THE ROLE OF BUCCAL NEURON B1 IN THE OSMOTICALLY-INDUCED ALTERATIONS IN HEART ACTIVITY IN THE TERRESTRIAL GASTROPOD, Limax maximus. I.G. Welsford* and C. Rhine Dept. of Biology, Keene State College, Keene, NH 03435.

Terrestrial gastropods, such as Limax maximus, can experience dramatic alterations in hemolymph osmolality due to evaporative water dramatic alterations in heritolyniph ostimating use to evaporative water loss across the moist integument. Previous work has implicated the small cardioactive peptides, SCP_A and SCP_B, in osmotically-induced alterations in heart activity. We investigated the potential role of buccal neuron, B1, which contains SCP-like immunoreactive material (SLM), neuron, B1, which contains SCF-like infinition active material (SLM), in these alterations. Exposure of the buccal ganglia alone to normal slug saline made hyperosmotic (190 mOsm/kg H₂O) by addition of mannitol (normal level is 145 mOsm/kg H₂O), caused a decrease in heart atrial contraction force of 48± 18.3% (X ± SEM, n=10). Exposure of the buccal ganglia alone to hyposomotic saline (110 mOsm/kg H₂O) caused an increase in these parameters (110 \pm 8.6%). B1 firing frequency increased (38 \pm 5.6%) in response to application of hyposmotic saline and decreased(-29 \pm 7.9%) in response to hyperosmotic saline. When B1 was hyper-polarized during exposure of the buccal ganglia to hyposmotic saline, the increase in heart activity was significantly reduced $(44 \pm 16.2\%; p < 0.001)$. Video-microscopic examination of the buccal ganglia during osmotic shock revealed osmotically-induced alterations in gangia during osmoue shock revealed osmoueany-induced attentions in apparent cell volume of B1 which were blocked by both HgCl₂ (0.1 mM) and pCMBS (0.01 mM). These results are consistent with the hypothesis that B1 is involved in osmotically-induced alterations in heart activity and that this process involves aquaporin-like water channels Supported by the Whitehall Foundation and NSF DUE-9352732

BEHAVIORAL PHARMACOLOGY

530.1

CONTINUOUS ACCESS TO SUCROSE INDUCES DEPRESSIVE-LIKE BEHAVIOR IN THE RAT V.J Djurić, D.H. Overstreet¹, D. Crosthwaite, E. Dunn and M. Steiner. Father Sean O'Sullivan Rsrch. Cntr., Dept. of Psychiatry, St Joseph's Hospital, McMaster Univ., Hamilton, Ontario, Canada L8N 4A6 and Skipper Bowles Cntr. for Alcohol Studies, Univ. of North Carolina, Chapel Hill, NC 27599-7175 USA

Ingestion of carbohydrate-rich meal enhances serotonergic transmission, and carbohydrate craving has been observed in many depressed patients. The objective of this study was to investigate whether continuous access to sucrose affects indices of depressive behavior in the rat. In two independent experiments, cholinergic- and serotonergic hypersensitive Flinders Sensitive Line rats (a genetic animal model of depression) and their control counterparts Flinders Resistant Line rats were allowed ad lib access to 16% sucrose solution supplementing their regular lab diet for 30 days. Subsequent behavioral tests revealed striking effects of sucrose consumption on depressive-like behavior. Rats of both lines that were exposed to sucrose had longer periods of immobility in the forced swim test relative to the control animals of both lines whose diet was not supplemented with sucrose ($F_{1,26} = 47.14$; p < .001 and $F_{1,12}$ = 9.26; p = .01; for the first and the second experiment, respectively). This finding was also paralleled with results from an open field test: rats that have been exposed to sucrose showed hypoactivity and thigmotaxis. Our data may help to explain serotonergic mechanisms that have been implicated in both eating and mood disorders in view of recent reports which indicate that swim test immobility is related to both cholinergic and serotonergic sensitivity

NEUROHORMONAL MODULATION OF CARDIAC PERFORMANCE AND CULTURED CARDIAC GANGLION NEURONS IN THE SHORE CRAB. M.A. Saver¹, J.L. Wilkens^{1*}, and N.I. Syed², Departments of Biological Sciences1 and of Medical Physiology2, University of Calgary, Calgary, Alberta, Canada T2N 1N4.

The modulatory effects of crustacean neurohormones on neurogenic heart performance were studied using perfused in situ hearts of Carcinus maenas Heart rate, extracellular EMGs, myocyte membrane potential, and contractile force were measured in response to proctolin, crustacean cardioactive peptide (CCAP), serotonin, octopamine, and dopamine. The amines and CCAP induced strong positive chronotropic effects, and moderate positive inotropic effects consistent with simple facilitation. Proctolin caused moderate positive chronotropic and large positive inotropic effects.

To understand the actions of neurohormones at the neuronal level, we have developed an enzymatic dissociation technique to isolate the cardiac ganglion (CG) and to culture the isolated ganglionic neurons. Sharp electrode intracellular recordings from large cells in intact ganglia revealed spontaneous pacemaker and bursting potentials, and showed responses to neurohormones consistent with those shown by intact hearts. The responses of cultured neurons during exposure to neurohormones were similar to those exhibited by intact ganglia. Our data demonstrate that isolated cardiac ganglion neurons maintain their intrinsic membrane properties in cell culture and remain responsive for pharmacological and biophysical analyses. These cells provide an opportunity to examine the neuronal mechanisms modulating excitability in pacemaker neurons. Supported by NSERC Canada.

PREFRONTAL COGNITIVE IMPAIRMENT IN THE PATHOPHYSIOLOGY OF THOUGHT DISORDER: EFFECTS OF NMDA ANTAGONISM C.M. Adler¹, T.Goldberg², A.K. Malhotra¹, I. Elman¹, T. Yoshikawa*³, D. Pickar¹, A. Breier¹ Experimental Therapeutics Branch, National Institute of Mental Health (NIMH), Bethesda, MD 20892. 2Clinical Brain Disorders Branch, NIMH, Washington, DC 20032. 3Clinical Neurogenetics Branch, NIMH, Bethesda, MD 20892.

Objective: The N-methyl-d-aspartate (NMDA) receptor has been implicated in the pathophysiology of thought disorder. We have hypothesized that dysfunction i prefrontal cortex cognitive processes may cause thought disorders. Ketamine is a general anesthetic that antagonizes the NMDA receptor at the PCP site and produces cognitive abnormalities in healthy controls (Malhotra et al, 1996). In this study, we sought to determine if ketamine produces thought disorder and if there is a relationship between thought disorder and prefrontal cognitive dysfunction. $\begin{tabular}{l} \underline{\textbf{Method:}} \\ A double \end{tabular}$ blind placebo controlled infusion of ketamine was performed in 10 normal volunteers (0.12 mg./kg. bolus followed by a 0.65 mg./kg./hour infusion). Thought disorder, working memory, and verbal fluency were assessed during each infusion. Thought disorder was rated with the Scale for the Assessment of Thought, Language, and Communication (TLC). Results: Ketamine induced thought disorder and impairment in working memory and verbal fluency. Conclusions: These data suggest that NMDA receptor antagonism is involved with the pathophysiology of both thought disorder and cognitive impairment. The relationship between these two NMDA receptor antagonist effects may provide informative data on the role of cognition in thought disorder. A relationship between a subset of thought disorder and cognitive dysfunction was noted.

This study was funded through the intramural program of the National Institute of Mental Health.

ANTI-IMMOBILITY EFFECTS OF A MELATONIN RECEPTOR AGONIST, BUT NOT ANTAGONIST, IN A GENETIC ANIMAL MODEL OF DEPRESSION. D.H. Overstreet*, O. Pucilowski, M.-C. Rettori# and P. Delagrange#. Skipper Bowles Center for Alcohol Studies, Univ. North Carolina, Chapel Hill, NC 27599-7178 and #IRIS, 92415 Courbevoie, France.

Univ. North Carolina, Chapel Hill, NC 27599-7178 and #IRIS, 92415 Courbevoie, France.

The Flinders Sensitive Line (FSL) rats have been proposed as a genetic animal model of depression because they exhibit increased REM sleep and their innately high immobility in the forced swim test is counteracted by the tricyclic antidepressants, imipramine and desipramine. This model was used to test the acute and chronic effects of two novel compounds which have either an agonist or antagonist-like effect at melatonin receptors. In the acute study FSL and control Flinders Resistant Line (FRL) rats received either vehicle (DMSO) or the agonist (\$ 20304, 1 or 20 mg/kg), or desipramine (DMI, 10 mg/kg) or 0 WM at 10:00. A single 5-min swim test was performed by a blind observer 1 hr later. Only DMI in the FSL rats slightly reduced immobility; no other treatment was effective. In the chronic study FSL and FRL rats received vehicle or the agonist (1, 5, 10 mg/kg) chronically at 08:00 for 14 days or vehicle or the antagonist (1, 5, 20 mg/kg) chronically at 10:00 for 14 days. The swim test was performed by a blind observer 25 hr later. Oneway ANOVAs indicated significant inter-group differences were primarily due to the large differences between the FSL and FRL rats. The only significant drug effect was a reduction in immobility in the FSL rats at the highest dose of the agonist. These findings suggest that the melatonin receptor agonist S 20304 may have antidepressant potential. Supported by IRIS.

THE EFFECTS OF THE D₁ DOPAMINE RECEPTOR AGONIST SKF-81297 ON SOCIAL-EMOTIONAL REACTIVITY AND ACOUSTIC STARTLE RESPONSE IN MICE. P. L. Gendreau^{1,2}, J. M. Petitto¹, J.-L. Gariépy², and M. H. Lewis^{1*}. ¹Department of Psychiatry, University of Florida, Gainesville, FL, 32610; ²Department of Psychology, University of North Carolina, Chapel Hill, NC, 27599.

Our previous studies suggested an important role for D₁ dopamine receptors in mediating emotional behavior. These studies examined emotional reactivity in a social context and used dihydrexidine, a dopamine agonist which is only 10-fold selective for D1 over D2 receptors. Thus, the present study examined the effects of the highly selective, full-efficacy D₁ agonist SKF-81297 on emotional reactivity in isolated C57BL/6 mice. Moreover, drug effects were examined in tests of both social and nonsocial reactivity. First, the effects of SKF-81297 (0, 1, 3, 10 mg/kg) were assessed in response to mild social contact provided by a nonaggressive conspecific. SKF-81297 increased escape/jump behavior and markedly reduced the frequency of social approach initiated by the test animal. These effects were fully blocked by the D₁ antagonist SCH-23390 (0.1 mg/kg) but only partially by the D2 antagonist sulpiride (20 mg/kg). In a second experiment, the effects of SKF-81297 (3 mg/kg) alone or in combination with SCH-23390 or sulpiride were examined in an acoustic startle experiment. SKF-81297 increased startle response and this effect was blocked by SCH-23390 but not by sulpiride. These results provide evidence for an important role for D₁-like dopamine receptors in the mediation of emotional reactivity to social and nonsocial stimuli. Supported by NSERC of Canada and MH45371.

THE EFFECTS OF PREFEEDING AND DOPAMINE AGONISTS ON WITHIN-SESSION MATCHING CURVE PARAMETERS OBTAINED USING A CONCURRENT VI 30 VI-INCREMENTING PROCEDURE. <u>B.J. Brockel* and D.A. Cory-Slechta</u>. University of Rochester, Rochester. NY 14642.

Twelve rats were trained on a 2-lever, concurrent variable interval (VI) schedule in which a complete matching curve could be obtained within a single 30-min session. One lever was associated with a "base" VI schedule (VI 30 s) while the other lever (incrementing lever) was associated with a percentage of the base VI. The percentage of the incrementing lever increased after every 6 reinforcers earned on this lever (i.e., 12%, 25%, 50%, 100%, 200%, 400%). Sensitivity and bias estimates were calculated using the generalized matching equation and were similar to parameters previously reported with matching curves generated using across-ession, concurrent VI procedures. Changing the base VI from 30 s to 60 s had no effect on overall response rates or bias and sensitivity parameters. In probe sessions in which reinforcement densities were altered, response rates were modified and obtained reinforcement ratios were similar to the programmed values. A prefeeding procedure produced decreases in overall response rates, increases in sensitivity, and alterations in bias estimates. Similar to prefeeding, the D2-D3 dopamine agonist guinpirole (0.0-3.0 mg/kg) and the D1-specific dopamine agonist SKF 82958 (0.0-0.4 mg/kg) decreased overall response rates. Low doses of the indirect-dopamine agonist d-amphetamine (0.25-1.0 mg/kg) increased response rates; whereas high doses (2.0-3.0 mg/kg) decreased rates. Of the 3 agonists, only quinpirole caused changes in sensitivity by producing a biphasic function of decreased sensitivities at low doses. Both d-amphetamine and quinpirole produced bias. These data indicate that a matching curve for concurrent VI schedules can be obtained within a single session using this procedure. In addition, this paradigm can be used to quantify the effects of alterations to the dopamine system on sensitivity to changes in reinforcement density and bias estimates. DISCRIMINATIVE STIMULUS CONTROL WITH OLANZAPINE: GENERALIZATION TO THE ATYPICAL ANTIPSYCHOTIC CLOZAPINE. S. E. Strong* and J. H. Porter. Psychology Dept., Virginia Commonwealth University, Richmond, VA 23184.

Olanzapine (Lilly & Co.) is a putative atypical antipsychotic that is currently being tested in clinical trials. Preclinical behavioral and pharmacological testing have revealed a profile very similar to the atypical antipsychotic clozapine. For example, in rats trained to discriminate clozapine from vehicle, olanzapine (1.25 mg/kg) substituted for clozapine, suggesting that olanzapine has discriminative stimulus properties similar to that of clozapine (Moore et al., 1992). The purpose of the present study was to determine if rats could be trained to discriminate olanzapine from vehicle in a two-lever discrimination procedure and, if so, if olanzapine would generalize to clozapine.

Initially, discrimination training with 22 rats was attempted with a training dose for olanzapine of 1.0 mg/kg (i.p.). Because of significant suppression of response rates, the training dose was reduced to 0.5 mg/kg and then to 0.25 mg/kg for 8 rats. For the 0.5 group, 11 of 14 rats acquired the two-lever discrimination (mean of 41.0 training sessions) and generalization testing (0.3125 to 2.0 mg/kg) yielded an ED $_{50}$ of 0.18 mg/kg (95% C.I. = 0.13 to 0.24 mg/kg). For the 0.25 group, 4 of 8 rats acquired the discrimination (mean of 48.0 sessions). No ED $_{50}$ was calculated as % drug lever responding was not below 50%. Clozapine fully substituted for olanzapine in all rats at one or more of the doses tested (0.156 to 10.0 mg/kg). These results support the suggestion that olanzapine has discriminative stimulus properties similar to clozapine, demonstrate that there is symmetrical generalization between olanzapine and clozapine, and support the conclusion that olanzapine has an atypical antipsychotic profile similar to that of clozapine in preclinical tests.

EFFECTS OF REPEATED ADMINISTRATION OF A LOW DOSE OF THE D2 AGONIST QUINPIROLE ON THE STIMULUS PROPERTIES OF D1 AND D2 DOPAMINE AGONISTS, M.J. Pokora,* and D.A. Cory-Slechta. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642. In the absence of tolerance, repeated administration of a presynaptic dose of the D2 agonist quinpirole (QUIN) might be expected to result in a sustained decrease in dopamine (DA) release and eventual DA receptor supersensitivity. If so, it could enhance the stimulus properties of D1 and D2 DA agonists. Bats were trained to discriminate the stimulus properties.

In the absence of tolerance, repeated administration of a presynaptic dose of the D2 agonist quinpirole (QUIN) might be expected to result in a sustained decrease in dopamine (DA) release and eventual DA receptor supersensitivity. If so, it could enhance the stimulus properties of D1 and D2 DA agonists. Rats were trained to discriminate the stimulus properties of either 0.05 mg/kg of the D2 agonist QUIN, or 6.0 mg/kg of the D1 agonist SKF38393 from saline using standard operant drug discrimination procedures. Following the determination of dose-effect curves for the training drug, drug discrimination was suspended and repeated twice daily injections of either saline or 0.05 mg/kg QUIN separated by 12 hr were initiated for 4-weeks. During the final 2 weeks of repeated QUIN, the first dose was replaced by a drug discrimination substitution test every other day to re-establish the training drug dose-effect curves. QUIN sensitivity was increased and SKF38393 sensitivity marginally increased by chronic saline administration, as indicated by average decreases in the ED₆₀ values derived from the dose-effect curves of 28% and 19%, respectively. In contrast, QUIN sensitivity decreased and SKF38393 sensitivity marginally decreased in response to chronic QUIN administration, as indicated by average increases of 27% and 28%, respectively, in dose-effect curve ED₅₀ values. Sustained D2 DA autoreceptor agonism thus appears to attenuate both D1 and D2 DA agonist stimulus properties. These data could indicate that DA tolerance develops with repeated low dose QUIN treatment with recovery occurring following its cessation, as indicated by increased sensitivity following chronic saline administration.

GRADUAL SLOWING IN RATS' RHYTHM OF LICKING
BEHAVIOR AS CHRONIC HALOPERIDOL DOSING ENSUES:
IMPLICATIONS FOR RODENT MODELS OF NEUROLEPTICINDUCED DYSTONIA AND PARKINSONISM. S.C. Fowler*
and G. Wang. Dept. of Human Development, Univ.
of Kansas, Lawrence, KS 66045.
Earlier reports indicated that acute

Earlier reports indicated that acute haloperidol treatment (0-0.24 mg/kg) dose-relatedly decreased force of rats' tongue contact with a force-sensing disk, but rhythm of licking, as quantified by power spectrum analysis, was little affected at these acute doses. We report here that chronic daily doses of 0.24 mg/kg haloperidol produced a gradual slowing of the lick rhythm that first became detectable after about 10 days and continued to slow through the 21-day dosing period. This effect was not observed for lower haloperidol doses (0.06 and 0.12 mg/kg, in separate groups of 12 rats each). Over the same time period, all three doses produced an enduring and doserelated tongue-force deficit that remained stable compared to the vehicle control group. Early tongue-force deficits induced by haloperidol may be related to acute dystonia, whereas the later developing rhythm slowing maybe reflective of concurrent dystonia and parkinsonism. Supported by MH43429.

CHOLECYSTOKININ ATTENUATION OF SKF 38393-INDUCED BEHAVIOURS DOES NOT INVOLVE REMOVAL OF DOPAMINE D2 RECEPTOR ACTIVITY.

J.M. Van Kampen* and A. Jon Stoess!. Clin. Neurol. Sci., University of Western Ontario, CANADA

The neuropeptide cholecystokinin (CCK) is known to interact with dopamine in various ways. We have demonstrated that CCK-8S effectively attenuates dopamine D, receptor mediated vacuous chewing movements (VCMs) and grooming. This ability of CCK to attenuate behavioural responses to a direct-acting agonist, suggests a postsynaptic action. However, for some dopamine-mediated behaviours dopamine D, and D, receptors demonstrate a synergistic relationship, requiring activation of both receptor types for their expression. In this context, attenuation of presynaptic dopamine release could alter the effects of a dopamine D, receptor agonist. In these experiments we sought to determine the role of dopamine D, receptors in the attenuation of SKF 38393-induced VCMs and grooming by CCK. Acute dopamine depletion by reserpine and amethyl-p-tyrosine in male Sprague Dawley rats blocked SKF 38393-induced VCMs and grooming (5 mg/kg s.c.) suggesting that tonic dopamine D, receptor activation may play an important role in the expression of these behaviours. However, this effect was not reversed by concurrent administration of the dopamine D, receptor agonist quinpirole (10, 30, 50 µg/kg i.p.). As well, in non-depleted animals, quinpirole potentiated the effects of CCK on both SKF 38393-induced VCMs and grooming. These data suggest that while CCK attenuation of presynaptic dopamine release remains a possible means of action, removal of tonic dopamine D, receptor activative does not appear to be involved.

ANXIOLYTIC EFFECT OF POLYAMINES MICROINJECTED INTO THE DORSAL PERIAQUEDUCTAL GRAY MATTER. A.P. Carobrez and J.G. Pereira-da-Cruz, Depto. de Farmacologia, CCB, UFSC, Florianópolis, SC, 88040-900

The relationship of the dorsal periaqueductal gray matter (DPAG) and anxioselective effects of drugs acting at the N-methyl-D-aspartate receptor (NMDAR) have been examined recently by our group. In brief, compounds applied within DPAG, that depress NMDAR/glycine-receptors, showed anxiolytic effects, whereas agonists of the glycine-site at the NMDAR exhibit a anxiogenic profile. NMDAR complex also supports binding sites for the polyamines and a dose-dependent effect, potentiation or inhibition of the NMDAR channel currents can be obtained. In the current studies the behavioral effects of spermidine (SD) or spermine (SP) into DPAG were analysed using male Wistar rats, with a chronically implanted cannula aimed to DPAG, placed in the elevated plus-maze test (EPM). An increase (p<0.05) in the open arms exploration, was observed after the microinjection (0.4 μ l) of 0.62 nmol of SD [Rao R(10,116)=2.33; p<0.05] or of 2.5 nmol of SP [Rao R(8,80)=2.49; p<0.05] into DPAG. The anxiolytic effect of 2.5 nmol SP $(0.2~\mu)$ was blocked in rats previously (5 min) microinjected (0.2 µl) with ifenprodil (5 nmol) or arcaine (4 nmol) into DPAG. In addition, SP (2.5 nmol, 0.2 µl) failed to show an increase in open arms exploration of rats pre-treated (5 min) with glycine (80 nmol, 0.2μ l). However, previous (5 min) treatment with \pm HA-966 (50 nmol, 0.2μ l) revealed an increase in open arms exploration in an ineffective dose of SP (1.25 nmol, 0.2μ l). The data obtained show that the anxiolytic action of the polyamines microinjected into DPAG is due to its action at the polyamine site of the NMDAR, sensitive to the specific antagonists, ifenprodil and arcaine. The data obtained also shows an interference on the anxiolytic action of polyamines applied to DPAG with compounds binding at the glycine sites of the NMDAR channel complex Supported by: Brazilian Government: CNPg and CAPES

COMPARISON OF THE BEHAVIORAL EFFECTS OF SELECTIVE INHIBITORS OF PHOSPHODIESTERASE TYPES (PDE2, PDE3, PDE4, AND PDE5). S. Frith. R.E. Maloney*, and J. M. O'Donnell. LSU Medical School, Shreveport, LA 71130.

Selective inhibitors of PDE4, such as rolipram, have been shown to produce antidepressant-like effects on a number of behaviors, including behavior maintained under a differential-reinforcement-oflow-rate (DRL) schedule. In order to begin to determine whether similar effects are produced by selective inhibitors of other PDE types, the effects of the PDE2 inhibitor trequinsin, the PDE3 inhibitor milrinone, the PDE4 inhibitors rolipram and Ro 20-1724, and the PDE5 inhibitor zaprinast on the behavior of rats maintained under variable interval (VI) 30-sec and DRL 72-sec schedules were determined. For comparative purposes, the effects of the tricyclic antidepressant desipramine also were determined. At the higher antidepressant desipramine also were determined. At the higher dose ranges tested, all drugs reduced response rate under the VI schedule, except for milrinone; at lower doses, trequinsin (3, 5.6 mg/kg), milrinone (3 mg/kg), rolipram (0.003 mg/kg), and desipramine (0.03 mg/kg) increased response rate. Only desipramine and rolipram produced clear antidepressant-like effects on DRL behavior, reducing response rate and increasing reinforcement rate; Ro 20-1724, however, did tend to increase average reinforcement rate. Selective inhibitors of PDE2, PDE3, and PDE5 did not produce antidepressant-like effects on DRL behavior. The pattern of behavioral activity of the selective PDE4 inhibitors most closely resembles that of the proven antidepressant desipramine. (Supported by grants from NIMH.)

530.10

AGING AND RESPONSES TO PROPOFOL IN RATS - R. Dirksen*, C.M. VanRijn. <u>J. VanEgmond, E.L.J.M. VanLuijtelaar, T. Vree</u>. Inst. Anesthesiology, Psychology NICI, Nijmegen University, Postbus 9101, 6500 HB Nijmegen, The Netherlands.

Aging may result in changes in GABA transmission and this transmission is essential to effects of various anesthetics including propofol ^[1]. This study compares effects of propofol between elderly and young adult WISW rats. No age-dependent differences were found in the incidence of narcosis (4 -20 mg/kg⁻¹) or in the potency of propofol to inhibit withdrawal reflexes to noxious stimuli (ED₃₀: 1.2 mg/kg⁻¹). The brain concentrations at given doses were similar for the two groups. The time course of these effects was however different, the narcosis lasted longer in the elderly than in the young adult animals (20 mg kg $^{-1}$: 25 min v. 17 min) and the reflex inhibition had a slower onset (t_{v_s} : 0.7 min v. 0.3 min) and a slower decay (t₄: 16 min v. 7 min) in the elderly than in the young adult rats. Noteworthy, plasma concentrations at given doses were higher in elderly than in young adult rats, and the $t_{\rm A}$ of plasma propofol was 8 min for the two groups. The elderly rats showed a greater reduction in heart rate and a higher incidence of apnea than the young adult rats. Moreover, propofol elicited a number of behavioral elements. The incidences of tail flicks, head and body shakes, and walking difficulties were lower in the elderly rats than in the young adult ones, whereas vacuous chewing occurred more often in the elderly than in the young adult animals. The observed shakes and walking difficulties are proposed to express abruptness of disruption of signal transfer in the central nervous system and consequently the transfer of faulty information to parts of the receiving neuronal networks during the transit between the awake and narcotic state [3]. The elderly rats showed a lower incidence of both items and recovered more slowly from narcosis. A higher incidence of vacuous chewing in elderly rats may reflect a low GABA activity in the substantia nigra, pars reticulata ^[1] [1] Dirksen, R. et al.: Abstr. Soc. Neurosci. 20: 1360; 1994. [2] Dirksen, R. et al.: Eur. J. Anaesth. S3: 41-49; 1990. [3] Cools, A.R. et al.: Ann. NY Acad. Sciences Vol. 525, 1988: 338.

THE EFFECTS OF TROPICAMIDE ON MYDRIASIS IN YOUNG RATS EXHIBITING A NATURAL DEFICIT IN PASSIVE-AVOIDANCE RESPONDING RD Smith.* CA Morgan & VL Coffin Schering-Plough Research Institute, Kenilworth NJ 07033.

The young rat at post-natal day 18-22 exhibits a natural deficit in

passive-avoidance responding that can be corrected with the acute systemic administration of different cholinomimetic drugs, such as tacrine (Smith et al., 707 pp13-21, 1996). In order to evaluate the generality of this apparent cholinergic hypofunction, different doses of the anticholinergic agent, tropicamide, were administered either systemically or dropped directly into the eye of young or adult rats. Tropicamide produced mydriasis in a dose-dependent manner. The ED50 for tropicamide dropped into the eye was 0.12% for adult rats and 0.25% for young rats. When doses between 0.3 and 100 mg/kg were delivered systemically, the mean time course for recovery to baseline pupil size systemically, the mean time course for recovery to baseline pupil size was accelerated in young rats. The average time to recovery across all doses was 112 ± 27 min (mean \pm SE) for young rats and 274 ± 70 min for adults. When subcutaneous tacrine was given immediately to young rats after training in a passive-avoidance response (PAR) task, retention was enhanced at testing 24 hours later in a dose-dependent manner. The response latencies were statistically different from saline-treated controls at doses of 0.003 and 0.01 mg/kg. This was not observed in adult rats. Taken together, these results suggest that the PAR, in addition to the mydracy response of the young rat to troiciamide may addition to the mydriacyl response of the young rat to tropicamide, may be regulated by a system of subsensitive cholinergic receptors.

530.14

EFFECTS OF SCOPOLAMINE ON DRL RESPONSE RATE IN RATS GIVEN TRIMETHYLTIN. J. N. Freeman, III, R. H. Baisden and M. L. Woodruff*. Dept. of Anat. & Cell Biol., Quillen Coll. Med., E. Tenn. St. Univ., Johnson City, TN 37614.
Trimethyltin (TMT) produces obvious gross damage to the hippocampus. Many of the

behavioral changes that follow TMT exposure can be attributed to hippocampal damage. TMT also significantly reduces the number of cholinergic muscarinic receptors in hippocampus (Earley et al., Neurochem, Int., 21, 351-366, 1992; Cannon et al., Mol. Chem. Neuropath, 23, 47-62, 1994). Because of the general damage caused to the hippocampus by TMT it is difficult to attribute specific behavioral changes to alterations in muscarinic receptors produced by the toxin. However, it could be that the TMT-induced reduction in muscarinic receptors under the state of the country of the state of the toxin. induced reduction in muscarinic receptors might alter behavioral response to anti-cholinergic agents. This possibility was examined in the present experiment. Twentytwo male Long-Evans rats were trained to respond for a food reinforcement on DRL schedules with gradually increasing intervals until the interval reached 15 s. Twelve of the rats were then given 6 mg/kg TMT (p.o.). Testing on the DRL schedule was resumed 6 wks later with a 3 s interval. The interval was increased by 2 sec every 5 days until it reached 15 s. After 10 wks of training the rate of response did not differ statistically between the groups and daily saline injections were begun. These were continued for 2 wks and then injections of 0.1, 0.2, 1, 1.5, 2 and 3 mg/kg of scopolamine were given in a random order with 5 days separating each injection. Saline injections were given on the days that scopolamine was not given and injections of methscopolamine that were control tasks that sopolarimite was not given and injections in heliosopolarimite that we equimolar to the 1, 2 and 3 mg/kg doses of scopolarimite were randomly interspersed. The 0.1 mg/kg dose increased responding in both groups and increased response rate in the TMT-treated rats more than controls. The 0.2 dose increased response rate in the control rats but not the TMT-treated rats. The higher doses decreased response rate in both groups, but significantly more in the TMT-treated rats. The 3 mg/kg methscopolamine injection reduced responding equally in both groups. These data indicate that pharmacologic challenge can reveal a behavioral effect of the reduction muscarinic receptors produced by TMT. (Supported by NIH grant ES 0407003-08.)

ROLE OF NITRIC OXIDE IN THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS: MAINTENANCE OF NORMAL SLEEP.
S. Datta*, E. Patterson, Z. Xie and D. F. Siwek, Dept. of Psychiatry, Harvard Med. School, Boston, MA 02115 & VA Hosp., Bedford, MA. Mesopontine cholinergic cells in the pedunculopontine tegmental (PPT) nuclei modulate the control of behavioral states by releasing acetylcholine to their target structures (Datta, Neurosci, Biobebay, Rev.

Mesopontine cholinergic cells in the pedunculopontine tegmental (PPT) nuclei modulate the control of behavioral states by releasing acetylcholine to their target structures (Datta, Neurosci. Biobehav. Rev. 19:67-84, 1995). These cells also synthesize nitric oxide (NO). This NO diffuses into the extracellular space and acts as a neuronal messenger. The present study examines the function of NO synthesis and its presence in the extracellular space in the PPT in the behavioral states of waking and sleep. Cats (n=5) were implanted with standard electrodes to measure states of waking, Slow-wave sleep (SWS), and REM sleep and with bilateral guide tubes for PPT microinjection. Five hr. free-moving polygraphic recordings were made following each of 3 discrete PPT microinjections (n_i) of: control saline (n_i=10, 0.25 μl); NO donor, S-Nitroso-N-acetylpenicillamine (SNAP, n_i=10, 3mM); competitive inhibitor of NO synthase enz., N^G-Nitro-L-arginine methylester hydrochloride (L-NAME, n_i=5, 10 mM). Following PPT microinjection of SNAP, SWS and REM sleep was increased by 50% and 67% respectively compared to the control microinjection. Microinjection of L-NAME reduced SWS and REM sleep by 32% and 58% respectively compared to control microinjection. The present result demonstrates that endogenous NO synthesized within the PPT cells functions as a paracrine signal in the control of behavioral states of sleep and waking by modulating local cholinergic cells. [Supported by grants from NIH, NS 34004-01A1 NEUA and William F. Milton award from Harvard Medical School to S. Datta].

UNIQUE BEHAVIORIAL EFFECTS OF A METABOLITE OF FELBAMATE; GLYCINE-LIKE?VL Coffin,* M Cohen-Williams. ME Grzelak & RD Smith. Schering-Plough Research Institute, Kenilworth NJ

Felbamate (2-phenyl-1,3-propanediol dicarbamate) is a novel antiepileptic with a unique structure and mechanism of action, possibly involving glycine sites at the N-methyl-d-aspartate (NMDA) receptor complex. A monocarbamate metabolite of felbamate (SCH 54388), was compared to felbamate in tests of pharmacological activity. The anticonvulsive effect of these two compounds was studied in three rodent models (CF-1 mice): NMDA-induced, electroshock (ECS)-induced, and pentylenetetrazol (PTZ)-induced convulsions. SCH 54388 weakly prevented NMDA-induced convulsions. SCH 54388 weakly prevented NMDA-induced convulsions. SCH 54388 weakly prevented NMDA-induced convulsions (0.5mmol/mouse) and ECS-induced convulsions (50 mA, 60 HZ, 0.2s through corneal electrodes) at 74 and 173 mg/kg-sc, respectively. These doses were 4 to 5-fold larger than effective doses of felbamate in the same models. In contrast, SCH 54388 potently prevented tonic convulsions produced by 100 mg/kg of PTZ, with an ED50 of 1.0 mg/kg-sc. Felbamate was 100-fold less potent in this test. Glycine did not block the effects of SCH 54388 in any of the models and was itself active in the PTZ-induced seizure model. Furthermore, SCH 54388 (0.01-10 mg/kg-sc. po) was able to prevent cognitive deficits produced with either scopolamine or MK-801, a non-competitive NMDA channel-blocker, on the mouse passive-avoidance response.

NOREPINEPHRINE ALTERS THE CENTRALLY CONTROLLED RATE AND PERIPHERALLY CONTROLLED WAVEFORM OF THE ELECTRIC SIGNAL IN A WEAKLY DISCHARGING ELECTRIC FISH. C. Lin. S. G. Gupta. L. I. Perrotti and R. E. Landsman*. Academy for the Advancement of Science and Technology, Lab. of Behavioral Ichthyology, 200 Hackensack Ave., Hackensack, NJ 07601. This study investigated the effects of norepinephrine (NE) on the electric organ discharge (EOD) in the weakly discharging electric fish, *Brienomyrus brachyistius*. Characteristics of this EOD are both centrally- and peripherally-controlled. Fish received either a NE or a vehicle control injection, or served as nonhandled controls. For each fish, both EOD rate data, taken every 5 seconds for 3 minutes, and one EOD were collected pre-treatment, post-treatment, 15 minutes post-treatment, and 30 minutes post-treatment. Pre- and post-treatment comparisons were made for both mean EOD rates and phase durations (expressed as % of pre-treatment). Two-way ANOVAs with repeated measures on one factor indicated significant condition x treatment period interactions for EOD rate [F(6.81) = 9.54, p < 0.0000005], durations of phases 2 [F(6.81) = 9.07, p < 0.000005] and 3 [F(6.81) = 2.79, p = 0.016], and for total EOD duration [F(6.81) = 3.48, p = 0.004]. Tests for simple main effects followed by multiple comparisons indicated that EOD rate decreased directly following the NE injection, differing from both controls, and remained at this level through 30 minu post-treatment. The durations of phases 2 and 3 increased 15 minutes after the NE injection, differing from both controls, where they remained through 30 minutes postinjection, differing from the vehicle control. No significant NE effects were found on the durations of phases 1 or 4. Neither EOD rate, nor EOD phase or total durations changed in the vehicle or nonhandled control fish over the study period. NE-induced changes in the centrally controlled EOD rate and the peripherally controlled EOD shape suggest that the EOD could serve as a model for the study of the simultaneous effects of neurotransmitters on peripherally- and centrally-mediated behavior. DETECTION OF, AND SCOPOLAMINE REVERSAL OF, LOW-DOSE PHYSOSTIGMINE-INDUCED INCREASES IN FORELIMB TREMOR IN THE RAT. J.A. Stanford* and S.C. Fowler. Dept. of Human Development, Univ. of Kansas, Lawrence, KS 66045.

The effects of the cholinesterase inhibitor physostigmine (<= 0.1 mg/kg) and the antimuscarinic scopolamine (<=0.2 mg/kg) were assessed separately and in combination in rats

The effects of the cholinesterase inhibitor physostigmine (<= 0.1 mg/kg) and the antimuscarinic scopolamine (<=0.2 mg/kg) were assessed separately and in combination in rats trained to use a single forelimb to exert 5-s bouts of continuous pressure on a forcesensing operandum. Power spectrum analysis of the resulting force-time recordings indicated that 0.1 mg/kg physostigmine substantially increased power in the 10-25 Hz frequency band (i.e., increased tremor), and this effect was completely reversed by 0.1 mg/kg of scopolamine HCl. Neither drug nor their combination affected power in the lower 5-9.9 Hz frequency band. The peak force observed at the beginning of each 5-s "response" was increased by physostigmine, decreased by scopolamine, and returned to vehicle levels when the drug treatments were combined. At doses low enough to permit the expression of operant behavior, cholinergic mechanisms adequately account for physostigmine's tremorogenic effects. Supported by MH43429.

THE CRITICAL ROLE OF NUCLEUS ACCUMBENS IN THE MEDIATION OF FIXED-INTERVAL SCHEDULE-CONTROLLED BEHAVIOR. D.A. Cory-Slechta*, R. Pazmino, M.J. Pokora and C. Bare. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Bare. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642. Low-level lead exposure selectively alters nucleus accumbens (NAC) dopamine (DA) binding and reliably modifies fixed-interval (FI) schedule-controlled behavior. To determine whether any relationship existed between these behavioral and binding effects of Pb, the role of NAC DA systems in mediating FI performance was assessed in noraml rats during daily 30 min sessions. Rats were first trained on a FI 1 min schedule of food reinforcement until behavior stabilized, At that point, the comparative effects of the irreversible DA antagonist EEDQ (90-150 ug total dose in a volume of 0.25 ul/side) microinjected bilaterally into either dorsal striatum (DS) or NAC on FI performance was examined in groups of 9 rats each. EEDQ microinjections into NAC produced doserelated decreases in FI response rates to levels of 40-70% of control over the first 1-2 subsequent sessions. Rates gradually recovered over 4-6 sessions. EEDQ microinjections into DS had no impact on FI performance. Sparing either D1 or D2 receptors by treatment with either the D1 antagonist SCH23390 (0.15 mg/kg) or the D2 antagonist eticlopride (0.1 mg/kg), respectively, prior to EEDQ microinjection into NAC restored FI response rates, and activation of D1 receptors alone (SCH23390 co-treatment with EEDQ) actually increased FI response rates above control levels. These data demonstrate that NAC DA function is critical for the mediation of normal F1 performance. The increased FI rates when only D1 NAC receptors are activated could reflect loss of D2 presynaptic control over DA synthesis and release. ES05017, ES05903 and ES01247.

FLUORIMETRY AND UNIFORM ROBOT-MADE CORTICAL PYRAMIDAL CULTURES MONITOR NEUROTRANSMITTER RECEPTOR MODULATION BY PHARMACEUTICAL AGENTS, <u>L.A. Riblet</u>, <u>B.D.Stein</u>, <u>R.M. Villalba and A.H. Cornell-Bell</u>. Viatech Imaging, Ivoryton, CT 06442.

Primary cortical cultures (>85% neurons) are constructed in 96 well

Primary cortical cultures (285% neurons) are constructed in 96 well Primaria plates (Falcon) using a fluid-handling robot (Tomtec Quadra 96). Neurofilament, GFAP and myelin basic protein and total DNA levels (SYTO-17, Molecular Probes) are measured on a CytoFluorII fluorimeter (PerSeptive Biosystems) to determine % of neurons, astrocyte and oligodendrocytes. DNA levels vary little from well to well (mean= 3.9% difference with S.E.= 0.89). Cell viability is monitored (Live Cell/Dead Cell). All dye loading and agonist or antagonist additions are made by robot. The Ca²+ dye Fluo3AM has been used to monitor receptor activation following robot addition of glutamate, GABA, ACh, norepinephrine, dopamine, 5HT, neuropeptides (VIP, NPY, and Substance P) and growth factors (IGF-1, NGF and EGF). Fluorescence is read pre and post agonist addition. Ca²+ in measurements are determined by a macro (Excel5.0) which determines %change in fluorescence (deltaf/F). This technology is sensitive enough to monitor effects of antagonists (MK801 and CNQX) on glutamate receptor subtypes (t-ACPD, kainate, AMPA and NMDA; all 100uM) at time courses extending from 15 sec to 3.0 min. Ca²+ in following KCI (1-50mM KCI) has been inhibited using Nimodipine (Bayer Pharmaceuticals) demonstrating the sensitivity of this system. Membrane potential changes (di-8 Anepps) following KCI depolarization and pH changes (BCECF) in response to extracellular matrix interactions have also been determined. Pharmaceutical effects on receptor activity in primary cortical cultures can be screened. These methods are sensitive enough to monitor second messenger signalling.

DOWN REGULATION OF α 2-ADRENERGIC

RECEPTORS BY HYPOXIA. N.R.Prabhakar*, D.Kline, P.Ernsberger S.Bibevski, and J.R.Romaniuk, Dept. of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH 44106.

Chronic hypoxia has long term physiological consequences and adaptations. In the present study, we examined the effects of prolonged hypoxia on α_2 -adrenergic receptors. Experiments were performed on rats exposed either to normoxia (n = 12) or to 24 hr. of hypobaric hypoxia (0.4 ATM; n = 12). Following which they were anaesthetized, artificially ventilated and bilaterally vagotomized. Arterial blood pressure, efferent phrenic and cervical sympathetic nerve activities were recorded. Systemic administration of guanabenz, an α_2 adrenergic receptor agonist inhibited respiratory rate in a dose-dependent manner with maximal responses seen at 60 and 100 μ g (37 \pm 8.4 % of control) without affecting the amplitude of the tidal phrenic nerve activity. Sympathetic nerve activity was augmented by about 40% at doses of guanabenz that depressed breathing. The effects of guanabenz appear to be of central nervous origin as they were unaffected by denervation of the carotid bodies. In animals exposed to 24 hr of hypokaric hypoxia, guanabenz-induced respiratory inhibition and sympathetic excitation were either markedly attenuated or abolished. [125 I] p - iodoclonidine binding analysis of rat brain membranes showed significant decreases (50 %) in α_2 -adrenergic receptor density in the dorsal but not in ventral pons-medulla of animals exposed to hypoxia. These results demonstrate that hypobaric hypoxia down regulates α_2 -adrenergic receptors in the brain stem in a regional specific manner and attenuates or abolishes the physiological responses to α_2 -adrenergic receptor agonist. Supported by NIH HL-45780 and HL-02599.

CHRONIC IMIPRAMINE TREATMENT MODULATES IMIDAZOLINE RECEPTORS IN RAT BRAINSTEM. H. Zhu, I. Paul, A. Halaris, J. E. Piletz*. Dept. of Psychiatry and Human Behavior, Univ. of Mississippi Medical Center, Jackson, MS 39216

Previous studies have suggested that α2-adrenoceptors as well as Previous studies have suggested that α_2 -adrenoceptors as well as nonadrenergic imidazoline receptors (subtypes IR_1 and IR_2) are linked to depression. In this study we have measured α_2 and I_1 -imidazoline binding sites with [${}^{18}IJ_{p}$ -iodoclonidine and I_2 -imidazoline binding sites with [${}^{18}IJ_{p}$ -iodoclonidine and assessed the effects of chronic imipramine treatment in vivo on these sites. The nonadrenergic IR_1 and IR_2 binding sites were assessed under a I0 μM NE mask of α_2 -depressed to the contractor of the same parameters. It, and Ik₂ binding sites were assessed under a 10 μ M NE mask of α_2 -adrenoceptors. Compared with saline-treated controls, impramine treatment (i.p.,20mg/kg/day for 25 days) had no effect on the density (Bmax) or affinity (K_D) of α_2 -adrenoceptors in brainstem membranes. However, the treatment decreased significantly the density of brainstem I₁-binding sites with no change in radioligand affinity in a dose dependent manner (minimum effective dose, i.p. 10mg/kg/day). Furthermore, it was found that 25 days o impramine treatment (i.p.,20mg/kg/day) could also lead to a significant enhancement in the density of IR₂-binding sites with no influence on the affinity. These results suggest that brainstem I₁-imidazoline receptors as well as I₂-imidazoline receptors might be targets for antidepressants. Supported by NIH grants MH49248 and MH42859

PERIPHERAL TARGETS INFLUENCE EFFICACY OF Synaptic transmissision between preganglionic and sympathetic neurons <u>p Devay^ed S McGehee and L W</u> Role. Dept of Anat and Cell Biol, Ctr for Neurobiol & Behav P&S, 722 W 168th St NY, NY 10032:

Sympathetic neurons innervate a variety of targets in vivo. Earlier studies showed that target contact influences the ACh responsiveness and the expession of nAChR subunit genes in embryonic chick autonomic neurons (Levey et al., Neuron 14: 153 1995. Devay et al., NS Abstr. 528.20,1995). Furthermore, distinct targets differentially after the profile of nAChR subunit genes expressed by sympathetic neurons. Thus co-culture of sympathetic neurons with embryonic kidney increases the magnitude of ACh-evoked currents, while heart co-culture decreases the responses. The profile of nAChRs channel subtypes are also differentially regulated by these targets (Devay et al., NS Abstr. 528.20,1995). In view of these findings we examined the impact of these target on synaptic

Naive sympathetic neurons were co-cultured with heart or kidney and innervated by preganglionic spinal cord explants. In control cultures, neurons were innervated by preganglionic neurons but no target was present. Spontaneous miniature EPSCs were recorded from sympathetic neurons and the expression level of nAChR subunits were examined in neurons and the expression level of inAcint submits were examined interes neurons. While innervation alone increases the levels of $\alpha 3$, $\alpha 5$ and $\beta 4$ mRNAs, input plus target greatly augments the levels of $\alpha 5$ mRNA relative to $\alpha 3$ and $\beta 4$. Examination of sympathetic neurons innervated in the presence of target also reveals significant increases in the amplitude of the synaptic currents compared with neurons innervated without heart or the synaptic currents compared with neurons innervated without heart or the synaptic currents compared by the form of the synaptic currents compared that target contact influences the kidney. These studies suggest that target contact influences the expression profile and/or distribution of nAChRs at sites of synaptic input on sympathetic neurons (supported by NS29071).

REGULATION OF α₂₄-ADRENERGIC RECEPTOR MRNA GENE EXPRESSION BY FORSKOLIN AND PHORBOL ESTER. M. A. Reutter*, E. M. Richards, and C. Sumners. Dept. of Physiology, College of Medicine, Univ. of Florida, Gainesville, FL 32610

Treatment of rat astroglial cultures with an adenylyl cyclase activator forskolin (FSK) or a PKC agonist phorbol 12-myristate 13acetate (PMA) resulted in time- and concentration-dependent decreases in steady state levels of α_{2A} -adrenergic receptor (α_{2A} -AR) mRNA. Membrane permeable analogues of cAMP induced decreases in a2A-AR mRNA to levels similar to those seen with FSK treatment (to 10-20% of control levels), indicating that the FSK-mediated decrease was due to increases in intracellular cAMP concentration. Analysis of cAMP content confirmed that FSK increased the cAMP content in these cultures of rat astroglia. Activation of PKC with phorbol 12, 13-dibutyrate or mezerein produced decreases in α_{2A} -AR mRNA levels similar to those seen with PMA, indicating that PKC also regulates this message. The degradation rate of the α_{2A} -AR mRNA (t_{1/2} ≈ 2 hr) did not change with FSK or PMA treatment, suggesting that the decreased steady-state levels observed were due to decreases in transcription of the α_{2A} -AR gene. (Supported by NIH grant NS-19441 to CS and an AHA-FL Affiliate graduate student fellowship to MAR)

ADRENALECTOMY DOES NOT PREVENT FLUOXETINE-INDUCED DESENSITIZATION OF 5-HT_{1A} AUTORECEPTORS IN THE RAT DORSAL RAPHE NUCLEUS. E. Le. Poul. N. Laaris. M. Harnon and L. Larfurney. INSERM U288, CHU Pritié-Salpétinère, 91 Bild de l'Hôpital, 75634 Paris cedex 13, France. Electrophysiological studies have shown that somatodendritic serotonin 5-HT_{1A} autoreceptors in the dorsal raphe nucleus (DRN) desensitize upon their chronic stimulation by exogenous agonists or 5-HT (through the blockade of its reuptake by selective inhibitors such as fluoxetine) in rats. This functional desensitization might be due to an alteration of transduction mechanisms which involve Gi/Go proteins. In rats with elevated plasma corticosterone levels, expression of Gi has been found to be reduced as a result of chronic stimulation of glucocorticoid receptors (GRI). Since 5-HT_{1A} receptor activation leads to an increased secretion of corticosterone, we investigated whether this hormone, through its negative influence on Gi synthesis, could be responsible for the 5-HT_{1A} autoreceptor desensitization in rats treated chronically with the 5-HT transporter blocker fluoxetine.

receptor desensitization in rats treated with micro properties. To this end, experiments were performed on mesencephalic slices from adrenalectomized (ADX) or sham-operated Sprague-Dawley male rats which had been treated with fluoxetine (5 mg/kg/day i p.) or saline for 3 or 7 days. A single barrel micropipette (15 MΩ) filled with 2M NaCl was used for extracellular recording of 5-HT neurons by the direct 5-HT $_{\rm 1A}$ agonist ipsapirone was similar in ADX (IC $_{\rm 50}$ =74 nM) and in sham-operated (IC $_{\rm 50}$ =67 nM) rats which had been treated with saline for 3 or 7 days. Administration of fluoxetine for 7 days resulted in a shift to the right of the concentration-response curve of ipsapirone which was as pronounced in ADX (IC $_{\rm 50}$ =226 nM), +205% as compared to saline, P<0.05) as in sham-operated rats (IC $_{\rm 50}$ =67 nM), +205%, P<0.05). A significant desensitization of 5-HT $_{\rm 1A}$ autoreceptors was also found in both groups after only a 3-day treatment with fluoxetine. Combined treatment with the specific GR antagonist RU 38486 (25 mg/kg/day); s.c.) did not affect the fluoxetine-induced shift to the right of the inhibition curve of ipsapirone in sham-operated as well as in ADX rats. Because the potency of ipsapirone to inhibit the firing of DRN 5-HT neurons was reduced by fluoxetine treatment to the same extent in the absence (ADX) or the presence (sham-operated rats) of conticosterone, it can be concluded that this hormone does not participate in the functional desensitization of 5-HT $_{\rm 1A}$ autoreceptors in rats chronically treated with 5-HT uptake blockers.

ly treated with 5-HT uptake blockers

531.6

UPREGULATION OF $\alpha7$ NICOTINIC ACETYLCHOLINE RECEPTORS IN RAT HIPPOCAMPAL CULTURES: PHARMACOLOGICAL CHARACTERISATION.

S.Wonnacott* and A.T.Rogers. Sch Biol Biochem, Univ Bath, Bath, BA2 7AY, U.K. The α 7 nicotinic acetylcholine receptor (nAChR) subunit, which has been correlated with [125] aBgt binding, is particularly abundant in the mammalian hippocampus. Chronic nicotine treatment in vivo, and exposure of hippocampal cultures in vitro to 10 µM nicotine for 7 days leads to an upregulation of surface [123] aBgt binding sites (Barrantes et al., Brain Res. 672: 228-236, 1995).

To provide a comprehensive pharmacological characterisation of this response, high density primary cultures of E18 rat hippocampal neurons were treated with nicotinic agonists and antagonists for 7 days prior to [1251]αBgt (10nM) binding assays (Kd ≈ 1nM). In the absence of drugs, cultures expressed 59.5±6.3(n=17) fmol [1 binding sites / mg protein. The agonists cytisine (20 μ M), nicotine (10 μ M), DMPP $(10\mu M)$ and anatoxin-a $(10\mu M)$ significantly increased the number of binding sites by $28\pm9\%$, $34\pm4\%$, $38\pm12\%$, and $61\pm8\%$ respectively above control levels, whereas the muscarinic agonist muscarine had no significant effect. The antagonists methyllycaconitine (MLA;100nM) and d-tubocurarine (10μM) gave increases of 23±7% and 26±8% respectively, but the non-competitive antagonist mecamylamine $(10\mu M)$ was without effect. Co-application of nicotine $(10\mu M)$ and MLA (100nM)resulted in an increase of $23\pm4\%$, close to that seen with each drug alone. Depolarisation of the neurons with KCl (20mM) elevated [125 $\Pi \alpha Bgt$ sites by $52\pm12\%$, while veratridine (1µM) had no effect.

These results suggest that occupancy of the binding site may trigger the upregulation response. The ability of KCl depolarisation to produce a similar response may signify the operation of Ca2+-mediated mechanisms, as proposed by De Koninck & Cooper (J. Neurosci. 15: 7966-7978, 1995) in cultured rat sympathetic neurons This study was supported financially by BAT Co. Ltd.

DISTRIBUTION OF GLYCINE RECEPTORS ON ABDUCENS MOTONEURONS AFTER BOTULINUM TOXIN BLOCKADE OF NEUROMUSCULAR TRANSMISSION. B. Moreno-López[§], R. de la Cruz^{*}, A.M. Pastor, J. M. Delgado-García and F. J. Alvarez[§] Lab. de Neurociencia, Facultad Biología, 41012-Sevilla, Spain and (§) Dept. of Anatomy, Wright State University, Dayton, OH. High doses of botulinum neurotoxin type A (BoNT) alter firing and synaptic

properties of abducens motoneurons. Inhibitory synaptic potentials virtually disappear for at least 2 months (Soc. Neurosci. 21:749, 1995). We have analyzed the distribution of glycine receptors in cat abducens motoneurons after BoNT injection (3 ng/Kg) in the lateral rectus muscle. Gephyrin, a protein of the glycine receptor complex, was detected using immunofluorescence and electron microscopy immunohistochemistry in abducens motoneurons at 5, 19 and 35 days post-treatment Motoneurons were identified by their immunoreactivity to calcitonin gene-related peptide or by the retrograde transport of horseradish peroxidase.

By immunofluorescence we found a significant reduction in the density of glycine receptor clusters by 19 and 35 days post-injection as compared to control values whereas by 5 days no significant change was observed. These data correlated well with the ultrastructural analysis of gephyrin-immunopositive postsynaptic densities, which also revealed a parallel reduction in the density of glycinergic presynaptic boutons. The distribution of glycine receptors over the somatic membrane surface was homogeneous in both control and treated motoneurons. Previous physiological results indicated that inhibitory synaptic transmission is abolished as soon as 3 days after BoNT injection. Therefore, physiological alterations were more pronounced and preceded structural changes affecting the number of postsynaptic receptors. The drop in the number of glycine receptors following BoNT blockade can be explained as a down-regulation related to the lack of trophic influence from the target or by a direct action of the toxin itself on the motoneuron cell body and/or its presynaptic inputs. (Supported by DGICYT PB-1175, NIH 33555 and NATO CRG 960221).

GABA, RECEPTOR SUBUNIT CHANGES IN THE INFERIOR COLLICULUS MAY RESULT IN ENHANCED RECEPTOR FUNCTION IN AGED RATS.

J.C. Milbrandt*, T. Blomquist, and D.M. Caspary. Dept. of Pharmacology, SIU School of Medicine, Springfield, IL 62702.

γ-aminobutyric acid (GABA) acting through GABA_A receptors is critically

involved in processing acoustic information in the inferior colliculus (IC). The GABA, receptor is thought to exist as a pentameric complex composed of an unknown combination of at least 13 possible subunits. The IC contains high unknown combination of at least 15 possible subunits. The Contains man concentrations of GABA and high levels of GABA, receptor binding, mRNA, and subunit protein. It appears that presynaptic markers for GABA neurotransmission are reduced in the IC of aged Fischer 344 (F344) rats (Caspary et al., 1995). The present study attempts to compare GABA, receptor subunit mRNA levels to subunit protein levels in the IC of F344 rats: 3-, 18-, and 26-months of age.

Using in situ hybridization, no significant age-related changes were observed in

the mRNA hybridization levels of the most common $(\alpha_1, \beta_2, \gamma_2)$ GABA_A receptor subunits in the IC. However, significant age-related increases in the α_2 and γ_1 receptor subunit hybridization levels were detected in the IC. Follow-up Western studied no significant changes in the α_1 , β_2 , and γ_2 subunit proteins, but a significant age-related increase in the γ_1 subunit protein. Western blot results were similar in two rat strains, the F344 and F344/Brown Norway F1 hybrid.

Previous studies suggest that the α_2 and γ_1 subunits, when assembled into a

Previous studies suggest that the α_2 and γ_1 subunits, when assembled into a GABA, Chevitan et al., 1988; Puia et al., 1991; Ducic et. al., 1995). These findings are consistent with an age-related increase in the ability of GABA to modulate binding at the picrotoxin site (Milbrandt et. al., 1996). In addition, GABA evoked Cl flux in age rats maybe higher than in young adults (unpublished). Taken together, an age-related increase in the α_2 and γ_1 subunits may represent a compensatory upregulation in order to increase the sensitivity of IC GABA_A receptors to GABA, and therefore maintain functional levels of inhibition in aged rats (Supported by NIH DC 00151)

EFFECTS OF THE LIGHT/DARK VARIATIONS ON GLUTAMATE RECEPTOR UP-REGULATION IN THE RAT CEREBELLUM. T. Morcol, J.W. Patrickson, J. Springfield, K.H. Thomas, and J.A. Whittaker. Department of Anatomy, Morehouse school of Medicine, Atlanta, GA 30310.

We have previously shown that certain receptor subtypes in the rat basal ganglia varies with environmental light/dark cycles or circadian rhythms. In this study, we examined the effects of variations in light/dark cycle on total protein expression and on the expression levels of glutamate receptor subtypes in the rat cerebellum. Functionally, the cerebellum is import in the coordination of movement, posture, and balance. This study was designed to determine a possible role for light induced glutamate receptor modulation of cerebellar output activity. Adult male Sprague-Dawley rats were entrained to constant light and constant dark conditions for 24 and 48 hour periods. Cerebellar tissue extracts were prepared and integral membrane proteins were solubilized for total protein determination. Digitonin solubilized receptors were fractionated to evaluate changes in glutamate receptor subtype expression using SDS-PAGE and Western blotting techniques. Our findings indicate that exposure to 48 hour constant light significantly increased total protein expression (approximately 2.5 fold) in soluble cerebellar membrane preparations. Glutamate receptor subtypes GluR1 and GluR4 were also found to be noticeably increased following 48 hours of constant light exposures. Whether these AMPA type glutamate receptors are expressed as individual subtypes or co-expressed combination of GluR1-GluR4 subunits is still undetermined. No significant changes in GluR1 or GluR4 expression levels were observed in the cerebellum under constant dark conditions and no detectable signal was observed for the GluR2/3 subtype. Immunohistochemical analysis of cerebellar tissues exposed to varying light/dark conditions demonstrated results consistent with the Western blot data and may sugge possible light-induced receptor modulation of cerebellar functions.. INCREASED DENSITY OF RENAL PERIPHERAL BENZODIAZEPINE RECEPTORS IN AUTOIMMUNE MICE. R. Drugan* 1. Schrott 2. D. Healy 1 and L. Crnic 1. Dept. of Psychology, Univ. of New Hampshire, 2. Dept. of Pharmacology Univ. of Minnesota Medical School and 3) Depts. of Pediatrics and Psychiatry University of Colorado Medical School. The female NZB X NZW Fl hybrid (B/W) mouse spontaneously develops a lupus-like autoimmune disorder. In comparison to non-autoimmune controls from the paternal progenitor NZW strain, 12 week old B/W female mice show increased anxiety-related behaviors in the elevated plus maze and decreased exploratory drive in the novel object task. The Peripheral Benzodiazepine Receptor (PBR) is altered in both acute and chronic states of anxiety or stress. We examined the PBR in several peripheral tissues in both B/W and NZW mice 8-12 days following behavioral testing. Importantly, previous work has demonstrated that stressinduced PBR changes return to baseline levels within 24 hours. All subjects were sacrificed by rapid decapitation and peripheral tissues were dissected on ice, fast-frozen and stored at -80°C until assay. In vitro radioligand binding of [3H]Ro5-4864 to PBR was conducted in lung, heart liver and kidney for both groups. We observed a significant and consistent increase in renal PBR in B/W mice in comparison to the NZW controls. This effect was confirmed by Scatchard analysis indicating an increase in density (Bmax) and not affinity (Kd). No other differences were observed. Research supported by NIMH grants 45475,10643 and

VARIATIONS IN ENVIRONMENTAL LIGHT/DARK CYCLE INDUCED CHANGES IN GLUTAMATE RECEPTOR EXPRESSION IN THE RAT HIPPOCAMPUS. P. Nagappan, T. Morcol, J.W. Patrickson, G. Small, K.H. Thomas, and J.A. Whitaker. Department of Anatomy, Morehouse school of Medicine, Atlanta, GA 30310.

In this study, we investigated the effects of environmental light variations on the expression of glutamate GluR1-4 receptor subtypes in the rat hippocampus. Glutamate is known to play key roles in learning and memory, behavioral functions, and in the entrainment of the hypothalamic suprachiasmatic nucleus to environmental light/dark cycles. In addition, the loss of hippocampal neurons in Alzheimer's disease and in CNS ischemic insults have been correlated with excessive glutamate release, resulting in cell death or altered excitatory amino acid (EAA) receptor sensitivities. The mechanisms underlying changes in EAA receptor functions remain unclear however, and it is not known whether EAA regulation follows a circadian pattern. Adult male Sprague-Dawley rats were entrained to constant light and constant dark conditions for 24 and 48 hour periods. Rats housed under 12 h light/12 h dark conditions were used as controls. Soluble membrane proteins were prepared from hippocampal tissue extracts and SDS-PAGE and Western blot analysis were performed to evaluate changes in total protein and glutamate receptor subtype expression. Although no significant change in total protein concentration was observed at constant dark conditions, exposure to constant light resulted in 1.5 to 2 fold increases in hippocampal total protein expression within 48 hours. Exposure to constant light (24 h and 48 h) induced a noticeable decrease in GluR1 receptor subtype expression, whereas an approximate 2-fold increase was observed in 48- hours of constant dark exposure. No detectable signal could be obtained for the GluR4 or GluR2/3 receptor subtypes. Immunohistochemical assays confirmed data obtained from Western blot analysis All results will be discussed relative to hippocampal function. Support: NIH Grants GM08248, RR03034 and NASA Grant NCCW0083.

PROTON POTENTIATION OF ATP-ACTIVATED INWARD CURRENT IN SENSORY NEURONS. Chaoying Li*, Robert W. Peoples and Forrest F. Weight. Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse & Alcoholism, National Institutes of Health, Bethesda, MD 20892-8205.

We studied the modulation of ATP-gated ion channels by protons in rat nodose and bullfrog dorsal root ganglion (DGR) neurons using the whole-cell patch-clamp technique. Both in nodose and DRG neurons, reduced external pH enhanced, whereas elevated external pH suppressed, the ATP-activated current. The pH producing the half-maximal effect (EC₅₀) was 7.1 - 7.2. Proton potentiation of ATP-extivated current is the physical part of activated current was voltage-insensitive, and did not involve a shift in reversal potential. Lowering pH shifted the ATP concentrationresponse curve to the left, decreasing the EC50 for ATP, but did not alter the maximal response to ATP. Protons decreased the rate of deactivation without affecting the rate of activation of ATP-gated ion channels, which is consistent with an increase in the affinity of ATP for its receptor rather than an increase in the concentration of one or more active forms of ATP. The time constant for desensitization of ATP-activated current was unchanged by acidic pH. Proton potentiation of ATP-activated current appears to be independent of intracellular pH. Treatment of neurons with diethylpyrocarbonate, dithiothreitol, 5,5'-dithio-bis-(2-nitro-benzoic acid), or N-ethylmaleimide did not affect proton potentiation of ATP-activated current. Our results suggest that extracellular protons, at physiological concentrations, could regulate the function of P_{2X} purinoceptors by modulating the affinity of the binding site for ATP on these ATP-gated receptor-channels. This work was supported by NIAAA, NIH.

THE ASTROGLIAL RESPONSE TO PSYCHOLOGICAL AND INFLAMMATORY STRESSORS IN TRANSGENIC ANIMALS EXPRESSING TYPE II GLUCOCORTICOID RECEPTOR (GR) ANTI-SENSE RNA. 1-12 B. Marchetti*, 1F. Gallo, 3R. Avola, 4G.P. Leanza, 1Z. Farinella, 2C. Tirolo, 2N. Testa, and 3N. Barden. Depts. 1Pharmacol. 3Biochem. and 4Physiol., Catania Univ., 2OASI Institute (IRCCS), Troina (EN), Italy, and 5Mol. Psychogen., CHUL, Quebec, Canada.

Transgenic animals with impaired type II glucocorticoid receptor (GR) function display a number of neuroendocrine, immune and behavioral abnormalities including a increased hypothalamus-pituitary-adrenal (HPA) axis activity; b. hyper-responsiveness of the T-helper cell compartment; and c. deficits in tests of anxiety and cognitive performance. Neurons of the hippocampal formation are known to be selectively vulnerable to certain stresses, and this may be the cause of impaired cognitive behavior Astrocytes have been found to express mRNA and protein for a number of defined neurotrophic factors such as members of the neurotrophin family, pleiotropic factors such as bFGF, as well as a number of cytokines, suggesting their potential role in neuronal survival/protection from cellular insults. In the present study we have attempted to assess the astroglial response to a number of stressful situations in transgenic mice expressing GR anti-sense RNA. For this aim, we have monitored alterations in glial fibrillary acidic protein (GFAP) and proliferative state, as markers of astroglia reactivity, basic fibroblast growth factor (bFGF)-like immunoreactivity and astroglial cytokine expression in response to different stresses, lipopolysaccharide (LPS), or dexamethasone (DEX) administration. Proliferation of the astroglial compartment was significantly stimulated in transgenic mice. While resistant to the effects of DEX, astroglial cells responded to LPS with a further stimulation of astroglial proliferative activity. On the other hand, the glucocorticoid feedback on astroglia cytokine expression and bFGF-like immunoreactivity was inefficient in transgenic mice. Further studies on alterations in different neurotrophins and their receptors are in progress to clarify whether a defective glucocorticoid feedback might alter the astroglial neurotrophic factor response to neuronal insults resulting in increased neuronal vulnerability.

SPATIAL AND TEMPORAL STUDIES OF IMMOBILIZATION-INDUCED CELLULAR ACTIVATION IN STRESS-RELATED NEURONS: ANOTHER NEUROGENIC STRESS MODEL H.-Y. Li* and C.-W. W. Department of Anatomy, Chang Gung College of Medicine and Technology, Tao-Yuan, Taiwan, R.O.C.

Previous findings suggest that the responses of hypothalamic neurosecretory neurons to neurogenic stress and systemic stress are mediated by differential driving mechanisms (Li, et al., PNAS, 93:2359-2364, 1996). To test the commonality among neurogenic stress models, acute immobilization stress was used to identify the pattern of cellular activation. Animals were immobilized by fixing rats on their backs against a board and securing each limb with tape for 2 hours, and were sacrificed at different time points after stress. Maximal Fos expression was detected at 1-2 hr and disappeared by 4 hr after stress. Cell groups displaying Fos-ir included the parvocellular division of paraventricular nucleus of hypothalamus (PVH), which is rich in CRF-containing neurons. Double immunohistochemical labeling onfirmed that the scattered Fos positive neurons in the surrounding of magnocellular PVH and dorsal edge of the supraoptic nucleus were oxytocinergic. Widespread Fos expression was also found in the limbic areas, including ventral lateral septum, bed nucleus of stria terminalis, and medial nucleus of amygdala. It is of interest to note the prominent Fos staining in the horizontal limb of diagonal band, which is suggested to be associated with serotonin-containing neurons in the raphe nuclei. where nociceptive information is relayed. In the brainstem, Fos expression was located in areas involved in processing somatosensory/nociceptive information, such as periaqueductal gray, raphe nuclei, and the dorsal column nuclei. Similar to footshock and restraint stresses, immobilization elicits Fos expression in the catecholaminergic neurons in the nucleus of the solitary tract and ventrolateral These findings indicate a similar pattern of cellular activation among immobilization and other neurogenic stress models. It remains to be determined the role of activated extrahypothalamic regions in conveying immobilization stress information to trigger neuroendocrine responses. (Supported by CMRP 587)

ELEVATED FAT INTAKE DURING LACTATION INCREASES STRESS RESPONSIVENESS OF PREPUBERTAL RAT OFFSPRING. <u>G. Trottier*</u>, <u>K. Koski², and C.-D. Walker</u>. Douglas Hospital Research Center, Depts of Psychiatry¹ and Nutrition², McGill University, Montreal, PQ H4H 1R3, Canada.

High fat diet and elevated plasma levels of free fatty acids are known to increase ACTH response to stress in adult rats. We investigated whether changes in fat intake during nursing could have prolonged effects on stress responsiveness in the offspring. Lactating females were fed either a control (C: 5% fat, 60% CHO), high fat (HF: 20% fat, 53% CHO) or low carbohydrate (LC: 30% fat, 24% CHO) diet during the last week of gestation and throughout lactation. Lipid, protein and CHO content of the milk was measured at different stages of lactation. After weaning, pups from the various maternal diets were kept on the C diet for 2 weeks and tested for their ACTH and corticosterone (B) response to 15 min swim stress on day 35 of age. Maternal energy intake and pup weight gain were not altered by the diets during the first 21 days of nursing although total milk lipid content was significantly increased in the HF and LC compared to C group. On day 35, after 2 weeks of normal diet, the magnitude and duration of the ACTH response to stress were significantly higher in pups from the HF compared to the C diet. Basal or stress-induced B secretion was similar between diet groups. Fat pad weight was higher in 21 day-old pups from HF and LC than C diet, but these differences were abolished by day 35. These results show that changes in maternal diet during the nursing period could have profound and prolonged effects on stress responsiveness in the offspring. These effects persist at least 2 weeks after weaning and return to a normal diet. Alterations in fat supply in the milk might produce long-term changes in energy distribution, liver function and food preference in pups, thereby influencing adrenocortical regulation. ENDOGENOUS CORTICOSTERONE DOES NOT INHIBIT NOCICEPTIVE RESPONSES IN THE FORMALIN TEST. B.K. Taylor, S.F. Akana*, M.A. Peterson, and A.I. Basbaum. Departments of Anatomy and Physiology and the W.M. Keck Foundation Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143-0452.

Hindpaw injection of dilute formalin produces acute and persistent nociceptive responses. Since physiological stress can significantly influence pain, we evaluated formalin-evoked nociceptive behaviors, cardiovascular responses, inflammation, and increases in plasma ACTH and corticosterone concentrations in adult, male Sprague-Dawley rats. After overnight acclimation to the test environment, we collected multiple 140µl blood samples via chronic carotid arterial catheters both before and after the injection of saline, 1.5% formalin, or 5.0% formalin. In a concentration-dependent manner, formalin produced flinching and licking behavior, increased paw thickness, and increased ACTH and corticosterone. Although we did not detect distinct acute and persistent phases of HPA activity, these results indicate that nociceptive input activates the HPA axis.

We next evaluated the contribution of formalin-evoked endogenous corticosterone release to the magnitude of nociceptive responses. All animals were instrumented with chronic femoral arterial catheters and then either sham-operated or bilaterally-adrenalectomized (ADX). Corticosterone (25 ug/ml) was supplied in the drinking water of the ADX group. Although ADX produced subtle decreases in licking behavior and formalin-evoked heart rate responses, it did not change flinching behavior, blood pressure responses, or the increase in paw thickness. We conclude that corticosterone released during the formalin test does not produce a strong feedback inhibition of nociceptive responses. Supported by NS21445, NS 14627 and DK 28172, and thanks to Mary Dallman for helpful comments.

DIFFERENTIAL TEMPORAL AND SPATIAL ACTIVATION OF VISCEROMOTOR CELL TYPES OF THE PARAVENTRICULAR NUCLEUS IN RESPONSE TO ACUTE AND REPEATED RESTRAINT. V. Viau* and P.E. Sawchenko. The Salk Institute, La Jolia CA 92037.

Habituation of HPA responses with repeated exposure to homotypic stress is well-documented. To explore the central bases for this effect, we compared the time courses of cellular activation seen in visceromotor compartments of the paraventricular hypothalamic nucleus (PVH) of rats subjected to a single 30 min restraint session or 2 weeks of repeated daily exposure. Acute stress-induced Fos-ir in the CRF-rich part of the hypophysiotropic zone, autonomic-related subdivisions, and in oxytocinergic aspects of the magnocellular system were all prominent in animals sacrificed at the termination of restraint (0 hr), peaked at 2 hr after stress, and abated to control levels by 3-4 hr. An additional cell group occupying the most medial aspects of the PVH and extending into the anterior periventricular nucleus displayed a Fos response that peaked at 0.5 hr post-stress and was diminished by 1 hr. The most marked departures from this pattern in repeatedly stressed rats were highly preferential attenuations of Fos-ir in the CRF-rich and periventricular aspects of the PVH. The repeated stress group also displayed a paradoxical recruitment of supraoptic vasopressin neurons to Fos expression at 1-2 hr post-stress. Finally, we also tracked the time course of CRF and AVP hnRNA within the parvocellular and magnocellular divisions of the PVH, respectively. In response to acute restraint, both primary transcripts peaked at 0 hr and reattained control levels by 0.5 hr post-stress. While the magnocellular AVP hnRNA response was enhanced and prolonged. Visceromotor compartments of the PVH are activated with distinct time courses following acute stress, and these compartments are differentially affected by repeated exposure. Early Fos-ir and hnRNA responses indicate that such recruitment is initiated during stress. (supported by NS-21182)

REDUCTION IN NORADRENERGIC POTENTIATION OF THE STRESS RESPONSE DURING LACTATION IN THE RAT IS ASSOCIATED WITH CHANGES IN ADRENERGIC $\alpha\text{-}2$ RECEPTOR DENSITY IN THE PARAVENTRICULAR NUCLEUS (PVN). D.J.Toufexis* and C-D Walker. Douglas Hospital Research center, Dept of Neurology and Neurosurgery, McGill University, Montreal, PQ H4H 1R3, Canada.

During lactation, tonically elevated glucocorticoid secretion and a blunted ACTH response to stressors are observed in the rat. The mechanisms underlying lactation-induced stress hyporesponsiveness remain largely unknown. In these studies we first tested the role of noradrenergic (NA) afferents to the PVN in mediating stress hyporesponsiveness. Virgin and lactating females on day 2 of lactation, received either sham- or 6-hydroxydopamine (6OH-DA) lesions over the PVN. Specific dopamine and serotonin reuptake blockers were given prior to lesioning to spare non-NA inputs. Nine days later plasma ACTH and corticosterone (B) responses to swim stress were significantly attenuated in lesioned compared to sham virgin females (p<0.05). In lactating females 6OH-DA lesions did not affect ACTH or B responses to stress. Next changes in α -1 and α -2 adrenergic receptor (AR) density were measured in virgins and throughout lactation (Days 3, 12, 21) by autoradiography using 3H-prasozin or 3H-rauwolscine as specific ligands. The density of α -2 AR binding decreased only in the DG. These results indicate that 1) brainstem NA inputs to the PVN act to potentiate ACTH stress response in virgin females, while in lactating rats this potentiation is absent and 2) changes in the level of α -2 adrenergic receptors might be involved in modulating the HPA axis during lactation. (Supported by MRC Canada).

PRENATAL PSYCHOLOGICAL STRESS IN THE CONGENITAL LEARNED HELPLESS RAT(cLH): BEHAVIORAL AND NEUROENDOCRINE CORRELATES S. Shukla and F. Edwards Department of Pharmaceutical Sciences, University of Maryland, Baltimore MD 21201

This study examined the effects produced by maternal restraint stress during pregnancy on behavioral indices of emotionality and on measures of hypothalamic pituitary-adrenal axis (HPA) physiology. The congenital learned helpless rat (cLH), a genetic model of depression, allowed the assessment of interaction between environmental influences aand genetic susceptibility. In an open-field paradigm, cLH rats stressed in utero exhibited significant increases in activity at day 14, 21, 45 and 90 (day 14, 55 %1; day 21, 45 & 90, 37%1), as compared to the cLH no stress group. In a hot plate test, the latency to hindpaw withdrawal was significantly increased in the cLH rats stressed in utero (day 14 & 21, 50 %1; day 45 and 90, 30 %1). At weaning, cLH rats tested in the spontaneous alternation paradigm displayed an increase in vacillatory behavior (decision making choice) but they also exhibited higher alternation patterns than the no stress control. However, these differences were not evident at day 45 and day 90. Adrenocorticotropin hormone (ACTH) and Corticosterone (CORT) plasma levels were monitored at day 7, 14, 21, 45 and 90 in both cLH stressed in utero and no stress cLH controls. In response to prenatal stress, baseline levels of ACTH and CORT were elevated 60% and 100 % respectively early in development (day 7 and day 14 only). At day 21, 45 and 90, there was no difference in basal levels of ACTH and CORT in the stress in utero group and the no stress control. Our results suggest that exposure to prenatal stress in the cLH rat has long term consequences such as a dampened emotionality profile. The altered functionality of the HPA axis was only evident in the early stages of development and the hypersensitivity of the system may contribute to the demonstrated blunted response to various stressors in the adult cLH rat. Supported by School of Pharmacy DRIF Grant.

532.9

EFFECT OF NEONATAL HIPPOCAMPAL AND AMYGDALA LESIONS ON SYMPATHO-ADRENAL SYSTEM AND HYPOTHALAMIC-PITUITARY-ADRENAL AXIS RESPONSIVENESS TO IMMOBILIZATION STRESS IN RHESUS MONKEYS. K. T. Kalogeras*, L. Malkova, K. Pacak, R. Kvetnansky, J. Bachevalier, P. W. Gold, M. Mishkin, and R. L. Wilder. Department of Psychiatry and Human Behavior, University of Mississippi Medical Center, Jackson, MS 39216; NIMH, NINDS and NIAMS, National Institutes of Health, Bethesda, MD 20892.

The amygdala has been shown to play a stimulatory role in the activation of both the sympatho-adrenal system (SAS) and the hypothalamic-pituitary-adrenal (HPA) axis during stress in rats. By contrast, the hippocampus is thought to either have no effect or play an inhibitory role. To examine the role of these two structures in the activation of the SAS and the HPA axis, we studied stress responses in adult rhesus monkeys that had received bilateral neonatal lesions of either the amygdala (A), the hippocampus (H), or both (AH) structures. The completeness of the lesions was verified by magnetic resonance imaging. A total of 3 A, 4 H and 3 AH lesioned animals (originally lesioned for behavioral studies) and 5 normal controls were exposed to 20 min immobilization stress. Blood samples were obtained through an indwelling iv cannula before, during, and after the stress. The SAS activation during stress was reflected by peak values of 2372475 pg/mL for epinephrine (EPI), and 1748±607 pg/mL for norepinephrine (NE) in normal controls, with all lesioned monkeys exhibiting a blunted response of plasma EPI (715±268, 708±291 and 567±219 pg/mL for A, H, and AH, respectively) and NE (870±103, 533±178 and 740±465 pg/mL, respectively). Plasma cortisol reached a peak of 17.7±2.4 µg/dL 5 min after termination of the stress in normal controls and gradually declined to baseline values (6.2±1.2 µg/dL). 120 min later. All lesioned primates showed a blunted cortisol response as well, reaching peak values of 11.4±5.5, 12.1±1.8 and 8.0±2.9 µg/dL for A, H, and AH resions, respectively. Arginine vasopressin and neuropeptide Y showed a trend of an attenuated response in lesioned primates. In conclusion, neonatal lesions of the amygdala as well as the hippocampus appear to decrease the responsiveness of the sympatho-adrenal system and the HPA axis to stress. Combined lesions of both structures do not result in an additive or synergistic effect. (Intramural NIH support).

RESTRAINT STRESS PRODUCES REGION SPECIFIC CHANGES IN RAT BRAIN PREPRO-TRH 178-199, A PROPOSED NOVEL CORTICOTROPIN RELEASE INHIBITING FACTOR. P.A. Rittenhouse*, E.P. Zorrilla, R.F. McGivern[#], and E. Redei. Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia PA 19104 and [#]Dept. of Psychology, San Diego State Univ., San Diego, CA 92120.

We have described that prepro-TRH 178-199 shows corticotropin release inhibiting activity in vitro and in vivo. As this peptide is encoded within the precursor for TRH, which is widely distributed in brain, the concentration of prepro-TRH 178-199 may change region specifically in response to stress. A specific RIA was developed with a sensitivity of 19 pg/tube using a polyclonal antibody and ¹²⁵I-Tyr¹⁷⁸-prepro-TRH 178-199 as tracer. Brain regions were dissected from adult male rats (n=6/group) at 9:00 am or 9:00 pm, and 30, 90 and 180 min after 5 min of restraint stress. The rank order of prepro-TRH 178-199 content (ng/mg protein) was: hypothalamus 9.2; septum 6.3; caudate 2.9; amygdala 0.82; prefrontal cortex 0.75; periaquaductal gray (PAG) 0.6. The highest amount was found in the median eminence (ME) at 3.6/tissue with negligible amounts found in other brain areas. There was a trend for a diurnal morning decrease in the ME, pituitary and septum with an increase in morning PAG. Following stress there was a regionally specific change in prepro-TRH 178-199 content $(F_{[5,16]}=1.98, p<0.05)$. A small increase at 30 min was seen in the hypothalamus, septum, caudate and amygdala followed by a decrease in the hypothalamus, caudate and amygdala at 90 or 180 min post-stress. Prepro-TRH 178-199 decreased in response to stress without an initial increase in the prefrontal cortex and PAG. In contrast, prepro-TRH 178-199 increased in the ME and pituitary at all time points post stress. These results show that this RIA is suitable for detection of prepro-TRH 178-199 concentrations, and suggest that brain prepro-TRH 178-199 is differentially sensitive to stressful stimuli. Supported by the Berman Foundation.

POSTNATAL HANDLING/MATERNAL SEPARATION ALTERS RESPONSES TO NOVELTY STRESS, OPEN FIELD EXPLORATION AND CENTRAL BENZODIAZEPINE RECEPTOR LEVELS IN ADULT RATS. C._Caldji¹*, S. Sharma¹, P.M. Plotsky² and M.J. Meaney¹, McGill Univ., Douglas Hosp. Res. Ctr., Montreal, Canada, H4H 1R3. ²Stress Neurobiology Lab., Dept. Of Psychiatry, Emory Univ., Atlanta, GA 30322.

Postnatal handling (H) results in reduced novelty induced fearfulness and increased forebrain 3H flunitrazepam binding compared to non-handled (NH) rats (Bodnoff et al., 1987, European J. Pharmacol. 144: 105-107). In the current study, H, NH and rats maternally separated for 180 minutes per day for the first 3 weeks of life (MS) were food deprived for 24 hours and placed in a novel environment with food. H rats showed a significantly reduced novelty induced suppression to feeding as compared to NH rats. In addition, MS rats made significantly less visits to the food as compared to H and NH rats. In a novel open field environment, H rats spent significantly greater time exploring this environment as compared to both MS and NH rats. 3H flunitrazepam binding autoradiography revealed that H rats had significantly greater levels of central benzodiazepine (CBZ) receptors in the lateral nucleus of the amygdala, the locus coeruleus (LC) and both C1-C2 adrenergic cell bodies as compared to MS rats. In addition, H rats also had significantly greater CBZ levels in the central nucleus of the amygdala and LC as compared to NH rats. These results suggest that extrahypothalamic regions such as the amygdala and the locus coeruleus may play an important role in controling the central events leading to the H rats enhanced inhibition of anxiogenic noradrenergic responses to novelty stress. (Supported by NIMH grant to PMP and MJM)

532.10

MATERNAL DEPRIVATION IN THE BROWN NORWAY RAT RESULTS IN LONG-TERM ALTERATIONS IN THE HYPOTHALAMUS-PITUTTARY-ADRENAL AXIS AND IN BEHAVIOR. J.O. Workel, E.R. de Kloet, M.S. Oilzi*. Div. of Medical Pharmacology, Leiden/Amsterdam Center for Drug Research, (LACDR), University of Leiden, P.O. Box 9503, 2300 RA Leiden, The Netherlands.

(LACDR), University of Leiden, P.O. Box 9503, 2300 RA Leiden, 1he Netherlands. Glucocorticoids play an important role in developmental processes. In the rat, corticosteroid levels are low from postnatal day (pnd) 4 until 14, even after stress. During this period, the stress hyporesponsive period (SHRP), maternal factors have an inhibitory influence on the hypothalamus-pituitary-adrenal (HPA) axis of the neonate, since maternal deprivation of the pup for 24 hours (DEP) results in an immediate increase in HPA reactivity. We hypothesized that a single 24-hour maternal deprivation at pnd 3 results in long-term alterations in HPA reactivity and behavior. We used male Brown Norway (BN) rats, a rat strain known for its long healthy life span. As indices for HPA activity we measured basal CRF mRNA in the hypothalamus, and both basal as well as stress-induced ACTH and CORT levels in plasma. We found that BN rats display a SHRP which resembles the one reported for albino rat strains. DEP at pnd 3 did not alter basal and stress induced HPA reactivity at pnd 10, but resulted in an enhanced ACTH response after stress at pnd 18. Comparing DEP rats and their controls (NDEP) at the age of 3 months, exposure to a novel environment resulted in a decreased CORT response, while ACTH levels were similar. At all ages tested, CRF mRNA expression was not different. Behaviorally, DEP rats showed an increased reactivity (exploration of an object in an open field) and an enhanced locomoter activity. Furthermore, DEP rats displayed a time delay in the acquisition of spatial learning in the water maze. Taken together, these data suggest that a single 24-hour maternal deprivation at pnd 3, results in long-term alterations in HPA reactivity and in behavior of young adult BN rats. We are currently investigating 12-month old animals. Supported by the Netherlands Organization for Scientific Research (NWO), grant # 554-545.

CORTICOSTERONE TONICALLY INHIBITS THE HPA AXIS RESPONSE TO AIRPUFF STARTLE IN CONSCIOUS RATS. K.V. Thrivikraman*, Y. Su, and P.M. Plotsky. Stress Neurobiology Laboratory, Dept. of Psychiatry & Behavioral Sci., Emory Univ., Atlanta, GA 30322.

We previously demonstrated that suppression of hypothalamic-pituitary-adrenal (HPA) axis activity by glucocorticoid-induced feedback was stressor-specific. Furthermore, it was speculated that this apparent specificity was related to differences in the neuronal pathways conveying stimulus-specific information to the neuroendocrine cells in the hypothalamic paraventricular nucleus (PVN). Thus a physical stressor, represented by a controlled hemorrhage (H) which elicits activation of hemodynamically sensitive brainstem catecholaminergic cell groups, was not responsive to feedback inhibition, whereas an emotional stressor, represented by airpuff-startle (APS) which does not activate these cell groups, was susceptible to feedback suppression. We have now extended these studies in adrenalectomized (ADX) rats with or without exogenous corticosterone (B) replacement to evaluate the contribution of stable circulating B within the basal range to this phenomenon. Four treatment groups of male Sprague-Dawley rats were used in this study: (1) sham-ADX (sADX), (2) ADX, (3) ADX +40%B subcutaneous pellet (pADX), (4) ADX+water containing 25µg/ml B in 0.5% saline (wADX). The pADX treatment maintained a body weight between 248-277g and achieved basal plasma ACTH and B levels of 30±3 pg/ml and 46±3 ng/ml (mean±sem), respectively. Basal ACTH and B levels of wADX as within the same weight range were 19±7 pg/ml and 16±6 ng/ml, respectively. Groups of rats from each treatment were exposed to either 20% H over 3 min or APS. The ACTH and B responses of sADX rats after either H or APS were similar to those of intact rats. Relative to sADX, the integrated ACTH response to APS mis on the surface of the product of th

Antagonism of release of ACTH in response to hypoxemia in fetal sheep by the CRH antagonist Astressin. P.W. Nathanielsz*, L.F. Buchwalder, W. Vale², J. Rivier², A. Yen, and T.J.McDonald. Laboratory for Pregnancy and Newborn Research, College of Veterinary Medicine, Cornell University, Ithaca, NY 14853 and ²The Salk Institute for Biological Studies, The Clayton Laboratories for Peptide Biology, La Jolla, CA 92037

The fetal hypothalamo-pituitary axis plays a critical role responding to various physiological challenges (e.g. hypoxemia) and in promoting the birth process. CRH and AVP have been implicated in ACTH regulation in late gestation. The present study evaluated Astressin-cyclo(30-33)[D-Phem¹2,Nle²1.38,Glb³0,Lys³3]- hCRF(12-41)inhibition of the ACTH response to hypoxemia in fetal sheep.

METHODS: Five fetal sheep were studied at 135-145 d (term 148 d in sheep).

Hypoxemia was induced via N_2 infusion to a maternal tracheal catheter for 1h. Fetal arterial blood was sampled at -30, -15 and 0 min before injection of either 0.8-1 mg Astressin or vehicle and at +15 and +30 min when hypoxemia started. Fetal PaO₂ fell ~7.5 mmHg (Fig. 1). Further samples were taken at 70, 90, 105, & 150 min. ACTH was measured by RIA.

RESULTS: Astressin reduced the rise in fetal ACTH peak by 70% (Fig. 1). CONCLUSIONS: This is the first demonstration that the fetal ACTH rise in response to hypoxemia in late gestation results predominantly from CRH stimulation. (HD 21350).

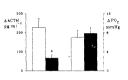

Fig. 1 Fetal plasma ACTH rise and PO2 fall during fetal hypoxemia with Astressin treatment (■) or vehicle (□), n=5 (mean±SEM). *p<0.05.

MIDLINE THALAMIC LESIONS ALTER HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) ACTIVITY IN CHRONICALLY STRESSED ANIMALS. S. Bhatnagar*, C.I. Horsley & M.F. Dallman, Dept. of Physiology, UCSF, San Francisco, CA, USA, 94143-0444.

We have previously shown that animals exposed to chronic, intermittent cold exhibit elevated circulating levels of ACTH and corticosterone in response to a novel, heterotypic stressor, restraint. In earlier studies using fos immunoreactivity, we identified, amongst other areas, the paraventricular nucleus of the thalamus (PVTh) as a potential site mediating these elevated responses. In the present study, we examined the role of the PVTh in HPA responses to a novel stressor in chronically stressed animals. Adult, male, Sprague-Dawley rats were stereotaxically injected with either ibotenic acid or vehicle into the midline thalamic area which encompasses the PVTh. 48 hours following surgery, animals were either exposed to 7 days of chronic, intermittent cold (4h a day at 4°C; CHR) or left undisturbed (CTL). On the eighth day, all animals were sampled via the tail vein prior to restraint, at 15 and 30 min during a 30 min period of restraint, and at 30 min following return to the home cage. We found that lesioned CHR animals exhibited elevated basal levels of ACTH relative to all other groups. Furthermore, midline thalamic lesions increased ACTH responses to restraint in both CTL and CHR animals, but these two groups did not differ from each other. As a result, the differences in HPA responses to restraint seen between non-lesioned CTL and CHR animals were eliminated in the lesioned groups. These data provide direct evidence for a role of the midline thalamic nuclei in regulation of HPA responses to acute stress and in regulation of chronic stress-induced hyperresponsiveness to novel stressors. COMBINED TYPE I AND TYPE II CORTICOSTEROID RECEPTOR ANTAGONISM ENHANCES BASAL AND ACUTE-STRESS INDUCED HPA AXIS ACTIVITY IN BOTH THE MORNING AND EVENING. P.J. Kim*, B.A. Kalman, M.A. Cole, M.S. Chi, E.S. Schuiling, R.L. Spencer. Dept. of Psychology, Univ. of Colorado., Boulder, CO 80309.

This study examined the relative roles of the corticosterone (CORT) receptor subtypes in mediation of CORT regulation of the basal and acute stress-induced activity of the HPA axis during the trough (AM) and the peak (PM) of the HPA axis circadian rhythm. One hour prior to one hour restraint stress, male Sprague-Dawley rats were injected sc with the putative selective CORT receptor antagonists, RU28318 (50mg/kg; Type I receptor antagonist), or RU40555 (30mg/kg; Type II receptor antagonist), or RU40555 (30mg/kg; Type II receptor antagonist), or the combination of both. RU28318 increased basal CORT in the AM, but not the PM, and had no effect on the HPA axis stress response at either time of day. RU40555 had no effect on basal or stress-induced CORT levels at either time of day. Treatment with the combination of RU28318 and RU40555 increased basal CORT, increased peak stress CORT levels and delayed the return of post-stress CORT levels to basal levels in both the AM and PM. Measurement of available corticosteroid receptor levels after antagonist treatment indicated that RU28318 occupied over 90% of Type I receptors and 30% of Type II receptors, whereas RU40555 selectively occupied 70% of Type II receptors. Thus, combined antagonist treatment alone, and this combined antagonist treatment was effective in increasing basal and stress-induced HPA axis activity in both the AM and PM. RESPONSE TO COLD STRESS FOLLOWING PRENATAL ETHANOL EXPOSURE. C. K. Kim*, P. K. Giberson, W. Yu and J. Weinberg. Department of Anatomy, University of British Columbia, Vancouver, B.C., Canada, V6T-1Z3.

Prenatal ethanol exposure (PEE) produces hyperresponsiveness to stressors in offspring. This study tested the hypothesis that PEE will result in increased physiological responses to chronic cold stress (4 °C for 0, 1 or 3 days), and increased sensitization to an acute stressor (15 min following IP stick) imposed during the chronic cold stress. The subjects were adult male and female offspring from prenatal ethanol exposed (E, 36% EDC), pair-fed (PF) and ad libitum-fed control (C) rats.

Adrencorticotropic hormone (ACTH) levels in males were not affected by cold stress, and although ACTH levels were significantly elevated following acute stress there was no sensitization. Females showed significantly elevated basal ACTH levels in response to cold stress, and E rats displayed significantly higher ACTH levels than PF rats following acute stress. Furthermore, overall ACTH levels were significantly higher in E compared to PF and marginally higher than in C females. Basal corticosterone (CORT) levels in males were significantly elevated following cold stress only in E rats; significant sensitization was evident in all groups. Females showed significantly elevated basal CORT levels following cold stress, and although CORT levels significantly increased with acute stress there was no sensitization. Corticosterone binding globulin levels were not affected by any of the experimental manipulations in either males or females. Overall body weights of both males and females significantly decreased with cold stress; this decrease was most pronounced in E males. Adrenal weight and adrenal/body weight ratios of males significantly increased with cold stress. Thus, PEE produced an elevated CORT response to chronic cold stress in males, and an elevated ACTH response to acute stress in females. (Supported by a grant from NIAAA to JW)

FOOTSHOCK INDUCED C-FOS PROTEIN IN THE BRAIN: EFFECTS OF ADRENALECTOMY. <u>L. A. Wetmore* and D. M. Nance</u>. Depts. Physiology & Pathology, Univ. Manitoba, Winnipeg, Manitoba, Canada, R3E 6W3. Footshock invokes neurochemical alterations in specific brain regions,

activates the hypothalamic-pituitary-adrenal (HPA) axis and affects both endocrine and immune system function. Corticosterone mediates inhibitory feedback on the HPA axis however, the interaction of corticosterone with footshock induced neurobiological changes is not entirely known. Using c-fos immunodetection, the functional neuroanatomy activated by footshock has been reported. In the present study, the role of the adrenal gland in footshock induced brain c-fos protein expression was examined. Rats were adrenalectomized (ADX) or SHAM operated and later exposed to footshock (+FS) or tone (-FS). A subgroup of ADX and SHAM rats were pretreated with dexamethasone (DEX) or saline (SAL). SHAM/+FS rats had identical brain c-fos protein immunostaining, as previously reported for unoperated rats. ADX alone did not alter brain c-fos immunostaining however, footshock induced c-fos protein in the hypothalamic paraventricular nucleus (PVN) was reduced. C-fos immunostaining in other brain regions was not altered by ADX. PVN c-fos protein in ADX/+FS rats was not reinstated by DEX. However, DEX pretreatment decreased footshock induced c-fos immunostaining in the PVN of SHAM rats, relative to SAL controls. SAL and DEX had no effect on brain c-fos protein in ADX/-FS or SHAM/-FS groups. The regionally selective effect of ADX on footshock induced c-fos protein highlights the importance of this region in stress processing. The data suggest a functional interaction between the adrenal gland and footshock regulated c-fos protein expression in the PVN, although the exact mechanisms involved remain to be determined. Supported by the Medical Research Council of Canada.

BLOCKING CORTICOSTEROID NEGATIVE FEEDBACK IMPAIRS THE EXPRESSION OF HABITUATION TO A REPEATED DISCRETE STRESSOR IN RATS. M.A. Cole*, B.A. Kalman, P.J. Kim, M.S. Chi, R.L. Spencer. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

The role of corticosterone (CORT) negative feedback in the expression of habituation of the HPA axis response to a discrete repeated stressor was investigated. Male, Sprague-Dawley rats were restrained for one hour a day in cylindrical, Plexiglas tubes for six consecutive days. On day six, one hour prior to restraint stress, rats were injected s.c. with either the combination of the putative selective Type I CORT receptor antagonist RU28318 (50mg/kg) and the selective Type II receptor antagonist RU28318 (50mg/kg) (n=6) or vehicle (n=6). Blood samples were collected for CORT measurement (days 1, 5, and 6) just prior to stress, 30 and 60 minutes into stress, and one hour after stress termination. All rats significantly habituated to the stress-induced CORT secretion by day five. The antagonist pretreatment on day 6 completely blocked the expression of the habituation. The day 6 peak CORT stress response in the antagonist group was significantly greater than their day 1 prehabituation levels in addition to being greater than the day 6 control (vehicle group) levels. Similar increases in peak stress response CORT levels were seen when these antagonists were administered one hour prior to stress in nonhabituated rats. These results indicate that expression of the habituated HPA axis stress response is dependent on CORT negative feedback. A possible implication is that an impairment in CORT negative feedback would interfere with HPA axis stress adaptation. [Supported by USPHS grants DK49143 and MH54742]

EFFECTS OF ACUTE CORTICOSTEROID RECEPTOR ANTAGON-ISM ON BASAL AND STRESS-INDUCED C-FOS-LIKE IMMUNO-REACTIVITY (C-FOS-LI) IN SPECIFIC BRAIN REGIONS. M.S. Chi, B.A. Kalman, M.A. Cole, P.J. Kim, R.L. Spencer*. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Psychology, Univ. of Colorado, Boulder, CO 80309.

The nature of the relationship between stress-induced c-fos protein induction in various brain regions and HPA axis activity remains to be established. Acute blockade of corticosteroid receptors with the combined sc injection of the Type I receptor antagonist, RU28318 (50 mg/kg) and of the Type II receptor antagonist, RU40555 (30 mg/kg) increases both basal and stress-induced corticosterone (CORT) secretion in the rat. We have examined the concurrent effect of this corticosteroid receptor antagonist treatment on c-fos protein induction in brain regions involved in HPA axis function (PVN of hypothalamus and hippocampus). Four groups of male Sprague Dawley rats were tested: 1) Vehicle + No Restraint, 2) Antagonist + No Restraint, 3) Vehicle + Restraint, and 4) Antagonist + Restraint. All rats were anesthetized and perfused transcardially with 4% paraformaldehyde in phosphate buffer 3 h after injection. Restraint rats were placed in Plexiglas tubes for the final 2 h prior to perfusion. C-fos-LI was visualized on brain sections using immunohistochemistry. Cell counts indicate that antagonist pretreatment of non-restrained rats resulted in an increase in c-fos-LI in PVN and pyramidal cells in hippocampus, however, the increase in PVN did not reach statistical significance. Stress nowever, the increase in PVN did not reach statistical significance. Stress produced a large increase in c-fos-LI positive cells in the parvocellular region of the PVN, which was comparable for both vehicle and antagonist pretreatment, perhaps due to ceiling levels of c-fos-LI resulting from the stress of restraint. ULTRADIAN RHYTHMS OF CORTICOSTERONE RELEASE: EFFECT ON

ULTRADIAN RHYTHMS OF CORTICOSTERONE RELEASE: EFFECT ON DIFFERENTIAL RESPONSE TO STRESS IN SPRAGUE-DAWLEY, FISCHER-344 AND LEWIS STRAINS OF RAT. C.D. Ingram*, R.J. Windle¹⁻² and S.L. Lightman¹ Dept. Medicine and ²Dept. Anat., Univ. Bristol BS8 1TD, Bristol, U.K. An automated system which allows frequent and remote blood sampling was used to study patterns of corticosterone (CORT) release in the female rat. In Sprague-Dawley (SD) rats, CORT release occurred in discrete pulses (26 ± 3 pulses) and control of the control of the short half life (<10 min) of exogenous CORT that we observe in the short half life (<10 min) of exogenous CORT that we observe in the second state pulses for expression state the drug lethough on given the short half life (<10 min) of exogenous COR1 mat we observe in adrenalectomised rats. Pulse frequency did not vary over the day, although an increase in pulse magnitude generated a circadian pattern of circulating glucocorticoid. The ultradian pattern of CORT release had a profound effect on the response to a mild psychological stress (white noise, 10 min, 114 dB). When the stress fell on the rising phase of a pulse, there was a large increase in plasma CORT, reaching 800 ± 152% of the mean pre-stress value at 20 min, before falling rapidly to baseline. However, when the stress occurred on the falling phase of the pulse no significant increase in plasma CORT was seen. This relationship between pulse pattern and responsiveness to stress was further studied in the Lewis (LEW) and Fischer-344 (F344) strains of rat which show differential sensitivity to stress. Both rischer-344 (r344) status of rat wind is now differential sensitivity to stess. Both strains showed pulsatile release of CORT similar to the SD rat (F344; 32±2; LEW: 31±1 pulses/24 h). LEW rats also showed a relationship between pulse phase and stress-induced CORT levels comparable to SD rats. However, the more reactive F344 rats displayed a prolonged elevation of CORT (60 min) following noise stress, and rats aispiayed a prolonged elevation of CNR (our min) following noise stress, and the phase of the pulse on which the stress fell did not affect the magnitude or duration of the response. Therefore, the HPA axis appears to alternate between periods of hormone release, during which it can respond to stress, and periods of quiescence, when it is unresponsive. The absence of quiescent periods in the F344 rat may account for its greater reactivity to stress and may provide a model for other conditions of stress hypersensitivity.

