARI administration, which was not the case for fenfluramine. The data also demonstrate that sibutramine has the pharmacological characteristics of a monoamine reuptake inhibitor and is not a 5-HT releaser. Supported by NIMH grant #51080 and Knoll Pharmaceuticals.

## 244.10

PRESYNAPTIC CONSEQUENCES OF 5,7-DIHYDROXYTRYPTAMINE IN THE AGING HIPPOCAMPUS. A. Dugar\*, C. Patanow, M.L. Billingsley and J.M. Lakoski. Depts. of Pharmacology & Anesthesia, The Pennsylvania State University College of Medicine, Hershey, PA 17033.

The hippocampus is vulnerable to selective damage with aging; however, few studies have examined age-related cellular physiological changes in this region following neurotoxic injury. Following administration of the neurotoxin 5,7-dihydroxytryptamine (5,7-DHT) into the fimbria-fornix/cingulum bundle (FF/CB) to denervate serotonergic afferents to the dorsal hippocampus, age-dependent alterations in hippocampal serotonergic function were investigated using electrophysiological and immunohistochemical techniques. Female Fischer 344 rats were anesthetized with sodium pentobarbital, pretreated with nomifensine (15 mg/kg, i.p.) and bilaterally injected with 5,7-DHT or vehicle (0.1% ascorbic saline) into the FF/CB (2  $\mu$ l total).

Extracellular *in vivo* recordings of hippocampal CA3 subfield pyramidal neurons in chloral hydrate anesthetized rats (3 and 18 mo) were performed three weeks post-lesion. Microiontophoretic applications of 5-HT, 8-OH-DPAT and WAY 100,135 were used to assess serotonergic neuronal function. The rate of recovery was significantly increased following application of 5-HT in the 18 mo 5,7-DHT group compared to the 18 mo Vehicle and 3 mo 5,7-DHT groups (3.3 and 2.6 fold, respectively). Immunohistochemical analysis of the hippocampus was performed using rabbit polyclonal antibodies directed against the presynaptically localized protein, SNAP-25. SNAP-25 expression did not decline in intact aged animals (3, 18, 21 and 29 mo) or in 18 mo animals following 5,7-DHT or vehicle treatment (7 and 21 days post-lesion).

The physiological data revealed the development of increased presynaptic sensitivity to 5-HT in aged animals following neurotoxic lesion, suggesting 5-HT neurotransmission is differentially altered in young versus old animals. These data provide evidence for an age-dependent decline in presynaptic function of the CA3 pyramidal neurons, which may underlie injury-induced responses in the aging hippocampus. Pub. No. 56A supported by PO1 AG 10514 (JML).

## 244.12

LACK OF EFFECT OF SEROTONIN LESIONS ON COCAINE-INDUCED SENSITIZATION. R. T. Windh\*, M. Martinez, G. Slean and K.A. Cunningham. Dept. Pharmacol. and Toxicol., Univ. Texas Med. Branch, Galveston, TX 77555.

The locomotor-activating effects of cocaine (COC) have been largely attributed to an increase in striatal synaptic dopamine (DA) subsequent to blockade of DA reuptake. Serotonin (5-HT) can modulate DA neurotransmission by interacting with both DA cell bodies and terminals, and it is generally reported that 5-HT exerts a negative net control on amphetamine-induced locomotor activity (LMA). The role for 5-HT in COC-induced LMA, or in the progressive increase in COC-induced activity known as sensitization, is not known. On the basis of these earlier studies, one might predict that 5-HT lesions would enhance COC sensitization; the present studies were undertaken to test this hypothesis. Parallel studies were run in which male Sprague-Dawley rats were treated with one of two 5-HT neurotoxins: *dl*-fenfluramine (FEN; 12 mg/kg sc, bid, 4 days) or 5,7-dihydroxytryptamine (DHT; 8  $\mu$ g base/2  $\mu$ l aCSF with 0.1% ascorbic acid, pH 7, injected into the dorsal raphe nucleus under pentobarbital anesthesia) or their vehicles, and then treated with a sensitizing regimen of cocaine (15 mg/kg ip, bid, 7 days) or saline (SAL; 1 ml/kg) in their home cages 4 (FEN study) or 7 days (DHT study) following neurotoxin treatment. LMA was assessed during a 45 min challenge with COC (15 mg/kg ip) 72 hrs after the last sensitizing injection. LMA in response to acute COC administration was not altered in either FEN- or DHT-lesioned rats compared to vehicle-treated controls. Two-way ANOVA of the LMA in response to the COC challenge indicated no main effect of lesion treatment ( $p=31$ , 1 for FEN and DHT studies, respectively), a significant main effect of repeated COC treatment indicating sensitization ( $p=.005$ , .02) and no interaction between the variables ( $p=.42$ , .26). Therefore COC treatment produced sensitization in each study, and neither FEN nor DHT altered the LMA response to acute COC or the expression of COC sensitization as assessed by this assay. Initial immunohistochemical analysis indicated substantial 5-HT loss in lesioned animals from each study; more quantitative assessments are currently underway. Supported by DA 06511 and DA 05637.

## 244.14

ELEVATIONS IN BODY TEMPERATURE THAT ARE INDUCED BY D-FENFLURAMINE (D-FEN) EXPOSURE CORRELATE WITH DECREASING CONCENTRATIONS OF SEROTONIN (5-HT).

C. W. Stewart, P. Clausen, J. F. Bowyer and W. Slikker, Jr.\* Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR 72079.

D-Fen induces elevation of core body temperatures in a warm dosing environment (> 25°C). Other reports demonstrate that d-fen exposure produces a dose-dependent decrease in 5-HT. In this experiment, adult male Sprague-Dawley rats were dosed with either 5 or 10 mg/kg d-fen in a 22 and 28°C dosing environment. All animals were sacrificed 7 days after d-fen exposure and 5-HT concentrations were measured by HPLC in the frontal cortex, hippocampus and striatum. In both dosing environments, there was a dose-dependent decrease in 5-HT concentrations. A negative correlation was observed between peak body temperatures of individual animals and 5-HT concentrations for both 5 and 10 mg/kg d-fen. To determine if the pharmacokinetics of d-fen were altered by the warm environment (28°C), plasma samples were taken (1, 2, 2.5, 3, 4 and 8 hrs) from another group of animals that were dosed with 5 mg/kg d-fen in a 22 and 28°C environment. Analysis of the means at each time-point revealed that pharmacokinetics of d-fen and d-norfenfluramine were not altered by the warm environment. These data indicate that as peak body temperatures increase, 5-HT concentrations decrease and that these effects induced by d-fen are not the result of pharmacokinetic alterations.

## 244.15

**INTERACTION BETWEEN THE FORCED SWIMMING TEST AND FLUOXETINE TREATMENT ON EXTRACELLULAR 5-HT IN THE RAT.** L.G. Kirby\* and J. Lucki. Departments of Psychiatry and Pharmacology, Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

This study examined extracellular levels of 5-hydroxytryptamine (5-HT) during the forced swimming test (FST), a behavioral test that is sensitive to the effects of antidepressant drugs. Cannulae were implanted under surgical anesthesia into either the striatum or lateral septum. One week later, dialysis probes were lowered through the cannulae and dialysis samples collected throughout two sessions of the FST: 1) a 15 min pretest swim, and 2) a 5 min test swim 24 hours later. The antidepressant fluoxetine (20 mg/kg, s.c.), a 5-HT selective uptake inhibitor, or saline was administered 23.5, 5, and 1 hour prior to the test swim. In the striatum, the pretest swim increased 5-HT by 80-90% in both treatment groups. On the second day, the test swim had no effect on 5-HT in saline-treated rats. Fluoxetine-treated rats showed higher basal levels of 5-HT on the second day. In contrast to saline treatment, the test swim decreased striatal 5-HT by 23%. In the lateral septum, the pretest swim produced a 40-50% decrease in 5-HT. On the second day, septal 5-HT did not change following the test swim in saline-treated rats. Fluoxetine-treated rats showed higher basal levels of 5-HT on the second day. In contrast to saline treatment, the test swim decreased septal 5-HT by 38%. 5-HIAA levels were decreased in both brain regions and treatment groups by 15-50% after each swim exposure, although fluoxetine decreased basal 5-HIAA levels on the second day in each region. Therefore, fluoxetine treatment prevented adaptation of the regional response of extracellular 5-HT ordinarily produced in the FST. Fluoxetine reversed the response to the initial swim in striatum and restored the response to the initial swim in lateral septum. It is possible that the ability of antidepressant drugs to alter the neurochemical adaptation to repeated swim might underlie their behavioral effects in the FST, a commonly used animal model of depression. Supported by USPHS grants MH 36262 and MH 17168.

## 244.17

**PRESYNAPTIC 5-HT<sub>1D</sub> RECEPTORS INHIBIT GLUTAMATE RELEASE IN HUMAN CEREBRAL CORTEX.** G. Maura, M. Marcoli, M. Tortarolo and M. Raiteri\*. Institute of Pharmacology and Pharmacognosy, University of Genoa, Genoa, Italy

Activation of 5-HT receptors has been reported to control excitatory amino acid transmission in rat central nervous system. In the present study the effects of 5-HT receptor activation on the release of endogenous glutamate from human cerebral cortex synaptosomes have been assessed. Synaptosomes were prepared from fresh cerebral cortex samples obtained from patients undergoing neurosurgery. Depolarization with high K<sup>+</sup> (15 mM) increased endogenous glutamate release from superfused synaptosomes; the depolarization-evoked overflow of glutamate was almost totally calcium-dependent. Serotonin or agonists selective for 5-HT receptor subtypes (receptor selectivity in parentheses) were found to inhibit endogenous glutamate overflow. The rank order of potency of agonists was: 5-HT ≥ sumatriptan (5-HT<sub>1D</sub>/5-HT<sub>1B</sub>) > 8-OH-DPAT (5-HT<sub>1A</sub>) >> phenylbiguanide (5-HT<sub>2</sub>). The inhibitory effect of 5-HT (0.1 μM) was insensitive to (+)WAY 100135 (5-HT<sub>1A</sub> antagonist), spiperone (5-HT<sub>1A</sub>/5-HT<sub>2</sub> antagonist) or ICS-205930 (5-HT<sub>2</sub>/5-HT<sub>1</sub> antagonist), at concentrations up to 1 μM. Metergoline, a 5-HT<sub>2</sub>/5-HT<sub>1</sub> receptor antagonist which has been reported to behave as a partial agonist or as a full agonist at 5-HT<sub>1D</sub> receptors, inhibited the endogenous glutamate overflow. Metergoline and 5-HT were almost equipotent as inhibitors of glutamate overflow. In preliminary experiments the 5-HT<sub>2</sub>/5-HT<sub>1</sub> receptor antagonist methiothepin prevented the effects of both 5-HT and metergoline.

It is suggested that glutamatergic axon terminals in the human cerebral cortex possess 5-HT receptors that mediate inhibition of glutamate release; the receptors resemble the 5-HT<sub>1D</sub> subtype.

**PHARMACOLOGICAL PROFILE OF THE MIXED 5HT-RE- UPTAKE INHIBITOR/5HT<sub>1A</sub>-AGONIST EMD 68843**  
G.D. Bartoszyk\*, A. Barber, H. Böttcher, H.E. Greiner, J. Leibrock, J.M. Martínez, and C.A. Seyfried. Merck KGaA Pharm. Res., CNS-Research, 64271 Darmstadt, Germany.

EMD 68843 (5-[4-[4-(5-cyano-3-indolyl)-butyl]-1-piperazinyl]-benzofuran-2-carboxamide, HCl) exhibited the following binding profile *in vitro* (receptor and IC<sub>50</sub>-values, resp.): 5HT<sub>1A</sub> 0.5 nM, σ 17 nM; affinity to 5HT<sub>1D</sub>, 5HT<sub>2A/C</sub>, 5HT<sub>4</sub>, D<sub>1/2/3/4</sub>, BZD/GABA, α<sub>1/2</sub>, H<sub>1/2</sub>, M<sub>1/2</sub>, opioid, NMDA, AMPA, kainate, glycine was ≥ 100 nM. Reuptake was inhibited *in vitro* with IC<sub>50</sub>-values of 0.2 nM for 5HT, 60 nM for NE, and 90 nM for DA and *in vivo* for 5HT with ED<sub>50</sub>-values of 0.7 mg/kg s.c. or 3.8 mg/kg p.o.. Accumulation of 5HTP was inhibited by 40% in rat striatum with 10 mg/kg p.o. whereas DOPA levels were not affected. In behavioral animal models, EMD 68843 inhibited ultrasonic vocalization in rats with ED<sub>50</sub>-values of 3.8 mg/kg s.c. and 12.8 mg/kg p.o. with a long duration of action; the effect was totally counteracted by the 5HT<sub>1A</sub> antagonist WAY 100635. After repeated treatment, EMD 68843 reduced immobility in the behavioral despair test and the tail suspension test in mice with doses of 30 to 55 mg/kg p.o.. The results characterize EMD 68843 as a drug with mixed antidepressant/anxiolytic activity.

## SEROTONIN TRANSPORTERS

## 245.1

**REGIONAL VARIATION OF EXPRESSION OF SEROTONIN TRANSPORTER MRNA IN DORSAL AND MEDIAN RAPHE NUCLEI.** M. Rattray\*, J. Lee<sup>1</sup>, G. Michael<sup>2</sup>, C. Bendotti<sup>3</sup> & J.V. Priestley<sup>1,2</sup>. <sup>1</sup>UMDS Biochem. & Mol. Biol., <sup>2</sup>UMDS Physiology, Guy's Hospital, London SE1 9RT, U.K. <sup>3</sup>Mario Negri Institute, Via Eritrea 62, 20157 Milan, Italy

We have previously noted that a number of drugs including fenfluramine, MDMA and PCPA down-regulate serotonin transporter (SERT) mRNA levels. Neurons in the ventromedial subdivision of the dorsal raphe nucleus (DRv) are more sensitive than neurons in the dorsomedial subdivision (DRd). The basis for this is unknown, but may be due to regional variation in expression of proteins involved in serotonin neurotransmission.

We have used radioactive *in situ* hybridization (ISH) using liquid emulsion autoradiography and image analysis techniques to determine the levels of expression of the mRNAs for SERT, tryptophan hydroxylase (Tph) and L-aromatic amino acid decarboxylase (AADC) in subdivisions of the dorsal raphe and in median raphe (MR). In addition we have combined SERT ISH with serotonin immunocytochemistry. SERT mRNA is expressed by all serotonin positive cells, but the levels of SERT mRNA and serotonin display a wide variation between individual neurons. The mean cellular expression level of SERT mRNA is highest in DRv, with neurones in the lateral wings of the dorsal raphe (DRl) having the lowest levels. SERT mRNA levels in MR and DRd were intermediate. Tph and AADC mRNA levels also showed regional variation (Tph mRNA levels in DRv ≥ MR >> DRl = DRd; AADC mRNA levels in MR ≥ DRv >> DRl = DRd). Conversely, the levels of serotonin immunoreactivity were lowest in DRv cells and highest in DRl cells. These results support the hypothesis that serotonin neurones have subtle differences in chemical phenotype, according to their location. This may account for variation in their drug response. **IMIPRAMINE CAN PROTECT SEROTONIN UPTAKE INHIBITION INDUCED BY CITALOPRAM.** C. Sur, H. Betz\* and P. Schloss. Dept. of Neurochemistry, Max-Planck Institute for Brain Research, Frankfurt am Main, Germany.

Tricyclic antidepressants and selective serotonin uptake inhibitors are widely used for the treatment of depression. To gain further insight into the interactions between imipramine, citalopram and serotonin (5-HT) at the rat serotonin transporter, SERT1, we have analyzed the effects of these drugs on 5-HT transport into a stable cell line expressing SERT1. Previously, we have shown that imipramine binds to two different sites on this molecule; a high affinity sodium-dependent site and a low affinity site that also binds citalopram. Competition experiments revealed that both citalopram and imipramine competitively inhibit 5-HT uptake. Whereas the K<sub>i</sub> value for citalopram was similar to its K<sub>d</sub> value, the inhibitory potency of imipramine was more than one order of magnitude lower than its K<sub>d</sub> value as determined in direct ligand binding. However, binding of imipramine to its high affinity site allosterically displaced citalopram. Consequently, in the presence of sodium ions, low concentrations of imipramine partially protected 5-HT transport from citalopram inhibition. These results confirm the existence of two distinct binding sites for imipramine on SERT1 and suggest that they may exert different effects on 5-HT uptake depending on which site is occupied.

## 245.3

## REGULATION OF THE SEROTONIN TRANSPORTER.

L. M. Hall\* and G. M. Anderson. The Child Study Center, Yale University School of Medicine, New Haven, CT 06510.

The regulation of the serotonin transporter (SERT) has been examined by a number of groups. A consistent finding has been the short-term down-regulation of transport rates ( $V_{max}$ ) following protein kinase C (PKC) activation. There are also reports that rapid regulation can occur after receptor stimulation, protein kinase G (PKG) activation, or following exposure to nitric oxide (NO). We now report that ADP does not reduce platelet 5-HT uptake through receptor stimulation, but rather via a non-competitive effect at the transporter; similar effects are seen in platelet and synaptic vesicles. A reported stimulatory effect of histamine on platelet 5-HT uptake was not observed in a series of studies examining a range (0.1-1.0  $\mu$ M) of histamine concs and exposure times. We also have not observed the stimulatory effects reported for NO and PKG activation on 5-HT transport by RBL cells or brain slices when studying the platelet SERT. Data from studies on the effects of protein phosphatase inhibitors, alone or in combination with PKC-activators, on synaptic vesicle and platelet uptake will also be presented. We will attempt to reconcile the varied results obtained using platelets, cell-lines, synaptosomes, and brain slices.

## 245.5

REGULATION OF SEROTONIN TRANSPORTER EXPRESSION BY CAMP AND INTERFERON IN VARIOUS TISSUES AND IN BEWO CELLS. O. Morikawa\*, T. Deai, N. Murakami, N. Sakai and N. Saito. Laboratory of Molecular Pharmacology, Biosignal Research Center, Kobe University, Kobe 657, Japan

The serotonin transporter (SET) is known to be the main target of the antidepressants. We have reported that we cloned the promoter region of SET from mouse genomic library and the promoter activity of SET was enhanced by the treatment of dibutyl cyclic AMP (Dib-cAMP) (Sakai et al. 1995). To elucidate the involvement of SET in the pathogenesis of the affective disorders, it is of interest to examine the mechanism of the transcriptional regulation of SET expression.

In the present study, we investigated the effect of Dib-cAMP, IFN- $\alpha$  and IFN- $\gamma$  on the transcriptional level of SET mRNA in Bewo cells which constitutively express SET, using Northern blot analysis. Significant increase in level of SET mRNA was observed by the treatment of Dib-cAMP for 24 hrs. The result was in agreement with the previous findings Dib-cAMP enhanced the promoter activity of SET assessed by CAT assay. The treatment of IFN- $\alpha$  and IFN- $\gamma$  produced slight increase in level of SET mRNA. It is suggested that the cAMP dependent process may regulate the SET expression and may be involved in the pathogenesis of the affective disorders. We also investigated the change in the level of SET mRNA in mouse brain stem, adrenal and bone marrow by the intraperitoneal administration of Dib-cAMP, IFN- $\alpha$  and IFN- $\gamma$ .

## 245.7

INTERACTION BETWEEN WAY 100635 A SELECTIVE 5-HT<sub>1A</sub> RECEPTOR ANTAGONIST AND LOW FLUOXETINE DOSE ON SEROTONIN LEVELS AT NERVE TERMINALS: AN IN VIVO MICRODIALYSIS STUDY. L. Malagie\*, C. Jacquot and A. M. Gardier. Lab. Neuropharmacol. JE DRED 92-372, Fac. Pharm Univ. Paris-Sud, F92296 Chateau-Malabry, France.

In the rat, a single administration of fluoxetine (Flx), a selective serotonin reuptake inhibitor (SSRI) at low doses, i.e., comparable to those used therapeutically, increases extracellular serotonin (5-hydroxytryptamine, 5-HT) levels in the vicinity of cell bodies and dendrites of serotonergic neurons of the median and dorsal raphe nuclei. In these areas, high densities of 5-HT<sub>1A</sub> autoreceptors and of 5-HT transporters have been described. This effect is more marked than that observed in regions rich in 5-HT nerve endings (frontal cortex FC, ventral hippocampus vHi) (Malagie et al., *Eur. J. Pharmacol.*, 286 (1995) 213). This could be explained by activation of somatodendritic 5-HT<sub>1A</sub> autoreceptors by endogenous 5-HT in the raphe nuclei, thus leading to decreases in the firing rate of serotonergic neurons, thereby limiting the frontocortical effects of the antidepressant. To test this hypothesis, we studied the changes in extracellular 5-HT levels in the FC and vHi, induced by the combined administration of a highly selective 5-HT<sub>1A</sub> receptor antagonist, WAY 100635 (0.1 mg/kg, i.v.), and Flx (1 mg/kg, i.p.) to conscious rats. In the 2 brain areas studied, no change in extracellular 5-HT concentrations was observed following Flx administration over the 210 min post-injection period. However, in animals co-administered with WAY 100635 + Flx, the maximal increase in 5-HT levels in FC dialysates was to 215% of the respective basal value (100%), while no change was found in hippocampal 5-HT. We also found that the major active metabolite of Flx, norfluoxetine (NFlx), concentrated in the frontocortical tissue but not in the hippocampal one, thus achieving a mean  $\pm$  S.E.M. [NFlx]-to-[Flx] concentration ratios of  $2.1 \pm 0.16$  and  $1.29 \pm 0.08$  n=7, respectively, as measured when the effect on extracellular 5-HT was maximal in FC, i.e., 120 min after Flx administration alone or combined with WAY 100635. Our data underline the role of somatodendritic 5-HT<sub>1A</sub> receptor blockade in revealing the neurochemical effects of clinically relevant SSRI doses.

## 245.4

Chronic cocaine binge administration fails to alter serotonin and norepinephrine transporter mRNA levels from behaviorally sensitized rats. S.A. Burchett\* and M. J. Bannon. Depts. of Psychiatry and Behavioral Neurosciences and Pharmacology, Wayne State University, Detroit, MI 48201.

Cocaine binds with high affinity to the dopamine, serotonin and norepinephrine transporters (DAT, SERT and NET, respectively). While the effects of cocaine administration on DAT expression have been investigated intensively, few studies have investigated changes in SERT and NET expression. Furthermore, both the dopamine and serotonin systems may be involved in the progressive development of the well-described phenomenon termed sensitization. In the present study, the effects of chronic cocaine in a binge paradigm of administration on DAT, SERT and NET transporter mRNA levels were compared in the brains of sensitized rats. Male Fisher rats were injected 3 times (spaced 1 hr apart) with 15 mg/kg cocaine for 14 days. Differences in the behavioral scores between day 1 and day 14 indicate that the cocaine treated rats had become sensitized during the treatment regimen. Quantitative *in situ* hybridization using antisense cRNA probes was utilized to map the distribution and abundance at the cellular level of the DAT, NET and SERT mRNAs. Although significant regional heterogeneity of DAT and SERT mRNA abundance was evident, chronic cocaine administration did not consistently alter the abundance of the SERT and NET mRNAs in the regions examined, suggesting that the SERT and NET in the rat do not exhibit compensatory changes in response to cocaine. In addition, correlational analysis indicates that SERT and NET mRNA levels do not underlie cocaine-induced sensitization. Supported by NIH grant DA 06470.

## 245.6

EFFECT OF CHRONIC CITALOPRAM TREATMENT ON THE SEROTONIN TRANSPORTER. J. Lawrence, H.J. Olverman, J.S. Kelly\* and S.P. Butcher. Department of Pharmacology and <sup>1</sup>Fujisawa Institute of Neuroscience, University of Edinburgh, 1 George Square, Edinburgh, EH8 9JZ.

This study was undertaken to investigate the effects of chronic treatment with citalopram, a selective serotonin uptake inhibitor used widely in the treatment of depression, on the distribution and density of serotonin transporter (SERT) sites in rat brain. Citalopram (10mg/kg s.c.) was administered twice daily for 21 days. The density of SERT sites was measured by immunohistochemical techniques, using antibodies raised against selected sequences of SERT, conjugated to keyhole limpet haemocyanin. The rats were perfused through the aorta with 4% paraformaldehyde, 0.05% glutaraldehyde. Brains were removed and cryoprotected in 30% sucrose overnight and then sectioned at 30  $\mu$ m. Sections were preblocked in PBS containing 4% normal goat serum for two hours then incubated with antibody (1:1000 dilution) overnight. SERT immunoreactivity was detected with the Vectastain ABC Elite kit. Chronic administration of citalopram produced a dramatic reduction in the density of terminal field staining in the striatum with a smaller reduction seen in the hippocampus. These data support the findings of Piñeyro et al (1994) where chronic paroxetine treatment was seen to reduce <sup>3</sup>H-5HT uptake and <sup>3</sup>H-paroxetine binding in rat hippocampal and cortical membranes. Similarly Lesch et al (1993) have demonstrated a significant reduction in SERT mRNA levels in rat midbrain, after chronic antidepressant treatment, as measured by Northern blot analysis.

## 245.8

MOLECULAR CLONING OF THE MURINE SEROTONIN TRANSPORTER GENE AND IDENTIFICATION OF BRAIN TRANSCRIPTION INITIATION SITES. A.L. Bauman\*, N. Flattem, M.D. Malone, J.D. Fritz, R.D. Blakely. Dept. of Pharmacology and Ctr. Mol. Neuroscience, Vanderbilt University Sch. of Medicine, Nashville, TN 37232.

The serotonin (5HT) transporter (SERT) is responsible for termination of synaptic transmission at central and peripheral serotonergic synapses. SERT gene expression in the CNS is restricted to midbrain and brainstem serotonergic neurons and regulated by cAMP, antidepressants, and growth factors. The mechanisms of cell-specific and activity-mediated SERT gene expression are not understood, nor are the consequences of compromised SERT expression. To pursue these questions, we have isolated a murine SERT (mSERT) genomic clone and have used 5'RACE to identify transcription start sites in mouse brain. Oligonucleotides complementary to mSERT cDNA sequences were used to identify an amplicon from mouse genomic DNA. The identity of the amplicon was verified by Southern blotting and direct sequencing. The amplicon primers were subsequently used to obtain a genomic clone from a murine ES 129 P1 library. Verification and mapping of the mSERT genomic clone was accomplished by Southern analysis using mSERT cDNA and oligonucleotide probes, as well as through direct sequencing. The mSERT genomic clone spans more than 20Kb and, like the human SERT gene, is comprised of multiple exons. 5'RACE reactions performed on mouse brain RNA identified 560 bp of 5' noncoding sequence upstream of the mSERT initiator methionine. The sequence has been mapped on the P1 clone, significantly upstream of previously reported initiation sites (Genbank U26452), and indicate at least one distal noncoding exon likely to contribute to CNS SERT mRNAs. (Supported by NIH grant DA07390)

## 245.9

**VOLTAGE-DEPENDENCE OF 5-HT-TRANSPORT-ASSOCIATED CURRENT.** A. Galli, C. I. Petersen, M. deBlaquiere, S. Ramsey, R. D. Blakely\* and L. J. DeFelice. Dept. of Pharmacology, Vanderbilt Univ., Nashville, TN 37232.

Serotonin (5-HT) transporters (SERTs) are the targets for antidepressants and drugs such as cocaine. We have microinjected cRNA encoding the *Drosophila* serotonin transporter (dSERT) into *Xenopus* oocytes to determine 5-HT uptake characteristics and the ion permeation of the 5-HT transporter under voltage-clamp conditions. Several recent reports indicate that co-transporters generate large currents that are incompatible with a fixed stoichiometry. Recently, channel behavior has been described in mammalian 5-HT transporters. Here we report the possibility that the channel mode of conduction is also able to provoke a non-stoichiometric-coupled 5-HT associated current. In these experiments the correlation of [<sup>3</sup>H]5-HT uptake with net charge movement in same voltage clamped oocytes shows the average quantity of charge translocated per 5-HT molecule varies with membrane potential and increases at negative voltages (150 e at -120 mV versus 15 e at 0 mV). By addressing the effect of voltage on [<sup>3</sup>H]5-HT uptake and associated currents, we can examine mechanistic aspects of 5-HT uptake at the single transporter level. Supported by NIH DA 07390, NS 34075-01, NARSAD.

**EXPRESSION, FUNCTION, AND DEVELOPMENT OF A 5-HT TRANSPORTER (SERT) IN THE PLASMA MEMBRANE OF THYROID FOLLICULAR CELLS.** H. Tamir\*<sup>1,2</sup>, K.P. Liu<sup>1</sup>, S.H. Hsiung<sup>1</sup>, R.D. Blakely<sup>3</sup>, A.F. Russo<sup>4</sup>, M.S. Clark<sup>4</sup> & M.D. Gershon<sup>2</sup>. 1. NYS Psych. Inst.; 2. Dpt. of Anat. and Cell Biol. P&S New York, NY 10032. 3. Dpt. of Pharmacol. Vanderbilt U. Nashville, TN 37232-6600; 4. Dpt. of Physiol. and Biophys. U. of Iowa Iowa City, IA 52242.

5-Hydroxytryptamine (5-HT) is synthesized by the neural crest-derived thyroid parafollicular (PF) cells. All PF secretory vesicles co-store 5-HT with calcitonin; therefore, 5-HT and calcitonin are always co-secreted. Because 5-HT stimulates follicular (F) cells and modulates their response to TSH, 5-HT may be a PF → F paracrine transmitter. If so, then a thyroid mechanism, analogous to the SERT of serotonergic neurons, would be required to inactivate 5-HT. Since the thyroid lacks serotonergic nerves, and PF cells do not take up 5-HT, we tested the hypothesis that the SERT is expressed by the putative F cell targets. mRNA encoding SERT was found in human thyroid glands and a rat F cell line (FRTL-5). The FRTL-5 cells also took up [<sup>3</sup>H]-5-HT by a process that was temperature and Na<sup>+</sup>-dependent, and antagonized by 5-HT-, but not catecholamine-selective uptake inhibitors. Antibodies to rat SERT immunocytochemically labeled F, but not PF, cells. Transporter-mediated uptake of [<sup>3</sup>H]-5-HT by F cells was found to arise early in development (E13 in mice) and to be maintained in adult life in mice, guinea pigs, and bats. These observations support the idea that 5-HT is a paracrine transmitter in the thyroid. Grant DK19743, NS12969, and NS15547.

## 245.13

**SEROTONIN TRANSPORTER CHIMERAS CONTAINING THE THIRD AND FOURTH EXTERNAL LOOP OF THE NOREPINEPHRINE TRANSPORTER.** Y. Smicun\* and G. Rudnick. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven CT 06510

To examine the role of the predicted external loops of the serotonin transporter (SERT) on its function, we created chimeric transporters in which the third and fourth external loops of SERT were exchanged with the corresponding loops of the norepinephrine transporter (NET). We expressed the SERT chimeras in HeLa cells using the vaccinia-T7 expression system and measured uptake of serotonin (5-HT), binding of the cocaine analog β-CIT, and cell surface expression. Transport of 5-HT by the third loop SERT-NET chimera was identical to that of wild-type SERT. The sensitivity of this chimera to the transport inhibitors cocaine, citalopram and desipramine was similar to that of wild-type SERT. These results suggest either that the amino acid composition of the third loop is not important for the function of SERT, or that the conserved amino-acids in the third loop of the two transporters are sufficient for transport and inhibitor binding. HeLa cells transfected with the fourth loop SERT-NET chimera were impaired in uptake of 5-HT, and membrane vesicles prepared from these cells did not bind β-CIT. The transporter also was not expressed in the cell membrane. These results suggest that the fourth loop chimera does not fold properly.

## 245.10

**ACUTE ADMINISTRATION OF RESERPINE MODULATES SEROTONIN TRANSPORTER GENE EXPRESSION IN A TIME DEPENDENT MANNER IN THE RAT BRAIN.** Q. Xiao, A. Pawlyk and S. M. Tejani-Butt\*. Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Despite recent advances in determining central serotonin function, the basic aspects by which serotonin neurotransmission is controlled and regulated are still not understood. Since the serotonin transporter (5-HTT) is involved in terminating the action of 5-HT that is released from the presynaptic nerve terminal, the regulation of the 5-HTT may be an important step in controlling 5-HT neurotransmission at the synaptic cleft. The present study investigated the effects of reserpine administration on 5-HTT gene expression in the rat brain. Male Sprague-Dawley rats were injected with reserpine (10 mg/kg, i.p.) and sacrificed at 8h, 3d, 7d or 21d after the injection. Control rats were injected with saline and sacrificed either 8h or 21d after the injection. The midbrain region was dissected, RNA isolated and probed for 5-HTT expression using Northern Blotting. Data were analyzed using Super-Anova followed by post-hoc Dunnett's test. While mRNA levels for 5-HTT were unchanged at 8h after reserpine, a significant decrease was noted at 3d and 7d (F=10; p<0.0001) with mRNA levels returning to control values by 21d. The results of this study provide useful information regarding the role that the 5-HTT may be playing in the homeostatic control of 5-HT neurotransmission at the synapse. (Research funds from USPHS grant NS 31699).

## 245.12

**TOPOLOGICAL LOCALIZATION AND DISULFIDE STATUS OF THREE CYSTEINE RESIDUES IN THE SEROTONIN TRANSPORTER** Jie-Guang Chen, Shuxian Liu-Chen and Gary Rudnick\*. Dept. of Pharmacology, Yale University, New Haven, CT 06510

Hydropathy analysis predicts three cysteines (C109, C200, and C209) in extracellular loops of rat serotonin transporter. We mutated these residues, singly and in combination, to either alanine or serine and expressed the mutant transporters in HeLa cells using the vaccinia-T7 transient expression system. Mutation of C109 to alanine had no effect on transport activity or surface expression of the transporter. However, inactivation of transport activity by the impermeant cysteine reagent (2-aminoethyl) methanesulfonate (MTSEA) was reduced in the C109A mutant. In the absence of Na<sup>+</sup>, MTSEA inactivation increased dramatically, and the effect of C109 replacement was more pronounced. Changing either C200 or C209 to serine resulted in a marked loss of transport activity and decreased surface expression of the fully glycosylated transporter. MTSEA rapidly inactivated the residual transport activity in mutant C200S, suggesting increased accessibility of a previously unreactive cysteine residue. The double mutant C109A-C200S was also very sensitive to MTSEA, but the reactivity of a C200S-C209S mutant was much lower, similar to that of the wild-type transporter. These results suggest that C200 and C209 are linked by a disulfide bond. This was further supported by the observation that surface expression of the transporter was normal in the C200S-C209S mutant. The Na<sup>+</sup>-dependence of transport and ligand binding was abnormal in both C200S and C200S-C209S mutants. The results suggest that C109 is in the first external loop and that C200 and C209 are linked by a disulfide bond in the second external loop of the serotonin transporter. Disrupting this disulfide may prevent proper Na<sup>+</sup> binding and produce a free sulfhydryl group that inhibits proper surface expression of the transporter. Supported by grants from USPHS-NIDA.

## 246.1

**ALGORITHMS FOR AUTOMATIC STRUCTURE IDENTIFICATION IN A 3-D RAT BRAIN ATLAS DEVELOPED AS TEMPLATE FOR IN SITU HYBRIDIZATION NEUROANATOMICAL DATABASE** A. Danckaert, D. Talabot-Ayer, M. Peitsch, N. Guex, J. Knowles, F. E. Bloom, E. Merlo Pich. Geneva Biomedical Research Institute, CH1228 Geneva, Switzerland, <sup>1</sup>Neuropharmacology, The Scripps Research Institute, La Jolla, CA. Mapping the brain distribution of novel genes is a fundamental step in the process of gene function identification. Since more than 50,000 genes are estimated to be present in the brain, a reasonable way to store, analyze, and compare these information is using neuroanatomical databases. Recent technological developments in the field of medical imaging, computer science, and networking has allowed neuroscientists to expand the concept of brain maps and databases. In the present work we describe the development of a neuroanatomical working station, portable on PC and Macintosh computer, whose major goal is to support the correct attribution of areas of specific hybridization signal for a gene product to a given neuroanatomical structure and/or cell group. A 3-D reconstruction of adult Wistar rat brain was obtained by averaging about 600 images collected from 5 animals in both coronal and sagittal cutting planes. The initial 3-D rendering was obtained by defining asymmetric voxel with a resolution between 25 and 120  $\mu$ m. Sections were stained with cresyl violet and regions of different staining intensities were identified on the captured image, separated by an automatic contour definition algorithm, reconstructed in 3-D, and named according to Paxinos (1986) and Swanson (1992) brain atlas. When a brain section containing in situ hybridization signal adjacent to a cresyl violet stained section is analyzed, an algorithm automatically attributes the signal to a given brain structure by comparing the location of the signal with the location of the structures defined in the "standard" brain, and store it in a database normalized over the "standard" brain. Funding was private.

**125I-AB-MECA LABELS A1 AND A2A ADENOSINE RECEPTORS IN RAT BRAIN.** D.R. Weaver\* and L.P. Shearman, Lab. Developmental Chronobiology, Pediatrics, Mass. General Hospital, Boston, MA 02114.

Adenosine modulates neuronal activity and neurotransmitter release through interaction with cell surface receptors of A<sub>1</sub>, A<sub>2A</sub>, A<sub>2B</sub>, and A<sub>3</sub> subtypes. 125I-AB-MECA (N6-4-amino-3-iodo-benzyladenosine-5'-N-methyluronamide) has high affinity for recombinant A<sub>1</sub> and A<sub>3</sub> receptors (Olah et al., Mol Pharmacol 45:978-982, 1994). We studied whether this ligand is useful for autoradiographic localization of A<sub>3</sub> receptors in rat brain. Slide-mounted sections were incubated in binding buffer (50 mM TRIS, 10 mM MgCl<sub>2</sub>, 1 mM EDTA, 2 U/ml adenosine deaminase), then incubated with 125I-AB-MECA (400 pM) in the same buffer for 90 min at 22° C, washed (10 min, 0° C), dried, and exposed to film for 7-14 d. Non-specific binding was defined with 10  $\mu$ M NECA.

The autoradiographic distribution of 125I-AB-MECA binding closely resembled the pattern of A<sub>1</sub>-receptor binding, with specific binding in cerebellum > hippocampus > thalamus > cortex = striatum. XAC (1  $\mu$ M) completely blocked specific 125I-AB-MECA binding, indicating binding was primarily to A<sub>1</sub>, not A<sub>3</sub> receptors, under these conditions. In the presence of CPX (50 nM, to block A<sub>1</sub> receptors), specific 125I-AB-MECA binding remained only in the neostriatum. Competition studies indicated that striatal 125I-AB-MECA binding in the presence of 50 nM CPX reflected binding to A<sub>2A</sub> receptors. Our studies indicate that 125I-AB-MECA labels A<sub>1</sub> and A<sub>2A</sub> adenosine receptors in rat brain. The level of A<sub>3</sub> receptor binding in rat brain appears insufficient to allow autoradiographic detection of this subtype. *Supported by HD29470. 125I-AB-MECA was generously provided by NEN Life Science Products.*

**IMMUNOHISTOCHEMICAL STUDIES ON THE LOCALIZATION OF ADENOSINE A1 RECEPTOR IN THE POSTNATAL AND ADULT RAT HIPPOCAMPUS.** T. Ochiishi\*<sup>1</sup>, A. Yukawa<sup>1</sup>, H. Miyamoto<sup>1</sup>, Y. Saitoh<sup>2</sup>, H. Nakata<sup>2</sup>, Y. Sekino<sup>3,4</sup> <sup>1</sup>Biosignalling Dept., National Inst. of Biosci. & Human Technol., Tsukuba, Ibaraki 305, <sup>2</sup>Dept. of Mol & Cell Neurobiol., Tokyo Metropolitan Inst. for Neurosci., Fuchu, Tokyo 183, <sup>3</sup>PRESTO, Res. Dev. Corp. of Japan, Mitsubishi Kasei Inst. of Life Sci., Machida, Tokyo 194, and <sup>4</sup>Dept. of Neurobiol. & Behav., Gunma Univ., Maebashi 371, Japan.

Adenosine has a potent inhibitory effect through its A<sub>1</sub> receptor in the central nervous system. Several studies have recently shown that adenosine acts as one of the regulatory factors for synaptic plasticity such as long-term potentiation. In order to elucidate cellular mechanisms underlying hippocampal plasticity, we focused on function of adenosine A<sub>1</sub> receptor in adult and developing rat hippocampus. In this study, we used the rabbit antiserum against the adenosine A<sub>1</sub> receptor protein purified from rat brain (Nakata, 1993) and examined when and where the adenosine A<sub>1</sub> receptor is expressed during the development and at adult rat hippocampus using immunohistochemical technique.

In the adult rat (3-months of age) brain, immunoreactivities to adenosine A<sub>1</sub> receptor were observed in the Ammon's horn and dentate gyrus. In the fields CA1 and CA3, around the cell body of pyramidal cells were immunostained. In addition, a little higher immunoreactivities were observed in the surrounding area of the pyramidal cells and their dendrites of the CA2 field. However, during the development, Ammon's horn was uniformly stained by this antibody until postnatal day 21 (P21). The mature type of immunopositive profiles were established from P21 to P28.

**CAN POSITRON EMISSION TOMOGRAPHY DETECT CHANGES IN INTRASYNAPTIC DOPAMINE? COMPUTER SIMULATIONS CAN OPTIMIZE THE EXPERIMENTAL DESIGN.** E.D. Morris<sup>1</sup>, C.A. Heidbreder<sup>1</sup>, T.S. Shippenberg<sup>1</sup>, M. Ernst<sup>1</sup>, B.T. Christian<sup>2</sup> and E.D. London<sup>1\*</sup> <sup>1</sup>Brain Imaging Section, NIDA, Baltimore, MD 21224 and <sup>2</sup>Dept. of Radiology, Massachusetts General Hospital, Boston, MA 02114.

Cocaine-induced inhibition of dopamine (DA) re-uptake results in increased intrasynaptic dopamine levels in forebrain regions. Computer simulations of a newly-modified model of receptor-ligand kinetics were performed to optimize the sensitivity of PET studies to changes in DA levels. A compartmental model of dynamic PET activity was developed (Morris et al., 1995): it assesses effects of transient changes in endogenous DA levels on receptor-ligand binding. The model requires knowledge of the inputs of exogenous and endogenous ligands to the system and their kinetic constants in brain tissue. The inputs are: (1) the amount of receptor-ligand which is injected as a single bolus, and (2) the dynamics of free DA in the neighborhood of the receptor. The dynamics of DA in the primate brain were derived from microdialysis assays of endogenous DA in the nucleus accumbens of the rat, before and after exposure to cocaine (Heidbreder et al., 1996). <sup>11</sup>C-Raclopride (RAC) was examined as a possible PET tracer. Its plasma input and tissue parameters were derived from the literature (Farde et al., 1989). Computer simulations examined the influence of several design considerations on the PET output: (1) timing of cocaine injection relative to RAC injection, (2) advantages of one DA-receptor ligand over another, (3) scanning duration, and (4) route of administration of cocaine challenge. An optimal design was defined as one that maximizes the weighted sum of squares difference between the simulated PET curves of 'rest' and of 'post-cocaine' experiments. Preliminary findings indicate that the optimal timing of cocaine injection is 5 min. prior to that of RAC. Changes in DA levels are undetectable with PET when cocaine injection follows RAC injection by 15 min. or more. Such simulations can help avoid unnecessary experimental manipulations of animals and facilitate interpretation of negative results.

## 246.4

**DISTRIBUTION OF A<sub>2A</sub> ADENOSINE RECEPTORS (A<sub>2A</sub>ARs) IN RAT BRAIN: CHARACTERIZATION OF MONOCLONAL ANTIBODIES AND IMMUNOHISTOCHEMICAL LOCALIZATION OF A<sub>2A</sub>ARs.** D.L. Rosin<sup>1</sup>, R. Woodard<sup>2</sup>, P.G. Guyenet<sup>1</sup> and J. Linden<sup>3</sup> <sup>1</sup>Depts. of Pharmacol., <sup>2</sup>Physiol. and <sup>3</sup>Medicine, <sup>3</sup>Univ. of Virginia, Charlottesville, VA 22908

The purine nucleoside adenosine exerts its diverse effects in the CNS through four receptor subtypes: A<sub>1</sub>, A<sub>2A</sub>, A<sub>2B</sub>, and A<sub>3</sub>. To better understand the cellular mechanisms of adenosine's actions, we have developed monoclonal antibodies directed against purified, full length, nondenatured human A<sub>2A</sub>AR, extended on the amino terminus with hexahistidine and the 8 amino acid FLAG epitope to facilitate purification. Antibodies recognized the purified receptor and not the FLAG peptide by ELISA. Immunohistochemical analysis of HEK293 cells expressing the human ARs or western blot analysis of membranes from transfected HEK293 cells demonstrates that the antibody recognizes the A<sub>2A</sub> but not the A<sub>1</sub> or A<sub>3</sub> subtypes; western blots revealed a weak (<5%) cross-reactivity to A<sub>2B</sub>AR. A 45 kDa glycosylated protein from rat striatum or A<sub>2A</sub>-transfected HEK293 cells was recognized by western blot. In rat brain intense A<sub>2A</sub>-like immunoreactivity (A<sub>2A</sub>-LI) was found in striatum, nucleus accumbens, and olfactory tubercles in a pattern similar to that reported by binding autoradiography or *in situ* hybridization for the receptor. Circumventricular organs (subfornical organ and area postrema) were also well labeled. A<sub>2A</sub>-LI in subpretectal nucleus solitarius was markedly reduced following nodose ganglionectomy; these data confirm the presence of A<sub>2A</sub>ARs on central terminals of rat vagal afferent neurons and suggest a modulatory role for adenosine in cardiopulmonary reflexes. In summary, we have developed and characterized specific anti-A<sub>2A</sub>AR antibodies; the discrete pattern of distribution of A<sub>2A</sub>-LI in rat CNS detected with these antibodies is consistent with other measures of receptor localization and supports a role for adenosine in modulating dopaminergic and cardiovascular function. *Supported by HL37942, HL28785, Scottish Rite Schizo. ## 246.6

**EARLY POSTNATAL EXPRESSION OF L-HISTIDINE DECARBOXYLASE AND HISTAMINE H<sub>1</sub> RECEPTOR IN THE RAT BRAIN.** T. Sallinen, M. Lintunen, K. Karlstedt, H. Fukui, K.S. Eriksson and P. Panula\*, Dept. of Biology, Abo Akademi Univ., 20520 Abo/Turku, Finland, Dept. of Pharmacology II, Osaka Univ., Osaka, Japan.

Histaminergic tuberomammillary neurons with developed projections are present in the neonatal rat brain. An other pool of brain histamine is in mast cells, that migrate into the brain during embryonic development. Some of these cells later migrate to the thalamus, but most of them disappear after postnatal days 10-12. The functions of these mast cells are still unknown. In this study the expression of the histamine synthesizing enzyme L-histidine decarboxylase (HDC) and histamine H<sub>1</sub> receptor was studied by *in situ* hybridization in the rat brain on postnatal days 0, 1, 2, and 5. High HDC expression and intense histamine immunofluorescence were found from day 0 in the tuberomammillary cell bodies as in adult rats, but also in the mast cells of the choroid fissure. Histamine-storing mast cells in adult brain did not express HDC. The HDC expression in the mast cells appeared on the day of birth and started decreasing on postnatal day 5. These results identify early mast cells as the only known site of HDC synthesis in the rat brain in addition to neurons. These mast cells differ from those observed in rat tissues in general, as they have both high histamine content and high expression of HDC. Histamine H<sub>1</sub> receptor mRNA was fairly evenly distributed in the rat brain on the day of birth, but the expression level increased in the hippocampus, hypothalamus, and cortex beginning on postnatal day 1, possibly indicating a correlation to the histamine containing mast cells, and the histaminergic neurons in the tuberomammillary nucleus. The contribution of early mast cells to histamine content will be determined by HPLC fluorometry.

## 246.7

**EXPRESSION AND CELLULAR LOCALIZATION OF B<sub>2</sub> BRADYKININ RECEPTOR mRNA IN RAT SENSORY NEURONS.** S. Yokoyama\*, H. Takeda, and H. Higashida. Dept. of Biophysics, Neuroinformation Research Institute, Kanazawa University School of Medicine, Kanazawa 920, Japan

We have previously demonstrated by cDNA cloning that both rat and mouse B<sub>2</sub> bradykinin receptors (BKR<sub>2</sub>) of the smooth muscle type are expressed in NG108-15 mouse neuroblastoma x rat glioma hybrid cells (BBRC 200: 634-641, 1994). The B<sub>2</sub> BKR of rat origin is identical with those cloned from rat uterus and PC12 pheochromocytoma cells. Using the cDNA as probe, we examined expression and cellular localization of B<sub>2</sub> BKR mRNA in adult rat dorsal root and trigeminal ganglia. In both tissues, RNA blot hybridization analysis identified RNA species of ~6000 and ~4000 nucleotides, consistent with those observed in NG108-15 cells. Reverse transcription polymerase chain reaction (RT-PCR) followed by DNA sequencing confirmed the presence of B<sub>2</sub> BKR mRNA. For *in situ* hybridization study, two digoxigenin-labeled RNA probes were prepared to recognize different parts of B<sub>2</sub> BKR mRNA. In dorsal root ganglia, these probes gave intense signals for B<sub>2</sub> BKR mRNA in neural cell bodies; small neurons were more frequently stained than large neurons. The tendency was less prominent in trigeminal ganglion neurons. These results suggest that the B<sub>2</sub> BKR of the smooth muscle type is involved in regulating pain conduction.

## 246.9

**SPECIFIC [<sup>125</sup>I]OB PROTEIN BINDING SITES LOCALIZED IN CHOROID PLEXUS, THALAMUS AND HYPOTHALAMUS IN RAT.** E.S. Corp\*, D.B. Conze, F. Smith and L.A. Campfield. The Bourne Laboratory, Cornell University Medical College, White Plains, NY 10605 and Hoffmann-La Roche, Nutley, NJ 07110.

OB protein (OB) is synthesized in fat, circulates in plasma and reduces appetite and body weight following peripheral or CNS administration in rats and mice. In the brain, OB protein receptors (OB-R) are expressed maximally in the choroid plexus (CP) in the lateral cerebral ventricle. The behavioral potency of OB injected icv and molecular studies indicating the presence of OB-R mRNA in hypothalamus suggest that OB-R are present in hypothalamus. However, the precise anatomical location of OB-R within the hypothalamus is not known. Prior to a survey for specific [<sup>125</sup>I]hOB binding sites in hypothalamus, we used quantitative receptor autoradiography to determine optimal binding conditions for [<sup>125</sup>I]hOB in the CP; and additionally, using homologous competitive binding assays, determined binding parameters for [<sup>125</sup>I]hOB in the CP. Specific binding of [<sup>125</sup>I]hOB was pH dependent (optimal, pH 6.0). Nonspecific binding was 10 to 12% of maximal binding. [<sup>125</sup>I]hOB bound with high affinity in the CP; K<sub>D</sub>, 0.3 ± 0.04 nM; B<sub>max</sub>, 8.5 ± 0.8 fmol/mg tissue. [<sup>125</sup>I]hOB binding in the CP was insensitive to unlabelled 1 μM insulin, 100 nM NPY, or 100 μM GTP-γ-S. Relative to binding measured in the CP, comparable levels specific [<sup>125</sup>I]hOB binding sites were detected in the meninges and surrounding tissue of the cerebral arteries; low to moderate levels of specific binding were measured in the ventrolateral nucleus of the thalamus (14 ± 3% of CP). In the hypothalamus, low levels of specific binding sites were localized and measured in the arcuate (ARC, 7 ± 2 % of CP) and ventromedial nucleus (VMN, 6 ± 1% of CP). Both the VMN and ARC are well-established as neural sites involved in the control of feeding the regulation of body weight. These data suggest that OB-R are present in VMN and ARC where they may mediate OB effects on appetite and body weight.

## 246.11

**DISTRIBUTION OF [<sup>125</sup>I]LEPTIN BINDING SITES IN RAT AND MOUSE BRAIN AND PERIPHERAL TISSUES.** M.M. Durkin\*, E.L. Gustafson, N. Adham, C. Gerald, B. Borowsky, Y. She, D.L. Linemeyer, and T.A. Branchek. Synaptic Pharmaceutical Corp., 215 College Rd., Paramus, NJ 07652.

We have utilized receptor autoradiographic techniques to determine the distribution of [<sup>125</sup>I]leptin binding sites in rat and mouse brain, as well as in selected peripheral tissues from both species. Incubation of tissue sections with 1 nM [<sup>125</sup>I]leptin resulted in binding in numerous tissues. The specificity of the binding was ascertained by co-incubation of the tissue with 100 nM purified mouse leptin, which completely inhibited the binding of [<sup>125</sup>I]leptin in all tissues.

The most intense autoradiographic signals were seen in the choroid plexus of the brain, in the lung, in the spleen, in lymph nodes, and in the thymus. The testes and omental fat tissue were negative, consistent with previous reports (Tartaglia et al., 1996). In order to determine the cell types, [<sup>125</sup>I]leptin was cross-linked to the tissues using either glutaraldehyde or paraformaldehyde, and the slides dipped in photographic emulsion. The CNS binding was restricted to cells of the choroid plexus, and no labelling was observed in the brain parenchyma. In the spleen, [<sup>125</sup>I]leptin binding sites were located in the red pulp, and on smooth muscle cells of blood vessels. In the lung, a high level of specific binding was observed in smooth muscle cells of the arterioles, and a lower level in the pulmonary artery. [<sup>125</sup>I]leptin binding sites in the thymus were found mainly on cells in the medullary region.

The pattern of [<sup>125</sup>I]leptin binding observed in the present study is mostly consistent with the reported localization of the cloned leptin receptor mRNA described by molecular biological techniques. In addition, we have now determined the cellular identity of the binding sites located in the rat and mouse CNS and periphery. Funded by Synaptic Pharmaceutical Corporation and Ciba-Geigy Limited.

## 246.8

**A NOVEL STRATEGY TO PREPARE FUNCTIONALLY ACTIVE [<sup>35</sup>S]LEPTIN: IDENTIFICATION AND CHARACTERIZATION OF A HIGH AFFINITY LEPTIN BINDING SITE IN THE CHOROID PLEXUS OF MOUSE AND RAT BRAIN.** Xiao-Ming Guan\*, Hong Yu, Michael R. Tota, Michael P. Graziano, Lei Xu, Patricia J. Hey, Lex H.T. Van Der Ploeg and Roy G. Smith. Department of Biochemistry and Physiology, Merck Research Laboratories, Rahway, NJ 07065

Leptin is the product of the recently identified *ob* gene, serving an important role in the control of food intake and energy homeostasis. To localize the leptin receptor in the brain, we developed a novel labeling strategy involving a cell-free expression system to produce a radioactively pure, native [<sup>35</sup>S]leptin probe for receptor autoradiographic studies. Using this radioligand, we identified a high affinity binding site for leptin in the choroid plexus of mouse and rat brains. This binding was specific to leptin, insensitive to GTP-γ-S, and highly concentrated in the choroid plexus. In addition to binding in the wild-type and *ob/ob* mice, equally potent binding of [<sup>35</sup>S]leptin was observed in the choroid plexus of the *db/db* mouse, an animal model that is proposed to have a defective leptin receptor. Similarly, ZDF rats, another commonly used animal model of diabetes and obesity, displayed leptin binding indistinguishable from wild-type rats. Our data provide functional evidence in support of the notion that insensitivity to leptin stimulation as observed in *db/db* and ZDF animals is not due to a deficiency in ligand binding domain of the leptin receptor, but rather is likely to be the result of abnormality occurring at a site(s) down stream from receptor binding.

Source of support: Merck & Co.

## 246.10

**DISTRIBUTION OF LEPTIN RECEPTOR (OB-R) mRNA IN THE CENTRAL NERVOUS SYSTEM OF THE RAT.** C.C. Cheung, S. Lok, J.L. Kuijper, D.S. Weigle, P.D. Finn\*, D.K. Clifton, and R.A. Steiner. Depts. PBIO, Ob-Gyn, and Medicine, Univ. Washington, and Zymogenetics, Inc., Seattle, WA 98195

Leptin is a secretory product of adipocytes and is thought to have a physiological role in the regulation of body weight and metabolism. The putative leptin receptor (OB-R) is the protein product of the *diabetic (db)* gene in the mouse and *fatty (fa)* gene in the rat, and mutations in *db* or *fa* result in obesity, hyperglycemia, and infertility. To learn more about leptin's action in the brain, we used *in situ* hybridization to determine the distribution of OB-R mRNA in rat brain tissue. A <sup>33</sup>P-labeled OB-R cRNA probe containing the region encoding the C-terminus of the extracellular domain, the putative transmembrane domain, and the box 1 motif in the cytoplasmic tail was used. We found OB-R mRNA to be highly expressed in the leptomeninges and choroid plexus lining the ventricles, in piriform cortex, and in the molecular layer of the cerebellum. Moderate levels of expression were detected in the thalamus (in the ventral medial, ventral posterolateral, ventral posteromedial, lateral dorsal, and lateral posterior thalamic nuclei). OB-R mRNA was found to be expressed at low to moderate levels in the hypothalamus (in the arcuate, dorsomedial, ventromedial nuclei, and the retrochiasmatic area) and CA1 pyramidal layer of the hippocampus. **Conclusion:** The widespread distribution of OB-R mRNA in the brain implies that the role of leptin extends beyond the regulation of food intake and metabolism and suggests that either leptin or a similar molecule may be expressed as an endogenous ligand in the brain. (Supported by NIH grant RO1 HD27142)

## 246.12

**NEUROKININ-2 RECEPTORS IN THE GUINEA-PIG GASTROINTESTINAL TRACT: REGIONAL AND CELLULAR DISTRIBUTION** A.L. Portbury\*, J.B. Furness, H.C. Wong, J.H. Walsh, N.W. Bunnett. Department of Anatomy and Cell Biology, University of Melbourne, Parkville, Victoria, 3052, Australia, <sup>2</sup>CURE Gastroenteric Biology Center, VA Wadsworth Medical Center, Los Angeles and <sup>3</sup>Departments of Physiology and Surgery, UCSF, San Francisco.

Results of studies concerning the localisation of the NK2 tachykinin receptor in the gut are ambiguous in that the autoradiographic localisation of the receptor does not correlate fully with the available pharmacological data. In order to clarify the distribution of this receptor in the guinea-pig gastrointestinal tract, we have carried out immunohistochemical studies using a polyclonal antiserum raised against the C-terminal region of the receptor. Immunoreactive nerve terminals, but never nerve cell bodies, were found throughout the myenteric plexus in all regions examined except the stomach and esophagus. NK2 receptor-immunoreactive terminals were rare in the submucosal and tertiary plexuses. Reactivity was always confined to the varicose portion of the axon; inter-varicose and terminal parts of the axons were non-reactive. Lesion studies in the small intestine revealed the reactive terminals to be intrinsic in origin and axially directed. NK2 receptors occurred on terminals of NOS interneurons. In addition to nerve terminals, smooth muscle cells were NK2 receptor-immunoreactive. The immunoreactivity was localised mainly to the cell surface where it appeared to be evenly distributed along the entire cell membrane. In most regions examined, NK2 receptor-immunoreactivity was seen on muscle cells of both the longitudinal and circular layers. In the caecum, the taenia displayed strong NK2 receptor-immunoreactivity. A subpopulation of epithelial cells at the bases of the glands in the proximal colon were strongly immunoreactive for the NK2 receptor, as were a minority of epithelial cells in the caecum, distal colon and rectum.

This work was supported by grants from: NH&MRC, Australia (JBF), and NIH grants DK 39954 & DK43207 (NWB) and DK41301 (JHW).

## 246.13

VASOPRESSIN/GALANIN NEURONS IN THE BNST AND AME COEXPRESS GALANIN RECEPTOR mRNA. M.A. Miller\*, P.E. Kolb, and M.A. Raskind. Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195.

The neuropeptides vasopressin (VP) and galanin (GAL) have been implicated in learning and memory processes. VP and GAL are coexpressed in several regions including the bed nucleus of the stria terminalis/medial amygdala (BNST/AMe) complex. These steroid-sensitive neurons project to the lateral septum (LS) and ventral hippocampus (VH), regions important for mediating the effects of both peptides on memory. GAL, cosecreted with acetylcholine (ACh) into the VH, has been hypothesized to act at a presynaptic receptor to inhibit further ACh release and at a post-synaptic receptor to antagonize the actions of ACh. To determine whether GAL, cosecreted with VP, could also directly regulate BNST/AMe neurons, we have used double in situ hybridization histochemistry to assess the coexpression of GAL receptor mRNA by these cells. GAL mRNA expressing neurons were detected in coronal sections through the BNST and AMe of adult male Wistar rats (n=5) using a digoxigenin-labeled cRNA probe (generously provided by Dr. Henry Friesen, University of Manitoba) and GAL receptor mRNA expressing neurons were detected using a radio-labeled cRNA probe (generously provided by Bristol-Myers Squibb). The majority of GAL mRNA expressing neurons in the BNST/AMe complex coexpressed the GAL receptor. GAL receptor mRNA expressing neurons were also present in the LS and VH. These results raise the possibility that, in addition to exerting post-synaptic actions within the LS and VH, GAL may directly modulate the activity and/or secretion pattern of VP/GAL neurons in the BNST and AMe. Supported by NS33606 (NIH) and AG10917 (NIA).

## 246.15

VASOPRESSIN, OXYTOCIN AND ANGIOTENSIN II RECEPTORS IN THE BRAIN OF INBRED POLYDIPSIC MICE.

M. Chritin<sup>1</sup>, Y. Ueta<sup>2</sup>, H. Yamashita<sup>2</sup>, K. Koizumi<sup>3</sup>, J.J. Dreifuss\* and E. Tribollet<sup>1</sup>. <sup>1</sup>Dept of Physiology, University Medical Center, 1211 Geneva 4, Switzerland; <sup>2</sup>Dept of Physiology, University of Occupational and Environmental Health, School of Medicine, Iseigoaka 1-1, Yahatanishi-ku, Kitakyushu 807, Japan; <sup>3</sup>Dept of Physiol., SUNY Health Sci. Ctr. Brooklyn, NY 11203, USA.

The STR/N strain of mice is characterized by extreme polydipsia and polyuria which are not due to abnormal vasopressin (AVP) production. These impairments are thought to result from central mechanisms leading to an abnormally increased appetite for water. However the nature of the central mechanisms involved has not been elucidated yet. In the present study, we have examined the distribution and density of AVP, oxytocin (OT) and angiotensin II (Ang II) receptors by *in vitro* autoradiography in these two strains. The distribution of the 3 types of receptors was similar in STR/N mice and in ICR mice, but the amount of AVP and Ang II receptors was markedly different in a few areas. A high number of AVP binding sites was found in the periventricular thalamic nucleus of polydipsic mice while this structure was only lightly labelled in control mice. Ang II binding sites were much less numerous in the magnocellular part of the paraventricular nucleus in polydipsic mice than in control ones. On the contrary, the amount of Ang II binding was markedly higher in the area-postrema and nucleus of the solitary tract area in polydipsic mice. These differences were found both in males and in female mice. The amount of OT binding sites was similar in polydipsic and control mice. These data further support the hypothesis that the AVP and Ang II central systems are involved in the mechanisms responsible for polydipsia in STR/N mice. Swiss National Science Foundation, Grant 31-00-040878.94. OTT Foundation.

## 246.17

IMMUNOCYTOCHEMICAL (ICC) LOCALIZATION OF NUCLEAR PROGESTIN RECEPTORS (PR) AND ESTROGEN RECEPTORS (ER) WITHIN THE RAT DORSAL RAPHE NUCLEUS (DRN). S.E. Alves\*, N.G. Weiland, S. Hayashi\* and B.S. McEwen. The Rockefeller University, New York, NY and \*Tokyo Metropolitan Institute for Neuroscience, Tokyo, Japan.

Evidence indicates a modulatory role for estrogen (E) and progesterone (P) on serotonergic (5-HT) activity in the rat brain, however the mechanism(s) of action remain unclear. Recently, E-induced PR have been localized within 5-HT neurons of the macaque DRN (Bethua, Neuroendo 60:50-61;1994). In this study, we investigated whether PR and/or ER exist within 5-HT neurons in rat DRN. Young adult female and male Sprague-Dawley rats were gonadectomized, and 1 wk later were treated with either vehicle or estradiol benzoate (EB, 10 µg in oil, sc, 1x day/2 days). Animals were transcardially perfused the next day with acrolein / paraformaldehyde, and sequential, dual-label ICC was performed on adjacent 40 µm sections with either a PR monoclonal (1:1600 Affinity Bioreagents) or an ER polyclonal antibody (1:40,000 Hayashi), followed by a tryptophan hydroxylase (TPH) polyclonal antibody (1:1000 Protos Biotech). Specific nuclear E-induced PR-immunoreactivity (-ir) and ER-ir were seen in both sexes scattered through the rostral DRN, and more discretely located along the lateral wings of this nucleus, and into the surrounding central grey. However, no colocalization of nuclear PR or ER with cytoplasmic TPH-ir was observed in either sex or treatment, indicating that the steroid targets are not 5-HT cells. These findings suggest a species difference in ovarian steroid regulation of 5-HT activity, perhaps indirectly via local interneurons in the rat. We are presently investigating possible sex differences in receptor distribution and attempting to identify the phenotype of the steroid receptor-containing cells. This study was supported by NS07080 to BSM, NS30105 to NGW and an NIH Endocrine Training Grant DK-07313-17.

## 246.14

AVP V<sub>1A</sub> RECEPTORS IN THE RHESUS MONKEY BRAIN. D.

M. Toloczko<sup>1,3</sup>, L. Young<sup>2</sup>, and T. R. Insel<sup>2,3</sup>. <sup>1</sup>Department of Anthropology and Organismic and Evolutionary Biology Program, University of Massachusetts, Amherst, MA 01003; <sup>2</sup>Department of Psychiatry, Emory University School of Medicine, Atlanta, GA 30322; and <sup>3</sup>Yerkes Regional Primate Research Center, Atlanta, GA 30329.

Binding sites for [<sup>125</sup>I]Lin-AVP were mapped in the rhesus monkey brain by using receptor autoradiography. Binding was found in layers II-III and V-VI of several cortical fields with labelling most intense within the cingulate, insular, and entorhinal cortices. These same layers were labeled in all prefrontal cortical fields. Subcortical regions with high specific binding included the mammillary bodies, the central nucleus of amygdala, and the olfactory and uncinate fasciculi. Competitive ligand binding results were consistent with binding to a V<sub>1A</sub> receptor. Furthermore, molecular studies supported a V<sub>1A</sub> receptor identity. V<sub>1A</sub> cDNA was amplified by RT-PCR from select rhesus brain regions. Using a probe derived from our clone of the rhesus liver V<sub>1A</sub> receptor, Southern blots confirmed the pharmacologic characterization. The pattern of binding found in several subcortical regions may be relevant to previous reports of AVP effects on memory. Supported by RR0165.

## 246.16

LOCALIZATION OF ESTROGEN RECEPTORS IN THE HIPPOCAMPUS OF MALE AND FEMALE RATS. N.G. Weiland\*, C. Orikasa\*, S. Hayashi\*, and B.S. McEwen. Neuroendocrinology, Rockefeller University, New York, NY and \*Tokyo Metropolitan Institute for Neuroscience, Tokyo Japan.

Several aspects of hippocampal function are altered by estrogen administration including increased agonist binding to NMDA receptors, modulation of GAD mRNA levels, and increased spine and synapse density of CA1 pyramidal neurons. Earlier autoradiographic studies using [<sup>3</sup>H]-estrogen uptake indicated that estrogen receptors (ER) were present in the hippocampus, but cellular and regional locations were not established. We used immunocytochemistry (ICC) to determine the cellular location of the ER and whether or not sex differences in the distribution of ER exist in the hippocampus and cortex. Young adult male and female rats were gonadectomized for one week. The animals were perfused with acrolein and paraformaldehyde, and ICC was performed (ER polyclonal antibody 1:40,000, Hayashi) on every 6th section (40 µm) from rostral to caudal hippocampus. ER immunoreactivity (ERir) was observed only in interneurons and exhibited both regional and rostral-caudal gradients. No sex differences were observed. The density of ERir cells were greatest in the dentate hilar polymorph region in rostral hippocampus (bregma minus 2.5 mm), fell to low levels in the middle regions, and were high again in the most ventral region of the hilus (bregma minus 4-4.5 mm). The radiatum of dorsal CA1 contained the second most dense population of ERir cells, with the greatest density at bregma minus 4-4.5 mm. ERir cells were scattered in a very low density (0-4 cells/section) in the remaining regions of hippocampus. These data demonstrate a mechanism for a direct action of estrogen in all regions with primary sites in the hilus of the dentate gyrus and CA1 of the hippocampus in both male and female rats. (Supported by NIH grants NS30105 to NGW and NS07080 to BSM.)

## 247.1

DIFFERENTIAL MODULATION OF  $\text{Ca}^{2+}$  MOBILIZATION EVOKED BY MULTIPLE RECEPTORS LINKED TO PHOSPHOINOSITIDE TURNOVER. E. del Río\*, C.P. Downes\* & D.G. Nicholls Neuroscience Institute and \*Biochemistry Department, University of Dundee, Dundee, DD1 9SY U.K.

$\text{Ca}^{2+}$ -release from intracellular stores has been studied by digital imaging of fura-2 microfluorescence of rat cerebellar granule cells in primary culture. Both the cholinergic agonist carbachol and the glutamatergic agonist 1S,3R ACPD are known to evoke PI-turnover and release of  $\text{Ca}^{2+}$  from intracellular stores. We now show that stimulation of cerebellar granule cells with agonists for other PI-linked receptors (noradrenaline, histamine and serotonin) leads to distinctive patterns of intracellular  $\text{Ca}^{2+}$ -mobilization. We also show that at 4 DIV the majority of the cerebellar granule cells in the primary culture population contain receptors for all these agonists, and all these receptors can couple to  $\text{Ca}^{2+}$ -mobilization.

When responses in polarizing and mildly depolarizing conditions (20 mM KCl) are compared four patterns of response can be distinguished: 1) metabotropic glutamate receptor activation by the agonist 1S,3R ACPD in 20 mM KCl conditions leads to both an enhanced PI-turnover and larger  $\text{Ca}^{2+}$ -release signals, 2) muscarinic receptor activation by carbachol in 20 mM KCl results in higher PI-turnover without any perceivable change in the size and distribution of the  $\text{Ca}^{2+}$ -release signal, 3) PI-turnover stimulation by histamine appeared insensitive to 20 mM KCl while the resulting  $\text{Ca}^{2+}$ -release signal was largely enhanced and 4) in the case of noradrenaline and serotonin PI-turnover was not enhanced by 20 mM KCl but the  $\text{Ca}^{2+}$ -release signal was moderately, but significantly enhanced in the presence of 20 mM KCl.

PHOSPHATIDYLINOSITOL 4,5-BISPHOSPHATE DECREASES THE ABILITY OF TUBULIN TO ACTIVATE  $\text{G}\alpha_q$ . L.S. Popova\*, E. Greene and M. M. Rasenick. Department of Physiology and Biophysics, University of Illinois, Chicago, IL 60612.

We have shown previously that the cytoskeletal protein tubulin is involved in the regulation of phospholipase  $\text{C}\beta_1$  ( $\text{PLC}\beta_1$ ). At low dimer concentrations, tubulin with a GTP analog bound activates  $\text{PLC}\beta_1$ , while at high concentrations it inhibits the enzyme. It is suggested that the interaction of tubulin with both  $\text{G}\alpha_q$  and  $\text{PLC}\beta_1$ , accompanied by a transfer of guanine nucleotide from tubulin to  $\text{G}\alpha_q$ , is responsible for  $\text{PLC}\beta_1$  activation. The  $\text{PLC}\beta_1$  substrate, phosphatidylinositol 4,5-bisphosphate ( $\text{PIP}_2$ ), binds to tubulin and prevents microtubule assembly. This interaction is thought responsible for the  $\text{PLC}\beta_1$  inhibition by tubulin, since it might prevent the access of the enzyme to  $\text{PIP}_2$ . Here we investigate further the effect of  $\text{PIP}_2$  on tubulin and the  $\text{m}_1$  muscarinic receptor-triggered tubulin- $\text{G}\alpha_q$  interaction. First, the ability of tubulin to bind and hydrolyze guanine nucleotide in the presence and absence of  $\text{PIP}_2$  has been tested. The incubation of tubulin with  $\text{PIP}_2$  decreases the amount of GTP bound to tubulin. At a tubulin to  $\text{PIP}_2$  molar ratio of 1:12, a 25% decrease in GTP binding is observed, however,  $\text{PIP}_2$  does not affect tubulin GTPase activity. This could be explained by  $\text{PIP}_2$  binding to a specific tubulin isotype. In membranes from Sf9 cells expressing  $\text{m}_1$  muscarinic receptors,  $\text{G}\alpha_q$  and  $\text{PLC}\beta_1$ , both carbachol and  $\text{PIP}_2$  increase the association of tubulin- $^{32}\text{P}$ AAGTP (azidoanilido-GTP) with the membrane. Carbachol, but not  $\text{PIP}_2$ , promotes the transfer of  $^{32}\text{P}$ AAGTP from tubulin to  $\text{G}\alpha_q$ . When carbachol stimulation is studied in cells expressing  $\text{m}_1$  muscarinic receptors and  $\text{G}\alpha_q$ , but not  $\text{PLC}\beta_1$ , no increase in the association of tubulin- $^{32}\text{P}$ AAGTP with the membrane, nor in the nucleotide transfer to  $\text{G}\alpha_q$  are observed. These results suggest a specific interaction between tubulin and  $\text{PIP}_2$  which decreases the guanine nucleotide binding to tubulin, but increases tubulin association with the membrane upon  $\text{m}_1$  muscarinic receptor stimulation. Thus, cholinergic signaling might modify both lipid and cytoskeletal components associated with the synaptic membrane.

## 247.5

ELEVATION OF INTRACELLULAR CALCIUM BY CARBACHOL AND DELTA OPIOIDS IN SH-SY5Y CELLS: CHARACTERIZATION OF THE COINCIDENT SIGNAL. A. Yeo, E.P. Kelly, P.J. Roberts\* and G. Henderson. Dept of Pharmacology, University of Bristol, Bristol, BS8 1TD, U.K.

In SH-SY5Y cells activation of Gi/Go-coupled receptors does not elevate intracellular free calcium  $[\text{Ca}^{2+}]_i$  but in the presence of ongoing muscarinic Gq-coupled receptor activation then Gi/Go coupled receptor activation now causes a further elevation of  $[\text{Ca}^{2+}]_i$ . Here we show that  $\delta$ -opioid receptor stimulation releases intracellular  $\text{Ca}^{2+}$  from the same thapsigargin-sensitive pool as muscarinic receptor activation.

$[\text{Ca}^{2+}]_i$  was measured in confluent monolayers of SH-SY5Y cells loaded with Fura2. DPDPE (30nM) elevated the peak increase in  $[\text{Ca}^{2+}]_i$  when it was applied simultaneously with carbachol and also elevated the plateau increase in  $[\text{Ca}^{2+}]_i$  when it was applied during a prolonged (5-30min) exposure to carbachol. In the absence of extracellular  $\text{Ca}^{2+}$  the elevation of  $[\text{Ca}^{2+}]_i$  evoked by a high concentration of carbachol (1mM) was not maintained but declined to the predrug level presumably because the  $\text{Ca}^{2+}$  stores had been emptied. Emptying of the stores in this way abolished both the elevation of  $[\text{Ca}^{2+}]_i$  evoked by bradykinin (acting at the Gq-coupled B2 bradykinin receptor) and by DPDPE (acting at the pertussis toxin-sensitive, Gi/Go-coupled  $\delta$ -opioid receptor).

Western blot analysis revealed that SH-SY5Y cells express only the  $\text{PLC}\beta_1$  and  $\text{PLC}\beta_3$  isoforms of  $\text{PLC}\beta$  with the  $\beta_1$  isoform appearing to be the more abundant. The lack of  $\beta_2$  activatable  $\text{PLC}\beta_2$  and the low level of  $\text{PLC}\beta_3$  in these cells may explain why  $\delta$ -opioid receptor stimulation alone does not elevate  $[\text{Ca}^{2+}]_i$ .

## 247.2

DISTRIBUTION OF PHOSPHATIDYLINOSITOL 3-KINASE (PI3K) ISOFORMS IN RAT BRAIN BY IMMUNO-HISTOCHEMISTRY AND  $^3\text{H}$ WORTMANNIN AUTORADIOGRAPHY AND IDENTIFICATION OF NOVEL PROTEIN INTERACTIONS. K. J. Hurt\*, R. Zakhary, and S. H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

PI3K exists as a dimer, usually composed of a p110 catalytic subunit and a p85 regulatory/adaptor protein. Upon activation of receptor tyrosine kinases, p110 is recruited to the membrane by p85 association with phosphotyrosines. The kinase catalyzes the formation of phosphatidylinositol-3,4,5-trisphosphate (PIP3) from PI45-bisphosphate (PIP2) and participates in the activation of mitogenic and morphogenic pathways. Distribution of PI3K catalytic and regulatory subunits in adult rat brain has been demonstrated using autoradiographic and immunohistochemical techniques. The differential localization suggests different roles or regulation of PI3K-mediated signaling in different areas of the brain. Investigation of interacting proteins in immunoprecipitation and yeast 2-hybrid experiments has also identified novel interactions of PI3K with known proteins in the brain. ## 247.4

EFFECT OF EXCITATORY AMINO ACIDS ON INOSITOL PHOSPHATE ACCUMULATION IN RETINAL PIGMENT EPITHELIUM. G. Frago and A. M. López-Colomé\*. Instituto de Fisiología Celular, Universidad Nacional Autónoma de México, Apdo. Postal 70-253, México 04510, D. F., México.

The retinal pigment epithelium (RPE) located between the choriocapillaries and the neural retina, plays a fundamental role in the maintenance of the structural and functional integrity of photoreceptors. We previously reported the presence of specific excitatory amino acid (EAA) receptors in chick and human RPE cells in culture, and in this work we have studied the effects of EAA on the inositol phosphate second messenger pathway in these cells. Primary cultures of RPE cells were prepared from 7-day-old chick embryos. Glutamic acid (L-GLU) at a concentration of 1 mM induced a 200% increase in  $^3\text{H}$ -inositol phosphates (InsPs) accumulation within 15 minutes in cells preincubated with  $^3\text{H}$ -myo-inositol in the presence of 10 mM lithium chloride. L-GLU analogues (1 mM) stimulated InsPs accumulation in the following order: L-GLU = NMDA > QA = KA > ACPD. The potency of EAA analogues for stimulating InsPs formation was determined within a concentration range from 10 nM to 1 mM. NMDA-induced response was significant since 5 minutes of stimulation and this effect was dependent on external calcium. The NMDA-induced response was completely blocked by MK-801 (50  $\mu\text{M}$ ) and CPP (200  $\mu\text{M}$ ) and partially inhibited by the  $\text{Ca}^{2+}$ -channel blockers verapamil (10  $\mu\text{M}$ ), Nifedipine (10  $\mu\text{M}$ ) and Dantrolene (30  $\mu\text{M}$ ). (+)- $\alpha$ -Methyl-4-carboxyphenylglycine showed effect as blocker and 3,5-Dihydroxyphenylglycine as agonist of the ACPD-response. These data suggest the presence of mGluRs (mGluR1 and/or mGluR5) as well as NMDA receptors in the RPE cells, coupled directly or through the influx of external  $\text{Ca}^{2+}$ , to phospholipase C activation. The physiological meaning of these effects in RPE remains to be elucidated, but studies under way suggest the possibility of an involvement in functions as cell division or phagocytosis. Supported by Grant 3375-N from CONACyT.

## 247.6

HETEROGENEITY IN CALCIUM SENSITIVITY OF MOUSE CEREBELLAR INOSITOL 1,4,5-TRISPHOSPHATE RECEPTORS. T. MICHIKAWA<sup>1</sup>, I. HIROTA<sup>1</sup>, S. KAWANO<sup>2</sup>, M. HIRAKAWA<sup>2</sup>, T. FURUICHI<sup>1</sup>, and K. MIKOSHIBA<sup>1,3</sup>. <sup>1</sup>Department of Molecular Neurobiology, Institute of Medical Science, University of Tokyo, Tokyo 108; <sup>2</sup>Department of Cardiovascular Disease, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, 113; and <sup>3</sup>Molecular Neurobiology Laboratory, Institute of Physical and Chemical Research (RIKEN), Tsukuba Life Science Center, Ibaragi 305, Japan

The inositol 1,4,5-trisphosphate ( $\text{IP}_3$ ) receptor ( $\text{IP}_3\text{R}$ ) is an  $\text{IP}_3$ -gated  $\text{Ca}^{2+}$  release channel localized on the intracellular  $\text{Ca}^{2+}$  storage sites, such as endoplasmic reticulum, in both neuronal and glial cells. It has been shown that the cerebellar  $\text{IP}_3\text{Rs}$  are regulated by cytoplasmic  $\text{Ca}^{2+}$  in a biphasic manner with the maximum activity of the channels at  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) of 200-300 nM. The biphasic  $\text{Ca}^{2+}$  dependence might provide for both feed-forward and feed-back effects on  $\text{Ca}^{2+}$  that is believed to be a key property to generate  $\text{Ca}^{2+}$  waves and  $\text{Ca}^{2+}$  oscillations.

To analyze the  $\text{Ca}^{2+}$  dependent regulation of the  $\text{IP}_3\text{R}$  more precisely, cerebellar  $\text{IP}_3\text{Rs}$  reconstituted into planar lipid bilayers were characterized at the single channel level.  $\text{IP}_3$ -dependent currents ( $\sim 120$  pS in 50 mM  $\text{Ba}^{2+}$ ) were measured in the presence of 2  $\mu\text{M}$   $\text{IP}_3$  and 2 mM ATP by using a voltage-clamp technique after incorporation of mouse cerebellar microsome vesicles into planar lipid bilayers.  $[\text{Ca}^{2+}]_i$  in a cytoplasmic side was varied from 0.2 to 1.5  $\mu\text{M}$  while maintaining free  $\text{Ca}^{2+}$  chelator (HEDTA) concentration at 1 mM. We found that there is a heterogeneity in the  $\text{Ca}^{2+}$  sensitivity among the cerebellar  $\text{IP}_3\text{Rs}$ . In addition to the channel whose maximum open probability was occurred at  $\sim 350$  nM  $[\text{Ca}^{2+}]_i$ , some channels revealed more low  $\text{Ca}^{2+}$  sensitivity with maximum open probability at 550-750 nM  $[\text{Ca}^{2+}]_i$ . The existence of two types of channel with different  $\text{Ca}^{2+}$  sensitivities provides a basis for complex patterns of intracellular  $\text{Ca}^{2+}$  signaling.

## 247.7

STRUCTURAL ANALYSIS OF THE LIGAND BINDING SITE OF THE TYPE I INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR. E. Yoshikawa, M. Morita, T. Monkawa, T. Michikawa, T. Furuchi\* and K. Mikoshiba, Department of Molecular Neurobiology, Institute of Medical Science, University of Tokyo, Tokyo 108

Inositol 1,4,5-trisphosphate receptor (IP<sub>3</sub>R) is a second messenger inositol 1,4,5-trisphosphate (IP<sub>3</sub>) induced Ca<sup>2+</sup> release channel. To define the structural determinants for IP<sub>3</sub> binding of the type I IP<sub>3</sub>R (IP<sub>3</sub>R1), we developed a means of expressing the N-terminal 734 amino acids of IP<sub>3</sub>R1 (T734), which contain the IP<sub>3</sub> binding region, in *Escherichia coli* (*E. coli*). The T734 protein expressed in *E. coli* exhibited a similar binding specificity and affinity for IP<sub>3</sub> as the native IP<sub>3</sub>R from mouse cerebellum. Deletion mutagenesis, in which T734 was serially deleted from the N-terminus up to residue 215, markedly reduced IP<sub>3</sub> binding activity. However, when deleted a little more toward the C-terminus (to residues 220, 223, and 225), the binding activity was retrieved. Further N-terminal deletions over the first 228 amino acids completely abolished it again. C-terminal deletions up to residue 579 did not affect the binding activity, whereas those up to residue 568 completely abolished it. In addition, the expressed 356 amino-acid polypeptide (residues 224-579) exhibited specific binding activity. Taken together, residues 226-578 were sufficient and close enough to the minimum region for the specific IP<sub>3</sub> binding, and thus forming an IP<sub>3</sub> binding "core". Site-directed mutagenesis was performed on 41 basic Arg and Lys residues, within the N-terminal 650 amino acids of T734. We showed that single amino acid substitutions for 10 residues, which were widely distributed within the binding core and conserved among all members of the IP<sub>3</sub>R family, significantly reduced the binding activity. Among them, three (Arg-265, Lys-508, and Arg-511) were critical for the specific binding, and Arg-568 was implicated in the binding specificity for various inositol phosphates. We suggest that some of these 10 residues form a basic pocket that interacts with the negatively-charged phosphate groups of IP<sub>3</sub>.

## 247.9

CALCIUM-INDEPENDENT CYTOSOLIC PHOSPHOLIPASE A<sub>2</sub> (cPLA<sub>2</sub>) IS THE MAJOR PLA<sub>2</sub> ISOFORM IN VERTEBRATE BRAIN AND IS EXPRESSED IN THE LIMBIC SYSTEM. R. Diaz-Arastia\*, L. Ma, and S. Jones, Dept. of Neurology, University of Texas Southwestern Medical School, Dallas, TX 75235, and Genetics Institute, Cambridge, MA 02140.

Phospholipase A<sub>2</sub> (PLA<sub>2</sub>) generates a number of putative second messengers which play key roles in normal synaptic plasticity as well as excitotoxicity. It is not clear which PLA<sub>2</sub> isoform is responsible for the production of lipid mediators in the brain. We have studied two intracellular PLA<sub>2</sub> isoforms which have recently been cloned and characterized. The first, a Ca<sup>2+</sup>-dependent cytosolic PLA<sub>2</sub> (cPLA<sub>2</sub>) comprises less than 10% of the total lipase activity present in neural tissues, and is expressed predominantly in astrocytes, as shown by immunohistochemistry. The other is a Ca<sup>2+</sup>-independent cytosolic enzyme (cPLA<sub>2</sub>) which can be resolved from the former isoform by standard chromatographic techniques. This enzyme is biochemically and immunologically similar (if not identical) to a cPLA<sub>2</sub> recently cloned from CHO cells (S. Jones, manuscript in preparation). Immunoprecipitation experiments confirm that this is the major PLA<sub>2</sub> activity in rat brain homogenates. The enzyme has a molecular mass of 85 kDa as measured by SDS-PAGE and non-denaturing gel-filtration chromatography. It is inhibited by bromoenol lactone (BEL), but unlike other Ca<sup>2+</sup>-independent PLA<sub>2</sub>s, it is not specific for plasmalogens and is not activated by ATP. It has a neutral pH optimum and is not specific for sn-2-arachidonyl phospholipids. Immunohistochemical localization of cPLA<sub>2</sub> in adult rat brain shows that it is enriched in neuronal cells in the hippocampus and piriform cortex. It is also expressed in other cortical neurons as well as in non-neuronal cells in other parts of the CNS.

## 247.11

NEURONAL NUCLEOTIDE RECEPTOR LINKED TO PHOSPHOLIPASE C: STIMULATION OF NEURO 2A CELLS BY UTP AND POSSIBLE REGULATION BY PKC SUBTYPE  $\epsilon$ . C.C. Chen\* and W.C. Chen, Institute of Pharmacology, College of Medicine, National Taiwan University, Taipei, Taiwan.

Incubation of Neuro 2A mouse neuroblastoma cells with UTP and UDP results in a concentration-dependent increase in the accumulation of inositol phosphates (IP) with equal potency and maximal effect, ATP, ADP and 2-MeSATP were much less potent. Cross-desensitization experiments indicated that UTP and ATP may interact with the same population of P<sub>2</sub> purinoceptor-P<sub>2U</sub>. The UTP- and ATP-induced IP accumulation were not affected by pretreatment of cells with pertussis toxin (PTX), indicating that the P<sub>2U</sub> purinoceptor in Neuro 2A cells is coupled to PTX-insensitive Gq protein. Short term (10 min) treatment of cells with 1  $\mu$ M TPA inhibited the UTP and ATP effects, the inhibitory effect was gradually attenuated with increased length of TPA treatment (1.5-6 hr) and was not seen after long-term (24 hr) treatment. Western blot analysis using eight protein kinase C (PKC) isozyme-specific antibodies showed that Neuro 2A cells express PKC $\alpha$ , PKC $\epsilon$ , PKC $\theta$  and PKC $\zeta$ . Following TPA treatment of the cells for various times (10 min, 1.5, 3, 6 or 24 hr), translocation of PKC $\alpha$ , PKC $\epsilon$  and PKC $\theta$  from the cytosol to the membrane was seen after 10 min or 1.5 hr treatment. However, partial and complete down-regulation of both membrane PKC $\alpha$  and PKC $\theta$  was seen after 3 and 6 hr treatment, respectively. In contrast, the TPA-induced translocation of PKC $\epsilon$  was maintained to 3-6 hr treatment and almost complete down-regulation occurred only after 24 hr treatment. The observed TPA-induced inhibition of UTP or ATP stimulated PI hydrolysis therefore correlated well with the extent of translocation of PKC $\epsilon$ , but not of PKC $\alpha$  or  $\theta$ . This study is the first to show the existence of the P<sub>2U</sub> purinoceptor in Neuro 2A cells and the possible involvement of neuronal PKC $\epsilon$  in regulation of the receptor-mediated PI turnover.

## 247.8

INCORPORATION OF RADIOLABELED PLASMA UNSATURATED FATTY ACIDS INTO RAT BRAIN SYNAPSES: EFFECT OF CHOLINERGIC STIMULATION. Collins R. Jones, M. Catherine Bennett\*, Toshinari Arai and Stanley I. Rapoport, Lab. of Neurosciences, National Institute on Aging, Bethesda, MD 20892-1582

Cholinergic stimulation has been shown to increase the turnover of arachidonic acid (AA, 20:4) and docosahexaenoic acid (DHA, 22:6) but not palmitic acid (16:0, PAM) in rat brain. We hypothesized that cholinergic stimulation would specifically increase the incorporation of these fatty acids into the synaptosomal fractions of rat brain. The fatty acid method developed in our laboratory allowed us to test this hypothesis under physiological conditions. [<sup>3</sup>H]AA (1.35 mCi/kg), [<sup>3</sup>H]DHA (1.35 mCi/kg) or [<sup>3</sup>H]PAM (20.7 mCi/kg) was infused intravenously for 5 min into awake, adult male rats before and after treatment with arecoline (15 mg/kg) and brain subcellular fractions isolated. Radiolabeled fatty acid incorporation into membrane phospholipid was measured and normalized to plasma exposure. More than 50% of incorporated [<sup>3</sup>H]AA, [<sup>3</sup>H]DHA or [<sup>3</sup>H]PAM was localized to synaptosomal phospholipids with 30% of the radiolabel entering microsomal phospholipid. Cholinergic stimulation with arecoline increased the incorporation of both [<sup>3</sup>H]AA and [<sup>3</sup>H]DHA but not [<sup>3</sup>H]PAM into the phospholipid of synaptosomal fraction by 400% and 100%, respectively. Incorporation of either polyunsaturated fatty acid was not altered in the myelin, mitochondrial or cytosolic fractions. It is likely that these polyunsaturated fatty acids play a role in synaptic membrane signal transduction processes involving phospholipase A<sub>2</sub> activation and can be used as probes to measure synaptic activity *in vivo*.

## 247.10

ARACHIDONIC ACID RELEASE IN RESPONSE TO P<sub>2</sub> PURINOCEPTOR ACTIVATION IN CULTURED ASTROCYTES. W.C. Chen, C.Y. Wen\* and C.C. Chen, Institute of Pharmacology and Anatomy, College of Medicine, National Taiwan University, Taipei, Taiwan.

ATP-induced arachidonic acid (AA) release was studied in [<sup>3</sup>H]AA-prelabeled cultured astrocytes. To characterize the P<sub>2</sub> purinoceptor-mediated effects of ATP, the subtype-specific agonists 2-methylthio ATP (2-MeSATP) and UTP were compared. ATP, UTP or 2-MeSATP induced a dose-dependent increase of [<sup>3</sup>H]AA release. The order of potency was ATP > UTP > 2-MeSATP, indicating that ATP interacted with both P<sub>2U</sub> and P<sub>2Y</sub> purinoceptors. ATP, UTP and 2-MeSATP induced a rapid increase of [Ca<sup>2+</sup>]<sub>i</sub> and a sustained [Ca<sup>2+</sup>]<sub>i</sub> increase. The Ca<sup>2+</sup> ionophore-A23187 mimicked the effects of these three agonists on AA release. ATP, UTP, 2-MeSATP or A23187-induced AA release was markedly decreased in the absence of external Ca<sup>2+</sup> in condition the sustained [Ca<sup>2+</sup>]<sub>i</sub> increase induced by these three agonists was abolished. Inorganic Ca<sup>2+</sup> channel blocker Co<sup>2+</sup> at 1 mM inhibited the ATP, UTP, 2-MeSATP or A23187-induced AA release. Long-term treatment of the cells with TPA resulted in attenuation of the ATP, UTP or 2-MeSATP response. Western blot analysis showed the expression of PKC $\alpha$ ,  $\delta$ ,  $\eta$ ,  $\theta$  and  $\zeta$  in astrocytes. The possible involvement of specific PKC isoforms in the regulation of P<sub>2</sub> purinoceptor agonists-induced AA release will be explored.

However, the P<sub>2U</sub> and P<sub>2Y</sub> agonists-induced Ca<sup>2+</sup> mobilization leading to extracellular Ca<sup>2+</sup> influx was essential for the AA release induced by ATP, UTP and 2-MeSATP.

## 247.12

SUBSTANCE P (SP) STIMULATES PHOSPHOLIPASE D IN CHINESE HAMSTER OVARY CELLS (CHO) EXPRESSING THE NK1 TACHYKININ RECEPTORS. M. Tencé\*, Y. Torrens, J.C. Beaujouan and J. Glowinski, INSERM U 114, Collège de France, 75005 Paris, France.

In CHO cells transfected with the rat NK1 receptor cDNA (CHO-NK1), SP activates several intracellular pathways: hydrolysis of phosphatidylinositols, activation of adenylate cyclase and release of arachidonic acid (Nakajima et al., *J. Biol. Chem.* 267:2437, 1992; Garcia et al., *Biochem. Pharmacol.* 48:1735, 1994). We report here that SP and the selective NK1 agonist, [Pro<sup>9</sup>]SP, also stimulate a phospholipase D (PLD) activity. In CHO-NK1 cells prelabeled with tritiated myristic acid, [Pro<sup>9</sup>]SP (10 nM) induced a sustained production of both tritiated phosphatidic acid and diacylglycerol. This effect resulted from the activation of a PLD since in the presence of ethanol, SP and [Pro<sup>9</sup>]SP also stimulated time- and dose-dependently, the formation of tritiated phosphatidylethanol (PEt) (EC<sub>50</sub>: 2 and 1 nM, respectively). This response exhibited a pharmacological profile typical for NK1 receptor. Indeed, neither Senktide nor [Lys<sup>5</sup>, MeLeu<sup>9</sup>, Nle<sup>10</sup>]NKA (4-10), selective agonists for NK3 and NK2 receptors, respectively, were efficient in stimulating the formation of PEt. Furthermore, the response induced by [Pro<sup>9</sup>]SP was inhibited by selective NK1 antagonists (RP 67580, SR 140333 and CP 96345). The stimulation of PLD by [Pro<sup>9</sup>]SP did not involve a pertussis toxin-sensitive G-protein. In contrast, protein kinase C seemed to play a crucial role in the regulation of PLD activity since inhibition or down-regulation of the kinase suppressed the formation of PEt induced by [Pro<sup>9</sup>]SP. This study suggests that PLD activation could be another signal transduction pathway involved in the mechanism of action of SP in central and peripheral tissues expressing NK1 receptors.

PHOSPHOLIPASE A<sub>2</sub> ISOFORMS IN RAT HIPPOCAMPAL SYNAPTOSOMES  
M.L. Ruehr and R.V. Dorman\*

Dept. of Biol. Sci., Kent State Univ., Kent, Ohio 44242

Phospholipase A<sub>2</sub> (PLA<sub>2</sub>) dependent-release of arachidonic acid (AA) has been implicated in synaptic plasticity. AA accumulation has been linked to neurotransmitter release from hippocampal mossy fiber synaptosomes (HMFS) and this effect is potentiated by another second messenger, diacylglycerol (Zhang and Dorman, Brain Res Bull 32:437-441, 1993). Here we show the presence of multiple isoforms of PLA<sub>2</sub> in HMFS and Ca<sup>2+</sup>-dependent translocation of PLA<sub>2</sub>, which is predicted to play a role in its activation. HMFS and P<sub>1</sub> synaptosomes were prepared from rat hippocampi, sonicated in buffer containing 0.5 mM Ca<sup>2+</sup> and separated into cytosolic and membrane fractions. Purity of each fraction was assessed through Western analysis of glucose-6-phosphate dehydrogenase (G-6-PDH), as the cytosolic marker, and Ca<sup>2+</sup>-ATPase, as the membrane marker. We observed, through densitometric analyses, that 92% of the G-6-PDH was associated with the cytosolic fraction, while 99% of the ATPase remained in the membrane fraction. These fractions were then probed with a PLA<sub>2</sub> antibody which labels the catalytic site. This antibody recognized protein bands with apparent molecular weights of 160 and 112 kDa in the cytosolic fraction and 112 and 35 kDa in the membrane fraction of the HMFS. In contrast, only one 80 kDa band was observed in homogenates from CHO cells or rat kidney. This antibody also labeled 112 and 35 kDa proteins in the cytosolic and membrane fractions of P<sub>1</sub> synaptosomes, respectively. In the HMFS, the 160 kDa PLA<sub>2</sub> isoform decreased in the cytosolic fraction as the concentration of Ca<sup>2+</sup> was increased from 0.05-5 μM, while the 112 and 35 kDa isoforms increased in the membrane fraction under these same conditions. Therefore, it appears that rat HMFS and P<sub>1</sub> synaptosomes contain several isoforms of PLA<sub>2</sub> which are differentially regulated when exposed to Ca<sup>2+</sup>.

## DESENSITIZATION OF M1 MUSCARINIC RECEPTOR-MEDIATED ACTIVATION OF NITRIC OXIDE SYNTHESIS. A.E. Cuadra\* Sheng Zu Zhu and E. E. El-Fakahany. Graduate Program in Pharmacology, Dept. of Psychiatry, University of Minnesota, Minneapolis, MN 55455.

The free radical nitric oxide (NO) is an important molecule in relation to various functions such as vascular smooth muscle relaxation, toxicity for invading bacteria, and has been implicated in the establishment of memory. It is therefore important to understand the mechanisms of regulation of this cellular messenger. In our laboratory we have established *Chinese hamster ovary* (CHO) cells which are stably transfected with the human M1 muscarinic receptor and neuronal NO synthase (NOS). M1 receptors cause the release of calcium from intracellular stores through synthesis of inositol triphosphate. Thus, this pathway is expected to activate the calcium dependent neuronal NOS. Incubation of these CHO cells with the muscarinic agonist carbachol (CBC) resulted in a time dependent activation of neuronal NOS. This response was measured by assaying the conversion of tritiated L-arginine into L-citrulline. This activation of NOS also depended on the concentration of agonist. Desensitization of this response was investigated. Transfected CHO cells were pretreated with 1 μM CBC for various time periods, ranging from one hour to 24 hours. Our results show no significant change in agonist induced citrulline formation after one hour of CBC pretreatment versus control. After 3 hours, a significant decrease of the maximal response was observed, being accompanied by a shift of the dose response curve to the right. Cells pretreated with CBC for twenty four hours showed very little increase in citrulline formation upon stimulation of muscarinic receptors.

CLONING AND CHARACTERIZATION OF POSTSYNAPTIC DENSITY 93 (PSD-93), AN nNOS INTERACTING PROTEIN  
J. Brenman\*, S. Craven, and D. Bredt, Dept. of Physiology, UCSF, San Francisco, CA 94143.

Nitric oxide formation in brain is efficiently coupled to calcium influx through NMDA type glutamate receptors. To elucidate possible mechanisms responsible for this coupling, we performed yeast two-hybrid screening to identify proteins which interact with nNOS. Two proteins were identified, the postsynaptic density proteins, PSD-93 and PSD-95. Here we report the cloning and characterization of PSD-93. PSD-93 is unique among PSD-95 / SAP-90 family members in its cerebellar postsynaptic distribution. PSD-93 is highly expressed in cerebellar Purkinje neurons. By immunostaining PSD-93 is enriched in Purkinje neuron soma and dendrites. This is in contrast to PSD-95 which is highly concentrated in the presynaptic plexus of cerebellar basket cells. Given that PSD-93 and PSD-95 each contain multiple potential binding sites for nNOS and the NMDA receptor, complexes involving oligomers of PSD-93/95 may help account for the functional as well as physical coupling of nNOS to NMDA receptors.

ACTIVATION OF A NICOTINIC ACETYLCHOLINE RECEPTOR STIMULATES PRODUCTION OF 8-LIPOXYGENASE METABOLITES IN ISOLATED CELLS OF *APLYSIA*. T. Tieman, J.S. Kehoe, J.H. Schwartz, and S.J. Feinmark\*. Department of Pharmacology and the Center for Neurobiology and Behavior, Columbia University, New York, NY, 10032 and Laboratoire de Neurobiologie, Ecole Normale Supérieure, Paris, France.

We previously reported that the formation of novel 8-lipoxygenase metabolites, including 8-HETE and 8-KETE, could be induced in the *Aplysia* central nervous system by activation of a nicotinic acetylcholine (ACh) receptor. This receptor induces a fast chloride conductance that is known to be activated selectively by suberyldicholine and blocked selectively by α-bungarotoxin (α-BTX). The 8-lipoxygenase metabolites were quantified by reverse-phase HPLC after the application of ACh (100 μM) or suberyldicholine (100 μM) to neural components from the total nervous system. Formation of these metabolites could be inhibited by α-BTX. We have now shown that these lipids can be produced by isolated neurons which are known to have this particular nicotinic receptor. As few as 20 isolated Medial cells from the pleural ganglion produced measurable 8-lipoxygenase products when exposed to suberyldicholine (100 μM). On the other hand, exposure of Medial cells to either GABA (200 μM) or glutamate (1 mM), both of which induce Cl-dependent responses in these cells, failed to stimulate metabolite formation. In control experiments on an equivalent number of isolated RB cells (known to have only the suberyldicholine- and α-BTX-insensitive receptor), suberyldicholine failed to induce production of these metabolites. These findings show that the metabolites are formed directly and selectively by neurons bearing the relevant ACh receptor, and they suggest that an increase in chloride conductance alone is not sufficient to activate the 8-lipoxygenase pathway. These data raise interesting questions as to how a presumably ionotropic receptor could activate lipid metabolism and what role these lipids may play in neural function. ## 247.16

## CYCLIC GMP-DEPENDENT PROTEIN KINASES: TARGETS OF NITRIC OXIDE IN THE RAT BRAIN. A-E-D El-Husseini\*, JA Williams, C Bladen, PB Reiner, SR Vincent. Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, University of British Columbia, Vancouver, B.C. Canada, V6T 1Z3.

Nitric oxide (NO) mediates a variety of biological functions such as neurotransmission, responses to inflammation, and neuronal excitotoxicity. In order to identify potential targets of NO we carried out two studies: First, type II cGMP-dependent protein kinase (cGK II) phosphorylation was measured in rat thalamus after application of NO *in vitro* or by electrical stimulation of the NO synthase (NOS)-containing mesopontine cells in anaesthetized animals. cGKII phosphorylation increased in response to NO *in vivo* as well as *in vitro*, which suggested that this kinase is a target of NO signalling. Second, we investigated the distribution of NOS and both the type I and type II cGKs throughout the brain using NADPH-diaphorase (NADPHd) histochemistry combined with either immunocytochemistry or *in situ* hybridization. Using cGKII specific antibodies, strong staining was observed in Purkinje cells in the cerebellum, and moderate staining in the posterior hypothalamus, olfactory bulb and spinal cord. Except for a few neurons in the olfactory bulb, cGKI neurons were negative for NADPHd. cGKII expression was determined by *in situ* hybridization using <sup>35</sup>S-labelled type II antisense riboprobes. High levels of expression were observed in cortex, olfactory bulb, thalamus, tuberal hypothalamus, septum, and brainstem. Neurons expressing cGKII were also negative for NADPHd. Taken together, these data support the notion of NO as a diffusible messenger, as it is produced in neuronal populations that project to or are in close proximity to distinct brain regions expressing targets for NO.

## IDENTIFICATION OF PROTEINS FROM RAT BRAIN THAT INTERACT WITH P70 S6 KINASE, P.E. Burnett\*, D.M. Sabatini, S. Blackshaw, and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD 21237.

Activation of p70 S6 kinase is a common feature of several mitogen stimulated signal transduction pathways. p70 S6 kinase is involved in control of translation via phosphorylation of the S6 ribosomal subunit. Neuronally relevant pathways include stimulation of PC12 cells by NGF. In an attempt to identify relevant neuronal targets of p70, a two hybrid screen was performed using a rat brain cDNA library.

We have identified two clones which interact specifically with p70. The first is a novel DHR (GLGF/PDZ) domain containing protein. The second is a brain enriched developmentally regulated transcription factor. We have confirmed interactions with *in vitro* binding assays and are investigating their potential as a substrates for p70 kinase activity.

## LIPOPOLYSACCHARIDE FEVER REQUIRES PRODUCTION OF PROSTAGLANDINS IN THE PREOPTIC AREA

T.E. Scammell\*, J.D. Griffin, and C.B. Saper. Dept. of Neurology, Harvard Medical School / Beth Israel Hospital, Boston, MA 02115

Prostaglandin E2 (PGE2) is essential for the production of fever, but the necessary sites of PGE2 synthesis are unknown. Since low doses of PGE2 rapidly produce fever when injected into ventromedial regions of the preoptic area (POA), we hypothesize that these regions are critical sites of PGE2 production during fever. We microinjected ketorolac, a water-soluble inhibitor of PGE2 production, into a variety of preoptic sites and measured its effect on the fever typically produced by intravenous lipopolysaccharide (LPS). Ketorolac inhibits both cyclooxygenase-1 and -2, the rate limiting enzymes in prostaglandin production. Intravenous injection of ketorolac completely blocked LPS fever for over 4 hours. Injection of ketorolac into the ventromedial preoptic area, the organum vasculosum of the lamina terminalis (OVLT), and immediately adjacent sites markedly attenuated LPS fever. In contrast, ketorolac injections more than 500 µm from the OVLT had little effect on fever. Vehicle injections, even into the peri-OVLT region, had no effect on LPS fever. These experiments demonstrate that prostaglandins produced in ventromedial preoptic regions surrounding the OVLT play an essential role in LPS fever.

## 248.3

## THE THERMOSENSITIVITY OF NEURONS IN THE VENTROMEDIAL PREOPTIC AREA OF THE HYPOTHALAMUS. J.D. Griffin\* and C.B. Saper. Department of Neurology, Beth Israel Hospital and Harvard Medical School, Boston, MA 02115

In response to an i.v. challenge with febrile doses of lipopolysaccharide (LPS), studies from our lab have demonstrated that Fos immunoreactivity is displayed by neurons in the ventromedial preoptic area (VMPO) of the hypothalamus. In addition, neurons in VMPO show distinct axonal projections to areas such as the anterior perifornical area (APF). We would suggest that synaptic input from LPS stimulated neurons in VMPO alters the activity of integrative thermosensitive neurons in the APF, resulting in a shift in the set-point temperature into the hyperthermic range. Further evidence that the majority of neurons in VMPO are GABAergic, and current models of thermoregulatory control, suggest that VMPO may have a comparatively high proportion of temperature insensitive neurons which are stimulated by LPS challenge and project to the APF. The present study has focused on determining the inherent thermosensitivities and morphologies of neurons in VMPO. In a sagittally sectioned tissue slice preparation from the rat hypothalamus, whole-cell recordings were made from neurons in VMPO. Spontaneously active neurons were classified as either warm sensitive ( $m \geq 0.8 \text{ imp} \cdot \text{s}^{-1} \cdot ^\circ\text{C}^{-1}$ ) or temperature insensitive. Neurons which did not show spontaneous firing rates were classified as silent. In addition, recorded neurons were filled with the intracellular stain biocytin (0.5%) to determine the exact location and morphology of each neuron. Neurons in VMPO showed similar variations in temperature sensitivity and morphology as compared to other areas of the hypothalamus, with 55% of the neurons classified as temperature insensitive and 30% as warm sensitive. Temperature insensitive neurons had dendrites which projected rostrally and caudally, while warm sensitive neurons had dendrites that projected laterally and medially. The results of this study suggest that there is no significant difference in the relative temperature sensitivities or morphologies of neurons in VMPO, compared to other areas of the hypothalamus. TEMPERATURE SENSITIVE HYPOTHALAMIC NEURONS: THERMAL EFFECTS ON GABA<sub>A</sub> SYNAPTIC INHIBITION. P. Wung Burgoon\* and J.A. Boulant. Department of Physiology, The Ohio State University, Columbus, OH 43210.

Previous studies suggest that cooling increases the amplitudes and durations of inhibitory postsynaptic potentials (IPSPs), which can decrease firing rate and, thereby, contribute to neuronal temperature sensitivity. Temperature influences the resistance of the postsynaptic membrane, but it also influences presynaptic & postsynaptic kinetics that determine inhibitory postsynaptic currents (IPSCs). To study thermal effects on these synaptic events, whole-cell patch clamp recordings were made in preoptic and suprachiasmatic regions of rat hypothalamic tissue slices. Current-clamp and voltage-clamp recordings examined the effect of temperature on IPSPs and IPSCs, which were reversibly blocked by 10 µM bicuculline. Cooling always increased postsynaptic membrane resistance, which can increase IPSP amplitude. While cooling increased the durations of both IPSPs and IPSCs, it often decreased IPSC amplitudes. The increase in IPSP amplitudes and durations with cooling appears to be due primarily to thermally-induced changes in membrane resistance. However, in some neurons, IPSP amplitudes remained constant during temperature changes. In these cases, cool-induced increases in membrane resistance appear to compensate cool-induced decreases in IPSC amplitude.

## EVIDENCE FOR DIRECT INTERACTION OF INTRAVENOUS LPS WITH THE CENTRAL NERVOUS SYSTEM. J.K. Elmquist\*, T.E. Scammell, and C.B. Saper. Dept. of Neurology, Harvard Medical School/Beth Israel Hospital, Boston, MA 02115.

It is clear that peripheral immune cues alter CNS activity, but the mechanisms by which these signals are conveyed to the brain remain controversial. Recent experimental results indicate that the vagus nerve is essential in transducing immune system signals following intraperitoneal administration of LPS (endotoxin) or cytokines. The role of the vagus nerve following intravenous (iv) administration is less understood but iv LPS induces the expression of Fos-like immunoreactivity (Fos-IR) in nuclear groups of the rat brain involved in regulation of acute phase response. Using adult male Sprague-Dawley rats, we performed intracranial rhizotomies of the left vagus nerve and subsequently challenged the rats with iv LPS. Unilateral interruption of vagal afferents did not prevent brain Fos-IR including that seen in the ventromedial preoptic area, paraventricular hypothalamic nucleus, and the nucleus of the solitary tract. Additionally, we used immunohistochemistry for cyclooxygenase 2 (COX 2), the inducible form of the enzyme responsible for the production of prostaglandins following iv LPS. Administration of iv LPS induced COX 2-like immunoreactivity (COX 2-IR) in perivascular cells throughout the brain. Double label immunohistochemistry revealed that the majority of the cells containing LPS-induced COX 2-IR also stained with a marker for perivascular microglia and meningeal macrophages. Moreover, intracranial vagotomy did not abolish the LPS-induced COX 2-IR in perivascular cells throughout the CNS. Our results indicate that interruption of vagal afferents arising in the left nodose ganglia does not prevent CNS activation by iv LPS. Furthermore, these findings indicate that circulating LPS or cytokines may directly interact with cells in the meninges and perivascular space throughout the brain to initiate the CNS mediated components of the acute phase response. This work was supported in part by USPHS grants NS33987, NS09474, and MH10832.

Sex differences in response to PGE<sub>2</sub>, IL-1β and LPS in conscious and anaesthetised rats. X. Chen, K.E. Cooper\* and Q. Pittman. Neuroscience Research Group, Dept. of Med. Physiol., University of Calgary, Calgary, Canada

The extrahypothalamic vasopressinergic system has been shown to play a role in reducing febrile temperatures. As this system is less well developed in female rats, we have compared the pyrogenic responses of male and female rats to LPS, PGE<sub>2</sub> and IL-1β. PGE<sub>2</sub> (25 ng/5 µl per rat icv) resulted in higher fevers in conscious and anaesthetised (50 ng/5 µl per rat) females than in their male controls. Both sexes showed dose-dependent febrile responses to IL-1β (0.4, 1 and 2 µg/kg ip), but no appreciable differences in fever were noticed except for a slightly higher response in females in the first phase of fever. This discrepancy was abolished in anaesthetised rats (1 µg/kg iv), so it may arise from behavioural changes to the injection or a different distribution of IL-1β following ip injections. In anaesthetised rats, IL-1β 1 µg/kg iv caused concurrent increases in heart rate and mean arterial blood pressure, with heart rate staying elevated throughout the testing period (5 hrs following iv injection) and blood pressure returning toward baseline as time proceeded. There were no sex differences in these cardiovascular responses. LPS (E. coli, 50 µg/kg ip) evoked the same magnitude of fever in both sexes. Blockade of AVP V<sub>1</sub> receptors (Manning compound, 1 mmol/5 µl icv) did not give rise to exaggerated IL-1β fever in female rats. The results suggest there is a sex-related difference in fever development to PGEs which is not apparent with IL-1β and LPS given peripherally, which may activate pathways that are not entirely PGE-dependent. Supported by MRC. Supported by MRC.

## ANTEROVENTRAL THIRD VENTRICLE (AV3V) LESION MAY BLOCK FEVER BY INCREASING PLASMA CORTICOSTERONE. W.S. Hunter\*, L.L. Murphy and M.J. Propes. Department of Physiology Southern Illinois University, Carbondale IL 62901.

We have demonstrated (1993,96) that AV3V lesions which ablate the organum vasculosum laminae terminalis (OVLT), block endotoxin (LPS) induced fever in guinea pigs and rats. Fever is blocked by dexamethasone pretreatment (Coelho et al. 1992) and is enhanced in rats treated with glucocorticoid antagonist before i.p. LPS injection (Morrow et al., 1993). We hypothesized that AV3V lesion would produce elevation of corticosterone (CS) by releasing inhibition of normal fever suppression mechanisms. To test this, groups of three 300-400 g male Sprague-Dawley rats were implanted with temperature sensitive radio telemetry devices (Minimitter). One rat in each group was sham operated and two had electrolytic lesions stereotactically placed in the AV3V region. Seven days post-lesion, after 1 h baseline recording, each rat was injected i.p. with 100 µg/kg E. coli LPS or vehicle. Four hours post-injection the rats were quickly decapitated, blood collected for CS analysis and brains fixed for histological analysis. Of lesioned rats, those with low (<0.6°C) or no fever had highest plasma CS levels (>500 pg/ml). Sham operated or lesioned rats given vehicle exhibited temperature elevation <0.5°C, and CS levels <185 pg/ml. Lesioned rats which febrile with LPS had intermediate CS levels. These data support the hypothesis that rats with AV3V lesions ablating the OVLT exhibit elevated CS sufficient to suppress fever. Funded in part by the Illinois Eagles.

## 248.7

**THERMORESPONSIVENESS OF VENTROMEDIAL HYPOTHALAMIC (VMH) NEURONS TO REPEATED SCROTAL COOLING AND HEATING AT DIFFERENT COLONIC TEMPERATURES** O. Li and J. Thornhill, Dept of Physiology, Col. of Med. Univ. of Sask. 107 Wiggins Rd, Saskatoon, SK. S7N 5E5, Canada.

Our previous studies have shown that neurons within the VMH specifically respond to changes in peripheral (scrotal) temperature of urethane anesthetized rats. In the present study, we determined if VMH thermoresponsive neurons could retain their same thermoresponsiveness to repeated scrotal thermal stimulation, when colonic temperature was reduced. Extracellular VMH neuronal activity was recorded with glass-micropipettes filled with 0.5 M sodium acetate containing 2% protamine sky blue from urethane anesthetized male Sprague-Dawley rats with colonic temperature kept at 37°C, 35°C and 33°C during scrotal cooling (ice pack) and heating (the same size pack containing 40°C hot water). With colonic temperature kept at 37°C, all of 9 warm responsive (WRN), 7 cold responsive (CRN) and 17 VMH temperature non-responsive neurons (TNRN) retained their same thermoresponsiveness to a second trial of scrotal cooling and heating. Another 19 WRNs, 11 CRNs and 21 TNRNs were tested at an initial colonic temperature of 37°C, then at 35°C with two trials of scrotal thermal stimulation. Furthermore, 11 of 19 WRNs, 7 of 11 CRNs and 15 of 21 TNRNs were further examined for their thermoresponsiveness when colonic temperature was 33°C to the third trial of scrotal heating and cooling. Again, these VMH WRNs, CRNs and TNRNs retained their same thermoresponsiveness to scrotal thermal stimulation regardless of changes in colonic temperature. These results suggest that thermoresponsiveness of VMH neurons to repeated thermal stimulation of the scrotum is retained even when colonic temperatures are acutely reduced. Supported by the MRC of Canada.

## 248.9

**CORE TEMPERATURE AND METABOLIC RESPONSES TO CRF ADMINISTRATION.** K.P. Sausen, S.T. Ahlers, C.L. Foreman, M.H. Quesada, C.-M. Staschen, and J.R. Thomas. Thermal Stress/Adaptation Program, Naval Medical Research Institute, Bethesda, MD 20889-5607.

This study compared core temperature (Tcore) and VO2 responses to corticotropin releasing factor (CRF). Eight Long-Evans rats underwent lateral ventricular cannulation and abdominal implantation of a telemetric thermal probe. Tcore and VO2 were recorded for 30 min before and for 90 min after intracerebro-ventricular injection of saline, 0.3 or 3.0 µg CRF. All rats received all doses, separated by 1 week. Data were examined as change from preinjection baseline to 10, 30, 60, and 90 min post injection. Tcore fell after CRF administration. Relative to saline, the Tcore drop was significant at 90 min for 0.3 µg, and at 60 and 90 min for 3.0 µg. VO2 fell over the course of the postinjection period for saline and 0.3 µg CRF, but not in the 3.0 µg condition. These data suggest a complex relationship between metabolic and thermoregulatory responses to CRF. Supported by Naval Medical Research & Development Command work unit 62233NM33C30.004-1002.

## 248.11

**INHIBITION OF CONSTITUTIVE NITRIC OXIDE SYNTHASE CAUSES HYPOTHERMIA.** Thomas F. W. Horn\* and Floyd E. Bloom. The Scripps Research Institute, Department of Neuropharmacology, La Jolla, CA 92037, USA.

Nitric oxide synthase (NOS) is localized in neurons of hypothalamic nuclei, in the brainstem as well as in the peripheral nervous system, suggesting a role in the regulation of autonomic functions. We tested whether nitric oxide (NO) blockers affect normal and elevated body temperature and gross motor activity in conscious rats using telemetry. The unspecific NOS-blocker L-NAME (50 mg/kg, i.p.) decreased baseline body temperature from 37.2 ± 0.1°C to a minimum of 36.2 ± 0.2°C (n=12). To distinguish the site of action and rule out effects due to blood pressure changes, we applied the normotensive cNOS-specific blockers 7-Nitroindazole (7-NI) or 3-Br-7-NI. The vehicle for the drug application (arachis oil) did not change normal body temperature when applied i.p. (37.2 ± 0.1, n=12). Body temperature minima due to i.p. 7-NI were observed approx. 90 min after injection in a dose-dependent manner: 37.4 ± 0.1 (1 mg/kg, n=11), 36.3 ± 0.1 (20 mg/kg, n=11, p<0.01), 35.9 ± 0.1 (40 mg/kg, n=11, p<0.01) and 34.8 ± 0.2 (50 mg/kg, n=11, p<0.001). Telemetered gross motor activity (cumulative over 6h post injection) was decreased after 1 mg/kg 7-NI and reached its minimum at 40 mg/kg. 3-Br-7-NI was found to be more potent by causing similar responses at a dose of 10 mg/kg. An i.p. of dose 10mg/kg L-NIL, a specific blocker of inducible NOS failed to alter body temperature. When febrile animals (100 µg E. coli-Lipopolysaccharide, LPS, i.p.), received 7-NI, no fever was observed, whereby the first peak of the biphasic LPS-fever was replaced by a hypothermia of approx. 50% as seen in non-febrile animals. However i.c.v. application of the soluble sodium salt of 7-NI (66 µg/kg in 5 µl, n=9) did not decrease body temperature, suggesting the peripheral nervous system as the site of action.

Our data are evidence that NO is involved in basal thermoregulation via the peripheral nervous system. The consideration of this effect will be important for future physiological and behavioral studies using blocking agents for NOS e.g. in the prevention of neuronal damage due to ischemia. Sup. by DAAD, HFSOP.

## 248.8

**THERMOSENSITIVITY OF A TRANSIENT OUTWARD CURRENT IN HYPOTHALAMIC NEURONS.** C.S. Wang and S.R. Kelso\*, Dept. of Biol. Sci., Univ. of Illinois at Chicago, Chicago, IL 60607

Whole-cell voltage clamp recordings were conducted in rat preoptic-anterior hypothalamic (POAH) tissue slices. POAH neurons are believed to be the center for thermoregulation in mammals. Sixty-three neurons were classified based on their firing rate response to temperature changes. 76% of the neurons were T-insensitive and 24% warm-sensitive. After determining thermosensitivity, a fast transient outward current was recorded, using TTX (0.5 µM) to block Na<sup>+</sup> currents, TEA (10 mM) to block delayed rectifier, and low concentration of Ca<sup>2+</sup> (0.2 mM) to minimize contributions from Ca<sup>2+</sup> currents.

Steady-state activation and inactivation of the current were similar to that of I<sub>A</sub> in other mammalian central neurons. It was also sensitive to 4-AP. Temperature insensitive cells showed a significantly higher amplitude of peak I<sub>A</sub>. Upon temperature elevation, there was a general increase in the amplitude of peak I<sub>A</sub> for T-insensitive cells, while the peak amplitude for warm-sensitive cells was decreased. The total current (by integration) of I<sub>A</sub> was decreased for both cell types with temperature being raised. However, the percent decrease of I<sub>A</sub> for warm sensitive cells is two to three times larger than that for T-insensitive cells. This larger decrease of I<sub>A</sub> for warm cells is presumably caused by an increased rate of inactivation of I<sub>A</sub> at a higher temperature. This may contribute to the bigger increase in firing rates in warm sensitive cells in response to raising temperature.

## 248.10

**NITRIC OXIDE SYNTHASE AND NITROTYROSINE IMMUNOREACTIVITY IN THE RAT FOREBRAIN FOLLOWING HEAT STRESS.** A.M. Zardetto-Smith\*, N.W. Kooy, S.J. Lewis and K. C. Kregel. Depts. of Anatomy, Pediatrics, Pharmacology and Exercise Science, Univ. of Iowa, Iowa City, IA 52242.

This study assessed nitric oxide synthase (NOS)/nitrotyrosine (NT) immunoreactivity (ir) in regions of the forebrain of normothermic rats and rats challenged with heat stress. Conscious male Sprague-Dawley rats were maintained either at normothermic core body temperature (T<sub>c</sub> = 38.0°C) or exposed to an ambient temperature of 42°C until T<sub>c</sub> reached 41°C. Heated rats were subsequently maintained at 41°C for 30 min. Both groups were returned to their home cages and after 12 h were euthanized with an overdose of pentobarbital (100 mg/kg, ip). After perfusion and post-fixation, brainstem sections were cut using a vibratome and processed for endothelial NOS-ir (ecNOS-ir), inducible NOS-ir (iNOS-ir), neuronal NOS-ir (nNOS-ir), or nitrotyrosine-ir (NT-ir) using the ABC immunoperoxidase technique. Heated rats showed increases in ecNOS-ir over controls in astrocytes near the ependymal lining of the third and lateral ventricles, in astrocytes populating the subfornical organ and median preoptic nucleus, and in astrocytes surrounding blood vessels. Normothermic rats showed nNOS in the supraoptic nucleus and magnocellular paraventricular nucleus, but heated rats showed an increased density of staining in these nuclei. Both normothermic and heat-stressed rats demonstrated iNOS and NT-ir within ependymal cells lining the ventricles; iNOS was also present in ependymal cells lining the floor of the superior horn of the lateral ventricle. The results indicate that (i) nNOS may be increased by a physiological level of heat stress; (ii) that ependymal cells may contain significant amounts of iNOS and NT; and (iii) that astrocytes at the ventricular interface may display increased ecNOS in response to hyperthermia. (Supported by NIH AG-12350 to K. Kregel).

## 248.12

**DIFFERENTIAL EFFECTS OF THREE COX INHIBITORS MICRODIALYZED INTO THE PREOPTIC AREA (POA) OF GUINEA PIGS.** E. Schic, M. Szekely, A. L. Ungar, and C. M. Blatteis\*. Dept. of Physiol. & Biophys., Univ. of Tennessee, Memphis, Memphis, TN 38163.

In guinea pigs, iv LPS promptly induces fever and enhances the production of PGE<sub>2</sub> in the POA, apparently via peripheral, vagally mediated signals to the central noradrenergic system; norepinephrine rapidly augments the local production of PGE<sub>2</sub>. If fever and PGE<sub>2</sub> were directly linked, the blockade of PGE<sub>2</sub> synthesis in the POA by locally applied COX inhibitors should prevent the concomitant increases in core temperature (T<sub>c</sub>) and preoptic PGE<sub>2</sub>, whereas, if PGE<sub>2</sub> were not an obligatory central mediator of fever, blockade of its synthesis should not abolish fever caused by iv LPS. To test this hypothesis, sodium indomethacin trihydrate (indo; 1.0 µg/µl artificial (a)CSF; pH 7.4) was microdialyzed bilaterally into the POA of conscious guinea pigs from 30 min before until 4 h after the iv injection of pyrogen-free saline (PFS; 0.2 ml) or LPS (2 µg/kg in 0.2 ml PFS). LPS augmented preoptic PGE<sub>2</sub> without raising T<sub>c</sub>, and indo pretreatment abolished this rise, indicating that, under these conditions, PGE<sub>2</sub> and fever are not correlated, probably due to inflammatory tissue reactions to the implanted probes. Indeed, when the POA was alkalinized with pH 7.8 aCSF, iv LPS produced biphasic increases in T<sub>c</sub> and preoptic PGE<sub>2</sub>, while sodium meclofenamate (1.2 µg/µl, soluble in pH 7.8) prevented the PGE<sub>2</sub> increase and reduced but did not block the fever caused by iv LPS. If alkaline aCSF potentiates (presumably through enhanced neuronal activity), then acidified aCSF should prevent (by depressing neuronal activity) the LPS-induced rises in PGE<sub>2</sub> and T<sub>c</sub>. Indeed, sodium salicylate (10 µg/µl, soluble in pH 3.5) inverted T<sub>c</sub> and prevented PGE<sub>2</sub> production caused by iv LPS. These results support the notion that PGE<sub>2</sub> is produced in the POA rather than peripherally in response to iv LPS. They also show that bilaterally implanted microdialysis probes and acid aCSF introduce local reactions that may vitiate the effects expected. (Supported by NIH grant NS-34857.)

**THERMOREGULATORY EFFECTS OF SEROTONIN 5-HT<sub>2C</sub> RECEPTOR GENE INACTIVATION.** A. M. Strack\* and L. Tecott. Depts. of Physiol. and Psych., UCSF, San Francisco, CA 94143

Serotonin (5-HT) modulates core temperature by action at multiple 5-HT receptor subtypes. To study the role of the 5-HT<sub>2C</sub> receptor in thermoregulation, we have used a 5-HT<sub>2C</sub> receptor mutant mouse strain (Nature 374: 542, 1995). Male knockout (KO) and wildtype (WT) mice were implanted with radiotelemetric temperature probes i.p. 1 week before experimentation.

m-chloro-phenylpiperazine (mCPP), a 5-HT<sub>2C</sub> agonist which produced an immediate hypothermia in WT, but not KO mice. Because mCPP inhibits food intake in WT, but not KO mice and core temperature correlates closely with feeding, we hypothesized that the differential temperature response between the groups resulted from differences in food intake. To test this, we fasted WT and KO mice for 24 hrs. Whereas, KO mice had no change in temperature, WT mice had decreased core temperature, beginning ~5 hrs after start of the fast. The differential time course between mCPP-induced and fasting-induced hypothermia suggests regulation of different 5-HT<sub>2C</sub> receptor mechanisms.

In a subsequent experiment, mice were housed at 5°C for 4 days to determine their responses to decreased environmental temperature. WT mice had decreased peak temperature at night and increased AM nadir temperature, resulting in a damped circadian oscillation in core temperature typical of circadian rhythms following stress. KO mice had a similar decrease in night peak amplitude, however nadir temperatures were higher on day 1 and lower on day 3 compared to control nadir values. The variance in circadian oscillation suggests that putting KO mice in cold unmasks a disruption in a circadian or a temperature feedback system due to lack of 5-HT<sub>2C</sub> receptors.

We conclude that the 5-HT<sub>2C</sub> receptor plays multiple roles in temperature regulation at sites yet to be elucidated. Supported by DK28172 and DA00282.

**THE RELATIONSHIP BETWEEN BODY TEMPERATURE AND ECF STRIATAL DOPAMINE LEVELS IN MICRODIALYSIS STUDIES.** T.H. Wu, L.N. Acworth and T.J. Maher. Div. Pharm. Sci., Mass. Coll. Pharmacy & AHS, Boston, MA 02115 and ESA Inc., Chelmsford, MA 01824.

Ample evidence has implicated a role for dopamine (DA) in the regulation of body temperature in animals. Observed striatal extracellular fluid (ECF) DA levels may be influenced by body temperature changes *in vivo* but also by factors affecting probe recovery in microdialysis experiments. In the present studies, animals were subjected to hyperthermic or hypothermic conditions to raise or lower body temperature and rectal temperature (RT) was monitored. Simultaneously ECF DA was determined in striatum using a 3 mm loop design microdialysis probe. Additionally, the *in vitro* recovery of DA by microdialysis probes was determined under similar temperature conditions as a reference for the *in vivo* studies. Following the elevation of RT in rats for 2 hrs with a temperature-controlled aluminum plate, RT increased to 40.4 °C. Following induced hypothermia for 2 hours with ice packs, RT was decreased to 22.8 °C. The linear relationship between the striatal DA level changes (%) and RT (°C) from baseline was statistically significant ( $p < 0.0001$ ;  $R = 0.825$ ). The slope of the regression line equaled 15.6 % / °C. For the *in vitro* recovery of DA, a linear regression line ( $p < 0.05$ ;  $R = 0.854$ ) existed, but with a much shallower slope (0.67 % / °C). These studies demonstrate that a linear relationship between RT and ECF striatal DA level changes in rats and that the changes in ECF DA are not mainly the result of changes in probe recovery.

**FUNCTIONAL ORGANIZATION OF HYPOPHYSIOTROPIC TRH NEURONS.** R. T. Zoeller, R. Lee, M. Curran, D. L. Fletcher, and D. E. J. Blazis\*. Department of Biology and Neuroscience and Behavior Program, Univ. Massachusetts, Amherst, MA 01003.

The pituitary-thyroid axis is controlled predominantly by neurons in the hypothalamic paraventricular nucleus (PVN) which synthesize and secrete thyrotropin (TSH)-releasing hormone (TRH). These neurons are clustered in the parvocellular division of the PVN and project uniformly to the median eminence. Cold exposure in rats produces a rapid increase in serum TSH which is dependent upon TRH secretion. We have previously demonstrated that cold exposure rapidly elevates cellular levels of the mRNA encoding TRH, indicating that hypophysiologic TRH neurons become activated by sensory afferents (adrenergic) mediating the thyrotropic response to cold. However, we were not able to conclusively determine whether all TRH neurons are activated by cold exposure. We have now used two approaches to determine whether all or a subset of TRH neurons in the PVN are activated by cold exposure. First, we have used dual-label *in situ* hybridization to determine that cold exposure does not induce *c-fos* expression in all TRH neurons of the PVN. In addition, we are testing whether TRH mRNA levels become selectively elevated in *c-fos* expressing cells. Second, we have cloned unique regions of adrenergic receptor subtypes to determine the composition of adrenergic receptors in TRH neurons and the proportion of TRH neurons exhibiting adrenoceptor expression. These two approaches should allow us to conclude whether all TRH neurons respond to cold exposure to elicit this neuroendocrine reflex. Supported in part by NSF IBN 9514835.

## 248.16

**CARDIOVASCULAR RESPONSES TO A NOVEL STRESSOR IN CHRONICALLY STRESSED ANIMALS.** M. Dallman, S. Bhatnagar, A.I. Basbaum & B.K. Taylor\*. Dept. of Physiology & Keck Center for Integrative Neurosciences, UCSF, San Francisco, CA, 94143-0444.

We have previously shown that chronic, intermittently cold-stressed animals exhibit elevated levels of adrenocorticotropin and corticosterone upon exposure to a novel stressor, restraint, compared to control animals. This enhanced neuroendocrine responsiveness to a novel stressor occurs despite the negative feedback effects of circulating corticosterone that is released by cold exposure. The present study assessed whether this enhanced responsiveness extends to other stress-sensitive systems, namely the cardiovascular system. Adult, male Sprague-Dawley rats were instrumented with indwelling femoral arterial catheters and 2-3 days later exposed to either 7 days of chronic, intermittent cold stress (4h/day at 4°C; CHR) or left undisturbed (CTL). On the 8th day, blood pressure (BP) and heart rate (HR) were monitored every minute during a baseline period, 30 min of restraint and for 30 min after return to the home cage. We did not observe any differences in baseline BP or HR between CTL and CHR animals. Over the 30 minute restraint period, peak BP and HR responses occurred within 2 min and then decreased similarly in CHR and CTL animals. Interestingly, when returned to the home cage, CHR animals exhibited lower BP and HR responses compared to CTL animals. Previous data have shown that some indices of autonomic responsiveness to restraint (i.e., brown fat temperature and plasma epinephrine) are not altered in chronically stressed animals. Thus, the present data support the notion that prior exposure to chronic stress has different effects on autonomic and hypothalamic-pituitary-adrenal responsiveness to novel stressors. Supported by the Medical Research Council of Canada, DK28172 and DA08377.

## OSMOTIC REGULATION

## 249.1

**MULTISYNAPTIC CONNECTIONS BETWEEN THE LAMINA TERMINALIS AND THE RAT KIDNEY.** B.J. Oldfield\*, L. Colvill, M. Giles and M.J. McKinley. Howard Florey Institute of Physiology and Medicine, University of Melbourne, Victoria, 3052, Australia.

There is evidence based on cerebral lesions in both sheep and rats that sites in the midline preoptic region can influence renal function. In the present experiments, the retrograde transsynaptic transport of the Bartha strain of pseudorabies virus has been used to map the multisynaptic pathways to the kidney. Thirty Sprague-Dawley rats were anesthetized with sodium thiopentone (60 mg/kg) and the left kidney exposed through a flank incision. Six 1.5 µl injections of a suspension of virus were made throughout the renal cortex and rats survived between 1 and 4 days. Identification of the transsynaptic spread of the virus throughout the CNS showed infected neurons sequentially in sympathetic preganglionic neurons of the lower thoracic cord (predominantly ipsilaterally), in premotor neurons in the medulla, pons, and paraventricular nucleus of the hypothalamus. At survival periods of 90 hours or longer virus positive neurons were identified in components of the lamina terminalis, the subfornical organ (SFO), organum vasculosum lamina terminalis (OVLT) and median preoptic nucleus as well as adjacent preoptic areas. Some of the infected neurons of the SFO and OVLT were fos-positive following 24 hours of dehydration. The data show the existence of a neural substrate via which osmotic and angiotensin-mediated changes may be detected at circumventricular sites and relayed to the kidney.

Supported by an Institute Block grant to the Howard Florey Institute by the National Health and Medical Research Council of Australia.

## 249.2

**ROLE OF SODIUM IN MODULATING RESPONSES TO OSMOTIC STIMULI IN RAT SUPRAOPTIC MAGNOCELLULAR NEURONS.** D.L. Voisin and C.W. Bourque\*. Centre for Research in Neuroscience, McGill University, Montreal, Canada, H3G 1A4.

In mammals, changes in natriuresis and diuresis through effects on the secretion of oxytocin and vasopressin are part of the physiological mechanisms which regulate osmolality of the extracellular fluid. Supraoptic neurons, which synthesize and secrete the neurohypophysial hormones, are themselves recognized as osmoreceptors. Recent biophysical studies in our laboratory have provided evidence supporting the involvement of stretch-inactivated cationic channels in the transduction process underlying osmoreception in supraoptic neurons. We have investigated how these osmoreceptor-mediated responses may be modulated by the concentration of sodium ions in the extracellular fluid. Whole-cell recordings obtained from isolated rat supraoptic neurons revealed that excess NaCl was more potent than osmotically equivalent excess mannitol in eliciting membrane depolarization and firing rate increases ( $n=5$ ). In voltage clamp, increases in external [NaCl] evoked a larger inward current than mannitol, but the underlying increase in membrane conductance was the same ( $n=5$ ). These data suggest that the permeation characteristics of osmotically-gated cationic channels permit the simultaneous detection of extracellular sodium concentration and osmotic pressure. Supported by the MRC (Canada) and le Programme Lavoisier (France).

## 249.3

**BURST FIRING AND ITS MODULATION IN NEURONS OF THE RAT ORGANUM VASCULOSUM LAMINA TERMINALIS (OVL) IN VITRO.** S.J. Gentles\* and C.W. Bourque. Centre for Research in Neuroscience, McGill University, Montreal, Canada, H3G 1A4.

The OVL has been proposed as an interface between the general circulation and the central nervous system. Intracellular recordings from OVL neurons *in vitro* have previously revealed the presence of a low threshold spike (LTS) upon depolarization from negative potentials [Nissen *et al.* 1993, *Am J Physiol* 264]. In many cells, the presence of an LTS contributes to the generation of rhythmic bursting activity. Extracellular recordings from OVL neurons were therefore obtained in explants of rat hypothalamus at 33°C. Electrical activity was monitored under resting conditions, and in response to the application of various drugs (eg. angiotensin II, atrial natriuretic factor, cholecystokinin, GABA, carbachol, NMDA, neurotensin and noradrenalin) and osmotic stimuli. Bursting activity consisting of repeated clusters (2-7 spikes at 40 to 60 Hz) was observed under resting conditions in 19 of 64 spontaneously active neurons. The characteristics of these bursts were modifiable by drug application in 6 of the 19 cells tested. The bursting pattern could also be induced in 5 of the silent cells tested. These results indicate that OVL neurons can display burst firing consistent with the presence of an LTS and that the expression of the bursting pattern can be modulated by neurotransmitters and osmotic stimuli. Supported by the Medical Research Council of Canada.

## 249.5

**c-fos PROTEIN (FOS) IMMUNOREACTIVITY IN ANTERIOR CIRCUMVENTRICULAR ORGANS (ACVO's) AND PERIOPTIC HYPOTHALAMIC NUCLEI (POHN) AFTER OSMOTIC CHALLENGE IN LATE GESTATION FETAL SHEEP.** T.J. McDonald\*, C. Li\*, M.J.M. Niland\*, A. Caston-Balderrama\* and M.G. Ross\*. Laboratory for Pregnancy & Newborn Research, Coll. Vet. Med., Cornell University, Ithaca, NY 14853; \*Perinatal Research Labs, Dept. OB/GYN, Harbor-UCLA Med. Ctr., CA 90502, (DK 43311).

**Introduction:** Polyhydramnios, a serious complication of pregnancy, is associated with abnormal fetal swallowing, eg. anencephaly, mandibulofacial dysostosis. Information on sensory neurons involved in swallowing comes primarily from studies in adults and implicates ACVO's and POHN. We hypothesized that the same sensory neural structures reported to modulate swallowing in postnatal animals will show Fos activation in the fetal sheep during an osmotic challenge.

**Methods:** Five fetal sheep brains [3 treated, 2 controls; = 130 days of gestation (dGA)] were immunostained for Fos. Seventy-five min prior to tissue collection the dams were given 20% mannitol (1 ml/kg/min for 10 min i.v.). ACVO's and POHN were scored for amount and intensity of Fos immunostaining as compared to controls.

**Results:** After the osmotic challenge, Fos increased in all ACVO's and POHN (Table 1) in comparison to controls.

**Conclusion:** Based on Fos immunostaining, all ACVO's and POHN participate in sensing systemic osmotic stimuli at 130 dGA. We speculate that, as in adults, fetal swallowing in late gestation is influenced by ACVO's and POHN.

SFO	MnPO	OVL	SON	PVN
+	++	+	+++	++

Table 1. Relative Fos activity of 130 day fetal sheep neurons 75 min after 20% mannitol infusion to dam. Increase in Fos immunostaining compared to controls: + light, ++ moderate, +++ heavy. SFO [subfornical organ]; MnPO [median preoptic nucleus (n.)]; SON [supraoptic n.]; PVN [paraventricular n.].

## 249.7

**HIGH RESOLUTION IMMUNOGOLD LOCALIZATION OF AQUAPORIN-4, A WATER CHANNEL, IN RAT BRAIN.** E.A. Nagelhus, S. Nielsen, P. Agre, and O.P. Ottersen\*. Dept. of Anat., Univ. of Oslo, P. O. Box 1105 Blindern, N-0317 Oslo, Norway; †Dept. of Cell Biology, Univ. of Aarhus, Denmark; ‡Dept. of Biol. Chem., Johns Hopkins Univ. School of Med., Baltimore, USA.

A new member of the aquaporin family, aquaporin-4, has recently been cloned and found by Northern blotting and *in situ* hybridization to be strongly expressed in brain (Proc. Natl. Acad. Sci. USA 91:13052-13056, 1994). We have used an affinity purified antibody raised against a synthetic peptide near the C-terminus of the cloned protein to investigate its precise localization. Immunoblotting demonstrated a 29 kDa and a 50-60 kDa band which were both completely ablated using peptide absorbed antibody. Light microscopy revealed strong immunostaining along the entire surface of the brain and particularly ventrally where the most prominent labeling occurred at mesencephalic and diencephalic levels. There was also strong labeling in the cerebellum, area postrema, and nucleus supraopticus. Postembedding immunogold analysis of the latter structures, and of the subfornical organ, spinal cord, and hippocampus, indicated that aquaporin-4 is restricted to glial membranes and to subpopulations of ependymal cells (those associated with the subfornical organ). The density of gold particles were particularly high in perivascular glial processes which displayed a stronger immunolabeling of the membranes facing blood vessels than of the membranes facing the neuropil. This polarization was confirmed by double labeling with different gold particle sizes revealing an inverse polarization in regard to the distribution of the glutamate transporter GLAST (see Neuron 15:711-720, 1995). The glia limitans displayed strong labeling, more intense on the pial surface than on the surface abutting on the neuropil. Following preembedding immunogold cytochemistry the silver enhanced 1.4 nm gold particles were associated with the cytoplasmic aspect of the glial membrane, consistent with an intracellular localization of the C-terminal. Our data indicate that aquaporin-4 is found in glial processes throughout the brain and that it is preferentially targeted to glial membranes associated with brain-blood or brain-liquor interfaces. ## 249.4

**IONIC CURRENTS OF CELLS OF THE SUBFORNICAL ORGAN THAT PROJECT TO THE SUPRAOPTIC NUCLEUS, R.F. Johnson, T.G. Beltz, R.E. Wachtel\* and A.K. Johnson.** Departments of Psychology, Pharmacology and Anesthesiology and the Cardiovascular Center, University of Iowa and the VA Medical Center, Iowa City, IA 52242-1407

The subfornical organ (SFO) activates areas of the brain involved in body fluid regulation when it detects elevated levels of angiotensin II in the blood. In so doing, it transduces the humoral signal to a neural efferent signal. To understand the transduction mechanism, we have started by examining the electrophysiological characteristics of cells of the SFO that project to the supraoptic nucleus (SON). Eleven-day-old rats received injections of rhodamine labeled beads aimed at the perinuclear region of the SON. After three days to allow retrograde transport, the SFO was removed and its cells dissociated and cultured. Whole-cell patch-clamp recordings were obtained from cells, that displayed the retrograde label, for 2-5 days. The typical family of currents observed to a step depolarization protocol consisted of a rapid inward current that rapidly inactivated and was followed by outward current that peaked and then declined to a steady state. The rapid inward current is characteristic of a sodium current and can be blocked with tetrodotoxin. The outward current appears to be a combination of two potassium currents. The first is a delayed rectifier that could be block with tetraethylammonium. The second is a transient A-current that requires a period of hyperpolarization before it can be activated by a step depolarization. Supported by NHLBI HL 14388 and NASA NAGW-4358.

## 249.6

**CALCITONIN RECEPTORS IN THE RAT SUBFORNICAL ORGAN STIMULATE WATER INTAKE**

H. A. SCHMID\* and M. RAUCH Max-Planck-Institute for Physiol. & Clin. Res., Kerckhoff-Institute, Parkstr. 1, 61231 Bad Nauheim, Germany.

Although numerous receptors for calcitonin (CT) have been described in the rat subfornical organ (SFO), their possible functional relevance has so far not been investigated. Due to the absence of a functional blood-brain-barrier in the SFO, blood-borne CT can reach and affect these central receptors and might thus cause central effects in addition to its well documented peripheral effect of lowering blood calcium levels. Using a brain slice preparation, the effect of bath applied rat-CT (rCT) and angiotensin II (AngII) on the extracellularly recorded electrical activity of SFO neurons was investigated. Superfusion with rCT ( $10^{-7}$  M) activated 62% and AngII ( $10^{-7}$  M) activated 85% of SFO neurons tested with both peptides (n=26). With only one exception, all rCT-responsive neurons could in addition be activated by AngII. The threshold concentration for CT was  $10^{-9}$  M and thus similar to the threshold concentration of AngII in this preparation. Because circulating AngII is known to stimulate water intake via its excitatory effect on SFO neurons, the effect of CT on water intake of water sated rats was investigated. Subcutaneous injection of AngII ( $2 \times 10^{-4}$  M, 200 µl) and rCT ( $4 \times 10^{-4}$  M, 200 µl) caused drinking in 9 of 11 and 6 of 9 rats, respectively, whereas only 1 out of 14 control rats drank during 60 min after the injection of saline. The cumulative water intake of all rats receiving AngII ( $2.6 \pm 0.5$  ml) or rCT ( $1.0 \pm 0.3$  ml) was significantly ( $p < 0.02$ ; Mann-Whitney rank sum) increased vs. the control ( $0.07 \pm 0.07$ ). These data provide the first direct evidence for an interaction of blood-borne calcitonin with neurons in the brain and suggest a similar effect of AngII and CT on water intake and possibly other SFO mediated physiological responses like salt appetite and release of antidiuretic hormone. Supported by DFG Si 230/1.

## 249.8

**VASOPRESSIN RESPONSE TO DEHYDRATION IN AGED BROWN NORWAY/FISCHER 344 RATS.** C. D. Sladek\* and K.L. Swenson. Dept. Physiology, Chicago Med. Sch., North Chicago, IL, 60064.

The plasma vasopressin (pVP) response to 72 hours of water deprivation is attenuated in 30 mo. old Fischer 344 (F344) relative to 4 mo old rats. This appears to reflect an inability to increase VP synthesis. In contrast, elevated pVP has been reported in the Brown-Norway (BN) strain of rats secondary to reduced renal VP responsivity. We evaluated the response to dehydration in the F1 cross of these strains, BN/F344F1, in order to determine the usefulness of this strain for future studies on the mechanisms by which aging impacts on regulation of VPmRNA. The following parameters were evaluated in male BN/F344F1 rats of 4 and 30 mos of age (NIA colony, Harlan SD) following 72 hrs of water deprivation (Dehyd) or water ad libitum (Hyd): change in body wt (ΔBW), hematocrit (Ht), urine osmolality (uOsm), pVP. The results are tabulated below:

AGE mo	H2O (m)	Status	ΔBW %	Ht %	uOsm mosm/kg	pVP pg/ml
4	(8)	Hyd.	0.0±0.4	44±1	1158±115	0.4±0.02
4	(8)	Dehyd.	-8.0±0.3*	50±1*	4440±32*	2.3±0.4*
30	(7)	Hyd.	0.2±0.2	40±3	1535±157	0.5±0.2
30	(6)	Dehyd	-6.1±0.2*	45±2*	2373±486	0.8±0.2

\* $p < 0.05$  vs hydrated of same age.

In spite of similar dehydration in the 4 and 30 mo old rats as indicated by the ΔBW and Ht, pVP was not elevated in the dehydrated old rats. This suggests that the effect of aging on the VP response to dehydration in BN/F344F1 rats is similar to that observed previously in F344 rats. Supported by NIH grant RO1-AG12701.

## 249.9

EFFECT OF AGING ON VASOPRESSIN RESPONSE TO DEHYDRATION IN FEMALE FISCHER 344 RATS. J. Canudoc-Vallero\* and C. D. Sladek. Dept. Physiology, Chicago Med. Sch., North Chicago, IL, 60064.

The plasma vasopressin (pVP) response to 72 hours of water deprivation is attenuated in male 30 mo. old Fischer 344 (F344) relative to 4 mo old rats. This appears to reflect an inability to increase VP mRNA content and consequently VP synthesis. Since gonadal steroids have been implicated in the regulation of VP mRNA content and gonadal steroid production is differentially effected by aging in males and females, we evaluated the VP response to dehydration in female Fischer 344 rats of 4, 12/13, 19/20, and 28 mos of age in order to determine if gender differences exist in the effect of aging on this response. Daily vaginal smears indicated that all the rats 19 mos of age and older were in pseudopregnancy (constant diestrus). Their responses were compared to young rats in diestrus. The following parameters were evaluated following 72 hrs of water deprivation (D) or water ad libitum (H): % change in body wt ( $\Delta$ BW), hematocrit (Hct), plasma osmolality (pOsm, mOsm/kg), and pVP (pg/ml); n=4-6. The results are tabulated below:

AGE	4		12/13		19/20		28	
H2O	H	D	H	D	H	D	H	D
$\Delta$ BW	5 $\pm$ 2	-11 $\pm$ 0	1 $\pm$ 2	-9 $\pm$ 0	0 $\pm$ 0	-9 $\pm$ 0	0 $\pm$ 0	-10 $\pm$ 0
pOsm	300 $\pm$ 3	313 $\pm$ 3	299 $\pm$ 2	308 $\pm$ 2	304 $\pm$ 4	307 $\pm$ 2	297 $\pm$ 1	316 $\pm$ 2
Hct	43 $\pm$ 2	50 $\pm$ 1	42 $\pm$ 2	47 $\pm$ 1	40 $\pm$ 1	42 $\pm$ 2	37 $\pm$ 1	41 $\pm$ 2
pVP	2 $\pm$ 0	14 $\pm$ 6	2 $\pm$ 1	16 $\pm$ 6	2 $\pm$ 0	26 $\pm$ 13	2 $\pm$ 1	12 $\pm$ 4

pVP was elevated by dehydration ( $F=27$ ,  $p<0.001$ ) irrespective of age ( $F=1$ ). Thus, gender differences exist in the effect of aging on the VP response to aging in F344 rats. Supported by NIH grant RO1-AG12701.

## 249.11

CENTRAL SEROTONIN INJECTION PRODUCES SUSTAINED INHIBITION OF RENAL SYMPATHETIC ACTIVITY IN VOLUME-DEPLETED RATS. K.E. Scrogin, R.L. Thunhorst\* and A.K. Johnson. Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242-1407

Central serotonin (5-HT) injections cause a slowly developing natriuresis in hydrated rats that is dependent on renal sympathetic nerves. In the present study, renal sympathetic nerve activity (RSNA) was recorded in mildly hypotensive, hypovolemic rats to determine if central 5-HT produces sympatho-inhibition. Mean arterial blood pressure (MAP), heart rate (HR) and RSNA were recorded in conscious, unrestrained rats. Rats were volume depleted by iv furosemide (4x1 mg/kg) and MAP lowered by iv minoxidil (2 mg/kg). Responses to 0 (n=3), 20 (n=9) or 100  $\mu$ g (n=8) icv, and 100  $\mu$ g (n=5) iv 5-HT were then recorded for 90 min. Furosemide increased MAP (8 $\pm$ 1 mmHg) and RSNA (35 $\pm$ 9% above baseline) and caused a cumulative urine excretion of 15.4 $\pm$ 0.5 ml. Minoxidil reduced MAP (-12 mmHg) and increased HR (24 $\pm$ 5 bpm) and further increased RSNA (37 $\pm$ 10% of pre-minoxidil levels). Dose-dependent reductions in RSNA of 20.9 $\pm$ 3.4 and 38.8 $\pm$ 6.8% were observed by 90 min after central 5-HT injection. Intravenous injection of 5-HT (100  $\mu$ g) caused a reduction in RSNA (17 $\pm$ 8% below baseline after 90 min) that was significantly less marked than that after the same dose given icv. The data indicate that central 5-HT produces a progressive and sustained renal sympatho-inhibition despite the unloading of arterial and cardiopulmonary baroreceptors. The results suggest a role for central 5-HT in long-term modulation of sympathetic-dependent renal function. Supported by NHLBI HL14388 and NASA NAGW-4358.

## 249.13

EFFECTS OF ADRIAMYCIN-INDUCED NEPHROTIC SYNDROME ON RENIN-ANGIOTENSIN SYSTEM MEDIATED WATER AND SODIUM INTAKES IN RATS. J. Xu, S.R. Robinson\* and A.K. Johnson. Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242-1407

The present study examined whether the renin-angiotensin system (RAS) is involved in the altered drinking behavior in adriamycin-treated rats. Rats were injected with either adriamycin (3.5 mg/kg) or saline through the sublingual vein. Adriamycin-treated nephrotic rats drank more water two weeks after adriamycin injection. Daily saline intake was not significantly different. Nephrotic rats showed reduced water intake following isoproterenol (30  $\mu$ g/kg, sc), overnight water deprivation and furosemide (10 mg/kg, sc) + captopril (2 mg/kg, sc). Saline intake also was blunted after furosemide + captopril. No difference in drinking was found after hypertonic saline (4%, sc). Before isoproterenol treatment, plasma renin activity (PRA) levels did not differ between groups while aldosterone levels were significantly lower in nephrotic rats. After isoproterenol treatment, elevation of PRA and aldosterone levels was significantly blunted in nephrotic rats. No difference in vasopressin levels between groups was found either before or after isoproterenol treatment. The results suggest that the extracellular rather than intracellular drinking mechanisms are disturbed in nephrotic rats and the RAS might be responsible for the reduced drinking response to acute thirst and sodium intake challenges. Supported by NHLBI HL 14388 and NASA NAGW-4358.

## 249.10

INHIBITION OF OSMOTICALLY STIMULATED VASOPRESSIN RELEASE BY 17 $\beta$ -ESTRADIOL AND DIHYDROTESTOSTERONE. K.L. Swenson\* and C.D. Sladek. Finch Univ. Health Sci./Chicago Med. Sch., North Chicago, IL.

In previous experiments, testosterone inhibited the osmotically stimulated increase in vasopressin (VP) release from hypothalamo-neurohypophyseal system (HNS) explants. Therefore, experiments were performed to determine which of the active testosterone metabolites, 17 $\beta$ -estradiol ( $E_2$ ) or dihydrotestosterone (DHT), was responsible for this inhibitory effect on VP. HNS explants were obtained from intact male rats. The explants were perfused in the presence or absence of  $E_2$  (50pg/ml) or DHT (3ng/ml) throughout the entire experiment. After a 4 hour equilibration period, half of all groups were exposed to a ramp increase in osmolality (40mosm total) during the last 6 hours. Perifusate was collected in 20 minute fractions for a total of 10 hours. Both  $E_2$  and DHT significantly inhibited the osmotically stimulated increase in VP as compared to controls (determined by RIA of the perifusate fractions). Therefore, both active testosterone metabolites,  $E_2$  and DHT, inhibited the osmotically stimulated increase in VP release. Steroid receptors have not been localized in VP neurons, suggesting that the results are due to a nongenomic effect of these steroids on the VP neuron or to genomic effects elsewhere in the osmotic circuitry.

Supported by NIH grant NS27975.

## 249.12

CHRONIC LASIX TREATMENT EARLY IN LIFE DISRUPTS DEVELOPMENT. G. Brandt, J. Diaz\* and R. McCowen. Dept. of Psychology, University of Washington, Seattle, Wa. 98195.

Male and female Long-Evans Hooded pups were assigned to one of three groups: Furosemide-inject once per day at 60mg/kg of body weight; saline control-inject once per day at 60 mg/kg of body weight; or non-inject controls. Once per day from day zero (day of birth) through day nine, pups were removed from dams, stimulated to induce micturition, and weighed. Pups were then injected or not, according to group assignment and kept in small cages set on a heating pad for 1 1/2 hours (the estimated peak time for action of furosemide). Pups were then once again stimulated to induce micturition, weighed, and returned to their respective dams. On day 15, pups were weighed and decapitated. Dependent measures taken include wet and dry weights for whole body, brain, heart, and spleen; tibia length, and blood glucose levels.

Furosemide-treated animals had significantly smaller whole-body wet weights by postnatal day 3 through day 15, and significantly smaller percent wet-brain-to-body weights on day 15. Percent brain water was not different. Tibia length was significantly shorter in furosemide-treated animals. Furosemide-treated animals were hyperglycemic on day 15, while saline-inject and non-inject control animals showed normal blood glucose levels. Blood glucose levels were not different on day 4 or day 10.

These data support the hypotheses that chronic furosemide treatment during critical periods of development results in an impaired rate of somatic growth, and may alter the normal course of brain development and other specific metabolic systems by the alteration of water and electrolyte balance. Further study is needed to determine if the alteration of sodium balance is the cause of abnormal development of specific systems and growth patterns.

## 249.14

EFFECTS OF CORTICOSTERONE ON CONTROL OF RENAL SYMPATHETIC NERVE ACTIVITY. D.A. Scheuer\* and S.W. Mifflin. Univ. Texas Health Science Center, San Antonio, TX 78284-7764.

Chronic increases in corticosterone (cort) produce hypertension, however the effects of cort on neural control of the circulation are poorly understood. Therefore, experiments were performed in male Sprague-Dawley rats (control (con), n=3, chronic cort treatment, n=5) to determine the effects of cort on baroreflex control of renal sympathetic nerve activity (RSNA). A minimum of 13 days after initiation of cort rats were anesthetized with Inactin (100 mg/kg, i.p.) and instrumented to measure mean arterial pressure (MAP), heart rate (HR) and RSNA. Baroreflex control of RSNA was determined, using intravenous infusions of phenylephrine and nitroprusside to change arterial pressure at the rate of 1-2 mmHg/sec, before and 2 and 3 hrs after administration of the glucocorticoid type II receptor antagonist Mifepristone (Mif, 30 mg/kg s.c.). Reflex curves were analyzed using a 4 parameter logistic function. Baseline MAP (124 $\pm$ 2 vs. 114 $\pm$ 3 mmHg) and HR (427 $\pm$ 6 vs. 369 $\pm$ 6 bpm) were greater ( $P<0.05$ ) in cort vs. con rats. RSNA, as a percentage of maximum, was 70 $\pm$ 5 and 72 $\pm$ 4% in con and cort rats, respectively. In cort rats MAP was significantly decreased 2 hrs (111 $\pm$ 2 mmHg) and 3 hrs (109 $\pm$ 4 mmHg) after Mif. Despite the reduction in MAP, HR (426 $\pm$ 12 and 433 $\pm$ 18 bpm) and RSNA (77 $\pm$ 7 and 75 $\pm$ 8%) were not significantly elevated 2 and 3 hrs after Mif. The pressure at midrange of the RSNA baroreflex curve in cort rats was 134 $\pm$ 3 mmHg before Mif, and was shifted to the left (121 $\pm$ 2 and 118 $\pm$ 2 mmHg;  $P<0.05$ ) 2 and 3 hrs following treatment of cort rats with Mif. In con rats Mif did not significantly change baseline MAP, HR or RSNA, or reflex control of RSNA. These results suggest that chronic elevations in cort modulates sympathetic regulation. **NORADRENERGIC NEURONS IN VENTROLATERAL MEDULLA INTEGRATE NEUROENDOCRINE FUNCTION OF VASOPRESSIN** S. Shioda\*, M. Iwase, I. Homma, S. Nakajo, K. Nakaya, T. Yada, A. Takaki, Y. Nakai Dept. Anat. (S.S., Y.N.) & Physiol. (M.I., I.H.) Sch. Med. and Lab. Biol. Chem. Sch. Pharmac. Sci. (S.N., K.N.), Showa Univ., Tokyo 142; Dept. Physiol. Sch. Med. (T.Y.), Kagoshima Univ., Kagoshima 890; Dept. Physiol. Fac. Med. (A.T.), Kyushu Univ., Fukuoka 812, Japan.

Although the pathway arising from noradrenalin (NA) neurons in the medulla is involved in the regulation of vasopressin (VP), the precise mechanism of action and biological significance of NA still need to be investigated. NA neurons of A1 cell group in the medulla made synaptic inputs to hypothalamic VP neurons as revealed by combined tract tracing with immunocytochemistry. Unilateral electrical stimulation (80-90  $\mu$ A at 50 Hz for 10 min) of A1 cell group induced bilateral increase of Fos-like immunoreactivity (F-LI) in hypothalamic neurosecretory neurons. Strong F-LI was visible in many VP neurons but rarely in oxytocin neurons as revealed with double immunostaining. *In situ* hybridization revealed that high level of VP mRNA was noted in the hypothalamus at 12 h and reached its peak at 24 h after stimulation. One  $\mu$ M NA increased cytosolic  $Ca^{2+}$  in isolated VP neurons. Dibutylryl cAMP also increased cytosolic  $Ca^{2+}$  in VP neurons. An inhibitor of protein kinase A (H89) inhibited NA-induced increase in cytosolic  $Ca^{2+}$  in VP neurons. These findings suggest that NA stimulates  $Ca^{2+}$  signaling pathway, which is at least partly mediated by cAMP-PKA pathway, and that the cAMP and  $Ca^{2+}$  systems participate in secretion and gene transcription of VP in response to physiological stimuli. (Supported in part by Ministry of Education, Science, and Culture of Japan)

**SHRINKAGE-INDUCED ACTIVATION OF  $Na^+/H^+$  EXCHANGE: ROLE OF MYOSIN PHOSPHORYLATION AND CELL DENSITY.** R.W. Putnam, L.D. Shrode, J.D. Klein, W.C. O'Neill, P.B. Douglas and R.W. Fyffe\* Dept. Physiol. & Biophys., Wright State Univ. Sch. of Med., Dayton, OH 45435.

The effect of cell shrinkage on the  $Na^+/H^+$  exchanger was studied in cultures of C6 glioma cells. In fully confluent cultures (4 days after plating), shrinkage resulted in a rapid alkalization of 0.6 pH unit at an initial rate of  $0.300 \pm 0.018$  pH/min ( $n=4$ ). This alkalization was dependent on the magnitude of cell shrinkage, resulted in a shift of the  $pK'$  of the exchanger for internal  $H^+$  ions, was inhibited by ML-7 (an inhibitor of myosin light chain kinase) and involved increased phosphorylation of an 18 kD protein (that co-localizes with myosin light chain, MLC). These data suggest that in C6 cells, like in primary astrocytes (Shrode et al., *Am. J. Physiol.* 269:C257-C266, 1995), shrinkage-induced activation of  $Na^+/H^+$  exchange involves phosphorylation of myosin light chain. Interestingly, little shrinkage-induced alkalization (only 0.044 pH unit at a rate of  $0.096 \pm 0.006$  pH/min;  $n=6$ ) was seen in subconfluent cultures of C6 glioma cells (2 days in culture, about 50% confluent).  $Na^+/H^+$  exchange was present in these cells since they showed amiloride-sensitive pH<sub>i</sub> recovery in response to  $NH_4Cl$ -induced acidification. The lack of shrinkage-induced alkalization persisted in subconfluent cells that were growth arrested (serum starvation) or that were differentiated by exposure to 0.25 mM di-butyl cAMP. However, MLC was still phosphorylated in these subconfluent C6 cells upon shrinkage. These data indicate that a step in shrinkage-induced activation of the  $Na^+/H^+$  exchanger between phosphorylation of MLC and the exchanger is missing in subconfluent cultures of C6 glioma cells. [Supported by JDF grant (to RWP) and NIH HL-47449 (to WCO).]

## NEUROENDOCRINE REGULATION: SUPRAOPTIC NUCLEUS

## 250.1

**MASKING OF A LOW THRESHOLD  $Ca^{2+}$  SPIKE BY AN A-TYPE  $K^+$  CURRENT IN RAT SUPRAOPTIC NEURONS.** T.E. Fisher\* and C.W. Bourque, Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, Canada, H3G 1A4.

In many mammalian neurons, T-type calcium currents mediate a low threshold, calcium dependent spike following depolarizations from negative potentials. Yet although the magnocellular neurosecretory cells (MNCs) of the rat supraoptic nucleus have a T-type current, their voltage-current relationship shows outward rather than inward rectification. To examine the interactions that underlie the near threshold behaviour of the MNCs, we compared the biophysical properties of a transient, A-type  $K^+$  current ( $I_A$ ) and low threshold  $Ca^{2+}$  currents ( $I_{Ca}$ ) using whole-cell patch clamp of acutely isolated MNC somata. While  $I_A$  and  $I_{Ca}$  activated at the same voltage (-60 mV),  $I_A$  was larger in amplitude (e.g. at -50 mV  $551 \pm 55$  pA,  $n=16$ ; vs  $92 \pm 9$  pA,  $n=36$ ) and activated more rapidly (e.g. times to peak amplitude at -50 mV of  $7.2 \pm 0.3$  ms vs  $33 \pm 1$  ms). Furthermore, blockade of  $I_A$  by addition of 10 mM 4-aminopyridine converts the outward rectification of MNC somata seen in current clamp to an inward rectification resulting in the activation of low threshold spikes. These data suggest that the electrogenic effect of calcium influx at low voltages is masked by the  $I_A$  and that the role of the T-type current may depend, rather, on intracellular effects of calcium ions such as the activation of calcium dependent conductances.

**SWELLING-INDUCED, 85 kDa cPLA<sub>2</sub> MEDIATED ARACHIDONIC ACID RELEASE IN THE HUMAN NEUROBLASTOMA CELL LINE CHP-100.**

S. Basavappa<sup>1</sup>, S. F. Pedersen<sup>2</sup>, N. K. Jørgensen<sup>2</sup> and E. K. Hoffmann<sup>2</sup>

<sup>1</sup>University Laboratory of Physiology, University of Oxford, Oxford OX1 3PT, UK and <sup>2</sup>August Krogh Institute, University of Copenhagen, DK-2100 Copenhagen Ø Denmark.

Upon exposure to hypoosmotic stress, cells initially swell and undergo regulatory volume decrease (RVD). Utilizing the pH sensitive fluorescent dye BCECF, a decrease in intracellular pH (pH<sub>i</sub>) after hypoosmotic stress was noted in CHP-100 cells. In cells loaded with <sup>3</sup>H-Arachidonic acid (<sup>3</sup>H-AA), exposure to hypoosmotic solution increased release of <sup>3</sup>H-AA by  $250 \pm 19\%$  ( $n=19$ ) as compared to control cells. Swelling-induced release of <sup>3</sup>H-AA was significantly inhibited by 15 min pretreatment with the potent inhibitor of the 85 kDa cPLA<sub>2</sub> AACOCF<sub>3</sub>, a trifluoromethyl ketone analogue of arachidonic acid (AA) ( $n=10$ ,  $p<0.05$ ) while the PLC inhibitor U73122 did not significantly alter the swelling-induced <sup>3</sup>H-AA release ( $n=6$ ). However, pretreatment with NPPB, which blocks Cl<sup>-</sup> permeability and the RVD response, significantly increased <sup>3</sup>H-AA release by  $423 \pm 68\%$  ( $n=6$ ). In single cells loaded with Fura-2, exposure to 50 and 200  $\mu$ M AA resulted in an elevation in intracellular  $Ca^{2+}$  level ( $[Ca^{2+}]_i$ ). Interestingly, cells initially acidified during exposure to AA, but then gradually alkalinized. The effect of AA on anion permeability was assessed in cells loaded with <sup>36</sup>Cl. Subsequent exposure to hypoosmotic stress rapidly increased efflux of <sup>36</sup>Cl and this efflux was significantly inhibited by 200  $\mu$ M AA. In addition, AACOCF<sub>3</sub> significantly ( $p<0.05$ ) blocked the swelling-induced <sup>36</sup>Cl efflux. Thus, the present studies indicate that arachidonic acid plays a key role during RVD.

**RAT BRAIN INTERSTITIAL VOLUME FRACTION AND N-ACETYL-ASPARTATE (NAA) MEASURED BY MICRODIALYSIS DURING ACUTE HYPONATREMIA.** T.N. Sager, J.A. Lundbak and A.J. Hansen\* Neuropharmacology, Novo-Nordisk A/S, DK-2760 Maaloev, Denmark.

In vitro studies indicate that brain interstitial volume fraction (IVF) is decreased during acute hyponatremia. However it is unknown, how brain IVF reacts *in vivo*. Acute hyponatremia in rats was induced by i.p. injection of distilled water. (10%+5% of body weight). This led to a 20% decrease in plasma  $[Na^+]$  after 1 h. We have previously shown that the relative loss (RL) of mannitol is directly related to IVF<sup>1</sup> and, hence, RL of <sup>3</sup>H-mannitol in the striatum was measured in the following hours using microdialysis. NAA has been implicated in nerve cell volume regulation and microdialysis was further used to measure interstitial [NAA]. The RL of <sup>3</sup>H-mannitol did not change during the course of the experiment indicating that the IVF remained unchanged. No change in [NAA] was observed either. These results compliments earlier findings using the same animal model where the IVF (using the TMA microelectrode technique) and brain water were determined. Despite a 20 % decrease in plasma osmolality the brain swelled only 10 % demonstrating volume regulation. The present results show that NAA has no role in the this response. The fact that IVF remained unchanged suggests that the interstitial space and the cells are equally responsible for this brain volume regulatory response.

**SHORT-LATENCY EFFECTS OF PROTEIN SYNTHESIS INHIBITION.** B.C. Wilson\*, T.M. Saleh & Q.I. Pittman, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

An antisense oligonucleotide (oligo) directed against oxytocin (OT) mRNA has been shown to have specific, short-latency effects on oxytocin-related lactational variables when injected into the SON of conscious, lactating rats. The mechanism(s) of action of antisense oligos are poorly understood, but it is known that these oligos interfere with translation in protein synthesis. We wondered if the same short-latency effects would result if translation was blocked using a protein synthesis inhibitor, anisomycin (AN). To determine an effective dose of AN, FOS immunohistochemistry following ip CCK (100 ng/kg) was carried out on 2 groups of male rats injected 4 h previously with 500 ng or 2  $\mu$ g AN into each SON. The higher dose of AN, but not the lower dose, abolished CCK-induced FOS expression. Using conscious, lactating dams, bilateral injections were made on three subsequent days of lactation: Day 8 (0.5  $\mu$ L aCSF; control), Day 9 (500 ng or 2  $\mu$ g AN dissolved in 0.5  $\mu$ L aCSF; experimental); Day 10 (0.5  $\mu$ L control) into the SON through guide cannulae. Four hours post-injection, 10 pups were re-introduced into the cage of each dam and assessments were made of maternal behaviour, pup weight gain and the number of milk-ejections occurring in a 30 min period after suckling was established. Both dosages of AN had no significant effect ( $p>0.05$ ) on maternal behaviour or litter weight gain (though weight gain was reduced). The number of milk-ejections observed in 30 mins was significantly ( $p<0.05$ ) reduced in a dose-dependent manner. These data demonstrate that blocking protein synthesis results in short-latency effects similar to those of antisense at a time before pituitary OT content is depleted. Thus, interference with translation may affect cellular secretory functions.

CNQX BLOCKS EXCITATORY RESPONSES OF RAT SUPRAOPTIC NEURONES EVOKED BY SUPRACHIASMATIC STIMULATION IN VITRO. L.-N. Cui, R. E. J. Dyball and J. Li\* Dept. of Anatomy, Univ. of Cambridge, Downing Street, Cambridge CB2 3DY, UK. and Dept. of Physiology, Univ. Coll. London, Gower Street, London WC1E 6BT, UK.

Secretion of vasopressin and oxytocin from magnocellular cells in the paraventricular and supraoptic nuclei (SON) of hypothalamus displays a circadian variation. Since the suprachiasmatic nucleus (SCN) of the hypothalamus represents the endogenous biological clock in mammals, it may also regulate the activity of magnocellular cells. We therefore investigated the projection from the SCN to the SON using an electrophysiological approach *in vitro*.

Coronal and horizontal hypothalamic slices from young male Wistar rats were perfused with artificial cerebrospinal fluid (ACSF). Single unit extracellular recordings were made from rat SON neurones, while stimuli (<1mA peak-to-peak) were delivered at 1 Hz to the SCN through a bipolar stimulating electrode. The responses of SON neurones to the stimulation was analyzed by creating peri-stimulus time histograms. A total of 46 cells were recorded of which 25 (54.3 %) responded to SCN stimulation; 17 neurones were excited and 8 neurones were inhibited. The excitatory responses were investigated further by adding CNQX (5 - 20  $\mu$ M), an antagonist of non-NMDA type of glutamate receptors, to the ACSF. In 4 of the 5 SON neurones tested, CNQX blocked the excitatory response. While the LD-APV (10 - 40  $\mu$ M), an antagonist of the NMDA type of glutamate receptor, had no effects on the 3 neurones tested.

The results suggest that there are functional projections from the SCN to the SON and that the pathway is mediated by the non-NMDA type of glutamate receptor.

We are grateful for the financial support of the MRC.

ELECTROPHYSIOLOGICAL AND MORPHOLOGICAL CHARACTERISTICS OF SUPRAOPTIC PERINUCLEAR ZONE NEURONS. W.E. Armstrong\* and J.E. Stern, Dept. of Anat. & Neurobiol., Univ. Tenn., Memphis, TN 38163.

Parvocellular neurons are sparse in the supraoptic nucleus (SON), but neurons in the area immediately surrounding the nucleus are thought to serve as interneurons. Cytoarchitecturally, this perinuclear zone (PZ) is ill-defined and contains several cell types, including GABAergic neurons thought to mediate baroreceptor-induced inhibition of vasopressin release. We recorded intracellularly from dorsal PZ neurons in ventral hypothalamic explants from male and female rats, characterized some basic membrane properties, and filled a subset with biotin tracers in order to study their dendritic and axonal trees. Electrophysiologically, PZ neurons (n = 23) were distinguished from SON neurons by having faster Na<sup>+</sup> action potentials, little subthreshold transient outward rectification, and strong subthreshold transient inward rectification reminiscent of low-threshold spiking neurons described elsewhere in the brain. The shape of the low threshold spike varied considerably across neurons, such that in some cells only a pair of Na<sup>+</sup> spikes were evoked, whereas in others a more extended burst was produced. Morphologically, the recovered PZ neurons were diverse; both bipolar or multipolar neurons were found, some with smooth and others with very spiny dendrites. In general, PZ neurons had more extensive dendritic trees than SON neurons, and most exhibited dendrites projecting into the SON. However, only a few of the filled PZ neurons had axonal projections into the SON. Some axons branched extensively within the PZ. Many PZ neurons had an axonal projection rostro-medial to the SON, in the region of the ventral preoptic area. These data suggest that while PZ neurons have common functional characteristics which distinguish them from SON neurons, several morphological subtypes are represented in this group, and only a small subset projects axons to the SON. Supported by NIH NS 23941 (WEA) and the Neuroscience Center for Excellence.

## 250.7

GABA<sub>B</sub> RECEPTOR-MEDIATED INHIBITORY ACTIONS IN RAT HYPOTHALAMIC SUPRAOPTIC NEURONS. N. Ibrahim, H. Yamashita\*, I. Shibuya, N. Kabashima & Y. Ueta Dept. of Physiol., Univ. Occup. & Environ. Health, Kitakyushu 807, Japan

GABA-immunoreactive neurons have been identified in the perinuclear region of the supraoptic nucleus (SON) and GABA potentially inhibits the electrical activity of SON neurons. The inhibitory action of GABA has been thought to be mediated exclusively by GABA<sub>A</sub> receptors. In this study, effects of GABA via GABA<sub>B</sub> receptors have been investigated. Using extracellular recording, rat hypothalamic slices containing SON magnocellular neurons were continuously perfused with a solution containing the GABA<sub>A</sub> antagonist, picrotoxin (50  $\mu$ M) and exposed to the GABA<sub>B</sub> agonist, baclofen (10 nM - 10  $\mu$ M). SON neurons were inhibited by baclofen in a dose-dependent manner. The inhibitory effects of baclofen were reversed by the selective GABA<sub>B</sub> antagonist, 2-hydroxy-saclofen (2OH-saclofen) also in a dose-dependent manner. Moreover, 2OH-saclofen alone potentiated the firing rate of SON neurons. Analysis of synaptic currents with a slice patch-clamp technique revealed that baclofen inhibited SON neurons both postsynaptically and presynaptically. These results indicate that GABA<sub>B</sub> receptors participate in the inhibitory action of GABA in the supraoptic magnocellular neurons.

## 250.4

MORPHOMETRIC STUDY OF OXYTOCIN AND VASOPRESSIN NEURONS IN THE SUPRAOPTIC NUCLEUS: MODULATION DURING LACTATION. J.E. Stern\* and W.E. Armstrong, Dept. of Anat. & Neurobiol., Univ. Tenn., Memphis, TN 38163.

The aims of the present study were to determine whether the cytoarchitecture of identified oxytocin (OT) and vasopressin (VP) neurons in the supraoptic nucleus (SON) differed either as a function of cell type or lactation. *In vitro* intracellular recordings were obtained from hypothalamo-neurohypophyseal explants prepared from virgin or lactating female rats. Neurons were intracellularly labelled with neurobiotin and reconstructed in three dimensions for morphometric analysis. SON dendrites exhibited little branching and there were no differences in the number of branches or spine density between cell type or as a function of lactation. Most of the dendrites projected ventrally toward the glial lamina and the total dendritic length per cell ranged from 912-1567  $\mu$ m. Axons were identified by their smaller diameter, beaded appearance and dorso-caudal trajectory, and were typically cut at the dorsal surface of the explant. The axon arose either directly from the soma (63%) or from a proximal dendrite (37%), but this difference did not vary between OT and VP cells. Only one case of an axon collateral was observed. During lactation, a significant enlargement of the somal area as well as an increase in the number of primary dendrites was observed in both cell types. Further analysis revealed that this increase was due to an increase in the number of short (<200  $\mu$ m) dendrites. The apparent dendritic volume of OT neurons was greater than that of VP neurons in both groups. In the case of OT neurons, a decrease in the average dendritic length was observed during lactation. Since apparent dendritic volume was unaffected, this suggests OT dendrites become shorter and fatter during lactation. On the other hand, the average dendritic length was not changed in VP neurons during lactation. These results suggest that there is dendritic reorganization among OT neurons during lactation which would accompany the well known synaptic reorganization. Supported by NIH NS 23941 (WEA) and the Neuroscience Center for Excellence.

## 250.6

MODULATION OF GABA CURRENTS IN HYPOTHALAMIC NEUROSECRETORY NEURONS BY THE NEUROACTIVE STEROID ALLOPREGNANOLONE. A. Fancsik\* and J.G. Tasker, Dept. of Cell & Molecular Biology, Tulane University, New Orleans, LA 70118.

The release of the hypothalamic hormones, oxytocin and vasopressin, is regulated by circulating levels of gonadal steroids and their metabolites. The progesterone metabolite allopregnanolone (3 $\alpha$ -hydroxy-5 $\alpha$ -pregnan-20-one) has been shown to modulate  $\gamma$ -aminobutyric acid A (GABA<sub>A</sub>) receptor mediated ionic currents in numerous cultured and acutely dissociated neuronal preparations. Allopregnanolone enhances GABA currents in the nerve terminals of the neurohypophysis (Zhang and Jackson, J. of Neuroendocrinol. 6:533, 1994). The aim of the present study was to determine the receptor-mediated effects of allopregnanolone on the magnocellular somata in the hypothalamic supraoptic nucleus (SON). Whole-cell voltage-clamp recordings were used in coronal slices of rat hypothalamus to record spontaneous GABA-mediated inhibitory postsynaptic currents (IPSCs) in SON magnocellular neurons. IPSCs were blocked by the GABA<sub>A</sub>-receptor antagonist bicuculline, and the decay phase of the average IPSC was best fitted by a double exponential. Bath application of allopregnanolone (1  $\mu$ M) caused an increase in the decay time constant of the average IPSC in 9 of 9 cells tested, which was accompanied by a decrease in the IPSC amplitude in 6 of the 9 cells. Intracellular application of allopregnanolone through the patch pipette had no effect in 9 of 10 cells, suggesting that the steroid acts at an extracellular membrane site. However, the internal application of allopregnanolone completely blocked the action of the steroid applied in the bath in 7 of 8 cells through an unknown mechanism. These results suggest that allopregnanolone may affect the kinetics of opening and closing of GABA<sub>A</sub> receptor channels in SON magnocellular neurons.

This study was supported by the LA American Heart Association and the NINDS.

## 250.8

EXTERNAL CALCIUM DEPENDENCE OF SYNAPTIC TRANSMISSION TO SUPRAOPTIC NEURONS IN THE HYPOTHALAMIC SLICES OF THE MOUSE. E. Honda, K. Inenaga\*, H. Yamashita\*, S. Nakamura and T. Hirakawa, Dept. Physiology, Kyushu Dental Col., Kitakyushu 803 and \*Dept. Physiology, Univ. Occup. Environ. Health Sch. of Med., Kitakyushu 807 Japan.

Excitatory postsynaptic currents (EPSCs) were recorded from neurons of the supraoptic nucleus (SON) of trimmed slice preparations of mouse hypothalamus, with blind patch clamp. The effects of perfusion of Ca free medium on the evoked EPSCs by focal stimulation dorsal or dorsolateral to the SON, the spontaneous EPSCs (sEPSCs) and miniature EPSCs (mEPSCs) were examined. The evoked EPSCs, sEPSCs and mEPSCs were almost blocked by the glutamate antagonist kynurenic acid (1 mM). Both the number and the amplitude of the sEPSCs were not significantly changed by tetrodotoxin. While the evoked EPSCs were completely abolished by the Ca free medium, the sEPSCs and mEPSCs still remained. Both the number and the amplitude of the sEPSCs and mEPSCs were not significantly changed by perfusion of the calcium free medium. When the extracellular potassium concentration was increased from 3 to 21 mM, the mEPSC frequency increased. The increased mEPSC frequency was suppressed by the perfusion of calcium free medium but the basal level of the mEPSC frequency persisted. These results imply that glutamatergic synaptic transmission to the hypothalamic neurosecretory cells, which are due to voltage-dependent (evoked EPSCs) and voltage-independent mechanisms (sEPSCs and mEPSCs), have high and low sensitivity to external Ca concentration, respectively. In previous studies, the Ca free medium was used for blockade of synaptic transmissions in hypothalamic neurons. The present study suggests that the Ca free medium is not suitable for that kind of purpose.

## 250.9

EFFECTS OF PACAP ON VASOPRESSIN RELEASE,  $[Ca^{2+}]_i$  AND IONIC CURRENTS IN RAT HYPOTHALAMIC SUPRAOPTIC NEURONS. I. Shibuya\*, J. Noguchi, N. Harayama, N. Kabashima, Y. Inoue, K. Tanaka, Y. Ueta, M. Nomura & H. Yamashita Dept. of Physiol., Univ. Occup. & Environ. Health, Kitakyushu 807, Japan

Pituitary adenylate cyclase activating polypeptide (PACAP) is localized in the magnocellular part of the supraoptic and the paraventricular nuclei (SON and PVN), however, the physiological function of PACAP is poorly understood. We have confirmed that PACAP type-I receptor mRNA is localized particularly in these nuclei by *in situ* hybridization histochemistry. To elucidate the role of PACAP in these nuclei, we measured vasopressin (AVP) release, cytosolic  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ), membrane potential and ionic currents in SON neurons of rats. PACAP ( $10^{-12}$ - $10^{-7}$  M) induced AVP release in SON slice preparations and  $Ca^{2+}$  rise in isolated SON neurons. The PACAP-induced  $Ca^{2+}$  rise was strongly dependent on extracellular  $[Ca^{2+}]_i$ . Moreover, PACAP caused depolarization and increased firing of action potential in the current-clamp mode of the patch-clamp technique and induced inward currents in the voltage clamp mode at concentrations as low as  $10^{-13}$  M. These results suggest that PACAP may play an important role in the physiological function of SON neurons via paracrine and/or autocrine.