EFFECTS OF UNILATERAL MECHANICAL STIMULATION OF THE OVARIAN PEDICLE PERFORMED ON EACH DAY OF THE ESTROUS CYCLE ON OVULATION AND NEURAL MONOAMINE-ACTIVITY IN THE POA-AHA. A. Dominguez-González*, M.E. Cruz and N.Cruz. UIBR, Fes-Zaragoza, UNAM, México

We have previously shown that hemiovariectomy performed at 13.00 h on each day of the estrous cycle affects ovulation and serotonin concentration of POA-AHA in different way (S.Nsc. 21;743.11;1995). Because there is evidence that Unilateral Mechanical Stimulation of the Ovarian Pedicle (UMSOP) performed at 07.00 h affects ovulation depending on the day of the cycle when it is performed (Med.Sci.Res. 18;819;1990), in present study we compared the effects of UMSOP performed at 13.00 on each day of the estrous cycle on ovulation rate and monoamine-activity in POA-AHA. Adult cyclic females rats were etheranaesthetized and laparotomized. Right (R-UMSOP) or Left (L-UMSOP) ovary was exteriorized, manipulated and returned to the abdominal cavity. A group of intact cyclic animals were used as control. All animals were killed on the next estrus day

L-UMSOP blocked ovulation when was done on D2 (0/4 vs.7/8); the activity of the serotoninergic-neuron of the left side of POA-AHA was significant lower than control (0.18±0.1 vs. 1.44±0.4, p<0.05), while changes in the right side of POA-AHA were not observed (1.39±0.8 vs.1.68±0.5). The R-UMSOP did not affect ovulation (4/6 vs 7/8) nor the serotoninergic neuronal activity. UMSOP performed on others days of the estrous cycle did not modify ovulation, nor neuronal activity.

Present results suggest that the stimulation of the ovarian pedicle affects ovulation and serotoninergic neuron in POA-AHA in an opposite way than

hemiovariectomy, and both present laterality.

BEHAVIORAL INTERACTIONS CAUSE A DECLINE IN GONADOTROPIN-RELEASING HORMONE IMMUNOREACTIVE CELL NUMBERS. V.C. Tai, L. E. Muske* and E. F. Rissman. Biology Department, University of Virginia, Charlottesville, VA 22903.

Previously we reported that in the female musk shrew, interactions which accompany the mating bout promote rapid

increases in the numbers of gonadotropin-releasing hormone immunoreactive (GnRH-ir) cells in olfactory-related forebrain regions (Dellovade et. al., Neuroendo. 62:385-395, 1995). In this study we asked whether the changes are caused by male-related olfactory stimuli. Females were housed in one of 4 conditions. Either they resided in a split cage in male-soiled bedding with an active adult male on the other side of a barrier, or under identical conditions, with an anesthetized male, or in a clean cage with a male on the other side of a transparent solid barrier. Control animals resided in a clean cage without a male present. After one hour females were perfused, brains removed, processed and stained for GnRH with a commercial antibody (SMI-41). A "blind" observer counted GnRH-ir neurons in the forebrain. Behavioral interactions with an awake male resulted in a decrease in the numbers of GnRH-ir cells located in the ventral forebrain (P<0.05). This effect was caused by changes in the GnRH cells located in the ventral forebrain (P<0.05). The data suggest that behavioral interactions, not pheromones, promote GnRH release from cell bodies and thus the appearance of fewer GnRH-ir cells in the hypothalamus. This work is supported by NSF IBN 94-12605 (EFR).

EFFECT OF ESTRADIOL (E) ON LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) AND LH RELEASE IN MALE SHEEP. Lubbers LS, Hileman SM, Kuehl DE, Ferreira SA and Jackson GL. Department of Veterinary Biosciences, University of Illinois, Urbana-Champaign, Il 61801.

In the male, the inhibitory effects of testosterone on LH release may be mediated in part by E. To determine the sites at which E acts, we tested the hypothesis that E acts first on the pituitary, to reduce responsiveness to LHRH, and then on the hypothalamus, to reduce LHRH release. Hypophyseal-portal cannulated, castrated male sheep were infused with E (15 ng/kg/h) or vehicle (V). Portal and jugular blood samples were collected at 10 min intervals for 4 h prior to, and for either 12 h (E, n=4; V, n=4) or 24 h (E, n=8; V, n=3) following the start of infusion. In animals sampled for 16 h, temporal changes of both LHRH and LH were assessed. In animals sampled for 28 h, only LH data were analyzed. Prior to the start of either the 12 h or 24 h infusion, LHRH and/or LH mean concentrations, pulse amplitude and interpulse interval (IPI) did not differ (p>0.05) between E- and V- infused animals. In animals sampled for 16 h, mean LHRH and LHRH pulse amplitude was greater (p<0.01) in the V-infused than E-infused males, however, there was no significant (p>0.05) effect of time or steroid x time interaction. LHRH IPI was unaffected (p>0.05) by infusion. In contrast, both mean LH and LH pulse amplitude declined within 4-8 h (p<0.01) after the start of E infusion while mean LH IPI was unaffected (p>0.05). In animals sampled for 28 h, both mean LH and LH pulse amplitude declined within 4-8 h (p<0.01) and remained suppressed for the remainder of the 24 h infusion period. Mean LH IPI was unaffected (p>0.05). In conclusion, in male sheep the acute inhibitory effects of E on LH release are achieved by reducing pituitary responsiveness to LHRH and not by decreasing LHRH release. (Supported by USPH HD-27453)

NEUROENDOCRINE REGULATION OF THE EFFECTS OF PMSG ADMINISTRATION ABOUT PREOVULATORY PEAK OF ESTRADIOL AND PROGESTERONE IN PREPUBERTAL RATS. J. Villavicencio*, M.C. Peñasco, R. Chávez and Díaz. Vicente. UIBR-FES Zaragoza, UNAM., and INNS-Zubirán, México, AP 9-020, CP 15 000.

Gonadotropin administration in prepubertal rats induce an increase in plasma progesterone levels and advanced ovulation, effects mediated by the central catecholaminergic system. In this work we study the participation of the cholinergic and catecholaminergic systems on preoxulatory peak of progesterone and estradiol in 27 days old rats treated with: a) PMSG (8 i.u), b) PMSG, 48 h after Reserpine (RSP: 2.5 mg/kg bw) or Atropine (ATR: 400 mg/Kg bw) and c) PMSG+RSP or ATR and 6 h later with hCG (10 i.u.). Animals were sacrified 54 or 72 h after PMSG treatment. The results are shown in the next table:
Group Ovulation Ova shed Estradiol Progestero

Огоцр	rate	Ova silica	(pg/ml)	(ng/ml)
54 h-PMSG	0/10	0 ± 0	118 ± 16	23 ± 2
PMSG+RSP	0/5	0 ± 0	145 ± 25	5 ± 1 a
PMSG+ATR	0/5	0 ± 0	$584 \pm 17 a$	9 ± 1 a
72 h-PMSG	14/14	16 ± 2	40 ± 9	17 ± 2
PMSG+RSP	2/9 a	0 ± 0 a	$211 \pm 30 a$	10 ± 1 a
PMSG+ATR	0/9 a	0 ± 0 a	144 ± 22 a	11 ± 2

a. p < 0.05 vs group PMSG same hour

All animals treated with hCG ovulated (PMSG: 6/6, 28±2 ova shed; PMSG+ ATR+hCG: 6/6, 10±2 ova shed and PMSG+RSP+hCG: 6/6, 17±1 ova shed). Our results shown that both steroid production and the ovulation are regulated by cholinergic and

catecholaminergic systems.

CHANGES IN CELLULAR GONADOTROPHIN-RELEASING HORMONE (GnRH) mRNA CONTENT IN THE ROSTRAL PREOPTIC AREA (PPOA) PRIOR TO THE ESTRADIOL-INDUCED LUTEINISING HORMONE (LH) SURGE IN THE EWE. T.G. Harris, N.P. Evans* J.E. Robinson, D.C. Skinner and A.E. Herbison. Lab. of

Neuroendocrinology, The Babraham Institute, Cambridge, CB2 4AT, U.K.

During the owine estrous cycle, the follicular phase rise in estradiol (E) stimulates the preovalutory LH surge by initiating a massive and sustained rise in GnRH. The objective of this study was to determine whether E-induced changes in GnRH secretion were associated with temporal changes in GnRH mRNA expression. 48 Clun Forest ewes were ovariectomised (OVX) and ovarian steroids replaced to mimic the follicular phase rise of E. Hourly blood samples for LH were taken through the follicular phase. Animals in group 1 were killed at five specific time points for follicular phase. Animals in group 1 were killed at five specific time points for analysis of GnRH mRNA expression using in situ hybridisation (18H): A Prior to E administration (n=6); B. 8 hrs after E (n=5); C, on the ascending limb of the LH surge (18-23h following E;n=5); D, at the peak of the LH surge (n=7); and E, 40 hrs after E (n=5). A separate group of animals (group 2) were killed at identical time points to assess changes in GnRH mRNA when E was not increased (n=5, each group). Animals were killed, and the rPOA rapidly dissected and frozen. Eyery tenth 12 µm coronal section through the rPOA was processed for ISH using a ³⁵-slabelled oligonucleotide probe directed against ovine GnRH. Cellular analysis revealed no origonactionate probe directed against ovine GnR1. Certain analysis reveaued no temporal changes in the number of GnR1 mRNA expressing neurons in either group. Analysis of cellular silver grain density in E-treated ewes revealed a non-significant increase in GnR1 mRNA content between points A (0.56±0.03 silver grains/µm²) and B (0.64±0.06) followed by a significant (P<0.05) decline to point C (0.47±0.04). Levels remained at this significantly depressed level through points D (0.47 ± 0.04) and $E(0.47\pm0.03)$. No significant temporal changes were detected in group 2. These data indicate that there is an E-induced decrease in GnRH mRNA expression prior to the GnRH surge. This suggests that changes in GnRH mRNA expression may preced the increased secretory activity of GnRH neurons at the time of the GnRH surge. TGH was supported by an MRC studentship.

DECREASE IN PEPOA FOS ACTIVATION DURING THE LH SURGE IN AGED RATS <u>W-W. Le</u>,* <u>I.M. Lloyd.</u> <u>P.M. Wise</u>, and <u>G.E. Hoffman</u>. Dept. Neurobiology, Univ. Pittsburgh, Pittsburgh, PA, 15261, Dept Anatomy Univ Oklahoma, Oklahoma City, OK 73190 and Dept. Physiology, Univ. Kentucky, Lexington, KY

Neurons in a narrow strip of the periventricular preoptic area (pePOA) regulate the activation of LHRH neurons in young female rats during the afternoon of proestrus. PePOA neurons are coordinately activated with LHRH neurons at the time of LH surge and possess receptors for both estrogen (ER) and progesterone (PR). Tract-tracing experiments determined that these neurons provide afferent input to LHRH neurons. In cycling middle-aged rats, the observed reductions in LHRH Fos activation and LH secretion during the LH surge raises the question of whether the decline the surge mechanism involves a diminution in pePOA neuronal activation. To test this hypothesis, we examined cFos staining in pePOA neurons in young (3-4 month old) and middle-aged (10-12 month old) animals. Double labeling of cFos/LHRH in LHRH neurons determined the activational status of the surge mechanism. All animals were perfused during the afternoon of proestrus at the time of the LH surge. A blood sample for plasma LH was taken at the time of perfusion. In the middle aged group, as expected, LH values and the degree of Fos activation in LHRH neurons were reduced by 60% and 58% respectively at the time of the surge and there was a similar reduction (57%) in cFos activation in pePOA as compared to the younger group (p<0.05). On an animal-by-animal basis, the level of pePOA activation reflected well the level of LHRH cFos activation. These data provide further support linking the pePOA to LHRH activation during an LH (Supported by NS 28730 and AG 02224). surge.

NON-ISOTOPIC MEASUREMENT OF LHRH FROM POSTNATAL HYPOTHALAMIC SLICE EXPLANT CULTURES. J.A. S.Wray. Lab. of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

Luteinizing hormone releasing hormone (LHRH) cells control gonadal function by regulating gonadotropin release from the pituitary. Studies on immortalized and embryonic LHRH neurons indicate that they express an array of membrane receptors and possess a variety of intracellular signalling pathways. However, study of intra- and extracellular signalling pathways in postnatal LHRH neurons is hampered by their dispersed location in the CNS. To examine regulation of LHRH release from primary LHRH neurons in an organotypic environment, a competitive enzyme-linked immunosorbant assay (EIA) was designed competitive enzyme-linked immunosorbant assay (ĒIA) was designed to measure LHRH from long-term, roller-tube slice explant cultures of PNS rat hypothalami. The EIA, which uses affinity-purified antibodies against mammalian LHRH, has a detection limit of 10 pg/ml, a range of 10-1000 pg/ml, an intraassay coefficient of variation (cv) of 2.2% (n=7), and an interassay cv of 2.0-6.8% (n=4); the ED₅₀ of the standard curve is 68.0 [50.4-91.8] pg/ml (n=4). LHRH extracted from slices prior to culturing measured 43.6±7.7 pg per 4 slices/animal (n=4). No sex differences were noted. The majority of LHRH was found in the slice containing the OVLT (21.5±3.1 pg), followed by the most caudal slice at the level of the SCN (14.9±6.9 pg). Slices containing the DBB and mPOA contained 8.9±3.2, and 8.7±0.5 pg LHRH, respectively. LHRH extracted from slices maintained in culture for 18-21 days was 5-fold greater than that extracted from freshly-cut slices. Preliminary 5-fold greater than that extracted from freshly-cut slices. Preliminary studies show that after 21 days in culture, 56 mM KCl stimulates a 6-fold increase in LHRH release over basal.

MECHANISMS OF LHRH RELEASE REGULATED BY GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR (GM-CSF). M. Kimura*, W. H. Yu, A. Walczewska, V. Rettori and S. M. McCann. Pennington Biomedical Research Center, Louisiana State Univ., Baton Rouge, LA 70808-4124, and CEFYBO-CONICET, 1414 Buenos Aires, Argentina.

and CEFYBO-CONICET, 1414 Buenos Aires, Argentina. Granulocyte-macrophage colony stimulating factor (GM-CSF), a hemapoietic cytokine, has a dose-related inhibitory effect on luteinizing-hormone releasing hormone (LHRH) release as we have shown recently. It is known that γ-aminobutyric acid (GABA) also inhibits LHRH release. However, glutamate and norepinephrine stimulate LHRH release resulting from the activation of nitric oxide (NO) neurons. In the present study, we examined in vitro how GM-CSF was involved in the regulation of LHRH release. Medial basal hypothalami were dissected from male rat brains. After 1-h preincubation, each individual tissue was incubated with recombinant murine GM-CSF (10-11 M) combined with either sodium nitroprusside (NP, NO releaser, 300 μM) or bicuculline (GABA, receptor antagonist, 10-3 M) for 0.5 h in Krebs-Ringer bicarbonate glucose media in a Dubnof metabolic shaker under 95 % 0,/5 % CO₂. LHRH release into media and NO synthase (NOS) activity in the tissues were determined by RIA and conversion of ¹⁴C-arginine to citrulline, respectively. GM-CSF completely suppressed NP-induced LHRH release (p < 0.01) and lowered NOS activity in the hypothalamus (p < 0.001). Bicuculline partially reversed the inhibitory effects of GM-CSF on LHRH release. The present results suggest that the action of GM-CSF on LHRH release uses a dual pathway: blocking stimulatory NO-induced release but signaling GABAergic neurons with an inhibition of the hypothalamic release of LHRH. THE GIRH SYSTEM AND PITUITARY GLAND RESPONSE DURING AGING. M.A. Ottinger*, A. Walz, Q. Li, and S. Ishii+. Dept. of Poultry Science and Cytoimmune Sci., Univ. of Maryland, College Park, MD 20742, USA and +Dept. of Biology, Waseda University, Tokyo 169-50, Japan

Age-related changes in the GnRH system of the male Japanese quail include a significant (p<0.05) reduction in both preoptic-septal region and the median eminence concentrations of cGnRH-I. Similarly, in vitro perifusion of longitudinal hypothalamic slices from young reproductive males compared to senescent males also showed a diminution of cGnRH-I release and reduced response to norepinephrine challenge. Surprisingly, plasma and pituitary gland LH levels were not found to decline significantly (collaboration with John Proudman, USDA, ARS). In a separate study, pituitary gland LH was studied immunocytochemically during aging. Male Japanese quail were grouped according to chronological age and sexual activity. Experimental groups included young, middle-aged and old males, categorized as sexually active or inactive. In addition, there were groups of young photoregressed and old senescent testosterone implanted males. Sections were analyzed using cell counts and image analysis (Opelco Image Analysis System) Results showed an age-related decline in the number of cells staining, size of the cells, and total area stained. Testosterone treatment increased immunostaining in old senescent males. These results provide evidence for age-related alterations in pituitary gonadotropin cell response that appear to be more distinct than age-related effects on the plasma or pituitary LH. NEURONS CULTURED FROM ADULT HYPOTHALAMUS EXPRESS LHRH, LHRH mRNA, AND RELEASE LHRH. P.W. Coates*, L. S. Thode[§], R.L. Norman and F.H. Gage[§] Biol./Biochem., TTUHSC, Lubbock, TX 79430, 'Dept. Physiol., SIU-SM, Carbondale, IL 62901 and 'Lab Genetics Salk Inst., San Diego, CA 92186.

We recently reported on a novel system for long and short-term culture of

neurons from normal adult (90 d. old) female rat hypothalamus (Coates et al., SN Abs., 1995) that was patterned after a system used to successfully culture adult hippocampal cells (Gage et al., PNAS, 1995). Adult-derived hypothalamic cells grown in serum-free, defined medium + FGF-2 proliferate abundantly and subpopulations differentiate into neuronal and glial-like cells. Such cells have been grown for over a year in continuous culture, can be passaged, cryopreserved and re-initiated into culture. To determine whether the cells can express a regionally specific hypothalamic neurohormone and its message, we examined the cultures with immunocytochemistry using the LRI and EL-14 antibodies for luteinizing hormone releasing hormone (LHRH). Approximately 40% of the cells were modestly immunopositive for LHRH. RT-PCR was used to analyze message for LHRH. mRNA for LHRH was detected unambiguously at 40 cycles from cells harvested at different culture times. radioimmunoassay (RIA) using the CRR11B73 antibody to LHRH was used to assess LHRH in media obtained from cultures after varying periods of time. RIA revealed that LHRH was released into the medium. Thus data from three independent analyses suggest that at least some cells in adult-derived hypothalamic cultures differentiate into neurons that display properties similar to typical mature hypothalamus in vivo. Supported by HD22806.

IMMUNOCYTOCHEMICAL LOCALIZATION OF GLUTAMATE, GLUTAMATE RECEPTORS OR NITRIC OXIDE SYNTHASE IN THE MEDIAN EMINENCE OF FEMALE RATS. S-I. Kawakami 1. H. Tsukamura 1. K-I. Maeda* 1 and M. Ichikawa 2. 1 School of Agricultural Sciences, Nagoya Univ., Nagoya 464-01, Japan. 2 Department of Anatomy and Embryology, Tokyo Metropolitan Institute for Neuroscience, 2-6 Musashidai, Fuchu-shi, Tokyo 183, Japan.

We have previously found that glutamate (Glu) or its agonists stimulate in vitro LHRH release from median eminence (ME) fragments of ovariectomized (OVX) rats. In the present study, we examined immunocytochemical localization of Glu, Glu receptors or nitric oxide synthase (NOS) in the external layer of the ME of OVX rats. Animals were perfused with 4% paraformaldehyde-0.1% glutaraldehyde in 0.1 M PB and 50 µm coronal sections were cut with a microslicer. After blocking, sections were incubated with polyclonal antibody raised against Glu, NR1, GluR1, GluR2/3, GluR6/7, mGluR2/3. mGluR5 or NOS. Immunoreactivity was visualized using ABC method and diaminobenzidine. Stained sections were embedded in Ouetol 812, cut on an ultramicrotome and observed with an electron microscope. Glu or Glu receptors immunoreactivity was observed in the nerve terminals of the ME. These nerve terminals contained clear and/or dense-core vesicles, and most of these formed nonsynaptic contacts. A few Glu-, GluR1-, GluR2/3- or mGluR5-immunoreactivity was observed in both pre- and postsynaptic areas. NOS-immunoreactivity was observed in both pre- and postsynaptic areas. NOS-immunoreactivity was found in glial processes and nerve terminals which contained dense-core vesicles. A few NOS-immunopositive synapses were observed, strong immunoreactivity was found on the postsynaptic density and mitochondria membrane. These results suggest that Glu and NO play a role in regulating LHRH release at the nerve terminals of the ME.

EVIDENCE THAT HYPOTHALAMIC NITRIC OXIDE SYNTHASE (NOS) mRNA LEVELS INCREASE BEFORE THE PREOVULATORY LH SURGE IN RATS: EFFECTS OF AGE. <u>A. Sahu*</u>. Dept. Cell Biol. & Physiol., Univ. Pittsburgh, Pittsburgh, PA 15261.

Recent evidence suggests an important role of nitric oxide (NO), a free radical gas, in regulation of GrRH and luteinizing hormone (LH) secretion. In the present study, we tested the hypothesis that gene expression of hypothalamic NOS, the enzyme that catalyzes NO production, is increased before the LH surge and that alteration in NOS neuronal activity may be one of the causal factors for the delayed and attenuated LH surge in didle-aged (MA) rats. Young (2-3 mo old) and MA (8-10 mo old) rats showing regular 4-day estrous cycles were killed at 1000, 1200, 1400, 1600, 1800, 2000 or 2200 h on proestrus. Trunk blood was collected for LH determination by RIA. Medial basal hypothalamus (MBH) was dissected out and frozen on dry ice. NOS mRNA levels in the MBH were measured by solution hybridization/RNAse protection assay using a cRNA probe for brain NOS and expressed in relation to cyclophilin mRNA. In young rats, the LH surge occurred at 1600 h with peak values at 1800 h. As compared to 1000 h, NOS mRNA levels increased significantly at 1200 h when LH levels were low basal, remained elevated during 1600 to 1800 h and returned to low levels by 2200 h. In MA rats, NOS mRNA levels remained unaltered between morning and afternoon associated with a delayed and attenuated LH surge. Also, NOS mRNA levels were significantly decreased at 1200, 1600 and 1800 h in MA rats as compared to those in young rats. These results show for the first time that hypothalamic NOS mRNA levels increase long before the LH surge in young rats and that this antecedent increase in NOS mRNA levels does not occur in MA regularly cycling rats. Overall, our results suggest an enhanced NOS neuronal activity, and thereby an increased NO production, before the generation of the LH surge. This early increase in NO production could play an important role in stimulating other excitatory neural signals that are obligatory for the prevoulatory LH surge. This caption for the prevoulatory LH surge in middle-aged rats. (Supported by NIH AG 10868).

GNRH AXONS TRAVEL WITH NEURONAL, NOT GLIAL, ELEMENTS WHEN EXITING PREOPTIC AREA (POA) EXPLANTS. M-C. Rogers, A-J. Silverman', M.J. Gibson, Dept.Med. & Fishberg Ctr. Neurobiol., Mount Sinai Sch. Med.NY 10029. Dept. Cell Biol. & Anat, Columbia Coll. Phys. & Surg. NY 10032.

GnRH fibers follow defined routes to project to the median eminence (ME) during development. Similarly, GnRH axons grow from intraventricular grafts in hypogonadal mice, to innervate the host ME. Using organotypic co-cultures of embryonic (E15) tissue in insert chambers, we showed that GnRH terminals grow from the POA explant preferentially towards a mediobasal hypothalamus (MBH) explant that includes the ME (Soc.Neurosc. Abstr. 20:664; 21:1898). These findings suggest the existence of a diffusable factor chemotropic for GnRH axons. The purpose of the present study was to evaluate associations of outgrowing GnRH axons with other elements on the membrane. Postnatal day 1 tissue was used, and as with E15, GnRH outgrowth was higher in the region facing the MBH (p<0.001). Double labeling for GnRH and GFAP, vimentin, or S100 was performed to see if GnRH terminals are using a glial substrate to grow on the membrane. Only erratic associations were seen between GnRH and glial processes. Staining for growth associated protein 43 (GAP-43) labels a general population of neurons elongating their axons. Double staining with GAP-43 and GnRH showed that, in contrast to its effect on GnRH axons, the MBH did not induce a differential outgrowth of those axons labeled with GAP-43. GAP-43 axonal outgrowth extended from all borders of the explants and always grew further from the POA explant than the GnRH fibers. Moreover, GnRH fibers traveled in the company of GAP-43 axons. In some cases, the GnRH axons followed a bundle of GAP-43-reactive fibers, and in other instances, GnRH axons appeared to be crossing on a dense network of GAP-43reactive fibers. Some GnRH axons growing on the membrane were also doublelabeled with GAP-43. Whether there is a sub-population of neurons that provide guidance to GnRH axons remains to be determined. Supported by NS20335.

ESTROGEN INCREASES NADPH-DIAPHORASE REACTIVITY IN THE HYPOTHALAMUS AND BASAL FOREBRAIN OF FEMALE RATS. T. J. Hebert*, Z. Zhao, J. M. Pace, C. S. Menard, and G. P. Dohanich. Department of Psychology, Tulane University. New Orleans, LA 70118 and Department of Psychology, University of Southwestern Louisiana, Lafayette, LA 70503.

NADPH-diaphorase histochemistry provides a useful method for identifying and characterizing neurons that produce nitric oxide (Hope et al.; PNAS, 88, 2811-2814; 1991). A previous study demonstrated that treatment with high doses of estrogen (10µg/day of estradiol benzoate for 2 days) resulted in an increase in the number of NADPH-diaphorase reactive neurons in the ventromedial nucleus of the hypothalamus (VMH) of female rats (Okamura, et al.; Endocrinology, 135, 1705; 1994). In an initial experiment, we determined the effect of natural cyclicity on diaphorase reactivity in the hypothalamus and basal forebrain. Gonadectomy significantly reduced the number of diaphorase reactive neurons in the VMH and horizontal limb, but not in the vertical limb, of female rats. In the VMH, diaphorase reactivity varied significantly across the estrous cycle, with the greatest number of diaphorase neurons detected at proestrus. An additional experiment indicated that estrogen treatment (10µg/day of estradiol benzoate for 3 days), similar to that previously reported to increase the number of diaphorase reactive neurons in the VMH, also increased the number of diaphorase reactive neurons in the horizontal limb, but not the vertical limb. These results indicate that the gonadal steroid, estrogen, can increase the activity of the nitric oxide synthase, NADPH-diaphorase, in areas of the hypothalamus and basal forebrain. TEMPORAL CHANGES IN THE HYPOTHALAMIC SEROTONINERGIC-NEURONAL ACTIVITY AFTER THE LESION OF THE DORSAL RAPHE NUCLEUS (DRN). M.E. Ayala, J. Monroy, L. Morales and R. Dominguez*. UIBIR. FES Zaragoza, UNAM. México AP 9-020 CP 15,000.

The lesion of the DRN of 30-day old rat blocked the ovulation, while the same treatment performed on 27-day old animals resulted in an increase on the number of ova shed by ovulating animals. To analize if the changes in ovulation depend on the hypothalamic serotoninergic-neuronal activity, the activity of the neuron was calculated as [5-hydroxyindole 3-acetic acid]/ [serotonin] measured by HPLC, in control, sham operated and rats with a lesion on the DRN performed on days 27 or 30 and autopsied every two days until first vaginal estrus. The figures 1 and 2, show the changes observed in 27-day and 30-day old rats.

Present results suggest that there the differences in the first ovulation induced by a lesion of the DRN on 27-day and 30-day old rats, are not related with the hypothalamic serotoninergic neural activity.

INHIBITION OF PROTEIN KINASE A (PKA) STIMULATES GNRH RELEASE IN GT1 CELLS AND DOES NOT BLOCK cAMP-INDUCED STIMULATION OF GNRH. <u>E.A. Vitalis, A.L. Choi and R.I. Weiner*</u>. Reproductive Endocrinology Center, UCSF, San Francisco, CA 94143.

Pharmacological and receptor-mediated activation of adenylyl cyclase (AC) and elevation of cAMP stimulate GnRH secretion from GT1 cells. To determine if PKA mediates the stimulatory action of cAMP, GT1 cells were treated with H-89, a selective, permeable inhibitor of PKA. In vitro PKA assays on GT1 lysates verified that the cells express PKA activity which is inhibited by H-89 in a dose-dependent fashion. Unexpectantly, H-89 treatment for 30 minutes caused a statistically significant, dose-dependent, stimulation of basal GnRH secretion from GT1 cells measured by RIA. Furthermore, it did not block GnRH release induced by dopamine, forskolin, or 8-Br-cAMP, agents which increase cAMP levels. The stimulatory effect of inhibition of PKA could be explained by removal of a negative feedback action upon AC. A family of AC isoforms have been described of which two, V and VI, are inhibited by PKA. By RT-PCR and restriction map analysis, we showed that the cells express AC types V and VI. In conclusion, elevation of cAMP in GT1 cells results in a stimulation of GnRH release which is not dependent upon PKA activation. We hypothesize that activation of PKA inhibits GnRH release via inhibition of AC resulting in a decrease in cAMP levels.

The Neurosteroid, 3α-Hydroxy-4-pregnen-20-one (3αHP), Suppresses GnRH-Induced FSH Release by Rapid Interaction With the Gonadotrope Membrane J.P. Wiebe*, L. Murphy, and M. Wolfe. Hormonal Regulatory Mechanisms, B&G Bldg, Univ. Western Ontario, London, Canada N6A 5B7.

The gonadal- and neurosteroid, 3aHP, has been shown to selectively suppress GnRH-induced pituitary FSH release in vivo and in vitro by means of the cell signaling pathway involving protein kinase C and Ca^{2+} mobilization. To determine if additionally $3\alpha HP$ action on the gonadotrope is at the level of the cell membrane, three approaches were used. [A]. $3\alpha HP$ was conjugated to BSA (26 moles 3α HP/mole BSA) to prevent entry into cells. Treatment with 3α HP-BSA resulted in a significant (p<0.01) suppression of, while progesterone(P)-BSA or 3β HP-BSA showed no effect on FSH release from female rat pituitary cells. [B]. Pituitary cell membrane fractions showed specific binding to [1,2,6,7- 3 H]3 α HP which was not displaced by 1200-fold P, 3 β HP or testosterone. [C]. The time course of suppressive action of 3 α HP in GnRH-induced FSH release was examined in a perifusion system employing pituitary cells attached to cytodex beads. Cells received a 5 min pulse of GnRH (10^{-7}M) with/without 3α HP or othbeaus. Cells received a 3 min pulse of GhRY (10 M) with/window surf of other steroids. GnRH pulses resulted in a short (10-15 min) 4-30-fold peak (above baseline) of FSH release. When a 5-min pulse of 3α HP (10^{-9} M) was applied simultaneously with the GnRH pulse, the GnRH-induced FSH release was completely suppressed while pulsing with P or estradiol resulted in a significantly greater (p<0.05) release of FSH than the control (GnRH only). When a 3α HP pulse was applied 5 min after the start of GnRH pulse, the GnRH-induced FSH release was about 85% of the control peak. The pituitary levels of 3α HP (measured by specific RIA) on the day of proestrus oscillate between a low of 6 ng and a high of 64 ng and show an inverse oscillatory relationship to the FSH levels. The results suggest that the 3α HP regulated suppression of GnRH-induced FSH release involves a rapid interaction of this neurosteroid with the gonadotrope membrane. (Supported by NSERC of Canada).

ACUTE ETHANOL INGESTION AND EXPRESSION OF SYNCHRONIZED LH PREOVULATORY SURGES USING A FOLLICULAR MODEL IN EWES. S. Goebbert, J. Klein, J. Rabii*, and JP Advis. Depts of Animal Sciences and

Biological Sciences, Rutgers University, New Brunswick, NJ 08903.
We developed an animal model for studying potential effects of ethanol (EtOH) ingestion on in vivo release of multiple neuropeptides, from discrete brain areas, during the genesis of a synchronized LH preovulatory surge. This synchronized follicular model used sequential P4 removal (P4 out, day 18) and E2 implantation of silastic packets (E2 in, 16h later) into cycling ewes (20 day synchronized cycle, P4 in on day 10, and E2 out on day 20). Gastric EtOH infusion (0.25 g/kg in a 25% saline solution) was provided at the beginning of a synchronized follicular phase (at E2 in) through a chronic abomasal cannula. For the next 18h, blood EtOH level was maintained between 0.15 -0.20 % (w/v) by further intragastric EtOH administration and hourly monitoring of blood EtOH (Sigma EtOH Diagnostic Kit). Plasma LH also determined at hourly samples was continued for up to 36h after E2 in. In this model, each ewe served as both control (saline abomasal infusion, LH surge onset: 18±2h ewe selved as obtained another state. Let's a selve a so other control selve (£10H abomasal infusion for 18h from £2 in, during another synchronized estrous cycle of the same ewe, LH surge onset: 26± 2h after £2 in, n=6). Each ewe underwent a control synchronized cycle, followed by an £10H experimental cycle, and then back to a control synchronized cycle. In control cycles, all surges began between 17-20h after £2 in, each lasted approx. 5h and reached peak LH values between 19 - 22h after E2 in. In experimental EtOH cycles, all surges began between 25 - 27h after E2 in, each lasted approx.7h and reached peak LH values between 28 - 29h after E2 in, each lasted approx.7h and reached or peak LH values between 28 - 29h after E2 in. Thus, our model allows study of neuroendocrine effects of EtOH in well-defined reproductive conditions (e.g. median eminence in vivo release of multiple neuropeptides after EtOH ingestion). NEUROENDOCRINE REGULATION: GROWTH HORMONE AND SOMATOSTATIN

534.1

EFFECT OF GONADAL STEROIDS ON GROWTH HORMONE (GH) RELEASE IN OVARIECTOMIZED SHEEP IN RESPONSE TO L-692,585, A NOVEL NON-PEPTIDYL GH SECRETAGOGUE. G. E. Dahl*1, E. Russek1, L. J. Craig1, C. H. Chang², G. J. Hickey², ¹University of Maryland, College Park, 20742 and ²Merck

Research Laboratories, Rahway, NJ, 07065.

L-692,585 (585) is a novel GH secretagogue that stimulates GH release in guinea rigs, pigs and dogs. Gonadal steroids influence endogenous GH secretion, but their impact on responses to 585 are unknown. Objectives of this study were to evaluate 585 stimulated release of GH in ovariectomized (O) sheep and to determine if steroidal environment (i.e. androgenic or estrogenic) influenced these responses. Also, the influence of steroidal environment on the GH response to 585, GHRH and 585+GHRH was determined. In a preliminary experiment, 585 at doses of .033 and .1 mg/kg BW stimulated GH release relative to saline injection in a dose dependent manner. Ewes (n=6) were ovariectomized and received estradiol (E; ~2-3 pg/ml), testosterone (T; ~2.5ng/ml) or no replacement (O) in random succession with a 2-3 wk equilibration period between each steroid. In Experiment 1, GH was quantitated in serum samples collected at 10-min intervals for 2 hr before and during a 6 hr period when 585 (.1 mg/kg) was administered i.v. at 1 hr intervals. Responses to 585 were analyzed using a pulse detection algorithm; increases in GH were detected to 106 of 108 injections. Responses, as assessed by area under the GH curve, were greatest with the first injection and declined with time (P<.01). Responses were not affected by steroidal treatment. In Experiment 2, responses to a single injection of 585 (.1 mg/kg), GHRH (.75 μg/kg), or the combination were assessed. Regardless of steroid GH AUC for GHRH was greater than that for 585 (P<.05). GH AUC for 585+GHRH was not different from GHRH. Steroid treatment altered GH AUC responses, with O≥T≥E (O vs. E, P<.05), but this effect of E was specific to GHRH. In summary, 585 stimulates GH secretion in sheep. Repetitive 585 stimulation is associated with a decline in GH output over a 6 hr period. Steroids had no effect on responses to 585 but E decreased responses to GHRH. Support from MD-AES & Merck Res. Lab.

BEDREST PREVENTS RELEASE OF TIBIAL GROWTH FACTOR BUT NOT GROWTH HORMONE IN RESPONSE TO MUSCLE ACTIVITY. G.E. McCall*, C. Goulet, J.A. Hodgson, R.E. Grindeland†, and V.R. Edgerton. Dept. of Physiological Sci., Univ. of California, Los Angeles, CA 90066 and NASA Ames Research Center, Moffet Field, CA 94035

Moffet Field, CA 94035†.

Homonal responses of 8 men to a muscle fatigue test before (-12 and -7 days), during (days 2/3, 8/9, and 13/14) and following (+2/3 and +10/11 days) 17 days of bedrest were studied. The fatigue test involved a series of unilateral isometric plantar flexions and included 4 maximal voluntary contractions (MVC), 48 contractions at 30% MVC, and 12 contractions at 80% MVC all performed at a 4:1 s work:rest ratio. Blood was collected prior to and immediately following the fatigue test to measure plasma growth hormone (GH) by radioimmunoassay and a tibial growth factor (TiGF) by bioassay of tibia epiphyseal cartilage growth in hypophysectomized rats. Plasma GH was unchanged by the fatigue test during all testing periods. Prior to bedrest plasma TiGF increased (p<0.05) following the fatigue test (-12 d 2146 ± 192 to 3565 ± 197; -7 d 2162 ± 159 to 4161 ± 204; μg • L⁻¹). During bedrest the TiGF response was absent at 2/3 d, and decreased (p<0.05) by 8/9 (2433 ± 185 to 2105 ± 106) and 10/11 d (2594 ± 211 to 2085 ± 109). Following bedrest the TiGF response at 42/3 d was not significant. The TiGF response had normalized by +10/11 d (1881 ± 75 to 4160 ± 315; p<0.05). Although significant (p<0.05) increases in thyroid hormone (T3 and T4) and decreases in cortisol and testosterone plasma concentrations occurred in response to the fatigue test, these changes were independent of bedrest. In response to the fatigue test, these changes were independent of bedrest. In conclusion, the release of TiGF in response to a fatigue test was inhibited by bedrest, but returned to normal 10/11 days following bedrest.

REDUCTION OF INTRINSIC NEGATIVE FEEDBACK REGULATION OF NEUROENDOCRINE AXES INCREASES THE APPROXIMATE ENTROPY (SERIAL IRREGULARITY) OF THE PITUITARY HORMONE RELEASE PROCESS FOR TSH, GH, AND LH. J.D. Veldhuis', A. Iranmanesh, S. Pincus Univ. of Virginia Hlh Sci Ctr, Charlottesville, VA, VA Med Ctr, Salem, VA, 990 Moose Hill Rd. Guilford, CT.

To evaluate feedback regulation of hypothalamo-pituitary-target organ axes, we investigated 3 paradigms of decreased negative feedback signaling. First, we sampled blood at 10 min intervals for 24 h in 6 men with primary hypothyroidism before and after L-thyroxine replacement. Secondly, men and women were subjected to a 5 day fast consisting of water only which reduced

women were subjected to a 5 day fast consisting of water only, which reduced plasma IGF-I concentrations and increased GH release in an "open loop" model. Thirdly, we administered the steroidogenesis inhibitor, ketoconazole, to lower testosterone secretion and reduce androgen negative feedback. To estimate Initially, we administered it sectoragents in initially, exconsists, to well testosterone secretion and reduce androgen negative feedback. To estimate network complexity, we used a model-independent and scale-invariant statistical measure of quantifiable regularity in the hormone profiles, approximate entropy (ApEn, PNAS 88:2297, 1991), with increased disorderliness or greater irregularity quantified by larger ApEn values. In primary hypothyroidism, ApEn for TSH increased significantly from 1.073 ± 0.081 (normal) to 1.514 ± 0.066 (hypoT4) (P=0.0086), and this increase was reversed by the administration of L-thyroxine (ApEn = 1.146 ± 0.1012 , P=0.013). Similarly, 24-hour GH profiles in fasting men and women with low IGF-I concentrations showed a rise in ApEn from 0.331 \pm 0.133 to 0.592 \pm 0.227 (P = 0.0072) (ICI 94:1277, 1994). Lastly, when testosterone concentrations fell, the ApEn of LH secretory time series rose from 0.638 \pm 0.032 to 0.893 \pm 0.022 (P<0.01). Collectively, these observations provide evidence for feedback-dependent modulation of hypothalamo-pituitary regulatory mechanisms that control the temporal secretory patterns of TSH, GH, and LH. Thus, we infer a general principle that for many endocrine networks reduction of intrinsic negative feedback is manifested in more irregular secretory dynamics at the target node. manifested in more irregular secretory dynamics at the target node.

D2 DOPAMINE RECEPTOR-MEDIATED REGULATION OF FOS PROTEIN EXPRESSION IN SOMATOSTATIN-CONTAINING NEURONS IN THE HYPOTHALAMIC PERIVENTRICULAR NUCLEUS IN MALE RATS. K.J.Lookingland*, S. Cheung, J.D.Johnson and K.E.Moore. Dept. of Pharm. & Toxicol., Michigan State University, East Lansing, MI 48824

Somatostatin (SS)-containing neurons located in the hypothalamic periventricular nucleus (PeVN) project to the median eminence. SS released from these neurons into the hypophysial portal blood inhibits growth hormor secretion from the anterior pituitary. The close proximity of SS perikayra to A14 dopaminergic neuronal axons in the PeVN suggests that these peptidergi neurons may be regulated by dopamine receptor-mediated mechanisms. To test this, the effects of agonists selective for either D₁ or D₂ receptors were examined for their ability to alter FOS immunoreactivity (IR) in SS-IR neurons in the PeVN. Frontal sections (30 μm) through the middle PeVN were chosen macroscopically and the number of SS-IR and Fos-IR + SS-IR cells were counted bilaterally. Ninety min after systemic injection of the D₁ agonist SKF 38393 (20 mg/kg; i.p.) there was no difference in the number of Fos-IR + SS-IR double labeled cells as compared with vehicle-treated controls. However, 90 min after systemic injection of the D_2 agonist quinelorane (100 μ g/kg; i.p.) the number of SS-IR neurons containing FOS-IR decreased from 13.60 ± 3.43 to 5.00 ± 1.38 in the PeVN. Prior administration of the D₂ antagonist raclopride (3 mg/kg; i.p.) had no effect per se, but prevented the quinelorane induced decrease in the number of SS-IR neurons with FOS-IR. These results reveal that selective activation of D2 receptors inhibits expression of FOS protein in SS-containing neurons in the PeVN. (Supported by NIH grant NS15911)

COMPARISON OF SPONTANEOUS ELECTRICAL ACTIVITY IN RAT SOMATOTROPHS AND LACTOTROPHS. S. Sankaranaravana* and S. M. Simasko. Dept. of VCAPP, College of Veterinary Medicine, Washington State Univ., Pullman, WA 99164-6520.

The perforated patch variation of whole cell patch-clamp technique was used to determine the characteristics of the spontaneous action potentials exhibited by primary cultures of rat somatotrophs and lactotrophs. This spontaneous activity is hypothesized to be responsible for spontaneous secretion from these cells. Pituitary cells were obtained from random-cycling female Sprague-Dawley rats. Lactotrophs were isolated using percoll-density gradient and identified using quinpirole-induced hyperpolarization. Somatotrophs were identified using the reverse-hemolytic plaque assay. Spontaneous action potentials were exhibited by approximately 75% of somatotrophs and 65% of the lactotrophs. The following characteristics of spontaneous action potentials in somatotrophs (n = 19, 1st value listed) and lactotrophs (n = 28, 2nd value listed) were significantly different (t-test, P < 0.002): threshold for spike generation: -38 ± 1 mV, -34 ± 0.8 mV, duration: 238 ± 20 ms, 500 ± 48 ms; peak amplitude -12 ± 2 mV, -17 ± 0.7 mV, slope of upstroke. 0.8 ± 0.1 mV/ms, 0.4 ± 0.06 mV/ms; and afterhyperpolarization: -51 ± 1.0 mV, -43 ± 1.0 mV. The underlying ionic basis for these differences and the significance in terms of regulation of secretion remains to be determined.

In both cell types removal of bath sodium caused a hyperpolarization that resulted in cessation of spontaneous action potentials and was associated with an increase in input resistance. However, the magnitude of the hyperpolarization was larger in lactotrophs (ΔV_M = -22 ± 2.5 mV, n = 25) than somatotrophs (ΔV_M = -13 ± 1.4 mV, n = 14). On the other hand, somatostatin-induced hyperpolarization in somatotrophs (ΔV_M = -18.5 ± 1) mV, n = 19. This suggests a difference in the relative proportion of background sodium current versus agonist-modulated in

expressed in these cells.

DIFFERENTIAL G PROTEIN-MEDIATED COUPLING OF SOMATOSTATIN RECEPTORS TO POTASSIUM AND CALCIUM CURRENTS IN PRIMARY CULTURED OVINE SOMATOTROPHS. <u>C. Chen*</u>. Prince Henry's Institute of Medical Research, P. O. Box 5152, Clayton, Victoria 3168, Australia. We have shown that Go2 protein mediates the reduction in Ca²⁺ currents

by somatostatin in primary cultured ovine somatotrophs (Chen & Clarke. J Physiol. 491:21-29, 1996). To investigate the role of G proteins in the augmentation of voltage-gated K+ currents by somatostatin, classical whole-cell recordings were made on ovine somatotrophs identified by postcen recording were made on owne somatoropis bentined by post-recording immunocytochemistry. Using Ca²⁺-free, TTX-containing (1 µM) bath solution and K⁺-containing pipette solution, outward transient (I_A) and delayed rectifying (I_K) K+ currents were recorded. Both I_A and I_K were reversibly increased by local application of somatostatin (10 nM) onto the recorded cells. After intracellular dialysis of GTP-y-S (0.2 mM) via whole-cell patch pipette, the increase in K+ currents by somatostatin became irreversible. However, dialysis of GDP- β -S (0.2 mM) significantly reduced the increase in K+ current by somatostatin. These data indicate an involvement of G proteins in the alteration of K+ current by somatostatin. In order to study the role of different subtypes of G protein, specific antibodies to various a subunits of G proteins were dialysed into the cells. Effective dialysis was confirmed by immunofluorescence staining of the antibodies in recorded cells. Intracellular dialysis of the antibodies to α i, but not that to α o, significantly attenuated the increase in K+ currents by somatostatin. The blocking effect on the response to somatostatin was more obvious with ai3 antibodies than ai1-2 antibodies. These results suggest that Gi proteins (probably Gi3) mediate the effect of somatostatin on K+ currents in ovine somatotrophs in primary culture whereas Go2 protein mediates the effect on Ca2+ currents. CELL-TO-CELL PROPAGATION OF CALCIUM SIGNALS DUE TO ELECTRICAL ACTIVITY IN ACUTE ANTERIOR PITUITARY SLICES. N. C. Guérineau*, L. Stoeckel, F. Mercier and P. Mollard. INSERM U401, Rue de la Cardonille, 34094 Montpellier Cedex, France

Individual endocrine pituitary cells, like neurons, generate action potential-linked [Ca2+]i transients leading to exocytosis. However, the exact role of membrane excitability in the entire gland is still unknown. We therefore studied calcium signals and associated electrical events in acute slices from guinea-pig anterior pituitary. Cells within cell cords are surrounded by basal membrane and conjonctive tissues. Spontaneous short-lived [Ca2+]i transients were detected in many cells tissues. Spontaneous snort-unce [Ca2**] transients were detected in finally cerus using real-time (30 to 480 frames / sec) confocal Ca2+ imaging (fluo-3 as fluorescent Ca2+-sensitive probe). These transients were presumably due to electrical activity, since action potential firing was found in ~ 80% of patch-clamped cells. In parts of the slices, neighboring cells (up to 4) showed spontaneous [Ca2+]i transients that occurred synchronously. Cells behaved like somatotrophs since somatostatin (100 nM) was effective in blocking synchronized [Ca2+]i transients. The involvement of apj junctions was investigated using octanol, a gap junction blocker. In some cases, octanol (1 mM) blocked cell-to-cell propagation of [Ca2+]i transients. No direct effect of octanol on [Ca2+]i spiking was noticed. Dye-coupling studies using neurobiotin (1% in the patch-pipette solution) showed that ~ 40% of cells were coupled to neighboring partners belonging to the same cell cord. Taken together, these data show that excitable endocrine (GH) cells synchronize their spontaneous [Ca2+]i transients via gap junctions within the anterior pituitary gland.

EXPRESSION OF GALANIN RECEPTOR mRNA BY SOMATOSTATIN NEURONS IN THE HYPOTHALAMUS OF THE MALE RAT. E. Grafstein-Dunn, R.A. Steiner, and D.K. Clifton*. Departments of Obstetrics & Gynecology and Physiology & Biophysics, University of Washington, Seattle, WA 98195

Galanin (GAL) is expressed in growth hormone-releasing

hormone (GHRH) neurons in the arcuate nucleus (ARC) and has been implicated in the control of growth hormone (GH) secretion; however, the target cells for GAL's action in the hypothalamus are unknown. Because GHRH neurons make synaptic contact with the somatostatin (SS) neurons that regulate GH—those with cell bodies in the periventricular nucleus (PeN)—we postulated that GAL acts at these synapses to influence GH secretion. To examine this and cortex. GAL-R1 mRNA signal levels (grains/cell) over SS and cortex. GAL-R1 mRNA signal levels (grains/ceil) over SS neurons in the PeN were significantly greater than background (p<0.0001), whereas signal levels over SS neurons in the cortex and ARC could not be distinguished from background. Conclusion: GAL released from GHRH neurons in the ARC can act directly on SS neurons whose cell bodies reside in the PeN. Based on GAL's putative cellular mechanisms of action, we infer that GAL inhibits SS secretion and thereby reduces SS's inhibition of GH secretion. NEUROENDOCRINE REGULATION: PROLACTIN

EFFECT OF CONTINUOUS AND DISCONTINUOUS ESTROGEN TREATMENT ON PROLACTIN (PRL) mRNA IN THE RAT PITUITARY AND

A. Dutt*, H. Bergen and D. W. Pfaff. Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia, PA 19104; Dept. of Anatomy, Univ. of Manitoba, Winnipeg, Canada and Dept. of Neurobiology and Behavior, The Rockefeller University, New York, NY 10021.

Besides the expected expression of the PRL gene by lactotrophs, surprisingly robust demonstrations of immunoreactive PRL have come from work with rat brain (Emanuele et al., Brain Res., 421:255-262, '87; Harlan et al., Neuroendocrinology, 49:7-22, '89), where PRL can promote female reproductive behavior (Harlan et al., Science 219:1451-1453, '83). To investigate estrogenic influence on PRL mRNA in pituitary and brain, we have used in situ hybridization with PRL P-32 labelled riboprobes, and experiments designed with concepts derived from Harris and Gorski, Endocrinology 103:240-245, '78. Discontinuous estradiol-17 treatments (2 i.p. injections of 5 μg at hours 0 and 8) were compared with continuous treatment (10 μ g estradiol benzoate s.c. in oil), sacrificed at hour 24. Control rats were treated with vehicle alone. In female rat anterior pituitary, both estrogen treatments raised PRL mRNA levels significantly, with continuous treatment yielding a larger effect. Examining female and male rat brain, small numbers of positive PRL mRNA expressing cells were detected. They were in medial hypothalamus (matching previous immunocytochemistry) and surprisingly, the amygdala. The magnitude of changes observed in pituitary PRL mRNA, suggest a difference in PRL responsiveness to discontinuous and continuou estrogen treatment

EFFECT OF ADENOSINE ON THE RELEASE OF PROLACTIN FROM THE ANTERIOR PITUITARY IN VITRO. W.H. Yu*, M. Kimura, A. Walczewska, J.C. Porter and S.M. McCann. Pennington Biomedical Research Center, LSU, Baton Rouge, LA 70808 and Department of OB/Gyn, University of Texas Southwestern Medical Center., Dallas, TX 75235.

Adenosine was identified as a pituitary cytotropic factor for hypothalamic dopaminergic neurons (Porter et al, 1995). It was reported that intraventricular injection of adenosine elevated plasma levels of prolactin (PRL) (Ondo et al, 1989) However, adenosine inhibited prolactin release in cultures of anterior pituitary cells (Schettini et al, 1993). To clarify the effect of adenosine on the release of PRL, we incubated hemi-anterior pituitaries with adenosine in the presence or absence of its receptor antagonists. After 1 h preincubation, hemipituitaries from adult male rats were incubated in fresh Krebs-Ringer bicarbonate (KRB) buffer containing adenosine, its receptor antagonist or both compounds. Incubation was continued for 3 h in a Dubnoff Incubator (50 cycles/min) in an atmosphere of 95% O₂-5% CO₂ at 37^0 C. The concentration of PRL in the medium was measured by RIA. Incubation with adenosine (10^3 to 10^{10} M) significantly stimulated PRL release. A selective A1 adenosine receptor antagonist, 8-phenyltheophylline (8-PT), had no effect on PRL release by itself, but significantly inhibited the adenosine-induced PRL release at doses of 0.1, 1 or 10 μ M. A more potent A1 receptor antagonist, 8-cyclopentyltheophylline (8-CPT), also suppressed PRL release when it was added to the medium together with adenosine. However, 8-(3-chlorotyryl) caffeine (CSC), an A2a receptor antagonist, had little or no effect on PRL release by itself or in the presence of adenosine. In conclusion, our results indicate that adenosine stimulates PRL release through the action of A1 adenosine receptors. (This work was supported by NIH grants DK43900 and MH51853.)

MELATONIN AND RHYTHMIC CHANGES OF TUBERO-INFUNDIBULAR DOPAMINERGIC NEURON ACTIVITY AND PROLACTIN SECRETION. <u>Y.S. Chu, S.H.H. Chan</u>, and J.T. Pan, Inst. Physiol., Natl. Yang-Ming Univ., Taipei, Taiwan R.O.C.

A diurnal rhythm of tuberoinfundibular dopaminergic (TIDA) neuron activity correlated with prolactin (PRL) secretion was recently reported. Whether melatonin plays a role in its regulation was the focus of this study. Under regular lighting environment (LD=14:10), melatonin given in the morning dose- $(0.01,\ 0.1,\ 1\ mg/kg,\ ip)$ and time- $(15,\ 30,\ 60\ min)$ dependently stimulated TIDA neuron activity as determined by DOPAC or DOPA levels in the median eminence. Serum PRL levels were concurrently inhibited. Melatonin given in the late subjective day (1600 h) seemed to be more effective on stimulating the lowered TIDA neuron activity and on inhibiting the increased PRL level than that given in early subjective day (1000 h). Under constant lighting (LL), basal TIDA neuron activity was increased and no diurnal variation could be observed. The stimulatory effect of melatonin still persisted, though. Given 4 interspersed injections of melatonin between 1800 and 0400 h for 3 days could restore the TIDA rhythm in rats under LL. To further test if melatonin indeed possesses an entraining effect on TIDA neuron activity, daily injections of melatonin (1 mg/kg at 1800 h) were conducted in rats kept under regular lighting for 10 days. The results showed that the treatment significantly decreased the afternoon PRL surge and induced a phase advance of the diurnal change in TIDA neuron activity. In all, melatonin may indeed play a role in regulating the rhythmic activity of TIDA neurons, and in turn, the PRL secretion. (Supported in part by grant NSC 85-2331-B010-071).

A NOVEL INTRAPITUITARY ENDOCRINE AXIS; MELATONIN AND PROLACTIN.

Morgan PJ*, P, Barrett, Webster CA JG Mercer, A Ross, DG Hazlerigg. Rowett Research Institute, Greenburn Road, Bucksburn, Aberdeen, AB21 9SB

It has been shown that melatonin may regulate seasonal cycles in plasma prolactin independently of the brain (Lincoln and Clarke 1994 J Neuroend 6:251-260). These results suggest regulation of prolactin secretion by melatonin may occur via the pituitary gland. In adult sheep melatonin receptors, detected through 2-[1231]-iodomelatonin binding, are not expressed on the pars distalis (PD) cells, of the pituitary gland, but are present on the cells of the pars tuberalis (PT). This suggests indirect regulation of prolactin secretion and lactotroph activity by melatonin through the PT. In these studies, two end-points have been used to detect the release of biologically active factors secreted from ovine PT cells cultures. The first is the expression of c-tos mRNA in, and the second is the release of prolactin by, PD cell cultures. Using Northern blotting for the c-fos mRNA, and dual *in situ* hybridization labelling for c-tos and prolactin mRNA it was found that conditioned medium from PT cells increased c-fos expression in ovine lactotrophs relative to controls. By RIA, the release of prolactin was also increased by culture medium conditioned by PT cells relative to controls. Similar experiments performed using medium conditioned by PD cells had no effect relative to controls. These experiments suggest therefore that ovine PT cells release a factor which enhances both c-fos gene expression and the secretion of prolactin by PD cells. This represents a new endocrine axis within the pituitary gland. We have called the factor released by the pars tuberalis, 'tuberalin'. Chromatographic isolation of this factor is in progress.

SOURCE OF DOPAMINERGIC CONTRIBUTIONS TO THE NEURO-ENDOCRINE REGULATION OF PROLACTIN SECRETION, <u>J. Gelineauvan Waes</u>, M. <u>Cassens and C. A. Johnston*</u>. School of Pharmacy, Dept. of Pharm. Sci., Univ. of Montana, Missoula, MT 59812. Dopamine (DA) from both the tuberoinfundibular (TIDA)

Dopamine (DA) from both the tuberoinfundibular (TIDA) and tuberohypophyseal neuronal systems has been implicated in the tonic inhibitory control of prolactin (PRL) secretion. The relative contributions of these DA systems on PRL secretion were studied using an in vivo rat model in which the neurointermediate pituitary (NIL) was exposed (SHAM) or surgically removed (NILX), leaving the anterior pituitary (AP) and its vascular connections to the hypothalamus (TIDA neuronal control) intact. Two weeks following NIL surgery animals were treated with alpha-methylparatyrosine (AMPT, 250 mg/kg BW, ip) to inhibit DA synthesis, and blood samples were obtained at 5 min before, and throughout the next 4 hr. In other animals the DA agonist, bromocriptine, was administered 2 hr after the AMPT injection to determine the effects of DA on PRL secretion. DA content and metabolism were analyzed in the median eminence and AP by HPLC with ED. DA content, metabolism, basal PRL, and the sensitivity of the AP PRL response to DA inhibition produced a much greater increase in plasma PRL in SHAM animals than in NILX animals. The data suggest that the NIL contains a PRL-releasing factor which is tonically inhibited by DA, or that another PRL inhibitory factor plays a greater role in NILX rats. This work was supported by NIH grant, MH48228 (CAJ).

ATRIAL NATRIURETIC PEPTIDE EXHIBITS A NEGATIVE MODULATION ON ANGIOTENSIN II'S STIMULATORY EFFECT ON TIDA NEURON ACTIVITY: NEUROCHEMICAL AND ELECTROPHYSIOLOGICAL STUDIES, <u>L.T. Pan' and S.H. Yen.</u> Inst. Physiol., Natl. Yang-Ming Univ., Taipei, Taiwan R.O.C.

Both atrial natriuretic peptide (ANP) and angiotensin II (AII) are located in the mediobasal hypothalamus and have been shown to affect the secretion of prolactin. Their effects on tuberoinfundibular dopaminergic (TIDA) neuron activity have not been reported and were the focus of this study. Intracerebroventricular injection of AII (0.01, 0.1 and 1 μ g) dose-dependently stimulated TIDA neuron activity in long-term ovariectomized, estrogen-treated rats as determined by 3,4-dihydroxyphenylacetic acid (DOPAC) concentration in the median eminence. The stimulatory effect of All (1 µg/rat, icv) was significantly inhibited by co-administered ANP in a dose-dependent manner (0.1, 1 and 10 μ g/rat, icv). In study using single-unit recording of dorsomedial arcuate (DM-ARC) neurons in brain slices, AII stimulated 67.2% of 64 units recorded. Few units were inhibited (6.3%) by it and the rest were not responsive. ANP alone was mostly ineffective on DM-ARC neurons (60% of 50 units), and it stimulated or inhibited only a few DM-ARC neurons: 24% and 16%, respectively. When ANP was co-administered with AII to AII-responsive units, however, it significantly attenuated the effect of AII in 75.8% of 33 units. The rest were not effective. Results from both in vivo and in vitro studies indicate that ANP can have a negative modulation on the stimulatory effect of AII on hypothalamic TIDA neurons. (Supported in part by grant NSC 85-2331-B010-051).

CENTRAL EFFECTS OF PROLACTIN ARE INHIBITORY FOR MILK EJECTION IN CONSCIOUS LACTATING RATS. Morales, MT*, Shapiro, E and Mena, F. Centro de Neurobiología, Universidad Nacional Autónoma de México, 04510 México D.F., México.

Previous work showed that in urethane-anesthetized lactating rats centrallyadministered PRL, i.e., intracerebroventricular (ICV) or intrathecally (IT), facilitated mammary contractility in response to exogenous oxytocin. These effects were exerted through inhibition of β-adrenergic neural elements regulating ductal tone within the mammary glands. The present experiments were designed to determine whether similar effects by PRL could be obtained in conscious than in anesthetized lactating rats upon normal milk ejection. The rate of milk ejection was determined by applying a 15 min period of suckling by the litter, following a 6h period of isolation. The results showed that centrallyadministered PRL in these rats provoked a dose-related, long-lasting inhibition of milk ejection. Thus, opposite effects of the hormone could be obtained upon milk ejection in anesthetized and concious rats. Further experiments measuring ductal tone as a mean to determine the mechanisms involved, showed that in conscious rats this effect of PRL was associated with increased ductal constriction within the mammary glands. Also, this effect was mimicked by ICV administration of the β-adrenergic agonist isoproterenol, and could be prevented, by prior systemic or central administration to the mother of the Badrenergic blocker propranolol. On the other hand, when administered to anesthetized rats, ICV-PRL counteracted the effect of centrally-administered isoproterenol upon ductal tone. These results indicate that centrally-administered PRL may modulate adrenergic mechanisms regulating milk ejection in conscious rats. Such influence, however, may be reversed through an anesthesia-mediated action

535.8

EFFECTS OF CHRONIC BROMOCRIPTINE TREATMENT ON HYPOTHALAMIC DOPAMINE FUNCTIONS DURING AGING.
P. S. MohanKumar, S. M. J. MohanKumar, S. K. Quadri, and J. L. Voogt. Department of Physiology, University of Kansas Medical Center, Kansas City, KS, Department of Anatomy & Physiology, Kansas State University, Manhattan, KS, 66506

Tuberoinfundibular dopaminergic (TIDA) neurons constitute a major hypothalamic dopaminergic system involved in the regulation of prolactin (PRL) through negative feedback mechanism. DA from the TIDA neurons inhibits PRL, which in turn, results in decreased activity of TIDA neurons. This study was done to investigate the effects of prolonged hypoprolactinemia produced by bromocriptine (BC), a dopamine agonist, on TIDA neuronal activity in the median eminence (ME) of middle-aged rats. BC was dissolved in alcohol, mixed with drinking water and given to 10-12 months old female Sprague-Dawley rats. The final concentration of BC was 25 μ g/ml of water containing 1.7% alcohol. Control rats received water-alcohol mixture only. After 6 months of treatment, TIDA activity was estimated by determining tyrosine hydroxylase (TH) activity in the stalk ME on the basis of accumulation of 1-dopa after administration of m-hydroxybenzylhydrazine (NSD 1015), a dopa decarboxylase inhibitor. TH activity (l-dopa, pg/µg protein) in BC-treated rats (11.9 ± 1.4) was significantly lower than that in the control rats $(19.6\pm1.8;$ p<0.01). The incidence of spontaneous mammary tumors in the BC-treated rats (5%) was markedly lower than that in the control rats (37%), strongly suggesting that BC-treated rats were hypoprolactinemic. These results indicate that no compensatory mechanisms are initiated by TIDA neurons to overcome the chronic loss of stimulatory effects of PRL. Supported by NIH grant AG 11561.

NALOXONE INCREASES HYPOTHALAMIC TYROSINE HYDROXYLASE ACTIVITY AND mRNA DURING LACTATION, <u>L.A. Arbogasi* and J.L. Voogt.</u> Dept. of Physiology, University of Kansas Medical Center, Kansas City, KS 66160

Dept. of Physiology, University of Kansas Medical Center, Kansas City, KS 66160 Naloxone (NAL), an opioid antagonist, blocks the suckling-induced PRL surge, indicating the endogenous opioid peptides (EOP) contribute to the control of PRL release during lactation. Yet, it is not clear if the EOP influence PRL secretion by reducing dopaminergic input. The aims of this study were: 1) to assess the effect of NAL on suckling-dependent PRL release and 2) to determine if NAL infusion alters TH activity in the stalk-median eminence (SME) and TH mRNA levels in the arcuate nucleus. Exp. 1; Lactating rats 7 days postpartum were constantly exposed to pups during the experiment. NAL (60 mg/kg/h) or saline was infused for 12h. Blood was collected before and at 2h intervals during the infusion. TH activity was assessed by the accumulation of 3,4-dihydroxyphenylalanine (DOPA) after m-hydroxybenzyl-hydrazine (25 mg/kg, iv). TH mRNA levels were evaluated by in situ hybridization. NAL lowered plasma PRL to <36% of control values at 4, 6, 8 and 12h. TH activity in the SME increased 2.5-fold after 12h NAL treatment. TH mRNA content in the arcuate nucleus of NAL-treated rats was greater than control rats. Litter (8 pups) weight in the NAL-treated group did not change during the 12h infusion, but control litters gained 5g. Both groups of dams spent equal time with the pups. Exp. 2; Pups were removed from the dams before the 12h NAL infusion and were returned after 11h Blood was collected before the infusion, at 3h intervals during pup separation and at 15, 30, 45 and 60 min after reunion with the pups. Plasma PRL in control and NAL-treated rats was low (1-15 ng/ml) during the separation period. The suckling-induced PRL surge in NAL-treated rats was attenuated to 9-25% of control levels (350-650 ng/ml). After a 1h suckling episode, TH activity in the SME of NAL-treated rats was 4.5-fold greater than controls. Litter weight gains were significantly less in NAL-treated rats. These data indicate that the EOP are an integral component for

RT-PCR ANALYSIS OF D1 DOPAMINE RECEPTOR SUBTYPES IN TURKEY BRAIN. S.A. Schnell,* S. You, D.N. Foster and M.E. El Halawani. Dept. of Animal Science, Univ. of Minnesota, St. Paul, MN 55108.

VIP is a prolactin-releasing factor in birds. Recently, our laboratory has shown that D1-specific dopamine receptor agonists stimulated vasoactive intestinal peptide (VIP) release from turkey hypothalamus. The genes encoding chicken D1A, D1B, and D1D receptor subtypes have been cloned and pharmacologically characterized. We have used the reverse transcription-polymerase chain reaction (RT-PCR) technique to determine the mRNA expression of D1 subtypes in various turkey brain regions.

Two µg total RNA from turkey cortex (CTX), cerebellum (Cb), hypothalamus (hypo), diencephalon (die), medulla (med), brainstem (BS), spinal cord (SC), pituitary (pit), pineal (pin), olfactory bulb (OB) and optic chiasm (OC) were reverse transcribed. Oligonucleotide primers specific for the carboxy terminus of chicken D1A, D1B or D1D dopamine receptors were used to generate a single turkey PCR product corresponding to the size predicted for each of the chicken D1 cDNAs. All of the central nervous system regions examined revealed the presence of each of the D1 receptor subtyes. The products from the D1A and D1B subtypes were subcloned, sequenced and shown to be >90% homologous to their chicken counterparts and were used as probes to determine the relative mRNA amounts in the different brain regions. The rank order for D1A mRNA: CTX>hypo>BS>SC>die>Cb>pin>med>OC>OB>pit; D1B mRNA: CTX>hypo>die>SC>OC>BS>Cb> pin>med>OB>pit.

Dopamine inhibits the release of PRL birds, mainly through tonic

Dopamine inhibits the release of PRL birds, mainly through tonic inhibition via D2 dopamine receptors. The present results indicate a possible modulatory role for dopamine on the release of prolactin in birds by D1 receptors as well. Supported by USDA grant 94-37203-0897.

FUNCTION OF GALANIN IN THE ANTERIOR PITUITARY OF ESTROGENTREATED FISCHER 344 RATS: AUTOCRINE REGULATION OF PROLACTIN SECRETION. A. Cai and J.F. Hyde, Dept. Anatomy and Neurobiology, Univ. Kentucky College of Medicine, Lexington, KY 40536.

Galanin peptide has been localized in lactotrophs, somatotrophs and thyrotrophs in the anterior pituitary of female rats. In order to obtain precise information of the specific population of galanin-expressing cells and to quantify the estrogen-induced changes in galanin cell phenotypes, we performed dual in situ hybridization to detect the colocalization of galanin mRNA with PRL and GH mRNAs in the anterior pituitary. Female Fischer 344 rats (n=6) were ovariectomized and half of the animals were implanted with an estradiol capsule s.c. After two weeks, animals were euthanized and dispersed anterior pituitary cells were prepared. Dual in situ hybridization was performed using ³³P-UTP (galanin) and digoxigenin-UTP (PRL or GH) labeled cRNA probes. In ovariectomized rats galanin mRNA signals were not detectable. In contrast, in estrogen-treated animals galanin mRNA was localized in 31% of lactotrophs and 2.3% of somatotrophs. Galanin-expressing cells, lactotrophs and somatotrophs were 16%, 51%, and 13.5% of the total cells in the anterior pituitary, respectively. Within those detectable galanin-expressing cells, more than 90% of cells coexpressed PRL mRNA and less than 5% of the cells coexpressed GH mRNA. Our data confirm that estrogen treatment dramatically increases the number of galanin-expressing cells in the anterior pituitary and the level of galanin gene expression in the individual cells. Galanin-expressing cells are mainly lactotrophs suggesting that galanin may contribute to the heterogeneous secretion of prolactin from lactotrophs, and galanin may regulate prolactin secretion in an autocrine manner. To support this hypothesis we are performing the reverse hemolytic plaque assay (prolactin secretion) combined with in situ hybridization (galanin mRNA) to measure the correlation of prolactin secretion and galanin gene expression in the same cell. Supported by NIH grant DK-45981 (J.F.H).

CIRCADIAN CHANGES OF CENTRAL DOPAMINERGIC NEURON ACTIVITY AND ITS DEVELOPMENTAL ASPECT K. R. Shieh, L. M. Mai^{*}, and J. T. Pan. Inst. Physiol., Natl. Yang-Ming Univ., Taipei, Taiwan ROC

We recently reported that a diurnal change of the tuberoinfundibular dopaminergic (TIDA) neuron activity exists in both intact and ovariectomized (OVX) female rats with or without estrogen replacement. However, a complete 24-h profile of TIDA and other central DA neurons' activities were not determined. Long-term OVX rats plus estrogen treatment for 6 days were decapitated every 4 h from 0100 to 2100 h. Either DOPAC or DOPA levels were determined in two groups of rats. Significant decreases of both ME DOPAC and DOPA levels were observed at 1700 and 1900 h. The dramatic change occurred at two times of the day, i.e., between 1300 and 1700 h and between 2100 and 0100 h. The activities of DA neurons in the ST and NA were significantly higher during the dark (2100-0500 h) compared with those during the light (0900-1700 h) phase. The rhythm of TIDA neuron activity has been correlated with the initiation of estrogen-induced PRL surge; while the rhythms observed in the ST and NA may be related to the animal's locomotor activity. We further determined the diurnal variations of TIDA neuron activity from pre- (28-, 35-, 39-day old), peri- (42-day) to post- (49day) pubertal female rats. There was a gradual increase in basal TIDA neuron activity during the development and the diurnal rhythm occurred only after puberty. Thus, this pre-determined, sex-specific rhythm of TIDA neuron activity appears to develop peripubertally

(This study was supported in part by grant NSC 85-2331-B010-071).

REPRODUCTIVE EXPERIENCE INCREASES STRIATAL AND HYPOTHALAMIC DOPAMINE LEVELS IN PREGNANT RATS.

1_F, Felicio*, J_C, Florio, L.H, Sider, P.E, Cruz-Casallas and

R.S. Bridges. 1 Department of Pathology, School of Veterinary
Medicine, University of São Paulo, Brazii; 2 Department of
Comparative Medicine, Tufts University, School of Veterinary
Medicine, North Grafton, MA, USA.

Effects of parity on dopaminergic function of rats were studied. Striatal and hypothalamic levels of dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), norepinephrine (NE), serotonin (5HT) and 5-hydroxyindoleacetic acid (5HIAA) as well as serum prolactin (PRL) levels of 7 days primi- and multigravid rats were compared. Brains and trunk blood were collected from 1200 to 1400 h on day 7 of pregnancy and assayed for monoamines and their metabolites, and prolactin, Multigravid rats showed a significant increase in striatal and hypothalamic dopamine levels (p<0.05). A tendency to increase in striatal DOPAC (p=0.06) levels was also observed in multigravid rats. Levels of other neurotransmitters and metabolites were not statistically different. Haloperidol (1 mg/kg) treatment induced a significant increase in multigravid 5HT striatal levels. There was no statistical difference among primi- and multigravid serum PRL levels after either saline or haloperidol treatment. These data suggest that prior parity produces a shift in dopaminergic activity in multigravid rats.

ELEVATED LEVELS OF CIRCULATING GROWTH HORMONE-RELEASING HORMONE ALTERS LACTOTROPH FUNCTION IN THE HUMAN GHRH TRANSGENIC MOUSE. J.P. Moore, Jr.*, A. Cai, and J.F. Hyde, Dept. Anatomy and Neurobiology. Univ. Kentucky College of Medicine, Lexington, KY 40536.

and Neurobiology, Univ. Kentucky College of Medicine, Lexington, KY 40536. Human growth hormone-releasing hormone (hGHRH) transgenic mice sustain a twenty-fold increase in circulating hGHRH, a sixteen-fold increase in plasma growth hormone (GH), and no difference in plasma prolactin levels when compared to non-transgenic siblings. After ten months of age an adenoma begins to develop within the anterior pituitary (AP) of hGHRH mice which is described as consisting primarily of somatotrophs. We have recently reported that GH as well as galanin secretion is significantly increased from individual pituitary cells of the hGHRH mouse as measured by the cell immunoblot assay (CIBA). This study focuses on the regulation of prolactin production and secretion within the AP of the 5 month old, male hGHRH mouse. We first performed the CIBA and discovered no significant differences in the amount of prolactin secreted from individual pituitary cells from transgenic and control mice. Preliminary studies utilizing dual in situ hybridization have revealed a significant increase in the number of mammosomatotrophs within the AP of the hGHRH mouse, yet plasma prolactin levels remained unchanged. To further investigate this discrepancy, we administered NSD-1015 (100 mg/kg, i.p.), a DOPA decarboxylase inhibitor, to both transgenic and control mice and observed a significant 2-fold increase in DOPA accumulation within the median eminence of the hGHRH mice, suggesting an elevation in dopamine production and secretion from the hypothalamus of transgenic mice. Taken together, these data suggest that elevated levels of hGHRH or GH can expand the population of prolactin-producing cells and can affect hypothalamic dopamine neurons regulating prolactin secretion from the AP of the hGHRH transgenic mouse. ESTRUS MODULATES STRESS EFFECTS ON BEHAVIORAL DESPAIR AND IMMUNE FUNCTION IN FEMALE RATS S.E. Hendricks*, J. Wieseler, A. Cvr, M.Frank, M. Nakamura, M. Menolascino, D. Johnson. Dept. of Psychol., Univ. Neb. at Omaha, and Dept. of Path. & Microbiol. and Dept. of Psychiatry, Univ. Neb. Med. Cntr., Omaha, NE 68198.

The forced swim test (FST) has been demonstrated to induce changes in behavior taken to reflect despair or depression that are sensitive to antidepressants. Specifically, the increased immobility observed in the second swim trial is reduced by prior exposure to antidepressants. Previous research has demonstrated that female rats in estrus are more resistant to some of the consequences of stress compared to anestrous rats. Among responses often observed to stress are reductions in immune competency particularly as measured by natural killer cell cytolytic activity (NKCA). Previous research in our laboratory demonstrated reduced NKCA in rats exposed to the FST. In the present study we evaluated effects on behavior in the FST and on NKCA in estrous and anestrous female rats. All rats were ovariectomized. Estrus was induced by 5 μg estradiol benzoate followed 40 hrs later by 500 μg progesterone. Rats were exposed to the first swim trial of the FST 6 hrs after the progesterone injection. Rats exposed to the first swim trial while in estrus, when exposed to the second trial 24 hrs later, exhibited less immobility than rats exposed to the first swim trial while in an anestrous state. Also, rats exposed to the first swim trial while in estrus exhibited higher levels of NKCA after the first swim trial compared to rats exposed to the first swim trial while anestrus. MODERATE STRESS ENHANCES, AND CHRONIC STRESS SUPPRESSES, CELL-MEDIATED IMMUNITY *IN VIVO*. F. S. Dhabhar* & B. S. McEwen. Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

Delayed type hypersensitvity (DTH) reactions are antigen-specific, cell-mediated immune responses which mediate beneficial (resistance to viruses, bacteria, and tumors) and harmful (allergic dermatitis, autoimmunity) aspects of immune function. Contrary to the popular notion that stress suppresses immune function, we have demonstrated that moderate stress significantly enhances a cutaneous DTH response. We have also shown that a stress-induced trafficking of leukocytes to the skin may mediate this enhancement.

Here we investigate the effects of varying the duration, intensity, and chronicity of stress on the DTH response. DTH was induced by challenging the pinnae of previously sensitized rats with the chemical antigen 2,4-dinitro-1-fluorobenzene (DNFB). Animals moderately stressed (2h restraint) immediately before challenge showed a significant enhancement of DTH as measured by an increase in pinna thickness relative to the pre-challenge baseline. Increasing the duration of stress to relative to the pre-challenge baseline. Increasing the duration of stress to 5h produced the same magnitude of enhancement as 2h restraint. Increasing the severity of stress (immobilization + mild shaking) produced an even greater enhancement of the DTH response. In contrast, increasing the chronicity of stress (6 h restraint/day, 6 days) significantly suppressed the DTH response. These results demonstrate a biphasic relationship between stress and immune function, such that moderate stress enhances, while chronic stress suppresses, an important class of immune responses in vivo. IMMUNE CORRELATES IN SUBTYPES OF DEPRESSIVE DISORDERS. A.V. Ravindran*, J. Griffiths, Z. Merali and H. Anisman. Dept of Psychiatry, Royal Ottawa Hospital, and School of

Major depressive disorder has been associated with immune alterations, including reduced mitogen-induced cell proliferation, diminished natural killer (NK) cell activity, increased interleukin-1β (IL-1), as well as variations of several lymphocyte subsets. While these immune alterations may be related to the mood disturbances, it is possible that the symptoms that characterize the disorder (e.g., anorexia, sleep disturbances, increased stress perception) contribute to the immune alterations. In the present investigation we assessed endocrine and immune alterations in major depressive and dysthymic (chronic, and immune alterations in major depressive and dysthymic (chronic, low grade depression) patients that exhibited either the typical (reduced sleep, reduced food consumption) or atypical symptom profile (increased sleep, increased eating). While plasma cortisol did not differ between groups, ACTH levels were modestly increased in major atypical depressive patients. The number of circulating NK cells was increased in all depressive groups, but this effect was greater in the major depressive than the dysthymic patients, and greater in typical than in atypical patients. Levels of IL-1 in supernatants of mitogen stimulated blood cells were also found to differ in the depressive subgroups. In particular while IL-1 was reduced in typical major depressive natients particular, while IL-1 was reduced in typical major depressive patients, a pronounced elevation of IL-1 was evident in the atypical patients. It appears that both mood disturbances and neurovegetative symptoms contribute to the immune alterations associated with depression.

CYTOKINE LEVELS IN MAJOR DEPRESSSIVE DISORDER, A. B. Negrão, J. Licinio*, M.-L. Wong, P. Bongiorno, T. D. Geracioti, P. W. Gold, M. Kling. Clinical Neuroendocrinology Branch, NIMH. NIH. Bethesda, MD 20892-1284.

Dysregulation of hypothalamic-pituitary-adrenal (HPA) function is an element in the pathophysiology of major depressive disorder. The cytokine IL-1ß can potently stimulate the HPA axis, and functions as a communication signal between the peripheral immune system and the central nervous system. In order to determine whether neuro-immune interactions might have a role in the pathophysiology of major depression we examined cytokine levels in patients meeting DSM-III-R criteria for major depressive disorder (MDD). Using a high sensitivity enzyme-linked immunoassay we measured circulating IL-1\beta levels in 16 healthy controls, and 14 depressed patients, 7 of whom were re-studied during the course of antidepressant treatment. We found that IL-1\beta levels were 0.33\pmu0.13 pg/ml in patients with MDD and 0.60±0.17 pg/ml in healthy controls (NS). During antidepressant treatment, there was a trend for a 20% increase in the basal plasma levels of IL-1ß. Further studies are being conducted to ascertain cytokine levels longitudinally in MDD.

IMMUNE AND BEHAVIORAL CORRELATES OF TYPICAL AND ATYPICAL DEPRESSION J. Griffiths*, A.V. Ravindran, Z. Merali and H. Anisman. Dept of Psychiatry, Royal Ottawa Hospital, and

School of Psychology, University of Ottawa, Ottawa, Ontario, Canada.

Although depressive illness has been associated with immune alterations, inconsistent and even contradictory data have been reported in this respect. It has been suggested that the appearance of immune variations may be related to the severity of depression. As well, the immune alterations may vary across subtypes of depression, given the marked differences of neurovegetative symptoms. In the present marked differences of neurovegetative symptoms. In the prescription we demonstrate that both typical major depressive (i.e., showing reduced eating, reduced sleep) and atypical patients (increased neurovegetative signs) show increased perception of day-to-day stresses, and the use of inadequate coping styles. Moreover, relative to controls, mitogen-induced cell proliferation was reduced in typical major depression, but not in atypical patients. Interestingly, in the atypical patients serum interleukin-1β levels were significantly higher than in corrected earn patients, with twingled depressive features. Following a 12 controls or patients with typical depressive features. Following a 12 week course of antidepressant treatment (sertraline), IL-1 levels returned week course of antidepressant treatment (sertratine), IL-1 levels returned to control values in those patients that showed a positive therapeutic response. It is suggested that the immune alterations associated with depression are independent of stress/coping factors. However, the immune variations may be secondary to the symptoms characteristic of the illness, or common mechanisms may support the immune alterations and the neurovegetative features of major depressive illness. SYSTEMIC ADMINISTRATION OF BACTERIAL LIPOPOLYSACCHARIDE (LPS) ENDOTOXIN INDUCES SYNTHESIS OF PITUITARY ADENYLATE CYCLASE ACTIVATING PEPTIDE (PACAP) IN CENTRAL NEURONES OF THE HYPOTHALAMO-PITUITARY-ADRENOCORTICAL (HPA)-AXIS OF THE RAT. P.J. Larsen*, D.S. Jessopt, J. Fahrenkrugt, and J. Hannibalt, Dept. Anatomy, Univ. Copenhagen, Denmark; †Dept. Medicine, Univ. Bristol, U.K., ‡Dept. Clinical Biochemistry, Bispebjerg Hospital, Copenhagen, Denmark

The neurosecretory neurones of the HPA-axis constitutively express corticotrophinreleasing hormone (CRH), but when challenged by various stressors they respond with de novo synthesis of neuropeptides specifying the type of stress. Among numerou stressors, icv infusion of colchicine is the only one capable of eliciting PACAP mRNA expression in the neurones of the HPA-axis of the rat. Presently, we demonstrate that an ip injection of LPS (500 µg/animal), partly mimicking the immunological stress associated with bacterial infections, induces PACAP mRNA expression in medial parvocellular region of the paraventricular nucleus (PVN) which harbours the neurones of the HPA-axis. LPS induced expression of PACAP and CRH mRNAs in the PVN peaked 24 hours after the infusion. After the LPS challenge, PACAP-immunoreactive cells became visible in the PVN and a dense plexus of PACAP-immunoreactive ner fibres emerged in the external layer of the median eminence, reflecting increased PACAP synthesis in the neurones of the HPA-axis. To further identify the signal(s) which mediate the LPS induced expression of PACAP synthesis in the HPA-axis, animals were injected intraperitoneally with either interleukin-1 β (IL-1 β) or tumor necrosis factor- α (TNF- α). However, neither of these cytokines induced PACAP mRNA synthesis in the HPA-axis, irrespective of the fact that the employed doses (1µg) caused rises in plasma corticosterone similar to that obtained by LPS. In addition, both IL-1B and TNF-α robustly induced CRH mRNA expression in the PVN. In conclusion, the LPS-induced PACAP mRNA expression in the central neurones of the HPA-axis is independent of the cytokines believed to be released from macrophages exposed to LPS.

INCREASED TUMORIGENESIS IN A TRANSGENIC MOUSE MODEL OF THE ENDOCRINE CHANGES SEEN IN DEPRESSION CAN BE REVERSED BY ANTIDEPRESSANT THERAPY. J.M.C. Blom^{2*}, N.Barden³, D. Viglienghi⁴, and G. Racagni⁴. *Center of Neuropharmacology, Univ. of Milan, 20133 Milan, Italy, and ⁸Molecular Psychogenetics, CHUL, Québec, Canada.

Episodes of severe depression affect up to 5% of the general population

and occur with a threefold higher frequency in patients with cancer. Given recent serious concerns regarding the carcinogeneity and the tumor promoting activity of antidepressants and the fact that antidepressants are prescribed for extensive periods of time, a transgenic mouse model of the endocrine changes observed in 60% of depressive patients characterized by partial knockout of glucocorticoid receptor gene expression, resulting in defective glucocorticoid feedback inhibition and HPA-Immune axis dysfunction, allowed to test the tumor promoting effects of this particular class of drugs in an animal that displays a pathophysiology similar to that observed in depression. Adult transgenic mice and intact controls were injected s.c. either with the chemical carcinogen 9.10 dimethylbenzanthracene (DMBA) or C-3 fibrosarcoma cells. Tumor incidence was 4 times higher in DMBA treated transgenics than in control animals (86% vs 23%). More importantly tumor incidence could be reversed by treatment with the antidepressant Desimipramine (33%). Similarly C-3 induced tumorigenesis was enhanced in transgenic mice as compared to control mice (60% vs 15%). Treatment of transgenies with DMI reduced tumor incidence by 50 % to only 30%. Furthermore, tumor incidence correlated with altered immune responsiveness, as measured by lymphocyte cell number and lymphoproliferative assays. These results indicate that in this animal model of depression where general defense mechanisms appear to be compromised, treatment with an antidepressant such as desimipramine, seemed to normalize and restore both neuroendocrine functioning as well as general defense mechanisms, resulting in decreased risk of tumor development

EVIDENCE FOR ACUTE PHASE ACTIVATION FOLLOWING EXPOSURE TO AN ACUTE STRESSOR. T. Deak*, J.L. Meriwether, M. Fleshner, R.L. Spencer, A. Abouhamze', L.L. Moldawer', L.R. Watkins, & S.F. Maier. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309, Dept. of Surgery, Univ. of Florida, Gainesville, FL. 32610. We recently reported that exposure to a single session of inescapable shock (IS) produces a reduction in corticosteroid binding globulin (CBG) 24 hrs later (Fleshner et al., 1995). Subsequent studies have shown that this effect is independent of glucocorticoid regulation. Since CBG is known to be a negative reactant of the acute phase activation), we investigated the possibility that exposure to IS leads to activation, we investigated the possibility that exposure to IS leads to activation of the acute phase response. After a baseline blood sample was taken from a lateral tail vein (300 µl in <2 min), rats were exposed to 100 inescapable tail shocks (5 sec, 1.6 mA, 1 min ITI), and blood samples were taken 6 hrs and 24 hrs following IS. Analysis of samples demonstrated that haptoglobin and seromucoid protein levels were significantly increased, CBG levels were significantly decreased, and there were no changes in serum albumin or total serum protein levels 24 hrs after IS. Since fever is also used as an index for acute phase activation, we investigated whether IS exposure leads to elevated core body temperature (CBT). Rats were implanted with thermisters under halothane anesthesia and permitted to recover for 3 days prior to experimentation. Baseline CBT was recorded, and rats either to elevated core body temperature (CBT). Rats were implanted with thermisters under halothane anesthesia and permitted to recover for 3 days prior to experimentation. Baseline CBT was recorded, and rats either remained in their home cages (HCC) or received IS. Subsequent readings of CBT were taken during IS. for 10 hrs following IS, and in the morning after IS. CBT was significantly increased during the shock session and for 1 hr immediately following IS treament. CBT was also significantly elevated in IS treated rats during the AM of the next day (p's<.05). All of these data support the hypothesis that IS exposure leads to activation of the acute phase response. Supported by NIH Grant MH45045.

CENTRAL GLUCOCORTICOID RECEPTOR DYSFUNCTION: PROFOUND CHANGES IN CIRCADIAN RHYTHM OF BODY TEMPERATURE AND LOCOMOTION, AND ALTERED NEUROENDOCRINE AND AUTONOMIC RESPONSES TO ENDOTOXIC STIMULATION. A.C.E. Linthorst*, S. Karanth, N. Barden¹, F. Holsboer and J.M.H.M. Reul. Max Planck Inst. of Psychiatry, Clinical Inst., Munich, Germany; Molecular Psychogenetics Lab., Laval Univ., Quebec, Canada

Recently, a transgenic mouse has been created bearing a transgene expressing antisense RNA directed against the glucocorticoid receptor (GR). In view of the intimate involvement of glucocorticoids in the cascade of responses following activation of the immune system, we investigated the consequences of impaired GR function for the physiological responses observed after an endotoxic challenge. First, plasma levels of ACTH, corticosterone and interleukin-6 (IL-6) were measured 1, 3, 6 and 24 hr after i.p. injection of endotoxin. We found that the transgenic mice show an amplified and prolonged endotoxin-induced increase in plasma ACTH, but not in corticosterone and IL-6. In a second set of experiments, mice were implanted with a biotelemetric transmitter for continuous recording of body temperature and locomotion. Transgenic mice showed markedly lower body temperature and locomotor activity levels during the dark phase of the diurnal cycle. I.p. administration of endotoxin caused a biphasic increase in body temperature in normal mice, returning to baseline levels ~15 hr after injection. In contrast, in transgenic mice endotoxin and saline produced similar increases in body temperature during the first 6 hr after injection. However, body temperature of endotoxin-injected transgenic mice started to rise after 6 hr and was still elevated 24 hr post-injection. In both strains the endotoxin produced an inhibition of locomotor activity and other signs of sickness. Our data demonstrate that central GR plays a pivotal role in the diurnal cycle of body temperature and behavioral activity and in the neuroendocrine and pyrogenic responsiveness to an endotoxic challenge Supported by the VW-Foundation (1/70 543)

CENTRAL α -MSH $_{(1-13)}$ BLOCKS STRESS-INDUCED ALTERATIONS IN TEMPERATURE, CORTICOSTERONE AND CBG. E.D. Milligan*, K. T. Nguyen, T. Deak, M. Fleshner, L. R. Watkins, and S. F. Maier. Dept of Psych. Univ. of Colorado, Boulder, CO.,

Both intracerebroventricular (i.c.v.) IL-1β and exposure to acute stressors such as inescapable tail shock (IS) activate acute phase stressors such as flescapane tail shock (15) activate acute phase responses (APRs) such as fever and decreases in carrier proteins including corticosterone binding globulin (CBG). These and other data have led to the suggestion that stressors may produce acute phase as well as other responses by inducing brain IL-1β. The pro-opiomelanocortin derivative, alpha-melanocyte-stimulating hormone (α-MSH₍₁₋₁₃₎) when injected i.c.v., has been shown to antagonize a variety of IL-1 β effects. We therefore sought to determine whether i.c.v. α -MSH₍₁₋₁₃₎ would block the effects of IS thought to be mediated by brain IL-18. Male Sprague-Dawley rats received either $0.5\mu g$ in $2.5\mu l$ α -MSH₍₁₋₁₃₎ or vehicle prior to a single session of 100, 5 sec., 1.6mA, with a 1 min. ITI ISs delivered to the tail via fixed electrodes, or control treatment. Core body to the tail via fixed electrodes, or control treatment. Core body temperature (CBT), from probe implanted i.p., and plasma corticosterone (CORT), assessed by RIA, were measured at times of IS-pre-exposure, the 25th and 100th tail shock, and 2, 24, and 48 hours after IS. CBG levels from plasma at pre-IS exposure and 24-hour post-IS exposure were measured by RIA. α -MSH $_{(i,13)}$ had no effect on CBT or the rise in CORT during IS. However, α -MSH $_{(i,13)}$ blocked the elevated CBT and basal CORT levels, and blocked the reduced levels of CBG and food intolar placement 24 hours after IS. These data provide further indirect intake, observed 24 hours after IS. These data provide further indirect support for a role of brain IL-1 β in mediating these outcomes of IS. Supported in part by grants, NIMH MH 45045 and NIH MH 55283.

STRESS-INDUCED NITRIC OXIDE SUPPRESSES SPECIFIC IMMUNITY IN KLH IMMUNIZED RATS.

RT Nguyen*, M Fleshner, LR Watkins, & SF Maier. Department of Psychology, University of Colorado at Boulder, Boulder, CO, 80309

Nitric oxide (NO) has been implicated as an important mediator in a variety of immune functions. NO is suppressive to T cell, but not B cell, proliferation in response to ConA or alloantigen [Fleshner et. al. 1995, J. Neuroimmunology (56):45-52]. Previous findings from our laboratory have shown that exposure to inescapable tail shock (IS) suppresses T cell proliferation and expansion to antigen. We, therefore, investigated whether IS could increase NO production by lymphocyte/monocytes and whether is could increase to production by symphocyte-indirecytes and in turn, result in a suppression of T cell expansion and T cell associated cytokines. Male Harlan Sprague Dawley rats were immunized with 200 µg IP of KLH and exposed to either IS (n=6) or returned to their home cages (HCC, n=6). Cells were collected from the peritoneal cavity, mesenteric lymph nodes, and spleen at 0, 48, & 96 hours after IS. Total cell numbers were assessed in each compartment. HCC animals showed an increase in cell number in response to KLH at 24 & 48 hours after immunization. In contrast, IS animals failed to show an increase in cell number in response to KLH. After 48 hours of cell culture, supernatants were harvested and assayed for nitrite & IFNy. NO production was enhanced by IS compared to HCC. In contrast, HCC-IFN γ levels showed an increase in response to KLH, while IS-IFN γ levels failed to show this increase at both 48 and 96 hours. Given the recent finding from our laboratory showing that IS can suppress the expansion of Thl-like cells in response to an antigen, these findings suggest that IS-induced production of NO may play a role in the mechanism of stress-induced immunosuppression. Supported by NIH Grant MH45045.

TUMOR NECROSIS FACTOR- α , INTERLEUKIN-18 AND INTERLEUKIN-2 PRODUCE DIFFERENTIAL EFFECTS ON HIPPOCAMPAL SEROTONERGIC NEUROTRANSMISSON, FREE CORTICOSTERONE LEVELS, BODY TEMPERATURE AND BEHAVIOR. S. Pauli*, A.C.E. Linthorst and J.M.H.M. Reul. Max Planck Inst. of Psychiatry, Clinical Inst., Munich, Germany

Recently, we have shown that i.p. injection of endotoxin results in an activation of distinct central neurotransmitter pathways, rises in free corticosterone levels, fever and behavioral depression (sickness behavior). Brain interleukin (IL)-1 was found to participate in the endotoxin-induced increase in hippocampal serotonergic neurotransmission. Moreover, the endotoxin effects were largely mimicked by i.c.v. injected human IL-18. Because endotoxin induces apart from IL-1 also other proinflammatory cytokines such as tumor necrosis factor- α (TNF- α) and IL-6, we included these cytokines in our studies. In addition, we investigated the effects of the non-inflammatory cytokine IL-2. *In vivo* microdialysis in freely moving rats was used to continuously monitor hippocampal extracellular levels of 5-HT and its metabolite 5hydroxyindoleacetic acid (5-HIAA), and free corticosterone. Biotelemetry was used to assess body temperature and locomotion. I.c.v. administration of mouse TNF-a produced a dose-dependent increase in free corticosterone levels and body temperature, but had no effect on hippocampal 5-HT and 5-HIAA. In contrast, i.c.v. injection of human IL-2 dose-dependently increased free corticosterone levels, body temperature and hippocampal concentrations of 5-HT and 5-HIAA. IL-2 produced behavioral depression, whereas TNF- α did not. Moreover, the effects of TNF- α and IL-2 on body temperature and free corticosterone followed different time courses. It may be concluded that cytokines produced as a result of immune and inflammatory challenges play differential but overlapping roles in the brain subserving homeostatic responses to cope with the challenge.

CILIARY NEUROTROPIC FACTOR IS A POTENT ANORECTIC CYTOKINE ACTING THROUGH HYPOTHALAMIC NEUROPEPTIDE Y S.P. Kaira*, B. Xu, M. Dube, A. Kaibara, D. Martin and L.L. Moldawer, Depts. Neuroscience, Physiology and Surgery, Univ. of Fla. Col. Med., Gainesville, FL 32610 and Amgen, Inc., Boulder, CO 80301

Anorexia is one of the most common neurological manifestation observed during acute and chronic disease. Neither the identity nor the mode of action of cytokine(s) that induce chronic anorexia is We evaluated the effects and mode of action of the cytokine, ciliary neurotropic factor (CNTF), on daily food intake and body weight gain in male rats. Daily intracerebroventricular (icv) injection of CNTF (0.5, 2.0 or 5 $\mu g/rat$) produced a steady dosedependent decrease in food intake and body weight over a 4-day treatment period. Food intake was suppressed by 80% with a concomitant loss of body weight by 20%. PreproNPY mRNA in the hypothalami of CNTF-treated rats was significantly less than in fasted or pair-fed controls (p < 0.05), and the characteristic fastinginduced increase in hypothalamic NPY gene expression was also blocked by CNTF. Further, acute, as well as chronic CNTF treatment markedly suppressed NPY-induced stimulation of feeding. Cumulatively, these results show that CNTF produces severe and persistent anorexia by decreasing both the synthesis as well as the post-synaptic stimulatory effects of hypothalamic NPY, the endogenous orexigenic signal. (Supported by NIH DK37273).

MODULATORY EFFECTS OF GLUCOCORTICOIDS AND CATECHOLAMINES ON HUMAN INTERLEUKIN-12 AND INTERLEUKIN-10 PRODUCTION: POTENTIAL RELEVANCE FOR CHANGES OF THE THI/THE BALANCE IN STRESS AND STATES ASSOCIATED WITH DYSREGULATION OF THE STRESS SYSTEM, LJ. Elenkov, D.A. Papanicolaou, R.L. Wilder, and G.P. Chrousos*, DEB, NICHD and ARB, NIAMS, NIH, Bethesda, MD 20892.

To examine the potential effects of stress on the Th1/Th2 balance, we studied the ability of 3 prototype stress hormones, dexamethasone, norepinephrine and epinephrine, to alter the production of interleukin (IL)-12 (p70) and IL-10 induced by bacterial lipopolysaccharide (LPS) in human whole blood. Dexamethasone inhibited LPS-induced bioactive IL-12 production in a dose-dependent fashion and at physiologically relevant concentrations; it had no effect on IL-10 secretion. The glucocorticoid-induced reduction of IL-12 production was antagonized by RU 486, a glucocorticoid-receptor antagonist, suggesting that it was mediated by the glucocorticoid-receptor. Norepinephrine and epinephrine also suppressed IL-12 production in a dose-dependent fashion and at physiologic concentrations: both catecholamines, however, increased, dose-dependently, the production of IL-10. The effects of either catecholamine on IL-12 or IL-10 secretion were completely blocked by propranolol, a b-adrenoreceptor antagonist, indicating that they were mediated by the b-adrenergic receptor. These findings suggest that the central nervous system may regulate IL-12 and IL-10 secretion, and, hence, the Th1/Th2 balance via the peripheral end-effectors of the stress system. Stress may, thus, cause a shift towards Th2, rather than generalized Th suppression. This shift may be responsible for the stress-induced increase of susceptibility of the organism to certain infections, and may influence their course. In addition, through this mechanism, states associated with chronic hyper- or hypo-activity of the stress system may influence the susceptibility of an individual to certain autoimmune, allergic, infectious or neoplastic diseases.

EFFECTS OF INTERFERONS ON CATECHOLAMINE SECRETION FROM BOVINE ADRENAL CHROMAFFIN CELLS. E. Tachikawa*, Y. Kondo, K. Kudo and T. Kashimoto. Dep. of Pharmacol., Sch. of Med. Iwate Med. Univ., Morioka 020, Japan.

When bovine adrenal chromaffin cells were previously exposed to human recombinant interferon (IFN) $^{-}\alpha$ (1,500 units/ml) for 72 hrs, the secretion of catecholamines from the cells stimulated by acetylcholine (ACh) (25 μ M) was greatly reduced. On the other hand, human fibroblast IFN- β and recombinant human IFN- γ had no effect on the secretion. The IFN- α inhibition was concentration (30-1,500 units/ml) - and time (18-96 hrs) -dependent manners. IFN- α also inhibited ACh-induced Ca²+ influx into the cells, whereas it inhibited neither Ca²+ influx into nor secretion from the cells induced by high K+. The inhibitory effect of IFN- α on the secretion was completely overcome by the equivalent human anti-IFN- α antibody and by the increase in ACh concentration (200 μ M) but not by the increase in the external Ca²+ concentration. These results indicate that IFN- α affects nicotinic ACh receptors, and reduces the Ca²+ influx and the consequent

receptors, and reduces the Ca^{2*} influx and the consequent secretion of catecholamines in bovine adrenal chromaffin cells stimulated by ACh. The results further suggest that immune systems may regulate the function of autonomic nervous systems via the immunotransmitter, IFN- α , and that the side effects occurring during IFN- α therapy (depression, neurasthenica, somnolence, lethargy, anorexia, etc.) may be related to the IFN- α action on the chromaffin cells.

536.14

EPINEPHRINE STIMULATES IL-6 RELEASE IN MAJOR DEPRESSION AND HEALTHY CONTROLS G. H. Pelton*, L. H. Price, R.T. Malison, G. R. Heninger, Clin. Neurosci. Res. Unit, Dept. of Psychiatry, Yale Univ. School of Med., 34 Park St., New Haven, CT 06519

In order to evaluate possible abnormalities in stress induced alterations in immune function in depressed patients, we have examined the interleukin-6 (IL-6) and cortisol (C) response to infused epinephrine (E) in six patients with Major Depression (MD) and four healthy controls (HC). METHODS: MD patients had HAM-D scores ≥18 and were drug-free for at least 3 weeks. All subjects underwent randomized double-blind testing with a 60-min continuous i.v. infusion of E 0.2 ug/kg/min or saline placebo (P). Plasma levels of E and norepinephrine, C, and IL-6 were measured, in addition to blood pressure (BP), heart rate (HR), and emotional state. RESULTS: In HCs, we previously reported a clear dose-response curve for effects of E on IL-6 levels (at E doses of 0.1, 0.15 and 0.2 ug/kg/min). At the 0.2 ug/kg/min dose, base-to-peak IL-6 change was significantly less in MDs than in HCs (p<.05), 5.5±3.4 pg/ml and 10.7 ±3.4 pg/ml, respectively. Baseline IL-6 levels were not significantly different. E produced a mean base-to-peak increase in systolic BP of 12± 15 mm HG and 15±12 bpm and 15±15 mm Hg and HR 20±10 bpm in MD and HCs respectively, that were not significantly different. IL-6 plasma levels peaked at 90 min and between 90 min and 180 min, C level tended to increase (p=0.061) during E vs P. Positive correlations between peak IL-6 and peak HR or change in IL-6 and change in C were seen in HC but not in MD. There was no change in emotional state in either group during E. DISCUSSION: This is the first demonstration that peripheral E causes an increase in plasma IL-6 levels in both HC and MD human subjects. The results support the hypothesis that E directly affects the immune system (probably via Beta receptors) in HCs, which may be dysregulated in MD. E may also indirectly effect the HPA axis via increasing plasma levels of IL-6. These results suggest a novel mechanism which could explain immune and HPA axis dysregulation during stress and depression. (Supported by NARSAD and the Stanley Foundation)

CENTRAL AMYGDALA LESIONS REDUCE BEHAVIORAL SUPPRESSION AFTER ENDOTOXIN. N.C. Tkacs*. Depts. of Psychiatry and Neurosciences. UMDNJ New Jersey Medical School and Grad. School of Biomedical Sciences, Newark, NJ 07103.

Administration of bacterial endotoxin (ETX) to rats induces centrallymediated responses including fever, stress hormone release, and behavioral suppression. This experiment tested the hypothesis that the central nucleus of the amygdala (CeA) mediates the behavioral response to ETX.

Behavioral and febrile responses to IV E. coli ETX 10 $\mu g/kg$ were recorded from rats with electrolytic or sham CeA lesions. Movements between two halves of a plexiglass chamber were recorded for 5 minutes, two hours after ETX injection. The rats were divided into three groups, based on activity data: SHAM (n=4), MISS (activity after ETX=shams, n=3), and LESION (activity after ETX>shams, n=5). Results (activity): SHAM=6.2±0.9 counts; MISS=5.7±1.3; LESION=15.8±1.7. ANOVA revealed a significant effect of lesion on activity (F=17.02, p=.0009). Fever was slightly but not significantly higher in SHAM rats, while MISS and LESION rats had identical fever profiles. Histological analysis showed that LESION rats had bilateral ablation of the mid-region of the CeA, 2.3 - 2.8 mm behind bregma) with sparing of the rostral and caudal poles of CeA. In MISS rats, bilateral damage only included the caudal CeA with unilateral sparing of the mid-region. These results support the hypothesis that the CeA mediates behavioral responses to systemic ETX treatment, and demonstrates a possible dissociation between fever and behavioral responses to ETX. ATTENUATION OF BEHAVIORAL ABNORMALITIES IN AUTOIMMUNE MICE BY SOLUBLE IFN-Y RECEPTOR TREATMENT. L.M. Schrott* and L.S. Crnic. Dept. of Pharmacology, Univ. of MN Med. School, Minneapolis MN 55455; Depts. Pediatrics and Psychiatry, Univ. of CO Med. School, Denver CO 80220. Autoimmune NZB x NZW F1 hybrid (B/W) mice develop reduced exploratory drive and increased anxiety behavior compared to non-autoimmune NZW mice as their lupus-like disease progresses. The present study examined if treatment with murine soluble IFNy receptor (sIFNyFN), a blocker of an early step in the cytokine cascade which retards disease progression, would attenuate behavioral alterations of B/W mice. Female B/W (n=19) and NZW (n=18) mice were injected 3 times a week from 6 to 13 weeks of age with either sIFNyR (3.33 µg/g; gift of L. Ozmen, Hoffmann-LaRoche) or saline vehicle and tested in the elevated plus maze (EPM) at 12 weeks and the novel object (NO) task at 13 weeks of age. Although B/W mice were less active and exploratory and more anxious than NZW mice, as seen in prior studies, sIFNyR treatment significantly attenuated these effects. Compared to B/W saline controls, sIFNyR treated B/W mice were more active in EPM (p<.02) and NO task (p<.006) and showed decreased EPM anxiety behaviors with greater % open arm time (p<.0004), shorter closed arm visits (p<.02), and less difference between closed and open arm visit (p<.008). In the NO task sIFNyR treated B/W mice explored more, as they crossed more % center squares (p<.0001), reared more (p<.02), and had shorter contact latency (p<.002), more contacts (p<.002), and more contact time with the NO (p<.009) than B/W saline controls. NZW mice were unaffected by sIFNyR treatment. Thus, down-regulation of autoimmunity by sIFNyR treatment was effective in attenuating behavioral abnormalities of B/W mice and suggest that prior differences seen between B/W and NZW mice in anxiety and exploratory behaviors are the result of autoimmune disease processes rather than genetic differences. These findings

HYDROLYSIS OF LEUCINE ENKEPHALIN IN HUMAN PLASMA AFTER SEVERE TRAUMA.

L. Bongiorno-Borbone*, A. Urbani, M. Marini, E. Trani, L. G. Roda,
Dept. Medicina Sperimentale, Universita Tor Vergata*, 00133 Rona,

Plasma hydrolysis of leucine enkephalin, and several cellular immunity parameters, have been evaluated in an homogeneous group of human subjects undergone severe trauma (proximal famur fracture). The possible relationship between the stressful event and the degradation of opioid peptides has been evaluated by chromatographic separation of the hydrolysis by-products formed in the presence of plasma obtained immediately after the trauma, and in controls obtained during a successive follow-up. By results obtained, trauma induces a net reduction in the amount of substrate hydrolyzed, as well as significantly modifying the pattern of the hydrolyzed, as well as significantly modifying the pattern of the hydrolyzis by-products formed. The analysis of these data indicates that the reduction of substrate hydrolysis is attributable in part to decreased activity of the enkephalin-degrading enzymes, in part to increased inhibition by the low molecular weight plasma inhibitors. In the same subjects, several of the immunological indexes measured underwent to quantitative relationship between reduction of hydrolysis and modifications of immune parameters does not however allow to hypothesize the existence of direct dependence between these two sets of data.

IMPAIRED FIGHTING BEHAVIOR IN AUTOIMMUNE MRL-lpr MALES. Boris Šakić*, Leonard Gurunlian, Judah A. Denburg, and Henry Szechtman. Departments of Biomedical Sciences and Medicine, McMaster University, 1200 Main St. West, Hamilton, CANADA L8N 3Z5.

We have reported previously that lupus-prone MRL-lpr mice float excessively in the forced swim test (an animal model of "behavioral despair") and show blunted concentration-intake response in the sucrose test (an animal model of "anhedonia"). The results are consistent with the hypothesis that development of systemic autoimmune disease produces depressive-like behavior. The present study is a further test of the above hypothesis. Fighting behavior and social encounters in autoimmune MRL-lpr males and congenic MRL +/+ controls were measured. It was expected that MRL-lpr males will show reduced fighting behavior as autoimmune symptoms develop. Twelveweek old males (n=10/ substrain) were housed singly for 4 weeks. Isolationinduced aggressiveness was tested in a resident-intruder paradigm where each mouse was either the resident or the intruder across nine sessions (one session/day). Frequency and duration of social contacts (sniffing, mounting, touching) and aggressive encounters (wrestling, biting, chasing) were measured during 10-min session by custom-made computer software. Social contact did not differ between the MRL-lpr and MRL +/+ males. However, fighting was reduced in autoimmune MRL-lpr males, as evidenced by rare fighting episodes and short aggressive encounters. These results strengthen the hypothesis that autoimmune disease produces depressive-like behavior and suggest that central mechanisms which mediate aggressiveness are targeted by immune factor(s).

TRANSDUCTION PATHWAYS INVOLVED IN THE DOWNREGULATION OF IL-2 EXPRESSION BY VIP. Z. Xin*, L. Sun, and D. Ganea. CMBN and Biological Sciences. Butgers Univ., Newark, NJ 07102.

Biological Sciences, Rutgers Univ., Newark, NJ 07102.

Neuropeptides have been reported to modulate the immune response in vivo and in vitro. Previous studies from our laboratory indicated that VIP inhibits IL-2 production by murine T lymphocytes and thymocytes activated through T cell receptors. In EL-4.IL-2 cells, a murine thymoma cell line expressing VIP-R2, VIP does not inhibit IL-2 production following stimulation with PMA and calcium ionophores. These results suggest that VIP interferes with T cell receptor mediated signal transduction pathways. Here we first investigated whether VIP affects cellular tyrosine phosphorylation, and/or the activity of TCRassociated tyrosine kinases (lck⁵⁶, fyn⁵⁹ and ZAP-70), which represent early events in T cell activation. Western blots using antiphosphotyrosine antibodies showed that VIP does not alter tyrosine phosphorylation at three different time points. VIP does not influence the activity of lck^{56} as demonstrated by both immunoblot and immune complex kinase assays in the absence or presence of enolase. In contrast, VIP induces ${\rm fyn}^{59}$ activity in unstimulated cells. We also examined the effect of VIP on IL-2 transcriptional factors. The binding activity of NF-AT, but not NF-kB, AP-1, and the TGGGC-binding is inhibited by VIP in electrophoretic mobility shift assays (EMSA). Since translocation and dephosphorylation of NF-AT mediated by calcineurin, a calcium-calmodulin dependent phosphatase, we investigated the effect of VIP on calcineurin activity, and compared it to forskolin, another cAMP inducer, and cyclosporin A, a known inhibitor of IL-2 expression. MOLECULAR CLONING OF THE cDNA CODING SEQUENCE OF IL-2 RECEPTOR- γ (γ_c) FROM MURINE FOREBRAIN AND HUMAN HIPPOCAMPUS: EXPRESSION BY ASTROCYTES AND NEUROBLASTOMA CELLS. J.M. Petitto 1 , Z. Huang 1 , C.M. Rinker 1 , M.K. Raizada 2 , D.L. Evans 1* and D.B. McCarthy 1 . Departments of Psychiatry 1 and Physiology 2 , University of Florida, Gainesville, FL, 32610.

IL-2 has been implicated in various neurobiological processes of the mammalian CNS. To understand how IL-2 acts in the brain, our lab has sought to determine the molecular pharmacological characteristics of brain IL-2 receptors (IL-2R). The lymphocyte IL-2Ry, an essential subunit for IL-2 signaling, is also a common subunit (γ_c) for multiple immune cytokines (e.g., IL-4, IL-7, IL-9, IL-15). Having previously cloned the α and β subunits of the IL-2R heterotrimer complex from normal murine forebrain, we examined the hypothesis that the brain IL-2Ry is derived from the same or a closely related gene coding sequence as that expressed by lymphocytes. In this study, we cloned and sequenced the full length IL-2Ry coding region from saline-perfused mouse forebrain and from a human brain were 100% homologous to their lymphocyte sequences. Northern analysis showed that the predominant mRNA transcript in murine brain was the expected size, but was expressed at very low levels compared to spleen. IL-2Ry was constitutively expressed in SCID mouse forebrain, primary astrocyte cultures, and by murine neuroblastoma and AtT-20 pituitary cells using RT-PCR. These data suggest the possibility that IL-2Ry could be an essential common subunit (γ_c) for multiple cytokine receptors which may be operative in the mammalian CNS. (Supported by NIH grant NS343623).

CORTICOTROPIN-RELEASING FACTOR (CRF) EXPRESSION IN THE IMMUNE SYSTEM FOLLOWING IL-2 ADMINISTRATION S.M. Brouxhon, D.L. Bellinger, D.L. Felten*. Dept. Neurobiol. & Anat. Univ. of Roch. Sch. of Med., Rochester, NY 14642, U.S.A.

A growing body of evidence has established the importance of cytokines in maintaining homeostatic conditions via a bidirectional communication between the neuroendocrine and immune systems. Recently, Raber et al (J.P.E.T., 1995) using an in vitro slice preparation, demonstrated a calcium- and dose-dependent release of CRF from the hypothalamus and amygdala following incubation with IL-2. In addition, IL-2 has been shown to regulate pro-opiomelanocortin (POMC) mRNA expression in pituitary cells (Brown et al., J. Immunol., 1987) as well as inducing a plasma increase in the POMC-derived products corticotropin (ACTH) and 8-endorphin (Denicoff et al., J. Clin. Endocr. Metab, 1989).

J. Clin. Endocr. Metan, 1989).

In this study, we examined CRF immunoreactivity in primary and secondary lymphoid organs following IL-2 administration in male Fischer 344 rats. Rats were administered IL-2 (50, 100, or 200ng/rat, i.p.) and sacrificed at varying time points (4, 12, and 24 hours) after treatment. The primary and secondary lymphoid organs were then removed and processed for immunocytochemistry (ICC). In vehicle-treated and non-treated rats we were unabled to demonstrate CRF-ir fibers in the thymus, spleen, or mesenteric lymph nodes. IL-2 administration induced the expression of CRF-ir nerves in the interlobular septa and capsular region of the thymus, and in the hilar region in the spleen.

region in the spleen.

IL-2 and monoclonal antibodies directed against IL-2 receptors have been used to treat a variety of hematologic malignancies, autoimmune diseases, and to prevent rejection following transplantation. Our findings suggest that IL-2 can interact with peptidergic neurons in the periphery, and indicate that more research needs to be done to determine the effect of IL-2 on nonlymphoid targets, including the central and peripheral nervous system.

IL-2 INCREASES IL-2R EXPRESSION IN SUPERIOR MESENTERIC-CELIAC GANGLION AND ALTERS SPLENIC NOREPINEPHRINE CONCENTRATION. D.L. Bellinger*. S. Brouxhon. D. Henderson. D.L. Felten. and S.Y. Felten. Dept. Neurobiol. & Anat. Univ. of Rochester Sch. of Med., Rochester, NY 14642, U.S.A. The autonomic nervous system through its innervation of lymphoid organs.

The autonomic nervous system through its innervation of lymphoid organs, provides a direct route for communication between the nervous and immune systems. Noradrenergic (NA) sympathetic innervation of both primary and secondary lymphoid organs has been well described with a variety of staining methods. NA innervation of the spleen is regional and specific, and distributes along the vasculature and in the parenchyma among cells of the immune system. Electron microscopic studies have demonstrated direct appositions between NA nerve terminals and Tlymphocytes and macrophages. This spatial relationship provides an anatomical substrate for neural signaling of cells of the immune system. Additionally, we have hypothesized that cells of the immune system may modulate sympathetic outflow through the release of signal molecules such as IL-2.

To explore this possibility, immunocytochemistry (ICC) for IL-2 receptors (IL-2R) was performed in superior mesenteric-celiac ganglion (SMCG) from male Fischer 344 rats following the administration of IL-2 (range of 50, 100, or 200 ng/rat, i.p.). IL-2R-immunoreactivity was greatly increased in the SMCG from IL-2-treated animals compared with vehicle-treated controls. Enhanced IL-2R immunoreactivity in SMCG neurons from IL-2-treated rats was observed at 4, 12, and 24 h after IL-2 treatment at each dose administered. Since the spleen is a target of SMCG neurons, we also examined splenic norepinephrine content in vehicle- and IL-2-treated rats. Norepinephrine concentration in spleens was significantly decreased at 4 h after treatment with 50 ng of IL-2. Splenic norepinephrine content was not significantly different from vehicle controls at any other dose or time point. This study provides evidence for the presence of IL-2R on sympathetic neurons, and suggests that IL-2 can alter sympathetic outflow to the spleen through its interaction with IL-2R on SMCG neurons. DIFFERENTIAL EXPRESSION AND POSSIBLE FUNCTION OF VIP-R1 AND VIP-R2 IN T LYMPHOCYTES. C. Coke, W. Sun, Z. Xin, and D. Ganea* CMBN and Biological Sciences, Rutgers Univ., Newark, NJ 07102.

Immune cells express specific receptors for immunomodulatory neuropeptides. Previous studies from our laboratory indicated that murine T cells express both VIP-R1 and VIP-R2. The two receptors are differentially expressed, with unstimulated cells expressing only VIP-R1, recent antigen-stimulated cultures expressing both VIP-R1 and VIP-R2, and fully differentiated T cell lines expressing only VIP-R2. The differential expression of the two VIP-Rs in T lymphocytes may reflect a different function in mediating the immunomodulatory effects of VIP. Our laboratory reported previously that VIP inhibits both IL-2 and IL-10 expression in antigen-stimulated normal T cells. Here we first studied the effect of VIP on IL-2 and IL-10 production in mature TH1 and TH2 cell lines, which express VIP-R2. VIP inhibits IL-2 production in TH1 cell lines, but does not affect IL-10 production in TH2 cell lines, suggesting that inhibition of IL-2 is mediated by VIP-R2, and inhibition of IL-10 by VIP-R1. This hypothesis was investigated next in normal splenocytes treated with various stimuli which induce IL-2 and/orIL-10 production, by studying the effects of VIP, the related neuropeptide PACAP, and different agonists and antagonists, in conjunction with the expression of the two VIP-Rs. The differential expression of the two VIP-Rs in T lymphocytes may reflect different functions in mediating the effects of VIP on cytokine production, and therefore, acquire an important physiological significance.

THE ROLE OF INTERLEUKIN-6 IN THE ACTIVATION OF THE HYPOTHALAMO-PITUITARY-ADRENOCORTICAL AXIS INDUCED BY ENDOTOXIN AND IL-1

Jianping Wang and Adrian J. Dunn*
Dept. of Pharmacology, LSU Medical Center, Shreveport, LA 71130.

Endotoxin (LPS) and interleukin-1 (IL-1) have been shown to be potent activators of the hypothalamo-pituitary-adrenocortical (HPA) axis, and both induce secretion of interleukin-6 (IL-6). LPS and IL-1 administration also increases brain 3-methoxy,4-hydroxy-phenylethyleneglycol (MHPG), as well as tryptophan and 5-hydroxyindoleacetic acid (5-HIAA), with peak responses at 2h and 4h following injection, respectively. Other studies have shown that IL-1 and IL-6 exhibit similar pharmacokinetics after i.p. or i.v. administration. However, the peak HPA axis responses to LPS and mlL-1β are around 2h after i.p. injection, whereas the response to IL-6 is significantly earlier (30-60 min). Moreover, the tryptophan and 5-HIAA responses to IL-6 appear earlier (2h), than those to LPS (6-8h) and IL-1

(4h).

LPS is known to induce IL-6 production and secretion starting around

1. 18 edministration (100 ng i.p.) was 1-2h after administration. Mouse IL-1β administration (100 ng i.p.) was shown to elicit a substantial, but short-lived increase of plasma IL-6 concentrations with a peak at 2h. Mice pretreated with a monoclonal antibody against mIL-6 showed attenuated corticosterone responses to IL-1 and LPS. However, anti-IL-6 treatment did not significantly alter the increases of MHPG, free tryptophan or 5-HIAA in either hypothalamus or brain stem. These results suggest that IL-6 may play a significant role in the LPS- and IL-1-induced stimulations of the HPA axis.

Supported by NIMH and NINDS (MH46261 and NS25370).

ENTERIC ENDOTOXIN MAY TRIGGER THE IMMOBILIZATION-INDUCED PLASMA IL-6 INCREASE. A. Takaki*, S. Shioda, A. Arimura, T. Hori. Dept of Physiol, Fac of Medicine, Kyushu Univ, Fukuoka 812-82, Japan; U.S.-Japan Biomed Res Labs, Tulane Univ, Belle Chasse, LA 70037, USA

Interleukin (IL)-6 has many non-immune functions including the production of acute phase proteins in the hepatic cells, the stimulation of the hypothalamic-pituitary-adrenal axis, the cytoprotection against lethal irradiation, etc. These pleiotropic activities of IL-6 must be important for the host defense against stress. We have recently demonstrated that immobilization (IM) stress increases plasma IL-6 levels; and that the partial hepatectomy or the hepatic sympathectomy attenuated IM-induced plasma IL-6 increase. Furthermore, the kupffer (K) and endothelial (E) cells in the liver were stained by anti-IL-6 antibody in the immobilized rats (Takaki et al., 1995). Since it is well known that physical stresses, such as burn injury, gut ischemia, cold exposure, etc., induce leakage of the intestinal flora and/or the bacterial endotoxin (LPS) into the circulation, we hypothesized that enteric LPS was released into the portal vein during IM stress, and then triggered the IL-6 production in the K and E cells in the liver. To confirm this possibility, LPS concentration in the portal plasma was measured in immobilized (1h) rats. Results showed that the portal LPS level certeinly increased in response to IM. The peak LPS level was about 3 times higher than that of the resting level (about 2pg/ml). The peak time was 30 min after the initiation of the restraint, whereas the restraint continued for 60 min. Since plasma IL-6 concentration began to increase at 30 min and reached to the peak level at 90-120 min, the portal LPS was likely to activate the K cell functions resulting in IL-6 release. In addition, the LPS stimulated IL-6 production in the K cells in a dose-dependent manner in vitro; and norepinephrine significantly enhanced this response. These data suggest that enteric LPS triggers the IM-induced plasma IL-6 increase, and that sympathetic innervation in the liver enhances this response

REGULATION OF IL-6 RELEASE FROM CORTICAL ASTROCYTES BY LPS: ROLE OF LIPOOXYGENASE PRODUCTS AND NITRIC OXIDE. Grimaldi M., ROLE OF LIPOCATOEINADE TROCES AND THE MAYER PAPER STATE OF THE PREZIOSE TO A STATE OF THE PREZIOSE OF A STATE OF THE PREZIOSE Pansini 5, 80131 Napoli, **Ist. Farmacologia, Univ. Cattolica del Sacro Cuore, Largo Francesco Vito 1, Roma; *Sist. di Oncologia Clinica e Sperimentale, Un. Neurobiologia C.B.A., Univ. Genova, Largo R. Benzi 10, I-16132 Genova; ITALY; ^ LAS/NINDS/NIH, 36 Convent Dr. Bethesda MD-20892, USA;

Among neuroactive substances released by astrocytes, interleukin 6 (IL-6), a pleiotropic cytokine that regulates immune responses and inflammatory processes, has been demonstrated to play a role in neuronal differentiation and survival. The mechanisms whereby Bacterial lipopolysaccharide (LPS), a component of gram negative bacteria wall, induce IL-6 release has not yet been clarified. Here we studied, by means of a bioassay, the modulation of IL-6 release from rat cortical astrocytes, induced by LPS, by anti inflammatory agents.

LPS stimulated concentration-dependently the release of IL-6 from rat cortical type I astrocytes. This LPS effect was not blocked by non steroidal anti inflammatory agents belonging to the class of cyclooxygenase inhibitors, while it was partially inhibited by lipooxygenase inhibitors. Dexamethasone (DEX) completely blunted the stimulatory effect of LPS upon IL-6 release. These data suggest that other mechanisms could be activated by LPS in order to fully achieve the stimulation of IL-6 release. Since LPS increased, and DEX inhibited, the expression of inducible nitric oxide synthase, we investigated the role of nitric oxide synthase inhibitors upon the stimulatory action of LPS. We found that L-NO-ARG, an inhibitor of nitric oxide production, inhibited the release of IL-6 induced by LPS in astrocytes.

We conclude that the stimulatory effect of LPS is achieved by the activation of either the metabolism of arachidonic acid with the production of lipooxygenase metabolites and by the activation of nitric oxide production, and that the high effectiveness of DEX could be due to the blockade of both of these pathways.

537.8

INTERLEUKIN-6-INDUCED POTENTIATION OF THE LOCOMOTOR

INTERLEUKIN-6-INDUCED POTENTIATION OF THE LOCOMOTOR RESPONSE TO AMPHETAMINE. S. Zalcman*. I. Savina, and R. A. Wise. Center for Studies in Behav. Neurobio. Concordia U. Montreal Canada H3G IM8. IL-6 is a macrophage and Th2 lymphocyte-derived glycoprotein that been detected in various central structures. It has been implicated in playing a role in various CNS pathologies, including ones associated with alterations of mesolimbic and mesostriatal activity. Zalcman et al. (1995) reported that IL-6 induced behavioral activating effects. In the present study, we examined locomotor responses to acute and repeated IL-6 administration. Long-Evans rats were administered IL-6 (0.0, 0.5, 1.0 or 2.0 μg, ip) and immediately thereafter placed in a locomotor box for two hours. Locomotor counts of rats receiving IL-6 (1 μg) were initially increased compared with those of controls. Although counts declined over the two hour period in all animals, a slower rate of decline was evident in IL-6-treated animals, whose counts significantly exceeded those of controls during the final 30 minutes of the session. The latter effect was also evident in rats treated with a 2 μg dose. Locomotion was reduced in rats treated with 0.5 μg of IL-6. Locomotor responses of rats receiving repeated intermittent administration of IL-6 were consistently greater than responses of rats that received repeated saline injections; however, responses did not increase with repeated injection. Interestingly, repeated IL-6 treatment appeared to sensitize animals to the locomotor-activating effects of amphetamine. In an initial treatment phase, rats received five daily injections of IL-6 (1.0 μg, ip) or saline and immediately thereafter were exposed to the test box for two hours. Daily counts of all animals declined over this five day treatment phase, although those of IL-6-treated rats were consistently higher (20%) than those of controls. Seven days after the last IL-6 injection, rats were administered amphetamine (1.0 mg/kg, ip) and again five days thereafter

CENTRAL OVEREXPRESSION OF INTERLEUKIN-6 MODULATES HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) FUNCTION. R. D. O' Shea*¶, F. E. Bloom¶, I. L. Campbell¶ and J. Raber¶#. ¶Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037; #New affiliations: Gladstone Molecular Neurobiology Program and Department of Neurology, University of California, San Francisco, CA 94141.

Interleukin-6 (IL-6) and IL-6-receptor mRNA and protein have been detected in

Interleukin-6 (IL-6) and IL-6-receptor mKNA and protein have been detected in different brain regions under normal and pathophysiological conditions. Although previous studies reported hypothalamic-pituitary-adrenal (HPA) axis stimulation after acute IL-6 administration, little is known about the chronic effects of IL-6 on the modulation of the HPA axis. Recently, a transgenic model was established in which CNS overexpression of IL-6, under the control of the glial fibrillary acidic protein promoter, produced severe neurologic disease with profound neuropathological manifestations (Campbell et al., 1993; Chiang et al., 1994). The function of the HPA axis in these IL-6 transgenic mice was investigated. IL-6 transgenic mice of the low expressor line G167 showed normal basal plasma corticosterone levels, but abnormally increased levels after restraint stress, as compared to non-transgenic littermate controls. The high expressor line G369 had elevated basal plasma corticosterone levels. Increased plasma corticosterone levels in G167, but not in G369 mice, were associated with increased adrenal corticosterone content and hyperplasia of both adrenal cortex and medulla. Notably, plasma ACTH levels and pituitary ACTH content were either not changed or decreased in these mice. G167 mice showed increased plasma levels of arginine vasopressin (AVP). The decreased ACTH response in the IL-6 transgenic mice and the adrenal hyperplasia in the Gl67 line support a direct activation at the level of the adrenal gland. The adrenal gland may be directly activated by AVP or be sensitized to ACTH. Thus CNS overexpression of IL-6 modulates the HPA axis in a complex, expression level-dependent fashion. These data further support a role for IL-6 in interactions between the neuroendocrine and immune systems. LIPOPOLYSACCHARIDE-INDUCED PROINFLAMMATORY mRNA EXPRESSION IN MIXED GLIA CYTOKINE CULTURES: SUPPRESSION BY PROTEIN TYROSINE KINASE INHIBITORS. G.-H. Jeohn, L.-Y. Kong, and J.-S. Hong*. Neuropharmacology Section, Systems Toxicology Branch, NIEHS/NIH, Research Triangle Park, NC 27709.

Protein tyrosine kinases are involved in signaling events for proinflammatory cytokine production in glial cells. However, the mechanisms by which protein tyrosine kinases influence the production of proinflammatory cytokines have not been well understood. This study examined the effects of two potent protein tyrosine kinase inhibitors, genistein and tyrphostin A25, on lipopolysaccharide (LPS)-induced mRNA expression for tumor necrosis factor- α (TNF α), interleukin- 1α (IL- 1α) or interleukin-6 (IL-6) in mouse primary mixed glia cultures. LPS dose-dependently increased the expression of the mRNA for TNF α , IL-1 α , or IL-6 in the mixed glia cultures. Genistein or tyrphostin A25 significantly inhibited the LPS-induced expression of the mRNA for these cytokines. These results demonstrate that protein tyrosine kinases are involved in the LPS-induced production of TNFα, IL-1α, or IL-6 in glial cells by modulating the transcription of the mRNA for these cytokines.

POTENTIAL ROLES FOR THE 75 KD TNF RECEPTOR AND INTERFERON-α IN SENSITIZING NEURONS TO TNF-α INDUCED CELL DEATH K.J. Sipe1. K.W. Kelley², R. Dantzer³ and J.A. Weyhenmeyer¹. Departments of ¹Cell and Structural Biology and ²Animal Sciences, University of Illinois, Urbana, IL 61801 and ³INRA-INSERM, Unité 394, Bordeaux, France.

Using the N1E-115 neuroblastoma line (N1E's) as a model system, we are examining the direct effects of the inflammatory cytokine, tumor necrosis factor-α (TNF), on neurons. We previously reported that the NIE's express only the 55kD TNF receptor (TNFR) which mediates TNF induced apoptotic cell death in the NIE's in the presence of the transcriptional inhibitor, ActD (ActD). A physiological agent that might sensitize neurons to TNF cytotoxicity is the antiviral cytokine, interferon α/β (IFN). Initial studies indicate that IFN is less potent than ActD in inhibiting N1E proliferation and in sensitizing the N1E's to TNF cytotoxicity. It is likely that viral infection is also required to obtain the full antiviral effect, including inhibition of RNA synthesis and proliferation, of IFN. If this is the case, concurrent viral infection, TNF and IFN production may represent one mode of neuronal destruction in viral infections of the CNS. Another mode of neuronal sensitization to TNF cytotoxicity may be the upregulation of the 75kD TNFR. While upregulation of the 75kD TNFR has been reported in TNF treated cells (Kalthoff et a., J. Biol. Chem. 268, 2762-2766), we have not observed this in N1E's. We are currently transfecting N1E's with an expression construct for the 75kD TNFR to examine this issu Although we anticipate that expression of the 75kD TNFR will increase N1E sensitivity to TNF cytotoxicity, based on the ligand passing model proposed by Tartaglia et al.(J. Biol. Chem. 268, 18542-8) and results in 75kD TNFR knock-out mice (Erickson et al., Nature 372,560-563), it is conceivable that that N1E's may express endogenous TNF that, in a membrane bound form, engages expressed 75kD TNFR, leading to cytoxicity in the absence of exogenous TNF. INTRACEREBROVENTRICULAR INJECTION OF ANTI-TNF-α BLUNTS THE ONSET OF THE ACTH RESPONSE TO ENDOTOXIN: IS THIS EFFECT DUE TO NEUTRALIZATION OF TNF-α WITHIN THE BRAIN OR IN THE PERIPHERY? A.V. Turnbull* and C. Rivier. Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037

Tumor necrosis factor-α (TNF-α) undoubtedly plays an important role in regulating neuroendocrine responses to inflammatory/disease processes. However, whether TNF-or acts within the brain or whether it influences the neuroendocrine hypothalamus via intermediates released in the periphery, remains unclear. In the present study, we found that intracerebroventricular (icv) injection of a specific, neutralizing rabbit anti-TNF-α antisera (5 µl) 20 h earlier, significantly blunted the onset of the ACTH response to intravenous (iv) lipopolysaccharide (LPS, 5µg/kg). However, in control experiments the same dose of antisera injected iv produced quantitatively similar effects. Surprisingly, the increase in plasma $TNF-\alpha$ biological activity (assessed by cytotoxicity to L929 cells) produced by LPS was similarly reduced by iv and icv anti-TNF- α treatment. Furthermore in normal animals injected with anti-TNF- α icv, recovery of TNF- α biological activity from "spiked" plasma samples was reduced. This inhibitory factor could be removed by pre-precipitation with a sheep anti-rabbit IgG, suggesting the presence of antisera in blood after icv injection. In separate experime we found that icv injection of a number of antisera, raised in different host species and against different peptides, produced rapid and sustained elevations in the plasma titer of the antisera as assessed by specific binding of the appropriate I¹²⁵-labeled ligand. Indeed after icv injection, measurable plasma titers were apparent within 30 min, and by 8 h of injection, plasma titers were equivalent to those observed after iv injection. Collectively, these data indicate that icv injection of antisera produces plasma titers sufficient to exert significant actions within the periphery, and suggest that TNF- α acts within the periphery to stimulate ACTH secretion in response to LPS Supported by NIH DK-26741.

INHIBITION OF LIPOPOLYSACCHARIDE-INDUCED NITRIC OXIDE AND CYTOKINE PRODUCTION BY ULTRALOW CONCENTRATIONS OF DYNORPHINS IN MIXED GLIA CULTURES. L.-Y. Kong*, M. K. McMillian, B.

DYNORPHINS IN MIXED GLIA CULTURES. L.-Y. Kong*, M. K. McMillian, B. C. Wilson, P. M. Hudson, L. Jin, G. Bing, and J.-S. Hong Neuropharmacology Section, Systems Toxicology Branch, NIEHS/NIH, Research Triangle Park, NC 27709.

Dynorphins are a major class of endogenous opioid peptides that modulate functions of immune cells. However, the effects of dynorphins on the immune functions of glial cells in the CNS have not been well characterized. As nitric oxide (NO) and the proinflammatory cytokine tumor necrosis factor-α (TNFα) produced by glial cells influence various physiopathological conditions in the CNS, this study examined the effects of dynorphins on the production of NO and TNFα from mouse glial cells treated with lipopolysaccharide (LPS). LPS induced a concentration-dependent increase in the production of NO or TNFα from the mouse primary mixed dia cultures. LPS induced a concentration-dependent increase in the production of NO or TNF α from the mouse primary mixed glia cultures. Ultralow concentrations (10⁻¹⁶-10⁻¹² M) of dynorphin (dyn) A-(1-8) significantly inhibited the LPS-induced production of NO or TNF α . The inhibitory effects of dyn A-(1-8) were not blocked by nor-binaltorphimine, a selective kappa (κ) opioid receptor antagonist. Ultralow concentrations (10⁻¹⁶-10⁻¹² M) of des-[Tyr¹]-dyn A-(2-17), a non-opioid analog which does not bind to κ opioid receptors, exhibited the same inhibitory effects as dyn A-(1-17). The production of NO and TNF α in the LPS-stimulated microglia-enriched cultures was significantly higher than that in the identically stimulated astrocyte-enriched cultures, indicating that microglia are more responsive to the stimuli which cause NO and TNF α production. These results suggest that dynorphins modulate immune functions of microglia and/or astrocytes in the brain and these modulatory effects of dynorphins are not mediated by classical κ opioid receptors. classical k opioid receptors.

ENCEPHALOPATHY INDUCED BY THE ASTROCYTE-TARGETED EXPRESSION OF INTERFERON-α IN TRANSGENIC MICE. Y. Akwa*¹, M. L. Eloranta², K. Sandberg³, H. Powell⁴, F. E. Bloom¹ and I. L. Campbell¹.¹ Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037 ² Univ of Uppsula, Sweden, ³ Astra Arcus Sodertälje, Sweden, ⁴ Dept. of Pathology, Usiv of Sep. Diago. CA. Univ of San Diego, CA.

Interteron- α (IFN- α) is an immunoregulatory cytokine pivotal in the anti-viral response that may be both protective or injurous to the host in viral infections of the central nervous system (CNS). In order to assess the possible neuropathogenic properties of IFN- α , we used a transgenic (Tg) approach to constitutively express IFN- α in the CNS of mice. Expression of IFN- α was targeted to astrocytes by placing the IFN- α gene under the regulatory control of a glial fibrillary acid protein (GFAP) genomic expression vector. Two GFAP- IFN- α Tg lines, termed GIFN-39 and GIFN-12, were developed with moderate and low levels of IFN- α mRNA expression in the brain, respectively. Significant production of IFN- α protein was demonstrated from astrocytes from GIFN-39 mice which were runted and moribund, died at 5-10 months of age. A similar but much less Interferon-α (IFN-α) is an immunoregulatory cytokine pivotal in the anti-viral which were runted and moribund, died at 5-10 months of age. A similar but much less severe phenotype was observed in some older (8-12 mo) GIFN-12 mice. In the brain severe phenotype was observed in some older (8-12 mo) GIFN-12 mice. In the brain of Tg mice a spectrum of alterations, correlated with the levels and distribution of transgene expression, was observed. At the cellular level, gliosis, angiopathy with mononuclear cell cuffing and progressive calcification affecting basal ganglia and cerebellum were prominent. Spongiform changes were evident in regions affected by calcification. At the molecular level, the expression of two IFN- α inducible genes, 2',5'-oligoadenylate synthetase and major histocompatibility complex class 1, were markedly increased. In conclusion, these findings demonstrate that the chronic cerebral expression of IFN- α is sufficient to produce specific structural and functional changes in the CNS. This model therefore offers great potential in further dissecting the mechanism of IFN- α in neuropathogenesis and developing therapeutic approaches to abolish the harmful actions of IFN- α . ANANDAMIDE EFFECTS ON NITRIC OXIDE AND CYTOKINES PRODUCTION BY ASTROCYTES STIMULATED WITH THEILER'S MURINE ENCEPHALOMYELITIS VIRUS OR LIPOPOLYSACCHARIDE. F. Molina-Holgado*, A. Lledó and C. Guaza. Instituto Cajal, CSIC, 28002 Madrid, Spain.

Astrocytes are an important cell population in the central nervous system (CNS) cytokine network. The astroglial response to diverse neurological disorders, such as multiple sclerosis (MS) or experimental allergic encephalomyelitis (EAE), include the production of nitric oxide (NO) as well as several cytokines. In the present study we showed that primary cultures of neonatal mouse cortical astrocytes directly exposed to lipopolysaccharide (LPS:1µg/ml, 18 hours) or to the Theiler's murine encephalomyelitis virus (TMEV), increased the release of nitrites (NO2), interleukin-6 (IL-6) and tumor necrosis factor- α (TNF- α). The presence of anandamide (10, 50 and 100 μ M) in the astrocyte (Balb/c mice strain) culture medium, an endogenous ligand for cannabinoid receptor, blocked dose-relatedly the LPS-induced release of NO₂ and TNF-α. Exposure of cultured astrocytes (SJL/J mice strain) to TMEV (10⁵ PFU, 24 hours) together with anandamide (10, 25 and 50 μ M) suppressed the stimulatory effects of TMEV infection on NO and TNF- α in a dose-related manner. By contrast stimulated IL-6 release from astrocytes exposed to TMEV or LPS treatment was enhanced by the presence of anandamide in a concentration dependent manner. These results strongly suggest that in glial cells the cannabinoid endogenous ligand, anandamide, exert a modulatory role which may have protective effects. These results could have important implications in the modulation of immunological and inflammatory processes in the CNS.

Th2-DERIVED CYTOKINES ACT AS IMMUNOSUPPRESSIVE FACTORS AND PROVIDE NEUROTROPHIC SUPPORT IN THE CNS. Chava Brodie* and Nurit Goldreich Department of Life-Sciences, Bar-Ilan University, Ramat-Gan, Israel 52900.

Astrocytes function as immunocompetent cells in the central nervous system and play an important role in immune-related processes by their interactions with various cytokines. The development of the immune response in the brain has been shown to be mediated by proinflammatory cytokines such as IL-1, IL-6, TNFα and IFNy, whereas, the Th2-derived cytokines, IL-4 and IL-10 have been implicated as negative regulators of immune responses in the CNS. In this study we characterized the expression of IL-4R and IL-10R in astrocytes derived from the cortex and the cerebellum and explored the effects of IL-4 and IL-10 on immune-related properties of these cells. We found that astrocytes express the mRNA for both the membranal and the soluble forms of the IL-4R, whereas, they do not secrete IL-4. In contrast, mRNA for both IL-10R and IL-10 are expressed by these cells. Pre-treatment of the cells with IL-4 and IL-10 inhibited both NO production and iNOS expression induced by LPS treatment as well as the secretion of TNF-α In contrast neither cytokine blocked NO production by astrocytes stimulated with exogenous TNF-α. Both IL-10 and IL-4 induced the secretion of NGF by astrocytes and synergized with TNF- α in this effect. These results suggest an important role for IL-4 and IL-10 as immunosuppressive and neurotrophic factors in the CNS during instances of CNS trauma and inflammation

GI 129471 INHIBITS LPS-INDUCED TNF-α RELEASE FROM PRIMARY CULTURES OF RAT ASTROCYTES P.S. Puttfarcken* A.M. Manelli, E.D. Cadman, and K. Shiosaki. Neuroscience Research, D-47W, Abbott Laboratories, 100 Abbott Park, IL 60064-3500.

Elevated levels of TNF-α have been reported in various CNS infections,

including HIV-1, meningitis, and following brain injury. TNF- α is synthesized as a precursor, then cleaved by a protease to yield the active form. Although a specific TNF- α processing enzyme(s) has not been identified, the effectiveness of selected hydroxamate-based inhibitors indicates that this enzyme resembles a matrix metalloproteinase (McGeehan et al., 1994; Gearing et al, 1994). Previous studies have demonstrated inhibition of lipopolysaccharide (LPS)-Previous studies have demonstrated inhibition of lipopolysaccharide (LPS)-induced TNF-α release by the metalloproteinase inhibitor of I 129471 in the periphery (McGechan et al., 1994). To investigate the ability of GI 129471 to inhibit TNF-α release in the CNS, rat astrocyte cultures were treated with In0g/ml LPS. Elevated TNF-α levels appeared within 1.5 to 3 hours, reached a maximum at 8 hours, and declined by 24 hours. This time course correlated with *in vivo* findings (see Nikkel et al., this meeting). Treatment with GI 129471 inhibited LPS-induced TNF-α release in a concentration-dependent manner with an estimated IC50 of 50 nM, a value approximately 2- to 3-fold manner with an estimated $\Gamma(S_0)$ of so fine, a value approximately 2- to 3-total more potent than that previously reported in the periphery (McGeehan et al., 1994). In contrast, pentoxifylline, a methylxanthine derivative previously determined to inhibit TNF- α production through a undefined mechanism, was less potent with an estimated $\Gamma(S_0)$ of $100 \, \mu M$. These data suggest that the enzyme(s) responsible for processing TNF- α may be similar in the CNS and periphery and that inhibition of this process may be a suitable target to investigate the pathophysiology of CNS disorders associated with elevated TNF-

INHIBITION OF KAINIC ACID-INDUCED ELEVATED TNF α LEVELS IN BRAIN BY ICV GI 129471. A.L. Nikkel*, K.E. Asin, P.S. Puttfarcken, E.D. Çadman, A.M. Manelli and K. Shiosaki, Neuroscience Res. Div., Pharmaceutical Discovery, D-47W, Bldg. AP9A, Abbott Laboratories, 100

Abbott Park Road, Abbott Park, IL 60064-3500.

Tumor necrosis factor alpha (TNFcx) has been implicated as a possible mediator of the brain's response to diverse forms of injury. The neurotoxin, kainic acid (KA), when administered systemically at doses that cause convulsions, produces widespread damage and cytokine induction, including an increase in TNFa mRNA express Other investigators have demonstrated that the metalloproteinase inhibitor, GI 129471 (Glaxo, Inc.), can block TNFα production both *in vitro*, from peripheral blood monocytes, and *in vivo*, in plasma (McGeehan et al., 1994). GI 129471 can also inhibit TNFa release from CNS-derived astrocytes (see Puttfarcken et al. this meeting).

We investigated the ability of ICV-administered GI 129471 to inhibit elevated TNFα in the brain, following SC-administered KA (10 mg/kg) to rats with indwelling cannulae terminating in the left lateral ventricle. TNF α levels from brain homogenates were quantitated by ELISA. In unoperated rats, TNF α levels were elevated within 3 hours, reached maximum within 9 to 12 hours, and declined within 18 to 24 hours post-KA treatment. Cannulated rats were subsequently pretreated with 30 µg G1 129471 or vehicle ICV just prior to KA or saline injection and again at 4 hours after KA or saline injection prior to sacrifice at 9 hours. ICV vehicle-treated rats that received KA and displayed convulsions exhibited elevated TNFa when compared to SC vehicle-treated controls. When compared to ICV vehicle controls, ICV GI 129471 significantly attenuated TNFα production in KA-treated, convulsing rats (45-63% reduction). ICV GI 129471 did not alter TNFα in SC vehicle-treated rats

(43-63)% feutures). TeV of 1729471 tut not after 1 fryth in 3C ventile-treated rats and did not affect the proportion of KA-treated rats that displayed convulsions. These data demonstrate that Gl 129471 can inhibit $TNF\alpha$ production in brain in the face of excitotoxic damage and suggest that $TNF\alpha$ inhibition may provide a productive area of investigation for CNS disorders that involve elevated $TNF\alpha$ production. INDUCTION OF TNF-α EXPRESSION BY PNEUMOCOCCAL CELL WALL COMPONENTS (PCW) IS INDEPENDENT FROM NFKB ACTIVATION IN CEREBRAL ENDOTHELIAL CELLS (EC). D.Freyer, A.Meisel, M.Weih*, K. Angstwurm, J.R. Weber, R. Manz, A. Ziegenhorn, W. Bürger, U. Dirnagl. Depts. of Neurology and Microbiology, Humboldt University Berlin, FRG.

Cell wall components of gram-positive Streptococcus pneumoniae, as they result from bacteriolysis, have experimentally been shown to cause meningeal inflammation, similarly to LPS of gram-negative bacteria. The cellular mechanisms during inflammation are well established for LPS and a central role of of the NF κB in regulation cascades has been demonstrated. However, little is known about the PCW-induced transduction cascade. In this study we investigated iNOS and $TNF\alpha$ expression in EC upon stimulation with PCW. EC were prepared from rat brain and cultivated by standard procedures. The activation by PCW was altered by unspecific and specific blocking of NFkB. For unspecific inhibition, EC were simultaneousely incubated with 0.1 mM pyrrolidine-dithiocarbamic acid (PDTC) and 5*105 cfu/ml PCW. According to the decoy approach, oligonucleotide duplexes (20µM) containing the cognate NFkB-binding site were used for specific NFkB inhibition. By using the unspecific approach the TNF α as well as the iNOS expression were reduced to baseline levels. In contrast, specific inhibition of NFkB produces only a 50-60% reduction of iNOS expression whilst the TNF α expression was increased by incubation with PCW and oligonucleotides to 140% of the value from incubation with PCW alone. These results suggest a different transcriptional activation of iNOS and TNFa. Since the antioxidant PDTC is known to have unspecific effects, it is more likely that in addition to NFkB there is a second inducible transcription factor for the transactivation of the iNOS gene and the $\mbox{TNF}\alpha$ expression upon stimulation with PCW seems to be independent from NFkB activation. SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS VII

538.1

INTERLEUKIN 6 (IL-6) SUPPRESSES AFFERENT SENSORY TRANSMISSION IN THE PRIAMRY SOMATOSENSORY (SI) CORTEX. K.H. Lee*, C.K. Won, H.C. Shin Dept. of Neurosurgery*, Dept. of Physiol., Coll. Med., Hallym Univ., Chunchon, Korea

Although IL-6 and IL-6 receptors are present in the adult cerebral cortex in the noraml rat, the functional role of IL-6 has not been characterized. In the present study, we have examined the effects of topical application of human recombinant IL-6 to the cortical surface on the afferent sensory transmission in the SI cortex of anaesthetized Quantitative determination of the effect of IL-6 on the afferent sensory transmission to the neurons in the SI cortex was carried out by generating poststimulus time histograms of unit responses to the stimulation of receptive field located in the whisker area of the face. Application of 0.1 U (n=8) IL-6 caused a slight reduction (-9.30±4.7%, p < 0.01, 15-20 min post-drug) in afferent sensory transmission 15-25 min after drug administration. Administration of 1.0 U (n=8) IL-6 exerted much stronger (-15.13 \pm 3.4%, p < 0.01, 20–25 min post-drug) and long-lasting, but reversible, inhibitory influences on the afferent sensory transmission. IL-6-induced suppression fully recovered by 60 min after drug. Lowest dose of IL-6 (0.01 U, n=8) as well as saline solution (n=9) containing 0.2% bovine serum albumin, used as a vehicle, did not affect afferent sensory transmission. The results of this study provide evidence that IL-6 may be involved in the processing of afferent sensory information in the SI cortex of rats (supported by KOSEF grant, 961-0701-1).

TIME COURSE OF EFFECTS OF LOCAL SUPERFUSION OF BICUCULLINE ON RECEPTIVE FIELD PROPERTIES AND TEMPORAL INTEGRATION OF RAT SOMATOSENSORY CORTICAL NEURONS. A. Benali, F. Spengler, R. Leonhardt*, H.R. Dinse. Institut f. Neuroinformatik, Ruhr-Univ. Bochum, Germany

We investigated the role of GABA₃-receptor mediated inhibition on a number of parameters reflecting cortical information processing properties such as receptive field (RF) organization, topographic maps, response latencies, temporal integration properties (repetition rate coding) and spontaneous and stimulus-induced activity. Neurons were recorded in layer IV of the fore- and hindpaw representation of somatosensory cortex of urethane anaesthetized rats. GABA₃-receptor antagonist (-) himselficial profiles the control of the forebicuculline-methiodide (BMI) was locally superfused (single application of 1µl of 1 mM, washed out after 1 h) onto the cortical surface restricted to about 1 mm² with the remaining cortex covered with paraffin film. In view of the highly interconnected cortical network properties, a local superfusion method was chosen in order to affect a large population of neurons.

Mapping RFs around the application site revealed that an area of 0.25-1 mm² v affected by the superfusion method used. Three different episodes of BMI effects could be distinguished: 1. Complete suppression of tactile-driven activity following BMI superfusion for about 10 to 20 min paralleled by high spontaneous, bursting activity. 2. Restoration of tactile responsiveness paralleled by severalfold RF enlargement and strong suppression of repetition rate responsiveness. 3. After washout, we observed recovery after 1 to 2 h. At the begin of this period, RF size was still highly enlarged and temporal integration was shifted towards lower cut-off frequencies due to a removal of suppression typical for short ISIs (35 ms).

The results indicate that BMI-mediated disinhibition affects all spatial and temporal aspects of cortical information processing tested. However, the time course of the effects includes transient episodes of complete suppression of sensory responsiveness. The differential results are compared to plastic reorganizational changes to elucidate the role of inhibition in cortical plasticity.

DIFFERENTIAL EFFECTS OF THE CA²⁺ INFLUXBLOCKER NIMODIPINE ON RECEPTIVE FIELD SIZE AND RESPONSE LATENCIES OF SOMATOSENSORY CORTICAL NEURONS OF AGED RATS. M. Jürgens* and H.R. Dinse, Institut für Neuroinformatik. Theoretische Biologie. Ruhr-Univ. Bochum RUB, Bochum, Germany

RUB, Bochum, Germany
During aging the regulation of Ca²⁺ homeostasis can be disturbed, among others by
an excessive influx through voltage gated calcium channels of the L-type. The
dihydropyridine Ca²⁺ antagonist nimodipine is able to block this type of channels,
thus protecting the cell from intracellular Ca²⁺-overload (Freund & Redding 1989,
Brain Res 654: 257).

We have previously shown that rats older 24 months display a number of age related impairments in sensorimotor state as well as in cortical organization (Spengler, Godde, Dinse 1995, Neuroreport 6: 469). In this investigation we studied the effects of long-term application of nimodipine on the cortical organization of RFs and response latencies of somatosensory neurons recorded in the fore and hindpaw representations of urethane anesthetized aged rats (23-30,5 months). In addition to electrophysiological recordings, the sensorimotor state of each animal was assessed.

In parallel to the beneficial effect on the overall state and walking pattern of the hindextremity, we found a significant influence on RF-size of the hindpaw compared to untreated age-matched animals. The positive effects resulted in a reversal of the normally observed age-related enlargement of RFs that came to match the values found in normal adult animals. This reversal was restricted to a period of 4 to 5 months. RFs on the forepaw that showed no age-related increase even in untreated animals, were not affected by nimodipine treatment. Response latencies of neurons from the hindpaw as well as the forepaw were not altered by nimodipine too, but showed the characteristic lengthening with chronological age. Taken together we were able to demonstrate an effect of nimodipine on cortical RF-organization, whereas response latencies remained unaffected. Accordingly, the results indicate a selective involvement of nimodipine in the treatment of age-related changes.

PERSISTENT REDUCTION IN WHISKER BARREL AREAS FOLLOWING SYSTEMIC AND LOCAL PARACHLOROAMPHETAMINE-INDUCED SEROTONIN DEPLETION IN NEONATAL RATS. F. Keller*, A.M. Persico', E. Calia', and S. Puglisi-Allegra*, Laboratory of Neuroscience. Libero Istituto Universitario Campus Bio-Medico. Rome, Italy, and Dept. of Psychology, Unix, "La Sapienza", Rome, Italy.

Increasing evidence supports neurodevelopmental roles for serotonin in several species. Whisker barrels located in the posteromedial barrel subfield (PMBSF) of the rodent somatosensory cortex allow reliable assessment of serotoninergic modulation of thalamocortical pathway development and plasticity. Single (P0) or repeated (P0 and P2) injections of parachloroamphetamine (PCA: 3.5 or 14 mg/kg s.c.) reduced left hemisphere PMBSF 5-HT and 5-HIAA content. assessed using HPLC on P7. by 32-60% (p<.001) and 10-45% (p<.001), respectively, compared with saline-injected rats. The right hemispheres of the same animals assessed using acetylcholinesterase histochemistry displayed 18.7% (p<.0001) and 14.2% (p<.01) reductions in mean whisker barrel and total PMBSF areas. respectively. Decreases in mean whisker barrel area appear to follow a gradient, ranging from 23.6% reductions in row-A (p<.0001) down to 14.9% decreases in row-E (p<.01). Systemic PCA also blunted body weight gain (126% increase with saline vs 30-57% increase with PCA between P0 and P7) and reduced mean brain weight by 12.5% on P7. We therefore employed elvax and gelfoam implants (see abs. by Persico & Keller) providing slowrelease of PCA or saline over the somatosensory cortex to verify the specificity of systemic PCA effects. Although saline-containing implants frequently produce non-specific reductions in whisker barrel and PMBSF areas. PCA-containing implants consistently produce much more sustained decreases, providing further support to intracortical 5-HT-mediated neurodevelopmental effects on thalamocortical pathways. GAP CROSSING TRAINING ENHANCES WHISKER PAIRING BIAS IN ACETYLCHOLINE DEPLETED RATS. R. N. S. Sachdev*, M. Stonecypher, M. Egli, R. G. Wiley', S.-M. Lu, F. F. Ebner. Institute for Developmental Neuroscience, Kennedy Center, Vanderbilt University, '& Dept. of Neurology, VAMC Nashville, TN 37203

Neurons in the D2 barrel column develop a bias in their responses after trimming all but two adjacent whiskers on one side of the adult rats face, such that these neurons respond more to whiskers that are spared or "paired". We have shown that whisker pairing plasticity can be prevented by depletion of acetylcholine (ACh) from the barrel cortex. In this study we have examined whether the whisker pairing bias can be restored when a naive ACh depleted animal is trained to use the "paired" whiskers in a gap crossing task For each experiment, two adult male litter-mates were depleted by making a single 1 µl injection of IgG 192-saporin (0.62 mg/ml) medial to the barrel field. A week after the injections, both animals were weighed and a food deprivation regimen was initiated. One week later, all whiskers -- except D2 and either D3 or D1 on the right side of the face -were trimmed. One rat was then trained everyday on a gap crossing task, while the other animal was handled daily but not trained on the task. In the gap-crossing task, the rat is placed on one of two platforms 60 cm above the desktop and is required to make a crossing over a variable gap between the two platforms by using its whiskers. One week after either pairing the whiskers or pairing and training on gap-crossing, the response properties in the D2 barrel column were assayed with extracellular single-unit recording. Following the recording session animals were perfused transcardially, their brains were fixed, sectioned and stained for cytochrome-C oxidase (CO) and acetylcholinesterase (AChE). Electrode tracks were confirmed in CO stained sections, and the depletion was confirmed on AChE stained sections. In the gap-crossing trained ACh depleted animals, a bias toward the paired whisker is apparent while in the untrained animals no significant bias develops, suggesting that the active use of whiskers can reinstate a whisker pairing bias even in the ACh depleted animal. OPTICAL IMAGING OF AGE-RELATED CHANGES OF RAT SOMATOSENSORY CORTICAL REPRESENTATIONS AND THEIR SENSITIVITY TO THE CA²⁵ INFLUXBLOCKER NIMODIPINE. <u>T. Berkefeld, B. Godde and H.R. Dinse (SPON: Europ. Brain Behav. Soc).</u> Institut für Neuro-informatik. Theoretische Richorie Ruhr, Univ. Rochum RUB. Rochum Germany.

Impairment of the Ca2+ homeostasis during aging is assumed to be causally related to many age-related neuronal changes. To address the question of age-related changes of cortical representational properties [Spengler, Godde, Dinse 1995 Neuroreport 6: 469] and their sensitivity to the Ca2+ antagonist nimodipine, we studied the functional organization of somatosensory cortex (SI) of aged nimodipine- and aged non-treated animals by means of optical imaging of reflectance changes of intrinsic signals and by recording local field potential (LFP) maps in supragranular and granular layers.

animals by means of optical imaging of reflectance changes of intrinsic signals and by recording local field potential (LFP) maps in supragranular and granular layers.

The size of the hindpaw representations of aged animals was significantly reduced compared to normal adults as measured both optically and electrophysiologically. We found a striking correspondence of areas of activation for different activity levels between optical imaging and LFP data recorded in layer IV. but not for layer IVIII. Several months of nimodipine treatment resulted in a substantial increase of the hindpaw representational areas which became even larger than in normal adult animals. This restaurative effect was more prominent for the optical imaging data, but also present in the LFP maps recorded in cortical layers IVIII and IV, suggesting an additional effect of nimodipine related to cerebral blood flow.

In contrast to the hindpaw with its age-related locomotion impairment, the forepaw

In contrast to the hindpaw with its age-related locomotion impairment, the forepaw maintains a fairly unimpaired behavior even in old animals. We observed that the forepaw representational areas were indeed comparable in adult and old, untreated animals, indicating a lack of age-related cortical degradations. After nimodipine treatment, the forepaw representations were not significantly increased. Combined, the results indicate a differential effect of nimodipine for the differentially affected foreand hindpaws, thereby suggesting a specific involvement of nimodipine in plastic and restaurative processes.

ELVAX vs GELFOAM IMPLANTS FOR SUSTAINED DRUG RELEASE OVER THE WHISKER BARREL FIELD: THE PCA-INDUCED SEROTONIN DEPLETION PARADIGM. A.M. Persico*. and F. Keller Laboratory of Neuroscience. Libero Istituto Universitario Campus Bio-Medico. Rome. Italy

Systemic drug treatments frequently produce neurodevelopmental effects with questionable specificity. Systemic parachloroamphetamine (PCA) treatment, for example, may reduce whisker barrel areas by specifically depleting cortical 5-HT, or by non-specifically reducing body weight in neonatal rats (see abs. by Keller et al.). To circumvent these limitations, implants providing sustained drug release over specific cortical areas have been employed. We have initially defined the stereotaxie coordinates for correct implant targeting by injecting India ink at P0 and verifying injection location relative to the posteromedial barrel subfield (PMBSF) at P7. We then compared PCA- and saline-containing implants made with clvax chips or with gelfoam. Both acetylcholinesterase histochemistry and 5-HT immunocytochemistry were performed to assess implant effects on thalamo-cortical and raphe-cortical pathways. Elvax chips of 2 x 2 mm size and approximate thickness of 200 μ or more. produced extensive tissue damage (no interpretable data out of 18 animals). Chips of approximately 100 μ yielded 1/11 informative brains when slid under the skull and 2/10 when the bone was removed and the chip covered with a sterile 7 x 7 mm Saran Wrap sheet. Gelfoam implants yielded 6 informative brains out of 7 animals. Rats receiving saline gelfoam implants, however, displayed 20-30% reductions in mean whisker barrel areas, which were instead unmodified in saline clyax-treated animals In conclusion, clear chips have the advantage of providing more interpretable results, while gelfoam implants provide much better yields. Given the limitations inherent to both these approaches, we are actively searching for new polymers to test for drug treatments localized over specific cortical regions

EFFECTS OF NOREPINEPHRINE (NE) DEPLETION IN THE RAT BARREL CORTEX S.-M. Lu*, R. Sachdev, M. Picklo, D. Robertson, and F. E. Ebner, Inst. for Dev. Neurosci., Kennedy Center and Dept. of Pharmacol., Vanderbilt Univ. Nashville, TN 37203

Previous studies have shown that trimming all but 2 whiskers (whisker-pairing) in an adult rat produces robust changes in cortical receptive field (RF) properties that can be used as an assay for the status of cortical activity-dependent plasticity (called whisker pairing plasticity). NE has been proposed as an important regulator of activity-dependent plasticity. The present experiments examine whether NE is a necessary requirement for whisker pairing plasticity to occur in adult rat barrel cortex.

NE innervation of barrel cortex was depleted using a dopamine-B-hydroxylase (DBH) immunotoxin, saporin conjugated anti-DBH antibody, which binds specifically to NE containing terminals when DBH is exposed extracellularly during NE release. The bound DBH immunotoxin is internalized and transported back to cell bodies in the locus coeruleus where the saporin kills the host cells. Fewer than 5% of the NE containing axons remain detectable in barrel cortex 10-14 days after a single 1 µl DBH immunotoxin (0.2 mg/ml) intracortical injection.

Cortical RF properties were recorded under urethane anesthesia from adult rats who

Cortical RF properties were recorded under uretnane anesthesia from adult rats who had a unilateral depletion of cortical NE with or without whisker-pairing. In normal adult rats, neurons in the D2 barrel column show the greatest response to stimulation of the D2 whisker, and a smaller, but equally smaller, response to stimulation of the D1 and D3 whiskers. Pairing of D2 and D1 whiskers for 7 days causes a significant increase in response to the intact D1 whisker by cells in the D2 barrel column and a decrease in response to the trimmed D3 whisker. This response bias is the most important indicator of plasticity. Following cortical NE depletion, there is a significant reduction in responses of D2 barrel column cells to stimulation of D2 and its neighboring whiskers but RFs can be mapped. Most importantly, the same whisker-pairing produces no shift toward greater responses to the intact D1 whisker. The results strongly support the idea that NE facilitates the synaptic modification necessary for whisker-pairing plasticity in adult rat cortex. (NIH grants NS-25907 and NS-09929)

EFFECTS OF CHOLINERGIC DEPLETION ON GAD IMMUNOREACTIVITY IN RAT PMBSF CORTEX P. Herron', L. Zhang', Z.C. Li', and J.B. Schweitzer'. Depts. of Anatomy and Neurobiology' and Pathology?, School of Medicine, University of Tennessee, Memphis, Memphis, Tennessee 38163. Immunocytochemical methods were used to examine the distribution of purpose and fiber impropriate for elements and distribution of purpose and fiber impropriate for elements and

Immunocytochemical methods were used to examine the distribution of puncta and fibers immunoreactive for glutamic acid decarboxylase (GAD) in the posteromedial barrel subfield (PMBSF) cortex after lesions of cholinergic neurons in nucleus basalis of Meynert (NBM). ACh neurons in NBM were selectively lesioned with intraventricular injections of an immunotoxin, 192 IgG-saporin. After seven to nine weeks postinjection survival times, animals were perfused with zinc aldehyde fixative, 30 µm tangential sections were processed for GAD immunoreactivity, and measurements were made using the NIH Image program.

Cholinergic depletion caused selective changes in the morphology of GAD+ barrels in the PMBSF cortex. The GAD immunoreactivity of puncta and fibers were significantly reduced in septa and the outer perimeter of barrel walls. The length, width, and area of barrels were reduced 10 to 20% in cholinergic depleted animals compared with controls. The optical density of GAD immunoreactivity in hollows was not affected by this treatment. These results suggest that long-term cholinergic depletion may lead to the loss of inhibitions in barrel walls and septa but not in hollows.

septa but not in hollows.

COMPARISON BETWEEN THALAMOCORTICAL AND INTRACORTICAL SYNAPTIC RESPONSES EVOKED IN VITRO. Y. Amitai and Z. Gil, Dept. of Physiology, Faculty of Health Sciences, Ben-Gurion University, Israel, 84105.

We explored differences in the properties of converging afferent inputs to a single cortical neurons in the barrel area. Thalamocortical slices were prepared from mature mice. Either thalamocortical (TC) or horizontal, layer 5 intracortical (IC) axons were stimulated, and responses in layer 5 neurons were recorded. Monosynaptic EPSPs had latencies less than 1.8 ms and low shape variance. Disynaptic thalamocortical IPSPs had latencies longer than 1.8 ms. All neuronal types, as defined by intrinsic firing patterns, received both TC and IC monosynaptic input. The shape parameters of monosynaptic EPSPs from the two inputs did not differ significantly. The rate-of-rise of EPSPs varied considerably across cells, but TC and IC-EPSP rate-of-rise onto single cells were correlated. The relative threshold for activation of excitation and inhibition were strikingly different between the two tracts: TC stimulation induced GABAA. dependent IPSPs at stimulus intensities equal to, or less than, those required for evoking excitation in 35% of the cells. In contrast, the threshold response to IC stimulation was always an EPSP, and only stronger stimuli could generate di- or polysynaptic IPSPs

We suggest that postsynaptic factors may tend to equalize the waveforms of TC- and IC-generated EPSPs in individual neurons. The TC pathway much more effectively activates feedforward inhibitory circuits than the horizontal IC pathway.

MODULATION OF TEMPORAL DYNAMICS OF SPONTANEOUS AND EVOKED UNIT ACTIVITY IN RAT SI BY PHARMACOLOGICAL ACTIVATION OF HOMOTOPIC SII. M. E. Jackson* and L. J. Cauller, GR41, Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688

Anatomical studies have demonstrated projections from supragranular neurons in rat SII to homotopic regions of SI. The purpose of this study was to determine the ability of the SII to SI projection to modulate the responses of SI neurons during peripheral somatic stimulation. Spontaneous and evoked extracellular multiunit and singleunit recordings were made with glass micropipettes in the supragranular layers of the forepaw representation in SI of urethane or Nembutal anesthetized rats. Extracellular activity was then recorded during slow infusion of the excitatory amino acid agonists L-glutamic acid and kainic acid through glass micropipettes inserted into homotopic areas ipsilateral SII. Pharmacological activation of supragranular neurons in SII altered both the frequency and temporal dynamics of spike trains recorded in SI. This effect was reversed by slow infusion of the excitatory amino acid antagonist kynurenic acid. Inactivation of SII by infusion of 2% lidocane had no effect in the anesthetized rat.

EFFECTS OF CHOLINERGIC DEPLETION ON THE CORTICAL FUNCTIONS IN FISHER HYBRID RATS Z.C. Li, J.B. Schweitzer, L. Zhang, P. Herron*, Dept of Anatomy and Neurobiology, School of Medicine, University of Tennessee, Memphis., Memphis, Tennessee 38163.

The effects of cholinergic depletion (CD) on evoked neuronal activities of posteromedial barrel subfield (PMBSF) in young and aged male Fisher hybrid rats were examined by extracellular recordings. We tested 110 cells for mean firing rate (MFR), receptive field (RF) size to standard vibrissal deflections of 3 degrees.

degrees.

We found: 1. CD did not affect the RF size in either young or aged animals compared to controls. 2. In aged rats, CD can significantly increase the MFR of PMBSF neurons to vibrissal deflections (P<.05). In young animals, CD treatment caused no difference in the MFR. 3. CD did not affect the MFRs of PMBSF neurons to deflections of the strongest surrounding whisker in either young or aged animals compared to controls.

The above results demonstrated that cholinergic depletion may

The above results demonstrated that cholinergic depletion may impair selected cortical processings in the aged animals and suggested that cholinergic innervation to the cortical neurons may play an important role in information processing in the somatic sensory cortex.

THE INFLUENCE OF INTRACORTICALLY EVOKED INHIBITION ON DIRECTIONAL SENSITIVITY OF NEURONS IN CAT S-1. A.A.Alexandrov* St.Petersburg State University, St.Petersburg, Russia.

Firing activity of the cortical neurons in vivo can be inhibited by glutamate, ejected microelectrophoretically 200-300 µm apart from a recording neuron. This inhibition was shown to be associated with glutamatergic excitation of the inhibitory GABA-ergic interneurons. In a single unit study of somatosensory cortex we investigated effects of this kind of inhibition on a properties of neuronal receptive fields such as directional sensitivity. Deflection of vibrissa coused spiking activity of S-1 neurons, which was often more intense in one direction of deflection than in the other directions. Distant application of glutamate during vibrissa testing usually suppressed responses in one direction of deflection more than in the other, e.g. there were cases when responses to some directions were completely blocked while responses to the other directions were not changed. Neurons without directional sensitivity might became directional-sensitive during glutamate application. Some directional-sensitive neurons become tuned to another directions of vibrissa deflection. Our data supports role for intacortical inhibition in formation of directional sensitivity of the S-1 neurons.

FUNCTIONAL CONNECTIONS BETWEEN BARREL-COLUMNS IN RAT CORTEX: RECORDINGS OF MULTIPLE SINGLE NEURONS. M. Lebedev*, G. Mirabella, and M.E. Diamond. Cognitive Neuroscience Sector, International School for Advanced Studies, Trieste, 34014 Italy.

This study addresses the relationships between barrel-columns in the vibrissal area of rat SI cortex. Normal rats were compared to rats receiving 3 days of whisker pairing (all whiskers on the right side of the snout were clipped except D2 and one neighbor, D1 or D3). The subjects were anesthetized and an array of up to 8 microelectrodes was inserted into the cortical region related to the caudal vibrissae of rows C-E. The array was advanced through cortex in steps of 100 µm. At each electrode tip, 3-6 individual neurons were isolated using spike waveform discrimination, yielding a sample of about 20-30 simultaneouslyrecorded single neurons. Spontaneous activity and activity evoked by controlled vibrissa deflection were recorded. Receptive field shifts previously described were confirmed -- column D2 neurons gave heightened responses to the paired neighboring whisker. correlation analysis indicated that potentiated connections between neurons in the two paired columns could offer an explanation for receptive field shifts. For example, the average value of crosscorrelation between neuron pairs in column D2 and D1 was more than twice as great after vibrissae D2/D1 were paired than in normal controls. The average time jitter between events in the two paired cortical columns decreased, suggesting more secure transmission of information between paired cortical columns. RECURRENT EXCITATION AND ITS CONTROL IN A MODEL OF RAT WHISKER BARREL CORTEX. J.A. Hartings, D.J Pinto, D.J. Simons*. Depts. of Mathematics, Neurobiology and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

We used a previously constructed model of a whisker barrel to examine how recurrent excitation, feedforward inhibition, and petwork-dependent inhibition, differentially modulate cortical

We used a previously constructed model of a whisker barrel to examine how recurrent excitation, feedforward inhibition, and network-dependent inhibition differentially modulate cortical responses to strong (temporally coherent) versus weak (temporally dispersed) afferent signals. The model consists of interconnected oppulations of excitatory and inhibitory units, which both receive direct inputs in the form of pre-recorded thalamic spike trains. By systematically varying connection strengths among populations we found that the positive feedback provided by recurrent excitation enhances inherent neuronal non-linearities, disproportionately amplifying cortical responses to strong inputs. Engagement of inhibitory units by this recurrent excitation confers a non-linear property to the network inhibition, and, with a brief temporal delay, this acts powerfully to counterbalance the explosive nature of the recurrent excitation. Feedforward inhibition (thalamus to inhibitory units) operates in a strict linear fashion, effectively reducing the amount of thalamic input and hence the engagement of recurrent excitation. The dynamics of synaptic integration creates a 'window of opportunity' for temporally coherent inputs to engage the positive feedback mechanisms of the network, producing a strong excitatory response. In this fashion, spatial contrast, e.g., principal vs adjacent whisker stimulation, is enhanced. Supported by NIH NS19950/NSF IBN9421380.

LAMINAR ANALYSIS OF MULTIPLE WHISKER INTERACTIONS IN RAT BARREL CORTEX. J.C. Brumberg*, D. J Pinto, H.T. Kyriazi, D.J. Simons. Depts. of Neurobiology and Mathematics/Statistics, University of Pittsburgh, Pittsburgh, PA 15261.

To assess the effects of multiple whisker interactions (up to 11), single unit recordings using glass micropipettes were obtained in fentanyl-sedated adult rats from neurons within different laminae of rat barrel cortex and from thalamic (barreloid) neurons. Using a condition-test paradigm, the columnar or principal whisker (PW) was deflected alone or in combination with adjacent and/or far whiskers (two arcs or rows from the PW). Consistent with previous intra- and extracellular data, layer IV barrel neurons displayed the earliest response onsets to PW deflections, and they had the smallest excitatory receptive fields. While the strength of inhibitory interactions among neighboring whiskers was roughly equivalent throughout the column, barrel neurons showed the greatest loss of surround inhibition during microinotophoresis of the GABA, antagonist bicuculline. In addition, barrel neurons showed the greatest receptive field expansion. Compared to barrel neurons, thalamic neurons displayed larger excitatory receptive fields and much less surround inhibition, even when up to 5 neighboring whiskers were stimulated along with the PW. Results suggest that: (1) inhibitory circuitry within the barrel strongly constrains receptive field size of layer IV neurons, (2) intercolumnar processing creates the larger receptive fields seen in the non-granular layers, and (3) intracolumnar connections originating in a barrel account for most of the between whisker-evoked inhibition observed throughout its column. Supported by NIH NS19950 and NSF IBN9421380.

THALAMOCORTICAL RESPONSE TRANSFORMATIONS OF VELOCITY AND AMPLITUDE IN THE RAT WHISKER BARREL SYSTEM. D.J. Pinto*, J.C. Brumberg, D.J. Simons. Depts. of Mathematics, Neurobiology, and the Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

Our previous modeling studies suggested that barrel neurons are more sensitive to the velocity of whisker deflection than to deflection amplitude. To examine this prediction, single unit recordings using glass micropipettes were obtained in fentanyl-sedated adult rats from thalamic (barreloid) neurons. The stimulation protocols entail moving the principal whisker in a randomly interleaved combination of five velocities and three amplitudes. Large and medium amplitude deflections produced barreloid responses of roughly the same magnitude, which decreased as deflection velocity diminished from very fast to very slow. Low amplitude deflections produced responses that were somewhat smaller and that showed a more pronounced decline as velocity was decreased. Regardless of deflection amplitude, responses were more temporally dispersed at slower velocities Population histograms were constructed from the thalamic unit responses and were used as input to our simulated barrel. Simulated responses depend more strongly on input dispersion than input magnitude. Moreover, the simulations lead to quantitative predictions about barrel neuron responses. These predictions are being tested directly by examining the responses of barrel neurons to whisker stimuli identical to those used to generate the thalamic input to the simulated barrel. Supported by NIH NS19950 and NSF IBN9421380.

DIFFERENTIAL MODULATION BY MOVEMENT OF SOMATOSENSORY CORTICAL RESPONSES ACROSS CUTANEOUS RECEPTIVE FIELDS. <u>Richard Courtemanchells</u>, <u>Gong-Duo Sun²</u>, <u>Marie-Thérèse Parentlege Vyes LamarrellDép. de Physiologie & CRSN, Univ. de Montréal, C.P. 6128, Succ. Centre-Ville, Montréal (Qc) Canada H3C 317; Épept of Physiology, Nanjing Univ., Nanjing, People's Republic of China.</u>

Recent studies have reported that rapid modifications of cutaneous receptive fields (RFs) can take place at multiple levels in the dorsal column-lemniscal pathway, following anesthesia or deafferentation. Complete gating during movement of the somatosensory response in areas 3b and 1 to an air-puff stimulus on the skin while preserving movement-induced activity has previously been observed. This could be explained by rapid movement-related modifications or displacement of cutaneous RFs explained by Lapin Invertine Treated moderations of displacement of educations at some level in the dorsal column-lemniscal pathway. This possibility was explored by recording the activity of 35 neurons in areas 3b and 1 of one female *Macaca* mulatta monkey during elbow flexions and at rest. Equal pressure air-puff stimuli were given at one (9/35 neurons) or multiple sites (26/35) within and on the edges of RFs located on the contralateral forearm. Response latencies for all cells ranged between 12-28 ms (mean:16 ms). Post-stimulus time histograms showed that 32/35 neurons had decreased responses to stimulus during movement compared with stimulus during rest. So far, air-puffs given at RF edges during movement have not produced response increases compared with air-puffs given at rest: RF shifts have not been found. However, while 9/26 neurons presented a uniform response decrease, 17/26 showed non-uniform decreases across multiple sites in the RF. This latter sample displayed proportions of decrease during movement compared to rest that varied across different regions of the RF. This argues against a simple suppression of information during movement, and offers evidence for more complex mechanisms of information processing in the somatosensory cortex and along the dorsal column lemniscal pathway during movement. Supported by various MRC and FCAR grants.

SPINAL MECHANISMS OF ANTI-ANALGESIA: LEARNED SAFETY SIGNALS BLOCK NON-OPIATE AS WELL AS OPIATE ANALGESIAS. M. McGorry*,B. Schwartz, D. Sisk, E.P. Wientelak¹, S.F. Maier,& L.R. Watkins, Dept. Psych., U. CO at Boulder, Boulder, CO 80309, & Macaleter, College, St. Paul, MN

WELL AS OPIATE ANALGESIAS. M. MCOOFTY-B. Schwaftz.

D. Sisk, E.P. Wiertelak ¹, S.F. Maier, & L.R. Watkins, Dept. Psych., U

CO at Boulder, Boulder, CO 80309 & ¹Macalster College, St. Paul, MN. We have previously shown that learned safety signals (light cues) can abolish analgesia produced by systemic morphine as well as by intrathecal (IT) μ & δ opiate agonists [Sci., 256 (1992) 830; Brain Res. 634 (1993) 214]. This raises the question of whether safety signals modulate only opiate analgesias, or whether non-opiate analgesias can be affected as well. Thus we tested the ability of learned safety signals to modulate non-opiate analgesias produced by IT serotonin (5HT) & GABA agonists.

Detailed methods of establishing & testing safety signals are described in the articles cited above. After extinguishing the danger signals associated with the context, baclofen (GABA-B agonist), & methyltryptamine (5HT-2 agonist), or phenylbiguanide (5HT-3 agonist) was injected epidurally under brief halothane anesthesia. Drugs found to be partial opiate analgesics were preceded by 15 mg/kg naltrexone s.c. to allow testing only of the non-opiate component of the analgesias. Safety signals abolished non-opiate analgesias mediated by GABA-B & by 5HT-3 receptors. No reversal of 5HT-2 analgesia was observed. Testing is continuing with 5HT-1 & GABA-A agonists.

Thus, anti-analgesia can profoundly modulate opiate, GABA, & 5HT mediated analgesias. These data extend the concept of anti-analgesia from meaning merely anti-opiate effects to the recognition that multiple analgesia systems can be profoundly modulated in this fashion. Supported by NIH NS31569 & Undergrad. Research Opport. Prog.

INTERACTION BETWEEN GABAB RECEPTOR ACTIVATION AND NEUROKININ-1 RECEPTOR GENE EXPRESSION IN RAT SPINAL CORD DURING NOCICEPTION. Kenneth E. McCarson* and S. J. Enna Dept. of Pharm/Tox/Therap., Univ. of Kansas Med. Ctr., Kansas City, KS 66160-7417 USA.

Gamma-aminobutyric acid (GABA) agonists for both GABÂA, and GABAB receptors induce analgesia in animal models of acute and chronic nociception, including the formalin test. It has been reported that substance P (SP) and the neurokinin-1 receptor (NK-1R) are involved in mediating the nociceptive responses to formalin; NK-1R antagonists inhibit various aspects of formalin-induced nociception and NK-1R gene expression is increased during formalin-induced nociception. Since the antinociceptive properties of GABAB receptor agonists may be due to their ability to reduce SP release evoked from spinal cord tissue, the present study was undertaken to examine the regulation of NK-1R gene expression by baclofen during neuronal activation of the spinal cord dorsal horn by formalin-induced nociception. Total RNA samples prepared from the lumbar spinal cords of rats receiving a drug pretreatment of baclofen (4mg/kg, s.c.) or saline followed by injection of formalin (5%, 100µ1) into the right hindpaw were assayed for NK-1R mRNA using solution hybridization - nuclease protection assays 6 hours after hindpaw treatment. Baclofen pretreatment completely abolished the flinching response to formalin during ten minutes of the late phase of the formalin test, but did not induce significant muscle weakness as measured in the inclined screen test. Preliminary results indicate the expression of NK-1 mRNA in the ipsilateral lumbar dorsal horn of the spinal cord is increased 6 hours following formalin treatment as compared to tissue obtained from sham treated rats. Pretereatment of animals with baclofen substantially reduced the formalin-induced increase in NK-1 mRNA levels in the ipsilateral spinal cord dorsal horn but had no significant effect on NK-1 mRNA levels in the ipsilateral spinal cord dorsal horn but had no significant effect on NK-1 mRNA levels in the ipsilateral spinal cord dorsal horn but had no significant effect on be such stantially reduced the formalin-induced increase in NK-1 mRNA levels in the ipsilateral spinal cord d

EFFECTS OF GABA, RECEPTOR ANTAGONIST ON TRIGEMINAL (V) SUBNUCLEUS CAUDALIS NOCICEPTIVE NEURONES IN NORMAL AND NEONATALLY CAPSAICIN (CAP)-TREATED ADULT RATS. C.Y. Chiang.* (C.L. Kwan, J.W. Hu and B.J. Sessle. Faculty of Dentistry, University of Toronto, Toronto, Ont. M5G 1G6, Canada.

Our previous studies have demonstrated that NMDA and segmental modulatory mechanisms may be involved in the CAP-induced neuroplastic changes in the receptive field (RF) properties of V caudalis nociceptive neurones in adult rats. Since GABA is involved as an inhibitory neurotransmitter in segmental modulation, the aim of this study was to test whether the GABA, receptor antagonist bicuculline (BIC) can influence the properties of caudalis nociceptive neurones in normal (n=5) and CAP (n=7) rats. Single neurone activity was recorded extracellularly in urethane/α-chloralose anesthetized and paralysed adult rats, and neurones were classified as wide dynamic range (WDR) or nociceptive specific (NS). RF properties were tested in each neurone before and for 60 min after BIC (3-5 μg/10 μl, i.t.) application, and any BIC-induced changes were expressed as a percentage (mean±S.E.M.) of control (i.e., pre-application) values. A total of 17 nociceptive neurones were studied (3 WDR, 3 NS in normal rats; 5 WDR, 6 NS in CAP rats). Consistent with our earlier findings, tactile and pinch RFs were expanded in CAP rats compared to normal rats. BIC application generally produced in both groups of rats seizure-like neuronal discharges with a 18-30 s latency and 3-10 min duration. BIC was also found to induce changes in RF properties that peaked at 5 min and lasted for 30 min. Compared to control values (100%), the peak changes in normal and CAP rats included, respectively, decreases in response threshold (3.5±1.4%; 14±8.3%), and increases in responses to pinch (656±523%; 231±34%). Another noteworthy change was the appearance of a tactile RF in the NS neurones of both normal and CAP rats. Furthermore, the tactile RF in the NS neurones in normal and CAP

MICROINIECTION OF SUBSTANCE PINTO THE KÖLLIKER FUSE (KF) NUCLEUS INHIBITS OR FACILITATES NMDA-EVOKED RESPONSES OF NEURONS IN THE SUPERFICIAL AND DEEPER DORSAL HORN OF THE MEDULLA. X-M. Wang*. K.M. Zhang and S.S. Mokha. Dept. of Physiology, Meharry Medical College, Nashville,

We have been investigating the modulation of excitatory amino acid evoked responses by activation of α_1 -adrenoceptors. Kölliker Fuse nucleus (KF) is one of the regions which may contribute to the noradrenergic modulation of somatosensory information in the dorsal horn of the medulla (trigeminal nucleus caudalis). No previous study has investigated the descending modulation of NMDA-evoked responses by stimulation in KF. The present study, therefore, investigated the effects of microinjection of substance P into KF on the NMDA-evoked responses of neurons in the superficial and deeper dorsal horn of the medulla. Extracellular single unit recordings were made from 23 neurons with the central barrel of a seven barreled microelectrode in rats anesthetized with urethane (1.5 g/kg, i.p.). The other barrels contained freshly made solutions of NMDA (50 mM, pH 8.0), AMPA (5mM, pH 8.0), clonidine (100 mM, pH 4.5), idazoxan (100 mM, pH 4.5) and CNQX (5 mM, pH 8.0). NMDA, AMPA, and CNQX were ejected with negative current whereas clonidine and idazoxan were ejected with positive currents. Neurons were characterized nociceptive specific (NS), wide dynamic range (WDR), low threshold (LTH) using natural stimuli (brush, pinch, squeeze, heat). Substance P (3.7 or 37 pmol) was microinjected through a guide cannula placed stereotaxically 1 mm dorsal to KF. Microinjection of substance P into KF produced inhibition of NMDA-evoked responses of neurons in the deeper dorsal horn whereas it produced inhibition or facilitation in the superficial dorsal horn. The inhibitory effect was antagonized by microiontophoretically applied idazoxan on 7/8 neurons. Clonidine produced an inhibitory effect on some (6/7) of these neurons. All neurons (6) facilitated by stimulation in KF were located superficially, and facilitation was blocked by CNQX in 2/2 neurons. We conclude that α2-adrenoceptors and AMPA receptors mediate the descending modulation from KF.

REDOX MANIPULATION OF NMDA RECEPTORS IN VIVO: ENHANCEMENT OF NMDA-ELICITED BEHAVIORS AND EFFECT ON DYNORPHIN-INDUCED ALLODYNIA. T.M. Laughlin* 1 , and G.L. Wilcox 1,2 . 1 Dept. of Pharmacology and 2 Program in Neuroscience, University of Minnesota, Minneapolis, Minnesota 55455.

Sulfhydryl reducing agents, such as dithiothreitol (DTT), potentiate NMDA receptor-evoked currents in vitro whereas oxidizing agents, such as 5,5'-dithio-bis-(2-nitrobenzoic acid) (DNTB), attenuate these currents. Reducing agents modulate current by reducing disulfhydrly bridges at the redox modulatory site located in the extracellular domain of the NMDA receptor. This involvement of the redox modulatory site involvement in neurotoxicity has been previously studied; here we examined the effect of this redox modulatory site on nociceptive spinal cord signaling in mice.

Drugs were diluted in 0.9% saline and administered intrathecally (i.t.) to male ICR mice. NMDA i.t. to mice induces caudally directed biting and scratching behaviors, which are counted during the first minute after injection. A five minute pretreatment with DTT (10, 30 nmol, i.t.) shifted the NMDA dose-response curve to the left, suggesting enhancement of receptor function through reduction of the redox modulatory site. Five minute pretreatment with 10, 30, and 50 nmol DTT potentiated the response to 0.3 nmol NMDA by 140, 160, and 230 percent, respectively. Increasing the 30 nmol DTT pretreatment time to 30 minutes produced additional enhancement of NMDA response. In addition to NMDA-induced behavior, we also tested the effect of DTT on tactile and cold allodynia induced by dynorphin A (1-17) (3 nmol, i.t.).

NMDA-induced behavior is a model used to study acute nociception. Potentiation of this behavior by DTT suggests that endogenous reducing agents may up-regulate NMDA receptor function, increasing responses to endogenous glutamate. Furthermore, enhancement of NMDA receptor function by endogenous reducing agents may enable spinal cord neurons to modulate receptor function in chronic neuropathic pain states. ADRENOCEPTORS (a,) MODULATE NMDA-EVOKED RESPONSES OF NEURONS IN THE MEDULLARY DORSAL HORN. K.-M. Zhang*, X.-M. Wang, A.M. Peterson, D.E. Brown, W.Y. Chen and S.S. Mokha Department of Physiology, Meharry Medical College, Nashville, Tennessee 37208.

Activation of a2-adrenoceptors has been reported to be involved in antinociception in animal and human studies. Microiontophoretically applied norepinephrine has been reported to produce reduction in the noxious stimuli evoked responses of neurons in the spinal dorsal hom. No comparable studies have been performed in the medullary dorsal horn, and the modulation of NMDA-evoked responses by activation of α_2 -adrenoceptors remains unknown. The present study, therefore, investigated the modulation of NMDA-evoked responses of neurons in the medullary dorsal horn by activation of α_2 -adrenoceptors. Extracellular single-unit recordings were made in the superficial and deeper dorsal horn of the medulla (trigeminal nucleus caudalis) in anesthetized rats (urethane, 1.5 g/kg, i.p.) using the central barrel of a seven barrel microelectrode. The drug barrels contained solutions of the following drugs: NMDA (50 mM, pH 8.2); DL-2-Amino-5-Phosphonovaleric acid (AP-5, 50 mM, pH 8.0); Clonidine (100 mM, pH 4.5) and Idazoxan (100 mM, pH 4.5). All drugs were ejected with positive current except NMDA and AP-5 which were ejected with negative current. Clonidine reduced the NMDA-evoked responses of 86% of nociceptive-specific (NS) neurons, 75% of wide dynamic range (WDR) neurons and 40% of low threshold (LT) neurons in the superficial dorsal horn. In the deeper dorsal horn, clonidine inhibited NMDA-evoked responses of 100% of NS neurons, 86% of WDR neurons and 20% of LT neurons. The facilitatory effect of clonidine were observed in 14% of NS, 25% of WDR, 60% of LT neurons in the superficial dorsal horn and 40% of LT neurons in the deeper dorsal horn. Idazoxan, α₁-adrenoceptor antagonist, reversed the inhibitory effect of clonidine in 12/16 neurons. It is suggested that a,-adrenoceptor activation produces a predominantly inhibitory modulation of the NMDAevoked responses of nociceptive neurons, and facilitation of low threshold neurons in the medullary dorsal horn.

OPIOID RECEPTORS (μ, δ) MODULATE THE NMDA-EVOKED RESPONSES OF TRIGEMINOTHALAMIC NEURONS IN THE RAT. S.S. Mokha* and X-M. Wang, Department of Physiology, Meharry Medical College, Nashville, Tennessee 37208.

We reported recently that activation of μ and δ opioid receptors produces a predominantly inhibitory modulation of the NMDA-evoked responses of nociceptive neurons (unidentified as to their projections) in the superficial and deeper dorsal horn of the medulla (Zhang et al. 1996, Brain Res.). However, the functional significance of EAA receptors in mediating the responses of physiologically characterized trigeminothalamic neurons and the opioidreceptor mediated modulation of EAA receptor-evoked responses of these neurons remains unknown. The present study was , therefore, designed to investigate the modulation of NMDA-evoked responses of trigeminothalamic neurons by activation of μ - and δ -opioid receptors. Extracellular single-unit recordings were made in the superficial and deeper dorsal horn of the medulla (trigeminal nucleus caudalis) in anesthetized rats (urethane, 1.5 g/kg, i.p.), using glass-coated platinum-plated tungsten microelectrode glued to a seen-barrel micropipette at an angle of about 20° . One barrel of the seven-barrel microelectrode contained 2 M NaCl for automatic current balancing. The remaining barrels were filled with freshly made solutions of the following drugs: NMDA (50 mM, pH 8.2); D,L-2-amino-5-phosphonovaleric acid (AP-5, 50 mM, pH 8.0); [D-Pen²⁻³]-Enkephalin (DPDPE, 20 mM, pH 4.0); DAMGO (20 mM, pH 4.0) and naloxone hydrochloride (10 mM, pH 4.5). NMDA and AP-5 were ejected with negative current while DPDPE, DAMGO and naloxone were ejected with positive current. Microiontophoretic application of NMDA activated 18/19 trigeminothalamic neurons. Administration of DAMGO, a selective μ opioid receptor agonist, reduced the NMDA-evoked responses in 77% of trigeminothalamic neurons. DPDPE, a selective δ opioid receptor agonist, produced inhibition of NMDA-evoked responses in 36% of neurons. The predominantly inhibitory modulation of NMDA receptor mediated responses of nociceptive trigeminothalamic neurons by activation of μ and δ opioid receptors may provide a neural mechanism for the antinociceptive actions of opioids

Antisense Mediated Downregulation of Spinal NMDA Receptors: Behavioral Consequences. Mary G. Garry, Ph.D.* Lloyd P. Walton, B.S., Harbhej Singh, M.D., and Jay Yang, M.D., Ph.D. Department of Anesthesiology, University of Texas Southwestern Medical Center, Dallas, TX 75235

N-Methyl-D-Aspartate (NMDA) receptors at the level of the spinal cord are known to have a role in pain processing and are believed to be involved in the development of morphine tolerance. Due to the toxicity of NMDA antagonists and the need for long-lasting therapies for chronic pain, we have used an antisense approach in an attempt to downregulate spinal NMDA-R1 receptors in the rat. In in vitro studies, we determined that PC-12 cells (which express functional NMDA receptors) incubated for 3 days in 100 µg of an 18-Mer ofigodeoxynaclotide (CAC/AGGTCCATGCTCCT) showed a decrease in NMDA receptor immunoreactivity when compared to normal cells. We then applied the antisense probe spinally in rats to determine whether this tool would be effective in reducing the pain behavior typically observed following intrathecal (i.t.) administration of NMDA. Briefly, male rats were implanted with i.t. cannulas to the lumbar level. Two days following recovery from implantation, baseline behavioral data was collected (# of caudally directed bites, scratches, and licks/min [BSL]). Next, an concete two or actually officered orders. Stratches, and intexturin [15:1], Next, antisense probe (100µg/10µI/day) or vehicle was administered i.t. for 3 days. To determine the downregulation of spinal NMDA receptors *in vivo*, i.t. NMDA (3mmol/10µI) was administered. Mean baseline BSL's were 3.57±0.99/min (n=14). In control animals, the # of BSL behaviors increased to 24±4.7/min (n=3) in response to NMDA. In the antisense treated animals, the NMDA response was reduced to 8.6±2.46 BSL's/min (n=3). In addition, this response was observed to be dose-related (20-100µg/day for 3 days). In summary, these data indicate that an antisense approach is a useful tool in the downregulation of NMDA receptors in the spinal cord; resulting in altered behavioral responses to NMDA. Studies are currently underway to determine the usefulness of this approach in the reduction of chronic pain and in the development of morphine tolerance. This work was supported by the Sid W. Richardson Foundation.

EFFECTS OF D-CYCLOSERINE PRETREATMENT ON THE INDUCTION OF PERSISTENT HINDLIMB FLEXION IN SPINALIZED RATS. M.F. Anderson* Department of Psychiatry, St. Elizabeth's Medical Center of Boston, Boston, MA 02135.

Unilateral stimulation (2mA, 7ms, 100Hz, 60min) across the upper hindlimb in the spinalized rat produces persistent hindlimb flexion. In this model, the N-methyl-D-aspartate (NMDA) antagonist, MK-801, effects a dose dependent reduction in flexion. After spinalization at T-7 of urethane anesthetized Long Evans rats, wound clips were applied bilaterally to the musculature of the right upper hindlimb and animals were pretreated with one dose of either sterile water (vehicle control) or D-cycloserine (0.1, 1.0, and 10.0 mg/kg, i.p.). After a 30min waiting period, current (2mA, 7ms, 100 Hz, 1 hr) was delivered across the clips. Following stimulation, flexion was not significantly different between the experimental and control groups; except, in the 10.0 mg/kg D-cycloserine group where flexion was significantly increased. These data suggest that induction of persistent hindlimb flexion in spinalized rats may be enhanced by agonists to the strychnine-insensitive glycine binding-site associated with the NMDA receptor. (Support: St. Elizabeth's Medical Center of Boston)

INHIBITION OF ACUTE THERMAL HYPERALGESIA BY DNQX IS SYNERGISTIC WITH THE ANTINOCICEPTIVE EFFECT OF MK-801 BUT NOT WITH THAT OF THE NONCOMPETITIVE NMDA ANTAGONIST CPP, C.S. Hornfeldt* and A.A. Larson. Department of Veterinary PathoBiology, University of Minnesota, St. Paul, MN 55108.

N-methyl-D-aspartate (NMDA) and non-NMDA excitatory amino acid (EAA)

receptors are thought to play a role in nociceptive transmission. We tested the hypothesis that both types of receptors are involved in acute thermal hyperalgesia. Hyperalgesia was induced by exposure of the tail of ether-anesthetized mice to a radiant heat source for 50 sec, a time sufficient to induce redness, but no blister. Twenty-five min later, 1 mg/kg of naloxone was administered i.p., unmasking a significant decrease in the tail-flick latency 5 min later when the tail was immersed in a water bath maintained at 46°C. Activity at NMDA and non-NMDA receptors was found to be necessary for thermal hyperalgesia as intrathecal injections of either MK-801 (dizolcipine), 6,7-dinitroquinoxalinedione (DNQX) or the competitive antagonist (\pm) -3-(carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP), injected 5 min prior to testing, each reduced the degree of hyperalgesia in a dose-dependent fashion. The effects of MK-801 plus DNQX and of CPP plus DNQX were determined using isobolographic analysis. Antinociception produced by DNQX plus MK-801 was synergistic whereas the effect of DNQX plus CPP was merely additive. These data indicate that the mechanism of action of MK-801 differs from that of CPP in this model of hyperalgesia in spite of their common ability to inhibit NMDA-induced activity. We postulate that MK-801 induces its anti-hyperalgesic effect by a mechanism that does not involve a simple inhibition of the NMDA receptor complex. The effect of MK-801 that is not due to antagonism of NMDA activity appears to be important for its ability to induce antinociception (Supported by NIDA 04090 to A.A.L.)

SPINAL GABA AGONISTS DIMINISH ALLODYNIA CAUSED BY NEUROPATHIC INJURY. <u>TP Malan, Jr., HP Mata, J Lai*, F Porreca</u>. The University of Arizona Pain Institute, Tucson, AZ 85724

GABA agonists diminish thermal hyperalgesia caused by nerve injury. However, sensitivity of nociceptive responses to antinociceptive drugs may depend on the specific sensory modality tested. For example, after spinal nerve root ligation thermal hyperalgesia is diminished by intrathecal (i.th.) morphine, while allodynia is insensitive to supramaximal i.th. doses of this opioid. This may be because thermal stimuli are carried by C-fibers, which contain presynaptic opioid receptors, while allodynia may be carried by \mathbf{A}_b fibers, which do not express opioid receptors. We hypothesized that because GABA receptors are found presynaptically on small unmyelinated fibers and large myelinated fibers (as well as postsynaptically), allodynia would be sensitive to intrathecal GABA agonists.

After approval by the Animal Care and Use Committee, male Sprague- Dawley rats (250-350g) were implanted with an i.th. catheter. After full recovery they underwent spinal nerve root ligation surgery. After 7 days they received isoguvacine (7.5 μ g, i.th.) baclofen (0.5 μ g, i.th.) or vehicle. Allodynia was assessed every 5 min by measuring withdrawal threshold to tactile stimulation using von Frey filaments.

Neuropathic injury decreased withdrawal threshold to tactile stimuli by 80%. After neuropathic injury, isoguvacine (GABA $_{\rm A}$ agonist) reduced allodynia (increased withdrawal threshold) by 50% of the maximum possible effect (MPE). Baclofen (GABA $_{\rm B}$ agonist) decreased allodynia by 100% of MPE.

Allodynia caused by neuropathic injury is sensitive to GABA agonists, supporting the hypothesis that sensitivity of different sensory modalities to pharmacologic agents may depend on the fiber types encoding the afferent input and the distribution of drug receptors. Strategies directed at increasing inhibitory control systems may prove useful in modulating neuropathic pain.

EFFECT OF INTRATHECAL (IT) MK801 IN A RAT MODEL OF POSTOPERATIVE PAIN. P.K. Zahn, T.J. Brennan*, G.F. Gebhart, Departments of Anesthesia and Pharmacology, University of Iowa, Iowa City, IA 52242 We have developed and characterized a rat model for postoperative pain. An incision causes reliable, quantifiable mechanical hyperalgesia that is inhibited by

We have developed and characterized a rat model for postoperative pain. An incision causes reliable, quantifiable mechanical hyperalgesia that is inhibited by systemic and IT morphine. The purpose of this study is to examine the effect of MK801, a noncompetitive N-Methyl-D-Aspartate (NMDA) receptor antagonist, on mechanical hyperalgesia in this model.

Rats with TT catheters were anesthetized with 2% halothane and underwent an incision as described (Brennan et al., Pain 64: 493). Two hours later, withdrawal threshold to punctate stimulation was determined by applying calibrated von Frey filaments adjacent to the wound. Each filament was tested once starting with 15 mN and continuing to 522 mN until a withdrawal response occurred. Response frequency to application of a 5 mm diameter plexiflas disk (attached to a 400 mN von Frey filament) directly to the wound was measured to assess a nonpunctate stimulus. Rats were tested at 10 min, 30 min, and 1 and 2 hrs after surgery and on postoperative day

In the saline treated group (n=5), the median withdrawal threshold decreased from 522 mN before surgery to 24 mN 2 hrs later. Hyperalgesia was persistent; the median withdrawal threshold remained less than 95 mN for 2 hrs. After administration of 4, 14, or 40 mnol MK801 TT, the median withdrawal thresholds remained less than 80 mN for the next 2 hrs. The mean response frequency for nonpunctate hyperalgesia in the saline treated group (n=5) increased from 0±0% before surgery to 100±0% 2 hrs later and was maintained for the next 2 hrs. In separate groups of animals (n=5 per group), after IT administration of 20 and 40 nmol MK801, the mean response frequencies were 80±13% or greater for 2 hrs. Similar results were observed on postoperative day 1 using these same doses of MK801. Unlike IT and systemic morphine, IT MK801 did not modify mechanical

Unlike IT and systemic morphine, IT MK801 did not modify mechanical hyperalgesia to punctate or nonpunctate stimuli in this rat model of postoperative pain.