## 250.11

ROLE OF PREOPTIC AREA IN THE REGULATION OF SUPRAOPTIC NEURONAL ACTIVITY IN RATS. Q. Z. Yang\* and G. I. Hatton. Department of Neuroscience, University of California Riverside, CA 92521

Neuroanatomical studies indicated the existence of direct projections from the median preoptic nucleus (Sawchenko & Swanson, 1983), medial preoptic area (MPO) and lateral preoptic area (LPO) (Weiss & Hatton, 1990). Experiments were undertaken to provide evidence for the existence of a synaptic connection between the supraoptic nucleus (SON) and the preoptic area. In horizontally cut brain slices including SON and the preoptic areas, intracellular and whole cell patch-clamp recordings were used to define sites in which electrical stimulation would evoke monosynaptic responses in SON neurons. Stimulation of the LPO usually evoked nearly equal numbers of fast IPSPs (10 cells) and EPSPs (9 cells) in 19 SON neurons. Stimulation of the MPO evoked more EPSPs (8/11) than IPSPs (3/11) in 11 SON neurons. These evoked IPSPs were blocked by bicuculline (10-20  $\mu$ M) or picrotoxin (50  $\mu$ M), suggesting GABA<sub>A</sub> receptor mediation. Of the remaining excitatory responses, most were blocked by non-NMDA receptor antagonists (NBQX or CNQX) at 3-10  $\mu$ M. In a few cases (3 SON neurons) evoked EPSPs persisted in CNQX (10  $\mu$ M) but were blocked by tropisetron (20  $\mu$ M), a selective 5-HT<sub>2</sub> serotonin receptor antagonist. Nanodrop applications of glutamate (10 mM) in the LPO and MPO usually increased firing frequency of the SON neurons for 10-15 s or a brief reduction followed by long-duration increase in firing frequency. These results support previous anatomical findings and suggest that the inputs from preoptic area play an important role in regulating activity of the SON neurons. Supported by NINDS grant NS 16942.

## 250.13

TARGETED REDUCTION OF OXYTOCIN (OX) GENE EXPRESSION: ELECTROPHYSIOLOGICAL AND IMMUNOCYTOCHEMICAL STUDIES OF SUPRAOPTIC NUCLEUS (SON) NEURONS. G.I. Hatton\*, W.S. Young III\*, Q.Z. Yang, S. Miyata and Z. Li, Dept. of Neuroscience, Univ. of California, Riverside, CA 92521; \*Lab of Cell Biology, NIMH, Bethesda, MD 20892

Magnocellular OX and vasopressin neurons in rat, but not cat, display distinct firing patterns and certain  $Ca^{2+}$ -dependent membrane potentials. Comparable data for the mouse are lacking, and the recent availability of mice with targeted reduction of OX gene expression permitted studies of possible influences of OX on intrinsic cellular properties. Whole-cell and sharp electrode recordings were made from SONs in slices from mutant and wild-type mice. In whole-cell mode, action potentials (mean  $\pm$  sem) =  $95 \pm 4.8$  mV, resting membrane potentials =  $-58.3 \pm 1.6$  mV, and input resistance =  $0.94 \pm 0.12$  G $\Omega$ . Hyperpolarizing current injection induced voltage responses suggestive of time-independent inward rectification. Depolarization to resting levels from -90 mV revealed neither low threshold spikes nor obvious delayed return to baseline, and there was little spike frequency adaptation to long depolarizing current pulses. Lucifer Yellow dye injections often yielded dye coupled neurons. Continuous and phasic firing patterns, depolarizing afterpotentials, plateau potentials and afterhyperpolarizations were also observed. Calbindin-D<sub>28k</sub> immunoreactivity tended to be heavily located in the normally OX-rich SON areas. Except for OX immunostaining, neurons from wild-type and mutant mice shared similar properties. Our studies provide preliminary data on SON neurons of normal and OX gene mutant mice, showing that firing patterns are rat-like and supporting the hypothesis that  $Ca^{2+}$  binding proteins, but not hormone content and local OX release, are important in generation of firing patterns and  $Ca^{2+}$ -dependent membrane potentials. $Ca^{2+}$  RELEASE FROM INTERNAL STORES: ROLE IN GENERATING DEPOLARIZING AFTERPOTENTIALS IN SUPRAOPTIC NUCLEUS NEURONS. Z. Li\* and G.I. Hatton, Dept. of Neuroscience, University of California, Riverside, CA 92521.

An increasing body of evidence indicates that  $Ca^{2+}$  induced  $Ca^{2+}$  release is involved in modulation of  $Ca^{2+}$ -dependent afterhyperpolarizations, neurotransmitter release from nerve terminals, expression of immediate-early genes, long-term potentiation and  $Ca^{2+}$  oscillations. In this study, influences of  $Ca^{2+}$  release from internal stores on the generation of depolarizing afterpotentials (DAPs) were investigated in magnocellular neurons of rat supraoptic nucleus (SON) using whole-cell patch recording techniques in brain slices. Recorded from more than half of the cells encountered, DAPs following evoked single spikes had an amplitude of  $3.00 \pm 0.19$  mV (mean  $\pm$  sem) and lasted for  $1.02 \pm 0.06$  s. Their sizes usually increased with the number of preceding spikes, but could be reduced or eliminated when intervals between consecutive current pulses evoking tens of spikes were short. DAPs were eliminated by removal of external  $Ca^{2+}$  ( $n = 25$ ), and significantly reduced by bath applications of nifedipine or  $\omega$ -conotoxin ( $n = 16$ ). Blockade of  $Ca^{2+}$  release from internal stores by perfusion with ryanodine or dantrolene ( $n = 14$ ), or direct diffusion of ruthenium red ( $n = 5$ ) into cells suppressed DAP amplitudes by ~50% and shortened their durations in all 19 cells tested. Depletion of  $Ca^{2+}$  internal stores by perfusion with thapsigargin or cyclopiazonic acid also inhibited DAPs by ~50% ( $n = 10$ ). Along with reduced DAPs, elimination of phasic patterns of firing was also observed. In contrast, caffeine, an agent known to enhance intracellular  $Ca^{2+}$  release, amplified DAPs and promoted phasic firing in 7 of 8 cells tested. These results suggest that  $Ca^{2+}$  influx via high-voltage activated  $Ca^{2+}$  channels in SON cells triggers ryanodine receptor-mediated  $Ca^{2+}$  release from internal stores. This process enhances DAPs and promotes phasic firing in SON cells, and thus increases vasopressin release. Supported by NINDS grant NS16942.

## 250.12

TAURINE IN RAT NEURAL LOBE: LOCALIZATION IN ASTROCYTES AND SELECTIVE RELEASE BY HYPOSMOTIC STIMULATION. S. Miyata\*, O. Matsushima\* and G.I. Hatton. Dept. of Neuroscience, University of California, Riverside, CA 92521; \*Dept. of Biological Science, Faculty of Science, Hiroshima University, Higashi-Hiroshima, 724 Japan.

Taurine, a generally inhibitory amino acid, is known to be present in the mammalian brain, but its physiological roles are unclear. In this study, taurine localization was accomplished using a well characterized monoclonal antibody against taurine itself. At the light microscopic level, taurine immunoreactivity was seen almost exclusively in the pituitaries, the neural lobe's resident astrocytes, and the cellular distribution pattern matched that of GFAP immunoreactivity previously described for these cells. Electron microscopy revealed strong immunoreactivity in the cell bodies and processes of these glia and, in addition, weak taurine immunoreactivity was sometimes found within neurosecretory vesicle-containing axonal processes. Using HPLC, hyposmotic stimulation (270 mOsm/kg) of neural lobes *in vitro* resulted in preferentially increased taurine release into the medium and reduced tissue content, compared to glutamic acid, glutamine or GABA, as measured by HPLC. These results suggest that taurine is mainly present in neural lobe astrocytes which are known to engulf the axons and terminals when demand for peptide release is low. Further, taurine's preferential release by hyposmotic stimulation possibly acts to inhibit oxytocin and vasopressin release from the terminals via its known GABA-like effects. Supported by NINDS grant NS09140.

## 250.14

METABOTROPIC GLUTAMATE RECEPTORS AND THE CONTROL OF VASOPRESSIN SECRETION FROM MAGNOCELLULAR NEUROENDOCRINE CELLS. Adriana Serie, Zheng Fan, Walid Al-Ghoul, Robert Greenwood\* and Rick Meeker, Department of Neurology, University of North Carolina, Chapel Hill, NC 27599

Vasopressin (VP) neuroendocrine cells are extensively innervated by glutamatergic terminals and are activated by agonists to each major type of ionotropic glutamate receptor. However, it has been surprisingly difficult to elicit robust secretion of VP *in vitro* by pharmacological activation of these receptors. To evaluate the potential contribution of metabotropic glutamate receptors (mGluRs) we used *in situ* hybridization to measure mGluR subtype mRNAs in the supraoptic nucleus (SON) and *in vitro* stimulation to evaluate the ability of agonists to evoke VP release. Three subtypes of mGluRs were found to be expressed in the SON *in vivo* in the following order of abundance: mGluR3 > mGluR1 >> mGluR7. RT-PCR confirmed the expression of mRNA for mGluR1 and mGluR3 in primary cultures which were used for stimulation studies. Addition of the mGluR agonist, 1S, 3R ACPD, resulted in a modest but significant release of VP which averaged  $1.03 \pm 0.43$  pg over prestimulation baseline. Inactive isomer and medium controls averaged  $-0.56 \pm 0.66$  and  $-0.36 \pm 0.29$  pg, respectively. The drug-induced release was largely due to the response of approximately one third (10/33) of the cultures which averaged  $3.80 \pm 0.47$  pg. This response is at least as great as the response induced by activation of ionotropic receptors and indicates that mGluRs of the mGluR1 subtype probably play an equally important role in the control of VP secretion by neuroendocrine cells.

Supported by NIH Grants NS13411 and NS30923.

## 250.15

## INHIBITORY ACTION OF TAURINE ON RAT SUPRAOPTIC MAGNOCELLULAR NEURONS.

N. Hussy\*, C. Deleuze, M.G. Desarménien & F. Moos. Biologie des Neurons Endocrines, CNRS UPR 9055, CCIPE, rue Cardonille, 34094 Montpellier 5, France. Taurine is likely to be involved in the regulation of cellular osmotic balance. In the supraoptic nucleus (SON), taurine is predominantly concentrated in glial cells (Decavel & Hattori, 1995). To understand its role in the osmotic regulation of the SON, we studied the effects of taurine on SON magnocellular neurons from adult male rats. Taurine (0.1-10 mM), applied onto whole-cell voltage-clamped acutely dissociated neurons activated a  $Cl^-$  current, as did GABA (30  $\mu$ M) and glycine (100  $\mu$ M). The current activated by 1 mM taurine was inhibited by strychnine (1  $\mu$ M, a concentration that specifically antagonized glycine receptors) but was unaffected by the GABA<sub>A</sub> receptor antagonist gabazine (3  $\mu$ M). Moreover, taurine- (at 1 mM) and glycine-activated currents were not additive. At higher concentration (10 mM), taurine was a weak agonist on GABA<sub>A</sub> receptors. Thus, taurine activates predominantly glycine receptors, with an  $EC_{50}$  of 406  $\mu$ M (established in the presence of gabazine). *In vivo* extracellular recordings of SON magnocellular vasopressin (AVP) neurons were obtained on anesthetized rats. Drugs were pressure-applied via double-barreled pipettes in the vicinity of the recorded neuron. Taurine (1 mM) inhibited the phasic activity of AVP neurons, decreasing the mean frequency of firing during active phases as well as the duration of the active phases. This effect was stronger in normally hydrated than in dehydrated rats. Strychnine (300 nM) triggered a phasic pattern on quasi-silent AVP neurons recorded in water-loaded rats and enhanced phasic activity in normally hydrated rats. Preliminary *in vitro* results indicate that hyposmotic solutions can elicit the release of taurine in the SON. These results suggest that taurine, acting mainly through glycine receptors, plays an important role in the regulation of SON magnocellular neurons, and more specifically in the inhibition of AVP neurons in hyposmotic condition, a situation likely to induce release of taurine from SON glial cells.

## 250.17

## DIFFERENTIAL INDUCTION OF TRANSCRIPTION FACTOR FAMILIES IN THE SUPRAOPTIC NUCLEUS (SON) AND ITS AFFERENTS. S.M. Luckman\*.

Dept. Neurobiology, The Babraham Institute, Babraham, Cambridge, CB2 4AT, U.K.

Infusion of saline at differing tonicities leads to the acute induction of *c-fos* and *jun B* mRNAs in the SON that correlates to the osmotic stimulus (Luckman *et al.*, 1996). *C-jun*, is repressed by infusion of 0.35M or 0.75M saline, but is co-induced at higher levels of stimulation (1.5M saline). To investigate this phenomenon further *c-fos* was compared to *nur77* and *egr1*, in both the SON and in putative afferent neurones of the nucleus tractus solitarius (NTS) following saline infusion or a single injection of CCK. Intravenous infusions were made into conscious, free-moving rats ( $n=4$  per group). The results of *in situ* hybridization are given as the mean number of silver grains per cell in all cells containing >20 grains within six counting frames per structure.

	<i>fos</i> /SON	<i>fos</i> /NTS	<i>nur</i> /SON	<i>nur</i> /NTS	<i>egr</i> /SON	<i>egr</i> /NTS
0.15M	36±5	32±2	55±10	38±2	47±2	40±2
0.75M	124±4*	36±1	96±10	40±3	88±6*	38±2
1.5M	373±25*	60±6*	172±19*	63±5*	98±8*	42±3
CCK	58±6	72±4*	85±11	88±5*	45±5	42±4
ANOVA	<0.0001	<0.0001	<0.001	<0.0001	<0.0001	>0.05

\* $P<0.01$  Dunnett's post-hoc comparisons to 0.15M group

Analysis of the dorsal SON, where oxytocin neurones predominate, detected an induction of *c-fos* by CCK (36±6 and 75±4;  $P<0.002$ , Student's *t*-test), not apparent in the ventral SON (35±4 and 41±3). There was no significant induction of *nur77* or *egr1* in the dorsal SON by CCK (62±14 and 103±1,  $P=0.08$ ; 47±1 and 45±5,  $P>0.05$ ), though the lack of significance for *nur77* may have been due to a number of neurones expressing high levels of this mRNA in the control group. These results show the differential induction of three transcription factor families in magnocellular neurones and their putative afferents depending on the stimulus. The infusion of 0.75M does not activate the NTS, while 1.5M saline or CCK do. The additional afferent input to the SON may be required to allow the previously observed co-induction of *c-jun*. (BBSRC funded).

## 250.19

## GRADED RECRUITMENT OF MEDULLARY CATECHOLAMINE AND HYPOTHALAMIC NEUROENDOCRINE CELLS BY HEMORRHAGE. D.W. Smith, K.M. Buller and T.A. Day\*, Dept. of

Physiology & Pharmacology, University of Queensland, AUSTRALIA 4072.

Hemorrhage stimulates pituitary release of vasopressin (VP), oxytocin (OT) and ACTH. Caudal medulla A1 noradrenaline cells play a crucial role in the VP response, but the role of medullary catecholamine cells in ACTH and OT responses is less clear. Using the *c-fos* technique we have now systematically investigated the recruitment of both hypothalamic neuroendocrine and medullary catecholamine cells by hemorrhage and have tested the effects of A1 lesions on hypothalamic cell responses. Rats were subjected to hemorrhages of 0, 4, 8, 12 or 16 ml/kg and 2 h later sacrificed and the brain processed for Fos, TH, PNMT, OT and VP immunolabelling. Only hemorrhages of 12 or 16 ml/kg produced significant hypotension (BP 50-75 mmHg for 15-45 min). These hemorrhages also significantly increased *c-fos* expression in A1, A2, C1 and C2 catecholamine cells, VP and OT neurosecretory cells, and cells of the medial parvocellular (MP) paraventricular nucleus, the latter being the primary location of tuberoinfundibular corticotrophin releasing factor cells. Only VP cells of the supraoptic nucleus responded to milder hemorrhages (8 ml/kg). Unilateral ibotenic acid lesions along the rostrocaudal extent of the A1 cell group one week prior to a 12 ml/kg hemorrhage produced moderate reductions in the responses of all three classes of hypothalamic neuroendocrine. This data supports a role for the A1 cell group in the relay of hemorrhage-related information to hypothalamic neuroendocrine cells but the large recruitment of other medullary catecholamine populations, notably A2 cells, suggests need for further study of their involvement. (Supported by NHMRC and NHF.)

## 250.16

## AP-1 DNA-BINDING ACTIVITY IN RAT SUPRAOPTIC NEURONS (SON) FOLLOWING FLUID IMBALANCE.

J.T. McCabe\* and K. Wang. Anatomy & Cell Biology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

The protein products of *c-fos* and *c-jun*, and certain related leucine zipper-containing transcription factors, form heterodimers (Fos-Jun and Jun-Jun family member heterodimers) and homodimers (Jun family members) that bind to the DNA consensus sequence, AP-1. Since the AP-1 DNA binding site is known to be essential for the transcription of certain genes, Fos and Jun dimerization and sequence-specific DNA binding represents a crucial link between cell stimulation and subsequent alterations in gene expression. Hypertonic saline injection causes a profound increase in mRNA levels and protein products in the SON [NEUR. ABST. '94, 1567 & '95, 875]. Using the gel shift DNA binding assay, AP-1-like DNA binding activity was determined in SON tissue nuclear extracts. SON tissue samples obtained from control (no injection) and hypertonic saline-stimulated rats contained a significant level of AP-1-like DNA binding activity and the observed band was equivalent to what was seen from incubation with HeLa cell extracts. Preincubation of SON extracts from osmotically stimulated animals with *c-Fos* antibody resulted in a supershifted band, while no Fos antibody-supershifted band was observed in tissue samples from non-injected rats.

## 250.18

## FOS EXPRESSION IN THE HYPOTHALAMIC MAGNOCELLULAR NEURONS OF PARTURIENT RATS. T. Kiyohara\*, S.-H. Lin, S. Miyata and T. Nakashima. Dept. of Applied Biol., Kyoto Inst. of Technol., Kyoto, 606, Japan.

In previous study, numerous Fos-positive hypothalamic magnocellular neurons were observed in parturient rats (2 hr after the first pup delivery) not in gestating ones, and Fos expression was limited in the period of early lactation. In the present experiment, Fos immunoreactivity was examined in animals of virgin, early stage of parturition, late stage of parturition and lactation using dual immunocytochemistry for Fos and oxytocin/vasopressin neuropeptides. Further, expression of *c-fos* mRNA in the hypothalamus of these groups were verified with *in situ* hybridization. In parturient rat brains (1 hr after the first pup delivery), there were few Fos-positive neurons in both supraoptic and paraventricular nuclei. No difference was seen between non-pregnant females and early parturient ones. During the late stage of parturition, there were significant increase in the number of Fos-positive oxytocinergic and vasopressinergic neurons. These results suggest that activation of magnocellular neurons which reflected in Fos expression is not critical for parturition itself, but may implicate in the expression of maternal behavior.

## 250.20

## CATECHOLAMINERGIC AFFERENTS TO THE MEDIAL SEPTAL AREA IN THE RAT. F. Condé\*, F. Chéruel and A.J. Baertschi. Lab. of Neuroendocrinology, University Paris-XI, 91405-Orsay (France), and Centre Médical Universitaire, Geneva (Switzerland).

Recent results of our laboratory suggest that the rostro-ventral part of the medial septal area (MSA) is involved, through its catecholaminergic innervation, in the splanchnic osmotic regulation of vasopressin. The present study was designed to determine the identity of the catecholaminergic neurons projecting to MSA. Afferent neurons were retrogradely labeled by fluorogold (FG) injections in the MSA. Their catecholaminergic content was checked by immunocytochemistry using antisera directed against tyrosine hydroxylase (TH, Eugene Tech), the first enzyme in the catecholamine synthesis, or against phenylethanolamine N-methyltransferase (PNMT, Y. Tillet, CNRS, Nouzilly, France), the enzyme which converts noradrenaline (NA) to adrenaline (A). The later enzyme was used to separate neurons of the C1-C2 (A) groups from the A1-A2 (NA) groups in the medulla. Our results show that no adrenergic innervation reaches MSA, as none of the FG-positive neurons located in the C1, C2 and C3 areas were PNMT-positive. The noradrenergic innervation of MSA originates in A2 area (nucleus of the tractus solitarius), and A6 (locus coeruleus), where all FG-positive cells were TH-positive, and in  $\approx 60\%$  of the A1 cells of the ventrolateral medulla. The dopaminergic innervation of MSA originates from the ventral tegmental area (A10 group), in which only  $\approx 60\%$  of the FG-positive cells were also TH-positive. Although in the incerto-hypothalamic dopaminergic system (A11, A13, A14 groups) FG-positive cells were intermingled among the TH-positive cells, none of them were TH-positive. These and previous results suggest three possibilities how splanchnic osmoreceptors can regulate vasopressin secretion: 1) via spinal inputs and a relay in A1 and MSA; 2) via vagal inputs and a relay in A2 and MSA; 3) via afferents projecting in A10 and a relay in MSA.

## 251.1

MODULATION OF BAROREFLEX FUNCTION BY ENDOGENOUS CATECHOLAMINES IN THE NUCLEUS OF THE SOLITARY TRACT (NTS) OF THE SPONTANEOUSLY HYPERTENSIVE (SH) RAT. A.P. Riley, L.E. Hayward, and R.B. Felder. Cardiovascular Center, Dept. of Internal Med, University of Iowa, Iowa City, IA 52242.

Both noradrenaline levels and  $\alpha$ -2 binding sites in the dorsal medulla are reduced in the SH rat compared to the normotensive Wistar Kyoto (WKY) rat. Previous studies have demonstrated that pharmacological blockade of endogenous catecholamines (eCAT) in the NTS of normotensive rats attenuates baroreflex function. In the present study the role of eCAT in the NTS on baroreflex function was examined in SH rats. Baroreflex curves were produced by stimulating the left aortic depressor nerve with increasing frequencies (2-15 Hz, 0.2 ms, 8V, for 10 sec) in urethane anesthetized SH and WKY rats (10-12 week old). Ipsilateral microinjection of idazoxan (IDAZ; 1000 ng/100 nl), an  $\alpha$ -2 receptor antagonist, in the caudal NTS significantly attenuated baroreflex control of mean arterial pressure (MAP;  $p < 0.001$ , see Table for MAP data) but not renal sympathetic nerve activity (RSNA) in WKY rats ( $n=4$ ).  $\alpha$ -2 blockade in SH rat significantly attenuated baroreflex control of MAP ( $p < 0.001$ ,  $n=4$ ; see Table) and RSNA ( $p < 0.003$ ). At the highest frequency of baroreceptor activation (15 Hz),  $\alpha$ -2 blockade attenuated baroreflex control of MAP to a greater extent in the SH vs WKY rat ( $59 \pm 8\%$  vs  $20 \pm 3\%$ , respectively;  $p < 0.01$ ). These results demonstrate that eCAT in the NTS play an important role in baroreflex neurotransmission in both normotensive and SH rats, and suggest that the SH rat may be more sensitive to changes in eCAT in the NTS compared to the WKY rat. Supported by HL 29302 (RBF).

## 251.3

EFFECTS OF GLUTAMATERGIC BLOCKADE IN THE NUCLEUS TRACTUS SOLITARI (NTS) ON CARDIOVASCULAR RESPONSES TO VOLUME LOAD IN ANESTHETIZED RATS. D.S.A. Colombari\*, E. Colombari, O.U. Lopes and S.L. Cravo. Dept. of Physiology, UNIFESP-EPM, São Paulo, SP 04023-900, Brazil.

The central pathways involved in the renal vasodilation induced by volume load (VL) have not been elucidated yet. Therefore, the purpose of this study was to verify the role of NTS glutamatergic receptors on the renal vasodilation induced by VL. Experiments were performed in adult male Wistar rats (280 - 320 g) anesthetized with urethane. The femoral artery and vein were cannulated for mean arterial pressure (MAP) recording and drug infusion, respectively. VL was induced either by iv infusion of 3% dextran or 4% Ficoll (1% bw, 0.4 mL/min). Renal blood flow (RBF) was recorded by Doppler flowmetry and expressed as the percentage of the baseline. Renal relative vascular conductance (RVC) was calculated by dividing Doppler shift (kHz) by the MAP (mmHg) and also expressed as percentage of the baseline. In control animals ( $N=9$ ) VL produced a transient hypertension ( $+23 \pm 4$  mmHg). RBF and RVC rose by  $171 \pm 18\%$  and  $133 \pm 12\%$  of baseline after 10 min, respectively, and remained elevated for 60 min ( $163 \pm 28\%$  and  $159 \pm 25\%$ , respectively). Ten min after bilateral microinjection of kynurenic acid (7.3 nmol/100 nL,  $N=6$ ) into the NTS, VL produced a transient hypertension ( $+33 \pm 4$  mmHg) but renal vasodilation was no longer observed. The increase in RBF after 10 min was reduced to  $119 \pm 8\%$  of baseline and the initial increase in RVC was abolished ( $87 \pm 8\%$ ). After 60 min RBF and RVC increases were not different from control ( $129 \pm 8\%$  and  $128 \pm 11\%$ , respectively). When saline was injected into NTS ( $N=6$ ), VL produced responses comparable to that observed in control animals. These data suggest that renal vasodilation induced by VL involve the activation of glutamatergic receptors in the NTS, probably associated with baroreceptor and/or cardiopulmonary primary afferents. Financial support: CAPES, FAPESP, Brazil.

## 251.5

FINE STRUCTURE AND PLASTICITY OF PHENYLEPHRINE-SENSITIVE NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT (NTS). C.A. Peto, R.K.W. Chan and P.E. Sawchenko. The Salk Institute, La Jolla, CA 92037.

Intravenous phenylephrine (PE) gives rise to patterns of Fos expression in the NTS that conform to the central distribution of the carotid sinus and aortic depressor nerves. This has been exploited to permit ultrastructural characterization of neurons presumed to comprise the first station in the processing of arterial baroreceptor afferent input, and to probe for stimulation-induced structural alterations. Freely moving rats were submitted to PE-induced hypertension (2.1-2.5  $\mu$ g/kg/min, 25 min, iv), perfused at varying intervals, and sections through the "baroreceptive strip" of the NTS prepared for preembedding immunolocalization of Fos-ir. PE-induced Fos-ir in the NTS was detectable at 30 min, and peaked at 2 hr, after the challenge. Labeled neurons formed a continuous strip extending from the dorsal aspect of the commissural NTS (NTScom) to the dorsal and dorsolateral subnuclei at the level of the area postrema (NTSap). Ultrastructurally, PE-sensitive neurons in these regions were small, round to ovoid in shape, with scant cytoplasm, and a generally unremarkable organelle complement. Barosensitive neurons were distinguished by extensively invaginated nuclei and highly developed Golgi apparatus; Fos-ir cells in the NTSap differed from those in NTScom in their moderately well-developed rough ER, more highly developed Golgi and less convoluted nuclei. Synaptic input to PE-sensitive neurons was sparse, and provided by terminals containing predominantly small, clear synaptic vesicles that formed some asymmetric, though predominantly symmetric, junctions evenly distributed over cell somata and primary dendrites. Structural alterations of Fos-ir cells seen over the 2 hr time course prompted comparisons between animals exposed to PE infusion for shorter (25 min) vs longer (2-3 hr) intervals. Prolonged stimulation was accompanied by accentuation of nuclear invaginations, marked accumulation of heterochromatin at their apices, and evidence of further development and activation of the Golgi, including increased incidence of vesicular budding, with electron lucent vesicles ostensibly dispersing and accumulating within nuclear invaginations. These may represent adaptations to facilitate changes in gene expression and/or to maintain neurotransmitter availability in the face of a persisting challenge. (supported by HL-35137)

## 251.2

PRESSOR RESPONSE OF CHEMOREFLEX IS NOT BLOCKED BY BILATERAL MICROINJECTION OF IONOTROPIC OR METABOTROPIC ANTAGONISTS INTO THE COMMISSURAL NTS. A.S. Haibara, L.G.H. Bonagamba and B.H. Machado. Dept. Physiology, School of Medicine of Ribeirão Preto, USP, 14090-900, Ribeirão Preto, SP, Brazil.

We have previously shown that bradycardic response of chemoreflex is blocked by NMDA antagonist into the commissural NTS. In the present study we investigated the effects of blockade of ionotropic or metabotropic receptors in the lateral portion of the commissural NTS (0.5 mm lateral to midline) on the cardiovascular responses of the chemoreflex induced by potassium cyanide (KCN; 20  $\mu$ g/rat, i.v.) in unanesthetized rats. Bilateral microinjections of 6,7-dinitroquinoxaline-2,3-dione [DNQX (0.5 nmol/100 nl), a non-NMDA antagonist], kynurenic acid [KYN (10 nmol/100 nl), an ionotropic antagonist] or  $\alpha$ -methyl-4-carboxyphenylglycine [MCPG (2.5 nmol/100 nl), a metabotropic antagonist] were performed into the NTS through guide cannulas previously implanted. In relation to the cardiovascular responses of chemoreflex: a) microinjection of DNQX or KYN produces a significant reduction on the pressor response ( $+64 \pm 4$  vs  $+34 \pm 7$  mmHg and  $+50 \pm 2$  vs  $+30 \pm 3$  mmHg, respectively), b) only KYN abolished the bradycardic response ( $-225 \pm 28$  vs  $-18 \pm 7$  bpm) and c) MCPG produces no changes in the pressor ( $+46 \pm 9$  vs  $+43 \pm 10$  mmHg) and bradycardic ( $-233 \pm 20$  vs  $-208 \pm 34$  bpm) responses. These data show that: 1) the bradycardic response of chemoreflex is blocked (KYN) but the pressor response is attenuated by KYN or DNQX and 2) MCPG produced no effects on the chemoreflex. We conclude that the cardiovascular component of the chemoreflex is mediated by ionotropic receptors (NMDA), while the pressor response is not blocked by ionotropic or metabotropic antagonists into the commissural NTS. Supported by FAPESP and CNPq.

## 251.4

MICROINJECTION OF AN INHIBITOR OF HEME OXYGENASE (HO) INTO THE NUCLEUS TRACTUS SOLITARI (NTS) INCREASES BLOOD PRESSURE IN CONSCIOUS RATS. E. Colombari\*, R.A. Johnson, M. Lavesa, D.S.A. Colombari, W.T. Talman, and A. Nasifletti. Dept. of Physiol., UNIFESP-EPM, São Paulo, SP 04023, Brazil. \*Dept. of Pharmacol., NYMC, Valhalla NY 10595, USA. †Dept. of Neurol., Univ. of Iowa & VAMC, Iowa City, IA, 52242, USA.

HO is an enzyme which degrades heme to form biliverdin and carbon monoxide (CO). Previous studies have shown that systemic administration of zinc deuteroporphyrin 2,4-bis-glycol (ZnDPBG, 45 mol/Kg, i.p.), an inhibitor of HO activity, increases blood pressure in rats. Since ZnDPBG-induced increases in arterial pressure and can be prevented by  $\alpha$ -1-adrenergic or ganglionic blockade, it suggests that ZnDPBG-induced increases in blood pressure may include a central component. It has been suggested that HO-derived CO may serve to modulate NTS function and that this low molecular weight gas may be a neuromodulator. The purpose of our study was to ascertain if HO-mediated formation of CO in the NTS may act locally to influence blood pressure. We used awake Sprague-Dawley rats to determine the blood pressure effects of ZnDPBG (4.5nmol/100nL) and CO (saturated in 100 nL of saline), microinjected into the NTS. Unilateral and bilateral microinjections of ZnDPBG increased arterial pressure ( $+16 \pm 4$  and  $+31 \pm 4$  mmHg, respectively), but did not affect heart rate. Unilateral microinjection of CO did not affect arterial pressure but did normalize the blood pressure in rats made acutely hypertensive by unilateral microinjection of ZnDPBG. This suggests that (1) a HO product being generated in the NTS can serve to lower blood pressure and (2) that in the NTS, local administration of exogenous CO exerts a vasodepressive action that is prominent in the presence of an inhibitor of endogenous CO production. We conclude that a product of HO, presumably CO, formed in the NTS may contribute to the regulation of blood pressure. Support: NIH HL 32205; HL 14388; HL 34300; HL 36670, HL 18579.

## 251.6

EFFECTS OF CAROTID SINUS NERVE TRANSECTION ON PHENYLEPHRINE-INDUCED FOS EXPRESSION IN THE NUCLEUS OF THE SOLITARY TRACT. R.K.W. Chan\* and P.E. Sawchenko. The Salk Institute, La Jolla, CA 92037.

We have previously described patterns of phenylephrine (PE)-induced Fos expression in the nucleus of the solitary tract (NTS) that conform to the central distribution of carotid sinus and aortic depressor afferents. To test whether Fos-immunoreactive (-ir) NTS neurons comprise the recipients of first-order baroreceptor inputs, and to identify the subregions supplied by individual afferents, we examined the effects of bilateral carotid sinus nerve transections (at 4-30 days after surgery) on the distribution and neurotransmitter specificity of NTS neurons exhibiting Fos-ir in response to sustained hypertension (25-35 mmHg) induced by intravenous PE infusion (2.1-2.5  $\mu$ g/kg/min, 25 min) in freely moving rats. Bilateral transection of carotid sinus nerves dramatically reduced (by 70.4%) the number of Fos-ir neurons in the dorsal 'baroreceptive strip' of commissural NTS (NTScom) at the level of the calamus scriptorius, a region innervated by the carotid sinus nerve. By contrast, only a moderate attenuation (26.0%) of the PE-induced Fos response was observed in the dorsal and dorsolateral aspects of NTS at the level of the area postrema level (NTSap), a region supplied by aortic depressor afferents. As was the case in PE-challenged sham-operated animals, Fos-ir barosensitive neurons in the NTSap displayed markers for nitric oxide. Saline-infused barodenervated animals did not display Fos expression in the NTS. Outside the NTS, carotid sinus denervation resulted in a moderate decrease (30.4%) in PE-induced Fos expression in presumed depressor neurons of the caudal ventrolateral medulla, a majority of which displayed markers of a GABAergic phenotype (GAD 67 mRNA). These effects of partial barodenervation were evident in animals challenged 4-14 days after surgery. Rats tested at 30 days displayed Fos responses that were not distinguishable from controls, and that were unaffected by re-stripping of the carotid sinus region. These findings support the view that Fos-ir neurons in the NTScom comprise the recipients of first-order baroreceptor inputs carried by the carotid sinus nerve. In addition, the results provide a basis from which to explore the mechanisms underlying recovery of baroreflex function following longer term carotid sinus denervation. WHOLE CELL RECORDINGS REVEAL AN NMDA RECEPTOR MEDIATED COMPONENT IN SENSORY AFFERENT TRANSMISSION IN THE NUCLEUS OF THE SOLITARY TRACT (NTS). M.L. Aylwin, J.M. Horowitz\*, and A.C. Bonham, Univ. of California, Davis, CA 95616

The participation of NMDA receptors in sensory afferent transmission in the NTS has been difficult to establish. We identified both NMDA and non-NMDA receptor-mediated synaptic currents in NTS neurons that received input from the solitary tract (ts) by examining ts-evoked excitatory post synaptic currents (EPSCs) at voltage steps from -90 to +60 mV. Rat transverse medullary slices (300  $\mu$ m thick) were superfused with (in mM) NaCl 125; KCl 2.5; MgCl<sub>2</sub> 1.0; NaH<sub>2</sub>PO<sub>4</sub> 1.25; NaHCO<sub>3</sub> 25; dextrose, 10; CaCl<sub>2</sub> 2.0; picrotoxin 0.1; bicuculline 0.01; bubbled with 95% O<sub>2</sub> / 5% CO<sub>2</sub>. Glass electrodes (3 - 6 M $\Omega$ ) contained (in mM) CsF 145; NaCl 5.0; MgCl<sub>2</sub> 1.0; EGTA 10; Hepes 10; MgATP<sub>2</sub> 3; NaGTP 0.2; pH 7.4. TS stimulation at 1 - 7 V, 0.1 ms, 0.5 Hz evoked EPSCs with onset latencies of 2.2 - 7.7 ms in 19 medial NTS neurons. 17 of these 19 neurons exhibited EPSCs having both a fast and slow component (Hestrin et al., J. Physiol. 1990). The fast component (peak at 5 - 6 ms) had an amplitude linearly related to voltage and was blocked by the non-NMDA receptor antagonist, NBQX (3  $\mu$ M; n = 2). The slow component (measured at 20 ms after the peak) was not linearly related to voltage, was revealed at potentials positive to 0 mV, and was abolished by the NMDA receptor antagonist, AP5 (50  $\mu$ M; n = 8). 7 of these 8 neurons had onset latencies of < 4 ms. AP5 had no effect on the fast component. Thus, both NMDA and non-NMDA receptors coexist on the same NTS neurons and are activated by primary afferent input from the ts.

ESTIMATION OF CARDIAC BAROREFLEX GAIN BY DRUG AND SPECTRAL METHODS IN NORMOTENSIVE AND HYPERTENSIVE RABBITS. Head GA, Lukoshkova EV, Godwin SJ, Janssen BJA, Gaudet EA, Malpas SC, Sheppard, K\* Baker Medical Research Institute, Prahran, Victoria. Power spectral analysis is now being used in the clinic to estimate baroreflex gain but there has been relatively little validation. We compared the gain of the baroreceptor-heart rate reflex estimated by "invasive" techniques and spectral analysis methods in conscious normotensive and hypertensive rabbits. In normotensive rabbits and animals made hypertensive for 1 week with an i.v. infusion of angiotensin II, cardiac baroreflex gain was assessed by infusion of phenylephrine and nitroprusside or caval cuff and compared to the gain estimated from the average transfer function between MAP and HR. In an initial study in conscious rabbits with an implanted renal sympathetic nerve electrode we found that the major sympathetic oscillations were between 0.2 and 0.4 Hz. In normotensive rabbits the baroreflex gain assessed by the average transfer gain between MAP and HR in this frequency region (coherence greater than 0.5) was higher than the gain obtained with the drug method ( $7.9 \pm 0.6$  vs  $6.2 \pm 0.5$  b/min/mmHg respectively,  $P < 0.05$ ). In animals with baroreflexes assessed by phenylephrine and caval cuff, the gain was higher than for the spectral method ( $8.0 \pm 0.4$  vs  $6.4 \pm 0.3$  b/min/mmHg, respectively,  $P < 0.05$ ). Estimates by each method were reproducible when measured on 5 separate occasions. Hypertensive rabbits had significantly reduced baroreflex gains compared to normotensives but now gain was similar for both spectral and drug methods ( $4.2 \pm 0.3$  vs  $4.4 \pm 0.7$  b/min/mmHg respectively). In sino-aortically denervated rabbits baroreflex gain estimated from the spectral method was much reduced and with very low coherence ( $0.2 \pm 0.03$ ) between MAP and HR. These studies show that the spectral power for MAP and HR in the frequency range between 0.2 and 0.4 Hz can be used effectively to estimate changes in baroreflex sensitivity for a group of normotensive or hypertensive rabbits but absolute gain values for the methods depend on the technique used.

## 251.11

THE DIAGONAL BAND OF BROCA (DBB) INHIBITS BAROREFLEX-INDUCED DECREASES IN RENAL SYMPATHETIC NERVE ACTIVITY. S.L. Bealer\*, Dept. Physiology, Univ. Tennessee, Memphis, TN 38163.

The DBB is a CNS site which mediates baroreflex-induced changes in vasopressin neuron activity. The present experiments determined if neurons in the DBB were also involved in control of changes in renal sympathetic nerve activity (RSNA) during increased arterial pressure (AP). RSNA and AP were evaluated in chloralose-anesthetized rats during iv infusions of four doses of phenylephrine (5-20  $\mu$ g/kg/min) before and following injection of 2  $\mu$ l isotonic saline or lidocaine (LIDO; 2%) in the DBB. The slope of the regression line comparing changes in AP and RSNA (% control) during iv phenylephrine was used as an estimate of baroreflex sensitivity. Prior to DBB injection, both groups had a similar relationship between AP and RSNA (Saline,  $-1.5 \pm 0.3$ ; LIDO,  $-1.2 \pm 0.3$ ). Following saline treatment this relationship was similar to control values ( $-1.2 \pm 0.4$ ), while LIDO injections resulted in a significant increase in baroreflex sensitivity ( $-2.3 \pm 0.3$ ). These data show LIDO injections in the DBB enhance baroreflex sensitivity of RSNA and suggest that this brain region tonically inhibits sympathoinhibition observed during acute increases in AP. ## 251.8

EXCITATORY VESTIBULAR NUCLEUS PROJECTIONS TO NUCLEUS TRACTUS SOLITARIUS: IMPLICATIONS FOR VESTIBULAR-AUTONOMIC INTERACTION.

Z. Zhou\* and C.-S. Poon, Harvard-MIT Division of Health Sciences and Technology, M.I.T., Cambridge, MA 02139.

The vestibular system plays an important role in maintaining stable arterial blood pressure during changes in posture and is responsible for eliciting motion sickness related vomiting. The nucleus tractus solitarius (NTS) is a region critical for autonomic and cardiorespiratory regulation and the triggering of emesis. Previous studies using neuroanatomic tracing and single-unit recording in vivo have shown that the NTS receives projections from the vestibular nucleus (VeN) in rabbit and cat. In the present study, we used an in-vitro brainstem slice preparation from Sprague-Dawley rats (1-3 weeks of age) to examine the synaptic connection between VeN and NTS. Whole-cell patch recordings were obtained from NTS neurons under voltage clamp (holding potential = -65 mV) at a level slightly rostral to obex. Electrical stimulation (0.1 ms impulses, 8-20 V) of the caudal medial VeN elicited monosynaptic postsynaptic currents (EPSCs) in medial and intermediate NTS neurons. No inhibitory postsynaptic currents were observed. The EPSC responses induced by VeN stimulation were almost totally blocked by application of CNQX (10-20  $\mu$ M), an antagonist for non-NMDA receptors. Thus, synaptic connections between the VeN and NTS are excitatory and are mediated in part by the neurotransmitter glutamate acting on non-NMDA receptors. (ONR grant N00014-95-0414 and NIH grant HL50641)

## 251.10

SEROTONIN<sub>3</sub> RECEPTOR AGONISTS INTO THE NTS INHIBITS THE BRADYCARDIA BUT PRODUCED NO CHANGES IN THE RESPIRATORY AND SYMPATHETIC RESPONSES TO CHEMOREFLEX ACTIVATION. C. Sévoz, J.C. Callera<sup>1</sup>, M.B. Emerit<sup>2</sup>, B.H. Machado<sup>1</sup>, M. Hamon and R. Laguzzi, INSERM U.288, C.H.U. Pitié-Salpêtrière, Paris, France; <sup>1</sup>FMRP-USP, Ribeirão Preto, Brazil.

We previously demonstrated that stimulation of 5-HT<sub>3</sub> receptors in the NTS blocks the cardiovagal component of both baro- and Bezold-Jarisch reflex in anesthetized rats, and of both baro and chemo-reflex in unanesthetized rats. In the present study we analysed the effects of intra-NTS microinjections of 5-HT or a 5-HT<sub>3</sub> receptor agonist, 1-(m-chlorophenyl)biguanide (CPBG) upon the cardiovascular and respiratory responses elicited by carotid body chemoreceptors stimulation (CBS) in anesthetized rats. CBS was performed by KCN (40  $\mu$ g/kg, i.v.) or by intra-carotid administration of saturated CO<sub>2</sub> saline in spontaneously breathing or in artificially ventilated rats, respectively. Local microinjections of 5-HT (2.5 and 5 nmol, n=6 for each dose) or CPBG (300-1200 pmol, n=6 for each dose) blocked in a dose-dependent manner, the atropine sensitive cardiac chemoreflex response ( $-94 \pm 14.5$  vs  $-5.3 \pm 2.3$  bpm for CPBG 1200 pmol). However, neither 5-HT nor CPBG affected the reflex increase in respiration and in lumbar sympathetic nerve discharge elicited by CBS. The inhibitory effect of 5-HT and CPBG upon the cardiovagal chemoreflex response was blocked by the prior intra-NTS microinjections of 5-HT<sub>3</sub> antagonists: zacopride (100 pmol, n=6) or ondansetron (100 pmol, n=6). These data taken together with those of our previous studies indicate that 5-HT<sub>3</sub> receptors within the NTS play a key modulatory role in the reflex control of cardiac activity. Supported by INSERM, FAPESP and USP/COFECUB.

ANGIOTENSIN POTENTIATES SOLITARY TRACT AFFERENT RESPONSES IN MEDIAL NUCLEUS TRACTUS SOLITARI (mnTS) NEURONS RESPONSIVE TO GLUTAMATE BUT NOT TO SUBSTANCE P. K.L. Barnes\* and D.M. DeWeese.

Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195.

Angiotensin (Ang) II may regulate neurotransmission in the mnTS via presynaptic Ang receptors that modulate the release of L-glutamate (Glu) from solitary tract (TS) afferents at mnTS synapses. This study evaluated the capacity of Ang II and substance P (SP) to modulate excitatory postsynaptic potentials (EPSPs) evoked by TS stimulation in mnTS neurons at the level of the area postrema, using whole-cell patch clamp recordings in horizontal rat medulla slices. In 9 neurons responsive to Ang II and Glu, but unresponsive to SP, the peak height and duration of TS-evoked EPSPs were significantly increased after Ang II (1  $\mu$ M). Either tetrodotoxin (TTX, 10  $\mu$ M, n = 3) or the kainate/AMPA antagonist DNQX (100  $\mu$ M, n = 3) blocked both the EPSPs produced by TS stimulation and all responses to Ang II. Ang II did not alter the EPSPs generated by TS stimulation in SP-responsive mnTS cells, and synaptic block with TTX failed to prevent Ang-induced excitation in these neurons. Thus TS-evoked EPSPs mediated by postsynaptic kainate/AMPA receptors are potentiated via presynaptic Ang receptors in those mnTS neurons responsive to Ang II and Glu, but unresponsive to SP. In contrast, mnTS neurons responsive to SP appear to have postsynaptic Ang II receptors, as we showed previously, which do not modify TS-evoked responses in these cells. These data reveal that Ang II may evoke hypotension and bradycardia in the mnTS via presynaptic Ang receptors that potentiate the release of Glu from baroreceptor afferents that synapse on mnTS neurons. (Support by NSF BNS-9109673).

**MORPHOLOGY OF GABAergic NEURONS WITHIN THE NUCLEUS OF THE SOLITARY TRACT (NTS) RECEIVING AORTIC NERVE INPUTS.** Steve Mifflin\* and Jing Zhang, University of Texas Health Science Center, San Antonio, TX 78284.

Immunocytochemical studies have revealed a large number of GABAergic neurons within NTS. The afferent inputs to these cells and therefore their functional role remains conjectural. To determine if GABAergic cells within NTS receive aortic nerve (AN) inputs, we recorded responses of NTS neurons to AN stimulation intracellularly in barbiturate anesthetized rats using electrodes filled with 2M K-citrate and 1.5-5% Neurobiotin. The AN evoked input was characterized as monosynaptic (MS; the second of 2 stimuli separated by 5ms evoked an input; minimal onset latency variability) or polysynaptic (PS). After characterization of the AN input, Neurobiotin was injected into the cell and avidin-Texas Red used to reveal the labelled cell; a polyclonal GABA antibody and standard immunocytochemical procedures were used to reveal GABA. Recordings were obtained from 5 MS and 12 PS neurons receiving an AN input. No MS evoked cells contained GABA, while 6 of the PS units did. Excitatory post-synaptic potential onset latencies in milliseconds were  $4.0 \pm 1.1$  (MS),  $18.1 \pm 1.7$  (PS, GABAergic) and  $18.8 \pm 2.9$  (PS, non-GABAergic). There was no difference between the PS units which contained GABA, PS cells which did not contain GABA and MS cells comparing; soma surface area at its largest in a single section in  $\mu\text{m}^2$  ( $252 \pm 34$ ;  $194 \pm 48$ ;  $258 \pm 55$ ); number of dendrites branching off of the soma ( $2 \pm 4$ ;  $2 \pm 8$ ;  $3 \pm 4$ ); the ratio of long to short axis in  $\mu\text{m}$  ( $27 \pm 3$  to  $14 \pm 1$ ;  $22 \pm 2$  to  $12 \pm 2$ ;  $27 \pm 4$  to  $13 \pm 1$ ) or subnuclear location within NTS. These results indicate that some GABAergic neurons within NTS receive polysynaptic aortic baroreceptor inputs. There is no obvious difference in somatic morphology between AN activated cells which contain GABA and those which do not. Supported by HL-41894.

**ULTRASTRUCTURAL CIRCUITRY OF CARDIORESPIRATORY REFLEXES: ARE THERE MONOSYNAPTIC PROJECTIONS FROM THE NUCLEUS OF THE SOLITARY TRACT (NTS) ON TO CARDIOINHIBITORY NEURONS IN THE NUCLEUS AMBIGUUS?** V. J. Massari\*, T. A. Johnson, W. Coleman, J.-M. Lauenstein, and P. J. Gatti, Dept. Of Pharmacology, Howard University College of Medicine, Washington, D.C. 20059.

Primary afferent cardiorespiratory neurons send a central projection into the NTS. When cardiorespiratory reflexes (such as the baro- and chemoreceptor reflexes) are initiated, efferent parasympathetic preganglionic effects on the heart are in large part mediated by neurons in the ventrolateral nucleus ambiguus (NA-VL). These neurons project to the heart via the vagus nerve. This study was designed to define the neuroanatomical circuitry connecting the NTS and the NA-VL. Five anesthetized cats received microinjections of an anterograde tracer into the NTS. After ten days a retrograde tracer was injected into the left atrial cardiac ganglion which selectively controls atrio-ventricular conduction. Three days later medullary tissues were processed for the light and electron-microscopic histochemical visualization of both tracers. By light microscopy, anterogradely labeled terminals in the ventrolateral medulla were seen surrounding retrogradely labeled negative dromotropic neurons in the rostral NA-VL. Labeled axons and terminals were also observed at the electron microscopic level in the NA-VL. Labeled axons were both myelinated (600-800 nm diameter) and unmyelinated (200-500 nm). Labeled terminals commonly contained numerous pleomorphic vesicles and several large dense core vesicles. Some labeled terminals formed axo-dendritic and axo-somatic synapses on negative dromotropic neurons. This is the first ultrastructural demonstration of a monosynaptic connection between neurons in the NTS and a functionally associated cardioinhibitory neuron in the NA-VL. Supported by a Collaborative Core Unit Award from Howard Univ. Grad. School and a grant from the Office of the President, Howard University.

## 251.17

**ENHANCED CARDIAC BAROREFLEX AND ATTENUATED ISOPROTERENOL RESPONSIVENESS FOLLOWING FOOD RESTRICTION IN AORTIC COARCTATION HYPERTENSION.** J.M. VanNess, M.E. Freeman\*, and J.M. Overton, Nutrition, Food and Movement Sciences, Department of Biological Science, Florida State University, Tallahassee, FL, 32306.

The purpose of this study was to examine the effect of short term food restriction on cardiac baroreflex function and beta-adrenergic responsiveness in aortic coarctation (AC) hypertension. AC hypertension was induced in 40 female Sprague-Dawley rats ( $222 \pm 6$  g) using a blunt 21 gauge needle as a guide. Four days later, rats were assigned to an *ad libitum* fed group (CON) or a food restricted group (FR) that received 60% of the food consumed by the CON group. Three weeks later carotid and jugular cannulae were implanted under halothane anesthesia for the measurement of pulsatile blood pressure (MAP) and infusion of drugs. FR rats had significantly lower resting MAP ( $119 \pm 4$  vs.  $150 \pm 7$  mmHg) and heart rate (HR;  $369 \pm 6$  vs.  $409 \pm 7$  bpm) than CON rats three days after cannulation. The HR and MAP responsiveness to bolus injections of isoproterenol (ISO) were examined after either ganglionic blockade (GB; 30 mg/kg hexamethonium, 0.1 mg/kg atropine) or without any pretreatment. FR rats had attenuated increases in HR and decreases in BP to ISO following GB (0.025, 0.05, 0.1, and 0.2  $\mu\text{g/kg}$ ) or without any pretreatment (0.025, 0.05, and 0.1  $\mu\text{g/kg}$ ). For example: 0.05  $\mu\text{g/kg}$  ISO increased HR  $92 \pm 12$  bpm and decreased MAP  $27 \pm 3$  mmHg in CON rats, the same dose increased HR by only  $51 \pm 7$  bpm and decreased MAP  $14 \pm 2$  mmHg in FR rats. Similar responses to ISO were seen in animals following GB. Cardiac baroreflex function was assessed by alternating hypertensive episodes using bolus injections of phenylephrine (PE; 0.25-1.0  $\mu\text{g/kg}$ ) and hypotensive episodes using sodium nitroprusside (NP; 2.5-15  $\mu\text{g/kg}$ ). FR rats had significantly greater reflex bradycardia in response to PE (slope =  $-1.42$  vs.  $-0.58$  bpm/mmHg). The reflex tachycardia in response to NP was not altered by FR (slope =  $-1.56$  bpm/mmHg in FR vs.  $-1.41$  bpm/mmHg in CON). These results indicate that FR may attenuate the HR and MAP responsiveness to a given level of sympathetic stimulation, and enhance cardiac baroreflex function.

JMV is a Graduate Student Research Fellow, Amer. Heart Assoc., FL Affiliate.

## 251.14

**INFLUENCE OF SELECTIVE EXCITATORY AMINO ACID RECEPTOR AGONISTS ON NUCLEUS OF THE SOLITARY TRACT (NTS) NEURONS RECEIVING AORTIC NERVE (AN) INPUTS.** Jing Zhang\* and Steve Mifflin, Univ of TX Hlth Sci Ctr San Antonio, TX 78284.

The influence of agonists for excitatory amino acid receptors (EAAs) on the discharge of AN evoked NTS neurons were investigated in pentobarbital anesthetized, paralyzed and artificially ventilated rats. NTS neurons receiving an AN input were classified as monosynaptic neurons (MSNs), second of two stimuli separated by 5 ms evoked discharge; minimal onset latency variability) or polysynaptic neurons (PSNs). EAA agonists were applied by microiontophoresis at currents of 5, 10, 20 & 40 nA. At these "doses", glutamate (100 mM) increased the firing rate ( $>1$  Hz) of some MSNs (5/9) and PSNs (6/8). There was no difference in glutamate potency between PSNs and MSNs (ANCOVA,  $P=0.18$ ). AMPA (10 mM,  $n=13$ , 6 MSNs & 7 PSNs), kainate (10 mM,  $n=8$ , 5 MSNs & 3 PSNs), *trans*-ACPD (selective metabotropic receptor agonist, 100 mM,  $n=9$ , 5 MSNs & 4 PSNs) excited AN evoked NTS neurons with similar potencies as glutamate. In contrast to non-NMDA and metabotropic EAA agonists, NMDA (100 mM) was more potent on PSNs than on MSNs (ANCOVA,  $P<0.01$ ). The effects of the EAA agonists on AN non-evoked NTS neurons were also tested in present study. All EAA agonists stimulated ADN non-evoked NTS neurons ( $P<0.05$ ) and *trans*-ACPD was less potent than other EAA agonists (ANCOVA,  $P<0.05$  vs each of other agonists). Our results indicate: 1. Not every NTS neuron receiving an AN input is sensitive to EAA agonists, suggesting that EAAs might not be the only transmitters used in baroreceptor afferent integration. 2. NMDA receptors are likely to play a role in the baroreflex at the level of PSNs, not MSNs. 3. Metabotropic receptors could mediate and/or modulate afferent integration by both MSNs and PSNs. Supported by HL-41894.

## 251.16

**FUNCTIONAL TOPOGRAPHIC DISTRIBUTION OF NEURONS OF THE PVH WHICH PROJECT TO THE NTS IN STRESSED RATS.** Danielle Champagne\* and Guy Drolet, Unité d'Hypertension, Centre de Recherche du CHUL, Université Laval, Québec, Canada, G1V 4G2.

The nucleus tractus solitarius (NTS) and the paraventricular nucleus of the hypothalamus (PVH) have major roles in the integration of endocrine and autonomic responses to stressful challenges. The NTS sends afferent projections to the PVH, suggesting that these neurons may be involved in conveying cardiovascular information to the PVH during stress. However, little is known about the functional relevance of these neuronal pathways with respect to stress. In this study, we have attempted to map specific subdivision of the PVH which are involved in the stress response, and which makes direct projections to the NTS, by combining Fos immunocytochemistry with retrograde tracing. The highest number of afferent neurons to the NTS were found in both, the ventromedial parvocellular part of the PVH (PVHmpv) and the ventral portion of the dorsomedial parvocellular part of the PVHmpd. Fewer retrogradely labeled neurons were also seen in the lateral parvocellular part of the PVH (PVHlp) and in the dorsal parvocellular part of the PVH (PVHdp). Exposure to neurogenic stress induced the activation of cell populations (Fos-ir) which were localized heterogeneously throughout the PVH. The distribution of PVH neurons which were double-labeled for Fos-ir and the retrograde tracer was restricted to some parts of PVH. The proportion of double-labeled neurons, Fos-ir/WGA-Au, represented 25% (PVHmpv), 25% (caudal PVHmpd) and 50% (caudal paraventricular zone) of the total number of retrogradely labeled neurons within the PVH. There were no double Fos-ir/WGA-Au cells in other levels of the PVH. The present study revealed the existence of different populations of neurons in the PVH that project directly to the NTS. The population of neurons which are activated by stress may provide important afferent information to the NTS for the integration of homeostatic responses to stressful challenges and, this may represent potential sites of dysregulation involved in the development of hypertension induced by chronic exposition to stress.

**BAROREFLEX-INDUCED ENDOGENOUS NITRIC OXIDE RELEASE FROM RVLN IN NORMOTENSIVE AND HYPERTENSIVE RATS.** D.M. Liu\*, R.P. Chao, A. L. Chiou and Y. Wang, Dept. of Pharmacology, National Defense Medical Center, Taipei, Taiwan, 100

Rostral ventral lateral medulla (RVLN), an integrated area of sympathetic activity in the brain stem, relays the neural transmission of the baroreceptor reflex. We and others previously found NMDA receptor is involved in baroreflex during bilateral carotid artery occlusion (BCCO). In this study, we first examined the interactions of NMDA and NO in the RVLN of urethane-anesthetized rats. The pressor area of RVLN was identified by electrical and chemical (NMDA) stimulation-induced hypertensive response. Extracellular NO concentration was measured through Nafion- and porphyrine-coated carbon fiber electrodes and *in vivo* chronoamperometry. We found that local application of NMDA to the RVLN elicited NO release and pressor response. Similarly, microinjection of NO donor sodium nitroprusside (SNP) or S-nitroso-N-acetylpenicillamine (SNAP) into RVLN resulted in a dose-dependent pressor response. To determine whether endogenous NO is involved in the baroreflex, we directly measured the NO concentration in RVLN during carotid clamping. We found that BCCO induced NO release and hypertension simultaneously. The increases of NO release and pressor response were reversibly antagonized by topical application of lidocaine to the carotid sinus nerve, suggesting that BCCO-induced NO release in RVLN is mediated by baroreflex, not by local ischemia. Furthermore, BCCO-induced endogenous NO release in SHR was significantly higher than that in WKY. Collectively, NO may serve as a mediator in baroreflex to integrate the sympathetic outflow in RVLN. The discrepancy of evoked NO release may differentially regulate the neurogenic vasomotor function in WKY and SHR. (This study is supported by a grant from the National Science Council of R.O.C.).

## 251.19

**THE CENTRALLY ACTIVE NO-DONOR, ISOSORBIDE DINITRATE ATTENUATES THE VAGAL BRADYCARDIA EVOKED BY THE BEZOLD-JARISCH REFLEX.** J. G. P. Pires\*, A. L. Domingues, M. T. Souza, A. L. T. Cardoso, S. R. Silva and H. A. Futuro-Neto. Dept. of Physiological Sciences, Biomedical Center, UFES, Vitória, ES-29040, Brazil.

Centrally produced NO is implicated in the modulation of autonomic functions. Previous studies had shown that i.v. nitroglycerin rapidly releases NO in the CNS. This study was designed to investigate the effects of isosorbide dinitrate (ISB), another NO donor agent, on the vagal bradycardia evoked by the Bezold-Jarisch (BJ) reflex. Male Wistar rats, 260-350 g, were pretreated with ISB, either chronically (1 mg kg<sup>-1</sup> d<sup>-1</sup>, i.p., 10 days; n=7) or acutely (1 mg kg<sup>-1</sup>, i.p.; 24, 19, 14 and 2 h before the test; n=7). Controls (C) received saline. The animals were anesthetized (urethane, 1.2 g kg<sup>-1</sup> i.v., after ether induction) and instrumented for recording blood pressure (BP) and heart rate (HR). Left jugular vein was cannulated for drug administration. Once BP and HR had stabilized a BJ reflex was evoked with phenylbiguanide (PBG; 10 µg kg<sup>-1</sup> i.v.) and repeated twice at 15-min interval. The rats were then treated i.v. with atenolol (At; 1 mg kg<sup>-1</sup>); after 10 min, three additional reflex bradycardias were elicited with PBG. Statistical differences were assessed by Dunnett's test after ANOVA. Results showed that acute treatment with ISB attenuated the reflex bradycardia (overall, after At: -173 ± 29 bpm vs -262 ± 16 bpm in C; p<0.05). The chronic administration of ISB, however, did not alter the BJ reflex (overall, after At: -250 ± 20 bpm vs -256 ± 21 bpm in C). These results are compatible with the hypothesis that NO plays a role in the central control of autonomic functions. The lack of influence of chronically administered ISB implies that tolerance was achieved. It has recently been shown that L-NAME, a NOS inhibitor, potentiates the BJ reflex (Araújo et al., *Braz. J. Med. Biol. Res.* 28:1009, 1995). Taken together with the present data, we suggest that locally released NO is able to inhibit the cardiac vagal motoneurons in rats. Supported by FCAA and CNPq.

## 251.21

**β-ENDORPHIN INHIBITION OF ENDOGENOUS NOREPINEPHRINE RELEASE FROM THE A2 NORADRENERGIC NUCLEUS: RECEPTOR SPECIFICITY AND LOCALIZATION.** J.A. Carr\* and M.M. D'Souza. Dept. Biol. Sci., Texas Tech Univ., Lubbock, TX 79409.

We used an *in-vitro* approach to determine the opioid receptor subtype mediating the inhibitory effects of β-endorphin (βE) on endogenous norepinephrine (NE) release from the A2 area of the caudal dorsomedial medulla (CDMM) in rats. The Na<sup>+</sup> channel blocker tetrodotoxin (TTX) was used to examine the role of propagated action potentials in βE-inhibition of evoked NE release. The inhibitory effect of βE on K<sup>+</sup>-induced NE release from CDMM slices was mimicked by the μ-opioid receptor agonist [D-Ala<sup>2</sup>, N-Me-Phe<sup>4</sup>, Gly-ol<sup>5</sup>]-enkephalin but not the δ-opioid receptor agonist [D-Pen<sup>2,5</sup>]-enkephalin (DPDPE) or the κ-opioid receptor agonist U-50488. The inhibitory effect of βE was blocked in a dose-dependent fashion by the μ-opioid receptor antagonist CTOP (Cys<sup>2</sup>, Tyr<sup>3</sup>, Orn<sup>5</sup>, Pen<sup>7</sup> amide). Tetrodotoxin inhibited NE release evoked by 25 mM K<sup>+</sup> in a dose related fashion but had no effect on basal NE release. The inhibitory effects of βE were not observed in the presence of TTX. These results suggest that βE acts on μ-opioid receptors to inhibit K<sup>+</sup>-evoked NE release from the A2 cell group. The fact that βE-inhibition of evoked NE release was abolished in the presence of TTX suggests that the μ-opioid receptors involved are not located on noradrenergic nerve terminals.

**AORTIC AFFERENTS INFLUENCE THE SYMPATHETIC T-RHYTHM RECORDED FROM RAT TAIL BLOOD VESSELS.** M.P. Gilbey and C.D. Johnson\*. Dept. Physiol., Royal Free Hosp. Sch. Med., London NW3 2PF, U.K.

Our studies have shown that the dominant rhythm (T-rhythm) in unitary sympathetic activity recorded from rat caudal artery and lateral vein is often non-respiratory-related (Johnson & Gilbey, *J. Physiol.* 476, 437-442 1994; 483, 103P-104P, 1995; 489, 160P-161P, 1995). The rhythm commonly presents as bursts of discharges (≈ 0.8 Hz). Here we have examined the influence of aortic nerve stimulation on the T-rhythm.

In anaesthetized rats (vagotomized, ventilated and paralysed) sympathetic unit activity was recorded from blood vessels using a focal recording technique (Johnson & Gilbey, 1994). Central respiratory drive was monitored via phrenic nerve activity. A stimulating electrode was placed on the left aortic nerve.

A short train of stimuli to the aortic nerve (ten 1 ms pulses at 100 Hz, voltage 2 x threshold for depressor response (0.5-10 V) delivered every 7 s for 47 trials per test) produced a transient, complete suppression of unit activity in both artery (latency to onset 590 ± 30 ms S.E.M., n=7) and vein (520 ± 30 ms, n=6) that entrained the T-rhythm in artery (7/7) and in vein (5/6). Continuous trains of stimuli (1 ms pulses, 50 Hz for 5 mins) slowed the frequency of the T-rhythm recorded from the artery during the first minute (from 0.65 ± 0.04 Hz to 0.54 ± 0.07 Hz, 3/3) which was sustained throughout stimulation (2/3). None of the units showed cardiac-related rhythmicity.

We conclude that although the sympathetic units did not have cardiac-related activity, discharges can be influenced by aortic nerve afferents (that have mainly a baroreceptor function in the rat). We suggest that the baroreceptor influence on sympathetic activity may be mediated via the modulation of the T-rhythm.

## 252.1

**LOCALIZATION OF CALCIUM BINDING PROTEIN CALRETININ IN THE CAT SUPERIOR COLLICULUS.** C.-J. Jeon\*, H.-W. Yang and M.-H. Jeon. Department of Biology, College of Natural Sciences, Kyungpook National University, Taegu, 702-701, S. Korea.

Previously, two calcium binding proteins calbindin-D28K and parvalbumin have been localized in the cat superior colliculus (SC) (Mize et al., 1991; 1992). The present study describes the distribution of another calcium binding protein calretinin and compares this labeling to that of calbindin-D28K and parvalbumin in the cat SC. Calretinin has been localized with antibody immunocytochemistry.

These experiments reveal two important features of SC organization. First, densely labeled calretinin-like immunoreactive fibers were found within the zonal and upper superficial gray layer. These fibers were varied in size and were distributed through the medial-lateral and rostral-caudal extent of the SC. A few varicosities and terminal swellings were also found on many of these fibers. Second, no calretinin labeled cells were found in this dense band of fibers. By contrast, anti-calretinin labeled cells formed two laminar tiers in the deeper SC. The first one was found within the deep optic and upper intermediate gray layers and the other one within the deep gray layer. The predominant anti-calretinin labeled cells were small to medium sized round, vertical fusiform, or stellate neurons. Some stellate neurons in the intermediate gray layer showed very large dendritic field with varicosities along dendrites. The very large projection neurons in the deep layers were not labeled by this antibody.

The present and previous results show that the three calcium binding proteins calbindin-D28K, parvalbumin, and calretinin have a unique neuronal sublaminal organization in the cat SC. Supported by KPNU 95 grant.

## 252.2

**LOCALIZATION OF TWO CALCIUM BINDING PROTEINS CALBINDIN-D28K AND CALRETININ IN THE RABBIT SUPERIOR COLLICULUS.** J.-K. Pyun\*, M.-H. Jeon\*, H.-W. Yang\*, W.S. Lee\* and C.-J. Jeon\*. <sup>1</sup>Department of Biology, Kyungpook National University, Taegu, 702-701, and <sup>2</sup>Department of Pharmacology, College of Medicine, Pusan National University, Pusan, 602-739, S. Korea.

Calcium plays a key role in signal transduction. We have localized two calcium binding proteins calbindin-D28K and calretinin and studied the distribution and morphology of labeled neurons in the rabbit superior colliculus (SC). Calcium binding proteins have been localized with antibody immunocytochemistry.

Anti-calbindin-D28K labeled neurons were concentrated in two layers: one within the upper superficial gray layer, and a second within the intermediate gray layer. Scattered calbindin labeled neurons also were found in the deep layers. The vast majority of calbindin labeled cells were small to medium sized round, vertical fusiform and stellate neurons. Some stellate neurons in the intermediate gray layer showed very large dendritic field with numerous prominent varicosities along each dendrite.

The morphology and distribution of anti-calretinin labeled neurons were similar to those of calbindin-D28K. However, the number of calretinin labeled neurons was much lower than that of calbindin-D28K in both superficial and intermediate layers. Calretinin immunoreactivity in the deep superficial gray layer consisted of many fibers which were not labeled antiserum against calbindin-D28K. These were small caliber fibers with a few varicosities along its course.

The two calcium binding proteins calbindin-D28K and calretinin thus reveal distinct distribution patterns in the rabbit SC. Supported by KPNU 95 grant.

NITRIC OXIDE SYNTHASE AND CHOLINE ACETYLTRANSFERASE ARE CO-LOCALIZED IN NEURONS PROJECTING TO THE PATCH-CLUSTER SYSTEM OF THE CAT SUPERIOR COLLICULUS. G.D. Butler, C.A. Scheiner, R.H. Whitworth\*, and R.R. Mize, Dept. of Anatomy and Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112

Nitric oxide synthase (NOS), identified by nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d) histochemistry, is found in fiber patches in the intermediate gray layer (IGL) of the cat superior colliculus (SC). These patches have characteristic patterns like those known to contain acetylcholine. We have used choline acetyltransferase (ChAT) antibodies and NADPH-d histochemistry to determine directly if the two substances are colocalized in the cat SC. We also confirmed the origin of these fibers from the pedunculopontine tegmental nucleus (PPTN) by injecting biocytin into the right PPTN of two cats. A computer-based microscope plotter was used to map the distribution of single and double labeled neurons in the PPTN and fibers in SC. NADPH-d labeled fibers formed two tiers of patch-like fibers, one superficial and the other deeper within the IGL. Adjacent sections labeled by ChAT produced a similar pattern of fiber labeling. Superimposed computer plots showed that the patches labeled by the two substances overlap. Double labeled sections also revealed fibers within the patches that contained both labels. In addition, NADPH-d and ChAT were colocalized in 94.6% of neurons in three sections through the PPTN. Counts of NADPH-d and ChAT labeled cells in adjacent sections suggested that NADPH-d labeled neurons are a substantial subset of the total ChAT population because the number of NADPH-d labeled neurons were 68.5-80.1% of ChAT neurons in these sections. In summary, our results provide direct evidence that neurons in the PPTN that project to the IGL contain both ChAT and NADPH-d (and thus presumably nitric oxide). Supported by NIH NEI-02973 and a Louisiana State Board of Regents Graduate Student scholarship.

## 252.5

### SUBCORTICAL NUCLEI CONTRIBUTING AXONS TO THE CRITICAL ZONE OF THE COMMISSURE OF THE SUPERIOR COLLICULUS: AN HRP STUDY IN THE CAT.

W.E. Todd & A.C. Rosenquist\*

Dept. of Neuroscience, Univ. of Penn., Phila., PA 19104

Transection of a critical zone of the commissure of the superior colliculus (CSC) restores visual orienting to a cat previously rendered hemianopic by a large unilateral visual cortical ablation (Wallace et al., *J. Comp. Neurol.* 284:429-450, 1989). The critical zone lies from approximately 58% to 68% of the distance between the posterior commissure (0%) and the caudal pole of the superior colliculus (100%). Transections of the CSC rostral or caudal to the critical zone do not lead to recovery of visual orienting (Wallace et al., *J. Comp. Neurol.* 284:429-450, 1989).

Over 40 subcortical nuclei project through the CSC (Edwards et al., *J. Comp. Neurol.* 184:309-330, 1977). In order to determine which subcortical nuclei send axons through the critical zone, we transected various regions of the CSC and injected HRP into the transection site. HRP is taken up by cut axons and transported retrogradely to their parent cell bodies. Analysis of the location of labelled cells revealed that two regions project almost exclusively through the critical zone of the CSC: the substantia nigra pars reticulata and a subregion of the pedunculopontine nucleus. Interestingly, destruction of either of these two nuclei contralateral to a cortical lesion has been shown to result in recovery (Wallace et al., *J. Comp. Neurol.* 296:222-252, 1990; Durmer et al., *Soc. Neurosci. Abstr.* 20: 1187, 1994).

## 252.7

### INACTIVATION OF THE CAT SUBSTANTIA NIGRA PARS RETICULATA AND SENSORY RESPONSIVENESS.

V.M. Ciaramitaro\* & A.C. Rosenquist

Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

Permanent destruction of the rat and cat substantia nigra pars compacta (SNpc) produces sensory inattention in the ipsilateral field (Feeney and Wier, *Brain Res.* 178:329-346, 1979; see Schultz, *Prog. Neurobiol.* 18:121-166, 1982 for review in rat). Reversible pharmacological inactivation of the cat substantia nigra pars reticulata (SNpr) also produces neglect of visual-auditory targets (Boussaoud & Joseph, *Exp. Brain Res.* 57:297-304, 1985), suggesting that destruction of the SNpr should also produce sensory inattention.

We compared permanent versus reversible inactivation of the cat SNpr on tests of orienting to visual, auditory and somatosensory stimuli. We have confirmed and extended previous findings. Unilateral injections of the GABA<sub>A</sub> agonist, muscimol, produced unresponsiveness to visual, auditory and somatosensory stimuli over several hours, with visual impairments being the most enduring. Thus, while responses to auditory or somatosensory stimuli were present, animals failed to respond to visual stimuli, suggesting that results are not simply due to a motor impairment. Injections of saline and the GABA<sub>A</sub> antagonist, bicuculline methiodide, were ineffective.

In contrast, we have failed to observe visual unresponsiveness after ibotenic acid lesions of the SNpr, but see some evidence for auditory and/or somatosensory unresponsiveness. However, motor biases prevented testing for several days post-lesion and deficits could have resolved in this time via compensatory mechanisms.

## 252.4

LOCALIZATION OF KAINATE AND N-METHYL-D-ASPARTATE RECEPTOR SUBUNITS IN THE CAT SUPERIOR COLLICULUS USING ANTIBODY IMMUNOCYTOCHEMISTRY. R.R. Mize\* and G.D. Butler, Department of Anatomy and the Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112.

Physiological evidence suggests that the quisqualate/kainate and n-methyl-D-aspartate (NMDA) receptors are localized at the same post-synaptic sites opposite glutamate containing synaptic terminals and that both are necessary to mediate long-term potentiation. To date, there is limited ultrastructural evidence that demonstrates directly the localization of these receptors at specific synaptic sites. We have employed electron microscope immunocytochemistry using silver intensified diaminobenzidine to localize the NMDAR1 subunit of the NMDA receptor and the GLUR5-7 subunits of the kainate receptor. We localized these receptor subunits in the superficial layers of the cat superior colliculus (SC) where numerous glutamate-containing synaptic terminals from the retina and visual cortex are known to terminate. Retinal terminals were identified by normal morphology and cortical terminals by degeneration after cortical lesion of areas 17-18. Antibody labeling to the NMDAR1 subunit was found along post-synaptic densities and internalized within profiles that were opposite synaptic terminals of retinal origin containing round vesicles and pale mitochondria and degenerating terminals of cortical origin. Post-synaptic profiles labeled by NMDAR1 included conventional dendrites and presynaptic dendrites which themselves contained pleomorphic vesicles and formed synapses with other profiles. GLUR5-7 antibody also labeled post-synaptic densities on both conventional dendrites and presynaptic dendrites opposite retinal and cortical terminals. Both antibodies also labeled receptor proteins at non-synaptic sites. These results show indirectly that the kainate and NMDA receptor proteins are likely colocalized at post-synaptic sites related to both major excitatory afferents to SC. Supported by NIH EY-02973.

## 252.6

### SMALL VOLUME RETROGRADE TRACER INJECTIONS INTO THE SUPERIOR COLLICULUS OF THE CAT REVEAL AN ANATOMICAL SUBSTRATE FOR RECOVERY OF THE VISUAL ORIENTATION RESPONSE IN THE HEMIANOPIC CAT

J.S. Durmer\* & A.C. Rosenquist

Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

Previous anatomical studies in the cat have shown multiple projections from brainstem nuclei to the superior colliculus (SC). Lacking in the literature is a systematic study of crossed SC afferents. In particular, the regional and topographical organization of crossed collicular afferents from the substantia nigra pars reticulata (SNpr) and the pedunculopontine nucleus (PPN) to the SC have not received much attention.

We have previously reported that in a cat with the unilateral removal of all known visual cortical areas (a hemianopic cat) transection of the commissure of the superior colliculus (CSC), destruction of a critical zone of the contralateral SNpr or ablation of a critical zone of the contralateral PPN, results in the return of visual orientation behavior in the previously hemianopic visual field (Wallace et al., *J. Comp. Neurol.* 296:222-252, 1990; Durmer et al., *Soc. Neurosci. Abstr.* 20:1187, 1994). Thus, recovery seems to depend on elimination of a contralateral projection to the SC.

This study demonstrates a topographically organized distribution of contralaterally projecting cells utilizing small volume injections of the fluorescent retrograde tracers diamidino yellow in one SC and fast blue into the mirror symmetric position of the other SC. By varying the rostrocaudal, lateromedial and dorsoventral position of these injections, the complex nature of contralateral SC afferents is revealed. (Supported by EY02654 & 5-T32-EY-07035-17)

## 252.8

### EFFECTS OF ANGIOTENSIN II ON THE VISUAL RESPONSES OF THE RAT'S SUPERIOR COLLICULUS DURING NEONATAL DEVELOPMENT.

A. Marois, S. Darveau, and C. Casanova\*, École d'Optométrie, Université de Montréal, Québec, Canada, H3C 3J7.

We recently reported that Angiotensin II (Ang II) yielded a strong suppressive effect on visual neuronal activity in the superior colliculus (SC) of adult rats (Merabet et al., 1994, *Neuroreport* 5: 2649). Since the density and proportion of angiotensinergic receptors vary during post-natal development, we were interested in characterizing and comparing the physiological effects of Ang II in neonatal rats at various stages of development (PND 10 to 40). The effect of Ang II on baseline and visually evoked collicular activity was studied in 6 groups of rats (10-15, 15-20 days, etc...). Experiments were carried out on pups anesthetized with urethane (25%). A recording-injecting microelectrode filled with the peptide was lowered into the superficial layers of the SC to record visual evoked potentials (VEP, Grass photostimulator). Ang II was injected at a concentration of 10<sup>-6</sup>M (volume of 30-40 nl at a rate of 10 nl/min). Preliminary results indicated that, in most cases, injection of Ang II provoked a reduction in the amplitude of the VEP (mean ± SD = 70 ± 11%), with no change in the latency of the potential. These effects were restricted to the superficial layers of SC, supporting autoradiographic studies which indicated that angiotensinergic receptors were distributed in the dorsal collicular layers. The strength of inhibition appeared to vary with age, being more pronounced in younger animals. In contrast to adult rats, recovery of the responses after injection of 10<sup>-6</sup>M Ang II was often either delayed or absent. These results suggest that, as for adult animals, Ang II has a suppressive effect on the activity of the superficial collicular layers in neonatal rats. In addition, there are some indications that the strength of the physiological action of Ang II may vary according to the stage of development, and therefore be related to the change of receptor density and/or proportion. Supported by MRC of Canada, FCAR, and FRSQ.

## 252.9

**HABITUATION AND DISHABITUATION OF DEEP TECTAL NEURONS IN THE MONGOLIAN GERBIL (*Meriones unguiculatus*): NOVELTY DETECTION.** M. G. Bigel\*, C. G. Ellard and S. Reinis, Dept. of Psychology, Univ. of Waterloo, Waterloo, Ontario, Canada.

Employing standard electrophysiological recording, three unique experiments were conducted to investigate the characteristics of habituation and dishabituation in deeper layer neurons of the superior colliculus (SC) of the Mongolian Gerbil. Results showed that habituation is common to neurons in the deeper layers of the SC and occurred as a result of repeated visual stimulation. It was found that neurons habituated at different rates but that not all neurons habituated to repeated stimulation. Further, it was found that a habituated neuron could not be dishabituated by changing the location of a stimulus within the neuron's receptive field or by changing the shape of the stimulus alone. However, a neuron's response could be reinstated by increasing stimulus intensity alone. There was no correlation between a neuron's rate of habituation and its location in the SC nor was there any relation between the strength of a cell's response (number of spikes fired at stimulus onset), its depth or rate of habituation. It was concluded that changing the intensity of a stimulus alone was sufficient to dishabituate a neuron. Results of this study suggest that neuronal habituation is a robust phenomenon related to novelty detection at the behavioural level and that the ability to detect novelty is dependent on unique features of the new stimulus. Research supported by an NSERC grant to C.G.E.

## 252.11

**DEVELOPMENT OF AUDITORY RESPONSIVENESS, TOPOGRAPHY, AND FUNCTIONAL CONVERGENCE WITH VISUAL INPUTS IN CAT SUPERIOR COLLICULUS (SC).** M.T. Wallace\* and B.E. Stein. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157

Auditory inputs play a critical role in the orientation functions mediated by the SC. Their role is accomplished not only by evoking responses to auditory cues, but also by their influence over visual responses. In the adult SC, auditory neurons respond robustly and with short latency, and have discrete spatiotopically-organized receptive fields (RFs). Despite the fact that the nature of auditory responses and the alignment of auditory and visual maps are key features in determining cross-modality interactions, little is known about their development in cat. Auditory SC development was examined in animals from 1-135 days postnatal (dpn). The first auditory neuron was seen at 5 dpn. Early neurons responded weakly, had long latencies (>100ms), habituated rapidly and lacked RFs. Auditory maturation was most accelerated from 21-45 dpn, when a coarse spatiotopic map became evident and was refined (RFs shrank by nearly 400%). During this period auditory responses became more robust, latencies shortened, auditory-visual map alignment became evident, and many neurons became overtly responsive to both auditory and visual cues. Although covert interactions among auditory and visual afferents are likely to be essential in guiding cross-modality alignment, there was a temporal disparity between map alignment and the ability of auditory cues to alter visual responses. These findings are consistent with the hypothesis that the mechanisms guiding map alignment are necessary but not sufficient for normal multisensory integration. Supported by EY06562.

## 252.13

**NEONATAL PATTERN DEPRIVATION FAILS TO DISRUPT NORMAL MAP ALIGNMENT OR CROSS-MODALITY INTEGRATION IN CAT SUPERIOR COLLICULUS (SC)** J.G. McHaffie\*, M.T. Wallace and B.E. Stein. Dept. Neurobiol. & Anat., Bowman Gray Sch. of Med., Winston-Salem, NC 27157.

The development of a spatiotopic auditory map and its alignment with the visuotopic map in the SC is known to depend on early visual-auditory experience. Presumably, such early cross-modality interactions are also essential if normal integration is to develop. The present experiments were initiated to determine whether patterned visual stimuli are necessary for: 1) the development of aligned visual, auditory, and somatosensory maps; 2) the appearance of multisensory (i.e., cross-modal) neurons; and 3) the maturation of normal cross-modality integration. Unimodal and multisensory neurons (n=29) were recorded in the SC of adult cats (n=2) whose eyelids were opened after having been sutured closed since before normal eye opening. Immediately after opening the eyes, it was apparent that visual, auditory, and somatosensory receptive fields (RF's) were topographically organized and aligned with one another. Multisensory neurons were frequently encountered (n=22) and had RF's that were in close spatial register. Visual-nonvisual cross-modality interactions also appeared normal: two modality-specific stimuli within their respective RF's produced response enhancement, but when one of these stimuli was outside its RF, either no enhancement or response depression was produced. The magnitude of the enhancement was greatest for minimally effective cues and when the peak periods of the two modality-specific discharge trains were overlapping. These data indicate that experience with patterned visual stimuli is not a critical factor in the maturation of cross-modality (i.e., visual-nonvisual) processes in the SC. Supported by NIH EY 06562, the Forsyth County United Way, and a BGSM Venture Grant

## 252.10

**VISUAL RESPONSES AND TOPOGRAPHY IN THE SUPERIOR COLLICULUS (SC) OF THE NEWBORN MONKEY.** B.E. Stein\*, M.T. Wallace & J.G. McHaffie. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157

The newborn rhesus monkey, like the newborn human, can make eye/head movements in response to visual stimuli. Despite the fact that these early behaviors are likely to involve the circuitry of the SC, little is known about the functional state of this structure at birth. In order to examine the organization of the visual representation at birth, single-unit extracellular recordings were done in the superficial SC of two newborn animals. In contrast to similar studies in an altricial species such as cat, both single and multiunit visual responses were readily recorded from these layers within hours of birth. A systematic series of electrode penetrations revealed a well organized, adult-like visuotopic map. In most respects, the response properties of neonatal SC neurons paralleled those of the adult: they responded robustly to stationary and moving stimuli, exhibited near adult incidences of velocity selectivity, surround inhibition and within-field spatial summation/inhibition, and were unselective for stimulus features such as shape, orientation and direction of movement. Neonatal SC neurons differed substantially from the adult in only two respects: receptive field size and latency. Neonatal receptive fields were on average 37% larger than in the adult, and response latency was more than twice (204%) as long (159.9 ± 36.5 ms vs. 78.5 ± 14.6 ms). These results demonstrate a surprising maturity of visual information-processing capabilities of the SC in the newborn monkey, which is likely to be necessary to subserve its visual orientation capabilities. Supported by NIH EY06562.

## 252.12

**CROSS-MODAL ORIENTATION BEHAVIORS: DEVELOPMENTAL COMPENSATION FOLLOWING NEONATAL LESIONS OF ASSOCIATION CORTICES.** L.K. Wilkinson<sup>1</sup>, M.T. Wallace<sup>2</sup> and B.E. Stein<sup>2</sup>. Dept. Psychology<sup>1</sup>, Virginia Commonwealth Univ., Richmond, VA 23298 and Dept. Neurobiology and Anatomy<sup>2</sup>, Bowman Gray School of Medicine/Wake Forest Univ., Winston-Salem, NC 27157.

The ability of the cat superior colliculus (SC) to integrate sensory inputs from different modalities in order to direct attentive and orientation behaviors is dependent on corticotectal influences; most notably, those from the anterior ectosylvian sulcus (AES) (Wilkinson et al., 1992; Wallace and Stein, 1993). However, if AES is removed at birth, corticotectal influences from the rostral lateral suprasylvian area (rLS) increase to compensate for the absent AES (Wilkinson et al., 1995). This compensation results in normal multisensory orientation behaviors. Surprisingly, in the present experiments, unilateral removal of AES and rLS at 5-7 days postnatal (dpn) degraded, but did not eliminate, the development of multisensory orientation behaviors. Thus, a significant enhancement in orienting to a visual stimulus which elicited 50% correct responses when presented alone occurred when this stimulus was paired with a spatially coincident neutral auditory stimulus (AES-rLS ablated animals=84% correct responses; normal animals=99%). Conversely, a significant decrease in correct responses occurred when the auditory stimulus was spatially disparate (AES-rLS ablated animals=6% correct responses; normal animals=1%). Thus, it appears that the compensatory hierarchy for normal multisensory behavior contains additional component(s) beyond AES and rLS. The source of these influences remain to be identified. Supported by NIH grant EY06562

## 252.14

**THE DISTRIBUTION AND POSTNATAL DEVELOPMENT OF NMDAR1 IMMUNOREACTIVITY IN THE CAT SUPERIOR COLLICULUS (SC).** K.K. Anstrom\*, J.G. McHaffie and B.E. Stein. Department of Neurobiology & Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

Recent studies indicate that NMDA receptor-mediated events play a role in sensory processing and crossmodal integration in the cat SC. The distribution and postnatal ontogeny of NMDA immunoreactivity were demonstrated with an antibody to the R1 subunit, the constant element of the NMDA receptor. In adults, the superficial laminae displayed dense neuropil label with a dorsoventral gradient, as well as homogeneously distributed, small-soma NMDAR1(+) neurons. In the deeper laminae, label was restricted to a mediolateral band of large-soma neurons in the upper aspects of the intermediate (SGI) and scattered neurons in the deep (SGP) laminae. Following HRP injections into the brainstem, virtually all HRP-labelled neurons were also NMDAR1(+), indicating that deep laminae output neurons, known to be involved in crossmodal integration, preferentially express NMDA receptors. In newborns, only a few labelled neurons were found in lateral SGI; the superficial laminae were devoid of label save for some cellular labelling in their most dorsal aspects. By PND 7, the adult pattern had been achieved in SGI and a few labelled neurons appeared in SGP; the superficial laminae had acquired light, homogeneous neuropil label. Between PND 10 and 24, NMDAR1(+) neurons increased in SGP to resemble the adult distribution; superficial neuropil label became denser but did not display a dorsoventral gradient until PND 46. Thus, superficial laminae NMDAR1 immunoreactivity undergoes a protracted period of postnatal maturation, whereas the deeper laminae acquire their adult-like pattern at or before the onset of crossmodal integration. Sponsored by NIH EY06562.

## 252.15

ROLE OF NMDA RECEPTORS IN MULTISENSORY INTEGRATION IN THE SUPERIOR COLLICULUS. J.H. Graham\*, J.W. Vaughan, S.J. Schaafsma, M.T. Wallace, B.E. Stein. Dept. Neurobiology & Anatomy, Bowman Gray School of Medicine/Wake Forest Univ., Winston-Salem, NC 27157.

The superior colliculus contains unimodal neurons that respond to visual, auditory, or somatosensory stimuli and multisensory (MS) neurons which can integrate combinations of these inputs and increase their overall response levels. In the present studies the effects of glutamatergic agonists and antagonists on these different sensory responses were investigated in the cat. Ionophoretically applied NMDA was found to be capable of enhancing responses to modality-specific stimuli and to multisensory combinations of stimuli in more than 80% of the MS neurons studied. The NMDA antagonist AP5 was able to antagonize NMDA's effects, and when applied alone, AP5 was able to reduce responding to both modality-specific and multisensory stimuli below control levels in the majority of these MS neurons, as reported by Binns and Salt (1996). Subpopulations of MS neurons were also encountered in which AP5 tended to increase multisensory integration. Furthermore, NMDA receptor activation and antagonism had greater effects on the unimodal responses of MS neurons than on their multisensory responses. Auditory responses in unimodal and MS neurons appeared less likely to be altered by NMDA or AP5, and the variability seen in this study as well as by others indicates that NMDA receptor activation and inactivation may be affecting auditory responses indirectly. Supported by NIH grant EY 06562 and NS 22543.

## 252.17

NEUROACTIVE SUBSTANCES IN PARABIGEMINAL CELLS WHICH PROJECT TO SUPERIOR COLLICULUS IN 13-LINED GROUND SQUIRRELS. R. J. Garcia-Mercado and N. Lugo\*. Department of Anatomy and Institute of Neurobiology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

The parabigeminal nucleus (Pb) has extensive reciprocal connections with the superficial layers of the superior colliculus (SC). Somata of parabigeminal neurons have been shown to contain substance P (SP), somatostatin (SS), neuropeptide Y (NPY), GABA, ChAT and tyrosine hydroxylase (TH). In the present experiments we sought to determine whether the parabigeminal cells projecting to SC are associated with particular neuroactive substances. Parabigeminal cells projecting to SC were retrogradely labeled by injecting fluorescent microspheres into the superficial layers of SC of anesthetized ground squirrels. After survival periods of two weeks to allow transport of the microspheres, the squirrels were again anesthetized and intracardially perfused with phosphate buffer (pH 7.4) followed by 4% paraformaldehyde in buffer. Brain sections 40  $\mu$ m thick were cut frozen on a sliding microtome and processed for immunofluorescence or with DAB-nickel enhanced avidin biotin complex (ABC) method. Cells containing microspheres were immunoreactive to antibodies to ChAT, NPY and SP. Most of these cells were ChAT positive. We could not demonstrate that cells reactive for antibodies to SS, GABA, TH contained microspheres. The GABA reactive cells were very small (10-15  $\mu$ m diameter) but SS- and TH-reactive cells were as large as other cells which did contain microspheres. This suggests that the SS- and TH-reactive cells may be interneurons or may project to targets other than SC. (Supported by NIH Grant MH-48190).

NADPH-DIAPHORASE POSITIVE NEURONS IN THE SUPERFICIAL LAYERS OF THE SUPERIOR COLLICULUS (SC) ARE ALTERED IN AGED RATS. A. Vercelli\* and S. Jhaveri. Dept. Anatomy, Pharmacology and Forensic Medicine, Univ. of Torino, Torino, Italy, and Dept. Brain & Cognitive Sciences, Mass. Institute of Technology, Cambridge, MA 02139.

The rat visual system exhibits a protracted maturation of the pattern of NADPH-d expression: adult-like patterns are seen around the time of eye opening. NADPH-d positive SC neurons are also vulnerable to denervation: monocular enucleation on P0 results in marked alterations in their dendritic fields (Vercelli et al., Neurosci. Abst. 1995). Here we present evidence on the morphology of NADPH-d expressing neurons in the retinorecipient tectal zones of aged rats.

Five albino rats, aged 20-26 months of age, were perfused with 4% paraformaldehyde, their brains postfixed for 4 h and 50  $\mu$ m thick sections cut coronally. Tissue was reacted with 1 mg/ml NADPH, 0.2 mg/ml NBT and 1% Triton in PB for 2 h at 37°C. Control sections from normal rats (6-12 months) were processed similarly. Care was taken to ensure that the intensity of the NADPH-d reaction was the same in the aged animals as in normal controls.