ACTIVATION OF NMDA RECEPTORS MEDIATES THE ENHANCEMENT OF FORMALIN-INDUCED PAIN BY INTRATHECAL BICUCULLINE M. Kaneko* and D.L. Hammond, Dept. of Anesthesia & Critical Care, Univ. of Chicago, Chicago, IL 60637

Intrathecal (i.t.) pretreatment with bicuculline (BIC), a GABA_A receptor antagonist, enhances the second phase pain behaviors produced by injection of formalin in the hind paw of the rat (Kaneko and Hammond, World Congress on Pain, 1996). This study investigated the role of N-methyl-Daspartate (NMDA) receptor activation in the enhancement of formalininduced pain behaviors by BIC. Sprague-Dawley rats were prepared with an i.t. catheter. One week later, rats were pretreated with either saline, 0.3 µg BIC, or 0.3 μg BIC and 0.3 μg of D-(-)-2-amino-5-phosphonovalerate (APV), followed 10 min later by a s.c. injection of formalin (0.25 - 2.5 %) The number of flinches and weighted pain scores were recorded for 60 min. In saline-treated rats, the concentration of formalin that produced the halfmaximal number of flinches in the second phase (FED₅₀) was 0.93 (95%CL: 0.84-1.03) %. BIC reduced the FED₅₀ to 0.44 (0.37-0.52) %. In rats in which APV was coadministered with BIC, the FED₅₀ was increased to 0.76 (0.67-0.86) %. APV similarly attenuated the enhancement of weighted pain scores induced by i.t. administration of BIC. This dose of APV by itself had no effect on formalin-evoked pain behaviors. These findings suggest that the enhanced responses to formalin in the late phase are mediated, in part, by an activation or "unmasking" of NMDA receptors in the spinal cord. (Supported by USPHS grant DE11423).

HISTOGRANIN ATTENUATES CHRONIC PAIN INDUCED BY PERIPHERAL NEUROPATHY, FORMALIN-INDUCED NOCICEPTION, AND DIRECT APPLICATION OF NMDA. J.B. Siegan*, A.T. Hama, and J. Sagen. Dept. Anatomy and Cell Biology. University of Illinois at Chicago, Chicago, IL 60612.

Work in our laboratory has demonstrated that transplantation of adrenal medullary tissue into the spinal subarachnoid space reduces pain sensitivity. The mechanism for the beneficial effects of the transplants in alleviation of persistent pain is unknown. A 15 amino acid peptide, histogranin, that was isolated from adrenal medullary tissue has been shown to antagonize NMDA receptor activation both in vitro and in vivo The goal of the following studies was to determine whether direct intrathecal application of the stable histogranin analog [Ser¹] HN (SHG) may account for the effects of adrenal medullary transplants and mimic these transplants in alleviating hypersensitivity in three models. All rats were implanted with intrathecal catheters for SHG application. Group 1: rats were pretreated with SHG (1.0µg or 4.0µg) prior to i.t. injection of NMDA (20, 10, 5 nmol); behavioral tests were performed to measure hypersensitivity. Group 2: Chronic constriction injury was induced by unilateral loose ligation of the sciatic nerve. Two weeks following ligation animals were treated with SHG (1.0μg, 2.0μg, or 4.0μg) and behavioral tests were performed to determine abnormal pain sensations. Group 3: 5% formalin was injected s.c. in animals either pretreated with SHG or saline, and flinches were counted every 5 minutes following injection. Results demonstrated that SHG attenuates NMDA hypersensitivity at higher doses, and abolishes this hypersensitivity at lower doses. SHG attenuated the tonic phase of formalin induced nociception, compared to saline pretreated animals. Neuropathic pain symptoms were also significantly alleviated by SHG in sciatic nerve ligated animals. These results parallel findings with adrenal medullary transplanted animals, and support the hypothesis that adrenal medullary transplants can produce agents which directly inhibit NMDA-mediated events in the spinal cord. ADL 2-1294, A PERIPHERALLY SELECTIVE OPIATE ANALGESIC D.L. DeHaven-Hudkins*, L. Cortes Burgos, H. Nagasaka and T.L. Yaksh Adolor Corporation, Malvern, PA 19355 and Dept. Anesthesiology, Univ. Calif. San Diego, La Jolla, CA 92093.

ADL 2-1294 is an opiate agonist with affinity for the μ (K_i = 3 nM), δ (K_i = 48 nM) and κ (K_i = 1156 nM) subtypes of the cloned human opiate receptor, and poor central bioavailability. The efficacy of ADL 2-1294 was established in a rat model of inflammatory pain which measures blood pressure changes in response to knee compression following injection of a 4% kaolin/4% carrageenan mixture into the knee joint cavity. Injection of 0.3 mg ADL 2-1294 into the intraarticular space of the knee results in potent antinociception that is antagonized by naloxone, whereas injection into the contralateral knee joint or via the i.m. route fails to inhibit compression-induced changes in blood pressure. ADL 2-1294 potently inhibits formalin-induced flinching during the late phase following i.paw injection (A₅₀ = 6 µg). The lack of effect of ADL 2-1294 on early phase flinching or following injection into the contralateral paw confirms the peripheral nature of the analgesia observed. Local injection of ADL 2-1294 also produces antinociception against Freund's adjuvant- (ED₅₀ = 20 μg) or tape stripping-induced hyperalgesia (ED₅₀ = 71 μg), as evidenced by decreased naw pressure thresholds. In all animal models examined, the analgesic potency of ADL 2-1294 was comparable to or better than that of ADL 2-1294 has potential therapeutic utility as a peripherally selective opiate analgesic which lacks many of the side effects generally associated with such opiates

DELIVERY OF ENKEPHALINS TO MOUSE SENSORY NEURONS BY A HERPES VIRUS ENCODING PROENKEPHALIN. S.P. Wilson*, D.C. Yeomans[†], M.A. Bender[§] and J. Glorioso[§]. Dept. of Pharmacology, Univ. of South Carolina Sch. of Med., Columbia, SC 29208; †Dept. of Anatomy and Cell Biology, Univ. Illinois, Chicago, IL 60612; [§]Dept. of Molecular Genetics and Biochemistry, Univ. of Pittsburgh, Pittsburgh, PA 15261.

A recombinant herpes simplex type 1 virus (KPE) containing a CMV immediate-early promoter-human proenkephalin cassette in the thymidine kinase locus was constructed and purified. Tissue culture cells infected with KPE synthesized proenkephalin by Western blot analysis. This virus and a similar virus containing the lac Z reporter gene (KZ) were then used to infect female Swiss-Webster mice (6 wks) to test functional expression in vivo. Application of viral suspensions to the abraded hairy or glabrous surface of the hindpaw resulted in numerous neurons expressing the transgene in ipsilateral dorsal root ganglia L3-L5 at 4-35 days postinfection. Mice infected with KZ or KPE were then tested for foot withdrawal responses to noxious radiant heat. In both normal mice and capsaicin-sensitized mice, systemic naloxone decreased foot withdrawal latencies at 3-5 days following infection with KPE but not with KZ. These effects were observed at low heating rates, mediated by C fibers, but not at high rates of heating, mediated by Aδ fibers. These results indicate that infection of small-diameter cutaneous afferents with a proenkephalin-encoding herpes virus results in opioidmediated, C fiber-specific antinociception. (Supported by NSF Grant IBN 94-09201)

SPINAL μ -, δ - and κ -opiate receptors mediate inhibition of the nociceptive tail withdrawal reflex evoked by intense peripheral electrical stimulation in the rat. V.V. Romita* and J.L. Henry, Depts. of Physiology & Psychiatry, McGill University, McGill University, McGill University, McGill University in the antinociception evoked by activation of high threshold primary afferents. This study determined whether spinal

opiate receptors mediate antinociception provoked by intense peripheral electrical stimulation in the tail-flick test. Conditioning electrical stimulation with 2 ms square pulses, at 4 Hz for 20 min at 20 times threshold (to elicit muscle twitch) to previously defined meridian points in the hindlimb inhibited the withdrawal reflex during the stimulation and the inhibition persisted for greater than one hour after the end of the stimulation in anaesthetized intact rats (n=8) and for up to 15 min in unanaesthetized spinal rats (n=12). In control anaesthetized intact (n=12) and unanaesthetized spinal rats (n=14) placement of electrodes with no stimulation produced no effect. In spinal rats, preadministration of naloxone (25 mg/kg; i.p.) completely blocked the evoked inhibition (n=10). In intact animals both naloxone (n=8) and β -FNA (10 nmols, i.th.; n=9) antagonized the inhibition during the stimulation and the persistent inhibition by 50-60 %. Tipp[ψ] (10 nmols, i.th.; n=7) and nor-BNI (10 nmols, i.th.; n=13) decreased the inhibition during the nor-BNI (10 mmols, 1.th.; n=13) decreased the inhibition during the stimulation by 30 % and 56%, respectively. Both antagonists completely blocked the persistent effect and even facilitated the withdrawal. The data suggest that the three types of opiate receptor differentially mediate the evoked antinociception. Spinal activation of μ -, κ - and, to a lesser extent, δ - opiate receptors partly mediate the evoked inhibition during the stimulation, while the persistent inhibition is dependent on activation of δ - and κ - and to a lesser extent μ-receptors. Supported by Canadian MRC

PRESYNAPTIC MODULATION BY A $\mu\text{-OPIOID}$ RECEPTOR AGONIST AT PRIMARY AFFERENT TERMINALS IN THE RAT SPINAL DORSAL HORN REVSALED BY OPTICAL IMAGING WITH A VOLTAGR-SENSITIVE DYE K. Murase*, K. Oda, M. Tanifuji, J. B. Park*, and P. D. Ryu*. Dept. Info. Sci., Fukui Univ., 3-9-1 Bunkyo, Fukui 910, Japan, and *Dept. Vet.Pharm.Toxicol, Seoul Nat'l Univ., Suwon, Korea. $\mu\text{-Opioid}$ receptors (MOR) exist at primary afferent C-fiber terminals. Evidence suggests that the MOR activation may lead to a reduction in Ca** influx into the terminals, and thus, diminishing transmitter release. We here report that, by a direct recording at the terminal s are reduced by a selective MOR agonist Tyr-o-Ala-Gly-N-Methyl-Phe-Gly-Ol(DAMGO), and that this effect of DAMGO is abolished by Ca** channel antagonists. Transverse slices of the rat spinal cord were stained with a voltage-sensitive dye RH-482. The light absorption change at the dorsal horn evoked by dorsal root stimulation was recorded

a voltage-sensitive dye RH-48Z. The light absorption change at the dorsal horn evoked by dorsal root stimulation was recorded by a high-resolution imaging system (SD1001, Fuji Micro.Dev.). Postsynaptic components of the optical response could be eliminated by adding excitatory amino acid receptor antagonists APV (30 μ M)+CNQX (5 μ M) in the perfusate. Because, the optical response in APV + CNQX was not modified by a further addition of ω -conotoxin GVIA (ω -CgTx, 1 μ M) and ω -agatoxin IVA (ω -Aga, .2 μ M), that are known to block synaptic transmissions by inactivating presynatic P and N-type calcium channels

Aga. . 2μM, that are known to block synaptic transmissions by inactivating presynaptic P and N-type calcium channels.

DAMGO suppressed the optically-recorded presynaptic activities in APV + CNQX at the superficial laminae dose-dependently (29%, 24% & 5% at 1, .3 & .1μM, respectively). This effect of DAMGO was absent in the presence of ω-CgTx and ω-Aga.

ANTINOCICEPTIVE EFFECTS OF $\mu,~\delta,$ and κ OPIATE AGONISTS AND ANTAGONISTS ON RAT FOOT WITHDRAWAL RESPONSES MEDIATED BY AS OR C NOCICEPTOR ACTIVATION Y. Lu, V. Pirec, and D. C. Yeomans* Dept. of Anatomy and Cell Biology, University of Illinois at Chicago. Chicago, Illinois 60612.

The purpose of this study was to determine if μ, δ , or κ opiate agonists preferentially attenuate nociceptive responses mediated by the activation of Ao or C fiber nociceptors. Ao or C fiber mediated responses were assessed by measuring latencies for foot withdrawals evoked by high or low rate skin heating respectively. Intrathecal application of the δ agonists DPDPE or DSLET produced dosedependent antinociception for responses to both high and low rate skin heating. These effects were antagonist reversible and showed approximately the same potency and dose response slope for both heating rates. The k agonist U50488 did not produce antinociception on either test using doses up to 500 nmoles. The mu opioid agonists morphine and DAMGO also produced dose-dependent, antagonist reversible antinociception for both $\,$ A δ and $\,$ C mediated responses. However, although μ opioids appeared to be more potent for C fiber mediated responses, the slopes of the dose-response lines for the high and low heating rates for both morphine and DAMGO were significantly different, precluding direct ED₅₀ comparisons. One possible explanation for the slope differences is that μ opioids act presynaptically on C-fiber terminals and postsynaptically on both $A\delta$ and C evoked activity in dorsal horn neurons. SPINALLY ADMINISTERED OPIOIDS WITH AGONIST ACTIVITY AT KAPPA2 OPIOID RECEPTORS ARE ANTIHYPERALGESIC DURING PERIPHERAL INFLAMMATION

J. Ho, A. J Mannes, R. Dubner and R. M. Caudle*. Neurobiology and Anesthesiology Branch, National Institute of Dental Research, NIH, Bethesda, MD 20892.

Previous work demonstrated that activation of kappa₂ opioid receptors inhibits the flow of current through N-methyl-D-aspartate (NMDA) receptors (J. Neurosci. 14:5580). These findings suggested that kappa₂ opioid receptor activation could be used to modify NMDA receptor-mediated responses. Numerous studies have demonstrated that intrathecally administered NMDA receptor antagonists inhibit hyperalgesia in rats, but do not influence normal pain sensation. These studies indicate that NMDA receptors are involved in hyperalgesia.

The present study examined spinally administered kappa2 agonists during inflammation of the rat hindpaw to determine if these agents were antihyperalgesic like NMDA receptor antagonists or analgesic like conventional opioids. Paw withdrawal latencies to heat were used to measure pain thresholds. Bremazocine and withdrawal laterices to heat were used to measure pain thresholds. Bremazogine and GR89,696, opioids with kappa2 agonist activity, inhibited the hyperalgesia associated with hindpaw inflammation. They did not elevate the latency of the inflamed paw above pre-inflammation levels nor did these agonists elevate the threshold of the non-inflamed paw. The ED50's were 155 and 2 nMols for bremazocine and GR89,696 The antihyperalgesic effect of these agents was blocked by co administration of naloxone. The selective mu agonist, DAMGO, and the delta agonist, DPDPE, elevated the paw withdrawal latencies of both the inflamed and noninflamed paws. These agonists also elevated paw withdrawal latencies above preinflammation levels. The kappa₁ selective agonist, U69,593, had no effect on either paw. These findings suggest that kappa₂ agonists are selective and effective antihyperalgesic agents that may act by inhibiting the flow of current through NMDA

SPINAL CORD ENDOGENOUS OPIOID MEDIATION IN ILLNESS-INDUCED & CONDITIONED HYPERALGESIAS

E. P. Wiertelak*, Department of Psychology, Macalester College St. Paul, MN 55105.

Intraperitoneal (IP) administration of lithium chloride (LiCl; emetic) or lipopolysaccharides (LPS; pyretic) induces a potent hyperalgesic state as measured by the tailflick test. Moreover, animals can learn to activate hyperalgesia in response to signals for impending illness, a phenomenon known as conditioned hyperalgesia. To investigate whether LiCl, LPS, or conditioned hyperalgesia mechanisms rely on spinal opiate activity, rats were implanted with intrathecal (IT) catheters and allowed one week post-surgical recovery. Parallel microinjection and testing methods were employed for the study of LiCl, LPS, and conditioned hyperalgesias to define the opiate natures of the resultant hyperalgesias, and allow for an initial comparison of the spinal opiate involvement in each event.

Conditioned hyperalgesia was acquired by rats in response to internal cues (taste) paired with illness (conditioned taste aversion). Compared to vehicle controls, IT injections of naltrexone reversed conditioned hyperalgesia, suggesting specific opiate involvement in the spinal cord. Intrathecal injections of naltrexone also completely reversed the illness-induced hyperalgesia resulting from IP LiCl or LPS, as compared to vehicle controls. Further IT studies using specific opiate receptor-subtype antagonists (CTOP, Naltrindole, Binaltorphimine) are in progress. To date, the data indicate these hyperalgesias involve common spinal systems. Supported by grant DA09289-02 from the National Institute on Drug Abuse at the National Institutes of Health.

DIFFERENTIAL CONTRIBUTON OF SUPRASPINAL AND SPINAL OPIOID RECEPTORS TO THE ANALGESIC ACTION OF SYSTEMIC MORPHINE IN THE FORMALIN TEST IN THE RAT C. Loo and A.I. Basbaum, Depts. Anat., Physiol. and W.M. Keck Fdn. Ctr. for Integrative Neurosci., UCSF, San Francisco.

The analgesia produced by systemic injection of morphine in acute nociceptive test results from a synergistic action at spinal and supraspinal sites (Yeung and Rudy, 1980). The relative contribution of each site to the analgesia, particularly in models of persistent pain is, however, not clear. To address these questions we studied the reversal of morphine analgesia produced by injections of i.e.v. and/or intrathecal (i.t.) naloxone methiodide (10ng-10ng), a quaternary opiate antagonist. Morphine (10mg/kg) was injected 10 min prior to a hindpaw injection of formalin (5%; 50µL). To selectively study the reversal of the analgesia in the tonic phase of the formalin test, we injected the antagonists in the interphase, i.e. before the onset of phase 2 pain behavior. Icv injections were made via a 3rd ventricle cannula, i.t. injections by lumbar puncture. Phase 2 formalin behavior was scored (time weighted method; paw favoring-1; lifting-2; licking-3) for up to 80 min after formalin.

tavoring-1; litting-2; licking-3) for up to 80 min after formatin.

The naloxone methiodide potency for reversal of phase 2 analgesia was greatest by the icv route. Thus, 10 µg icv produced an 81.9% reversal; 10 µg i.t. only produced a 35.7% reversal (compared to rats that received saline). Furthermore, the minimal dose for producing some antagonism was 10 ng icv, but 100 ng was required i.t. When different doses were combined, we did not detect synergistic reversal. Importantly, complete reversal of phase 2 analgesia (100%) could only be produced by simultaneous injections (e.g. 10 µg icv and i.t.). This indicates that multiple sites must be accessed by systemic morphine to produce complete analgesia in this test.

Since it is unclear whether or not different populations of spinal cord

Since it is unclear whether or not different populations of spinal cord nociresponsive neurons are regulated by supraspinal or spinal morphine, we are also studying the spinal cords of these rats for expression of the fos protein when analgesia is reversed by concomitant icv and i.t. antagonist injections. Futhermore, this evidence for additivity rather than synergy in a tonic pain test is being tested with simultaneous microinjections of morphine. Support: DA 08377 & NS21445.

SUPRASPINAL/SPINAL ANTINOCICEPTIVE SYNERGY OF SELECTED OPIOID DELTA AGONISTS IN MICE. M.H. Ossipov, K.P. Mayfield, T.W. Vanderah, J.M. Lashbrook, T. P. Malan, Jr. and F. Porreca, University of Arizona Pain Institute at the Health Sciences Center, Tucson, AZ 85724.

A multiplicative antinociceptive interaction of morphine activity at spinal and

supraspinal sites has been clearly established and is probably responsible, in part, for the clinical utility of this compound in normal dose-ranges. While synergistic actions of opioid µ receptor agonists have been shown, it is unclear whether a similar interaction exists for opioids acting via the delta (δ) receptor. Response to acute nociception was measured by determining the warm-water (55°C) tail-flick latency before and after intracerebro-ventricular (i.e.v.), intrathecal (i.th.) or i.th. plus i.e.v. (1:1 fixed ratio) injection of the peptidic opioid δ agonists [D-Ala², Glu⁴]deltorphin (DELT), [D-Pen², D-Pen⁵]enkephalin (DPDPE) or the non-peptidic, SNC-80. The δ receptor selectivity of the highest studied i.c.v. or i.th. doses of these agonists was confirmed by showing antagonism with naltrindole (δ antagonist) but not with nor-binaltorphimine (κ antagonist) or β -funaltrexamine (μ antagonist). The respective A_{50} (\pm 95% C.L.'s) values for DELT given *i.th.*, *i.c.v.* and *i.th.* plus *i.c.v.* were $78 \pm 40 \ \mu g$, $6.1 \pm 1.9 \ \mu g$ and $6.6 \pm 1.9 \ \mu g$ and 2.4 μ g, respectively. The respective A50 (± 95% C.L.'s) for *i.th.*, *i.e.v.* and *i.th./i.e.v.* DPDPE were 17 ± 7.4 μ g, 13 ± 3.5 μ g and 7.1 ± 2.7 μ g, while these respective values for SNC-80 were 110 ± 19 μ g, 140 ± 25 μ g and 155 ± 16 μ g. Isobolographic analysis revealed that the spinal/supraspinal antinociceptive interaction for DELT and for DPDPE to be synergistic. In contrast, the spinal/supraspinal antinociceptive interaction for SNC-80 was found to be sub-additive. These data indicate that a multiplicative antinociceptive interaction between opioid δ agonists given i.th. and i.e.v. can be demonstrated for some, but not all, opioid δ agonists. The sub-additive interaction found with SNC-80 may represent different preferential sites or mechanisms of action of this compound. Such analysis will be important in determining the potential clinical application of compounds acting through opioid δ receptors. Supported by the NIDA.

PAIN FACILITATION INDUCED BY OPIATES: AN OPIOID OPPOSING PROCESS BLOCKED BY THE NMDA ANTAGONIST MK 801. <u>LP. Laulin, A. Larcher, E. Célerier, M. Le Moal* and G. Simonnet,</u> INSERM U. 259, rue Saint Saëns, 33077 Bordeaux, France

A. Larcher, E. Célerier, M. Le Moal* and G. Simonnet, INSERM U. 259, rue Saint Saens, 33077 Bordeaux, France.

Several trends of evidence suggest that the development of tolerance to opiates would result in the activation of compensatory systems rather than in the desensitization of opiate receptors. Such compensatory systems, acting as opioid-opposing systems, awould mask the effects of opiates like analgesia by inducing opposite effects such as hyperalgesia or allodynia. This hypothesis also implies that these opioid-opposing systems might be activated even after a first administration of opiates. Recently, we have demonstrated the reality of this phenomenon by studying the variations of the rat nociceptive threshold using the tail-flick latency test to a thermic stimulus (water bath at 52°C). We have observed that a single administration of heroin (2.5 mg/kg) induced a 2 hours analgesia followed by a hyperalgesia of similar duration. Moreover, the administration of naloxone (1 mg/kg) during the analgesic phase did not only reverse the analgesia but also induced a clear hyperalgesia, indicating that opioid-opposing systems were simultaneously activated. In addition, tolerance could develop very rapidly since a second administration of heroin, as soon as 2 hours after the first injection, elicited an analgesic effect 3 times lower than the first one. According to previous works which have reported that tolerance could be prevented by chronic treatment with NMDA antagonist, the effect of MK 801 on opioid-opposing systems activation by heroin administration was studied. Pretreatement of the animals with an injection of MK 801 (0.15 mg/kg) resulted in a significant increase in both amplitude and duration of the analgesic effect of acute heroin (1 mg/kg); MK 801 also blocked in a dose-dependant manner (0.1-0.3 mg/kg) the hyperalgesia provoked by the administration of naloxone during the heroin-induced analgesia. At last, acute tolerance observed for a second injection of heroin, was totally prevented by a previous

LOSS OF ANTIALLODYNIC AND ANTINOCICEPTIVE SPINAL/SUPRASPINAL MORPHINE SYNERGY IN NERVE-INJURED RATS. D. Bian, M.H. Ossipov*, M.L. Nichols, T.P. Malan, Jr. and F. Porreca. Univ. Arizona Pain Institute, Tucson, AZ 85724.

It is well known that the antinociceptive potency of morphine is markedly influenced by a substantial multiplicative interaction at spinal and supraspinal sites. It has recently been shown, however, that i.th. morphine is not effective in suppressing tactile allodynia in animals with an L5/L6 nerve ligation injury, and that the opiate loses both antinociceptive potency and efficacy in the tail-flick test in these animals. It is conceivable that nerve ligation injury alters central nociceptive processing in a manner to alter opioid-mediated descending inhibitory mechanisms resulting in a loss of the spinal/supraspinal synergy observed with morphine. To test this hypothesis, nerve injury was produced by unilateral ligation of the L5 and L6 spinal roots of the sciatic nerve of rats. Response to acute figation of the 15 and 15 spinal roots of the Scatte reve of 1 as., Response to a cute nociception was measured by determining the warm-water (52°C) tail-fick latency. Tactile allodynia was measured by probing with calibrated von Frey filaments. Morphine was given i.th., i.c.v. and in a 1:1 ratio of i.th. plus i.c.v. Data were converted to % maximal possible effect (%MPE). In sham-operated rats, the antinociceptive (tail-flick) A_{s_0} 's of i.th, i.c.v, and i.th plus i.c.v morphine was 1.9 (1.0 - 3.4) μg , 3.2 (2.3 - 4.5) μg and 0.30 (0.2 - 0.6) µg, respectively, and in nerve-ligated rats the A₅₀ values were 3.7 (1.4 -10) μg , 1.5 (0.3 - 6.9) μg and 4.5 (3.1 - 6.3) μg . Isobolographic analysis indicated that the antinociceptive interaction between *i.th*, and *i.c.v*, morphine was synergistic in sham-operated rats and additive in nerve-ligated rats. The antiallodynic A_{50} values of *i.c.v*. morphine alone and with 1:1 *i.th.* morphine were 1.9 (1.3 - 2.8) µg and 0.82 (0.57 - 1.2) μg, representing a non-significant 2.3-fold shift in the i.c.v. morphine dose-response curve which was not synergistic; *i.th* morphine alone was inactive. These data indicate a loss of spinal/supraspinal antinociceptive and antiallodynic synergy of morphine in the nerveinjured rat and may reflect an altered role of descending modulatory systems mediated by supraspinal morphine. The loss of synergy may underly the perceived resistance of clinical neuropathic pain to opioid therapy. Supported by USPHS Grants from the NIDA.

MICROINJECTION OF MORPHINE IN THE A7 CATECHOLAMINE CELL GROUP PRODUCES HYPERALGESIA. J. E. Holden* and H. K. Proudfit,

Dept. of Pharmacology, University of Illinois at Chicago, Chicago, Il 60612. The A7 catecholamine cell group contains noradrenergic neurons that innervate the spinal cord dorsal horn and stimulation of these neurons produces potent antinociception. We have previously identified methionineenkephalin-containing (mENK) neurons in the ventromedial medulla (VMM) that project to tyrosine hydroxylase-immunoreactive neurons in the A7 cell group. The present experiments determined the role of these mENK neurons in the modulation of nociception. The first experiment determined the effects of microinjecting the excitatory amino acid, monosodium glutamate, into the A7 area in female Sprague-Dawley rats. Glutamate produced a significant antinociceptive effect (p< .05). The second experiment determined the effect of microinjecting the non-selective opioid receptor agonist, morphine sulfate (MS), into the A7 area. MS produced a significant hyperalgesic effect compared to saline controls (p<.0001). This hyperalgesic effect was reversed by microinjection of the opioid antagonist, naltrexone, in the A7 cell group, which indicates that the MS effect was

mediated by opioid receptors.

These results confirm previous observations that activation of neurons in the A7 cell group produces antinociception and lead to the conclusion that MS produces hyperalgesia by inhibiting neurons in this region. These findings suggest that mENK neurons in the VMM facilitate nociception by

inhibiting neurons in the A7 cell group.

INESCAPABLE SHOCK (IS) POTENTIATES MORPHINE ANALGESIA 24 HRS LATER: THE ROLE OF MU OPIOID RECEPTORS IN THE DORSAL RAPHE NUCLEUS (DRN).

RECEPTORS IN THE DORSAL RAPHE NUCLEUS (DRN).

SE Hammack* CE Hartley, LC Sutton, SF Maier, & LR Watkins. Dept
Psych, U Colorado, Campus Box 345, Boulder, CO 80309.

Inescapable tailshock (IS), but not identical escapable tailshock,
potentiates morphine analgesia 24 hrs later as measured by the tail flick
(TF) test. Previous experiments have shown that IS potentiates analgesia to a broad range of systemic morphine doses as well as to morphine microinjected into discrete sites in the raphe bulbospinal pathway. The present experiments characterize the involvement of mu receptors in the dorsal raphe nucleus (DRN), a site believed to mediate many of the effects produced by IS

Rats implanted with DRN cannulae received either 100 IS (1mA, 5 sec, 1 Rats implanted with Driv canning are received either 100 f (1mA, 5 sec, 1 min ITI) or restraint. Baseline TF latencies were measured 42 hrs later followed by microinjection of the mu receptor agonist DAGO (0.3 μg) or equivolume vehicle (1 μl saline). Fifteen min later, 3 TF latencies were measured every 10 min for 1 hr. Neither IS nor restraint groups given saline vehicle exhibited analgesia. IS groups exhibited a profound potentiation of DAGO analgesia when compared with restraint controls.

These data suggest that mu opioid receptors in the DRN are critical to IS induced potentiation of morphine analgesia. Ongoing experiments are aimed at further characterizing the opioid receptor subtypes involved both at the time of IS and 24 hrs later. Supported by NIMH grant MH50479 and the Undergraduate Research Opportunities Program.

ANTINOCICEPTION PRODUCED BY MICROINJECTION OF DELTA OPIOID RECEPTOR AGONISTS INTO THE VENTROMEDIAL MEDULLA OF THE RAT. S. N. Thorat* and D. L. Hammond. Dept. of Anesthesia & Critical Care, Univ. of Chicago, Chicago, IL 60637.

The role of supraspinal ventromedial medullary sites, such as the n. raphe magnus (NRM) and n. reticularis gigantocellularis pars alpha (NGCpα), at which selective delta opioid receptor agonists may act to produce antinociception was investigated in adult male Sprague-Dawley rats. Animals were stereotaxically implanted under ketamine/xylazine anesthesia with a guide cannula aimed at either NRM or NGCpa. One week later, either [D-Alai Glu⁴]deltorphin (DELT; delta-2 agonist) or [D-Pen^{2,5}]enkephalin (DPDPE; delta-1 agonist), were microinjected into the NRM or NGCpa. The nociceptive threshold was determined at 0, 15, 30, 45 and 60 min after the microinjection of DELT or DPDPE using the tail-flick and 55°C hot-plate tests. Administration of DELT (0.02 - 2.0 nmol/0.25 μl) or DPDPE (0.64 - 5.8 nmol/0.25 μl) into NRM or $NGCp\alpha$ dose-dependently increased the tail-flick latency, with a peak effect occurring at 30 min and 45 min, respectively. At the highest dose tested, DELT increased the tail-flick latency to a maximal value of 10.6 ± 0.8 sec whereas DPDPE increased the tail-flick latency to a maximal value of 10.1 ± 0.8 sec. Microinjection of DELT or DPDPE did not produce any significant antinociception in the hot-plate test. These results provide evidence that activation of delta-1 or delta-2 opioid receptors in the ventromedial medulla is sufficient to produce antinociception in the tail-flick test. The lack of effect in the hot plate test may be a result of the high intensity thermal stimulus applied in the hot-plate test or the administration of an inadequate dose. (Supported by USPHS grant DA 06736).

OPIOID RECEPTOR MEDIATED PAIN FACILITATION EVOKED BY PAG & ENDORPHIN IS MODULATED BY STRESS AND SPINAL CHOLECYSTOKININ A.A. Hawranko*, DL. Smith, P.J. Monroe, and D.J. Smith Depts. of Anes. and Pharm./Tox. West Virginia University, Morgantown, WV

Although opioids are usually associated with pain inhibition, under certain conditions they may produce pain facilitation (JPET 265:286, 1993). Moreover, the pain facilitory effect of opioids may be modulated by behavioral states such as anxiety (Neurosci. Abs. 21:1169, 1995). A region of the brain associated with the integration of pain and stress is the periaqueductal gray (PAG). This area contains β-endorphin (βE), and is a site of origin of opioid receptor-activated pain facilitory processes. In the current study, the participation of spinopetal cholecystokinin (CCK) neuronal processes in the pain facilitory effect of BE from the PAG was evaluated. Antinociception (tail flick test) occurring from the microinjection of BE into the PAG is enhanced by co-administration of the opioid receptor antagonist CTP at doses lower than those required to block antinociception. This is consistent with the notion that opioid receptors involved in pain facilitory function have a high affinity for opioid drugs. Furthermore, the intrathecal administration of proglumide, a CCK receptor antagonist, also enhances the response to BE. As previously shown, noxious stress reduces the antinociceptive potency of BE, and causes a dose of BE which is ineffective in non-stressed rats to become clearly anti-analgesic. Like in the non-stressed rat, each of these actions is reversed by CTP, or is attenuated by proglumide. Thus, an opioid activated CCK-dependent pain facilitory system dampens the overall antinociceptive potency of BE, and is highly prominent during stress. It may provide a basis for increased pain sensitivity with opioid agonists, and paradoxical analgesia associated with low doses of opioid antagonists

INESCAPABLE SHOCK (IS) POTENTIATES MORPHINE ANALGESIA 24 HRS LATER: THE ROLE OF THE MU OPIOID RECEPTORS IN THE LUMBOSACRAL SPINAL CORD.

CE Hartley*, SE Hammack, LC Sutton, SF Maier, & LR Watkins-Department of Psychology, U Colorado, Boulder, CO 80309. We have recently shown that IS, but not restraint or identical escapable shock, produces a marked enhancement of analgesia 24 hrs later when

we have recently shown that is, but not restraint of itentical escapatic shock, produces a marked enhancement of analgesia 24 hrs later when morphine either is delivered systemically or microinjected into discrete sites within the raphe bulbospinal pathway. The present experiments replicate and extend previous findings by examining the involvement of mu opioid receptors in lumbosacral spinal cord.

Adult male albino rats were exposed either to 100 inescapable tailshocks (IS; 5 s, 1 min variable 1TI, 1 mA, delivered by fixed fuseclip electrodes) or to an equivalent period of restraint. Rats were then tested for pain responsivity using the tailflick (TF) test in a novel environment 24 hrs later. After baseline TF assessment, rats were briefly exposed to a short-acting inhalant (methoxyflurane) to allow a single epidural drug injection to be made. Each rat received either 0.25 µg morphine, 18.75 ng DAGO, or equivolume vehicle (10-15 µl saline). Full recovery from anesthesia occurred within 1-2 min. Beginning 15 min after injection, 3 TF latencies were assessed each 10 min for 60 min. Analgesia was not observed in any saline groups. Likewise, restraint groups given morphine or DAGO failed to exibit analgesia. In contrast, profound morphine and DAGO analgesia was present in IS groups.

These data demonstrate a striking potentiation of morphine and DAGO analgesia 24 hrs after inescapable tailshock and suggest that mu opioid receptors in the lumbosacral spinal cord are critical to this phenomenon. Ongoing experiments are aimed at further characterizing the opioid receptors involved at the time of IS and testing. Supported by UROP & NIMH grant MH50479.

PERIAQUEDUCTAL GRAY INHIBITION OF DORSAL HORN NEURONS: THE CONTRIBUTION OF ENDOGENOUS OPIOIDS ACTING VIA MU RECEPTORS. D. Budai* and H.L. Fields. Depts. of Neurology and Physiology and the Keck Center for Integrative Neuroscience, University of California, San Francisco, CA 94143.

Activation of neurons in the midbrain periaqueductal (PAG) inhibits both dorsal horn neurons and behavioral responses to noxious stimuli. Activation of neurons in the midbrain periaqueductal (PAG) inhibits both dorsal horn neurons and behavioral responses to noxious stimuli. Although PAG elicited behavioral antinociception can be antagonized by naloxone, no descending opioid-mediated inhibition of dorsal horn neurons has been demonstrated. In the present study, we examined the contribution of spinal mu opioid receptors to the descending modulation of somatosensory processing. Extracellular recordings were made from single nociresponsive dorsal horn neurons of the rat in response to iontophoretically applied excitatory amino acids (EAA; NMDA or kainic acid) or to noxious heat delivered to the tail. Descending inhibition was evoked by the activation of ventral PAG cells using microinjection of 30-50 ng bicuculline (BIC). After BIC administration, responses of nociceptive dorsal horn neurons to noxious heat were decreased by 60-80% within approximately 15 minutes. The inhibition lasted for 40-50 minutes. This inhibition was transiently reversed by iontophoretic application of the opioid antagonists naloxone and CTOP. In the absence of PAG BIC, naloxone but not the selective mu opioid receptor antagonist, CTOP, had an excitatory influence on dorsal horn neurons. Responses to iontophoresed EAAs were also influenced by PAG BIC. However, the inhibition of the EAA responses did not consistently follow that of the heat responses. This is the first demonstration that endogenous opioids acting via spinal mu opioid receptors contribute to brainstem control of spinal dorsal horn neurons. This inhibition may result in part from presynaptic inhibition of afferents to dorsal horn nociresponsive neurons. Supported by PHS grant, DA 1949.

NALOXONE REDUCES THE VENTRAL PERIAQUEDUCTAL GRAY-INDUCED INHIBITION OF DORSAL NEURONS IN RATS. Q. Shen, Y.B. Peng, Huw Rees*, W.D. Willis. Department of Anatomy and Neurosciences and The Marine Biomedical Institute, The University of Texas Medical Branch at Galveston, Galveston, Texas

We tested the effects of naloxone hydrochloride, a specific opiate antagonist, on the responses and ventral periaqueductal gray-induced inhibition of dorsal horn cells of the lumbar spinal cord in rats anesthetized with pentobarbital sodium (50 mg/kg, i.p.,). Naloxone was administered through microdialysis fiber with its open membrane placed in the dorsal horn. Extracellular single unit responses were recorded from the dorsal horn neurons in the vicinity of the microdialysis fiber. Naloxone was tested on nociceptive dorsal horn neurons. Significant increases of the background activity and responses to brush, press and pinch stimuli were observed in all tested cells. There was also a significant block of the ventral periaqueductal gray-induced inhibition of activities to brush, press and pinch (from 40% to 18%, 66% to 32%, 70% to 36%, respectively) in these cells. These results suggest that the opioid receptors in the spinal cord are involved in the ventral periaqueductal gray-induced inhibition of dorsal horn neurons. (This study was supported by NIH Grants NS 09743 and NS11255)

NALOXONE-INDUCED HYPOALGESIA: EVIDENCE FOR THE EXPRESSION, BUT NOT ACQUISITION, WITH THE TAIL-FLICK RADIANT HEAT TEST. H. Foo*. Psychology, Northern Territory University, Darwin, NT 0909, Australia.

Previous research has shown that rats given pairings of naloxone in combination with exposure to the heated floor of the hot-plate apparatus come to acquire hypoalgesia. This hypoalgesia has been evidenced by a decrement in nociceptive responding across assays for acute pain (eg. hot-plate test) and for chronic pain (eg. formalin test). The present experiments constitute an investigation of 'naloxone-induced hypoalgesia' with the tail-flick radiant heat test. Experiment 1 showed that rats exposed to pairings of naloxone and a heated floor were hypoalgesic when then tested for their latencies to flick their tails in response to the application of radiant heat, providing further evidence for the generality of the hypoalgesic response that have been detected previously. Experiment 2 examined whether rats given pairings of naloxone and exposure of radiant heat to the tail come to acquire hypoalgesic response. In contrast to the finding of hypoalgesia in rats that have been given naloxone in combination with immersion of their tails into heated water (cf. Rochford & Stewart, 1987), the present investigation found no evidence for hypoalgesia in rats injected with naloxone in advance of exposure of their tails to radiant heat. The discrepancy in these findings is explained in terms of procedural differences that were employed in the two studies. (This research was supported by a grant from the Northern Territory University)

540.20

THE EFFECT OF PLACENTA INGESTION ON KAPPA-OPIOID ANTINOCICEPTION IN RATS. J.M. DiPirro, T.M. Vanderwerf, and M.B. Kristal*. Behavioral Neuroscience Program, Dept. of Psychology, University at Buffalo, NY 14260.

Ingestion of POEF (Placental Opioid-Enhancing Factor), found in placenta and anninotic fluid, produces a dramatic enhancement of opioid/opiate-mediated antinociception in the rat, but alone does not produce antinociception. POEF ingestion was found to produce enhancement of morphine-induced antinociception but left morphine-induced hyperthermia unmodified, in the same rats. In an attempt to determine whether this differential effect was due to opioid-receptor specificity, we undertook a series of studies to evaluate the effect of POEF ingestion on antinociception produced by i.c.v. injection of preferential opioid-receptor agonists. Initial studies showed that POEF ingestion enhances \(\delta\)-mediated antinociception and inhibits \(\mu\)-mediated antinociception. The present study investigated the effect of POEF on the antinociception produced by the preferential kappa-receptor agonist spiradoline (U-62,066).

Ten minutes after ingesting placenta or control substance (1.0 g), rats were injected with spiradoline (200 nM/ 4 µl, i.c.v.) or vehicle. Antinociception (hindpaw-lick/jump latency) was assessed using a 52°C hot-plate algesiometer 20 minutes after i.e.v. injection.

The results indicate that, unlike δ - and μ -antinociception, κ -antinociception appears to be unaffected by POEF. Future studies will determine whether this finding is related to spiradoline dose or the absence of κ -receptor involvement in POEF enhancement.

Supported by NSF grant IBN 91-23748, and funds supplied by the office of the Dean of the Faculty of Social Sciences, awarded to M.B.K.

PAIN MODULATION: PHARMACOLOGY-OPIATES II

541.1

ANALGESIC ACTION OF DIHYDROCODEINE (DHC) IS NOT DUE TO FORMATION OF DIHYDROMORPHINE (DHM) I. Jurna*, J. Baldauf and W. Fleischer. Dept. of Pharmacology, Univ. of the Saarland, D-66421 Homburg, and Mundipharma, D-65549, Limburg, Germany.

The analgesic efficacy of DHC ranges between those of morphine and codeine. DHC is assumed to act by its O-demethylated product, DHM. To test this hypothesis, experiments were carried out on rats in which pain-related nociceptive activity was elicited in neurons of the thalamus VPL and VPM by electrical stimulation of afferent C fibers in the sural nerve. DHC injected i.v. depressed evoked nociceptive activity in a dose-dependent way, the ED50 being 0.47 mg/kg. Blocking O-demethylation by pretreatment with metyrapone or cimetidine failed to reduce the effectiveness of DHC. Since, in addition, DHC was twice as potent as DHM (ED50 0.97 mg/kg i.v.), it is concluded that DHC produces analgesia by itself.

541 9

CROSS-TOLERANCE TO MORPHINE ANALGESIA IN RATS INJECTED WITH ETHANOL, BUT NOT IN RATS THAT ORALLY SELF-ADMINISTERED ETHANOL. A. L. Vaccarino, R. L. Bell, L. C. Couret, Jr., G. A. Olson, R. D. Olson & J. H. McLean*. Department of Psychology, University of New Orleans, LA 70148.

Previous studies have shown cross-tolerance between morphine- and ethanol-induced analgesia. In the present study, we examined the effects of ethanol pretreatment (oral self-administration vs ip injections) on subsequent tolerance to ethanol-induced analgesia (EIA) and cross-tolerance to morphineinduced analgesia (MIA). In experiment 1, male Long-Evans rats were injected with ethanol (2.5 g/kg, ip) or an equal volume of saline once a day for 2 days. On day 3, the animals were tested for either EIA (2.5 g/kg, ip) or MIA (10 mg/kg, ip) in the hotplate test (52°C, 60 sec cut-off period). Rats pretreated with ethanol showed tolerance to EIA and cross-tolerance to MIA. In experiment 2, rats were given increasing amounts of ethanol added to their drinking water over a 15-day period. The concentrations of ethanol were five days of 5%, five days of 10% and five days of 15%. A control group of rats had plain tap water to drink. On day 16, all animals were given plain tap water to drink. On day 17, the animals were tested for EIA (2.5 g/kg, ip) or MIA (10 mg/kg, ip) in the hotplate test. Rats allowed to self-administer ethanol showed tolerance to EIA, but did not show cross-tolerance to MIA. Thus, when ethanol is experimenter-administered it is cross-tolerant with MIA, but when ethanol is self-administered it is not cross-tolerant with MIA.

541.3

(-)-NORPSEUDOEPHEDRINE ENHANCES THE ANALGESIC EFFECTS OF MORPHINE P. Nencini* S. Fraioli, D. Perrella, V. Sorana, T. Pascucci, C.V. Nucerito, Institute of Medical Pharmacology, University of Rome "La Sapienza", P.le A. Moro 5, 00185 Rome, Italy

Like amphetamine cocaine and other psychomotor stimulants, weak amphetamine-like agents, such as phenylpropanolamine and ephedrine potentiate the analgesic effects of morphine. In the present study we investigated the ability of (-)-norpseudoephedrine (NPE), apparently less active in terms of amphetamine-like properties of its enantiomer phenylpropanolamine, to influence both the analgesic effects of morphine and its discriminative stimulus properties. In male mice NPE (5.6-10.0-17.0 mg/kg i.p.) did not prolong the latency to lick or to remove paws from a plate warmed at 54°C. However, at the dose of 17 mg/kg it significantly potentiated the analgesic effect of 3.2 mg/kg of morphine (ANOVA of the area under the curve from 0 to 120°: F.11.90=9.574, p=0.001). These results were replicated in rats by use of the formaline test, which measures the numbers of hindpaw flinches produced by injecting 50 µl of formaline into the dorsal surface of the paw. NPE 17 mg/kg increased the effect of sub-analgesic doses of morphine (0.56 and 1.0 mg/kg), as measured by the area under the curve of the late nociceptive phase, from 25' to 60' (ANOVA: F.8,53=5.098, p=0.001). In rats trained to discriminate between 0.5 mg/kg of amphetamine and saline in a two-lever operant behavior reinforced by water access. NPE induced a dose-dependent increment of drug lever responding from 0% at 1.0 mg/kg to 100% at 32.0 mg/kg. In contrast, NPE did not generalize for the morphine discriminative stimulus up to the dose of 56.0 mg/kg, which produced a substantial reduction of the response rate. However, when given in combination, NPE attenuated the discriminative stimulus properties of morphine and potentiated its reduction of the response rate. In conclusion, NPE enhances the analgesic effect of morphine in mice and rats. This NPE effect is probably mediated by its amphetamine-like properties and does not offect a generalized enhancement of morphine's actions. SEASONAL VARIATION IN ANALGESIC THRESHOLDS TO MORPHINE AND MELATONIN ANALGESIA IN AMPHIBIANS. C. W. Stevens* and L. L. Deason, Oklahoma State University, College of Osteopathic Medicine, Tulsa, OK 74107-1898.

Seasonal variation in the analgesic effects of opioids have been noted in mammals as well as the analgesic effect following melatonin administration. For the past three years, morphine (100 nmol/g, s.c.) was administered monthly to separate groups of Northern grass frogs, Rana pipiens. Nociceptive thresholds (NT) and analgesic effects were estimated using the acetic acid test. Morphine was most effective during Spring and Summer months. Baseline NT also varied seasonally, but did not account for the differences seen in morphine effectiveness. Systemic administration of melatonin (10-1000 nmol/g, s.c.) gave an ED50 of 455 nmol/g and melatonin effects were not blocked by naltrexone (100 nmol/g, s.c.) pretreatment. To examine the effect of photic input, optic nerves were sectioned and light blocked to the pineal. Blinded animals had increased NT compared to sham-operated controls. Frogs placed in 24h total darkness also showed an increased NT compared to control group in the lab. These studies suggest that there may be a seasonal variation in opioid sensitivity and that melatonin may regulate baseline nociceptive thresholds in this species. Supported by the Whitehall Foundation and NIH grant DA07326.

SPINAL OPIOID PHARMACOLOGY IN THE FROG: CHEMICAL, THERMAL AND MECHANICAL SENSITIVITIES S. Willenbring and C.W. Stevens. Dept. of Physiology and Pharmacology, Oklahoma State Univ., College of Osteopathic Medicine, Tulsa, OK 74107

We have previously demonstrated the use of chemical (topical acetic acid), thermal (radiant heat) and mechanical (von Frey filament) stimuli as quantifiable behavioral response assays in the northern grass frog (Rana pipiens). These three stimulus modalities appear to be neurologically distinct in that (1) all three are sensitive to systemic morphine, yet (2) only thermal and chemical responses are diminished by adrenergic analgesia, while (3) only mechanical and chemical responses become hypersensitive following nerve injury. The present study assessed changes in all three sensory modalities after spinal administration of various opioid receptor subtype agonists: μ agonists morphine and fentanyl (10 and 30 nmol, each); δ agonists DADLE, DSLET, DPDPE and deltorphin (30 and 100 nmol, each); k agonists CI-977 and U50488 (30 and 100 nmol, each). Significant elevations of all three sensory thresholds were observed to varying degrees in each subtype category, though not with every drug in each category. Effects of all agonist drugs were abolished by prior systemic administration of the non-specific opioid receptor antagonist naltrexone (100 nmol/g). In the naltrexone pretreated morphine group, thermal and mechanical thresholds were significantly lower than control. It appears that all three sensory modalities are altered by activation of opioid receptors; however, variations within and between subtype categories suggest that these mechanisms may not be specifically or exclusively mediated via classical opioid receptors. COMPARISON BETWEEN ANALGESIC AND IMMUNE EFFECTS OF MORPHINE AND TRAMADOL IN MICE, <u>Paola Sacerdote, Mauro Bianchi,</u>
<u>Barbara Manfredi and Alberto E. Panerai*</u>, Dept. Pharmacology, University of
Milano, Via Vanvitelli, 32, 20129 Milano, Italy

Tramadol is a centrally acting opiate analgesic drug mainly used for the treatment of acute pain that shows moderate selectivity for the μ -opioid receptor. It is well known that morphine, the classical μ receptor agonist, exerts an uppressive action in several species. Since the interference of tramadol with the immune function has not been investigated yet, we compared the effects of the acute administration of morphine (2.5, 5.0, 10, and 20 mg/kg s.c.) and tramadol (1.0, 5.0, 10, 20, 40 and 80 mg/kg s.c.) on nociceptive thresholds (by hot-plate test) and immune responses (ConA-induced splenocytes proliferation and natural killer activity) in the mouse. Moreover, we evaluated the effects of the chronic administration (2 weeks) of morphine (10 mg/kg s.c.) and tramadol (20 mg/kg s.c.) on the same parameters. After acute administration, the antinociceptive effect of morphine was evident at all doses, while the immunosuppressive effect was evident starting at 10 mg/kg. After chronic treatment, tolerance developed for both the antinociceptive and immunosuppressive effect of morphine. Acute tramadol induced an analgesic effect at the doses of 20, 40, and 80 mg/kg, while, at difference from morphine, it induced a stimulation of immune responses. This effect was evident also at non-analgesic doses. Moreover, tolerance did not develop to the antinociceptive effect of tramadol, but it developed to its immunostimulatory effect. Our data indicate that the pharmacodynamic profiles of tramadol and morphine are totally different. The lack of immunosuppression observed after tramadol administration could be taken into consideration in the choice of pain treatments, e.g in post-operative pain.

THE DEVELOPMENT OF MORPHINE TOLERANCE AND DEPENDENCE IN RATS WITH CHRONIC PAIN-LIKE BEHAVIOR FOLLOWING SPINAL CORD ISCHEMIA J.-X. Hao*, W. Yu, X.-J. Xu and Z. Wiesenfeld-Hallin, Karolinska Institute, Dept. Clin. Neurophysiol., 141 86 Huddinge, Sweden

Institute, Dept. Clin. Neurophysiol., 141 86 Huddinge, Sweden It is unclear whether or not patients with chronic pain develop tolerance and dependence to opiates. Data from experimental studies have also yielded conflicting results. We have examined the development of tolerance and dependence to morphine injected onto the spinal cord in a rat model of chronic pain following spinal cord injury, where the animals exhibit an allodynia-like response to mechanical and cold, but not heat, stimuli. Ten µg intrathecal (i.i. morphine completely relieved the marked allodynia-like response to innocuous mechanical stimuli. The analgesic effect of this dose of morphine injected twice daily was, however, diminished within a few days. Tolerance to the antipocicentive effect of morphine assessed days. Tolerance to the antinociceptive effect of morphine assessed with the tail flick test also developed similarly in rats with chronic pain and normal controls. Both groups exhibited similar spinal signs of naloxone-precipitated withdrawal after three weeks of i.t. morphine treatment. The results suggest that the presence of chronic pain did not prevent the development of morphine tolerance and dependence, even when morphine was used to treat the chronic pain itself. BEHAVIORAL EXPERIENCE DIFFERENTIALLY ALTERS THE ANTINOCICEPTIVE EFFECT OF MORPHINE AND (±)-EPIBATIDINE IN MICE. A.W. Bannon*, K.L. Gunther, and M.W. Decker. Abbott Laboratories, Neuroscience Discovery, D-47W, AP-9A, Abbott Park, IL 60064-3500

In this study, open field exposure and measurement of rectal body temperature (i.e., behavioral experience) prior to antinociceptive testing was found to significantly reduce (41%) the jump latency of saline

was found to significantly feduce (+1) the jump latency of same treated animals compared to animals that were not exposed to the behavioral experience (i.e., behaviorally naive). In behaviorally naive animals, a significant reduction (24%) in jump latency was observed following treatment with a dose of naltrexone that attenuates the following treatment with a dose of naltrexone that attenuates the antinociceptive activity of morphine. In general, prior behavioral experience did not alter the response observed following morphine treatment. In contrast, prior behavioral experience significantly increased the jump latency 197% of animals treated with (±)-epibatidine, a compound acting a nicotinic cholinergic receptors, compared to behaviorally naive mice treated with the same dose of (±)-epibatidine. To assess the level of stress induced by the behavioral experience, plasma corticosterone levels were determined in groups of state of the contraction of the contract mice following activity monitoring and measurement of rectal body temperature at the time when analgesia testing was started. Following the behavioral experience, corticosterone levels were significantly increased to 127% of control (i.e., behaviorally niave animals). Overall, these results indicate prior behavioral experience may alter the baseline response of control animals and differentially modulate the antinociceptive activity of opiates and non-opiates. (supported by Abbott Laboratories)

541.8

ACUTE OPIOID TOLERANCE IN MOUSE SPINAL CORD YIELDS RESULTS COMPARABLE TO THOSE OBSERVED IN CHRONIC OPIOID TOLERANCE MODELS. C.A. Fairbanks* 1, K.F. Kitto¹, G.L. Wilcox¹.²¹ Department of Pharmacology, ⁴Graduate Program Neuroscience, U of MN, Minneapolis, Minnesota. The mechanistic similarity between acutely and chronically-induced morphine tolerance has been previously proposed but remains largely unexplored. The present experiments sought to examine the modulation of acutely-induced spinal morphine tolerance by three receptor systems: I the NMDA receptor, II the imidazoline receptor, III the α2A adrenergic receptor. Acute tolerance to morphine was induced in male ICR mice (15-20 g) by intrathecal (i.t.) injection of morphine (40 nmols). Antinociception was detected via the hot water (52.5° C) tall flick test. I Morphine tolerance attenuation was tested using NMDA receptor antagonists (competitive and non-competitive respectively) dizolcipine (MK801) and LY235959. II Attenuation of tolerance was also tested through co-pretreatment of morphine with agmatine, an imidazoline₁ receptor agonist with no activity at the α2 drenergic receptor. III Selective activation of α2A adrenergic receptors was accomplished by administration of a mixture of α2 adrenergic agonist UK, 14-304 or dexmedetomidine and α2c antagonist prazosin (1 μM). Mice with a mutation (D79N), created by gene targeting strategies, that selectively disrupts function of the α2A subtype permit examination of this subtype in opioid tolerance. The α2A receptor relationship with acute spinal morphine tolerance was evaluated by comparison of this D79N mutant strain against the wild-type counterparts. I Coinjection (i.t.) of the NMDA antagonists MK801 (1 μg) or LY235959 (1 ng) with morphine (40 nmols) altenuated acute tolerance to morphine measured 8 h later. II Coinjection (i.t.) of agmatine (4 nmols) with morphine (40 nmols) also attenuated the development of tolerance. III Acute tolerance to morphine was not accompanied by cross tolerance to UK,14-304 or de

texmediation (a However, cross-totelance was observed in origin sericular activation of α2_A receptors.

The results of these experiments are in accordance with previous results reported in models of chronically-induced morphine tolerance. This agreement persists across three independent receptor systems. This study attests to the powerful predictive value of acute induction as a model for opioid tolerance. MORPHINE-INDUCED ANTINOCICEPTION: A COMPARATIVE STUDY OF MALE AND FEMALE RATS, P.E. Stewart* and J.A. Gasiewski. Dept. of Physiology & Pharmacology, Philadelphia College. of Osteopathic Medicine, Philadelphia, PA 19131

Data obtained from both preclinical and clincal investigations show that gender can affect pharmacological responses. exploratory study, the influence of gender on opioid-mediated antinociception in rats was investigated. Following baseline tail-flick latency (TFL) measurements, male (250-300g, 7-8 weeks) and ageor weight-matched female Sprague-Dawley rats were injected (s.c.) with morphine sulfate. The dose range of morphine was 0.3 to 10.0 mg/kg (1 ml/kg injectate volume). TFL measurements were obtained at 10, 20, 40, 60, 80, 100, and 120 minutes after injection of morphine. The resulting ED₅₀ (95% confidence interval) values of 0.66 mg/kg (0.59-0.74 mg/kg) for males, 0.74 mg/kg (0.69 - 0.80 mg/kg) for age-matched females, and 1.16 mg/kg (0.65 - 1.86 mg/kg) for weight-matched females were not statistically different (P > 0.12). Likewise there was no difference in the response with respect to duration (P = 0.97). One explanation for finding no difference may be that the present study did not monitor the estrus cycle. In fact, the animal testing order may have minimized any influence of a particular day of the estrus cycle. Future studies will address the influence of the estrus cycle on the antinociceptive action of systemic morphine. Supported by intramural funding sources from PCOM

EFFECTS OF VIP 11-28 AND NALOXONE ON ANALGESIA IN RATS. D. Conde and B. R. Komisaruk*. Institute of Animal Behavior, Rutgers-The State University of NJ, Newark, NJ 07102.

The analgesia produced by vaginocervical mechanostimulation (VS) is mediated in significant part by the pelvic nerve (Cunningham, et al. 1991), which terminates in spinal cord (Chinapen, et al, 1992) in regions of VIP concentration (Basbaum and Glazer, 1983, Kawatani et al. 1986; Nadelhaft, 1983). VIP is released into spinal cord in response to VS (Komisaruk, et al, 1989). Furthermore, VIP administration has been reported to produce analgesia (Komisaruk et al. 1988). Incubation of VIP, a 28-amino acid peptide, with spinal cord homogenates yields several fragments, one of which is VIP 11-28 (Barbato, et al. 1988). Intrathecal (IT) surgery and ovariectomies were performed in 250-320 g rats at least 2 weeks before administration of VIP 11-28 or lactated Ringer's solution. Both groups were tested immediately after IT injection and every 10 minutes thereafter for one hour. IT administration of VIP 11-28 (16.4 μg in 5 μl lactated Ringer's) produced a significant elevation of TFL at 30 and 60 minutes post injection (18.7% and 24.7%, respectively) compared to baseline preinjection values, and 16.8% and 17.5%, respectively, over the control group at the same time periods. Preinjection TFL did not differ significantly between the groups, and the control group showed no significant changes in TFL across the 60 minute test period, supporting our earlier studies with this peptide fragment. Pretreatment with naloxone (10mg/kg IP) did not significantly attenuate the TFL-elevating effect of VIP 11-28. The present findings indicate that VIP11-28 exerts an analgesic effect that is, at least in part, independent of the endogenous opiate system. Support: NIH-GM08223-11

ESTROLIS CYCLE AND OVARIECTOMY ALTER NOCICEPTIVE BEHAVIORS AND MORPHINE-INDUCED ANALGESIA IN THE FORMALIN TEST AND A NOVEL ELECTRICAL STIMULATION PARADIGM. M. Vincler*, W. Maixner*, G. Essick*, and A.R. Light*, Departments of Pharmacology*, Prosthodontics*, and Physiology*, University of North Carolina, Chapel Hill, NC 27599-7545. The role of ovarian hormones in nociception and morphine-induced analgesia has been examined extensively. Pain sensitivity thresholds have been shown to fluctuate during estrous cycling and in response to ovariectomy using some thermal and electrical paradigms. However, the results of these studies have been inconclusive and contradictory. Our laboratory is examining estrous cycling and ovariectomy (OVX) on nociceptive behaviors and morphine-induced analgesia using two behavioral paradigms: the formalin test and a novel electrical stimulation paradigm. Results from the electrical stimulation paradigm show that phase of estrous alters the latency to bar press and reflex force (p<.01), but not early vocalization (p>.05). Specifically, animals exhibited the following behaviors across shock intensities: faster latencies during proestrus than during metestrus; greater reflex force during proestrus than during both estrus (p<.01) and metestrus (p<.05). The effects of OVX and morphine-induced analgesia on these behaviors are currently being investigated. In the formalin test, preliminary results have indicated that OVX did not modify behavioral responses (flinch/shake and lick/bite) when compared to sham OVX animals. However, when phase of estrous cycle was considered, significant differences emerged. Proestrus animals exhibited significantly less flinch/shake responses compared to OVX animals in Phase 1 and Phase 2 of the formalin test. Diestrus animals exhibited significantly shorter durations of lick/bite responses compared to animals in proestrus, metestrus, or OVX animals in Phase 1, but not Phase 2 of the formalin test. Preliminary results suggest that OVX animals are more sensitive to the analgesic effects of morphine (1mg/kg and 3mg/kg) than sham OVX animals. The significance of these differences are currently being investigated. Supported by NIDA grants DA04420 (A.R.L.) and DA07244-04 (L. D.).

DAMGO INHIBITS PROSTAGLANDIN E2-INDUCED POTENTIATION OF A TTX-RESISTANT NA* CURRENT IN RAT SENSORY NEURONS IN VITRO. M. S. Gold* and J. D. Levine Depts. of Medicine, and Oral Surgery and Division of Neuroscience, UCSF, Box 0452A, San Francisco CA 94143-0452

We have tested the hypothesis that the μ -opioid agonist. [D-Ala²,N-Me-Phe⁴,Gly⁵-ol]enkephalin (DAMGO), inhibits prostaglandin E_2 (PGE2)-induced modulation of a tetrodotoxin-resistant voltage-gated Na^+ current (TTX-R I_{Na}) in putative nociceptors in vitro. Patch-clamp electrophysiological techniques were used on cultured dorsal root ganglion neurons from the adult rat. PGE₂ (1 μ M) induced a 103 +/-22.8 % increase in peak TTX-R I_{Na}. The PGE₂-induced increase in TTX-R I_{Na} in the presence of 1 μ M DAMGO (24.9 +/- 7.7%), was significantly less than that induced by PGE₂ alone. In contrast, when DAMGO was applied after PGE₂, PGE₂-induced increase in TTX-R I_{Na} (85.3 \pm 19.6%) was not significantly different than the increase in the current induced by PGE2 alone. Preapplication of naloxone (10 μM) blocked DAMGO-induced inhibition of the PGE2-induced increase in TTX-R I_{Na}. DAMGO, alone, had no effect on peak TTX-R I_{Na} (1.4 +/- 1.5 % of baseline). Our observation that DAMGO prevents PGE2-induced potentiation of TTX-R I_{Na} is consistent with the suggestion that modulation of TTX-R I_{Na} underlies the hyperalgesic agent-induced increase in the excitability of nociceptors associated with sensitization and hyperalgesia. Furthermore, our data suggest that inhibition of hyperalgesic agent induced modulation of TTX-R I_{Na} may be a novel mechanism underlying opioid-induced antinociception

EFFECTS OF PRENATAL MORPHINE EXPOSURE ON ANALGESIA PRODUCED BY VAGINOCERVICAL STIMULATION IN RATS, S. T. Cunningham*¹, Ilona Vathy² and B. R. Komisaruk¹. ¹Inst. Animal Behavior, Rutgers, The State Univ. NJ, Newark, NJ 07102 ² Dept. Psychiat/Nsci. Albert Einstein Col. Med., Bronx, NY 10461.

Vaginocervial stimulation (VS) induces analgesia, as measured by (1) increased latency to flick tail away from a radiant heat source (TFL) and (2) elevated vocalization threshold (VOC-T) to electroshock of the tail. increased latency to flick tail away from a radiant heat source (TFL) and (2) elevated vocalization threshold (VOC-T) to electroshock of the tail. Opiatergic (Hill and Ayliffe, 1981; Steinman et al., 1983) and mono-aminergic (Crowley et al., 1977; Cunningham et al., 1995) mechanisms modulate this analgesia. The present study investigated the effects of prenatal morphine exposure on analgesia produced in adult female rats by: morphine administration, VS, and dopamine receptor antagonists + VS. In expt 1, in response to adult morphine treatment (1 mg/kg SC), rats treated with saline prenatally showed a 124% greater increase in TFL than rats that received morphine prenatally (although both groups did show significant analgesia to morphine), supporting previous findings by Vathy et al (1992; 1995). In expt 2, VS produced a significantly (196%) greater increase in TFL in the prenatal morphine-treated rats than in the saline controls. In expt 3, all rats were challenged with 0.05 mg/kg IP of the D1 antagonist SCH 23390, the D2 antagonist spiperone hydrochloride, and distilled water, in counterbalanced order. Consistent with previous results (Cunningham and Komisaruk, 1995; Crowley et al., 1977), SCH 23390 produced a dose-dependent potentiation of VOC-T during VS, with no significant effect on TFL. Spiperone produced a dose-dependent increase in TFL and VOC-T during VS. However, prenatal morphine treatment did not differentially affect the potentiation of VS-produced analgesia by these dopamine receptor antagonists. We conclude that the potentiation of VS-produced analgesia by prenatal morphine is evidently due to factors other than alterations in endogenous opioid or dopaminergic mechanisms. ACTIVATION OF PERIPHERAL CCK_B- BUT NOT CCK_A-RECEPTORS INHIBITS LOCAL OPIOID ANALGESIA IN INFLAMMATION. L. Zhou*1,2, M. Schäfer1,2, C. Stein2. 1Preclin. Pharmacol., DIR/NIDA/ NIH, ²Dep. of Anesth., Johns Hopkins Univ.,

There is abundant evidence that cholecystokinin (CCK) attenuates opioid analgesia within the central nervous system. Recent studies showed that dorsal root ganglion neurons in the rat also express CCK snowed that dorsal root ganglion neurons in the fat also express CCN receptors which are transported both to central and peripheral nerve terminals. The present study investigated whether CCK modulates peripheral opioid analgesia in inflamed tissue. In Wistar rats, a painful hindpaw inflammation was induced by Freund's adjuvant and nociceptive thresholds were assessed by a paw pressure test. The peripheral antinociceptive effects of intraplantar (i.pl.) [D-Ala2,N-Me-Phe⁴,Gly-ol⁵]-enkephalin (DAMGO, 10 μg) and fentanyl (1.5 μg i.pl.) were dose-dependently inhibited by CCK_{desulfated} (0.001-1.0 μg i.pl.), a primary CCK_B-agonist. CCK_{sulfated}, a CCK_A-agonist, did not reverse DAMGO- or fentanyl-induced peripheral analgesia. The anti-opioid effect of CCK_{desulfated} was dose-dependently antagonized by the CCK_B receptor antagonist L365,260 (0.05-5µg i.pl.), but not by the CCK_A receptor antagonist L364,718. At these doses, CCK agonists alone did not alter baseline thresholds in inflamed or noninflamed paws. These results indicate that activation of peripheral CCKB- but not CCKAreceptors attenuates the local antinociceptive effects of μ-receptor selective opioid agonists in inflamed tissue. The most likely mechanism for the anti-opioid effect of CCK is an interaction of opioid and CCK_Breceptors on sensory nerve terminals at the second messenger level.

NOCICEPTIN OR ANTINOCICEPTIN: POTENT SPINAL ANTINOCICEPTIVE EFFECT OF ORPHANIN FQ/NOCICEPTIN IN THE RAT, X.-J. Xu*, J.-X. Hao and Z. Wiesenfeld-Hallin, Karolinska Institute, Dept. Clin. Neurophysiol., S-141 86 Huddinge, Sweden.

An endogenous agonist of an orphan receptor that has similarities to opioid

receptors has been recently isolated from brain (Reinscheid et al., Science, 270:1995; Meunier et al., Nature, 377:1995). It has structural similarities to opioid peptides, but has negligible affinity for μ, δ and κ opioid receptors and has very high affinity for the G-protein-coupled orphan receptor LC132. Nanomolar concentrations of the peptide, termed orphanin FQ (Reinscheid at 1, 1995) or nociceptin (Meunier et al., 1995), inhibited forskolin-stimulated adenylyl cyclase, caused motor deficits when injected intrathecally (i.t.) and hyperalgesia when injected intracerebroventricularly (i.c.v.) in mice. Thus, it was concluded that this peptide has a pro-nociceptive function. We examined the function of this peptide in more detail with electrophysiological and behavioral

In contrast to the hyperalgesic effect of nociceptin/orphanin FQ reported after i.c.v. injection in mice, we found a dose-related inhibition of the flexor reflex in decerebrate, spinalized, unanesthetized rats. The antinociceptive effect of this peptide was not reversed by large doses of naloxone (opioid antagonist), atipamezole (α2 adrenoceptor antagonist) or bicuculline (GABA-A receptor antagonist), indicating that it did not exert its effect via the most important spinal inhibitory systems. We also tested the effect of i.t. nociceptin/orphanin spinar initiotory systems. We also tested the effect of it. noticeptinyopnatin FQ in behaving animals and found a potent, dose-related antinociception on the tail flick test, with no signs of motor impairment. No effect of nociceptin/orphanin FQ was found on spinal blood flow with laser Doppler flowmetry. Thus, this peptide may represent a new class of analgesics.

CIRCUITRY UNDERLYING "ANTI-OPIOID" ACTIONS OF ORPHANIN FQ (OFQ) IN THE ROSTRAL VENTROMEDIAL MEDULLA (RVM). M.M. Heinricher*, S. McGaraughty and D. Grandy. Div. Neurosurgery and Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.
The rostral ventromedial medulla (RVM) has received considerable attention

in efforts to understand the mechanisms of opioid analgesia. Two classes of physiologically identifiable RVM neurons with distinct responses to opioids have been characterized. "Off-cells," are invariably activated, although indirectly, by opioids, and there is strong evidence that this activation is crucial to opioid antinociception. "On-cells," thought to enable or facilitate nociception, are directly inhibited by opioids. "Neutral cells" are unaffected by opioid administration, and their role in nociception has not been determined

OFQ, the newly identified endogenous ligand of the "orphan" opioid receptor LC132 has been shown in mice to reverse opioid analgesia when given icv The aim of the present study was to characterize the effects of OFQ on identified RVM neurons, and to determine whether OFQ modifies the well-defined direct and indirect effects of opioids within this region. To this end, single cell recording was combined with local infusion of OFQ in the RVM of rats lightly anesthetized with barbiturates. Local infusion of OFQ profoundly suppressed the firing of all three cell classes and blocked opioid-induced activation of offcells. Local OFQ also blocked the antinociceptive effects of DAMGO infused within the RVM, but not of morphine given systemically.

Insofar as activation of off-cells is sufficient to produce a behaviorally

measurable antinociception, these results suggest that OFQ blocks the antinociceptive effects of opioids acting within the RVM by preventing activation of this cell class

EFFECTS OF CENTRALLY ADMINISTERED ORPHANIN FOON TAIL-FILCK LATENCY AND MOTOR ACTIVITY IN RATS K.R. Gogas*, Julie Thompson and John C. Hunter, Department of Analgesia, Institute of Pharmacology, Neurobiology Unit, Roche Bioscience, Palo Alto, CA 94304 Orphanin FQ (ORFQ), a seventeen amino acid polypeptide isolated from rat brain that has some sequence similarity to the opioid peptides, has been suggested as the endogenous ligand for the orphan receptor ORL-1 (Opioid-like receptor 1; Reinscheid et al., 1996, Meumier et al., 1996). Intracerebroventricular (icv) administration of ORFQ in mice has been associated both with hyperalgesia in the tail-flick and hot-plate tests and with reductions in motor activity (einscheid et al., 1996, Meunier et al., 1996). Whave therefore tested the effects of icv ORFQ on tail-flick latency and motor activity in rats to determine whether the purported hyperalgesic and motor effects seen in mice can be extended across species. Male Sprague-Dawley rats (90-120 g; Harlan) were used for all experiments. For the tail-flick study, animals received direct icv injections of either vehicle (PBS) or ORFQ (0.01-10 mnol in 2 µl; n=7-8) one hr after baseline testing, At 10 and 30 min post-dose, tail-flick latencies were again assessed for each animal. Data analysis showed that none of the ORFQ treated groups were significantly different from vehicle in either the changes from pre-dose or actual post-dose latency times. To assess the effects of ORFQ on motor activity, reverse-light exceled animals received icv injections of ORFQ (0.01-10 nmol) and were immediately placed into standard perspex transfer cages equipped with San Diego Instruments Automated Cage Activity Systems. Their activity was monitored over three 15 min intervals. Analysis of the motor activity data showed that the total activity of animals receiving doses of 1.0 nmol and 10 nmol ORFQ was significantly lower than vehicle during the first 15 min interval only. While the finding that icv ORFQ inhibits motor activity indicates tha

INTRACEREBROVENTRICULAR INJECTION OF ORPHANIN FQ INDUCES

HYPERALGESIA AND ATTENUATES ACUPUNCTURE ANALGESIA IN RATS. C.B.Zhu, X.L.Zhang, S.F.Xu, X.D.Cao and G.C.Wn, State Key Lab. of Medical Neurobiology, Shanghai Med. Univ. Shanghai 200032, China.

Orphanin FQ(OFQ) is a newly discovered heptadecapeptide which is distinct from other endogenous opioid peptide in pain modulation. In the present study, the effects of OFQ on the response of rats to noxious stimulation and acupuncture analgesia were reported. The steadily increasing current was applied at tail tip of rats as noxious stimulation. The smallest intensity of the current provoking the tail-flick was recorded as pain threshold(PT). Electroacupuncture (EA) was applied at "Zu-San-Li" (St 36) and "Kun-Lun" (UB 60)points.

The results showed that the OFQ at a dose of 0.1 µg/20 µl(55 pmol, icv) has no

effect on rats' response to noxious stimulation. At a dose of $\mu g/20 \mu l(0.55 \text{ nmol})$, OFQ induces a significant decrease of PT which lasted for about 2 in(P<0.01, w control rats). EA induced obvious increase of PT in control rats, while in OFQ(1 μ g/20 μ l)-treated rats, the EA-induced increase of PT was much lower(P<0.01). When the dose of OFQ was added up to 10 μ g/20 μ l (5.5 nmol), the rats showed an obvious decrease not only in pain threshold 10-30 min after OFQ injection but also in muscular tone 30 min later. In addition, 10 µg OFQ induced ataxia in most rats.

After blocking the biogenesis of OFQ receptor with repeated icv injection of antisense oligonuciootide, the rats displayed significant increase in PT compared with saline-treated animals(P<0.01). In these rats, EA showed a better analgesic effect than in control rats(P<0.01). When the OFQ was administered (1 μ g/20 μ l) to antisense-oligo-treated rats, it showed no effect on the response of rats to noxious stimulation. In another set of experiments, the rats were icv injected with decapeptide(Arg-Lys-Ser-Ala-Arg-Lys-Leu-Ala-Asn-Gin)(1 11g/20 11), a fragment of OFQ, the animals displayed no change in pain threshold. Taken together, these data indicate that the newly discovered OFQ induces hyperreaction of rats to noxious stimulation and attenuates acupuncture analgesia.

PAIN MODULATION: PHARMACOLOGY-AMINO ACIDS, ANESTHETICS, ANTIDEPRESSANTS

ANTAGONISMOF BACLOFEN ANTINOCICEPTION BY AN aCON TO THE K+CHANNEL CODING MBKI GENE C. Chekrdini, N. Galeotti, 'S. Capaccioi, 'A. Quatrore, 'L. Papucci and A. Bartolini Deps of Pharmacology and 'Pathology, I-50134 Florence, Iraly, SPON: Eur. Brain and Behav. Soc.

The stimulation of GABAB receptors provokes the opening of several K+channels in central neurones by a PTX-inhibitable mechanism (Gähwiler and Brown, 1985). The antinociception induced by the GABAB agonist baclofen was antagonized not only by PTX pretreatment (Hoehn et al., 1988), but also by K+-channel blockers (Ocaña et al., 1993). To further investigate the role of K+-channels as intracellular effectors in baclofen-induced antinociception, the effects produced by antisense-mediated switching off of the K+-channel expression were examined in mice. A specific aODN targeting the translation start region of the MBK1 K+-channel mRNA was designed. Mice were randomly assigned to an antisense, degenerated or vehicle group. Each group received a single i.c.v. injection on days 1, 4 and 7. The effect of the aODN treatment was evaluated 72 h and 7 days after the last i.c.v. injection by using the mouse hot-plate test. The aODN (1-2-3 nmol per injection) produced, at 72 h, an antagonism of the baclofen (4 mg/kg s.c.) induced antinociception. The degenerated and vehicle treatments did not produce any antagonism of baclofen induced antinociception in comparison with naive and saline i.c.v. injected mice. This observation ruled out the possibility that the antagonism exerted by aODN could be due to an aspecific sequence-independent action on cerebral structures. A quantitative RT-PCR study demonstrated a reduction of mRNA levels only on the aODN treated group. Mice receiving the aODN treatment did not show any modification of spontaneous motility and motor coordination tested respectively by the Animex apparatus and the rota-rod. The modulation of central K+-channels represents, therefore, an important intracellular step in the antinociception induced by baclofen.

inhibition of phosphoprotein dephosphorylation enhances the RESPONSES OF CAT SPINAL DORSAL HORN NEURONS TO PERIPHERAL NOXIOUS AND NON-NOXIOUS STIMULI AND TO NMDA AND QUISQUALATE. V. Radhakrishnan* and J.L. Henry. Departments of Physiology and Psychiatry, McGill University, Montreal, Quebec.

Protein phosphorylation plays an important role in various neuronal functions. Phosphorylated proteins are dephosphorylated by protein phosphatases. The role of dephosphorylation in spinal sensory mechanisms is not known. Therefore, in the present study we tested the effect of okadaic acid, an inhibitor of protein phosphatases PP-1 and PP-2A, on the responses of spinal dorsal horn neurons to various peripheral stimuli and to the excitatory amino acids NMDA and quisqualate. Single neuronal activity was recorded extracellularly from L₂-L₂ segments of the spinal dorsal horn using multibarrelled electrodes in chloralose-anesthetized cats. Okadaic acid, NMDA and quisqualate were applied by iontophoresis. Okadaic acid did not affect the on-going activity of 34 (30 WDR and 4 non-nociceptive neurons) of the 37 neurons tested; the remaining three WDR neurons that showed an increase in excitation were not included in this study. The responses to noxious thermal stimulation (n=9) and to pinch (n=4)were enhanced by okadaic acid by 30-70%. The responses of 4 non-nociceptive and 2 WDR neurons to hair stimulation were also enhanced (20-40%), while the response of one WDR neuron was depressed (25%). The responses to a train of high intensity electrical stimulation of the superficial peroneal nerve were enhanced in $\frac{5}{2}$ (20-40%), depressed in one (30%) and unaffected in 3 WDR neurons. The responses to iontophoretic application of NMDA (n=5) and quisqualate (n=2) were also enhanced (60-90%). In general, the results indicate that okadaic acid facilitates the responses of spinal dorsal horn neurons to both noxious and non-noxious stimulation and to the excitatory amino acids NMDA and quisqualate. Thus, inhibition of dephosphorylation appears to increase the responses of dorsal horn neurons to various excitatory inputs. A corollary is that the protein phosphatases PP-1 and PP-2A may play a role in limiting the responses of dorsal horn neurons to sensory stimuli. (Supported by MRC and by NINDS)

CYCLOOXYGENASE INVOLVEMENT IN EXCITATORY RESPONSES

CYCLOOXYGENASE INVOLVEMENT IN EXCITATORY RESPONSES TO SYNAPTIC INPUTS, EXCITATORY AMINO ACIDS AND SUBSTANCE P IN RAT SPINAL DORSAL HORN NEURONES IN VIVO. G.M. Pitcher and J.L. Henry*, Depts. Physiology & Psychiatry, McGill Univ., Montreal (Quebec) H3G 1Y6 Canada.

The purpose of this electrophysiological study is to examine the effects of inhibition of cyclooxygenase (COX), which synthesizes prostaglandins from arachidonic acid, on responses of rat spinal dorsal horn neurones to synaptic inputs and to iontophoretic application of NMDA, AMPA, Quis and substance P. Male Sprague Dawley rats (325-350 g) were anaesthetized (Napentobarbital; 50 mg/kg) and the cord was cut at T9. Single unit extracellular spikes were recorded using multibarrelled micropipettes. Neurones were classified functionally on the basis of their responses to natural cutaneous stimuli. Responses to these synaptic inputs and to Neurones were classified functionally on the basis of their responses to natural cutaneous stimuli. Responses to these synaptic inputs and to excitatory amino acid and NK-1 receptor agonists were similar to those reported previously. The COX inhibitor, indomethacin (2.0-10.0 mg/kg, i.v.), preferentially depressed the excitatory responses to glutamate (n=4/4), Quis (n=8/9) and AMPA (n=7/8) but failed to alter the response to NMDA (n=6/6). Indomethacin also depressed the excitatory responses to substance P (n=5/5). In addition, indomethacin attenuated synaptically elicited nociceptive responses of WDR neurones (n=6/6), including both the initial, fast component and the late, slow afterdischarge. Responses of nonnociceptive neurones to hair stimualtion, innocuous touch and pressure were unaffected by indomethacin (n=9/9). The data indicate a selective effect of inhibition of COX on nociceptive responses of dorsal horn neurones in the unarrected by Indometration (n=9/9). The data indicate a selective effect of inhibition of COX on nociceptive responses of dorsal horn neurones in the rat. The depression of responses of these neurones to Quis, AMPA and substance P suggests that the depression of the synaptically elicited responses is mediated at least partially via an action in the spinal cord.

THE EFFECTS OF EXCITATORY AMINO ACIDS (EAAs) ON THE DISCHARGE OF ARTICULAR SENSORY RECEPTORS IN RATS. N. B. Lawand*, K. N. Westlund and W. D. Willis. Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77555-1069.

Previous behavioral experiments have shown that intraarticular injection of EAAs produce hyperalgesia and mechanical allodynia in awake rats (Lawand et al., 1996), indicating that hyperalgesia depends, in part, on EAAs that act on the peripheral terminals of primary afferent fibers. The aim of the present study is to examine the effects of these amino acids on the discharges of articular mechanoreceptors in the knee joint of anesthetized rats.

Extracellular recordings were made from the medial articular nerve in rats anesthetized with pentobarbital. Glutamate and aspartate were applied intraarterially close to the joint in concentrations of 10.9 M up to 10.3 M. Response characteristics to mechanical or chemical stimulation of articular sensory receptors were identified. Following administration of the amino acids an excitation of the primary articular afferents occurred and the responses of these fibers to mechanical stimuli of the joint was enhanced. These results provide evidence for the involvement of excitatory amino acid receptors in peripheral nociceptive transduction and suggest an important role for these receptors in the development of hyperalgesia associated with joint infammation. DOSE RESPONSE EFFECTS OF AP-5 AND NBQX ON CHRONIC CENTRAL PAIN FOLLOWING SPINAL CORD HEMISECTION. A.D. Bennett*, M.D. Christensen and C.E. Hulsebosch. Dept. of Anat. and Neurosci. and Mar. Biomed. Inst., Univ. of Texas Medical Branch, Galveston, TX 77555

Spinal cord injury (SCI) often results in dyesthesias in human patients. We recently developed a SCI mammalian model of chronic central pain in which the spinal cord is hemisected at T11 in rats and results in the development of mechanical allodynia and thermal hyperalgesia similar to that seen in humans. Excitatory amino acids could play an important role in the development of chronic central pain behavior observed after spinal hemisection. Our studies were designed to test if AP-5 and NBQX, NMDA and non-NMDA receptor antagonists, respectively, were effective in reducing behavioral symptoms of chronic central pain in rats in a dose response manner. We used accepted tests of mechanical and thermal allodynia to measure the responses to a variety of somatosensory stimuli. Supraspinal responses were tested using thermal stimuli. Our data validate earlier studies of the temporal development of both mechanical and thermal allodynia in both forelimbs and hindlimbs 21 days after hemisection and the maintenance of allodynia which persists for months. Intrathecal injections of graded doses in 10 µl volume of AP-5 or NBQX (from 200 µM to 5 mM) resulted in inhibition of mechanical and thermal allodynian in a dose dependent manner with presurgical values achieved at 5 mM doses. We interpret these data to support the involvement of NMDA and non-NMDA receptors in the development of chronic central pain. (Supported by NIH grant NS 11255 and the Kent Waldrep National Paralysis Foundation.)

NITRIC OXIDE RELEASE INTO THE KNEE JOINT CONTRIBUTES TO THE DEVELOPMENT OF HEAT HYPERALGESIA AND INFLAMMATION IN AWAKE ARTHRITIC RATS. W. D. Willis, N. B. Lawand and K. N. Westlund*. Marine Biomedical Inst., Univ. Of Texas Medical Branch, Galveston, TX 77555

Acute peripheral inflammation depends on the release of chemical mediators which produce edema formation as a result of plasma protein extravasation from the local microvasculature. Nitric oxide (NO) has been identified as a potent vasodilator "endothelium-derived relaxing factor" which is present in the endothelial cells lining the blood vessels and in neuronal tissues. NO causes vasodilatation by relaxing vascular smooth muscle via stimulation of guanylate cyclase. Previous studies have shown that inflammatory mediators induce the formation and release of NO. The aim of the present study is to investigate the involvement of NO in the peripheral processing of nociceptive information and the development of inflammation.

Male Sprague Dawley rats were anesthetized with a short acting barbiturate

(Brevital) and injected intraarticularly with a mixture of 3% kaolin and carrageenan. Paw withdrawal latency to radiant heat was tested before and at 4hrs after induction of inflammation. Immediately after the test, a nitric oxide synthase inhibitor (L-NAME; 30µg) was injected directly into the knee joint. PWL to heat stimuli was then tested at 5, 6, 7, and 8 hrs post induction of inflammation. Assessment of joint inflammation was done by measuring the knee joint circumference. Our findings show that L-NAME injected intraarticularly blocked the development of heat hyperalgesia and the inflammation on the treated side. In another experiment, nitric oxide was found to increase in the knee joint after inflammation as measured by a NO sensitive electrode. These results suggest that endogenous NO is released at the site of the inflammation, inducing vasodilatation, edema formation and mediating peripheral nociceptive transduction. A POSSIBLE ROLE FOR THE NMDA RECEPTOR-NITRIC OXIDE CASCADE IN THE ROSTRAL VENTROMEDIAL MEDULLA IN MEDIATING SECONDARY HYPERALGESIA. M.O. Urban*. S.V. Coutinho and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242.

We have recently demonstrated an involvement of descending pair facilitatory systems from the rostral ventromedial medulla (RVM) model of secondary hyperalgesia produced by mustard oil (a C-fiber excitant) measuring the spinal tail-flick reflex (TF) in awake rats. The present experiments were designed to determine a potential role for NMDA receptors and nitric oxide in the RVM in mediating this hyperalgesia. Topical application of mustard oil (20 μl, 100%) to the skin of the left hind leg produced a facilitation of the TF that was dosedependently inhibited by microinjection of the NMDA receptor antagonist APV (1-1000 fmol) in the RVM 5 min prior to mustard oil. Injection of the nitric oxide synthase inhibitor L-NAME into the RVM (100-1000 nmol) produced a similar inhibition of mustard oil hyperalgesia while the inactive enantiomer D-NAME was without effect. Additionally, NADPHdiaphorase histochemical staining revealed an increase in positive cells in the RVM following topical application of mustard oil. Injection of NMDA (1-60 pmol) alone into the RVM produced a facilitation of the TF that had a short duration (12 min) and was inhibited by prior injection of L-NAME (1000 nmol). These data suggest that activation of NMDA receptors in the RVM produces a facilitation of spinal nociception via nitric oxide and support a potential role for the NMDA receptor-nitric oxide cascade in the RVM in mediating secondary hyperalgesia produced by mustard oil. BEHAVIORAL AND ELECTROPHYSIOLOGICAL EFFECTS OF DEXTRORPHAN IN A PRIMATE MODEL OF PERIPHERAL NEUROPATHY, K. Gondesen*, S.M. Carlton, H. Rees, and W.D. Willis. Dept. of Anatomy and Neurosciences, Marine Biomedical Institute UTMB, Galveston, TX 77555-1069

This study addresses the efficacy of Dextrorphan (DEX), a non-competitive NMDA antagonist, in attenuating behavioral and electrophysiological abnormalities

antagonist, in attenuating behavioral and electrophysiological abnormalities previously documented in a monkey model of peripheral neuropathy.

In an anesthetized monkey (Macaca fascicularis), one L7 spinal nerve was tightly ligated and a sham operation performed on the contralateral side. A small laminectomy was performed and a 4 French eatheter was placed in the intrathecal space near the lumbar enlargement and connected to a small reservoir implanted subcutaneously. Compared to presurgery levels, the animal demonstrated an increased sensitivity (allodynia) on the plantar surface of the experimental foot to mechanical stimulation with von Frey hairs and brushing with a camel hair brush 4 days post-surgery. On subsequent days, a 500ul bolus injection of 10, 50 or 100nm of DEX was delivered 1T. The first test period of each day established baseline; following administration of DEX, testing was repeated at 15, 30, 60, 120 and 180 min intervals. A bolus of 50 and 100nm DEX produced a decreased response to von Frey hairs and brush on the experimental foot throughout the testing period. Responses remained decreased, taking up to 2 days to recover. The lowest dose had various effects ranging from very little or no change to increased responses. No change in muscle tone and no cognitive effects were observed at any dose.

In electrophysiology experiments, 3 doses of DEX were applied through a

In electrophysiology experiments, 3 doses of DEX were applied through a microdialysis fiber (0.1, 0.3 and 1mM). Recordings were made from WDR spinothalamic tract (STT) cells. DEX inhibited the response of STT cells to graded cutaneous stimuli (brush, press, pinch and squeeze). The inhibition was dose

dependent.

These results suggest that DEX alleviates pain behaviors resulting from nerve injury. At a cellular level, DEX modulates the central processing of STT cells. Therefore, DEX may be a suitable therapeutic drug for the treatment and management of neuropathic pain. NS11255, NS27910.

OPIATES AND OPIATE RECEPTORS IN PERIPHERAL SENSORY AXONS. S. M. Carlton*, S. Zhou, and R. E. Coggeshall. Department of Anatomy and Neuroscience and Marine Biomedical Institute. University of Texas Medical Branch, Galveston, Texas 77555-1069.

Cutaneous nerves contain opiate receptors and peripheral opiates relieve inflammatory pain. We now ask what proportion of unmyclinated cutaneous axons contain opiate receptors, whether any of the opiates themselves can be found in normal cutaneous unmyclinated axons and whether peripheral opiate ligands can block noninflammatory pain.

For the anatomical studies, blocks of skin were taken from normal rats perfused with mixed aldehydes and immunostained for either enkephalin peptide or the μ and δ opiate receptors. For the behavioral studies, rats were briefly anesthetized with halothane and the glabrous skin of the 3rd hind toe was injected with glutamate (20 μ l), either alone or co-injected with the μ receptor ligand DAMGO or the δ receptor ligand DPDPE.

The anatomical studies showed that 32% of peripheral cutaneous unmyelinated axons express the μ opiate receptor (N=3), 30% express the δ receptor (N=1) and 17% were immunoreactive for the enkephalin peptide (N=3). The behavioral studies demonstrated that peripherally administered glutamate resulted in significant pain behaviors and these behaviors were attenuated by DAMGO but not DPDPE.

We conclude that both opiate receptors and the opiate enkephalin are present in normal rat unmyelinated cutaneous axons and that peripherally administered opiate ligands can relieve glutamate-induced pain. It remains to be determined whether opiates and their receptors are colocalized and whether the proportions of axons expressing opiates and opiate receptors change in various pain states. Supported by NIH NS27910, NS10161, NS11255.

PERIPHERAL NMDA RECEPTORS PLAY A ROLE IN CAPSAICIN HYPERALGESIA. C.E. Prioleau*, R.E. Coggeshall and S.M. Carlton. Dept. of Anatomy and Neurosciences, Univ. of TX Medical Branch, Galveston, TX 77555

Anatomical evidence from our laboratory documents the presence of NMDA receptors on unmyelinated axons in the glabrous skin. Activation of these receptors by subcutaneous injection of glutamate or NMDA results in pain behaviors. Intradermal capsaicin activates unmyelinated cutaneous fibers and produces pain. The present study investigates the role of peripheral NMDA receptors in capsaicin pain.

Male Sprague-Dawley rats were briefly anesthetized with halothane and the glaborous skin of the third hind toe was injected with 10µl of either phosphate buffered saline (PBS, n=5) or the glutamate antagonist MK-801 (.001, .01, or .05mM, n=2 for each dose). Five minutes later, 10µl of capsaicin (1, 10, or 100 µg. n=3 for each dose) was given at the same site.

Compared to baseline and vehicle control scores (n=5), rats injected with PBS+capsaicin showed increased spontaneous pain as measured by an increased number of flinches, and mechanical allodynia and hyperalgesia as measured by increased responses to stimulation with von Frey filaments. These nocifensive behaviors increased in a dose dependent fashion and remained localized to the area of the injection site. Rats injected with MK-801+capsaicin showed a dose-dependent reduction in the nocifensive behaviors to near baseline levels.

These data indicate that activation of peripheral NMDA receptors contributes to the pain induced by capsaicin injection and suggests that local application of glutamate antagonists may be clinically useful for the treatment of pain. Supported by NS11255 (SMC and REC) and NS27910 (SMC).

ROLE OF EXCITATORY AMINO ACID RECEPTORS IN NERVE-INJURY INDUCED PAIN. M.L. Nichols, D. Bian, S. Wegert, M.H. Ossipov, T.P. Malan, Jr. & F. Porreca. Univ. Arizona Pain Institute, Health Sciences Center, Tucson, AZ 85724.

The present studies examine the antiallodynic effects of different classes of intrathecal (i.th.) excitatory amino acid (EAA) antagonists in a nerve ligation model of neuropathic pain in rats. Nerve injury was produced by tight ligation of the L5/L6 spinal nerves, resulting in stable and long-lasting tactile allodynia shown by a decreased threshold to paw withdrawal elicited by probing with von Frey filaments. Threshold response to thermal nociceptive stimuli were evaluated using the warm-water (55°C) tail-flick test or the radiant-heat induced foot-flick test in sham-operated or nerve-injured rats. In nerveligated rats, i.th. morphine did not alter tactile allodynia (up to 100 µg) and did not alter the withdrawal threshold to von Frey filaments in sham-operated controls. In nerve injured rats, hyperalgesia could be demonstrated in the foot, but not the tail and i.th. morphine produced antinociception in both endpoints with decreased potency and in the tail-flick test with decreased efficacy. 1.th. MK801, a non-competitive NMDA antagonist, did not affect allodynia at non-behaviorally toxic doses (i.e., up to 3.5 μ g) or produce antinociception in tail-flick or foot-flick endpoints. Pretreatment with *i.th.* MK-801, however, restored antiallodynic efficacy of *i.th.* morphine and increased the antinociceptive potency and efficacy of i.th. morphine in the tail-flick test. Presuppression of foot hyperalgesia with i.th. MK-801 did not alter the potency of i.th. morphine to suppress the foot-flick response. Allodynia was unaffected by i.th. metabotropic antagonist, (L)-AP3. In contrast, CNQX, a competitive AMPA antagonist, produced doserelated antiallodynic actions with an A_{50} value (95% C.L.) of 0.7 (0.4-1.3) μg ; no behavioral toxicity was evident in CNQX treated rats over this dose range. These data suggest that (a) allodynia associated with peripheral nerve injury results, in part, from activation of EAA receptors and that such activity limits the antiallodynic and antinociceptive effects of opioids, and (b) that blockade of AMPA receptors can directly block the evoked allodynia associated with nerve injury. PERIPHERAL GLUTAMATE AND SUBSTANCE P RECEPTORS PLAY A ROLE IN PAIN BEHAVIORS. S. Zhou* and S. M. Carlton. Marine Biomedical Institute. Univ. of Texas Medical Branch. Galveston TX 77555

Institute, Univ. of Texas Medical Branch, Galveston, TX 77555.

Our previous work has shown that injection of glutamate (GLU) or its agonists into rat glabrous skin induces mechanical allodynia and mechanical hyperalgesia. It is unknown what role, if any, peripheral GLU receptors plays in the generation of heat hyperalgesia and spontaneous pain. Furthermore, it has been previously reported that substance P (SP) can enhance GLU-induced activity in the spinal cord. The presence of SP receptors on peripheral axons suggest that a similar mechanism may exit in the skin. In the present study we demonstrate a role for NMDA, non-NMDA and SP receptors in peripheral pain mechanisms.

A total of 120 male Sprague-Dawley rats (320-380g) were used in this study. Mechanical (von Frey filaments, bending forces of 6.7, 10.4, 18.8 and 39.2 mN) or thermal (44°C hot water) stimuli were applied to the tail of each rat. GLU (RBI, 5mM), SP (RBI, 0.01mM), phosphate buffered saline (PBS) and combinations of Glu+SP, Glu+MK-801 (0.01mM) and Glu+CNQX (0.1mM, 0.3mM) were injected (20 ul) subcutaneously, 5.5-6cm from the tip of the tail.

The results show: 1) injection of GLU alone results in the generation of

The results show: 1) injection of GLU alone results in the generation of mechanical allodynia, mechanical and heat hyperalgesia. 2) MK-801 and CNQX reduced these GLU-induced behaviors, 3) compared to the injection of GLU alone, SP+GLU resulted in enhanced pain behaviors, including the generation of spontaneous pain (tail flicks in the absence of any stimuli).

The data indicate that peripheral NMDA and non-NMDA receptors play a role not only in mechanical allodynia and hyperalgesia, but also in heat hyperalgesia. Furthermore, similar to central mechanisms, SP can potentiate GLU-induced pain in the periphery. (Supported by NS11255 and 27910 to SMC).

PERIPHERAL NMDA RECEPTORS CONTRIBUTE TO THE PAIN BEHAVIORS OBSERVED IN THE RAT FORMALIN TEST. E. M. Davidson. S. L. Knock and S. M. Carlton. Marine Biomedical Institute. University of Texas Medical Branch, Galveston, TX 77555.

Previous work in our laboratory has demonstrated the presence of peripheral

Previous work in our laboratory has demonstrated the presence of peripheral NMDA receptors on unmyelinated axons in the glabrous skin of the rat. Moreover, glutamate or NMDA injected peripherally have been shown to induce pain behaviors which are attenuated by MK-801, an NMDA antagonist. The present study investigated the involvement of NMDA receptors in the pain behaviors observed in the formalin test, a well-known and frequently used pain model.

Male Sprague-Dawley rats were briefly anesthetized with halothane and the glabrous skin of the 3rd hind toe was injected with either 30µl phosphate buffered saline (PBS, n=5) or MK-801 (0.001mM, n=6). Ten minutes later. 15µl of 5% formalin was injected in the same area. Pain behaviors were assessed for 30 minutes post-injection by measuring time spent licking and/or elevating the injected paw, and counting flinches during 5 minute intervals.

Compared to baseline, rats injected with PBS+formalin demonstrated significant increases in both pain behaviors. In contrast, rats treated with MK-801+formalin showed less time licking/clevating the injected paw compared to PBS+formalin, however, the number of flinches was not significantly different between the 2 groups. MK-801+formalin rats showed decreased pain behavior during the second but not the first phase of the formalin test.

These results suggest that peripheral NMDA receptors play a role in pain perception, contributing to formalin-induced pain and possibly inflammatory pain. (Supported by NS11255 and NS27910 to SMC).

SUBCUTANEOUS CO-INJECTION OF LIDOCAINE AND DEXTROMETHORPHAN GIVE A PROLONGED ANALGESIC BLOCK. J. K. Birknes¹, B.S., M. Vladimirov¹, M.D., Ph.D., Donald Johnson², Ph.D., F. S. Caruso², Ph.D., and G. R. Strichart², Ph.D.,* (1)Pain Research Group, Dept. of Anesthesia Research Laboratories, Harvard Med. Sch., Brigham and Women's Hospital, Boston, MA 02115 and (2)Algos Pharmaceuticals Corp., Collingwood Plaza, 4900 Route 33, Neptune, NJ 07753-6804

The effectiveness for cutaneous analgesia of dextromethorphan hydrobromide (DM*HBr; F.W.=370.3), a noncompetitive antagonist of the N-methyl-D-aspartate receptor, and lidocaine hydrochloride (LID*HCl: F.W.=270.8), alone and in combination, was investigated in conscious unanesthetized male Sprague- Dawley rats and Dorcet-cross sheep. The cutaneous trunci muscle reflex (CTMR), characterized by twitches of the lateral thoraco-spinal muscles in response to a brisk pinch of the overlying skin, was used as an indicator of nociception. The degree and duration of CTMR inhibition was estimated at regular intervals after subcutaneous injection of 0.6 mL of drug solution in the rat. The dose dependence of duration for LID showed that 1.25 mg/ml led to an incomplete block of the CTMR with partial inhibition lasting for 26.3 \pm 2.0 min ($\overline{X}\pm$ S.E., n=15), while 1.75 mg/ml DM produced a complete block of CTMR for 62.5 \pm 6.5 min and partial inhibition for 270.0 \pm 41.8 min (n=6). Co-injection of LID and DM at these doses resulted in a complete block for 112.5 \pm 19.6 min and a partial inhibition of the CTMR for 18.7 \pm 3.0 hours (n=6). Similarly, in the sheep, subcutaneous injection of 7 mL of 20 mg/ml LID abolished the CTMR for 30 min, with full recovery occurring at 420 min (n=8). Co-injection of this LID dose and 7 mg/ml DM abolished CTMR (94.4 \pm 5.6% inhibition) for 180 min with complete recovery at 22 hrs (16.7 \pm 8.3% inhibition, n=9). Altogether these results show a 4-6 fold potentiation in duration of LID induced analgesia by DM. We conclude that this may represent a new mechanism of peripheral analgesia that would be promising for clinical application. Supported by a grant for Algos.

VOLATILE GENERAL ANESTHETICS AFFECT A NEURAL PATHWAY IN *DROSOPHIL4* . Meigiu Lin* and Howard A. Nash. Lab. of Molecular Biology, National Institute of Mental Health, Bethesda, MD 20892.