In 4 of the 5 aged rats, density of reactive SC neurons was significantly reduced when compared to normals. This decrease was especially evident in the medial and lateral SC. Dendrites of NADPH-d containing cells were shorter and appeared to have fewer vertically-oriented branches. Whether this reflects decreased expression of NADPH-d, or results from an actual atrophy of the dendrites remains to be determined. There was also an increase in the percent of neurons with horizontally oriented dendrites.

These results demonstrate profound age-related changes in the morphology of the SC neurons. The possibility that these changes are a consequence of corresponding alterations in the cells of the retina is being investigated.

## 252.16

SPATIAL ORGANIZATION OF MULTISENSORY CELLS IN THE DEEP LAYERS OF CAT SUPERIOR COLLICULUS (SC). D.C. Kadunc\*, J.W. Vaughan and B.E. Stein. Department of Neurobiology & Anatomy, Bowman Gray School of Medicine/ Wake Forest Univ., Winston-Salem, NC 27157.

The receptive fields (RFs) of multisensory neurons in cat superior colliculus (SC) are surprisingly large given their presumptive role in target location. However, cross-modality RF heterogeneity might provide greater spatial precision than would be predicted by RF size. As a test: 1) stimuli (e.g., visual-auditory) were paired at various coincident RF locations; and paired so that 2) one stimulus was fixed at a location within the RF and the influence of the other was at progressively greater disparities. 92% of the cells revealed the presence of a "best area" within the RF where multisensory responses and cross-modality integration were most effective. Similarly, the majority (62%) of neurons showed that multisensory integration was maximal when the spatial disparity between the two stimuli was minimized despite the fact that all stimuli were within their excitatory RFs. It is likely that these factors covary so that RF heterogeneity and the size and location of the neuron's best area may provide a better picture and offer greater insights toward understanding multisensory integration than absolute RF size. ## 252.18

EFFECTS OF ANGIOTENSIN II (AII) IN THE SUPERIOR COLLICULUS (SC) OF HAMSTER. W.R. Bauer\*, Y. Zhang, R.W. Rhoades and R.D. Mooney. Dept. of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699

The superficial layers of the SC have a high density of AII receptors. Our *in vivo* studies suggested that these modulate visual activity of SC neurons by postsynaptic mechanisms. To test whether AII had pre- or postsynaptic effects, we made intracellular recordings from superficial SC neurons, using an SC slice preparation in which EPSPs were evoked by stimulation of the attached optic tract. Depolarizing postsynaptic responses in these neurons were evoked by micropressure applications of glutamate during synaptic blockade with a low  $\text{Ca}^{2+}$ -high  $\text{Mg}^{2+}$  superfusion solution. In 18 of 22 neurons (82%), AII (1  $\mu$ M) reduced EPSP amplitude by an average of  $51 \pm 16$  (s.d.)% ( $p < 0.001$ ) and reduced glutamate depolarizations by an average of  $40 \pm 21$  ( $p < 0.001$ ). These effects were correlated ( $r = 0.66$ ;  $p < 0.01$ ). In the remaining 4 neurons (18%), application of AII increased the EPSP amplitude by  $183 \pm 71$ % ( $p < 0.05$ ), but had no effect on glutamate-evoked depolarization in 3 of these cells and produced a 20% increment in the fourth. As previously reported, there was no correlation between the effects of AII on EPSP amplitude and those on membrane potential. There was no significant difference in the effects of AII on membrane potential between periods of superfusion with normal Krebs solution and with low  $\text{Ca}^{2+}$ -high  $\text{Mg}^{2+}$  solution. Thus, the suppressive effects of AII in the SC appear to be mediated at a postsynaptic site; whereas the facilitation, observed in only a few neurons, may involve presynaptic modulation.

ANALYSIS OF VISUALLY EVOKED FIELD POTENTIALS IN THE OPTIC TECTUM OF THE PIGEON. J. C. Letellier\*, C. Madrid, G. Marin, D. Morales, J. Mpodozis, C. Rozas and M. Velasco. Laboratorio de Neurobiología y Biología del Conocer, Facultad de Ciencias, Universidad de Chile, Santiago, Chile.

The pigeon's optic tectum is a highly organized 14 layers structure, receiving 2.6 million contralateral retinal fibers. Retinal axons end at layers 2 to 7, while tectal output is mainly made of cells located in layers 10 to 13. Here we analyze, in the anesthetized pigeon, the synaptic events following the visual activation of the tectal retinal afference, using multiunit recordings of incoming retinal fibers and visually evoked Local Field Potentials (LFP). LFP were obtained at different tectal depths, spaced by 50  $\mu$ m. Brief flashes, delivered monocularly, were used as visual stimuli.

At the superficial layer 1 the LFP begins, after a 20 ms latency, with a large negative phase followed by many secondary negative peaks located at regular intervals within the next 50 ms. This polyphasic profile shows more peaks, increasing amplitudes and shorter latencies at higher flashes intensities. At 300-350  $\mu$ m, which corresponds to the end of the retinorecipient layers, the LFP profile shows an inversion of all its negative components, thus, in layers 8 to 14 it begins with a large positive peak. At any depth, the LFP profile reflects mostly the synaptic currents associated with retinal synapses, since flashes do not trigger action potentials in tectal cells. In the pigeon the ganglion cell population has five conduction velocity groups, consequently the interpretation of the origin and changes of the various LFP components is complex. Multiunit recordings show that retinal fibers, in response to flashes, give a quasi-periodic train of bursting activity lasting 20-50 ms with frequencies in the 20-60 Hz range. Each burst generates a peak in the LFP similar to the one obtained using single shock electrical stimulation of the optic nerve. The overall complex LFP profile, as well as its changes according to depth, are then the combination of peaks generated by these retinal bursts. These characteristics of the LFP profiles provide a physiological marker of retinorecipient layers and of the retinal activity which produce them (Supported by FONDECYT 1950687).

ON THE MOSSY FIBRE PROJECTION FROM THE NUCLEUS OF THE BASAL OPTIC ROOT TO THE VESTIBULOCEREBELLUM IN PIGEONS: COLLATERALS TO THE VESTIBULAR AND CEREBELLAR NUCLEI B. Linkenhoker, A.F. Kingstone\* and D.R.W. Wylie, Department of Psychology, University of Alberta, Edmonton, Alberta, Canada, T6G 2E1.

In the generalized anatomy of the cerebellar circuit, mossy fibres (Mfs) terminating in the granule layer of the cerebellar cortex often send collaterals to nuclei which receive input from Purkinje cells in the zone to which the Mfs are projecting. In pigeons, the nucleus of the basal optic root (nBOR) has been shown to project as Mfs to folium IXc,d of the vestibulocerebellum. It has also been demonstrated that Purkinje cells in the pigeon vestibulocerebellum project to the vestibular and cerebellar nuclei. Given these facts, one might expect that the Mfs arising from nBOR send collaterals to the vestibular and cerebellar nuclei. In this study, we made small injections of biotinylated dextran amine (BDA) into nBOR of three pigeons which resulted in the anterograde labelling of Mfs projecting to folium IXc,d. In all three cases, Mf collaterals were observed to terminate heavily in the cerebellar nuclei. Most of these terminals were adjacent to the fourth ventricle in the medial margin of the lateral cerebellar nucleus, and the ventral margin of the medial cerebellar nucleus. Terminal labelling was also found in cerebellovestibular process. In one case, a Mf collateral terminated in the tangential nucleus, superior vestibular nucleus and the descending vestibular nucleus. This research was supported by grants from NSERC and AHFMR to D.R.W.W..

SYNAPTIC TARGETS OF CROSSED ISTHMOPECTAL AXONS IN *XENOPUS*: IMPLICATIONS FOR PLASTICITY. K. K. Rybicka and S.B. Udin\*, Dept. of Physiology & Biophysics, SUNY, Buffalo, NY 14214.

Visual activity during development is required for the ipsilateral visual input to *Xenopus* tectum to come into register with the contralateral map. Correlated activity is hypothesized to be the cue by which a Hebbian process stabilizes isthmotectal synapses (which relay ipsilateral visual input) when they are located near to retinotectal synapses with matching visual field locations. In order to test this hypothesis, we have begun to identify the tectal cells upon which isthmotectal axons synapse and to determine whether retinotectal axons terminate on the same dendrites.

Isthmotectal axons were labeled with HRP, and tectal cells were labeled by post-embedding immunogold reaction with antibodies to GABA. Ultrastructural examination reveals that some isthmotectal axons terminate on GABA-positive dendrites. Other axons contact unlabeled postsynaptic structures that were consistent in appearance with the GABA-poor zones of GABA-positive dendrites.

To determine whether retinotectal axons synapse onto the same dendrites, we surveyed all of the processes post-synaptic to filled isthmotectal axons. The most common non-isthmotectal inputs were GABA-positive. Surprisingly, we found no inputs with typical retinotectal features of round, clear vesicles, pale mitochondria, and asymmetric synapses. These results indicate that retinotectal-isthmotectal interactions are more complex than originally assumed.

## 253.2

SOME INTRIGUING PROPERTIES OF THE ONGOING VISUAL ACTIVITY IN THE TECTO-FUGAL VISUAL PATHWAY OF THE AWAKE PIGEON. J. Mpodozis\*, J. C. Letellier, C. Madrid, G. Marin, D. Morales, C. Rozas and M. Velasco. Laboratorio de Neurobiología y Biología del Conocer, Facultad de Ciencias, Universidad de Chile, Santiago, Chile.

The retinotectofugal pathway is considered the main system mediating visual perception in birds. At least 90% of retinal ganglion cells project to the tectum. In acute preparations, retinal and tectal cells exhibit complex movement sensitive receptive fields. Here we report the first results concerning the response properties of retino-tecto-fugal neurons in the awake and head-restrained pigeon.

Extracellular recordings reveal that a) the spontaneous ongoing activity in the tectum is extremely low when the bird is looking at a static visual scene, b) when an object is moved against a background in the visual field, tectal cells respond vigorously, as expected for movement sensitive cells, but they are not stimulated with large and coherent motion of the visual background, c) as many other birds, pigeons perform, once a second, large cyclotorsional saccades with 3 to 6 cycles of 30Hz oscillations. During these saccadic oscillations most tectal cells remain silent even when the image moves in the retina at speeds encompassing the normal range of stimulating speeds.

These results are intriguing as pigeons are capable of complex static visual discriminations that appear mediated by the tecto-fugal system. Furthermore, this tectal lack of activity is also puzzling, as tectal cells, including the main output located in layer 13, receive a direct retinal input that should be active in these conditions. These results open two non-trivial possibilities: a) the retina is self silenced during saccades and whole field motion b) an inhibitory, non-retinal, intra or extra tectal signal affects the processing of retinal activity at tectal level. (Supported by FONDECYT 1950687).

## 253.4

PROJECTIONS OF THE NUCLEUS OF THE BASAL OPTIC ROOT IN PIGEONS: A STUDY USING THE ANTEROGRADE TRACER BIOTINYLATED DEXTRAN AMINE D.R.W. Wylie\* and B. Linkenhoker, Dept. of Psychology, Univ. of Alberta, Edmonton, AB, Canada, T6G 2E1.

The nucleus of the basal optic root (nBOR) of the Accessory Optic System has been implicated in the visual control of compensatory head and eye movements. Previous anatomical studies have shown that the nBOR projects, (i) bilaterally to the vestibulocerebellum, oculomotor complex (OMC), inferior olive and the interstitial nucleus of Cajal, (ii) ipsilaterally to the pretectal nucleus lentiformis mesencephali, and (iii) to the contralateral nBOR. In this study, we made small injections of biotinylated dextran amine (BDA) into nBOR in three pigeons. In addition to confirming the projections listed above, we found numerous others. Bilateral projections to the vestibular nuclei, pontine nuclei (caudally), nucleus Darkschewitsch, central grey, red nucleus and mesencephalic reticular formation were found. The cerebellar nuclei received ipsilateral projections as did several subnuclei of the dorsolateral thalamus, and the lateral geniculate nucleus. Sparse projections were also observed to the ipsilateral tectum, several pretectal nuclei, and several sites in the mesencephalon. We also found a different projection pattern to the OMC than that previously reported. Whereas previous studies found projections to the ventral subdivision (OMv) and dorsolateral subdivision (OMdl) on the ipsilateral and contralateral sides respectively, we found a bilateral projection to the OMv and a contralateral projection to OMdl and the dorsomedial subdivision of the OMC. This research was supported by grants from NSERC and AHFMR to D.R.W.W..

## 253.6

RELATIVE INPUT FROM IPSILATERAL AND CONTRALATERAL NUCLEUS ISTHMI TO DIFFERENT LOCI OF THE FROG OPTIC TECTUM DEPENDS ON RETINOTOPIC LOCATION. E.A. Dudkin and E.R. Gruberg\*. Biology Dept., Temple Univ., Phila., PA 19122.

The inferior visual field of each eye of *Rana pipiens* extends from about 60° contralaterally past the midline in front to 180° ipsilaterally in the back. When input from the left nucleus isthmi is cut and the right eye is intact but occluded, the animal no longer responds to prey stimuli in the right (contralateral) inferior visual field. An equivalent statement can be made for the right n. isthmi input and the left eye.

To explore the anatomical basis for such a result we have injected HRP at single, circumscribed locations in tectal lobes, and counted the number of ipsilateral and contralateral n. isthmi cells that are backfilled. At tectal injection sites representing the inferior contralateral visual field, an average of 4.1 times more labeled cells are found in the contralateral nucleus isthmi than in ipsilateral n. isthmi. At tectal injection sites representing the inferior ipsilateral monocular visual field, an average of 3.4 times as many labeled cells are found in ipsilateral n. isthmi as in contralateral n. isthmi. After unilateral optic tract cut (which also severs contralateral isthmotectal input), animals respond to prey stimuli in the superior visual field for 2 to 3 days post surgery; after this time responsiveness diminishes rapidly. Similar results are seen after unilateral optic nerve cut. At tectal HRP injection sites representing the superior visual field, approximately the same number of labeled cells are found in the ipsilateral and contralateral n. isthmi. Our results suggest that there is a threshold input from n. isthmi that enables the frog to respond to prey stimuli in different parts of the visual field. Supported by NIH grant EY04366.

## 253.7

**BINOCULAR INTERACTIONS AND VISUAL FIELD SPECIFIC PROJECTIONS IN THE TECTO-ROTUNDAL PATHWAY OF THE PIGEON.** O. Güntürkün\*, B. Diekamp, B. Hellmann and C. Theiss. AE Biopsychologie, Fakultät für Psychologie, Ruhr-Universität Bochum, 44780 Bochum, Germany.

The pigeon's retina projects topographically onto the contralateral tectum (TO) with the superior retina, pointing to the lower visual field, being represented in the inferior TO. The tectal projections to the n. rotundus (Rt) were assumed to be mainly ipsilaterally organized with no binocular interactions at rotundal level. We reanalyzed this system with anatomical and electrophysiological techniques.

Ventral TO-injections of biotinylated dextranamine labelled a dense and bilateral network of fibers and terminals throughout the entire Rt and triangularis (T). In contrast, dorsal TO-applications always exhibited a different tracing pattern with most fibers and boutons being restricted to the T. These results, showing visual field specific projections to the Rt, are supported by data of intra-TO heterogeneities of cell- and glutamate receptor-densities: the ventral half of layer 13 had a significantly higher neuron density than the dorsal half. Concomitantly, AMPA-Glu R2/3-like cells were more numerous in the ventral TO. No AMPA Glu R1- or R4-like neurons could be detected in layer 13. Thus, dorsal and ventral TO (representing upper and lower visual fields) differ in their internal structure and their Rt-projections with glutamate being a key transmitter in this system.

In recordings from the Rt, neurons responsive to a contralateral whole-field stimulus showed robust excitatory and inhibitory responses, while ipsilateral stimuli had nearly always no effects. However, a substantial number of cell responses to a contralateral stimulus were modulated by additional ipsilateral stimuli. These binocular responses showed either facilitatory (binocular spike rate > contra + ipsi spike rate) or inhibitory interactions. Our data indicate for the first time on single unit level that rotundal cells receive binocular input with a number of cells showing complex modes of integration of these two afferents.

## 253.9

**AGE-RELATED CHANGES IN CALCIUM-BINDING PROTEINS EXPRESSION ON CHICK ACCESSORY OPTIC NUCLEUS.** C.A.B. Toledo\*,<sup>1</sup> S. Medeiros,<sup>1</sup> and L.R.G. Brito,<sup>2</sup> Dept. of Physiol. Sciences, Federal Univ. of Santa Catarina, Florianópolis, SC, and <sup>2</sup>Dept. Physiol. Biophys., Inst. Biomed. Sci., Univ. São Paulo, SP, Brazil.

Some calcium-binding proteins have been implicated in the buffering of cytosolic calcium. It is possible that this action might differ according to the age of the animal. In this study, immunocytochemical techniques were used to analyze the distribution of the calcium-binding proteins (CBP) calbindin (Calb), calretinin (CaR), and parvalbumin (PV) during aging on bird's accessory optic nucleus (nucleus of the basal optic root, nBOR). Four young (two weeks old) and four old adult (ten-twelve months) chickens (*Gallus gallus*) were perfused, the brains postfixed, cryoprotected, frozen, and cut at 30 µm in the coronal plane. Monoclonal antibodies against Calb and PV (Sigma) and an antiserum against CaR (Chemicon) were used with conventional immunoperoxidase and immunofluorescence techniques to detect and quantify those proteins. Usually, many cells with somata sizes ranging from 10 to 25 µm (PV + and CaR +) and 5 to 10 µm (Calb+) were found into nBOR. Comparing old and young birds, no differences regarding size and shape were seen. However, we detected a notable decrease of the number of cells and fibers exhibiting CBP immunoreactivity in old animals. That reduction was not observed for other immunopositive nuclei used as immunohistochemical controls. The results were consistent and observed in all of those three proteins but it appeared to be more evident for PV. These data indicate that some cytosolic process can be altered in the chick nBOR during aging and it could include metabolic changes involving CBPs.

## 253.11

**DIRECTION-SENSITIVE IPSP INPUT TO THE ACCESSORY OPTIC SYSTEM OF TURTLE.** N. Kogo\* and M. Ariel. Department of Anatomy and Neurobiology, Saint Louis Univ., St. Louis, MO 63104.

We described last year the unitary EPSP inputs to the Basal Optic Nucleus (BON) of turtle using a reduced in vitro brainstem preparation in which the retinas remained attached but many dorsal structures were removed, i.e. tectum, cerebellum and dorsal thalamus. In that preparation, we observed IPSPs on only few occasions. However, when an intact brainstem preparation is used, we find that the probability of spontaneous IPSPs in the BON cells is dramatically increased. To see the IPSPs clearly, we added QX314 to the patch pipette solution to block Na<sup>+</sup> spikes so that the membrane potential could be depolarized in the current clamp mode. Holding the membrane potential at -25 to 0 mV, large spontaneous IPSPs were regularly observed.

When the contralateral optic nerve was stimulated during this recording, a prolonged IPSP was also observed after the fast EPSP. This evoked IPSP did not follow high frequency stimulation, suggesting that it is mediated by a polysynaptic pathway. More importantly, during retinal stimulation by a moving pattern, IPSPs occurred more frequently during motion that was opposite the preferred direction of the EPSP input. When bicuculline was applied to the bath solution of the brain chamber (separate from the retinal chambers), these IPSPs disappeared and the visual response to pattern motion became entirely direction-sensitive EPSPs. During lidocaine application to the contralateral retina, spontaneous IPSPs still occur. These results suggest that brainstem dorsal structure(s) may mediate an inhibitory input to BON. Direction-sensitive responses are also found in the pretectal lentiform nucleus, making it a likely source of this inhibitory input. (NS 33190 to MA).

## 253.8

**3D-MORPHOLOGY OF INTRACELLULARLY LABELED NEURONS IN THE TECTO-FUGAL PATHWAY OF THE CHICK.** H. Luksch and H.J. Karten\*. Dept. of Neuroscience, UCSD, San Diego, La Jolla, CA, 92093.

In birds, visual information is processed by two parallel systems, the thalamofugal and the tectofugal pathway, which can be homologized with the mammalian geniculocortical and colliculo-pulvino-cortical pathways, respectively. Recent studies (Karten et al., in prep.) have shown that elements of the tectofugal pathway in the stratum griseum centrale (SGC) can be further subdivided on the basis of the termination fields in their target structure, n. rotundus: type 1 cells project to the anterior portion, whereas type 2 cells project to the posterior part of n. rotundus. In this study we analyzed the three-dimensional morphology of these neurons and additional elements of the tectofugal pathway by intracellular staining. In chick hatchlings, fluorescent beads were pressure-injected stereotactically into different nuclei of the tectofugal pathway. After survival of three days, animals were sacrificed and brains were sliced on a vibratome. Backlabeled neurons were identified with an epifluorescence microscope, impaled under visual control and filled with biocytin. Filled neurons were reconstructed with camera lucida and using confocal microscopy, and dendritic fields were measured. To determine input onto labeled cells, retinal afferents were traced using cholera-toxin B subunit.

In the SGC of the chick optic tectum, cell types defined by their connectivity have intriguing morphological differences. Type 1 is found in the superficial SGC and has very large dendritic fields (3 to 4 mm) that can cover up to one third of the tectum with distal dendrites arborizing in layer 5b; these dendrites have specialized terminal structures that contact retinal afferents. Type 2 is found in the deeper SGC and has dendritic fields of comparable width, but these dendrites never reach layer 5b. In the n. rotundus, neurons have conspicuous claw-like dendritic endings that presumably contact tectal efferents; this connection is currently being investigated. Additionally, the morphology of the small retinal ganglion cells that presumably project onto SGC-type 1 cells will be demonstrated. Our findings will be discussed in relation to the physiological characteristics of neurons of the tectofugal pathway.

Supported by NIH/NINDS (NS24560) to HJK and DFG (Lu 622/1-1).

## 253.10

**VISUALIZATION OF BASAL OPTIC TRACT TERMINALS BY ANTEROGRADE TRACERS.** J. Martin, N. Kogo and M. Ariel\*. Dept. of Anatomy & Neurobiology, Saint Louis Univ., St. Louis, MO 63104.

The present study examined the light microscopic appearance of direction-sensitive retinal ganglion cell axons terminating in the turtle's basal optic nucleus (BON). These axons were labelled by injections into the basal optic tract (BOT) that was visualized on the ventral surface of the in vitro turtle brainstem. Either biotinylated dextran amine was iontophoresed extracellularly into the BOT or neurobiotin was injected intracellularly into physiologically identified axons. After up to 16 hours for tracer transport, the brains were fixed in 4% paraformaldehyde, sectioned parasagittally at 100 µm, soaked in ABC-Triton, reacted with diaminobenzidine and counterstained.

Analysis of extracellularly filled retinal axons revealed about three times more axons just inside the BON's rostral border than at its caudal border and thick (2-4 µm) axons within 100 µm from the ventral border with thin (<2 µm) axons positioned throughout the nucleus. Of all the labelled axons, only thin axons extended caudally from the nucleus, perhaps indicating some labelling of non-BOT fibers. The intracellular filled axons were morphologically similar to the extracellular findings of size and position within the BON. All had thick main axons that run along the BON's ventral surface, from which primary branches extended obliquely within the BON. From the primary branches, smaller branches arborize to form beaded varicosities or boutons that clustered within a region of 50 µm or less. These clusters may account for areas of synaptic contact onto BON cells of specific direction preferences. (Supported by NS 33190 to MA).

## 254.1

TEMPORAL SENSITIVITY OF COLOR OPPONENT NEURONS IN HUMAN VISUAL AREAS MEASURED WITH FMRI S.A. Engel<sup>1</sup> and B.A. Wandell<sup>2</sup>, <sup>1</sup>Dept. of Psychology, UCLA, Los Angeles, CA; <sup>2</sup>Dept. of Psychology, Stanford University, Stanford CA

Primate cortex contains opponent color neurons that are excited by some wavelengths of light and inhibited by others (e.g. blue vs. yellow). Previously, we have used fMRI to detect the presence of opponent neurons by measuring the amount of stimulus contrast needed to generate a criterion response for various colored stimuli. For example, more contrast is needed to generate a criterion response to a mixture of blue and yellow than to either light alone. Here we report that the relative sensitivity of these mechanisms changes with the temporal frequency of the stimulus. Subjects viewed color contrast reversing patterns that alternated with a uniform field at 1/42 Hz. The patterns reversed at either 1 Hz, 4 Hz, or 10 Hz. Eight planes of fMRI data were acquired in the occipital lobe every three seconds (TE = 40, TR = 750, FA = 70). Responses were measured as the amplitude of the 1/42 Hz harmonic that best fit the fMRI signal. Responses were averaged within areas that were identified as V1 or V2 based on functional maps of their retinotopic organization. At low temporal frequencies (1 Hz) data from areas V1 and V2 indicate the presence of opponent color neurons. For example, more contrast is needed to produce a criterion response to a sum of blue and yellow stimuli than to either stimulus alone. At higher temporal frequencies (10 Hz) data from areas V1 and V2 mainly reflect the activity of L+M cone (luminance) neurons. Hence, the relative amount of fMRI signal arising from blue-yellow opponent neurons decreases rapidly with increasing temporal frequency. This low-pass temporal sensitivity, present in V1 and V2, resembles the results of psychophysical measurements of human opponent colors mechanisms.

## 254.3

MODULAR ARCHITECTURE OF CELLS PROJECTING FROM PRIMARY VISUAL CORTEX (V1) TO AREA MT J.D. Boyd\* & V.A. Casagrande, Depts of Cell Biology & Psychology, Vanderbilt University, Nashville, TN 37232

Within primate V1, patterns of anatomical connections form the structural bases for parcelating different types of visual information. Thus, connections differ radially between layers and tangentially between cortical modules defined by high and low cytochrome oxidase (CO) activity. CO blobs and interblobs are centered within layer IIIB and cells in these zones send projections to different compartments of area V2. Although CO periodicities that align with the CO blobs have been reported to occur in cortical layers above and below layer IIIB, consistent differences that relate to the periodicities in these other layers have not been identified. In this study we examined the tangential organization of cells in V1 projecting to area MT in the bush baby, a prosimian primate.

Injections of cholera toxin B conjugated to colloidal gold (CTB-Au) were made in four bush babies. Cortical hemispheres were either flattened and cut tangentially or blocked and cut parasagittally. Sections were reacted for CTB-Au to identify retrogradely labeled cells in V1 and/or CO to identify CO compartments and layers. A few sections were stained for myelin to verify that injections were in MT.

The main finding was that V1 cells projecting to area MT formed a patchy mosaic in which the highest concentrations of retrogradely labeled cells were located in layer IIIC (IVB of Brodmann) directly below the centers of the CO blobs in IIIB. As predicted from the work of others, MT injections also resulted in bands of labeled cells in V2 with wider center to center spacing than the clusters in V1, as well as clusters of labeled cells in area DL with similar spacing to that of V2. These findings are in agreement with some reports indicating that layer IIIC consists of at least two anatomical compartments, only one of which projects to MT. At present, the functional significance of these compartments remains to be determined. Supported by EY01778, EY03778, EY08126, AND HD15052.

## 254.5

PATCHY CONNECTIONS FROM AREA 17 TO AREA 21A COLOCALIZE WITH CYTOCHROME OXIDASE BLOBS IN CAT VISUAL CORTEX. Bevil Conway, Jamie Boyd and J. Matsubara\*, Depts Ophthalmology and Anatomy, Univ of Brit Columbia, Vancouver, B.C.

We have shown that in cat area 17, the Y- and W-cell projections from the LGN terminate in the lower and upper portions of the cytochrome oxidase (CO) blobs, respectively. We also reported that the cells projecting from area 17 to posterior medial lateral suprasylvian (PMLS) are clustered within the lower portions of the CO blobs. Together, these results suggest that a modular organization to the Y-type processing stream exists in cat area 17, and beyond into PMLS. In this study we report that another group of cells, those in area 17 that project to 21A, is also patchy and colocalizes with the upper portions of CO blobs in cat visual cortex. After tracer injections in 21A, labeled pyramidal cells in area 17 were located throughout L 2/3, but slightly denser in lower L2/upper L3 and lower L3, reflecting a bilaminar organization in the coronal plane. In flattened sections of area 17, the labeled cells were arranged in tight patches with an interpatch spacing ranging 0.5-0.9 mm. Alternate serial sections stained for CO revealed that the labeled cells were localized to the CO blobs. Since the pattern of patchy labeling arising in area 17 from injections in 21A so resembled the labeling arising after PMLS injections, we undertook double labeling studies to determine whether the same populations of cells in area 17 projected to both areas 21A and PMLS. FITC- and Texas Red-labeled dextrans were injected into 21A and PMLS, respectively, and revealed that separate populations of pyramidal cells projected to each area.

Thus, this study suggests that area 17 is organized into at least two output-defined modules that are marked by CO histochemistry and demonstrates the presence of novel forms of columnar organization that may be related to the segregation of efferent processing streams in area 17 and beyond into extrastriate visual cortex of the cat. CHROMATIC PROPERTIES OF NEURONS IN STRIATE CORTEX OF THE MACAQUE MONKEY. A. Hanazawa\*, I. Murakami, H. Komatsu, Lab. of Neural Control, Natl. Inst. for Physiol. Sci., Myodaiji, Okazaki 444, Japan.

Chromatic properties of neurons were studied in striate cortex of a macaque monkey performing a visual fixation task. Color selectivity of neurons was studied by using stimuli evenly distributed on the C.I.E. xy-diagram and was characterized with respect to summation of cone signals. Seventeen of seventy-eight neurons (22%) showed color selectivity which coincided with an assumption of linear summation (fitting to a model,  $p < 0.01$ ). Most of the other neurons were tuned to a limited extent of hue or saturation with a manner indicative of some nonlinear processing.

We found that many striate neurons have sensitivity to center-surround combination of colors or to color contrast. The responses of most neurons (20/22) to a small stimulus were suppressed by a large surrounding stimulus. Usually, such suppression was caused by the same and near colors as that of the center stimulus. In addition to this, we also observed suppression by distant colors. In some neurons, suppression was always induced by particular colors regardless of the color of the center stimulus. In other neurons, the surrounding color that induced suppression depended on the center color.

These results suggest that striate cortex plays an important role in constructing sharp tuning to the color from opponent color representation and in detecting color contrast.

Supported in part by a grant from the HFSP and by JSPS fellowship for Japanese Junior Scientists.

## 254.4

EXCITATORY AND INHIBITORY SYNAPTIC CIRCUITS OF PARALLEL PATHWAYS TO THE CO BLOBS OF PRIMATE VISUAL CORTEX. Y. Ding\*, J.D. Boyd & V.A. Casagrande, Depts of Cell Biology & Psychology, Vanderbilt University, Nashville, TN 37232-2175

The cytochrome oxidase (CO) rich blob compartments in the primary visual cortex (V1) of primates have been shown to be physiologically and anatomically distinct. These compartments within cortical layer III are unique in that they receive direct thalamic input from the koniocellular (K) lateral geniculate nucleus (LGN) pathway and indirect input via cortical layer IV from the parvocellular (P) and magnocellular (M) LGN pathways. How are these parallel streams integrated within the CO blobs? To answer this question we compared the types of synapses in owl monkeys formed by K axons labeled via injections of WGA-HRP into the LGN with synapses formed by P and M target cells in layer IV labeled via injections of PHA-L. The neurochemical content of both pre- and postsynaptic profiles were identified by postembedding immunocytochemistry for GABA and glutamate. Samples were restricted to CO blobs within cortical layer IIIB. This study demonstrates that all K axons and majority of axons from layer IV within the CO-blobs use glutamate, the major excitatory amino acid as a neurotransmitter. However, K axons and layer IV axons exhibit differences in synaptic relationships to CO blob cells. Two thirds of the K axons terminated on dendritic spines, the majority of which could be identified as glutamatergic. The remaining K axons terminated on dendritic shafts of which about half contained GABA, the major inhibitory amino acid neurotransmitter and the remaining contained glutamate. In contrast, axons from layer IV terminated mainly on dendritic shafts, slightly more than half of which were positive for glutamate. Thus, within the CO blobs the vast majority of direct K pathway axons terminate on excitatory neurons, whereas more than a third of layer IV axons (presumably providing the indirect input from the P and M pathways) terminate on inhibitory interneurons. Taken together, these results suggest that the K pathway and the P and M pathways use different strategies to contribute to the processing of visual information within layer III. Supported by EY01778, EY08126, and HD15052.

## 254.6

INVESTIGATION OF POTENTIAL CO-LOCALIZATION OF CYTOCHROME OXIDASE WITH NOS OR NMDAR1 IN MACAQUE V1 AND V2 NEURONS. B.J. Anderson\* and M.T.T. Wong-Riley, Dept. of Cellular Biology & Anatomy, Med. Coll. of Wis., Milwaukee, WI 53226.

Nitric oxide (NO) is a gaseous intra- and inter-cellular messenger in the CNS. NO production can be triggered by the activation of NMDA and other glutamate receptors. Previously, we have shown that cytochrome oxidase (C.O.)-rich non-pyramidal neurons in layers 2/3 of macaque V1 received glutamatergic synapses on their somata. The present study addressed whether neurons immunoreactive for NOS or NMDA receptor subunit 1 (NMDAR1) had high levels of C.O. activity. Macaque striate cortical sections were reacted for C.O. histochemistry followed by immunogold silver staining for NOS or NMDAR1. We found two populations of NOS-immunoreactive (ir) neurons: (a) a relatively rare population of intensely-labeled, small-to-medium sized neurons with low levels of C.O. activity; and (b) moderately-labeled neurons that varied in size, location, and C.O. levels. Medium-sized cells of the latter group had moderate to high levels of C.O. in puffs, but low to moderate levels of C.O. in interpuffs. In layer 4B, large NOS-ir non-pyramidal neurons were darkly reactive for C.O. In 4C, some, but not all, NOS-ir neurons were rich in C.O. In layers 5 and 6, C.O.-rich cells were often NOS-ir, but C.O.-poor ones could be either NOS-positive or negative. NMDAR1-ir neurons were most common in layer 2, where C.O. activity was relatively low. A few NMDAR1-ir in layers 4, 5 and 6 had moderate to high levels of C.O. In V2, NOS was heterogeneously distributed among C.O.-rich and -poor cells. In layers 3/4, cells intensely stained for NOS were again low in C.O., while cells with moderate amounts of NOS had moderate levels of C.O. However, cells darkly reactive for C.O. did not exhibit NOS-ir. Scattered neurons in layers 2, 3, and 4 were NMDAR1-ir with variable C.O. levels. Our data suggest that NOS-ir and NMDAR1-ir neurons in V1 and V2 have variable demands for oxidative metabolism. Supported by NIH R01EY05439.

## 254.7

**HUMAN BRAIN NITRIC OXIDE SYNTHASE: ISOLATION, SUBCLONING, SEQUENCING, AND IN SITU HYBRIDIZATION OF TRANSCRIPTS IN MACAQUE STRIATE CORTEX.** M. Wong-Riley\* and Z. Huang. Dept. of Cellular Biology & Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226.

We have previously shown that cytochrome oxidase-rich zones in the macaque striate cortex contained higher levels of neurochemicals related to excitatory glutamatergic synapses, such as NMDA receptors and nitric oxide synthase (NOS). As a first step to determine if the expression of NOS in the macaque visual cortex is regulated at the transcriptional level, we isolated NOS cDNAs from a human occipital cortex cDNA library by PCR, subcloned them into the plasmid pCMT<sup>TM</sup> vector (Invitrogen), and transformed into OneShot competent cells (Invitrogen). Sequence analysis confirmed that human brain NOS cDNAs were isolated. Riboprobes were generated by *in vitro* transcription, labeled with digoxigenin or with  $\alpha$ -<sup>35</sup>S-thioUTP (uridine 5'-[ $\alpha$ -<sup>35</sup>S-thio] triphosphate), and applied to monkey brain sections by *in situ* hybridization. Results indicate that NOS mRNAs were restricted to specific neurons in the primary visual cortex. Sense controls showed no labeling. Studies are underway to determine if NOS gene expressions are regulated by neuronal activity. Thus, adult primate visual neurons have the transcriptional machinery to produce NO, an important intra- and inter-cellular messenger, which is likely to play a critical role in excitatory synaptic circuitry within the striate cortex. Supported by NIH grant R01EY05439.

## 254.9

**COVERAGE OF THE VISUAL CORTEX BY NITRIC OXIDE GENERATING PROFILES.** F. Hester\*, J. Gemmill, P.R. Montague† and M.J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham and Division of Neuroscience, Baylor College of Medicine†.

Nitric Oxide (NO) has been proposed to act as a diffusible chemical messenger in the central nervous system. Endogenous cortical NO production that results from N-methyl-D-aspartate receptor (NMDAR) activation enhances the subsequent release of other neurotransmitters, including glutamate and norepinephrine (Montague, et al., *Science*, 263:973, 1994). Thus, we proposed that NO can functionally link cerebral cortical synapses. This requires substantial coverage of the cortex by NO-generating cellular processes from a small subpopulation of nitric oxide synthase (NOS) positive neurons. We have quantified the volumetric coverage of the cortex by NADPH diaphorase positive neuronal varicosities in three-dimensional space. Two adult tri-colored guinea pigs were perfused with 2% glutaraldehyde. Vibratome sections through visual cortex (area 17) were made at 100  $\mu$ m, tissue was processed for NADPH diaphorase activity, sections were post-fixed in 1% OsO<sub>4</sub>, dehydrated in 100% ethanol, embedded in Spurr's plastic (without propylene oxide) and polymerized. This procedure maintained the 3-dimensional integrity of the tissue (< 5% shrinkage in any plane). Using a 100x oil immersion objective and 3 dimensional digitizing microscope workstation, the X-Y and Z-coordinates were digitized for each NADPH diaphorase positive neuronal varicosity (n=2271 varicosities, 6 sections) in 100  $\mu$ m cubes of supragranular, granular and infragranular cortical layers. The average density is 1.1, 0.9 and 1.0  $\times 10^6$  varicosities per mm<sup>3</sup> in cortical layers 2/3, 4 and 5/6, respectively with nearest neighbor distributions of  $14.9 \pm 0.5$   $\mu$ m,  $22.2 \pm 0.8$   $\mu$ m and  $20.7 \pm 0.8$   $\mu$ m. Thus, the visual cortex is richly covered by NADPH diaphorase positive profiles suggesting the capacity for generation of a substantial NO signal in a cortical volume.

## 254.11

**RESPONSE PROPERTIES OF NEURONS IN AND NEAR PINWHEEL-CENTERS IN ORIENTATION PREFERENCE MAPS OF CAT VISUAL CORTEX.** I. Gödecke<sup>1</sup>, P.E. Maldonado<sup>2\*</sup>, C.M. Gray<sup>2</sup>, and T. Bonhoeffer<sup>1</sup>. <sup>1</sup>Max-Planck-Institut für Psychiatrie, 82152 München-Martinsried, FRG, <sup>2</sup>Center for Neuroscience, University of California, Davis, CA 95616, USA

In the mammalian visual system, optical imaging techniques have shown that neurons responding best to different orientations form highly ordered patches which are organized in a pinwheel-like fashion around "orientation centers". While these imaging techniques have the advantage of getting information about large areas of cortex they have a limited spatial resolution which is at best 100  $\mu$ m. This circumstance hinders gaining information about the detailed arrangement of neurons and their response properties which is of particular interest in some unique locations in cortical maps such as pinwheel-centers. Do neurons show reduced orientation selectivity the closer they are to the centers? Or are these centers literally singularities where adjacent neurons are precisely tuned, but to radically different orientations?

In order to answer these questions, we have employed the tetrode technique which allows accurate discrimination of individual neuronal spike trains from multiple single unit recordings. We could record up to eight different cells from the vicinity of the tetrode tip, within an estimated radius of 65  $\mu$ m. In our experiments we used intrinsic imaging to obtain orientation preference maps from area 17 and 18 in seven cats. Subsequently, tetrodes were utilized to precisely determine the response properties of single neurons in- and outside of orientation centers. These recordings revealed that neurons in pinwheel-centers are as selective for stimulus orientation as those in other locations of the cortex. The scatter of the preferred orientation, however, is markedly higher than in the rest of the cortex. In 19% of the recording sites in pinwheel centers (N=81) the largest difference in orientation preference for all cell pairs exceeded 60°, compared to 7° at recording sites outside such centers (N=76). In 8 orientation centers, we found cell pairs with orthogonal preferences (> 80°). This indicates that the orientation centers can be considered "singularities" where iso-orientation patches of all orientation preferences converge onto a single point. **THE DISTRIBUTION OF NADPH-DIAPHORASE/NITRIC OXIDE SYNTHASE (NOS) CELLS WITHIN THE LAYERS AND FUNCTIONAL COMPARTMENTS OF PRIMATE V1 AND V2.** A. E. Wiencken and V. A. Casagrande\*. Dept. of Cell Biology, Vanderbilt University, Nashville, TN 37232-2175

Nitric oxide, a proposed neurotransmitter, is speculated to be involved in a large number of neural processes. Data gathered by our lab and others have demonstrated that high levels of NADPH-diaphorase (a histochemical marker for NOS) co-localize with high cytochrome oxidase (CO) activity within the layers and functional compartments of V1 and V2 in several primate species. In V1, NADPH-diaphorase is dense within layer IV and the CO blobs in layer III, while in V2, NADPH-diaphorase activity colocalizes with the thick and thin CO stripes. Our objective was to determine which cells were responsible for NOS positive neuropil activity in the functional compartments of V1 and V2 and to further characterize these cells. We used both direct and indirect histochemical methods as well as immunocytochemistry to identify NOS containing cells and processes in V1, V2, the LGN and pulvinar of bush-babies, owl monkeys, and squirrel monkeys. CO histochemistry and Nissl staining were used to identify layers and compartments in adjacent sections. Results show that NADPH/NOS cell staining is absent from the LGN and pulvinar suggesting that NOS positive neuropil staining in V1 and V2 arises from cortical cells. Two main classes of non-pyramidal NADPH/NOS neurons can be identified in V1 and V2 of all three species; a more numerous lightly staining population with small somata, and a darkly staining population that occurs at low density. With the exception of layer IV of V1, which contains a lower density of darkly stained NADPH/NOS positive cells, no relationship was found between the distribution of NADPH/NOS cells and the dense NADPH-diaphorase positive neuropil in V1 and V2. Asymmetrical dendritic/axonal distributions of the larger, more densely labeled NADPH/NOS cells is one possible source of the cortical neuropil staining. However, the low density of the darkly labeled NADPH/NOS cells, as well as the relatively high density of the darkly stained network of axons that could be observed in the functional compartments of V1 and V2 are suggestive of another extrinsic source. ## 254.10

**ORIENTATION MAPS OF SUBJECTIVE CONTOURS IN CAT V1 AND V2.** B.R. Sheth\*, J. Sharma and M. Sur, Department of Brain and Cog. Sci. MIT, Cambridge, MA 02139.

We investigated responses to subjective contours in visual cortical areas V1 and V2 in adult cats, using optical imaging of intrinsic signals and single-unit recording. The imaging experiments demonstrate that V2 contains a map of the orientation of subjective gratings characterized by a modular representation of orientations and singularities at the intersection of orientation domains. Neurons that prefer similar subjective and luminance orientations are clustered separately from neurons that prefer different orientations, leading to an elaborate pinwheel-like representation of neurons with adjacent response preferences. V1 contains fewer neurons that respond to subjective gratings but these are also organized in modular fashion. Our single-unit studies show that many more cells in V2 (7 of 28 cells) compared to V1 (1 of 28 cells) respond to the identical orientation of luminance and subjective edges. However, many cells in V1 (9 of 28 cells) are partially responsive to subjective edges. Electrode penetrations made normal to the cortical surface reveal that most neurons in the same column respond in a similar manner to subjective contours. These data suggest that a strong response to subjective edges does not arise *de novo* in V2; instead, considerable preprocessing of the perceptual signal takes place in V1. Thus, V1 and V2 process subjective contours in tandem, via single neurons that are organized into maps specialized for the representation of subjective edges. Supported by EY07023 (MS), a McDonnell-Pew Fellowship(BRS) and a Fogarty Fellowship (JS).

## 254.12

**SEPARABILITY OF STRENGTH AND LATENCY IN THE RESPONSES OF STRIATE CORTICAL COMPLEX CELLS TO STIMULUS ORIENTATION AND CONTRAST.** T.J.Gawne\* and B.J.Richmond. Lab of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892.

Previously we showed that the response strength of complex cells is primarily a function of stimulus orientation, while the response latency is more strongly affected by the cue that defined the stimulus, e.g., contrast (Gawne et al., 1994). However, the separation of response strength to orientation and latency to contrast is not perfect, especially at low contrasts. Latency in particular is strongly affected by both orientation and contrast. We report here that the relationships between the response parameters strength and latency, and the stimulus parameters orientation and contrast, can be accurately modeled as two equations in two unknowns.

$$\text{Magnitude} = a_1 \cos(\theta) + a_2 \log_{10} \alpha + a_3 \quad (1)$$

$$\text{Latency} = b_1(2 - \log_{10} \alpha) \cos(\theta) - b_2 \log_{10} \alpha + b_3 \quad (2)$$

where *Magnitude* is in spikes/sec,  $\theta$  is the orientation angle from 0 to  $\pi$ ,  $\alpha$  is the contrast in percent, and *Latency* is in ms.

We recorded from 37 striate cortical complex cells in an awake primate that were presented with flashed, stationary bars of contrast from 5 to 94%, and of 12 evenly distributed orientations. This model accounted for  $61.2 \pm 2.3\%$  of the variance of the response strength and  $67.5 \pm 3.4\%$  of the variance of the response latency, the same accounted for by a general ANOVA model using many more parameters (23). The nervous system could make use of response latency and strength together, solving the problem of two equations in two unknowns to eliminate the problem of a less than perfect correspondence between strength and orientation, and latency and contrast. Support: IRP/NIMH/NIH.

## 254.13

**A MODEL OF SIMPLE-CELL ORIENTATION TUNING: FEEDFORWARD TUNING AND CORRELATION-BASED INTRACORTICAL CONNECTIVITY.** A.E. Krukowski\*, N.J. Priebe and K.D. Miller, Graduate Groups in Biophysics and Neuroscience, W.M. Keck Center for Integrative Neuroscience, and Department of Physiology, UCSF, San Francisco, CA 94143-0444.

We study a model 2-D sheet of layer IV simple cells in cat primary visual cortex, to determine which neuronal and synaptic characteristics and which connectivity schemes are consistent with observed functional responses. We use conductance-based integrate-and-fire models of regular-spiking (adapting) excitatory and of fast-spiking inhibitory cells, as well as four time-varying synaptic conductances (ampa, nmda, gabaA and gabaB). Inputs come from 2-D LGN sheets of ON and OFF cells, modeled as contrast-dependent filters producing instantaneous firing rates from which Poisson spike trains are generated.

We first consider tuning in the absence of intracortical connections. Gabor-shaped receptive fields with experimentally constrained aspect ratios and numbers of subfields robustly account for the sharpness of afferent orientation tuning reported by Ferster et al. (1996), who studied tuning of the 1st harmonic of voltage response to sinusoidal gratings. While we replicate these results, we also find that the mean (0th harmonic) responses are not tuned. Thus, the spike rate of simple cells receiving only feedforward geniculate input would not be well tuned, particularly at high contrast which creates high mean input levels.

Intracortical connectivity must suppress this mean input, and achieve contrast invariance in orientation tuning. We are studying schemes in which intracortical connectivity is determined by the degree of correlation between two cells, as would result from Hebb-type learning rules. Intracortical patterns of excitatory and inhibitory connectivity then have similar orientation tuning, as observed experimentally; differences primarily involve spatial phase rather than orientation. Preliminary results show that such schemes can achieve realistically tight, contrast-invariant orientation tuning. We are exploring whether other experimental constraints on an orientation model can also be satisfied.

Supported by a Howard Hughes Predoctoral Fellowship (A.E.K.), an NIH Predoctoral Training Grant GM07449 (N.J.P.) and by grants from the Whitaker Foundation, the Searle Scholars' Program and the Lucille P. Markey Charitable Trust.

## 254.15

**SPATIO-TEMPORAL PATTERNS OF SPONTANEOUS ACTIVITY AND ORIENTATION TUNING IN THE SURROUNDING OF EXCITOTOXIC LESIONS IN THE CAT VISUAL CORTEX.** G. Schweigart\*, U.T. Eysel, Dept. of Neurophysiology, Ruhr-Universität Bochum, D-44780 Bochum, Germany.

Based on the hypothesis that single cell properties in the visual cortex are dependent on the functional state and anatomical integrity of the cortical neuronal network we were interested in the intracortical spatio-temporal activity pattern following small localized excitotoxin injections.

Single cells were recorded extracellularly in the anesthetized adult cat visual cortex (area 17 and 18) with a linear array of 7 tungsten in glass electrodes with inter-electrode distances of 1 mm. Control recordings of spontaneous activity, RF maps and orientation tuning were obtained for each electrode position prior to injection of 1-2 µl 1% ibotenic acid close to one of the recording electrodes. The cats were kept at background illumination for 12 hrs and the activity was continuously measured. Thereafter RFs were remapped and orientation and direction tuning was again tested with moving light bars.

Immediately after injection the spontaneous activity at the nearest electrodes displayed short episodes of high frequency discharges followed by a complete loss of activity. At electrodes 2-3 mm away from the injection site significant increases of average activity, characteristic bursts, and transient periods of synchronization between the still active recording sites were observed. When retested between 12 and 24 hrs RF size appeared unchanged while the orientation and direction specificity was significantly reduced or abolished at electrodes with increased maintained activity close to the lesion. With increasing time post lesion a sharpening of orientation tuning and recovery of direction specificity was often observed at these sites accompanied by a significant reduction of background activity. Most interestingly the preferred orientations recorded at the very same sites before and after lesioning could display remarkable shifts.

The reappearance of specificity combined with a shift of preferred orientation in given orientation columns indicates lesion-induced cortical plasticity associated with the early phase of functional recovery. Supported by Deutsche Forschungsgemeinschaft Ey 8/23 & SFB 509 - TP C4.

## 254.17

**FUNCTIONAL MRI IN ANESTHETIZED SQUIRREL MONKEYS** Stacy S. Klinke\*, Jingna Wei, Donald Deyo and Michael J Quast Univ. Of Texas Med. Branch, Galveston, TX 77555-1143

In order to demonstrate functional brain imaging in anesthetized primates, quantitative measurements of regional cerebral blood volume (rCBV) in squirrel monkeys were calculated using contrast enhanced magnetic resonance imaging (MRI) techniques. Three female *Saimiri sciureus* monkeys were anesthetized with isoflurane in N<sub>2</sub>O/O<sub>2</sub>. Monkeys were positioned on a 6.5 cm. proton surface coil with fiber optic lights directed at both eyes for photic stimulation. High resolution multislice spin echo (SE) imaging was performed on a 4.7 T MRI system (Varian, Palo Alto, CA) before and after intravenous injection of a superparamagnetic iron oxide contrast agent (Advanced Magnetics, Inc., Cambridge, MA) during periods rest and photic stimulation. Our in plane spatial resolution of 0.23 mm/pixel was sufficient to resolve the stripe of Gennari, which had higher blood volume than other cortical layers in the primary visual cortex. The rCBV's (ml/100g tissue) from selected brain regions are reported (mean±SE):

Region	CBV (off)	CBV (on)	% change
V1 cortex	1.96±0.26	2.28±0.28	16.3
Lateral geniculate	3.08±0.48	3.57±0.52	15.9
Superior colliculus	1.72±0.31	2.07±0.28	20.4
Non-vis. thalamus	1.92±0.19	2.11±0.14	9.9

Statistically significant changes were detected in the visual cortex (p=.0171) and V1 grey matter (p=.0085) using a one-way ANOVA. Regionally specific alterations in cerebral blood volume were observed in anesthetized squirrel monkeys during visual stimulation using high resolution rCBV imaging. Supported in part by the Whitaker Foundation.

## 254.14

**THE RESTRUCTURING OF VISUAL CORTICAL ORIENTATION PREFERENCES AFTER A LESION DESCRIBED BY A LAMINAR MAP MODEL.** D.M. Gorinevski\*, F. Wörgötter<sup>1</sup>, U.T. Eysel<sup>1</sup>, W. v. Seelen<sup>2</sup> Dept. of Neurophysiol., Inst. for Neuroinformatics<sup>2</sup>, Univ. of Bochum, 44780 Bochum, Germany.

A linear model based on two continuous scalar neural fields for thalamic and cortical neural activities was developed to simulate maps of cortical orientation selectivity as revealed by optical recording of intrinsic intracortical signals in the visual system of the cat. We restricted the system to a steady state as a possible fit for the slow intrinsic imaging signals and used inhomogeneously distributed anisotropic interaction kernels to represent the functional anatomy of the thalamo-cortical and the intracortical connections. A radial basis function network was used for the approximation of stimuli, cortical signals and intracortical interactions. Under these assumptions we could reproduce the well-known parameters of cortical maps such as realistic receptive fields and point-spread functions by re-transformation of the resulting integral equation to an equivalent form with solely feed-forward interactions applying the Galerkin method. The geometrical organization of the experimentally recorded high definition maps of orientation preference and tuning strength was then approximated by the modelled interaction geometry. We have simulated the changes in the mapped preferred orientation and tuning strength induced by thermal intracortical lesion. These changes were characterized by the loss of intracortical inputs from the area destroyed by the lesion and could be modelled. Consequently, we were able to quantify the relative weights of the thalamo-cortical and the intracortical interaction components in the model.

Thereby, we introduced a quantitative decomposition of the measurable intracortical functions into these two components, which normally cannot be quantified directly because they are interacting with each other. This way, the model covers the aspect of sub- and intracortical connectivity not only in the existing orientation maps but it can also to some degree explain intracortical plasticity after lesioning.

## 254.16

**FMRI SIGNAL AMPLITUDES REPRESENT STIMULUS CONTRAST IN HUMAN VISUAL AREAS V1, V2, AND VENTRAL OCCIPITAL CORTEX.** M.R. Peters, B.J. Anderson, K.A. Williams, D.P. Miller\*, and E.A. DeYoe. Dept. of Cellular Biology and Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226. \*Div. of Psychology, Carthage College, Kenosha, WI 53140.

The human psychophysical contrast response function (CRF) is a power function with an exponent of 0.7. However, most neuronal CRFs in macaque V1 are best described as hyperbolic functions (Albrecht & Hamilton, 1982). To identify potential sites for the locus of the contrast magnitude percept, FMRI signal amplitudes from twelve levels of stimulus contrast were cross-correlated with functions representing physical and psychophysical contrast magnitudes, and functions similar to those described for neuronal CRFs.

Subjects estimated contrast magnitude at the beginning of 16 sec presentations of each of twelve sinusoidal gratings. Each grating was presented five times and followed by a 16 sec presentation of a uniform field with the same space average luminance as the gratings. Averages of FMRI signal amplitudes for gratings in ascending order of contrast were cross-correlated with: 1) log of the corresponding psychophysical estimates, 2) log of stimulus contrast and 3) hyperbolic reference functions. FMRI signal amplitudes from voxels in V1, V2 and ventral occipital cortex (lingual gyrus and along collateral sulcus) cross-correlated well with all three reference functions (>.82, p<.001). Although functions correlating best varied from voxel to voxel, clusters of voxels with high correlations were found in the same or similar locations in V1, V2 and ventral occipital cortex regardless of response function used. Correlations were not as strong outside of these areas.

Supported by NIH EY10244 (to EAD) and Chapman Foundation of Milwaukee (to MRP).

## 254.18

**CONTRAST- AND CONTEXT-DEPENDENT MODULATION OF SINGLE-CELL RESPONSES ELICITED IN CAT AREA 17 BY COMPOUND STIMULI** K. Mizobe, T. Kasamatsu\*, U. Polat and A.M. Norcia The Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115

Visuocortical cells change response magnitude when their classical receptive field (CRF) is concurrently stimulated with a second stimulus outside the CRF. The biological significance of this interaction is mostly unknown. Recently, collinear (i.e., co-axial and co-oriented) stimuli are shown to reduce the contrast detection threshold of foveally viewed targets in human psychophysics (Polat & Sagi, 1994) and to augment the amplitude of human VEPs at low contrast (Polat & Norcia, 1996).

Recording from area 17 of anesthetized and paralyzed cats, here, we studied how single cortical cells modified their responses when stimulated by contrast reversal of collinearly presented Gabor patches. A Gabor patch was optimally fitted to the CRF in isolation or together with two flanking high-contrast Gabors. The latter had either the same or different orientation as that of the center patch and was presented outside the CRF. The contrast threshold was estimated by a contrast-sweep method. We found: 1) Significant modulation, including both facilitation and suppression, of the CRF responses was obtained when the three Gabors were arranged collinearly. 2) For many cells the effect was clearly contrast-dependent, with facilitation at near-threshold contrast of the target and suppression at supra-threshold contrast. The latter may be mediated through both GABA<sub>A</sub> and GABA<sub>B</sub> receptors (Mizobe et al., Abstr. Soc. Neurosci., 21, 1995). *Elongated collinear-interaction fields* maintained by short- and long-range lateral connections may underlie perceptual grouping. Supported by SKERI and EY06579.

CONTRAST ADAPTATION EFFECTS MODELED AS THALAMOCORTICAL AND INTRACORTICAL SYNAPTIC TRANSMISSION CHANGES. D.C. Somers\*, E.V. Todorov, A.G. Siapas, and S.B. Nelson<sup>2</sup>. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA and Dept. of Biology<sup>2</sup>, Brandeis University, Waltham, MA.

Visual cortical neurons exhibit reduced responsiveness after exposure to high contrast stimuli. Several proposed adaptation mechanisms, such as cellular "fatigue" and inhibitory synaptic processes, fail experimental tests. Here, we investigated effects of activity-dependent synaptic efficacy within a cortical circuit model using analysis and simulation; transmission failure probability ("synaptic fatigue") at each thalamocortical and intracortical synapse varied with its recent average synaptic activity level. Prior to investigating adaptation effects, cortical connections were tuned as follows: orientation-selective, cortical excitation strongly amplified low contrast thalamocortical input while inhibitory inputs increased at high contrasts to yield saturating contrast response functions (CRFs). Reduction of efficacy at thalamocortical synapses was observed to shift CRFs rightward along the log contrast axis. Fatigue of intracortical excitatory synapses lowered CRF slope and inhibitory synaptic fatigue raised saturation response levels. Combination of these adaptation mechanisms into a single model yielded a contrast gain control mechanism (cf. Ohzawa et al. '85) which centered the steepest (and most sensitive) part of the CRF near the adapting contrast level for a broad range of contrasts. The synaptic fatigue model accounts for data that cellular fatigue and inhibitory pool models cannot: adaptation effects are stimulus-specific and hysteresis effects for staircase presentation of stimulus contrasts were larger than orientation hysteresis effects (cf. Bonds '91); all efficacies changed during contrast sweeps, but only cortical synapses changed during orientation sweeps. McLean & Palmer (ARVO '96) recently reported that contrast adaptation is eliminated by blockade of pre-synaptic glutamate autoreceptors. Our results are consistent with that finding; disabling changes in excitatory transmission abolished adaptation. However, best model results were obtained with fatigue of all synaptic classes. Thus, we predict that adaptation stimuli yield increased responses under blockade of glutamate autoreceptors and that saturation responses decrease under blockade of GABA autoreceptors only.

Calcium coding and computation in cortical pyramidal neurons: spike adaptation, contrast enhancement, and decorrelation. Xiao-Jing Wang\* Center for Complex Systems and Department of Physics, Brandeis University, Waltham, MA 02254, USA.

Based on data from recent dendritic recording and calcium imaging experiments, and by computer simulations of a two-compartment conductance model, we investigate the interplay between voltage-dependent electrical activity and the intracellular calcium dynamics in cortical pyramidal neurons. A main characteristic of these cells is spike adaptation when subject to a constant stimulus. The time course of spike adaptation can often be approximated by a mono-exponential law,  $f(t) = A + B \exp(-t/\tau_{\text{adapt}})$ , where  $f(t)$  is the instantaneous firing rate. By assuming that the spike adaptation is produced mainly by a calcium-dependent potassium conductance ( $g_{\text{AHP}}$ ), we derive this exponential law semi-analytically, and relate the adaptation time constant ( $\tau_{\text{adapt}}$ ) with cellular parameters such as  $g_{\text{AHP}}$  and the calcium decay time constant. By the same token, we introduce the notion of "calcium modes" when the calcium conductances are distributed over a multi-compartmental dendrite.

The spike adaptation property endows the pyramidal neurons with interesting computational functions. With our model three phenomena are demonstrated here. (1) When the input consists of a periodic train of pulses, the response of the cell is sharply tuned to the lower input frequencies, similar to the observed contrast adaptation in the visual cortical neurons. (2) If an input is random and correlated in time, the signal is decorrelated in the cell's output ("efficient coding" and "novelty detection"). (3) In the presence of two or several inputs of slightly different amplitudes, the cell can selectively respond to the strongest input and suppresses the others ("selective attention").

THE LATERAL-POSTERIOR COMPLEX: ITS INVOLVEMENT IN STIMULUS-DEPENDENT OSCILLATIONS AND ITS RELEVANCE TO THE BINDING HYPOTHESIS. S. Molotchnikoff and S. Shumikhina\* Département de sciences biologiques, Université de Montréal, C.P. 6128, succursale centre-ville, Montréal, Québec, H3C 3J7, Canada.

The lateral posterior complex (LP-P) is a vast thalamic structure which may represent an interface linking virtually all striate and extra-striate areas through afferent and efferent connecting fibers. Hence the LP-P is in a key position to influence visually evoked cortical responses. We propose that the LP-P is a major player in the neuronal computation which leads to binding several components of a single image. The general strategy is to record single cell evoked activity in the visual cortex with stimuli suitable to generate  $\gamma$ -range oscillation within their responses. In a second step the LP-P is deactivated with GABA micro-injections. Experiments are carried out on anaesthetized cats. Results are summarized as follows: 1) the LP-P cells exhibit oscillations ( $\gamma$ -range) which are tied to specific properties of the target. 2) A blockade to the LP-P results in a) a sharp decline of the cortical stimulus dependant oscillation, b) a decrease of oscillatory synchronization between two cortical sites, and c) an absence of differential responses when additional targets are introduced in the visual field. Indeed when the LP-P is depressed, the magnitude of cortical discharges remains unaffected regardless of the number of targets applied. This latter effect may be due to LP-P influences on the impact of the receptive field's periphery. The LP-P may both modulate the cortical stimulus-dependant oscillations and contribute to the formation of synchronised cellular assemblies. Supp: NSERC and FCAR

## 255.2

SYNCHRONOUS ACTIVITY BETWEEN PRIMARY VISUAL AND SENSORIMOTOR CORTEX IN THE AWAKE BEHAVING CAT. C. Chiang\*, A. von Stein, and P. König. The Neurosciences Institute, 10640 John J. Hopkins Drive, San Diego CA 92121.

Previous work in anesthetized cats has demonstrated that the brain may use temporal coding to process vision, where synchronous neural activity in visual cortex serves to bind related features of a scene into a perceptual whole. It has been proposed that such synchronicity may be a common feature to other aspects of brain function as well. However, evidence that the temporal coding scheme is relevant to actual behavior has been largely indirect (Roelfsema et al., 1995).

Here, we examined the activity of primary visual cortex (area 17) and sensorimotor association cortex (area 7) during a visuomotor paradigm in the awake cat. Cats were alternately presented with two different visual stimuli and trained to respond by either watching one (condition 1, pure vision) or by pressing a lever after seeing the other (condition 2, vision and movement required). During the task, we used intracortical electrodes to record local field potentials simultaneously in both area 17 and area 7. Cross-correlation analyses revealed that activity in area 17 and area 7 is more synchronous during condition 2 than during condition 1 (average relative modulation amplitude for slow frequency ranges =  $0.22 \pm 0.03$  for condition 2,  $0.11 \pm 0.03$  for condition 1;  $p = 0.02$ ). Also, activity in one area almost always preceded activity in the other, as the majority of these correlations did not occur with zero phase lag. In addition, for both area 17 and area 7, autocorrelogram amplitude was consistently lower in condition 2 than in condition 1 (condition 2 = 29% of condition 1 for area 17, 56% for area 7), indicating that synchronization of activity within each area was also greater during the part of the task requiring both vision and movement. Our results provide direct physiological evidence that temporal coding may be used to link the neural substrates involved in visuomotor integration. Supported by Neurosciences Research Foundation.

EXPECTANCY DRIVEN SYNCHRONIZATION BETWEEN PRIMARY VISUAL CORTEX AND PARIETAL CORTEX IN CATS. A. von Stein\*, C. Chiang, P. König. The Neurosciences Institute, 10640 John J. Hopkins Drive, San Diego CA 92121.

Findings on visual cortical interactions indicate that neurons of functional ensembles unite into synchronous patterns of activity. So far this synchronization has been shown to be stimulus-induced, reflecting stimulus-specific properties. If synchronization however is a true correlate of perception, it is not enough to show that it can be reproducibly induced by stimuli. The formation and ignition of cell ensembles should be dependent on the meaning of a stimulus, i.e. its behavioral relevance and the cat's contextual expectancy.

To determine the role of synchronization for this "top-down"-guided binding into cell ensembles, we recorded local field potentials from different cortical layers and areas in an expectancy paradigm in behaving cats. Cats were trained to attend and discriminate two different visual stimuli. They learned to respond to the one by watching it and to the other by pressing a lever after seeing. From time to time unexpected stimuli were intermingled and their response observed. We found two types of cortical responses. Strong synchronizations between different layers of one column were induced independent of stimulus type and expectancy. They had zero phase lag and expressed in the high frequency ("gamma") range, resembling the classical synchronizing response to visual stimuli. For the synchronization between areas, we found a consistent synchronization between area 17 and sensorimotor associative areas during the motor-response associated stimulus. These interareal synchronizations had their prominent peaks in the slow frequency ranges (e.g. 4-7 Hz) and showed significant phase lags indicating that the associative area might lead over the primary visual area. They seem to be higher between supragranular layers than between infragranular layers. If gamma band synchronizations were present, they had zero phase lag. Our findings indicate that the slow frequencies might play a role in long range cortical interactions. Phase lagged slow frequency synchronizations induced by the animal's expectancy might reflect the top-down driven binding of ensembles into meaningful entities. ## 255.4

SYNCHRONIZATION OF VISUAL RESPONSES BETWEEN THE CORTEX, LGN AND RETINA IN THE ANESTHETIZED CAT. M. Castelo-Branco, S. Neuenschwander, S. Herculano and W. Singer\* Max-Planck-Institut für Hirnforschung, Deutschordenstraße 46, 60528 - Frankfurt a. M., Germany.

Periodic activity is often associated with the synchronization of spatially distributed responses in the cortex. Recently, oscillatory patterning within a broad range of frequencies was described for visual responses in retinal ganglion cells which is reliably transmitted by the lateral geniculate nucleus (LGN), raising the question of how oscillatory inputs contribute to synchronous oscillatory responses in the cortex.

We have made simultaneous recordings from visual areas 17 and 18 as well as the retina and LGN to examine how the occurrence of synchronization in the cortex follows subcortical oscillatory responses. A sliding window correlation analysis was employed to evaluate the development of synchronization of oscillatory responses over time.

Strong synchronization of oscillatory activity may occur between cortical, geniculate and retinal responses, even when the receptive fields are far apart. There is, however, a marked difference between areas 17 and 18 in the incidence of correlation with geniculate and retinal ganglion cells. Twenty-two out of 63 pairs of cells between area 18 and LGN showed significant correlated activity (35%), in contrast to only 4 out of 223 LGN-A17 pairs (1.8%). A similar difference occurs between A18 and A17 and the retina: only 1 out of 22 retina-A17 pairs correlated significantly their responses (4.5%), while 8 out of 15 retina-A18 pairs showed correlated oscillatory activity (53%).

The finding that oscillatory responses in the cortex, LGN and retina are often unrelated excludes a simple feedforward mechanism for cortical synchronization. However, the observation of strong correlated activity between area 18 and the retina and LGN suggests that oscillatory input may indeed contribute to the oscillatory patterning of neuronal responses in the cortex. FAST OSCILLATIONS IN V1 OF AWAKE MONKEY: SYNCHRONIZATION DEPENDS ON CORTICAL DISTANCE, ON ANGLE BETWEEN PREFERRED ORIENTATIONS AND ON STIMULUS ORIENTATION. A. Fries, R. Eckhorn and H. J. Reitboeck\*, Neurophysics, Dept. Physics, Philipps-Univ., D-35032 Marburg, Germany.

Fast synchronized oscillations of visual neurons ( $\gamma$ -range: 30-100 Hz) have been proposed to provide a temporal label for linking different features of a visual object into a perceptual entity [Eckhorn et al. 1988, Biol. Cybernetics 60: 121-130]. In the present work we studied the coupling strength among oscillatory signals generated in pairs of spatially separate groups of neurons according to their cortical distance the angle between their preferred orientations and the respective stimulus orientations. Neural group activities were recorded as multi unit activities (MUA) and local field potentials (LFP, 1-141 Hz) from 101 positions (up to 7 electrodes in parallel) from the upper layers of V1 in an awake, fixating monkey. Pairs of recordings were classified according to their horizontal cortical distance (in steps of 0.75 mm up to 4.5 mm) and to the angle between the preferred orientations ( $0^\circ$ - $30^\circ$ ,  $30^\circ$ - $60^\circ$ ,  $60^\circ$ - $90^\circ$ ). Coupling strength of recording pairs was quantified by the peaks in the  $\gamma$ -range (i) for the coherence and (ii) for normalized cross-spectra. For comparison to overall activity we used the center peaks of cross correlograms. Visual stimuli were sinusoidal gratings (1.33 cyc/°, high luminance contrast), drifting at  $v = 1.5^\circ/\text{s}$  in 8 different directions.

We found 4 major results: 1.) LFP and MUA coherence (1-141 Hz) declined with cortical distance. 2.) Coherence of fast oscillatory components of MUA strongly depended on stimulus orientation. 3.) The low frequency components of MUA coherence did almost not depend on stimulus orientation. 4.) For a given cortical distance the highest values of coherence in the  $\gamma$ -range were found at stimulus orientations corresponding to the average (half angle) among the preferred orientations at the two recording sites. While the cross-spectra revealed qualitatively similar results the center peaks of cross-correlograms yielded only weak dependence on stimulus orientation. This indicates together with (2.) and (3.) that the stimulus specific lateral interactions are due to couplings among fast oscillatory and not among the broad-band signal components. RELATION BETWEEN OSCILLATION FREQUENCY OF THE EEG AND OF SYNCHRONOUSLY DISCHARGING CELL ASSEMBLIES. M.H.J. Munk\*, S. Herculano and W. Singer, Max-Planck-Institut für Hirnforschung, Deutschordenstraße 46, Frankfurt a.M. 60528, Germany.

Activating the mesencephalic reticular formation (MRF) in anesthetized cats desynchronizes the EEG and facilitates synchronization of distributed neuronal responses evoked by coherent light stimuli. This suggests that arousal leads to enhanced coupling among cortical neurons and increases the size of synchronously active cell ensembles. Here we investigate with multielectrode recordings from A17 and A18 of anesthetized cats putative relations between ensemble size and oscillation frequency. When the EEG is dominated by low frequencies (around 4 Hz), light responses are unreliable and show no stimulus-related synchronization of discharges. When the EEG shifts into the alpha-range (10-14 Hz), light responses become vigorous and auto-correlograms of multi-unit responses may exhibit a robust modulation in the range of 70-100 Hz, indicating that local clusters of neurons synchronized their responses in this high frequency range. Long-distance correlations in this frequency range also occur, even across the hemispheres. After MRF stimulation, when the EEG is desynchronized, the responses of local clusters of neurons engage in stable synchronous, oscillatory discharges, with frequencies lowered to the range of 30-50 Hz, and long-distance correlations become frequent. Interestingly, in the cases where the frequency range remained 80-100 Hz during MRF activation, the oscillatory modulation did not increase, although long-range synchronization could become enhanced. These results suggest that increasing the size of synchronously active cortical cell assemblies reduces the oscillatory frequency of the responses, which is compatible with theory. The high frequency oscillations seen during alpha-activity could reflect either oscillatory input from the retina that is unmasked by the lack of cortically generated oscillations, or the dynamics of local cortical micro-ensembles.

POSSIBLE CELLULAR MECHANISMS FOR AROUSAL-INDUCED HIGHER FREQUENCY OSCILLATIONS: ACETYLCHOLINE AND ACPD INDUCE REPETITIVE BURST FIRING IN VISUAL CORTICAL NEURONS. D.A. McCormick and L.G. Nowak, Section of Neurobiology, Yale Univ. Sch. Med., New Haven, CT 06510.

Arousal from slow wave sleep is associated with the abolition of slow, synchronized oscillations, such as spindle and delta waves, and the occurrence of higher frequency (20-70 Hz) oscillations in thalamocortical systems. Recordings in vivo demonstrate that these higher frequency oscillations can be associated with repetitive burst firing in unique populations of cortical neurons. Here we investigated the possibility that repetitive higher frequency burst firing may be induced by activation of cholinergic or glutamate metabotropic receptors.

Intracellular recordings from the cat or ferret primary visual cortex maintained in vitro revealed a sub-population of neurons, including layer V pyramidal cells, that generate trains of "single" spikes upon depolarization. Local application of acetylcholine, the muscarinic agonist methylcholine, or the glutamate metabotropic receptor agonist ACPD resulted in depolarization and the activation of single spike activity, followed by the generation of repetitive burst discharges with an interburst discharge frequency of 15-50 Hz. The regularity, but not the occurrence, of these burst discharges was inhibited by reducing  $[\text{Ca}^{2+}]_o$  to 0.5 mM and raising  $[\text{Mg}^{2+}]_o$  to 8 mM, suggesting that these events are not generated solely by the activation of  $\text{Ca}^{2+}$  conductances.

We suggest that the activation of a muscarinic receptors by ascending cholinergic fibers, and glutamate metabotropic receptors, perhaps from cortico-cortical interconnections, can induce repetitive burst firing in a subpopulation of cortical neurons thereby setting the stage for the generation of synchronized neuronal oscillations. Supported by NIH and NSF.

CORTICAL FEATURE-BINDING: NEURONAL OSCILLATIONS CAN OCCUR WITH MS-TIME-SCALE SYNCHRONY, DESPITE LONG AXON CONDUCTION DELAYS, WHEN INTERNEURONS FIRE SPIKE DOUBLETS. R.D. Traub\*, J.G.R. Jefferys & M.A. Whittington IBM Watson Res. Ctr., Yorktown Heights, NY 10598, University of Birmingham School of Medicine, Birmingham B15 2TT, U.K. and Imperial College School of Medicine at St. Mary's, London W2 1PG, U.K.

Synchronized neuronal oscillations in the gamma frequency band (30-70 Hz) have been implicated in feature-binding in the visual cortex, by Singer & Gray among others. Consistent with this notion, synchrony of neuronal oscillations occurs at distances at least 7 mm within a hemisphere and across the corpus callosum. The cellular mechanism of long-range synchronization is mysterious, given that axon conduction delays may be several ms or more at such distances. We propose a simple model, generalized from hippocampal and neocortical slice studies showing that interneuron networks alone can generate gamma oscillations (Whittington, Traub & Jefferys, *Nature* 373 (1995) 612-615). The model consists of a chain of interconnected cell groups with a) both tonic and fast (AMPA receptor-mediated) excitation of interneurons by pyramidal cells; b) GABA-A receptor-mediated inhibition of both pyramidal cells and interneurons; and c) axonal conduction delays are negligible within cell groups, but between neighboring cell groups can be up to 5 ms. When AMPA-receptor-mediated excitation of interneurons is sufficient to induce spike doublet firing, but not otherwise, gamma oscillations occur that are synchronized on the ms time scale, from one end of the chain to the other. Consistent with data from the Eckhorn lab, oscillations in large neuronal ensembles occur at lower frequencies than in small ensembles. Thus, known or testable properties of neurons and of local synaptic circuits can, in principle, account for gamma oscillations that are tightly synchronized over distances of many mm.

## 255.8

MODIFICATION OF DISCHARGE PATTERNS OF NEOCORTICAL NEURONES BY INDUCED OSCILLATIONS OF THE MEMBRANE POTENTIAL. M. Volgushev\*, M. Chistiakova and W. Singer Ruhr-Universität Bochum, Dept. Neurophysiology, D-44780 Bochum and Max-Planck-Institute for Brain Research, Deutschordenstr. 46, D-60528 Frankfurt/M. Germany.

Neuronal networks have the tendency to engage in oscillatory activity. Here we report that oscillatory modulation of the membrane potential by current injection affects substantially the discharge patterns of neocortical neurones in vitro. Whole-cell recordings were made from layer 2-3 pyramidal cells in slices of the rat visual cortex. Oscillations of the membrane potential were induced by injection of sine-wave currents. With injection of suprathreshold currents spikes occurred preferentially at the positive peaks of the oscillations with a phase shift that depended on the time constant of the membrane, the actual membrane potential and the amplitude of the oscillatory modulation. When paired with subthreshold modulation of the membrane potential, small EPSPs evoked discharges only during a narrow window of the oscillation cycle while large EPSPs elicited trains of spikes that were phase locked to the oscillations. The timing of responses to synaptic activation depended only little on the timing of afferent stimulation but was essentially determined by the oscillation cycle. Thus, an oscillatory modulation of the membrane potential gates transmission of synaptic input with high temporal precision, introduces variable phase-dependent delays between synaptic input and the postsynaptic response and generates precisely timed responses, the frequency of which depends on the oscillation frequency rather than on the amplitude of the synaptic event. We propose that these effects contribute to the synchronization of activity of distributed neurones.

PERCEPTION RELATED SYNCHRONIZED OSCILLATIONS IN MONKEY STRIATE CORTEX IN A BINOCULAR RIVALRY TASK. M. Kottmann and R. Eckhorn\*, Dept. Physics, Neurophysics, University Marburg, D-35032, Germany.

Recent investigations revealed that single unit spike rates in monkey visual cortex can correlate with the perceived orientation of rivaling gratings (Leopold & Logothetis 1996, *Nature* 379:549). In the present investigation we asked whether the previously observed synchronized cortical oscillations (35-80 Hz) occur also during binocular rivalry (BR) in a perception related way. BR was induced in a dichoptic view of two overlapping Gabor-gratings (width  $1.2^\circ$ , 3 cyc/°, lumin. 69 cd/m<sup>2</sup>, max. contrast 0.96, monitor frame rate 94 Hz) presented at orthogonal orientations for 400 ms (to prevent perceptual switching). While the monkey (macaca mulatta) kept his fixation ( $\pm 0.5^\circ$ ) he reported his perception by pressing a key (rewarded by juice). The overall correctness of the reports was established by changing the gratings relative contrast randomly and plotting the respective psychometric function (which proved to be similar to those of 3 human subjects). Responses of single- (SUA), multiple-units (MUA) and local field potentials (LFP, 1-140 Hz) were recorded in parallel by 7  $\mu$ -electrodes and were characterized with respect to orientation tuning, ocularity, average response power, oscillation index, and synchronization among spatially separate positions. We found perception related activity, including synchronized oscillations, in many recordings with imbalanced contrast among the gratings. With identical strength of stimulation to the left and right eye (to which the monkey reported the orientations at equal probability) many recording sites had MUA and LFP power that was significantly perception related in correspondence to the single cell results of Leopold & Logothetis. More interestingly, under these conditions oscillatory signals and especially their spatially synchronized components (cortical range: 4 mm) were significantly correlated with the perceptual responses. We conclude that synchronized oscillatory signals do not only occur specifically coupled to stimulus- and RF-properties but also to internal perceptual states without physical changes in stimulation. **OPTICAL IMAGING REVEALS PATTERNS OF BINOCULAR INTERACTION IN CAT PRIMARY VISUAL CORTEX.** Frank Sengpiel\*, Imke Gödecke\*, Colin Blakemore\* and Tobias Bonhoeffer\*. \*University Laboratory of Physiology, Oxford OX1 3PT, UK, and \*Max-Planck-Institut für Psychatrie, 82152 München-Martinsried, Germany

For most cells in cat area 17, the response to an optimally oriented drifting grating presented to one eye is tonically suppressed when an orthogonally oriented grating is shown to the other eye. Such *interocular suppression*, which might underlie binocular rivalry, probably results from intracortical inhibition (Sengpiel et al., *Vision Res.* 35, 179-195).

We used optical imaging of intrinsic signals to visualize patterns of responses in area 17 of anaesthetized paralysed cats to dichoptically presented drifting gratings. When gratings of orthogonal orientations were shown to the two eyes with simultaneous onset, activity maps did not differ significantly from those obtained by summing responses to each of the two gratings presented monocularly. In contrast, dichoptic stimulation (duration, 3.5 sec) that was preceded by 2 sec of monocular 'conditioning' presentation of one of the two gratings resulted in a response non-linearity. Compared with the monocular control response to the conditioning grating alone, the presence of the second, rivalrous grating caused not only the expected activation of regions of cortex preferring its particular orientation, but also a reduction in activity that was most pronounced in regions responding most strongly to the orientation of the first grating. Maps were similar, whether the contra- or the ipsilateral eye was stimulated first, although in the latter case facilitation and suppression elicited by stimulation of the other eye were slightly stronger.

Our data indicate that the pattern of interocular suppression generated by a particular stimulus combination mostly reflects the layout of orientation domains and to a much lesser degree the variations in ocular dominance.

**SUPPRESSIVE BINOCULAR INTERACTIONS IN THE PRIMARY VISUAL CORTEX (V1) OF INFANT RHESUS MONKEYS.** Y. Chino\*, E.L. Smith III, S. Hatta, & H. Cheng. College of Optometry, University of Houston, Houston, TX 77204-6052.

Although it has been shown that neurons in primate V1 are sensitive to interocular image disparities as early as the 6th postnatal day, little is known about the nature of early cortical binocular interactions. In this investigation, we compared binocular and monocular responses in 244 cells of 6 anesthetized and paralyzed infant rhesus monkeys ranging in age between 6 days and 16 weeks and in 239 units of 6 adult monkeys. Following the determination of a cell's optimal monocular parameters, we measured the responsiveness of individual neurons to the relative interocular spatial phase disparities of dichoptically presented sine wave gratings. The peak and mean binocular response amplitudes were compared to each cell's monocular responses. Prior to the age of 4 weeks, binocular responses were dominated by suppressive interactions even if cells were sensitive to interocular spatial phase disparities. Binocular suppression was particularly robust when orthogonally oriented gratings were employed. The results suggest that intracortical binocular suppression in V1 may contribute to the lower overall binocular response amplitudes found in infant monkeys.

**MAPPING OCULAR DOMINANCE COLUMNS IN HUMAN V1 USING FMRI.** R. S. Menon\*, S. Ogawa and K. Ugurbil. The John P. Roberts Research Institute, London, ON Canada N6A 5K8, Lucent Technologies Bell Laboratories, Murray Hill, NJ USA 07974 and Centre for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN USA 55455.

GRASS goggles (Quincy, MA) flashing at 10 Hz were used for photic stimulation, modified so that all light emitting diodes (LEDs) but one were masked out on each side. 13 normal subjects were used. Binocular stimulation ("B" state) sandwiched between periods of darkness ("D" state), was used to identify primary visual cortex. Monocular stimulation using the left ("L" state) or right ("R" state) flashing LED was used to delineate ocular dominance columns. Each of the states, B, D, L and R were typically 1 minute in duration. All fMRI experiments were performed using an in-plane resolution of 391 by 391 microns on a 4 T whole-body human imager (Varian/Siemens) (TE=30 ms, TR=50 ms, slice thickness=3 mm, Flip Angle=22° 256x256). Cross-correlation analysis (corr. coeff. >0.5) was used to identify pixels that responded to left or right eye photic input. Only the images with the alternating monocular stimulation were used for the correlation with the reference waveforms. Binocular stimulation was tested for using a simple t-test of the B minus D states. We found that in certain areas of V1, the correlation analysis detected pixels that oscillated in synchrony with the left-right stimulus paradigm. At the correlation values used, NO pixels were detected outside the brain suggesting these are not random. In addition, these pixels are found as alternating clumps of pixels along the line of Gennari visible in some of our images, suggesting that they are confined to layer 4C of V1. We note that the Blood Oxygen Level Dependent (BOLD) signal within a column does not return to zero during stimulation of the alternate eye suggesting that there are both specific and non-specific components to the fMRI maps.

**DEVELOPMENT OF FACILITATORY AND SUPPRESSIVE BINOCULAR INTERACTIONS IN THE CAT PRIMARY VISUAL CORTEX.** Tobe C.E. Freeman, Frank Sengpiel, and Colin Blakemore. SPON: Brain Research Association. University Laboratory of Physiology, Oxford OX1 3PT, U.K.

Binocular neurons in the cat's primary visual cortex (V1) generally show enhanced responses when stimulated through both eyes with optimally oriented gratings of appropriate retinal disparity. However, the response to an optimal grating in one eye is usually suppressed if an orthogonal grating is presented to the other eye (Sengpiel et al. 1995, *Vision Res.* 35:179-95). We have examined the time-course of development of both facilitatory and suppressive binocular interactions.

We recorded from V1 in kittens aged two to five weeks. For each cell, the dominant eye viewed an optimally oriented drifting grating while moving gratings of various orientations were presented intermittently to the other eye, so as to obtain an orientation tuning curve of interocular interaction. We also tested for disparity selectivity by varying interocular phase.

Interocular suppression was seen in kittens as young as two weeks of age. However, the average strength of suppression (for orthogonally oriented gratings) during the third and fourth weeks was significantly less than that observed in the adult ( $p < 0.05$ ; two-tailed *t*-test) and not until five weeks did it reach adult levels. Binocular facilitation was also observed throughout this time. Interestingly, the orientation tuning of binocular facilitation was significantly wider at three weeks than at four weeks, when it almost reached adult levels ( $p < 0.01$ ). It is likely that the maturation of binocular facilitation (as well as of monocular orientation tuning) reflects, in part, the refinement of clustered horizontal connections in V1. The modest increase in interocular suppression might depend on the strengthening of inhibitory connectivity that is less topographically specific and is present surprisingly early.

**OPTIMIZATION PRINCIPLES FOR CORTICAL MAPPINGS: OCULAR DOMINANCE COLUMNS.** G.J. Goodhill\*. Sloan Center for Theoretical Neurobiology, The Salk Institute, La Jolla, CA 92037.

A common intuitive principle for understanding the structure of cortical maps is that "similar features are represented nearby in the cortex". Particular mathematical versions of this principle are implemented in certain self-organizing algorithms. However, these algorithms embody only a small subset of possible assumptions regarding the measurement of feature similarity, closeness in the cortex, and the degree of topography of a mapping. For instance, in models that assume that features can be represented by points in a low-dimensional space, it is not possible to independently vary the similarity between each pair of features. Such assumptions are generally made for computational convenience rather than biological relevance.

An alternative approach is to first choose measures of similarity, closeness and topographic match, and then optimize directly using techniques such as simulated annealing. This permits investigation of the consequences of a wider variety of assumptions. I explore this approach for the simple case of the ocular dominance column map in primary visual cortex. Recent theoretical (Goodhill, *Biol. Cybern.* 69:109 (1993)) and experimental (Löwel, *J. Neurosci.*, 14:7451 (1994)) work suggests that the strength of between-eye correlations partly determines ocular dominance column periodicity in the cat. Here I use an optimization framework to investigate the influence on periodicity of other parameters that govern the correlational structure of visual stimulation.

**FUNCTIONAL EYE DOMINANCE DOMAINS IN V1 OF SPECIES LACKING ANATOMICAL SEGREGATION OF LGN AFFERENTS.** J.D. Pettigrew\*, A.W. Roet, and K. Fritsches. Vision Touch and Hearing Research Centre, Univ. of Queensland, 4072, Australia. †Section in Neurobiology, Yale Univ. School of Medicine, New Haven, CT.

It is known that abnormal visual experience during postnatal development can change V1 ocular dominance column organization, even in its spatial period and form (1,2,3). Altered visual experience during development can also induce the formation of ocular dominance domains in species which normally lack clear anatomical segregation, such as marmosets, squirrel monkeys, owl monkeys, sheep, owls, and flying foxes. We now examine the possibility that visual experience can dynamically modulate ocular dominance patterns in such animals.

We have investigated this possibility using optical imaging and electrophysiology in species normally lacking anatomical segregation of LGN afferents in layer IV of V1 (the flying fox and the marmoset monkey). Anesthetized, paralyzed animals were presented with visual stimuli of varying orientations in different sequences and periods of ocular stimulation. Functional segregation of ocular dominance domains were examined in relation to the parameters of interocular stimulation. Their relation to the observed orientation and direction selective domains were also examined. Preliminary evidence indicates that certain visual stimulation paradigms can lead to functional segregation of ocular dominance domains and that these domains exhibit variable periodicity. These results suggest some constraints in the underlying pattern of segregation, whether this develops normally or whether it is induced. 1. Löwel, *J. Neurosci* 14:7451-7468, 1994. 2. MOTION-STEREO INTEGRATION AND THE PULFRICH-LIKE PHENOMENON. N. Qian\* and R. A. Andersen. Center for Neurobiology and Behavior, Columbia University, 722 W. 168th St., New York, NY 10032; Division of Biology (216-76), Caltech, Pasadena, CA 91125.

Many psychophysical and physiological experiments indicate that visual motion analysis and stereoscopic depth perception are processed together in the brain. However, little computational effort has been devoted to combining these two visual modalities into a common framework based on physiological mechanisms. We propose such an integrated model in this presentation. We have previously developed a physiologically realistic model for binocular disparity computation (Qian, 1994, *Neural Computation*, 6:390-404). Here we demonstrate that under the general assumptions that V1 cells are well tuned to spatiotemporal frequencies and there exists a phase difference (and/or positional shift) between the left and right receptive fields of a binocular cell, our stereo vision model can be combined naturally with motion energy models to achieve motion-stereo integration. As an application of the model, we show that it gives a unified explanation of the classical Pulfrich depth illusion and its more recent generalizations to dynamic noise patterns and stroboscopic stimuli. In these illusions, one sees depth in a physically flat spatiotemporal stimulus when a neutral density filter is placed in front of one of the two eyes. The filter is known to create a temporal delay in the neuronal responses of the covered pathway. Unlike previous explanations, our model can account for different variants of the Pulfrich effect without introducing any *ad hoc* assumptions. Central to our explanation is our demonstration that model cells with the general physiological properties of real visual cortical cells treat a temporal delay as an equivalent binocular disparity regardless of whether the spatiotemporal stimulus contains coherent motion or not.

## 255.19

MODELS OF APPARENT MOTION AT THE SINGLE NEURON LEVEL - COMPARISONS TO VISUAL CORTEX NEURONS. C.L. Baker Jr.\* McGill Vision Research Unit, Dept. of Ophthalmology, McGill University, Montreal, Canada.

Many standard models of motion detection use a linear combination of responses of spatiotemporally band-pass filters with spatial and temporal offsets. Such quasi-linear models can account for some aspects of directional sinusoidal grating and reverse-correlation measurements in visual cortex neurons.

Direction selectivity in single cortical neurons can also be obtained with "apparent motion" of a bar-shaped stimulus presented in each of two successive spatial positions, separated by a stimulus onset asynchrony (SOA) and a spatial displacement. The band-pass spatial filtering of standard quasi-linear models correctly predicts a cyclical dependence on displacement, with a reversal of preferred direction for displacements larger than about half the period (Baker & Cynader, 1986).

However the dependence of a neuron's direction selectivity on SOA does not generally show a similar cyclical variation or reversal for large SOA values (Baker & Cynader, 1988). This lack of temporal reversal is very difficult to reconcile in a general way with quasi-linear models in which the temporal filtering is entirely band-pass, but is predicted by models which nonlinearly combine temporally low-pass (sustained) with temporally band-pass (transient) filters. The latter temporal signals might arise from lagged and non-lagged cells of the lateral geniculate nucleus (Saul & Humphrey, 1992).

## 255.18

## DETECTION OF FIRST AND SECOND ORDER MOTION

A. Grunewald\* and H. Neumann, Division of Biology, California Institute of Technology and Abteilung Neuroinformatik, University of Ulm.

Psychophysical studies suggest that there are different mechanisms for detection of first and second order motion. Recent physiological evidence suggests that simple cells in area 17 of the cat respond to first order motion, but not to second order motion, while complex cells respond to both types of motion (Zhou & Baker, 1993). Simple cells are phase sensitive, while complex cells are not. Does phase sensitivity explain ability to detect first or second order motion? We developed a neural model of motion detection that accounts for both types of motion detection. ON and OFF channels independently process contrast information. Simple cells are phase sensitive because they receive ON and OFF inputs at different spatial regions. Responses are sharpened through interactions between cells tuned to opposite phases. Complex cells are phase insensitive because they receive ON and OFF input at the same spatial regions. Responses are sharpened through feedforward center-surround interactions. Complex cells inhibit simple cells, thus sharpening their direction selectivity. Simple cells respond to first order motion, but not to second order motion through their phase sensitivity. Complex cells respond to any changes in ON or OFF responses. Thus they respond to first and second order motion. The model also shows that a reversal of contrast polarity in apparent motion does not imply separate ON and OFF motion detection (Wehrhahn & Rapp, 1992).