The identity of the physiologically relevant target(s) of general

anesthetics remains controversial. In previous studies we have shown that a neural component of the startle response of Drosophila is sensitive to the general anesthetic halothane and that its sensitivity is affected by genetic alteration of a potassium channel. The sensitive component contributes to the long-latency $(4.34 \pm 0.06 \text{ msec})$ response, measured as the time between application of an electrical stimulus across the fly's eyes and the appearance of an evoked potential in the muscles that effect the escape behavior. In contrast, responses with intermediate (2.23 \pm 0.04 msec) or short (1.43 \pm 0.02 msec) latencies are much less sensitive to halothane. To localize the portion of the brain that is unique to the long-latency response, we determined the positions of stimulating electrodes that permit the occurrence of this response and compared them to positions which only permit shorter responses. The long-latency response is obtained only when electrodes remain in the retinal layer and fail to penetrate into the optic lobe. This strongly suggests that the anesthetic-sensitive component lies in the visual pathway that connects the lamina with the Col A neurons that innervate a descending giant fiber. Three other general anesthetics: methoxyflurane, enflurane, and desflurane, are also differentially effective in inhibiting the long-latency response. As with halothane, their potency correlates well with their effectiveness in inducing gross behavioral changes.

SPINAL GABAPENTIN IS ANTINOCICEPTIVE IN THE RAT FORMALIN TEST. N. Shimoyama, M. Shimoyama, A.M. Davis, C.E. Inturrisi and K.J. Elliott*. Dept. of Pharmacology, Cornell U. Med. Coll. and Pain Research Program, Dept of Neurology, MSKCC, NY, NY 10021.

Anticonvulsants have analgesic properties and are used in the management of pain in patients (Elliott, 1995). Gabapentin is a new anticonvulsant (MacDonald, 1994) that interacts with a CNS L-type Na+-independent amino acid transporter (Su, 1995). Clinical experience (KJE) and case reports suggest gabapentin has analgesic properties in patients (Mellick 1995, Segal 1996). To determine whether gabapentin has antinociceptive properties through a spinal action, pretreatment with gabapentin prior to the formalin test, a model of central sensitization, was examined. Gabapentin, 6, 20, and 60 ug, or saline in a volume of 5 ul was administered intrathecally 10 minutes prior to the injection of intraplantar formalin to SD rats. In the saline-pretreated animals, formalin produced a stereotypical behavioral response consisting of flinching and licking of the injected paw. Gabapentin at the dose of 6 ug, did not affect flinching or licking behavior as compared to saline control. Gabapentin at 20 ug and 60 ug decreased flinching and licking behaviors as compared to saline control in a dose-dependent manner. At 20 ug, gabapentin pretreatment decreased flinching by 50% and licking by 30%. At 60 ug, gabapentin decreased flinching by more than 60% and decreased licking by more than 90%. These results indicate that spinal gabapentin is antinociceptive, possibly via an enhancement of inhibition through a gaba-ergic mechanism. ANTAGONISM OF CLOMIPRAMINE AND AMITRIPTYLINE INDUCED ANALGESIA BY AN AODN TO THE MBK1 GENE N. Gakoti. C. Grekardini. 'S. Caraccioli. 'A Quatrone. 'I. Papucci and A Bartolini Depts of Pharmacol and 'Pathol, 1-50)34 Florence, Italy, SPON: Eur. Brain and Behaw. Soc.

PTX-sensitive G-proteins are responsible for inhibition of adenylate cyclase activity and modulation of several K+ and Ca²⁺ channels (Hille, 1994). The tricyclic antidepressant (TCAs) drugs clomipramine and amitriptyline are able to produce antinociception by activating the serotoninergic system that provokes the activation of a PTX sensitive G-protein (Galeotti et al., 1996). In order to investigate whether K+-channels are involved in clomipramine and amitriptyline induced antinociception, the effects produced by an aODN to the K+-channels were examined in mice. A specific aODN targeting the translation start region of the MBK1 K+-channel mRNA was designed. Mice were randomly assigned to an antisense, degenerated or vehicle group. Each group received a single i.c.v. injection on days 1, 4 and 7. The effect of the aODN was evaluated 72 h and 7 days after the last i.c.v. injection by using the mouse hot-plate test. The aODN (1-2-3 mmol per injection) produced, at 72 h, a dose-dependent antagonism of clomipramine (25 mg/kg s.c.) and amitriptyline (20 mg/kg s.c.) induced antinociception. The antagonism of TCAs induced analgesia disappeared at 7 days indicating a lack of irreversible damage or toxicity by the aODN treatment. The degenerated and vehicle treatments did not produce any antagonism of the TCA induced antinociception in comparison with naive and saline i.c.v. injected mice. This observation ruled out the possibility that the antagonism exerted by aODN could be due to an aspecific sequence-independent action on cerebral structures. Moreover, a quantitative RT-PCR study demonstrated a reduction of mRNA levels only on the aODN treated group. These results indicate that the modulation of K+-channels is an important intracellular step in clomipram intracellular step in clomipramine and amitriptyline antinociception. PRESENCE OF INHIBITORY CUTANEOUS RECEPTIVE PREDICTS DIFFERENTIAL EFFECT INTRAVENOUS LIDOCAINE ON HEAT-EVOKED SPINAL NEURONAL RESPONSES, <u>T.J.Ness</u>*. Dept. Anesthesiology, University of Alabama at Birmingham (UAB) Birmingham, AL 35294

Intravenous lidocaine has previously been demonstrated to have a differential inhibitory effect on two classes of neurons excited by a visceral stimulus, colorectal distension (NS Absts 20:135.13). One feature which differentiated these two neuronal groups was the presence or absence of inhibitory cutaneous receptive fields.

The present study examined the effects of intravenous lidocaine on lumbosacral spinal neurons excited by radiant heating of the hind paw. Extracellular recordings were made from sixteen L3-L5 dorsal horn neurons in spinally transected, decerebrate rats. Neurons were characterized for excitatory and inhibitory responses to nonnoxious (brush, heat) cutaneous stimuli; eight neurons were inhibited by noxious cutaneous stimuli applied to nonsegmental sites; the other eight had only excitatory receptive fields

Consistent (± 20% on 3 trials) excitatory responses to 50°C, 15 s radiant heating of the ipsilateral hind paw were determined. Cumulative doses of intravenous lidocaine (0.25, 1 and 4 mg/kg) were administered at 16 minute intervals and repeat heating trials performed every 4 minutes. Similar to studies of neurons excited by colorectal distension, intravenous lidocaine produced a dose-dependent inhibition of heat-evoked neuronal responses that was significantly greater in neurons without inhibitory cutaneous receptive fields.

EFFECTS OF ANTIDEPRESSANTS ON THE C-FIBER-EVOKED NOCICEPTIVE REFLEX IN RATS C. Mestre**, T. Pelissier,
A. Hernandez* and A. Eschalier* Dept. of Anesthesia & Critical Care, Univ. of Chicago, USA, Dept. of Pharmacol., Faculty of Medicine, Univ. of Chile, Santiago, Chile; Dept. of Pharmacol., Faculty of Medicine, Clermont-Ferrand, France.

Results from experimental and clinical studies indicate that antidepressants have specific analgesic effects which appear to be independent of the antidepressant efficacy. To determinate the site of this antinociceptive action, the effect of clomipramine (CMI) and desipramine (DES), two antidepressants which inhibit the reuptake of serotonin and norepinephine, respectively, was studied in male Sprague-Dawley rats, after intravenous (i.v.), intrathecal (i.t.) or intracerebroventricular (i.c.v.) administration. The C-fiber-evoked reflex was examined. Electromyographic activity was measured in the biceps femoris muscle elicited by electrical stimulation of the ipsilateral sural nerve receptive field in urethane anesthetized rats. The results demonstrate that, following i.v. administration, both antidepressants produced a dose-dependent depression of the C-fiber reflex (-50±9 and -43±5% for CMI and DES, respectively) I.t. administration of the highest dose of DES inhibited the C-fiber reflex (-32±5% vs. i.t. saline), whereas CMI produced only a small decrease (-16±3% vs. i.t. saline). After i.c. v. injection, only CMI produced a dose-dependent depression of the C-fiber reflex (-91±7% vs. i.t. saline). The results suggest that these drugs mediate their antinociceptive effects via distinct central site depending on their monoaminergic profile. Antidepressants that inhibit serotonin reuptake may act at the supraspinal level, probably by activating the bulbospinal inhibitory pathway, whereas antidepressants that inhibit noradrenaergic reuptake may act at a spinal site.

ENTRAINMENT OF RHYTHMIC BURSTING INDUCED BY BLOCK OF SYNAPTIC INHIBITION IN THE NEONATAL RAT SPINAL CORD E. Bracci, M. Beato, L. Ballerini* and A. Nistri, Int Sch Adv Studies (SISSA), 34013.

Spinal networks are able to provide the basic features of motor rhythmic patterns which are modulated by proprioceptive and sensory inputs. A highly regular pattern of motoneuronal bursting develops in the rat spinal cord in vitro after simultaneous block of GABA, and glycine receptors by bicuculline (20 µM) and strychnine (1 μM), respectively. Such bursts, comprising several intraburst oscillations, appear spontaneously with an average duration of about 7 s and an average frequency of about 2/min. We studied if dorsal root stimulation could entrain such a rhythmic bursting. Bursts were recorded either intracellularly from individual lumbar motoneurons or extracellularly from lumbar ventral roots. A single stimulus (0.1 ms; 5-10 V) to a lumbar dorsal root during interburst quiescent period elicited a burst with duration and oscillatory structure dependent on the interval from the end of the last spontaneous burst; closer stimulations elicited shorter and less structured events. Trains of stimuli were able to entrain bursting at frequencies ranging from 0.05 to 1.0 Hz. When stimulations were delivered at higher frequencies they still elicited a short reflex response. At such stimulation rates, however, bursts developed at low frequency independently of external inputs. In the range of intervals in which the entrainment was possible, burst duration and number of intraburst oscillations decreased as stimulation frequency increased. At the maximum frequency compatible with entrainment, burst duration was reduced to 25-8 % of the one of spontaneous events. Thus, in the absence of synaptic inhibition, spinal networks exhibited a high degree of adaptability of their rhythmic motor response to dorsal root synaptic inputs, although at high stimulation rates they generated bursts unrelated to reflex activity. CHEMICAL MICROSTIMULATION IN BRAIN LOCOMOTOR REGIONS IN LARVAL LAMPREY. A. Hagevik*, A. Oxner McGaha, and A.D. McClellan, Div. of Biological Sciences, Univ. of Missouri, Columbia, MO 65211

In the present study, chemical microstimulation, using pressure ejection of excitatory amino acids (EAA) or their agonists, was used to map brain locor regions in larval lamprey (Petromyzon marinus). In vitro brain/spinal cord preparations (n = 10) were used, and locomotor activity was recorded from ventral roots. During the experiment, effective stimulation sites were marked with Alcion blue to determine their proximity to descending brain neurons and the trigeminal system, which were labeled prior to the experiment with HRP.

Diencephalon. Microstimulation with EAA or their agonists in the lateral of the diencephalon, near the Di cell group, elicited spinal locomotor activity but usually with delays greater than 10 s.

Mesencephalon. Chemical microstimulation with D-glutamate, L-glutamate, kainate, or quisqualate in the lateral part of the mesencephalon as well as near the MRN cell group elicited spinal locomotor activity with short latency.

 $\underline{\textit{Rhombencephalon.}} \quad \textit{The most effective locomotor regions were in the lateral}$ areas of the rostral rhombencephalon in the alar plate. However, short latency otor activity could also be elicited in or near the ARRN and sometimes the MRRN. Stimulation in the PRRN usually elicited tonic spinal motor activity

In summary, in the mesencephalon, effective chemical microstimulation sites probably represent higher order locomotor control centers, such as the mesencephalic locomotor region (MLR). In the rhombencephalon, lateral locomotor regions may correspond to sensory pathways (e.g. trigeminal) that have inputs to brainstem locomotor centers. At least some of the descending neurons that activate spinal locomotor networks appear to reside in the ARRN and MRRN. The functional relationship between these various areas is yet to be determined. STEPPING MOVEMENTS IN PARAPLEGIC PATIENTS INDUCED BY EPIDURAL SPINAL CORD STIMULATION

Y Gerasimenko¹, WB McKay, FE Pollo, MR Dimitrijevic*
Division of Restorative Neurology and Human Neurobiology, Baylor College of Pavlov Institute of Physiology, St Petersburg, Russia.

In this report, we summarize our findings in five complete paraplegic patients

recorded during sustained tetanic stimulation of the posterior structures of the lumbar spinal cord. Subject ages ranged from 18 to 43 and spinal cord lesions were between C5 and T7. They all retained spinal motor neuron reflex excitability. Stimulation was delivered through a 4 electrode catheter celectrodes 1 or 3 cm apart) introduced into the epidural space between the T11 and T12 vertebrae. By stimulating the posterior portion of the lumbar spinal cord with single stimuli at 1 Hz, we documented the location and adjusted it to be within the L2-L3 segments by eliciting muscle twitches from the quadriceps and

Stepping movements and electromyographically recorded patterns of motor unit activity were observed most frequently when the cathode was over L2-L3 spinal cord segments, stimulus frequency was 20 to 50 Hz, pulse width between 0.3 and 1 ms and a strength of 5.5 to 8.5 mA was provided. The frequency of stepping movements and EMG bursts elicited was about 0.3 Hz. In addition, we found that the interval between the onset of tetanic stimulation and the appearance of movements was in the range of 5 to 7 seconds. After cessation of stimulation, rhythmic EMG activity could persist for up to 8 seconds.

These observations are consistent with our previous report that stepping

movements can be obtained with continuous tetanic input to the spinal cord in paraplegics (Rosenfeld et al, Abstr 21:688, 1995).

SIMULATION OF SPINAL SEGMENTAL REFLEXES: THE ALTERNATE GOLGI REFLEX D. P. Bashor* and S. M. Merkel Dept. of Biology, UNC Charlotte, NC 28223

A simulation system was used to investigate the neuronal interactions of stretch (IA), classical Golgi tendon (IB), and "alternate" IB reflexes. The simulation consisted of 14 cell and 6 fiber populations (100 elements each) representing a pair of antagonistic motoneuron (MN) populations with their associated paired IN populations: Renshaw, IA and IB INs, and excitatory and inhibitory IN pools. A pair of Alternate IB IN populations provided MN excitation. Fiber inputs included paired IA and IB afferents, tonic descending excitation to all cell populations, and a "modulator" used to vary the excitability of the Golgi-related populations. The force output of the MNs was estimated by an "activity index", the product of fraction of cells active and the mean spike frequency. In a representative experiment, the baseline agonist-antagonist activity index ratio was 10:10. Activation of agonist IA afferents alone changed this ratio to 34:4. The agonist IB fibers were then activated at the same time as the IA afferents. By modulating the relative excitability levels of the "classical" IB IN and the "Alternate" IB IN populations, a range of activity index ratios were achieved, from those in which agonist IB activation reduced the agonist-antagonist difference ("classical" effect), to those in which IB activation increased the agonist-antagonist difference ("alternate" effect) Supported by UNC Charlotte.

ESTIMATION METHODS IN LOCOMOTION NETWORK ACTIVITY. J. Tabak, C.R. Murphey, and L.E. Moore*. Phys. & Biophys., UTMB, Galveston, TX 77555, and Eq. Neurobiol., CNRS URA 256, Univ. Rennes 1, France. In previous studies using the simple neural network model of Roberts & Tun-

stall (1989, 1995), we demonstrated critical influences of the voltage-dependent activation of NMDA receptor channels in controlling fictive swimming of Xenopus embryos, including stabilization of alternating versus synchronous activity, rhythmic activity without inhibition and struggling-like behavior. Nonlinear estimation methods were applied to single cell and network responses in order to more quantitatively determine the role of cellular electrotonic structure, voltagedependent channel kinetics and synaptic properties. Current-clamp responses and frequency-domain driving point admittance measurements were fitted to a Rall-type Hodgkin-Huxley model to estimate both the passive electrotonic structure of the cell and the voltage-dependent channel activation kinetics

1) In analysis of model-generated data, frequency domain method proved more accurate in obtaining estimates in a lumped soma/dendritic cable model with potassium and sodium voltage-gated conductances. 2) Problems of nonuniqueness for either the time- or frequency-domain analysis alone can be sig-nificantly reduced by simultaneously fitting of both time- or frequency-domain data. 3) Comparisons across data sets from individual cells showed a) changes in leakage resistance with time attributed to membrane recovery from microelectrode penetration, or b) discrepancy for the activation kinetics of the potassium conductance, suggesting that a current having different effects on the two kinds of measurements was left out of the model.

Cluster analysis of solutions reveals relationships between the parameters and sensitivity analysis shows which parameters are likely to be well estimated. Network "training" methods were also used in order to obtain estimates of synaptic parameters from measurements of swimming activity.

MOTOR OUTPUT ELICITED BY CONTINUOUS EPIDURAL STIMULATION IN PARALYZED SPINAL CORD INJURED HUMANS

FE Pollo*, WB McKay, Y Gerasimenko¹, MR Dimitrijevic
Division of Restorative Neurology and Human Neurobiology, Baylor College of
Medicine, Houston, Texas; ¹Paylov Institute of the RAS, St Petersburg, Russia.

Five spinal cord injured subjects with neurophysiologically documented complete lesions between C5 and T7 were studied 15 to 65 months post injury Catheters containing 4 electrodes, 1 or 3 cm apart, were introduced into the epidural space overlying the lumbosacral spinal cord. Electrical stimulation ranging in frequency from 1 to 80 Hz and amplitude of up to 30 mA was applied. Stimulus rates below 20 Hz brought muscle 'twitch' responses with no patterning. However, stimulus frequencies above 20 Hz elicited a variety of movements and motor unit activation patterns. Movements produced included uni-and bilateral withdrawal, extensor, cross-extensor and stepping movements in the supine position. Patterns of motor unit activation were categorized as: tonic activation of one or more muscle groups; bursting of one or more muscle groups at a frequency of 0.3 to 0.5 Hz that could be simultaneous or reciprocal about a single

joint, proximal or distal, or multiple joints, afternating between the two lower limbs with patterns resembling those recorded during locomotion.

These results suggest that depending on the stimulus site and parameters, multi-muscle activation patterns resembling those recorded during ambulation and stepping movements can be elicited in humans paralyzed by spinal cord

Funding provided by the V.L. Smith Foundation for Restorative Neurology and The Kent Waldrep Institute for Paralysis Research.

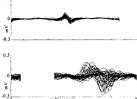

CENTRAL MODULATION OF EMG RESPONSES TO SPINAL CORD STIMULATION. AM Sherwood* JA Halter. DC Lee. WB McKay. Y Gerasimenko! MR Dimitrijević Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston TX 77030, (¹from: Pavlov Institute, St Petersburg, Russia).

Continuous stimulation of the posterior aspect of the lumbosacral spinal cord through epidural electrodes has been shown to elicit alternating patterns of locomotor-like EMG activity in spinal cord injured humans [Rosenfeld et al., Abstr 21:688, 1995]. We studied this motor output in five paralyzed spinal cord injured individuals, whose lesions were from C5 to T7, sustained 18 to 65 months before the study. Surface electrodes were used to record over major muscle groups of the legs. Spinal cord stimulation (SCS) through electrodes at vertebral level L1 activated the spinal motor neuron pool, recordable as surface electromyographic activity. Two sets of 100, successive, superimposed, tibialis anterior responses to stimulation with a 25 ms period (at t=0) are shown. For clarity, portions of the traces with responses to stimuli at t=+25 ms (upper) and at t=-25 ms (lower), respectively, were excluded. Synchronous responses (upper) suggest relatively direct activation of the motor pool, which were also constant in amplitude. Changing conditions, here, changing stimulus current from 4.1 ma (upper) to 5.1 ma (lower), resulted in less synchronous lower amplia.

resulted in less synchronous, lower amplitude, delayed (*8 ms), less consistent responses. The lower trace activity was taken from the midst of a 2 second burst, representative of burst patterns with periods of

We suggest that a spinal pattern generator activated by the SCS was responsible for modulation of the response.

Reflex Pathway Modulation in FDL and EDL Motoneurons Differs During Fictive Scratching Versus Locomotion in the Cat. A.M. Degtyarenko, E.S. Simon*, T. Norden-Krichmar and R.E. Burke. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892

Our laboratory has shown that disynaptic cutaneous EPSPs (central latency ≤ 2.0 ms) in flexor digitorum longus (FDL) motoneurons (MNs) by low-threshold (2xT) superficial peroneal (SP) afferents are powerfully enhanced during the early flexion phase of fictive locomotion (Exp Br Res 83:489, 1991). Last year, we reported that disynaptic IPSPs from SP are similarly enhanced in extensor digitorum longus (EDL) MNs during the flexion phase (SN Abstr #171.4, 1995). In contrast, disynaptic EPSPs produced by the medial plantar nerve (MPL) are suppressed during the flexion phase of locomotion in both FDL and EDL MNs. All three sets of disynaptic PSPs are due to distinct sets of last-order interneurons. We have found that modulation of these cutaneous reflex pathways is quite different during fictive scratching. The disynaptic (latencies > 2.0 ms) SP PSP components (EPSPs in FDL and IPSPs in EDL MNs) exhibit some modulation with scratching phase but are nevertheless smaller than during rest. However, fictive scratching does not suppress transmission in all disynaptic pathways; disynaptic group I EPSPs exhibit similar enhancement during the flexion phase of both fictive locomotion and scratching in both FDL and EDL MNs, during periods when the motoneurons are depolarized and active. These observations suggest that different spinal circuits are involved in the generation and transmission of rhythmic neural output during fictive locomotion versus scratching.

543.11

RHYTHMICAL EMG ACTIVITY RECORDED IN JAW OPENER AND CLOSER MUSCLES. USING JAW ATTACHED ISOLATED BRAINSTEM PREPARATION IN VITRO. <u>S.TANAKA, M.KOGO*, T.MATSUYA and S. H. CHANDLER</u>. The First Dept. of Oral & Maxillofacial Surgery, Osaka Univ., Faculty of Dentistry. Dept. of Physiological Science, Univ. of California, Los Angeles, 90024.

Our previous study showed rhythmical trigeminal activity can be elicited in isolated brainstem preparation in vitro. We used 0 to 2-day-old neonatal Splague Dawley rats deeply anesthetized with halothane. The preparation and recording were performed in the recording chamber with modified Krebs solution, which were equilibrated with 95% O2 and 5% CO2. Bath application of NMA and bicuculline elicited rhythmical jaw movements. Rhythmical EMG activities were recognized in jaw opener (digastric) and jaw closer (masseter) muscles. Bilateral synchrony was recognized in each muscle. However, no synchrony was found between digastric and masseter activities. It is likely that two coupled rhythm generating circuits related to trigeminal activity exist in the brainstem: One for jaw closing (masseter) and the other for jaw opening (digastric).

CENTRAL PATTERN GENERATOR IN HUMAN: MOTOR RESPONSES EVOKED BY AND SPINAL CORD EVOKED POTENTIALS RECORDED FROM EPIDURAL ELECTRODES AT DIFFERENT LOCATIONS MR Dimitrijević, JA Halter*, Y Gerasimenko¹, AM Sherwood and WB McKay Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston TX 77030, (¹from: Pavlov Institute of Physiology, St Petersburg, Russia)

A previous study has demonstrated that it is possible to elicit patterned activity resembling stepping in the lower extremities of chronic spinal cord injured humans through continuous stimulation of the posterior aspect of the lumbosacral spinal cord using epidural electrodes [Rosenfeld et al., Soc. Neurosc. Abstr 21:688, 1995]. Furthermore, the location of the epidural electrodes and the stimulus intensity were found to significantly effect the character of the patterned motor activity. In this study, we extend these early observations and also examine the character of the motor responses to single stimuli and the properties of spinal cord evoked potentials (SCEPs) recorded via the epidural electrodes. As described in a companion study (Pollo et al., this volume) the motor responses in five paralyzed spinal cord injured individuals were examined. SCEPs were recorded from the epidural electrodes resulting from electrical stimulation to the tibial nerve at the popliteal fossae (duration: 0.5ms, rate: 3.1pps and supramaximal to soleus activation). In one case, with the cathode at the lower T12 region and anode at the upper T12 region, the motor responses resulting from spinal cord stimulation at low rates (1pps) could be seen to recruit proximal musculature preferentially whereas stimulation at higher rates (30pps) was seen to preferentially recruit patterned activation of the distal musculature. The SCEPs showed a maximal postsynaptic potential present between the cathode and anode. Correlation was seen in the amplitudes of SCEPs with left versus right tibial nerve stimulation and the activation of left versus right motor responses at 1pps whereas the patterned activity evoked by higher stimulus rates sometimes showed a opposite relation. Supported by the Vivian L. Smith Foundation for Restorative Neurology and Kent Waldrep Institute for Paralysis Research.

Patterns of Reflex Modulation are Markers for the Structure of the Central Pattern Generator for Locomotion in the Cat. R. E. Burke*, A. M. Degtyarenko and E. S. Simon. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892-4455
Our laboratory has demonstrated robust enhancement of disynaptic

Our laboratory has demonstrated robust enhancement of disynaptic EPSPs in flexor digitorum longus (FDL) and of disynaptic IPSPs in extensor digitorum longus (EDL) motoneurons during the early flexion phase in well-developed fictive locomotion after stimulation of low threshold afferents in the superficial peroneal (SP) nerve (Exp. Brain Res. 71:568, 1988; 83:489, 1991; SN Abstr #171.4, 1995). Such stereotyped associations between cyclic motoneuron activity and cutaneous disynaptic pathway modulation results from convergence of state-dependent output from the locomotor central pattern generator (CPG) onto specific sets of last-order interneurons. The patterns provide information about the structure of the CPG as well as about the organization of reflex pathway interneurons. For example, FDL motoneurons occasionally fire strongly during the extensor phase of fictive stepping, with or without the normal bursting during early flexion, and with no change in cyclic activity in other muscles. Disynaptic SP EPSPs are not enhanced during such extensor phase firing and exhibit degrees of flexor phase enhancement that vary directly with the level of remaining flexor phase FDL activity. This suggests that CPG output to the FDL and the SP pathway interneurons is tightly linked during early flexion and can be bypassed under some locomotor states. In addition, we have found that the same patterns can often be found during bouts of fictive stepping that are irregular or incompletely developed. These "natural experiments" provide examples that allow identification of specific subfractions of the flexion phase during fictive locomotion.

543.12

GASP-LIKE ACTIVITY IN THE TRANSVERSE RHYTHMIC SLICE PREPARATION OF MICE. J.M. Ramirez*, P. Telgkamp, F.P. Elsen and D.W. Richter. Department of Physiology, University of Göttingen, 37073 Göttingen, FRG.

The transverse brainstem slice containing the pre-Bötzinger complex (pBC) has been used as an *in vitro* model for studying the central respiratory system of rats (Smith et al. 1991. Science 254: 726) and mice (Funk et al. 1994. J. Neurophys. 72: 2538; Ramirez et al. 1996. J. Phys. 429: 599). This preparation generates spontaneous rhythmic activity that can be recorded as output-activity from hypoglossal (XII) rootlets. It is assumed that this activity reflects the eupneic respiratory motor output which is in phase with inspiration. We performed selective lesioning experiments in medullary slice preparations obtained from 2 to 3 week old mice (P14-21). At this age anatomical landmarks, such as the nucleus ambiguous, are clearly visible under the dissecting microscope. Following removal of the pre-Bötzinger complex of one side, rhythmic activity was abolished in 5, but persisted in 4 preparations. In these preparations, the amplitude of XII rhythmic activity was decreased, but the shape of integrated activity was not significantly changed. Upon removal of the pre-Bötzinger complex of both sides, rhythmic XII activity ceased in all examined cases. In 5 out of 9 pre-Bötzinger complex lesioned preparations, bursts of hypoglossal activity could still be elicited in response to hypoxia or during recovery from hypoxia. However, these bursts were different from those generated during eupneic conditions: the onset of XII activity was nuch steeper and the amplitude of integrated XII activity exceeded that observed under eupneic conditions. We never observed such high-amplitude, gasp-like bursts in the presence of the pre-Bötzinger complex. Thus, we hypothesize that the respiratory center inhibits gasp activity under normoxic conditions. This hypothesis is supported by the finding that similar bursts were generated following blockade of GABAergic inhibition with 20µM bicucculline.

OPTIMIZING THE TORQUE-TIME CURVE IN HUMAN PARALYZED MUSCLE USING FORCE-FEEDBACK CONTROL R.K. Shields*, Y.J. Chang. Physical Therapy Graduate Program, University of Iowa, Iowa City, IA 52242

Four stimulation strategies have been described when activating paralyzed muscle. According to the force-frequency curve, increasing the frequency of stimulation (HF) causes increased force on the linear segment of the curve (Shields and Chang, 1996). Reducing the frequency (LF) is effective when neuromuscular transmission is compromised (Jones, 1981). A variable frequency stimulation (VFT) enhances force by a catch-like property (Binder-Macleod, 1992; Chang and Shields, 1995) while a constant frequency (CFT) is the usual method for activating paralyzed muscle. At what point one strategy becomes more effective than the other during repetitive activation (fatigue) has not previously been assessed. We used real time force-feedback to trigger each strategy so that the optimal method to activate paralyzed muscle during fatigue could be determined. Six chronically paralyzed individuals (> 1 year) and two acutely paralyzed individuals (< 6 weeks) had the soleus muscle activated with a 10-pulse CFT (15 Hz) train using a fixed lon, 2 off duty cycle for 120 consecutive contractions. When the force dropped 10% the stimulation frequency either increased 15% (HF), decreased 10% (LF), or a variable frequency train (VFT) (6 ms doublet followed by 15 Hz train) was applied. Only one strategy was studied during a given experiment. At least a 2% change was required before the new strategy was accepted. In the chronically paralyzed group, the HF strategy was 16% and 9% more effective than the CFT and VFT, respectively, during the first 40 contractions (16%) The VFT was 20% more effective than the HF strategy towards the end of the protocol. The LF strategy was rarely (2%) accepted. These findings indicate that the most effective strategy to attenuate fatigue of paralyzed muscle depends on the muscle's activation history. The mechanism each strategy uses to overcome fatigue will be discussed.

ESTIMATION OF COUPLING STRENGTH FOLLOWING REGENERA-TION OF THE LAMPREY SPINAL CORD. T. Kiemel and A. H. Cohen*.

Department of Zoology, University of Maryland, College Park, MD 20742.

Data of fictive swimming from isolated lamprey spinal cords bathed in D-

glutamate were analyzed under four conditions: (i) medial tracts lesioned 8-10 months previously with acutely lesioned lateral tracts (n=4); (ii) lateral tracts lesioned 8-10 months previously with acutely lesioned medial tracts (n=5); (iii) intact medial tracts with acutely lesioned medial tracts (n=5); and (iv) intact lateral tracts with acutely lesioned medial tracts (n=5). All lesions were performed just rostral to the first dorsal fin. Data from regenerates was previously published.

Activity was recorded from one ventral root rostral and one ventral root caudal to the lesion site. Bursts were detected and a sequence of burst times for each root was calculated. Burst times were fitted by a model of two noisy phase oscillators using a maximum-likelihood approach. Parameters in the model include the strength of descending and ascending coupling across the lesion site, the amount that one oscillator slows down or speeds up the other oscillator as a function of the relative phase between the oscillators. In the case previously-lesioned tracts, coupling strength provides a quantitative mea of the quality of regeneration.

In one animal with previously-lesioned medial tracts and one animal with previously-lesioned lateral tracts, coupling strength was not significantly different from zero, indicating no evidence of regeneration in these animals. All terent from zero, indicating no evidence of regeneration in these animals. All other previously-lesioned tracts had coupling strengths significantly different from zero. These results corresponded exactly with a statistical test for regeneration based on the crosscorrelation of spike trains. Coupling strengths of previously-lesioned tracts tended to be less than the coupling strength of intact tracts and the coupling strengths of medial tracts, whether previously-lesioned or intact, tended to be less than the coupling strength of lateral tracts.

SURVEY OF BIOPHYSICAL PROPERTIES OF DESCENDING BRAIN NEURONS IN LARVAL LAMPREY. D.T. Rouse, X. Quan, and A.D. McClellan*, Div. of Biological Sciences, Univ. of

Reticulospinal (RS) neurons integrate synaptic inputs from many sources and contribute significantly to the descending control of locomotion. The biophysical properties of RS neurons are important determinants of how synaptic inputs will be transformed to a particular firing pattern. In the present study, intracellular recordings were made in <u>in vitro</u> brain/spinal cord preparations (n = 29) from larval lamprey (<u>Petromyzon marinus</u>) to determine the biophysical properties of identified and non-identified RS neurons (n = 131).

Spike frequency adaptation (SFA): SFA was observed in almost all of the descending neurons, including Muller cells.

Bursting: During constant depolarization, some descending neurons, particularly in the PRRN, fired a short burst, while at higher current intensity these neurons fired several short bursts

<u>Delayed excitation (DE):</u> About 24% of the descending neurons showed a delay in firing (max. = 160-350 ms) in response to a depolarizing current pulse when preceded by a hyperpolarizing pulse. DE was observed in some of the neurons in the MRN, ARRN, and MRRN, and was seen reliably in Muller cells M1 and M2.

Post inhibitory rebound (PIR): About 10% of the descending neurons fired one

a few action potentials following a hyperpolarizing current pulse. PIR was observed in some neurons in the ARRN, MRRN, and PRRN.

In summary, RS neurons in the lamprey are heterogeneous in their biophysical properties which presumably reflects the type of integration needed by each cell. A determination of the ionic and pharmacological bases for these properties will provide insight into the mechanisms by which these cells integrate synaptic inputs and activate the spinal locomotor networks

SPINAL INTERNEURONS INVOLVED IN THE ESCAPE BEHAVIOR IDENTIFIED BY IN VIVO CALCIUM IMAGING IN ZEBRAFISH. E. Forbell, N.F. Cambronero, S. Ross and J.R. Fetcho*. Dept. Neurobiology and Behavior. SUNY at Stony Brook, NY 11794.

SUNY at Stony Brook, NY 11794.
Seven classes of interneurons in larval zebrafish spinal cord have been identified morphologically in a study by Bernhardt et al. (JCN 302:603). We have begun to study the functional roles of these interneurons in the transparent, larval fish by using calcium imaging techniques. We focused initially on the question of whether one class of spinal interneuron, the circumferential descending interneurons (CiD cells) were involved in escape behaviors. These neurons have an axon which extends ventrally from the soma to a region near the Mauthner axon and then runs caudally and dorsally in an axonal bundle with the axons of other CiD cells. The neurons are very similar morphologically to the descending interneurons (DIs) in goldfish which are monosynaptically excited by the Mauthner cell (which initiates the escape) and in turn electrotonically excite primary motoneurons, thus contributing to the rapid C-bend in the escape behavior. The morphological similarities between the CiDs in zebrafish and the Dls in goldfish led to the prediction that CiDs would also be activated during escapes. To examine this, we backfilled CiD cells by an injection of calcium green dextran into dorsal caudal spinal cord. We imaged the calcium increases in the somata of these cells during spinal cord. We imaged the carctum increases in the somata of these cens during escapes elicited by a light, abrupt touch to the contralateral head or tail produced by a piezoelectric device. We found that the CiD cells responded during escapes as expected based upon their similarity to the well studied DIs in goldfish. These observations emphasize the morphological and functional similarities between the spinal organization in zebrafish and goldfish. These similarities will allow imaging studies of activity in populations of identified interneurons in zebrafish which will compliment the data obtained about their synaptic connectivity from intracellular studies in the much larger goldfish. Taken together, these data will provide a more complete view of the rules by which activity in neuronal populations controls behavior. Supported by NIH NS26539.

EFFECTS OF ACETYLCHOLINE ON FICTIVE SWIMMING AND SPINAL NEURONS IN THE LAMPREY. J.T. Buchanan* & K.A. Quinlan. Department of Biology, Marquette University, P.O. Box 1881. Milwaukee, WI 53201-1881.

Motoneurons of the lamprey spinal cord are considered to be passive output elements of the locomotor system. However, it has been reported recently (Perrins & Roberts, J. Neurophysiol. 73: 1013, 1995) that in the Xenopus embryonic spinal cord, motoneurons synaptically interact with spinal interneurons and may participate in rhythmogenesis. As a first step toward assessing the possible involvement of motoneurons in rhythmogenesis in lamprey, we have examined the effects of acetylcholine on fictive swimming and on spinal neurons.

Fictive swimming was induced in the spinal cord/notochord preparation by superfusion with N-methyl-D,L-aspartate (0.2 mM), and ventral root activities were monitored with suction electrodes. Application of acetylcholine (0.01-1 mM) to the bath decreased the mean cycle period of fictive swimming and induced or enhanced slow modulation (period =20 sec) of the swim rhythm. Mecamylamine (0.02 mM), a nicotinic receptor antagonist, could block acetylcholine action, and could suppress slow modulatory rhythms present in the absence of added acetylcholine

Acetylcholine (10 mM) was also applied locally to the cord surface during intracellular microelectrode recordings from motoneurons and proposed locomotor interneurons (lateral interneurons and CC interneurons). In the presence of tetrodotoxin, acetylcholine produced depolarizations and increases in membrane conductance of these cells. These actions were blocked by mecamylamine or dtubocurarine. In normal Ringers, local application of acetylcholine elicited a barrage of ipsps in CC interneurons, indicating that the acetylcholine strongly excited inhibitory interneurons synapsing upon nearby CC interneurons

These results suggest that motoneurons and interneurons of the lamprey spinal cord possess excitatory nicotinic acetylcholine receptors, and stimulation of these receptors during fictive swimming can alter the fictive swim cycle period.

NORADRENALINE MODULATES RECIPROCAL GLYCINERGIC INHIBITION AND REDUCES SWIMMING FREQUENCY IN XENOPUS LAEVIS TADPOLES. J.R. McDearmid and K.T. Sillar. Gatty Marine laboratory, School of Biological and Medical Sciences, University of St. Andrews, Fife KY16 8LB, Scotland.

The biogenic amine noradrenaline (NA) has been shown to modulate locomotor rhythm generation in vertebrates, but little is known of its mechanism of action. We have examined the effects of NA on fictive swimming in α-bungarotoxin immobilized Xenopus laevis tadpoles. At 1-20µM, NA slows the swimming frequency by up to 50%. Reciprocal mid-cycle glycinergic inhibition is a fundamental component of the synaptic drive which influences cycle period in the central pattern generator of several vertebrate systems. We therefore studied the effects of NA on this component of fictive swimming by recording intracellularly from myotomal motoneurons in the spinal cord. We find that NA reversibly enhances the size and duration of glycinergic mid-cycle inspe

To investigate a possible presynaptic site of action for NA, tetrodotoxin (TTX) was applied to block Na+-dependent action potentials. Under these circumstan spontaneous, strychnine-sensitive ipsps are recorded which reflect the quantal release of glycine from the terminals of spinal glycinergic commissural s. NA increased the rate of occurrence of the spontane affecting the distribution of their amplitudes. These data provide evidence for a direct facilitatory action of NA on the glycine release mechanism.

In conclusion these results show that NA is capable of reducing the frequency of swimming in Xenopus tadpoles. We propose that this effect is mediated, at least in part, through the presynaptic facilitation of glycine release from commissural interneurons. This enhances the mid-cycle inhibitory component of the swimming cycle and thereby delays the onset of the next cycle. upported by the BBSRC and the Royal Society of London.

ANTAGONISTS UNMASK COMPONENTS OF EXCITATORY SYNAPTIC DRIVE TO MOTORNEURONS DURING SWIMMING IN *XENOPUS* TADPOLES. F.Y. Zhao and Alan Roberts*, School of Biological sciences, University of Bristol, Bristol BS8 1UG, UK.

To investigate the contributions of chemical and electrical synaptic input during swimming locomotion in hatchling Xenopus tadpoles, we made intracellular recordings from motorneurons during fictive swimming in immobilised animals. We then used a microperfusion system to apply antagonists locally to the recorded neuron to block specific synaptic components (dihydro-β-erythroidine (DHβE) for nicotinic ACh receptors (nAChR); kynurenate (Kyn) for glutamate (GluR); DHBE plus Kvn for nAChR and GluR; Cd++ for all chemical synapses). Tonic depolarization has no electrical component and is mainly glutamate dependent. ACh and an unidentified component play minor roles. Glutamate and ACh provide most of the fast EPSP underlying spikes but there is also a clear electrical component. We have proposed that the relative contributions of glutamate, ACh and electrical synapses will change as a function of longitudinal position and the frequency of fictive swimming. These proposals have been tested by measuring the effects of antagonists in motorneurons at different longitudinal positions during swimming at different frequencies. Supported by the Wellcome Trust.

SENSORY NEURON ACTIVATION OF MODULATORY PROJECTION NEURONS. <u>DM Blitz' & MP Nusbaum</u>. University of Pennsylvania School of Medicine, Department of Neuroscience, Philadelphia, PA 19104.

The neural network located in the stomatogastric ganglion (STG) of the crab Cancer borealis produces the pyloric and gastric mill rhythms. STG network activity is modulated by projection neurons whose somata are located in the other ganglia (CoGs & OG) of the stomatogastric nervous system. Several of these projection neurons have been identified and their effects on the STG network characterized. However, little is known about the behaviorally-relevant pathways whereby these neurons are activated. We found recently that a pair of previously identified stretch receptors, the gastro-pyloric receptor cells (GPR1&2: Katz et al, J Neurophysiol 62:558, 1989) activate a subset of the projection neurons that influence the STG network. Specifically, GPR activates modulatory commissural neuron 1 (MCN1: Coleman & Nusbaum, J Neurosci 14:6544, 1994) and commissural projection neuron 2 (CPN2: Norris et al, J Neurophysiol 72:1451, 1994). Either tonic or rhythmic stimulation of GPR co-activates MCN1 & CPN2, resulting in the activation of a distinct gastric mill rhythm from the STG network. The effects of GPR can outlast its stimulation for up to several minutes.

Interestingly, while low frequency stimulation of GPR (5Hz) excites MCN1 & CPN2, higher frequency stimulation (20-30Hz) has mixed excitatory & inhibitory effects on these neurons. GPR contains ACh, 5-HT (Katz et al, J Neurophysiol 62:558, 1989) and an allatostatin-like peptide (Skiebe & Schneider, J Exp Biol 194:195, 1994). We are working to determine the relative contributions of each GPR transmitter to the strong, long-lasting influence of GPR on MCN1 & CPN2.

TWO NOVEL TACHYKININ-RELATED PEPTIDES FROM THE CRAB NERVOUS SYSTEM. <u>AE Christie**. CT Lundquist*</u>, DR Nässel*<u>& MP Nusbaum*</u>. ¹Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia, PA 19104. ¹Department of Zoology, Stockholm University, S-10691 Stockholm, Sweden.

Previous studies have shown that tachykinin-related peptides (TRPs) are likely to be present in the stomatogastric nervous system (STNS) of the crab Cancer borealis (Goldberg et al., Cell Tiss Res, 252:515, 1988; Blitz et al., J Comp Neurol, 354: 282, 1995). We recently isolated two novel TRPs from the crab CNS that show strong amino acid sequence similarity to several insect TRPs, including locustatachykinin (LomTK), a peptide that modulates neural network activity in the crab stomatogastric ganglion (STG). The CNS from 160 C. borealis were used for extraction via an acidified solvent. Four reverse-phase HPLC column systems were used to obtain pure peptides. A cockroach hindgut muscle contraction bioassay and a radioimmunoassay utilizing LomTK I antiserum were used to monitor all collected fractions, as was done previously for other TRPs (Muren & Nässel, in press, NY Acad Sci USA). We isolated two novel peptides and had their amino acid sequences determined by Edman degradation. The sequences were confirmed by mass spectroscopy and chemical synthesis to be APSGFLGMR-NH₂ and SGFLGMR-NH₃, We named these peptides

Cancer borealis tachykinin-related peptide la and lb (CabTRP la and lb), respectively. Superfusion of synthetic CabTRP la (10⁴ M) to the isolated C. borealis STG excited both the pyloric and the gastric mill systems. CabTRP la increased the frequency and intensity of ongoing pyloric motor patterns. It also excited most gastric mill neurons. A full gastric mill rhythm was not elicited, but some gastric mill rhythm-like activity was evident. We are continuing to examine the actions of CabTRP la on the STG motor patterns and to determine the tissue distribution of this peptide in the crab STNS. Supported by F32-NS09718 (AEC), IBN-9309804 & HFSP (MPN) and the Swedish Natural Science Research Council (DRN).

SYNAPTOTAGMIN-LIKE IMMUNOREACTIVITY IN THE STOMATOGASTRIC NERVOUS SYSTEM OF THE CRAB, CANCER PRODUCTUS: A MARKER FOR SYNAPTIC NEUROPIL. J. M. Parrish, D. Goerlitz, K. Graubard*, University of Washington, Seattle, WA. 98195.

Goerlitz, K. Graubard*. University of Washington, Seattle, WA. 98195.
Synaptotagmin is an abundant integral membrane protein found in synaptic vesicles, making it a good antigen for a synapse-specific antibody. The Drosophila synaptotagmin gene has been cloned and an antiserum (DSYT2) made to the highly conserved cytoplasmic domain (Littleton et al., Development 118: 1077-1088, 1993). Using confocal microscopy, we have found that the DSYT2 antibody (gift of Dr. Hugo Bellen) reveals synaptotagmin-like immunoreactivity in the stomatogastric nervous system (STNS) of the marine crab, Cancer productus.

The synaptotagmin-like staining on crab PD muscle ibers and in the STNS corresponds to known synaptic regions. Terminal varicosities on PD muscles stain similarly to those on crayfish muscle reported by Cooper et al. (Brain Res. 703: 214-216, 1995). In the STNS, synaptotagmin-like labelling is extensive and punctate. In the stomatogastric ganglion (STG) the label is intense and densely packed in the peripheral neuropil, while the core is almost devoid of staining. Neuropilar staining extends beyond the STG itself into the adjacent stn and dvn nerves. Patches of neuropil in the sons and at the stn-son junction also label. Some fibers in the stn and dvn stain near the STG and decrease in number as distance from the ganglion increases.

the ganglion increases. In preparations double-labeled for synaptotagmin and for the neuromodulator cholecystokinin (CCK $_{C36}$), preliminary results show that anti-CCK $_{C36}$ labeled profiles coincide with a subset of the total synaptotagmin-like labelling in the peripheral STG neuropil. Other preparations containing Lucifer Yellow-filled neurons were labeled with anti-synaptotagmin. Primary and secondary neurites occasionally traverse labeled regions. Fine neurites, however, nearly always lie in regions of synaptotagmin-like staining, often at the very edge of the neuropil border. Fine neurites that trail into the dvn and stn also lie in anti-synaptotagmin labeled regions. Supported by NiH grant NS15697 (to KG).

TWO PROCTOLIN/GABA NEURONS ELICIT DISTINCT MOTOR PATTERNS FROM THE SAME NEURAL NETWORK. M. Bartos* & MP. Nusbaum. Univ of Pennsylvania, Sch of Med, Dept of Neurosci, Philadelphia, PA, 19104. The rhythmically active neural network in the crustacean

The rhythmically active neural network in the crustacean stomatogastric ganglion (STG) generates the gastric mill and the pyloric rhythms. In the crab, *Cancer borealis*, modulatory neurons project from other ganglia (COGs, OG) to innervate the STG and elicit distinct versions of the gastric mill and the pyloric rhythm. Two of these modulatory neurons, MPN and MCN1, contain both GABA and the neuropeptide proctolin. Previously, Nusbaum & Marder (J Neurosci 9:1591, 1989) showed that MPN activation and proctolin superfusion elicited the same pyloric rhythm. MCN1 also elicits a pyloric rhythm (Nusbaum et al, J Neurosci 12:2706, 1992), but we have found that this rhythm is different from that produced by MPN stimulation or proctolin application.

Like MPN stimulation and proctolin application, MCN1 stimulation enhances the pyloric cycle frequency of slow rhythms (<1 Hz) but does not alter the frequency of fast rhythms. The activity levels and phase relationships of the pyloric motoneurons, however, are different during MCN1 stimulation than during times of MPN activity or proctolin application. For example, MCN1 elicits a stronger activation of the PD and VD neurons and a weaker activation of IC. These differences appear to result at least partly from the fact that MCN1 contains a second neuropeptide, CabTRP-la (Christie et al, this volume), that is not found in MPN. There is also electrical coupling between MCN1 and several pyloric neurons. We are extending these studies to determine whether the presence of CabTRP-la, and the electrical coupling, is sufficient to account for the different pyloric rhythms elicited by MCN1, MPN and proctolin. Supported by NS-29436, IBN-9309804 and HFSP (MPN).

AMINE EFFECTS ON GLUTAMATE RESPONSES IN THE PYLORIC MOTOR NETWORK. B. R. Johnson* and R.M. Harris-Warrick. Neurobiology and Behavior, Cornell University, Ithaca, NY

Dopamine (DA), serotonin (5HT) and octopamine (Oct) each have a unique, distributed spectrum of effects on graded synaptic strength in the pyloric network of the stomatogastric ganglion from the spiny lobster, *Panulirus interruptus*. This modifies the motor pattern generated by the pyloric network. We examined amine effects on the inhibitory responses of pyloric neurons to iontophoresis of glutamate (Glu), one of two pyloric transmitters, to determine the synaptic sites of amine modulatory action. DA and Oct strongly enhanced the Glu response in the PY and LP neurons, DA strongly reduced the Glu response in the VD and PD neurons, and 5HT reduced the Glu response in VD. The amines had only weak effects on the Glu responses of the other pyloric neurons. DA enhanced the Glu response of LP and PY even after pharmacological block of I_A and I_h , currents that DA reduces and enhances, respectively, and which account for some of DA's effects on neuronal activity. These results suggest sites of amine action. For example, despite DA inhibition of PD and VD responses to Glu, DA enhances synaptic Glu input to these cells, suggesting a predominant action of DA to enhance presynaptic release onto these cells. Both synaptic and iontophoretic Glu input to LP and PY is enhanced by DA and Oct, suggesting a post-synaptic mechanism on these cells. Supported by NIH grant NS 17323 and the Human Frontier Science Program.

GLUTAMATE'S ROLE IN THE EXPRESSION OF LEECH SWIMMING: GATING CELL ACTIVATION OF THE OSCILLATOR.

SWIMMING: GATING CELL ACTIVATION OF THE OSCILLATOR. M. S. Thorogood*. S. L. Melson and P. D. Brodfuehrer. Department of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

Previous studies have demonstrated a role for L-glutamate in initiation of the swim motor program of Hirudo medicinalis. First, focal application of glutamate or one of its agonists excites the swim-gating interneuron, cell 204. Second, 6,7-dinitroquinoxaline-2,3-dione (DNQX) blocks input from swim-trigger interneuron, cell Tr1, to cell 204. Third, the direct connection from mechanosensory cells to cell Tr1 is similarly antagonized by DNQX. Here we ask if glutamate is required for the expression of fictive swimming. Initially, we monitored the effect of non-NMDA antagonists on DP nerve-induced swim episodes. In the presence of 10-4 M DNQX, the ability of DP nerve stimulation to evoke swimming disappeared. Cell 204 also lost its ability to initiate swimming following DNQX exposure. We then examined glutamate's involvement at the level of the swim oscillator, which includes cells 208, 115 and 28. In the absence of disynaptic connections, focal application of 10-3 M In the absence of disynaptic connections, focal application of 10⁻³ M kainic acid, a glutamate agonist, resulted in excitation of cell 208. In addition, exposure of the nerve cord to 10⁻⁴ M DNQX or 10⁻⁵ M 6-cyano-7-nitroquinoxaline-2,3-dione resulted in elimination of the monosynaptic connection from cell 204 to each of the three swim oscillator connection from cell 204 to each of the three swim oscillator interneurons. The direct signal from cell 208 to the dorsal exciter motoneuron cell 3, however, persists in the presence of 10-4 M DNQX, suggesting that this synapse is not glutamatergic. Thus, glutamate is involved at multiple levels of the leech swim motor program: initiation of swimming via the cell Tr1 swim-initiating pathway and in expression of swimming via cell 204's output to the swim oscillator. (NSF Grant IBN-95-14617 and a Whitehall Foundation Grant).

MODULATORY ACTION OF INHIBITORY NEUROTRANSMITTERS ON THE MUDPUPPY (Necturus maculatus) LOCOMOTOR PATTERN. K. Jovanović, T. Petrov, J.J. Greer and R.B. Stein, Division of Neuroscience, University of Alberta. Edmonton, Alberta T6G 2S2, Canada

Inhibitory amino acids such as glycine and GABA play an important role in generating and/or coordinating rhythmic motor patterns in a wide variety of species. To further investigate their role in locomotion of walking amphibians, we used an in vitro preparation isolated from the mudpuppy. The preparation consisted of the first five segments of the cervical spinal cord and the right limb attached by the brachial plexus. During NMDA-induced locomotion rhythmic motor output (EMG) was recorded unilaterally from the forelimb flexor and extensor muscles. After a welldefined walking pattern was established, the effects of neuroactive substances such as glycine, strychnine, and variety of GABA_A and GABA_B receptor agonists and antagonists were observed. Use of nipecotic acid, a GABA uptake blocker, indicated that an endogenous release of GABA occurs during NMDA-induced locomotion. The results of this study suggest that GABAergic and glycinergic systems are active during NMDA-induced locomotion in the mudpuppy. This activity appears not to be essential for the locomotor rhythmogenesis but may play a role in mediating reciprocal antagonism that coordinates the locomotor pattern. Glycine and GABA, receptor activation affects rate control, flexor-extensor antagonism and regular EMG burst pattern whereas GABA_B receptor activity primarily affects the frequency of the locomotor rhythm. The preliminary results obtained by using immunohystochemical techniques indicate that glycine and GABA-immunoreactive cell bodies ranging from 15-20 μm in diameter are located within the central grey matter 200-400 μm below the dorsal surface of the spinal cord. Further investigation should provide more insight to the connections of these cells with the rest of the neuronal network underlying locomotion in the mudpuppy. Supported by MRC and NCE.

FOOD EXTRACTS STIMULATE THE FEEDING MOTOR PROGRAM IN HELISOMA, IN PART BY ACTIVATING DOPAMINERGIG INTERNEURON NIA. A.D. Murphy*, E.M. Quinlan and B.C. Arnett. Dept. Bio. Sci., Univ. Illinois at Chicago, Chicago, IL 60607.

Watermelon extract potently stimulates feeding when applied to intact snails and also when perfused into the oral cavity of semiintact preparations. Feeding is mediated by the triphasic feeding motor pattern (FMP). Dopamine (DA) is the most potent and reliable neuromodulator that is known to activate FMP and feeding behavior. Electrical stimulation of interneuron N1a also can evoke FMP. Double staining of physiogically characterized neurons N1a, by injection of Reactive Red #4 and use of the FaGlu histochemical stain for indicated that interneuron Nla contains Watermelon extract activated neuron Nla, and feeding behaviour in semi-intact preparations. These dopaminergic effects are partially antagonized by Sulpiride and by Haloperidol, DA antagonists that previously have been shown to be effective for some molluscan DA receptors.
Supported by NSF grant BNS 91-21374.

EFFECTS OF METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION ON FICTIVE LOCOMOTION IN THE LAMPREY P. Krieger*, A. El Manira and S. Grillner. Nobel Institute for Neurophysiology, Dept. of Neuroscience, Karolinska Institutet 171 77

Activation of group I metabotropic glutamate receptors (mGluRs) with the specific agonist (RS)-3,5-dihydroxyphenylglycine (DHPG) increases the frequency of the locomotor rhythm and causes a depolarization of neurons in the spinal cord. The effect on locomotordriven EPSPs were studied in split-bath experiments where only the rostral part of the spinal cord was activated by NMDA, while DHPG was applied to the caudal part. DHPG depolarizes neurons in the caudal part, thus increasing the excitability of the neurons for the same given locomotor drive. These effects are all blocked by the group I mGluR antagonists (+)-MCPG and (RS)-1-aminoindan-1,5-dicarboxylic acid. The effects of DHPG are similar to those seen with the mGluR agonist 1S,3R-ACPD. The group III agonist L-AP4 causes a small reduction of the locomotor frequency. L-AP4 reduces the amplitude of IPSPs evoked by stimulating crossing axons and in some cases L-AP4 also reduces the amplitude of locomotor-driven EPSPs. In combination with our previous results, this suggests that activation of group I mGluRs have an excitatory effect on network neurons and that activation of presynaptic group II and III mGluRs causes a decrease in transmitter release Supported by the Swedish Medical Research Council, project no. 11562

DRUG EFFECTS ON MOTION SICKNESS SYMPTOMS IN CAT, J.B. Lucot*. Dept. Pharmacology, Wright State Univ., Dayton, OH 45435. The motion sickness rating scale of Suri, et al (Aviat. Space Environ. Med, 50:614,1979) uses observable signs which correlate with vomiting. While not nausea, both they and nausea reflect activity in the neural circuitry underlying vomiting that is different from the motor act of vomiting

With no effect on vomiting, combined, but not separate, block of alpha and beta adenoceptors increased defecation, while amphetamine increased urination and salivation. Peripheral muscarinic block decreased salivation and defecation while increasing urination and salivation. Peripheral muscarinic block decreased salivation and defecation while increasing urination. Scopolamine additionally decreased licking and increased panting. Drugs that decrease vomiting and appear to decrease symptoms by an effect on the neural path for vomiting include scopolamine, 5-HT1A agonists, a histamine synthesis inhibitor and NMDA channel blockers. Blocking NK-1 receptors has no effect on symptoms even at doses abolishing vomiting

The most common symptom (licking) seems a motor act associated with vomiting. Other common symptoms reflect parasympathetic activity Pharmacological studies of motion sickness must consider direct drug effects on autonomic function to avoid false negative and false positive results.

NASA/Lilly/Pfizer

HEPES BUFFER SUPPRESSION OF SPONTANEOUS NEURONAL NETWORK ACTIVITY. S. R. Laufer*, G. W. Gross and D. C. Tam. Center for Network Neuroscience, Dept. of Biological Sciences, Univ. of North Texas, Denton, Tx 76203.

Neurons and glial cells both express multiple pH regulatory mechanisms that require bicarbonate or CO2, or both, to regulate intracellular pH. HEPES-buffered media is commonly employed in place of standard HCO3-CO2 buffer to maintain extracellular pH but does not provide the intracellular buffering power of HCO3. We compared the spontaneous activity of cultured spinal cord networks under their normal bicarbonate-CO2-buffered minimal essential medium (NMEM) at pH=7.35 with activity under HEPES (20mM)-buffered medium (HMEM). Murine spinal cord neurons were cultured on an array of 64 photoetched microelectrodes. Replacing the NMEM with HMEM elicited immediate changes in the activity particularly an overall reduction in the amplitude and the number of integrated bursts. This becomes more profound with the duration of exposure to the HMEM. The suppressive effects on activity were not immediately reversed by returning the culture to NMEM. After recovery of activity a second 20 minute exposure to HMEM produced even greater inhibition than the first. The inhibitory effects continued to increase after removal of the HMEM. A 20 minute HMEM exposure typically blocked recovery of the initial spontaneous network activity for hours. Burst data analysis revealed wide alterations in all six integrated burst parameters measured: rate, amplitude, duration, period, interval, and mean burst area. The results suggest that HEPES buffered media, ever. for a relatively brief time, can produce marked inhibition of spontaneous neuronal activity accompanied by disruption of normal network activity patterns. (Supported by ONR N00014-94-1-0686)

EVOKED SYNAPTIC POTENTIALS ARE TRANSIENTLY DEPRESSED FOLLOWING RHYTHMIC ACTIVITY IN THE EMBRYONIC CHICK SPINAL CORD. B. Fedirchuktand M.J. O'Donovan. Laboratory of Neural Control, NINDS, NIH, Bethesda MD 20892.

MD 20892.

Rhythmic activity in the spinal cord of the embryonic chick is episodic and neural excitability is decreased following a bout of rhythmic activity. One mechanism that could contribute to this decreased excitability is a reduced efficacy of transmission through synaptic pathways. In order to assess this possibility, experiments were conducted on isolated E10 to E11 embryonic chick spinal cords. Electrical stimulation of the ventrolateral tract (VLT) or a dorsal root (DR) at the lumbosacral levels was used to evoke postsynaptic potentials in lumbosacral motoneurons and interneurons which were recorded as compound potentials in the ventral roots (VR) and VLT respectively. These potentials were examined before and after rhythmic episodes.

The amplitudes of VLT and DR-evoked potentials recorded from both the VR and VLT were decreased after either spontaneously occurring or electrically evoked rhythmic activity. This reduction of the evoked potentials persisted for minutes after a rhythmic episode indicating that there was a prolonged reduction in the efficacy of these synaptic pathways. The amplitudes of both the early and late components of the VR and VLT potentials could be reduced, and the reduction of the later portion resulted in a marked decrease in the duration of the potential. In some examples, only the late component was affected indicating that interposed interneurons may make polysynaptic pathways more susceptible to this modulation. Repetitive antidromic activation of motoneurons in the absence of rhythmic activity was not effective in altering the VLT-evoked VR potential suggesting that the modulation is produced by; 1) postsynaptic effects initiated by rhythmic activity but not antidromic stimulation, and/or 2) presynaptic effects. Experiments investigating these possibilities are continuing. Supported by the NIH and the MRC of Canada.

ELECTROMYOGRAPHIC ANALYSIS OF SPONTANEOUS MOVEMENTS IN THE EMBRYONIC ZEBRAFISH (DANIO RERIO). Uri Cohen, Anne Donevan*, and Michael J. O'Donovan. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

The zebrafish is widely recognized as an excellent model system for studying vertebrate neuronal development but little attention has been devoted to the emergence and function of spontaneous neural activity within the spinal cord and brain. We have begun to examine this question by recording the spontaneously occurring electrical activity from muscles in the body wall of zebrafish embryos. Electrical activity was recorded from the muscle using a suction electrode applied to the skin. Vigorous electrical signals were recorded, clustered into bursts that coincided with movements of the animal. The electrical activity was reversibly depressed following bath application of curare (10-100µM) indicating its origin from muscle. Our initial recordings have been from 1-2 day old embryos and we have found great variability in the burst frequency between embryos. This variability may be due to inter-embryo variation, developmental changes in the episode frequency, and/or sensitivity of the activity to environmental factors. Typically bursts were brief (< 1 sec) but occasionally much longer discharges were observed that were organized sometimes into multiple cycles in some experiments bursts were organized sometimes into multiple

cycles. In some experiments bursts were organized into couplets.

These data indicate that it is feasible to quantify the early activity of the developing zebrafish using electromyography. Further experiments are in progress to establish developmental changes in the activity and the role of the spinal cord in its genesis. Supported by NIH and the Howard Hughes medical scholars program.

NITRIC OXIDE: DISTRIBUTION AND EFFECTS ON SPONTANEOUS RHYTHMIC ACTIVITY IN EMBRYONIC CHICK SPINAL CORD. P.A. Carr*, P. Wenner and M.J. O'Donovan. Lab. of Neural Control. NINDS, NIH. Bethesda. MD 20892

The complete complement of neurochemicals responsible for mediating the spontaneous episodic activity observed in isolated embryonic chick spinal cord remains to be determined. Results in cat suggest that nitric oxide (N.O.) may be utilized by a subpopulation of locomotor-related spinal neurons (Carr et al. Brain Res. Bull. 37:213-218, 1995). Here, we have examined the possible role of N.O. in chick spinal rhythmic activity. NADPH-diaphorase histochemistry was used to examine the presence and distribution of the N.O. synthesizing enzyme. N.O. synthase, in the developing chick spinal cord. The distribution of NADPHdiaphorase histochemical reaction product was examined in transverse sections of perfusion fixed spinal cord from embryos between embryonic day 4 (E4) and 18 (E18) of incubation. Weak to moderate labeling of blood vessels was observed at most ages. Putative neuronal labeling was first observed in lamina IV (large clustered cells), the lateral funiculus and in the vicinity of the central canal (small cells) in E9-E14 animals. In older animals (E15-E18), large labeled cells could be also be observed in Hoffman's nucleus and the ventral horn in addition to small cells distributed throughout the dorsal horn. A rostrocaudal survey of the spinal cord of E10 animals revealed labeled cells (lamina IV, central canal region and dorsal lateral funiculus) confined to sections spanning mid-thoracic to mid-lumbosacral segments. To investigate the effect of N.O. on spontaneous rhythmic activity, an N.O. synthase inhibitor was bath applied to the E10 chick embryo spinal cord preparation. Results suggest that inhibition of N.O. synthase may decrease the frequency of spontaneously occurring episodes of electrical activity in the chick spinal cord. Supported by the NIH and MRC (Canada).

SPONTANEOUS RHYTHMIC ACTIVITY IN SPINAL CORD PREPARATIONS FOLLOWING SURGICAL ABLATION OF MOTONEURONS. P. Wenner* and M.J. O'Donovan. NINDS, NIH, Bethesda, MD 20892-4455.

In the isolated chick embryo spinal cord preparation rhythmic activity consisting of multiple cycles of depolarizing potentials occurs spontaneously in motoneurons and many interneurons. Previous experiments designed to specifically abolish discharge in motoneurons demonstrated that spinal cord pieces devoid of motoneuronal activity were still competent to generate a single (non-regenerative) spontaneously occurring depolarizing potential. Recently, similar results were observed in preparations of the dorsal half of the spinal cord, which did not contain motoneurons. While these experiments suggest that motoneuron activity was not necessary for spontaneous activity to occur, they did not address a possible motoneuronal role in shaping the pattern of activity (i.e. regenerative activity consisting of multiple cycles). To do this experiments were performed in which the motor column was surgically removed. Spinal cord preparations composed of 2 lumbosacral segments (LS1-2 or LS3-4) were produced in which the motor column on one side was surgically ablated using a fine tungsten needle. These preparations were then hemisected and extracellular recordings were obtained using suction electrodes placed on the ventral white matter. Both the control and lesioned hemicords produced spontaneously-occurring episodic activity consisting of multiple cycles. This demonstrates that the motor nucleus is not necessary for regenerative activity. The number of cycles in a given episode was reduced in the lesioned hemicord compared to that of the control hemicord. Motoneurons may therefore play a role in the number of cycles generated per episode, but it is clear from histological examination of the tissue that even in the cleanest motoneuron lesions, some interneurons were destroyed. This interneuronal damage could also account for the observed differences between control and lesioned hemicords.

544.16

HOMEOSTATIC REGULATION OF RHYTHMIC NEURAL OUTPUT IN THE DEVELOPING CHICK SPINAL CORD. Nikolai Chub and Michael J. O'Donovan*. Lab. Of Neural Control, NINDS, NIH. Bethesda, MD 20892.

Spontaneous rhythmic activity in the isolated cord of the chick embryo is generated by a network comprised of several classes of neuron including glutamatergic, GABAergic and possibly cholinergic types. Following bath application of either excitatory blockers (AP-5 100μM, CNQX 20μM, DHβE 100μM) or inhibitory blockers (bicucultine 50μM, Strychnine 20μM) spontaneous activity was blocked for a period of time (1-5hr) but then recovered in the presence of the antagonists. Combined application of the antagonists was not associated with recovery over a 4 hour monitoring period. The efficacy of the antagonists was assessed during recovery by their ability to block glutamatergic or inhibitory reflex pathways. Once recovered, the rhythmicity was remarkably similar to control activity, although it occurred more slowly. Following excitatory blockade the alternating pattern of flexor and extensor discharge was preserved. These findings suggested that spontaneous rhythmic activity in the chick cord can be supported by predominantly inhibitory or excitatory networks. This idea was confirmed by changes in the equilibrium potential (EP) of the synaptic drive measured under voltage clamp in ventrally located neurons. Following excitatory blockade the EP of the synaptic drive became ~10mV more negative with respect to control and approached the GABA EP. In the presence of inhibitory antagonists the EP of the synaptic currents became ~25mV more positive. These findings suggest that the rhythmic output of the spinal cord is resistant to major pharmacological perturbations and exhibits a form of short term plasticity that may reflect homeostatic regulation of the network output. Funded by NIH.

Mg[™] REVERSIBLY BLOCKS SPONTANEOUS LOCOMOTOR ACTIVITY PRODUCED BY LARVAL BULLFROG CENTRAL NERVOUS SYSTEM *IN VITRO*. Shehzad H. Choudry and G.R. Davis, Jr.* Department of Biology, Wofford College, Spartanburg, SC 29303

Previous studies have shown that the isolated central nervous system (CNS) of larval bullfrogs (Rana catesbeiana) produces spontaneous episodes of locomotor activity. However, these results were obtained from preparations maintained in Ringer's solution that did not include Mg⁻⁺, a natural component of extracellular fluid. Does spontaneous locomotor activity depend upon the omission of Mg⁺⁺ from the bathing solution?

Larvae (Taylor & Kollros Stage IV to XI) were anesthetized with Tricaine and the CNS was removed to a chamber containing Mg**-free Ringer's solution maintained at 4-14°C. Suction electrodes were applied bilaterally to ventral roots which innervate axial swimming muscles. Seventeen of 19 preparations produced episodes of spontaneous locomotor activity. Nine of these spontaneously active preparations were subsequently placed in Ringer's that included 1.6 mM Mg*. Spontaneous locomotor activity was immediately abolished in six of nine preparations, while in two preparations the activity was eliminated within seven minutes. One preparation produced a single episode after 20 min. in Mg*-Ringer's. All nine preparations resumed spontaneous locomotor activity 15-90 min. after being returned to Mg*-free Ringer's. These results suggest that Mg** reduces the excitability of the isolated CNS, perhaps by 1) attenuating synaptic transmission by competing with Ca** and/or 2) via a mechanism involving NMDA receptors. (Support: Howard Hughes Medical Institute grant to Wofford College)

LOCOMOTOR-LABELLED NEURONS ARE DIFFUSELY DISTRIBUTED IN THE NEONATAL RAT LUMBAR SPINAL CORD. C. Cima*, D. Fyda, L. Song, M. Sawchuk, L.M. Jordan & S. Hochman.

Our principal objective is to identify and characterize the spinal neurons which encode the locomotor rhythm. Sulforhodamine is a fluorescent dye thought to be taken up endocytotically in synaptically-active neurons. We used bath incubation of sulforhodamine (0.0001 - 0.0005%) in the isolated intact neonatal rat spinal cord (P0-P4) to identify synaptically-active neurons during evoked locomotor activity. Previously, Kjærulff et al (*J. Physiol.* 478:265, 1994) used sulforhodamine to label neurons active during locomotor activity induced by serotonin and NMDA (5.0 - 7.5 μ M) in elevated [K¹]₀ (7 mM). However, we have observed that identical concentrations of NMDA and [K¹]₀ label a significant fraction of spinal neurons in intermediate laminae even in the absence of locomotion. Hence we have used brainstem electrical stimulation (medio-ventral medulla: 150 μ A, 0.5 ms, 10 Hz) or bath application of serotonin alone (10-20 μ M) to evoke locomotion in order to identify activity-labeled neurons more directly related to the observed behavior.

Serotonin-induced locomotor activity was monitored by recording from L2 and L5 ventral roots which reflect activity in flexors and extensors respectively (Cazalets et al. J. Neurosci. 15:4943, 1995). Locomotor frequency remained relatively constant (typically at 0.1 Hz) for the duration of sulforhodamine incubation (2.5 - 4 hours). Locomotor activity was associated with a diffuse distribution of spinal neuronal labelling dominated by cells in intermediate laminae. Control values of labeling were observed when bath applied serotonin did not evoke locomotor activity. Similar labelling patterns were observed with brainstem electrical stimulation-evoked locomotor activity. In comparison to Kjærulff et al (1994), a much reduced number of activity-labeled neurons were observed.

Future studies will involve histochemical and electrophysiological characterization of locomotor-labelled neurons. Supported by the Manitoba Health Research Council.

SULPHORHODAMINE-LABELLED CELLS IN BRAINSTEM OF THE IN VITRO NEONATAL RAT FOLLOWING ELECTRICALLY-EVOKED LOCOMOTION. D.M.Fyda. S.Hochman, & L.M.Jordan.* Dept. of Physiol., Univ. Manitoba, Winnipeg, Manitoba R3E 0W3.

Electrical stimulation of the medioventral medulla (MED) evokes locomotion in the invitro neonatal rat brainstem-spinal cord preparation (Atsuta et al., J. Neurophysiol., 64:727, 1990) at a time when most supraspinal inputs to at least the thoracic cord are intact (by E20.5). Electrical stimulation (150uA, 0.5ms, 10Hz) of the MED evoked locomotion which was sustained for 1-1.5 hr in the 1-3 day old neonatal rat brainstem-spinal cord preparation (post-collicular decerebration) with hindlimbs attached. During locomotion the activity-dependent label sulphorhodamine (0.0005%) was present in the bath and enabled us to assess the brainstem distribution of neurons activated during or following locomotion. Brainstem labelling occurred ventrolaterally from the trapezoid bodies to the inferior olive and extended across the pontine transverse fibers. Ventral labelling was more prominent ipsilateral to the stimulation site although the vigor and rhythmicity of locomotion appeared more prominent in the hindlimb contralateral to the stimulation site. Dorsally, the lateral reticular formation and lateral lemniscus, the rubrospinal tract and pontine trigeminal nucleus were also labelled. Labelling appeared to be specific to the locomotion-evoking site since similar stimulation in ventromedial brainstem sites which failed to produce locomotion evoked labelling only in the stimulation site itself with only sporadic labelling occurring throughout the brainstem. Preparations which remained undisturbed in the presence of the sulphorhodamine showed virtually no brainstem labelling. These results provide a first attempt at localizing the brainstem areas activated during electrically-evoked locomotion in the in-vitro neonatal rat brainstem-spinal cord preparation and suggest possible pathways which may be involved in the initiation or maintenance of locomotion in the neonatal rat. Supported by the Medical Research Council of Canada.

The number of postsynaptic currents necessary to produce locomotor-related cyclic information in neurons in the neonatal rat spinal cord. Morten Raastad*, Bruce R. Johnson and Ole Kiehn. Division of Neurophysiology, University of Copenhagen, Denmark.

Synaptic transmission by activation of ionotropic receptors is the main form of neuronal communication in neural networks such as those responsible for neuronal communication in neural networks used has those responsible for network activity, we analysed synaptic input to interneurons that may participate in locomotor networks in the isolated spinal cord from neonatal rats. Locomotor related activity was induced by bath application of NMDA in combination with 5-HT, or by muscarinic agonists, and monitored by recording motoneuron bursts from the ventral roots L2 and L5. Intracellular, voltage clamp recordings were made from neurons close to the central canal and in lamina VII by using the tight-seal recording technique. In many cells that received locomotor-related cyclic modulation of their membrane currents, putative unitary postsynaptic currents (PSCs) could be identified. The strength of the synaptic signals could be expressed by their relative contribution to the total cyclic current modulation. We therefore estimated the number of synaptic currents needed to account for the observed locomotor related current fluctuations in 16 cells. The average cyclic current modulation was calculated as the difference between the current integral (charge) during the first and second half of the locomotor related cycles. This modulation index was divided by the average charge of the PSCs. Between 17 and 250 average PSC per second were needed to produce the observed cyclic current modulation in different cells. In most cells, 90% of the charge of an average PSC was delivered within 17 to 25 ms. In some cells, the excitatory PSCs had a faster time course, down to 5 ms. We conclude that very few (1-4) synapses need to be active simultaneously in order to produce the observed cyclic current modulation, giving the individual PSCs a powerful influence on the postsynaptic cell. CONTEXTUAL FEAR CONDITIONING POTENTIATES ACOUSTIC STARTLE RESPONSES IN RATS. P.W. Frankland**, C. Dockstader*, R.J. McDonald*, 'Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724 and 'Department of Psychology, University of Toronto, Toronto, Ont., Canada.

The acoustic startle reflex is a short-latency motor response to a loud and unexpected noise that is modifiable by experience. For example, startle amplitudes are potentiated in the presence of a cue that has previously been paired with an aversive event such as the delivery of foot shock (e.g., Davis et al., 1993). Conversely, startle amplitudes are attenuated in the presence of a cue that has previously been paired with a pleasurable event such as the delivery of food (Schmid et al., 1995). The modification of startle responsivity in the presence of these cues appears to be amygdala mediated.

Here we test whether exposure of rats to a context where they previously received shock potentiates acoustic startle responses. Rats (n=12) were initially tested for startle in two sessions. On each of two consecutive days rats were placed in a startle chamber and presented with 40 startle-eliciting stimuli. The mean startle amplitude of each rat in the second of these two sessions served as a pre-training baseline. One day following the this session, rats were placed back in the startle chamber where they received 0 (n=4), 1 (n=4) or 3 (n=4) 0.6 mA shocks during a 5 minute period. One day following this context training, they were placed back in the startle chamber and presented with 40 startle stimuli. In the no shock and 1 shock conditions, startle amplitudes post-training were not significantly different from the pre-training baseline. However, in the 3 shock condition, post-training startle amplitudes were significantly increased compared to pre-training baselines. These results suggest that contextual fear stimuli as well as cued fear stimuli potentiate acoustic startle responses. The effects of amygdala and hippocampal lesions on potentiation of startle are presently being examined. (Work supported by Connaught grant to RJM).

AN ANALYSIS OF CONTEXTUAL, AUDITORY AND GENERALIZED AUDITORY-CUE FEAR, J. W. Rudy*and C. R. Pugh. Department of Psychology, University of Colorado, Boulder, Co. 80309

A number of variables such as damage to the hippocampal formation,

A number of variables such as damage to the hippocampal formation, age, strain, and post-conditioning isolation have been shown to influence contextual but not auditory-cue fear conditioning. These dissociations have led to the view that contextual and auditory-cue fear conditioning are mediated by different neural systems. In the present experiments we extend this analysis to the study of generalized auditory-cue fear. We report that several of the variables that affect contextual fear conditioning also influence generalized auditory cue fear. Specifically, more generalized fear was found when (a) rats were isolated in a novel environment than when returned to their home cages immediately after conditioning, (b) when the retention interval was 3 hrs rather than 24 hrs, (c) in 18-day-old compared to 25-day-old rats and (d) when scopolamine was injected following the conditioning trials. Moreover, exposure to the auditory cue 24-hours prior to conditioning eliminated both the isolation and scopolamine effects. These results suggest that similar memory processes are involved in contextual and auditory-cue fear conditioning. To observe the similarity, however, one must measure generalized auditory-cue fear conditioning, because variables that influence contextual fear conditioning have no effect on direct auditory-cue fear conditioning. The results also support the view that both contextual and auditory-cue fear conditioning depend on two independent processes, one that constructs a representation of the stimulus and another that associates the representation with the aversive outcome. We suggest that it is the stimulus construction process that is commonly affected by the variables we investigated.

A SELECTIVE ROLE FOR CORTICOSTERONE IN FEAR CONDITIONING, C. R. Pugh*, M. Fleshner, D. Tremblay and J. W. Rudy.

Department of Psychology, University of Colorado, Boulder, Co. 80309

There is evidence that optimal long-term memory may depend on a basal level of corticosterone. We examined the contribution of corticosterone to contextual fear conditioning which rats display to the static features of the environment in which shock occurs and to auditory cue fear conditioning they display to a phasic tone paired with shock. The Type II glucocorticoid antagonist, RU 38486 impaired contextual fear conditioning. Compared to sham operated and normal control rats, adrenalectomized rats showed reduced long-term-contextual fear conditioning. However, neither their short-term contextual fear nor their auditory-cue fear conditioning was impaired. Contextual fear conditioning in adrenalectomized rats with corticosterone replacement matched the level of controls. Moreover, rats exposed to the context prior to adrenalectomy showed normal long-term contextual fear conditioning. Dehydoepiandrosterone (DHEA), a "functional" glucocorticoid antagonist produced the same pattern of results as adrenalectomy. Thus, corticosterone's role in fear conditioning is selective: It appears to contribute to the neural processes that support the construction of a representation of the context. These results add to a growing literature indicating that contextual fear conditioning depends upon two proces One process constructs a representation of the context while the other associates that representation with the aversive experience. These conclusions are similar to those derived from the effects of hippocampalformation damage and suggest that corticosterone may be exerting its effects through the hippocampal formation.

Memory Deficits and ECS: Conditioned fear and neurochemistry vary with stimulus laterality. <u>Laura Fochtmann*</u>, <u>Andrew Francis, James McCaughran</u> Dept. of Psychiatry, SUNY-Stony Brook, Stony Brook, NY 11794-8101.

Electroconvulsive therapy (ECT) is effective in severe mood disorders but its use is limited by memory disruption. In patients, cognitive side effects vary by memory task and are less with unilateral (UL) vs. bilateral (BL) stimuli. Our studies of conditioned fear response (CFR) compare memory effects of BL vs UL electroconvulsive shock (ECS) in CF-1 mice

CFR was induced over 5 trials (CS-US) by pairing a tone (CS) with aversive footshock (US). Mice then received sham ECS, a single BL ECS 24 hr prior to retention testing, or 6 daily BL or UL ECS. Retention of CFR was manifested by reduced locomotion in parallel extinction trials (no US) in either the training-box without CS (context) or in a simulated home cage during the CS (cue). A course of BL ECS eliminated the contextual CFR. A course of UL ECS or a single BL ECS did not abolish the CFR but did decrease the CFR relative to sham ECS. In contrast, the cue CFR was reduced in all ECS groups. Thus, the CFR discriminates the memory disruption induced by chronic BL ECS from that of chronic UL ECS or a single BL ECS. Since CFR memory deficits depend on the specific task, the number of ECS and electrode placement, the data also suggest that CFR can model the memory effects of ECT

Quantitative autoradiography was used to measure changes in receptors in the amgdala and hippocampus with these ECS schedules since these structures are linked to the cued and contextual components of the CFR. With BL vs UL ECS, we also observe distinct changes in glutamatergic and catecholaminergic receptors. These may relate to the differential disruptions of memory with clinical use of BL and UL ECT

FORNIX LESIONS AND OLFACTORY FEATURE POSITIVE AND FEATURE NEGATIVE CONDITIONAL DISCRIMINATIONS IN PAVLOVIAN CONTEXTUAL FEAR CONDITIONING. G. D. Gale*, S. G. Anagnostaras, & M. S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90095.

The hippocampus has been implicated in the processing of conditional, contextual, and configural cues during learning. We examined the acquisition of fear to a context when one feature of the context signaled either the presence or absence of shock. Female Long-Evans rats with bilateral lesions of the fornix or sham lesions were trained on either a feature positive discrimination (POS) where an ammonia odor served as the cue for shock, or a feature negative discrimination (NOS) where the *absence* of the ammonia odor served as the cue for shock. During discrimination training POS subjects received separate sessions in which 3 unsignaled footshocks (2-s, 1 mA; 60-s ITI) were presented in the presence of ammonia and no shocks were presented in the absence of ammonia; NOS subjects allso received separate sessions during which shocks were presented in the absence of ammonia and no shocks were delivered in its presence. Neither NOS or POS subjects reliably learned to discriminate the shock context based on the olfactory cue. Relative to NOS subjects acquisition of conditioned fear to the shock context was enhanced in POS subjects, suggesting that olfactory cues enhance the rate of contextual fear conditioning. In POS subjects fornix lesions but not sham lesions blocked generalization decrement to the absence of ammonia. Renewal of conditioned fear in the presence of the olfactory cue following extinction sessions was unaffected by fornix lesions in both NOS and POS subjects. Taken together these results suggest that of lactory cues enhance the acquisition rate of contextual fear conditioning but do not enhance discriminibility. Supported by NIMH grant (MH39786) to MSF.

DIFFERENTIAL ANTEROGRADE EFFECTS OF ELECTROCONVULSIVE SHOCK ON CONTEXTUAL LEARNING, CONDITIONED AND UNCONDITIONED FEAR. M.G.M. Oliveira*, O.F.A. Bueno and E.B. Gugliano. Dept. Psicobiologia, UNIFESP-EPM, São Paulo, SP, Brasil, CEP 04023-062.

Distinct amnestic treatments have differential effects on contextual learning (CL) and classically conditioned fear (CF) response in rats. This has been shown after paradoxical sleep deprivation, hippocampal lesion and chronic pre-training electroconvulsive shock (ECS) administration. The purpose of the present study was to investigate the effects of a unique ECS administered 1h, 2h or 4h before training on CL, CF and on unconditioned fear (UF). Rats were trained in a step-through inhibitory avoidance apparatus comprised of a dark shock compartment interconnected with a white safe compartment. After entering the dark box they received 5 paired tone (90dB/1sec)-shocks (1 mA/1sec) 15 sec apart. Twenty-four hours later half the animals were submitted to the step-through inhibitory avoidance test in the same apparatus (CL test), and the other half was placed in a new environment (open-field arena) where freezing time was measured for 8 min. During the 4th min the same tone as presented during training sounded. Freezing after the tone was a measure of CF while that before tone was a measure of UF. Fourty eight hours after training, the animals submitted to CL test were tested on the open-field and vice-versa. ECS when administered 1h, 2h or 4h before training impaired inhibitory avoidance performance as compared to control animals. This is interpreted as an anterograde amnesia for CL. When administered 1h or 2h before training ECS decreased UF, suggesting an anxiolytic effect of ECS, as well as decreased freezing after tone. As no interaction (tone x group) was found, this latter decrement is better interpreted as due to the anxiolytic rather than to an amnestic effect of ECS on this task. Finantial support: AFIP and CNPq.

EFFECTS OF LIDOCAINE INJECTION INTO THE HIPPOCAMPUS ON EFFECTS OF LIDOCAINE INJECTION INTO THE HIPPOCAMPOS OF CONTEXTUAL FEAR CONDITIONING INDUCED WITH FOOTSHOCKS OF HIGH AND LOW INTENSITIES. R. A. Prado-Alcalá*. A. Vazdarjanova*. G. L. Quirarte*, and J. L. McGaugh*. Center for the Neurobiology of Learning and Memory and Departments of Psychobiology and Pharmacology, University of California, Irvine, CA 92717-3800, and ³Medicine School, National University of México, México, D.F., 04510.

Contextual fear conditioning is readily induced when rats are given inescapable footshocks (UCS) in a distinct environment (CS). Lesions of the hippocampus produce both anterograde and retrograde amnesia of contextual fear conditioning. This experiment examined the effects of bilateral infusions of 1µL of 2% lidocaine into the dorsal hippocampus administered immediately conditioning. Rats were placed inside a trough-shaped alley and given 5 consecutive footshocks of low or high intensities. Freezing behavior was measured before footshock delivery as well as 24 h after training. In agreement with previous lesion studies, the posttraining infusions of lidocaine produced a significant retention deficit in the animals trained with low footshock; in marked contrast, these infusions were ineffective when high footshock intensity was used during training. These data indicate that the involvement of the dorsal hippocampus in memory consolidation of contextual fear conditioning is dependent upon footshock intensity during training. EXCITOTOXIC DORSAL HIPPOCAMPUS LESIONS AND PAVLOVIAN FEAR CONDITIONING IN RATS. S. Maren*†§, G. Aharonov†, and M. S. Fanselow†, †Dept. of Psych., Univ. of Calif., Los Angeles, CA 90095-1563; §Dept. of Psych., Univ. of Mich., Ann Arbor, MI 48109-1109.

Electrolytic lesions of the dorsal hippocampus (DH) have been reported to produce

deficits in both the acquisition and expression of conditional fear to contextual stimuli in rats. To assess whether damage to DH neurons is responsible for these deficits, we examined the effects of selective N-methyl-D-aspartate (NMDA) lesions of the DH on both the acquisition and expression of fear conditioning in rats. In Experiment 1, rats were placed in observation chambers and given three tone (90 dB, 2 kHz, 10 s)-footshock (1 mA, 2 s) pairings with a 74 s ISI. Seven days before or 7, 28, or 100 days after conditioning bilateral lesions were made in the DH using NMDA (20 µg/µL, 0.8 µL/side); control rats received sham surgery with no drug NMDA (20 µg/µL, 0.8 µL/side); control rats received sham surgery with no drug infusion. Following conditioning or surgery, fear to the context of the conditioning chamber was assessed by returning the rats to the chambers and scoring freezing; fear to the tone was assessed in a different chamber the following day. Results showed that DH lesions produced severe retrograde deficits in context fear when made up to 28, but not 100, days following training; DH lesions made before training did not affect contextual fear conditioning. Tone fear was modestly impaired by DH lesions at all training-to-lesion intervals. In Experiment 2, retrograde, but not anterograde, DH lesions produced modest deficits in context fear using an unsignaled check presenting. In Experiment 2, acceptance and expertise in Subsections and expertise in Dulesions reduced. anterograde, DH testons produced modest dentits in context tear using an unsignated shock procedure. In Experiment 3, anterograde electrolytic DH lesions produced modest deficits in context fear using both signaled and unsignaled shock procedures. This pattern of results reveals that neurons in the DH are not required for the acquisition of context fear and have only a minimal role in expressing context fear acquired with unsignaled shocks. However, DH neurons have a critical and time-limited role in the expression of contextual fear acquired with signaled shocks. We suggest that this pattern of results was obtained because context fear can be mediated by conditioning to either unimodal cues (hippocampus-independent) or a configure of polymodal background cues (hippocampus-dependent). Supported by NIMH grant (MH39786) to MSF and an NRSA (MH11061) to SM.

TIME-LIMITED RETROGRADE AMNESIA OF CONTEXTUAL FEAR CONDITIONING AFTER ELECTROLYTIC DORSAL HIPPOCAMPAL LESIONS IN RATS. S. G. Anagnostaras*°, S. Maren°†, & M. S. Fanselow. Dept. of Psychology, University of California, Los Angeles, CA 90095 and Dept. of Psychology, Univ. of Michigan, Ann Arbor, MI 48109.

CA 90095 and † Dept. of Psychology. Univ. of Michigan, Ann Arbor. MI 48109. As with other hippocampal-dependent learning, we have reported that electrolytic lesions of the dorsal hippocampus (DH) produce a severe deficit in contextual fear if made I day, but not 28 days, after a signaled fear conditioning session. Here we examine retrograde amnesia (RA) of contextual fear produced by DH lesions in a within-subjects design and the effect of signaling on the temporal gradient of RA. Unlike our previous reports, rats had both a remote and recent memory at the time of the lesion. In Exp. 1, animals were given 10 shocks (2-s, I-mA, 60-s ITI; unsignaled training: no tones) in one context (remote) and 10 shocks in a different context 40 days later (recent), followed by DH lesions 1 day later. Relative to shamperated controls, DH animals exhibited a mild RA for both remote and recent operated controls, DH animals exhibited a mild RA for both remote and recent contextual fear memory with no evidence of a temporal gradient. For Exp. 2, we repeated the study with *signaled training*; animals were given 10 tone (10-s. 85-dB, 2 or 8-kHz)-shock (2-s, 1-mA; 70-s ITI) pairings in one context (*remote*) and 10 toneshock (a different tone) pairings in a different context 50 days later (recent), followed by DH lesions 1 day later. Relative to controls, DH rats exhibited no deficit in remote contextual fear, but recent contextual fear memory was practically abolished. Thus, the temporal gradient of RA of contextual fear produced by DH lesions depends critically on the way that contextual fear is induced at the time of conditioning. When shocks are signaled during training (even though signals are not present during testing). DH lesions produce a severe, but time-limited RA. When shocks are unsignaled during training, the same lesions produce a mild, temporally-stable RA. unsignated outring training, the same tesions produce a mild, temporarity-static RA. These results are consistent with those reported by Kim & Fanscalow (1992, Science. 256) who observed time-limited RA after a signaled conditioning session. Signaled training may be required to fully engage the hippocampus in contextual fear conditioning because the context serves as a less valid or "background" predictor of the shock in this condition. Supported by NIMH grant (MH39786) to MSF.

ALTERATIONS IN GAP-43 AS A FUNCTION OF CONTEXTUAL FEAR CONDITIONING IN C57BL/6 AND DBA/2 MICE. Elizabeth A. Young and Jeanne M. Wehner, Institute for Behavioral Genetics, University of Colorado, Boulder,

C57BL/6 mice perform well on contextual fear-conditioned learning while DBA/2 mice show impaired contextual but normal auditory conditioning. Thus, these strains can be used to dissociate neurochemical changes that are specific to learning. DBA/2 mice show reduced hippocampal protein kinase C (PKC) activity but little is known about specific phosphoprotein substrates in these strains. Hippocampal GAP-43, a presynaptic membrane-associated PKC substrate was quantified using Western blots in hippocampal membranes from naive C57 and DBA mice, after exposure to shock only, or at various times after contextual fear conditioning. Naive C57 and DBA mice were not different in the amount of GAP-43. However, only C57 mice showed significant effects of contextual conditioning. At 3 and 24 hrs. after training, hippocampal membrane-associated GAP-43 was increased 37% and 49% over naive C57s. The shock-only group showed no alterations in GAP-43 at any time tested. These results suggest that GAP-43 may play a role in contextual fear conditioning. (MH-48663 and AA-00141)

MK-801 DISRUPTS THE ACQUISITION AND EXPRESSION OF CONDITIONED FEAR IN THE ACOUSTIC STARTLE PARADIGM. T. Haralambous, J. Cranney and G. Paxinos*. School of Psychology, The University of New South Wales, States 2002 August Sydney, 2052, Australia.

Sydney, 2052, Australia.

The non-competitive NMDA receptor antagonist, dizocilpine (MK-801) disrupts freezing in the acoustic startle paradigm (Cranney et al., Neurosci. Abs. vol.20, p.1009, #413.16). This study attempted to determine whether this disruption by MK-801 was due to a block of the acquisition of conditioned fear (as opposed to this disruption of freezing resulting from possible sensoring or or total damaget affects. conditioned fear (as opposed to this disruption of freezing resulting from possible sensorimotor or state dependent effects). Four groups (n=12) of rats were administered either MK-801 (0.1 mg/kg, s.c.) or saline 15 min prior to conditioning (Day 1), test (Day 2), or both. The conditioning phase consisted of 3 startle stimulus sessions (50 min apart) of 10 (115-dB, 5 ms-rise/fall, 30 to 90-s ISI) white noise stimuli, which commenced 60-s after exposure to the context. As expected, MK-801 disrupted the acquisition of conditioned fear, but in addition it appeared to disrupt the expression of conditioned fear. Other possible explanations for this apparent block of expression of conditioned fear include an interaction of either the sensorimotor effects or state dependent learning effects of MK-801, with a block of conditioned fear acquisition. Alternatively the results could be explained in terms of the anxiolytic actions of MK-801.

NMDA ANTAGONISTS BLOCK THE FACILITATORY EFFECTS OF CONTEXT PREEXPOSURE ON ONE-TRIAL CONTEXTUAL FEAR CONDITIONING. D. L. Stote* & M.S. Fanselow. Department of

Psychology, University of California, Los Angeles, CA, 90095.

In one-trial contextual fear conditioning, a rat is placed in a novel chamber and after a specified interval receives an aversive footshock. When tested at a later time for conditional fear the rat freezes in response to these chamber or "contextual" cues. One factor that contributes to the level of fear in this procedure is the length of the placement-to-shock interval used during training. An immediate placementto-shock interval results in no appreciable fear and intermediate placement-to-shock intervals (e.g. 10-30 sec) result in low levels of fear. In contrast, intervals of 90 sec or more evoke high levels of contextual fear. When rats are preexposed to the context 24 hours prior to training they show high levels of fear at intermediate placement-to-shock intervals compared to non-preexposed controls. It seems that without preexposure the intermediate intervals do not allow sufficient time for the animal to form a representation of the context prior to the footshock. This suggests that there are 2 processes involved in context conditioning: forming a representation of the context and forming an association between that representation and shock. NMDA mediated processes have been implicated in contextual fear conditioning. Intracerebroventricular application of the NMDA antagonist APV attenuates acquisition of conditional fear to the training context but it is not known if this is due to a disruption of either contextual representation formation or the context-shock association. To answer this question, we administered d,I-APV (5 µg, ICV) or MK801 (.1 mg/kg IP) during preexposure to a conditioning context. Both NMDA antagonists blocked the facilitatory effects of context preexposure. These results suggest that NMDA receptors are important for the learning that occurs during the context preexposure period. Supported by a NIMH grant (MH39786) to MSF.

THE EFFECT OF CURRENT INTENSITY ON FOS PRODUCTION OF FEAR CONDITIONED MICE AFTER ACQUISITION. <u>S.Milanovic*1.2</u>, <u>O.Stiedl</u>¹, <u>F.Henn²</u>, and <u>I.Spiess¹</u> 1Dept. Mol. Neuroendocrinol., Max

Planck Inst. Exp. Med., Goettingen; ²Central Inst. Mental Health, Mannheim, FRG.
The relationship of behavior induced by fear conditioning and FOS production in the brain of C57BL6/J male mice after acquisition has been investigated. Mice were placed into the conditioning chamber, and after 182 s, a foot-shock (ES) of constant current (2s) and different current intensities (0,2,0.7,1.3 or 2.0 mA) was applied (context/ES arrayse). Another resume for mice (context terms) was only aspected to the current (2s) and different current intensities (0.2, 0.7, 1.3 or 2.0 mA) was applied (context/ ES groups). Another group of mice (context group) was only exposed to the conditioning chamber for 182 s. The brains of mice were analyzed immunohistochemically for the production of FOS 30, 60, 90 and 180 min after acquisition. Additionally, mice of the context/ ES groups and the context group were tested for contextual retention 24 h after acquisition. The freezing score of the context/ ES (0.7-2.0 mA) groups was markedly increased in comparison to the corresponding values of the context/ES (0.2 mA) group were analyzed individually, it was found that 60% of the animals associated context (CS) with foot shock (US). The activity of the context or the context/ES (0.2 mA) groups was significantly lower than the activity of the context or the context/ES (0.2 mA) group. The only brain region that showed differences in FOS production between mice of the context/ES (0.2mA) group, the context group and all other groups was the neamyedaloideus medialis. In this context group and all other groups was the nc.amygdaloideus medialis. In this nucleus of mice of the context group, FOS production was apparent 30 min after acquisition, reached the maximum at 60 min and returned to the baseline at 180 min. FOS production was significantly higher at all time points in the same nucleus of mice of the context/ES (0.7-2.0 mA) groups compared to mice exposed to context only and did not return to the baseline after 180 min. The FOS production pattern of the context/ ES (0.2 mA) group was either similar to the context group or the context/ES (0.7-2.0 mA) groups. This split may be related to the individual differences found in the retention tests of the same group. (Supported by the Max Planck Society and the Central Inst. Mental Health)

HIPPOCAMPAL LESIONS ATTENUATE LATENT INHITION OF CONTEXTUAL FEAR CONDITIONING IN THE RAT. D.Lukes, J.Cranney* M.Kiernan¹ and R.F. Westbrook. School of Psychology, University of New South Wales, Sydney, 2052, and Charles Sturt University, Bathurst, 2795, N.S.W., Australia

Latent inhibition refers to the relative difficulty with which a pre-exposed stimulus may come to serve as a conditional stimulus. Four groups of male, Wistar rats were used (total N=48). Two groups were bilaterally lesioned by infusing n-Methyl-d-Aspartate (NMDA) in fields CA1 and the dentate gyrus of the dorsal hippocampal formation. Two further groups received corresponding sham operations. One group from each surgical condition received ten, 20-min pre-exposures in the to-be-conditioned environment. The two remaining groups received no pre-exposure. All rats were then conditioned to the environmen using a single footshock (1.0 mA, 1.0s). The next day all rats were replaced in the conditioning environment and observed for freezing in the absence of footshock Sham operated rats which received pre-exposure froze significantly less than did subjects comprising the three other groups. Among non pre-exposed animals, no significant difference for conditioned freezing was observed between lesioned and sham rats. Results were taken as indicating that NMDA lesions constrained to fields CA1 and the dentate gyrus of the dorsal hippocampus are able to attenuate latent inhibition of contextual fear conditioning. However, such conditioning in the absence of pre-exposure was not affected by these lesions in the present preparation. Further research into the effects of hippocampal lesions on contextual conditioning is being undertaken. [Supported by the Australian Research Council.1

ACCUMBAL LESIONS ATTENUATE CONTEXTUAL FEAR CONDITIONING IN THE RAT. M.J. Kiernan*, G. Bailev, J. Sims, D. Lukes and J. Cranney, Psychology, Univ. of New South Wales, Sydney. 2052, and 'Charles Sturt University, Bathurst, 2795, Australia.

Contextual fear conditioning, as indexed by freezing, occurs in normal rats following the presentation of an aversive unconditioned stimulus in a specific context/environment, two groups of male Wistar rats were used in this experiment. One group (n=12) was lesioned bilaterally by infusing n-Methyl-D-Aspartate (NMDA) into the accumbens nucleus. The other group (n=8) received corresponding sham operations. Following recovery, all rats were conditioned to the environment using three 1-mA. 1-s footshocks (ISI=20 s). The next day rats were replaced in the conditioning environment and observed for freezing in the absence of footshock. The lesioned rats displayed significantly less freezing than did the sham rats. Current experiments are exploring alternative explanations of the results, including possible deficits in (a) the formation of contextual representations, (b) general conditioning, or (c) motivation. There are no differences in locomotor and exploration measures. A model of the role of the accumbens nucleus in contextual conditioning will be presented. MEDIAL PREFRONTAL CORTEX LESIONS AND THE ACQUISITION AND EXTINCTION OF CONTEXTUAL FEAR CONDITIONING. F.A. Guarraci* and S.L. Young. Dept. of Psychology, University of Vermont, Burlington, VT 05405.

Morgan, Romanski and LeDoux (1993) found that medial prefrontal cortex (mPFC) lesions prolong extinction to discrete conditioned fear stimuli, but have no impact on the extinction of background contextual cues. In the present experiments we tested the effects of mPFC lesions, on foreground context conditioning.

Forty-eight Long-Evans rats were used. In Experiment 1, sixteen rats were placed in operant chambers for 180s and then received 1 footshock daily for 5 days. Freezing behavior was measured to assess conditioned fear. Rats were matched according to freezing and given either electrolytic lesions of the mPFC or sham lesions. Following recovery, all rats were exposed to the contextual cues for 330s daily for 8 days. During conditioning, all rats acquired contextual fear. The lesions had no affect on the rate of extinction but reduced the level of freezing during testing. These results suggest that the mPFC may be important for the retrieval of contextual fear.

In Experiment 2, we compared the effects of mPFC lesions on the acquisition or retrieval of conditioned contextual fear. Thirty-two rats received mPFC or sham lesions either before conditioning or the day after conditioning. All rats were placed in operant chambers for 180s and then received 3 footsbocks, 60s apart. During conditioning, all rats acquired contextual fear. During extinction, all rats were freezing less than 1% of the time by day 3. However the rats with mPFC lesions made after conditioning froze significantly less on days 1-2 of extinction training. Interestingly, rats with mPFC lesions made prior to conditioning were not significantly different from either sham lesioned group.

In conclusion, our results indicate that the mPFC may be involved in the retrieval of recently learned, emotionally significant events, and similar to the findings of LeDoux and colleagues, is not important to the acquisition or extinction of contextual fear. LESIONS OF THE HIPPOCAMPUS IMPAIR ACQUISITION BUT NOT RETENTION OF INHIBITION. <u>S.C. Benoit, T.L. Davidson, and L.E. Jarrard*.</u> Purdue Univ., West Lafayette, IN; Washington and Lee Univ., Lexington, VA 24450.

Davidson, Benoit, and Jarrard (1995) found that the capacity of hippocampal rats to inhibit responding to contextual cues depended on the number of unsignalled food Unconditioned Stimuli (USs). Both control and ibotenate lesioned hippocampal animals showed similar conditioned activity in the absence of unsignalled USs but activity of hippocampal rats was greater than controls when unsignalled USs had been delivered in the training context. To determine whether this was a deficit in learning or in performance, the present experiment employed a similar training procedure except that rats were lesioned after training was completed. Rats (N = 32) were given 15 daily training sessions during which a 10-sec tone CS predicted the delivery of a food US. Half of these animals also received 3 unsignalled presentations of food per session (Group 3 US) while the other half received no unsignalled USs (Group 0 US). Following training and recovery from surgery, hippocampal and control rats were given 14 sessions of extinction (i.e., no food was delivered). Results of extinction testing showed that there was no difference between control and hippocampal animals in responding to the context. If lesions produced only a performance deficit, elevation of responding would be expected. However, relative to controls, hippocampal animals in both 0 and 3 free US groups showed less extinction to the tone suggesting that hippocampal animals had difficulty learning inhibition to the now non-reinforced CS. The pattern of results indicates that removing the hippocampus impairs the rats' ability to learn inhibition to cues that have undergone both excitatory and inhibitory training. DESIONS OF THE DORSAL HIPPOCAMPUS OR BED NUCLEUS OF THE STRIA TERMINALIS (BNST) BLOCK FREEZING BUT NOT ENHANCEMENT OF THE STARTLE REFLEX IN A CONTEXT PREVIOUSLY PAIRED WITH SHOCK. K. A. McNish*, J. C. Gewirtz, and M. Davis. Depts. of Psychiatry and Psychology, Yale Univ. Sch. of Med., New Haven, CT 06508.

The roles of the dorsal hippocampus and BNST were assessed in the expression of contextual fear conditioning using two measures of conditioned fear: freezing and enhancement of the acoustic startle reflex. A discriminative contextual fear conditioning paradigm was developed which demonstrated both conditioned freezing and enhanced startle in a context previously paired with footshock, relative to a context in which footshock had never been presented. Both the degree of freezing and magnitude of startle enhancement were directly related to the shock intensity used during training (0, 0.3, 0.6, 1.2 mA). Post-training lesions of the dorsal hippocampus or the BNST produced a complete blockade of freezing to an aversive context, but no attenuation in the enhancement of startle. These data suggest that the hippocampus and BNST may form part of the same circuitry involved in freezing to an aversive experimental context. The sparing of context-induced enhancement of startle following lesions of either the hippocampus or BNST suggests that there may be residual fear to the experimental context in the absence of these structures. Alternatively, performance effects of these lesions on either startle or freezing could account for the lack of correlation between the two measures. DORSAL HIPPOCAMPAL LESIONS PRODUCE ANTEROGRADE BUT NOT RETROGRADE AMNESIA OF LATENT INHIBITION TRAINING INDEPENDENT OF CONTEXTUAL MEMORIES. <u>S. L. Young* and R. J.</u> Frohardt. Department of Psychology, University of Vermont, Burlington, VT 05405.

The present experiments examine the role of the dorsal hippocampus in latent inhibition. The latent inhibition procedure consisted of a training phase of nonreinforced exposure to a tone followed by a phase of tone-shock pairings. Tone preexposure retarded acquisition of the conditional response, freezing, showing that the training procedure produced latent inhibition. Hippocampal lesions block latent inhibition. Since latent inhibition may be a phenomenon that depends upon the animal associating contextual cues with the tone, the lesions may disrupt latent inhibition by interfering with contextual learning. Therefore, we examined whether latent inhibition is subject to the same sorts of manipulations as contextual fear conditioning.

Hippocampal lesions produce both anterograde and retrograde amnesia of context conditioning. We asked if hippocampal lesions produce both retrograde and anterograde annesia of latent inhibition. Subjects were given hippocampal lesions or sham surgery before or after latent inhibition training. Lesions given before but not after training blocked latent inhibition suggesting that the effect of the lesions on latent inhibition may not be due to disruption of contextual associations.

not after training blocked latent inhibition suggesting that the effect of the lesions of latent inhibition may not be due to disruption of contextual associations. In a separate experiment, we gave the animals an opportunity to learn the experimental context before assessing the effect of the lesion on latent inhibition. We precyposed the animals to the experimental context or an alternate context 28 days before hippocampal lesioning or sham surgery. This procedure prevents the learning deficit caused by hippocampal lesions in context conditioning. However, the context precyposure did not after the impact of hippocampal lesions on latent inhibition. These results also indicate that the effect of dorsal hippocampal lesions on latent inhibition may not be due to disruption of a context-tone association. This research was supported by UVM Psychology Department.

MULTIDIMENSIONAL EFFECTS OF HIPPOCAMPAL SUBFIELD LESIONS ON ATTENTIONAL PERFORMANCE OF A SERIAL REACTION TIME TASK IN RATS. K. L. Stacey, A. M. Bratt, S. P. Kelley, R. M. Chase and G. Mittleman*. University of Memphis, Memphis, TN 38152.

The purpose of this experiment was to compare the relative attentional

contributions of different hippocampal subfields. A serial reaction time task (5CHOICE) was used which required animals to successfully discriminate the location of a randomly presented 3W target light in the presence of different types of distractors. Animals with lesions of subiculum, fimbria-fornix, dentate gyrus, and whole hippocampus were compared to unoperated controls for decrements in performance across different distractor modalities (3W light and 105dB white noise), different temporal distractor positions (2.5 s before or concurrent with the target), and different distractor durations (1s and 5s) within eight 30-minute sessions. Comparisons to baseline and across lesions were made using percent correct, percent incorrect, percent misses, correct latency, incorrect latency, and response bias as dependent measures. Rats with lesions of the subiculum and the entire hippocampal formation displayed heightened distractibility, increased strategy use, and impaired habituation as well as showing an abnormal insensitivity to changes in distractor modality. Rats with fimbria-fornix or dentate gyrus lesions showed no deficits under any These results indicate that disruption of the experimental conditions. perforant path has a greater impact on attentional performance than disruption of fornical input or output pathways and creates attentional deficits that are roughly analogous to those found in schizophrenia. A SEARCH FOR HEMISPHERIC SPECIALIZATION FOR VISUAL MEMORY IN MACAQUES. Robert W. Doty', Ruiming Fei, Ross D. Rugaber, and Andreas E. Savakis, Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

In human subjects the right hemisphere is commonly more efficient than the left in visual processing. The situation is unclear for macaques. Two male M. nemestrina, MA and MV, with optic chiasm, callosum and anterior commissure cut are presently being tested. One or the other eye/hemisphere views a series of 140 images, subtending 21° on a 17-inch color monitor. A "new" versus a "repeat" image for the session requires direction of gaze to points above or below the image, respectively, for 400 msec at >200 msec latency. From 0-3 other images may intervene (the "lag") following initial presentation. After initial training of MA, 3 types of images have been used, randomized from an inventory of 600-1200 items of each type, using R and L eyes on alternate days. The types are: 1) "general" (objects, scenery); 2) nonobjective multicolored patterns; 3) human faces (cropped to elliptical format but including differences in age, sex, race, beard, spectacles). With type 1, N=1278 trials for each hemisphere, d' was identical, 1.78 (ca 81% correct) for each. Again, with type 2) material, N=1452, d' was the same for each hemisphere, 1.61. Human faces were so difficult, however, as to require reduction of "lag" to a single intervening image, in which case, for N=645, d'=1.61 for right, 1.40 for the left hemisphere (p = .18, no significant difference). Animal MV, performing more erratically and not exceeding lag of 1, with N=568 trials for type 1 images, has d'=1.53 for right versus 0.93 for left (p=.002); and for type 3, N=426, d'=1.33 and 0.93 for right versus left (p=.04), suggesting a hemispheric difference. Bias from surgical sites should favor right hemisphere in MA but not MV. Obviously the issue remains unresolved and work continues! Supported by grant #NS20052 from NINDS.

WORKING MEMORY IN INFEROTEMPORAL CORTEX: AN EXPERIMENTAL TEST OF ATTRACTOR NETWORK BEHAVIOR. V. Yakovlev | S. Fusi². D.J. Amit², S. Hochstein* and E. Zohary! Dept. of Neurobiology, ²Racah Institute of Physics, Hebrew University, Jerusalem, 91904, Israel.

An experimental paradigm was designed to critically test the hypothesis that neurons in inferotemporal (IT) cortex operate as an attractor neural network. Single cell activity was recorded in area IT of a macaque monkey performing a delayed match-to-sample task. Stimuli, from a set of 30 geometrical colored images, were shown for 500 ms with an intervening delay period of 5 sec. We determined for each cell the two stimuli that evoked the strongest and weakest visual response, and used them subsequently. The sample stimulus was degraded by random RGB noise, while the test stimulus was always intact. Stimulus degradation modulated both the monkey's behavior and the cells' visual activity: As the degradation level was increased, the monkey's performance deteriorated until it reached chance level. Correspondingly, in most IT neurons higher stimulus degradation led to weaker neuronal response. Several neurons maintained a sustained discharge during the inter-stimulus-interval following the best stimulus Furthermore, in one distinct experiment the delay activity was unaffected at low levels of degradation in marked contrast to a change in the neural response to the same degraded stimuli. Then, beyond a certain level of degradation, the delay activity disappeared. This type of behavior is in accordance with the attractor picture, in which to each distribution of delay activities corresponds a basin of attraction. Stimuli within the basin lead to identical delay activity distribution. Once outside the basin, the delay activity undergoes a major change. Supported by Israel Min. of Science & Arts

A ROLE FOR PREFRONTAL CORTEX IN BOTH WORKING MEMORY AND ATTENTION: DISSOCIATION BETWEEN DMTS AND DNMTS PROCEDURES. J.M. Williams* & B. Givens Dept. of Psychology, The Ohio State University, Columbus, OH 43210.

An operant task was designed to separately assess medial septal area (MSA) and prelimbic/infralimbic (PLIL) cortex contributions to working memory and attention/ stimulus encoding processes. Given reported differences between delayed match-to-sample (DMTS) and delayed nonmatch-to-sample (DNMTS) procedures, this experiment also examined the contributions of the MSA and PLIL to these two procedures. Rats were tested in an operant chamber with three lights located on the front panel. Levers were located beneath each light. In the sample phase, rats were presented with either a signal in which the center light was illuminated or no signal. To assess the attentional components of the task, signal length was varied (1 to 2 seconds). After the sample stimulus, a delay of 0 or 2 seconds was introduced. This delay constituted the memory component of the task. During the choice phase, a light appeared randomly over either the right or left lever. The opposite side remained unlit. In order to obtain a reward, rats were required to press the lever that either matched (DMTS group) or did not match (DNMTS group) the sample stimulus.

DNMTS results indicated that the MSA is more involved in the working memory components of the task, whereas the PLIL is more involved in the attentional/stimulus encoding components of the task. Results of the DMTS study indicate that there are distinct differences between DMTS and DNMTS procedures, including difficulty of task (as indicated by trials to criterion and post-surgery baseline performance), and PLIL involvement in attention and working memory. In contrast to the DNMTS rats, DMTS rats show delay-dependent and stimulus length-independent deficits following PLIL infusions, indicating that, for the DMTS group, the PLIL is more involved in the working memory components of the task and not the attentional/stimulus encoding aspects of the task. Results suggest that DMTS and DNMTS differences should be considered when assessing the neuroanatomy of cognitive processing and may explain some of the debate as to whether the PLIL is involved in attentional or mnemonic processing. CONTEXT-RECALL MEMORY SCANNING IN TWO PRIMATE SPECIES. A.F. Carpenter*, G. Pellizzer and A.P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417.

Six human subjects and one rhesus monkey performed a visuomotor context-recall memory scanning task. The task required memorizing a sequential list of visual stimuli, then choosing which of them is the correct target for motor response based on the serial order relations between the stimuli. A series of circular targets ("list stimuli") were shown in a random sequence on a monitor, stimuli remained on the screen throughout the entire trial. When one of these stimuli changed color ("test stimulus"), the subject had to move a cursor toward the stimulus that <u>followed</u> the test stimulus in the original sequence. Human subjects performed the task with lists of 1-7 stimuli in a randomized design; the moukey performed the task with lists of 3-5 stimuli presented in blocks.

In both species the mean reaction time increased as a linear function of the number of stimuli in the list, suggesting that subjects "scan" the list items in memory. The slope of this relation was over 3 times higher in the monkey (344 mssec/list item) than in the human subjects (101 msec/list item); this implies that the monkey's rate of memory scanning is much slower than that of the humans. When the test stimulus was presented immediately following the last list stimulus both species exhibited a "recency effect" such that responses were faster and more accurate for targets presented later in the list that for those presented earlier. When a 2 see delay was imposed between the last list stimulus and the test stimulus, human subjects did not exhibit this recency effect. These findings indicate that (i) monkeys can perform recall (in addition to recognition) memory tasks, and (ii) both monkeys and humans seem to utilize a memory scanning process in performing context-recall tasks, albeit at different rates. (Supported by NIH grant NS17413)

ACTIVITY OF PREFRONTAL (PF) NEURONS DURING AN OBJECT AND SPATIAL MEMORY TASK E.K. Miller*, S.C. Rao, and G. Rainer Dept. of Brain and Cog. Sciences, MIT., Cambridge, MA 02139

A variety of studies suggest that visual working memory (WM) for objects and for spatial information are processed independently in separate regions of the PF cortex. To determine whether any PF neurons can contribute to both object and spatial WM, we recorded from the lateral PF cortex while a monkey performed a task that required memory for both types of information. The task began with a brief presentation of a sample object at the center of gaze followed by a delay. Then, two test objects were briefly presented at two of four possible extrafoveal locations. One of the test objects matched the sample, the other was a nonmatch. Following another delay, the monkey was required to make a saccade to the remembered location of the match. Thus, this task employed two delays. In the first ('what' delay) the monkey had to retain object information in WM, while in the second ('where' delay) it had to retain spatial information in WM.

We have preliminary results from 46 PF neurons that exhibited high levels of activity during one or both delay intervals (delay activity). Based on MRI data, these neurons were located ventral to the principal sulcus, near the border of areas 46 and 12. Some neurons showed only sample-selective delay activity during the 'what' delay (7/46, or 15%) and other neurons showed only location-selective delay during the 'where' delay (8/46, or 17%). Surprisingly, many neurons (17/46, or 37%) showed both sample- and location-selective delay activity during alternate phases of the task. That is, they exhibited sample-selective delay activity during the 'what' delay and location-selective delay activity during the 'what' delay and location-selective delay activity during the 'where' delay. These findings demonstrate the existence of PF neurons that contribute to both WM for objects and WM for spatial information.

POSTTRAINING OR PRETEST INFUSION OF GLUTAMATE ANTAGONISTS INTO THE MEDIAL PREFRONTAL CORTEX IMPAIRS MEMORY FORMATION OR RETRIEVAL IN AN INHIBITORY A VOIDANCE TASK. K. C. Liang* & S.-J. Hu. Dept. of Psychology, Natl'. Taiwan Univ., Taipei, Taiwan, 10764, R.O.C. The medial prefrontal cortex (mPFC) is implicated in affective functions. We have

The medial prefrontal cortex (mPFC) is implicated in affective functions. We have previously shown that the mPFC is more involved in retrieving a remote (21-day) affective memory than a recent (1-day) one (Liang & Liao, Soc. Neurosci. Abst., 1995, 21, 1448). To pursue this finding further, the present study examined the roles of N-methyl-D-aspartate (NMDA) and \(\alpha \) -amino-3-hydroxy-5-methyl-4-isoxazole propionate (AMPA) receptors in the mPFC in formation and retrieval of affective memory.

Male Wistar rats were bilaterally implanted with cannulae into the mPFC. They were trained on a one-trial step-through inhibitory avoidance task (foot shock 1.75 mA/1 s) and tested for retention either 1 or 21 days later. Five min. prior to the test, rats received infusion (0.5 μ L) of 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) or 2-amino-5-phosphonovaleric acid (APV) into the mPFC. Results indicated that pretest infusion of CNQX (0.3 μ g) into the mPFC had little effect on 1-day retention but impaired 21-day retention, whereas pretest infusion of APV (2.5 μ g) had no effect on either test. To examine the role of mPFC in memory formation, pre- or posttraining drug infusion was administered. Lidocaine impaired 1-day retention when infused into the mPFC shortly before and after training, but had no effect if given 4 hrs later. Posttraining intra-mPFC infusion of CNQX (0.3 μ g or 1.0 μ g) caused a time-dependent memory deficit in both 1- and 21-day tests. Posttraining intra-mPFC infusion of APV at various doses caused no amnesic effect in the 1-day test. However, a marked memory deficit was apparent if rats given 2.5 μ g APV were tested 21 days later.

These findings, taken together, suggest that in the mPFC, transmission through AMPA receptors may be involved in processing information of aversive tasks, and NMDA-dependent plasticity may underlie formation of long-term affective memory. (Supported by a grant NSC-84-2311-B002-025 from the government of R.O.C.)

THE EFFECTS OF FRONTAL CORTICAL LESIONS IN THE RAT DEPEND ON THE PROCEDURAL DEMANDS OF TASKS TRAINED IN THE RADIAL ARM MAZE (RAM) . M.C. Porter*, B.M. Glode, J.R. Pelletier & R.G. Mair. Dept. Psychol., Univ. New Hampshire, Durham, NH 03824.

Rats were trained on a computer controlled 8 arm RAM task and then given lesions of MDn projection areas or sham surgery. After recovery they were trained on six tasks, beginning with standard RAM, then two versions of a four forced choice procedure, and then three versions of a two choice DNMTS task. Rats with lesions of the medial wall (MW) region or MW combined with cortex dorsal to the rhinal sulcus showed similar impairments. Lesioned animals were not impaired on the two choice DNMTS when the alleys used for training were selected at random on a trial by trial basis. They were significantly impaired: (1) on the standard and four forced choice tasks and (2) when the same alleys were used to train two choice DNMTS on all trials. Training animals in the dark or increasing delays up to 15 minutes had no significant effects on the severity of deficits. Supported by grant RO-1 NS26855 from NINDS to RGM.

THALAMIC AMNESIA RECONSIDERED: EXCITOTOXIC LESIONS OF THE INTRALAMINAR NUCLEI (ILn), BUT NOT THE MEDIODORSAL NUCLEUS (MDn) DISRUPT OLFACTORY CONTINUOUS DNMTS PERFORMANCE. R.G. Mair*, Y.P. Zhang, J.A. Burk, B.M. Glode, M. Foye, & J.R. Pelletier. Dept. Psychol., Univ. New Hampshire, Durham, NH.

In rats, large lesions of thalamus that include portions of the MDn and the ILn disrupt olfactory continuous delayed non-matching to sample (cDNMTS). To compare the effects of lesioning ILn and MDn, rats were trained to perform this task and then given either sham surgery or an excitotoxic lesions of one of these structures. Surprisingly rats with the ILn lesion were impaired while the rats with MDn lesions were not. None of the lesion groups were impaired on a subsequent olfactory discrimination that used go/no go procedures comparable to cDNMTS. In previous studies of central olfactory system lesions we have observed comparable impairments only after complete lesions of pyriform cortex. While surprising, these findings are consistent with results for a place DMTS task (Burk & Mair, this meeting). Supported by grant RO-1 NS26855 from NINDS to RGM.

DIFFERENT HIPPOCAMPAL - CORTICAL - STRIATAL - THALAMIC CIRCUITS MEDIATE DELAYED VS NON-DELAYED FORAGING IN THE RAT. Stan B. Floresco*. Jeremy K. Seamans and Anthony G. Phillips. Department of Psychology, Univ. of British Columbia, Vancouver, B.C., V6T 124. The ventral CAl/subiculum (vCAl/sub) region of the hippocampus, the prelimbic cortex (PL) and the nucleus accumbens (NAc) comprise a neural circuit that has been implicated in the efficient performance spatially-mediated foraging tasks. The first series of experiments assessed the nature of the interactions between these brain regions by utilizing a transient lidocaine-induced disconnection procedure. Rats were well-trained on one of two versions of a spatially-cued radial-arm maze task and then received a unilateral lidocaine infusion into the VCAl/sub and a contralateral lidocaine infusion into the PL or the NAc. Disconnections between the vCAl/sub and the PL severely disrupted foraging during a delayed spatial win-shift (SWSh) task, in which the rat was required to obtain information about the location of food, hold it over a 30 min delay and use this information later to guide foraging. However, similar vCAl/sub-PL disconnections did not disrupt performance of a non-delayed random foraging (RF) task, in which rats were required to locate 4 pellets placed randomly on an 8-arm maze. Conversely, disconnections between the vCAl/sub and the NAc impaired performance on the RF task, but not the delayed SWSh task. These results suggest a functional dissociation between the brain circuits involved in delayed and non-delayed spatially-mediated foraging.

The mediodorsal nucleus of the thalamus (MD) is part of an anatomical loop which includes the PL and the NAc. As such, the MD may be part of a neural circuit that mediates foraging strategies across a delay. In a separate experiment, two groups of well-trained rats received bilateral infusions of lidocaine into the MD prior to either the test phase of the delayed SWSh task, but not the RF task, a pattern of deficit

AUDITORY SPATIAL WORKING MEMORY IN BARN OWLS: DISRUPTION BY PHARMACOLOGICAL INACTIVATION OF THE FOREBRAIN ARCHISTRIATUM, E. I. Knudsen* and P. F. Knudsen. Dept. of Neurobiology, Stanford Univ. Sch. of Med., Stanford, CA 94305-5401.

The central nervous system continuously stores information about the spatial locations of potentially important stimuli in a temporary form referred to as spatial working memory. We are using the barn owl to referred to as spatial working memory. We are using the ball was a explore the pathways and mechanisms that mediate auditory spatial working memory. We evaluated auditory spatial working memory using a delayed-response task. First, the owl fixated a zeroing light. Then a noise burst was presented from a hidden, movable speaker. The owl a delayed-response task. First, the owl fixated a zeroing light. Then a noise burst was presented from a hidden, movable speaker. The owl made a stimulus-guided head saccade to the sound source. The noise was turned off and the owl re-oriented to the zeroing light. When the zeroing light was turned off, the owl made a memory-guided head

Seconds right was turned off, the own made a memory-guided nead saccade and strike at the location of the speaker.

Neuronal inactivation (muscimol; 0.5 - 1.0 μg) in a region of the barn owl archistriatum that is functionally analogous to the mammalian frontal eye fields caused owls to lose the ability to respond to the remembered locations of auditory stimuli: the owls were unable to make memory-guided head saccades or memory-guided strikes at auditory targets. In contrast, archistriatal inactivation had no effect on stimulusguided responses to auditory stimuli. The memory-dependent deficit was selective for acoustic events that occurred in the hemifield contralateral to the side that was inactivated. The data demonstrate that in the avian archistriatum, as in the mammalian prefrontal cortex, there exists a region that is essential for the expression of spatial working memory. Supported by NIDCD #RO1 DC00155-16.

THALAMIC AMNESIA RECONSIDERED: EXCITOTOXIC LESIONS OF THE INTRALAMINAR NUCLEI (ILn), BUT NOT THE MEDIODORSAL NUCLEUS (MDn) DISRUPT PLACE DMTS PERFORMANCE. J.A. Burk*, B.M. Glode, J.R. Pelletier & R.G. Mair. Dept. Psychol., Univ. New Hampshire, Durham, NH 03824.

In rats, large lesions of thalamus that include portions of the MDn and ILn disrupt performance on DNMTS and DMTS based on place cues. In this study, rats were trained to perform a place DMTS task and then given excitotoxic lesions of either (1) the ILn, (2) the MDn, (3) the L-IML site (which affects both ILn and MDn and has previously been associated with DMTS impairments), or (4) sham surgery. The excitotoxic L-IML lesions had effects consistent with previous studies of rats with RF L-IML lesions. Surprisingly ILn lesions caused severe deficits while MDn lesions had little effect. None of the lesion groups were impaired on a subsequent serial reversal learning task based on place cues. While surprising, these findings are consistent results for an olfactory cDNMTS task (Mair et al, this meeting). Supported by grant RO-1 NS26855 from NINDS to RGM.

DIFFERENTIAL OUTCOMES ENHANCES MEMORY
PERFORMANCE ON OPERANT MATCHING-TO-POSITION IN
NORMAL AND THIAMINE DEFICIENT RATS.
L. Savage*, S. Pitkin. K. Knitowski, K. Daly, & A. Ganzekaufer.
Department of Psychology, SUNY-Binghamton, NY 13905
Numerous studies have demonstrated that rats with
Pyrithiamine-induced Thiamine Deficiency (PTD) have extensive

diencephalic damage and are severely impaired at acquiring new tasks that require the use of "working memory". The Differential Outcomes (DO) procedure, which correlates specific reinforcers with specific discriminative stimuli, improves performance of normal subjects on various conditional discrimination tasks. Previous research (Savage & various conditional discrimination tasks. Previous research (Savage & Langlais, 1995) revealed that implementing the DO procedure in the T-maze version of Matching-to-Position (MTP) completely eliminated the PTD-induced learning deficit, but not the PTD-induced memory deficit. In the current study we implemented the DO procedure in an operant version of MTP and found that, although it did not enhance learning of the total, it did halp improve about them. the task, it did help improve short-term memory performance in both normal and PTD-treated rats. Additionally, normal and PTD-treated rats were administered i.p. injections of scopolamine and MK-801. Rats, both normal and PTD-treated, trained with the DO procedure continued to have better memory performance than rats trained with a non differential procedure when administered scopolamine, but not MK-801. Using the DO procedure allows brain damaged subjects to utilize different undamaged information processing systems, and affects the influence of amnesic drugs. This research was supported by a SUNY Faculty Award to L.S.

ROLE OF MONKEY CEREBELLAR DENTATE NUCLEUS IN PROCEDURAL MEMORY. X. Lu*, O. Hikosaka, and S. Miyachi. Dept. of Physiol., Juntendo Univ. Sch. of Med., Tokyo, 113. Japan

To examine whether the cerebellum is involved in learning and memory of sequential procedures, we trained a monkey on a sequential button press task (2x5 task) (Hikosaka et al., J. Neurophysiol., 74, 1652-1661, 1995). On pressing of a home key, 2 of 16 (4x4) LED buttons (set) were illuminated, and the animal had to press them in a predetermined order which he had to find by trial and error. A total of 5 sets (hyperset) were presented in a fixed order as a trial. An error at any set aborted the trial. In one block, a hyperset was repeated until 10 successful trials were completed. The monkey had learned 22 hypersets daily so that he could perform them with few errors. We asked whether, by the reversible functional blockade of the dentate nucleus (DN) with muscimol, the monkey had difficulty in performing the learned hypersets or difficulty in learning newly generated hypersets, or both.

First, we recorded from neurons in DN through guide tubes which were implanted with the aid of MRIs; many of them showed clear task-related changes only when the pisilateral hand was used. Among them was a group of neurons that displayed exclusive or enhanced activity changes for the first button press compared with the second press in each set. They were considered as sequence-dependent neurons. We then injected muscimol (1 µl x 5 µg/µl) into the site where such sequence-dependent neurons were recorded. We found that the number of errors for the learned hypersets increased when performed by the ipsilateral (p<0.001), but not contralateral (p>0.05) hand. In contrast, the number of errors for new hypersets showed no significant increase with either the ipsi- or contralateral hand (p>0.05). These results suggest that the cerebellar DN is critical for storage and/or retrieval of long-term procedural memory rather than its acquisition.

EFFECTS OF MIDLINE AND LATERAL CEREBELLAR LESIONS ON MOTOR AND NON-MOTOR LEARNING IN RATS. <u>C. Joyal* J. Caston and R. Lalonde</u>. Faculté des Sciences de Rouen, Laboratoire de Neurophysiologie sensorielle, Mt-Saint-Aignan, France, 76011 and Groupe de Recherche en Neuropsychologie, Université de Montréal, Canada.

Rats lesioned either in the midline cerebellum, comprising the vermis and fasticial nucleus, or the lateral cerebellum, comprising the cerebellar hemispheres and dentate nucleus, or in the fastigial nucleus only were evaluated in a series of motor and non-motor learning tests. Rats with midline lesions had difficulty in maintaining their equilibrium on a bridge and were slower before turning upward and traversed less squares on an inclined grid. They were not impaired for muscle strength when suspended from a horizontal wire Rats with lateral lesions had milder deficits on the bridge and were not affected in the other two tests. In the Morris water maze test, rats with lateral lesions were deficient in spatial orientation, whereas rats with midline lesions were deficient in visuomotor coordination. Lateral lesions had no effects on visual discrimination learning. These results illustrate the differential influence of midline as opposed to lateral cerebellar regions on both motor and non-motor behaviors. Fastigial nucleus lesions decreased the time spent in equilibrium and latencies before falling on the bridge and the distance travelled along the inclined grid but had no effect on muscle strength when suspended from the horizontal string. Quadrant entries and escape latencies were higher in rats with fastigial lesions during the hidden platform condition of the Morris water maze but not during the visible platform condition. It is concluded that fastigial-lesioned rats are impaired in equilibrium and spatial orientation but with repeated trials learn to improve their performances. This work was supported by scholarships to C.C. Joyal from CRSNG and FCAR.

546.17

EFFECTS OF ELECTRICAL STIMULATION AT MEDIAL AND LATERAL PARAFASCICULAR NUCLEUS ON TWO-WAY ACTIVE AVOIDANCE. <u>A. Vale-Martínez</u>, M. Martí-Nicolovius, G. Guillazo-Blanch and I. Morgado-Bernal. Dept. de Psicobiologia i Metodologia de les Ciències de la Salut, Edifici B, Universitat Autònoma de Barcelona, 08193 Bellaterra (Barcelona), SPAIN.

Posttraining parafascicular intracranial electrical stimulation (PF ICS) can have facilitatory, detrimental or neutral effects on 2-way active avoidance acquisition (5 sessions, 1 daily, 10 trials each) and long term retention (LTR) (1 session, 10 trials). To test whether facilitatory effects of PF ICS on this task could be due to the application of the treatment at the medial or lateral parafascicular nucleus (PF), rats were implanted with an electrode at PF. Immediately after each acquisition session, experimental rats were electrically stimulated at the PF for 10 minutes. According to the electrode tip locations, experimental rats were divided in 6 groups: 3 medial PF groups (Anterior-ICS, Central-ICS and Posterior-ICS) and 3 lateral PF groups (Anderior-ICS, Central-ICS and Posterior-ICS). Two control groups were used (Medial control and Lateral control) depending on the electrode implantation laterality.

Our results showed that posttraining medial PF ICS has detrimental effects on 2-way active avoidance that are attributed to the medial PF relations with the limbic system. The same treatment applied at lateral PF confirmed facilitatory (Posterior ICS), detrimental (Central-ICS) and neutral (Anterior-ICS) effects on this task, depending on the affected antero-posterior area of the nucleus. Facilitatory effects are discussed in terms of PF relations with the subparafascicular nucleus (SPF) and PF projections to the raphe nuclei system. Detrimental effects might be a result of lateral PF relations with the motor system.

LESIONS OF THE CEREBELLAR NUCLEI IMPAIR SEQUENCE LEARNING IN A SERIAL REACTION-TIME TASK. P.D. Nixon and R.E. Passingham (SPON: Brain Research Association) Department of Experimental Psychology, University of Oxford, Oxford OX1 3UD.

Several groups have claimed that cerebellar patients are impaired on the serial reaction-time task, a test of procedural learning. However, it is not certain that in these studies the pathology was confined to the cerebellum

We therefore trained monkeys pre-operatively on a SRT task with 4 target stimuli. The stimuli lit in a repeating sequence (SEQ). Learning was measured by the decrease in response times for each sequence of 4 moves (STs) compared with the times when the stimuli were lit in random order (RAN). When performance on the SEQ condition was optimal, bilateral lesions were placed in the lateral cerebellar nuclei, using kainic acid; the remaining animals served as unoperated controls.

In the operated animals post-operative STs for the SEQ and RAN conditions were, as expected, considerably increased, This was true both for reaction times and movement times. Unexpectedly, the STs for the RAN condition were slower than would be predicted by the motor impairment alone. However, all the operated animals showed evidence of some retention of the sequence. All the animals were then given a new repeating sequence to learn. The control group took 1400 trials to reach their previous level of performance, whereas the lesion group failed to reach their level after 2000 trials. These data confirm the results obtained for patients.

ROLE OF THE INFERIOR OLIVARY COMPLEX IN MOTOR SKILLS AND MOTOR LEARNING IN THE ADULT RAT. L. Rondi-Reig#, N. Delhaye-Bouchaud#, J. Mariani#*, J. Caston\$ #Lab. de Neurobiologie du Développement, Institut des Neurosciences (CNRS URA 1488) Univ. P&M Curie, 75005 Paris, France. Lab. de Neurophysiologie Sensorielle Faculté des Sciences, Univ. de Rouen, France.

In order to determine the role of the inferior olivary complex (IOC) of adult rats in motor learning, we studied the behavior of animals whose IOC was destroyed using i.p. injection of 3-acetylpyridine. Muscular strength, motor coordination and equilibrium of animals were tested using different motor tasks: hanging test, stumbling test and unrotated rod test. The different scores show that 3-acetylpyridine treated rats had motor coordination and static equilibrium deficiencies, whereas their hanging capabilities were intact when compared to controls. Animals were also trained upon an unrotated rod or upon the rod rotating at 5, 10 or 20 rpm. 3-acetylpyridine treated rats were able to maintain their equilibrium on the unrotated rod and at 5 rpm. Moreover after motor training at 5 rpm, rats were able to improve their motor skills and reached the same score as controls. Despite their good motor skills, animals were unable to maintain their equilibrium when rotated at 10 and 20 rpm. These results suggest that the inferior olivary complex is needed for learning of motor sequences involving a high synchronization of movement. (supported by a MRE grant 92.C.0756)

ROLE OF RAT "BARREL" CORTEX IN TACTILE LEARNING. <u>L.A.</u> <u>Harris, R.F. Westbrook, and M.E. Diamond*</u>, Sch. of Psychology, Univ. of New South Wales, Syndey, 2052 Australia and Cognitive Neurosci. Sector, International Sch. for Advanced Studies, Trieste 34014 Italy.

We are using the gap-crossing task to investigate in what way the rat primary somatosensory "barrel" cortex contributes to the identification of objects contacted by the whiskers. Rats are trained without visual information (under red light) to obtain food by crossing a gap from one elevated platform to another. Trained rats show whisker-dependent crossing, traversing wide gaps (up to 16 cm) where they can detect the goal platform only by projecting the whiskers in front of the snout. The behavior is cortex-dependent: gap-crossing ability is abolished if vibrissal barrel cortex is ablated, and naive rats cannot learn the task after such ablation. We are examining to what extent gap-cross learning is horizontally distributed across cortex. Rats are trained with 4 whiskers on one side of the face. Once the task has been learned, these 4 "trained" whiskers are cut off and 4 new "prosthetic" whiskers are glued to whisker stumps -- either to the stumps of the trained whiskers, to 4 different stumps on the same side of the face, or to 4 stumps on the other side of the face. The rats are then re-tested. If they can immediately use information from prosthetic whiskers attached to "untrained" stumps it means that off-centre barrel-columns (those deprived of whisker input during training) must have participated in the acquisition of the gapcrossing task, or else have access to the learned information. (Supported by NINDS 32647, the Whitehall Foundation, and M.U.R.S.T.).

THE EFFECT OF AUDITORY SHUTTLE-BOX LEARNING ON THE AMINERGIC TRANSMISSION SYSTEMS OF ASSOCIATIVE BRAIN AREAS OF GERBILS. H. Stark* and H. Scheich, Federal Institute for Neurobiology (IfN), Brenneckestr. 6, 39118 Magdeburg, Germany

Auditory cortex has been shown to be a site of widespread neuronal learning processes even in the context of simple auditory conditioning behavior and parts of the prefrontal cortex are a site of the working memory In view of their presumed role in determining behavioral and motivational relevance of incoming information we investigated whether the dopaminergic and serotonergic systems are involved in learning activities of both brain areas. Using chronic brain microdialysis technique samples from auditory cortex and medial prefrontal cortex were obtained before, during and after daily footshock avoidance training simultaneously from trained gerbils and passive control animals or pseudotrained animals. Levels of extracellular dopamine (DA), homovanillic acid (HVA) as metabolite of the dopaminergic system as well as 5-hydroxyindoleacetic acid (5-HIAA) as metabolite of the serotonergic system were systematically analyzed. The common response of the dopaminergic systems of sensory and associative brain areas appeared to reflect the initial formation of the behaviorally relevant association exclusively during the first training day while the serotonergic response appeared to correlate with the stress level of animals. PARADOXICAL INFANTILE OLFACTORY MEMORIES. R.M. Sullivan*, M. Landers and D.A. Wilson, Department of Zoology, University of Oklahoma,

Neonatal rats can learn to avoid or approach an odor. However, under most circumstances, neonatal rats will learn an odor preference, even when the reinforcer used during conditioning is clearly aversive to the pup. For example, pairing an odor with a moderate shock produces a subsequent preference for the conditioned odor. During the end of the second week of life, conditioning becomes similar to the adult, so that odor and 1mA shock pairing now produces an odor aversion This

series of studies further explores this developmental change in offactory learning. Pups were given odor (2ul citral) and shock (.7 mA. 1 sec, 3 min IT1) pairings for a single 30 min training session. Olfactory learning was assessed in a 2-odor choice test (citral vs familiar clean bedding odor). **Experiment 1** assessed the age at which pups change from learning a preference to learning an aversion from odor-shock conditioning. The results show that PN9 pups learn/express an odor preference whereas PN10 pups learn/express an aversion, illustrating a developmental change in the representation of this training from appetitive to aversive learning. Experiment 2 assessed whether pups would express a preference (typical of PN9) or express an aversion (typical of PN10) when trained on PN9 but tested on PN10. The results showed that pups trained on PN9 exhibit a preference when tested on either PN9 or PN10. Experiments 3 and 4 assessed whether the olfactory memory could be changed by extending the training from PN9 (preference learning) to PN10 or beyond (aversion learning). The results PN9 (preference learning) to PN10 or beyond (aversion learning). The results showed that when learning began during the period of preference learning and extended into the period of aversion learning, pups continued to express a preference. Together, these results suggests that once an olfactory memory is formed, the original memory trace continues to be strengthened by subsequent experience, despite dramatic developmental changes in the representation of this training from appetitive to aversive learning. AP-5 and L-NAME block sensory-sensory conditioning in waking rat barrel cortex. M. Maalouf, O.E. Valdivia, A.A. Myasnikov and R.W. Dykes*. Département de physiologie, Faculté de Médecine, Université de Montréal, Montréal, Québec. Several studies have shown that the behavior of cortical neurons changes during

learning, yet, few of them have demonstrated if such changes are a form of cortical plasticity or merely a reflection of subcortical events. Delacour et al. (1987) showed by recording from neurons in barrel-cortex of awake rats that paired stimulation of the principal whisker (named S2) and a non-adjacent one (S1) enhances the response to S1 of some neurons representing S2 in the cortex. We hypothesized that this sensoryof some neurons representing \$2.5 in the cortex. We hypothesized that this sensory-sensory conditioning is a form of cortical learning that relies on a mechanism similar to hippocampal long-term potentiation. We recorded a total of 70 barrel cortex neurons during 50 pairings of \$1 and \$2.1 in each pairing, the ending of \$1 preceded the beginning of \$2 by 300 ms and the duration of each was 750 ms. The interval between two pairings was randomly chosen between four preset values (5, 7, 9 or 11 s). Of the 25 neurons that received this conditioning paradigm, 5 showed a significant increase in the response to S1. The behavior of 30 neurons was evaluated during the same conditioning paradigm while applying by microiontophoresis, either the NMDA-receptor antagonist, AP5 (17/30), or the nitrous oxide synthase inhibitor, L-NAME (13/30). Changes in the response to S1 were not seen in any of these cases. Finally, no changes were observed in the activity of (15) neurons while the rats underwent a truly random conditioning paradigm consisting of 50 non-paired stimulations of S1 and S2. We conclude that the changes in neuronal responsiveness are attributable to a cortical mechanism that depends upon NMDA receptors and may involve nitrous oxide as a potential retrograde messenger (Supported by the Medical Research Council of Canada and the Faculty of Medecine of the University of Montréal).

LEARNING TASK DEPENDENT DIFFERENCES IN INTER-REGIONAL CORRELATIONS, BUT NOT MEAN VALUES, OF FLUORO-DEOXYGLUCOSE UPTAKE IN YOUNG RATS. M.W.

REGIONAL CORRELATIONS, BUT NOT MEAN VALUES, OF FLUORO-DEOXYGLUCOSE UPTAKE IN YOUNG RATS. M.W. Lilliquist*. A. Amsel. & F. Gonzalez-Lima. Dept Psychology & Instit. for Neuroscience, Univ. Texas at Austin, Autsin TX, 78712, USA.

We assessed the pattern of brain activity during performance of two closely-matched learning tasks, using "C-floror-deoxyglucose (FDG) uptake as an index of neural activity. Pre-weanling rat pups were trained to traverse a straight alley runway for food reward, according to one of two schedules of reinforcement. Half of the subjects were rewarded according to a 50% quasirandom "irregular" schedule, which results in greater persistence and greater resistence to extinction. The other half were rewarded in a 50% nonrandom manner, consisting of rewarded and nonrewarded trials in "regular" alternation. Under the regular schedule, animals displayed discrimination by faster running speed on reward trials and slower running speed on nonreward trials. FDG uptake occurred at the end of acquisition, during the last 50-trial training session, at which point the regularly-rewarded subjects were exhibiting asymptotic discrimination. FDG uptake from 50 brain regions was measured in "C units from autoradiograms developed from serial sections of each brain. Means analysis of within-subject normalized FDG uptake revealed few differences. In contrast, analysis of the correlations between brain regions revealed marked differences between regular and irregular reward schedules. In particular, uptake values in the majority of brain regions measured were highly correlated in the irregularly-rewarded subjects, while only a small minority of regions were correlated in the regularly rewarded animals. The widespread inter-correlations between FDG uptake in brain regions may represent a closer functional coupling of brain activity in animal that faces situations of ongoing inconsistency, in comparison to the more stable situation which occurs after extended training with regularly alternating reward. This work supp with regularly alternating reward. This work supported by NIAAA grant #AA07052 and NSF grant #IBN9222075.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS XI

SEX DIFFERENCES IN CONDITIONED ANALGESIA AND FREEZING. H.S. Stock*, B.J. Caldarone, D.L. Mongeluzi, & R.A. Rosellini. Dept. of Psychology, University at Albany: SUNY, Albany, NY

Prior research in our laboratory has shown that males exhibit higher levels of conditioned fear-induced enhancement of morphine analgesia compared to females. One possible explanation for this observed behavior is that context conditioned fear was not present for the females. Another possible explanation is that males and females differ in the stress-induced activation of a system(s) that is involved in pain-inhibition. An experiment was conducted to determine if males and females exhibited differential levels of freezing and conditioned analgesia during exposure to a conditioned fear context. The results of the experiment showed that while conditioned fear males and conditioned fear females exhibited similar freezing levels, conditioned fear males exhibited higher levels of conditioned analgesia compared to conditioned fear females. These findings suggest that the sex difference in conditioned fear-induced enhancement of morphine analgesia may be due to a sex difference in the stress-induced activation of a system(s) involved in pain-inhibition.

WATER MAZE PERFORMANCE AND SWIM STRESS: TOLERANCE AND SEX DIFFERENCES M.Kavaliers*, T. S. Perrot-Sinal and K.-P. Ossenkopp. Neuroscience Program, University of Western Ontario, London, Canada, N6A 5C1

Performance on a water maze task, whereby individuals have to acquire and retain the location of a submerged hidden platform, involves both "spatial" and "non-spatial" components. This study examined the swim stress-induced analgesia (SSIA) arising from protocols associated with water maze task acquisition (single and repeated 1 min swim trials (22°C) with and without a hidden platform; block of 4 swim trials) in male and female deer mice. Sex differences were evident in the levels of analgesia, the development of tolerance, and the neuromodulatory correlates of SSIA. Males displayed significantly higher initial levels of SSIA (1 min swim) and developed tolerance more readily than females. Presence of the hidden platform facilitated the development of tolerance. There were also sex differences in the neuromodulatory substrates of SSIA. One min swims induced a "non-opioid" (naloxone-insensitive) analgesia that was attenuated by the competitive NMDA antagonist, NPC 12626, in males but not in females. The SSIA arising from the "block" of swims was of a mixed opioid and "non-opioid" nature and insensitive to the NMDA antagonist in females. These various swim associated "non-spatial" factors likely contribute to the expression of sex differences in spatial aspects of water maze performance. (supported by NSERC)

STRESS FACILITATES AVERSIVE PAVLOVIAN CONDITIONING IN MALES, BUT NOT IN FEMALES. G. E. Wood* & T. J. Shors Dept. Psychol., Prog. Neurosci., Princeton Univ., Princeton, NJ 08544 -1010.

The effects of gender and inescapable stress on aversive Pavlovian eyeblink conditioning were studied. Male and female Spraque-Dawley rats were analyzed under stressed and unstressed conditions. Stressed subjects were restrained and exposed to 30, 1 s per minute, 1 mA tailshocks, and then returned to their home cage. Twenty four hours later, all subjects received classical conditioning (paired stimuli) or explicitly unpaired stimuli. Conditioned subjects were exposed to an 85 dB white noise burst, which was paired with a 0.7 mA periorbital eyelid shock. During the acquisition, stressed males exhibited facilitated conditioning, whereas stressed females exhibited significantly impaired conditioning relative to their genderspecific unstressed controls. These results suggest that exposure to the stressor used here facilitates acquisition of the conditioned response in males, while suppressing it in females. In addition to the stress effects observed on learning, unstressed females acquired the conditioned response at a facilitated rate compared to unstressed males. No effects of stress or gender were observed in the performance of subjects receiving explicitly unpaired stimuli. These data emphasize the importance of incorporating dimorphic responses into current models of stress and learning.

DYNAMICS OF WORKING MEMORY ACROSS THE ESTROUS CYCLE. M.E. Blasberg*, R.W. Stackman, C.J. Langan, and A.S. Clark. Department of Psychology, Dartmouth College, Hanover, NH 03755.

Fluctuations in circulating gonadal steroids have been shown to influence both morphological and physiological features of the CA1 subfield of the hippocampus in female rats. Despite evidence for this plasticity, little is known regarding the functional or behavioral impact of these changes. purpose of this study was to evaluate spatial working memory on a delayed-non-match to sample (DNMTS) radial arm task across the estrous cycle.

non-match to sample (DNMTS) radial arm task across the estrous cycle. Twenty adult Long-Evans female rats were maintained at 85% body weight and housed in a reverse cycle room (lights off 1300 hrs). Throughout the four months of testing, vaginal smears were collected daily at 1200 hrs and females were tested for sexual receptivity with a stud male daily at 1600 hrs. Working memory testing was conducted daily between 1000-1300 hrs.

No estrous cycle variations in acquisition or post-acquisition performance on the standard 8-arm radial maze task were present. With a 1 hour delay imposed, we observed no influence of estrous cycle day on working memory in the DNMTS task. No significant pattern of changes in correct choices, retroactive, or proactive errors occurred as a function of day of the estrous cycle. Latency per choice, a measure of performance, not memory, was cycle. Latency per choice, a measure of performance, not memory, was significantly increased on proestrous relative to all other cycle days. The effect of a 4 hr delay on DNMTS performance across the estrous cycle is currently under investigation.

Although synaptic connectivity varies considerably across the estrous cycle, our results to date suggest that spatial working memory is remarkably stable. Supported by NIDA-08574 to ASC.

EFFECTS OF ESTROGEN AND ENVIRONMENT ON RADIAL MAZE ACQUISITION. J. M. Daniel, A. J. Fader, A. Spencer, B. E. F. Wee*, and G. P. Dohanich. Department of Psychology, Tulane University, New Orleans, LA 70118

The independent and interactive effects of estrogen and environment on acquisition of an 8-arm radial maze were determined in adult female rats. During the first 5 days of maze training with all arms baited, intact females reared in a complex environment made significantly more correct choices than intact females reared in isolation or ovariectomized females reared in either environment. During 19 additional days of training, females reared in a complex environment made more correct choices than females reared in isolation. During the first 5 days of training in a second experiment, ovariectomized females implanted with Silastic capsules of estradiol (25%) for 30 days prior to training and reared in a complex environment made significantly more correct choices than females with estradiol implants reared in isolation or females with cholesterol implants reared in either environment. During 19 additional days of training, females with estradiol implants made more correct choices than females with cholesterol implants. Results indicate that estrogen and environment can enhance radial maze acquisition, both independently and interactively. awards BNS-9021447 and BNS-9514816

STRATEGIES FOR LEARNING ACROSS THE ESTROUS CYCLE IN FEMALE RATS. D. L. Korol*, J. M. Couper, C. K. McIntyre and P. E. Gold. Department of Psychology and Neuroscience Graduate Program. University of Virginia, Charlottesville, VA 22903.
Fluctuations in hormones across the estrous cycle lead to large changes in synaptic density in certain brain areas. These changes are likely to be accompanied by differences in performance on behavioral tasks. Recently, we and others found that at times of high estrogen, females perform worse in the spatial version of the swim task than at times of low estrogen. Perhaps, differences are due to shifts in behavioral strategy and not to deficits in processing spatial information per se. We undertook the following experiments to test whether performance on other spatial tasks exhibits differences across the estrous cycle, and whether rats at low estrogen adopt a spatial strategy while rats at high estrogen adopt a response strategy during learning. Vaginal smears were taken at the same time daily from young adult virgin female Sprague-Dawley rats. In the first experiment rats were trained on an appetitive 2-choice discrimination task in a T-maze, with the opportunity to use either a spatial or a experiment rats were trained on an appetitive 2-choice discrimination task in a T-maze, with the opportunity to use either a spatial or a response strategy during training. After criterion performance was reached, a probe test was administered to assess strategy type. At stages of high estrogen, a greater proportion of rats relied on a response strategy, whereas at stages of low estrogen, a greater proportion relied on a spatial strategy. In the next experiment, rats were tested in a Y-maze on a rewarded spontaneous alternation task for 10 consecutive days, i.e. across two estrous cycles. No differences between estrous phases were noted for alternation scores or arm entries. However, a shift from a spatial to a response strategy emerged over the 10 days of testing regardless of stage. The results suggest that fluctuations in gonadal steroids might differentially influence behavioral strategies on different tasks, perhaps by affecting specific neural systems. Supported by NIA (AGO7648) and NINDS (NS32914).

EFFECTS OF ESTROGEN TREATMENT ON T-MAZE ALTERNATION IN FEMALE AND MALE RATS. A. J. Fader, A. W. Hendricson, and G. P. Dohanich. Department of Psychology, Tulane University, New Orleans, LA 70118.

Estrogen influences performance on various tasks of learning and memory in both humans and nonhumans. In the present experiments, the effects of estrogen treatment on reinforced T-maze alternation were examined. Gonadectomized female and male rats were treated daily with intramuscular injections of estradiol benzoate (5 $\mu g/kg$) or oil vehicle for 8 days prior to T-maze training and throughout 12 days of training. Estrogen treatment induced a mild, but significant, enhancement of T-maze acquisition in gonadectomized females, but not in gonadectomized males. When administered 15 minutes prior to testing on the thirteenth day, the muscarinic antagonist, scopolamine hydrobromide (0.2 mg/kg), significantly impaired alternation in females and males that were treated with oil. Estrogen treatment counteracted the effect of scopolamine on performance in females, as reported previously with higher doses of estrogen (25 µg/rat for 3 days, Dohanich, Fader, and Javorsky, *Behav. Neurosci. 108:988,* 1994). However. estrogen treatment did not reverse the effects of scopolamine in males. Results indicate that estrogen enhances T-maze acquisition and performance in female rats, but not in male NSF awards BNS-9021447.

THE EFFECTS OF ESTROGEN ON PERFORMANCE OF A HIPPOCAMPAL-DEPENDENT TASK. B. Berry*, R. McMahan, and M. Gallagher. Department of Experimental Psychology, University of North Carolina, Chapel Hill, NC

The density of dendritic spines in the CA1 region of the rat hippocampus has been shown to fluctuate in a manner dependent upon concentrations of circulating estrogen, an effect demonstrated in both ovariectomized and normally cycling animals. We assessed learning based on hippocampal-dependent spatial navigation in female rats at identified points in the estrus cycle corresponding to low (estrus) and high (proestrus) circulating estrogen. background training in water maze procedures, rats learned the location of an escape platform in the maze in a single session of 8 training trials. A strong spatial bias for the escape platform was also evident in a probe trial used to assess retention of learning 30 min after the training session. This entire protocol was completed in less than an hour. The performance of the two groups of female rats (estrus and proestrus) was indistinguishable on all behavioral measures, irrespective of the stage of estrus cycle during the task. These results indicate that rapid learning and retention for spatial information over a relatively short interval may be preserved despite morphological alterations in hippocampal dendritic spine density in the normally cycling female rat. ESTRADIOL EFFECTS ON RAT SPATIAL MEMORY, V.N

ESTRADIOL EFFECTS ON RAT SPATIAL MEMORY, V.N. Luine*, J. Rentas, L. Sterbank and K. Beck. Psychology, Hunter College of CUNY, New York, N.Y. 10021.

Estradiol (E₂) affects memory in a number of paradigms in both animals and humans. In order to understand the nature of E₂ effects, several experiments using the 8-arm radial maze, a spatial memory task, were done. Rats were ovariectomized, trained on the maze, and E₂ was given (24 h before testing) via s.c. implanted silastic capsules which generated diestrus E₂ levels. No effects were seen in five regular trials when all arms were baited. With delays of 3-5 h after the 4th choice, the treated rats performed better, the number of correct choices was higher. E₂ batted. With delays of 3-5 h after the 4th choice, the treated rats performed better, the number of correct choices was higher. E₂ was without effect in longer delays. Since these results suggested that E₂ may enhance memory, a four arms baited paradigm was utilized to quantitate working and reference memory. Reference errors (RME) are entrances to unbaited arms and provide a measure of learning while working memory errors (WME) are returns to a previously visited baited arm and provide a measure of memory. Five blocks of five trials each were analyzed, and E₂ was without effect on RMEs. WMEs were lower in blocks 4 and 5 of E₂ treated rats. Finally, E₂ silastics were implanted prior to training and 3 weeks before trials to determine if lack of effects in training and 3 weeks before trials to determine it lack of effects in regular trials was due to the short duration of E₂ treatment. A significant interaction between treatment and trials was seen; E₂ treated rats performed generally better. These results show that estradiol enhances performance of a spatial memory task and suggest that the effects are related to enhancements in memory, not learning. Further, sufficient time (days) may be necessary for estradiol's enhancing effects on memory (RCMI-RR03037)

SEX AND AGE EFFECTS ON DENDRITIC SPINE DENSITY IN CA1 OF THE HIPPOCAMPUS.
S.G. Warren*, E.Robinson, E.J.Chesler and J.M.Juraska.
Psychology Dept., University of Illinois, Champaign, IL

The density of dendritic spines and synapses in CA1 of the hippocampus varies across the estrous cycle of young female rats. These rapid morphological changes correspond to the circulating levels of estrogen and progesterone. When female rats age the estrous cycle ceases and they enter a state in which gonadal hormone levels no longer vary on a daily basis (called estropause). Here we investigated the morphological changes that occur with the natural cessation of the estrous cycle in aging female rats. Using Golgi stained tissue, dendritic spine density of young cycling females was compared to 12-15 month old and 22-24 month old estropausal females. In addition, young, middle aged and aged males were examined. Preliminary analysis indicates that young males have a greater density of spines than young females and females in estrus have more spines than 12-15 month old estropausal females. Analysis of the remaining groups is currently underway. Supported by NSF IBN 9310945 to JMJ and SGW was supported by HD07333.

WATER MAZE ESCAPE LATENCIES DECREASE IN OLD RATS WITH LOW POSTNATAL TESTOSTERONE EXPOSURE. K. Schultz*, N. Ward, M. Roberts, A. Wintink, L. Francis & T. Williams. Psychology Department, University of Winnipeg, Winnipeg, MB, Canada R3B 2E9

We have examined the extent to which the allocentric water maze performance of 240 old (1 year), adult (85 days) and adolescent (50 days) male and female Long-Evans rats was effected by pre- and post-natal choline supplementation and by post natal testosterone manipulation. One half of the animals tested had been exposed to enhanced choline levels throughout gestation and for 21 days after birth. Equal numbers of males and females were represented in each group. One half of these males had been gonadectomized one day after birth and half of the females received injections of testosterone on postnatal days three and five. All animals were housed in same sex groups in enriched environments following weaning.

Contrary to expectations, repeated measures analysis of variance revealed that across ages there were no significant choline treatment effects. However, the effects of testosterone on performance varied with sex, age and treatment level. Animals with low testosterone levels (control females, gonadectomized males) showed decreasing escape latencies with age while those with higher testosterone levels (control males, testosterone injected females) exhibited their shortest escape latencies as adults. At one year, these latencies returned to the longer, adolescent levels. These behavioural patterns were reflected in variations in the size of the hippocampal dentate gyrus. Thus, while perinatal manipulations of choline failed to have long term effects on allocentric maze performance, those of testosterone persisted into old age. SPATIAL LEARNING IN RATS - THE EFFECT OF SEX AND PRIOR FAMILIARIZATION WITH NON-SPATIAL ASPECTS OF THE TASK T. S. Perrot-Sinal, M. Kavaliers and K.-P. Ossenkopp. Neuroscience Prgm., University of Western Ontario, London, Canada N6A 5C2.

Performance of male and female laboratory rats was examined on a stationary hidden platform task (spatial task) in the Morris water maze after prior familiarization with non-spatial aspects of the task. Non-stationary hidden platform (NSP) training was used to familiarize animals with the general requirements of the water maze task (i.e., swimming, escape via the platform etc.) without providing spatial information (i.e., no extra-maze visual cues available). Performance on the spatial task was assessed in males and females who had received prior NSP training compared to rats with only a baseline swim prior to spatial training. NSP training resulted in faster acquisition of the spatial task in both males and females. Additionally, NSP trained animals showed improved retention of the acquired spatial task. A sex difference favoring males on both acquisition and retention of the spatial task was noted only in animals which had not received previous NSP training but not in those with prior NSP training. Moreover, there was an apparent reversed sex difference favoring females on some measures of spatial performance in NSP trained animals. These results suggest that performance on the water maze task, including the expression of sex differences, can be altered by previous familiarization with "non-spatial" aspects of the task.

SPATIAL MEMORY DECLINE IN AGED, NON-CYCLING FEMALE RATS VARIES WITH THE PHASE OF ESTROPAUSE. J.M.Juraska* and S.G.Warren. Psychology Dept. University of Illinois, Champaign, IL

We have previously reported that spatial memory on the Morris water maze varies with the estrous cycle in young adult female rats. Here we investigated the effects of the natural cessation of the estrous cycle (estropause) in aging female rats. Performance of male rats declines on this task as they reach old age, however little is known about the memory decline of females. Females were tested on the Morris water maze at 22-24 months of age, many months following the cessation of the estrous cycle. Females in persistent estrus were compared to those in anestrus. Those in persistent estrus, who have naturally higher levels of estrogen, performed significantly better than those in anestrus. In a comparison with young cycling females, both aged groups were found to perform poorly relative to females in estrus but not those in proestrus. These data suggest that the lowest levels of estrogen in aged females may be detrimental to spatial learning, while the highest estrogen levels in young adult females is detrimental. Supported by NSF IBN9310945 to JMJ and SGW was supported by HD07333.

Consequences of estrogen loss and replacement on cognitive function of surgically menopausal monkeys. Mary Lou Voytko* and Jennifer Hinshaw. Dept. of Comparative Medicine, Bowman Gray Schl. of Med., Winston-Salem, NC 27157.

Increased forgetfulness and decreased attention are commonly experienced by postmenopausal women. Whether these cognitive changes are related to the loss of estrogen associated with ovarian failure in menopause rather than to age per se is not clear. To address this issue in a primate model, we determined the effects of estrogen loss associated with ovariectomy and subsequent estrogen replacement therapy (ERT) on performance in several behavioral tasks in young female cynomolgus monkeys (n=5). After pretraining on visual discriminations, delayed response, a visuospatial cued task or a simple reaction time task, monkeys were ovariectomized and then continually reassessed on the tasks over 3 months. At that time, 2 monkeys began ERT and 3 monkeys received placebo. Repeated assessment of the tasks occurred for 5 months. Neither learning, memory or reaction time were affected by estrogen loss or ERT. In contrast, spatial orienting to a cue was disrupted by estrogen loss and these alterations were reversed following ERT but not placebo. These cognitive results are the first to be obtained from a primate model of menopause and suggest that estrogen loss associated with ovarian failure may be contributing to alterations in attention of postmenopausal women. EARLY ANDROGEN-INDUCED ALTERATIONS IN STRESS RESPONSIVENESS, MONOAMINERGIC SYSTEM, AND COGNITIVE PERFORMANCE: POSSIBLE BASIS FOR ADHD. <u>J. A. King C. F. Ferris, Y. Delville, S. Adolphe, and B. Ray.</u> Department of Psychiatry, University of Massachusetts Medical Center, Worcester, MA 01655.

Numerous reports suggest that attention deficit hyperactivity disorder (ADHD) is more prevalent in males than females. Pharmacological treatment of ADHD is based mostly on alterations in the monoaminergic systems. The spontaneously hypertensive rat was been utilized as an animal model of ADHD by many researchers. These studies were designed to evaluate the effects of testosterone administration on behavior, the neuroendocrine system, and the monoaminergic system in the animal model of ADHD. Neonates were microinjected with testosterone (100 ug) or vehicle into the frontal lobe of the cortex, on postnatal day 10. On postnatal day 45 they were evaluated for their performance on the Morris swim Maze and open field activity, and their plasma levels of adrenocorticotrophin (ACTH) after stress, and dopamine oreactivity in the frontal lobe of the cortex. In the water maze, ADHD animals took significantly longer to find the platform than Wistar controls (p \leq 0.05). This deficit was enhanced with acute androgen administration. Plasma ACTH levels were increased in the ADHD animals exposed to testosterone (p≤ 0.05), whereas dopamine immunoreactivity was decreased. Taken together, these studies suggest that early androgen treatment of ADHD may alter the monoaminergic system in a manner that further facilitates cognitive impairment and may modulate the hypothalamic-pituitary response to stress

SEX AND SEASONAL DIFFERENCES IN RELATIVE HIPPOCAMPAL VOLUME IN PARASITIC AND NON-PARASITIC COWBIRDS. N. S. Clayton*,

L. C. Reboreda and A. Kacelnik. Section N.P.B., UC Davis, Davis CA 95616.

In brood parasites, spatial ability to locate and return to hosts' nests may have selected for an enlargment of the hipppocampus relative to the remainder of the telencephalon (RHV) when compared to non-parasitic species; and this enlargement may occur only in the breeding season when searching for hosts' nests. To test this hypothesis, RHV was measured in the breeding and non-breeding season for 3 cowbird species which differ in whether one, both or neither sex search for hosts' nests. In the breeding season, only female shiny cowbirds (Molothrus bonariensis) search for host nests and therefore females should have a larger RHV than do males; in Screaming cowbirds (M. rufoaxillaris), both sexes inspect hosts' nests in the breeding season, so both sexes should have a large RHV; and in non-parasitic bay-winged cowbirds (M. badius) neither sex searches for hosts' nests, and neither sex should have a large RHV. Birds were captured in Buenos Aires in the breeding (n=36) and non-breeding season (n=26), given a lethal intraperitoneal overdose of sodium pentobarbital (8ug/g), and perfused transcardially with 0.85% heparinized physiological saline followed by 4% pertused transcardially with 0.85% heparimized physicological sanine followed by 4% paraformaldehyde. Brains were removed, post-fixed for 14 days, dehydrated and embedded in polywax. 40 µm coronal sections were cut, and every fifth section stained with Nissi. To calculate RHV, the area of hippocampus and remainder of the telencephalon was measured in each section and volumes computed using a WACOM digitizing tablet and NIH Image® software. The results support the predictions. In the breeding season, shiny cowbird females had larger RHV than the males, whereas there were no sex differences in RHV in screaming or bay winged cowbirds, but screaming cowbirds had larger RHV than did baywing cowbirds. Comparisons of RHV in the breeding and non-breeding season show that both male and female screaming cowbirds had larger RHV in the breeding season whereas only female shiny cowbirds had significantly larger RHV in the breeding season, and in bay winged cowbirds there was no evidence of a seasonal difference for either sex.

SINGLE UNIT ACTIVITY IN MEDIAL PREFRONTAL CORTEX OF RATS PERFORMING AN OPERANT VIGILANCE TASK. K. Hutchinson*, M. Sarter, and B. Givens. Neuroscience Program. Ohio State University, Columbus, OH 43210

The medial prefrontal cortex (mPFC) is thought to be critical for sustained attention To examine this function of the mPFC, single unit activity was recorded from prelimbic cortex in rats performing a vigilance task that required the detection of brief visual signals (25-500ms) and the discrimination of signal from nonsignal events. Under control conditions, neural activity was not well correlated (5/75 cells) with specific task events (stimulus onset or behavioral responses). With the addition of a distractor stimulus (1 Hz flashing houselight), a reliable suppression of neural activity, as well as a decrease in vigilance performance, was observed. The suppression of neural activity by the distractor may be mediated by increases in acetylcholine (see Sarter et al, Cog. Brain Res., 1996). Preliminary attempts to manipulate the cholinergic inputs to the mPFC by local infusion of scopolamine during unit recording suggest an interaction between acetylcholine and suppression of single unit activity produced by the distractor stimulus. Current experiments assess mPFC unit activity before and after local cholinergic deafferentation with 192 IGg Saporin. In control experiments, task related cells showed correlated unit activity to the presence of the light (7/13 cells) in a visual discrimination task, whereas activity correlated to the motor response (9/14 cells) in a variable interval task. The data indicate that the behavioral correlates of mPFC neural activity depend on task requirements and also suggest that cholinergic input may have a role in vigilance related changes in neural activity. *Supported by ABMRF.

CONDITIONED DOPAMINE RELEASE WITHIN THE PREFRONTAL CORTEX AND NUCLEUS ACCUMBENS. J.B. Mitchell* P.D. Callahan, B.L. Croce and R.J.

Bierwirth. Dept. of Psychology, Boston College, Chestnut Hill, MA 02167.

We investigated the effect of classical conditioning on dopamine (DA) release within mesocorticolimbic terminal fields, the medial prefrontal cortex (mPFC) and nucleus accumbens, core (NAC). Male rats received 8 pairings of a conditioned stimulus (CS; light or tone) with an unconditioned stimulus (UCS; food). During each pairing, the CS was presented and 2 min later the UCS was delivered. The CS was left on for the 10 min during which the subject was allowed to eat. Extracellular DA concentrations were measured within the NAC and the mPFC using high speed DA concentrations were measured within the NAC and the mPFC using high speed chronoamperometry. The electrochemical signal was obtained by applying a ± 0.55 V pulse, relative to a $\Delta g/AgCl$ reference electrode, to a carbon fiber electrode, at a rate of 5 Hz. Exposure to a CS that had previously been paired with food elicited an increase in the electrochemical signal within both the NAC and the mPFC. The increase during exposure to the CS was larger within the NAC than within the mPFC (p <.05), and the response to the CS was smaller than the response to food within both areas (p<<.05). Interestingly, the temporal characteristics of the response differed between the two areas. Within the mPFC the signal reached maximum amplitude more quickly (113.2 \pm 38.3 sec) than within the NAC (300.8 \pm 90.6 sec). The response also returned to baseline more quickly within the mPFC than within the The response also returned to baseline more quickly within the mPFC than within the NAC (205.2 \pm 36.7 and 414.0 \pm 88.4 sec, respectively). That is, although presentation of the food-paired CS increased the electrochemical signal within both the NAC and the mPFC, the NAC showed a larger and longer lasting response while the response within the mPFC corresponded, at least approximately, to the time during training when the subject had experienced the CS prior to UCS delivery. These results indicate that stimuli that have been paired with a naturally rewarding stimulus increase activity within the mesocorticolimbic DA system. Supported by Boston College.

548.3

ACTIVITY OF DOPAMINE NEURONS DURING LEARNING IN A FAMILIAR TASK CONTEXT. J. Hollerman* and W. Schultz. Institut de Physiologie, Univ

Fribourg, CH-1700 Fribourg, Switzerland.

Midbrain dopamine (DA) neurons were recorded in two monkeys during performance of a simultaneous visual discrimination task using either familiar stimuli, which had established significance, or novel stimuli, which had to be learned by trial and error. Consistent with previous reports, DA neuron responses to liquid reward were reduced during established task performance with familiar stimuli in comparison to reward delivered unpredictably outside the task. However, when novel stimuli were introduced DA neuron responsiveness to task reward was responsible in the propriet of the propriet transiently reinstated despite the familiar task context. Responsiveness was most elevated before the subjects exhibited clear signs of learning of the significance of the novel stimuli, but was frequently maintained for a number of additional trials. These data suggest that a decrease in the predictability of reward, even in a familiar context, results in larger DA neuronal responsiveness to reward, Furthermore, a period of consistent stimulus-reward pairing is necessary for DA responses to a predicted reward to disappear. The partial predictability of reward during learning of the novel stimuli was reflected in a depression of activity observed in erroneous trials at the time reward would have been delivered for a correct behavioral response. The influence of temporal predicability was tested using familiar stimuli but varying the reward delay. Activations were increased when reward was delivered earlier or later than anticipated. Depressions were observed at the normal time of rewar only if reward delivery was late. Thus DA neurons respond with activation to reward delivery when its occurrence or the time of its occurrence (or both) is not reliably predicted. In a complementary manner, DA neuronal activity is depressed when a predicted reward fails to occur at (or before) the predicted time. Thus DA meurons signal a mismatch between the prediction of reward and its occurrence. The fact that such mismatches and corresponding DA signals occur most frequently in learning situations may provide the long sought link between DA and learning. (Supported by Swiss NSF, Roche Research Foundation and NIMH MH10282)

NEURONAL ACTIVITY IN PRIMATE ORBITOFRONTAL CORTEX DURING

LEARNING. L. Tremblay* and W. Schultz. Institut de Physiologie, Univ. Fribourg, CH-1700 Fribourg, Switzerland.

On the basis of lesion effects and anatomical connections, a major function of orbitofrontal cortex appears to concern the motivational control of voluntary behavior. As the function of motivation becomes particularly apparent during the adaptation of behavior to new contingencies, we investigated the activity of single orbitofrontal neurons in a learning set situation in which animals repeatedly adapted to new stimulus-response associations within a known task structure.

The underlying task was a delayed go-nogo motor paradigm in which both the behavioral reaction and the obtained outcome were indicated by an initial instruction picture. Animals reacted to a subsequent uniform trigger stimulus with one of three possible reactions involving, respectively, juice-rewarded movement, juice-rewarded non-movement and unrewarded movement. During learning trials, new instruction pictures were used while the rest of the task remained unaltered, and animals had to associate the new instruction pictures with the know behavioral reactions and outcomes. In two monkeys, 148 neurons were studied in both familiar and learning situations. Of these, 95 neurons responded to instruction stimuli, 44 responded to situations. Of including response to instruction statistically pulse reward and 38 showed activity anticipating juice reward. During learning, most responses to instructions increased strongly (56/95). They initially lost selectivity for the behavioral reaction or trial outcome and regained it many trials after the monkey had learned the new significances. Instruction responses often decreased or completely disappeared when animals failed to learn the new instruction pictures (15/95). By contrast, reward-related activations showed little changes during learning. Most reward responses (26/44) and reward anticipatory activations (21/38) showed similar amplitudes, durations and selectivities in learning and familiar trials. Interestingly, reward anticipatory activity occurred initially also in unrewarded trials but abruptly disappeared when this trial type was acquired. These data suggest a participation of orbitofrontal cortex in associating environmental signals with behavioral reactions and predicted outcomes of behavior. Supported by Swiss NSF and FRS of Quebec.

DECREASE OF GLUTAMATE RELEASE DURING THE DELAYED ALTERNATION TASK PERFORMANCE IN THE DORSOLATERAL PREFRONTAL CORTEX OF THE MONKEY - RELATIONSHIP BETWEEN GLUTAMATE AND DOPAMINE RELEASES T. Kodama*, M. Watanabe, M. Odagiri and K. Hikosaka Dept. Psychol., Tokyo Metropol. Inst. for Neurosci., Musashidai 2-6, Fuchu, Tokyo 183, JAPAN

Tokyo 183, JAPAN
We reported, in the companion presentation, the increase of dopamine release during the delayed alternation (DA) task in the dorsolateral prefrontal cortex (PFC) of the monkey. Since glutamate is a major excitatory neurotransmitter in the mammalian CNS, we investigated further the glutamate release during this working memory task, examining also possible relationship between dopamine and clutamate releases.

Two monkeys, which had been trained on both DA and sensory-guided control (CON) tasks, were served for this experiment. Extracellular fluids were obtained from the dorsolateral PFC by in vivo microdialysis method during the animal's task performance. Levels of dopamine and glutamate in the fluids were determined by the highperformance liquid chromatography (EICOM, Kyoto).

Significant decrease of glutamate release was observed during the DA as compared to CON in the dorsolateral PFC. Two way analysis of variance (task by neurotransmitter) indicated that there was significant interaction between them. The results suggest that there is a mechanism which coordinates glutamate and dopamine releases defice the action between them.

during the spatial working memory task.

MNEMONIC CODING AND OTHER FUNCTIONAL NEURONAL

MNEMONIC CODING AND OTHER FUNCTIONAL NEURONAL PROCESSING IN THE MONKEY PREFRONTAL CORTEX. S. Carlson*, P. Rämä, H. Tanila, I. Linnankoski, H. Mansikka. Inst. Biomedicine, Dept. Physiology, University of Helsinki, Finland.

The role of the prefrontal cortex (PFC) in spatial working memory processing has been demonstrated in many experimental studies on monkeys as well as on humans. Several studies have also shown that the PFC responds to sensory stimulation outside of memory task context. In the present work we recorded single neuron activity in the PFC of monkeys in two experimental situations: while monkeys were performed no task but visual, auditory and somatosensory stimula were presented to them.

The data were obtained from three monkeys trained to perform the DA task. From the total number of neurons recorded 32 % fired in relation to the task performance. Three types of task related neuronal activity were recorded: delay-, delay and movement -, and movement-related activity. The majority (70%) of the delay-related neurons could not be activated by any of the sensory stimuli used and did not fire in relation to the movements of the monkey. On the other hand, the majority of all neurons (67%) responding to stimulation outside of the task context did not fire in relation to the DA task. Furthermore, 42 % of all recorded neurons responded neither to the task performance nor to the various stimuli. These results demonstrated that in addition to its role in working memory processing the PFC exhibits responsiveness to many kinds of visual stimuli and also possesses functions neither related to spatial memory processing nor to simple sensory responsiveness.

PREFRONTAL CORTEX UNITS IN AN AUDIO-VISUAL DELAY TASK Mark Bodner, James K. Kroger, Tony Liang, and Joaquín M. Fuster *. Dept. Psychiatry and Brain Research Inst., UCLA School of Medicine, Los Angeles, CA 90024.

The dorsolateral prefrontal cortex (DPC) is essential for the bridging of temporal gaps between perception and consequent action. The DPC performs temporal gaps between perception and consequent action. The DTC performs this function by supporting the cortical processes of working memory and motor set (Fuster, 1989). Previously, DPC neurons were seen to participate in the memory of visual and spatial stimuli for prospective (delayed) motor response. The main purpose of this research is to examine the role of DPC units in working memory of the auditory modality. Single units are recorded from DPC in monkeys performing an audio-visual task with a delay. On each trial, the animal is presented with a tone of high (3000 cps) or low (240 cps) pitch. After a 10-sec delay (auditory retention period), two color lights (red and green) appear simultaneously in two side-by-side stimulus-response buttons (relative position of colors changing randomly). If pitch was high, the animal must press red for liquid reward; if pitch was low, it must press green. Cells in the region of the sulcus principalis show firing frequency changes related to one of more of the task's events: (a) auditory cue; (b) visual cue; (c) motor response; (d) reinforcement. Auditory "memory cells" have been observed: these cells show sustained elevated firing during the delay. In some, the delay-elevated firing is selective for one tone. In conclusion, DPC units respond to the auditory and visual stimuli that the animal utilizes in a cross-modal and cross-temporal task. Some of those units appear related to the working memory of auditory information. These findings highlight the supramodal character of the functions of DPC and their role in the mediation of cross-temporal contingencies. (NIMH)

INCREASE OF DOPAMINE RELEASE DURING THE DELAYED ALTERNATION TASK PERFORMANCE IN THE DORSOLATERAL PREFRONTAL CORTEX OF THE MONKEY – AN IN VIVO MICRODIALYSIS STUDY

M. Watanabe*, T. Kodama, M. Odagiri and K. Hikosaka Dept. Psychol., Tokyo Metropol. Inst. for Neurosci., Musashidai 2-6, Fuchu, Tokyo 183 JAPAN

Dopamine in the primate prefrontal cortex (PFC) plays important roles in the learning and performance of the delayed response (DR) and delayed alternation (DA) tasks; depletion of dopamine in the PFC induces impairments in DR and DA, and iontophoretic application of dopamine agonist and antagonist modulates task-related activity of PFC neurons. However, there has been no study examining dopamine

PFC neurons. However, there has been no study examining dopamine release in relation to DR or DA in the PFC.

We trained three monkeys on both DA and sensory-guided control (CON) tasks. The animal had to respond to right and left keys alternately being intervened by a 5 s delay period in DA, while it was required to respond to the key which was being indicated by the cue after each 5 s delay period in CON. Thus, the animal had to retain the spatial working memory in DA, but not in CON. Brain extracellular fluid samples were obtained by in vivo microdialysis method from dorsolateral arcuate orbital and premotor areas of the frontal cortex. dorsolateral, arcuate, orbital and premotor areas of the frontal cortex.

dorsolateral, arcuate, orbital and premotor areas of the frontal cortex. Significant increase of dopamine release was observed during the DA as compared to CON in the dorsolateral PFC, while no such significant increase was observed in other areas of the frontal cortex. The results indicate that dorsolateral area of the PFC is the focus of the dopamine release during the spatial working memory task.

This study was supported by the grant from the Ministry of Education, Science and Culture of Japan (No. 05610081, 0661008).

NEURONAL NETWORKS RELATED TO WORKING MEMORY PROCESSES IN THE PRIMATE PREFRONTAL CORTEX REVEALED BY CROSS-CORRELATION ANALYSIS

S. Funahashi*, S. Hara, and M. Inoue. Dept. of Cognitive Sci., Grad. Sch. of Human & Environment. Studies, Kyoto Univ., Kyoto 606-01, Japan.

To examine neuronal networks related to spatial working memory processes in the primate prefrontal cortex, we analyzed multiple-neuron activity while monkeys performed an oculomotor delayed-response task with 8 cue positions. We isolated 2 or 3 single-neuron activities from multiple-neuron activity, determined each neuron's function in relation to the task events, and made cross-correlograms between pairs of isolated

neurons to determine an input-output relationship.

An excitatory correlation was found in the majority of the neuron pairs examined, although some pairs exhibited an inhibitory correlation and the remaining showed no correlation. Most of the cross-correlograms were asymmetrical with peaks at latencies of 1~2 ms, suggesting that the effects are mainly mono-synaptic. An excitatory correlation was found from neurons having a visual response to neurons having delay activation from neurons having a visual response to neurons naving delay activation or an oculomotor response and from neurons having delay activation to neurons having delay activation or an oculomotor response. These neuron pairs showed similar tuning characteristics. These results indicate the presence of information flow from neurons which receive sensory input to neurons which output motor information through neurons which store mnemonic information in the prefrontal cortex. Furthermore, the presence of excitatory correlation among neurons having delay activation suggests that these interactions play an important role in processing and integrating information stored in working memory. A NEURAL LEARNING MODEL BASED ON THE ACTIVITY OF PRIMATE DOPAMINE NEURONS. R.E. Suri and W. Schultz*, Institute of Physiology, University of Fribourg, CH-1700 Fribourg, Switzerland.

In physiological recordings from alert monkeys in our laboratory, midbrain dopamine neurons respond phasically to unpredicted rewards or to conditioned stimuli predicting rewards. The activity of dopamine neurons is depressed when the animal does not receive the predicted reward, suggesting that they code a deviation between predicted and actually occurring reward. Dopamine neurons were also recorded in more specific Pavlovian and instrumental conditioning situations: Discrimination between two stimuli, generalisation of conditioned stimuli, delay of predicted reward, reward earlier than predicted, variable CS2-CS1 interval and spatial delayed response behaviour.

A neural network model operating in time steps of 100 msec is presented, which reproduces the responses of midbrain dopamine neurons and the behaviour of the monkey in all these investigated situations. The sensory input is pre-processed by an attention mechanism, which allows only the stimulus with the highest motivational and physical salience to be represented in short term memory. This compressed sensory representation serves as input to two adaptive components of the model, emitting a global predictive reinforcement signal and controlling behavioural output, respectively. The predictive reinforcement signal and controlling behavioural output, respectively. The predictive reinforcement signal very much resembles the biological activity of dopamine neurons and serves for learning the motivational salience of stimuli, the stimulus-reward association and the stimulus-

mouvational satience of stimult, the stimulus-reward association and the stimulus-action association. It is computed by temporal changes in the prediction of reinforcement (temporal difference learning according to Sutton & Barto 1981). The model implicates that the diffusely projecting dopamine neurons are involved in attention and predictive learning. We suggest that the model may be successful in learning of behavioural sequences, discrimination between stimuli and preparative to the contraction of generalisation

REDUCTIONS IN ORBITOFRONTAL GLUCOSE METABOLISM ARE ASSOCIATED WITH MEMORY DEFICITS IN AGED RHESUS MACAQUES. J.A. Roberts, J.L. Eberling, P.R. Rapp, M.H. Tuszynski, W.J. Jagust*. California Regional Primate Research Center, University of California, Davis, CA 95616; Center for Functional Imaging, Lawrence Berkeley National Laboratory, University of California, Berkeley, CA 94720; Ctr For Behav Neurosci, SUNY - Stony Brook Stony Brook, NY 11794; Dept. Neurosci., University of California - San Diego, La Jolla, CA 92093-0608.

Aged nonhuman primates show increased variability in a variety of neurobiological measures, including brain volume, brain weight, neurochemical measures, and regional cerebral glucose metabolism (rCMRglo). This variability is paralleled by variability in memory performance. We used positron emission tomography (PET) and ¹⁸F-fluorodeoxyglucose (FDG) to evaluate the relationship between rCMRglc and performance on a delayed response (DR) task in 10 aged rhesus macaques.

Performance on the DR task was assessed within two weeks of the PET study, and retromance on the DR task was assessed within two weeks of the PET study, and animals were identified as either memory impaired or memory unimpaired based on the comparison of their performance to the performance of young control animals. Using a high-resolution PET scanner, we scanned 6 brain levels. To correct for global scaling effects and to reduce the between subject variance, rCMRglc ratios global scaling effects and to reduce the between subject variance, rCMRglc ratios were constructed by dividing rCMRglc values for each region of interest by rCMRglc value for the entire brain. Unpaired one-tailed t-tests were used to determine if impaired animals showed reductions in rCMRglc ratios relative to unimpaired animals in temporal cortex, prefrontal cortex, orbital frontal cortex to hippocampus. The impaired animals showed significantly (p<0.05) lower rCMRglc ratios in orbitofrontal cortex than the unimpaired animals. No other significant changes were observed. These fingings suggest that behavioral deficits in aged animals may reflect the differential vulnerability of specific brain regions, and support the use of PET to evaluate relationships between brain physiology and behavior in the aged nonhuman primate model. TIME-DEPENDENT INCREASES IN DISCRIMINATIVE AVOIDANCE RESPONSES AND SHIFTS OF TRAINING-INDUCED NEURONAL ACTIVITY IN LIMBIC THALAMUS. M. Gabriel* and J. H. Freeman, Jr. Department of Psychology and Beckman Institute, University of Illinois, Urbana, IL 61801

Neuronal discharges in response to a conditional stimulus in various layers of cingulate cortex and nuclei of limbic thalamus (anterior and mediodorsal nuclei) attain maximum (peak) frequency in particular stages (early, intermediate or late) of discriminative avoidance learning (Gabriel et al., Behav. Brain Res., 46 (1991) 175-185). Here we asked whether the areaspecific peaks of training-induced neuronal activity (TIA) change with the passage of time alone, as in memory consolidation, or require the repetition of training trials (practice). Multi-unit activity was recorded in the cingulate ortex and the anterodorsal (AD), anteroventral (AV) and mediodorsal (MD) thalamic nuclei as rabbits learned to prevent a foot-shock by stepping in an activity wheel after one tone (CS+) and to ignore a different tone (CS-). Two groups of rabbits were given a single session of training (S1, 120 trials) followed by a second session (S2) either immediately or 48 hours later. The frequency of avoidance CRs increased from S1 to S2 significantly more in the group given a 48-hour delay than in the group given a 0-hour delay (p < 0.03), replicating the "incubation effect" (Gabriel, J. Comp. Physiol. Psychol., 66 (1968) 412-416). AD and MD thalamic TIA increased from S1 to S2 in the 0hour group but not in the 48-hour group (p < 0.02, p < 0.01). AV thalamic TIA increased from S1 to S2 in the 48-hour group but not in the 0-hour group (p < 0.01). Significant time-dependent TIA changes were not found in either the anterior or posterior cingulate cortex. Thus, changes of thalamic TIA, highly similar to previously found trial-related changes, can occur with the passage of time alone (Support: NIH NS26736).

NEURAL REPRESENTATION OF REWARD CONTINGENCY IN THE RAT ANTERIOR CINGULATE CORTEX

K.Takenouchi¹, H. Nishijo², T.Uwano², M.Takigawa¹ and T.Ono². Dept. Physiol.², Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-01, and Dept. Neuropsychiatr.¹, Fac. Med., Kagoshima Univ., Kagoshima 890,

Japan.
Neuronal activity was recorded from the anterior cingulate cortex (AC) Japan.

Neuronal activity was recorded from the anterior cingulate cortex (AC) of behaving rats during configural associative learning. The rats were trained to lick a protruding spout just after a conditioned stimulus (CS) to obtain reward fintracranial self-stimulation (ICSS), or sucrose solution) or to avoid shock. The CSs included both elemental (auditory or visual stimuli) and configural (simultaneous presentation of auditory and visual stimuli) predicting reward outcome opposite to that predicted by each stimulus presented alone) stimuli. Of 62 AC neurons responding during the task, 38 and 4 responded differentially and nondifferentially to the CSs, respectively. Of the 38 differential neurons, 33 neurons showed excitatory (n=10) and inhibitory (n=23) responses selectively to the CSs predicting reward, and were located mainly in the Cg1 and the Cg3 of the rostral part of the AC, respectively. The remaining 20 neurons responded mainly during ICSS and/or ingestion of sucrose, and were located sparsely in the Cg1 of the rostral part of the AC and densely in the Fr2 of the caudal part of the AC. Analysis by the multidimensional scaling of 38 differential CS-related neurons categorized the CSs into 3 groups based on reward contingency regardless of physical characteristics of the stimuli in a two dimensional space; the 3 CSs (2 elemental and 1 configural) predicting sucrose solution, the 3 CSs (2 elemental and 1 configural) predicting no reward, and the lone CS predicting ICSS. The results suggest that the AC is topographically organized, and plays an important role in the processes from recognition of reward availavility of conditioned stimuli to execution of licking behavior.

POSITION SENSITIVITY OF HIPPOCAMPAL INFEROTEMPORAL UNITS. Anna Nowicka*1,2, James L. Ringo1 and Stephen O'Neill¹ University of Rochester, Rochester NY 14642; ²Nencki Institute of Experimental Biology, 02-093 Warsaw, Poland.

In a visual discrimination task, head-restrained macaques had their eye movements monitored with the scleral search coil technique. The monkeys had to move their eyes to one of five different positions to maintain gaze on an image. The image was then extinguished and the monkeys maintained fixed gaze on the target position in the dark. About 20% of single units recorded from the hippocampus showed statistically significant sensitivity to target position in the dark. A similar fraction were significantly affected by target position in the light, (even though fixating the same visual images). A slightly lower fraction of inferotemporal units also showed target position sensitivity

The five positions were on a horizontal line, consisting of a center position and 10 and 20 degrees right and left of it. The fields appeared in a variety of orderly types, some showing greater activity for targets in the middle (inverted U shaped), greater activity for the side targets (U shaped), greater activity for right side target, or greater activity for left side targets. No units showed patchy fields. For most of these cells, the firing rates differed by a factor of two or more between the positions with most and least activity. Supported by grant NS26526 from NINDS.

EFFECTS OF ENTORHINAL CORTEX LESIONS ON DISCRIMINATION LEARNING, RESPONSE TO CONTEXT AND TRAINING-INDUCED NEURONAL ACTIVITY IN RABBITS. J. H. Freeman, Jr.*, A. Weible, J. Rossi and M. Gabriel. Department of Psychology and Beckman Institute, University of Illinois, Urbana, IL 61801

Neuronal activity was recorded in the cingulate cortex, basolateral amygdala and hippocampus as rabbits learned to prevent a foot-shock by stepping in an activity wheel after one tone (CS+) and to ignore a different tone (CS-) after receiving either sham surgery or electrolytic lesions in the entorinal cortex. The surgery groups acquired avoidance CRs at the same rate. Discriminative (greater activity during the CS+ than the CS-) and excitatory (increased activity from pretraining) neuronal activity was seen in the entorhinal cortex during an intermediate stage of learning (p < 0.01). Entorhinal cortex lesions produced a deficit in the magnitude of CS-elicited neuronal discharges in the basolateral amygdala (p < 0.01) but enhanced neuronal activity in the hippocampus (p < 0.01). The training-related development of neuronal excitation and discrimination in the anterior and posterior cingulate cortex was unaffected by lesions in the entorhinal cortex. Both surgery groups showed significantly fewer CRs during an extinction test in a novel context relative to the original context (p < 0.02). Unlike the hippocampus, the entorhinal cortex does not play a role in the detection and behavioral response to novel background stimuli. However, the lesion group showed fewer inter-trial responses during the standard extinction test (p 0.01), indicating an impairment in conditioning to the context. Amygdaloid neuronal discrimination was also impaired in the lesion group during the standard extinction test (p < 0.05). These results indicate that the entorhinal cortex and its connections with the amygdala are involved in conditioning to background stimuli. (Support: NIH grant NS26736).

REWARD CONTINGENCY-RELATED NEURONAL RESPONSES IN THE RAT LATERAL SEPTAL NUCLEI.

N. MATSUYAMA¹, H. NISHIJO², T. UWANO², R. TAMURA²*, T. ASAKURA¹ and T. ONO².

¹Dept. Physiol., Fac. Med., Toyama Med. and Pharmaceu. Univ., Toyama 930-01, and ¹Dept. Neurosurg., Fac. Med., Kagoshima Univ., Kagoshima 890, Jana 890.

Kagoshima 890, Japan.

It has been suggested that the septal nuclei (SP) integrate information from the limbic system such as the amygdala, cingulate, entorhinal cortex, and hippocampal formation, and send those activity was recorded from the rat lateral SP during associative learning and discrimination of sensory stimuli (CSs) associated with or without reinforcements; sucrose solution and intracranial self-stimulation (ICSS). Sensory stimuli included auditory (1200, 2800, 4300 Hz), visual (light) and configural (simultaneous presentation of tone and light) stimuli. Of 174 SP neurons recorded, 51 responded with excitation (n=32) or inhibition (n=19) in one or more phases of the task. Of these 51 neurons, 14 responded selectively to CSs predicting reward (CS+related), 4 to CSs predicting nonreward (CS-related), 9 nondifferentially to all CSs, and 15 responded mainly during the ingestion/ICSS phase. Activity of the CS+- and CS--related neurons changed flexibly based on and intermediate parts of the lateral SP. These results suggest that the lateral SP is deeply involved in discrimination of reward-contingency of stimuli.

CHOLINERGIC FOREBRAIN MECHANISMS IN CORTICAL MAP REORGANIZATION. M.P. Kilgard* and M.M. Merzenich. Keck Center, UCSF, San Francisco, CA 94143.

Extensive frequency discrimination training can result in a several fold increase in the area of owl monkey auditory cortex rold increase in the area or own monkey auditory cortex representing the trained frequency. Electrical stimulation of the rat basal forebrain paired with tone presentation can increase single unit evoked responses for >30 minutes. The goal of this study was to determine whether electrical stimulation of the rat cholinergic basal forebrain (100-150uAmp 20 pulses 100Hz train) paired with tone presentation (250msec 50dB SPL) results in enduring auditory cortex reorganization. Rats were chronically implanted with bipolar electrodes and received 300-500 pairings per day for ~15days. The auditory cortex was then mapped under barbiturate anesthesia using 80-120 microelectrode penetrations. Multi-unit tuning curves were generated at each penetration site. Our preliminary findings demonstrate that pairing of stimulation of basal forebrain with tones was sufficient to drive largescale, enduring (>24 hours) cortical reorganization. The area of the cortical surface responding to the paired frequency was increased by >2.5-fold over naive controls. Sites near the middle of the expanded region often showed long latencies of 60-80msec, compared to 12-25msec for controls. Future studies will examine the effect of basal forebrain stimulation on the representation of more complex auditory stimuli, such as AM and FM modulated stimuli. [Supported by NIH grant NS-10414, Hearing Research, INC., and NSF predoctoral fellowship.]

MODELING THE FUNCTIONAL ROLE OF ACETYLCHOLINE IN THE HIP-POCAMPUS. G.V. Wallenstein, B.P. Wyble and M.E. Hasselmo*. Dept. of Psychology and Prog. in Neuroscience, Harvard University, Cambridge, MA 02138.

A biophysical model of area CA3 was employed to study how septal ACh interacts

A biophysical model of area CA3 was employed to study how septal ACh interacts with cellular conductances to shape population behavior. Cholinergic effects were modeled by (i) blocking $I_{K(Lah)}$; (ii) suppressing the adaptation current, $I_{K(AHP)}$; and (iii) reducing excitatory synaptic transmission between pyramidal cells. Under low $I_{K(AHP)}$ conditions, accurate completion (of a degraded input pattern) was impaired due to an increase in pyramidal cell firing not unique to the given input pattern. Moderate levels of the excitatory synaptic conductance (\bar{g}_{AMPA}) , indirectly reduced the burst refractory period in pyramidal neurons and promoted the recruitment of large numbers of these cells into globally-synchronous firing resembling englishiform. large numbers of these cells into globally-synchronous firing resembling epileptiformlike events observed in vitro. Subsequently reducing \bar{g}_{AMPA} to approximately 15% of its normal value resulted in successful completion, demonstrating accurate associative

memory. An investigation of the $\frac{\partial f_{N}}{\partial f_{N}}$ memory. An investigation of the $\frac{\partial f_{N}}{\partial f_{N}}$ memory. An investigation of the $\frac{\partial f_{N}}{\partial f_{N}}$ memory are revealed the transition boundaries between these functionally different forms of behavior. The effects of ACh were also investigated in a large-scale network model of the hippocampus. Systemic administration of scopolamine was modeled by blocking the cellular effects of acetylcholine, resulting in memory impairments replicating data from studies on human subjects. This blockade of cholinergic effects impaired the encoding of new input patterns (decreasing delayed free recall from 42% to 3%), but did not impair the delayed free recall of input patterns learned before the blockade. The impairment was selective to the free recall but not the recognition of stored items. The model contained simulations of entorhinal cortex, dentate gyrus, regions CA3 and CA1. Separate vectors representing item and context were presented sequentially to entorhinal cortex. Self-organization in the dentate gyrus formed sparse representations of these patterns, and associations between context and item representations were formed in region CA3. One context pattern was associated with each list item during presentation. Reactivation of context during retrieval caused a subset of the items to be recalled in order of strength. Attractor dynamics controlled activity within parts of the model, allowing recall and preventing the simultaneous activation of multiple items. - NiMil grant R29 MH52732 and ONR grant NO 0014-93-1-0595.

AN OLFACTORY ASSOCIATIVE MEMORY TASK INVESTIGATING CHOLINERGIC MODULATION IN THE RAT PIRIFORM CORTEX. Bergman, R.E.*, De Rosa, E. and Hasselmo, M.E., Harvard University, Department of Psychology, Cambridge, Ma.

This behavioral study was conceived to investigate the role of acetylcholine (ACh) in learning an associative odor memory task. The two experimental tasks were specifically designed to compare learning odor pairs with and without shared components. In each of the experimental tasks two different odor cues were simultaneously presented from two separate sniff ports in a 16-channel flow dilution olfactometer. Rats were required to label each presented odor pair with a behavioral response - 'short' or 'long' - in order to receive reinforcement. The nonoverlapping (NO) task was comprised of odor pairs without shared components. An example of a NO task would be, odor pair AB was reinforced if short response, CD reinforced if long response, EF short etc. In the overlapping (O) task, comprised of odor pairs with shared components, every odor pair component was then labeled with a short and a long response e.g. AB short, AF long, EB long, EF short etc. The above study was designed to test the prediction that muscarinic cholinergic antagonists will decrease the rate of acquisition for the O task. This was predicted by two lines of decrease the rate of acquisition for the O task. This was predicted by two lines of evidence: (1) electrophysiological studies in the piriform cortex that have demonstrated that ACh selectively suppresses synaptic transmission at intrinsic fibers but not afferent fibers (Hasselmo & Bower, *J. of Neurophys.*, 67, 1222) and (2) computational modeling of these physiological findings suggesting that these effects of ACh may act to reduce interference between overlapping representations of information stored in memory (Hasselmo et al., J of Neurophys., 67, 1230). The model predicts that a loss in cholinergic modulation would impair the learning of associations in odor pairs with overlapping components because the loss of cholinergic suppression would allow recall of previous stored associations to interfere with storage of new associations. We hypothesize that the muscarinic antagonist scopolamine should increase interference in the O task causing a greater deficit in acquiring the O task than the NO task.

DEVELOPMENT OF A TECHNOLOGY THAT ALLOWS GENE KNOCKOUT ONLY IN THE FOREBRAIN.

Cindy W. Tom^{1,2}, Joe Z. Tsien¹, Chong Chen*^{1,2}, Mark Mayford³, Eric R. Kandel³ and Susumu Tonegawa^{1,2}, ¹H.H.M.I., ²Ctr for Learning & Memory, MIT, Cambridge, MA 02139, ³Ctr for Neurobiol. & Behavior, Columbia Univ., New York, NY 10032

The conventional gene knockout technology results in ubiquitous deletion of the gene of interest throughout the body. It is often desirable to restrict the deletion to cells of a specific tissue or type. We report our progress in developing such a tissue/cell type-restricted gene targeting method. We used the α -Cam kinase II promoter to drive Cre expression because this promoter allows for selective expression of a transgene in forebrain regions. Several Cre transgenic lines were generated and crossed to another transgenic mouse line, provided by Mercer & Anderson, in which the expression of LacZ transgene depends on Cre/LoxP-mediated recombination. Histological analysis of brain sections stained with X-gal allows identification of several Cre transgenic lines, in which Cre/LoxP-mediated recombination is restricted to several forebrain regions. These Cre transgenic lines should be useful to target gene deletion to the forebrain or its subregions.

Supported by NIH R35-C8-53874 grant and a HHMI grant.

BEHAVIORAL AND ELECTROPHYSIOLOGICAL ANALYSIS OF MICE LACKING THE CREM GENE.

Julie A. Blendy* 1, Jeffrey H. Kogan², Gunther Schutz 1 and Alcino J. Silva².

German Cancer Research Center, University of Heidelberg, D-69120 Heidelberg, Germany.

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724.
The cAMP signaling pathway has been implicated in a number of biological processes. CREB and CREM are members of the leucine zipper transcription factor family which are activated in response to increases in intracellular cAMP levels. Previous studies have shown that mice with a targeted mutation of the CREB gene have deficient long-term memory. In addition, hippocampal long-term potentiation (LTP) is impaired in these mice (Bourtchuladze et al., Cell 79:59-68, 1994).

We have recently generated mice with a null mutation of the CREM gene. These mice appear healthy, and exhibit no obvious impairment of growth or development. However, the males are sterile due to an arrest of spermatogenesis. To begin to address the role of CREM in central nervous system function we tested these mice in a contextual fear conditioning task in which animals are trained to associate a particular context with an aversive stimulus. Conditioned animals, when associate a particular context with an aversive summus. Condutioned animals, when exposed to the context, refrain from all but respiratory movements. This behavior, termed freezing, can be used to determine the degree of learning and memory in an animal. A single 3 min training trial resulted in similar levels of freezing in wild type and mutant mice immediately following the shock. In addition, there appears to be no difference in freezing when mice are tested 30 minutes post training. Furthermore, when mice are returned to the same context 24 hours later, wild type Furthermore, when mice are returned to the same context 24 hours later, wild type and mutant animals do not display significant differences in freezing behavior. These results are in contrast to the earlier findings with CREB mutants which show deficient long-term (24 hour) memory. The CREM mice will be further examined in the spatial version of the Morris water maze and electrophysiological studies of synaptic transmission and LTP in hippocampal brain slices will be conducted. (Supported by grants from the Whitehall, Beckman, Klingenstein, Merck and McKnight Foundations)

EFFECTS OF INTER-TRIAL INTERVAL ON THE MEMORY AND THE LONG-TERM POTENTIATION DEFICITS OF CREB MUTANT MICE. Jeffrey H. Kogan*¹, Jodi Coblentz¹, Zach Marowitz¹, Julie A. Blendy², Gunther Schutz², and Alcino J. Silva¹. Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA. ²German Cancer Research Center, University of Heidelberg, D-69120 Heidelberg, Germany.