## 255.20

RECONSTRUCTION OF MOTION TRAJECTORIES FROM THE DYNAMIC POPULATION REPRESENTATION OF NEURONS IN CAT VISUAL CORTEX. D. Jancke\*, A.C. Akhavan, W. Erhagen, G. Schöner, H.R. Dinse, Institut f. Neuroinformatik, Theoret. Biol. Ruhr-Univ. Bochum RUB, Germany and Centre de Recherche en Neurosciences Cognitives, CNRS, Marseille, France.

The representation of moving stimuli in primary visual cortex has been subject of many studies of individual cells and their spatio-temporal receptive field structure. Tuning to movement parameters such as velocity and movement direction has been observed. However, it has been impossible to reconstruct from individual cell responses the cortical representation of moving stimuli, and thus to link spatial information and movement information. This is important, however, in order to assess the influence of cooperative interactions on the representation of moving stimuli.

We have estimated the representation of a moving stimulus, a square of light (0.4 degrees) moving at various velocities (4.4, 8.8, 15, or 42 degrees/sec) by populations of neurons (extra-cellular recordings in adult anesthetized cat, foveal representation in primary visual cortex). The receptive fields of single cells were first measured to determine the retinal location represented by each neuron. The responses of all neurons to a moving stimulus (presented for all neurons at identical retinal coordinates independent of their RF locations) were analyzed in short time slices and represented as levels of activation on the retinal space, with each neuron contributing at the location of its RF center. The peak of this time-dependent population representation can be tracked and directly compared to the stimulus motion on the retina.

We found that the population response follows the stimulus on the retina with a velocity dependent delay. At 8.8 deg/sec the peak position in the population representation closely matches the current position of the stimulus with near zero delay. For faster speeds a phase lag, for slower speeds a phase advance is observed. We interpret this finding as evidence for contributions of dynamic cooperativity to the representation of moving stimuli in primary visual cortex.

## AUDITORY SYSTEMS: CENTRAL PHYSIOLOGY—BRAINSTEM

## 256.1

COMPARISON OF ACOUSTIC RESPONSE PROPERTIES OF UNITS RECORDED INTRACELLULARLY AND EXTRACELLULARLY FROM DORSAL COCHLEAR NUCLEUS (DCN) OF UNANESTHETIZED DECEREBRATE GERBILS (*Meriones unguiculatus*). J. Ding, A.M. Berglund, and H.F. Voigt\* Dept. of Biomedical Engineering, Boston University, Boston, MA 02215-2407, and \*Dept. of Otolaryngology, Harvard Medical School, Boston, MA 02114-3096.

The gerbil DCN is a complex laminated neural structure, consisting of many cell types with diverse responses to acoustic stimulation. In an effort to associate response properties with cell morphology, we have been conducting intracellular recording and marking experiments on unanesthetized decerebrate gerbils using sharp glass electrodes. In this study, the effects of electrode impalement on the response properties of DCN units were investigated. To do so, various response measures of units recorded intracellularly were compared with those recorded extracellularly using the same type of recording electrodes. Only intracellular units with resting membrane potentials < -50 mV and action potentials > 40 mV were included. Units were classified according to the response map scheme. Forty three (43) intracellular units (9 type I/III, 9 type II, 25 type III) were compared with 87 extracellular units (19 type I/III, 10 type II, 58 type III). Type II units have significantly weakened acoustic responses when recorded intracellularly. Their mean thresholds to best frequency (BF) tone bursts and to broadband noise were increased by 40-50% and the mean maximum BF- and noise-driven rates were decreased by nearly 60%. Intracellularly recorded type I/III units have significantly lower maximum BF-driven rates. The only significant difference for type III units is an enhanced noise response when recorded intracellularly. These results suggest that the intracellular microelectrode affects these various unit types differently. Weaker acoustic responses most likely result from membrane disruption, but heightened responses may be related to chloride-channel interference by the KCl recording solution.

## 256.2

NEURONAL CONTROL OF TRANSCRIPTION OF A SYNAPTIC TRANSPORTER, GLYT2, IN THE DORSAL COCHLEAR NUCLEUS OF RAT EVOKED BY CHANGES IN AUDITORY PRIMARY AFFERENT ACTIVITY. N.H. Barmack\* and H.-Y. Qian. R.S. Dow Neurol. Sci. Inst., Portland, OR 97209.

Synaptic transporters, found in both neurons and neuroglia, provide a mechanism for the termination of the action of synaptic transmitters by removing the transmitters from the synaptic cleft. However, it is possible that neuronally-expressed transporters, could themselves be regulated by neuronal activity. Such a mechanism could adjust the discharge rate of a postsynaptic neuron around an optimal operating point over a period of hours. The regulation of transporter transcription by neuronal activity was investigated in the present experiment.

Neurons within the dorsal cochlear nucleus (DCN) of the rat express both the neurotransmitter, glycine, and a synaptic transporter, GLYT2. The DCN receives its major afferent input from the auditory nerve. We have manipulated the activity in this nerve by: 1) Cutting the nerve, 2) Detaching the middle ear bones from the tympanic membrane, thereby preventing spontaneous acoustic stimulation, and 3) Selectively stimulating the intact auditory system with pure tones (10 kHz and 40 kHz; 80-90db). Forty-eight hours after each of these procedures was performed, the rats were anesthetized, the brainstem was removed and prepared for hybridization with an oligonucleotide probe that was inverse complementary to the cDNA sequence 1978-2012 of rat GLYT2.

Cutting the auditory nerve or removing the ossicular chain caused a reduction in the level of GLYT mRNA in the ipsilateral DCN relative to the contralateral DCN. This reduction was greater in the deeper layer of the DCN. Conversely, stimulation for 24-48 hours with 10 kHz or 40 kHz signals, caused spatially discrete increases in GLYT2 mRNA that matched locations within the DCN predicted on the basis of the tonotopic map of the DCN. These data provide evidence for neuronal regulation of GLYT2. Abnormal neuronal regulation of GLYT2 might account, in part, for symptoms associated with tinnitus. Supported by NIDCD DC02557.

## 256.3

CALCIUM SIGNALING IN DENDRITES OF DORSAL COCHLEAR NUCLEUS NEURONS. S.C. Molitor\* and P.B. Manis. Otolaryngology-HNS, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

To understand the calcium dynamics associated with activity in dorsal cochlear nucleus (DCN) neurons, we studied the temporal and spatial properties of calcium transients elicited by somatically initiated action potentials in pyramidal and cartwheel cells. Thin brain slices, 200-250  $\mu$ m thick, were prepared from P13-P18 rat pups. Whole-cell voltage- and current-clamp recordings were made from selected cells using electrode solutions supplemented with the calcium indicators Calcium Green-1 (150  $\mu$ M) or Fluo-3 (250  $\mu$ M). Fluorescence images of the proximal dendritic arbors were sampled while performing physiological manipulations.

In pyramidal cells, calcium transients could be evoked by single action potentials, and summated when trains of 2-16 action potentials were elicited. Action potentials evoked calcium transients in primary, secondary and tertiary dendrites; in general the fractional fluorescence change increased with distance from the soma. The amplitude of the fluorescence signals became smaller with distance from the soma when the soma was voltage-clamped with an action potential in the presence of TTX, indicating that the depolarization from the action potential actively propagated into the dendritic tree.

Cartwheel cells generate bursts of action potentials superimposed upon a slow depolarization. Individual bursts generated large fractional changes in the fluorescence signal which could be measured over all of the visible portions of the dendritic tree. Preliminary evidence suggests that the fractional change in fluorescence at dendritic branch points can be larger than in nearby regions of the unbranched dendrite.

Somatically generated action potentials produce increases in calcium levels in the proximal dendrites of DCN pyramidal and cartwheel cells. One effect of such changes in free calcium levels would be to communicate the ongoing activity of the cell, wherever initiated, throughout the dendritic tree.

## 256.5

PROPERTIES OF A LOW-THRESHOLD POTASSIUM CURRENT IN VENTRAL COCHLEAR NUCLEUS NEURONS. J.S. Rothman and P.B. Manis\*, Otolaryngology-HNS, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

A low-threshold potassium current, which is present in a subpopulation of ventral cochlear nucleus neurons and activates at potentials below -50 mV, was investigated in terms of activation and inactivation kinetics, as well as 4-aminopyridine (4AP) sensitivity. In these experiments whole-cell voltage-clamp recordings were taken from acutely isolated ventral cochlear nucleus neurons of pigmented guinea pigs. All currents were measured in the presence of TTX and 10  $\mu$ M cadmium.

4AP sensitivity was measured by computing the change in slope conductance at the knee of current activation as a function of drug concentration (0.01-4.0 mM). The dose response curve was then fitted with a Hill equation, giving an estimate for  $K_i$  of 75  $\mu$ M.

Activation kinetics were investigated by hyperpolarizing cells to potentials near -100 mV and then stepping to potentials near -50 mV. Under these conditions, currents showed sigmoidal-rise kinetics and were best fit with an exponential function ( $\tau = 4.18 \pm 0.75$  msec) raised to a power of  $2.3 \pm 0.3$ .

In a number of cells, the low-threshold potassium current also showed voltage-dependent inactivation, where inactivation was always incomplete. The magnitude of the low-threshold current measured near -50 mV varied depending on the size of a 100 msec prepulse; larger hyperpolarizing prepulses elicited larger currents at -50 mV. Steady-state current-voltage relationships as a function of prepulse potential were fit to a Boltzmann equation. Results show an average half-inactivation voltage of -65 mV and an equivalent gating charge in the range 1.5 to 2.8. The non-inactivating portion of the current ranged from 40 to 70% of the current that could be elicited by a -110 mV prepulse.

Supported by NIDCD grant P60 DC00979.

## 256.7

INTRINSIC MEMBRANE PROPERTIES AND FIRING CHARACTERISTICS OF NEURONS IN THE VENTRAL NUCLEUS OF THE LATERAL LEMNISCUS STUDIED IN RAT BRAIN SLICE. S.H. Wu\*, Laboratory of Sensory Neuroscience, Institute of Neuroscience, Carleton Univ., Ottawa, Canada K1S 5B6.

The ventral nucleus of the lateral lemniscus (VNLL) is a distinct group of neurons in the lateral lemniscus. The VNLL receives inputs mainly from the contralateral ventral cochlear nucleus and contains a variety of morphological cell types. It has been shown that the VNLL not only gives rise a set of parallel pathways to the auditory midbrain, it is also important for analyzing and encoding of auditory temporal information. In this study we have examined the membrane properties and discharge pattern of VNLL neurons in a rat brain slice preparation. Brain slices (400  $\mu$ m) were taken through the VNLL of young albino rats (18-37 days old) and were maintained in a small chamber perfused with warm oxygenated saline solution. Intracellular recordings were made with 4 M potassium acetate filled glass micropipettes inserted into the VNLL under direct visual control. Responses to an intracellularly injected current pulse showed that cells in the VNLL can be classified into two groups. One cell type was characterized by nonlinear current-voltage relationships and suprathreshold depolarization elicited only one action potential. The other cell type was characterized by a roughly linear current-voltage relationship and generated multiple action potentials with either a single fast after hyperpolarization (AHP) or a two-component AHP (fast and slow) in the suprathreshold range. The discharge rate of most cells was constant for the duration of the current pulse (60-100 ms), but some cells showed accommodation. Steady-state hyperpolarization of VNLL neurons could change their response to a subsequent depolarization, resulting in a longer latency to the first spike or a longer first interspike interval. These results suggest that the intrinsic membrane conductances of VNLL neurons may contribute to the generation of the temporal firing patterns observed in response to acoustic stimuli *in vivo*. ## 256.4

A POSSIBLE VENTRAL COCHLEAR NUCLEUS (VCN) SOURCE OF INHIBITION UPON T-STELLATE CELLS. M.J. Ferragamo\*, N.L. Golding and D. Oertel, Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53706

To examine interconnections which underlie responses to acoustic stimuli of stellate cells *in vivo*, we explored responses to shocks of the auditory nerve with intracellular recordings from anatomically identified cells in parasagittal slices of the murine cochlear nucleus. Stimulation of the auditory nerve evoked not only early excitation as previously reported (Oertel et al., 1990), but also a long train of inhibitory postsynaptic potentials (IPSPs). Trains of IPSPs lasted tens to hundreds of milliseconds. IPSPs were more consistent when the nerve was stimulated repetitively (100 ms duration, 100 Hz), when  $Mg^{+2}$  was removed or with addition of 10  $\mu$ M bicuculline. Strychnine (1  $\mu$ M) abolished IPSPs revealing them to be glycinergic. Amino-5-phosphono-valeric acid (APV; 100  $\mu$ M), an NMDA receptor antagonist, also blocked IPSP trains, indicating that NMDA receptors contribute to driving the neurons responsible for the late, long duration inhibition observed in t-stellate cells. IPSP trains were observed in isolated VCN slices, indicating that inhibitory interneurons lie in the VCN.

In VCN interneurons, located just below the granule cell layer at the DCN border, auditory nerve stimulation evoked late, long duration (tens to hundreds of milliseconds) depolarizations which often resulted in trains of spikes whose timing resembled that of the trains of IPSPs in t-stellate cells. Late depolarizations were enhanced by either stimulus trains or  $Mg^{+2}$  removal, were blocked by APV, and were voltage dependent. These cells have long dendrites and an extensive local axonal arborization which are both organized across the tonotopic axis of the VCN. We speculate that this input may be imposing wide inhibitory side bands upon choppers observed *in vivo* (Rhode and Smith, 1986). (Supported by NIH grant DC00176)

## 256.6

EFFECTS OF SYNCHRONOUS DEPOLARIZATION ON GLYCINE-INDUCED CURRENTS IN DEVELOPING RAT AUDITORY BRAINSTEM NEURONS. K.H. Backus\* and E. Friauf, <sup>1</sup>Dept. Gen. Zool., Univ. Kaiserslautern, 67653 Kaiserslautern, <sup>2</sup>Center Physiol., Univ. Frankfurt, 60590 Frankfurt, Germany.

The maturation of both excitatory and inhibitory synaptic connections in the auditory brainstem appears to be activity-dependent. Whereas several mechanisms for the development of excitatory synapses have been proposed, there is, at present, no conclusive concept for inhibitory synapses. Interestingly, the reversal potential of inhibitory synapses changes considerably during development, possibly due to a change of the  $Cl^-$  equilibrium potential towards more negative values. This results in a parallel shift from depolarizing to hyperpolarizing transmitter action. Thus, inhibitory synapses may stabilize through a similar mechanism as excitatory synapses do. In order to investigate possible effects of synchronous depolarizing activity on glycine-induced currents, we applied the perforated patch-clamp technique to neurons in acute brainstem slices of young rats. We used gramicidin as the membrane-perforating agent, which allowed the recording of whole-cell currents without impairing the intracellular  $Cl^-$  concentration. At a holding potential of -60 mV, glycine application (0.1-1 mM) induced current responses which reversed between -70 and -40 mV. When depolarizing pulse trains were applied in the presence of glycine, attempted to simulate coincident excitatory inputs, the reversal potential of the glycine-induced currents shifted in the positive direction. We conclude that the simultaneous activation of glycine receptors and excitatory input may cooperatively drive  $Cl^-$  into the neurons and consequently lead to an acute positive shift of the  $Cl^-$  equilibrium potential, thus resulting in a pronounced depolarization when glycine is subsequently released. The context-dependent shift of the  $Cl^-$  gradient could acutely assist in the specific strengthening of glycinergic synapses. Supported by the DFG (SFB 269).

## 256.8

ELECTROPHYSIOLOGICAL PROPERTY OF OLIVOCOCHLEAR NEURONS IDENTIFIED BY VITAL STAINING IN THE RAT. KIYOHIO FUJINO\*, KONOMI KOYANO, and HARUNORI OHMORI, Dept. of Physiol. and <sup>2</sup>Otolaryngol., Fac. of Med., Kyoto Univ., Kyoto 606-01, JAPAN.

Membrane properties of cochlear efferent (olivocochlear; OC) neurons of the rat (postnatal day 5-11) were investigated using whole-cell patch clamp method in slice preparation. OC neurons were retrogradely labeled with Texas Red injected into the cochlea, and alive neurons were clearly identified under a fluorescent microscope during experiment. Two groups of lateral and medial OC neurons (LOC, MOC) demonstrated distinct membrane properties. In current clamp experiments, both neurons showed tonic firing pattern in response to the depolarizing current pulses. However LOC neurons had a longer first spike latency than that of MOC neurons. The latency became longer when the membrane potential was hyperpolarized, and became shorter when the membrane potential was depolarized or 4-AP was applied extracellularly. In voltage clamp experiments, transient outward currents were observed in both groups of the neurons. LOC neurons had two components of the currents; fast inactivating current ( $I_h$ ) with inactivation time constant ( $\tau_h$ ) of 70-120 ms, and slow inactivating current ( $I_{kd}$ ) with  $\tau_h$  of 500-2000 ms, while MOC neurons had only the fast inactivating current ( $I_h$ ) with  $\tau_h$  of 20-60 ms. The half inactivating potentials ( $V_{1/2}$ ) of these currents were; -34.8 mV for  $I_h$  LOC, -38.5 mV for  $I_{kd}$  LOC, and -75.0 mV for  $I_h$  MOC. The  $I_h$  of both neurons were sensitive to 4-AP, and the  $I_{kd}$  of LOC was sensitive to TEA. The difference in the expression of these currents should be responsible for the difference in firing properties of these neurons. (Supported by a grant in aid from Japanese ministry of education to K.K. (07680892).)

## 256.9

**INTRINSIC MEMBRANE PROPERTIES SUPPORT THE "CHOPPER" FIRING PATTERN: AN IN VITRO STUDY OF THE LATERAL SUPERIOR OLIVE (LSO).** T.J. Adam\*, D.W.F. Schwarz, and P.G. Finlayson. Rotary Hearing Center, Dept. of Surgery (ENT), Univ. of British Columbia, Vancouver, B.C., Canada. V6T 2B5.

The "chopper" response pattern is characterized in vivo by a precise first spike latency and subsequent regular firing. We investigated intrinsic membrane properties that support this pattern, recorded intracellularly from LSO neurons in rat brainstem slices. Injection of depolarizing current pulses (200 ms) led to regular firing with precise ( $\pm 0.1$  ms) first spike latency. Firing rate and the precision of spike timing increased, and latency decreased, with current strength. There was a linear rate-current relationship. Rate accommodation, observed during the pulse, was more pronounced with stronger depolarizations. At subthreshold levels we observed a depolarizing hump preceding a plateau with rectifying properties attributed to voltage activated and  $\text{Ca}^{2+}$ -dependent  $\text{K}^{+}$  conductances. The hump was resistant to application of tetrodotoxin ( $0.6 \mu\text{M}$ ) and persisted in  $\text{Ca}^{2+}$ -free extracellular solution containing the  $\text{Ca}^{2+}$  channel blocker  $\text{Co}^{2+}$  ( $50 \mu\text{M}$ ). It is, therefore, probably not caused by the activation of an inward current. Nevertheless, the threshold for firing of the first spike was always reached during the hump which contributes to the exceptional latency precision of LSO neurons. Application of  $\text{Ca}^{2+}$  channel blockers in  $\text{Ca}^{2+}$ -free media, and of the  $\text{K}^{+}$  channel blockers 4AP ( $50 \mu\text{M}$  to  $2 \text{ mM}$ ) and TEA ( $1$  to  $20 \text{ mM}$ ), indicated the contribution of several  $\text{K}^{+}$  conductances to spike repolarization and afterhyperpolarization which also caused the regularity and accommodation of firing. These results indicate that the "chopper" pattern is largely caused by intrinsic properties of LSO neurons that do not depend on synaptic inputs.

**SOUND CONDITIONING ENHANCES RESPONSES AND PERIPHERAL EFFECTS OF OLIVOCOCHLEAR NEURONS.** S.G. Kujawa, M.C. Brown\* and M.C. Liberman. Dept. of Otolaryngology & Laryngology, Harvard Medical School and Eaton-Peabody Laboratory, Massachusetts Eye & Ear Infirmary, Boston, MA 02114.

Sound conditioning by repeated exposure to moderate-level noise reduces damage from subsequent high-level exposure and enhances cochlear distortion product otoacoustic emissions (DPOAEs) and compound action potentials (e.g., Kujawa and Liberman, Abstr. ARO XIXth Mtg., 1996). The mechanisms underlying these conditioning-related phenomena are unknown; however, the olivocochlear (OC) system has been implicated in similar protective effects (Zheng et al., Abstr. ARO XIXth Mtg., 1996). In the present experiments, we investigated the behavior of the OC pathway in sound conditioned animals. Guinea pigs were conditioned by exposure to noise (2-4 kHz band, 85 dB SPL, 6hr on/18hr off, for 10 consecutive days). Five days after exposure, conditioned animals and untreated controls were tested via DPOAE-based assays of sound-evoked OC effects in the cochlea (Liberman et al., J. Acoust. Soc. Am., in press) or via direct measurement of the responses of single OC neurons. The DPOAE-based assays showed increased OC-mediated effects on cochlear output in conditioned animals. Single OC neuron responses to moderate- and high-level sound (monaurally or binaurally presented) also were enhanced in conditioned animals, although thresholds and spontaneous rates did not differ significantly from controls. Results suggest that sound conditioning strengthens the OC reflex by enhancing the responsiveness of OC neurons. This reflex enhancement may contribute to sound conditioning-related protection from acoustic overexposure.

## 256.13

**BILATERAL COCHLEAR ABLATION ALTERS SYNAPTIC EFFICACY IN DEVELOPING GERBIL LSO NEURONS.** V.C. Kotak\* and D.H. Sanes. Center for Neural Science, New York University, NY, NY, 10003.

Functional denervation of inhibitory or excitatory transmission by unilateral cochlear ablation clearly alters synaptic transmission at developing gerbil lateral superior olivary (LSO) neurons (Kotak & Sanes, J Neurosci, 16:1836, 1996; ARO Abstr. 19:474, 1996). In this study, we assessed synaptic function following simultaneous inhibitory and excitatory denervation before hearing onset. Bilateral cochlear ablations were performed at P7 (under hypothermia) to decrease spontaneous glutamatergic and glycinergic transmission at LSO. Whole-cell voltage-clamp recordings were then obtained from LSO in brain slices from control and manipulated animals at P10-13. Evoked excitatory and inhibitory postsynaptic currents (EPSCs & IPSCs) were obtained at  $-55 \text{ mV}$  with QX-314 and cesium in the pipet solution. To assess the efficacy of the remaining afferents to LSO, minimum amplitude EPSCs & IPSCs were analyzed. Since EPSCs and most IPSCs were inward, they were differentially characterized by their reversal potential ( $E_{\text{EPSC}} \sim 0 \text{ mV}$ ,  $E_{\text{IPSC}} \sim -30 \text{ mV}$ ;  $n=16$ ). The average minimum EPSC amplitude ( $\pm \text{SEM}$ ) was significantly reduced in manipulated neurons compared to controls ( $-7.3 \pm 0.9 \text{ pA}$  vs.  $-10.2 \pm 0.9 \text{ pA}$ ;  $t=2.1$ ;  $df=20$ ;  $p=0.04$ ). Similarly, the average minimum IPSC amplitude was significantly smaller in neurons from ablated animals, compared to controls ( $-6 \pm 1 \text{ pA}$  vs.  $-10.1 \pm 0.9 \text{ pA}$ ;  $t=2.98$ ;  $df=19$ ;  $p=0.007$ ). In contrast, preliminary recordings indicate that NMDA receptor-mediated synaptic currents are more prominent in neurons from ablated animals, as assessed with AP-5. These results suggest that while afferents may die or weaken following denervation, an up-regulation of NMDA receptors can, nevertheless, potentiate excitatory transmission. **INTEGRATION TIME OF BINAURAL COINCIDENCE DETECTION.** P. X. Joris\*, Lab. voor Neuro- en Psychofysiologie, Univ. of Leuven, B-3000 Leuven, Belgium, and Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53706.

The ability of humans to detect interaural time differences (ITDs) as small as  $20 \mu\text{s}$  contrasts sharply with their inability to follow fast temporal changes in this binaural cue, reflected in estimates of binaural integration time  $\sim 100 \text{ ms}$  (Grantham, D.W., J. Acoust. Soc. Am., 72:1178-1184, 1982). The source of this "binaural sluggishness" has not been studied physiologically.

Responses were obtained from ITD-sensitive single cells in the inferior colliculus of pentobarbital-anesthetized cats. Waveforms (4 kHz wide low-pass noise) with a sinusoidally varying interaural correlation were created digitally and presented over a calibrated, closed acoustic system. Interaural correlation was modulated from full correlation to anticorrelation at frequencies between 1 and 1000 Hz. Sensitivity to this modulation was measured by a synchronization index measured from period histograms binned at the modulation frequency.

All cells followed changes in interaural correlation. The magnitude and phase of synchronization were consistent with ITD-sensitivity to unmodulated correlated, uncorrelated, and anticorrelated stimuli. Synchronization magnitude decreased with increasing modulation frequency, with cutoff-frequencies  $\sim 1$  order of magnitude higher than published psychophysical cutoffs. The highest frequency giving significant modulation was 500 Hz. Some cells showed an unexpected frequency doubling and sharp ITD-tuning to both correlated and anticorrelated stimuli, presumably based on envelope information.

These results suggest that binaural sluggishness does not originate in the binaural coincidence detector, but at a level above the inferior colliculus. Supported by NIH grant DC-00116.

**INHIBITORY INFLUENCE OF THE SUPERIOR OLIVARY COMPLEX ON THE AUDITORY NERVE RESPONSE RECORDED IN UNANESTHETIZED RATS.** E.G. Meloni\*, J.L. Beaton, and M. Davis. Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT.

Efferent innervation of the rat cochlea originates within subdivisions of the superior olivary complex (SOC) of the brainstem including the ventral nucleus of the trapezoid body, lateral superior olive, and a region surrounding the lateral superior olive (Vetter & Mugnaini, 1992) comprising the olivocochlear efferent system. Despite the well described anatomy of this system, the role of the olivocochlear efferent system in modulating auditory transmission remains unclear. In a series of three experiments we used lesion and chemical inactivation and activation techniques to assess the role of this system on auditory function in unanesthetized rats.

In Experiment 1, animals received bilateral electrolytic lesions of the SOC and a bundle of four 25 m nichrome wires was implanted into the ventral cochlear nucleus for extracellular recording of the compound action potential generated by the auditory nerve (N1 component). One week later, potentials were recorded from awake animals using a 10 kHz tone at different stimulus intensities in the presence and absence of background noise. A between-subjects analysis indicated a significant enhancement of the auditory nerve response in the SOC lesioned animals compared to sham lesioned animals. In addition, background noise masked this response to a greater extent in the SOC lesioned animals than shams. In Experiments 2 and 3, bilateral infusion cannulas were implanted into the SOC along with recording electrodes in the ventral cochlear nucleus. One week later, baseline potentials were recorded from awake animals followed by an infusion of lidocaine (10%, 0.5 ml) or kainate (15 pmol) into the SOC. Chemical inactivation of the SOC by lidocaine enhanced the auditory nerve response whereas chemical activation of the SOC with kainate reduced the response. Taken together, these data suggest that the olivocochlear efferent system exerts an inhibitory influence on auditory transmission in unanesthetized rats. **SYNAPTIC EXCITATION AND INHIBITION IN THE LATERAL SUPERIOR OLIVE.** X.W. Fu\*, S.H. Wu, and J.B. Kelly. Laboratory of Sensory Neuroscience, Institute of Neuroscience, Carleton Univ., Ottawa, Canada K1S 5B6.

The lateral superior olive (LSO), one of the major nuclei of the superior olivary complex, is known to receive bilateral innervation and, as such, forms a neural network for the early comparison of binaural differences involved in sound localization. In the present study, the synaptic excitation and inhibition of the LSO neurons were investigated in a brain slice preparation of the auditory brainstem. Brain slices ( $400 \mu\text{m}$ ) were cut in the frontal plane through the LSO of albino rats (14-22 days old) and maintained *in vitro*. Whole-cell patch recordings were made from LSO neurons while the fibers of the trapezoid body were stimulated with a bipolar tungsten electrode. Confirmation of the morphology of neurons in the LSO was obtained by biocytin staining. Recordings were made from three morphological types of neurons: fusiform, multipolar and small round cells. In 16 LSO neurons the ipsilateral and contralateral excitatory responses were completely blocked by the AMPA antagonist, CNQX ( $10 \mu\text{M}$ ). The EPSPs in another 3 LSO neurons had two components, one sensitive to CNQX and the other to APV. Cyclothiazide ( $100 \mu\text{M}$ ), which blocks desensitization of AMPA receptor, potentiated the EPSPs and increased the incidence of suprathreshold responses. Stimulation of the contralateral trapezoid body elicited an IPSP, with a reversal potential of about  $-76 \text{ mV}$ . It was unaffected by the GABA receptor antagonist, picrotoxin ( $25 \mu\text{M}$ ), but was blocked by the glycine receptor antagonist, strychnine ( $0.25-1 \mu\text{M}$ ). These data indicate that the excitation of LSO could be mediated by an excitatory amino acid acting on both AMPA and NMDA receptors. Contralateral inhibition of LSO is mediated through strychnine-dependent glycine receptors. There was no correspondence between types of synaptic responses mediated by different receptors and the morphological class of biocytin-labeled neurons. Supported by NSERC.

## 256.15

SEROTONERGIC MODULATION OF INHIBITORY AND EXCITATORY SYNAPSES IN GERBIL LATERAL SUPERIOR OLIVE. **K. K. Fitzgerald\*** and **D. H. Sanes**. Center for Neural Sci., New York Univ., New York, NY 10003.

The lateral superior olive (LSO), a brainstem auditory nucleus, receives ipsilateral excitation from the cochlear nucleus and contralateral glycinergic inhibition via the medial nucleus of the trapezoid body (MNTB). Since alterations of synaptic activity in the gerbil LSO during postnatal development produce profound changes in synaptic efficacy and morphology (Sanes & Takacs, 1992; Kotak & Sanes, 1995), it was of interest to examine modulation of synaptic transmission in this nucleus. Immunohistochemical staining in gerbils (*Meriones unguiculatus*, P10-16) demonstrated that MNTB contains serotonin (5-HT)-positive puncta, suggesting the possibility that 5-HT is a modulator in the MNTB/LSO circuit.

Using whole-cell voltage-clamp recording from LSO neurons in brain slices from P7-12 gerbils, we examined the ability of 5-HT (100  $\mu$ M) to modulate spontaneously occurring IPSCs, MNTB-evoked IPSCs, and ipsilaterally evoked EPSCs. The most pronounced effect of 5-HT was a dramatic increase in the frequency of spontaneous IPSCs in LSO neurons from P7-8 animals (mean increase =  $1.6 \pm 0.6$  Hz,  $p < .05$ ,  $N=8$ ), suggesting a presynaptic facilitatory action of 5-HT on MNTB neurons. 5-HT produced differential effects on evoked synaptic transmission. Evoked EPSCs were substantially depressed (mean reduction = 51%,  $N=4$ ). In contrast to the serotonergic facilitation of spontaneous inhibitory transmission, the effects of 5-HT on evoked IPSCs were mixed; both depression and facilitation were observed. These results suggest that 5-HT may be an important modulator of inhibitory and excitatory synaptic transmission during development, and may also regulate interaural level difference coding in the adult LSO. ## 256.17

POPULATION-INTERVAL MODELS FOR BINAURALLY-CREATED PITCHES. **P.A. Cariani\*** Eaton-Peabody Laboratory, Massachusetts Eye and Ear Infirmary, 243 Charles St., Boston, MA 02114.

Pitches created by binaural interaction (dichotic combination tones, single & multiple phase-delay pitches, dichotic repetition pitch) have traditionally been explained using spectral-pattern models that analyze "rate-place" profiles of interaural coincidences in the medial superior olivary nucleus (MSO) of the auditory brainstem. Here, we propose an alternative, population-interval model, in which the binaural pitches that are heard always correspond to the most frequent interspike interval present in the MSO.

Computer simulations and our own physiological studies indicate that similar population-interval models can account for a wide range of monaural "periodicity pitches" at the level of the auditory nerve (AN) and cochlear nuclei (CN). Anatomical and physiological evidence suggests that MSO cells act as interaural coincidence detectors that cross-correlate frequency-tuned CN inputs whose timing patterns faithfully preserve those of each auditory nerve. MSO discharge patterns thus largely reflect the time structure of spike train cross-correlations for corresponding fibers in each AN.

(1) Two successive harmonics (600, 800 Hz) presented to different ears produce a dichotic combination pitch at their fundamental  $F_0$  (200 Hz). AN fibers over a wide range of characteristic frequencies (CFs) phase-lock to each tone with similar latencies, such that binaural spike train inputs will "beat" with each other at the MSO, coinciding most frequently at time intervals of  $1/F_0$  ms. (2) Noise that is interaurally out-of-phase save for one in-phase frequency band at  $f_0$  produces a pitch at  $f_0$ . For each CF, noise generates many intervals at  $1/CF$  in AN fibers. Many more coincidences will be produced for CFs that correspond to  $f_0$  (same interaural spike latencies), than for other CFs, producing many more intervals at  $1/CF_0 = 1/f_0$ . For multiple-phase delays at  $f_0$ ,  $2f_0$ ,  $3f_0$ , intervals at  $1/f_0$ ,  $1/2f_0$ ,  $1/3f_0$  are mainly produced, as well as some multiples, resulting in a predominant population interval at  $1/f_0 = 1/F_0$ . (3) When noise is presented dichotically with interaural delay  $\tau$ , a repetition pitch at  $1/\tau$  is heard. Since AN discharges follow noise envelopes, a similar spike pattern follows on the delayed side, so that coincidences will amplify stimulus periodicities of  $\tau$  in each CF-channel, and intervals at  $\tau$  will prevail. Supported by NIH NIDCD Grants 02356 & 02258.

## 256.19

MODULATION OF AUDITORY CELLS BY EYE AND EAR POSITION IN THE SUPERIOR COLLICULUS OF THE BEHAVING CAT. **Luis C. Populin\*** and **Tom C. T. Yin**. Neuroscience Training Program and Dept. of Neurophysiology, University of Wisconsin. Madison, WI 53706.

The superior colliculus (SC) is a model system for studying sensorimotor interactions. It appears to contain maps of visual and auditory space as well as motor maps. However, the visual map is retinotopically organized while the auditory map is based upon head coordinates. Studies in monkeys have shown that the maps shift with eye position (Jay and Sparks, 1987) and thus appear to be motor, rather than sensory, maps. Comparable studies in the cat are less clear.

To address this problem, we studied auditory responsive cells in the SC in cats using a variety of behavioral tasks that include fixation, saccades, delayed saccades and sensory probe trials to visual and/or acoustic targets.

Most auditory responsive cells in the intermediate and deep layers of the SC responded best to broadband noise stimuli presented from a region of the contralateral sound field and more strongly when the cat was not fixating a visual target. Many responded to both visual and auditory stimuli and some responded prior to saccades. Of particular interest is that the discharge of some cells varied with the angle of gaze: their responses to identical acoustic stimuli changed as a function of eye position.

While at first glance these results concur with those described in the monkey, they should be interpreted with caution since, unlike the monkey, the cat moves its ears extensively. Measurements of pinna position show that the cat systematically moves its ears as the visual fixation changes. Thus, the changes in pinna position associated with changes in eye position could account for the modulation.

## 256.16

THE ROLE OF INHIBITION IN THE MATURATION OF INTERAURAL LEVEL DIFFERENCE PROCESSING. **S.K. Thornton\***, **M.N. Semple** and **D.H. Sanes**. Center for Neural Science, New York University, N.Y. 10003.

Development of binaural properties in the central auditory system has rarely been studied quantitatively *in vivo*. We have examined maturation of interaural level difference (ILD) processing of neurons in the anesthetized gerbil inferior colliculus (IC). Tonal stimuli at best frequency were delivered dichotically via calibrated, closed systems. Responses of single EI (contralaterally excited, ipsilaterally inhibited) neurons were recorded at three ages: 17-18, 24-25 and >40 days after birth. Maximum discharge rate increased with age, and other excitatory measures (including thresholds, latencies, dynamic ranges, and rate-level slopes) were similar at all ages. In contrast, inhibition was relatively weak in 17-25 day animals. For example, the slopes (spikes/dB) of ILD functions were shallower and more irregular than those recorded in adults. These immaturities may further restrict processing of complex binaural stimuli. To test this hypothesis, we modulated (trapezoidally) the SPL at the inhibitory ear.

Compared to the control condition (left panel A&B), decreasing ipsilateral SPL initiated a long-lasting "release" from inhibition in adults (right panel, A) and a more abbreviated release in young gerbils (right panel, B). This protracted maturation of inhibition may allow binaural coding properties to become optimized in response to changing acoustic parameters, including head size. Supported by NIH DC00540 (DS), DC01767 and W. M. Keck Foundation (MS).

## 256.18

THE CONTRIBUTION OF THE DORSAL NUCLEUS OF THE LATERAL LEMNISCUS TO BINAURAL RESPONSES IN THE RAT'S INFERIOR COLLICULUS: INTERAURAL TIME DIFFERENCES. **S. A. Kidd** and **J. B. Kelly\***. Lab. of Sensory Neuroscience, Institute of Neuroscience, Carleton University, Ottawa, Ontario, Canada K1S 5B6.

Previous studies from our laboratory have shown that the dorsal nucleus of the lateral lemniscus (DNLL) makes a substantial contribution to the suppression of binaural responses in the contralateral central nucleus of the inferior colliculus (ICC) (Li and Kelly, 1992). Pharmacological blockade of neural activity in DNLL results in a partial release from the ipsilateral inhibition normally produced by interaural intensity differences (IIDs). The present study was undertaken to determine the effects of DNLL blockade on ICC responses to interaural time differences (ITDs). Single unit responses to binaurally presented clicks were recorded from anesthetized rats before and after local injection of the excitatory amino acid antagonist, kynurenic acid (2 mM in Locke's solution), into the DNLL. Before injection binaural responses were strongly inhibited by ITDs that favored the ipsilateral ear. Binaural suppression was evident at both short (0-1 ms) and long (1-20 ms) ITD intervals. After injection of kynurenic acid the extent of binaural suppression was greatly reduced in the contralateral ICC for both short and long ITD values. The data support the idea that the DNLL is important for shaping binaural responses and that it contributes to both short term and persistent inhibition in the contralateral inferior colliculus (Camey and Yin, 1989; Fitzpatrick et al., 1995; Yang and Pollak, 1994; Yin, 1994).

This research was supported by a grant from NSERC (Canada).

EFFECTS OF INJECTIONS OF GABA AGONISTS INTO THE PEDUNCULOPONTINE NUCLEUS (PPN) ON THE P13 MIDDLE LATENCY AUDITORY EVOKED POTENTIAL IN THE RAT. **H. Miyazato\***, **R.D. Skinner** and **E. Garcia-Bill**. Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

The human P1 (or P50) middle latency auditory evoked potential, which is characterized by: 1) sleep state dependence, 2) rapid habituation, and 3) blockade by scopolamine, is a useful tool in assessing psychiatric disorders. In anxiety disease and schizophrenia it is disabituated, and in narcolepsy its amplitude is reduced. In our rat model, the potential having the same characteristics as the human P1 occurs at a latency of 13 msec (P13). In order to better characterize the generation of this potential, intracranial injections of neuroactive compounds were made into the PPN, the presumed source of this potential.

Under anesthesia, adult male Sprague-Dawley (n=5) rats were implanted with epidural screws at the vertex and the auditory cortex (ACx) for EEG recording. For microinjections, 22 ga stainless steel guide cannulae were implanted in the PPN bilaterally. In alert rats, averaged evoked potential responses following auditory stimuli (32 trials, 103 dB rarefied clicks 100  $\mu$ sec in duration, 0.2 Hz) were made before and after intracranial injections (0.1  $\mu$ l). Injections of GABA or the GABA agonist, muscimol, were found to reduce the amplitude of the P13 potential in a dose-dependent manner. While GABA (1-5 mM) greatly reduced the P13 potential briefly (5-10 min), muscimol in doses of 1, 5, or 10 mM reduced the P13 potential for durations of 30, 60 and 100 min, respectively. The Pa potential recorded from the ACx (lemniscal pathway) was not affected.

These results suggest that the manifestation of the vertex-recorded P13 response can be blocked by activation of a known inhibitory GABAergic synapse at the level of the PPN, providing further evidence that the P13 potential is generated, at least in part, by PPN outputs.

**CLONING OF A cDNA FROM RAT OLFACTORY EPITHELIUM ENCODING AN IP<sub>3</sub> RECEPTOR PROTEIN.** D. I. Kalinoski\*, C. DellaCorte, L. C. Johnson, D. Restrepo, J. Jackson, and R. Dotson. Monell Chemical Senses Center, Philadelphia, PA.

Inositol 1,4,5-trisphosphate has been implicated as a second messenger in responses to selected odorants. Biophysical studies (Lischka 1995) have provided evidence of direct gating of plasma membrane channels by IP<sub>3</sub> in rat olfactory neurons. Antibodies directed against the IP<sub>3</sub> R type localize to cilia of olfactory neurons and recognize proteins of Mr 260, and 120 KD in Western blots (DellaCorte, 1995). An IP<sub>3</sub> photoaffinity analogue specifically labeled proteins of 120 kD in the same preparation, suggesting multiple forms of the IP<sub>3</sub> R may be present in olfactory neurons (Restrepo, 1992). To examine the molecular identity of the olfactory IP<sub>3</sub> R a partial cDNA with homology to known IP<sub>3</sub>Rs was amplified from ciliary RNA by RT-PCR. This cDNA was used for Northern analysis and cDNA library screening. Hybridization with bands of 10 kb and 4 kb was observed in rat olfactory RNA. Restriction digests of 32 positive clones obtained from the library screen have been isolated and inserts of 250 bp to ~3 kb identified. Studies are being conducted to determine the sequences of these clones, and to establish whether multiple isoforms of the IP<sub>3</sub>R are encoded in olfactory neurons. (Supported by NIH DC-01228 and DC-00566)

## 257.3

**T-TYPE Ca<sup>2+</sup> CURRENT SERVES FOR SPIKE GENERATION NEAR THE THRESHOLD LEVEL IN THE OLFACTORY RECEPTOR CELL.** F. KAWAI, T. KURAHASHI & A. KANEKO\* Dept. of Inform. Physiol., Natl. Inst. for Physiol. Sci., Okazaki, 444, Japan;

The graded receptor potential of olfactory cells is encoded into spike trains that travel to the olfactory bulb. Contrary to the widely accepted concept that the action potential of olfactory cells is a Na<sup>+</sup> spike, we recorded action potentials from the isolated newt olfactory cell even in a Na<sup>+</sup>-free solution. To understand the ionic mechanism of spike generation, membrane currents were analyzed under the whole-cell patch clamp condition. We found that the transient inward current activated by membrane depolarization was a mixture of Na<sup>+</sup> and Ca<sup>2+</sup> currents (I<sub>Na</sub>, I<sub>Ca</sub>). I<sub>Ca</sub> was activated at membrane voltages more positive than -70 mV. The half-maximal activation was obtained at -44 mV, about 10 mV more negative than that of I<sub>Na</sub>. The decay phase of I<sub>Ca</sub> or I<sub>Na</sub> could be fitted well by a single exponential function with a time constant of 9 - 21 msec (I<sub>Ca</sub>) or 0.9 - 1.6 msec (I<sub>Na</sub>). I<sub>Ca</sub> was blocked by 0.1 mM Ni<sup>2+</sup>, but unaffected by either 0.1 mM Cd<sup>2+</sup> or 1 μM nifedipine. These observations suggest that I<sub>Ca</sub> is a T-type Ca<sup>2+</sup> current. To evaluate the relative contribution of I<sub>Na</sub> and I<sub>Ca</sub> to spike generation, receptor cells were stimulated by current injection under the current clamp mode. The spike generated by injection of the least effective current disappeared by adding 0.1 mM Ni<sup>2+</sup> to the medium, but an increase in current intensity generated a new spike in Ni<sup>2+</sup>-containing solution. These observations indicate that T-type Ca<sup>2+</sup> current serves for spike generation near the threshold level.

**OLFACTORY CELL CULTURES AND TISSUES CONTAIN mRNA FOR THE D1, D2-LONG - AND D2-SHORT DOPAMINE RECEPTORS.** N.L. Koster<sup>1</sup>, N. M. Richtand<sup>1,2</sup>, and S. K. Pixley<sup>1</sup>. <sup>1</sup>Dept. of Cell Biology, Neurobiology and Anatomy, <sup>2</sup>Dept. of Psychiatry, College of Medicine, Univ. of Cincinnati, Cincinnati, Ohio 45267.

Olfactory receptor neuron (ORN) axons transfer information to the olfactory bulb (OB). One subset of the OB neurons contacted, dopamine-producing interneurons, may affect this transfer by presynaptic modulation. The radiolabeled dopamine receptor (DAR) ligand, [<sup>3</sup>H] spiperone, binds to only those regions of the adult rat OB that contain ORN axons (Nickell et al., *NeuroRep* 2:9). DARs increase the ability of the OB neurons to discriminate between odorants, based on effects observed after systemic application of spiperone (Wilson and Sullivan, *J. Neurosci.* 15:5574). The DAR subtypes are grouped into "D1-like" DARs (D1 and D5) and "D2-like" DARs (D2, D3, D4). The gene coding for the D2 DAR is alternatively spliced to yield a D2-long and a D2-short form.

To determine the expression and cell-type specificity of olfactory DARs, we examined olfactory tissues, ORN-containing cultures (Pixley, *Neuron* 8:1191) and dissociated OB cultures. Using the reverse transcriptase polymerase chain reaction, we detected the mRNA for the D1, D2-long and D2-short DARs in olfactory mucosa and olfactory bulbs from newborn rats. Messenger RNA for the D1, D2-long, and (in most cultures) the D2-short DAR subtypes was detected in 15 day, ORN-containing cultures. Cultured ORNs labeled with an antibody to the D2/D3 DAR (#AB1502, Chemicon). D2-long and D2-short mRNA was detected in two out of three OB cultures. Some D2/D3 DAR immunopositive OB cells also immunolabeled for tyrosine hydroxylase, the rate-limiting enzyme in dopamine production.

This research was supported in part by NIDCD NIH grants DC00150 to NLK and DC00347 to SKP.

## 257.2

**CHARACTERIZATION OF GCAP IN RAT OLFACTORY TISSUES.** C. Moon\*, P. Jaber and G.V. Ronnett. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The activation of photoreceptor guanylyl cyclase (GC) is the critical step to restore cGMP level from light-induced cGMP hydrolysis<sup>1</sup>. The regulation of photoreceptor GC is mediated by a soluble activating protein that can sense changes of the intracellular calcium concentration<sup>2</sup>. Guanylyl cyclase activating protein (GCAP) is suggested to be a member of calcium-dependent activator of photoreceptor GC<sup>3,4</sup>. Two GCAPs, GCAP-1 and GCAP-2 have been identified to date, and both GCAPs can stimulate rod outer segment GC or recombinant retGC in low calcium concentration<sup>4-6</sup>. The calcium-dependent stimulation effect is abolished by increase of calcium concentration.

Our laboratory has identified novel pGCs in rat olfactory cilia and the pGCs can be activated and produce cGMP by various odorants. However, the precise regulatory mechanism of olfactory pGC has not been determined yet. Preliminary immunohistochemical study by using anti-GCAP-1 antibody showed positive identification of GCAP in rat olfactory tissue. Moreover, purified GCAP-1 could potentiate cGMP production in lower calcium concentration from our pilot experiment using isolated rat olfactory cilia. Taken together, our preliminary observation strongly suggests that GCAP exists in olfactory tissue and regulate olfactory pGC in calcium-dependent mode.

**ODORANT-INDUCED OUTWARD CURRENT IN FROG OLFACTORY RECEPTOR NEURONS (ORNs) IS MEDIATED BY CYCLIC AMP.** R.Y.K. Pun\* and S. J. Kleene. Univ. of Cincinnati, Cincinnati, OH.

It is well established that odorant-induced responses in ORNs of vertebrates are mediated via the activation of cAMP-gated channels. The odorant-activated response usually has a long latency, taking several hundred msec before a response occurs. This latency presumably is related to the time it takes for the cAMP level to increase sufficiently to act on the cAMP-gated channels after the activation of the second messenger cascade. Although odorant-induced hyperpolarizations and outward currents have been reported, invariably, direct application of cAMP has produced an inward current. Whether such odorant-induced outward currents are mediated via cAMP-gated channels or other second messenger systems has never been established. We characterized the outward current responses to the odorant isoamylacetate (10 mM) in frog ORNs, and compared them to responses elicited by 8-cpt-cAMP, a potent analog of cAMP, using the perforated-patch recording technique.

At -60 mV, ORNs that responded with an outward current to odorant application also responded to the cAMP analog (500 μM) with an outward current. When compared on the same cell, the odorant-induced response was larger in amplitude than that evoked by 8-cpt-cAMP, but the duration of the odorant response was shorter. Both odorant and 8-cpt-cAMP responses had short latencies (less than 100 msec), and both responses had similar voltage dependency: the amplitudes of the responses increased when the holding potential was more negative and decreased when membrane potential was less negative. Our results indicate that both depolarizing and hyperpolarizing odorant responses in vertebrate ORNs may be mediated by cAMP.

## 257.6

**LONG-LASTING ADAPTATION OF OLFACTORY SENSORY NEURONS IS SELECTIVELY IMPAIRED BY INHIBITORS OF THE CO/GMP SECOND MESSENGER SYSTEM.** T. Leinders-Zufall\* and F. Zufall. Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

While much information has been obtained over the past years on the mechanisms of how odorants excite olfactory receptor neurons (ORNs) very little is known about the molecular steps leading to olfactory adaptation. By applying repeated odor stimuli and using perforated patch recordings under voltage-clamp from isolated salamander ORNs we have elicited long-lasting adaptation (LLA) of the odor response. LLA is clearly coupled to the stimulus strength and is characterized by a strong reduction in peak current amplitude to a given stimulus. This reduced odor responsiveness can continue for several minutes after a brief 100-ms long odor pulse but recovers completely so that the effect can be triggered several times. One manifestation of LLA is a shift to the right of the stimulus-response curves, together with a substantial reduction in saturating odor currents. Because the properties of LLA closely match the effects of exogenous carbon monoxide (CO) or cGMP, we tested the consequences of a variety of pharmacological blockers of the cGMP second messenger system. LLA can be uncoupled from excitation and entirely be prevented in the presence of agents that act as inhibitors of the CO-producing enzyme heme oxygenase-2, such as zinc protoporphyrins. In contrast, specific blockers of nitric oxide synthase have no effect on LLA. A series of control experiments ruled out that the effects of the CO pathway blockers were due to unspecific actions at the level of sGC or at the CNG channels. It is also demonstrated that Ca<sup>2+</sup> entry is required for LLA to occur; LLA can be abolished by reducing the external Ca<sup>2+</sup> concentration to ≤ 1 μM. These findings demonstrate that distinct second messenger pathways acting in parallel in a given ORN mediate different functions of olfactory transduction, excitation and long-lasting adaptation. The results strongly suggest that endogenous CO is released in an individual ORN in response to odor stimuli of a given strength resulting in cGMP formation, tonic activation of the CNG channels and Ca<sup>2+</sup> entry, thus mediating one form of sensory adaptation. Supported by NIDCD grant RO1 DC02227.

## 257.7

SUPPRESSION OF ODORANT-INDUCED AND cAMP-INDUCED CURRENTS IN OLFACTORY RECEPTOR NEURONS OF THE NEWT. H. Yamada and K. Nakatani\*, Institute of Biological Sciences, University of Tsukuba, Tsukuba, Ibaraki 305, Japan

It has been reported that odorants can suppress the odorant-activated current. However, little is known about the mechanism of this phenomenon. We have studied this question by making recordings from an isolated newt olfactory receptor neuron in macro-patch whole cell configuration. We employed a rapid bath solution change system as well as intra-pipette perfusion. Using the above techniques, we observed that odorants suppressed the odorant-induced current at various holding potentials, which confirms the result reported by Kurahashi et al (1994). To avoid the intracellular effects of  $Ca^{2+}$ , we used the positive holding potentials to observe outward current for most of the rest of the experiments. Upon perfusing cAMP in the pipette, an outward current was observed. The step of odorant stimulus suppressed this cAMP induced current and the conductance decreased. On the other hand, odorant stimulus did not cause any conductance change in the absence of cAMP in the pipette. During the intra-pipette cAMP perfusion, the current recovered to the initial level after the end of each odorant stimulus. After stopping the cAMP perfusion, which means no additional supply of cAMP, the current did not recover to the initial level. This effect accumulated with multiple stimuli. Furthermore, upon adding IBMX in the bath, we observed a current induced by cAMP that, we think, resulted from the inhibition of PDE. This current was also suppressed by an odorant stimulus. Our results suggest that the decrease in intracellular cAMP concentration may underlie the mechanism of suppression. (Supported by Toray Science Foundation, Japan)

## 257.9

ODORANT-SENSITIVE ADENYL CYCLASE IS FUNCTIONALLY INHIBITED BY ODORANT IN PRESENCE OF FORSKOLIN. S. Sinnarajah, P. I. Ezech\*, S. Pathirana, L. J. Myers, and V. Vodyanov. IBDS, Dept. of Physiology and Pharmacology, College of Veterinary Medicine, Auburn, AL 36849.

To characterize the odorant-olfactory receptor-G $\alpha$  second messenger pathway, the adenylyl cyclase (AC) activity of ciliary membranes was analyzed by cAMP radioimmunoassay (PerSeptive Diag.). Olfactory cilia from the olfactory epithelium of the rat (Sprague-Dawley) were isolated by sucrose gradient centrifugation, and exposed to a mixture of odorants containing equal parts of ethyl butyrate, eugenol, (+)-carvone, and (-)-carvone. The basal AC activity was found to be very low. In the presence of 10  $\mu$ M GTP and 2 mM ATP odorants at concentration between 10 and 1600  $\mu$ M induced a dose dependent production of cAMP. The dose response curve revealed low and high affinity binding sites with apparent  $K_d$  and (AC activity) $_{max}$  equal to  $1.8 \pm 0.5$ ;  $34.1 \pm 2.5$   $\mu$ M, and  $23.3 \pm 3.0$ ;  $50.6 \pm 6.4$  nMmin $^{-1}$ mg $^{-1}$ , respectively. G $\alpha$ -antibodies (Santa Cruz Biotech.) inhibited the AC activity induced by odorants with the apparent  $K_d$  for the inhibition reaction and (inhibition) $_{max}$  estimated as  $0.2 \pm 0.05$   $\mu$ M and  $88.0 \pm 7.0$  %, respectively. AC could be directly activated by 10  $\mu$ M forskolin alone; however the AC activity induced by forskolin could be significantly inhibited by addition of 10  $\mu$ M odorant mixture. This functional inhibition of AC activity by odorants could be significantly abolished by 0.2  $\mu$ M of G $\alpha$ -antibodies. Because the AC inhibition in the presence of forskolin was controlled by odorants and G $\alpha$ -antibodies, and could not be controlled by G $\beta$  or  $\gamma$ -subunits we hypothesize that in presence of forskolin, AC is functionally inhibited by odorants through direct interaction of components of receptor-G $\alpha$  pathway with AC, or cross-talk with other endogenous enzymes. This mechanism of inhibition may be important for understanding of attenuation of odorant-stimulated cAMP levels in olfactory neurons. Supported by FAA grant 93-G-058.

HOMOMERIC CYCLIC NUCLEOTIDE-GATED CHANNELS FORMED BY CLONED RAT OLFACTORY SUBUNIT 2 ARE GATED BY NITRIC OXIDE. M.-C. Broillet\* and S. Firestein, Department of Biological Sciences, Columbia University, New York, NY 10027.

We have previously reported that NO can directly activate the cyclic nucleotide-gated (CNG) channel from salamander olfactory neurons independently from the cAMP second messenger cascade. Its action could be via the chemical modification of SH groups. The native CNG channel is thought to be a hetero oligomer of rOCNC1 and rOCNC2 subunits. In cloned reconstituted CNG channels, the rOCNC1 subunits form a homomeric channel that can be activated by cAMP. The second subunit, rOCNC2 is either not expressed at the membrane or cannot be activated as a homomeric channel by cAMP. Nevertheless, we have transfected human embryonic kidney (HEK) 293 cells with the second subunit rOCNC2 of the rat olfactory CNG channel. Patch-clamp recordings under excised inside-out configuration were made 1 and 2 days after transfection. No CNG activated conductances could be recorded when cAMP (50-500  $\mu$ M) was perfused. However, after cAMP had been washed out, the nitric oxide donor, S-nitrosocysteine (SNC, 100  $\mu$ M) was added to the cytosolic solution, resulting in single channel openings and long bursts of openings. The single channel conductance of the NO-gated rOCNC2 is smaller than that of the native CNG channel or the rOCNC1 subunit homomer, or of the heteromeric reconstituted rOCNC1 and rOCNC2 channel. The open channel shows multiple poorly resolved levels of conductance. At least four are apparent in the amplitude histogram. A difference in the P region amino acid sequence between the rOCNC1 and the rOCNC2 channels (E342 versus D234) might explain this channel behavior. These results suggest that rOCNC2 subunits do form a channel expressed at the membrane of the 293 cells. This channel can be gated by NO, which might be its physiological ligand. The possibility of using NO to activate the second subunit of the CNG channel should aid in understanding the contribution of this subunit to the wild type channel.

THE ROLE OF BINDING INTERACTIONS IN THE TRANSDUCTION OF COMPLEX ODORANT MIXTURES. L.R. Gentilecore\*, R.A. Gleeson\*, and C.D. Derby\*

\*Department of Biology, Georgia State University, Atlanta, GA 30302-4010. \*The Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

Individual odorants bind to specific receptor sites and activate specific transduction pathways. When odorants are combined in a mixture, the resultant response of an olfactory receptor neuron (ORN) is usually less than the sum of the responses to the individual odorants. It has been suggested that the predictability of response magnitude of ORNs to mixtures is dependent not only on the transduction processes activated by each component in the mixture, but also the inhibitory interactions between components at the ligand receptor site, termed binding interactions (Daniel et al., 1996). In the spiny lobster, biochemical and electrophysiological studies suggest that binding interactions can shape the responses of ORNs to binary mixtures (Olson and Derby, 1995; Daniel et al., 1996). However, since most biologically relevant odors are complex mixtures, we examined the binding interactions of complex mixtures containing up to 7 compounds.

Biochemical techniques were used to examine the binding of two radiolabeled compounds, adenosine 5' monophosphate (AMP) and taurine, in the presence of mixtures of up to 6 non-competitors (AMP, betaine, L-cysteine, L-glutamate, ammonium chloride, DL-succinate, and taurine) and up to 2 competitors (6-chloropurine and xanthosine 5' monophosphate for AMP; hypotaurine and  $\beta$ -alanine for taurine). We asked the following questions: 1) To what degree do different mixtures inhibit binding of AMP and taurine to their receptor sites? and 2) Does the degree of binding inhibition caused by a mixture result from the sum of the individual effects of that mixture's components? Our results indicate that the magnitude of inhibitory binding due to a mixture is dependent on the composition and intensity of the mixture, rather than the sum of the binding interactions of single components and the radioligand. Further, we find that inhibition by mixtures can be as great as 25 % for AMP and 50 % for taurine.

ODORANT-REGULATED K $^{+}$  CONDUCTANCE IN RAT OLFACTORY NEURONS. F.W. Lischka, J.H. Teeter and D. Restrepo\*, Monell Chemical Senses Center and Department of Physiology, University of Pennsylvania, Philadelphia, PA.

Stimulation of olfactory receptor neurons (ORNs) by odorants elicits elevations in the concentration of adenosine 3',5'-monophosphate (cAMP) and inositol-1,4,5-trisphosphate (InsP $_3$ ) causing opening of cation channels permeable for Ca $^{2+}$  resulting in an increase in intracellular Ca $^{2+}$  concentration ([Ca $^{2+}$ ] $_i$ ). It has been proposed that the cAMP-mediated increase in [Ca $^{2+}$ ] $_i$  elicits opening of Ca $^{2+}$ -activated Cl $^{-}$  channels causing cell depolarization, while the InsP $_3$ -mediated increase in [Ca $^{2+}$ ] $_i$  causes opening of Ca $^{2+}$ -activated K $^{+}$  channels eliciting cell hyperpolarization. However, if both cAMP and InsP $_3$  act through an increase in [Ca $^{2+}$ ] $_i$ , the question arises as to why cAMP does not stimulate opening of both the Ca $^{2+}$ -activated K $^{+}$  as well as the Cl $^{-}$  channels. To explore this issue we recorded odorant-stimulated currents in rat ORN under voltage clamp conditions using the perforated patch clamp technique. While some ORN responded to odorants known to increase cAMP production with stimulation of a current displaying the characteristics of the cAMP-gated nonspecific cation conductance, in a large percent of the cells (72%) the odorants suppressed a voltage-dependent K $^{+}$  conductance. The odorant-regulated K $^{+}$  conductance was inhibited by internal Cs $^{+}$  and external TEA, and its IV relationship displayed a negative slope region at positive potentials. Elevation of cAMP levels by brief stimulation with IBMX did not suppress the K $^{+}$  conductance. These experiments suggest that the regulation of a K $^{+}$  conductance by odorants plays a role in olfactory transduction. (Supported by NIH DC-00566).

## 258.1

**CANDIDATE LIGAND-BINDING SITE IN HUMAN OLFACTORY RECEPTORS LOCATED BY MOLECULAR MODELS AND POSITIVE SELECTION MOMENTS.** Michael S. Singer<sup>1</sup>\*, Yitzhaq Pilpel<sup>2</sup>, Doron Lancet<sup>2</sup> and Gordon M. Shepherd<sup>1</sup>. Section of Neurobiology<sup>1</sup>, Yale School of Medicine, New Haven, CT 06510; and Membrane Research and Biophysics<sup>2</sup>, Weizmann Institute of Science, Rehovot 76100 Israel.

Ben-Arie *et al* (93, *Hum Mol Gen* 3, 229) have recently reported sequences for members of a cluster of putative olfactory receptors (ORs) on human chromosome 17. In the absence of reliable functional assays for human OR specificity, we have followed previous analyses with two computational methods: molecular models and positive selection moments. Molecular models of several human ORs (such as 17-2, 17-4, 17-23) were built and automatically docked with over 70 odor molecule structures. The results point to odor molecules that may show preferential affinities for particular receptors and identify residues that may interact with the odor molecules. Positive selection moments, calculated for the  $\alpha$ -helical sixth transmembrane domain (TM6), were next used to identify residues that have been preferentially diversified by positive selection and are thus likely to interact with odor ligands. The results suggest that residues 622 and 625, which are commonly serines or threonines, could form critical H-bonds with odor ligands. The studies present new methods for the synthesis of evolutionary and structural data and provide leads for future studies of OR function.

## 258.3

**UP-REGULATION OF NGF mRNA IN NASAL MUCOSA FOLLOWING EARLY UNILATERAL NARIS OCCLUSION IN RATS.** J.S. Stewart<sup>1</sup>, D.M. Cummings<sup>2</sup>, B.K. Fiske<sup>2</sup>, P. Neff<sup>2</sup>, P.C. Brunjes<sup>2</sup>, & J.B. Tuttle<sup>2</sup>. <sup>1</sup>Washington and Lee Univ., Lexington, VA & <sup>2</sup>Univ. of Virginia, Charlottesville, VA

Gong, *et al.* (*J. Comp. Neurol.* 344) reported a developmentally regulated pattern of NGF receptor immunoreactivity (NGFr-IR) in the olfactory system, with up-regulation of NGFr-IR in the olfactory nerve and mucosa following chemical lesion of the ipsilateral epithelium. After unilateral naris occlusion in rats on postnatal day 2 (P2), Gómez-Pinilla, *et al.* (*Devel. Brain Res.* 48) found increased NGFr-IR in ipsilateral olfactory bulbs at 60 days of age. This increase was postulated to be the result of elevated NGF protein levels in olfactory tissues ipsilateral to the closed naris. In the present study, we used competitive-quantitative reverse transcriptase PCR (rtPCR) to measure levels of NGF mRNA in olfactory mucosae from unilaterally odor-deprived rats. Unilateral naris occlusion (or sham occlusion of controls) was performed on P1, and olfactory epithelial tissue collected on P2, P10, or P30. Results from tissues collected at P30 (N=2) show an average 70% increase in NGF mRNA in epithelium ipsilateral versus contralateral to the occluded naris. Epithelial tissue collected at P2 (N=1), showed a 148% increase in NGF mRNA in tissue ipsilateral versus contralateral to the occlusion. Similar analysis of olfactory bulbs from these animals is in progress. These preliminary findings are consistent with the results of Gómez-Pinilla, *et al.*

## 258.5

**THE EFFECT OF GROWTH FACTORS ON THE DEVELOPMENT OF ADULT OLFACTORY RECEPTOR NEURONS *IN VITRO*.** N. Liu, G. Yorke\* & F.J. Roisen. Anatomical Sci. & Neurobiol., Univ. of Louisville Med. Sch., Louisville, KY 40292.

Studies in this lab have shown that chemical trauma to adult mouse olfactory epithelium (OE) stimulates mitotic activity *in situ* which continues in culture. Bipolar cells in these cultures are likely to be olfactory receptor neurons (ORN), since they are immuno-positive for 200 kD neurofilament protein, olfactory marker protein, neuron specific, microtubule-associated protein tau, and immuno-negative for GFAP and keratin. BDNF has been shown to promote the survival of embryonic and neonatal ORNs while EGF enhanced mitosis of the basal cells in neonatal OE. Low affinity NGF receptors are expressed on olfactory nerve Schwann cells but not on ORNs, therefore, NGF may be implicated in ORN maturation. The present studies applied BDNF (100 ng/ml), NGF (40 ng/ml), or EGF (4 ng/ml) to cultures of OE to examine their effects on the growth and differentiation of the ORNs. CD1 mice were exposed to an atmosphere containing an atomized solution of 2% ZnSO<sub>4</sub> for 30 min; 4 days later OE was removed and trypsinized. The cells were cultured with or without the trophic agents in medium consisting of Minimum Essential Medium supplemented with 10% FBS and gentamicin for 2-3 weeks. The number of ORNs (bipolar cells) and their neurite lengths were determined every 3-4 days; data were analyzed with two factor ANOVA. Under these conditions BDNF increased the bipolar cell number ( $p < 0.0001$ ). EGF and NGF did not alter the number of ORNs. None of the agents appeared to affect neurite elongation. Failure of the cells to respond to NGF is consistent with the belief that bipolar cells are ORNs. To determine if the maturation of ORNs could be enhanced, BDNF + NGF + EGF were applied simultaneously. Surprisingly, the average number of ORNs per field was increased ( $p < 0.01$ ); however, neuritegenesis remained unaltered. The uniform immunolocalization of MAP2 and tau proteins in both short and long processes of the ORNs suggests that none of the agents enhanced maturation. This study demonstrates that adult ORNs retain their capacity to respond mitotically to BDNF. Ongoing studies seek to identify agents and conditions which promote ORN differentiation. **OLFACTORY NEURON CELL LINES: A WINDOW INTO THE ROLE OF CELL SURFACE CARBOHYDRATES IN NEURITE OUTGROWTH.**

A.C. Puche\*, P.F. Bartlett\*, V. Lapatis\*, and B. Key\*, Dept. Anatomy and Cell Biology, University of Melbourne, Parkville 3053 Victoria, Australia. \* Walter and Elisa Hall Institute, Parkville 3053 Victoria, Australia.

The primary olfactory projection does not form a precise point-to-point topographical map between the olfactory neuroepithelium and the surface of the olfactory bulb. Near neighbour relationships between individual primary sensory olfactory neurons (PONs) in the olfactory neuroepithelium are not maintained by their axonal projections in the olfactory bulb. However, subpopulations of PONs dispersed throughout the neuroepithelium project to discrete regions of the olfactory bulb. Our laboratory has identified a number of PON subpopulations that are distinguished by expression of a specific array of cell surface carbohydrates. We hypothesize that this 'chemical code' imparts guidance information directing axon growth to the topographically appropriate region of the olfactory bulb. Olfactory sensory neuron cell lines were generated by retroviral infection and used to assess the role of carbohydrates in neurite outgrowth. Dissociated cells of the clonal cell lines 4.4.1 and 4.4.2 were grown on a substrate of neoglycoproteins (bovine serum albumin derivatized with either  $\beta$ -lactose,  $\alpha$ -fucose,  $\alpha$ -galactose,  $\beta$ -galactose, or N-acetyl-lactosamine). Lactose and N-acetyl-lactosamine were strong and specific neurite outgrowth promoters in both cell lines, whereas fucose promoted neurite growth from only the 4.4.1 cell line. Primary cultures of olfactory neurons also respond specifically to immobilised N-acetyl-lactosamine and the blood group B carbohydrate. Additionally, neoglycoproteins used for *in vivo* ligand binding histochemistry on the adult olfactory bulb revealed the presence of carbohydrate receptors in the nerve fibre layer. These results suggest that olfactory sensory neurons are capable of responding to a specific subset of carbohydrates, and that complimentary carbohydrate receptors are present in the olfactory pathway. Interactions between these molecules may influence axon growth/guidance in the olfactory system.

## 258.4

**COMPARISON OF SALAMANDER OLFACTORY AND VOMERONASAL RECEPTOR CELL DIVISION RATE: VARIATION WITH NATURAL LIFE CYCLE.** E.P. Dawley\*, S. Wagner, C. Stankiewicz, A. Fingerlin, W. Sands, H. Kerlin and D. Nibouar. Ursinus College, Collegeville, PA 19426.

Continued mitosis of cells within the olfactory/vomeronasal epithelium to produce new receptors cells is thought to be an adaptation to replace receptors damaged by daily exposure to odorants. We propose that new receptors also may be generated prior to the breeding period of salamanders to enhance chemoreception for courtship activities. Chemoreception may be particularly important for mate recognition and courtship among salamanders, and in previous work we showed that the volume of the vomeronasal epithelium of red-backed salamanders (*Plethodon cinereus*) varies on a yearly cycle. Both males and females have significantly larger vomeronasal organs in the summer pre-breeding period than at any other time of the year. We injected freshly collected salamanders with 5-bromo-2'-deoxyuridine (BRDU), a thymidine analog which is incorporated into the DNA of dividing cells, and used immunocytochemistry to locate cells containing BRDU. Salamanders collected in the summer had significantly more labeled cells than salamanders collected in May or October (ANOVA, single classification). Hormones (e.g., testosterone) may affect receptor cell division rate, and differences in circulating hormones throughout the year may correlate with differences in receptor cell division rate. Testosterone injected into animals or added to olfactory organ cultures, increased numbers of labeled receptor cells over baseline levels.

This research was supported by grants from the Whitehall Foundation, HHMI, NSF, and the Ursinus Undergraduate Research Fund.

## 258.6

**INSULIN AND INSULIN-LIKE GROWTH FACTOR I (IGF-I) IN THE OLFACTORY SYSTEM.** N. E. Rawson\*, C. DellaCorte and H. W. Rees. Monell Chemical Senses Center, Philadelphia PA 19104-3308.

The factors responsible for the unusual regenerative capacity of the olfactory system are not understood. The adult rat olfactory bulb exhibits higher levels of insulin (INS) and IGF-I than any other brain area, yet their functions are not understood. In peripheral nerves and neuronal cultures, INS and IGF-I promote growth and differentiation. To see if they might play a role in the ongoing regeneration of the olfactory epithelium (OE) we are studying the distribution of INS, IGF-I and their receptors using immunohistochemistry and *in situ* hybridization. Immunostaining for IGF-I receptor suggests low levels of expression in normal, adult OE, with substantially more immunostaining in response to reduction of plasma INS and IGF-I by induction of diabetes with streptozotocin. PCR products made using primers designed to selectively amplify IGF-I and its receptor, and the INS receptor from OE cDNA were cloned and sequenced, and were  $\geq 99\%$  homologous to published sequences. Cloned products were used to generate riboprobes for ribonuclease protection assays and *in situ* hybridization. Results suggest local synthesis of IGF-I within the olfactory epithelium, where the initial stages of olfactory neuron replacement occurs. This work funded in part by NIH-NIDCD Grant DC02876-01.

## 258.7

**OLFACTORY RECEPTOR DATABASE: TOOLS FOR SHARING AND ANALYSING PUBLISHED AND UNPUBLISHED SEQUENCES.** Matthew D. Healy<sup>1</sup>, Jason E. Smith<sup>2</sup>, Michael S. Singer<sup>2</sup>, Prakash M. Nadkarni<sup>1</sup>, Perry L. Miller<sup>1</sup>, and Gordon M. Shepherd<sup>2</sup>. Center for Medical Informatics<sup>1</sup> and Section of Neurobiology<sup>2</sup>, Yale School of Medicine, New Haven, CT 06510

Olfactory receptors, believed to be initial sites of odor transduction, form the largest gene family yet identified. Information on these receptors has accumulated from laboratories worldwide. To enhance communication between laboratories and to reduce problems of accessibility, duplication of effort, and scarce links between related data, we have built the Olfactory Receptor DataBase (ORDB). The database, available via the World-Wide-Web (WWW), serves as a common repository for olfactory receptor sequences in both nucleotide and amino acid form. The ORDB is a medium-scale database combining the dedicated features of local databases with the comprehensive information content and broad accessibility of a central server. In addition to sequences, ORDB provides BLAST similarity searches, molecular models, references, e-mail links, and notes from studies of receptor function or distribution. The database includes both published and unpublished data. Unpublished sequence headers are reported by similarity searches, but actual sequences are not disclosed; to maintain data confidentiality, users contact the submitter directly via the e-mail links provided. ORDB has been instrumental in enabling recent correlated mutation analysis and positive selection analysis of olfactory receptor sequences.

ORDB can be accessed at URL: <http://senselab.med.yale.edu/ordb>

Supported by grants to GMS from NIMH, NASA, and NIDCD (Human Brain Project), and to PLM from NLM (IAIMS).

## 258.9

**ADENOVIRUS COMPONENT SYSTEM MEDIATES GENE DELIVERY TO OLFACTORY NEURONS.** M. Pyrski<sup>1</sup>, T. Kohout<sup>2</sup>, T.B. Rogers<sup>2</sup>, A.I. Farbman<sup>3</sup> and F.L. Margolis<sup>1\*</sup>. Depts. of Anatomy<sup>1</sup> and Biochem.<sup>2</sup> Univ. Maryland Sch. of Med., Baltimore, MD 21201; Dept. Neurobiol.<sup>3</sup>, Northwestern Univ., Evanston, IL 60208.

We have utilized an efficient adenovirus-based DNA delivery system to selectively transfect olfactory receptor neurons (ORN) *in vitro*. Organotypic explant cultures of embryonic day 17 rat olfactory mucosa were transfected, after 1 day in culture, with a plasmid containing E.coli *lac-Z* under the control of the CMV promoter. Of several liposomal formulations tested initially, Lipofectamine was most effective. Although its efficiency was below 10%, most of the stained cells showed a specific localization and a typical neuronal shape. Successful transfection was evident after 24 hrs and visualized by incubation of the explants or 10  $\mu$ m cryosections with x-gal. Immunocytochemistry in tissue sections with anti-OMP and anti- $\beta$ -gal confirmed the delivery of functional plasmid to the ORN target cells. To increase the efficiency we used the adenovirus component system that avoids the need to generate recombinant adenovirus constructs. Adenovirus component system mediated gene transfer utilizes an absorbable complex of replication-defective virus (Ad5dl312), poly-L-lysine and plasmid DNA. This adenovirus system has been reported to successfully transfect 70% of cardiac myocytes in monolayer culture (Rogers et al., 1996). In our olfactory explant cultures, use of this receptor-mediated transfection with at least 1x10<sup>10</sup> complexed virus particles per explant, showed significantly elevated efficiency compared to Lipofectamine. The transfected cells were ORN as demonstrated by their characteristic shape and typical localization in the caudal-dorsal part of the explant. Further, the high specificity of the transfection was indicated by the low numbers of labeled sustentacular cells and chondrocytes and the double labeling (i.e., OMP+,  $\beta$ -gal+) of ORN. Application of this technique provides opportunities to selectively manipulate ORN phenotype in explant cultures to study the regulation of olfactory function. Future directions include additional characterization of the mechanisms regulating ORN gene expression, phenotypic rescue of ORNs from which genes have been deleted, overexpression of gene products and delivery of anti-sense RNA to create phenotypic gene deletions. (support from Dept. of Anatomy UMAB)

## 258.11

**ELECTRO-OLFACTOGRAMS IN MAN.** T. Hummel\*, M. Knecht and G. Kobal. Dept. of Pharmacology, Krankenhausstr. 9, Univ. of Erlangen-Nürnberg, 91054 Erlangen, Germany

After chemical stimulation of the human olfactory epithelium it is possible to record negative responses (electro-olfactogram, EOG) which are interpreted as the summated receptor potentials of the olfactory nerve. Stimulation was performed with substances believed to exclusively excite fibers of the olfactory nerve (vanillin 2.1 ppm; hydrogen sulfide 0.8 ppm). Stimulants were presented with stimulus durations ranging between 250 and 1000 ms (interstimulus interval 2-120 s). EOG was recorded by means of tubular electrodes (cutaneous reference contralateral bridge of the nose; impedance  $\leq$  8 k $\Omega$ ; bandpass DC to 30 Hz, sampling rate 125 Hz). Investigations in more than 60 subjects revealed the following major results:

- EOG amplitudes increased in relation to the subjects' intensity estimates; latencies of EOG onset decreased with increasing stimulus concentrations.
- An increase of stimulus duration produced an increase of EOG amplitudes; in contrast, latencies of EOG onset remained constant.
- When using repetitive stimulation the amplitude produced by the second stimulus was as great as the first responses' amplitude indicating that the peripheral encoding is less subject to desensitization compared to the subjective perception of odors.
- Only in 2 of 18 trials clear responses to both olfactory stimulants (H2S, vanillin) could be recorded in the same location; in line with immunohistochemical findings the results indicate that odorant receptors are not dispersed homogeneously throughout the olfactory epithelium. In addition, endoscopic localization of EOG recording sites indicated that olfactory tissue is located more anteriorly than previously thought.

## 258.8

**ENHANCEMENT OF OMP IMMUNOREACTIVITY IN INDIVIDUAL ORNs FOLLOWING OLFACTORY BULBECTOMY IN THE RAT.** V. McM. CARR<sup>\*</sup> and A.I. FARBMAN. Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208-3520.

Olfactory Marker Protein (OMP) is a 19kDa cytoplasmic protein of unknown function found in mature olfactory receptor neurons (ORNs) of the olfactory epithelium (OE). Following olfactory bulbectomy (OB-X), the proportion of ORNs mature enough to express OMP declines greatly. However, we have noticed that the intensity of OMP immunoreactivity (IR) in the few remaining mature ORNs appears enhanced relative to that of mature ORNs in nonbulbectomized OE.

To verify this observation rats were subjected to unilateral OB-X and perfused at 1d-6mos post-OB-X. 10  $\mu$ m paraffin sections were prepared and reacted with goat  $\alpha$ -OMP (1:500-1:50,000; generously provided by Dr. F. Margolis). OMP IR was visualized by immunoperoxidase techniques. Results confirmed our earlier observations: at all post-operative periods and all  $\alpha$ -OMP titers examined OMP IR was higher in individual ORNs in operated than unoperated OE. Moreover, at 1:40,000 OMP(+) ORNs were no longer distinguishable in control OE while even at 1:50,000 a few could still be seen ipsilaterally. These observations indicate that ORN OMP levels rise in absence of the ORN bulbar synaptic targets. This may be related to the still unknown function of OMP.

Supported by NIH grants DC02774, DC01593, and DC 00347.

## 258.10

**ADENOVIRUS-MEDIATED GENE TRANSFER IN OLFACTORY NEURONS *IN VIVO*.** H. Zhao<sup>\*1</sup>, J. Otaki<sup>2</sup> and S. Firestein<sup>2</sup>. <sup>1</sup>Interdepartmental Neuroscience Program, Yale University, New Haven, CT 06510, <sup>2</sup>Department of Biological Sciences, Columbia University, New York, NY 10027.

We have developed a technique using adenovirus vector to efficiently transfer exogenous genes into olfactory neurons *in vivo*. A replication incompetent adenovirus (type 5) carrying the reporter gene *lacZ* which codes for the enzyme  $\beta$ -galactosidase was applied in solution to the olfactory epithelia of rats under anesthesia at a titer of 10<sup>10</sup> pfu/ml.  $\beta$ -gal expression was observed one day post infection and was maximal at 3-10 days post infection. Expression could be detected for at least 21 days post infection. Expression patterns were heterogeneous, ranging from a few percent to 25% of the cells in different regions of both turbinate and septal epithelium. Staining was stronger in the olfactory vs. respiratory epithelia. In olfactory epithelium staining was almost entirely restricted to olfactory neurons.  $\beta$ -gal staining was also observed in the olfactory axons so that nerve bundles could be traced to their targets in the glomerular layer of the olfactory bulb. Intense staining of some glomeruli was evident at 21 days post infection. Another foreign protein, human p75, was similarly expressed in rat olfactory neurons using another adenovirus construct. In neither case was there any evidence of cell loss or tissue damage due to viral infection.

These results demonstrate that recombinant adenovirus can be used for expressing exogenous genes in olfactory neurons. This technique could be used to express foreign proteins or to manipulate expression levels of olfactory specific proteins, including the odor receptor, putative axon guidance and growth molecules, or elements of the transduction cascade.

Supported by NIDCD.

## 259.1

**AXONAL REGENERATION IN THE CNS OF *APLYSIA* FOLLOWING BILATERAL CEREBRAL-BUCCAL CONNECTIVE LESIONS.** S.L. Johnson, M.L. Schroeder, J.A.D. Sánchez, and M.D. Kirk\*. Division of Biological Sciences, University of Missouri - Columbia, Columbia, MO 65211.

Following bilateral crushes to the Cerebral-Buccal Connectives (CBCs) of *Aplysia californica*, rhythmic biting is selectively abolished, but recovers within 14 days postlesion (Scott et al. 1995). Recovery of rhythmic biting is mediated by regeneration of axons in the CBCs. To determine the nature and time course of axonal regeneration we used Biocytin backfills to trace fibers that had regenerated across the crush site. Backfills into the buccal ganglia were made at 0, 3, 7, 9, 12, 14, and 17 days postlesion. Secondary labeling of Biocytin was achieved with Streptavidin Lissamine Rhodamine. Labeled axons were then examined with laser confocal microscopy and epifluorescence microscopy. Biocytin provided distinct labeling of regenerating axons, especially at early times postlesion. Regenerating axons were small in caliber, varicose, and occasionally branched. They often traveled a tortuous path through the core of the CBC and usually terminated in a swollen structure, likely to be the growth cone. Regenerating axons grew toward the buccal ganglia at a rate of approximately 125  $\mu\text{m}/\text{day}$  and by 9 days postlesion some fibers had entered the ganglionic neuropil. By 12 days postlesion they had traversed the buccal commissure and invaded the contralateral ganglion. These results correlate with physiological evidence that synaptic connections between cerebral and buccal neurons begin to appear at 14 days postlesion. (Supported by NIH grant NS30832 to MDK)

## 259.3

**Regeneration of the neuromuscular connections in the locomotory system of the pteropod mollusc *Clione limacina*.** Yuri V. Panchin<sup>1,2</sup>, Pavel V. Zelenin<sup>1</sup> and Lyudmila B. Popova<sup>1\*</sup>. <sup>1</sup>A. N. Belozersky Institute of Physico-Chemical Biology, Moscow State University, 119899 Moscow, Russia; <sup>2</sup>Institute of Problems of Information Transmission, Russian Acad Sci., Moscow, Russia.

Neural network for rhythmic wing movements in the swimming mollusc *Clione limacina* is a well studied system. Dorsal (D) and ventral (V) phase motoneurons innervate corresponding wing muscles projecting via ipsilateral wing nerve. When motoneurons axons are crushed in the nerve the regeneration starts and results in a complete restoration of the function in 1-2 months. After axotomy numerous fine neurites start to grow predominantly in the direction of the denervated muscles and reach them in 8-15 days. At this stage motoneurons display no preference to the dorsal or ventral muscles. Motoneurons of the D and V phase have branches that project not only to the corresponding muscles but equally to the antagonistic muscles. Correspondingly muscles fibers display correct, incorrect and mixed innervation. After 2 weeks of regeneration selection starts and a number of wrong neurites and neuromuscular junctions begins to decrease so, that in 1.5-2 months all the wrong axons are withdrawn and the muscles are innervated only by appropriate motoneurons. Thus, similar to the neuromuscular regeneration in vertebrates, the neuromuscular regeneration in mollusc involves the process of the selection of the motoneuron inputs. This implies the role of the synaptic activity in the choice of the appropriate innervation. Supported by RFBR grant 96-04-49115.

**MORPHOLOGY OF THE LARVAL SENSORY NEURONS IN THE IMAGINAL LEG DISK OF THE BLOWFLY.** E. P. Lewis\* and G. S. Pollack. Dept. of Biology, McGill University, Montreal, Quebec, Canada, H3A 1B1.

Five bipolar neurons in the imaginal leg disk of the blowfly *Phormia regina* are associated with a larval sense organ, Keilin's organ. At metamorphosis, this sensory system undergoes extensive rearrangement; three of the neurons undergo programmed cell death, and the remaining two persist and innervate campaniform sensilla of the adult leg (Lakes-Harlan et al., J. Comp. Neurol. 308:188, 1991). We used dye-filling techniques in order to clarify the anatomical and developmental relationships in this system. Single neurons were injected with DiI so as to selectively stain their dendritic terminations, which were imaged, together with cuticular features, using confocal microscopy. The identities of the stained neurons were determined by relative position following retrograde staining of the entire group of neurons with DiO. Central projections were visualized with neurobiotin.

The three neurons that are destined to degenerate at pupation were the ones that innervate the hairs of Keilin's organ; the anterior-most, middle, and posterior-most of the neurons innervate, respectively, the lateral, medial and posterior hairs. The dendrite of the anterior of the two persisting cells terminates medial to the cluster of hairs of Keilin's organ, and the posterior persisting neuron terminates posterior to the hairs. The central projections from the neurons are of two types: a group of three laterally projecting axons and a group of two medially projecting axons. The lateral projections are those of the three non-persisting cells, while the medial projections are those of the persisting neurons. These results suggest that there are two fundamentally different classes of neurons associated with Keilin's organ. Those in the first class are strictly larval neurons that service Keilin's organ and degenerate when no longer required, while the neurons in the second class are retained and possibly remodelled to function in the adult. (Supported by the Natural Sciences and Engineering Research Council of Canada).

**REGENERATION OF SYNAPTIC CONNECTIONS FOLLOWING BILATERAL LESIONS TO THE CEREBRAL-BUCCAL CONNECTIVES IN *APLYSIA*.** J.A.D. Sánchez\*, Y. Li, S.L. Johnson, M.L. Scott, and M.D. Kirk. Div. of Biological Sciences, University of Missouri-Columbia, Columbia, MO 65211.

Previous studies in *Aplysia* have demonstrated that rhythmic biting, a component of consummatory feeding behavior, is selectively abolished by bilateral crushes of the Cerebral-Buccal Connectives (CBCs) and recovers within 14 days postlesion (Scott et al. 95). In this study we tested for regeneration of specific cerebral-buccal synaptic connections in *Aplysia californica* that may contribute to this functional neural regeneration. Synaptic connections made by Cerebral-Buccal-Interneurons (CBI's) on buccal neurons and their ability to elicit buccal motor programs (BMP's) were tested at various times postlesion. Multiple simultaneous intracellular recordings were made from cerebral (CBI-1, CBI-2) and buccal (B4/5, B31/32, B63) neurons. Following CBC crush, all synaptic connections were initially eliminated. At 14-15 days postlesion, CBI-2 could elicit a single burst of BMP and in 3 of 20 cases produced multiple bursts of BMP, while in only 3 of 5 preparations CBI-2 elicited observable 1:1 epp's in B31/32. At 14-15 days postlesion CBI-1 did not produce observable epp's in B4/5, however, in 1 of 4 preparations tested CBI-1 elicited a single cycle of BMP. At 20-24 days postlesion, CBI-2 produced 1:1 epp's in B31/32 and reliably elicited multiple cycles of BMP. Also 20-24 days postlesion, CBI-1 reliably produced 1:1 epp's in B4/5; however, these synaptic potentials were small and labile. By 50+ days postlesion, the amplitudes of synaptic inputs to buccal neurons by cerebral neurons approached those observed in control preparations. (Supported by NIH grant RO1 NS30832 to MDK)

## 259.4

**ANATOMICAL EVIDENCE OF SENSORY AND MOTOR FUNCTION IN EARLY SEROTONERGIC NEURONS FROM *HELIOSOMA* EMBRYOS.** J.I. Goldberg\*, R. Koss and T.J. Diefenbach. Dept. of Biological Sciences, Univ. of Alberta, Edmonton, AB Canada T6G 2E9.

In *H. trivolis* embryos, one of the earliest events in neural development is the differentiation of a single bilateral pair of serotonergic neurons, embryonic neurons C1 (ENC1). The primary neurite of ENC1 projects ventrally towards the pedal band of cilia, where profuse neurite branching occurs in conjunction with the differentiation of ciliary cells. Previously, we provided pharmacological evidence that serotonin released from ENC1 stimulates ciliary activity in the underlying pedal cells, and thereby modulates a cilia-driven locomotory behavior. In the present study, anatomical analyses were carried out to provide further support that ENC1 functions as a motor neuron. Moreover, experiments were conducted to test the novel hypothesis that ENC1 also functions as a sensory neuron. The anatomical methods employed in this study include transmission electron microscopy (TEM), scanning electron microscopy (SEM) and confocal microscopy combined with serotonin immunofluorescence (CM-SI). TEM of the pedal region revealed ENC1 neurites in close association with the basal surface of ciliated epithelial cells. Whereas clusters of synaptic vesicles were found in ENC1 at some sites, postsynaptic specializations were not normally seen. Thus, ENC1 may affect pedal ciliary cells through the paracrine action of serotonin on broadly distributed receptors. In addition to the descending neurite, we observed a large-caliber neurite projecting dorsally from the ENC1 soma that appeared under CM-SI to reach the dorsoanterior surface of the embryo. Both SEM and Normarski DIC microscopy revealed a surface structure at this same location with a ciliated morphology resembling vertebrate olfactory chemoreceptors. TEM analysis confirmed that this specialized surface structure was contiguous with the dorsally-projecting ENC1 neurite. Together, these anatomical data suggest that ENC1 is a sensory-motor neuron that forms a one-cell neural circuit for regulating an early embryonic behavior.

**DAILY AND CIRCADIAN RHYTHMS IN THE MIGRATION OF SCREENING PIGMENT GRANULES IN PHOTORECEPTOR TERMINALS OF THE HOUSEFLY.** E. Pyza\* and I. A. Mejnertzhagen<sup>1</sup>. Zool. Museum, Inst. Zoology, Jagiellonian University, Ingardena 6, 30-060 Kraków, Poland and <sup>1</sup>Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

Screening pigments in the retinal photoreceptors of insects migrate during the day towards the photoreceptive rhabdomeres and disperse in the cytoplasm during the night. This migration is light-induced and acts as a pupil mechanism. Pigment granules are moreover not only found in the somata but also the synaptic terminals of photoreceptors, in the first optic neuropile, or lamina, where they innervate small groups of lamina interneurons, including monopolar cells L1 and L2. The numbers of synapses established by each terminal exhibit daily and circadian fluctuation. We now examine the numbers of 390-nm diameter ommochrome pigment granules in photoreceptor terminals, during the day and night of day/night (LD) conditions, under constant darkness (DD), and after a 1-h light pulse in DD. Pigment granule profiles were counted at proximal and distal depths in the lamina. Overall, for all conditions examined, there were 55% more pigment granules in receptor terminals at a proximal depth in the lamina than distally. In flies held in LD the number of granules was 47% greater at proximal depths, and 59% greater at distal depths in the lamina, at the beginning of night than it was at the beginning of day. In DD, the number of granules decreased significantly compared with LD, but a circadian rhythm in their number was still detected. The largest number of pigment granules was at the end of subjective day for both proximal and distal lamina levels. A light pulse at the beginning of either the subjective day or the subjective night increased the number of granules in the proximal depth of the lamina, but not distally. Thus the number of photoreceptor terminal pigment granules changes by both direct exposure to light and a circadian mechanism, which during the night is interpreted to move pigment granules out of the soma to more proximal depths, in the lamina.

Supported by grants to I.A.M. (NIH EY-03592, NSERC A 0065) and to E.P. (NSERC ISE IS-0136, HHMI 75195-543102).