Studies in Aplysia, Drosophila and mice indicate that the transcription factor CREB plays a key role in both long-term memory and synaptic plasticity. We have previously shown that mice with a targeted disruption of the α and the δ isoforms of CREB are deficient in both long-term memory and hippocampal long-term potentiation (LTP). Findings in Aplysia and Drosophila suggest that increases in CREB activity can eliminate the requirement for multiple training sessions with long intervals between training trials to elicit long-term memory. We have found that CREB mutant mice, bred into a C57BL/6x129Sv background, trained in the spatial version of the Morris water maze at two trials/day with extended inter-trial intervals perform normally. In contrast, mutants trained at two trials/day with short inter-trial intervals perform poorly compared to controls. Furthermore, CREB mutants intensively trained in the water maze (12 trials/day for 5 days) perform as

well as controls and have normal long-term memory when tested at 28 days.

We have also found that long, but not short, inter-trial intervals can elicit normal contextual long-term memory in CREB mutant mice bred into a C57BL/6 background. In addition, control levels of both early-, and late-, CA1 LTP can be induced in CREB mutant neurons with spaced tetani (3X10 theta bursts at 10 min intervals), but not with massed tetani (3X10 theta bursts at 1 min intervals). In intervals), but not with massed tetani (3.10 neta bursts at 1 min intervals). in controls, both of these tetani can trigger a late-LTP that is protein synthesis-dependent. On the other hand, protein synthesis-independent LTP, induced with a single tetanus (100 Hz/1 sec, 100 μsec pulse width) is identical in mutants and controls. These results indicate a role for CREB-mediated transcription in both LTP and in the formation of long-term memory. (Supported by grants from the Whitehall, Beckman, Klingenstein, Merck and McKnight Foundations)

THE INVOLVEMENT OF THE NF1/RAS PATHWAY IN HIPPOCAMPAL FUNCTION. 1A. J. Silva, ¹K.P. Giese, ¹P. Chen, ²W. Edelmann, ²R. Kucherlapati, ^{1,3} P. Chapman, ^{*4}R. Kuhn, and ¹N. Fedorov.

¹Cold Spring Harbor Laboratory, New York 11724, ²Albert Einstein College of Medicine, Bronx, NY 10461, ³Cardiff University of Wales, Cardiff CF13US, UK, 4University of Köln, 50931 Köln, FRG.

Our behavioral and electrophysiological studies have implicated the NF1 GTPase Our benavioral and electrophysiological studies have implicated une Nrt G1784 activating protein in hippocampal function. NF1 is known to regulate ras, a family of small GTP-binding proteins. Our electrophysiological studies showed that mice lacking N-ras (an isoform present in the brain) have larger hippocampal EPSPs than controls. G150%. Interestingly, NF1 mutant mice, which presumably have higher levels of active ras, show smaller EPSPs than controls. presumany have might reversed a curve lass, show smaller E-75 than controls. In both mutants, synaptic plasticity appears normal (PPF, LTP and its reversal). Behavioral studies found that both NF1 mice and N-ras mutants show clear Benavioral studies found mat both NFT mice and NFTas mutants show clear deficits in the hidden-platform version of the water maze, but not on the visible-platform test. These results indicate that a disruption of N-ras results in abnormal hippocampal function. To further investigate the role of the ras signaling pathway in learning/memory we generated mutant mice deficient for the guanine-nucleotide releasing factor (GRF). GRF is expressed exclusively in brain and is one of the rate-limiting factors for ras activation. With the mutants described above, it is impossible to sectify the mutations to choose it lieses and to specific time. impossible to restrict the mutations to chosen tissues and to specific time-windows. To overcome these limitations we have been developing an inducible gene targeting approach. It uses the Cre recombinase fused with the ligand-binding domain (LBD) of modified steroid receptor proteins. Upon ligand-driven induction than (LBD) of mounter startor tectors proteins, open ligatestance induction than the mutation should be restricted to the specific region(s) where the fusion construct is expressed (i.e. in the hippocampus) and to a chosen time (i.e., in adults after induction). We are currently testing this methodology in micro. This work was supported by the Whitehall, Merck and Beckman Foundations.

SPATIAL LEARNING AND HIPPOCAMPAL LONG-TERM POTENTIATION IN MICE LACKING ZFP37. M. Nosten-Bertrand¹, S. Davis², C. de Zeeuw⁴, B. Koekkoek⁴, D. Michalovich³, N. Faucon Biguet^{1*}, J. Mallet¹, S. Laroche², F. Grosveld³, N. Galjarl³ (1) LGN, CNRS UMR9923, Hôpital de la Pitié Salpétrière, 75013 Paris, France; (2) CNRS URA 1491, Univ. Paris-Sud, 91405 Orsay, France; (3) Dept. of Cell Biology and Genetics and (4) Dept. of Anatomy, Erasmus Univ., 3000 DR Rotterdam, The Netherlands.

Biology and Genetics and (4) Dept. of Anatomy, Erasmus Univ., 3000 DR Rotterdam, The Netherlands.

Murine Zfp37 is a member of a large family of C2H2-type zinc finger proteins. It is characterised by two domains: the zinc finger region at its C-terminus, which may be involved in nucleic acid binding or in protein-protein interactions, and a so-called KRAB domain at its N-terminus, which could function as a transcriptional repressor region. An important target of Zfp37 expression are neurons of the adult CNS. To investigate the function of this gene, mutant mice expressing bacterial beta-galactosidase instead of Zfp37 were generated. Homozygous mutant animals are healthy, fertile and no abnormal housing behavior was detected.

Since Zfp37 is highly expressed in the hippocampus, we decided to investigate spatial learning and memory tested in the watermaze in Zfp37 homozygous knock out mice. Preliminary data show that the Zfp37-deficient mice are impaired in spatial learning compared with their wildtype littermates. Their ability to express long-term potentiation in the perforant path input to the dentate gyrus and the Schaffercommissural input to the CA1 in vivo is currently under investigation. (Supported by CNRS)

THE NF1 MUTATION AFFECTS HIPPOCAMPAL SYNAPTIC FUNCTION AND HIPPOCAMPAL-DEPENDENT LEARNING.

¹N. Fedorov, ¹P. Frankland, ¹R. Bourtchuladze, ¹Z. Wang, ¹Z. Marowitz, ¹F. Lee, ¹G. Lazlo, ²T. Jacks and ¹ A. J. Silva.* ¹Cold Spring Harbor Laboratory, New York 11724, ²Massachusetts Institute of Technology, Boston MA, 02139.

Approximately half of children with neurofibromatosis type I (NF1) have learning disabilities of unknown etiology. These cognitive deficits are due to heterozygous mutations in NF1, a GTPase activating protein. Since NF1 is highly expressed in the hippocampus, we concentrated our studies of NF1 (heterozygous) mice on learning and memory tasks sensitive to lesions of this structure (water maze). Our rearring and memory tasks sensitive to resolute the state of the studies showed that NF1 mice have specific spatial learning deficits, even though we and others could not identify any significant brain neuroanatomic pathology. NF1 mice, as NF1 patients, do not have a complete loss of spatial abilities. Instead, we found that the NF1 mice need much more training than littermate controls to reach comparable levels of performance. Control tests indicated that vision, motor coordination, and motivation are normal in these mice. Interestingly, similar to NFI patients, memory seems to be unaffected by the NFI mutation in mice: Once trained the NFI mutants retain spatial information as well as controls. Electrophysiological studies in the hippocampal CA1 region of NF1 mice showed that PPF, PTP, synaptic depletion rates, levels of axonal depolarization (pre-synaptic volleys), and the probability of neurotransmitter release are normal in these mutants. However, for a given stimulation strength, the slope of the EPSPs is smaller in the mutants (>40%), suggesting that the NF1 mutation affects post-synaptic function. These results suggest that a deficit in synaptic transmission may underlies the learning abnormalities in NF1 patients.

MEMORY INTEGRATION IN COMPLEX LEARNING: A NOVEL NETWORK MODELING APPROACH. Y. M. Yufik, M. Voloshin (1), V Zhukarev* (2), Inst. Medical Cybernetics, Inc. Potomac(1), MD 20854, UMD NJ/RWJ MS (2), Piscataway, NJ 08854.

Neuropsychological processes underlying human capability to integrate diverse partial experiences into coherent memory structures are not fully understood. A new model called Virtual Network (VN) (Yufik, 1994; Yufik & Sheridan, 1995) defines memory integration mechanisms in complex learning. Learning produces a hierarchy of networks in the associative cortex. Formation of networks is accompanied by their spontaneous selfpartitioning into flexible, internally cohesive and weakly coupled subnets, or packets. The principles of network self-partitioning have been derived from the studies of neuronal ensembles (Bechtereva, 1988) and the models of motor control mechanisms in basal ganglia (Voloshin, 1994). The VN model treats associative packets and networks as physical structures subject to the laws of thermodynamics. Packet stability is determined by the balance of associative forces inside the packet and at the boundaries, and is influenced by the specific and non-specific (emotional) performance feedback represented as the "temperature factor." The model explains successfully some main features of complex learning in norm and pathology, and predicts the degree of cognitive complexity of learning and control tasks. A new method of computer memory management derived from the VN model demonstrates better than two orders of magnitude improvement in the performance of control algorithms in comparison with conventional memory.

CONTROLLING LEARNING AND MEMORY USING TETRACYCLINE-REGULATED EXPRESSION OF A Ca²⁺-INDEPENDENT CaMKII TRANSGENE. M.E. Bach*, E.R. Kandel, R.D. Hawkins, and M. Mayford. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

To gain temporal control over when a gene is expressed in genetically modified mice and thereby circumvent developmental effects we employed the tetracycline regulatable tTA system. When the tetracycline analog doxycycline is administered in the drinking water, expression of a Ca²⁺-independent CaMKII transgene is blocked. When the drug is withdrawn, expression is restored. Two lines of transgenic mice were generated. In the first line moderate transgene expression was found in the striatum, amygdala, cortex, and the CA1 region of the hippocampus, whereas in the second line the transgene was strongly expressed but only in the striatum and lateral amygdala. Both lines were assessed on the conditioned fear task in which a novel context and a distinct cue are paired with an aversive stimulus. If learning occurs, then both the context and cue will elicit fear as evidenced by the behavior freezing. Transgenic mice in the first line did not exhibit a conditioned fear deficit whereas in the second line a severe impairment in both context and cued conditioning was observed. When mice in the second line were treated with doxycycline to shut off the transgene, no learning impairment was observed. However, when we reactivated the transgene and then assessed fear retention six weeks later a severe deficit in freezing was observed. We next measured unconditioned freezing in the second line and found transgenic mice overexpressing CaMKII froze similarly to wild-type mice. This suggests that the conditioned fear impairment observed in mice overexpressing CaMKII may be due to a deficit in learning or memory consolidation and not a performance deficit. These results also demonstrate that the transgene does not exert its effect on learning and memory through an indirect effect on neuronal development. Supported by HHMI & NIMH.

THE ROLE OF THE AUTOPHOSPHORYLATION OF α CamkII and of the Potassium Channel Subunit Kv β 1 for Learning and Memory, K.P. Giese*1, N.B. Fedorov¹, S. Li-Rong², D. Reuter³, T. Leicher³, I.F. Storm², O. Pongs³ and A.I. Silva¹. ¹Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724, USA, ²Institute for Neurophysiology, Oslo N 0317, Norway, ³Center for Molecular Neurobiology, 20246 Hamburg, Germany.

The α -isoform of the Ca^{2+}/cal modulin-dependent kinase II ($\alpha CaMKII$) can autophosphorylate at T286 which leads to trapping of Ca^{2+}/cal modulin (CaM) and gives rise to CaM-independent activity. To test whether this autophosphorylation event is important for learning/memory, we generated mutant mice with a point mutation in the $\alpha CaMKII$ gene (T286A) leading to the inactivation of the autophosphorylation site. Homozygous mutants are impaired in cued and contextual learning, whereas heterozygotes are normal in fear conditioning. These results indicate that the autophosphorylation of $\alpha CaMKII$ at T286 is necessary for some forms of learning/memory.

To study if the modulation of voltage-gated K^{+} channels is involved in learning/memory, we generated mutant mice lacking the modulatory K^{+} channel subunit Kv&1. The presence of Kv&1 leads to an A-type inactivation of some voltage-gated K^{+} channels. The Kv&1-deficient mice are normal in open-field behavior, and have normal contextual and spatial learning. However, reversal learning in the Morris water maze is impaired in these mutants. These results suggest that the modulation of A channels affects some forms of learning/memory.

SUBSTITUTION OF MITOCHONDRIAL DNA (mtDNA) INDUCES NEURAL AND BEHAVIORAL MODIFICATION IN MICE, P.L. Roubertoux*, F. Maarouf, I. Le Roy, R. Moutier, M.-C. Busnel and M. Carlier, URA CNRS 1294, Génétique, Neurogénétique, Comportement, CDTA, CNRS and Université, Orléans, France, 45071 Orléans cedex 2.

The mtDNA makes up less than 0.2 % of the total DNA in mouse. It is entirely transmitted by the mother. The laboratory strains of inbred mice share mtDNA from identical origin *M. m. domesticus* origin except NZB that has mtDNA from *M. m. brevirostris* origin. Two congenic strains for mtDNA have been developed: NZB with mtDNA from CBA/H and CBA/H with mtDNA from NZB. The congenic strains have now reached 25 and 26 backcross generations respectively. The mtDNA transfer was checked by PCR amplification and Alu 1 digestion. The primers (from Dr. Yonekawa) are specific of the D. loop region of the mtDNA, that presents polymorphisms between NZB and CBA/H. The effects of mtDNA substitution appeared for motor behaviors (measured from birth to adulthood) and underlying brain structures. These effects were always in interaction with nuclear genotype.

NEW ROLES FOR NMDA CHANNELS IN NETWORKS WITH THETA/GAMMA OSCILLATIONS, <u>O. Jensen</u>, <u>M. Idiant* and John E. Lisman</u>, Center for Complex Systems, Brandeis University, Waltham MA02254-9110.

We have proposed that gamma oscillations serve as a timing mechanism to subdivide a theta cycle so that a network can keep ~7 memory patterns active at the same time, in accord with psychophysical measurements (Science 267:1512, 1995). We now extend this model by adding modifiable recurrent collaterals. This allows us to study the transition from short-term to long-term memory based on physiological Hebbian rules. Our analysis shows that kinetics of the NMDA channels is crucial: since different memories are active in different gamma cycles, the life-time of NMDA channels relative to the period of a gamma oscillation (~25 ms) will determine the type of memory formation. NMDA channels with a short life-time (<25 ms) will build up auto-associations among the active patterns in STM. Short-lived NMDA channels have been found in some regions of cortex. Such networks will have the properties of attractor network. Remarkably, such networks also provide very reliable short-term memory for unique lists of known items. NMDA channels with long lifetimes, as found in the hippocampus, are not suitable for the formation of autoassociative memory. Rather they function to form hetero-associations among the active memories, e.g., to link different memories in a sequence. We show that the CA3 region of the hippocampus is well suited for the storage and retrieval of sequences. A surprising finding is that NMDA-mediated synaptic transmission would function well in sequence recall, suggesting that some forms of recall may be sensitive to NMDA channel blockers. Finally we apply our model to study the hippocampal place cell problem. We hypothesize that the hippocampus stores the path as a sequence during learning. During readout the current position stimulates recall of locations to come The model predicts that the average phase advance of place cells firing is one gamma period per theta cycle.

IMPAIRED MOTOR COORDINATION IN MICE LACKING A GTP-BINDING PROTEIN SUBUNIT. W. Sun*1, S. Offermanns², J. J. Kim¹, R. F. Thompson¹, and M. I. Simon², ¹Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520. ²Division of Biology, California Institute of Technology, Pasadena, CA, 91125.

Heterotrimeric G proteins are GTP-binding proteins involved in cellular signal They relay signals from cell surface receptors to intracellular transduction. Cells can respond to a variety of hormones, peptides, and neurotransmitters through G-proteins. $G\alpha_q$ is a recently cloned α subunit of the G protein family. It is insensitive to pertussis toxin and activates phospholipase C (PLC), leading to an increase in intracellular inositol triphosphate (IP3) and diacyglycerol. Several brain neurotransmitters receptors have been linked to Gazincluding metabotropic glutamate receptors, serotonin receptors, and muscarinic receptors. Mice lacking the gene coding for $G\alpha_q$ were generated by homologous Mice deficient in $G\alpha_q$ show markedly progressive ataxia. Homozygous mutants show clearly abnormal walking patterns as compared to those of heterozygotes and wildtypes. Impairments in motor coordination was further manifested in stationary and rotating rod tests. In the stationary rod test, homozygotes do poorly when compared to heterozygotes and wildtypes, although they show some improvement with repeated trials. In the rotating rod (10 rpm) test, the homozygotes performed poorly and showed little improvement with repeated trials whereas the heterozygotes and the wildtype mice did better and showed significant improvement. Eye-blink conditioning on the mice is currently in progress.

PRENATAL ACUTE EXPOSURE TO ORGANIC LEAD ENHANCES LTP IN THE 15-DAY OLD PUP HIPPOCAMPUS *IN VIVO*. <u>A.Z.</u> <u>Elliott* & V. Miletic</u>. Dept. Comp. Biosci. & Environ. Tox. Cntr., Univ. Wisconsin, Madison, WI 53706

We examined whether prenatal and postnatal acute exposure to triethyl lead (TEL) modifies the expression of long-term potentiation (LTP) in electrophysiological recordings in the young rat hippocampus in vivo. Pups were given a single subcutaneous dose of TEL (0 or 5 mg/kg) in utero on gestation day 18 (E18) or on postnatal days 1, 8 or 15 (P1, P8, or P15, respectively). On P15, a male and a female from each litter were anesthetized with urethane (1.2-1.5 g/kg), and prepared for conventional recording of hippocampal field potentials. A bipolar stimulating electrode was lowered into the CA3 region, and the glass recording electrode (0.5- $2M\Omega$) was positioned in the CA1 region until a maximal response to the CA3 stimulus was observed. LTP was induced by tetanic stimulation (one 400ms train of five 50ms pulses at 50Hz), and recordings of field potentials were repeated at 0.5, 1, 2, 3, and 4 hours post-tetanus. The population spikes (PS) for all pups exposed to TEL postnatally (P1, P8, or P15) were similar to that of controls. However, pups exposed to TEL in utero showed an enhancement of LTP (200% above controls at 2 hours). The enhancement of LTP by TEL is the opposite effect of that seen by inorganic lead, previously reported to attenuate LTP. These data indicate that the molecular form is important in assessing the effect of lead on LTP. Further, E18 is a critical time of exposure at which pups are most sensitive to TEL. The data further suggest that the alteration of LTP may contribute to lead's neurotoxic action in the developing rat hippocampus. (Supported by NIH NS21278).

N-(2-CHLOROETHYL)-N-ETHYL-2-BROMOBENZYLAMINE HYDROCHLORIDE REDUCES THE AMPLITUDE OF AUDITORY EVOKED POTENTIALS IN A PAIRED-TONE PARADIGM IN THE ALBINO RAT. <u>C.M. Specht* and D.W. Shucard</u>. Departments of Neurology and Psychology, SUNY at Buffalo, 100 High St. (D-6), Buffalo, NY 14260.

The brain stem nucleus locus coeruleus is the primary source of forebrain norepinephrine and the sole source of neocortical and hippocampal norepinephrine. In addition, it has been widely implicated as modulating behavioral measures of attention, vigilance, arousal, and memory. Our laboratory has focussed on fast habituation (FH) as an index of cognitive activity in terms of the amount of attention devoted to the processing of sequential auditory stimuli. In the paired-tone paradigm, FH is demonstrated when the amplitude of the auditory evoked potential (AEP) in response to the second tone of the pair is reduced relative to that of the first. This project was designed to determine whether the locus coeruleus is involved in FH.

Male Sprague-Dawley rats were injected with a single dose (50 mg/kg, i.p.) of N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine hydrochloride (DSP-4; Sigma), a neurotoxin that lesions noradrenergic neurons arising form the locus coeruleus. They were tested one week later.

Pre-lesion baseline AEPs in response to pairs of acoustic stimuli

Pre-lesion baseline AEPs in response to pairs of acoustic stimuli demonstrated FH. After DSP-4 lesioning of the locus coeruleus, however, the overall amplitudes of the AEPs in response to both tones were reduced compared to baseline.

It appears that the widely divergent projections of the locus coeruleus may modulate the phenomenon of FH. These data increase the validity of FH as a measure of attention in the brain by associating the phenomenon with a physiological system also known to be involved in attentional processes. Supported in part by the Department of Neurology Research Fund.

CARBACHOL DEPOLARIZES ASTROCYTES AND INDUCES POSITIVE SLOW POTENTIALS AT THE HIPPOCAMPAL FISSURE. J. Brankačk*, Y. Verbny, Y. Yanovsky and H.W. Müller-Gärtner. Dept. of Nuclear Medicine, Heinrich-Heine-University Düsseldorf and Reaserch Center Jülich GmbH, Jülich, Germany

The hippocampal theta rhythm recorded in vivo during urethane anaesthesia and wheel running consists of alternating (4 to 12 Hz) and sustained potentials. Amplitudes of both components are maximal at the hippocampal fissure. The muscarinergic agonist carbachol was shown to induce theta-like oscillations in hippocampal slices. The aim of the current study was to test the hypothesis that acetylcholine acting on astrocytes near the hippocampal fissure induces the sustained negative potential recorded during Transversal hippocampal slices were perfused with artificial cerebrospinal fluid. Intracellular recordings from 36 astrocytes at the hippocampal fissure revealed a mean membrane potential of 84.75±0.73 mV. Carbachol (CCh, 0.5 to 100 µM) added to the bath, depolarized the membrane of all tested cells. The mean depolarization for 10 $\mu \dot{M}$ CCh was 5,44±0.87 mV (N=18, range 1 to 14 mV) and the mean latency 103.78±6.49 s. CCh caused a slow extracellular positive potential shift, increased pyramidal cell ring and induced bursts and oscillations. Tetrodotoxine (TTX, 0.75 µM) abolished bursts and oscillations, induced a negative extracellular potential, hyperpolarized astrocytes but did not abolish the depolarizing effect of CCh. The muscarinergic depolarizing effect on astrocytes is not the cause of the negative sustained potential during theta.

C/EBP AND C-FOS GENE EXPRESSION IN LONG TERM MEMORY OF APLYSIA AND CHICK, C. Bessho*, K. Morikawa and H. Ageta, Dept. of Physics. Kyoto Sagyo Univ. Kyoto 603 Japan.

Physics, Kyoto Sagyo Univ., Kyoto 603 Japan.

Recent works show that cAMP response binding protein (CREB) is a mediator of long term memory from aplysia to mice, that CCAT enhancer binding protein (C/EBP) is required for the consolidation of long term facilitation in aplysia sensory-motor neuron synapses and that c-fos gene is induced in LTP. To detect the C/EBP and c-fos gene expression in aplysia neurons and chick brain during long term memory, we perform ed RT-PCR using primers coding a part of C/EBP or c-fos gene and cDNA from reverse transcribed RNA of aplysia ganglia treated with serotonin or chick brain after bitter taste avoidence training. Aplysia kurodai abdom inal and pleural ganglia including sensory neurons were incubated in L15 -ASW solution containing 10 μ M serotonin at 18 $^{\circ}$ C for an hour and a half and the others as the controll were done in L15-ASW. Chicks were presented with a small chrome bead dipped in water or the bitter aversant methylanthranilate (MEA). At 1 day after training, chicks were tested and their brains were taken. Total RNA was extracted from aplysia gangli on and chick brain using RNAzol. The first-strand cDNA was generated following T. Ito's method. PCR amplification was performed under the following condition: 93 ° C for 1 min, 50 ° C for 1.5 min and 72 ° C for 2 min. The process was repeated for a total of forty cycles. We have found that C/EBP gene was induced in aplysia pleural ganglion treated with 5-HT and that c-fos like gene was expressed in aplysia abdominal gangli on treated with 5-HT. We also found that C/EBP gene was induced in the brains of chicks pecking bead dipped in MEA but that it was expressed in the brain of chick doing bead dipped in water.

C-FOS EXPRESSION IN RATS WHEN LEARNING AN ACTIVE VISUAL AVOIDANCE DISCRIMINATION. E.R. Delay*, S.L. Patrick, and J.M. Walker, Dept. Psychology, Regis University, Denver, CO 80221 and Walter S. Hunter Laboratory of Psychology, Brown University, Providence, RI 02912.

c-Fos-like immunoreactivity (c-FLI), an indicator of certain types of neuronal activity, is thought to be expressed by processes related to learning. For example, Tischmeyer et al. (Behav. Neural Biol., 1990 (54): 165-171) reported increased Fos mRNA expression after brightness discrimination learning. The present study examined c-FLI in CNS structures after discrimination training in which rats received 50 trials to learn to avoid shock cued by an increase in light intensity in a 4-way shuttle device. c-FLI expression in this group was compared to c-FLI seen in rats of four stimulus matching conditions: 1) exposure to the test apparatus, 2) shock intensity and duration, 3) light intensity and duration, and 4) the combined but noncontiguous presentation of light and shock stimuli. Generally, c-FLI was lowest in rats in the test exposure condition and the highest in the combined-noncontingent stimulus group. Cortical c-FLI to the light cue was greatest in secondary visual areas. Exposure to shock induced c-FLI in posterior retrosplenial cortex and amygdaloid nuclei. c-FLI appears to occur in structures thought to be involved in visual avoidance learning.

AMNESTIC EFFECT OF MONOCLONAL S-100β and S-100α ANTISERA ON ONE-TRIAL PASSIVE AVOIDANCE MEMORY FORMATION IN DAY-0LD CHICKS. Brona S. O'Dowd, Wei Q. Zhao, Kim T. Ng, Andrew J.P. Francis* and Stephen R. Robinson. VTHRC, University of Queensland, QLD., AUSTRALIA. The β subunit of the calcium-binding dimeric protein S-100 is upregulated in Alzheimer's disease and Down's syndrome, and has been implicated in memory-land disease.

The p subunit of the caicium-binding dimeric protein S-100 is upregulated in memory-related processes. Up to now, the involvement of the α subunit of S-100 in memory has not been examined. In the present study, day-old chicks (Gallus domesticus) trained on a one-trial passive avoidance task received intracranial injections (10µ1 per hemisphere) of either saline or monoclonal antisera to S-100β (1:500, Sigma), S100 α (1:50, Sigma) or one of a range of concentrations of carbonic anhydrase antisera (1:50-1:10,000, Sigma). Compared to control chicks that had been injected with either saline or the carbonic anhydrase antisera, those injected with either the S-100 α antisera experienced significant retention deficits (p < 0.05). The S-100 β antisera needed to be administered between 5 minutes before and 5 minutes after training and produced a decline in recall from 20 minutes post-training, the start of the A phase of the intermediate memory (ITM) stage of the Gibbs-Ng three-stage memory model¹. The S-100 α antisera, on the other hand, could be administered up to 20 minutes after the training trial, producing amnesia from 30 minutes post-training, the point of transition between the A and B phase of the ITM stage. Our immunohistochemical studies showed that S-100 antisera are rapidly taken up into cells (within 20 minutes). Thus, although the antisera are likely to be acting on extracellular 5-100 binding sites, they may also prevent the respective S-100 proteins from binding to their intracellular targets. The finding that memory loss occurred at different times after training depending on the subunit of S-100 antisera injected suggests that the β and α subunits may act through separate memory-related mechanisms operating at different times after the aversive experience.

DISSOCIATIONS BETWEEN BEHAVIORAL RECOVERY AND RESTORATION OF ACTIVITY IN THE DEAFFERENTED VESTIBULAR NEURONS AFTER A UNILATERAL LABYRINTHECTOMY IN THE ALERT GUINEA PIG. L. Ris. B. Capron, C. de Waele, P-P. Vidal and E. Godaux*. Lab. of Neuroscience, Univ. of Mons-Hainaut, 7000 Mons, Belgium and LPPA, CNRS, Paris, France.

In the guinea pig, a unilateral labyrinthectomy induces postural disturbances and an ocular nystagmus on the one hand, and a collapse of the spontaneous activity in the neurons of the ipsilateral vestibular nuclei on the other hand. These initial changes are followed by an abatement of the behavioral symptoms and by a restoration of the resting activity in the deafferented vestibular neurons. The aim of this study was to compare the time courses of those two recoveries.

Postural disturbances were measured from videorecordings whereas ocular nystagmus was recorded using the search coil technique. For neuronal-discharge measurements, animals were prepared for chronic extracellular recording of single unit activity. The criterion used to select the 1333 analysed vestibular neurons was their recruitment by an electrical shock on the vestibular nerve.

Although there was a rough parallelism between bevavioral and neuronal recoveries, some discrepancies emerged. (1) During the first 90 min after labyrinthectomy, while vestibular neuronal activity was collapsed, an important step in the postural recovery occurred (the animal which could not stand up began to manage to do it). (2) The major part of the abatement of the nystagmus occurred during the first 10 h after labyrinthectomy while vestibular neuronal activity remained collapsed during that period. (3) Behavioral static vestibular compensation was almost finished 48 h after the lesion while a significant part of the restoration of the neuronal activity still occured after that time.

We conclude that restoration of neuronal activity in the vestibular nuclei in only one of the mechanisms underlying vestibular compensation.

SENSORIMOTOR ASYMMETRIES FOLLOWING UNILATERAL LESIONS OF THE RAT SOMATIC SENSORIMOTOR CORTEX: NEGLECT, EXTINCTION OR HYPOKINESIA? <u>C. E. Raad* and T.M. Barth</u>. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

Previous work has shown that unilateral lesions in several different

Previous work has shown that unilateral lesions in several different areas of the rat somatic sensorimotor cortex (SMC) produce behavioral asymmetries on a bilateral-tactile extinction test. Specifically, unilateral lesions of the rostral forelimb area (RFL), the caudal forelimb area (CFL), or the anteromedial cortex (AMC) produce a preference for contacting an adhesive patch placed on the forelimb ipsilateral to the cortical lesion. The present study attempted to distinguish between the asymmetries following unilateral lesions the AMC or the RFL. The specific question asked was whether the appearance of a sensorimotor asymmetry required the simultaneous presentation of bilateral-tactile stimulation (i.e. extinction) in the form of an ipsilateral bias or if unilateral stimulus presentation alone would reveal a behavioral asymmetry in the form of contralateral neglect (i.e. no response to contralateral stimuli) or long latencies to contact patches placed on the contralateral forelimb (i.e. hypokinesia). Rats were given either unilateral lesions in the RFL or AMC, or a sham surgery. During the first five days after surgery, the rats with RFL lesions showed an asymmetry with both bilateral and unilateral testing procedures. On the bilateral test, RFL-damaged rats showed an ipsilateral bias. However, with unilateral tests the RFL-damaged rats showed inoger latencies to contact a patch placed on the contralateral forelimb when compared to pisilateral latencies and to sham control rats. In contrast AMC-damaged rats failed to show an asymmetry with the unilateral testing procedure and therefore required the presence of bilateral-tactile stimulation. These data suggest the sensorimotor asymmetry following RFL lesions may be characterized as a hypokinesia, whereas lesions in the AMC produce an asymmetry more closely resembling tactile-extinction. Supported by TCURF #5-23745.

NMDA RECEPTOR BLOCKADE DOES NOT BLOCK THE IMMEDIATE "UNMASKING" THAT FOLLOWS MEDIAN NERVE TRANSECTION IN ADULT SQUIBREL MONKEYS OR REVERSE REORGANIZATION ONCE IT HAS OCCURRED. W.A. Myers², J.D. Churchill^{1,2}, J. Besheer², S.E. Voss², N. Muja², and P.E. Garraghty^{*1,2}, ¹Prog. Neur. Sci., ²Dept. Psych., Indiana

University, Bloomington, Indiana, 47405.

We have previously shown that most of the reorganization that typically follows median nerve transection in adult squirrel monkeys is dependent on normally-functioning NMDA receptors. Here, we have evaluated two hypotheses. 1) Is the immediate "unmasking" found after median nerve transection NMDA receptor-dependent? 2) Are NMDA receptors necessary for both the initiation and the maintenance of reorganizational changes, or only the former? We implanted subcutaneous osmotic minipumps to deliver CPP systemically. Drug delivery was initiated either before examining the immediate effects of median nerve transection, or after reorganization had presumably occurred. For the first set of experiments, NMDA receptor blockade was initiated either 1 or 4 weeks prior to multiunit mapping in area 3b followed by transection of the median nerve and a remapping of the cortex For the second set of experiments, median nerve transection was followed 4 weeks later by either 1 or 4 weeks of NMDA receptor blockade prior to a terminal cortical mapping experiment. We found that the immediate unmasking of new receptive fields after acute nerve injury was not prevented by NMDA receptor blockade; nor were completely reorganized cortical maps dependent upon NMDA receptors for their maintenance. We conclude that dependent upon NWDA teceptors for their maintenance. We conclude that the immediate unmasking is likely due to release from tonic inhibition, and that the later phase of reorganization, as for LTP in the hippocampus, is dependent on normally-functioning NMDA receptors for its initiation, but not for its maintenance. SURVIVING TISSUE SURROUNDING CORTICAL DAMAGE IS VULNER. SURIVINIG TISSUE SURROUNDING CORTICAL DAMAGE IS VULNER-ABLE TO BEHAVIOR-DEPENDENT GLUTAMATE ELEVATION AND IMMUNE SYSTEM ACTIVITY. J.L. Humm*, S.T. Bland, R.R. Cocke, D.C. James, J.E. Gotts, J.K. Sexton, R. A. Gonzales & T. Schallert. Institute for Neuroscience & Departments of Psychology and Pharmacology, University of Texas at Austin, Austin, TX 78712. Following injury to the forelimb area of the sensorimotor cortex (FL-SMC), rats were fitted with casts of the non-impaired forelimb, which forced overuse of the contralateral limbs for 2 weeks. This procedure greatly expanded the injury and severely disrupted recovery of contra-

greatly expanded the injury and severely disrupted recovery of contra-lateral limb function (Kozlowski, et al. *J. Neurosci.*, in press). Primary injury to FL-SMC may render surrounding cortical and subcortical tissue susceptible to overuse-related glutamatergic activity. In casted rats, the NMDA receptor antagonist, MK-S01 (1mg/kg daily, a dose that did not reduce forelimb activity), prevented lesion expansion and improved recovery of function. Microdialysis experiments indicated that behavioral activity is associated with increased levels of dialysate glutamate in brain regions surrounding the FL-SMC. The role of the immune system was examined in additional experiments. Animals forced to overuse their impaired limbs after FL-SMC damage, while being simultaneously injected with the T-cell immunosuppressant, Cyclosporin A, exhibited sparing of subcortical tissue and facilitation of behavioral recovery. The bacterial endotoxin, LPS, which stimulates cytokine (IL-1) production, aggravated cortical damage in the absence of forced limb overuse. We propose that a cascade of events triggered by behavioral pressure or immunological processes may be lethal to otherwise-surviving tissue after brain injury. RECOVERY FROM LOCOMOTOR PLACING DEFICITS FOLLOWING UNILATERAL CORTICAL LESIONS IN THE RAT: A FLOOR EFFECT. C. L. Hart*, M.R. Hoane and T.M. Barth, Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

There is considerable evidence that suggests preoperative and/or

There is considerable evidence that suggests preoperative and/or postoperative experience may affect the severity of lesion-induced deficits and the rate of behavioral recovery after damage to the cortex. In some of these studies rats are placed in either an "enriched" or an "impoverished" environment, with the "enriched" environment condition promoting the restoration of function. Other studies have manipulated the amount of task-specific practice and found that practice may also affect recovery. The present study was designed to investigate whether manipulations of the housing environment could be directed towards promoting restoration of a specific function. The task we chose was the foot-fault test. In this task rats are required to locomote on a grid floor (openings in the grid were 3.5 cm) by placing their limbs on the rungs of the grid. A "foot-fault" occurs when the rat misplaces the forelimb and it falls through an opening in the grid or when the forelimb slips off one of the rungs through an opening in the grid or when the forelimb slips off one of the rungs into the opening. The housing manipulation was the floor of the home cage. Postoperatively, some rats were placed into standard wire mesh cages with a grid floor (1.25 cm openings) and other rats into similar cages, but with a solid floor. All rats received a small unilateral electrolytic lesion in the forelimb area of the somatic sensorimotor cortex (SMC) and were then placed into the individual cages. Behavioral testing began on postoperative day 2. Surprisingly, the results were that rats housed in the cages with solid floors showed a reduction in the number of postoperative foot-faults and an acceleration of behavioral recovery when compared to those housed with the grid floor. These data suggest that the grid floor used in the home cage may have promoted the development of behaviors incompatible with the task. Supported by TCURF #5-23745.

Norepinephrine Manipulation and Postoperative Practice Influence recovery of Locomotor Placing Following Cortical Lesions in the Rat. S.L. Irish *† & T.M. Barth, †Q.P. Corporation, Tokyo, Japan & Dept. of Psych., Texas Christian University, Ft. Worth, TX 76129.

The NE neurotransmitter system has been of interest for its role in recovery of

function following SMC lesions as well as its role in sensorimotor learning. Drugs that enhance NE activity have been shown to facilitate recovery of locomotor placing that enhance NE activity have been shown to facilitate recovery of locomotor placing following SMC lesions in the rat while drugs that deplete NE retard recovery. It has been proposed that drugs that enhance NE activity facilitate recovery by activating distant areas depressed following brain damage. Similar to the effects of NE-acting drugs on recovery, manipulations of NE also influence the rate of motor learning. Therefore, an alternative explanation of the NE effect on recovery might be that NE-acting drugs affect recovery by influencing sensorimotor learning as the rat learns an attribute the hardest of the sensor of the sensor of the sensor of the sensor of the sensor of the sensor of the sensor of the sensor of the foot-fault and beam-walking the sensor of the sensor o tests by manipulating postoperative practice and NE levels. Following surgery subjects were divided into either practice or no-practice groups. Postoperative testing suppers were divided into entire plactice or in-practice groups. Postoperative testing began for the practice groups on day 2 and for the no practice groups on day 14. Subjects were given posttrial injections of saline, yohimbine, or clonidine every other day following surgery. It was hypothesized that if NE-acting drugs influence recovery merely through a relief of diaschisis then pharmacological manipulations would influence recovery regardless of postoperative practice. On the other hand, if NE-acting drugs influence recovery through enhancement of learning strategies then no drug effect would be observed until it was given in conjunction with postoperative practice. The findings were that postoperative practice had the strongest influence on recovery of foot-faults and beam-walking ability. NE-acting drugs only influenced recovery on the foot-fault test and this influence appears to be independent of postoperative practice. Therefore, both a release from diaschisis and sensorimotor learning may be acting in the recovery process. NE-acting drugs may affect diaschisis while practice may affect sensorimotor learning.

DOES THE ONSET OF BEHAVIORAL TESTING AFFECT THE EFFICACY OF MAGNESIUM CHLORIDE TO PROMOTE RECOVERY FOLLOWING CORTICAL LESIONS IN THE RAT. M.R. Hoane* and T.M. Barth.

Department of Psychology, Texas Christian University, Ft. Worth, TX 76129. In studies investigating the behavioral effects of neuroprotective drugs the onset of post-operative testing has varied considerably. In some experiments testing has begun 24 hrs post-injury and in other cases, one or two weeks may testing has begun 24 hrs post-injury and in outer cases, one or two weeks may pass before behavioral testing begins. The purpose of the present study was to examine the effects of delaying post-operative testing following cortical lesions and to determine if delays affect the efficacy of the neuroprotective agent magnesium chloride (MgCl₂). Rats received unilateral electrolytic lesions of the sensorimotor cortex (SMC) and a regimen of MgCl₂ (1 mmol/kg) starting at specific post-operative intervals (15 min, 8 hr, or 24 hr) or saline. Forelimb placing tests were initiated post-operatively starting on day 2, day 8, or day 14 after the lesion. The results indicated that recovery of forelimb placing seems to occur in the absence of post-operative practice. Moreover, when testing began on day 2 all MgCl₂ treated animals showed a facilitation of behavioral recovery. day 2 all MgCl₃ reacted animass showed a real relation to benavioral recovery. That is, the window of opportunity includes treatment beginning at 24 hours after the injury. However, when testing is begun either on day 8 or 14 there were no significant differences in recovery between the MgCl₂ and saline treated rats. These data suggest that onset of testing is an important factor to consider when evaluating the effectiveness of drugs that may be beneficial to recovery of function. This research was funded by TCURF #5-23745.

EVIDENCE FOR ALTERATIONS IN THE FORM OF SYNAPTIC CONNECTIVITY IN THE CORTEX OPPOSITE UNILATERAL SENSORI-

CONNECTIVITY IN THE CORTEX OPPOSITE UNILATERAL SENSORIMOTOR CORTEX LESIONS: TIME-DEPENDENT DEGENERATIVE AND
SYNAPTIC STRUCTURAL CHANGES. T.A. Jones* Dept. of Psychology and
Behavioral Neuroscience Program, Univ. Washington, Seattle, WA 98195.
Unilateral lesions of the forelimb representation area of the sensorimotor
cortex (FLsmc) in adult rats have been found to result in dendritic growth
and synaptogenesis in layer V of the motor cortex contralateral and
homotopic to the lesions (Jones & Schallert, 1992; 1994; Jones, Kleim &
Greenough, 1995). The neuronal growth appears to be influenced by
lesion-induced changes in the use of the forelimbs. The present study used
electron microscopy and stereological procedures to assess possible electron microscopy and stereological procedures to assess possible structural alterations in axonal processes and their synaptic connections in layer V contralateral to FLsmc lesions. Myelinated axons were reduced in volume fraction, volume per neuron and number per unit area in comparison to sham-operated rats at 10 but not 18 days after the lesion, consistent with lesion-induced degeneration and subsequent growth. Following this, at a time point corresponding to increases in the total number of synapses per neuron (30 days), the lesions were found to result in a marked increase in the proportion and the number per neuron of individual axonal boutons forming synaptic contacts with 2 or more dendritic spines (multiple synaptic boutons). Furthermore, the number of synapses per neuron with perforated subsynaptic plates, which are believed to be associated with enhanced synaptic efficacy, were increased in comparison to shams. These findings are suggestive of alterations in the pattern and possibly the strength of synaptic connections. Together, these changes may represent a lesion-initiated and behavior-influenced major restructuring of synaptic connectivity in the cortex opposite FLsmc lesions. Supported by MH35321 and MH55525.

LIGHT DEPRIVATION AFTER FRONTAL CORTEX INJURY REDUCES LOCOMOTION, STRIATAL FOS EXPRESSION, AND RECOVERY TIME FROM UNILATERAL NEGLECT. J.M. Vargo¹. H.V. Lai² and J.F. Marshall². ¹Dept. of Surgery, Hennepin County Medical Center and Dept. of Neurosurgery, Univ. of Minnesota, Minneapolis, MN 55415, ²Dept. of Psychobiology, Univ. of California, Irvine, CA 92717-4550.

Light-deprivation (LD) after unilateral aspiration of medial agranular cortex (AGm) produces accelerated recovery from unilateral neglect, but the neural mechanisms mediating this recovery are unknown. Neglect after AGm ablation is associated with hemispheric asymmetries (lesioned < intact) in striatal c-fos expression, while spontaneous recovery under normal light cycle conditions is associated with symmetrical c-fos expression. This study examined striatal c-fos expression 5 days after AGm ablation in rats experiencing 48 h of either LD or 12h light/12h dark cycling (12/12) soon after surgery. All lesioned rats demonstrated severe multimodal neglect before being placed in their respective light conditions. After 48 h, all were maintained under 12/12 conditions. During LD, horizontal motion was reduced in both unlesioned and lesioned rats (P < .001). By postoperative day 4, only lesioned rats that had experienced LD showed significant recovery from neglect (P < .001). LD reduced the numbers of amphetamine-induced (5 mg/kg, i.p.) Fos-positive nuclei seen in left or right dorsolateral striatum in both lesioned and unlesioned rats ($P \le .007$). In lesioned rats, those that underwent LD had less hemispheric asymmetry in Fos expression (lesioned/intact = $.76 \pm .04$) than did those experiencing the 12/12 cycle (.61 ± .05). Less motion during the light-cycle manipulation was associated with greater recovery on postoperative day 4 (r = -.611, P=007), and with greater hemispheric symmetry in striatal Fos on postoperative day 5 (r=-499, P=041), suggesting that LD may produce accelerated recovery by reducing asymmetries in subcortical functioning.

LIGHT DEPRIVATION INDUCED RECOVERY FROM SEVERE NEGLECT INDUCED BY UNILATERAL DESTRUCTION OF THE POSTERIOR PARIETAL CORTEX IN RATS. J.V. Corwin* and

 K.J. Burcham. Psych. Dept., Northern III Univ., DeKalb, IL 60115.
 Light deprivation (LD) has been found to produce dramatic sparing and recovery of function from neglect induced by unilateral lesions of the medial agranular prefrontal cortex in rodents, the rodent analog of area 8. However, the area most often related to severe neglect in humans is the inferior parietal lobule (IPL). In the present study we examined whether LD would produce accelerated behavioral recovery of function from neglect induced by unilateral destruction of the posterior parietal cortex (PPC), the rodent analog of the IPL.

Subjects received unilateral PPC lesions and were tested for the presence of severe neglect of visual, tactile, and auditory stimulation. If severe neglect was obtained, the subjects were randomly placed into one of three groups: a 48 hr LD group, a 48 hr constant light group, or a normal light/dark cycle group. After the environmental manipulation, the subjects were tested for multimodal neglect 3 times per week for 3 weeks.

The LD group demonstrated significantly greater recovery than the controls (p's < 0.01). Significant recovery was present across all sensory modalities on the first test post LD, and lasted for the duration of testing. The results provide further support for the therapeutic effectiveness of LD on neglect induced by cortical lesions. Further, the results of studies of the effects of LD suggest that LD may provide significant therapeutic effects in situations where the behavioral deficits are related to a disruption of dopaminergic mechanisms.

EFFECTS OF ENTORHINAL LESIONS ON THE DISTRIBUTION OF GLUTAMATE RECEPTORS IN THE MONKEY HIPPOCAMPAL FORMATION. A.L. Jongen-Rêlo* and D.G. Amaral. Dept. of Psychiatry and Center for Neuroscience, University of California, Davis. Davis, CA

Leonard et al. (J.Neurosci., 1995, 15(4): 5637-5659) demonstrated that Macaca Fascicularis monkeys with bilateral entorhinal cortex (EC) lesions were transiently impaired in the performance of the delayed nonmatching to sample task. In addition, a significant transverse expansion of the perirhinal terminal field in the CA1 region of the hippocampus was bernimal terminal net of the terminal net of the impocaripus was observed in the lesioned animals. Since the entorhinal and perirhinal inputs to the hippocampal formation are glutamatergic, we have now investigated whether the distributions of NMDA and AMPA receptors were altered in the hippocampal formation of these EC lesioned monkeys. Animals were hippocampal formation of these EC lesioned monkeys. Animals were sacrificed approximately 1-1 1/2 years after their neurosurgical procedure and sections through the hippocampal formation of lesioned and control animals were immunohistochemically processed with antibodies against NMDAR2a/b and AMPA GluR1 and GluR2/3 subunits. Initial qualitative analysis indicates that immunoreactivity for GluR1, GluR2/3 and NMDAR2a/b was increased in the outer one third of the molecular layer of the dentate gyrus and in the stratum lacunosum-moleculare of the hippocampus. While neuropil staining appeared to be slightly increased in the hilar region of the dentate gyrus, cellular labeling in CA3 was similar in both groups of animals. Interestingly, GluR2/3-immunoreactivity was markedly decreased in the layer II pyramidal cells of the presubiculum. We are currently investigating alterations in other neurotransmitter systems. are currently investigating alterations in other neurotransmitter systems. PERCEPTUAL CORRELATES OF NEURAL PLASTICITY IN THE ADULT HUMAN BRAIN: AN UPDATE. D. Rogers-Ramachandran* and V. S. Ramachandran , UCSD, La Jolla, CA 92093-0109.

In 1991, we examined two arm amputees and found that they

systematically referred sensations from the ipsilateral face to the phantom (Ramachandran et al., *Science*). We suggested that this was at least partially due to the remapping of sensory input from face into regions in the brain that ordinarily represent the (amputated) hand. We were also able to show cortical remapping as revealed by MEG (Yang, Ramachandran, Galen et al., *Nature*, 1992) -- changes that may be analogous to those reported in monkeys (Pons, 1991). We suggested analogous to those reported in monkeys (Pons, 1991). We suggested that, in addition to referral of non-painful sensations, referred pain may also be caused by remapping, an idea that is consistent with the recent observations of Taub et al. (*Nature*, 1996).

We have now studied over 18 patients. Seven systematically refer

touch from face to the phantom. In some (but not all), the referral was modality specific, e.g., warmth, cold or vibration on the face was perceived as warmth, cold or vibration on the phantom and the referral was also topographically organized. Thus the emergence of such referred sensations is a robust phenomenon that probably arises due to remapping in the sensory areas of the brain. However, the absence of visual feedback may lead some patients to eventually "ignore" the referred sensations, or the sensory input might be recognized as abnormal" by higher centers and interpreted as pain instead of touch

These results demonstrate a surprising amount of plasticity in adult humans and may be clinically important for phantom pain. Supported by NIMH.

LACK OF EVIDENCE FOR SUBSTANTIAL SPROUTING IN THE MOLECULAR LAYER OF THE MONKEY DENTATE GYRUS FOLLOWING **Poet of Cell Biology, Univ. Salamanca. Spain and **Dept. of Psychiatry and Center for Neuroscience, University of California, Davis. Davis. CA 95616. In a previous behavioral study (Leonard et al., 1995; J. Neurosci. 15:5637-5659), five Macaca fascicularis monkeys were subjected to bilateral lesions of the entorhinal cortex. Animals survived for approximately 1-1 1/2 years after surgery during which they were behaviorally tested and demonstrated a transient initial memory impairment followed by normal performance just prior to sacrifice. In order to determine potential morphological substrates of prior to sacrifice. In order to determine potential morphological substrates of this functional recovery, three neuroanatomical techniques were employed to examine possible plasticity in the cyto- and fiber architecture of the hippocampal formation: NADPH-diaphorase (ND) histochemistry, acetylcholinesterase (AChE) histochemistry, and choline acetyltransferase (ChAT) immunocytochemistry. ND and AChE labeled both neurons and dense fiber plexuses whereas ChAT immunoreactivity demonstrated prominent and regionally selective fiber systems. None of these markers demonstrated substantial alterations in fiber or cell labeling in the deafferented hippocampal formation. Minor changes included a reduction of ND-positive fibers in the dentate gruss and the relative expansion of the diffuse AChE staining present in the supragranular zone of the dentate molecular layer. But, no clear evidence of collateral sprouting was observed. Since a significant transverse expansion of the peririhinal cortical projection Since a significant transverse expansion of the perirhinal cortical projection to the hippocampal formation was observed in these same animals (Leonard et al., 1995), it can be concluded that not all fiber systems in the primate hippocampal formation demonstrate morphological plasticity. In particular, and in contrast to what has been demonstrated in the rat, we observed little or no evidence of sprouting in the dentate gyrus following entorhinal lesions. EFFECTS OF PRENATAL ALCOHOL EXPOSURE ON GAP43/B50, c-MYC AND N-MYC PROTEIN LEVELS IN FETAL RAT HIPPOCAMPUS, CEREBELLUM, STRIATUM AND HYPOTHALAMUS. J.H. Hannigan*, L.M. Treas, M.A. Sperry, D.E. Saunders. Fetal Alcohol Research Center, C.S. Mott Center, Department of Ob/Gyn, Wayne State University, Detroit, Michigan, USA 48201

We reported previously that alcohol exposure in cultured LA-N-5 human neuroblastoma cells (Saunders, et al Dev Brain Res, 86, 16, 1995) and in young (≤ 10 days) postnatal rats decreased growth-associated protein 43 (GAP43/B50) and increased c-myc and N-myc levels. Similar effects were not seen reliably *in vivo* in hippocampus of young offspring of Long-Evans rats given 4 g/kg or 6 g/kg of ethanol by intubation from gestational day 8 (GD 8) through GD 19. In the current study using a similar in vivo design and prenatal alcohol exposure, GAP43/B50, c-myc and N-myc protein levels were measured immunohistochemically at GD18 in fetal rat hippocampus, cerebellum, striatum and hypothalamus. Fifty cells per brain were assessed for levels of each protein (ROD-background) in both proliferating (periventricular) and differentiating zones of the 4 brain areas. GAP43/B50 levels in the differentiating zone of hippocampus were 81% to 88% of control levels following 4 g/kg to 6 g/kg of prenatal alcohol, whereas N-myc levels were 117% to 130% of control levels, respectively. There were no significant changes in c-myc levels, and effects in intubation stress control rats (0 g/kg ethanol) were not reliable. Comparisons of these results among brain areas in cells at different developmental stages can indicate critical periods and specific neurotrophic or regulatory mechanisms of alcohol teratogenesis in in vivo systems. Results are consistent with effects in the in vitro LA-N-5 cultures, and suggest that alcohol-induced alterations in these differentiation-regulating proteins in rat brain contribute to the life-long CNS sequelae that produce neurobehavioral dysfunction after prenatal alcohol exposure

KAINIC ACID INDUCED LIMBIC SEIZURES, ELECTRICAL KINDLING AND LTP IN VIVO INCREASE EXPRESSION OF TENASCIN-C IN RAT HIPPOCAMPAL NEURONS. M. Nakie, N. Mitrovic*, D. Manahan-Vaughant, L. Butler°, J. McNamara°, G. Sperk#, K. Reymannt, M. Schachner. Department of Neurobiology, Swiss Federal Institute of Technology, Zürich, Switzerland, °Epilepsy Research Laboratory, Duke University Medical Center, Durham, N.C., USA, #Department of Pharmacology, University of Innsbruck, Innsbruck, Austria, †Department of Neurophysiology, Federal Institute of Neurobiology, Magdeburg, Germanv.

We have investigated changes in the expression of the extracellular matrix molecule tenascin-C (TN) in different models of synaptic plasticity in the hippocampus of adult rats in vivo: kainic acid induced limbic seizures, electrical kindling and long-term potentiation (LTP). Changes in TN mRNA and protein levels were revealed by in situ hybridization, immunocytochemistry and Western blot analysis. Under control conditions, TN mRNA was not detectable in all paradigms tested, while protein was detectable in the strata oriens and lacunosum moleculare of CAI and in the molecular layer and at the inner surface of the granule cell layer in the dentate gyrus. Drastic up-regulation of TN mRNA, seen as early as 4 h after a single intraperitoneal kainic acid injection, was followed by a decrease of message to control levels 24 h later and increase in protein level throughout the whole dentate gyrus. Thirty days after injection, mRNA and protein levels were slightly elevated in CA3 pyramidal cells, when compared to control levels. Twenty four hours after evoking generalized seizures by electrical kindling of the amygdala, TN mRNA was slightly up-regulated throughout the pyramidal cell layer in the stimulated but not contralateral hemisphere. This increase was observed also 5-8 weeks later but confined to the CA3 subregion. Four hours after eliciting LTP via stimulation of the perforant pathway, TN mRNA was up-regulated in granule cells and some pyramidal cells of the hippocampal formation. Twenty four hours after simulation TN mRNA was no longer detectable. Together with previous observations on the ability of TN antibodies to decrease acoustic imprinting in chicken, our data indicate that TN is involved in changes underlying synaptic plasticity in several paradigms.

ALTERATIONS IN THE GLYCINERGIC NEUROTRANSMITTER SYSTEM ARE ASSOCIATED WITH STEPPING BEHAVIOR IN NEONATAL SPINAL CORD TRANSECTED RATS. R.J. Talmadge, R.R. Roy, and V.R. Edgerton*. Dept. of Physiological Sci. and Right Res. Inst. LUCI A. Los Angeles. CA. 900.95

Dept. of Physiological Sci and Brain Res. Inst. UCLA. Los Angeles. CA 90095. To elucidate if adaptations in specific neurotransmitter systems are associated with training-induced improvements in hindlimb stepping behavior after spinal cord injury. 12 neonatal (Neo) rats (7 days old) were randomly placed into 3 groups. One group (Neo-ST) was subjected to a mid-thoracic spinal cord transection (ST). A second group (Neo-ST-Tr) was subjected to ST and trained to step on a motorized treadmill 15 min/day. 5 days/week for 12 weeks. A third group served as controls. Locomotor ability was determined by mean step length during 30 sec of bipedal hindlimb stepping at 0.9 m/s. Mean step length was lower in both ST groups compared to control. The Neo-ST-Tr rats had longer step lengths than Neo-ST. Quantitative western blot determinations of two subunits of the glycine receptor macromolecule. i.e., the α_1 -subunit (48 kDa) of the receptor and gephyrin (93 kDa), revealed that step training normalized an increase in the total amount of each subunit in the lumbar cord (L3-L5) of Neo-ST rats. Thus, locomotor training resulted in significant improvements in hindlimb stepping ability and normalization of glycine receptor protein subunits. These data suggest that the glycinergic neurotransmitter system is involved in stepping behavior and is modulated by spinal cord injury and subsequent locomotor training. Supported by NIH grant NS 16333 and American Paralysis Association grant TA1-9402-1.

BEHAVIORAL AND NEUROCHEMICAL RECOVERY FROM PARTIAL 6-OHDA LESIONS OF THE SUBSTANTIA NIGRA(SN) IS BLOCKED BY DAILY TREATMENT WITH D1 RECEPTOR ANTAGONIST, SCH 23390. A. Emmi.* H. Rajabi and J. Stewart. Center for Studies in Behavioral Neurobiology, Dept. Psychology, Concordia University, Montreal, Canada, H3G 1M8.

Partial unilateral lesions of the SN produce a transient sensori-

Partial unilateral lesions of the SN produce a transient sensorimotor asymmetry. We reported recently that behavioral and neurochemical recovery from partial 6-OHDA lesions of the SN is blocked by daily treatment with glutamate receptor antagonists, MK-801 and CPP. Here we report that a D1 DA receptor antagonist, SCH 23390, can also prevent recovery following the same lesions. After surgery some animals were treated daily on Days 1-8 with SCH 23390; others were given the inactive isomer, SCH 23388. In behavioral tests on Day 3 before the daily injection, all animals showed rotation ipsilateral to the lesion. On Day 15, animals given the inactive isomer no longer displayed asymmetrical rotation, whereas SCH 23390-treated animals continued to rotate ipsilaterally. Microdialysis on Days 16-17 confirmed that in animals given the inactive isomer, there were no differences in basal DA between the lesioned and nonlesioned side. In contrast, basal levels of DA on the lesioned side of SCH 23390-treated animals were lower compared to those on the nonlesioned side. These findings suggest that D1 DA receptors play a role in the development of the long-lasting compensatory changes in intracellular events that accompany recovery from partial lesions of the nigrostriatal pathway. EFFECTS OF MONOCULAR ENUCLEATON AT BIRTH UPON LEARNING OF A VERTICAL-HORIZONTAL DISCRIMINATION IN HOODED RATS. F. Yagi* and F. Okutani. Neuropsychology Lab., Kochi Med. Sch., Nankoku, Kochi 783, Japan.

Previously we have demonstrated that adult albino rats with one eye removed at birth (OEB) relearn a black-white discrimination faster than those monocularly enucleated at maturity (QET) when relearning is conducted after lesioning of the visual cortex contralateral to the remainig eye (Type A Exp.). This faster relearning phenomenon is considered to be one behavioral expression of the functioning of the expanded uncrossed visual pathways (expanded UXVPs) resulting from monocular enucleation at birth. However, neither OEBs nor OETs were able to master the discrimination when the experiment was conducted without previous learning following the same surgical treatment (Type B Exp.). We hypothesized that this occurs because the cue to discriminate might be close to the threshold of discrimination for either the normal UXVPs or the expanded UXVPs. In order to gain insight into hypothesis, the present study was undertaken using hooded rats as subjects which possess larger and more efficient UXVPs. In the Type A Exp. OEBs relearned discrimination of the 10-mm stripes [0.44 cycles/degree (c/d)] faster than OETs, yet in the Type B Exp. neither OEBs nor OETs were capable of acquring that discrimination. However, they could originally master the discrimination equally well when the width of stripes was broadened to 30 mm (0.15 c/d). And when the width of stripes was systematically reduced thereafter, the width of the smallest stripes for the expanded UXVPs to discriminate was found to be 6 mm (0.73 c/d) and that for the normal UXVPs 10 mm (0.44 c/d). These findings were discussed in relation to the hypothesis advanced on our previous data in albino rats

BIOLOGICAL RHYTHMS AND SLEEP: CIRCADIAN RHYTHMS III

FORSKOLIN RESETS THE CIRCADIAN OSCILLATOR IN XENOPUS RETINAL PHOTORECEPTORS. M. Hasegawa and G. M. Cahill* Dept. of Biology, Univ. of Houston, TX 77204.

Previous studies indicate that the Xenopus retinal photoreceptor layer (PRL) contains a circadian oscillator that drives rhythmic melatonin release in constant darkness. This oscillator can be entrained in vitro by cyclic light or activation of D2like dopamine receptors. Both light and dopamine can influence cyclic nucleotide pathways in photoreceptors. Therefore, we have begun to investigate the possibility that cAMP regulates the PRL oscillator. The PRL were prepared and cultured individually for 5 days in flow-through culture chambers by methods previously described (Cahill and Besharse, 1993, Neuron; 10: 573-577). We examined the effects of forskolin, a drug that increases cAMP by stimulating adenylate cyclase. A single 6-h pulse of forskolin (1 µM) increased melatonin synthesis and reset the oscillator in a phase-dependent manner. Forskolin caused phase delays when PRLs were treated during the late subjective night or early subjective day, and phase advances when PRLs were treated during the late subjective day, resulting in a "darkpulse" type of phase response curve. Maximum phase delay (-2.15±0.33 h: n=4) and phase advance (2.97±0.30 h: n=4) were induced by the pulse at zeitgeber time (ZT) 21 and ZT 9, respectively. These phase-shifting effects were blocked or attenuated by light or quinpirole pulse at the same time. A pulse of 1,9dideoxyforskolin (1 µM), an inactive analog, did not induce phase shifts or affect melatonin synthesis. When PRLs were exposed continuously to 1 μ M forskolin, melatonin levels were increased at all phases of the rhythm, but the period of the rhythm was not affected. These results suggest that changes of cAMP level can reset the oscillator in the Xenopus retinal PRL and are consistent with, but do not prove, the hypothesis that light and dopamine reset the oscillator through suppression of cAMP. ROLE OF THE INTERGENICULATE LEAFLET (IGL) AND OLFACTORY BULBS IN PHOTIC AND NONPHOTIC ENTRAINMENT IN DIURNAL OCTODON DEGUS. N. Goel and T.M. Lee, Dept. of Psychology, 525 East Hall, University of Michigan, Ann Arbor, MI 48109.

Octodon degus is a diurnal rodent species with stable, robust behavioral circadian responses to photic and social (olfactory) entrainers. This experiment determines the role of the intergeniculate leaflet (IGL) and the olfactory bulbs in mediating olfactory and photic information to the biological "clock" in degus. Female degus were housed in entrained conditions for 3 weeks to obtain the phase angle of entrainment for wheel-running and body temperature rhythms. Animals then received bilateral IGL lesions (n=16), sham IGL operations (n=4), bilateral olfactory bulbectomies via aspiration (n=10) or sham bulbectomies (n=5). After surgery, females were rehoused in entrained conditions for 3 weeks to assess phase angle. Next, animals underwent a sixhour phase advance of the LD cycle, first with photic cues present for 3 weeks, and subsequently with both social and light cues present for 3 weeks; in both cases reentrainment rate was measured. Finally, animals were maintained in constant darkness (DD) for 5 weeks to determine tau. Following behavioral testing, the tissue will be processed with cresyl violet staining to determine the accuracy of IGL lesions and olfactory bulbectomies. In the IGL-lesioned animals, immunocytochemistry will be used to assess neuropeptide Y (NPY) fibers, terminals and cells in the suprachiasmatic nucleus (SCN) and IGL. Data collection is still in progress and therefore the results will be presented at the meeting. NIMH grant R03MH49089.

ApC/EBP mRNA HAS A CIRCADIAN RHYTHM AND IT IS AFFECTED BY

ApC/EBP mRNA HAS A CIRCADIAN RHYTHM AND IT IS AFFECTED BY LIGHT IN THE EYE OF APLYSIA. S. Hattar and A. Eskin.* Dept. Biochem. and Biophys. Sci., Univ. of Houston, Houston, TX 77204.

The CCAAT enhancer-binding protein transcription factors (C/EBP) represent a family involved in terminal differentiation of a variety of cells including adipocytes, enterocytes, and monocytes. These transcription factors also play a role in mediating induction of memory by serotonin (5-HT) in Aplysia (Alberini et al., 1994). Because 5-HT also regulates the circadian mythm in Aplysia, we investigated the role of C/EBP in the ocular circadian system. ApC/EBP mRNA in eyes, measured by ribonuclease protection assays, changed mythmically when arimals were kept in 12:12 light-dark cycles. ApC/EBP was lowest during the late day time and highest during the late night time. Changes persisted for at least a few cycles when animals were kept in constant darkness. Some preliminary results indicate that the rhythm of ApC/EBP also persists in vitro when eyes are kept in culture. In another set of experiments, we have begun to investigate the effects of light and 5-HT on the isolated eyes. Light pulses given at CT 18-19:30 or CT 18-24 when light phase advances the rhythm, produced large increases in ApC/EBP. In preliminary experiments the effect of light does not affect the phase of the rhythm, also produced large increases in ApC/EBP. affect the phase of the rhythm, also produced large increases in ApC/EBP, ApC/EBP is the first *Aplysia* gene shown to vary rhythmically. ApC/EBP may be involved in activating certain genes that are important in the generation of the rhythm. A better understanding of the role of ApC/EBP will emerge from future studies of the protein changes of this gene. (Supported by MH41979).

AGING ALTERS THE CIRCADIAN RHYTHM OF *APLYSIA* EYES, <u>M. Sloan* and A. Eskin.</u> Dept. of Biochem. & Biophys. Sci., Univ. of Houston, TX 77204. It has been shown that aging affects the circadian rhythms of mammals (Turek et

al., 1995). We have begun to investigate aging changes in the circadian rhythm of spontaneous nerve impulses from the isolated eye of Aplysia californica

Aplysia of various ages, from 4 months to 14 months, were obtained from the University of Miami Aplysia Resource Facility, Miami, Florida. Animals were maintained in artificial sea water at 15°C and entrained to a light/dark cycle (LD 12:12) for at least 3 cycles. Isolated eyes, with their attached optic nerves located inside a polyethylene tube containing an electrode, were placed in recording chambers containing buffered filtered sea water. The circadian rhythms of spontaneous optic nerve impulses were recorded in DD conditions.

The amplitude of the rhythms progressively decreased with age. 4-6 month old animals had robust rhythms averaging a peak value of around 309 spikes per hour on the first day, decreasing to around 119 on the fifth day. 9-10 month old animals had medium rhythms averaging a peak value of around 245 spikes per hour on the first day, decreasing to around 75 on the fifth day.12-14 month old animals had much weaker rhythms, averaging a peak value of around 177 spikes per hour on the first day, decreasing to around 36 on the fifth day. Also, the phase angle of the entrained rhythm of the isolated eyes was more delayed in older animals. On the other hand, the free-running period of the rhythm did not appear to change with age,

although a greater percentage of older eyes displayed arrhythmicity.

Another interesting finding was that 63% of a group of 545 animals, ages 12-14 months, had cloudy lenses. Recordings of rhythms from these eyes had starting peak values around 175 spikes per hour, but quickly fell off after the first day to a level below 50 spikes per hour, becoming arrhythmic thereafter. These findings indicate that aging has some pronounced affects on the circadian system in eyes of Aplysia. (Supported by MH41979)

COUPLING BETWEEN TWO PHOTORECEPTOR SYSTEMS THROUGHOUT MONOCHROMATIC LIGHT IN CRAYFISH PROCAMBARUS, V. Inclán-Rubio* and A.Borgonio-Aguilar Departamento de Fisiología. Facultad de Medicina, UNAM. AP. 70-250. CP04510. México, D.F.

The circadian rhythm result from the complexity integration between endogen rhythms and environmental signals. These rhythms could be couple to environmental signals due to their ability to be synchronized. In the crayfish Procambarus, there are at least two photoreceptor systems, retinal and caudal. It is known that the white light stimuli upon the caudal photoreceptors of the sixth abdominal ganglion (6th AG) in the crayfish increases the electric activity along the abdominal chain, evoking an inhibitory effect on the amplitude of the electric response to the light of the visual photoreceptors (electroretinogram, ERG). The ERG presents circadian characteristics. The objective of this work is to study the entrainment characteristics of the ERG circadian rhythm when monochromatic light (ML) is applied on the 6th AG. We worked with Procambarus clarkii adult. The ERG was obtained with a conventional recorder technique under a L:D (12:12) photoperiod. In the 4th day of recording, a ML stimulus was applied (590 or 632 nm) along one hour and 400 lux intensity, at four different circadian times (6,12,18 and 24 CT). After six days changes were analyzed. Upon the results we can see that (a) the ML (590 y 632 nm) decreases the amplitud of the ERG always after the light stimulation; (b) the phase response curve shows delays at 6 and 24 CT (590 nm) and 12 CT (632nm) and advances at 12 and 18 CT (590 nm) and 6,18 and 24 CT (632 nm); (c) the presence of a transitory state lasting from 24 to 36 hrs in both ML, and (d) oscillation level change when light was applied during subjective night for both ML. These results show the functional relationship between the caudal and retinal photoreceptor systems and a particular entrainment range for each wave length codified by the 6th AG.(PAPIT-DGAPA: IN204593).

OLOMOUCINE, A CYCLIN DEPENDENT KINASE INHIBITOR, PHASE SHIFTS THE *APLYSIA* EYE RHYTHM POSSIBLY VIA INHIBITION OF TRANSCRIPTION. N. Sankrithi*, Q. Tran, and A Eskin. Department of Biochemical and Biophysical Sciences, University of Houston, Houston, TX 77204 Cyclin levels oscillate and consequently control the activity of cyclin-dependent kinases. If cyclin dependent kinases were involved in opisthobranch ocular rhythms, then inhibiting them would affect the phase and/or period of the rhythm. Olomoucine, a purine analog, acts as a competitive inhibitor of ATP for cyclin dependent kinases *in vitro* with relative specificity (Vesely, 1994). Isolated eyes in constant darkness were exposed to 100 μ domoucine at various phases. Single 6h pulses of olomoucine produced phase delays in the *Aplysia* ocular rhythm at all phases tested. Response curves with all delay phase shifts are characteristic of inhibitors of transcription and translation was examined by investigating 3H uridine and 3H leucine incorporation into TCA precipitable material. Label was given during the last 4h of 6h treatments of olomoucine. Olomoucine inhibited uridine incorporation by $84\pm4\%$ (n=4) during CT 7-13. During the same phase, olomoucine did not inhibit leucine incorporation. Also, isoolomoucine (100 μ M), an inactive analog of olomoucine, did not inhibit transcription nor did it phase shift the rhythm. These results suggest that olomoucine's action on the circadian rhythm could be mediated through inhibition of transcription (Supported by MH41979). MH41979)

FROM PHOTORECEPTORS TO CIRCADIAN RHYTHMS IN A BLIND MAMMAL (Spalax ehrenbergi) H.M. Cooper *, J. Negroni, R.G. Foster, W. DeGrip, J.K. Bowmaker, A. Szél, E. Nevo CERVEAU et VISION. INSERM U-371, 69675 Bron. FRANCE: Imperial College. London. UNITED KINGDOM.: Department of Biochemistry. University of Nijmegen. THE NETHERLANDS: Inst. of Optibulmology, London, UNITED KINGDOM.
Semmelweis, Budapest, HUNGARY; Inst. of Evolution. Haifa, ISRAEL

We have used molecular approaches, opsin immunohistochemistry, mcrospectrophotometry (MSP), activity recordings, retrograde tracing and viral tract tracing methods to dissect out the photic pathway regulating circadian physiology in the blind mole rat, Spalax. Spalax demonstrates clear entrainment of locomotor activity by light and expresses an endogenous circadian rhythm in constant darkness. As in other mammals. the induction of c-fos expression in the SCN by a light pulse is gated by the phase of the endogenous clock: c-fos immunopositive cells are only observed following photic stimulation administered during the subjective night. The SCN receives is innervated by almost all retina ganglion cells. Their morphology, demonstrated by transneuronal transport of Alpha-Herpes virus or by carbocyanine dyes (Dil) suggests the presence of a single morphological class. Ganglion cells appear to receive input from at least two classes of photoreceptors. Using several antibodies directed against different visual photopigments, we find that the majority of photoreceptors contain a rod-like pigment, whereas a small population contains a short wavelength cone-like photopigment. These results differ from previous RT-PCR analysis which revealed the presence of a single opsin closely homologous to the mouse green cone pigment. Further molecular dissection and *in situ* MSP measures of photoreceptors should help to clarify the identity and absorbance properties of these cells.

MODULATORY ACTIONS OF THE CRAYFISH SINUS GLAND IN THE CIRCADIAN RHYTHM OF THE RATE OF CONTRACTION OF THE HEART. J. Hernández-Falcón*(1), J. Serrato (2) and F. Ramón(3).

(1) Depto. Fisiología, Fac. Med., UNAM, (2) Depto. Fisiología, Biofísica y Neurociencias, CINVESTAV, IPN, (3) Div. Posgrado, Fac. Med., UNAM, México, D.F. 04510, MEXICO. Circadian oscillations of numerous animal functions are

entrained by light in accordance with day-night cycles. In crayfish the rate of contraction of the neurogenic heart shows a circadian rhythm in which accelerator and inhibitor nerves are involved.

The aim of this work was to assess the role of a neurohemal organ such as the sinus gland in the circadian rhythm of the rate of contraction of the crayfish heart. Thus, heart rate was continuously monitored during 5-7 days in control, blinded, sinus gland and eyestalk excised adult animals subjected to natural photoperiod, constant darkness and constant lightness. Results show that the rate of contraction of the heart oscillates with a period of 22.12 + 3.6 hours in control and blinded animals. Excision of sinus gland or eyestalks do not change the period of the oscillation, but amplitude, activity level and lpha/
ho values decrease. These results indicate that the circadian rhythm of the rate of contraction of the crayfish heart is under neural and humoral control.

EFFECT OF THE RED MONOCHROMATIC LIGHT UPON THE SYNCHRONIZING MECHANISMS OF THE MOTOR ACTIVITY RHYTHM OF THE JUVENILE CRAYFISH P. clarkii. Miranda-Anaya, M; Barrera-Mera, B. and Fanjul-Moles, M. L*. Lab. de Neurofisiología. Facultad de Ciencias; Depto. de Fisiología. Fac. Medicina, UNAM, México D. F. a. p. 70-371

Red monochromatic light synchronizes locomotor activity rhythm during the ontogeny in crayfish. The objective of this work was to study the putative circadian photoreceptors involved in this phenomena. Three groups of 60 days old crayfish consisting of 1) animals with a restricted lesion in retina, 2) animals with a restricted lesion in supraesophagic ganglion and 3) intact control animals. All the animals were individually recorded with a motor activity recording system; ten days under dark constant conditions, other 10 days under a 24 Hs skeleton photoperiod cycle (SP), consisting of two red light signals (25 Wm.-2s-1) and afterwards transferred again to constant darkness conditions during 10 days. Results analyzed by means of actograms and chi square periodograms, indicated that intact animals display a unimodal activity rhythm (τ=23.7±1.8) able to sinchronize to SP (τ =24± 0.5). Retine injured animals showed an evident longer activity rhythm (τ =25.5±1) synchronizing under SP (τ =24.2±0.4). Supraesophagic injured animals showed mostly a lack of rhythmicity under constant conditions and were unabled to sinchronize to SP. These results, although preliminary, could indicate in the crayfish extraretinal synchronizing mechanisms sensible to the monochromatic red light.

MODULATION OF TONIC IMMOBILITY BY MELATONIN IN 10-11 DAY OLD CHICKENS (G. GALLUS). Z. A. Rodd, N. B. McCutcheon, D. J. Shillito, & G. G. Gallup, Jr. Dept. of Psychology, University at Albany: SUNY, Albany, NY 12222

Tonic immobility (TI) is an innate behavior which is reliably elicited by a brief period of manual restraint. After initial struggling, the animal assumes a motionless, catatonic-like posture which persists in the absence of further restraint. Previous theories pertaining to TI, have linked the behavior to a state of sleep. Additionally, a number of researchers have studied the similarities between TI and rapid eye movement (REM) sleep. A previous study reported that melatonin inhibited REM sleep in young The intent of the studies was to determine whether melatonin influenced TI in a similar manner as REM in chicks. The present series of studies were conducted to examine the effects of an administration of melatonin on the susceptibility to and The results indicated that duration of TI in young chicks. melatonin exerted an inhibitory influence on the duration of and susceptibility to TI. These results were comparable to the reported inhibitory influence melatonin expressed on REM sleep in young chicks. Therefore, the effects of melatonin on TI parallel the effect of melatonin on sleep parameters in young chicks.

QUIPAZINE MIMICS THE EFFECTS OF A LIGHT PULSE ON MELATONIN RHYTHMICITY AND INDUCES SUPRACHIASMATIC NUCLEUS FOS EXPRESSION IN THE RAT.

. J. Kennaway, R. W. Moyer and K. S. Türker*. Departments of Obstetrics and

Gynaecology and Physiology, University of Adelaide, Adelaide, South. Australia, 5005. Serotonergic pathways to the suprachiasmatic nucleus (SCN) are thought to modulate the effects of light on circadian rhythmicity. The evidence comes from in vitro studies of the effects of serotonin agonists on SCN neuronal firing rate rhythms in rats and in vivo studies in hamsters showing that serotonergic agonists block SCN c-fos induction by light. To determine the physiological consequences of activation of serotonergic pathways to the SCN, we have investigated the effect of a serotonin agonist on rhythmic melatonin production and SCN c-fos induction in rats. Wistar male albino rats (100g) were initially kept in a 12L:12D photoperiod and then continuous darkness. Thirty hours after initiation of continuous darkness (CT18), rats were injected with saline vehicle, quipazine (1-10 mg/kg) or exposed to a 2 lux, 15 minute light pulse and urine collected hourly for a further 3 subjective nights. Administration of vehicle had no acute effect on the excretion of the melatonin metabolite 6-sulphatoxymelatonin (aMT.6S) whereas both guipazine and the light pulse resulted in a significant and prolonged suppression of melatonin production. On the next night, the time of onset of the aMT.6S excretion was unaffected by the vehicle treatment (0.2 \pm 0.2h), but was significantly delayed by quipazine treatment (1.5 \pm 0.2h) and the light pulse (2.7 ± 0.5h). In other experiments at CT18 both quipazine (5-10 mg/kg) and light treated animals (2 lux, 15 minutes) showed intense c-fos protein immunoreactivity of cell nuclei in the ventrolateral SCN, whereas no immunoreactivity was observed in the vehicle treated animals. These results show for the first time that administration of a serotonin agonist mimics both the acute suppression and phase delaying effects of light on pineal gland rhythmicity in the rat. The latter response and the induction of fos protein in the ventrolateral SCN suggests that serotonergic pathways are important mediators of light effects in the rat. These results contrast with previous data reported for the hamster This research was supported by the NHMRC of Australia.

ONSET OF PRENATAL ENTRAINMENT BY MELATONIN IN THE SYRIAN HAMSTER. M. Viswanathan* and F.C. Davis. Dept. of Biology, Northeastern Univ., Boston, MA 02115.

Day/night rhythms of the mammalian circadian pacemaker occur during late gestation and are entrained by rhythms of the mother. The maternal signal or signals responsible for causing prenatal maternal entrainment have not yet been identified. However, there is evidence in hamsters that the pineal gland hormone, melatonin, can mediate prenatal entrainment. Melatonin when given daily to pregnant hamsters during the last 4-5 days of gestation or given only once on day 15 of gestation sets the phase of the pups rhythm at weaning. The aim of the present study was to determine when during gestation a single prenatal melatonin injection can set the phase of the offsprings' circadian rhythm.

Pregnant Syrian hamsters were maintained in constant dim light and SCN ablation was done on day 7 of gestation. They received a single intraperiloneal injection of melatonin (25µg) at different stages of gestation (E 11.75,12.25°,12.75°,13.25,13.75,14.25, and 14.75.(° in progress). After the injection the hamsters and their pups born on day 16 of gestation were left undisturbed until the pups were introduced individually into the wheel cage on postnatal day 20 (weaning). The activity rhythms of the pups were recorded for 3-4 weeks and the phases on the day of weaning were determined.

A single melatonin injection when given on F13.25, 13.75, 14.25, 14.75.

pups were recorded for 3-4 weeks and the phases on the day of weaning were determined.

A single melatonin injection when given on E13.25, 13.75, 14.25, 14.75 successfully set the phases of pups' rhythms whereas melatonin on E 11.75 failed to set the phases. Since SCN neurogenesis in Syrian hamster is complete on E12.5 (Davis et al 1990), the present results indicate that the circadian pacemaker (SCN) responds to melatonin only after SCN neurogenesis is completed. It is likely that the mechanisms for the generation of oscillations and/or for entrainment by melatonin require postmitotic differentiation of SCN cells. Supported by NIH grant HD 18686.

ELF-EMF EXPOSURE AND NOCTURNAL MELATONIN PRODUCTION IN HUMANS:AN11-WEEK EXPOSURE STUDY WITH A HEATLESS ELECTRIC

Michinori KABUTO¹*, Yoshika KUROKAWA¹ and Seung Chul HONG

¹Jpn. Natl. Inst. Environ. Studies, 16–2 Onogawa, Tsukuba City, Ibaraki, 305 JAPAN

²Univ of Tokyo Faculty of Med, Bunkyo-ku, Tokyo, 113 JAPAN With respect to the suggested effects of ELF-EMF (extremely low frequency electromagnetic fields) in our daily lives on melatonin (MEL) production, especially on its nocturnal rise, and also its rhythm, four healthy young subjects were exposed to ELF-EMF of around 5 μ Tesra at its peaks using a self-made sheet of "heatless blanket" being wired with electric code connected with an usual electric blanket during sleep every night for 11 weeks. Ten urine specimens were collected for 5 time-periods of 1800-2400, 2400-400, 400-800, 800-1200 and 1200-1800 hours during successive three days a week. MEL excretion rate (UMER, ng/hr) was obtained based on malatonin measurements with a RIA method (Bühlmann Lab AG). Amplitude and 24-hr rhythm of the UMERs were estimated with the Cosinor method on the basis of the three-day data per week for one week before, initial and last phase (2 weeks each) during, and two weeks after exposure. Only in one out of the four subjects, a marked reduction of the amplitude of UMER during 2400-400 hours and a delay of the acrophase was observed for the last two weeks during exposure. This result seems to support some reported in vivo animal experiments and also findings for female electric blanket users, suggeting a possible effect among highly sensitive individuals. It should be noticed, however, that there were generally large individual as well as intra-individual variations in UMER values, the reason of which has now been investigated with increasing the number of subjects. (This study was supported by NIES grant T-13 & H-16)

DIURNAL VARIATIONS IN MELATONIN RECEPTOR AND mRNA EXPRESSION IN CHICK BRAIN. S. Iacob*, M.I. Masana and M.L. Dubocovich, Dept. Molec. Pharmacol. Biol. Chem. and Northwest. Univ. Inst. Neuroscience, Northwestern Univ. Med. School, Chicago, IL 60611

ML, melatonin receptor density in retinorecipient areas of chick brain displays distinct diurnal rhythms, with higher levels during the day (Brooks and Cassone, Endocrinol., 131:1297, 1992). Here we report correlations between diurnal oscillations in specific 2-[125I]-iodomelatonin binding and melatonin receptor (ml_{1a} , ml_{1c}) mRNA expression in chick brain. Chicks (21 days old) maintained on a 14 /10 L/D cycle, were sacrificed every 4 hours: ZT2, ZT6, ZT10, ZT14, ZT18 and ZT22 (ZT0 = onset of light). Coronal brain sections throughout the telencephalon, diencephalon and mesencephalon were processed for quantitative receptor autoradiography with 2-I12 iodomelatonin (60 and 240 pM) (specific binding defined with 1 µM melatonin) and in situ hybridization with antisense and sense ml, and ml, [35S]-riboprobes. Specific 2-[125I]-iodomelatonin binding was higher during daytime. Both primary [optic tectum (OT), DSV] and secondary [rotundus (ROT) and triangularis (T) nuclei] visual brain areas exhibited higher levels of specific binding during the day, peaking at ZT10. Binding density to tertiary visual input recipient areas [ectostriatum (E)] did not oscillate. Expression of ml1a melatonin receptor mRNA in the ROT and E was higher at ZT2, while ml_{1c} melatonin receptor mRNA expression in the pineal gland and the E was higher at ZT6 and ZT10. In summary, these findings suggest that melatonin receptor protein and mRNA expression in chick brain visual areas follow diurnal rhythms. [Supported by MH42922 to MLD]

MECHANISMS UNDERLYING INCREASES IN MELATONIN RECEPTOR DENSITY FOLLOWING WITHDRAWAL OF MELATONIN. M.I. Massana*, P. Witt-Enderby and M.L. Dubocovich, Dept. Mol. Pharmacol. Biol. Chem. and Northwest Univ. Inst. Neurose., Northwestern Univ. Med. School, Chicago, IL 60611.

Mammalian melatonin receptor expression exhibits a diurnal rhythm. In the pars tuberalis this rhythm is generated by fluctuations in plasma melatonin, while in the suprachiasmatic nucleus the rhythm is regulated by light and is suppressed in constant dark (Brain Res., 641:92, 1994). Two mammalian melatonin receptors cDNAs have been cloned; the ml $_{\rm in}$ in the retina (Cell, 83:1059, 1995). Here we report the effects of withdrawal from melatonin exposure on the density and regulation of the human ml $_{\rm in}$ melatonin receptor. CHO cells stably transfected with the human ml $_{\rm in}$ melatonin receptor. CHO cells stably transfected with the human ml $_{\rm in}$ melatonin for 8 hours and 2-[128 I] iodomelatonin binding was measured at different times after cessation of melatonin treatment. A time dependent increase in 2-[128 I] iodomelatonin binding was observed after melatonin withdrawal, reaching a plateau (~150%) at 8 hours. Melatonin receptor mRNA levels also increased following one hour and reached a value of ~300 % following 16 hours after cessation of melatonin treatment. In addition, pertussis toxincatalyzed ADP ribosylation of the inhibitory G-protein (heterotrimeric form Gia $\beta\gamma$) increased in a time-dependent manner following melatonin withdrawal. In summary, the increase in 2-[128 I] iodomelatonin binding could be due to increases in melatonin receptor protein and, at least in part, to the stabilization of the high affinity complex melatonin/melatonin receptor/G protein. These results suggest that in vivo, the nocturnal melatonin exposure may be one of the mechanisms by which diurnal regulation of melatonin receptors occurs. [Supported by USPHS grant MH42922 (MLD) and F32 HL08965 (PWEI)]

EVIDENCE THAT THE MEL1A MELATONIN RECEPTOR MEDIATES MELATONIN-INDUCED VASOCONSTRICTION OF RAT CAUDAL AND CEREBRAL VESSELS. A. J. Watson', P. Agarwal, G. D. Goggins, E. Ryan and C. D. Mahle. C. N. S. Drug Discovery, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

The effects of the pineal hormone melatonin are mediated through high affinity G protein-coupled receptors. Melatonin binding sites have been described in vascular tissue, notably rat caudal and anterior cerebral arteries. In rat caudal artery, the non-hydrolyzable GTP analog, Gpp(NH)p, induced an attenuation of $2^{-1^{125}}$ ljiodomelatonin binding, consistent with the interaction of the binding site with a G protein. In rat tail artery, melatonin $(10^{-12}\ to\ 10^{-4}\ M)$ had no direct effect on baseline tension. Melatonin, 2-iodomelatonin and S-20098 induced a dose- and concentration-dependent potentiation of precontracted rat caudal and anterior cerebral arteries. The potentiating effects of melatonin were not altered in the presence of the α -adrenergic antagonists prazosin or phentolamine, or by blockade of sodium-dependent neurotransmitter release with tetrodotoxin. Finally, we show, by reverse transcription-polymerase chain reaction (RT-PCR) that mRNA for the MEL1A melatonin receptor is present in both rat caudal and cerebral arteries. Degenerate RT-PCR of melatonin receptor transcripts from caudal artery demonstrates that these are bona fide MEL1A sequences, and not those of a closely related subtype. Transcripts corresponding to other melatonin receptor subtypes were not detected. These results suggest that the MEL1A receptor is the mediator of melatonin-induced vasoconstriction.

551.19

Melatonin, secreted from the pineal during the night, modulates circadian rhythms and sleep/wake cycles. The presence of melatonin receptors in certain vascular beds suggests a role for melatonin in vascular regulation. We now report molecular and pharmacological data indicating that human and rat cerebral and peripheral arteries express functional melatonin receptors of the ML $_{1A}$ subtype. Melatonin receptor fragments were amplified from human cerebral arteries by reverse transcriptase-PCR using degenerate primers for the known ml $_{1a}$ and ml $_{1c}$ receptors, and identity with the ml $_{1a}$ receptor was confirmed by cloning. Functional effects of vascular melatonin receptors were characterized using rat middle cerebral and tail arteries in vitro. Melatonin (1-100 nM) directly constricted cannulated, pressurized cerebral arteries and potentiated constriction of tail arteries, effects antagonized by luzindole with a pK $_{\rm B}$ value (6.4) that correlates with the binding affinity of luzindole for recombinant ml $_{1a}$ (6.8) but not ml $_{1b}$ (8.0) or ml $_{1c}$ (5.5) receptors. Thus melatonin appears to regulate the cerebral circulation of humans and other mammals via vascular ML $_{1A}$ receptors. Activation of these receptors may contribute to circadian variations in cerebral blood flow and onset of stroke as well as to possible side effects of melatonin administered for sleep disorders. NIH HL-50775 and MH-42922

IDENTIFICATION OF NOVEL BENZIMIDAZOLES WITH HIGH AFFINITY AND SPECIFICITY FOR THE MELATONIN ML₂ BINDING SITE, K. S. Takaki, B. T. Watson, R. A. Deshpande, G. N. Karageorge, I. P. Yevich, A. A. Ortiz, A. Johnson, R. McGovern, D. Molstad, N. Sarbin, I. Stanley, C. Mahle. Bristol-Myers Squibb Co., Wallingford, CT 06492.

Melatonin has been found to bind to a number of distinct sites but the significance of all of these has yet to be elucidated. The human $M_{\rm L_A}$ receptor, found in the SCN, has been cloned and is presumed to mediate the chronobiotic effects of melatonin. The human ML_{\rm IB} receptor has also been cloned but its localization and function have yet to be determined. In addition, a binding site for melatonin in hamster hypothalamus has been reported to which no function has been ascribed. This ML, site is distinguishable from the ML_{\rm IA} and ML_{\rm IB} receptors because of its high affinity for the α_1 adrenergic antagonist, prazosin. We have identified a series of novel benzimidazole derivatives which are highly selective for the melatonin ML_binding site found in hamster hypothalamus. These compounds do not bind to ML_{\rm IA}, ML_{\rm IB} or α_1 receptors. In addition, members of this series have been shown to possess anticonvulsant properties when evaluated in the maximal electroshock or pentyleneterazol-induced seizure models. A systematic structure affinity relationship study was performed to optimize ML_-selectivity and resulted in the identification of a lead compound with better affinity and selectivity for the ML_-site than melatonin.

Effects of a melatonin agonist and antagonist on hamster suprachiasmatic nucleus (SCN) neurons in vitro. G. Scott, P. Delagrange*, B. Guardiola-Lemaître, E. Mocaër and B. Rusak, Dalhousie Univ., Halifax, Nova Scotia, Canada B3H 4J1.

S-20098 (N-(2-(7-methoxy-1-naphthyl) ethyl) acetamide) acts as a melatonin receptor agonist as demonstrated by its ability to entrain daily rhythms in locomotor activity and its ability to suppress firing of photically responsive cells in the SCN *in vivo*. Neurophysiological effects of S-20098 *in vivo* are partially attenuated by systemic injections of S-20928 (N-(2-(1-naphthyl) ethyl) cyclobutyl carboxamide), a putative melatonin receptor antagonist. Because systemic injections did not identify the target at which these effects occurred, we have investigated the effects of S-20928 on responsiveness of single SCN cells in an *in vitro* brain slice preparation to melatonin and to S-20098.

lonophoretic application or pressure ejection of S-20098 (1mM in 2% DMSO; 0-80nA; 1-7 psi; 5-120s duration) or melatonin onto single SCN cells potently attenuated spontaneous firing in a current- or pressure-dependent manner. S-20098 or melatonin also attenuated the activational effects on single SCN cells of ionophoretically applied NMDA (0-40nA; 10-30s duration). S-20928 (1 mM in 2% DMSO; 1-7 psi; 35-120s duration) had no effect on cell firing when pressure ejected alone, but its prior application was able to antagonize the suppression of firing rates by application of S-20098. These results indicate that S-20098 potently suppresses spontaneous and NMDA-evoked firing in SCN cells *in vitro*, presumably by acting at melatonin receptors, and that S-20928 acts directly on SCN cells to antagonize these effects.

ML_{1B} MELATONIN HETERORECEPTORS MEDIATE PRESYNAPTIC INHIBITION OF DOPAMINE RELEASE FROM RABBIT RETINA.
M. L. Dubocovich*, S. Iacob, K. Mistry and M. I. Masana. Dept. Mol. Pharmacol.
Biol. Chem. and Northwestern Univ. Institute for Neuroscience, Northwestern Univ.
Med. School, Chicago, IL 60611.

Melatonin receptors were originally classified based on kinetic properties and pharmacological profiles into the ML, and ML, classes (TIPS, 16° : 50, 1995). The ML, class contains at least three molecular receptor subtypes, i.e., ml₁₁, ml₁₁, ml₁₂, with about 60 % amino acid homology among themselves (Cell 83: 1059, 1995). To identify subtype-selective drugs, we compared the pharmacological profiles of the recombinant ml₁₁, (human), ml₁₂, fuluman) and ml₁₂ (*Xenopus* melanophore) receptors expressed in COS 7 cells with the well characterized functional melatonin heteroreceptor in rabbit retina. The relative order of agonist potencies to inhibit the calcium-dependent release of dopamine from retina was identical to the order of affinities (pKi) of the analogues for the recombinant ml₁₁₂, [S20098 (12) > mel (9.8) \geq 6Clmel (9.7) \geq 2Imel (9.7) \geq 6,7 Cl2CH, mel (9.7)], but not the ml 1, [2Imel (10.2) > S20098 (9.1) \geq mel (9.1) \geq 6,7 di Cl2CH, mel (8.3) \geq 6Cl mel (7.9)]. Partial agonists [e.g., 5-methoxy-luzindole, N-acetyltryptamine] and competitive melatonin receptor antagonists (e.g., 4-phenyl-2-chloroacetamidotetraline, 4-phenyl-2-propionamidotetraline, 4-phenyl-2-acetamidotetraline, luzindole] distinguished the ml₁₃ (pKi: 7.4, 6, 6.4, 6.3, 6, 5.6) subtypes. These analogues showed 100 times higher affinity for the ml₁₃ recombinant subtype. The corresponding dissociation affinity constants (K₀) of these analogues (pK₀: 10.2, 9, 9.3, 9.5, 8.8, 7.7) to antagonize the melatonin-induced inhibition of dopamine release correlated with their affinities (pKi) for the ml₁₃ but not the ml₁₄ or ml₁₂ subtypes. We conclude that the presynaptic melatonin heteroreceptor modulating dopamine release is the ML₁₈ subtype. Supported by MH 42922.

AGE- AND SEX- RELATED COMPARISONS OF VOCAL CONTROL REGIONS IN FREE-LIVING DARK-EYED JUNCOS (JUNCO HYEMALIS). Cynthia C. Gulledge* and Pierre Deviche. Institute of Arctic Biology. University of Alaska Fairbanks, Fairbanks AK 99775-7000.

In songbirds, neural control of singing behavior is accomplished via an interconnected set of vocal control regions (VCRs), collectively called the vocal control system. Other studies have shown that VCR volumes are sexually dimorphic in species in which only the males sing. In the spring and early summer, adult male dark-eyed juncos sing a long-distance song from tree-tops, while adult female juncos and juveniles of both sexes do not. We have shown previously that male junco VCR volumes change seasonally. being large during breeding, and smaller afterwards in the fall. We collected adult and juvenile male and female juncos from a wild population near Fairbanks, Alaska, in the fall, when no juncos were singing. A blood sample was collected immediately after capture to be assayed for androgen. Brains were fixed with 4% paraformaldehyde via intracardiac perfusion, sectioned then stained with thionin. Vocal control regions (Area X. MAN, HVC, RA) and one non-vocal control region (n. rotundus) were measured. VCRs were 3-7 times smaller in females than in males (depending on the region), and some regions were smaller in fall adults than in fall juveniles. Neither the size of the n. rotundus nor plasma androgen concentrations differed among groups. Thus, VCR volumes of juncos are sexually dimorphic, and plasma androgen concentrations do not act as the proximal determinant of VCR size outside of the breeding season Supported by NSF award BNS-9121258 to P.D

PERCEPTUAL SELECTIVITY CORRELATES WITH I-MAN NUCLEAR VOLUME IN A NON-SINGING FEMALE SONGBIRD. K. Cleal, S. E. Allan*, A.P. King, D.R. Sengelaub, and M.J. West. Departments of Psychology and Biology, Indiana University, Bioomington, IN 47405.

and Biology, Indiana University, Bloomington, IN 47405. Song production in brown-headed cowbirds (Molothrus ater) is sexually dimorphic. Males use song during courtship, with virtually all copulations preceded by at least one vocalization. During the breeding season, captive females respond to song playbacks with a copulatory posture, the frequency of which can be used to measure the relative potency of individual songs. Females show strong individual differences in song selectivity; while all females respond more frequently to high potency songs, some are less discriminating, responding to low potency songs as well. We have begun to assess the neural basis of song selectivity in female cowbirds, examining the brain nuclei involved in song production, perception, and learning. Song selectivity, the difference in response frequency to high and

Song selectivity, the difference in response frequency to high and low potency song, was evaluated in adult females. Morphology of song nuclei in males and females was examined in frozen, thionin-stained sections (40 $\mu m)$. Consistent with the sexual dimorphism in song production, volume, neuron number, and neuron size within HVC, RA, and Area X were up to 10 times larger in males than in females. In contrast, no sex differences were observed in I-MAN, a structure previously implicated in song learning and perception. Furthermore, I-MAN volume varied due to individual differences in neuron number, and was strongly correlated (r=0.96; p<.001) with song selectivity in females. Thus, although female cowbirds do not sing, their I-MAN is as large as that of males, and may be involved in discrimination of male song quality. Supported by NSF 88 21152 (MJW)

SEASONAL PLASTICITY OF THE SONG SYSTEM IN WILD NUTTALL'S WHITE-CROWNED SPARROWS. E. Brenowitz*, L. Baptista, K. Lent, and J. Wingfield. Depts. of Psychol. & Zool., Univ. of WA, Seattle, WA 98195 & Calif. Academy of Science, San Francisco, CA 94118.

Seasonal changes in song behavior and the morphology of song nuclei in the brain occur in nearly all species of seasonally breeding songbirds studied. The only published report of a seasonally breeding bird that *lacks* seasonal plasticity in the song nuclei is for the Nuttall's race of White-crowned sparrow (Zonotrichia leucophrys) (Baker et al. '84). Their study used captive sparrows that were exposed to long-day (LD) or short-day (SD) photoperiods in the laboratory. In a study of the conspecific Gambel's race of white-crowns (Smith et al. '95), we found that plasma levels of testosterone (T) in captive males may be lower than those of wild breeding males. Seasonal changes in plasma T serves as the dominant proximate mechanism underlying changes in the song nuclei (Smith et al. '93). It is possible, therefore, that the LD Nuttall's white-crowns in Baker et al.'s study did not experience plasma T levels high enough to stimulate growth of the song nuclei. To test this possibility, we measured seasonal patterns of song, hormones, and song nuclei in wild Nuttall's white-crowns.

Adult males were captured in spring (April, $n\!=\!10$) and fall (September, $n\!=\!9$), bled for hormone analysis, and perfused. The volumes of song nuclei and other regions were measured in Nissl stained sections. Song was recorded in the field at both times of year.

We found pronounced seasonal changes in the size of song nuclei and in T levels. Spring: fall ratios were: HVC = 2.23^* , RA = 1.80^* , Area X = 1.57^* , T = 24.2^* (* = P ≤ 0.005 , t-test). The thalamic visual nucleus Pt did not change in size (S:F = 0.96). These results indicate that, as in other seasonally breeding species, there is seasonal plasticity in the song system of Nuttall's white-crowned sparrows. (NIH MH53032 & NSF DCB-9005081)

INDIVIDUAL DIFFERENCES IN HVC NEURON NUMBER PREDICT DIFFERENCES IN THE PROPENSITY FOR AVIAN VOCAL IMITATION. <u>B. C. Ward, E. J. Nordeen*, and K.W. Nordeen</u>. Dept. Brain and Cog. Sci. and Neuroscience Program, U. Rochester, NY 14627.

In several species of passerine songbirds, the overall volumes of two different vocal control regions (the HVC and RA) correlate with song repertoire size. It is unlikely that these correlations reflect effects of song learning on neural growth since early deafening does not diminish the size of these regions. In the present study, we explored an alternative hypothesis; that normal variation in the size of song regions affects how much song material can be faithfully imitated.

Within 8 days of hatching, male zebra finches were isolated from adult song and raised to independence by their mother. At 30 days, they were housed permanently in a large cage with two adult tutors and their mates. Songs were recorded at 120 days of age, and birds then were sacrificed to measure neuron number and nuclear volume for HVC, RA and Area X.

The tutors produced 16 distinct syllables, but the subjects copied no more than 6 syllables, and never copied from both tutors. Several measures of brain space correlated significantly with the number of syllables copied from the tutors, but not with total repertoire size. Individual differences in the volume of the HVC and number of HVC neurons strongly predicted the number of syllables copied from the tutor (r = .93; r = .95, respectively; p<.01). RA volume and neuron number also correlated with the amount of learned song material, but less strongly (r=.70; r=.66, respectively). Neither Area X volume nor neuron number correlated well with measures of song learning. NIMH MH 45096.

RELATIVE VOLUME OF L-MAN IN FEMALE WARBLER SPECIES VARIES WITH THE NUMBER OF SONGS PRODUCED BY CONSPECIFIC MALES. <u>T.J.DeVoogd¹, J.A.Cardin¹, T. Szekely², J. Büki³</u> and <u>S.W.Newman⁴*</u>. ¹Dept. Psychology, Cornell Univ., Ithaca, NY; ²Dept. Zoology, Kossuth Univ., Debrecen, Hungary; ³Ornith. Soc., Budapest, Hungary; ⁴Dept. Anat., Univ. Mich., Ann Arbor, MI.