## 259.7

CIRCADIAN RESPONSIVENESS IN THE FLY'S EYE AND EFFECTS OF 5-HT AND PDF. B. Chen, J.A. Meinertzhagen and S.R. Shaw\*, Institute for Neuroscience, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

Two sets of wide-field neurons ramify throughout the optic lobe behind the fly's compound eye. They extend neurites into the first visual neuropile, or lamina, which contains the photoreceptor input synapse. One set of cells is immunoreactive to 5-HT the other to pigment-dispersing factor (PDF), and both are thought to release their contents parasympactically. Although their actions are so far unclear, they have been proposed to function as whole-field neuromodulators of vision, possibly involved in the control of rhythmic circadian changes that occur in the sizes of identified lamina monopolar neurons and the numbers of their synapses (Meinertzhagen and Pyza, 1996, TINS 19, in press). We have re-examined the question of circadian rhythmicity in the visual response, and also tested the effects of these putative neuromodulators after local injections in small (nanoliter) volumes.

Flies (*Calliphora*, *Musca*) reared on a normal light/dark cycle were transferred to constant darkness for long-term electroretinogram (ERG) recordings of the lamina's ON- and OFF-transients, generated by the large monopolar cells. Over several days, modest but consistently larger transients could be found during the subjective night phase than during the subjective day. We do not yet know if these changes in amplitude are linked to the neuroanatomical rhythmicity exhibited by the neurons.

The effects on the ERG of 5-HT, PDF and various other candidate transmitters were examined by injecting small quantities into the haemolymph of the head, to target the optic lobe, or, directly into the retina. 5-HT strongly enhanced the ON- and OFF-transients when injected into the haemolymph around the optic lobe, an action reversed by injected 5-HT antagonists. 5-HT had an opposite action when injected into the retina. The rapidity of onset of the effects may indicate a direct action at different receptor sites, in the lamina and retina. PDF injected into the haemolymph of the head also strongly affected the ERG transients.

## 259.9

VISUAL PIGMENTS AND PHOTORECEPTOR CLASSES OF DEEP-SEA SHRIMPS. T.W. Cronin, J. Kent, T. Frank, E. Widder, J.C. Partridge, P. Herring, and P. Robinson\*, Dept. of Biological Sciences, University of Maryland Baltimore County, Baltimore, MD 21228; Harbor Branch Oceanographic Institute, Fort Pierce, FL 34946; School of Biological Sciences, University of Bristol, Bristol BS8 1UG U.K.

The photic environment of the deep sea contains the remains of downwelling sunlight, filtered by the overlying water to a limited waveband centered near 475 nm, together with a diversity of bioluminescent emitters. The visual pigments of deep-sea fishes tend to absorb maximally in the waveband transmitted by the water and emitted by bioluminescent animals, and thus have  $\lambda_{max}$  in the spectral range between 450 and 500 nm. We collected a diversity of deep-sea shrimps using midwater sampling gear capable of maintaining living specimens in total darkness, as well as a benthic trawl sampling at depths near 4500 m. Visual pigments were determined using microspectrophotometry of cryosections from eyes quick-frozen and stored at low temperature immediately after collection. Most species had a single visual pigment ( $\lambda_{max} \approx 490$  nm) throughout the retina, but two oplophorid shrimp species (*Systellaspis debilis* and *Oplophorus spinosus*) possessed a second, unexpectedly short-wavelength photoreceptor class peaking near 410 nm. An analysis comparing the spectrum of downwelling light with typical bioluminescent emission spectra suggests that these species may be capable of discriminating bioluminescence from downwelling light, enabling them to counter bioluminescent camouflage systems. Supported by NSF Grant IBN-9413357, NERC Grant GR3/9329 and studentship GT4/93/3/A, and by the Harbor Branch Oceanographic Institute.

## 259.11

EXAMINATION OF ELECTRICAL PROPERTIES OF GLIAL AND EXTRACELLULAR COMPARTMENTS IN FLY FIRST VISUAL NEUROPILE. Kettunen, P., Weckström, M.\* and Uusitalo, R. Department of Physiology, University of Oulu, 90220 Oulu, Finland.

In the insect visual systems major signal processing takes place in the first visual neuropil, lamina, in the synapses between photoreceptors and the first visual interneurons, large monopolar cells or LMCs. The synapse is characterised by multiple release sites (up to 200 per presynaptic photoreceptor), tight sealing of the synaptic zones inside glial "cartridges", and graded membrane potentials on both sides of the synapse. The photoreceptor transmitter, histamine, opens fast  $Cl^-$  channels in postsynaptic LMCs, thus creating a light-dependent current source potentially able to charge the extracellular space. We examined the non-cellular compartments and lamina glial cells with sharp ( $R_{in}$  up to 100 M $\Omega$ ) glass microelectrodes and varying light stimulation protocols, including prolonged dark and light adaptation. To identify the extracellular space and/or cellular elements we used both markings with Lucifer Yellow and cell membrane permeabilization with intracellular injections of a detergent substance, DMSO. The results show putatively the presence of several extracellular spaces different from the haemolymph. The extracellular compartments exhibit relatively large changes in their voltage, up to 30 mV (compared to haemolymph) in light stimulation, meaning that the normally recorded membrane potentials of neuronal elements should be re-interpreted. The putative glial elements are characterised by very negative dark resting potentials and changes in their input resistance with light stimulation.

## 259.8

MONOPOLAR CELL AXONS IN THE LAMINA CARTRIDGE OF THE FLIES *DROSOPHILA*, *MUSCA* AND *CALLIPHORA* EXHIBIT GLUTAMATE-LIKE IMMUNOREACTIVITY. I.A. Meinertzhagen\* and X.J. Sun, Life Sciences Centre, Dalhousie University, Halifax, NS, B3H 4J1, Canada.

Glutamate is a well-characterized neurotransmitter at the neuromuscular junction in insects. Whether it is used as a neurotransmitter in the insect's central nervous system is, by contrast, less well documented. The first optic neuropil of the compound eye in insects, the lamina, is possibly the best understood piece of neuropil, with neuron types and synaptic organization that are both structurally well identified. Even though the transmitter phenotype of most of these neurons remains unexplored, several lines of evidence suggest the utilization of glutamate. Using antibodies raised against glutamate and a pre-embedding immunoelectron microscopic technique, we have studied the distribution of the glutamate immunoreactive neurons in the lamina of three species of flies, both at the light microscopic and ultrastructural levels. In white eye mutants of the flies *Musca domestica* and *Calliphora erythrocephala* two of the lamina's monopolar cells, L1 and L2, major relay neurons to the second neuropile or medulla, both show clear immunoreactivity. In addition, these cells' medulla terminals are also immunoreactive, as well as the lamina axon of a third monopolar cell, apparently L3. Generally the lamina axons but not their dendritic spines exhibit immunoreactivity. In white eye *Drosophila melanogaster*, L1 or L2, or both, are immunoreactive. In *Musca*, L2's feedback synapses upon photoreceptor terminals are sites of localized presynaptic immunoreactivity. These findings, taken with other physiological and molecular biological findings, indicate that the monopolar cells in the lamina may store glutamate, which they could use as a neurotransmitter, either in the lamina (in the case of L2) or at their terminals in the medulla.

## 259.10

SYNAPTOTAGMIN IMMUNOREACTIVITY: SUBCELLULAR LOCALIZATION *IN VIVO* AND *IN VITRO* IN *DROSOPHILA* PHOTORECEPTOR TERMINALS AND A MARKER FOR DIFFERENTIATING NEUROPILE REGIONS OF THE VISUAL SYSTEM. Chinglu Li\*, X.J. Sun and I.A. Meinertzhagen, Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

The differentiation of photoreceptors in the visual system of *Drosophila melanogaster* includes the early appearance of immunoreactivity to the presumed transmitter, histamine. We have previously reported that synaptotagmin, a synaptic vesicle protein, is expressed in the axons of differentiating photoreceptors that extend from eye-disc fragments *in vitro*. The expression pattern is punctate and occurs independent of contact with target cells; all growth cones are also immunopositive. We have now examined whether the protein is located on synaptic vesicle membranes or whether it exists as protein clusters along the neurites in the cultures. Using DSYT2, an antibody that recognizes the cytosolic domain of the synaptotagmin molecule, we compared the expression of this protein by light- (LM) and electron-microscopy (EM) in both cultured photoreceptors and *in vivo* preparations. Cultures of photoreceptors were initiated from pupae 5h after pupariation. Immuno-EM revealed that synaptotagmin is expressed on synaptic vesicle membrane in cultures maintained for 5 days *in vitro* (DIV). Immuno-positive vesicular structures resembled those found *in vivo* in adult photoreceptor terminals. Prior to this, punctate immunoreactivity to DSYT2 was detected in 3DIV cultures by both LM and EM, but no obvious synaptic vesicles were detected at this stage. Thus prior to the appearance of synaptic vesicles, synaptotagmin may initially exist in cytosolic form.

Synaptotagmin has been implicated in neurite outgrowth, but its role in development is still unresolved. Based on knowledge of the subcellular localization of synaptotagmin in differentiating synaptic terminals, we have used synaptotagmin immunoreactivity to highlight synaptic areas of the differentiating nervous system *in vivo*. The early expression of synaptotagmin in constituent neurites provides a powerful tool to display the early elaboration of neuropile regions. Immunoreactivity was imaged in wholemount preparations using confocal microscopy, and reconstructed image stacks were used to create a 3-dimensional morphogenetic series of the neuropiles of the developing brain.

## 259.12

DYNAMICS OF SLOW AND FAST VISUAL TRACKING BY FLIES: NEUROMUSCULAR SUBSTRATE AND SENSORY STIMULATION.

C. Gilbert\*, P.O. Zanen, R.S. Edgecomb, and A. Pantelias, Dept. Entomology, Cornell University, Ithaca, N.Y. 14853

Around the yaw axis, flies move their heads to perform slow visual tracking and faster saccades and optokinetic nystagmus (OKN). We studied the neural basis of these differential dynamics of head yaw in the fleshfly (*Neobellieria bullata*), by combining a newly developed PC-based video-microscopic 3-D measuring method, intra- and extracellular recording of motoneurons and muscle fibers, and histochemical stains of succinic dehydrogenase (SDH) in TH muscles. When viewing a horizontally drifting vertical luminance grating (34° period), stationary flies produce only very slow tracking. After changes in drift direction tracking has a faster velocity which subsequently declines to a steady velocity. Head angular velocity increases with drift velocity for stimulus contrast frequencies from 0.3-1.0Hz then plateaus to 7.0 Hz. Tethered, flying flies produce OKN more often after removal of the halteres. Small amplitude OKN occurs at the end of travel of the slow phase. Electrophysiological properties and differential staining for the oxidative enzyme SDH are correlated in TH muscles, including a newfound TH3 muscle. TH1 stains lightly and has moderate duration psp (0.72±0.2ms at half maximum amplitude). TH2 stains heavily and has significantly faster psp (0.57±0.09ms). TH3 comprises two distinct bundles: lateral, heavily staining fibers with fast psp and medial lightly staining fibers with very slow psp (2.18±0.5ms). We are currently studying differential activation of TH muscles during slow and fast head movements.

Supported in part by a grant from The Whitehall Foundation to CG.

## 259.13

INTRACELLULAR RECORDING AND STAINING OF VISUAL CELLS IN THE FIRST OPTIC LOBE OF *DROSOPHILA MELANOGASTER*. C.-F. Wu,\* Biological Sciences, Univ. of Iowa, Iowa City, IA 52242.

It is important to establish the links between the genes and behavior such that the biochemical defects and corresponding behavioral changes can be understood in neural terms. However, neurons in the *Drosophila* central nervous system are thought to be too small in size for serious physiological investigations. An attempt was initiated two decades ago to study the cell types and their physiological properties in the first optic lobe, lamina, in the brain. Using intracellular microelectrode techniques, electrical potentials in response to light stimuli were recorded and the cells were stained by injection of a fluorescent dye via the same micropipette. The structure of the lamina and the surrounding tissue were also studied by scanning electron microscopy. The results indicated that different cell types, identifiable by intracellular staining, produce either depolarizing or hyperpolarizing potentials of characteristic kinetic properties. By applying currents to shift membrane potential, the reversal potentials of the light responses could be determined. The large number of response types characterized by distinct kinetic properties and reversal potentials observed reflects a rich variety of synaptic processes in the visual pathway.

The data provide the necessary groundwork for further analyses of a large collection of *Drosophila* mutants known to be defective in the development or physiology of the visual system. This work also serves to demonstrate that many neurons in the *Drosophila* brain are accessible to cellular physiological analysis.

I thank Dr. William Pak, in whose lab a large portion of the work was initiated and accomplished, for support and encouragement. Supported by NIH grants to W.L. P. and C.-F. Wu.

## 259.14

SHAKING-B DISRUPTS THE ELECTRICAL COMPONENT OF A MIXED ELECTRO-CHEMICAL SYNAPSE IN ADULT

*DROSOPHILA*. J.R. Trimarchi\* and R.K. Murphey, Neuroscience and Behavior Program, Dept. of Biol. Univ. of Massachusetts, Amherst, MA 01003.

We have begun to characterize the synapses between haltere afferents and the first basalar flight motor neuron (B1mn). Our results suggest that these synapses are mixed electro-chemical synapses. Staining haltere afferents with the small intracellular dye neurobiotin results in dye coupling to B1mn. Neurobiotin also passes from B1mn into haltere afferents. A mutation in *shaking-B* that eliminates electrical synapses in the visual giant fiber pathway (Krishnan *et al.*, 1993; Phelan *et al.*, 1996), abolishes the dye coupling between haltere afferents and B1mn.

Stimulation of haltere afferents reliably evokes electromyograms (EMGs) from the B1 muscle that occur at short latencies. In *shaking-B* mutant flies, stimulation of haltere afferents evokes B1 EMGs that occur at abnormally long latencies. Intracellular recordings from B1mn indicate that the *shaking-B* mutation eliminates the electrical component of mixed synapses but does not disrupt the chemical component. Supported by postdoctoral NRSA grant 1 F32 NS09700-01 to J.R.T. and NIH NS-15571 to R.K.M.

## CORTEX: HUMAN STUDIES I

## 260.1

Temporally Resolved Human Brain Activity of Delayed Cued Movements studied by fMRI, W. Richter, S.-G. Kim\*, Center for Magnetic Resonance Research, Univ. of Minn., Minneapolis, MN 55455

To examine whether hemodynamic responses (measured by dynamic fMRI) may be used to investigate serial neuronal processes in different regions, a well-known delayed visuo-motor task, studied extensively in monkeys, was used. The task consists of visual presentation, delay period and cued finger movements; delay times were systematically varied between 1 and 9 seconds. fMRI images covering visual cortex, parietal lobules, and motor areas were acquired using a single-shot EPI technique with a temporal resolution of 200 msec, and movement and reaction times were recorded simultaneously. Motor execution was performed following a GO cue and monitored by a motion sensor. We found that bilateral associative visual cortex and parietal lobules were activated following the visual presentation. Furthermore, the supplementary motor area was activated during the delay time and before the actual motor execution. The primary motor cortex was activated weakly, but significantly, during the delay period, suggesting its involvement in motor preparation. Large activation was seen in the primary motor cortex following finger movements. This finding shows that dynamic fMRI studies can resolve serial neuronal activity during performance of visually-instructed, delayed motor tasks. It is recognized that the plethora of neural processes that operate in a domain of tens of milliseconds will remain beyond the capabilities of fMRI; however, many behavioral tasks involve mental processes lasting from hundreds of milliseconds to several seconds. In this case, fMRI may be able to resolve the processing sequence. (Supported by RR08079 and NS32919).

## 260.3

Mental Practice and Motor Skill Acquisition: An fMRI Study, J.E. Deutsch,<sup>1,2</sup> W.C. Liu,<sup>1</sup> J. Maldjian,<sup>1</sup> J. DeLuca,<sup>3</sup> UMDNJ-SHRP,<sup>1</sup> Department of Radiology, UMDNJ-NJMS,<sup>2</sup> Newark, NJ 07107, Kessler Institute for Rehabilitation<sup>3</sup>

Physical practice of a complex finger movement sequence was demonstrated to improve motor skill performance with changes in M1 associated with motor learning (Karni *et al.*, 1995). Imagining and performing movements appear to share the same neural substrates, suggesting that either strategy may be used for motor learning (Jeannerod, 1995). The purpose of this study was to explore the effect of mental practice on the acquisition of a motor skill.

Five subjects were instructed in 2 complex finger movement sequences. Videos of 30 sec. trials served to record baseline speed and accuracy as subjects executed both sequences. They were assigned one sequence to mentally practice for 5-10 min. daily. Speed and accuracy were measured for the trained and control sequences at 3, 7 and 10 days post training. Two of the subjects were imaged, on the 1st and 7th day, with BOLD fMRI using a single slice SPGR technique (24 cm FOV, 5 mm slice thickness, 256x128 matrix) on a conventional GE 1.5 Tesla clinical scanner. The TR/TE/flip angle combination utilized was 40/30/30. The paradigm consisted of cycles of 30" rest/20" activity for a total of 2'20". Functional maps were created using custom software developed in IDL utilizing the fourier transform cross-correlation function. Maximum correlation maps from the fourier transform cross-correlation function were thresholded at a  $P < .01$  and a minimum % signal change of 0.5 %. ROIs were drawn and activation volumes compared. To reduce spurious activation a 2-pixel nearest neighbor rule was applied.

After 1 week of practice all subjects improved their trained sequence speed ( $F_{(2,8)}=48.7, p<.001$ ). There was no significant activation for the complex motor tasks on day 1. On day 7 activation in the contralateral sensorimotor cortex was significant. Mental practice improved motor function which was represented by a change in sensorimotor cortex activation. \*Supported by NIDRR H133P40003

## 260.2

FUNCTIONAL MRI ACTIVATION PATTERN OF MOTOR AND LANGUAGE TASKS IN BROCA'S AREA P. Erhard\*, T. Kato, P.L. Strick\* and K. Ugurbil, Center for Magnetic Resonance Research, Univ. of Minnesota, Minneapolis, MN 55455, # State University of New York, New York, NY

Broca's area located in the inferior frontal lobe and the frontal operculum includes parts of Brodmann's areas (BA)44, BA45 and possibly BA46, is not well defined either anatomically or functionally. Twelve healthy, right handed subjects (4 males) were asked to perform different motor tasks including (I) random tongue movement, (II) toe movement, (III) complex instruction guided finger tapping, (IV) copying of displayed hand shapes and, (V) a language task. We used multislice fMRI with a relatively high resolution and investigated whether areas activated by motor tasks overlap with activation induced by language tasks. The language task showed activation in the lower part of BA6, in BA44, BA45, and in BA46. The toe task, the finger task and the handshape copying task also activated in the inferior part of BA6, in BA44 and to less extend in BA45 and BA46. The more complex motor task (handshape copying) shows relatively larger activation areas in both BA45 and BA46. The tongue-motor task activated in BA44 and the lower part of BA6 but to a much less extend in BA45 and in BA46. Our data shows that Broca's area, in particular the inferior part of BA6, BA44, and the frontal opercular part is involved in several different motor activities related to extremities and facial areas.

## 260.4

CORTICAL REPRESENTATION OF HAND AND FINGER MOVEMENTS IN MAN STUDIED BY MAGNETOENCEPHALOGRAPHY. J. Volkmann\*, A. Schnitzler, R. Seitz, O. W. Witte and H. J. Freund, Dept. of Neurology, Heinrich-Heine-University, D-40225 Düsseldorf, Germany.

Using whole-head neuromagnetic recordings (Neuromag™ 122-channel MEG) and time-varying multi-dipole modeling we could reliably separate the cortical generators of motor output and reafferent activity for different hand and finger movements (index finger extension, index finger abduction, thumb flexion, little finger abduction and wrist flexion) in 4 right-handed volunteers.

The average distance between dipolar generators for the respective movements within primary motor cortex (M1) was  $5.4 \pm 1.82$  mm in the right and  $9.3 \pm 3.8$  mm in the left hemisphere across subjects. Sources of reafferent activity in primary somatosensory cortex (S1) were usually less separated showing a higher degree of overlap. In all subjects, the size of hand motor area was estimated by the smallest cube containing the dipole solutions for all five movements. The cube volume was consistently larger ( $p < 0.05$ , t-test) in left (mean  $433.5 \pm 62.8$  mm<sup>3</sup>) than in right M1 (mean  $243.5 \pm 138.4$  mm<sup>3</sup>). In contrast no significant hemispheric asymmetry was found for reafferent activity in primary sensory cortex. Whether the observed M1 asymmetry is related to handedness remains to be shown.

The observed patterns of movement representation did not correspond to the 'classic' M1 homunculus or semihomunculus and were distinct for each subject. This mismatch reflects the difference between the classical approach to define somatotopy on the basis of observing the artificial hand/finger movements evoked by brain stimulation and the study of the relation between cortical activation and voluntary movements. Our results show that even different movements of the same digit are encoded by spatially segregated neuronal populations in primary motor cortex as can now be studied non-invasively in human subjects. (Supported by the Deutsche Forschungsgemeinschaft, SFB 194, Z2)

## 260.5

**ACTIVATION OF CORTICAL MOTOR AREAS DURING FINGER MOVEMENT SEQUENCES OF DIFFERENT COMPLEXITY.** J. Ashe\*, P. Dassonville, X.-H. Zhu, K. Ugurbil, S.-G. Kim. Brain Sciences Center, VAMC, and Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN 55417.

The exact determinants of functional activation within motor areas of the brain have not been fully elucidated. The complexity of the motor output appears to be one of these determinants. Traditionally, complex motor tasks have been defined in terms of *memorized* sequences of movements. In the present study, we examined the effects of varying the level of complexity within a series of *visually-instructed* finger movement sequences. In this context, the complexity related to the uncertainty of the upcoming visual stimulus. We obtained BOLD-based fMRI multislice axial images at 4 Tesla while subjects performed visually-instructed finger movements with the left and right hands. Subjects were cued to move the appropriate finger by a visual display on which four stimuli, arranged horizontally, were illuminated individually in either a predictable (i.e., simple) or randomized (i.e., complex) sequence at a frequency of 0.75 Hz. After delineating the boundaries of primary motor cortex, supplementary motor area (SMA), preSMA, and premotor (PM) cortex using anatomical landmarks, we compared the levels of activation in each area during the simple and complex sequences. We found the following: (1) In general, all areas showed significant increases in activation during both sequences for ipsilateral and contralateral movements. Exceptions were left primary motor cortex during simple ipsilateral movements and right primary motor cortex during both simple and complex ipsilateral movements. (2) There were consistently greater activations in PM, SMA and preSMA for the complex sequence than for the simple. (3) The trend toward greater activation during complex sequences was more evident during contralateral, rather than ipsilateral, movements. (Supported by NIH grant NS32437.)

**SELECTIVE ACTIVATION OF POSTERIOR PARIETAL CORTEX DURING PRISM ADAPTATION.** D. M. Clower\*, J. Votaw, J. M. Hoffman, G. E. Alexander. Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322.

Adaptation of reaching trajectories to the effects of displacing prisms is a paradigm that has been used extensively in human psychophysical studies to explore the plasticity of internal coordinative mappings between visual input and motor output. Few studies, however, have attempted to localize the cortical regions responsible for such sensorimotor remapping. To address this issue, we have used 3-D PET (positron emission tomography) with bolus injections of  $^{15}\text{O}$ -labelled water to measure regional cerebral blood flow in seven male subjects who performed a set of targeted reaching tasks that included: 1) a control task in which subjects reached to visual targets on a touchscreen with no visual distortion; 2) an adaptation task in which subjects reached to targets viewed through laterally displacing prisms; and 3) an error correction task in which the target moved as the subject was reaching, such that a trajectory correction was required to obtain the new target. The prism adaptation task involved both sensorimotor adaptation and trajectory error correction, while the error correction task involved only the latter variable. Using an analysis of variance which effectively subtracted the results of the error correction task from those of the adaptation task, we were able to localize the cortical fields involved in sensorimotor adaptation independent of error correction processes. Our results indicate that a highly focal region of the posterior parietal cortex is active during the sensorimotor remapping that accompanies prism adaptation. *Funded by Emory University.*

**INTERACTION OF INHIBITION AND FACILITATION IN HUMAN MOTOR CORTEX: A TRANSCRANIAL MAGNETIC STIMULATION STUDY.**

U. Ziemann\*, J. C. Rothwell\*, M. C. Ridding\*, <sup>1</sup> Dept Clin Neurophysiol, Univ. Göttingen, D-37075 Göttingen, Germany. <sup>2</sup> MRC Human Movement & Balance Unit, The Institute of Neurology, London WC1N 3BG, U.K.

Focal paired transcranial magnetic stimulation (TMS) was used in twelve healthy volunteers to study the interaction of intracortical inhibition (ICI) and intracortical facilitation (ICF) in the motor cortex. The effect of one or two subthreshold conditioning stimuli (CS) on the size of the EMG response in the contralateral abductor digiti minimi (ADM) muscle to a suprathreshold test stimulus was evaluated.

A single CS inhibited the test response at interstimulus intervals (ISIs) of 1-4 ms, while the response was facilitated at ISIs of 6-20 ms. These effects probably occur at the cortex level since the same CS had no effect on the size of the H-reflex elicited at appropriate ISIs in the active ADM. ICI and ICF appear to be due to separate mechanisms since (i) ICI had a lower threshold (70% of active motor threshold) than ICF (80%); (ii) ICI was independent of the current direction in the brain induced by the CS, while ICF was maximal with a posterior-anterior, but minimal with a latero-medial current; (iii) When inhibitory and facilitatory CS were given together at ISIs of 3ms and 10ms, the effect on the size of the ADM response is best described by an interaction model, which assumes the linear multiplicative integration of independent inputs to the target cell population (in the form of  $Y=ICI \cdot ICF$ ).

Our results suggest that subthreshold TMS is capable of activating separate populations of inhibitory and excitatory interneurons which about equipotentially can modulate the excitability of corticospinal neurons in human motor cortex.

## 260.6

**DIFFERENCES IN THE FUNCTIONAL LATERALIZATION OF CORTICAL MOTOR AREAS DURING FINGER MOVEMENTS.**

P. Dassonville\*, X.-H. Zhu, S.-G. Kim, K. Ugurbil, J. Ashe. Brain Sciences Center, VAMC, and Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN 55417.

Neurophysiological studies in monkeys have shown that the various cortical motor areas differ in the extent to which the corresponding motor-related activity is lateralized. For example, there are clear differences in the proportion of cells in the supplementary motor area (SMA) and the primary motor cortex that are activated with ipsilateral movements. However, the extent of these differences has not been fully elucidated. To test the functional lateralization of cortical motor areas in humans, we obtained BOLD-based fMRI multislice axial images at 4 Tesla while subjects performed randomized sequences of visually-instructed finger movements with the left and right hands. For individual subjects, we delineated the boundaries of primary motor cortex, SMA, preSMA, and premotor (PM) cortex using anatomical landmarks, and compared the volumes of activated cortex within these areas during ipsilateral and contralateral movements. The principal findings were: (1) All areas were significantly activated during both ipsilateral and contralateral movements, with the exception of right primary motor cortex during ipsilateral movements. (2) The extent of functional lateralization differed among the areas, with primary motor cortex the most strongly lateralized ( $p < 0.001$ ), followed by SMA ( $p < 0.05$ ) and PM (n.s.). In contrast, preSMA showed no indication of lateralization. (3) There were hemispheric asymmetries in the extent of lateralization: the combined activity of primary motor cortex and SMA was more lateralized in the right than in the left hemisphere. These differences in functional lateralization may account for some of the differences in the severity of deficits following lesions of the various cortical motor areas. (Supported by NIH grant NS32437.)

## 260.8

**MODALITY RELATED PARCELLATION OF HUMAN PARIETAL CORTEX IN TRAJECTORIAL MOVEMENT CONTROL.** F. Binkofski, S. Posse, J.S. Shah, H.W. Müller-Gärtner, A. Kleinschmidt, R.J. Seitz\*, H.-J. Freund. Dept. of Neurology, Heinrich-Heine-University, Düsseldorf, Germany, Forschungszentrum Jülich GmbH, Jülich, Germany.

The pattern of activation of the cortical areas involved in trajectory movement control was examined by fMRI. Five healthy right-handed volunteers (37.4  $\pm$  3.5 SD years) performed three types of previously practiced movements: (1) self-initiated figure-8 movements of the right index, (2) visual figure-8 tracking with the right index, both performed at 1.5 Hz and (3) blindfolded imagery of figure-8 index movements. An EPI method (TR: 3s, TE: 66ms,  $\alpha$ : 30°) utilizing the BOLD effect was employed. Ten slices of 3mm thickness oriented parallel to the AC-PC plane and positioned above the corpus callosum were acquired. The MR protocol consisted of 5 cycles alternating between task (15s) and rest state (15s). After movement correction correlation analysis using a threshold of 0.5 and regional analysis thresholded at z-score of 3 were performed. Movements were associated with significant activation in contralateral M1, S1 and SMA, with a greater involvement of SMA during the self-initiated movements. All three conditions activated bilateral premotor cortex. The anterior portion of the intraparietal sulcus (AIP) was most strongly activated by task 1, whereas both visual tracking and imagery preferentially activated posterior parietal cortex (PPC). This provides evidence that the same movement trajectory requires involvement of different neuronal aggregates depending on the nature of the sensory-motor transformations: internal kinesthetic representations in AIP and visual representations in PPC.

## 260.10

**INTRACORTICAL INHIBITION IS INCREASED DURING POST-EXERCISE DEPRESSION OF MOTOR EVOKED POTENTIALS**

DS Stokic\*, WB McKay, L Scott, AM Sherwood, MR Dimitrijevic

Division of Restorative Neurology and Human Neurobiology  
Baylor College of Medicine, Houston, Texas 77030

We have previously reported that motor evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS) of the motor cortex are depressed following sustained maximal voluntary contraction (MVC). The aim of this study was to determine whether intracortical inhibition, as demonstrated by paired magnetic stimulation, is involved in the post-exercise MEP depression.

In seven healthy subjects MEPs were recorded from both tibialis anterior (TA) muscles. Conditioning and test stimuli were given at 2, 4, 6 and 8 ms interstimulus intervals (ISIs) using a double cone coil centered over the vertex. Conditioning stimuli were 0.9 x individual MEP threshold during 10% MVC of the right ankle dorsiflexors (32  $\pm$  4% of stimulator output). Test stimuli were 1.25 x individual MEP threshold in relaxation (66  $\pm$  6%). Control and conditioned stimuli (5 each, 15 s apart) were randomly delivered in relaxation, before and after the MVC of the right ankle dorsiflexors performed for 1 min.

Before MVC, conditioning magnetic stimuli produced a significant inhibition of both left and right TA MEPs at 2 ms ISI (65% of control) with progressive recovery thereafter. After MVC, control MEPs were decreased in the exercised TA (mean  $\pm$  SE, 938  $\pm$  95  $\mu$ V before and 325  $\pm$  48  $\mu$ V after MVC;  $p < 0.001$ ) with no change in the non-exercised TA (433  $\pm$  48  $\mu$ V and 484  $\pm$  54  $\mu$ V, respectively). Intracortical inhibition was more pronounced after MVC in the exercised TA only (additional MEP decrease of 22% on average,  $p < 0.001$ ).

This finding suggests that increased intracortical inhibition is at least in part responsible for post-exercise depression of MEPs.

## 260.11

**VOLITIONAL MULTIJOINT AND SINGLE JOINT MOVEMENTS EMPLOY DIFFERENT FUNCTIONAL ORGANIZATION OF THE CNS** W.B. McKay\*, D.S. Stokic, W.J. Eaton, A.M. Sherwood, M.R. Dimitrijevic  
Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, Texas.

We have previously reported that maximal volitional contraction of a muscle focally reduces the responsiveness of the motor cortex to transcranial magnetic stimulation (TMS) (McKay et al., *Exp Br Res*, 105:276-282, 1995). In the current study, we examined motor cortex responsiveness changes when a muscle is activated as part of a multi-muscle, multi-joint effort. Six healthy subjects, 32 to 53 years of age, were seated in a chair equipped to measure contraction forces. In the first session, they performed a maximal isometric multi-joint contraction consisting of hip flexion and ankle dorsiflexion for 1 minute. The second session required ankle dorsiflexion alone. TMS over the scalp vertex elicited motor evoked potentials (MEPs) recorded through surface electrodes placed over the major muscle groups of both lower limbs. Stimuli were delivered at one minute intervals for five minutes before and after exercise. Both force and EMG amplitude in the exercised TA decreased at a similar rate during the single joint contraction and the multi-joint exercise. However, TA MEP amplitudes showed post-exercise depression only following the single joint effort ( $p < 0.05$ ). TA MEP amplitudes decreased from  $1018 \pm 173 \mu V$  to  $430 \pm 88 \mu V$  after the single joint effort but were unchanged from  $1195 \pm 217 \mu V$  before and  $1088 \pm 192 \mu V$  following the multi-joint exercise. These results suggest that activation of a muscle such as the TA in the context of a multi-joint, multi-muscle contraction probably occur as a result of a different functional organization of CNS structures from that of the relatively isolated muscle activation needed for a single joint movement.

## 260.13

**A HIGH FREQUENCY RESONANT CIRCUIT IN HUMAN MOTOR CORTEX** V.E. Amassian\*, J.C. Rothwell\*, M. Redding\*, A. Priori\*, and R. Jalinous\*  
Dept. of Physiology, SUNY Health Sci. Ctr. Brooklyn, NY 11203; \*MRC Human Movement Control & Balance Unit, Inst. of Neurology, London WC1N 3BG, UK; \*MAGSTIM Co. Dyfed, SA34 0HR, UK.

Indirect (I) corticospinal tract (CT) responses to an electrical stimulus to primate motor cortex are remarkably periodic ( $\sim 2$ ms). We sought evidence of a periodic circuit in humans by transcranially stimulating motor cortex with an HF train of magnetic pulses oriented for transynaptic activation of CT neurons. To optimize the need for temporal facilitation, subjects were relaxed and the stimulus reduced so that 2 pulses at, e.g., 1.5-1.7ms interval elicited a near-threshold response in First Dorsal Interosseus (FDI). In 3 of us, 3-4 pulses elicited optimal FDI responses at interpulse intervals of 1.6-1.7ms (Fig. 1); the optimum period in a fourth subject was 1.3ms, but was undefinable in the fifth. Our findings probably reflect coincidences of periodic magnetic transynaptic excitation with periodic cortical interneuron chain activity at  $\sim 600$  Hz, thereby supporting the hypothesis of a clock-like time quantizer in motor cortex (Neurosurgery, 1987, 20: 74-93).

Fig. 1. In the same subject, 10 summed responses are plotted versus intervals; inset, summed responses at 1.5 and 1.7 ms intervals.

## 260.15

**MOTOR CORTEX EXCITABILITY DURING TASK PERFORMANCE IS RELATED TO HAND PREFERENCE IN MAN** M.A. Nordstrom\* and J.G. Semmler  
Department of Physiology, University of Adelaide, Adelaide 5005, Australia.

Motor unit synchronization is weaker in first dorsal interosseus (FDI) muscle from the dominant hand of right-handed (RH) subjects than the non-dominant hand during index finger abduction (Semmler & Nordstrom, *Exp. Brain Res*, 104:115-125, 1995). One possible explanation is that corticomotoneuronal (CM) cells controlling FDI are more active when the non-dominant hand is used in this task. We have tested this hypothesis using magnetic (TMS) and electrical (TES) transcortical stimulation, which activate the corticospinal pathway at different sites (Rothwell et al., *Exp. Physiol.* 76:159-200, 1991). The responses to TMS (but not TES) are significantly influenced by CM cell activity. In eight RH subjects, TMS at passive threshold strength were applied (20 trials,  $< 0.2$  Hz) while the subject performed isometric index finger abduction at various forces (0.5 N to 50% maximal voluntary contraction (MVC)). Motor evoked potentials (MEPs) were recorded from FDI surface EMG. Mean ( $\pm$  SD) passive threshold TMS strength did not differ significantly between hands (dominant vs. non-dominant;  $41 \pm 3\%$  vs.  $43 \pm 8\%$ ; paired t-test,  $P > 0.05$ ). MEP areas (normalised to FDI M-wave area) increased with contraction strength, a consequence of increased excitability of cortical and spinal neurons. For the pooled data, normalised MEPs were consistently larger in the non-dominant hand, ranging from 208% of the dominant hand in the weakest contraction (0.5 N) to 123% in the strongest (50% MVC). The protocol was repeated in five of these subjects using passive threshold TES. MEPs following TES were facilitated by muscle contraction to a similar extent in each hand, indicating no lateral differences in spinal excitability. We conclude that during simple index finger abduction, CM cells controlling FDI are more active, and therefore contribute relatively more to the net excitatory command, when the non-dominant hand is used for the task. ## 260.12

**THE SILENT PERIOD INDUCED BY TRANSCRANIAL MAGNETIC STIMULATION IN PATIENTS WITH ASTERIXIS** M.A. Pastor\*, C. Garcia de Casasola, A. Ibricu, A. Espi, J.I. Herrero, J. Quiroga, J. Prieto, J. Artieda  
Dept. of Neurology, and Dept. of Internal Medicine, University Clinic, University of Navarra, 31080 Pamplona, Spain.

The excitatory motor evoked potentials (MEPs) and the inhibitory silent period responses (SPRs) to focal transcranial magnetic stimulation (TMS) were studied in the right extensor carpi radialis (ECR) in 15 normal subjects and 6 patients with asterixis. A Novamatrix Magstim device, with a maximal magnetic field strength of 2T, and a loop diameter 7 cm figure of eight coil was used. The stimulus was delivered to a grid of 1 cm sites on the scalp, to locate the maximum duration silent period. The stimuli were delivered at 1.5 individual motor threshold intensity. MEPs and SPRs were recorded from the right ECR via surface electrodes. Patients were tested while relaxed for the MEP, and trained to sustain 50% maximum level of tonic muscle contraction for the SPR. Contraction force was continuously monitored. The recordings were made with a sweep duration of 500 ms and a prestimulus period of 75 ms. The SPR duration was calculated from the stimulus artifact to the first reappearing EMG burst. In all patients the presence of asterixis was checked, recording ECR and FCR EMG, while stretching the arm, through surface electrodes. Motor threshold, expressed in percentage of the maximal stimulator output, was defined as the stimulus level where out of six consecutive stimulus, three responses of at least 30uV were defined on the screen by one of the authors blind to the stimulus intensity. There was a significant difference in magnetic stimulation motor threshold between patients and age-matched controls ( $t=4.3$ ;  $p < 0.01$ ). In the control group the mean duration of the SPR in ECR was 164.2, SD 43.6. The mean patients SPR was significantly prolonged 255.6, SD 60.7 ( $t=4.7$ ;  $p < 0.05$ ). These results suggest that there may be a cortical dysfunction between excitatory and inhibitory mechanisms in patients presenting negative motor phenomena such as asterixis.

**CORTICAL MOTOR OUTPUTS DURING DYNAMIC ISOMETRIC CONTRACTIONS: A SINGLE-JOINT, MAGNETIC STIMULATION STUDY.** Q. Soto-Téllez, A. Roy, S. Connolly, H. Abdulhadi, K. H. Chiappa and D. Cros\*  
Dept. of Neurology, Massachusetts General Hospital, Boston, MA.

Single cell recordings of corticomotoneuronal cells have shown populations with phasic responses relative to the tonic or ramp components of an isometric contraction. This may imply different cortical mechanisms for dynamic versus static contractions. We have previously shown that a mild static background contraction is sufficient to generate a change in the directional response of the twitch evoked with cortical magnetic stimulation, which corresponds closely to that of the background contraction. In these experiment we evaluated cortical outputs evoked with the same methodology, during dynamic linear and circular contractions. 5 normal subjects were studied. The right hand/forearm were immobilized with a cast, except for the second digit. This digit was introduced into a rigid ring which was attached to 2 orthogonally-oriented force transducers, allowing isometric force changes to be recorded in a vertical plane ( $360^\circ$ ). The contralateral motor cortex was stimulated using a large circular coil centered around the vertex at a stimulation intensity 10 % above threshold. The evoked twitch was defined by dF/dt plots, and its vectorial attributes (magnitude and direction) compared to those of the immediately preceding contraction (30-50 ms) defined by the same method. 3 paradigms were studied according to the type of background (facilitating) contraction: 1) Static forces in 8 directions of the workspace; 2) Linear dynamic contractions at constant dF/dt in 8 directions; 3) Circular dynamic contractions at constant dF/dt. A tight correlation was found between the direction of facilitation and the direction of the evoked twitch in both the linear static and dynamic contractions ( $r^2 > 0.87$ ). During circular trajectories, the direction of the evoked twitch closely matched that of the tangent of the circle defined by the facilitation period ( $r^2 = 0.88$ , slope 0.76 ( $\pm 0.04$ )). These results show that the active components (as opposed to postural) of movements are selectively enhanced during dynamic contractions, and suggest a fundamental role of the motor cortex in the specification of immediate trajectory changes. VOLTAGE-DEPENDENT OUTWARD CURRENTS IN VESTIBULAR SENSORY NEURONS FROM CHICK EMBRYO BRAIN SLICES. G. Gamkrelidze\*, and K.D. Peusner. Dept. of Anat. and Cell Biol., George Washington Univ. Sch. of Med., Washington, DC 20037.

The tangential vestibular nucleus (TN) represents a good model system for studying the development of signal processing in the vestibular system. Previous work in our laboratory has identified two main neuron types in the TN, principal (PC) and elongate cells (EC) based on morphology and electrophysiology. To further characterize these TN neurons at critical developmental ages, we are studying voltage-gated outward currents in 16 day chick embryo brain slices using whole-cell patch-clamp technique. The recording pipette contained 0.1% biocytin that allowed for morphological identification of the recorded neurons (n=5). Neurons were first characterized according to their responses to current steps and vestibular nerve stimulation under current clamp. Then voltage clamp recordings were performed in the presence of 2 $\mu$ M Tetrodotoxin to block inward sodium currents. Initial surveys of membrane currents from a holding potential -60mV utilized voltage steps from -90mV to +30 mV with 5mV increments (n=12). All cells had outwardly rectified I-V curves and peak currents were about 1-1.8 nA at +30mV. PCs generated an outward current in the range of -20 to -30 mV that did not show significant inactivation during a 200 ms voltage step. In contrast, ECs generated a transient outward current, which was followed by an outward current with little inactivation, both of which activated at -40 to -50 mV. The transient and sustained components of the current were further separated using a prestep to -120 mV. The sustained portion was partly blocked by 10mM Tetraethylammonium, while the transient current was fully activated at about -100mV and expressed full steady state inactivation at about -40 mV. This work is the first description of membrane currents in TN neurons. Experiments are currently underway to further separate and characterize the different membrane currents, which could account for differences in excitability reported between PCs and ECs. Supported by NIH grant #DC00970.

## 261.3

CANAL-SPECIFIC MONOSYNAPTIC EXCITATION AND DISYNAPTIC INHIBITION OF SECOND ORDER VESTIBULAR NEURONS IN THE FROG. H. Straka\*, S. Biesdorf and N. Dieringer. Dept. Physiology, Pettenkoferstr. 12, 80336 München, GERMANY.

Second order vestibular neurons (2°VN) receive a monosynaptic, glutamatergic excitation following ipsilateral vestibular nerve stimulation. In addition, most of these 2°VN were disynaptically inhibited by glycine (15 out of 16) or GABA (26 out of 29). Here we specify the pattern of convergence of excitatory and inhibitory inputs on 2°VN from individual semicircular canal nerves of the ipsilateral labyrinth. To that end, we recorded in-vitro synaptic potentials in 2°VN following separate electrical stimulation of the horizontal, anterior or posterior canal nerve before and after bath-application of bicuculline (0.5 $\mu$ M) or strychnine (0.5 $\mu$ M).

Most 2°VN (88 out of 99) received a monosynaptic EPSP from only one of the three semicircular canal nerves. Few neurons (N=10) received a monosynaptic EPSP from two canal nerves and one neuron received a monosynaptic EPSP from all three canal nerves. In 2°VN characterized by a monosynaptic EPSP from one canal nerve, stimulation of one of the other two canal nerves evoked a heterogeneous pattern of synaptic potentials consisting of di- and polysynaptic EPSPs, polysynaptic IPSPs or no response at all. Comparison of the amplitudes of EPSPs recorded before and during the application of glycine or GABA receptor antagonists revealed the presence of disynaptic IPSPs in these 2°VN (14 out of 14). As a rule, the monosynaptic excitation and the disynaptic inhibition of a given 2°VN originated from the same canal nerve (13 out of 14). However, horizontal canal-related 2°VN were not inhibited exclusively by glycinergic nor were vertical canal-related 2°VN inhibited exclusively by GABAergic vestibular interneurons.

## 261.5

RESPONSE OF NEURONS IN NUCLEUS FASTIGII IN PHASE-SHIFTED BINAURAL GALVANIC LABYRINTH POLARIZATION. H.-G. Schlosser, W. Guldin\*, O.-J. Grüsser. Freie Universität Berlin, Univ.-Klinik, Benjamin Franklin, Dept. of Physiology, Amimallee 22, 14195 Berlin, Germany.

Cells of Nucleus fastigii integrate vestibular stimuli. In anaesthetized Norwegian Rat both labyrinths were stimulated independently by galvanic sinewave currents, while extracellular single-unit recordings were performed on Nucleus fastigii. The independent polarization was performed by sinewave currents between two spheric silverchloride-electrodes (ssCE) for each labyrinth. One ssCE was implanted epidurally above the occipital cerebral hemisphere, the other was placed by an earbar through the Meatus acusticus externus in front of Membrana tympani. The flowing currents were constantly sinewave shaped by voltage regulation. Glass micropipettes (tip diameter 1.0 $\mu$ m; R = 30M $\Omega$ ) filled with Pontamine Sky Blue were used for recording and allowed an exact iontophoretic localization.

Most of the cells investigated responded to polarization of each of the labyrinths, some only to ipsilateral or contralateral stimulation. The neuronal response was analyzed with peristimulus time histogram and fast fourier transformation.

Between recordings of 20 periods of stimulation (0.5 Hz) the polarization sinewaves of the labyrinths were phase-shifted between each other in steps of 90 degrees. At a phase-shift (P) of 180 degrees one labyrinth is polarized at the most when the other is at its minimum. Nevertheless this synergistic stimulus of both sides did not provide maximum responses in all cells. Optimum responses of cells were sometimes aroused at P = 90 deg, or even P = 360 deg, i.e., when both labyrinths are polarized in phase. The investigated cells showed an upper frequency-limit between 10.0 and 30.0 Hz to a binaural, p = 180 deg stimulation. The minimum current amplitude for cell responses in Nucleus fastigii varied between 52 $\mu$ A and 118 $\mu$ A. It was similar to the threshold of ocular movement in rat.

## 261.2

PHYSIOLOGICAL CORRELATES OF VESTIBULAR COMPENSATION IN ISOLATED, IN VITRO WHOLE BRAINS FROM HEMI-LABYRINTHECTOMIZED GUINEA-PIGS. N. Vibert\*, A. Babalian, M. Mühlenthaler and P.-P. Vidal, L.P.P.A., CNRS-Colège de France, 15 rue Ecole de Médecine, 75270 Paris cedex 06, France and <sup>1</sup>Dpt. de Physiologie, CMU, 1 rue Michel-Servet, 1211 Geneva 4, Switzerland.

Vestibular compensation following unilateral labyrinthectomy is a model of post-lesional plasticity in the central nervous system. Just after the lesion, the deafferented vestibular neurons (VNs) are silent, whereas the discharge of contralateral VNs is strongly increased. The associated postural and oculomotor disorders disappear in 2 days in the guinea-pig, as a normal activity is restored in both vestibular nuclei. We used data obtained in isolated whole brains of normal guinea-pigs as reference to search for the cellular changes underlying vestibular compensation in brains of hemilabyrinthectomized animals.

In vitro whole brains were obtained from young guinea-pigs 3 to 8 days after labyrinthectomy. During the dissection, vestibular nerves were cut on both the deafferented and intact sides. In vivo, such an acute deafferentation of vestibular neurons on the intact side triggers in compensated animals the Betcherew's phenomenon: A postural and oculomotor syndrome appears, which is the mirror image of the one induced by the first lesion. Interestingly, this phenomenon was also observed in isolated brains from compensated guinea-pigs. Indeed, extracellular recordings revealed an asymmetry between the resting activities of VNs in both medial vestibular nuclei: their mean discharge was higher on the compensated side than on the newly deafferented side. Furthermore, a spontaneous nystagmus could be recorded from abducens nerves. This result demonstrates that some of the changes underlying vestibular compensation were retained in deafferented brains. In particular, we found that VNs on the compensated side received a stronger than normal excitatory spinal input, whereas the reverse was true for VNs on the intact side. These data fit with the hypothesis that an increased efficiency of cervical proprioceptive inputs to deafferented VNs would be partly responsible for the recovery of their normal discharge during compensation.

This work was supported by the CNRS, the CNES, and the Fondation pour la Recherche Médicale.

DYNAMIC RESPONSES OF PIGEON PRIMARY OTOLITH AFFERENTS TO LINEAR ACCELERATION. X. Si, D. E. Angelaki and J. D. Dickman\*. Department of Anatomy and Surgery, University of Mississippi Medical Center, Jackson Mississippi 39216.

Otolith afferent responses in pigeons have been studied during linear acceleration. At 2 Hz, the mean maximum gain was 367 spikes/s/g with a range between 65 to 1421 spikes/s/g. Phase leads ranging between 0 and 53 degrees re acceleration were observed. The tuning ratios (minimal/maximal sensitivity) of most afferents (88%) were lower than 0.1 suggesting that these fibers are one-dimensional (cosine-tuned). A response vector (relative to acceleration) was determined for each afferent with 74% of the vectors being directed out of the contralateral ear. Electrical polarization of the labyrinth was used to apply Galvanic currents to the pigeon vestibular primary afferents in order to study the cv (coefficient of variation) and cv\* value. Otolith units were then grouped according to their cv\* values into regular, intermediate and irregular classes. In addition, the response dynamics were tested on 18 otolith afferents. The gains of the irregular units had greater increases than the intermediate and regular units as stimulus frequency increased between 0.25 Hz to 10 Hz. The phase values remained consistently flat for all three groups across frequency. However, the more irregular firing otolith afferents had larger phase advances than regular firing units. The high gain, flat phase lead and small tuning ratios suggest that pigeons may have a simple one dimensional yet very sensitive otolith afferent system, as required for specialized flight behavior.

Supported in part by the NIDCD (DC01092) and NASA (NAGW-4507).

## 261.6

LINEAR DYNAMICS AND EYE POSITION SENSITIVITY OF PREPOSITUS NEURONS IN THE ALERT GERBIL. G.D. Kaufman\* and A.A. Perachio. Departments of Otolaryngology, Physiology & Biophysics and Anatomy & Neurosciences, Univ. TX Medical Branch, Galveston, TX 77555-1063.

The prepositus hypoglossus nucleus (PrH) has been implicated in horizontal eye velocity storage. This area has reciprocal connections with cells in vestibular, mesencephalic visual, and inferior olivary structures. We have developed an alert gerbil preparation with an eye coil system and extracellular single unit recordings in order to define the signals carried by PrH neurons in the lateral-eyed rodent model. With n>86 PrH cells characterized by pure linear and angular accelerations, a heterologous pattern of unit activity emerges. Dynamic responses were similar to those reported in the primate. Many cells exhibited complex multi-dimensional sensitivity and spatiotemporal convergence, while some had simple 1-D sensitivity to otolith input. Some multi-D cells exhibited vectors of maximum sensitivity with spatiotemporal properties (phase lead re: acceleration of 90 degrees) opposite to that found in medial vestibular cells. Other units responded to canal stimulation only. Many (~30%) of the units burst during the inhibitory portion of the angular rotation cycle, correlating with the quick phase of nystagmus and indicating an eye position component. The findings suggest that the PrH could serve an integrative role in many facets of vestibular function. The gerbil linear VOR response will also be discussed. NIH DC-00385 and DC-00111

## 261.7

PHYSIOLOGIC DIVERSITY AMONG HORIZONTAL SEMICIRCULAR CANAL AFFERENT NEURONS IN THE CHINCHILLA. L.F. Hoffman\*. Div. of Head & Neck Surgery, UCLA School of Medicine, Los Angeles CA 90095.

In this study individual primary afferent neurons innervating the horizontal semicircular canal crista were investigated to determine whether the system dynamic response characteristics exhibit parallel diversity to that exhibited by the single frequency responses [Baird et al., J. Neurophys. 60:182, '88]. Barbiturate-anesthetized chinchillas were prepared for electrophysiologic recording by exposing the superior vestibular nerve approximately 2 mm proximal to the horizontal ampulla. Body temperature was monitored via a rectal probe and closely regulated via a servo-controlled heating system. With the animal restrained in a special head holder on a rotatory turntable, glass micropipettes were used to record spontaneous and stimulus-evoked spike trains from horizontal semicircular canal afferents. Discrete frequency sinusoids were used over a broad stimulus bandwidth (0.0125 - 3.2 Hz) to characterize the system response dynamics of individual afferents. Each afferent's spontaneous discharge was analyzed for coefficient of variation (CV). Response gains and phases relative to stimulus velocity were determined from input-output functions and discrete Fourier analysis of the evoked cycle histograms, respectively. At each frequency examined response phases relative to stimulus velocity exhibited considerable diversity, even for afferents within restricted ranges of spontaneous discharge coefficient of variation. For example, afferents exhibiting CVs greater than 0.2 exhibited ranges of response phases to 0.05Hz sinusoids of 35° (30° - 65°). These same neurons exhibited a similar range of response phases to 0.4Hz sinusoids (0° - 35°). Similar diversity in phase was observed for lower (i.e. 0.0125Hz) and higher (i.e. 1.6Hz) stimulus frequencies. However, the respective phase differences between frequencies were not parallel for each afferent. The data from this study suggest that the system response dynamics for chinchilla horizontal semicircular canal afferents are represented by diversity in their transfer functions, even for afferents with comparable spontaneous discharge CVs.

OTOLITH SIGNALS AND CENTRAL PROCESSING IN RAT HORIZONTAL VOR. K.J. Quinn\*, S.A. Rude, S.C. Brettle, and J.F. Baker. Northwestern University, Chicago, IL 60611

Otolith participation in vertical vestibulo-ocular reflex (VOR) is widely recognized but a contribution of gravity sense to horizontal VOR during low frequency oscillations has been demonstrated only in cats. To study otolith signals and velocity storage we recorded horizontal VOR in pigmented rats using chronically implanted scleral search coils. Upright horizontal VOR was recorded during sinusoidal vertical axis rotations and velocity steps, with the head pitched 43° down to provide strong horizontal and minimal vertical canal activation. Horizontal VOR was also recorded during yaw in 'on side' (90° rolled) and 'upside down' (180° rolled) head orientations. While canal stimulation was identical in the three conditions, on side rotations provided a dynamic otolith input and upside down rotations altered static otolith signals.

In the upright orientation, low frequency (0.035 - 0.1 Hz) horizontal VOR was phase-advanced compared to cat and monkey (avg = 35° at 0.1 Hz,  $\pm 9.9$  sd, n=12). Time constants estimated from 0.05 to 1 Hz sinusoidal rotations averaged 2.5s (n=12) and from 50°/s velocity steps averaged 3.5s  $\pm 1.9$  sd (n=7). In upside down head orientation, VOR phase was further advanced (73°  $\pm 34$ ° sd at 0.1 Hz, n=12) and both estimates of the time constant were smaller (sine avg 0.9s; step avg 2.8,  $\pm 1.1$  sd). This difference suggests either velocity storage when upright or velocity leakage when upside down. In the on side orientation, VOR phases were less advanced than in the other 2 orientations (-1.4°  $\pm 15$ ° at 0.1 Hz, n=8), indicating that a dynamic otolith input results in a phase-accurate low frequency horizontal VOR in rats.

GRAVITY DEPENDENCE AND SPATIAL PROPERTIES OF VESTIBULAR REFLEXES IN DORSAL NECK MUSCLES OF THE SQUIRREL MONKEY. J.E. Killian\* and J.F. Baker. Northwestern University Institute for Neuroscience, Chicago IL 60611

We recorded electromyographic activity bilaterally using implanted wire electrodes in three dorsal neck muscles of two squirrel monkeys during vertical sinusoidal rotations in total darkness. Thirteen sets of 0.25 Hz, 30° rotations in 16 different vertical planes spaced 22.5° apart were completed, with the monkey initially oriented upright or upside down. In alert but calm animals, muscle activity varies sinusoidally with the rotation. Each muscle is most active for a particular plane of vertical rotation; activity during rotations in other planes is a function of the cosine of the angle between that plane and the plane producing the greatest response. Semispinalis is activated best by rotations near pitch with some roll. Roll rotations excite Splenius best, while Occipitocapularis's preferred direction lies between those of Semispinalis and Splenius. Compared to corresponding neck muscles previously studied in the cat (Banovetz et al. *Exp. Brain Res.*, 1995), neck muscles in the squirrel monkey are more active in response to roll rotations. This difference in the organization of the spatial properties of the vestibulocollic reflex likely echoes the constraints imposed by the different anatomical arrangement of the head-neck system between the two species.

Responses for all muscles generally peak in phase with maximal angle of tilt. However with the monkey oriented upside down, this peak is consistently 180° opposite to the response when the monkey is rotated about an upright position. Upside down, the monkey reflexively acts to rotations by moving the head even more. The strategy of spatial cooperation among the muscles is unchanged, but the gravitational context dictates a different goal. Thus the vestibulocollic reflexes are under the control of an otolith gravity signal: when upright, vestibulocollic reflexes stabilize the head by compensating for rotations; but when upside down, they are anticomensatory and work with the rotation to right the head with respect to gravity.

MAXIMUM INFORMATION-PREDICTING MODELS OF BULLFROG SEMICIRCULAR CANAL AFFERENT SPIKE TRAINS. M.G. Paulin\* and L.F. Hoffman. Dept. of Zoology, University of Otago, New Zealand & Division of Head and Neck Surgery, UCLA School of Medicine, Los Angeles CA 90095.

This study was undertaken to develop and test new methods of spike train analysis and to apply those methods to investigate the diversity in response dynamics of semicircular canal afferent neurons. We use a class of nonlinear models and a maximum information prediction rate criterion to select an optimal model from this class for each neuron. Bullfrogs were subjected to band-limited (0.05 to 4 or 10 Hz) Gaussian rotational velocity stimuli, with transitions optimized to minimize integrated torque change. Afferent spike times measured with 1ms resolution were converted to spike rates by Gaussian convolution, which optimally preserves timing information while lowering signal bandwidth [Paulin, Biol. Cyber. 66:525, 1992]. Dynamic linear - static nonlinear (ARMA-polynomial) cascade models were fitted to the stimulus-response data. For each neuron we searched over model structures and rate estimation bandwidths. The rate at which each model predicts information about the neuron's responses to novel stimuli was estimated using crossvalidation data collected at the same time as the fitting data. Best information-predicting models had bandwidths comparable to the mean firing rate of the modelled neuron. These models reproduced dynamic features of the semicircular canal afferents studied, predicting spike times in response to novel stimuli as accurately as the neurons themselves do on repeated trials. Some afferent neurons transmit information about the whole head rotational velocity waveform, while others provide enhanced information about specific features of the waveform. Our modelling technique identifies stimulus features associated with particular afferents. These results are congruent with previous reports of functional diversity in semicircular canal afferent responses, but we extend those reports by representing the functional properties of individual neurons in a form naturally suited to analysing the differential roles these neurons may play in collective computation in the CNS.

## 261.10

LOW FREQUENCY DYNAMICS AND OTOLITH SIGNALS ON ANTERIOR AND POSTERIOR CANAL VESTIBULO-OCULAR NEURONS IN ALERT CATS. S.C. Brettle\* and J.F. Baker. Northwestern University, Chicago, IL 60611

Accurate low frequency behavior of the vertical vestibulo-ocular reflex (VOR) requires central processing or otolith input to compensate for the advanced phase of the primary canal afferents. We recorded 188 neurons in five alert cats in order to investigate velocity storage and otolith signals on vestibular nucleus neurons. Neurons were classified according to latency of orthodromic responses to ipsilateral labyrinth electrical stimulation and antidromic responses to oculomotor nucleus stimulation.

During horizontal axis sinusoidal pitch rotations, the head velocity signal on vertically sensitive second-order neurons is accurate in the middle frequency range, with a phase of -97°  $\pm 17$ ° s.d. (n=98) re acceleration at 0.5 Hz. At lower frequencies however, anterior canal oculomotor-projecting second-order neurons (AC-VON) code velocity more accurately than posterior canal oculomotor-projecting second-order neurons (PC-VON) recorded at 0.05 (AC-VON, -89° $\pm 9$ , n=7; PC-VON, -65° $\pm 22$ , n=8) and 0.02 Hz (AC-VON, -66° $\pm 21$ , n=5; PC-VON, -37° $\pm 22$ , n=6). The AC-VON phase advance only 8° $\pm 7$  (n=7) from 0.5 Hz to 0.05 Hz while the PC-VON advance 32° $\pm 23$ . Median time constants for PC-VON were 7.7 seconds (n=8) and 19.1 seconds (n=7) for AC-VON. Extension of the velocity code for AC-VON may contribute to longer time constants for upward than downward VOR.

To separate canal responses from otolith responses at low frequencies, 9 second-order vestibular nucleus neurons were recorded during both horizontal and vertical axis (on side) pitch at 0.05 Hz. The AC neurons consistently exhibited large phase advances with the removal of a dynamic otolith input (72° $\pm 26$ , n=4) while the PC neurons were less affected (3° $\pm 28$ , n=5). The otolith input to AC-VON may reflect a greater otolith role in upward than downward VOR. Supported by EY07342.

## 261.12

VESTIBULAR-ONLY (VO) NEURONS AND VELOCITY STORAGE. B. Cohen\*, S.B. Yakushin, B. Sheliga and T. Raphan. Depts. Neurol. & CIS, Mt. Sinai Sch. of Med. & Brooklyn College, CUNY, New York, 10029

Activity of VO neurons in rostral MVN was studied in paradigms that elicited velocity storage. Animals were tested during steps of constant angular velocity, during yaw axis optokinetic nystagmus (OKN) and after-nystagmus (OKAN) in upright and on-side positions, and during rotation around axes tilted from the vertical (off-vertical axis rotation, OVAR). Exposure to a stationary surround was used to test effects of light dumping during post-rotatory nystagmus. Visual and oculomotor contributions to unit firing were also determined. In all tests VO neural activity was related to the velocity storage component of eye velocity and not to eye velocity per se. The activity of VO neurons did not depend on the state of alertness, and unit firing was maintained despite loss of eye velocity due to drowsiness. During constant velocity rotation, time constants (Tc's) of VO neurons decreased with increases in stimulus velocity as did eye velocity Tc's, but unit Tc's were always longer. Eye velocity but not VO neural activity changed rapidly during exposure to a stationary surround during light dumping. During OKAN cross-coupling, activity of Type I VO neurons was related only to horizontal, not to vertical or roll eye velocity. All VO neurons had a bias component during OVAR and cells receiving otolith information were modulated as a function of head position with regard to gravity. These data demonstrate that VO neurons have a strong link to the horizontal component of velocity storage and have the requisite activity for its realization. The same is not true for other classes of vestibular neurons described earlier. SUPPORT: NS00294, NAG 2-706, EY01867, EY04148

## 261.13

## VESTIBULAR-ONLY (VO) NEURONS AND THE SPATIAL ORIENTATION OF VELOCITY STORAGE.

S.B. Yakushin\*, B. Sheliga, T. Raphan and B. Cohen. Depts. Neurol. & CIS, Mt. Sinai Sch. of Med. & Brooklyn College, CUNY, New York, 10029

The spatial orientation of VO neurons in rostral MVN of rhesus monkeys was studied and related to the spatial orientation of velocity storage. Axes of maximal sensitivity (AMS), i.e., axes around which rotation gave maximal modulation of firing rate were determined for each unit by sinusoidal rotation around a spatial vertical axis with the animal upright or statically tilted backward or forward, and by pitching about a horizontal axis with different head orientations to the pitching plane. OKN & OKAN were also given in upright and tilted positions. The AMS of most VO units was tilted forward about 20°, indicating input solely from the lateral canals. Some neurons were also modulated when the head was pitched. Based on phase relative to head position with regard to gravity, most Type 1 VO units had convergent information from the otoliths. Other VO neurons had their AMS about the upright position, with the same peak as horizontal eye velocity. These units had input both from a lateral and vertical canal. Type 2 VO neurons received input primarily from the vertical canals. Time constants (Tc's) of VO neurons were reduced along with the horizontal Tc during OKAN in on-side positions. A horizontal Type 2 VO neuron had activity related to the cross-coupled component of vertical eye velocity. Thus, Type 1 & 2 VO neurons receive not only lateral canal, but otolith and vertical canal-related activity and alter their Tc's appropriately during cross-coupling. We propose that an network of VO neurons could implement the spatial orientation of velocity storage. SUPPORT: NS00294, NAG 2-706, EY01867, EY04148

## CENTRAL REPRESENTATIONS OF THE STIMULI THAT DRIVE MOTOR LEARNING IN THE VOR. Jennifer L. Raymond\* and Stephen G. Lisberger. Department of Physiology and W.M. Keck Foundation Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

To place constraints on the neural mechanisms for the induction of motor learning in the vestibuloocular reflex (VOR), we examined the responses of Purkinje cells in the floccular complex to stimuli that drive learning. We recorded simple spike (SS) and complex spike (CS) responses in Horizontal Gaze Velocity Purkinje cells (HGVPs) to pulses of head and visual stimulus motion that increased (x2) or decreased (x0) the gain of the VOR. Pulse durations ranged from 80-1000 ms.

The average SS response to ipsiversive head turns was an initial decrease in firing rate for both x0 and x2 stimuli, followed by an increase in firing rate for x0 stimuli or a further decrease in firing rate for x2 stimuli. The differential SS responses to x0 and x2 stimuli were sustained from about 100 ms after the onset of the stimulus to about 100 ms after the offset of the stimulus. For contraversive head turns, responses were in the opposite directions.

The average CS response to ipsiversive head turns was a sustained decrease in firing rate for x0 stimuli and a sustained increase in firing rate for x2 stimuli from about 100 ms after the onset of the stimulus to about 100 ms after the offset of the stimulus. For contraversive head turns, responses were in the opposite directions.

Both the correlation of the sustained CS response with the vestibular stimulus and the correlation of the sustained SS response with the vestibular stimulus contained information about whether the gain of the VOR needed to increase or decrease. However, for short-duration ( $\leq 100$  ms) stimuli, these responses did not overlap with the vestibular stimulus in time, suggesting that a plasticity mechanism may compare a CS or SS response with a vestibular stimulus that preceded it in time.

## 261.17

## THE LINEAR VESTIBULO-OCULAR REFLEX (LVOR) FOLLOWING LABYRINTHECTOMY. G. D. Paige\*, L. Telford, S. H. Seidman, and P. Boulos. Dept. of Neurology, Univ. of Rochester, Rochester, NY 14642.

Horizontal and vertical LVOR responses were recorded during inter-aural (IA) and dorso-ventral (DV) translational oscillations (0.5-4 Hz, 0.1-0.5g peak) before and after unilateral labyrinthectomy in squirrel monkeys. Response sensitivities (in °/cm) and phases were analyzed in relation to stimulus characteristics (frequency and motion axis), vergence angle, and recovery time post-lesion. The normal high-pass dynamics of the translational LVOR, and the influence of vergence, remained after labyrinthectomy. However, sensitivities generally decreased, both at dark vergence (1 meter-angle) and as a function of vergence (in °/cm/meter-angle), followed by modest recovery over time. Phase displayed a novel post-lesion lead, even at 4 Hz (roughly 10°). Interestingly, the axis of ocular response shifted after labyrinthectomy. This was most noticeable as a roll of the response axis toward the unlesioned side during IA motion, manifested as the appearance of a small vertical response component along with the larger horizontal response. The axis shift declined over time, consistent with an adaptive shift in response axis toward normal. The phenomenon did not occur in the angular VOR, and may reflect the off-sagittal tilt of the remaining sacculus, operating in the absence of counteracting influences from the opposite endorgan. The two eyes behaved roughly conjugately after labyrinthectomy, indicating that a single utricle and sacculus can drive the LVOR binocularly, as do canal-driven reflexes. Finally, all angular and linear VORs were abolished following a second labyrinthectomy.

## 261.14

## EYE AND HEAD COORDINATION DURING HEAD-FREE GAZE PURSUIT IN THE RHESUS MONKEY: ACTIVITY OF VESTIBULAR NEURONS.

J.E. Roy\* and K.E. Cullen. Aerospace Medical Research Unit, Department of Physiology, McGill University, Montreal, Canada.

The activity of neurons in the vestibular nuclei of alert rhesus monkeys were characterized during combined eye-head tracking. Monkeys were trained to 1) pursue a moving visual target and 2) cancel their vestibular ocular reflex by fixating a visual target which moved with the vestibular turntable. Target or table motion consisted of a sine wave (0.5 Hz, 40°/s peak velocity) in the horizontal plane. Neurons were first classified in the head-restrained monkey during spontaneous eye movements, smooth pursuit, cancellation of the VOR (VORc), and VOR in the dark (VORd).

Three classes of neurons are considered below: 1) neurons which were sensitive to ipsilateral head movements (VIs), 2) neurons which were sensitive to ipsilateral head movements and contralateral eye movements (VIEIs), and 3) neurons whose head and eye velocity sensitivities were in the same direction during smooth pursuit and VORc respectively (EVs). Following the initial characterization of the cells, the monkey's head was released. Although the target remained well within their oculomotor range ( $\pm 50^\circ$ ), monkeys made significant use of both head and eye movements to track target motion. During some trials, head motion was momentarily ( $\approx 100$  ms) halted (by a friction clutch). The activity of VI neurons during combined eye-head pursuit and rapid gaze shifts was well predicted by their head velocity sensitivity during VORc and VORd. In contrast, the activities of VIEI and EV neurons during head-free tracking were not well predicted by a linear model based on head-fixed head and eye movement sensitivities. In particular, the modulation of the activity of VIEI neurons during head-free pursuit was generally less than that predicted by the head-fixed characterization of these neurons, suggesting that the modulation of these pathways was reduced during head-free tracking. Our results indicate that head-fixed models do not adequately describe VIEI and EV vestibular neuron discharges during head-free tracking. (Supported by the Medical Research Council of Canada).

## 261.16

## THE EFFECT OF UVULONODULAR LESION ON NEURONAL PROPERTIES IN THE LATERAL VESTIBULAR NUCLEUS OF RATS DURING NATURAL OTOLITH STIMULATION. B. Jiang, C.H. Lai and Y.S. Chan\*. Department of Physiology, Faculty of Medicine, The University of Hong Kong, Sassoon Road, Hong Kong.

To investigate the contribution of the cerebellar nodulus and uvula on the response characteristics of otolith neurons in the lateral vestibular nucleus, the properties of these neurons to constant velocity off-vertical axis rotations (OVAR), which selectively stimulate the otolith receptors, were studied in adult Sprague-Dawley rats with or without acute ablation of the uvulonodular lobe. All rats were decerebrated under halothane anesthesia. In rats with intact cerebellum, most neurons showed symmetric bidirectional response sensitivity ratio ( $\delta$  defined as the CW gain over the CCW gain) which remained stable with velocity while 23% of the sampled neurons showed velocity-variable and asymmetric bidirectional response sensitivity. In uvulonodular lesioned rats, however, the proportion of neurons showing asymmetric and velocity-variable  $\delta$  values increased to 79%. The spread of the  $\delta$  values over the velocity spectrum was characteristic of each neuron sampled. In uvulonodular lesioned rats, the  $\delta$  spread of the asymmetric neurons ranged from 0.17 - 2.87 while the corresponding values in control rats was 0.35 - 0.67. Another unique feature observed in uvulonodular lesioned rats was the occurrence of some asymmetric neurons that were responsive only to OVAR of one direction but not to both; this feature was not found in control rats. Our results suggest that the cerebellar nodulus and uvula constitute part of the neural substrate in modulating the gravity-dependent responses of central vestibular neurons during natural otolith stimulation. [Support: HKRGC]

## 262.1

**TAIL AND EYE MOVEMENTS ELICITED BY ELECTRICAL STIMULATION OF THE OPTIC TECTUM IN GOLDFISH.** B. Torres, L. Herrero, F. Rodríguez, C. Salas and P. Nunez-Abades\*. Dept. of Animal Physiology and Biology and Dept. of Experimental Psychology, Univ. Sevilla, Spain.

Current studies on the superior colliculus involvement in the motor codification of eye, head and/or body movements in mammals support two main suggestions: 1) the metric properties of the movement are encoded by both the collicular locus of activity and the amount of such activity, and 2) depending on the species the colliculus plays a role not only in orienting but also in escape responses. This work was aimed to investigate these two suggestions in the optic tectum of goldfish. Experiments were carried out in restrained goldfish with the tail free to move. Fish tail and eye movements were recorded in the awake animals following the electrical microstimulation of several tectal loci and as function of stimulus parameters. Low intensity (10 - 120  $\mu$ A) stimulation elicited conjugated contraversive eye movements and the contraction of the axial muscles contralateral to the stimulated tectum. These movements are compatible with the generation of orienting responses. The amplitude and velocity of these orienting movement depended on the tectal stimulated locus and on stimulus parameters. High intensity stimulation (up 120  $\mu$ A) elicited the contraction of the axial muscles ipsilateral to the stimulated tectum and eye retraction. These movements are compatible with the generation of escape responses. Finally, the threshold to elicit the escape response varies with the tectal zone. Supported by a CICYT PB93-0916 grant.

## 262.3

**DIVERGENT AXON COLLATERALS FROM THE ROSTRAL SC TO THE PRETECTAL ACCOMMODATION-RELATED AREA AND THE OMNIPAUSE NEURON AREA IN THE CAT.** Y. Nagasaka, K. Ohtsuka\* and A. Sato. Dept. of Ophthalmology, Sapporo Medical Univ. Sch. of Med., Sapporo, Hokkaido 060, Japan.

We previously indicated that the circumscribed area in the rostral SC, which corresponds to the area centralis, is involved in the control of lens accommodation in the cat. Recent studies indicated that the area centralis of the SC is also involved in the control of the active fixation (saccade suppression). This area projected to the pretectum, where accommodative responses were evoked by electrical stimulation, and the nucleus raphe interpositus (RIP), which corresponded to the omnipause neuron area. In this study, we investigated collateralization of efferent fibers from the accommodation-related area in the SC to the pretectal accommodation-related area (PA) and the omnipause neuron area in the RIP of the cat using a fluorescent double-labeling technique. This study was conducted in 2 cats, weighing 2.5-3.5 kg. Retrogradely labeled neurons in the ipsilateral SC were examined following injections of fast blue into the RIP and diaminidino yellow into the PA, or vice versa. Neurons projecting to the RIP were located in the intermediate layers in the rostral SC, while locations of neurons projecting the PA were scattered in the SC. Double-labeled neurons were located in the circumscribed area in the rostral SC, which corresponded to the area centralis. The presence of double-labeled cells indicated that the accommodation-related area in the rostral SC contains neurons whose axons collateralize to project to both the PA and the omnipause neuron area. These findings suggest that the rostral SC is involved in the control of both accommodation and the active fixation.

## 262.5

**DESCENDING INTRACOLLICULAR PATHWAYS TO THE INTERMEDIATE GRAY LAYER IN THE TREE SHREW.**

T. Ha, P. Lee, G. I. Augustine and W. C. Hall\*. Department of Neurobiology, Duke University, Durham, NC 27710

A visual pathway from the superficial to the intermediate gray layer may play a role in saccade selection. Cells in the deep part of the superficial gray layer receive visual input from both the retina and the cortex and project to the underlying optic layer. The optic layer projects in turn to the intermediate gray layer, which contains most of the efferent cells that project to the gaze centers of the pons. Some intermediate cells have apical dendrites that extend into the optic layer; they may receive visual input directly from superficial gray layer cells or indirectly from optic layer cells. The dendrites of other intermediate cells avoid the optic layer, but may receive visual information from the descending optic layer axons. This intracollicular circuit is highly columnar and may play a role in generating presaccadic responses of a subset of intermediate layer cells. Patch clamp studies are now underway to examine the influences of the descending pathway on intermediate layer cells. Supported by NIH grant EY 08233.

## 262.2

**NEAR-RESPONSE-RELATED NEURAL ACTIVITY IN THE ROSTRAL SUPERIOR COLLICULUS OF THE CAT.** H. Jiang\*, D. Guitton and K. E. Cullen. Montreal Neurological Institute and McGill University, Montreal, Quebec, Canada, H3A 2B4.

The rostral superior colliculus (SC) has been linked to the neural control of active fixation in both cat and monkey. Cells in the so-called 'fixation zone' are tonically active during fixation and pause during eye saccades (monkey) or head-free gaze shifts (cat). The rostral SC of cats has also been implicated in the control of accommodation, and we report here on the activity of neurons in this area that modulate their discharge in response to stimuli moving towards or away from the animal. Cats were trained to make vergence eye movements in response to approaching or receding visual food targets. Trials were performed either in the light or, when the ambient light was unexpectedly turned off, at a random time either before or after vergence eye movements had been initiated. Thus, in the latter condition, a portion of a vergence movement was made in the dark. Two types of neurons were observed: a) cells that paused during vergence eye movements made in the light or dark but not during conjugate saccadic eye movements; b) cells whose discharge frequency profile resembled vergence velocity but also were not modulated during saccadic eye movements. These near-response-related discharges were recorded from neurons generally located deeper in the rostral SC than fixation cells. Electrical micro-stimulation in this region induced disconjugate eye movements and sometimes pure vergence responses. We conclude that the fixation zone of the cat's SC is involved in changing fixation from far to near (or vice versa) targets. This leads to the interesting hypothesis that the SC controls gaze shifts between targets located anywhere in 3-dimensional space.

## 262.4

**MOVEMENT FIELDS OF THE SUPERIOR COLLICULUS IN TRAINED CATS.** Choongkil Lee\* and Incheol Kang. Dept. of Psychology, Seoul National Univ., Seoul Korea 151-742.

Pattern of movement fields of the superior colliculus in the cat has been controversial (Guitton et al., 1993; Sparks, 1993; Peck et al., 1994). Since this pattern is critical for understanding collicular mechanism controlling saccadic eye movements, we tried to determine the pattern in trained cats.

Cats, pre-trained to attend to LED's, were trained for water reward to make saccades to briefly-presented visual targets (LED's) spaced 4 deg apart, spanning  $\pm 30$  deg in a tangent array. Neural activities recorded from the superior colliculus were classified into visual (related to stimulus on and off) and motor (related with saccade) components. For unambiguously-classified motor activities, indices of activity level such as number of motor spikes or its density estimate derived by convoluting with a variable kernel, were plotted against horizontal and vertical amplitudes of saccades. To confirm the idea of "moving hill" proposed by Munoz et al. (1991), the location of peak density in relation to the onset or offset time of saccades along the "best direction" was also plotted against the vectorial amplitude of saccades.

Saccades with similar amplitude and direction were often associated with highly variable motor activity. When the average trend was considered, the distal border of movement fields were bounded for the "best amplitude" up to 15 deg. The temporal gap between the peak density for motor activity and the movement offset was not fixed across saccades along the "best direction". These results that we have obtained so far are inconsistent with the idea of "moving hill" hypothesis. (Supported by KOSEF grant 91-01-00-04).

## 262.6

**CHARACTERIZATION OF SUPERIOR COLLICULUS RESPONSES TO INTRINSIC STIMULATION.** M.A. Meredith\* and A.S. Ramoa. Department of Anatomy, Virginia Commonwealth University, Richmond, VA.

While a great deal is known regarding the functional dependence of the superior colliculus (SC) on its various sensory and motor inputs, recent evidence indicates that a rostro-caudally oriented intrinsic circuit is critical to SC-mediated functions such as fixation and orientation. The current experiments sought physiological evidence for SC interneurons that might participate in such a circuit. Adult ferrets ( $n=4$ ) provided para-sagittal slices of the SC that were placed in an interface chamber at 35°C. Routine *in vitro* methods were used to record extracellular action potentials in spontaneously active neurons and their responses to electrical stimulation (concentric bipolar, 37-300  $\mu$ A, 0.1 ms) presented at rostral and at caudal SC sites. Electrical stimulation was conducted alone or combined with d-APV/CNQX (to block excitatory synaptic transmission).

More than two-thirds ( $n=23/34$ ) of the SC neurons studied responded to intrinsic SC stimulation: 9 showed brief (avg. duration = 16.6 $\pm$ 13.2 ms) increases in firing frequency, 10 revealed relatively long (avg. duration = 55.6 $\pm$ 24.5 ms) decreases in spontaneous activity, and 4 responded with both excitation and post-excitatory suppression (avg. duration = 12.5 $\pm$ 5 ms; 65.0  $\pm$  10 ms, respectively). An overwhelming number ( $n=17/23$ ) was affected by rostral stimulation sites, 5 were influenced from caudal stimulation sites, and only one was influenced from both rostral and caudal sites. Fifty  $\mu$ M d-APV/200  $\mu$ M CNQX picrospritzed between the stimulation and recording site accentuated the suppressive effects of stimulation in 3 of 4 neurons. Adding 25  $\mu$ M d-APV/6  $\mu$ M CNQX to the bath, eliminated suppressive as well as excitatory responses at the recording site, indicating that the stimulation had excited intrinsic inhibitory interneurons. These data are consistent with the presence of a rostro-caudal intrinsic circuit within the SC and support the hypothesis that SC interneurons can influence SC-mediated behaviors. Supported by NSF grants IBN-9308576 (MAM) and IBN-9421983 (ASR).

## 262.7

**DISTRIBUTION AND TARGETS OF COLLICULAR EFFERENT CELLS: MULTIPLE TRACER STUDIES IN THE CAT AND MACAQUE.** E. Olivier and P.J. May\*, Lab. of Neurophysiology, U. of Louvain, Brussels, Belgium and Depts. of Anatomy & Neurology, U. of Mississippi Med. Ctr., Jackson, MS 39216.

Intracellular investigations that classify superior colliculus (SC) efferent neurons distinguish T-cells, which project to the contralateral SC, and X-cells, which instead project to the contralateral brainstem and spinal cord. These may subserve eye, and combined head and eye movements, respectively, but their overall population characteristics are unknown. Injections of different fluorescent tracers at separate sites in the cat were used to demonstrate the distribution of tectal neurons projecting to the contralateral SC, and to the contralateral pontine reticular formation and spinal cord. Tectotectal cells (T-cells) were found in the rostral half of the SC and were widely distributed from stratum opticum to the deep gray layer. Only a small portion (~20%) of these T-cells also projected to the contralateral pons. These were constrained to the intermediate gray layer, and made up 15% of the total number of cells projecting in the predorsal bundle (PDB). No T-cells showed spinal projections. The PDB cells without a commissural projection (X-cells) were found from the intermediate to deep gray layers and were distributed evenly within the SC. About half of the tectopontine X-cells also send a projection to the spinal cord. Only a few cells projected exclusively to the spinal cord. In macaque monkeys, T-cells had a much more extensive rostrocaudal distribution than in the cat. The distribution of tectopontine cells was similar to the cat's, but was limited to the intermediate gray layer. Tectospinal neurons were very rare. In view of the monkey's limited direct tectospinal projection, we investigated the tectoreticulo-reticulospinal connection. BDA injected into the SC labeled terminals that contacted HRP labeled reticulospinal neurons primarily in the pontomedullary reticular formation. However, only tectal terminals were found in the reticular formation immediately ventral and rostral to the sixth nucleus. Thus, species specific differences exist in the somatic location and terminal distribution of tectal efferent populations. These data are needed to formulate a coherent model of SC function in eye and head control. Supported by NIH Grant # EY09762 (PJM)

**THE PRIMATE SUPERIOR COLLICULUS MAKES USE OF EYE POSITION FOR INITIATING SACCADIC MOVEMENTS.** M. Paré\* & D.P. Munoz, MRC Group in Sensory-Motor Neuroscience, Queen's University, Kingston, Ontario, Canada K7L 3N6.

Because conspicuous targets can be located anywhere in the visual field and the oculomotor range is limited, it is crucial to keep the eyes centered in the orbit to permit maximal orbital reserve both at the start and end of an impending saccade of undetermined direction. Little is known about the neural mechanisms responsible for recentering the eyes or the related problem of initiating saccades from different eye positions. We have reported previously that saccade latency is: (1) influenced by initial eye position such that the initiation of saccades toward the central orbital position is facilitated (Paré & Munoz, *Soc Neurosci Abstr* 21:1193, 1995); and (2) inversely related to the level of preparatory neuronal activity in the superior colliculus (SC) (Dorris et al., *Soc Neurosci Abstr* 21:1193, 1995). We now report on two experiments designed to test whether SC activity is modulated by eye position. In the first experiment, the activity of neurons with preparatory discharge - buildup neurons - was recorded while monkeys initiated saccades from different eye positions in the gap task. In the second experiment, saccades were evoked electrically using near-threshold stimuli while monkeys fixated (visually or not) a target whose location was varied randomly. When the initial eye position was shifted eccentric in a direction opposite to the direction of the saccades encoded by the SC site under study: (1) the level of SC preparatory activity was enhanced; and (2) saccades were more easily evoked by electrical stimulation. In both experiments, the orbital position effect was potentiated by the release of ocular fixation afforded by the introduction of a gap period. These results suggest that the SC uses initial eye position for initiating saccades and that the eye position sensitivity of SC neurons is gated by fixation-related signals. The motor commands sent to the SC may be either combined with eye position signals in the SC or already modified by eye position.

**TARGET UNCERTAINTY ALTERS NEURONAL ACTIVITY IN THE MONKEY SUPERIOR COLLICULUS.** M.A. Basso\* and R.H. Wurtz, Laboratory of Sensorimotor Research, National Eye Institute, NIH, Bethesda, MD 20892.

The primate superior colliculus (SC) contains neurons that are related to events preceding the initiation of saccadic eye movements. Munoz and Wurtz (1995) demonstrated that buildup neurons have a long lead sustained increase in firing frequency prior to the initiation of saccadic eye movements. Moreover, in a gap task with one target and two possible locations, buildup neurons showed a sustained activity prior to the specification of the saccadic target. Glimcher and Sparks (1992) identified prelude burst neurons which also have a long lead increase in activity prior to the onset of saccadic eye movements. Prelude burst neurons begin discharging after the specification of the saccadic target. The present experiment was designed to assess the activity of burst, buildup, and fixation cells of the SC in a task that temporally isolated events leading up to and including saccade initiation.

The onset of a centrally located LED initiated a trial. The monkey was required to remain fixating for a random delay after which, 1, 2, 4, or 8 possible targets were presented. The array remained illuminated for a random period (uncertainty) and then one of the targets dimmed (selection). Another random period preceded the removal of the fixation point which signaled the monkey to initiate a saccade to the dimmed target (initiation).

During the period of uncertainty, buildup neurons showed an increase in activity in the 1 & 2 target conditions. Less activity was present in the 4 & 8 target conditions. In the 4 & 8 target conditions, buildup activity occurred only after saccade target selection. During this selection period, little additional buildup occurred in the 1 & 2 target conditions. Fixation neurons tended to show activity that was the reverse of buildup neurons, i.e., increasing activity with increasing target uncertainty in the 4 & 8 conditions. Burst neurons remained inactive until the signal to initiate a saccade was presented irrespective of the number of possible targets. We conclude that buildup activity is dependent upon the predictability of the saccadic target, and that fixation neuron activity is related to the probability of making a saccade. Burst neuron activity is unaffected. Supported by the National Eye Institute.

**THE EFFECT OF EYE POSITION ON THE VISUAL RESPONSES OF SINGLE UNITS IN THE PIGEON OPTIC TECTUM** Paul C. Knox, H.C. Whalley. (SPON: Brain Research Association) Centre for Neuroscience, University of Edinburgh, Crichton St, Edinburgh, Scotland.

Many areas of the visual system are known to receive signals indicating the position of the eyes in the orbit. Although the muscles which move the eyes, the extraocular muscles (EOM), contain stretch receptors, and the afferent signals from these are known to reach many visual processing areas, they are not generally considered as a likely source of eye position information. We have found that EOM afferent signals do modify the visual responses of single units in the superficial layers of the pigeon optic tectum (OT) in a manner which suggests that they may signal eye position.

Extracellular visual responses were recorded from the superficial layers of the left OT of paralysed, decerebrate adult pigeons. Visual stimuli were projected to the right eye and the left eye was moved passively by means of a suction contact lens. Visual responses were collected with either the eye held in the central resting position or held deflected by up to 20° in one of four directions (up, down, beak, tail). Sets of eight interleaved PSTHs were compiled online.

The visual responses of many units were clearly modified by holding the left eye at an eccentric position. Approximately 50% of units were affected in a similar manner for all eccentric positions tested, i.e. holding the eye up or down, to the beak or tail would either decrease or increase the amount of firing in response to the visual stimulus by a comparable amount. Other units were modified only at particular positions. Application of local anaesthetic to the eye carrying the lens did not alter the effects. None of the units responded to mechanical stimulation of the area around the left eye. The receptive field was remapped routinely, and there was no evidence that its position altered in response to deviation of the left eye. Therefore EOM afferents may convey information concerning eye position in the orbit to the OT.

**SUPERIOR COLLICULUS ACTIVITY DURING SACCADIC EYE MOVEMENTS PERTURBED BY AIR-PUFF INDUCED BLINKS.** H.H.L.M. Goossens, A.J. van Opstal, and C.C.A.M. Gielen\*. Univ. of Nijmegen, Dept. Biophysics, Nijmegen, The Netherlands.

Recent findings suggest that the monkey superior colliculus (SC) may be part of the local feedback loop that controls the dynamics of saccadic eye movements, because the instantaneous activity of many saccade-related burst neurons (SRBNs) exhibits a monotonic relation with the current motor error. So far, it has been difficult to substantiate this hypothesis further because of the stereotyped nature of saccades. Recent experiments, aiming at perturbing the saccade trajectory, applied electrical stimulation at crucial stages of saccade execution (omnipause neurons, SC fixation cells), with the possible risk of stimulating adjacent pathways.

In order to circumvent these potential problems, we have perturbed saccadic eye movements noninvasively with saccade-triggered air puffs on the eye. Eye- and eye-lid position were recorded with search coils. Two monkeys were trained to make saccades to flashed targets in darkness. We recorded from SRBNs in the deep SC and compared the activity for perturbed and unperturbed saccades into the movement field.

Reflexive blinks result in a rapid upward-directed eye movement between 5 and 15 deg amplitude. Despite the absence of visual feedback, spatial perturbations of saccade trajectories are consistently compensated. Blink-induced perturbations may result in: (1) a transient decrease in SRBN activity near blink onset, (2) a prolongation of SRBN activity in line with increased saccade duration such that the burst offset remains tightly coupled with saccade offset. These findings are compatible with the presumed role of the SC in the feedback control of saccades.

## 262.12

**IS THE DEVIATION OF SACCADIC EYE MOVEMENTS EVOKED BY COLLICULAR STIMULATION DUE TO A LINEAR RESETTABLE INTEGRATOR?** S. Sadehghpour, A. Pouget, J. Schlag\* and M. Schlag-Rey, BRI and Dept. of Neurobiology, UCLA, Los Angeles, CA 90095-1763.

When the superior colliculus is stimulated shortly (<40ms) after a visually guided saccade, the resulting eye movement is systematically deviated from the control vector in the direction opposite to the visually guided saccade. Furthermore, the amplitude of the deviation decays exponentially as a function of the intersaccadic interval. These data have been taken as evidence for the existence of a linear resettable integrator hypothesized by several models of saccadic control (Nichols and Sparks, J.N. 1995, 73: 431). This integrator hypothesis predicts that the amplitude of the deviation should be a linear function of the amplitude of the visually guided saccade. We shall present experimental data showing that the relationship between the amplitude of deviation and amplitude of initial saccade is in fact sigmoidal, i.e., it increases linearly with amplitude up to 10-20° and saturates for larger amplitudes. We shall discuss two alternatives to the resettable integrator hypothesis, one involving a damped eye position signal and the other relying on the refractory period of collicular neurons, and compare their respective predictions with our experimental findings. ## 262.13

ACTIVITY OF SUPERIOR COLLICULUS BURST NEURONS DURING SACCADIC-VERGENCE INTERACTIONS. L. E. Mays\*, Dept. of Physiological Optics and Vision Science Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

The occurrence of a saccade in conjunction with a vergence eye movement results in an increase in peak vergence velocity. The occurrence of convergence in conjunction with a saccade usually results in a lower peak velocity of the saccade. This low saccadic velocity is not due to mechanical effects since the peak firing rate of horizontal medium-lead burst neurons, which control horizontal eye velocity, is also lowered when a saccade occurs during convergence. In other situations which result in low saccadic velocities, such as saccades to remembered target locations, the activity of superior colliculus (SC) burst neurons is lower than usual. The purpose of this experiment was to determine if the activity of SC burst neurons during saccades with convergence is lower than that for comparable saccades alone.

The activity of monkey SC burst neurons with movement fields ranging in amplitude from 2° to 10° was recorded during normal saccades and saccades in association with 6° of convergence. The amplitude and velocity of each saccade were calculated using the average of the left and right horizontal eye position (i.e., cyclopean eye position) and vertical eye position. The locations of the movement fields for SC burst neurons were not significantly altered by convergence. The peak velocity of saccades was reduced by convergence. For most SC burst neurons, both the peak firing rate and number of spikes in the burst were lower for saccades made in association with convergence. The mechanism by which saccades are slowed by convergence is not known. (Supported by NIH grants EY03463 and EY03039 and the McKnight Endowment Fund for Neuroscience).

GRAVITY INFLUENCES THE COLLICULAR CODE OF SACCADIC DIRECTION. M.A. Frens, Y. Suzuki, K. Hepp, B. Hess, and V. Henn (SPON: European Neuroscience Association) Neurology Department, University Hospital, CH 8092 ZÜRICH, Switzerland.

We investigated the influence of the direction of gravity on the relation between activity in the deep layers of the Superior Colliculus and oculomotor output. Chronically prepared rhesus monkeys were put in different static roll positions, and eye position was monitored in three dimensions by means of the dual search coil method.

Based on single unit recordings and electrical microstimulation, we found that the saccade vector generated by the Colliculus reorients with respect to a head-fixed coordinate system. Typically the vector rotates in a direction that is opposite to the head roll direction. The amount of reorientation exceeded the amount of ocular counterroll that was observed as a result of rolling the head.

Therefore we conjecture that the Colliculus works in a coordinate system that is neither space-, head- or eye-fixed. It is argued that mechanisms downstream of the Colliculus are responsible for this reorientation.

During visually-guided saccades, the collicular reorientation has no effect on the oculomotor output. In the absence of a target systematic deviations are observed that are in the same direction as the change in collicular output.

## 263.1

CHEMICAL COMPOSITION OF THE PRIMATE ZONA INCERTA (ZI). D. K. Donahoe, S. H. Guest, and T. P. Ma\*, Departments of Anatomy (1) and Neurology (2), University of Mississippi Medical Center, Jackson, MS 39216.

We studied the chemical composition of the dorsal (ZId) and ventral (ZIV) laminae of the zona incerta in six cynomolgus monkeys (*Macaca fascicularis*) using immunohistochemical and histochemical techniques at the light microscopic level. Animals were deeply anesthetized and perfused through the heart with aldehyde fixatives. Fifty  $\mu$ m frontal sections were obtained with a freezing microtome. Alternating sections were placed in a primary antibody (GABA, calbindin [CB], parvalbumin [PA], glutamate [glut] or aspartate [asp]) for up to 36 hours, followed by the appropriate secondary, and then visualized using the ABC technique. Other sections were stained for acetylcholinesterase (AChE), cytochrome oxidase (CO), NADPH-diaphorase, Nissl, and/or fiber. Controls eliminating primary, secondary, or ABC had the expected results. There were two populations of GABA-IR cells, small and medium-large cells. Small cells were fairly uniformly distributed, but medium-large cells were primarily located in the ZIV. These small cells likely represent the small local circuit cells and the medium-large cells are the projection neurons. Medium-large PA-IR cells, which had a similar morphology to GABA-IR neurons, were also found in ZIV. While no CB-IR cells were observed, background CB staining was present in ZIV but absent in ZId. A few AChE stained neurons were located in the ZId, but not in ZIV. A small number of lightly stained NADPH cells were found in ZIV. Cytochrome oxidase has been used as a marker to distinguish between ZIV and ZId. There were a few medium-large CO-stained neurons within the ZIV. Results of glutamate and aspartate immunostaining were equivocal. It is our impression that asp-IR neurons are primarily in ZIV whereas glut-IR neurons are located in both. Except for presumed GABAergic local circuit neurons, our results do not show simple relationships between neurotransmitters and incertal cells. However, GABA does appear to be the predominant transmitter in this nucleus. The extent of background staining and the reactivity of the cells lend support to the idea that the zona incerta integrates information from multiple pathways and may provide control signals to its efferent targets such as the superior colliculus.

## 263.2

ELECTROPHYSIOLOGICAL PROPERTIES OF NUCLEUS PREPOSITUS HYPOGLOSSI NEURONES IN GUINEA PIG BRAINSTEM SLICES. M. Serafin\*, N. Vibert\*, C. de Waele\*, P.P. Vidal\* and M. Mühlenthaler, CMU, 1211 Geneva 4, Switzerland and \*LPPA, CNRS-Collège de France, Paris, France.

The nucleus prepositus hypoglossi (PH) is involved in oculomotor control by its ability to convert a velocity signal arising from the medial vestibular nuclei into a position signal following a process of integration. In the abducens nuclei, this position signal is compounded with a velocity signal arising from the vestibular nuclei in order to generate compensatory eye movements contributing to gaze stabilization. The cellular mechanisms involved in such a transformation are basically unknown. As a first step toward understanding that process, we have investigated the intrinsic properties of PH neurones and found four major cell types within a database of 86 neurones. All of them were endowed, although to a variable extent, with an Ih rectification and subthreshold plateau potentials revealed by brief membrane depolarizations. In addition, the first two types of PH neurones were characterized by rather broad action potentials, a single AHP and an A-like current, whereas the last two types demonstrated a thinner spike, a double AHP and plateau potentials that were particularly prominent (due to the presence of a sodium persistent current). The distinction in between the first (type A, n=15) and second cell type (type A+clusters, n=12) relied on the presence of only a small A-like current in the first type, and subthreshold oscillations and clusters (both of them sensitive to TTX) in the second. The distinction between the third (type B, n=45) and fourth cell type (type B+LTS, n=14) was related to the presence of potent low-threshold calcium spikes in type B+LTS neurones. In addition, type B cells were shown to have long-lasting calcium plateau potentials in presence of either TTX alone, or when potassium conductances were blocked by TEA and 4-AP. Interestingly type A+clusters cells were found in the rostral part of the nucleus and type B+LTS were found only in its ventral part. The location of the B+LTS cells suggests that they could correspond to the burst driving neurones or the vertical bursters. (Swiss NSF, PIC CNRS/MDRI 292).

## 263.3

PHARMACOLOGICAL CHARACTERIZATION OF NUCLEUS PREPOSITUS HYPOGLOSSI NEURONES IN GUINEA PIG BRAINSTEM SLICES. M. Mühlenthaler\*, N. Vibert\*, C. de Waele\*, P.P. Vidal\* and M. Serafin, Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and \*LPPA, CNRS-Collège de France, Paris, France.

In a companion abstract (Serafin et al. 1996, this meeting) we have demonstrated that neurones of the nucleus prepositus hypoglossi (PH) can be subdivided into four major cell types (type A, A+clusters, B and B+LTS) depending on their intrinsic membrane properties. In order to further support this view, we have attempted to determine the responsiveness of the various PH cell types to the major neurotransmitters/neuromodulators which are present in pathways that project to this nucleus. In three of the four cell types (type B+LTS not being yet investigated pharmacologically), brief bath-application of carbachol and histamine had a depolarizing action (with the exception of 2/5 type A+clusters cells which were hyperpolarized by carbachol). The effect of carbachol was in addition shown to persist in TTX, suggesting that it was postsynaptic. In contrast, serotonin and noradrenaline had excitatory or inhibitory effects depending on the cell type. Indeed, both transmitters had depolarizing and excitatory effects on type A and B PH neurones, but hyperpolarizing and inhibitory effects on type A+clusters cells (both effects persisted in TTX). Interestingly, although type B PH cells were always depolarized and excited by serotonin, a transient decrease in firing rate (sometimes accompanied by a transient membrane hyperpolarization) preceding the excitatory phase suggests the presence of a complex response, possibly involving two different serotonergic receptor subtypes (Bobker, J. Neuroscience 1995). Interestingly, in PH type B cells (as in type B cells in the medial vestibular nucleus), long-lasting application of NMDA induced a rhythmic bursting activity (in presence of a DC hyperpolarization). These results indicate that PH neurones are not only heterogeneous in term of their intrinsic membrane properties but also with respect to their neurotransmitter sensitivity. (Swiss NSF, PIC CNRS/MDRI 292).

## 263.4

LONG LEAD BURST NEURONS IN THE OCULOMOTOR BRAINSTEM CARRY SIGNALS APPROPRIATE FOR MOVEMENT PREPARATION. A. Handel & P. W. Glimcher\*, Center for Neural Science, New York University, New York, NY 10003.

We studied saccadic long lead burst neurons (LLBNs), a class of brainstem neurons originally defined by Luscher & Fuchs ('72), in two awake-behaving rhesus macaques. A delayed saccade paradigm was used to examine the temporal relationship between the onset of the high frequency burst response of these units and saccadic onset (burst lead). Burst lead and burst amplitude were found to vary systematically with the metrics of the saccade. The longest burst leads for each neuron, 55 msec on average, were associated with movements confined to a restricted portion of the oculomotor range.

The activity of LLBNs was also studied while monkeys performed a movement selection task. Subjects initially fixated a central yellow LED for 300-500 msec. Two eccentric yellow LEDs were then co-illuminated for 600-1200 msec, one above and one below the horizontal meridian. The fixation LED then changed color to either red or green. Red indicated that the monkey would be rewarded for aligning gaze with the upper LED ( $\pm 3-6^\circ$ ) after the offset of the fixation LED 400-1000 msec later; green specified the lower LED as the saccadic goal. The remaining LED served merely as an irrelevant visual distractor. For many LLBNs, firing frequency during the interval after the fixation LED changed color, but before it was turned off, was correlated with the metrics of the future movement. We defined the selectivity of each unit to be the maximal response for targets minus the maximal response for distractors, divided by their sum. This index served as a measure of how differently a unit responded to an LED when it served as a saccadic target versus when that same LED was irrelevant to the task.

The population of LLBNs showed a selectivity for targets over distractors that was less than that reported for collicular prelude bursters but similar to the selectivity of Area LIP neurons. Together these data suggest that LLBNs cannot lie between the colliculus and the alpha motoneurons in the colliculo-pontine saccadic circuit.

CHANGES OF REMEMBERED SACCADIC AND FIXATION DURING TEMPORARY INACTIVATION OF THE MESENCEPHALIC RETICULAR FORMATION (MRF) V. L. Silakov\* and D. M. Waitzman, VA Connecticut, 555 Willard Ave, Newington, CT 06111.

Neurons in the MRF burst before and during visually guided (VG) saccades and have a lower level of discharge during the delay period between the brief presentation of a visual stimulus and the execution of a remembered (REM) saccade to that stimulus. Eye movements of three, awake, rhesus monkeys were recorded using a scleral search coil before, during and after the injection of muscimol (1 - 3 µg), a GABA(A) agonist, into the MRF. Injections in the rostral portions of the MRF produced hypometric vertical saccades (both up and down). The primary position of gaze was shifted either up or down depending upon the injection site. The trajectories of vertical and oblique saccades were markedly curved. Injections of muscimol into the caudal MRF produced hypometria of contraversive saccades. Trajectories of both vertical and contraversive horizontal saccades were curved. Injections at the caudal-ventral pole of the MRF produced hypermetric saccades. Following caudal injections macro-saccadic square-wave jerks to the contraversive side were generated during attempted fixation. Evidence of saccade hypometria and reduced saccade velocity suggest that one role of the MRF is to excite portions of the superior colliculus (SC) and/or other supranuclear eye movement regions. The generation of square wave jerks following suppression of the caudal pole of the MRF could be the result of inhibition of omnipause neurons located in the pontine raphe or the fixation zone of the SC. Supported by NIH Research Grant EY 09481 and the Dept. of Veterans Affairs.

## 263.7

RETROGRADE TRANSNEURONAL LABELLING OF HORIZONTAL EYE MOVEMENT CIRCUITS WITH RABIES VIRUS. N.M. Gerrits<sup>1</sup>, W. Graf<sup>2</sup>, N. Yatim<sup>2</sup> and G. Ugolini<sup>3</sup>. <sup>1</sup>Dept. of Anatomy, Erasmus Univ. Rotterdam, The Netherlands; <sup>2</sup>CNRS - Collège de France, 75270 Paris Cedex 06, France; <sup>3</sup>Lab. de Génétique des Virus, CNRS, 91198 Gif-Sur-Yvette, France. (SPON: European Neuroscience Association).

Retrograde transneuronal tracing with rabies virus allows a specific labelling of synaptically connected neurons (Ugolini, 1995, J. Comp. Neurol. 356:457). This method was applied to the oculomotor system to test the hypothesis of a modular organization of eye movement circuits. In guinea pigs, rabies virus (CVS strain) was injected unilaterally into the medial rectus (MR) muscle. This muscle was chosen because of its special innervation pattern (ascending tract of Deiters, abducens internuclear pathway). The CNS distribution of the virus was studied immunohistochemically at sequential 12 hr intervals from 1.5 to 5 days post-inoculation (p.i.). Transneuronal transfer was time-dependent. Initially, labelling involved only MR motoneurons (first-order) in the ipsilateral oculomotor nucleus. At 2 days p.i., the onset of transfer visualized abducens internuclear neurons contralaterally. Other cell groups of the horizontal system were labelled transneuronally at 2.5-3 days p.i., i.e., prepositus hypoglossi neurons, medial vestibular nucleus neurons, oculomotor interneurons, reticular formation neurons associated with saccade generation. From 3.5 days p.i., transfer to higher-order neurons revealed a zonal organization in the cerebellar flocculus and ventral paraflocculus, in addition to labelling of other cell groups (e.g., paramedian tract neurons, Scarpa's ganglion, superior and descending vestibular nuclei, Y group, fastigial nucleus and interstitial nucleus of Cajal). Other cortical and subcortical cell groups were labelled at longer survival times. These results suggest a modular organization only at the level of basic neuronal circuits involved in spatial coordination of eye movements. (Supported by CNRS, UPR9053)

## 263.9

ROLE OF NUCLEUS RETICULARIS TEGMENTI PONTIS (NRTP) IN 3-D SACCADIC CONTROL. J. Van Opstal<sup>1</sup>, K. Hepp<sup>2</sup>, Y. Suzuki<sup>3</sup>, V. Henn<sup>3</sup>. <sup>1</sup>Biophysics Dept., Univ. Nijmegen, The Netherlands; <sup>2</sup>Physics Dept., ETH Zürich, Switzerland; <sup>3</sup>Neurology Dept., Univ. Hospital, Zürich, Switzerland.

It is well-documented that voluntary eye movements are constrained by Listing's law (LL), which states that eye position vectors lie in a plane (Listing's plane, LP) throughout the trajectory. In recent experiments we have shown that LL is implemented downstream from the deep layers of the Superior Colliculus (SC), but controversy exists whether LL results from a precise tuning of the 2-D visuomotor input with the mechanical properties of the oculomotor plant, or to a neural control that accounts for the noncommutative kinematics of 3-D rotations. In order to investigate whether the cerebellar pathway is involved in the neural implementation of LL, we recorded from single-units in the NRTP of three rhesus monkeys during rapid eye movements in 3-D, performed electrical microstimulation during spontaneous eye movements in the light, and induced local unilateral NRTP inactivation with small (<700 nl) muscimol injections.

In contrast to the SC, 30% of the NRTP units has a 3-D movement field, with positive and negative torsional components of optimal saccade vectors bilaterally represented. Stimulation produced eye displacements with either a positive or a negative torsional component, depending on the depth within the NRTP, rather than on the laterality of the stimulation site. The first spontaneous saccade following stimulation immediately resets the eye into LP. This torsional reset mechanism is selectively disrupted after a unilateral muscimol injection.

Our results indicate that the NRTP contributes to the stabilization of LP against torsional errors of the saccadic system. We conclude that the saccadic burst generator is 3-D under all conditions (not only during vestibular stimulation), and that LL is implemented by a neural control strategy.

## 263.6

EFFECTS OF IBOTENIC ACID (IBO) LESIONS OF THE MESENCEPHALIC RETICULAR FORMATION (MRF) ON PRIMATE SACCADIC. D. M. Waitzman\* and V. L. Silakov, VA Connecticut, 555 Willard Avenue, Newington, CT 06111.

Temporary inactivation of the MRF using the GABA(A) agonist muscimol produces dysmetric saccades and changes in fixation (see Waitzman and Silakov, *Soc. Neurosci. Abst.*, 1996). We have now explored the effects of activating and then destroying cells using IBO. Eye movements of one awake rhesus monkey were recorded using a scleral search coil before, during and after three separate injections (3 X 7.5µg) of IBO into the MRF. Histologically verified lesions were located at the caudal pole of the MRF where single unit activity related to contraversive saccades had been recorded. Two phases of eye movement changes were found. The initial excitatory phase (first 4 hours) of IBO produced hypermetric ipsi- and contraversive visually guided (VG) and remembered (REM) saccades. The trajectories of saccades of specific amplitudes were curved. During the 2 to 5 days following IBO lesion VG saccades became normometric. Recovery of REM saccades was distinctly different: contra- and ipsiversive saccades remained curved and hypermetric. The changes in ipsiversive remembered saccades were evident for 4 months following the third IBO lesion. Permanent changes in REM rather than VG saccades suggest MRF neurons aid in the retention of the visual activity required to move the eyes to a target. Curved saccade trajectories and increased gain support our idea that MRF neurons participate in the local feedback pathway controlling saccade amplitude. Supported by NIH Research Grant EY 09481 and the Dept. of Veterans Affairs.

## 263.8

NEUROTRANSMITTERS OF ABDUCENS INTERNUCLEAR AND ASCENDING TRACT OF DEITERS INPUTS TO THE MEDIAL RECTUS MOTONEURONES IN THE CAT OCULOMOTOR NUCLEUS. L.T. Nguyen\* and R.F. Spencer, Department of Anatomy, Medical College of Virginia, Richmond, VA 23298.

Abducens internuclear (Abd IN) and ascending tract of Deiters (ATD) inputs are the principal excitatory connections to medial rectus motoneurons that are related to the control of conjugate horizontal eye movements. Previously, we have demonstrated differences in the morphology, mode, pattern and soma-dendritic organization of Abd IN and ATD synaptic endings labelled anterogradely with biocytin. The present study extends these observations to the ultrastructural localization of the excitatory amino acid neurotransmitters, glutamate and aspartate, using a postembedding immunogold procedure combined with the preembedding immunoperoxidase localization of anterogradely transported biocytin from the abducens nucleus and the ventral lateral vestibular nucleus. Consistent with their spheroidal synaptic vesicle content and the asymmetric pre-/postsynaptic membrane profile, both Abd IN and ATD synaptic endings are labelled with glutamate and aspartate, despite their individual morphological differences. The coexistence of glutamate and aspartate, however, may indicate neurotransmitter versus metabolic functions that are associated with these amino acids. Consequently, physiological differences between these two inputs are likely to be related more to the postsynaptic receptor that is associated with each input.

COMBINED EYE AND HEAD GAZE-PURSUIT RESPONSES IN MONKEY NUCLEUS RETICULARIS TEGMENTI PONTIS (NRTP). D.A. Suzuki\*, K.F. Betelak and R.D. Yee. Dept. of Ophthalmology, Indiana University, Indianapolis, IN 46202.

A question currently exists concerning whether or not the eye and head movement control systems regulating gaze shifts are independent. NRTP may be a good candidate structure to investigate this question, since it receives inputs from motor cortex and has been shown to contain a population of units that encode smooth-pursuit eye velocity.

Neuronal activity was recorded from NRTP in order to determine if head movement signals also exit in NRTP and if so, to determine whether or not populations of eye and head movement related units are independent. Monkeys were trained to generate combined eye and head gaze-pursuit movements in the horizontal plane. Eye and head positions were monitored with a phase-angle type CNC coil system.

Some NRTP cells did exhibit direction selective responses during gaze-pursuit movements. During some epochs, the monkey switched from an eye-only to a head-only strategy of gaze pursuit. The gaze-pursuit units continued to respond during both the eye-only and head-only portions of the gaze-pursuit movement in the preferred direction. These units appeared to encode a gaze velocity signal, i.e., both eye and head velocity signals. Modulations in unit activity were not observed during spontaneous head movements, suggesting a non-vestibular origin for the head-related activity. Whether the head velocity signal was vestibular in origin or an efference copy signal requires further study.

The results indicate that, at least at the level of NRTP and with respect to gaze-pursuit, signals regulating eye and head movements are not independent. Support: RPB & NIH (EY09082) grants.

## 263.11

**SHIFT AND ROTATION OF LISTING'S PLANE AFTER BILATERAL LESION OF THE ROSTRAL INTERSTITIAL NUCLEUS OF THE MLF.**

Y Suzuki\*, D Straumann, V Henn. Neurology Department, University Hospital Zurich, CH-8091 Zurich, Switzerland.

Static tilt of the head about the earth-horizontal axis changes tonic otolith input and, subsequently, modifies the orientation of Listing's plane. Head tilt about the roll axis shifts Listing's plane in the opposite torsional direction (counter-roll), and head tilt about the pitch axis counter-rotates the plane about this axis (Haslwanter et al, Vision Res 1992).

In three rhesus monkeys, we bilaterally inactivated neurons in the rostral interstitial nucleus of the MLF (riMLF) with kainic acid. Additional lesions in the nearby interstitial nucleus of Cajal were excluded histologically after the perfusion of the animals. Moreover, there was no phase shift of the three-dimensional vestibulo-ocular reflex due to the lesions, which indicates that the velocity-to-position integrator was unaffected by the kainic acid injections.

Before and after inactivation, monkeys were put in different pitch or roll tilt position from prone to supine or from 90° right ear-down to 90° left-ear-down in 30° step. Spontaneous eye movements were recorded with dual magnetic search coil.

The counter-rolling of Listing's plane was preserved after riMLF-inactivation (Suzuki et al., Exp Brain Res 1995). The counter-rotation of Listing's plane during static head pitch was also observed after riMLF-inactivation, however, its gain was significantly reduced by 17-42%.

Results imply, although basic three-dimensional vestibulo-ocular reflexes are preserved, parameters for static vestibulo-ocular reflexes might be modified by the abolition of burst generator input.

## 263.12

**Response of saccade related neurons in the primate brainstem during head-free gaze shifts to double target steps.** L. Ling, J.O. Phillips\*, Y. Jwamoto, S.D. Newlands and A.F. Fuchs. Department of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195

During head-unrestrained tracking of a target which jumps twice in rapid succession during the saccadic latent period, the animal's responses exhibit clear dissociations between the gaze and head movements. The behavioral results suggest that the systems which control eye and head motility process information about the new target step differently. We recorded from cells in the brainstem of primates to examine whether the dissociations are manifested at the level of the saccadic burst generator.

For burst units the strict relationship between number of spikes and saccade amplitude is always maintained. During dissociated responses composed of two head and one eye movements, burst units are not active unless a saccade in the on-direction is observed. Similarly, omni-pause neurons (OPN) pause only if a saccade is present. This suggests that the burst generator is commanded to execute the eye movement which gets expressed.

Usually the eye responses are separated by a minimal inter-saccadic interval of ~150 ms. However, in some cases gaze shifts follow each other back-to-back. OPNs pause throughout the turn-around. Directional burst units discharge only for the saccadic component in the on-direction. Omni-directional burst units discharge continuously, joining the burst for each movement component. Thus the activity of the burst generator is fully expressed and the saccadic system operates in a strictly sequential fashion.

This work was supported by NIH grants EY00745 and RR00166.

## 263.13

**THE SACCADE BURST-GENERATOR DURING RAPID HEAD-ON-BODY ROTATIONS: GAZE RELATED ACTIVITY OF PRIMATE INHIBITORY BURST NEURONS.** K.E. Cullen\*, A. Ross and J.E. Roy. Aerospace Medical Research Unit, Department of Physiology, McGill University, Montreal, Canada.

Short lead inhibitory burst neurons (IBNs) located in the pontine reticular formation burst during saccades made in the ipsilateral direction. Previous studies in the head-restrained monkey have shown that the number of action potentials generated in a burst is well correlated with saccade amplitude, and peak firing frequency is well correlated with peak saccadic eye velocity. In the present study, we recorded the activity of IBNs in the rhesus monkey during a paradigm in which the animal's head was passively rotated relative to its body (PHBR). In control experiments, we recorded the activities of abducens neurons (ABNs) which receive projections from IBNs, and Type I pure vestibular neurons (VNs), during PHBR.

In the PHBR paradigm, the applied head movement typically evoked a compensatory vestibulo-ocular reflex during the first 100-200 ms, after which the gaze trajectory (gaze = eye-in-head + head-in-space) was directed towards the ongoing movement of the head. During these shifts in gaze, the eye's contribution to the ongoing movement was relatively small, and most often poorly correlated with the amplitude of the coincident gaze movement. Accordingly, this paradigm effectively allowed us to uncouple the interdependence between gaze and eye movements that generally occurs during voluntary combined eye-head gaze shifts. As was expected, ABN activity was best correlated with eye movements while VN activity was best correlated with head movements. In contrast, analysis of IBNs, revealed that the activity of these neurons was significantly better correlated with gaze movements than either eye or head movements during PHBR. This observation is in agreement with the results of our previous studies which have characterized the activity of IBNs during active combined eye-head gaze shifts (Cullen et al. 1994). We conclude that that primate brainstem "saccade" burst-generator operates in a coordinate frame which is referenced to the movement of the visual axis in space. **CONTROL OF POSTURE AND MOVEMENT: MOTOR UNITS**

## 264.1

**MOTOR UNIT TORQUE IN COMPARTMENTS OF THE LATERAL GASTROCNEMIUS MUSCLE OF THE CAT.** A.J. Sokoloff\*, A.W. English, T.R. Nichols and T.C. Cope. Depts. of Physiology and Anatomy, Emory Univ., Atlanta, GA 30322.

Many muscles are composed of different 'compartments', each comprised of an unique set of motor units. Although proposed as a functional element of neuromuscular control, the biomechanical features of compartments and their constituent motor units have received little study. Here we report the ankle torques of single motor units in different compartments of the cat lateral gastrocnemius muscle (LG). LG motor units were penetrated intra-axonally in ventral rootlets, stimulated to tetanus, and sagittal (dorsiflexion/plantarflexion) and transverse (abduction/adduction) isometric torques determined with a biaxial transducer attached at the calcaneus. The resultant of each motor unit was expressed as an angle relative to pure plantarflexion (90°) and adduction (0°) torques. Motor unit membership was determined visually or by antidromic stimulation of compartment nerves. Motor units were studied in three of the four LG compartments.

In our preparation, LG motor units produced only adduction and plantarflexion torques. Torque angles for compartment LG1 motor units were 79-83°, for compartment LG2 motor units 78-86°, and for compartment LG3 motor units 84-87°. There was no correlation between motor unit torque angle and torque magnitude. These findings demonstrate that LG motor units produce adduction (off-sagittal) torques in addition to plantarflexion (sagittal) torques. Future studies will determine whether motor units are selected in movements according to compartment membership or motor unit torque.

## 264.2

**SPIKE TRIGGERED AVERAGING OF MOTOR UNIT ACTIVITY IN PUTATIVE PARTITIONS OF HUMAN BICEPS BRACHII** J.F. Prather\*, J.L. Denef, T.L. Duncan, J.M. Heinzmann, E.M.C. Smith, R.L. Segal. Div. Physical Ther. and Neuroscience Program, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Partitions within the human biceps brachii (BB) may exist, allowing the central nervous system to differentially activate a segment of the muscle in a task-specific manner. This study examined whether correlated activity exists between putative BB partitions. Twelve subjects performed three trials of five isometric upper limb tasks in which electromyographic (EMG) activity was recorded by pairs of indwelling fine-wire electrodes placed in the BB short head (BBSH) and in the three putative partitions of the BB long head (BBLH). Data from each recording site were analyzed using spike triggered averaging (STA) to look for time-locked activity. A motor unit from the site of interest was time amplitude window discriminated with the acceptance pulse triggering the averaging computer. Typically, 100 sweeps were averaged in each STA trial. Averages from 0 to 10 msec. after the trigger and from 10 to 20 msec. after the trigger were quantified. For each trial, the data from all recording sites were analyzed to examine for time locked activity. Analysis of three subjects has demonstrated that one subject had almost no time locked activity across sites. The second subject had extensive time locked activity, and the third had an intermediate amount. Analyses from all 12 subjects will be coupled with data on the patterns of activation order reported by Segal et al. (Neurosci. Abstr. 1996) to determine whether the putative partitions are differentially activated. Supported by NICHD NCMRR grant HD 32571

## 264.3

PARTITIONING OF THE HUMAN BICEPS BRACHII R.L. Segal\*, J.L. Denef, T.L. Duncan, J.M. Heinzmann, E.M.C. Smith, J.E. Prather. Div. Physical Ther. and Neuroscience Program, Emory Univ. Sch. of Med., Atlanta, GA 30322.

The human biceps brachii (BB) participates in elbow flexion, forearm supination and shoulder flexion. Partitions within the BB may exist, allowing the central nervous system to differentially activate a segment of the muscle in a task-specific manner. This study examined if a relationship exists between the function of the putative BB partitions and the anatomical evidence for partitioning of the BB found in a previous study (Segal, 1992). Twelve subjects performed three trials of five isometric upper extremity tasks in which electromyographic (EMG) activity and force/torque outputs were recorded. Pairs of indwelling fine-wire electrodes were placed in the BB short head (BBSH) and in the three putative partitions of the BB long head (BBLH). Activation order (AO), time of activation (TA) and recruitment threshold (RT) of motor units were determined for each task. AO and TA were studied to determine whether consistent patterns of activation existed between the recording sites. RT was studied to determine the force/torque levels at which activation of motor units in each of the recording sites occurred. Significant differences existed for AO and TA between the BBSH and different combinations of the BBLH partitions. For example, BBSH, regardless of task, was activated after the putative central and lateral partitions of BBLH. TA was significantly different for one task in comparison to the other four tasks. For RT, significant differences were evident between certain tasks. These results suggest that differences exist between the BBLH and BBSH, but may not occur within the BBLH itself. Supported by NICHD NCMRR grant HD 32571

## 264.5

VARIATION IN THRESHOLD FORCE FOR MOTOR UNIT RECRUITMENT. T.C. Cope\* and A.J. Sokoloff. Dept. Physiology, Emory Univ., Atlanta, GA 30322.

Some recent reports stress substantial variation in motor unit force threshold, i.e. the level of whole muscle force at which a unit begins to fire (e.g. Romaguera et al., *Exp. Brain Res.* 1993). Here we report on the variation of force thresholds for motor units in the medial gastrocnemius (MG) muscle of decerebrate cats. Twenty eight motor units exhibiting a large range in physiological properties (conduction velocity 59-115 m/s, tetanic force 2-29 g, and twitch contraction time 21-95 ms) were recruited in multiple reflex contractions (20-93 trials) evoked by ramp-hold-release stretches of the MG muscle. The mean coefficients of variation in force threshold for individual units were distributed with a median of 11.5% and an upper quartile of 24%. Only 2/28 values exceeded 36% (61% and 82%). Intrinsic variation in unit force threshold may be even lower than these values suggest since multiple regression analysis showed that some of the observed variation in force threshold was related to variation in whole-muscle baseline force, peak force, and/or rate of change in force during the ramp. Force threshold variation was additionally studied in 6 pairs of motor units during ramp stretches in which both units in a pair were recruited (13-49 trials/pair). Few cases of reversal in recruitment order were observed for any of these pairs: reversals in recruitment order occurred in only 3/13 and 3/26 ramps for 2 unit pairs with near thresholds (mean force thresholds differing by less than 10%), and in only 3/117 ramps for the remaining pairs. These findings demonstrate that variation in motor unit force threshold is modest and not accompanied by frequent reversals in motor unit recruitment order.

## 264.7

MOTOR UNIT FIRING RATES DECLINE DURING LOW-FORCE SUSTAINED ISOMETRIC CONTRACTIONS IN HUMANS. L. Griffin, S.J. Garland\* and T. Ivanova. Dept of Physical Therapy, Univ. of Western Ontario, London, ON, Canada, N6G 1H1

The notion of "muscle wisdom" describes a process whereby a decline in motor unit firing rate accompanies the slowing of muscle contractile properties with fatigue. Previously, using a dynamic submaximal (20% MVC) fatigue protocol, we found that motor unit discharge rates in the triceps brachii muscle were maintained (1). It could be argued that contractions of only 20% MVC may induce low intramuscular pressures and possibly little reflex inhibition from trapped metabolites. We sought to determine whether motor unit discharge rates in triceps brachii muscle decline during low-force sustained isometric contractions. Subjects performed a 10 min sustained isometric elbow extension contraction at 20% MVC to induce the same 30% drop in MVC as in the dynamic protocol. Subcutaneous fine wire electrodes were used to record motor unit activity from the lateral head of triceps brachii muscle. Most motor units that were active from the beginning of the fatigue task demonstrated a reduction in discharge rate. However, newly recruited motor units tended to maintain a constant rate or an increased discharge rate. These findings were similar to that found in biceps brachii muscle (2). Thus, the maintenance of discharge rate found previously during a dynamic fatigue task cannot be attributed to the low force level or to any unique characteristics of the triceps brachii muscle.

## 264.4

THUMB POSITION INFLUENCES THE RELATIONSHIP BETWEEN SPIKE-TRIGGERED-AVERAGE FORCE AND RECRUITMENT THRESHOLD OF LOW THRESHOLD MOTOR UNITS. M. Bilodeau\*, R.M. Enoka. Dept. Biomedical Engineering, Cleveland Clinic Foundation, Cleveland, OH, 44195 and Physical Therapy Graduate Program, University of Iowa, Iowa City, IA, 52242.

It has been shown that activation of the first dorsal interosseous (FDI) muscle is influenced by whether the thumb is extended or abducted (Laidlaw et al: *Soc Neurosci Abstr* 21: 1920). The purpose of the present study was to evaluate the effect of thumb position on the force exerted by FDI motor units (MUs). The activity of 53 MUs was recorded from the FDI of 7 volunteers using fine wire (25  $\mu$ m) electrodes. The abduction force exerted by the index finger was recorded at the first interphalangeal joint. The experimental task consisted of a slow ramp increase in the abduction force until a MU became active, and thereafter, sustaining the MU discharge at a minimum rate for 2-3 minutes. The activity of each MU was recorded with the thumb alternately secured in two positions: 1) fully extended in the horizontal plane; and 2) abducted by about 90 degrees in a plane perpendicular to the horizontal. For the abducted and extended thumb positions, respectively, the MU force (mean $\pm$ SD) was 5.9 $\pm$ 5.9 and 3.8 $\pm$ 2.7 mN, the recruitment threshold was 413 $\pm$ 445 and 225 $\pm$ 274 mN, and the average force during the minimum discharge rate task was 504 $\pm$ 517 and 444 $\pm$ 328 mN. The association between spike-triggered-average force and either recruitment threshold or average force was greater when the thumb was extended ( $r=0.79$  and  $0.78$  respectively) compared with abducted ( $r=0.18$  and  $0.20$ ). These findings indicate that altering the line of pull of FDI by changing thumb position influences the association between the spike-triggered-average force and the recruitment threshold of MUs.

## 264.6

MOTOR UNIT BEHAVIOR DURING ISOMETRIC CONTRACTIONS OF COOLED MUSCLE. R. Samadani\* and W. Z. Rymer. Sensorimotor Performance Program, Rehabilitation Institute of Chicago, Chicago, IL 60611, and Dept. of Biomedical Engineering, Northwestern University, Evanston, IL 60208.

In normal muscle, there exists a precise and orderly relation between the discharge rates of motoneurons and the mechanical properties of the muscle fibers they innervate. In this study, we used cooling of the first dorsal interosseus muscle of the hand to induce slowing of twitch contraction, to determine whether there was a compensatory alteration in the discharge properties of the associated motor units. If such rate alterations were evident, this would support the hypothesis that the CNS uses afferent information about contractile properties of muscle to control motoneuron discharge rate. We recorded surface electromyographic activity and single motor unit firing rates via intramuscular fine wire electrodes, before and after 4-6°C cooling. Subjects performed isometric contractions and ramps to 25% MVC under both normal and cooled conditions. Our findings were that with a 5°C decrease in intramuscular temperature, time to peak twitch increased 65%-70%, and tetanic force decreased during electrical stimulation at 10 Hz-50 Hz. For a given voluntary static force level, increases of 5.8%-31.3% in mean firing rates were observed in cooled muscle, indicating a loss of muscle efficiency (in that higher discharge levels are required to accomplish the same force). In contrast, the mean initial motor unit interpulse intervals during ramping voluntary contractions were not systematically changed. It appears that motoneuron discharge is not modified acutely to match muscle contractile properties. Funding: NRSA (T32HD07418)

## 264.8

THE COMMON MODULATION OF MOTOR UNITS DURING SLOW WRIST MOVEMENT IN MAN. N. Kakuda\* and M. Nagaoka. Department of Neurology, The National Rehabilitation Center for the Disabled, 4-1 Namiki, Tokorozawa, 359, JAPAN.

It was investigated if slow wrist movement is controlled by discontinuous motor output. In 11 healthy volunteers (4 males and 7 females, 22-45 years old), discharges of two motor units from m. extensor carpi radialis (ECR) as well as joint kinematics were recorded while the subject repeated slow wrist extension movement of 15 degree at 5 deg/sec. The coherence analysis performed on spike trains revealed the common modulation of two motor units between 6-12 Hz in 30 out of total 36 pairs (83 %). It was concluded that an agonist motoneurone pool (ECR) was modulated at 6-12 Hz. The functional significance was indicated in two aspects. First, the common modulation of motor units was significantly correlated to angular acceleration, suggesting that the modulation was so deep as to contribute to kinematics. Second, the common modulation of motor units disappeared during isometric contraction in 23 pairs, implying the task-dependent change. This work was supported by the Ministry of Health and Welfare of JAPAN.

## 264.9

**DIRECTIONAL TUNING OF SINGLE MOTOR UNITS.** U. Herrmann\* and M. Flanders. Dept. of Neuroscience, University of Minnesota, Minneapolis, MN 55455.

The activation patterns of single motor units (SMUs) during isometric forces in different directions were studied. The main question of interest was whether SMUs of the same muscle show different "best directions" of activation such that different populations within one muscle are activated for forces in different directions.

The activity of SMUs in several human arm muscles was recorded with intramuscular electrodes during force ramps at the wrist in 20 different directions covering the sagittal or frontal plane. The activity of one unit was identified off-line by its characteristic shape and amplitude. For each unit, steady state firing rate and threshold force for recruitment were determined for each direction. A unit's best direction was determined from the frequency data by fitting it with a cosine function and/or from the threshold data with linear regression.

Preliminary results from SMUs (n=20) in biceps of two subjects show that there are significant differences in the directional tuning of SMUs of the same muscle in the same subject for forces in the sagittal plane. While the activation ranges of SMUs overlap to a large extent, their best directions appear to be staggered covering a range of approximately 50 degrees in the upward-backward and upward-forward directions.

## 264.11

**MOTOR UNIT INTERSPIKE INTERVAL VARIABILITY IN OLDER HUMANS.** M.R. Roos, C.L. Rice\*, D.M. Connelly, and A.A. Vandervoort. Faculty of Kinesiology, Centre for Activity and Ageing, University of Western Ontario, London, Canada.

Reports about motor unit (MU) interspike interval (ISI) variability in older ( $\geq 75$  yrs) humans are limited, and the results are equivocal. Further, the majority of these studies have been conducted in small hand muscles, and at low force levels. Thus, the main purpose was to quantify age-related changes in MU discharge variability throughout the entire range of voluntary force in the vastus medialis. Five elderly (75-85y) and 4 young (21-30y) male subjects made several visits to the laboratory for MU recordings. MU firing rates were recorded with fine tungsten needle electrodes during contractions at force levels ranging from threshold to MVC. MU sequences were identified with overlaid shape recognition of individual spikes, and all identified MU trains with 5 or more ISIs were analysed for standard deviation (SD) and coefficient of variation (CV) of ISI. Results indicate that at all voluntary force levels, older subjects have higher SDs and CVs of ISI than young. Preliminary data from the tibialis anterior indicate similar results. Increase in MU discharge variability may be the result of MU reorganization and coincident reductions in MU numbers.

## 264.13

**A 20 CHANNEL PERIPHERAL NERVE INTERFACE: RECORDING AND STIMULATION IN MAMMALIAN SCIATIC NERVE.** A. Branner, H. Kolb\*, R.A. Normann, John A. Moran. Laboratory in Applied Vision & Neural Sciences, University of Utah, Salt Lake City, UT 84112

Multichannel interfaces capable of accessing individual fascicles have not been used in peripheral nervous system despite their recent application in the central nervous system. The problem of nerve block and degeneration associated with nerve crush resulting from implantation may have limited this application. We have used a high velocity insertion technique as a possible means to circumvent this problem.

The electrode array has two rows of ten, 1 mm long electrodes that project out from a 1 by 4 mm base. It is made of silicon and is insulated with polyimide. The electrodes are separated by glass at their base and the tips are covered with platinum. Teflon insulated Pt/Ir wires are soldered to the back of the array and provide connection to the data acquisition system. Electrode impedance varied between 50 and 200 M $\Omega$ . We implanted the array into the sciatic nerve which was supported by a grooved stainless steel platform.

Acute experiments were made in 13 rats and two cats. Spontaneous signals had amplitudes as large as 370  $\mu$ V. 50  $\mu$ V responses were evoked by mechanical stimulation in another preparation. In some experiments we found activity on 40% of the electrodes. As expected, it was relatively easy to stimulate the nerve. For a 0.1 second train of 50 Hz biphasic pulses, each 0.2 msec long, we found a minimal muscle twitch threshold of 4  $\mu$ A and a mean value of 36  $\mu$ A. In some animals, stimulation via all electrodes was possible. Recordings from afferent and efferent axons suggested that there was either no or minimal acute nerve injury resulting from the implantation. Following removal of the electrode array and recovery from surgery, no motor deficits in the implanted limb were observed.

These results suggest that the use of high density multichannel arrays in the peripheral nervous system is possible. Long-term applications are being evaluated.

This project is sponsored by a State of Utah Center of Excellence Grant.

**RESPONSES OF SINGLE MOTOR UNITS IN THE HUMAN FINGER FLEXOR TO ELECTROMAGNETIC BRAIN STIMULATION.** S. J. Garland and T. S. Miles\*. Department of Physiology, The University of Adelaide, Adelaide, SA 5005, AUSTRALIA

The pattern of responses evoked in single motor units in the human flexor digitorum profundus muscle (FDP) by electromagnetic brain stimulation was measured. Depending on the timing relative to the last spike, weak stimuli evoked spikes at about 20 ms latency in some trials, and at about 50-80 ms in others. Motor unit potentials were evoked at the longer latency only in trials in which no short-latency response was elicited in that unit, and only when the stimulus was given during the first half of the interspike interval. When given during the second half of the ISI, the stimulus evoked a corticospinal response but no second-peak response. The motoneurone fires at either short or longer latency but not both, because if it discharges at corticospinal latency, it will still be hyperpolarised when the Ia afferent volley arrives about 30-60 ms later. The motoneuronal response at second-peak latency was not modified when both FDP and the extensors of the distal finger joint were prevented from pulling on the distal phalanx. Hence, this second-peak response is not secondary to a stretch reflex provoked by stimulus-induced activation of the finger extensors, nor is it the result of a cutaneous signal resulting from stimulus-induced movement of the finger. Its latency is consistent with the idea that the corticospinal volley evoked by the stimulus activates both alpha and beta motoneurons innervating FDP. The beta motoneurons cause the spindles to twitch, exciting Ia fibres, thus activating the motoneurone reflexly.

**MULTI-CHANNEL MOTOR UNIT CLASSIFICATION DURING ACTIVE FORCE MODULATION USING A NEURAL NETWORK ALGORITHM.** Duke C.C. Du and Gary Kamen\*. Dept. of Exercise Science, Univ of Massachusetts, Amherst.

We developed a motor unit classification system using the fuzzy Adaptive Resonance Theory (ART) neural network algorithm. The system categorized human motor unit action potentials (MUAPs) solely by their waveform shapes obtained from a 3-channel recording. In this implementation, network resonance (correct identification) was reached when the fuzzy similarities between the top-down expectation and the bottom-up presentation of the input vectors rendered the best likelihood identification of recognized clusters. A vigilance parameter was used to determine maximum dissimilarity of new vectors. The classification system drew nonlinear boundaries; these boundaries also varied throughout the progress of the categorization. The same neural network was used to resolve superpositioned waveforms. The procedure used a half-length waveform of the maximal energy as the top-down expectation vectors. These expectation vectors of all the clusters were employed in the order of their half-length energy levels. Whenever a segment of the composite waveform made the network resonant, a full length non-superpositioned AP from the most adjacent clustered spike was used to subtract the waveform energy from the composite waveform. This iterative classification and subtraction procedure continued until all the clusters were exhausted. In comparison with known data recognized using manual waveform identification, the implementation of this multi-channel fuzzy ART algorithm produces: 1) similar accuracy, 2) elimination of a pre-training procedure, and 3) extraction of superpositions. The results of this classification system includes both firing time information as well as MUAP waveform features.

**THE EFFECT OF MOTOR UNIT ACTION POTENTIAL SHAPE ON THE EMG: COMPUTER SIMULATIONS BASED ON SINGLE UNIT RECORDINGS.** M. Hulliger\* and S.J. Day. Dept. of Clinical Neurosciences, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

The electromyogram (EMG) is an aggregate representation of the individual action potential (AP) contributions from motor units (MUs) close to the recording electrode. Recently, it has been demonstrated that individual MUAPs summate algebraically (essentially linearly) (Day et al., Proc. Canadian Soc. Biomech. 9, 1996). Therefore, the recorded EMG reflects addition of signal components with the same polarities, and subtraction (cancellation) of components with opposite polarities. The EMG is of considerable interest for the diagnosis of various peripheral neuromuscular disorders. In the present study, sets of recorded MUAP shapes were manipulated to mimic the properties that are observed for different electrode configurations or motoneuron diseases, and subsequently used in a computer simulation of muscle activation to determine the effect of MUAP shapes on the EMG signal.

In acute cat experiments, a substantial proportion of the soleus MU pool was isolated and their MUAP shapes were recorded for two electrode configurations. Data from a few experiments were pooled to form a library of experimentally recorded, realistic and often complex MUAP shapes. Furthermore, for some applications the duration or complexity of MUAPs was systematically altered and input into a computer simulation, which replicated various recruitment and rate modulation strategies, based on the independent activation of appropriate numbers of MUs. The activation patterns of individual MUs were simulated as MUAP trains. The aggregate EMG was estimated by algebraic summation of all MUAP trains.

Systematic alterations of the MUAPs shapes, that were used in simulating isometric muscle activation, had considerable effects on power spectra and the relation between the averaged rectified EMG and the ensemble activation rate. The results from these studies indicate that in future simulations of muscle activation it will be beneficial to use large numbers of experimentally recorded MUAP waveforms, since the wide variety of MUAP shapes obtained for any electrode configuration cannot be represented by small numbers of arbitrarily fabricated waveforms. Supported by AHFMR and MRC Canada.

## 265.1

A NEURAL NETWORK MODEL OF THE SPINAL CORD FOR ARM CONTROL. N. Schweighofer, F. E. Pollick\*, Human Information Processing Research Laboratories, ATR, 2-2 Hikaridai, Seika-cho, Soraku-gun, Kyoto 619-02 Japan.

According to the concept of muscle synergy, descending motor commands are transformed into a set of several muscle co-activations. This transformation is an ill-posed problem in the sense that the muscle tensions cannot be uniquely determined from prescribed trajectories and forces. We investigated the acquisition of this transformation using a biologically plausible neural network model of the C3-C4 region of the spinal cord which sends its output to a 2 joint, 6 muscle arm model. Since the ill-posedness of this transformation can be solved by minimizing the sum of the motor command change, we propose that known descending neuro-modulatory pathways provide the spinal network with a reinforcement signal which is related to the motor command change. However, if the spinal cord network is not *a priori* provided with coarse connection pattern, the reinforcement learning does not converge. We mimic the development of the coarse connectivity of the network with a genetic algorithm. When the genetic algorithm converges we select the network which gives the best performance. We then train this network with the reinforcement signal from the neuromodulatory pathway. Our results show that, after learning, coordinated arm movements can be executed with reasonably good accuracy.

RECRUITMENT ORDER OF RETICULOSPINAL NEURONS FOR THE CONTROL OF SWIM VELOCITY IN LAMPREY. T. Wannier, H.P. Clamann\* and H.-R. Lüscher, Dept. of Physiology, University of Bern, Bülhplatz 5, 3012 Bern, Switzerland

In lamprey, the supraspinal control of locomotion is accomplished mainly by the reticulospinal (RS) system. The axons of the RS neurons lie ipsilaterally in the spinal cord where they provide excitatory input to spinal neurons. During locomotion, RS neurons receive phasic inputs, and are presumably rhythmically active with a cycle duration corresponding to the duration of the swim cycle. The temporal and spatial characteristics of the propagation of the population of action potentials along RS axons was investigated using a computer model. The results suggest that if changes of velocity are obtained by recruiting RS neurons independently of their size and conduction velocity, a phasic input from RS neurons will act on segments during the inhibited phase of their cycle. Such an input would probably hinder a smooth rostro-caudal propagation of the contraction wave. In contrast, recruiting RS neurons by size provides a mechanism for stabilizing the propagation of the contraction wave.

To investigate if recruitment of RS neurons by size may occur in lamprey, the activity of RS neurons was recorded with a surface electrode on the spinal cord, and their recruitment to stimulation of cranial nerves with currents of successively higher intensities was investigated. For this purpose, the *in vitro* preparation of the brainstem-spinal cord of the lamprey was used. A Vaseline barrier was built between the brain and the spinal cord. The brain was bathed in Ringer and synaptic transmission was blocked in the spinal cord. Under these conditions, the wave of RS action potentials evoked by stimulating a cranial nerve reaches the electrode level with a delay which decreases as the amplitude of the stimulation increases. The data suggest that in lamprey rhythmic activation of RS neurons recruited by size may be the mechanism underlying the supraspinal control of swimming velocity.

## 265.5

REFLEX ORGANIZATION AND CONTROL OF FORCE-FIELD PRIMITIVES IN FROG SPINAL CORD. S.E. Giszter\*, M.R. Davies and W. Kargo, Dept Neurobiology and Anatomy, MCPHU, Philadelphia, PA 19129.

In our previous work we explored the hypothesis that the combined effect of motion based reflex feedback and muscle properties lead to multi-joint force-fields that can be simply described as a time-varying scalar modulation of the isometric force-field 'primitive' that was measured in spinal frogs with the limb held immobile. We have now shown that during reflex behaviors the basic orientation of forces following periods of motion closely matches those generated in isometric conditions. However, we also showed that the magnitude of force production could differ significantly. The net effect of this was to alter force field structure and force us to reject the simple hypothesis of uniform scaling of the isometric primitive.

Our current experiments are aimed at understanding the control of force magnitude as a force-field evolves during reflex behavior. We use a 'phantom' haptic interface robot to interact with the frog limb. We are able to present different 3 DOF impedance fields to the limb. We have initially concentrated on the effects of environmental stiffness. Our results suggest that the control of reflex force-fields can be separated into two additive effects. The first control is based on the initial limb configuration and was well captured in early isometric work. This can be summarized as an elastic force-field. The second control is based on the impedance encountered by the limb and force magnitude is uniform across the workspace. This force-field represents a low or zero stiffness force control. These two controls can be summarized as two separate force-fields, one elastic and one of uniform magnitude, which sum to determine the net driving torques and interaction forces. How these controls vary through a trajectory and whether they are adequate to fully explain the free space limb kinematics is our current focus. The results have implications for the notion of motor primitives, for models of motor learning using force-fields, and for equilibrium models of limb motion. Supported by NIH R29-NS34640-01.

FORELIMB MOTONEURON POOLS ARE CONSERVED IN VERTEBRATES. J.M. Ryan\*, J. Cushman, B. Jordan, and C. Baier, Biology Dept., Hobart & William Smith Colleges, Geneva, NY 14456.

A complete description of the anatomical organization of the neurons innervating homologous limb muscles is a prerequisite to any test of the neuromotor conservatism hypothesis. This study used the retrograde neuronal tracer WGA-HRP to selectively label the motoneuron pools of seven homologous forelimb muscles in 30 iguanas (*I. iguana*), 58 mice (*M. musculus*), and 42 bats (*E. fuscus* and *M. lucifugus*). The muscles studied were Mm. pectoralis, spinodeltoideus, biceps brachii, lateral and long heads of triceps brachii, and the mammalian supraspinatus and infraspinatus, or its homolog, the reptilian supracoracoideus. In vertebrates, motoneurons are arranged in longitudinal columns of cells in the ventral horn of the spinal cord. The number of neurons per pool ranged from 70 - 119 in mice, 40 - 87 in bats, and 58 - 114 neurons in iguanas. In both iguanas and mice the motor pools for the spinodeltoideus, biceps, and the supracoracoideus (or its mammalian homologs) lie cranial to the pectoralis and triceps motor pools. In the transverse plane, the pectoralis pool lies medial to those of the other muscles studied. The pools of the biceps and spinodeltoideus are located dorsal and lateral to the pectoralis and supracoracoideus (or its homologs in mammals). The resulting motor pool maps demonstrate that the anatomical organization of motoneurons in reptiles has been retained in both quadrupedal and flying mammals and is independent of the anatomical specialization of the forelimb. Funded by a Whitehall Foundation grant G1AM-01 and NSF grant IBN-9318681 to JM Ryan.

## 265.4

MODULARITY OF THE FROG SPINAL CORD MOTOR SYSTEM. P. Saltiel\*, M. Tresch and E. Bizzi, Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Electrical microstimulation of the lumbar grey with the limb held isometrically is known to produce only a few types of convergent force fields of distinct orientations. In order to verify that non-axonal elements underlie this finding and to delineate their topography, NMDA iontophoresis (-100nA x 30 sec) was applied to the spinal cord at sites where electrical stimulation through the same pipette had elicited a force response. At the responsive sites, forces clustered with the same five orientations (abduction=ABD, rostral flexion=RF, flexion to body=FB, adduction=ADD, caudal extension=CE) than the set of forces obtained with electrical stimulation, confirming earlier results (Soc Neuro Abs 1406,1994). The chemical stimulation seemed focal in that many penetrations had both NMDA-responsive and silent sites, with the distance between the closest active and silent sites being on the average 293µ, and sometimes as little as 100µ.

Out of 72 active sites (33% of tested sites) in 13 frogs, 18 responded with a single tonic force (5 ABD, 5 RF, 3 ADD, 5 CE). These tonic sites defined a coarse topography: CE was obtained from lower cord segment 7 to mid-segment 8 at a depth of 860±189µ, RF from segment 8 at 1098±171µ, ADD from lower segment 8 at 881±121µ, ABD from mid-segment 9 to mid-segment 10 at 1324±142µ.

46 sites responded with a rhythm usually involving two or three types of forces. Not all possible combinations of forces were seen. Each of the most common rhythms (RF,FB; RF,FB,ABD; ADD,CE,FB) could be elicited from two or three regions of the cord. These consisted of regions similar to or close in location to the tonic regions capable of producing those forces that represented components specific to that rhythm, as well as an additional caudal region in segment 10 from which any of these rhythms could be elicited.

These results support the idea of modularity of the motor system within the frog spinal cord as well as the existence of a topographic organization to these modules. They may also provide a framework in which to investigate the hard-wired aspects of the circuitry underlying the genesis of spinal cord rhythms. (Supported by ONR-N00014/90/J/1946).

## 265.6

AN *IN VITRO* ADULT MAMMAL WHOLE SPINAL CORD PREPARATION. Z. Jiang, R.M. Brownstone\* Depts. of Physiology and Surgery, University of Manitoba, Winnipeg MB Canada R3E 0W3

The 'classical' preparation to study spinal cord physiology is the *in vivo* cat. Recently, isolated *in vitro* spinal cord preparations have been developed using neonatal rats<sup>1,2,3</sup> or mice<sup>4,5</sup>. These preparations have allowed for the close examination of cellular properties during, for example, locomotor activity. In addition, the hemisectioned adult mouse spinal cord has been studied *in vitro*<sup>6</sup>. We now report the development of a whole *in vitro* spinal cord preparation in an adult mouse with lumbar roots intact.

Mice up to 21 days of age were decapitated and eviscerated after being anesthetized with ketamine. In oxygenated artificial CSF a vertebral section was performed from cervical spine to sacrum, and the spinal cord with lumbar roots was carefully dissected free. The cord was then secured in a Sylgard-lined dish. Suction electrodes were used to monitor activity in ventral roots and/or white matter funiculi. Suction electrodes may also be used for stimulating dorsal roots or the spinal cord. Neurochemicals including serotonin, NMDA, Noradrenaline, mianserin, and propranolol may then be added to the solution to produce or block activity.

There is a dramatic increase in tonic motor activity following the addition of serotonin to the bath. In addition, there was some evidence of alternating rhythmic activity seen in contralateral ventral roots of the same lumbar segment in response to a combination of serotonin and NMDA.

This demonstrates that this preparation allows for the study of intact adult mammalian spinal cord physiology *in vitro*.

## 265.7

## DIFFERENTIAL MODULATION OF SPINOCEREBELLAR RESPONSES BY SEROTONIN IN THE CAT

A.M. Rankin, G. Bosco, and R.E. Poppele\*. Dept of Physiology and Neuroscience Graduate Program, Univ. of Minnesota, Minneapolis, MN 55455.

We previously examined the firing patterns of neurons of the dorsal spinocerebellar tract (DSCT) during passive movements of the hindlimb. In response to a small amplitude perturbation applied to the limb, the cells exhibit a stereotyped pattern of firing broadly tuned to the direction of movement. They also linearly encode the position and direction of movement of the foot relative to the hip. Raphe stimulation or systemic 5-HTP, a serotonin precursor, produced complex and differential effects on these responses. A common finding was a reduced sensitivity to static foot position, resulting in a nearly uniform firing rate during passive movements of the foot throughout the workspace. However, the overall mean firing rate was essentially unchanged, indicating that the effect is not simply due to a serotonergic inhibition of an excitatory input. Furthermore, the reduction of the position sensitivity could occur even when the neuron retained its sensitivity to movement. These findings suggest that multiple spinal circuits may be involved in the production of DSCT responses and that they may be differentially sensitive to modulation by serotonin. Serotonin may thus provide a useful tool for investigating spinal circuitry responsible for DSCT behavior. (Supported by NIH Grant NS21143)

## 266.1

## PROPERTIES OF MINIATURE IPSCs IN CA1 INTERNEURONS OF THE RAT HIPPOCAMPUS IN VITRO. S. Nurse\* and J.-C. Lacaille. Centre de recherche en sciences neurologiques, Département de physiologie, Université de Montréal, Montréal, Canada H3C 3J7.

Hippocampal interneurons form inhibitory synaptic connections with each other, in addition to the contacts made onto principal cells. However, the properties of inhibitory currents at individual synapses in interneurons have not been characterized. Miniature inhibitory postsynaptic currents (mIPSCs) were recorded in CA1 interneurons from several layers (stratum oriens, radiatum and lacunosum-moleculare), and their properties compared to those of pyramidal cells. Interneurons and pyramidal cells were visually identified in hippocampal slices from 3-4 week-old rats, using Nomarski optics and a near-infrared CCD camera. Whole-cell recordings were made using patch pipettes (4-8 M $\Omega$ ) containing (in mM) 140 KCl, 5 NaCl, 2 MgCl<sub>2</sub>, 10 HEPES, 2 ATP-tris, 0.4 GTP-tris. Voltage clamp recordings of mIPSCs were made at -80mV during bath application of 50 $\mu$ M AP5, 20 $\mu$ M CNQX and 0.5 $\mu$ M TTX (n=9 interneurons and 4 pyramidal cells). The mean frequency ( $\pm$ sd) of mIPSCs was similar in interneurons and pyramidal cells (0.8 $\pm$ 1.0 vs 1.1 $\pm$ 0.6 Hz, respectively). Mean peak amplitude of averaged mIPSCs was also similar in both cell types (23.6 $\pm$ 8 vs 35.8 $\pm$ 12 pA). Mean rise time of averaged mIPSCs were significantly slower in interneurons than pyramidal cells (2.2 $\pm$ 0.6 vs 1.1 $\pm$ 0.3 ms). The decay of averaged mIPSCs was well fitted by a single exponential function, but the mean decay time constant was faster in interneurons (11 $\pm$ 1.9 vs 14.2 $\pm$ 3.0 ms). In all cells, mIPSCs were blocked by 25 $\mu$ M bicuculline. Thus, mIPSCs in interneurons were GABA<sub>A</sub>-mediated, as in pyramidal cells, but their kinetics differed. These results suggest that the properties of individual inhibitory synapses may differ on interneurons and pyramidal cells.

## 266.2

## GAMMA OSCILLATIONS IN CA1 MINI-SLICES. A. M. Borroni\* and W. B. Levy. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Under certain behavioral conditions, rhythmic events can be observed in the CA1 region of the hippocampus. The most prominent example is the 5-8 Hz oscillation, the theta rhythm. This rhythm reflects the coordinated activation of currents in many hippocampal neurons but is most likely driven by afferents from the septum and the entorhinal cortex. Within a cycle of theta, a faster gamma oscillation (30-60 Hz) can be observed. This rhythm is prominent in other regions as well and is associated with behavioral activation. The importance of understanding the mechanism underlying this gamma rhythm derives from its hypothesized role in short-term memory and perceptual binding. Here we demonstrate that, as with the theta rhythm, gamma oscillations can be generated in the CA1 region in vitro by activating muscarinic receptors. However, unlike theta rhythms in vitro, gamma oscillations occur in CA1 even when this region is isolated from all extrinsic inputs (CA1 mini-slices). Similar to gamma oscillations in vivo, the frequency of the gamma oscillations can be decreased by enhancing GABA<sub>A</sub> inhibition. They are also blocked by the GABA<sub>A</sub> antagonist bicuculline methiodide. The synchronization of gamma oscillations across CA1 and the recording of these events extracellularly suggest that this rhythm reflects the coordinated activity of many cells rather than a single cell. Thus, gamma oscillations in vitro are likely to reflect inhibitory currents generated at pyramidal cell somata by networks of synchronized inhibitory interneurons. By adding muscarinic agonists, gamma oscillations similar to those seen in vivo can be produced in CA1 thus providing a reduced system for the study of this phenomenon. Supported by NIH 5-T32-NS07199 to AMB and NIH NS15488, and MH00622 to WBL.

## 266.3

## ASSOCIATIVE LONG-TERM DEPRESSION IN LAYER II OF MEDIAL ENTORHINAL CORTEX. D. X. Zhang\*, N. L. Desmond and W. B. Levy. Dept. of Neurosurgery, University of Virginia, Charlottesville, VA 22908.

Alonso et al. (1990) reported LTP in the entorhinal cortex (EC). Here we report a LTD that apparently has an associativity requirement for its induction. Horizontal slices from young adult rats were maintained in an interface chamber. Three stimulating and one recording electrodes were placed in each slice. The extracellular recording pipet was placed at the border between layers I and II of the medial EC. Two stimulating electrodes were placed in layer I, with one on the lateral (Lat) and the other on the medial (Med) side of the recording electrode. The third stimulating electrode was placed in layer III medial to the recording pipet. We measured the initial slopes of the responses. Conditioning stimulation of Lat and/or Med at the test intensities consisted of 150 trains (1 train/2 sec). Each train had 4 pulses at an interpulse interval of 300 ms. The total number of conditioning pulses for Med or Lat was 600. During co-conditioning of Lat and Med, each Med pulse was always delayed 150 ms relative to each Lat pulse. Only co-conditioning of the Lat and Med induced statistically significant LTD. The slopes of the Lat and Med responses decreased 18.8 $\pm$ 4.6% (N=16, t=4.09, p<0.001) and 21.5 $\pm$ 4.7% (N=16, t=4.56, p<0.001), respectively, at 60 min after co-conditioning. Although the responses tend to decrease, there were no significant long-term changes in any responses when either Lat alone or Med alone is conditioned using 600 or 1200 pulses.

Supported by NIH NS15488 and MH00622 to WBL. NLD was also supported by NIH MH50670.

## 266.4

## DISTAL DENDRITIC ACTIVATION MODULATES THE INDUCTION OF LTP OF THE SCHAFER COLLATERAL RESPONSE IN HIPPOCAMPAL CA1. W. B. Levy\*, N. L. Desmond and D. X. Zhang. Dept. of Neurosurgery, University of Virginia, Charlottesville, VA 22908.

The existence of laminated inputs along the proximodistal axis of oriented neurons and the possibility of electrical or chemical compartmentation within a neuron have led to the idea of selective interlaminar interactions. Here we investigate an interaction between the distal perforant path (PP) input to hippocampal CA1 and the more proximal Schaffer collateral (Sch) input to s. radiatum. Transverse hippocampal slices from male rats (140-225g) were maintained in an interface chamber. CA3 and DG were dissected after chopping. The PP and Sch stimulating electrodes were placed in CA1 s. lacunosum-moleculare and s. radiatum, respectively. Recording pipets were also placed in these two laminae. The PP stimulating current was chosen to prevent any noticeable overlap between the two inputs. Conditioning consisted of 10 trains (1/200 ms). The Sch and PP trains contained 5 and 10 pulses, respectively, at 100 Hz. The PP train began 2 pulses earlier and ended 3 pulses later than the Sch train. The control conditioning paradigms were Sch alone or PP alone. The data reported here are measurements of the initial slopes of the Sch pEPSPs in s. radiatum. Comparisons between control and paired conditioning are between slices. Sch conditioning alone induces significant LTP (35.4 $\pm$ 7.2%; N=11, p<0.001). However, paired conditioning of the Sch and PP inputs leads to essentially no LTP of the Sch response, i.e. Sch+PP conditioning increases the Sch response only 4.6 $\pm$ 4.3% (N=15, p>0.05). Therefore, we conclude that sufficient inhibition is available in the distal PP input to prevent the induction of homosynaptic LTP in CA1 s. radiatum.

Supported by NIH NS15488 and MH00622 to WBL. NLD was also supported by NIH MH50670.

## 266.5

SPONTANEOUS, FAST REPLAY OF LEARNED SEQUENCES BY A CA3 NETWORK MODEL. D. A. August\* & W. B. Levy. Univ. of Virginia Health Sciences Center, Dept. of Neurosurgery, Charlottesville, VA 22908.

Recent results from McNaughton's lab suggest that the hippocampus serves as an intermediate-term memory store that teaches the cerebral cortex. During sleep, the hippocampus replays events that were experienced earlier in the day. This replay is much faster than the originally sensed events as measured by hippocampal cell firing and their correlations. Previously, we presented a model of hippocampal region CA3 that 1) spontaneously replays a learned sequence (Mina & Levy, 1993) and for which 2) the speed of replay in a sequence completion problem is controlled by the level of inhibition (Prepcius & Levy, 1994). These self-modifying networks consisted of sparse, recurrently connected McCulloch-Pitts neurons. Here we report an extension of this CA3 model that uses integrate and fire neurons. When inhibition is decreased from the level used during learning and random activity is added, this modified network spontaneously replays a fast version of a previously learned sequence. We term such speeded up replay temporal compression. Not surprisingly when inhibition is lowered to produce spontaneous replay, neural firing rates increase compared to rates during learning. The amount of temporal compression observed ranged from 20-80 fold. Most interestingly, we were unable to get spontaneous replay at the same speed as a sequence was originally learned. Apparently, the only way to replay the sequence at the speed experienced during learning is to pace the system with external inputs. Supported by NIH MH10702 to DAA. WBL supported by NIH MH00622, MH48161, and Pittsburgh SuperComputing Center Grant BNS950001P.

## 266.7

IDENTIFICATION OF INTERNEURONAL SUBTYPES IN CULTURES OBTAINED FROM POSTNATAL HIPPOCAMPUS. M. Mynlieff\*. Dept. of Biology, Marquette University, Milwaukee, WI 53201-1881.

Morphological identification of cell types in short term cultures obtained from the superior region of the hippocampus of postnatal day 7-14 Sprague Dawley rat pups is not possible. Whole cell patch clamp recording in the current clamp mode after 24-96 hours in culture was used to determine if the action potential (AP) duration would be a useful criteria in distinguishing cell types. Single APs could be elicited by a 0.1-0.2 ms 2000 pA depolarizing pulse. The average membrane potential and input resistance were  $-47.5 \pm 1.9$  mV ( $n=27$ ) and 708 M $\Omega$  ( $n=26$ ), respectively. A frequency distribution of the AP duration measured at half-maximal amplitude showed 3 distinct groups of neurons (#1,  $1.4 \pm 0.1$  ms,  $n=10$ ; #2,  $2.1 \pm 0.1$  ms,  $n=10$ ; #3,  $3.2 \pm 0.2$  ms,  $n=7$ ). Based on correlations with studies by Lacaille and coworkers using intracellular recording in identified cells in slices, I propose that group 1 represents basket cells, group 2 represents vertical cells and group 3 represents a combination of stellate cells and pyramidal cells. Further analysis of the fast afterhyperpolarization is needed to distinguish between pyramidal cells and stellate cells. In contrast to the interneurons in a slice preparation, these cells offer good voltage control and environmental control. By waiting a minimum of 24 hours before recording, the cells become more stable than acutely dissociated neurons and will show recovery of functions damaged by enzymatic treatment. Future studies will record from these cells in current clamp mode to quickly characterize the AP before switching to voltage clamp recording to characterize the currents present in the different types of interneurons.

## 266.9

INSULAR AND TEMPORAL CORTICAL EFFERENTS IN THE MONKEY. B. Turner\* and M. Knapp. Dept. Anatomy, Howard Univ. Coll. of Med., D.C. 20059.

The anterior temporal and insular cortices are important in the initial stages of learning and memory formation. To determine likely sites of subsequent stages of these functions, we plotted all efferent connections from subdivisions of these regions using Fink-Heimer and autoradiographic series. **RESULTS:** Taste **IA:** To cortex-heavy in prorhinal and frontal insular cortices. To limbic-heavy in lateral and basal amygdaloid nuclei. To striatum-heavy in ventral putamen. Audition **IA:** To cortex-moderate in frontal areas 10, 11, and 13; lightly in subcallosal cingulate and prorhinal cortex. To limbic-heavy in lateral amygdaloid nucleus. To striatum-lightly in tail of caudate. **TGd:** To cortex-heavy in subcallosal cingulate. To limbic-heavy in lateral and basal accessory nuclei. To striatum-moderate in tail of caudate. Vision **TE posterior:** To cortex-heavy in area 8 (superior bank of inferior arcuate sulcus). To limbic-lightly in amygdala. To striatum-heavy in ventral putamen and tail of caudate. **TE anterior:** To cortex-moderate in prorhinal/perirhinal cortex. To limbic-heavy in lateral and basal amygdaloid nuclei. To striatum-heavy in ventral putamen and tail of caudate. **TGv:** To cortex-heavy in prorhinal/perirhinal cortex, lightly in dorsal bank of principal sulcus. To limbic-heavy in lateral and accessory basal amygdaloid nuclei. To striatum-heavy in ventral striatum, ventral putamen and tail of caudate. **Conclusion:** Temporal and insular projections to other cortical regions are light; those to the tail of caudate and ventral putamen are extremely limited in spatial extent. The amygdala and the hippocampus (prorhinal/perirhinal cortex) have heavy inputs from all temporal and insular sense modalities; and are therefore the best candidates for subsequent stages in learning and memory.

## 266.6

CONTROLLING ACTIVITY IN A RECURRENT CA3-LIKE NEURAL NETWORK MODEL. O. V. Yousukhno\* and W. B. Levy. Univ. of Virginia Health Science Center, Dept. of Neurosurgery, Charlottesville, VA 22908.

We are studying sparse, randomly connected recurrent networks of McCulloch-Pitts neurons as a model of hippocampal region CA3. Neuronal firings in such a randomly connected network appear random. The activity of the network (percentage of neurons that are active) fluctuates under the control of a shunting, fast feedback inhibition, which is proportional to the activity. In this model there are large fluctuations of activity; such large fluctuations impair network performance. Here we show how activity levels can be better controlled if a leak inhibitory conductance is added.

Consider the following: suppose that activity differs from the desired activity value,  $A$ . We want, on the average, the activity at the next time step to equal  $A$ . What inhibition should the network generate?

Because of the random connectivity of the network, this question is answered by numerically solving probabilistic equations of activity. The resulting relationship between the desired inhibition and preceding activity is well approximated by a linear function in the activity range of interest. In addition to a function that varies proportionally with activity, a constant level of inhibition is needed. Essentially this is equivalent to adding a constant shunting leak conductance. Both constants in this linear relationship depend on the desired level of activity.

Incorporating this modified form of shunting inhibition substantially reduced activity fluctuations in the computational model. In the case of 10% average activity, the fluctuations decreased from a 5-fold span (highest to lowest) in the old model to just 1.3 when the proper leak shunt was added.

## 266.8

INVOLVEMENT OF CHOLINERGIC NEURONS OF THE LATERODORSAL TEGMENTAL NUCLEUS IN THE INHIBITORY RESPONSES IN THE BASAL FOREBRAIN OF THE RAT. L.A. Kadishevitz, S.M. Brudzynski, Department of Clinical Neurological Sciences, London Health Sciences Centre, University of Western Ontario, London, Ontario, N6A 5A5 Canada.

There is ample evidence that the laterodorsal tegmental nucleus (LDT) contains a major group of cholinergic neurons innervating diverse regions of the rat brain. It had been demonstrated in a preliminary study that electrical stimulation of the LDT had a predominantly inhibitory effect on the mean firing rate of the basal forebrain neurons. The goal of the present study was to demonstrate that these inhibitory responses are mediated by cholinergic transmission. Extracellular single unit responses were recorded from the anterior hypothalamic-preoptic region (AH-POA) before and after single pulse (0.2-2 ms, 200-800  $\mu$ A) stimulation of the LDT. Stimulation of the LDT produced inhibitory responses in 52 neurons (mean inhibition time  $36.7 \pm 7.2$  ms, SEM for 400  $\mu$ A), and excitatory responses in 17 neurons in the AH-POA. Iontophoretic ejection of scopolamine into the AH-POA reversed inhibitory responses of 6 neurons to LDT stimulation while the excitatory responses ( $n=2$ ) remained unchanged. In 4 rats, the recording sites in the AH-POA, from which inhibitory responses were obtained, were subsequently injected with the membrane lipophilic dye DiA (0.1-0.2  $\mu$ L). Analysis of fixed tissue preparations using a confocal laser microscope (MRC 600) revealed clusters of retrogradely labelled neurons in the LDT. The present results demonstrate that the cholinergic transmission in the AH-POA is involved in the inhibitory effects of the LDT stimulation.

Supported by the Medical Research Council of Canada.

## 266.10

MEDIAL AND ORBITAL PREFRONTAL CONNECTIONS OF THE MIDBRAIN PERIAQUEDUCTAL GRAY OF THE MACAQUE. X. An, R. Bandler\* and J. L. Price. Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110; Dept. of Anatomy and Histology, Univ. of Sydney, NSW, Australia 2006

Recent research suggests that distinct, longitudinal columns of midbrain periaqueductal gray (PAG) neurons play important roles in coordinating different emotional coping strategies. A lateral PAG column mediates active emotional coping strategies (fight/flight, hyper-reactivity, hypertension, tachycardia), whereas a ventrolateral PAG column mediates a more passive emotional coping strategy (quiescence, hyporeactivity, hypotension, bradycardia). Previous studies in the rat revealed that a number of specific medial, orbital and lateral cortical fields project densely to terminate as longitudinal afferent columns within specific rostrocaudal portions of the PAG. In the macaque, recent studies indicate that the orbital and medial parts of the prefrontal cortex (PFC) can be subdivided into at least 22 discrete areas. This study, in *Macaca fascicularis*, examined PFC to PAG connections. Retrograde tracer injection (fast blue) centered in ventrolateral PAG resulted in strong bilateral labeling (with an ipsilateral bias) in extensive medial PFC areas (32,25,24,9) and select orbital PFC areas (12o,1ai,13a). Anterograde tracer (biotinylated dextran amine, fluororuby) injected in medial and orbital PFC areas (25,12o,13a) verified that these areas project to the ventrolateral PAG. Other studies indicate that these extensive medial and select orbital PFC areas are linked by substantial intracortical connections; receive inputs from the same regions of mediadorsal thalamic and basal amygdaloid nuclei; and project strongly to the ipsilateral hypothalamus. It has been suggested previously that these medial and select orbital PFC areas constitute a "medial" PFC network. By targeting the ventrolateral PAG columnar circuit this "medial" PFC network is organized in a manner to allow it to modulate or trigger the somatic and autonomic reactions coordinated by the ventrolateral PAG column. Other "orbital" PFC areas do not appear to project strongly to the ventrolateral PAG. (Supported by NIH grant DC00093 and Australian NHMRC grant 950143)

## 266.11

ORBITAL AND MEDIAL PREFRONTAL CORTICAL PROJECTIONS TO THE HYPOTHALAMUS IN MACAQUE MONKEYS. D. Öngür\*, X. An and J.L. Price. Dept. of Anatomy & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110

Previous evidence from rats indicates that the orbital and medial prefrontal cortex (OMPFC) modulates autonomic function through projections to the hypothalamus and brainstem. Loss of these connections may underlie many of the behavioral deficits seen with lesions of the OMPFC in humans, but the connections have not been well defined in primates. We investigated the projections from the OMPFC to the hypothalamus in monkeys, in relation to architectonic areas defined from staining patterns with several methods. Two networks can be recognized within the OMPFC based on their cortical and subcortical connections: a medial network that involves medial prefrontal areas and selected orbital areas, and an orbital network that involves other orbital areas.

Five injections of retrograde axonal tracers in the hypothalamus and ventral midbrain of three monkeys (*Macaca fascicularis*) produced labeled cells in selected areas of the ipsilateral OMPFC. An injection in the anterior lateral hypothalamus labeled cells primarily within the medial network, including medial areas 32 and 25 and orbital areas 12o, 14c, 13a and 1ai. Another injection centered just lateral to the ventromedial hypothalamic nucleus labeled cells in the same areas and also in other agranular insular areas 1am, 1ai, 1al and 1apm on the posterior orbital surface. Many fewer cells were labeled in more rostral prefrontal areas. In other experiments, anterograde tracer injections into several areas in the OMPFC (25, 13a, 12o) labeled extensive axonal projections to lateral and medial parts of the hypothalamus.

In summary, the OMPFC has a substantial projection to the hypothalamus, primarily from areas within the medial network, and from the agranular insular areas. These areas receive substantial inputs from several limbic structures as well as olfactory and visceral afferents, and provide for higher cortical control of autonomic function. Supported by NIH grant DC00093 and by the Division of Biology & Biomedical Sciences of Washington University.

INTRAHYPOTHALAMIC INJECTION OF GABA<sub>A</sub> ANTAGONIST REDUCES THE BLOOD CONCENTRATION OF CALCIUM AND POTASSIUM IN RATS. S. Aou\*, K. Shiramine, K. Araiishi, and T. Hori. Dept. of Physiology, Fac. of Med., Kyushu Univ., Fukuoka 812, Japan.

The rat hypothalamus has been shown to be sensitive to calciotropic hormones (Matsui et al 1995; Shimizu et al 1986) and regulates calcium metabolism via the vagus nerves (Aou et al 1993; Ma et al 1994). To further elucidate neuronal involvements in blood calcium homeostasis, effects of intrahypothalamic injection of bicuculline methiodide (BM, 5-40 ng/0.2-0.5 µL), a GABA<sub>A</sub> antagonist, on the blood concentration of calcium and other electrolytes were investigated in freely moving female rats. BM injection into the lateral hypothalamic area (LHA) elicited decreases in the blood calcium (0.05-0.1 mM) and potassium (0.2-0.5 mM) levels without affecting sodium and chloride ions. BM injection into the paraventricular hypothalamic nucleus (PVN) also induced hypocalcemia but not hypokalemia. The hypocalcemic response to LHA injection of BM was eliminated by a gastric vagotomy, while that to PVN injection was suppressed by a vagotomy of the thyroid/parathyroid branches. Both hypocalcemic and hypokalemic effects of BM injection into the LHA were antagonized by either a peripherally acting β-adrenoceptor antagonist (nadolol, 2 mg/kg, iv) or a histamine H<sub>2</sub> blocker (ranitidine, 5 mg/kg, iv). The results suggest that hypothalamic neurons regulate blood calcium homeostasis via at least two different vagal pathways, the vagus innervating the stomach or the thyroid/parathyroid glands. Histamine H<sub>2</sub> and β-adrenergic receptors are involved in the LHA-mediated hypocalcemia and hypokalemia. Supported by Grants-in Aid (No. 07557008) for Scientific Research from the Ministry of Education, Science and Culture, Japan).

## 266.15

LACTATE INDUCED PANIC RESPONSE IN RATS WITH CHRONIC GABA DYSFUNCTION IN THE DORSOMEDIAL HYPOTHALAMUS (DMH) IS ASSOCIATED WITH INCREASED NOREPINEPHRINE RELEASE IN THE DMH. S.R. Keim\*, J.S. Katner and A. Shekhar. Dept. of Psychiatry, Indiana Univ. Med. Center, Indianapolis, Indiana 46202.

Intravenous infusion of sodium lactate elicits a panic-like response in rats with chronic dysfunction of GABA in the dorsomedial hypothalamus (DMH). Increased activity of norepinephrine (NE) pathways is also implicated in panic responses and GABA appears to regulate NE release in the DMH. Therefore, the present study was conducted to test if NE release in the DMH was altered during a lactate infusion using *in vivo* microdialysis. Rats were fitted with femoral arterial and venous catheters and baseline heart rate (HR), blood pressure (BP) responses to lactate infusions (0.5M, 10 ml/Kg i.v. in 20 min) were obtained. Specially constructed loop style microdialysis probes that also had a chronic injection cannulae which was connected to an Alzet infusion pump filled with the GABA synthesis inhibitor L-allylglycine (L-AG; 3.5 nmoles/0.5µl/hr) were implanted into the DMH. After 3 days of recovery, microdialysis probes were infused with artificial cerebrospinal fluid (1.5 µl/min) and baseline dialysates were collected in 20 min fractions. Rats were once again tested with either i.v. lactate or saline infusions while continuing to collect dialysis samples. Infusions of lactate and not saline resulted in significant increases in extracellular NE levels in the DMH. These results suggest that the lactate induced panic responses are associated with an increased release of NE in the DMH. (Supported by MH 52691, AAMHRE and IUMC Biomedical grants)

## 266.12

TOPOGRAPHY OF PROJECTIONS FROM THE HYPOTHALAMUS TO PREFRONTAL CORTICES IN THE RHESUS MONKEY. N.L. Rempel-Clower\* and H. Barbas. Dept. Health Sci., Boston Univ., Boston, MA 02215

The hypothalamus has widespread projections to the cortex. However, the topography of hypothalamic projections to most cortical areas in the monkey has not been characterized in detail. We studied hypothalamic projections to prefrontal cortices using injections of retrograde tracers in orbital, medial, and lateral prefrontal areas. All of the prefrontal areas investigated received projections from the hypothalamus, and most retrogradely labeled neurons were found in the posterior hypothalamus. There were differences in the rostrocaudal organization of hypothalamic projection neurons directed to the structurally distinct limbic and eulaminate prefrontal cortices. Specifically, injections in eulaminate prefrontal areas (e.g., areas 46 and 8) primarily labeled neurons in the posterior hypothalamus, and only a few neurons in the tuberal hypothalamus. Injections in limbic prefrontal areas (e.g., PAl, Pro, area 32, area 25) also primarily labeled neurons in the posterior hypothalamus, but in comparison with eulaminate areas, more neurons were labeled in the anterior and tuberal regions of the hypothalamus. There were additional differences in the topography of projection neurons directed to limbic cortices. Labeled neurons projecting to limbic orbitofrontal areas were more prevalent in lateral hypothalamic regions (lateral hypothalamic area, magnocellular tuberomammillary nucleus, paramammillary nucleus) than in medial regions. In contrast, labeled neurons projecting to limbic medial areas were more prevalent in medial hypothalamic regions (posterior hypothalamic area, dorsal hypothalamic area, perifornical nucleus) than in lateral regions. Labeled neurons directed to eulaminate prefrontal areas were distributed equally in the lateral and medial hypothalamus. Results suggest that hypothalamic projections to prefrontal areas originate in areas associated with autonomic function, and there was no evidence of projections from areas with endocrine function (e.g., paraventricular nucleus, supraoptic nucleus). (Supported by grant NS24760.)

## 266.14

EFFECTS OF ESTRADIOL AND TAMOXIFEN ON CELL ATP LEVELS IN PREOPTIC AND HYPOTHALAMIC SLICES. J.M. Gray\* and K.M. Raley-Susman. Depts. of Psychology and Biology and Program in Biopsychology, Vassar College, Poughkeepsie, NY 12601.

An *in situ* slice system has been used extensively to study the effects of altered environmental conditions (e.g., ischemia, NMDA) on neural metabolism in hippocampus. Although several investigators have used a hypothalamic slice preparation to examine effects of steroids on electrophysiological properties of neurons, little work has been done using a hypothalamic slice preparation to explore metabolic function in this area. Prior to manipulating conditions, we therefore validated this preparation, comparing results of morphological integrity, protein synthesis and tissue ATP levels to those previously reported for hippocampus. Based on these criteria, we found that 400µ slices from the region between the anterior preoptic area and the medial basal hypothalamus from ovariectomized, young adult rats were viable for up to 8 hr, with tissue ATP levels falling between 12-24 hr.

Incubation of slices with 10<sup>-8</sup> to 10<sup>-6</sup>M estradiol for 4 hr had no effect on ATP levels. Incubation of the slices for 4 hr with the triphenylethylene antiestrogen, tamoxifen (TAM), however, yielded site-specific and dose-specific changes in ATP levels. Addition of 10<sup>-8</sup>M TAM significantly increased ATP levels in preoptic area and anterior hypothalamic (POA-AH) slices, while having no effect on medial hypothalamic (mHT) slices. Addition of 10<sup>-6</sup>M TAM had no effect in POA-AH, but significantly decreased ATP levels in mHT. Incubation with high doses (10<sup>-6</sup>M) of fluphenazine, a phenothiazine with similar properties to TAM on a variety of calcium sensitive systems (e.g., binding to calmodulin, inhibition of protein kinase C), had effects similar to those found with the lower doses of TAM, that is a selective increase in ATP levels in the POA-AH region.

ORGANUM VASCULOSUM LAMINA TERMINALIS (OVLt) IS A CRITICAL RELAY SITE FOR THE LACTATE INDUCED PANIC RESPONSE IN RATS WITH CHRONIC GABA DYSFUNCTION IN THE DORSOMEDIAL HYPOTHALAMUS. A. Shekhar\* and S.R. Keim. Dept. of Psychiatry, Indiana Univ. Med. Center, Indianapolis, Indiana 46202.

Intravenous infusion of sodium lactate elicits a panic-like response in rats with chronic dysfunction of GABA in the dorsomedial hypothalamus (DMH). The present study was conducted to test if the circumventricular organ OVLt is a potential site that could detect increases in plasma lactate levels and activate the DMH. Rats were fitted with femoral arterial and venous catheters and baseline heart rate (HR), blood pressure (BP) responses to lactate infusions (10 ml/Kg i.v.) were obtained. Unilateral chronic injection cannulae connected to a detachable Alzet infusion pump filled with the GABA synthesis inhibitor L-allylglycine (L-AG; 3.5 nmoles/0.5µl/hr) were implanted into the DMH. Another chronic injection cannula was implanted into the region of the OVLt. After establishing the development of increased baseline anxiety and physiological responses to lactate, rats with DMH GABA dysfunction were once again tested with lactate after injection of either artificial cerebrospinal fluid (a-CSF) or tetrodotoxin (TTX; 100 nl of 10 µM) into the OVLt. Injecting TTX and not a-CSF into the OVLt significantly blocked the lactate induced panic response. Further, direct injections of lactate (100 and 500 nl) into the OVLt elicited a dose-dependent, robust panic-like responses in these rats, suggesting that the OVLt may be the primary afferent site for the lactate induced panic responses in this model. (Supported by MH 52691, AAMHRE and IU Biomedical grants)

## 266.17

METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES INVOLVED IN THE MODULATION OF MAGNOCELLULAR NEURONS OF THE HYPOTHALAMIC SUPRAOPTIC NUCLEUS. L.A. Schrader\* and J.G. Tasker. Neuroscience Training Program and Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118.

Activation of metabotropic glutamate receptors attenuates intrinsic K<sup>+</sup> currents in magnocellular neurons of the supraoptic nucleus (SON) and reduces glutamate and GABA release from presynaptic terminals (Schrader and Tasker, Soc. Neurosci. Abstr. 20: 347). We used the whole-cell patch clamp technique in coronal slices of the rat hypothalamus to determine the metabotropic glutamate receptor subtypes involved in these effects.

L(+)-2-Amino-4-phosphonobutyric acid (L-AP4, 200  $\mu$ M), specific for mGluR subtypes 4, 6, and 7, decreased the frequency of spontaneous excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs) to 30-50% of that seen in normal medium, and reduced the excitatory postsynaptic current (EPSC) evoked by electrical stimulation to 50-60% of control. L-AP4 also reduced the frequency of miniature EPSCs and IPSCs, suggesting a presynaptic locus for L-AP4 action. Application of (RS)-3,5-Dihydroxyphenylglycine (DHPG, 50-100  $\mu$ M), an agonist specific for mGluR1 and mGluR5, reduced the transient K<sup>+</sup> current to 40-60% of control values in 5 of 8 neurons. The outward rectifying K<sup>+</sup> currents were also attenuated to 45-70% of control values in 6 of 8 cells studied. Leak conductances were reduced to 70-90% of control values by DHPG. These studies indicate that glutamate modulates intrinsic K<sup>+</sup> currents in magnocellular neurons by acting at group 1 (mGluR1 and 5) and decreases both glutamate and GABA release from presynaptic terminals with actions at group 3 receptors (mGluR4, 6, and 7). This work was supported by grants from the Louisiana American Heart Association and NINDS.

## 266.19

SEVERE REDUCTION OF DEFENSIVE BEHAVIOR BY DISCRETE HYPOTHALAMIC CHEMICAL LESIONS. N.S. Canteras\*, S. Chiavegatto, L.E. Ribeiro do Valle and L.W. Swanson†. Dept. of Physiol. & Biophys., Inst. Biomed. Sci., Univ. of São Paulo, SP, 05508-900, Brazil. (†) Dept. of Biological Sciences, Univ. of Southern California, LA, CA, 90089-2520.

In the present study we first determined which hypothalamic regions display altered *Fos* levels when a rat is exposed to a natural predator. Five adult male Wistar rats were placed individually for 10 min. in a closed wire-meshed compartment inside a larger arena containing an adult male cat. One hour later rats were deeply anesthetized and perfused transcardially, and the brains prepared for immunohistochemistry in a standard way. All animals displayed species-specific defensive behavior, and a similar pattern of increased hypothalamic *Fos*-immunoreactivity. The most dramatic increase was localized to the dorsal preammylary nucleus (PMD), and major increases were also observed in the anterior perifornical region, anterior hypothalamic nucleus, and dorsomedial part of the ventromedial nucleus.

To examine a possible role of the PMd in defensive behavior expression, bilateral ibotenic acid lesions were then made, as well as control chemical lesions placed in regions adjacent to the PMd. For this, 10 adult male Wistar rats were exposed initially for 15 min. to an adult male cat (same protocol as for the *Fos* experiments), and their responses were videotaped for behavioral analysis. Several days later ibotenic acid lesions were made, and 10 days after lesion placement the rats were exposed again to a cat for 15 min. In contrast to the control group, bilateral PMd cytotoxic lesions (n=5) almost eliminated the incidence of escape responses (jump directed to the top of the test cage or vigorous running away from the predator) and freezing.

Notably, the *Fos*-responsive cell groups in the medial hypothalamus are interconnected in a distinct neural system, and the present results suggest that the PMd may act as a necessary "final common pathway" for hypothalamic influences on the expression of innate defensive behavior. Supp.FAPESP 93/0019-8.

## COMPARATIVE NEUROANATOMY: HIGHER VERTEBRATES

## 267.1

PROLACTIN (PRL) AND GROWTH HORMONE (GH) NEURONS FOUND WITHIN THE AVIAN FOREBRAIN AND DIENCEPHALON IN DIFFERENT REPRODUCTIVE STATES. R. Ramesh<sup>1</sup>, W.J. Kuenzel<sup>1\*</sup>, J.D. Buntin<sup>2</sup>, and J.A. Proudman<sup>3</sup>. <sup>1</sup>Dept. of Poultry Sci., Univ. of Maryland, College Park, MD 20742, <sup>2</sup>Dept. Biol. Sci., Univ. of Wisconsin, PO Box 413, Milwaukee, WI 53201, <sup>3</sup>USDA, ARS, GGPL, Beltsville, MD 20705.

Avian species, such as turkeys and ring doves, show clear broody behavior which ultimately results in the termination of egg laying and rapid onset of incubation behavior. In our investigations into the neuroendocrine mechanism responsible for the shift in behavior, we observed that specific antibodies for identifying pituitaries also revealed immunostained neurons. The study documents specific forebrain and diencephalic regions where nuclei were identified using antibodies to synthetic avian PRL and turkey GH. Growth hormone immunoreactive (ir) neurons were found in the hippocampus (Hp, turkey only), periventricular hypo. n. (PHN), paraventricular n. (PVN), medial ventromedial hypo. n. (VMN), inferior hypo. n. (IH) and infundibular hypo. n. (IN). Dense GH ir fibers were found in the external zone of the median eminence. Regarding PRL neurons, two reproductive states were analyzed: laying versus incubation states. Plasma prolactin levels for ring doves and turkey hens in the laying and incubation periods were, respectively: 0.27  $\pm$  0.36 and 3.73  $\pm$  0.41; 38.4  $\pm$  8.7 and 164.3  $\pm$  12.5. In the turkey hen, PRL neurons were found in the Hp, amygdala, bed n. of the pallidum commissure (nCPa), PHN, bed n. of the stria terminalis (nST), preammylary and lateral mamillary n., dorsal IN and lateral hypo. area. In the ring dove, PRL neurons were identified in the amygdala, septal area, nST and nCPa. A difference was found within the nCPa of both turkey and dove brains between the two reproductive states. In both species PRL neurons were weakly ir and less numerous in laying birds (n=4). Brains sampled from incubating birds (n=4) showed more numerous, darkly ir PRL neurons. Since the nCPa is the major site of gonadotropin-releasing hormones (GnRH) in avian brains, perhaps PRL-like neurons may directly interact (negatively) with GnRH neurons when birds become broody.

## 266.18

ELECTROPHYSIOLOGICAL EVIDENCE FOR LOCAL EXCITATORY INPUTS TO THE PARAVENTRICULAR NUCLEUS IN RAT HYPOTHALAMIC SLICES. C. Boudaba, K. Szabó and J.G. Tasker\*. Dept. of Cell & Molecular Biology, Tulane University, New Orleans, LA 70118.

Rhythmic bursting patterns in hypothalamic neurosecretory neurons often mediate the pulsatile release of hormones from the pituitary gland. In neurons of the paraventricular nucleus (PVN), patterned electrical activity may depend in part on local excitatory and inhibitory synaptic inputs to neurosecretory cells. A previous study showed evidence for local inhibitory inputs to PVN parvocellular and magnocellular neurons (Boudaba et al., Soc. Neurosci. Abstr. 21:1665, 1995). The aim of the present study was to determine whether PVN neurons receive local excitatory synaptic inputs. Excitatory postsynaptic potentials (EPSPs) were recorded in PVN neurons in coronal, horizontal and parasagittal slices (400-500  $\mu$ m) using conventional intracellular and patch-clamp recordings. Local neurons were selectively stimulated with glutamate microdrop application (20 mM). During recordings, cells were classified as magnocellular or parvocellular according to electrophysiological criteria (Tasker & Dudek, J. Physiol. 434:271, 1991), and were injected with biocytin (0.3-1%) for subsequent immunohistochemical identification with antibodies to neurophysin, oxytocin or vasopressin. In preliminary experiments, glutamate microdrops around the PVN in the three slice planes evoked EPSPs in 12 of 116 (10%) of the PVN neurons tested. Glutamate-evoked EPSPs were recorded in magnocellular as well as in parvocellular neurons. Zones responding to glutamate microstimulation were located in anterior, lateral and dorsomedial hypothalamic areas. Further studies are necessary to determine whether local excitatory inputs to PVN neurons are involved in the patterned electrical activity of these neurons and the pulsatile release of pituitary hormones. This study was supported by NIH NS31187, NSF IBN-9315308, and a grant from the LA Board of Regents.

## 266.20

A SEX DIFFERENCE IN NEURODEGENERATION OF THE HUMAN HYPOTHALAMUS C. Schultz, H. Braak and E. Braak (SPON: European Neuroscience Association), Zentrum der Morphologie, J. W. Goethe-Universität, D-60590 Frankfurt, Germany.

The human mediobasal hypothalamus (MBH) of 64 individuals (33 males and 31 females [mean age: 77 y. and 78 y.]) was examined for Alzheimer type cytoskeletal pathology. Coronal sections (100  $\mu$ m) were stained with the Gallyas silver technique for neurofibrillary pathology, the Campbell Switzer technique for amyloid deposits, and antibodies for abnormally phosphorylated tau protein (AT8, Alz-50) and paired helical filaments (PHF-1). A conspicuous pathology was identified in the MBH. It was characterized by axon-like varicose processes, contacting small vessels of the posterior median eminence and the adjacent infundibular (or arcuate) nucleus. This pathology was visualized by the Gallyas technique and by the antibodies AT8, Alz-50 and PHF-1. Alzheimer-type PHF were also present at the ultrastructural level. Remarkably, the cytoskeletal pathology of the MBH exhibited a striking sex-specific prevalence: while it was noted in 24 males (79%), it was identified in only 2 females (6%). Although this sex-specific hypothalamic pathology is demonstrated by techniques which label Alzheimer type cytoskeletal pathology, it also affects non-demented elderly males, devoid of Alzheimer-related neocortical pathology. The MBH pathology thus appears to develop independently of Alzheimer's disease. The cytoskeletal lesions of the male MBH may lead to an impairment of the parvocellular neurosecretory system. Such a decline has been previously suggested for the hypothalamic stimulation of gonadotropin secretion in elderly men.

This study was supported by the Deutsche Forschungsgemeinschaft.

## 267.2

COMPARATIVE LOCALIZATION OF NITRIC OXIDE SYNTHASE AND TYROSINE HYDROXYLASE IN THE BRAIN OF THE CHICKEN. G. Brünig\*, Dept. of Anatomy, Free University, D-14195 Berlin, Germany

Nitric oxide synthase is known to be expressed in a subpopulation of neurons in the brain of avian species. The distribution pattern reveals remarkable similarities to that of dopaminergic and noradrenergic neurons. Catecholamine- and nitric oxide-synthesizing neurons were detected by double-labeling immunofluorescence microscopy. In addition, nitric oxide synthase was detected by NADPH diaphorase histochemistry.

Tyrosine hydroxylase- and nitric oxide synthase-positive neurons were coextensive in medial thalamic nuclei, mamillary nuclei, area ventralis of Tsai (AVT), substantia grisea centralis (GCT), nucleus tegmenti pedunculopontinus (TPc), locus coeruleus and subcoeruleus. Only a minority of neurons in the AVT, GCT and TPc stained for both enzymes. Nitric oxide synthase-positive neurons did not appear to be a preferred target of catecholaminergic fibers in any part of the brain.

The present results indicate that nitroergic and catecholaminergic neurons are coextensive but represent mostly separate populations of cells. Nitric oxide may function as an intercellular messenger between dopaminergic and noradrenergic neurons, and other as yet chemically ill-defined neuron populations.

## 267.3

**DISTRIBUTION OF NEUROTRANSMITTERS, RELATED ENZYMES, AND NEUROPEPTIDES WITHIN THE PIGEON CAUDOLATERAL NEOSTRIATUM** L.V. Ritters\*, J.T. Erichsen, J.R. Krebs, V.P. Bingman. Dept. of Psychology, Bowling Green State Univ., Bowling Green, OH 43403; Dept. of Optometry & Vision Sci., Univ. Wales, Cardiff, P.O. Box 905, Cardiff CF 1 3XF, Wales UK; Edward Grey Institute of Field Ornithology, Dept. of Zoology, Oxford OX1 3PS, England.

The caudolateral neostriatum (NCL) has recently been implicated in homing pigeon navigation. Additionally, NCL has been considered a possible homologue to mammalian prefrontal cortex (PFC). Although, NCL has been found to receive dense dopaminergic innervation, little is known about the distribution of other neuroactive substances within this region. The present study was performed to elaborate upon the current understanding of NCL neurochemistry, and to further investigate possible NCL/PFC similarity. The distribution of three neuroactive substances (tyrosine hydroxylase (TH), choline acetyltransferase (ChAT), and serotonin (5HT)) and five neuropeptides (cholecystokinin (CCK), leucine enkephalin (LENK), substance P (SP), vasoactive intestinal polypeptide (VIP), and somatostatin (SS)) was investigated using immunocytochemistry. All substances investigated were found within NCL. TH immunoreactive fibers were found to coil around unlabeled parikarya within NCL. Within TH rich regions of NCL, sparsely distributed smooth ChAT fibers were observed. Sparse fiber and terminal-like 5HT labeling was also concentrated in regions lining the lateral ventricle. CCK terminal-like labeling and sparsely distributed LENK fibers also appeared dense along the ventricle. SS labeled cells were observed throughout NCL. The distribution of labeled VIP fibers was found concentrated in more caudal regions of NCL, while the densest SP labeling was confined to the dorsal half of NCL suggesting regional subdivisions within NCL. Results suggest that the distribution of TH, ChAT, and 5HT within NCL is similar to that observed in rodent PFC.

## 267.5

**IMMUNOHISTOCHEMICAL CHARACTERIZATION OF THE STRIATAL INPUT TO NEURONS OF THE DORSAL PALLIDUM IN PIGEON, WITH PARTICULAR EMPHASIS ON PALLIDO-THALAMIC NEURONS.** L. Medina\* and A. Reiner. Dept. Anat. and Neurobiol., College of Medicine, The University of Tennessee, Memphis, TN 38163.

The dorsal pallidum possesses many similar features in birds and mammals. In both vertebrate groups, the principal neuronal type of the dorsal pallidum is a large, fusiform neuron that co-contains GABA, parvalbumin (PV), and the neuropeptide LANT6. Further, in both vertebrate groups the dorsal pallidum receives input from substance-containing (SP+) and enkephalin-containing (ENK+) neurons of the striatum and, in turn, projects to the thalamus and the substantia nigra. In mammals, the dorsal pallidum is subdivided into two segments: a lateral segment receiving mainly ENK+ striatal input, and a medial segment receiving mainly SP+ striatal input. The dorsal pallidum of birds is not subdivided into segments, although the ENK+ and SP+ striatal inputs seem segregated onto separate sets of pallidal neurons. In the present study, we have investigated the pallidal targets of the ENK+ and SP+ striatal input in pigeons, by way of double-label immunofluorescence experiments in the dorsal pallidum to label ENK+ or SP+ fibers of striatal origin and either: (1) PV+ pallidal neurons; or (2) pallido-thalamic projection neurons after injecting a retrograde tracer in the pigeon thalamus. Our results indicate that the perikaryon and proximal dendrites of 54% and 46% of PV+ pallidal neurons, respectively, are covered by either SP+ striatal fibers or ENK+ striatal fibers. About 45% of pallidothalamic neurons are covered by ENK+ striatal fibers, whereas 20% of them are covered by SP+ striatal fibers. The results suggest the existence of separate striato-pallidothalamic pathways in pigeons, adding a new similarity between avian and mammalian basal ganglia. Supported by NS-19620 (A.R.), NS-28721 (A.R.), and NIH Shared Instrumentation Grant PHS-RR08385 (to Dr. Andrea Elberger).

## 267.7

**OBSERVATIONS ON THE THALAMUS OF THE BOTTLENOSE DOLPHIN (*TURSIOPS TRUNCATUS*).** P. Manger, M. D. Szymanski, M. Sum, M. Sutter\*, & L. Krubitzer. Center for Neuroscience and Department of Psychology, University of California, Davis, Davis CA 95616, U.S.A.

Brains of three dolphins were obtained post-mortem and fixed by immersion in 10% formaldehyde for periods of up to 2 years. The thalamus of one of these animals was dissected and sectioned coronally into 50 µm sections, and stained for Nissl and myelin. Detailed analysis indicates that the overall morphology and nuclear subdivisions of the thalamus are similar to other mammals. However, the relative size and detailed architecture of some nuclei differ dramatically. The subdivisions of the ventrobasal nuclear group, including VPM, VPI, and VPII can be clearly defined, and compartmentalization of the VPM nucleus, similar to that reported previously for monkeys, is evident. This may correlate with the dolphin's frequent use of the rostrum in tactile exploratory behaviors, and also with the use of the intricate nasal sac system of the blowhole for sound production. Although the packing density of neurons in VPI is somewhat reduced, this nucleus is large, and is likely to receive inputs necessary for the sensory control of the skin muscles, which may be used to optimize hydrodynamic flow over the surface of the body. Unlike many other mammals, the lateral geniculate nucleus is not laminated. The lack of distinct layers in the LGN is not surprising given the limited penetration of light through the water, and the poor visual acuity of dolphins. Nucleus ellipticus is not found in other mammals, but in the dolphin is extraordinary in both size and appearance. We propose that this nucleus may be related to echolocation abilities described in dolphins. The medial geniculate complex is greatly expanded, particularly the dorsal nucleus. Similar expansions have been observed in other echolocating mammals such as microchiropteran bats. Finally, a large interthalamic fiber tract connecting the two sides of the thalamus extends from the level of the pulvinar to the level of the ventrobasal nuclei. This tract may play a crucial role in subcortical transfer of interhemispheric information, and may compensate for the significantly reduced corpus callosum in these mammals.

## 267.4

**AGE-RELATED CHANGES IN CELL PROLIFERATION IN HOMING PIGEONS.** V. Simon, R. Strasser, V. Bingman, and D.A. Holtzman\*

Neuroscience Program, Oberlin College, Oberlin, OH 44074, & \*Department of Psychology, Bowling Green State University, Bowling Green, OH 43403.

Relatively few studies have examined whether postnatal neurogenesis changes as a function of age. Two-week old, four-week old, and adult pigeons (n=3, for each group) were injected with the thymidine analog, 5-bromo-3-deoxyuridine (BrdU), and sacrificed 1-2 hours later. Brains were fixed with 4% paraformaldehyde, sectioned at 10 µm, and immunostained for BrdU. The ventricular layer was divided into twelve regions corresponding to adjacent brain structures, and the total number of labeled cells/square mm (cell density) was determined for each region. For two- and four-week old birds, a significant difference was found in the distribution of proliferating cells across ventricular regions (p<0.05). In these birds, regions adjacent to the parolfactory lobe (LPO), nucleus accumbens/bed nucleus of stria terminalis (NA/BNST), dorsal hyperstriatum (HD) and paleostriatum (PA) showed higher levels of cell proliferation compared to other ventricular regions. Cell density varied as a function of age in the ventricular regions adjacent to the LPO, NA/BNST, accessory hyperstriatum, neostriatum, ventral hyperstriatum, septum, hippocampus, and dorsolateral cortex, with two-week old birds exhibiting the highest labeled cell densities (p<0.05 for all structures). No age-related differences were observed in the ventricular regions adjacent to HD, PA, archistriatum, and pyriform cortex. Regions with highest cell proliferation in the homing pigeon correspond to high proliferation zones seen in other vertebrate taxa. Preliminary data for Hu protein expression, an early neuronal marker, has revealed many labeled cells along the ventricles of young birds. This suggests that many neurons are produced within the first four weeks of postnatal life. Further, double BrdU/Hu-labeled cells have been found within the brain parenchyma in short survival animals. We are currently quantifying these data. Supported by NCR grant RR08700 to DAH & NIMH grant MH52315 to VB.

**ANATOMICAL COMPARISONS BETWEEN NEURAL PATHWAYS IN THE BUDGERIGAR AND NEURAL PATHWAYS MODULATING ACOUSTIC STARTLE IN MAMMALS.** K. J. Heaton\* & K. K. Cookson. UMCP, College Park, MD, 20742.

The modulation of acoustic startle in mammals depends on a complex set of modulatory pathways that include the hippocampus, amygdala, hypothalamus, midbrain central gray, parabrachial region, and pontine reticular region. The present investigation describes pathways tracing studies that reveal several similar pathways in a species of parrot, the budgerigar (*Melopsittacus undulatus*). For example: (1) the medial archistriatum receives input from the auditory neostriatum and from the parabrachial region, (2) the archistriatum projects directly to the caudal pontine reticular region and projects to the intercollicular midbrain, which in turn projects to the caudal pontine reticular region, and (3) the hippocampus and the medial hypothalamus share afferent and efferent projections with the medial and ventral archistriatum. Furthermore, the modulation of acoustic startle in mammals is related to cholinergic activity in the hippocampus and the caudal pontine reticular region and to dopaminergic activity in the hypothalamus. Immunohistochemical staining for choline acetyltransferase (ChAT) and tyrosine hydroxylase (TH) in the budgerigar shows ChAT-labeled fibers in the hippocampus and pontine reticular region and TH-labeled fibers and somata in the medial hypothalamus. However, despite general similarities in connections and histochemistry, the detailed subregional organization of nuclei in these pathways differs in budgerigars and mammals. Developing an avian model of acoustic startle for comparison with mammals may provide insights into the structure-function relationships of these pathways. Supported by NIH grant MH40698 to S.E.B. and Whitehall grant J91-17 to W.S.H.

## 267.8

**CO-LOCALIZATION OF GALANIN AND TYROSINE HYDROXYLASE IN PURKINJE NEURONS OF THE RAT BUT NOT OF THE MOUSE.** A.E. Kresse\*, D.M. Jacobowitz and G. Skofitsch. Histopharmacology Unit, Dept. Zool., KFU, A-8010 Graz, AUSTRIA, and Lab. of Clin. Sci., NIMH, Bethesda, MD 20892, U.S.A.

Galanin (GAL) is a widely distributed 29 amino acid long neuropeptide with multiple biological effects in a variety of different subsystems of the central nervous system. We previously reported detailed mappings of the localization of GAL-like immunoreactivity (GAL-LI) and mRNA (Skofitsch and Jacobowitz, 1985, 1990). The coexistence of GAL and tyrosine hydroxylase (TH), the indicator enzyme for catecholaminergic neurons, has been shown before for several regions of the brain (Melandier et al., 1986; Sutin and Jacobowitz, 1991). In the present study, however, we demonstrate to our knowledge for the first time the localization of GAL mRNA in Purkinje neurons of distinct regions of the cerebellar cortex of the rat. *In situ* hybridization (ISH) was done using two different radio-labeled synthetic oligonucleotide probes complementary to the nucleotides 152-199 of rat, and to the nucleotides 115-153 of porcine GAL mRNA, respectively. We were able to localize GAL mRNA in male Sprague Dawley rats, however not in C57Bl/6J mice, in Purkinje cells of the flocculus, paraflocculus, the paramedian lobe, and the crus 1 of the ansiform lobe, as well as throughout the lobuli of the vermis and to a lesser extent in the crus2 of the ansiform lobe. Based on the nearly complete match of this distribution pattern with reports of the localization of TH immunoreactivity in the rat and mouse cerebellum, we were able to demonstrate the co-localization of GAL and TH in rat Purkinje cells using ISH for localizing TH and GAL mRNA on adjacent sections and the immunocytochemistry for TH in sections that were subsequently hybridized for the detection of GAL mRNA. Although Purkinje neurons are considered to be GABAergic, the presence of TH in a subpopulation of these cells has so far been shown in the mouse, human and rat. However, the specific biological function of the TH and GAL expression in Purkinje neurons still remains to be elucidated.

Supported by the Austrian Scientific Research Fund, grant number P7050M.

## 267.9

CONSTRUCTION OF A 42 MICRON 3D RAT BRAIN ATLAS FROM NISSL STAINED SECTIONAL MATERIAL. J. Nissanov<sup>1\*</sup>, D. Kozinska<sup>2</sup>, C. Gustafson<sup>2</sup> and O. Tretiak<sup>1,2</sup>. <sup>1</sup>Biomed. Eng. & Sci. Inst., <sup>2</sup>Elec. Comp. Eng., Drexel Univ., Philadelphia, PA 19104

The utility of brain atlases is undergoing substantial change from passive guides to active tools for automatic segmentation of neuroanatomical regions and as standard reference sets for multianimal, multimodality fusion of experimental data. In this new role, the need for 3D atlases has become acute. We report on a 3D atlas of intermediate, 42 micron, isotropic resolution. The brain is of a male Sprague-Dawley rat weighing 304g. No fixative was utilized and the fresh brain was rapidly frozen in dry ice cooled isopentane. The tissue was cut on a Leica Polycut cryostat equipped with a blockface imaging system and the sections stained with cresyl violet. Each section was aligned to its corresponding blockface image using rigid body 2D distance-based alignment. This iterative algorithm searches for the transformation which minimizes the distance between the section contour and the outline of the tissue on the blockface. Navigation through this 66MB 3D dataset is possible using Macintosh-based software from the Computer Vision Center for Vertebrate Brain Mapping, a NIH Biomedical Technology Resource located at Drexel University. The software permits rapid resampling through the data along any arbitrary plane of view. The atlas can be used to store and exchange regions of interest with BRAIN, the autoradiographic analysis program from this NIH resource. (Supported by NIH P41RR01638).

## 267.11

A THREE DIMENSIONAL MULTI-MODALITY BRAIN MAP OF THE NEMESTRINA MONKEY A.W. Toga<sup>\*</sup> and A.F. Cannestra Lab. of Neuro Imaging, Division of Brain Mapping, Department of Neurology, UCLA School of Medicine, Los Angeles, CA 90095

A three dimensional multi-modality computerized map of the nemestrina monkey brain was created with serial sectioning and digital imaging techniques. An adult female Macaca nemestrina weighing 7.2 kg was used in constructing this atlas. CT, PET, and MRI were performed on the monkey before the specimen's head was frozen and cryoplaned. Closely spaced (50 mm) of the specimen blockface images were then digitally acquired and modified to produce whole head and brain only 3D image sets. The resulting data sets were organized into a digital volume and repositioned into a stereotaxic coordinate system defined by Horsley and Clark (1908). From the rotated data sets, orthogonal images were obtained by digitally resampling the volume in order to produce a full set of coronal, sagittal, and horizontal images. Stereotaxic reference grids were applied to each image indicating the A/P, M/L, or H<sub>x</sub> (depending on orientation of cut) position within the digital volume. The amygdala, bony skull, cornea, eyes, fornix, hippocampus, internal capsule, lateral geniculate, optic nerve, optic radiations, orbit, pons, putamen, septum, substantia nigra, superior colliculus, and ventricles were outlined from the cryosection data set and 3D surface models reconstructed. Structural labels indicating nuclei, tracts, and other neuroanatomical features were incorporated into coronally sliced cryosection images spaced at 500 mm. The CT and MRI data sets were reconstructed into a digital volume and co-registered to the cryosection volume in the Horsley-Clark reference space. CT and MRI co-registration was performed by landmark matching and fiducials. The PET data volume was co-registered to the cryosectioned volume by using a ratio method. All images constructed from this 3D map are available via the Internet using an anonymous file transfer protocol (FTP) and the World Wide Web ([www.loni.ucla.edu](http://www.loni.ucla.edu)). The foremost advantage of this digital map is an integrated multimodality three dimensional representation which is not possible with traditional atlases. Funding was provided by the Human Brain Project MH/DA52176.

## 267.13

TALAIRACH DAEMON: AUTOMATED MAPPING OF SURFACE ANATOMY ONTO STANDARDIZED COORDINATES. C. S. Freitas, J. L. Summerlin, J. L. Lancaster, P. T. Fox \*. Research Imaging Center, University of Texas Health Science Center at San Antonio, San Antonio, TX 78284-6420.

Standardized, 3D coordinates (Talairach & Tournoux, 1988) are used with steadily increasing frequency for analyzing and reporting human neuroimaging research. While 3D coordinates are precise, quantitative descriptions of locations (and location variances), more traditional (but less quantitative) anatomical descriptions, such as surface anatomy (sulci/gyri) and architectonic areas, are needed to allow comparisons between coordinate-based data and those not using standardized coordinates. The T&T (1988) atlas does include Brodmann area (BA) labels, but lacks explicit boundaries between BAs and has many inconsistencies and errors. Consequently, mapping of BAs to standardized coordinates is labor intensive and notoriously inconsistent. For this reason, we have created an electronic tool that uniquely maps BAs and surface-anatomical terms to standardized coordinates.

The T&T (1988) atlas was digitized and manually traced (*Alice*, HP/IG) into a quasi-hierarchy of anatomical regions. Hemispheres, lobes, lobules, gyri and nuclei were outlined and labeled. Gray matter, white matter and CSF were also segmented. For cerebral cortex, all BAs were traced as 3D volumes. BA segmentation was based upon the T&T (1988) labels, but with numerous enhancements. All modifications were rule-based and justified by primary publications of Brodmann and others.

The anatomical regions thus defined were entered into a database served by a UNIX Daemon: Talairach Daemon (TD). TD is a multi-threaded, memory-resident, application running on a Sun Sparcstation 20 optimized for high-speed random access by coordinates. TD currently retrieves BA, gyrus, lobe and hemisphere. TD can be accessed from remote applications using TCP/IP sockets. Initial client programs include a Java applet for rapid Internet access. Future access is planned for the BrainMap™ database and for software packages that analyze and display human brain images (e.g., SN and SPM). TD will improve the accuracy and consistency with which coordinate-based studies make reference to traditional anatomical nomenclature. TD's electronic format facilitates emendation. (Funded by P20DA52176-01)

## 267.10

MAPPING THE MIDSAGITTAL CORPUS CALLOSUM IN THE RAT: TOPOGRAPHICAL CORRESPONDENCE OF CALLOSAL REGIONS WITH CORTICAL SUBDIVISIONS.

M. Noonan<sup>\*</sup>, M.A. Sanfilippo, D.J. Chmielec, Jr., M.A. Smith. Canisius College, Buffalo, New York 14208.

The location in the midsagittal plane of fibers within the corpus callosum of the rat are mapped in correspondence with cortical region. Results are reported from both HRP and silver-staining following localized cortical treatments.

A detailed map is presented delineating the callosal regions corresponding to each Zilles subdivision. Fibers corresponding to most cortical areas are segregated and distinctly bundled in their passage through the callosum at the midline. However, the fibers of some subdivisions overlap and intermingle extensively. In general, there is an anterior-posterior correspondence relating cortical area and callosal locale. Additionally, there is a tendency for fibers associated with medially-located cortical regions to cross in dorsal layers of the callosum and more laterally-located regions to cross in ventral layers. The genu of the callosum consists of fibers corresponding to medial prefrontal cortex (e.g., DPC, IL, MO, VO, Cg3), the trunk includes fibers corresponding to frontal and parietal cortex (e.g., FR1&2 and PAR1&2), and the splenium consists largely of occipital and retrosplenial fibers (e.g., OC2L, RSA, RSC).

The results are expected to guide future callosotomy studies in which only selected regions of the cortex are disconnected.

Supported by NSF: RUT-9209551.

## 267.12

COMPUTATIONAL NEUROANATOMY OF THE HUMAN INFERIOR PARS OPERCULARIS. Z. Caramanos<sup>\*</sup>, G. Posner, F. Tomaiuolo, D. MacDonald, A.C. Evans and M. Petrides. Montreal Neurological Inst., McGill Univ., Montreal, Canada, H3A 2B4.

Volumetric analysis of the inferior portion of the pars opercularis (IPO) was carried out on high-resolution MRIs obtained from 54 healthy volunteers (20 females, 34 males; mean age (sd): 25.5(8.2) yrs). MRIs were acquired on a 1.5 T magnet as datasets of 160 contiguous T<sub>1</sub>-weighted, 1-mm thick, sagittal slices and transformed into a standardised stereotaxic space (Talairach & Tournoux, 1988). A single investigator, blind to side, used an automatic segmentation technique to identify grey and white matter in the left and right IPO. Grey matter included tissue caudal to the ascending ramus, rostral to the precentral sulcus; dorsal to the sylvian fissure (SF), and ventral to the first protuberance encountered dorsal to the SF. White matter included tissue completely encompassed by IPO grey matter. Thus defined, we could consistently identify a region containing part of Broca's Area and Brodmann's area 44. The presence of the diagonal sulcus (dS) and its effects on IPO volume were also examined.

Repeated measures and *post hoc* analyses of variance examining the effects of SEX, SIDE and TISSUE TYPE on IPO volume found: (i) a large main effect ( $p < .001$ ) of TISSUE TYPE [Grey Matter > White Matter: mean volume (sd) was 6.2(1.4) vs. 2.2(0.7) cc]; (ii) a small interaction ( $p = .003$ ) of SEX by TISSUE TYPE (Female Grey > Male Grey,  $p = .04$ : 6.7(1.6) vs. 5.9(1.3) cc]; and (iii) a small interaction ( $p = .03$ ) of SIDE by TISSUE TYPE [Left White > Right White,  $p = .04$ : 1.2(0.5) vs. 1.0(0.4) cc]. No main effect of SEX or SIDE, or 3-way interaction was found ( $p > .05$ ). The dS was found bilaterally in 14 brains, only on the left in 11, only on the right in 12, and was not present in 17. No interaction of SEX with location or number of dS was found ( $\chi^2$ ,  $p > .05$ ). No interaction of dS NUMBER with SEX, with TISSUE, or with SIDE was found on IPO volume ( $p > .05$ ), but there was a main effect ( $p < .001$ ) of dS NUMBER on total IPO volume [(1 dS = 2 dS) > 0 dS,  $p < .009$ : 8.7(1.7) vs. 9.5(1.7) vs. 7.0(1.8) cc].

In addition to characterising IPO grey and white matter in the normal adult human brain, probabilistic maps of the IPO were created by averaging individual IPO volumes across these 54 brains. Such maps can, for example, be used to localise functional imaging activation peaks in this area with greater certainty than was previously possible.

## 267.14

BRAIN VOLUME AND ITS COMPONENTS IN LIVING APES AND HUMANS. K. Semendeferi<sup>\*</sup>, J. Rilling<sup>2</sup>, T.R. Insel<sup>1</sup> and H. Damasio<sup>1</sup>.

Department of Neurology<sup>1</sup>, University of Iowa, IA 52245, Department of Anthropology<sup>2</sup>, Emory University, Yerkes Regional Primate Research Center<sup>3</sup>.

Here we report preliminary results of an ongoing collaborative effort to use novel neuroimaging techniques for the comparative analysis of the living human and ape brains (bonobo, chimpanzee, orangutan, gibbon, as well as the macaque). Thin, contiguous MR images of the brains were obtained. These were reconstructed in 3D using Brainvox. Volume of the whole brains and some of their major components were estimated.

The two hemispheres were separated and major sulci were identified across species. The volume of the hemispheres, of the cortex and immediately underlying white matter (the white matter core of the gyri), of the frontal lobe and of the temporal lobe were calculated.

The relative size of the cortex and immediately underlying white matter of the hemisphere in relation to the whole brain is 80% in the human, 77.6% in the bonobo, 75.3% in the chimpanzee, 78% in the orangutan, 77.6% in the gibbon, and 82.2% in the macaque. The relative size of the temporal lobe is 18.8% in the human, 18.9% in the bonobo and 15.4% in the chimpanzee. The relative size of the frontal lobe is similar in the human, bonobo and chimpanzee (38.9 %, 38.3 %, and 35.5% respectively).

Supported by NIH NINDS PO1 NS19632 and P51-RR00165.

## 268.1

**Neuroanatomic substrate of the distinction between real and imagined voices.** H. Szechtman\*, K. Bowers, E. Woody, R. Chirakal, G. Firsirotu, M. Thompson, E.S. Garrett and C. Nahmias. Depts of Biomedical Sciences and Nuclear Medicine, McMaster Univ, Hamilton, Ontario, L8N 3Z5, and \*Dept of Psychology, Univ of Waterloo, Waterloo, Ontario, CANADA

Hallucinations, which are imagined voices that are perceived as coming from the external world, raise the question of how the brain "discriminate(s) between imagined events and events in the real world" (Bentall, *Psychol Bulletin*, 107:82-95, 1990). Here we examined brain activity (regional cerebral blood flow, rCBF, measured with  $H_2^{15}O$  and PET) during 4 separate conditions: at rest and while the subjects were hearing, imagining, and hallucinating voices. The entire procedure was carried out under hypnosis using highly hypnotizable subjects. Analysis using Statistical Parametric Mapping (Friston et al, *JCBFM*, 11:690, 1990) revealed a circumscribed region in the anterior cingulate that was more active during hearing and hallucinating voices than during imagining voices. Thus, this site may tag imaginal events as originating in the external world versus being self-generated. If so, hallucinations may arise from a malfunction of the cingulate.

(HS is a Research Associate of the OMHF. Supported by Ontario Mental Health Foundation).

## 268.3

**PET EVALUATION OF COGNITIVELY RELATED NEUROPHYSIOLOGICAL SEQUELAE ACCOMPANYING INCIDENTAL FINDINGS OF MICROVASCULAR ISCHEMIC DISEASE IN THE ELDERLY: PRELIMINARY RESULTS.** G. Esposito\*, B.S. Kirkby, J.D. Van Horn, D.R. Weinberger, K.F. Berman. Unit on PET, CBDB/NIMH/NIH, Bethesda, MD, 20892.

In the elderly, MRI evidence of microvascular ischemic disease (MID) has been associated with more pronounced decline in some cognitive abilities. PET studies have suggested that the presence of risk factors for cerebrovascular disease may be associated with greater reduction of regional brain activity with age. To investigate whether cognitive abilities and brain activity during working memory changed in the presence of asymptomatic MID, we used the oxygen-15 water PET method (approximately 42 mCi/scan) with measured arterial input to calculate absolute CBF (ml/100g/min) in three subjects (2W, 1M; mean age 73) in whom the diagnosis of MID was made solely on the basis of incidental findings on MRI scans and in the absence of clinical findings or complaints. The MID patients were compared to eight well-screened controls (2F, 8M; mean age 70) during performance of the Wisconsin Card Sort (WCS) as well as during a sensorimotor control task (WCSc). White matter changes were rated by a neuroradiologist as mild/moderate in subjects 1 and 2 and marked in subject 3. Images were stereotactically normalized and smoothed (20,20,12 mm in the x,y and z dimensions) using the SPM95 package. rCBF data of each of the three MID were compared to those of the controls with Z-statistics (significance threshold  $p < 0.01$ ). Cognitive performance for each MID subject was above the mean for the control group. During both the WCS and the WCSc, we found no significant reductions in absolute global CBF in any of the MID subjects. Higher rCBF was found in some cortical regions adjacent to areas of white matter MRI hyperintensities: in prefrontal and temporal cortex in subject 1, in temporal cortex in subject 2, and in prefrontal cortex in subject 3. rCBF activation (WCS minus WCSc), however, did not differ between any of the MID subjects and the control group. The results in this small cohort suggest that WCS performance and rCBF activation may be unaltered in asymptomatic subjects with MRI-diagnosed MID. Further studies in larger patient populations will be necessary to confirm these preliminary results.

## 268.5

**CEREBRAL METABOLIC EFFECTS OF TRIIODOTHYRONINE IN ADULTS WITH RESISTANCE TO THYROID HORMONE.** J. A. Matochik\*, P. Hauser, A. J. Zametkin, B. D. Weintraub and R. M. Cohen. Lab. of Cerebral Metabolism, NIMH, and Molecular and Cellular Endocrinology Branch, NIDDK, Bethesda, MD 20892.

Resistance to thyroid hormone (RTH) is caused by mutations in the hormone-binding domain of the hTRB gene encoding the thyroid hormone receptor- $\beta$ . The most prominent behavioral manifestation of RTH is deficits in attention. To evaluate the hypothesis that triiodothyronine ( $T_3$ ), the active form of thyroid hormone which has sympathomimetic action, may ameliorate the functional abnormalities of RTH, seven adults (4 females, 3 males) received two PET scans to measure cerebral glucose metabolism during the performance of a sustained attention task, one scan while on  $T_3$  treatment and the second scan off hormone treatment for at least four weeks. There was no significant change in either global or regional glucose metabolism between the two PET scans. Performance on the attention task was also unaffected by hormone treatment, with the scores on this task being considerably below normal performance levels in both conditions in RTH subjects. Subjects with RTH in the present study had higher metabolic values in the anterior cingulate (on both PET scans) than we have previously observed in unaffected subjects successfully performing our attention task. Despite the relatively low statistical power of the present study,  $T_3$  does not appear to have a robust effect on cerebral metabolism or attention.

Supported by the NIH Intramural Research Program.

## 268.2

**A POSITRON EMISSION TOMOGRAPHY STUDY OF TRANSIENT SLEEP REDUCTION, LIMBIC ACTIVITY AND ATTENTIONAL CONTROL.** R. Mahurin, M. Liotti\*, H. Mayberg, F. Zamarrripa, S. McGinnis, and P. Fox. Research Imaging Center, University of Texas Health Science Center, 7703 Floyd Curl Dr., San Antonio, TX 78284.

We examined the relationship between resting-state  $^{15}O$ -positron emission tomography (PET) regional cerebral blood flow (rCBF), transient sleep reduction, emotional state, and attentional performance in normal subjects. Degree of sleep reduction was calculated by subtracting hours slept on the night preceding the PET scan from self-reported typical hours of sleep. Regression analysis revealed significant positive correlations between reduced sleep and rCBF in paralimbic cortical and limbic subcortical regions, including striatum, anterior cingulate, and mesial-frontal/temporal areas. In contrast, significant negative correlations were found between sleep reduction and rCBF in widespread neocortical regions, including dorsolateral frontal, parietal, occipital, and superior temporal. Sleep reduction was associated with dysphoria, anxiety, and irritability as well as increased false alarms on a continuous response attentional test. In summary, transient sleep reduction appears associated with relative increases in resting-state subcortical-limbic brain activity, decreases in resting-state neocortical activity, release of dysphoric emotions, and impaired response control. The data suggest that sleep reduction disrupts and reverts the normal balance between tonic neocortical inhibitory mechanisms and subcortical limbic influences. (Supported by EJLB Foundation and PHS Grant #P20-MH52176)

## 268.4

**FRONTAL AND PARIETAL BLOOD FLOW ACTIVATION DURING AN AUDITORY TASK DIFFERENTIATE SCHIZOPHRENIC PATIENTS WITH AND WITHOUT PRIMARY NEGATIVE SYMPTOMS** W.T. Carpenter\*, A.C. Lahti, H.H. Holcomb, M. Zhao, R.W. Buchanan, C.A. Tamminga. MPRC, University of Maryland School of Medicine, Baltimore, MD 21228.

We previously reported that schizophrenic patients with deficit symptoms (primary negative symptoms) were distinguished from nondeficit patients and normals in a PET/FGD study by reduced metabolism in thalamus and in frontal and parietal cortex (Tamminga, 1992). We now report  $H_2^{15}O$ /PET data on prospectively identified schizophrenic patients with (n=6) and without (n=8) deficit symptoms and normal controls (n=12). PET scans were obtained while patients were neuroleptic-free. During the scan, subjects performed a tone frequency recognition task. This is a graded error related task, where percent accuracy is fixed between groups (80±5%). Four rest, sensory motor control and tone recognition task scans were obtained from each subject. Statistical Parametric Maps (SPM 95) were created to contrast rCBF activity patterns between groups. Deficit schizophrenics showed significant increased activation in superior frontal cortex and reduced activation in right prefrontal cortex compared to normals, while the nondeficit patients showed significant reduced activation of the occipital cortex compared to normals. When deficit and nondeficit schizophrenics were contrasted, the deficit patients showed significant reduced activation in bilateral parietal cortex ( $R = 0.002$ ,  $L = 0.023$ ) and right middle frontal cortex ( $p = 0.003$ ) compared to the nondeficit schizophrenics. These data suggest that deficit schizophrenics, in spite of performing the task with similar accuracy, appear to have different "dynamic rules" compared to normals and nondeficit patients.

## 268.6

**A FEASIBILITY STUDY OF THE SAFETY AND EFFICACY OF ALBUMIN MICROBUBBLES IN TRANSCRANIAL DOPPLER.** R.E. Stoll\*, S.M. Otis, B.W. Chopko. Scripps Clinic And Research Institute, La Jolla, CA, 92037.

Transcranial color and spectral Doppler ultrasonography (TCD) is a dynamic, non-invasive method of examining the intracranial circulation in patients with known or suspected cerebrovascular disease. However, in some patients the clinical utility of TCD examinations is limited by poor tissue penetration and inadequate imaging of vessels, which has driven the search for agents to enhance visualization of the intracranial vasculature. Albumin microbubbles (AM) in the form of Albunex, a commercially available ultrasound contrast agent, is a sterile, nonpyrogenic solution of echogenic microspheres produced by sonication of 5% human albumin aqueous solution. The microspheres reflect ultrasound waves, leading to enhanced signal intensity. We examined the safety and efficacy of AM in TCD in an open-label feasibility study of 10 adult patients. A baseline (noncontrast) TCD examination was conducted just prior to an AM-enhanced study, hence each patient served as his or her own control. AM was administered intravenously in 10 to 30 cc boluses and concurrent TCD was performed. No adverse effects were observed. Three of ten patients showed minimal improvement over the baseline TCD in ability to visualize intracranial vasculature. These three patients had significantly lower systolic blood pressures than those who showed no evidence of improvement. AM have been proven to pass the pulmonary circulation and appear in the left ventricle. We hypothesize that AM may not survive the left ventricular systolic shear forces intact in order to pass into the cranial circulation in sufficient quantity to provide echogenic foci for ultrasound studies. Further studies are indicated to determine the viability of AM in passage through the heart, great vessels, and into the cerebral circulation. Funded by Mallinckrodt Medical.

## 268.7

HEPARAN SULFATE AND HEPARIN ATTENUATE REGIONAL CEREBRAL BLOOD FLOW (rCBF) INCREASE IN EXPERIMENTAL BACTERIAL MENINGITIS? J. R. Weber, K. Angstwurm, D. Freyer, M. Weish, C. Busch, W. Bürger, and U. Dirnagl Depts. of Neurology and Microbiology\*, Charité, D-10098 Berlin, Germany.

Recent reports point to antiinflammatory effects of substances which inhibit selectin mediated leukocyte rolling. Heparan sulfate (HS) and Heparin bind to P- and L-selectin and inhibits acute inflammation. We tested the hypothesis whether HS and heparin have an effect in experimental bacterial meningitis on rCBF.

**Materials and methods:** Male wistar rats were anesthetized and mechanically ventilated. Meningitis was induced by intracisternal injection (i.c.) of pneumococcal cell wall components (PCW). rCBF was measured continuously over 6 hours with laser Doppler flowmetry. pCO<sub>2</sub>, PO<sub>2</sub>, and pH were measured every 2 hours and mean arterial blood pressure were monitored continuously during the experiment.

LDF % / group	0h	3h	6h	WBC/CSF
controls (NaCl i.c., n=6)	100	103 ± 7	114 ± 11*	7 ± 4*
PCW i.c. (n=6)	100	169 ± 29	234 ± 37	2598 ± 871
PCW + Heparin 86U (n=4)	100	111 ± 16	122 ± 20*	237 ± 95*
PCW + HS 250 µg (n=4)	100	159 ± 27	203 ± 31	1997 ± 708
PCW + HS 500 µg (n=5)	100	131 ± 19	142 ± 23*	436 ± 209
PCW + HS 1250µg (n=6)	100	109 ± 8	120 ± 16*	132 ± 87*

Statistically significant \* (p < .05), ANOVA Duncan test, data mean ± SD compared to untreated and HS in lowest dose.

**Conclusion:** Heparansulfate and Heparin attenuate the increase of rCBF and WBC in the CSF. Inhibition of leukocyte rolling may lead to a new adjuvant strategic in meningitis.

## 268.8

THE EFFECTS OF THE CLINICAL IMPROVEMENT OF SCHIZOPHRENIC SYMPTOMS ON BRAIN SPECT. C.J. Shin, I.W. Chung\*, S.S. Koong, S.G. Choi. Department of Neuropsychiatry, Chungbuk Nat. Univ. Hosp., Chungju, Chungbuk 360-240.

This study investigated the relationship between regional blood flow changes of brain and clinical improvement of symptoms in 10 maleschizophrenic patients. Single-photon emission computed tomography (SPECT) imaging with 99mTc-HMPAO was performed second and sixth weeks after admission and concurrently psychopathology was examined by Positive and Negative Symptom Scale. All patient were finally categorized into two groups, improvement or no change. We examined the difference of the changes in two functional images between groups. Prefrontal cortical activity showed no significant difference between two groups and clinical improvement had no effect on that. However, second SPECT images of no change group showed lower left temporal lobe activity than that of improvement group. Our results probably suggest that temporal lobe activity have relation to underlying schizophrenic symptoms.

By Grant of Chungbuk National University Hospital.

## 268.9

RELATIONSHIP BETWEEN REGIONAL BRAIN TEMPERATURE AND BLOOD FLOW BEFORE AND AFTER DEEP HYPOTHERMIC CIRCULATORY ARREST. J.W. Kuluz\*, B. Gelman, R. Perryman, D. Mulvaney, N. Wang, CL. Schleen. Dept. of Pediatrics and Surgery, Univ. of Miami, Miami, FL 33101.

Deep hypothermic circulatory arrest (DHCA) and cardiopulmonary bypass (CPB) for repair of congenital heart disease in children are associated with neurologic sequelae including seizures and cerebral infarction. This may be caused by flow-metabolism imbalance secondary to temperature effects on vascular resistance during the cooling and rewarming periods associated with bypass.

**Methods:** 5 piglets (10 ± 2 kg) were anesthetized and catheterized. Temperature probes were placed in 6 brain regions: 2 anterior and 1 posterior superficial cortex, diencephalon, and both caudate nuclei. Deep hypothermia (15-18 °C) was achieved on CPB gradually over 40 min followed by DHCA for 45 min and slow rewarming over 40-80 min. Regional CBF (microspheres) was measured at baseline, and at 4 time points during rewarming. Group 1 piglets (n=2) received pH-stat (corrected for temperature) and group 2, alpha-stat (n=3) blood gas management.

**Results:** The mean coefficient of variation of regional brain temperature increased during both cooling (7.0%) and rewarming (4.5%) compared to baseline (0.8%). Deep structures rewarmed at a faster rate than superficial cortex. Large variation in regional CBF was observed. CBF remained very low in cortex in 4 of 5 animals, whereas more complete restoration of CBF was attained in deep structures. Severe hypoperfusion was more common in gp 2, especially in superficial structures. After complete rewarming, global CBF was greater in gp 1 (71% vs 36% of baseline).

**Conclusion:** Cooling of the brain during CPB and rewarming after DHCA resulted in heterogeneous changes in regional brain temperature and blood flow. pH-stat management resulted in higher flow and may protect against ischemic injury. Regional differences in the effectiveness of cooling and rewarming may explain unexplained postoperative regional ischemia and clinical neurologic sequelae.

UNILATERAL LESION OF HIPPOCAMPAL CA1 SUBFIELD DUE TO TRANSIENT FOREBRAIN ISCHEMIA PLUS UNILATERAL HYPERTHERMIA, AND ITS DYNAMICS OF CBF AND BRAIN TEMPERATURE. E. TABUCHI<sup>1</sup>\*, R. TAMURA<sup>1</sup>, H. HAGINO<sup>2</sup>, H. KURIMOTO<sup>1</sup>, M. KURACHI<sup>2</sup>, T. ONO<sup>1</sup>.

<sup>1</sup>Depts. of Physiology & <sup>2</sup>Neuropsychiatry, Toyama Medical & Pharmaceutical Univ., Toyama 930-01, Japan.

It is known that the hippocampal CA1 subfield (CA1) is particularly vulnerable to ischemia and neurons are susceptible to hyperthermia during ischemia. We produced an unilateral lesion of CA1 due to transient forebrain ischemia plus unilateral hyperthermia, and bilaterally monitored cerebral blood flow (CBF) in CA1 and brain temperature (BT) to know its hemodynamics, using rats. They were subjected to 10 min ischemia by bilaterally occluding the common carotid arteries one day after permanent occlusion of the vertebral arteries. After the experiment, the brains were perfused and fixed, and the number of normal neurons in CA1 and some other brain regions were histologically investigated. The number of normal neurons significantly decreased only at heated side of CA1. Mean CBF decreased during ischemia to about 25% and increased transiently after ischemia to 110% at both unheated and heated sides, compared with the pre-ischemic level. There was no change in CBF between sides. BT decreased immediately after start of ischemia at both sides and BT at heated side started increasing 5 to 10 min after start of ischemia compared with unheated side, but BT did not change between sides after reperfusion of blood. In addition, there was a positive correlation between the post-ischemic hyperemia and the degree of decrease in CBF during ischemia.

## 268.11

EXERCISE-INDUCED SPECIFIC BRAIN COOLING EFFECT, S. Yeo\*, M. Scarborough. School of Nursing, University of Michigan, Ann Arbor, MI 48109-0482

Acute exercise increases body temperature, but usually does not involve the hypothalamic regulatory mechanisms of fever. Thus, the setpoint at the PO/AH area remains unchanged. Some argue that in order for the setpoint to remain unchanged, the brain has to be cooled aggressively during the heat production period. This theory, specific brain cooling, has been proven with various mammalian species.

The purpose of the study was to assess the effect of exercise-induced hyperthermia on brain and deep trunk temperature. Eight women, age 18 to 50 years old (30.9 ± 12.6; M ± S.D.), participated in the study. Subjects performed their regular aerobic exercise in a temperature controlled environment while body temperature (ear and rectal) and heart rate (HR) were measured simultaneously and repeatedly before, during, and after exercise. Glass mercury rectal thermometers (Baxter Healthcare Corporation, Deerfield, IL) were used for measurement of deep trunk temperature, an infrared tympanic membrane thermometer (Thermoscan Pro-1, Thermoscan Inc., San Diego, CA) for measurement of brain temperature, and a portable heart rate monitor (Polar Pacer, Polar Electro Inc., Port Washington, NY) for monitoring heart rate.

Rectal temperature was higher than brain temperature for all but one of the forty pairs observed. Resting mean temperatures at the two sites indicated .6 °C difference (36.8 ± .14 °C at the brain and 37.4 ± .12 °C at deep trunk; M ± S.E) and this mean difference gradually increased. The mean difference at 30 minutes into exercise (36.6 ± .20 °C at the brain and 37.9 ± .11 °C at deep trunk; mean ± S.E) was the largest (1.3 °C), then gradually becoming smaller. The time pattern varied for the two modes of temperature (F=9.67; p<.001). Rectal temperature changed over time (F=7.86; p<.002), and brain temperature did not (F=1.5; p=.25), indicating that brain temperature did not respond to exercise. While rectal temperature was strongly correlated with HR (r=.60), brain temperature did not correlate either with rectal temperature (r=.02) or with HR (r=.08). Thus deep trunk temperature responds to exercise at moderate levels. On the other hand, brain temperature does not increase due to exercise. Supported by NIH (K07 NR00047).

## 269.1

HIPPOCAMPUS, TIME, AND MEMORY, REVISITED. A. Dietrich\*, J. D. Allen, B. N. Bunnett. Dept. of Psychology, University of Georgia, Athens, GA 30605.

Rats with lesions to the hippocampus proper and the subiculum were tested for timing behavior and temporal memory. Using the peak procedure, they were trained to discriminate a 40 s interval and a retention gap tested the memory for time. Results were interpreted within the theoretical framework of the internal clock and with respect to current theories on hippocampal function. Timing behavior was unaffected by either lesions and no shifts in the temporal discrimination functions were observed. The lesions also failed to show a deficit in the memory for temporal events. For all groups, the retention gap increased the mean peak time by the time of the gap. This indicated that all rats used the stop rule which required the use of working memory. Thus, it was concluded that the hippocampus is neither necessary for accurate timing behavior nor for the memory of temporal events.

## 269.3

AN ANATOMICALLY GROUNDED THEORY OF RODENT NAVIGATION. A.D. Redish\*, D.S. Touretzky. School of Computer Science and Center for the Neural Basis of Cognition, Carnegie Mellon University, Pittsburgh PA 15213.

Drawing on proposals of several other research groups concerning the neural implementation of path integration (McNaughton et al., 1996), place field formation by competitive learning (Sharp, 1991), pattern separation and completion in hippocampus (Marr, 1969), and maintenance of an internal head direction representation (Skaggs et al. 1995, Elga et al., 1996), we synthesize a comprehensive theory of rodent navigation grounded in anatomy and tested in computer simulations. In doing so, we have adapted the proposals to each other, demonstrated that the resulting system accounts for a broad spectrum of data, and revealed interactions between the components that lead to explicit, testable predictions.

*Sensory cues* enter the place code via deep Entorhinal Cortex and are refined by competitive learning in the deep-to-superficial EC connections. The path integrator's representation is maintained as a hill of activity in a 2D array of cells in subiculum, and *path integration* is accomplished by shifting this hill in a loop that includes parasubiculum and superficial EC. A representation of *head direction* is maintained by an analogous hill of activation in a 1D array of cells in postsubiculum, and is updated similarly by a loop including the anterior thalamic nuclei. Rodents represent their position within a coordinate system that is goal or task dependent; selection of the appropriate *reference frame* occurs by pattern separation and completion in the dentate gyrus and CA3/CA1 subsystems.

While reference frame information (critical for episodic memory) is represented in CA1, path integrator coordinates (critical for navigation) are represented in subiculum, suggesting an anatomical separation between navigation (fornix, subcortical projections) and episodic memory (deep EC, cortical projections). Funded by the Center for the Neural Basis of Cognition.

US DEVALUATION DOES NOT ATTENUATE WIN-STAY RESPONDING IN RATS ON THE RADIAL MAZE. J. R. Sage\* and B. J. Knowlton. Dept. of Psychology, University of California, Los Angeles, CA 90095.

Previous studies have implicated the caudate nucleus in stimulus-response (S-R) habit learning. However, the content of this learning has not been examined using traditional S-R versus stimulus-stimulus (S-S) differentiation procedures. In order to characterize the nature of the association learned by rats in the caudate-dependent win-stay task on the radial maze, we employed a US devaluation procedure using conditioned taste aversion (CTA). Rats were trained to approach baited arms on the maze which were signaled by a light. When the animals reached a high level of accuracy, the food reinforcer used on the lighted arms was paired with LiCl injections for the experimental group. When performance was then reassessed on the maze, the experimental group continued to approach the lighted arms with similar accuracy and speed as compared to the control groups and to pre-CTA performance. The results suggest that the rats are not recalling the food reinforcer in order to mediate their response to the light. As previously suggested, an S-R, rather than S-S, association may be characteristic of win-stay and caudate dependent learning. Supported by the UCLA Academic Senate.

## 269.2

TRANSFER OF DISCRIMINATION LEARNING ACROSS DIFFERENT TEMPORAL RANGES. S.P. Clarke\*, R.B. Ivry. Dept. of Psychology, University of California, Berkeley, Berkeley, CA 94720

If separate neural systems are involved in representing temporal information across different ranges, then animals trained to discriminate between stimuli of short duration should show no transfer of learning to a discrimination between stimuli of a longer duration, and vice-versa. To test this hypothesis, rates of learning were assessed for each of two groups of 12 Fisher 344 rats. One group was trained on a short range discrimination (SR; 200 vs. 800 msec), the other on a long range discrimination (LR; 20 vs 80 sec). Both groups were then transferred to a medium range discrimination (MR; 2 vs. 8 sec) with the lever mapping reversed for half the animals in each group. The results of this experiment suggest that the animals trained on the SR task showed some transfer to the MR task while those in trained on the LR task did not. One curious finding is that the animals in the SR to MR group with the lever mapping reversed showed better performance after the transfer than all other groups. A second experiment will control for contextual cues and seek confirmation that the animals attended to the relevant stimulus dimension. Groups of animals will be trained on the SR, MR or LR temporal discrimination or an intensity discrimination. The intensity task will provide a baseline to assess the effects of contextual cues after transfer to the temporal discrimination. The other groups will be transferred to stimulus durations within the original training range. The lever mapping manipulation will be effected in half of each of these groups to assess how well the animals attended to the relevant stimulus dimension. This work was supported under a grant from the Whitehall Foundation and NINDS grant #NS30256.

Long Term Depression and Navigation: a simulation model. S. L. Morgan, J. Spruill, G. Yuen\*, T. J. Teyler. Dept. Neurobiology, NE Ohio College of Medicine, Rootstown, OH & Tenn State Univ. Nashville, TN.

Animals have the ability to navigate through extremely complex environments with relative ease. The hippocampus has been implicated as a spatial map of the environment, as evidenced by the well documented existence of place cells and an ensemble code for space (O'Keefe and Nadel, 1978; Wilson and McNaughton, 1993). We have attempted to modify an original model by Neil Burgess (1994), based on hippocampal anatomy and physiology, in an effort to enhance its navigational capabilities. The modified model consists of five layers and one thousand neurons with a feedforward architecture and a simple population code for space. The model calls for a random connectivity of the place cells at the start of the trial followed by an experience dependent long term potentiation (LTP) like mechanism that can increase synaptic weights in the place cell layer. Initial experiments indicated that the model allowed for good navigation in a controlled environment but the initial random connectivity provided conflicting navigational signals at times. If initial random connections were weighted heavily they could act as extraneous "attractants" that prohibited the rat from navigating to the goal correctly. We decided to implement a form of long term depression (LTD) in order to trim out some of the extraneous initial connectivity. Our preliminary data indicates that the implementation of LTD has, by trimming initial random connections, enhanced the ability of the rat to navigate to the goal. (Supported by ONR N00014-92-J1372)

## 269.6

SPATIAL LEARNING BY HIPPOCAMPAL RATS IN THE MORRIS WATER TASK. T. Schallert\*, L. B. Day, M. Weisend, & R. J. Sutherland. Dept. of Psychology, University of Texas at Austin, Austin, TX 78712 and University of New Mexico, Albuquerque, NM 87131.

Day and Schallert (*Behav. Neurosci.*, 1996) showed that impairments caused by anticholinergic drugs in standard water maze task studies may be the result of deficits in ability to inhibit non-efficient escape strategies. Special training procedures designed to promote the use of spatial search strategies and to prevent non-spatial strategies revealed that drugged rats and controls did not differ in acquisition or in probe trials in which the hidden platform was moved. In the present study, rats with kainate-colchicine hippocampal lesions and controls were tested in the Morris Water Task using similar training procedures. That is, instead of using a small platform for all trials, an oversized hidden platform that occupied nearly the entire pool was used during the early trials and was effectively "shrunk" into one quadrant of the pool by substituting smaller platforms over subsequent trials. Rats were released from the 4 compass points. During the probe trial, hippocampal animals showed increases in distance and latency to arrive at the new platform location comparable to controls, and swam preferentially in the previously-correct quadrant. Although the nature of the information that was controlling the trajectories in the hippocampal rats appeared to differ from that of control rats, it appears that compared to traditional training, our procedure enables rats with hippocampal damage to adopt a strategy supporting superior spatial localization performance. Funded by NS 23964.

## 269.7

DIFFERENCES IN THE SPATIAL CODING PATTERNS OF VENTRAL SUBICULAR NEURONS IN SIMPLE AND COMPLEX ENVIRONMENTS. R.G. Phillips<sup>1</sup>, H. Tanila<sup>1</sup> & H. Eichenbaum. *Contr. Behav. Neurosci.*, SUNY Stony Brook, NY 11794 and <sup>1</sup>Dept. of Neurology, Univ. of Kuopio, 70211 Kuopio Finland.

Neurons in hippocampal fields CA1-3 encode spatial representations of intramaze cues, extramaze cues and usually combinations of these and other fixed cues. Because the subiculum is the main target of hippocampal output, an attempt was made to determine if cells in this area code information in the same way as hippocampal neurons. Rats were chronically implanted with two movable tetrodes for unit recording and trained to explore a four-arm radial maze, receiving lateral hypothalamic stimulation as a reward at the end of each arm. Recordings were made in two conditions: (1) a complex environment of intramaze cues consisting of distinctive visual, tactile, and olfactory stimuli, and distal cues consisting of visual patterns attached to a curtain surrounding the maze; and (2) a simple environment in which all arms were blank and a single visual cue remained on the curtain.

In the complex environment no ventral subicular neurons showed identifiable location, cue, or reward related firing patterns, but instead tended to fire equally throughout the maze. However, when the number of cues was reduced to create the simple environment, some ventral subicular cells showed distinct place fields. These place fields did not follow the remaining extramaze cue when it was rotated, but instead changed their firing patterns qualitatively or disappeared. The original place fields were recovered when the cue was returned to its original position. These findings suggest that cells in the ventral subiculum encode spatial relations between a simple cue and the fixed environmental stimuli, but in a manner different from that of the hippocampus proper. Supported by NINDS, NIMH.

## 269.9

THE HOMING PIGEON HIPPOCAMPAL FORMATION AND LEARNING STRATEGIES FOR GOAL RECOGNITION. R. Strasser<sup>\*</sup> & V. P. Bingman. *Psychology Dept.*, Bowling Green State University, Bowling Green, Ohio 43403.

The role of the hippocampus may vary depending on the behavior displayed and context. To better understand these differences, learning strategies and the role of the hippocampal formation (HF) were examined in an indoor food-site and an outdoor loft recognition task. In Experiment 1, pigeons with lesions to HF and control pigeons were trained to find food hidden in one of four uniquely colored bowls, located next to a landmark, in a constant location in a room. HF lesioned pigeons learned to choose the correct bowl faster than controls ( $p=0.0197$ ). Subsequently, on four unrewarded test trial types, two cues were placed in conflict to each other and the third cue was removed. Controls chose randomly in all test trials except when the correct color bowl was placed in conflict with the landmark. In contrast, in all test trials, pigeons with HF lesions made appropriate responses to stimuli associated with food reward during training trials. If the correct color was an option, it was preferentially chosen by the HF lesioned birds. The results suggest control pigeons encode a holistic representation of the goal that is sensitive to environmental manipulations. Pigeons with HF lesions, however, appear to use a relatively simple, associative learning strategy and therefore, choose appropriately even with changes in the relationship among the stimuli. The role of HF in goal recognition was then examined in a different context involving home loft recognition. Control and HF lesioned homing pigeons were raised in either a loft facing west with red boards or a loft facing east with green boards. Pigeons were later tested with the boards switched between the two lofts. Control pigeons returned to the loft that occupied the correct location but the wrong color and HF lesioned pigeons chose both lofts equally. In this task, HF lesioned pigeons do not appear to respond preferentially to color. Although there are behavioral and contextual differences between these two tasks, together they suggest that pigeons with HF lesions can still identify goals, however, the learning strategies used to identify a goal are much different than those used by control pigeons.

## 269.11

BEHAVIORAL EFFECTS OF QUANTITATIVE ISCHEMIC DAMAGE TO HIPPOCAMPAL CA1 IN ADULT FEMALE RATS. T.L. Briones<sup>\*</sup> & B.A. Therrien. *The University of Michigan*, Ann Arbor, MI 48109-0482

CA1 neurons in the hippocampus (HPC) are selectively vulnerable to effects of cerebral ischemia. Evidence exists that damage to CA1 neurons result in spatial learning deficits and that gender difference exists. However, findings relating the extent of CA1 damage and behavioral deficits are conflicting and no studies have been done using female animals. The purposes of this study were to determine: 1) the duration of ISCH in female rats that would result in confined damage to CA1; and 2) the effects of CA1 cell loss on the degree of spatial learning impairment. Adult female Wistar rats were randomly assigned to receive either 5 min ISCH ( $n=3$ ), 10 min ISCH ( $n=5$ ) or sham surgery ( $n=7$ ). The 4-vessel occlusion method was utilized to induce global cerebral ischemia. After a 3-day recovery period, rats were tested for 6 days in the Morris water maze. Behavioral testing revealed that rats with ischemic damage were markedly impaired compared to shams in both directional heading error (DHE) and swim time ( $p=.01$  and  $p=.05$ , respectively). Histological analysis showed moderate damage to CA1 (10% to 18%) and CA3 (8% to 15%) with minimal damage to CA2 (<10%) in the 5 min ISCH group. In comparison, significant ( $p<.05$ ) damage was seen in the 10 min ISCH group in CA1 (52% to 65%), CA2 (18% to 30%), CA3 (20% to 32%), and subiculum (<15%). No damage to other brain regions was seen in either groups. Animals with greater CA1 cell loss have longer mean swim time (sham =  $8.15 \pm 0.9$  sec, 5 min ISCH =  $12.45 \pm 2.8$  sec, and 10 min ISCH =  $16.29 \pm 3.3$  sec;  $p=.00$ ) and showed increased DHE (sham =  $25.40 \pm 2.64$  degrees, 5 min ISCH =  $34.90 \pm 5.88$  degrees, and 10 min ISCH =  $41.44 \pm 5.46$  degrees;  $p=.01$ ) in the spatial learning task. We conclude that cell loss in both 5 and 10 min ISCH was not confined to CA1; and that greater extent of CA1 cell loss results in persistent spatial learning deficits in female rats with cerebral ischemic damage.

## 269.8

PERFORMANCE ON A CONDITIONAL ASSOCIATIVE LEARNING TASK BY RATS WITH LESIONS OF THE FORNIX OR DORSAL HIPPOCAMPUS. V. Sziklas<sup>\*</sup>, S. Lebel, and M. Petrides. *McGill University*, Montreal, Canada.

Rats with lesions of the fornix (F), the dorsal hippocampus (H), or a control operation (OC) were trained on a spatial conditional associative learning task (CAL) in which they had to learn to associate particular scenes with specific visual stimuli. They were subsequently trained on a spatial working memory task, the eight-arm radial maze. Animals with damage of the fornix were able to learn the CAL task at a rate comparable to that of the OC animals. Performance of the H group, however, was significantly impaired in comparison with both the OC and the F groups. Both the F and H animals were impaired on the radial maze. The present finding of a dissociation between the effects of F and H lesions on the CAL task suggests that the spatial learning deficit following damage of the fornix may be specific to remembering places the animal has visited on a given trial while leaving intact the ability to learn associations between specific scenes and arbitrary visual stimuli located within them. By contrast, lesions of the hippocampus appear to lead to a more general spatial learning impairment.

This work was supported by a grant from NSERC.

## 269.10

THE EFFECTS OF IBOTENIC ACID CA1 HIPPOCAMPAL LESIONS, OR PERFORANT PATHWAY KNIFE TRANSECTIONS, ON SPATIAL MEMORY IN THE RAT. L. Stubley-Weatherly<sup>\*</sup>, J.W. Harding, and J.W. Wright. *Dept. of Psychology*, Washington St. Univ., Pullman, WA 99164-4820

Although a substantial body of literature exists documenting the role of the hippocampus in learning and memory, there is less consensus concerning the behavioral involvement of discrete hippocampal regions. The present experiments examine specific hippocampal neurocircuitry in relation to spatial memory. Male Sprague-Dawley rats served as subjects, with rats in experiment 1 receiving either bilateral knife transections of the Perforant Pathway (PP) or cortex control knife cuts. Animals in experiment 2 received either ibotenic acid-induced bilateral lesions (IBO) of the hippocampal CA1 region, or aCSF vehicle control infusions. Upon recovery, subjects were tested on a motor skills task, later followed by a spatial learning and memory paradigm utilizing the water maze. Acquisition of the spatial task, using a hidden platform within the water maze, was conducted for 8 consecutive days. A Probe trial and Visual platform cue test were also conducted on days 8 and 9, respectively. Preliminary data suggests that animals with PP transections demonstrate the greatest performance deficit in this memory task. The IBO animals also show impaired performance, but to a lesser extent than PP rats. Both groups performed significantly worse than their respective controls. Additionally, preliminary studies indicate that the icv delivery of an angiotensin-IV analog facilitates performance in animals with hippocampal neurocircuitry damage.

## 269.12

THE EFFECTS OF BRIEF BRAIN ISCHEMIA ON STAGES OF MESSAGE PROCESSING AND THEIR CELLULAR MECHANISM. Z.Y. Yang, J.X. Cai<sup>\*</sup>. *Kunming Institute of Zoology, Chinese Academy of Sciences*. China 650223.

In this study, we examined which stages of message processing were affected by brief ischemia in mongolian gerbils. Occluding the common carotid arteries for 10 min induced brief ischemia. The step-through apparatus was used for memory test, the training or error numbers and the latency were recorded as memory grade. The cell numbers per unit length of CA1 region were counted. All results were analyzed with unpaired t-test. I. To study the effect of ischemia on message acquisition, the operation was done 5 days previous to training, the criterion of successful training was that the animals do not enter the dark room in 5 min. The training numbers was used to measure the ability of message acquisition, and in sham group, it was  $2.778 \pm 0.278$  ( $n=9$ ) while in ischemia group was  $5.9 \pm 0.924$  ( $n=10$ ) ( $0.0005 < P < 0.005$ ); II. To study message consolidation, naive gerbils received operation immediately after one-trial training. 5 days later, the animals were tested. The error numbers of sham group ( $E_s$ ) was  $2 \pm 0.5$  ( $n=8$ ), that of ischemia group ( $E_i$ ) was  $5.375 \pm 0.706$  ( $n=8$ ) ( $0.0005 < P < 0.005$ ); the latency of sham group ( $L_s$ ) was  $78.375 \pm 41.490$ , that of ischemia group ( $L_i$ ) was  $2.375 \pm 0.625$  ( $0.025 < P < 0.05$ ); III. To study message represent, naive gerbils were trained one-trial, then retrained every day for 5 min until they did not enter dark room for three consecutive days, then operation was given. After 5 days relaxation, the animals were tested.  $E_s = 0.333 \pm 0.142$  ( $n=12$ ),  $E_i = 0.636 \pm 0.310$  ( $n=11$ ) ( $0.1 < P < 0.375$ );  $L_s = 235.917 \pm 29.862$ ,  $L_i = 221.455 \pm 34.722$  ( $0.375 < P < 0.4$ ); In histological check, the cells of CA1 region of sham group was  $205.586 \pm 1.788$  /mm ( $n=29$ ), that of ischemia group was  $109.690 \pm 5.664$  /mm ( $n=29$ ) ( $P < 0.0005$ ). These results indicated that brief ischemia resulted in the impairment of the acquisition and consolidation of message, but not the represent of message, and the impairment was directly related to the delayed neuron death in CA1 region of hippocampus. (This work was supported by Chinese Academy of Sciences KY-85-05.)

**IMPAIRMENTS ON A MOVEMENT INTEGRATION TASK IN RATS WITH FIMBRIA-FORNIX LESIONS.** I.Q. Whishaw\* and J. Tomie, Department of Psychology, University of Lethbridge, Lethbridge, Alberta,

The ability of animals to monitor their movements to subsequently produce shorter paths is referred to as movement integration. It is displayed most dramatically by animals taking short direct homeward paths after circuitous outbound excursions. We have developed a test of movement integration and have compared the performance of control and fimbria-fornix (FF) rats. The task takes advantage of the tendency of rats to carry large pieces of food to a shelter rather than eat in the open. Thus, rats were placed in a burrow that they leave in search of food. Once they learned to return directly to the burrow with food, the location of the burrow was changed. Both control and FF rats searched for food and carried it to the burrow but the FF rats were slower in learning to return to the correct burrow than were control rats. The results provide evidence of a definitive impairment in path integration in rats with FF lesions and the results are discussed in relation to the hypothesized role of the hippocampal formation in spatial behavior. Supp. NSERC of Canada

## 269.15

**A SELECTIVE ANTAGONIST OF ALPHA-2 ADRENOCEPTORS FACILITATES THE EXCITABILITY OF THE DENTATE GYRUS AND IMPROVES THE RETENTION OF THE RADIAL ARM MAZE TASK.** A. Ylinen<sup>1,2\*</sup>, M. Pitkänen<sup>1</sup>, R. Pussinen<sup>2</sup>, A. Haapalinna<sup>1</sup>, E. Koivisto<sup>1</sup>, R. Lappalainen<sup>2</sup>, J. Sirviö<sup>2</sup> and P. Riekkinen<sup>1,2</sup>. <sup>1</sup>Dept. of Neurology and <sup>2</sup>A. I. Virtanen Institute, University of Kuopio, Kuopio, Finland, <sup>3</sup>Orion Corporation, Orion-Farmos Pharmaceuticals, Turku, Finland

A specific and selective alpha-2 antagonist, atipamezole, which is known to increase the release of noradrenaline, was found to dose-dependently enhance the excitability of granule cells to the perforant path stimulation in awake rats. Atipamezole, by the dose of 300 µg/kg but not by the dose of 1000 µg/kg, increased the size of population spike while it did not affect the slope of excitatory postsynaptic potentials. The administration of alpha-2 antagonist failed to enhance the potentiation of synaptic responses when measured 24 hours after (when its effect on synaptic transmission was disappeared) high frequency tetanus in the dentate gyrus. However, behavioral data indicated that 300 µg/kg atipamezole improved the retention (6 hours) of radial arm maze task (increased number of correct choices before first error) possibly reflecting an enhanced memory encoding. Although the facilitation of the excitability of granule cells and enhanced intermediate-term memory may not be causally related to each other, those findings are in line with the content that noradrenergic innervation in the dentate gyrus modulate coming information to the hippocampus which facilitates 'noticing'.

## 269.17

**DYNAMIC REWARD AND SPATIAL CODES OF CAUDATE NUCLEUS NEURONS.** S. J. Y. Mizumori\*, K. E. Unick & B. G. Cooper, Department of Psychology, University of Utah, Salt Lake City, UT 84112

In addition to the nucleus accumbens (Lavoie & Mizumori, 1994), the caudate nucleus may contribute dynamic spatial and reward information to guide navigation (Mizumori & Cooper, 1995). 104 caudate neurons were recorded as 6 rats performed multiple spatial memory trials on a radial maze. Alternating maze arms contained large or small amounts of reward. Consistent with our previous report, a variety of spatial correlates were observed, such as head direction and/or location, and directional movement relative to maze geometry or to 180° turns at the arm ends. Here, performance in darkness often resulted in elevated overall firing rates accompanied by a change in the location component of the spatial correlate (59 cells tested). The directional component of these same cells was rarely altered during dark trials. Thus, single caudate neurons contribute to dead reckoning and landmark-based navigation, suggesting an involvement in both response and environmental spatial learning.

During asymptote maze performance, 6 cells were sensitive to different magnitudes of reward: they increased or decreased firing just prior to encounters with large or small reward (but not both), or differentially discharged during consumption of these rewards. One of these cells was tested during acquisition of the maze task. A shift in the temporal relationship between cell firing and reward consumption was observed. On Day 1 of training, the cell preferentially fired during consumption of large rewards with no consistent location bias. By Day 7, the same cell anticipated encounters of large rewards by about 500 msec with a location bias. Thus, individual caudate neuron reward and spatial codes appear to be experience-dependent. [Supported by AG09299 and IBN 9514880]

Male mice from nine different inbred strains were tested at the age of three months in an 8-arm radial maze with only four out of eight arms containing food rewards, permitting simultaneous assessment of working (WM) and reference memory (RM). In the first experiment, the maze was always placed in the same way (allowing the use of intra-maze cues). In the second one, the maze was turned by 45° between trials (prohibiting the use of intra-maze cues). Other animals from the same strains were processed histologically to estimate the strain-specific extents of the hippocampal intra- and infrapyramidal mossy fiber projections (IIPMF). Turning of the maze significantly decreased performance in a strain-dependent manner. The extents of the IIPMF correlated strongly with both WM and RM if the maze was turned between trials. Similar correlations were only found in the early phases of learning in the other condition. We conclude that the IIPMF are involved in spatial learning and that non-spatial within-maze cues may influence learning performance in some inbred strains.

**THE EFFECTS OF HIPPOCAMPAL CCK<sub>B</sub> RECEPTOR ACTIVATION ON PLACE LEARNING IN THE MORRIS WATER MAZE IN RATS.** R.J. McDonald<sup>1\*</sup>, K.A. Cappell<sup>1</sup>, F.J. Vaccarino<sup>1,2</sup> and N.J. DeSousa<sup>1</sup>. <sup>1</sup>Dept. of Psych., Univ. of Toronto, Toronto, Canada, *MSS 1A1*; and <sup>2</sup>Clarke Inst. Psychiatry, Toronto, Canada, *MST 1R8*.

The present experiment examined the effects of intra-hippocampal infusions of pentagastrin, a CCK<sub>B</sub> agonist, on performance in the Morris water maze, a paradigm involving hippocampal based memory.

Nine male Wistar rats implanted with bilateral cannulae into the hippocampus were randomly assigned to either vehicle or pentagastrin (10 nM) treatment groups (n= 4 and 5, respectively). Behavioral testing in the water maze was divided into two phases: a visible platform phase (days 1, 2, 4, 5, 7, and 8) during which a small platform protruded above the level of the opaque water; and an invisible platform phase (days 3, 6, and 9) in which the platform was submerged below the surface of the water. In both cases, the location of the platform remained constant and the task was to swim from four different start locations to the platform over eight daily trials. Animals were pretreated with their respective treatment on visible platform days only and tested drug-free on the invisible platform days.

Results showed that on the visible platform days treatment groups did not differ significantly across several measures including latency to platform, swim path distance, swim speed or percentage of time spent in the correct quadrant. However, on the invisible platform days pentagastrin treated rats spent a significantly greater percentage of time navigating in the correct quadrant than their controls, reaching maximal performance on their first day.

These preliminary data demonstrate that activation of hippocampal CCK<sub>B</sub> receptors facilitates place learning and that this effect is not due to changes in motivational, perceptual, or motoric processes. **IBOTENIC LESIONS OF THE NUCLEUS ACCUMBENS IMPROVE DETECTION OF SPATIAL NOVELTY AND RADIAL MAZE PERFORMANCE IN DBA/2 MICE CHARACTERIZED BY A GENETIC HIPPOCAMPAL DYSFUNCTION.** M. Ammassari-Teule<sup>1</sup>, A. Mele and P. Rouillet. Ist. di Psicobiologia e Psicofarmacologia, C.N.R., Dip. Genetica e Biologia Molecolare, Università di Roma "La Sapienza" Rome, Italy and Inst. Neurosciences, CNRS-URA 1488, Université Paris VI, France.

C57BL/6 (C57) and DBA/2 (DBA) inbred mice with either bilateral ibotenic lesions of the nucleus accumbens or sham lesions were repeatedly placed in an open field containing five objects. After habituation to the object configuration, their reactivity to the displacement (spatial change) or to the substitution (non spatial change) of some of these objects was examined. When sham-lesioned mice were considered, strain differences concerning the reactivity to spatial change were found. C57 fairly reacted to the new configuration by exploring more the displaced than the non displaced objects while DBA did not show any reaction. Both strains, however, equally reacted to nonspatial change by spending more time in contact with the new object than with the familiar ones. When lesioned mice were considered, DBA with nucleus accumbens lesions showed a clear reaction to spatial change that was not present in sham-lesioned animals. This lesion, however, did not affect the reactivity to spatial change in C57 and leaved the reactivity to non spatial change of both strains intact. Subsequently, when tested in a radial eight-arm maze, C57 performed better than DBA. Spatial learning performance was similar in lesioned and sham-lesioned C57 mice. Conversely, DBA lesioned mice made more errorless trials and displayed a higher proportion of 45° angle turns than DBA sham-lesioned mice. The behavioural improvement observed in lesioned DBA mice supports the view that, in that strain, the nucleus accumbens may exert an inhibitory control on limbic structures and cortical areas more directly involved in the modulation of spatial learning. The fact that inbred mice represent extreme but still normal models of neural and behavioral functioning suggests that poor spatial learning performance recorded in individuals belonging to natural populations may depend on such an inhibitory mechanism.

**SELECTIVE CHOLINERGIC IMMUNOLESIONS OF THE MEDIAL SEPTAL AREA DO NOT IMPAIR SPATIAL WORKING MEMORY.** R.W. McMahan<sup>1</sup>, T.J. Sobel<sup>1</sup>, M. Gallagher<sup>1,2\*</sup>, and M.G. Baxter<sup>2</sup>. <sup>1</sup>Department of Psychology and <sup>2</sup>Curriculum in Neurobiology, Univ. North Carolina, Chapel Hill, NC, 27599.

Based on non-selective lesions, the septo-hippocampal pathway has traditionally been thought of as essential for spatial memory. The immunotoxin 192 IgG-saporin was injected into the medial septal area of male Long-Evans rats to remove selectively cholinergic innervation of hippocampus. Control (vehicle) and lesioned rats were tested post-operatively on a water version of a radial arm maze task. A water version of this task was implemented to exclude food restriction motivation and local intramaze cues, while also increasing the spatial memory load compared to the standard Morris water maze task. Rats were placed in the center of the maze, facing the junction of two arms (varied randomly), and allowed to swim down the maze arms to escape on a hidden platform located 1cm below the surface of opaque water. Rats were able to escape from each of the eight arms once during a session, because each platform was removed following a successful escape. After initial training, a delay was interposed. In the pre-delay component, four of the arms were blocked from entry. In the post-delay component, all arms were available for escape. The delays were 60 sec, 1 hr, 3 hr, and 6 hr. Errors that occurred after the delay were scored in 2 categories: retroactive, in which the rat searched an arm previously chosen for escape before the delay, and proactive, in which the rat searched an arm that had already been chosen for escape after the delay. Retroactive errors increased with longer delays, but were unaffected by the lesion. Proactive errors, which did not vary with delay, were also unaffected by the lesion. Results indicate that normal spatial working memory is possible without the septo-hippocampal cholinergic projection. (Supported by NIH grants K05-MH01149 and P01-AG09973 to MG)

**EFFECTS OF SELECTIVE CHOLINERGIC OR ELECTROLYTIC LESIONS OF THE MEDIAL SEPTAL AREA ON SPATIAL DELAYED ALTERNATION IN WEANLING RATS.** C.S. Carter<sup>1\*</sup>, M.G. Baxter<sup>2</sup>, and M.E. Stanton<sup>1,3</sup>. <sup>1</sup>Dept. Psychol. and <sup>2</sup>Curriculum Neurobiol., Univ. North Carolina, Chapel Hill, NC 27599; <sup>3</sup>Neurotoxicology Division, US EPA, Research Triangle Park, NC 27711.

The hippocampus is important for cognitive development, and structures associated with it, such as cholinergic afferents from the medial septum and vertical limb of the diagonal band (MS/VDB), may contribute to the ontogeny of behaviors that rely on the hippocampus for their expression. Fornix transection disrupts the development of performance in weanling rats in an appetitive T-maze task: spatial delayed alternation (Freeman and Stanton, *Behav. Neurosci.*, 105:386-395, 1991). The present study was designed to examine more specifically the role of the cholinergic septal projections to the hippocampus in this effect. Rat pups were given MS/VDB lesions on postnatal day (PND) 17, either by electrolytically destroying the whole structure or by specifically targeting cholinergic neurons with the immunotoxin 192 IgG-saporin, and were tested behaviorally on PND26. Sham-operated control rats acquired the task rapidly. Both the electrolytic- and saporin-lesioned rats were impaired on the first block of training but improved across blocks of training. Averaged across blocks, electrolytic-lesioned rats were more impaired than saporin-lesioned rats relative to controls. AChE histochemistry revealed a loss of cholinergic fibers to the hippocampus in both lesioned groups. Electrolytic-lesioned rats had damage throughout the MS/VDB whereas saporin-lesioned rats showed only loss of cholinergic neurons, with GABAergic neurons intact. Hence, both cholinergic and noncholinergic projections from the MS/VDB to the hippocampus may contribute to the ontogeny of spatial delayed alternation. Based on the relative lack of effect of specific cholinergic lesions of the MS/VDB on other spatial learning and memory tasks in adults, this may also reflect a specific developmental role for the septohippocampal cholinergic projection. **NEONATAL 5,7-DHT LESIONS ALTER PERFORMANCE OF PASSIVE AVOIDANCE AND A NOVEL ODOR DISCRIMINATION TASK IN ADULT MICE** M. Libbey<sup>1</sup>, J. Berger-Sweeney<sup>1</sup>, C.F. Hohmann<sup>2\*</sup>. <sup>1</sup>Department of Biological Sciences, Wellesley College, Wellesley, MA 02181; <sup>2</sup>Department of Biology, Morgan State University, Baltimore, MD 21239.

We have shown previously that electrolytic lesions to the basal forebrain (BF) on postnatal day (PND) 1 interrupt cholinergic innervation of cortex and produce profound alterations in behavior and cortical morphology that persist into adulthood (*Int. J. Develop. Neurosci.* 12:239-253). In our electrolytic BF lesion model, the cholinergic neurons, of interest, are destroyed but so are the monoaminergic fibers en route to cortex. To determine the contribution of the monoaminergic system to the behavioral impairments, we performed lesions using the monoaminergic toxin 5,7-DHT (DHT). Unilateral (UNI) and bilateral (BILAT) lesions to the BF were performed on PND1 in 25 BALB/cByJ mice; 13 littermates were controls. The mice developed normally to adulthood when locomotor activity, passive avoidance retention, and odor discrimination with delayed non-match-to-sample learning were assessed. The BILAT males exhibited a significant passive avoidance retention deficit relative to the other groups. Both the UNI and BILAT groups (both sexes) performed a novel odor discrimination with delayed non-match-to-sample task significantly more accurately and more quickly than controls. The female BILAT group was slightly, but significantly, hypoactive relative to the other groups. The results indicate that the subcortical monoaminergic projections to cortex that pass through the BF influence adult behavior and probably contribute to some of the deficits noted previously in the electrolytic BF lesion model. We are currently testing electrolytic lesion groups on this novel odor discrimination task. (Supported by NSF IBN 9222283)

## 270.4

**COMBINED SELECTIVE LESIONS OF BOTH SEPTOHIPPOCAMPAL AND CORTICOPETAL BASAL FOREBRAIN CHOLINERGIC PROJECTIONS DISRUPT ATTENTIONAL PROCESSING BUT NOT SPATIAL LEARNING.** M.G. Baxter<sup>1\*</sup>, D.J. Buccil<sup>1</sup>, P.C. Holland<sup>2</sup>, and M. Gallagher<sup>2</sup>. <sup>1</sup>Curriculum Neurobiol. and <sup>2</sup>Dept. Psychol., Univ. North Carolina, Chapel Hill, NC 27599; <sup>3</sup>Dept. Psychol., Duke Univ., Durham, NC 27708.

The immunotoxin 192 IgG-saporin can be used to produce selective lesions of basal forebrain cholinergic neurons, permitting direct assessment of the role of these neurons in cognitive function. Most studies with this toxin have shown that selective cholinergic lesions of individual basal forebrain nuclei disrupt attention but do not impair learning and memory. Simultaneous damage of cholinergic neurons throughout the basal forebrain cholinergic system (BFCS) produced by intracerebroventricular infusions of 192 IgG-saporin produces deficits in learning and memory, but these lesions also result in cerebellar Purkinje cell loss and motoric impairments that complicate the interpretation of the behavioral results. We examined both spatial learning and attentional processing in rats given injections of 192 IgG-saporin stereotactically placed in both the MS/VDB and nbM/SL, in an attempt to produce near-complete BFCS damage without cerebellar damage. These lesions produced an average of 78% depletion of hippocampal choline acetyltransferase (ChAT) activity and 64% depletion of cortical ChAT activity without affecting striatal ChAT activity. Spatial learning (assessed in the Morris water maze) was entirely normal in lesioned rats. Attentional processing was assessed in an associative learning task in which relationships between conditioned stimuli (CSs) are manipulated to alter attention to the CSs. Control rats showed a modulation of attention that was reflected in improved associative learning; this effect was not present in the lesioned rats. These results provide further support for the hypothesis that the BFCS is involved in attention, but not memory processes. ## 270.6

**MEDIAL FRONTAL CORTEX LESIONS: EFFECTS ON BEHAVIORAL PLASTICITY IN THE USE OF SPATIAL AND KINESTHETIC CUES IN RATS.** W.L. Isaac<sup>\*</sup>, S.A. Williams, and S.V. Isaac. Psychology, East Tennessee State University, Johnson City, TN 37614.

The role of medial frontal cortex (MF) of rats in using spatial and kinesthetic cues on a plus-maze was examined. Contradictory reports of performance changes in maze tasks following MF lesions suggests the need to better characterize the cues utilized during behavioral recovery of function. Using a Place versus Response task provides an opportunity to this end. Male Long-Evans rats (50 days old at surgery) were used. It was a 2x2x5 (Surgery x Task x Blocks of Days) mixed groups design with a repeated measure. ANOVAs were used to assess behavioral measures. All subjects acquired their tasks although controls met criterion in fewer days than MFs. Reversal within the Place or Response task for the rats demonstrated marked differences in behavioral plasticity between groups. Controls reversed the Place habit more easily than MFs, and MFs reversed the Response habit more easily than Controls. This lends support to the idea that MF lesions reduce behavioral plasticity on spatial tasks. It also suggests that MF lesions increase reliance on kinesthetic cues without impairing the use of such cues. (ETSU Grant-in-Aid)

## 270.7

**COMPARISONS OF RIGHT VS. LEFT VENTROLATERAL ORBITAL CORTEX LESIONS ON ALLOCENTRIC SPATIAL LEARNING IN RATS.** K.J. Burcham\*, B. Haskins and J.V. Corwin. Psych. Dept., Northern Illinois Univ., DeKalb, IL 60115.

Two interconnected regions of rodent neocortex, the ventrolateral orbital cortex (VLO) and posterior parietal cortex (PPC) have been found to be involved in the learning of allocentric spatial tasks. Further, the effects of unilateral PPC lesions have indicated a lateralized effect: right but not left PPC lesions produce a significant deficit in allocentric spatial tasks. In the present study, we examine the effects of unilateral VLO lesions to determine if the VLO is also lateralized for allocentric spatial processing.

Four groups of subjects received either: unilateral right or left VLO lesions, bilateral VLO lesions, or sham control lesions. Subjects were tested for allocentric spatial learning in a Cheeseboard-maze. Subjects must learn to locate a food reward that is maintained in a constant location relative to extramaze cues, when the placement of the subject is varied. All subjects received 5 days of acquisition training followed by 5 days of reversal training.

The results indicated that during acquisition bilateral VLO operates were impaired relative to shams and right VLO operates ( $p < .05$ ). Left VLO operates were impaired relative to right VLO operates only on Day 1 of acquisition ( $p < .05$ ). During reversal learning, the bilateral VLO group was impaired relative to the right VLO group ( $p < .05$ ). The results provide limited support for the contention that the VLO is asymmetrically organized for allocentric spatial processing.

## 270.9

**DORSAL INSULAR CORTEX LESIONS IMPAIR THE RECALL, BUT NOT THE ACQUISITION OF THE MORRIS WATER MAZE.**

C.E. Ormsby\*, C.L. González-Rodríguez, and F. Bermúdez-Rattoni. Dpto. Neurociencias, Instituto de Fisiología Celular, México, D.F. 04510, México.

The insular cortex (IC) of the rat is a structure that has been characterized as mediating several aversive conditionings. Lesions of the IC impair the acquisition and retention of conditioned taste aversions, Morris water maze (MWM), and inhibitory avoidance (IA), suggesting this is an associative area for aversively motivated and visceral learning. The present experiments were made in order to examine the role that different portions of the IC have on the Morris water maze (MWM) and inhibitory avoidance (IA). Wistar rats were bilaterally lesioned in one of three portions of the IC. One was lesioned in the dorsal (external) IC (IC-DOR group), another one was lesioned ventrally (internal) to the IC (IC-VEN), and another was lesioned in the adjacent parieto-temporal cortex (PTC group). Results showed that the IC-VEN group had impaired acquisition of the IA and MWM tasks, whereas the IC-DOR group were able to learn the IA task and showed normal acquisition of the MWM, but had impaired recall on a test trial made 24 hrs later. The PTC group did not show impairment in any of the tasks. Histologies showed that the IC-VEN group had additional lesions in the ventral caudate, claustrum and endopiriform nucleus; whereas the IC-DOR lesions only involved cortical tissue.

## 270.11

**IMPAIRED SPATIAL MEMORY AND BEHAVIORAL ANOMALIES IN SEGMENTAL TRISOMIC TS65DN MICE.** P.J. Yarowsky<sup>1</sup>, G.E. Demas<sup>2</sup>, S.L. Klein<sup>3</sup>, L.J. Kriegsfeld<sup>4</sup>, B.K. Krueger<sup>5</sup>, and R.J. Nelson<sup>6</sup>. Depts. of Pharmacology<sup>1</sup> and Physiology<sup>2</sup>, Univ. of Maryland Sch. of Med., Baltimore, MD 21201 and Dept. of Psychology, Behavioral Neuroendocrinology Group<sup>3</sup>, The Johns Hopkins Univ., Baltimore, MD 21218.

Ts65Dn mice have a triplicated portion of chromosome 16 syntenic to the distal end of human chromosome 21. In order to determine their suitability as an animal model of Down syndrome (DS), we have investigated their spatial memory, anxiety, aggression, and reproductive behavior in Ts65Dn mice. Six month old Ts65Dn mice displayed levels of spontaneous alternation in a T-maze comparable to controls, demonstrating that simple spatial memory was not impaired. However, on 8 of 10 daily trials in a 12-arm radial maze (RAM), controls performed significantly above chance on the initial 12 choices, while Ts65Dn mice performed only near chance levels, indicating a deficit in spatial working memory. On trials 9 and 10, Ts65Dn mice performed as well as controls but required a greater number of choices to complete the RAM. After a 50-day retention period, control mice performed above chance levels when retested, while the improved performance of Ts65Dn mice was lost, suggesting that long-term memory was also defective. In an elevated plus maze, Ts65Dn mice did not display higher anxiety levels which could affect their performance in the RAM; they visited open arms more frequently and spent more time in open arms than did controls. In tests of aggression, Ts65Dn displayed increased offensive, but decreased defensive, aggression relative to controls. Ts65Dn mice also displayed reproductive anomalies, attempting fewer intromissions with an estrous female compared to controls. Ts65Dn mice behaved normally in several sensorimotor tests. Thus, many of the behavioral characteristics of Ts65Dn mice are similar to those of DS.