In some songbird species, the males learn large numbers of songs, a process that appears to have been driven by female choice of males with the most complex songs (Catchpole, 1987; Bensch & Hasselquist; '92). Species differences in a male's capacity for vocal learning are correlated with species differences in the relative volume of HVC (DeVoogd et al., '93; Szekely et al., '96), a nucleus essential for song production (Nottebohm et al., '76). Effective female choice requires not only that a female identify the song of her species but also discriminate songs of greater and lesser complexity. We examined the brains of females of 7 sylviid warbler species, caught in May, perfused with 10% formalin, sectioned and Nissl stained. We find that differences in the relative volume of 1-MAN across species are closely related to the complexity of songs produced by males of the species. In males, this nucleus is essential for song learning (Bottjer et al., '84) and contains cells responsive to the bird's own song (Doupe & Konishi, '91). The relative volumes of HVC, RA and n. rotundus in the females do not show this association. Thus, aspects of structure in a nucleus that may be involved in song perception differ between females of species that experience different auditory demands--perhaps providing the acuity that underlies evolutionary selection for enhanced learning ability. EFFECTS OF CASTRATION ON THE VOLUME OF SONG CONTROL NUCLEI AND TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN MALE CANARIES G.F. Ball*, T.P. Hahn, E. Edmonds, and J. Balthazarı Department of Psychology, Behavioral Neuroendocrinology Group, Johns Hopkins University, Baltimore, MD 21218; Lab of Biochemistry, Univ. of Liège, Belgium Canaries (Serinus canaria) possess a neural circuit that mediates the learning and production of song. Several nuclei in this circuit such as the High Vocal Center (HVC)

Canaries (Serinus canaria) possess a neural circuit that mediates the learning and production of song. Several nuclei in this circuit such as the High Vocal Center (HVC) change seasonally in that the apparent volume of the nucleus is larger in the spring when plasma levels of testosterone are high than in the fall when they are low. The seasonal change in volume is not apparent if one defines the boundaries of HVC based on cells containing estrogen receptors or based on cells that project to the song nucleus, robustus archistriatalis (RA). In this study we investigated the effects of castration on the volume of HVC, RA and another song control region, area X. Nuclear boundaries were defined based on Nissl staining characteristics or based on dense immunoreactivity for the enzyme tyrosine hydroxylase (TH-ir). Photosensitive male canaries (N=12) were held on short days (7L:17D) and 7 males were castrated and 5 were sham castrated. The males were then transferred to long days (16L:8D) and affer 6 weeks they were perfused and their brains collected. Sections were collected throughout the forebrain and alternative sections were either Nissl stained or stained for TH with an immunocytochemistry procedure. The volume of HVC, RA and area X as reconstructed based on the Nissl stained sections was smaller in the castrated males than in the intact males. This difference in HVC was also apparent when one defined the boundaries of HVC based on the dense plexus of TH-ir fibers. Castration also induced an apparent anatomical reorganization of the TH innervation of HVC. TH-ir fibers were more or less randomly distributed in the HVC of intact birds but they formed dense basket-like ring structures around a limited number of cells in the HVC of castrates. These data suggest that testosterone is required for the spring increase in song control to the VC and the defined by TH-ir changes seasonally in a T-dependent fashion. Supported by NIH grant MH

HIGH VOCAL CENTER AND ENCEPHALIZATION: SPECIALIZATION AND DEVELOPMENTAL CONSTRAINTS

DC. Airey, J.K. Niederer, A.L. Nelson, T.J. DeVoogd* & B.L. Finlay.
Department of Psychology. Cornell University, Ithaca. NY 14853.
In mammals, developmental timetables of neurogenesis predict brain structure size (Finlay and Darlington, 1995). For example, larger mammalian brains have a proportionally larger neocortex because the period of neurogenesis associated with neocortex is longer for larger-brained mammals. Adaptive specializaciated with neocoriex is longer for larger-brained mammals. Adaptive specialization of brain function must occur in the context of such developmental constraints. In birds, an analysis of published data suggests the avian neostriatum is also proportionally larger in larger-brained birds. Additionally, the neostriatum occupies a greater proportion of the telencephalon in Passeriformes than in either Columbiformes or Galliformes (Rehkaemper et al., 1988). In songbirds, the High Vocal Center (HVC) is a neostriatal nucleus involved in the produc-

the High Vocal Center (HVC) is a neostriatal nucleus involved in the production of learned vocalizations. The relative size of HVC predicts song complexity across more than fifty species (DeVoggd et al., 1993; Szekely et al., in press). A larger relative HVC tends to confer increased behavioral complexity. These findings suggest that differences in HVC size between species may relate to differences in the size of the inclusive neostriatum or overall telencephalon size. We examined the relation between size of HVC and telencephalon in 42 species of songbird from published data. We also measured the size of the neostriatum in 19 songbird species. We find a significant relation between size of HVC, neostriatum, and telencephalon. Interestingly, neostriatum or telencephalon each significantly predict song repertoire size in simple regressions. In a multiple regression predicting song repertoire size from HVC, neostriatum, and telencephalon size, the only significant factor is HVC size. neostriatum, and telencephalon size, the only significant factor is HVC size. We suggest that evolutionary forces operate at the level of both overall brain size (neostriatum, telencephalon) and at the level of dedicated neural circuits

NEURAL PATHWAYS THEORIZED TO MEDIATE AFFILIATIVE AND AGONISTIC VOCALIZATIONS IN BUDGERIGARS (MELOPSITTACUS UNDULATUS). K.K. Cookson*, S.E. Durand, and K.J. Heaton. Deptartment of Psychology, UMCP, College Park, MD, 20742-4411

Budgerigars offer a model for investigating the relationship of neural pathways mediating unlearned and socially learned vocalizations. Previous studies have shown that budgerigars incoporate socially learned contact calls into their reproductive warble, and that their reproductive vocalizations stimulate gonadal activity and reproductive behaviors. Preliminary pathway tracing studies reveal several connections between vocal learning pathways, the preoptic area (POA), and ventral hypothalamus (Hy): (1) the POA projects to the magnocellular nucleus of the dorsomedial thalamus (DMm), DMm projects to the central nucleus of the anterior archistriatum (AAc), the central nucleus of the lateral neostriatum (NLc), the POA, and the Hy, and (3) the ventral Hy projects to the lateral neostriatum (NLs, NLc), to the region of the oval nucleus of the anterior neostriatum (NAo), and to the medial archistriatum (Am). Budgerigars also produce unlearned agonistic calls, which in other birds are mediated by the medial and ventral archistriatum (AM, Av), the hypothalamus, and the intercollicular midbrain (ICo). Preliminary pathway tracing studies in budgerigars show that: (1) the Am and the Av project to the ICo, (2) regions of ICo receiving input from Am and Av project to the hindbrain and to the dorsomedial nucleus of the ICo (DM), which in turn projects to the hindbrain, and (3) the ventral Hy receives projections from the Am and the Av, and the ventral Hy projects to the Am. These pathways have few or no connections with telencephalic vocal learning The thalamic DMm may play an important role in coordinating vocal behavior, especially at the level of the archistriatum, since it is connected to pathways mediating both unlearned and socially learned vocalizations. TESTOSTERONE ACCUMULATION IN SPINAL MOTONEURONS OF A "WING-SNAPPING" BIRD. <u>B.A. Schlinger*</u> Dept.of Physiological Science and Lab. of Neuroendocrinology of the Brain Research Institute, UCLA, Los Angeles, CA 90095

The study of birdsong has contributed substantially to our understanding of the neural and hormonal substrates underlying brain development and adult brain function. However, many birds use a variety of mechanisms to communicate visually and acoustically and we know little about the neural and hormonal bases of these behaviors. The Golden-collared manakin (Manacus vitellinus) is a member of a family of sub-oscine birds that are common in neotropical forests. These birds are highly sexually dimorphic in plumage and in behavior. Breeding males engage in vigorous courtship displays that include much physical activity. Males also make sounds like very loud finger-snapping. Remarkably, these sounds are not vocal (syringeal) but are produced by the wings. Since wing-snapping is a sexually dimorphic reproductive behavior, I tested whether spinal motoneurons in these birds are sensitive to sex steroids. Breeding manakins (from Panama) were injected with 3H-testosterone (3H-T). After sacrifice 90 mins later, spinal cords were removed, frozen, shipped to the US, sectioned longitudinally and prepared for autoradiography. Silver grains were counted over cell nuclei and adjacent neuropil (background). Grain densities (3- to 13-times background) were found over medium to large neurons (somas 237-1140 sq. µm) found centrally and ventrally in the spinal brachial enlargement. These data suggest that these cells are sensitive to T. Thus, T may act directly on spinal motoneurons to control wing-snapping in male manakins. Supported by UCLA Academic Senate.

COMMON ORGANIZATIONAL FEATURES IN BUDGERIGAR AND OSCINE FOREBRAIN VOCAL CONTROL SYSTEMS. Sarah E. Durand*, James T. Heaton and Steven E. Brauth. Dept. of Psychology, Univ. of MD, College Park, MD 20742

Connections of vocal control nuclei in budgerigars were examined with pathway tracing techniques. Afferent and efferent pathways associated with the magnicellular nucleus of the dorsomedial thalamus (DMm), the oval nucleus of the ventral hyperstriatum (HVo), and a newly defined region, the medial division of the oval nucleus of the anterior neostriatum (NAom), reveal that important similarities exist between the budgerigar and oscine models.

A specific projection from central DMm innervates NAom. NAom is afferent to 1) the central nucleus of the archistriatum (AAc) which projects to brainstem vocal motor nuclei, and 2) the magnicellular nucleus of the lobus parolfactorius (LPOm). LPOm projects back to DMm. Pathways through DMm and NAom resemble the oscine "recursive loops" through Area X of LPO. Although HVo is clearly not homologous to the oscine "high vocal center" of the caudolateral neostriatum, it may share functional correlates with the latter given the connections of HVo with thalamic, neostriatal and paleostriatal nuclei: HVo is afferent to both the circuit through DMm and NAom, via projections onto LPOm, and to the principal descending motor pathway, via projections onto lateral neostriatum. In addition, HVo may be a source of auditory input to the forebrain vocal control system: biocytin injections into HVo fill neurons in the auditory neostriatum overlying nucleus basalis and scattered cells in hyperstriatum and neostriatum overlying Field L2. Furthermore, HVo lesions severely disrupt vocalization in both nestling and adult budgerigars. In sum, the psittacine "high vocal center" may reside in hyperstriatum. Support: DC00105-02 to SED. MH40698 to SEB.

552.10

SEX DIFFERENCES IN VOCAL BEHAVIOR IN BUDGERIGARS ARE ASSOCIATED WITH SEX DIFFERENCES IN THE VOLUME OF SEVERAL VOCAL CONTROL NUCLEI. A. A. Nespor*, R. J. Dooling, & G. F. Ball. Dept. of Psych., University of MD. College Park, MD 20742 & Dept. of Psych., Behavioral Neuroendocrinology Group, Johns Hopkins Univ., Baltimore, MD 21218.

Budgerigars produce a complex vocal repertoire that develops through learning and includes a long rambling song called warble. Warble is produced almost exclusively by males. In songbirds such differences in vocal behavior are associated with marked sex differences in the volume of several nuclei in the telencephalon that are part of the song control system. Sex differences in the brain that might be related to sex differences in vocal behavior have not been identified in any psittacine (parrot) species such as the budgerigar. We compared the volume of several vocal control nuclei in male (n=5) and female (n=5) budgerigars. We focused on vocal control areas in the budgerigars analogous to areas in the songbird brain known to exhibit marked sex differences in volume. This includes the oval nucleus of the anterior hyperstriatum ventale (HVo most similar ro MAN); the magnicellular nucleus of the parolfactory lobe (LPOm, most similar to area X); the central nucleus of the anterior archistriatum (AAc, most similar to RA) and the central nucleus of the lateral neostriatum (NLc, most similar to HVC). We delineated the boundaries and re-constructed the volume of these nuclei in adult budgerigars with the use of three different methods. Alternate sections throughout the forebrain were either Nissl stained or labeled via autoradiographic methods for muscarinic cholinergic receptors (as defined by N-methyl scopolamine binding) or alpha-two adrenergic receptors (as defined by para-amino clonidine binding). With the use of all three methods to delineate nuclear boundaries it was found that the volume of HVo was larger in males than in females but LPOm was not. No sex differences in receptor density were discerned. A significant difference was also found in the volume of AAc and NLc based on the Nissl defined boundaries. These data suggest that sex differences in song in budgerigars are associated with sex differences in the volume of telencephalic vocal control nuclei. MYOTOPIC REPRESENTATION OF SYRINGEAL MUSCLES IN THE HYPOGLOSSAL NUCLEUS OF THE COWBIRD. J. Ruan and R.A. Suthers*. Indiana University School of Medicine, Bloomington, IN 47405.

The vocal organ, or syrinx, of songbirds is controlled by six pairs of muscles which are innervated by motoneurons in the tracheosyringeal portion of the hypoglossal nucleus (nXIIts). We used retrograde tracing techniques to examine the myotopic organization of motoneurons in nXIIts of the brown-headed cowbird (Molothrus ater ater). Cholera toxin subunit B conjugated horseradish peroxidase was injected into individual muscles and the location of labeled cells in nXIIts was mapped. Data from 5 syringeal muscles (2 to 5 adult males for each muscle) indicate that a myotopic map exists in this motor nucleus, with the motoneurons for each muscle being distributed in different, though partially overlapping, regions along its rostrocaudal and mediolateral axes. Motoneurons of syringealis ventralis (vS) are mainly located in the rostral portion of the nucleus. Tracheobronchialis dorsalis (dTB) and syringealis dorsalis (dS) are both represented in the caudal portion of the nucleus, where dTB extends laterally and dS extends medially. Motoneurons to tracheolateralis are located along the lateral portion of the nucleus and neurons innervating the sternotrachealis occupy a small caudolateral region. The results suggest a functional organization in nXIIts. Ventral muscles such as vS, which are primarily involved with controlling the frequency or phonetic properties of song, are controlled by the rostral part of nXIIts, whereas the dorsal adductor muscles dS and dTB, which control the timing of ipsilateral phonation by regulating airflow through that side of the syrinx, share its caudal portion. CONTRIBUTIONS OF ENHANCED TYPE-B CELL EXCITABILITY AND SYNAPTIC STRENGTH TO INHIBITION OF TYPE-A CELLS IN HERMIS-SENDA: A PHYSIOLOGICAL ANALYSIS. J.W. Fost and G.A. Clark. Program in Neuroscience, Princeton University, Princeton, NJ 08544.

During conditioned suppression of phototaxis in Hermissenda, the inhibitory type-B photoreceptors exhibit both increased excitability and synaptic facilita-tion at efferent B-A synapses. Both of these changes have been proposed to contribute to the conditioning-dependent decrease in firing of type-A photoreceptors, and, hence, the reduction in phototaxis. To examine the relative contributions of each form of plasticity, we induced baseline firing ($ar{x}=3.49~\mathrm{Hz}$) in type-A cells with DC injections (to mimic light-induced activity), and then superimposed artificial inhibitory PSPs of various magnitudes and frequencies. To explore the isolated effect of synaptic facilitation, we increased PSP magnitude (from 1.0 mV to 2.0 mV, as measured in A-cell soma) while maintaining a constant PSP frequency. Conversely, to quantify excitability effects, we increased PSP frequency (from 12.6 Hz, corresponding to three B-cells at 4.2 Hz, to 17.3 Hz = 3 × 5.77 Hz) while maintaining constant PSP size. Results showed that both forms of plasticity, in isolation or in combination, decreased A-cell firing rates. A-cells in the default condition fired at 3.49 Hz, slowing significantly both in the large PSP condition (3.15 Hz, LSD planned comparison p<0.001), and in the high excitability condition (3.07 Hz, LSD p<0.0003). Effects of large PSP and enhanced excitability together slowed A-cells to 2.97 Hz (LSD p<0.00005). These results suggest that each of these forms of plasticity, though modest, can

contribute to reduced A-cell output in the real circuit.

COOLING INDUCED RETROGRADE AMNESIA IN C. ELEGANS. Glenn E. Morrison* and Derek van der Kooy. Neurobiology Research Group, Dept of Anatomy, University of Toronto, Toronto, ON, Canada, M5S 1A8. We have previously demonstrated the ability of C. elegans to learn using an associative conditioning assay that paired an ion CS with a food US (E. coli). In this study we have investigated phases of memory formation using brief (15 minute) cold shock presentations at various times before, during or after conditioning. Cold shock was found to block the formation of memory if given either during conditioning, immediately following conditioning (0-15 minutes) or 15 minutes following conditioning (15-30 minutes). Cold shock did not block memory formation if given one hour following conditioning. As well, if the worms were given sufficient time to recover from cold shock (one hour), then treatment before conditioning did not affect the formation of memory Thus, we have identified at least two phases of memory formation in C elegans for associative learning, one (short term memory) which is labile and affected by cold shock and a second (long term memory) which is stabile and not affected by cold shock. Interestingly, cold shock given 30 minutes or 15 minutes prior to conditioning did block the presence of memory measured immediately following conditioning. However, if tested three hours following conditioning, worms cold shocked 30 minutes prior to conditioning demonstrated learned preferences. Moreover, worms cold shocked at 15 minutes following conditioning still demonstrate memory deficits when tested three hours following conditioning. These results suggest that the deficits seen in worms cold shocked prior to conditioning are deficits in retrieval (i.e. the deficits are seen immediately following but not three hours after conditioning), whereas the worms cold shocked in the 30 minutes following conditioning suffer from deficits in memory consolidation. Supported by NSERC Canada.

DYNAMIC REGULATION OF THE SIPHON WITHDRAWAL REFLEX OF APLYSIA IN RESPONSE TO CHANGING ENVIRONMENTAL CONDITIONS J.W. Yuan, T.M. Fischer*, and T.J. Carew. Yale Univ., Dept. Psych., New Haven, CT 06520

Previous cellular studies examining activity-dependent inhibition in the siphon withdrawal reflex (SWR) of *Aplysia* predicted that inhibition in the SWR network should be activated by weak tactile input (Fischer and Carew, 1995). To directly test this prediction, we examined the effect of weak input (turbulence) on the duration and threshold of SWR. For each animal, the SWR was examined in both calm and turbulent conditions; turbulence was generated by bubbling air into the sea water. The duration of the SWR was significantly reduced in turbulent conditions (x %-45) in comparison to calm (baseline) conditions (N=10, p<0.05). This adaptation occurred within one min of turbulence onset and was stable over time. Recovery back to baseline levels occurred within one min of restoration to calm conditions. In examining modulation of this adaptive behavior, we found that tail shock (60-80mA AC, 1 sec) did not after the turbulence-induced reduction of SWR duration, but it did produce a significant *increase* in response duration in shocked animals 10 min after returning to calm conditions (N=10, p<0.05); there was no increase in controls (exposed to either turbulence alone or shock alone). Finally, cellular

controls (exposed to either turbulence alone or shock alone). Finally, cellular experiments revealed that turbulence also induced a significant reduction in reflex input to siphon motor neurons (\$ %=50; N=5; p<0.01). We also examined the threshold of the SWR by determining the minimum current (through an implanted wire in the siphon) required to elicit the SWR. SWR threshold significantly increased (\$ %=39) within 1 min of turbulence onset (N=10, p<0.05). Recovery occurred within 1 min after offset of turbulence. Tail shock had no significant effect on the turbulence-induced increase in threshold. Taken collectively, our results indicate that the SWR network promotes a rapid and dynamic adjustment in response to changing environmental conditions. Supported by NIH grant MH48672 to TJC.

A PARADOXICAL FORM OF ACTIVITY-DEPENDENT FACILITATION MAY UNDERLIE CONTEXT LEARNING IN HERMISSENDA

I.A. Muzzio*, A.C. Talk, & L.D. Matzel

Department of Psychology Rutgers University New Brunswick NJ 08903 Most modern learning theories suggest that contextual stimuli should acquire

associative strength in much the same manner as discrete conditioned stimuli (CSs). In the present experiments, *Hermissenda* were trained to discriminate between adjoining light and dark contexts. Thirty unsignalled rotations were presented during each of three 7 min sessions in one of the two contexts. Prior to training, the animals displayed a slight preference for the lit context. After exposure to unsignalled rotation, animal's preferences shifted strongly to the lit side if unsignalled rotations were presented in the dark, or to the dark side if unsignalled rotations were presented in the light. Prior research has indicated that the B photoreceptors of the Hermissenda eye undergo several forms of activity (i.e., Ca²¹)-dependent facilitation (e.g., an increase in neuronal input resistance and evoked spike frequency) following pairings of discrete light and presynaptic vestibular stimulation. Similar facilitation was observed during in vitro experiments following presentations of presynaptic stimulation during a persistent 7 min light. Moreover, ratiometric analyses using the fluorescent indicator fura-2AM determined that intracellular Ca²⁺ concentrations increased at least five-fold early during a 7 min light presentation and dissipated to only half that level by the end of the presentation. These results suggest that activity-dependent facilitation might underlie learning about diffuse contextual stimuli as well as discrete stimulus presentations. Paradoxically, such a mechanism cannot account for both context learning and temporal specificity in classical conditioning, which has also been observed behaviorally in Hermissenda. These results suggest that modifications of sensory receptors are insufficient to account for the full range of associative processes observed in this animal

SHORT-TERM NOCICEPTIVE SENSITIZATION OF A DEFENSIVE STRIKING RESPONSE IN MANDUCA SEXTA. E.T. Walters, P.A. Illich , J.C. Weeks P. Le and S. Bell. Dept. Integrative Biol., Univ. TX-Houston, TX 77030; Inst. Neurosci., Univ. Oregon, Eugene, OR 97403.

Sensitization of defensive responses following noxious mechanical

stimulation occurs in mammals, snails, and leeches (Walters, Int. Rev. Neurobiol. 36:325, 1994) but has not, to our knowledge, been reported in insects. We tested larvae with a soft von Frey hair applied sequentially to the side of each proleg (8 stimuli at 10-s intervals) every 5 or 15 min. This gentle test sequence rarely evoked overt responses. In contrast, hard poke of a proleg using a stiff hair, or sharp pinch of a proleg with forceps, usually evoked 1 or more rapid strikes of the head towards the site of noxious stimulation. A single stiff poke (n=7 animals) or pinch (n=10) to a proleg significantly enhanced the number of strikes evoked by the weak test sequence 5 min, but not $10\,\mathrm{or}$ more min, later. Four rapid pinches to a proleg had the same effect (n=5). Eight pinches to a proleg increased the period in which strikes were evoked by weak test stimuli to 30 min, and the effect was similar for intertest intervals of 5 (n=10) and 15 (n=9) min. No significant increase in strike responses was observed 1 or 24 hr after any of the pinch protocols. No difference was seen at any time between responses to test stimuli applied to the pinch site and to other sites, including contralateral sites. These results show that an insect can display robust sensitization of defensive responses for up to 30 min after noxious stimulation. Unlike some types of nociceptive sensitization, this example in Manduca appears to be neither persistent nor site specific. It may be a form of defensive arousal (Walters 1994) having parallels to appetitively induced "central excitatory states" reported in insects. SENSITIZATION OF THE OLFACTO-CARDIAC RESPONSE PROTOPHORMIA TERRAENOVAE. A. M. Angioy*, P. Muroni, N. Piroddi, C. Reali and I. Tomassini Barbarossa. Department of Experimental Biology, Section of General Physiology, University of Cagliari, Viale Poetto 1, 09126 Cagliari, Italy

Olfactory stimulation evokes the "vegetative" response of heart-beat reversal in blowflies. Persistent cardiac responses are induced by repetitive stimulation with behaviorally-repellent odor concentrations. On the other hand, acquisition and retention of response habituation occur, i.e., non-associative learning and memory formation develop, with behaviorally nonrepellent odor concentrations. Here we report results on sensitization of the cardiac response in adult Protophormia flies. Simultaneous recordings of heart activity and sensory input were performed on intact specimens. Behaviorallyrepellent odor concentrations delivered on fly antennae induce a ten-fold decrease of the olfacto-cardiac response threshold. The response to olfactory stimulation can be promptly restored in habituated flies by intensely stimulating mechano-taste receptors on the labellar area. A faster rehabituation results after the antagonistic process of sensitization develops Supported with funds from the Italian Ministry for Universities

ALTERATIONS IN SYNAPTIC ACTIVITY TO AND WITHIN A CPG MAY UNDERLIE THE OPERANT CONDITIONING OF AERIAL RESPIRATORY BEIJAVIOUR IN LYMMAEA. G. Spencer*, T. Inoue, R. Cotter, N. Syed and K. Lukowiak. Neuroscience and Respiratory Research Groups. University of Calgary, Calgary, Alberta, T2N 4N1 and Arabian Gulf University/CMMS, Manama, Rahrain.

Bahrain.

Lymnaea are bimodal breathers and aerial respiration occurs when the animal becomes hypoxic. Aerial respiratory behaviour is controlled by a central pattern generator (CPG). Three identified interneurons were found to be both necessary and sufficient to produce rhythmicity. Rhythmicity is the result of emergent properties of the network and is normally triggered by activity in RPeD1. This aerial respiratory behaviour can be operantly conditioned by the contingent presentation of a tactile stimulus to the respiratory orifice, the pneumostome, each time the snail attempts to breathe in the hypoxic pond water. A training period of 0.5 h per day, twice daily results in learning which persists for up to 4 weeks. Yoked Control animals do not exhibit significant changes in their aerial respiratory behaviour. Isolated nervous systems from both Operant Conditioned and Yoked Control snails were examined using a blind experimental procedure. We found that the level of spontaneous activity in RPeD1 was reduced in the ganglionic preparations from Operant Conditioned animals compared to controls. The inferred activity of another CPG neuron (IP3I) was also different in Operant as compared to control preparations. Further, the ability of RPeD1 (when depolarized to produce action potentials) to induce rhythmicity in the circuit was reduced in the Operant Group compared to the control group preparations. A higher-order interneuron (RPeD11) which mediates whole animal withdrawal behaviour is excited by tactile stimulation of the pneumostome area and directly inhibits the CPG. Associative learning may, therefore, be mediated by changes in both intrinsic membrane properties and changes in synaptic connectivity within the CPG network, which affect the emergent network properties. These change may be brought about by the activity of RPeD11 onto the CPG network. Supported by MRC (Canada).

MULTIPLE MECHANISMS CONTRIBUTE TO THE INFLUENCE OF INTERTRIAL INTERVALS ON LEARNING IN HERMISSENDA

R.R. Ramirez, I.A. Muzzio, A.C. Talk, & L.D. Matzel*
Department of Psychology, Rutgers University, New Brunswick, NJ 08903

It has been universally observed that longer intertrial intervals (ITIs) produce better learning than massed trials. In Hermissenda, pairings of light and rotation result in a conditioned foot contraction to light when pairings are spaced 60 or 120 sec apart, but not with shorter ITIs. In vitro conditioning procedures have determined that the longer ITIs produce an increase in declination and the time to show the product with a cumulative depolarization during successive pairings that has been suggested as a potential mechanism underlying learning. To further study the effects of the ITI on facilitation and its relation to cumulative depolarization, animals were trained using an *in vitro* conditioning procedure (light paired with hair cell stimulation) to evaluate changes in excitability (input resistance and evoked spike rate). Animals received pairings at either 30, 120, 240, or 480 sec ITIs. Increasing degrees of facilitation (resistance and evoked spikes) were observed with increasing ITIs. However, cumulative depolarization was greatest in cells trained with the 120 sec ITI whereas none was observed with either 240 or 480 sec ITIs. Since both light transduction and voltagedependent Ca2+ flux across the B cell membrane is impeded by steady-state depolarization, this likely contributes to the weaker facilitation at ITIs less than 120 sec. Since no cumulative depolarization was observed in either the 240 or 480 sec ITI conditions, the enhanced facilitation in the 480 sec condition must depend on a second mechanism, possibly the inactivation of protein phosphatases that are activated during each trial. This later possibility is presently under investigation.

CONDITIONED INHIBITION IN <u>Hermissenda</u>: LEARNING THAT LIGHT SIGNALS THE ABSENCE OF ROTATION. G. Britton and J. Farley, Program in Neural Science, Indiana University, Bloomington, IN 47405.

We previously reported (Britton et al., 1995, Soc. Neurosci. Abstr. 21:1266) that Hermissenda exposed to explicitly unpaired presentations of light and rotation show an increase in phototactic behavior, i.e., <u>H.c.</u> learn to approach a light that has, in the past, signaled the absence of rotation. Observations of behavior in a light gradient in an underwater open field indicated that 24 hr following training, animals that had received explicitly unpaired presentations of light and rotation moved closer to the center of the light gradient than they did before conditioning. In contrast, animals that had received random presentations of light and rotation, presentations of light alone, or no training at all failed to show these changes. Prior to conditioning, measurements of animals' trajectories of movement indicated that they were, on average, oriented neither towards nor away from the center of the light gradient, but rather perpendicular to it. Following training, animals that had received explicitly unpaired presentations of light and rotation moved in such a way that they were oriented towards the light. Control animals' movements were oriented either slightly away from the light (random control) or perpendicular to it (light-alone, untrained). Intracellular recordings from synaptically intact Type B photoreceptors obtained 24-48 hr following training revealed that explicitly unpaired training produced a significant decrease in the steady-state light response as well as a decrease in action potential frequency. The latter was observed most reliably during the first of three successive light steps. No training-associated changes were observed in resting membrane potential or dark input resistance. These results further clarify the behavioral characteristics of conditioned inhibition in H.c., and uggest that retention of conditioned inhibition is mediated via persistent reductions in B cell excitability. A WHOLE-BRAIN "IN-VITRO" PREPARATION FOR ELECTROPHYSIOLOGICAL RECORDING FROM ADULT DROSOPHILA MUSHROOM BODY NEURONS N.J.D.Wright* and Y.Zhong. Cold Spring Harbor Laboratory, 1 Bungtown Road, Cold Spring Harbor, New York 11724 The paired mushroom body structures (MBs) found in the insect brain are known to be important for olfactory learning and memory. The fruit fly has been extensively utilized as a model for the study of the molecular basis of learning and memory due to its amenability to genetic manipulation. Behavioral mutants may provide a unique tool to dissect the neural basis of learning and memory if the electrophysiology of the MBs can be examined. Previously we have utilized a genetic marker (lacZ) in order to study identified mushroom body neurons in culture but were unable to observe any synaptic events. We are therefore developing a whole-brain preparation using the specific expression of "green fluorescent protein" to identify and record intracellularly from these structures. Our initial results have confirmed the viability of the tissue and we have been able to record membrane potentials (-30 to -70mV), action potentials, complex bursting patterns and synaptic events from identified neurons. We are currently studying these MB neurons and their response to olfactory nerve stimulation and how this may be altered in learning and memory mutants.

THE EFFICACY OF EXPOSURE TO COLD AS THE UNCONDITIONAL STIMULUS IN DROSOPHILA MELANOGASTER. L. L. Phelan*, Z. A. Rodd, & R.A. Rosellini, Dept. of Psychology, University at Albany: SUNY, Albany, NY 12222.

Exposure to cold as an Unconditional Stimulus (US) was investigated in D. melanogaster using a Pavlovian odor conditioning paradigm. The initial study employed a delayed conditioning procedure which consisted of a 60 s exposure to an odor as a Conditional Stimulus (CS) in conjunction with the putative US consisting of a 15 s exposure to an environment maintained at 0° C. The CS-US delayed conditioning groups showed greater avoidance of the odor CS than either CS-Only, US-Only, and Unpaired CS / US groups. A second study examined the impact of the duration of exposure to the US (either 0, 5, 10, 15, 20, or 30 sec) on conditioning to the odor CS. The results demonstrated that conditioning increased as a function of increasing US duration in the 0-20 sec range. At the longest duration employed (30 sec), no evidence of conditioning to the CS was observed. An additional study examined the temporal relationship between presentation of the CS and the US. The results demonstrated conditioning to the odor CS at forward trace intervals of 5 and 30 sec but not 60 sec. Additionally, there was evidence for backward excitatory conditioning to the odor CS at a backward trace interval of 5 sec. To our knowledge, the present studies are the first to demonstrate the efficacy of exposure to cold as a US in Pavlovian aversive conditioning in D. melanogaster. (This research was supported by personal funds).

TURNING BEHAVIOR IN THE PREDATORY SEA SLUG PLEUROBRANCHAEA: FUNCTIONAL ANATOMY AND NEURAL MECHANISMS. J. Jing and R. Gillette. Department of Molecular and Integrative Physiology, University of Illinois, Urbana, IL 61801.

Orienting and avoidance turns are major components of *Pleurobranchaea*'s stimulus-directed behaviors, typically the former is accompanied by locomotion (ciliary movement). Turn decisions are made by integrating sensation with motivational state and learning experience. Avoidance turns can be reliably elicited by asymmetric electrical shocks to tentacles and oral veil; such turns are relatively stereotypic actions that are completed within 35 s post-stimulus. The main muscles involved in turning appear to be a prominent muscle band, the lateral body wall muscle (LBWM), which originates from lateral columellar muscle and more distributed large muscle fascicles of longitudinal muscle of the foot (LMF). Anterior portions of LBWM terminate in diverse head organs, like the oral veil, tentacles, and rhinophore as well as the mouth, oral tube and buccal mass, indicative of roles in head movement and feeding. Major nerve innervation of LBWM comes from the posterior lateral body wall nerve (pLBWN) of the pedal ganglion, and the LMF is innervated by the pedal nerves (PNs). Unilateral lesion of both of these nerve sets eliminated ipsilateral turning, while turning was not eliminated by lesion of either LBWM or LMF nerves alone; this suggests that both muscles contribute to turning. Unilateral lesion of PNs did eliminate ciliary movement on the lesioned side of the foot. Differential activity with similar timing as turning behavior in bilateral nerves, in particular the pLBWNs, can be recorded in the hemi-animal preparation, when aversive shocks that can elicit turning in the intact animal are delivered to the tentacle and oral veil on one side. Similar motor patterns in the pLBWNs can be induced by depolarizing the swimming interneurons A3bc, suggesting their possible role in turning. These observations provide a basis for further investigation of the premotor decision mechanisms for orienting or avoidance turns. Supported by NIH ROI NS26838.

LONG-TERM DEPRESSION OF THE CRAYFISH LATERAL GIANT RESPONSE BY A LONG TRAIN OF LOW FREQUENCY STIMULATION OF PRIMARY AFFERENTS. Sunhee C. Lee* Dept of Physiol, College of Dept of Physiol, College of Medicine; Div of Neurosci, Med Res Ctr, Ewha Womans University, Seoul, Korea

A descending tonic inhibition (TI), observed during restraint or feeding in crayfish, is known to depress selectively the lateral giant (LG), a command neuron for one form of escape reactions, without affecting the sensory processing (Krasne & Wine, 1975). It is also known that TI originates in the rostral parts of the CNS. The present study was aimed at finding a physiological mechanism that is responsible for a long-term depression (LTD) of the LG response. Crayfish preparations whose descending influence was removed by severing the nerve cord between thorax and abdomen were used. The results showed that a long train of low-frequency stimulation (LFS) of the primary afferents (PAs) cause LTD of the LG response without affecting the sensory processing. A 5 min long train of 0.2 ms pulses at 1-5 Hz caused a significant increase in LG firing threshold by a test pulse to sensory roots at once per min (111 \pm 18 %, mean \pm SEM; n =15. P < 0.01) and 30 min after LSF, it was still increased by $66 \pm 11 \%$ (P < 0.01). The same LFS however, did not change the threshold for firing of interneuron-A (IN-A), one of the largest sensory interneuron. A strong LFS (2-4 times LG threshold) was more effective at depressing the LG response than those of a weak LFS. preliminary result showed that the LG response to PAs from an unstimulated segment is also depressed if that to PAs in another segment has been depressed by The present results suggest that the increased firing threshold for LG, but not for IN-A, caused by the LSF may be due to the activation of tonic inhibition Experiments using picrotoxin are currently underway to assess the possibility that repetitive LFS of PAs may activate a GABAergic inhibitor (Vu & Krasne, 1993), which may also originate in the abdomen. LONG-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS: EFFECTS OF SPACED VS MASSED TRAINING AND INHIBITION OF SYNAPTIC TRANSMISSION J. Mauelshagen, C.M. Sherff*, & T.J. Carew. Yale Univ., Dept. Psych., New Haven, CT 06520

At *Aplysia* tail sensory neuron (SN) to motor neuron (MN) synapses, 5 spaced applications of serotonin (5HT) induce short-term and long-term synaptic facilitation (STF and LTF). We recently identified a rapid time course of decay of STF (15 - 30 min) after 1 to 4 spaced pulses of 5HT, while 5 pulses resulted in a unique prolonged intermediate phase of facilitation (ITF, 60 to 90 min; Mauelshagen et al, *Neurosci. Abs.* 1995). In the present study, we further investigated the requirements for ITF and LTF induction.

In one experiment, we examined the effect of spaced (5 x 5 min. 15 min.

further investigated the requirements for ITF and LTF induction. In one experiment, we examined the effect of spaced (5 x 5 min, 15 min interval) or massed (1 x 25 min) 5HT applications on both ITF and LTF. We monitored the monosynaptic EPSP from SN to MN before 5HT (baseline), at 5 min after the start of 5HT (STF), across 1 hr immediately after 5HT (ITF), and at 20 - 24 hrs after 5HT (LTF). With both massed (M) and spaced (SP) 5HT applications we observed significant STF (M and SP: n=14, pc.001) and significant ITF at 0, 15, 30 and 45 min after 5HT (M and SP: pc.05 in all cases). In a subset of preparations (M: n=5; SP: n=4) in which we could test for LTF, both massed and spaced paradigms were able to induce LTF.

In a second experiment, we asked whether synaptic transmission is necessary for the induction of STF and LTF. First we established that artificial seawater (ASW) with 3x normal Mg²⁺ and no Ca²⁺ (MASW) blocked both

seawater (ASW) with 3x normal Mg²⁺ and no Ca²⁺ (MgASW) blocked both spontaneous and evoked EPSPs in tail MNs. Next, 5HT was presented in 5 spontaneous and evoked EPSFs in tail MNS, Next, SHI was presented in 5 SP applications in MQASW. To assess STF, we briefly perfused the ganglia with ASW after the first 5HT pulse. We observed both significant STF (n = 14, p<.03), and 24 hrs later, significant LTF (n=6, p<.02). These data show that the induction of STF and LTF does not require synaptic transmission either directly from SNs to MNs or indirectly through heterosynaptic pathways. Support by a DFG grant to J.M. and NIH grant R01-MH-14-1083 to TJC.

ODOR AVOIDANCE CONDITIONING IN D. MELANOGASTER: THE EFFECTS OF CONDITIONING PARAMETERS ON AVOIDANCE LEARNING. R.A. Rosellini*, Z. A. Rodd, D. Byers, & L. Phelan, Dept. of Psychology, University at Albany: SUNY, Albany, NY 12222.

The present series of studies investigated associative odor avoidance conditioning in Drosophila melanogaster. The first set of studies investigated whether variables which are known to influence associative learning in mammals would have the expected effect in the Benzer group odor avoidance learning paradigm in D melanogaster. The variables investigated were: 1. Number of Trials of Conditioning, 2. Inter-Trial-Interval (ITI), and 3. Intensity of the Unconditional Stimulus (US). The results of these studies demonstrated that the strength of an odor avoidance conditioned with electric shock as the reinforcer was a function of the: 1. number of acquisition trials (1, 3, or 6) administered with increasing number of trials producing greater learning, 2. length of the ITI (0, 15, 30, or 90 s), with increasing intervals resulting in greater learning, and 3. intensity of the US (0, 10, 20, 40, or 80 v) with increasing intensities from 10 to 40 volts resulting in progressively increasing avoidance and a decrement in the learning at the 80 volt intensity. A second set of studies investigated the impact of the three conditioning variables in individual D. melanogaster. The individual learning results were consistent with the effects of each of the variables investigated in the group conditioning paradigm. The overall findings of these two sets of studies, whether employing the group or individual learning conditioning paradigm, were consistent with the extant literature on the impact of these variables in mammalian associative learning in general and avoidance learning in particular. (This research was supported by personal funds).

SPACED RATHER THAN MASSED CONDITIONING LEADS TO PROTEIN SYNTHESIS DEPENDEND LONG-TERM MEMORY IN HONEYBEES R Menzel*, Freie Universität Berlin, Institut für Neurobiologie, Königin-Luise-Str. 28/30, D - 14195 Berlin, Germany

Previous studies lead to the astonishing result that > 95% protein synthesis inhibition in the bee brain by the translation blocker cyclo-(Wittstock et al. 1993, J. Neuroscience 13, 1379-86). We now find that different forms of LTM are formed after massed and spaced conditioning.

Bees were conditioned with 5 to 8 trials using various olfactory, mechanosensory or infrared (temperature increase) stimuli as conditioned stimuli, and sucrose as unconditioned stimulus. The conditioned response was proboscis extension (PER). Intervals between conditioning trials varied between 30 sec (extremely massed) and 30 min (extremely spaced). Memory tests were performed at intervals of 1 to 7 days. Spacing of conditioning trials leads to higher and longer lasting memory scores. Furthermore, memory at 3 or more days is more resistant to extinction after spaced conditioning than after massed conditioning. Transcription was blocked to > 50% in the bee brain by injection of 2 or 4 µg actinomycin D per animal into the flight muscle. LTM tested after > 2 days is significantly impaired after spaced conditioning, but unimpaired after massed conditioning. Blockade of translation with cycloheximid leads to similar effects if training is weak, but no effects were found after strong conditioning. (Supported by DFG grant Me 365/16-1)

PATTERNED JAW MOVEMENTS DURING REJECTION OF SEAWEEDS IN APLYSIA KURODAI. T. Nagahama* and N. Shin. Dept. of Biol., Fac. of Sci., Kobe Univ., Kobe 657, Japan

Japanese species, Aplysia kurodai usually feeds Ulva and Undalia well. In the present experiments we collected several species of seaweeds at the location alive with animals, and explored whether animals were attracted to the test seaweeds against *Úlva* by two choice experiments and whether animals ingest them. Animals were attracted to *Pachydictyon (Pac.)* as well as Ulva, but they strongly rejected it when it was pushed into their mouth. On the other hand, Dictyoteris (Dic.) was more repellent than Ulva, but animals often ingested it which was pushed into their mouth. These results suggest that Pac. and Dic. may induce the different preferential behavior of animals in the sense of smell and the sense of taste and/or touch. Gelidium (Gel.) was more repellent than Ulva, and also induced the rejective response when it was pushed into the mouth.

Recording activity of jaw-closing (mm) and -opening (ma) muscles in free-moving animals showed that the onset of the mm activity, which always started later than the ma activity during each cycle of ingestion of raw *Ulva*, was advanced toward that of the ma activity during each cycle of rejection of raw *Pac.* or *Gel.*. Semi-intact experiments also showed that application of the extract of *Ulva*, *Pac.* and *Gel.* to the lips produced application of the extract of *Olva, Fac.* and *Olva, Pac.* to the high produced similar patterns in firing of the jaw-closing motor neurons to the mm activity. Video analysis showed that application of *Ulva* extract to the lips produced maximum jaw-opening in the radula protraction phase and still produced half-opening state in the earlier time of radula-retraction phase while application of Pac. or Gel. extract did not produce half-opening state and the jaws smoothly closed in the radula-retraction phase. These results are consistent and suggest that the rejection of *Pac.* or *Gel.* may be induced as a result of chemoreception.

FMRF-AMIDERGIC NATURE OF PLEURO-BUCCAL PROJECTING NEURONS COMMON TO DIVERSE PULMONATE MOLLUSCS. M. Alania and D.A. Sakharov*. Inst. Devel. Biol., 117808 Moscow, Russia

In gastropod molluscs, activity of the buccal central pattern generator (CPG) for feeding is generally arrested during activation of the CPG for defensive withdrawal. We used a nickel lysine axon filling technique for examining a variety of species with the aim to determine if they are provided with projecting neurons comparable with those found earlier in Helisoma. In this latter pulmonate snail, two bilaterally symmetric cells in the pleural ganglia were suggested to be responsible for this motor coordination since they project to the buccal ganglia and suppress activity of the CPG for feeding (Murphy, 1990, Brain Res. 525, 300). We studied both basommatophoran, fresh-water pulmonates (Lymnaea stagnalis, L. auricularia, Planorbarius corneus) and stylommatophoran, terrestrial ones (Bradibaena fruticum, Helix pomatia, H. lucorum, Limax cinerea-niger). In all these molluscs, like in Helisoma, a neuron projecting to the ipsilateral cerebro-buccal connective, the PIB (pleuralbuccal) cell, was found to occur in the right and left pleural ganglia. Identity of PIB cells of diverse species was established due to a unique route of the axon which traverses the ipsilateral pedal ganglion on its way to the cerebral one. Since FMRF-amide is known to inhibit the gastropod CPG for feeding, we combined a biocytin axon filling technique with FMRF-amide immunostaining in the same CNS preparation. In two species examined with this dual-labelling technique, L. stagnalis and P. corneus, the experiment has proved unambiguously that the PIB cells are immunoreactive to FMRF-amide. The results thus suggest conservation of the cellular basis, and involvement of FMRF-amide in the mechanism, of the motor coordination in question. Grants INTAS-93-3504 and RFFI-96-04-49181.

THE CONTRIBUTION OF ENVIRONMENTAL FACTORS IN THE DEVELOPMENT OF THE RESPIRATORY NETWORK IN LYMNAEA STAGNALIS. P.M. Herman*, A.G.M. Bulloch and K. Lukowiak. Neuroscience Research Group, HSC, University of Calgary, Calgary, AB, T2N 4N1, Canada.

Respiration in Lymnaea is bi-modal: 1) across the skin and 2) via the lung by opening and closing of the lung orifice (i.e. the pneumostome). This study investigated the relative contribution of genetic and environmental factors in the development of aerial respiratory behavior and its underlying neural network. To this end, animals were raised from eggs without ever being able to experience lung breathing. Behavioral experiments showed that these animals were competent to open and close their pneumostome. The average duration of each opening was not different but, both in normoxic as well as in hypoxic conditions, the total breathing time and the number of pneumostome openings was significantly decreased when compared with control animals. Intracellular recordings in the isolated CNS and Lucifer Yellow stains of respiratory network neurons showed that the electrophysiological properties and projections of these cells are indistinguishable from control animals. We conclude that aerial respiration is not necessary for the normal development of the respiratory circuitry. However, while aerial respiration per se occurs in animals prevented from performing this behavior during the course of the normal development, such rearing has significant effects on major components of aerial respiratory behavior. COMPUTATIONAL PRINCIPLES OF A TINY NERVOUS SYSTEM. S.R. Lockery and M.B. Goodman.* Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

The anatomical connectivity of the nervous system of the nematode

The anatomical connectivity of the nervous system of the nematode *C. elegans* has been described almost completely. Little is known, however, about the biophysical properties of individual neurons, which may have complex input-output functions to compensate for their small number (302). We tested this idea using whole-cell current clamp recordings from neurons (n = 24) whose processes project into the nerve ring, the major site of synaptic integration in *C. elegans*. In some cases, cells were identified using green fluorescent protein expressed under the control of a neuron-specific promoter. In all cells examined, the response to a negative current pulse was a simple exponential hyperpolarization. The response to a positive current pulse had two components: a fast rising phase that accounted for most of the total depolarization followed by a slow rising phase that began once the membrane potential reached about 0 mV. The rate of depolarization in the slow phase may have been reduced by a voltage- and time-dependent outward current seen in voltage clamp. This current activated between -10 and +40 mV and decayed with a time course that matched the slow rising phase observed in current clamp. Action potentials could not be elicited. Thus, the electrical behavior of *C. elegans* neurons is remarkably simple and homogenous. These findings suggest that the rich behavioral repertoire of *C. elegans* reflects complexity of the connections between neurons rather than complexity of the individual neurons temps.

complexity of the individual neurons themselves.

BEHAVIORAL RESPONSES OF CRAYFISH ANTENNULES TO ODORANT AND HYDRODYNAMIC STIMULI. <u>DeF. Mellon*</u>, Dept. Of Biology, Univ. Of Virginia, Charlottesville, VA 22903.

All decapod crustaceans flick their antennules in the presence of sensory stimulation. Antennular flicking is thought to enhance the detection of odorant stimuli; for example, it is known to facilitate the onset of highfrequency impulse trains to odorants in the olfactory receptor neurons of the spiny lobster (Schmitt BC & Ache BW, 1979, Science 205:204-206). In several species, flicking behavior is accelerated in the presence of odorant stimuli and also by water currents. I have studied antennular flicking in the crayfish Procambarus clarkii to compare the relative influence of odorant and hydrodynamic stimulation upon both the intensity and the frequency of this behavior. I recorded from single fibers in the phasic portion of the antennular depressor muscle during stimulus presentations to the external filament. Responses to odorant stimuli had long latencies and were characterised by prolonged trains of highfrequency flicks and tonic activity in the slow portion of the depressor muscle. Responses to water pulses had very low stimulus thresholds, short latencies and consisted of single flicks. Responses to brief, single pulses of water persisted even during prolonged washing of the antennules with constant-velocity water currents. This suggests that hydrodynamic receptors on the antennules can detect turbulent eddy features of the imposed currents that may also contain steep concentration gradients of chemical stimuli. Supported by grant IBN-9319406 from NSF.

NEURAL CONTROL OF THE MALE COPULATORY ORGAN IN THE SNAIL LYMNAEA STAGNALIS. P.A.C.M. De Boer, A.W. Pieneman, R.F. Jansen and A. Ter Maat.* Graduate School Neurosciences Amsterdam, Research Institute Neurosciences, Vrije Universiteit, Faculty of Biology, De Boelelaan 1087, 1081 HV Amsterdam, The Netherlands.

Male copulatory behavior of the hermaphroditic snail *Lymnaea stagnalis* is complex. The behavior consists of an appetitive phase that is highly variable in temporal structure, followed by a fixed consummatory phase. The appetitive phase is composed of five elements including locomotion (Mounting and Circling) and movement of the male copulatory organ (Eversion, Probing and Withdrawal). We are studying the neural control of the male copulatory organ.

Almost 400 neurons, concentrated in five different groups in the CNS, have projections to the male copulatory organ. One of these groups is found in the anterior lobe of the right cerebral ganglion. In these cells a number of colocalized peptides has been found, most notably conopressin and APGWamide. We have started to examine the effect of these peptides on the eversion of the male copulatory organ. Injection of conopressin into the body cavity induces a partial eversion whereas injection of APGWamide induces a total eversion. The neurons of the anterior lobe project to the male copulatory organ via the penis nerve. Animals with a lesion of this nerve were also injected with conopressin and APGWamide. It was found that in these animals a total eversion lasts indefinitely. This suggests that an intact penis nerve is necessary for withdrawal of the organ. We are currently investigating the motor control of the male copulatory organ in Lymnaea.

NEURAL NETWORK MODELS OF CHEMOTAXIS IN C. ELEGANS. T. C. Ferrée, B. A. Marcotte, J. T. Pierce, S. R. Lockery.* Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

Nematodes move up chemical gradients by detecting changes in concentration at the tip of the nose and biasing their normal sinusoidal locomotion toward higher concentrations (klinotaxis). Laser ablations of identified neurons in *C. elegans* have shown the neural circuit for chemotaxis is a highly interconnected network of chemosensory neurons, interneurons, and motor neurons with feedforward and feedback connections (C. Bargmann, unpublished). Moreover, physiological recordings from neurons in *C. elegans* suggest that they are functionally isopotential and that signal propagation is largely graded. To understand how such a nervous system might control chemotaxis we constructed a reduced model and used a neural network optimization algorithm (simulated annealing) to find sets of connections that produce chemotaxis. Many such sets were found. These results suggest that the biological network may be one of many different possible solutions for chemotaxis in graded neural networks.

possible solutions for chemotaxis in graded neural networks. Supported by NIMH MH11373, NIMH MH51383, NSF IBN 9458102, ONR N00014-94-1-0642, the Sloan Foundation, and The Searle Scholars Program.

A mechanism to regulate sexual proclivity in the snail

J.M. Koene and R. Chase*, Dept. of Biology, McGill Univ., Montreal, Canada. Sexual proclivity, i.e. the probability that mating will occur, varies with the duration of sexual isolation in the garden snail Helix aspersa (Adamo & Chase, 1990). We hypothesized that proclivity is related to the amount of sperm available for mating. The sperm are stored in the hermaphroditic duct (HD) prior to copulation. We estimated the amount of stored sperm by measuring the dry weight of the HD. Snails which were sexually active. but non-copulating, had significantly heavier HDs than either non-active snails or snails that had just copulated. Thus, the change in the amount of the stored sperm corresponds to the variation in sexual proclivity. Previous work in the pond snail, Lymnaea stagnalis, has shown that a neural signal provides information about the amount of the sperm available (De Boer, Koene, Jansen and Ter Maat, in prep.). In Helix aspersa a branch of the nervus intestinalis (ni) innervates the HD. The activity of the ni-branch was recorded with a suction electrode in a semi-intact preparation while the normal increase in volume of the HD was mimicked by injections of saline The recordings showed that inflation of the HD increased spiking activity in the ni-branch. This indicates that in Helix aspersa a nervous connection exists between the HD and the CNS that is capable of providing information about the amount of sperm available for copulation. We conclude that a general mechanism operates in snails, and possibly in other animal groups, that informs the animal when sufficient sperm are available for the successful fertilization of eggs. HOW DOES THE PARASITIC WASP COTESIA CONGREGATA SUPPRESS FEEDING IN ITS HOST THE TOBACCO HORNWORM, MANDUCA SEXTA? Shelley A. Adamo1*. Charles E. Linn2, and Nancy E. Beckage³. Dept. Psychol., Dalhousie Univ., Halifax, NS, CANADA ². Dept Entomol., N Y State Agri. Sta., Geneva, NY 3 Dept of Entomol., Boyce Hall, Univ. of Calif., Riverside, CA.

The parasitic wasp, Cotesia congregata, lays its eggs within the body of its host, the larval form of Manduca sexta. Host behaviour appears normal until about 8 h prior to the parasitoids' emergence from its host. Once the wasp larvae emerge, M. sexta feeding and locomotion declines dramatically. This change in host behaviour may be to the advantage of the wasp. Unparasitized M. sexta eat wasp pupae. Despite the decline in feeding and locomotion, hosts with emerged parasitoids have normal reflexes and show no other signs of debilitation Concomitant with the change in host behaviour, octopamine concentration increases from 22.2 \pm 2.1 pg/ μ L to 143.7 \pm 7.8 pg/ μ L (measured using HPLC-ED) in the hemolymph of the host. In unparasitized M. sexta increased octopamine levels correlate with increased activity. The co-occurrence of high hemolymph octopamine levels and low behavioural arousal in parasitized M. sexta is opposite to that observed in unparasitized M. sexta and other insects.

Wasp larvae moult to the 3rd instar when cultured in vitro. Injections of media from wells containing newly moulted wasp larvae into unparasitized M. sexta induces a temporary depression of feeding in the hornworm. Media from cultured 2nd instar wasp larvae has no effect on feeding when injected into unparasitized *M. sexta*. This suggests that factor(s) secreted by the parasitoid may be involved in the suppression of host feeding. The wasps do not appear to secrete octopamine Supported by an NSERC grant to S.A.A. and a USDA grant (92-37302-7470) and NSF grant (IBN-9420638) to N.E.B.

OCTOPAMINE MIMICS EFFECTS OF PARASITISM ON THE FRONTAL GANGLION AND FOREGUT OF THE MOTH MANDUCA SEXTA C. I. Miles* S. A. Adamo', R. Booker, and N.E. Beckage. Neuro. and Behav., Cornell University, Ithaca, NY 14853 "Dept. Psychol, Dalhousie Univ., Halifax, NS, CANADA, and 'Dept. of Entomology, Univ. of Calif., Riverside, CA Larvae of the moth Manduca, that are parasitized by the wasp Cotesia congregata exhibit a dramatic decline in feeding about 8 hours before the parasite larvae emerge from their host. We examined the function of the foregut and the ganglion which innervates it, the frontal ganglion (FG), in both unparasitized and parasitized Manduca larvae. Neurons in the FG of unparasitized larvae are always active, firing in a rhythmic bursting pattern. The foreguts of normal animals typically exhibit posteriorly directed peristalsis; consistent with the FG and foregut playing a role in swallowing. Parasitized Manduca examined before they stop feeding show normal activity in the FG and normal peristalsis of the foregut. However, concomitant with the cessation of feeding in parasitized Manduca, the foregut stops moving and the FG neurons fire in an arrhythmic pattern. These animals may make chewing movements but they do not appear to swallow food. Similar effects on FG and foregut activities are observed if the blood from non-feeding parasitized Manduca is applied to the FG and foregut of an unparasitized control animal, indicating that a factor in the parasitized animals' blood produces these effects. Octopamine levels in the blood of non-feeding parasitized control animals or parasitized control animals or parasitized animals or bareasitized animals or bareasity animals that are still feeding (S. A. Adamo et al., submitted). Applying this concentration of octopamine levels in the blood from non-feeding parasitized animals or bareasity animals or parasity animals or parasity animals that are still feeding (S. A. Adamo et al., submitted). Applying this concentration of octopamine in the host's blood. This inc

THE EFFECT OF OCTOPAMINE ON DIETARY SELF-SELECTION BY THE COCKROACH, RHYPAROBIA MADERA. H. Rosen, T.L. Uhlendorf, A.M. Zein, H.D. Can and R.W. Cohen*. Department of Biology, California State University, Northridge, CA 91330.

Insects have the ability to self-select an optimal diet from a choice of two or more incomplete diets that lack an essential nutrient. Previous work has shown that 5-hydroxytryptamine (serotonin) regulates carbohydrate feeding in insects. Our study details the pharmacological effects of the neurotransmitter octopamine on feeding behavior of the Madeira cockroach, Rhyparobia madera. Experimental nymphs were offered a choice of lyophilized casein (protein) or sucrose cubes (each cube contained 0.3% of either an octopamine agonist synephrine or antagonist phentolamine), and were compared to controls consisting of untreated cubes Although not statistically significant (p>0.05), the nymphs ate slightly more of the synephrine-treated cubes compared to controls. However, the nymphs fed phentolamine-treated diets ate 80% less (p<0.001; ANOVA) of both diets than the controls. These results suggest that octopamine, unlike serotonin, does not affect nutrient self-selection. When $R.\ madera$ nymphs were given a complete diet of 20% casein/80% sucrose cubes which had drugs (synephrine or phentolamine) incorporated, similar results were seen: Nymphs fed phentolamine-diets ate 90% less than controls (p<0.001; In order to separate the effects of taste from any neurophysiological changes caused by phentolamine or synephrine, *R. madera* nymphs were injected with a drug or saline (control) and then allowed to feed on 20:80 diets for 24 hours. The nymphs injected with synephrine ate the same as controls, while phentolamine-injected nymphs ate 75% less than controls. Taken together, these results suggest a major regulatory role for octopamine in the onset of feeding in insects.

INGESTIVE BEHAVIOR: FOREBRAIN MECHANISMS

EFFECTS OF SODIUM DEPLETION ON THE ACTIVITY AND SENSITIVITY OF NEURONS LOCALIZED IN THE SEPTO-PREOPTIC REGION. F. Liénard , O. Galaverna, S.N. Thornton, and S. Nicolaïdis. I.E.S.G.I., CNRS UPR 9054, Groupe Neurobiologie des Régulations, Collège de France, 75231 Paris, cedex 05, France.

Sodium (Na*) depletion is known to activate the renin-angiotensin II (AII)-

aldosterone system (RAAS). Aldosterone production is increased as well as the renin activity and hence circulating AII levels are enhanced. Furthermore, Na* depletion induces a robust intake of hypertonic salt solutions.

This electrophysiological study examined, in the SFO and in the MnPO, the effect of Na* depletion on the neuronal responsiveness to iontophoretic application of AlI, losartan (AT-1 receptor specific antagonist), PD123319 (AT-2 receptor specific antagonist), and aldosterone. Rats were depleted with the natriuretic, furosemide (0.5 mg/0.5 ml sc, 2 injections separated by 2 hours group LASIX) and had no access to any source of salt. Electrophysiological experiments were performed under urethane anaesthesia on the fifth day following the depletion. The control group was not depleted and was fed with a normal Na+ diet.

No changes were found in the number of spontaneously active neurons (control: 11.1 ± 1.6 vs LASIX 9.4 ± 1.4, mean ± SEM). Preliminary results in LASIX treated rats revealed an increase in short term inhibitory responses to iontophoretic application of AII (100% of responding cells) that were not reversed by AT-1 or AT-2 receptor specific antagonists (losartan or PD123319 respectively). Whereas in control rats, AII produced both an excitation (75% of responding cells) which could be inhibited by losartan or PD123319, and an inhibition (25% of responding cells).

These results suggest that depletion–induced avidity for salt could be encoded by

an inhibitory action of AII on neuronal activity. This is in contrast to mineralocorticoid induced salt appetite which is accompanied by increased neuronal responsiveness to locally applied AII and decreased long term AII-induced inhibition. Thus, the central mechanism of salt appetite appears to depend on a complex pattern of induction.

SPECIFIC CONTROL OF FEEDING BY EXCITATORY AND INHIBITORY AMINO ACIDS IN THE SHELL SUBREGION OF THE NUCLEUS ACCUMBENS. T.R. Stratford*, C.J. Swanson and A.E. Kelley. Department of Psychiatry, University of Wisconsin Medical School, Madison, WI 53706

Previous work in this laboratory has demonstrated that blockade of AMPA/kainate receptors in the shell subregion of the nucleus accumbens (AcbSh) with DNQX (250-750 ng) induces pronounced feeding in satiated rats (Maldonado-Irizarry, et al., J. Neurosci., 1995). Expanding on this finding, we have recently discovered that while this treatment increases intake of both solid and liquid foods, it does not alter water intake or time spent gnawing wooden blocks. This strongly suggests that the system is involved specifically in the control of food intake. We also have found that activation of these receptors via bilateral microinjections of AMPA (50 ng) into this region significantly suppresses food intake in food-deprived rats. Blockade of AMPA/kainate receptors most likely increases food intake by disrupting a tonic excitatory input to the AcbSh, thus decreasing the firing rate of a population of local neurons. Since the application of GABA agonists into the AcbSh also decrease neuronal activity, we investigated the effect of microinjections of the GABAA agonist muscimol (1-100 ng) and the GABA_B agonist baclofen (17-187 ng) on food intake in non-deprived rats. Both treatments dose-dependently increased food intake without altering water intake. At the highest doses, the GABA agonists immediately elicited a period of intense feeding during which the rats injected with baclofen ingested an average of 4.2 g of solid chow (30 min test), and those injected with an equimolar dose of muscimol ingested an average of 7.2 g. Taken together, these results suggest that glutamatergic and GABAergic systems in the medial nucleus accumbens play an important, and possibly specific, role in the modulation of food intake. (Supported by NIDA DA04788)

EFFECT OF OPIATE AGONISTS MICROINJECTED INTO NUCLEUS ACCUMBENS ON SUCROSE DRINKING IN RATS. Min Zhang and Ann E. Kelley*. Dept. Psychiatry, University of Wisconsin Medical School, Madison, WI 53706

Previous studies have indicated that central opioid peptides play an important role in the modulation of ingestive behaviors. The nucleus accumbens (N.Acc.), a brain region involved in reinforcement, contains high levels of opiate receptors. The present investigation was undertaken to determine the relative involvement of opiate receptor subtypes in sucrose drinking. Morphine (0, 0.5, 5 µg/0.5µl), the mu agonist D-Ala2,NMe-Phe4,Glyol5 (DAMGO; 0, 0.025, 0.25 and 2.5 μg), the delta agonist D-Pen2,5-enkephalin (DPEN; 0, 0.031, 0.31, 3.1 µg), the kappa agonists U50,488H (0, 0.0186, 0.186, 1.86 µg), and dynorphin (0, 0.05, 0.5, 5 µg) were microinfused into N.Acc. Intake (g) of a 5% sucrose solution, drinking duration, locomotion, rearing, and grooming were measured in a 30-min session in rats previously adapted to sucrose. After microinjection into N.Acc, morphine induced a robust increase in both sucrose intake and drinking duration at the low dose, while having a suppressive effect at the higher dose. DAMGO enhanced sucrose drinking at lower doses, and suppressed drinking at the highest dose. DPEN also increased sucrose intake, but only at the highest dose. U50488H and dynorphin had no effect on sucrose drinking behavior. The opioid agonists had little or no effect on spontaneous motor behaviors. These findings demonstrate that both mu and delta receptors within the accumbens, especially mu receptors, may have an important modulatory role in ingestion. Kappa receptors in this region appear not to be involved in this behavior. Further experiments will examine the effects of mu agonists on other ingestive behaviors such as water intake, as well as whether responses within the core and shell subregions can be differentiated. Supported by NIDA grant DA09311.

MORPHINE MICROINJECTIONS IN THE SHELL (BUT NOT IN THE CORE) OF THE NUCLEUS ACCUMBENS ENHANCE FEEDING AND PALATABILITY. S. Peciña* and K. C. Berridge. Department of Psychology, The University of Michigan, Ann Arbor, MI 48109.

It is a well established finding that the Nucleus Accumbens (NAcc) plays a major role in the mediation of opioid-induced feeding behavior, an effect which seems to be at least partially mediated by an enhancement in the perceived The NAcc is divided into two anatomically and palatability of tastes. pharmacologically distinct subareas, the shell and the core, which may play different roles in feeding (Kelley, 1995). Do these subareas play different roles in the mediation of opioid-induced feeding? We injected 0.5 µg/0.5 µl/ side of morphine into two groups of rats implanted with bilateral intracranial cannulae aimed at the shell (A=2.0, L=0.9, V=7.5) or the core (A=2.0, L=1.9, V=7.5) of the NAcc. Increases in food intake (i.e. commercial baby cereal) were measured at 15 min, 1 hr, 2 hrs and 3 hrs after morphine microinjections. Increases in taste palatability to a 2% sucrose solution were measured using the taste reactivity technique (Grill and Norgren, 1978) at 15 min, 1 hr and 2 hrs. The results of our preliminary studies showed that morphine selectively enhanced feeding and taste palatability at all times tested in the shell but not in the core of the NAcc. The findings of the present study suggest that the NAcc is a functionally heterogeneous structure with respect to opioid-induced enhancement of feeding and that opioid circuits in the NAcc shell make a special contribution to the mediation of opioid-induced feeding and taste affect.

IMMEDIATE-EARLY GENES IN THE AMYGDALA PLAY AN ESSENTIAL ROLE IN CONDITIONED TASTE AVERSION. R. Lamprecht and Y. Dudai*, Weizmann Institute of Science, Rehovot 76100, Israel.

Dudai*, Weizmann Institute of Science, Rehovot 76100, Israel.

We study the role of gene expression in rat brain in conditioned taste aversion (CTA). We recently reported that several immediate early genes (IEG's) including c-fos are differentially modulated following LiCl i.p., an unconditioned stimulus used in CTA training, in several rat brain areas including the central amygdaloid nucleus (CeA) (NeuroReport 7: 289, 1995). To further elucidate the functional significance of IEG's in CTA, we specifically and locally inhibited translation of c-fos and of the cAMP response element binding protein (CREB), which was shown to be involved in transcriptional regulation of c-fos. We microinjected 5nmol of phosphorothioate modified oligodeoxynucleotides (PONs) antisense to CREB or to c-fos bilaterally into the CeA. Microinjection of CREB antisense 14 hr before CTA training significantly impaired CTA memory tested 3 days later (aversion index (Al) 73+/-5, vs. 96+/-1 in sense micro-injected controls, n=11-17). CREB antisense 7 days before training, or 3 days after training and before testing, was ineffective (95+/-3 vs. 93+/-4, n=5-7). Microinjection of c-fos antisense 8 hr before training reduced c-fos protein in the amygdala to 57% and significantly impaired CTA memory (71+/-6 vs. 92+/-2 in sense micro-injected controls, n=9-11). Injection of c-fos antisense 4 days before training, or before testing, or injection 2 mm above the CeA, was ineffective (93+/-2, 95+/-2, and 91+/-3, respectively, n=6 each). Our findings thus indicate that CREB and c-Fos in the amygdala play an essential role in CTA learning. (Supported by the US-Israel Binational Science Foundation, Jerusalem.)

MICRODIALYSIS REVEALS THAT BOTH FOOD INGESTION & STRESS FNHANCE CRE RELEASE AT THE CENTRAL AMYGDALOID NUCLEUS

ENHANCE CRF RELEASE AT THE CENTRAL AMYGDALOID NUCLEUS.

J. McIntosh*¹, P. Kent¹ & Z. Merali^{1,2}, ¹School of Psychology & ²Dept. of Pharmacology, University of Ottawa, Canada.

There is increasing evidence that the central nucleus of the amygdala (Ce), plays a key role in the control of visceral, autonomic and ingestive responses. Recent work in our lab has shown that CRF levels at the Ce change in response to food intake, and that CRF antagonist blocks various endocrine and behavioral effects of bombesin (BN). The 1st objective of this study was to determine, via in vivo micro-dialysis whether the release of CRF and BN is altered during spontaneous food intake. Probes were implanted at the Ce and four 30-min baseline samples were collected during the light phase, followed by 6 more samples during the dark phase. Animal's food consumption was visually observed (under red light). Upon meal initiation, the collection tube was changed and 30-min samples were collected during and after the meal. When compared to baseline, prandial and post-prandial conditions showed a marked elevation in CRF release while there was only a slight elevation in the release of BN. The 2nd objective of the study was to measure changes in CRF and BN release in response to immobilization stress. As before, four 30-min baseline samples were collected, following which rats were exposed to two 20 min periods of manual restraint (spaced 2.5 h apart). Five 30 min samples were collected during and after each restraint episode. Stress increased both CRF and BN release at the Ce. CRF and BN increases became significant at the 3rd and 4th samples, respectively, following 1st stress and continued to rise throughout. These results demonstrate that 1) CRF and BN are released at the Ce in response to both aversive and positively reinforcing situations, and 2) the stress related release of both CRF and BN is sustained and not prone to rapid adaptation, suggesting that these peptides at the Ce may mediate the more long-term effects of stress

CYTOTOXIN TARGETING OF OXYTOCIN (OT) RECEPTIVE CELLS OF CENTRAL AMYGDALA: OT RECEPTORS AND SALT APPETITE. T. Vargas, M.Blake*, W.K. Samson. Physiology and Pharmacology, UND School of Medicine, Grand Forks, ND 58202.

Targeting of OT receptive cells with ricin A chain-oxytocin conjugates revealed a potential role for OT in the control of salt appetite (AJP 69:R245-R251, 1995). Using the same model system (PEG-induced hypovolemia with ip mannitol-induced elevation in plasma osmolality) we examined the effect of our cytotoxin treatment on OT-receptor distribution in central amygdala (CA) of the rat, an area of distinct, dense OT binding. Rats received lateral ventricular injection of ricin A chain-OT conjugate (5 μg in 5 μl vehicle) to target for compromise cells bearing OT receptors or a similar injection of unconjugated ricin A chain (toxin control). As expected, rats pretreated with ricin A chain-OT cytotoxin conjugates drank significantly more (72%) saline in response to hypovolemic, hyperosmotic challenge, than controls seven days after icv injections. Autoradiographic analysis of I-125 ornithine vasotocin (OVTA) binding in CA was conducted using phosphor imaging (Image Quant Program) in frontal sections of brains from these rats. Total (ratio of CA/cortex) OVTA binding of ricin A chain-OT conjugate treated rats was significantly (29%) less that that present in controls. In addition to this decrease in binding density, a significant spread of OVTA receptor distribution was observed (31% and 32% in volume and area). We hypothesize that this spread in receptive field was due either to compensatory axonal sprouting or glial infiltration since astroglia express OT receptors. (NSF grant #9507751S).

BODY WATER COMPARTMENTATION IN SODIUM-DEPLETED RATS WITH LESIONS OF THE SUBFORNICAL ORGAN. E. M. Starbuck*, J. R. Lane, and D. A. Fitts. Dept. of Psychology. Univ. of Washington. Seattle, WA 98195.

and D. A. Fitts. Dept. of Psychology, Univ. of Washington, Seattle, WA 98195
We previously reported that rats with lesions of the subfornical organ (SFOX) expressed salt appetite during sodium depletion only when they were well hydrated with water during the depletion period. Sham-lesioned rats fully expressed a salt appetite under both euhydrated and underhydrated conditions. Since differences in saline intake may have resulted from differences in body fluid content or distribution between sham-lesioned and SFOX rats, we repeated these experiments in order to measure plasma electrolyte levels, osmolality, protein concentration, and hematocrit at the usual time of the salt appetite test in the previous experiments. SFOX and sham-lesioned rats were given 10 ml/kg furosemide (sc) followed during the next 22 hr by 3 intragastric administrations of either 2 ml/kg water (SFOX, n = 10; sham, n = 9) or 10 ml/kg water (SFOX, n = 12; sham, n = 8). Rats were then rapidly anesthetized, and a 10-ml sample of blood was drawn by cardiac puncture. Results of plasma assays revealed higher plasma potassium levels in rats with SFO lesions than in sham-lesioned rats. No significant differences were found in plasma osmolality, protein, sodium concentration, or hemtocrit among the rats in the different lesion and hydration conditions. No interaction was found for sodium excretion or water balance between the lesion and hydration conditions. Thus, the reduced salt intake in underhydrated SFOX rats in previous studies does not appear to result from a gross difference in content or distribution of body water Supported by NS22274.

DOES THE K-ATP CHANNEL ON HYPOTHALAMIC NEURONS

DOES THE K-ATP CHANNEL ON HYPOTHALAMIC NEURONS AUTO-REGULATE VIA PHOSPHORYLATION? V.H. Routh*, J.J. McArdle, and B.E. Levin. Depts Neurosci, and Pharmacol & Physiol, NJ Med Sch (UMDNJ), Newark NJ 07103; Neurology Service, DVA Medical Center, E. Orange NJ, 07018.

ATP-sensitive K* channels (K-ATP) exist on glucosensing neurons in the ventromedial hypothalamic nucleus (VMN), a key site for regulating autonomic activity. Inactivation of K-ATP channels by ATP increases neuronal firing rate. Thus, the VMN K-ATP channel may serve as a mechanism whereby metabolic status ATP channel may serve as a mechanism whereby metabolic status influences autonomic activity. Neither the mechanism of this inactivation nor the requirement of low levels of ATP for K-ATP channel activity is understood. To explore this issue, we recorded K-ATP channel activity in cell attached and excised inside-out (io) patches of VMN neurons isolated from neonatal rats. When io patches of VMN neurons isolated from neonatal rats. When io patches were exposed to symmetrical K^+ , single channel currents reversed at 0 mV and had a conductance of approximately 50 pS at a holding potential of 20 mV. While the basal open probability (P_o) fluctuated greatly making it difficult to obtain satisfactory concentration-response relations, both 10 mM ATP/0.1 mM ADP and 100 μ M glibenclamide reduced P_o . The non-specific kinase inhibitor H7 (200 μ M) decreased P_o and prevented the inhibitory effect of ATP on K-ATP channels of io patches. This observation suggests that the K-ATP channel of VMN neurons may suggested for a neuronal Ca⁺⁺-activated K⁺ channel, whose P_0 is increased by ATP (Reinhart & Levitan, J. Neurosci. 15(6): 4572-9, 1995). Supported in part by the American Diabetes Association.

LATERAL HYPOTHALAMIC AFFERENTS ASSOCIATED WITH NMDA-ELICITED EATING STUDIED BY REVERSE DIALYSIS OF NMDA AND FLUOROGOLD. E.M. Tomkins*, M.A. Duva, C.Y. Kuo, L.M. Moranda, B.G. Stanley. Depts. Neurosci. & Psych., Univ. CA, Riverside, CA 92521.

To reveal the origins of lateral hypothalamic (LH) afferents associated with eating elicited by excitatory amino acid agonists, reverse microdialysis was used to deliver NMDA and the retrograde tracer Fluorogold (FG) into the LH of adult male rats. NMDA (3.3 mM) infused through the probe elicited intense, sustained eating, usually beginning within 3 min and averaging 13.7gm within 45 minutes. Subsequently, 0.2% FG was administered via the dialysis probe at 5 µl/min for 30 min. After 3-4 days with the dialysis probe in place, rats were perfused and 60 µm horizontal sections were collected, dehydrated and observed with a fluorescent microscope. Observations revealed that the FG spread about 0.5 mm around the probe tip. In association with the NMDA-elicited eating responses. retrogradely-labeled cells were consistently found in the infralimbic and perirhinal cortex, core and shell of the accumbens, olfactory tubercle, ventral pallidum, anterior and central amygdala, bed nucleus of the stria terminalis, subfornical organ, median preoptic, lateral preoptic area, posterior hypothalamus, ventral tegmental area, substantia nigra, raphe nuclei, medial and lateral parabrachial, and the caudal part of nucleus tractus solitarius. This study reveals a pattern of LH afferent labeling associated with NMDA feeding, and suggests that reverse dialysis of neuroactive compounds with anatomical tracers may be useful in revealing the neural substrates of some behaviors

ADAPTATION TO AN IMBALANCED AMINO ACID DIET (IMB) IS ATTENUATED FOLLOWING IBOTENIC ACID LESIONS (IBO-L) OF THE DORSOMEDIAL HYPOTHALAMIC NUCLEUS (DMNL) IN RATS. <u>J.F. Evans</u>, <u>L.L. Bellinger* and D. W. Gietzen.</u> Dept. of Biomedical Sci., Baylor College Of Dentistry, Dallas, TX. 75246 and Vet. Med. Anat. Phys. & Cell Biol. Univ. of Calif., Davis, CA 95616.

Rats show food intake (FI) suppression in as little as 3 h after giving an IMB; this Rats show food intake (F1) suppression in as little as 3 h after giving an IMB; this decrease in F1 can be attenuated by giving Tropisetron (TROP) a 5HT, receptor antagonist. Wang et al., (The FASEB J. 8:A385, 1994) showed c-Fos expression in the DMN 2 h after giving rats an IMB. In the present study male S. D. rats were given IBO DMNL or sham operations (SHAM). The rats were placed on chow for 7 d and then basal diet for 9 d; the DMNL rats were hypophagic (P<0.01) compared to SHAM. On basal diet the rats were injected i.p. with saline (SAL) 1 h prior to lights out and FI recorded 3, 6, 12 and 24 h later. Following this the rats were injected with SAL or TROP (9mg/kg): SHAM + SAL (218g BW, n=9); SHAM + TROP (214g BW, n=10); DMNL + SAL (195g BW, n=11); and DMNL + TROP (200g BW, n=12) and 1 h later presented with an isoleucine IMB; the BWs of the DMNL grps were less (p<0.01) than SHAMs. For both SAL treated grps their 3, 6, 12, and 24 h FI (expressed as a % of their basal FI) were similar and ranged from 33-49% of their basal FI. The TROP grps FI were similar, but greater (P<0.01) than the SAL grps (range 53-78%). On day 2 IMB FI of the SHAM-TROP grps was higher (p<0.01) than the other grps whose FI were similar. On day 3 the DMNL-TROP grp's FI was less (P<0.01) than all other grps. On days 4-7 the FI of the DMNL grps was less (P<0.01) than the SHAMs. BW (expressed as a percentage of last day on basal BW) changes reflected FI and by day 4 both DMNL grps weighed less (P<0.01) than the SHAMs. The data show that IBO-L of the DMN doesn't affect the ability of TROP to attenuate the FI suppression caused by IMB. The IBO DMNL attenuates the rats normal adaptation to the IMB. Supported by DK42274 to D.W.G. and BCD Research Funds.

TCDD CANCELS THE EFFECTS ON BODY WEIGHT OF LESIONS OF VENTROMEDIAL HYPOTHALAMIC AND PARAVENTRICULAR NUCLEI. Jouni T. Tuomisto, Mikko Unkila, Raimo Pohjanvirta, Matti Viluksela and Jouko Tuomisto* Laboratory of Toxicology, Division of Environmental Health, National Public Health Institute, P.O.B. 95, FIN-70701 Kuopio, Finland.

Body weight set point (BWSP) is a descriptive term for the level of body weight that will be defended in certain conditions. Very few chemicals change the BWSP as their toxic effect, but TCDD (2,3,7,8-tetrachlorodibenzop-dioxin) and its congeners have this effect (Pohjanvirta & Tuomisto, Pharmacol. Rev. 46:483, 1994). Since some hypothalamic lesions influence BWSP, it is of interest to study their interactions with TCDD effects. Typical lesions causing increased food intake and increased body weight are those of ventromedial hypothalamic and paraventricular nuclei (VMN and PVN, resp.). In Han/Wistar (Kuopio) rats a large dose of TCDD was able to completely abolish the lesion-increased food intake and lowered the body weight to approximately the same lowered level as TCDD in sham-operated controls. After lesions of VMN the effects were more dramatic than after those of PVN, in fact the obese animals stopped eating totally for 10 to 14 days, until their body weight had dropped to the same level or lower as in controls given TCDD. After each type of lesion there was interaction between the lesion and TCDD (ANOVA). This is contrary to the effects of TCDD on diet induced obesity where there was no interaction (ANOVA), i.e. TCDD lowered the body weight in the same manner both in obese and lean animals. In obese Zucker rats leptin receptor is non-functional, and there was also an interaction between the phenotype and TCDD. We predict that the site of action of TCDD on the regulation of body weight is distal from these nuclei and also distal from the leptin receptor, and that TCDD could be used as a tool in obesity studies.

FEEDING ELICITED BY N-METHYL-D-ASPARTATE (NMDA) IN THE FEEDING ELICITED BY N-METHYL-D-ASPARTATE (NMDA) IN THE LATERAL HYPOTHALAMUS (LH) IS SUPPRESSED BY A TYROSINE KINASE INHIBITOR. A.M. Khan^{1,2}, D.S. Welsbie², A.M. Khan², C.S. Ton², J. Nikpur², E.R. Gillard², P.P. Pir², and B.G. Stanley^{2,4}. Depts. of ¹Biochemistry, and ²Neuroscience & Psychology, Univ. of California, Riverside, CA 92521.

Increasing evidence suggests that the activity of NMDA receptors can be modulated by intracellular phosphorylation. In particular, protein tyrosine kinase inhibitors have been shown to decrease NMDA receptor-mediated calcium influx in vitro (Wang, Y.T. and Salter, M.W., Nature, 369 (1991) 233). We have recently shown that NMDA injected into the LH of satiated rats markedly stimulates eating behavior, and that a NMDA receptor antagonist can suppress natural eating (Stanley, B.G. et al., Brain Res., 613 (1993) 88; Am. J. Physiol., 270 (1996) R443). To investigate whether NMDA-elicited eating is modulated by phosphorylation, adult male Sprague-Dawley rats (n=25) with indwelling LH guide cannulas were injected with the protein tyrosine kinase inhibitor, genistein (240 nmol), followed by NMDA (10 nmol). Compared to vehicle, LH injection of NMDA elicited significant eating $(7.9 \pm$ 1.9 g in 30 min, p<.05) and this response was suppressed by as much as 53% with genistein pretreatment (3.7 \pm 1.1 g in 30 min, p<.05). In contrast, 240 nmol of dadzein, an inactive analog of genistein, did not suppress NMDA-elicited feeding (7.1 \pm 1.8 g in 30 min). These results suggest that tyrosine kinase-mediated signaling may be an important cellular mechanism regulating NMDA-elicited eating in the LH. (Supported by NIH grant NS 24268)

HYPOTHALAMIC GALANIN AND DIETARY OBESITY. J.T. Alexander*, J.T. Dourmashkin, D. Chan, A. Manitiu, J. Wang, and S.F. Leibowitz. The Rockefeller University, New York, N.Y. 10021

To identify an animal model of dietary obesity, adult male Sprague-Dawley rats (n=100), allowed to select freely from 3 macronutrient diets over a 4-week period, were compared to a group of rats (n=14) given a single balanced nutrient diet (protein 27%, carbohydrate 45% and fat 28%) for the same period. Comparisons between these two groups revealed little difference in total Kcal intake (100-105 Kcals). However, in the nutrient choice group, daily fat intake increased from 31 Kcals (balanced diet subjects) to 42 Kcals (p<0.05), enhancing total dietary fat to >41% and reducing dietary carbohydrate to 25% This rise in fat ingestion was positively correlated with body fat (e.g., inguinal fat pad, r=+0.61, p<0.05) and body weight (r=+0.56, p<0.05) and was and pad, 1^{-1} (1.7), p = 3.00 and p = 3.00 and accompanied by a significant (p < 0.05) decline in insulin (-25%) and corticosterone (-45%) levels and a rise in glucose (+7%). To characterize associated changes in the brain, additional animals, allowed to select from the 3 nutrients, were separated into 2 groups that consume either high (>45% of total diet) or low (<15%) amounts of fat. Their brains were analyzed for galanin (GAL) mRNA using in situ hybridization with digoxigenin labeled cRNA probe. Results indicate higher number (+45%) of neurons expressing GAL (40±2 vs 24±2 cell number/mm², p<0.05), specifically in the anterior portion of the paraventricular nucleus (PVN). While a small difference was seen at the middle portion of the PVN, no difference was seen in the medial preoptic area or the arcuate nucleus or in other hypothalamic areas. This high level of GAL gene expression, seen in animals of greater body weight, may be due to the suppression of insulin and corticosterone.

HYPOTHALAMIC GALANIN GENE EXPRESSION IN RELATION TO A HIGH-FAT DIET IN ADULT MALE RATS. J. Wang*, I. Silva, C Harris, M. Bhattacharyya and S.F. Leibowitz, Rockefeller Univ., N.Y. 10021

With injections into the hypothalamic paraventricular nucleus (PVN), galanin (GAL) stimulates fat and carbohydrate intake, and GAL antisense oligonucleotides suppress fat intake. Through studies of endogenous GAL, levels of this peptide in the PVN are found to be positively related to the rats' natural daily intake of fat but inversely related to carbohydrate or protein intake. This relationship was examined further in animals that were maintained on a single high-fat (60% fat + 10% carbohydrate, n=5), high-carbohydrate (63% carbohydrate + 10% fat, n=5) or standard lab chow (n=4) diet. 3 weeks on these diets, the rats were intracardially perfused and their brains examined using in situ hybridization with digoxigenin labeled cRNA probe for mRNA levels and immunocytochemistry for peptide analyses. Comparisons between the high-carbohydrate rats and chow-fed rats showed similar GAL mRNA or peptide measures in the hypothalamic areas examined. However, high-fat diet rats, compared to low-fat diet subjects, showed an increase in neurons expressing GAL mRNA (+36%, 6.97 \pm 0.6 vs 4.45 \pm 0.7 cell number/ mm², p<0.05) and in peptide immunoreactivity (p<0.05) in the anterior PVN, as well as increased peptide immunoreactivity (342.6 \pm 81.2 vs 143.6 \pm 18.5 objects/mm², +238%, p<0.05) in the external zone of the median eminence. No significant group differences were seen in other hypothalamic areas (medial preoptic area, arcuate nucleus, or dorsomedial nucleus) where GAL neurons are concentrated. These results show clear, anatomically specific changes in GAL mRNA and peptide immunoreactivity suggesting a positive relationship between this neurochemical and dietary fat.

555.17

INDUCTION OF NEUROPEPTIDE Y MRNA IN THE ARCUATE NUCLEUS BY FASTING IS ATTENUATED IN DIET-INDUCED OBESITY. H. T. Bergen*, T. M. Mizuno, and C. V. Mobbs, Dept. of Anatomy, U. of Manitoba, Winnipeg, MB, Canada and Fishberg

Neuropoptide Y (NPY) in the hypothalamus increases food intake and body weight, and NPY mRNA levels in the arcuate nucleus increase in response to fasting. NPY mRNA levels in the arcuate are also elevated in some models of obesity. This study was performed to determine whether regulation of NPY mRNA is altered in diet-induced obesity. Mice (CBA and C57BL/6J strains) were fed either rodent chow (control) or a high-fat, high-carbohydrate diet for 14 weeks. This diet produced obesity in both strains. The mice were either fasted for 48 hours or fed ad lib before being killed. NPY mRNA levels in the arcuate nucleus were assessed by in situ hybridization. In control CBA mice, fasting increased NPY mRNA. In contrast, in obese CBA mice, fasting did not significantly increase NPY mRNA levels as compared to non-fasted mice. In addition, NPY mRNA levels were lower in obese CBA mice than in controls NPY mRNA levels were lower in obese CBA mice than in controls under both fasted and fed conditions. In control C57BL/6J mice, fasting increased NPY mRNA levels. Although fasting also increased NPY mRNA levels in obese C57BL/6J mice this effect was more modest as NPY mRNA levels were significantly lower in fasted obese than in fasted control mice. These results suggest that dietinduced obesity is not associated with increased NPY activity in the arcuate nucleus and that induction of NPY mRNA by fasting is attenuated in diet-induced obesity. THE DISTRIBUTION OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR (GLP1-R) mRNA IN THE RAT BRAIN. P.J. Shughrue*, M.V. Lane and I. Merchenthaler. Women's Health Research Institute, Wyeth-Ayerst Research, Radnor, PA 19087. GLP-1 has been shown to dramatically reduce food intake in fasted rats. The effect of

GLP-1 has been shown to dramatically reduce food intake in fasted rats. The effect of GLP-1 or feeding is both dose dependent and blocked by a GLP-1 receptor antagonist, exendin. GLP-1, when injected intracerebroventricularly, has also been found to attenuate the stimulatory effect of neuropeptide Y on appetite and induce the expression of c-fos in brain regions associated with appetite and feeding. While great strides have been made in understanding the role of GLP-1 in the brain, little is known about the distribution of GLP1-R and RIS in still hybridization histochemistry to determine the anatomical distribution of GLP1-R mRNA in the rat brain. The brains of female rats were frozen and 20µm cryostat sections collected on microscope slides. The section-mounted slides were hybridized sections collected on microscope stides. The section-mounted stides were hybridized with a ³⁵S-labeled antisense riboprobe complimentary to GLP1-R mRNA, stringently washed and appossed to emulsion. The results of these studies revealed an extensive distribution of GLP1-R mRNA throughout the rostral-caudal extent of the brain; with the majority of the perikarya concentrated in the hypothalamus, pons and medulla. A dense accumulation of GLP1-R mRNA-containing cells was observed in the supraoptic, paraventricular, arcuate and dorsomedial nuclei of the hypothalamus; raphe nuclei; mucleus. In addition, GLP1-R mRNAnucleus of the solitary tract and spinal trigeminal nucleus. In addition, GLP1-R mRNA was detected in the lateral septum; diagonal band of Broca; bed nucleus of the stria terminalis; periventricular nucleus; amygdala; posterior thalamic nuclei; and central gray. The results of these *in situ* hybridization histochemical studies have provided detailed and novel information about the distribution of GLP1-R mRNA in the rat brain. In addition, this morphological data provides important information about the neuronal systems modulated by GLP-1 and their potential role in feeding behavior.

NALOXONE DOES NOT BLOCK NEUROPEPTIDE Y-INDUCED c-fos EXPRESSION IN THE PARAVENTRICULAR NUCLEUS. J.D. Pomonis*, A.S. Levine, and C.J. Billington. Graduate Program in Neuroscience, Univ. of Minnesota and VA Medical Center. Minneapolis, MN 55417

Neuropeptide Y (NPY) is a powerful orexigenic agent that has its primary site of action in the hypothalamus, especially the paraventricular nucleus (PVN). The effects of NPY on food intake and thermogenesis can be blocked by peripheral or central injection of the opioid antagonist naloxone. This blockade by central administration has been shown to be site-specific. When injected into the PVN, naloxone must be administered at high doses in order to inhibit the effects of NPY injected into the PVN. However, low doses of naloxone injected into the nucleus of the solitary tract (NTS) block the effects of PVN administered NPY. In this study, rats were injected with saline or 1 mg/kg naloxone (i.p.) 30 minutes prior to a PVN injection of either saline or 1 µg NPY. Rats had ad lib access to food except for one group that received peripheral saline and PVN NPY. One hour following the PVN injection rats were sacrificed and tissue was processed for c-Fos immunoreactivity (Fos-IR). Fos-IR in the PVN was significantly increased in all animals receiving PVN NPY compared to those that received PVN saline injections, regardless of compared to those that received PVN saline injections, regardless of food intake {F(4,14)=5.111, p=0.0094}. Thus, even when naloxone blocked feeding induced by NPY, the NPY-induced Fos-IR in the PVN remained elevated. These data suggest that the effects of naloxone are mediated downstream from the PVN, presumably in the NTS, rather than via efferent projections from the NTS to the PVN. (NIH DKA 42698)

REDUCTION OF NPY2-36'S OREXIGENIC POTENCY BY ESTRADIOL IN OVARIECTOMIZED RATS IS ASSOCIATED WITH NEUROPEPTIDE Y RECEPTOR MODULATION IN THE PERIFORNICAL HYPOTHALAMUS. T.K. Bhatti, D.B. Conze N. Geary, R.C. Young* and E.S. Corp. E.W. Bourne Lab, Cornell University Medical College, White Plains, NY 10605.

Ovariectomy (OVX) produces a profound increase in body weight (BW) in rats that is prevented by replacement treatment with estradiol benzoate (EB). Central NPY has been implicated in hyperphagia and obesity, and it is possible that EB's effects on food intake (FI) and BW may arise through a regulatory action of EB on NPY receptors. To investigate this possibility, we tested the potency of NPY2-36 to stimulate FI after lateral icv injection in OVX rats (n=12) receiving either chronic EB treatment (5 μ g/rat, 3 days per week) or the oil vehicle. After one month of treatment EB rats weighed less than controls (EB, 270 \pm 5g vs. oil, 319 \pm 8g, p<0.01). NPY2-EB rats weighed less than controls (EB, $270 \pm 5g$ vs. oil, $319 \pm 8g$, p<0.01). NPY2-36 stimulated dose-related increases in FI in both groups; however, analysis by 2-way ANOVA of total FI revealed a significant treatment x dose interaction, p< 0.02. This occurred because 1000 pmole NPY2-36 stimulated feeding less potently in EB-treated rats than in oil-treated rats (see Table, *p<0.05 Tukey's test).

100 2.1 ± 0.6 1.4 ± 0.4 Vehicle 0.4 ± 0.2 0.3 ± 0.1 7.3 ± 1.0 3.9 ± 0.9* Oil EB 3.4 ± 0.5

We next determined parameters of [1251]PYY receptor binding in the perifornical region of the hypothalamus. EB treatment resulted in a 56% downregulation of receptor number; Bmax (fmol/mg tissue) EB, 22 ± 4 vs. oil, 50 ± 12 , pc 0.05. NPY receptor affinity, however, was increased in the EB-treated; KD's (nM) EB, 0.4 ± 0.1 vs. oil, 1.2 ± 0.4 , pc0.02. These data indicate that EB decreases the orexigenic potency of NPY2-36 and produces a downregulation of NPY receptor number. However, the upregulation of receptor affinity suggests that further studies are required to clarify the influence of EB treatment on NPY, its receptors and the regulation of FI and BW Supports (Dairyana's Fund CIMC Whitehall Foundation and MEMS 1135). and BW. DECREASED INTAKE OF A LIQUID DIET FOLLOWING INTRA-PVN INJECTIONS OF GLUCAGON-LIKE PEPTIDE-1. L.R. McMahon* and P.J. Wellman. Dept. of Psychology, Texas A&M University, College Station, TX 77843-4235.

ICV administration of glucagon-like peptide-1 (7-36) amide (GLP-1) dose-dependently suppresses food intake in rats (Turton et al., Nature, 1996). Although the locus of action is unknown in rat brain, ICV administration of GLP-1 induces c-fos activation within rat paraventricular hypothalamus (PVN). The present study sought to determine whether intra-PVN administration of GLP-1 acts to suppress food intake in rats. Adult male rats (n=14) were prepared with indwelling guide cannulae aimed at the PVN. Rats were allowed access to a palatable liquid diet (Ensure) during a daily 60 minute test period with intakes measured every fifteen minutes. Intra-PVN administration of GLP-1 (0, 0.01, 0.05, 0.1, and 0.2 ug) did not alter latency to feed, but did induce a significant dose-dependent suppression of liquid diet intake during the first 15 minutes of the 60 minute test periods. These results suggest that a portion of the central action of GLP-1 on feeding may result from interactions with cells within the PVN.

Support Source - Texas A&M University

CENTRAL INFUSION OF LEPTIN (OB PROTEIN) AND GLP-1-(7-36) AMIDE DIFFERENTIALLY STIMULATE C-FOS EXPRESSION IN RAT BRAIN. T.E. Thiele, G. van Dijk, J.C. M. Donahey, L. Arthur Campfield, F. J. Smith, L.L. Bernstein, S.C. Woods*, and R. J. Seeley. Dept. of Psychology, U. of Washington, Seattle, WA 98195.

Considerable evidence suggests that leptin and glucagon-like peptide-1-(7-36) amide (GLP-1) are regulators of food intake. Given the different physiological characteristics of these peptides, it was hypothesized that reduction in food intake following central infusion of leptin or GLP-1 is mediated by different neural substrates. To examine this question, male Long-Evans rats were infused with either synthetic CSF (s-CSF), leptin (3.5 µg dissolved in s-CSF), or GLP-1 (10.0 µg dissolved in s-CSF), into the third ventricle. Relative to s-CSF, both leptin and GLP-1 reduced food intake by approximately 60% during the first 4 hr-period of the dark phase. As revealed by c-Fos immunohistochemistry, central infusion of leptin and GLP-1 produced c-Fos expression in the region of the paraventricular hypothalamus and the central amygdala. On the other hand, leptin selectively induced c-Fos expression in the dorsomedial hypothalamus, whereas GLP-1 selectively produced c-Fos in nucleus of the solitary tract, area postrema, lateral parabrachial nucleus, and the arcuate hypothalamic nucleus. Because c-Fos expression following leptin and GLP-1 infusion were observed mainly in separate regions of the brain, results suggest that these peptides modulate food intake and body weight via different central mechanisms.

CENTRAL LEPTIN INJECTION INDUCES NEURONAL ACTIVATION IN RAT HYPOTHALAMUS. A.E. Willing*, D. Hwang, D.A. York, and H.-R. Berthoud, Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, Louisiana, 70808.

With the cloning of the mouse ob gene, it recently became possible to distribute the state of the observed the legical publish in produced in

With the cloning of the mouse ob gene, it recently became possible to directly test the role of the ob gene product, leptin, which is produced in adipose tissue, on the regulation of body weight and feeding. Central and peripheral leptin administration decrease both food intake and body weight in ob and diet-induced obese mice (Campfield et al, Science, 269,1995). More recently, the leptin receptor was cloned and found to be present in the lung, kidney, choriod plexus, and hypothalamus of the mouse (Tartaglia et al, Cell, 83, 1995). The aim of this study was to determine the central site of leptin action by measuring c-fos expression in response to leptin, vehicle, or artificial CSF injection. Guide cannuli were aimed at the lateral ventricle in male Sprague-Dawley rats and correct injector placement was verified by the drinking response to angiotensisn II (15 ng/ 3 μ I). One week later, the animals were injected with either recombinant mouse leptin (1 or 10 μ g in 5 μ l which we produced, or as a gift from Ciba, Switzerland), the leptin fusion protein (5 μ I) or artificial CSF(5 μ I) and then perfused 90 min later. c-Fos immunocytochemistry on 50 μ m frontal sections taken through the entire brain demonstrated that central leptin injection increased c-fos expression in the hypothalamus (paraventricular, dorsomedial, lateral, ventromedial nuclei), amygdala, and paraventricular thalamus. This suggests either that leptin receptors are present on neurons in these nuclei or that these neurons are part of a neural network that is activated by leptin. It supports the hypothesis that leptin acts directly at brain sites to control body weight and food intake. Supported by NIH grants DK47348, DK41868 and USDA 93-37200-8961.

ACTIVATION OF FOS-LACZ BY PERIPHERAL AND CENTRAL INJECTION OF OB PROTEIN (LEPTIN): IMPLICATIONS FOR DOWNSTREAM SIGNALING PATHWAYS. R.J. Smeyne*1, M. Renzetti², F. Smith², ¹Neurogenetics Program and ²Department of Metabolic Diseases. Hoffmann-La Roche, Nutley, NJ 07110.

The product of the recently cloned ob gene, Leptin, has been shown to have remarkable biological import in the regulation of body weight in rodents. This protein has been demonstrated to reduce food intake as well as increase energy expenditure. Little is known about the central and peripheral signaling pathways which underlie these biological properties. To investigate this question, we injected Fos-lacZ (FLZ) transgenic mice with purified recombinant mouse Leptin through IV or ICV administrative routes in order to map out the anatomical pathways used in ob gene signaling. Two hours following IV Leptin injection, we find FLZ labeling in both CNS and peripheral tissue. Sites of expression following peripheral injection include the liver, kidney, skeletal muscle and areas of brown and white fat. In the nervous system, expression of FLZis seen in a cerebral cortices and a vast number of diencephalic and hindbrain nuclei. In order to see if the central and peripheral activation was a direct CNS effect, we injected Leptin via ICV. When administered by this route, we found that the peripheral expression, except in brown fat, disappeared. In addition, far fewer areas of the CNS demonstrated FLZ expression. One exception was the arcuate, DM and VPM nuclei of the hypothalamus. This work suggests that there must be both peripheral and central receptors that can activate OB signaling. Further work should define this matter.

556 2

DISTRIBUTION OF LEPTIN BINDING AND RECEPTOR MRNA IN THE OBESE MOUSE BRAIN. M.E. Goldstein*'. J. Wang'. R.A. Parker*. T.G. Kirchgessner*. H.K. Chan. R.N. Wright'. A.S. Eison'. CNS' and Metabolic Diseases* Depts, Bristol-Myers Squibb Co., Wallingford, CT 06492 and Princeton, NJ, 08543.

Leptin, a circulating protein synthesized by adipose tissue, regulates feeding in response to changes in adipose mass. To investigate the mechanism by which the brain responds to leptin, we have examined the distribution of 1251-leptin binding and leptin receptor mRNA using receptor autoradiography and in situ hybridization. Leptin binding is observed in the choroid plexus, meninges and major blood vessels of ob/ob, ob/+, db/db mouse brains and in rat brain. Though no binding is detected in the arcuate nucleus, we see high levels of leptin receptor mRNA in this region of ob/ob and db/db mice, in addition to other hypothalamic nuclei, choroid plexus, and meninges. Lower levels of receptor mRNA are seen in the arcuate of lean animals (ob/+ mouse and rat) suggesting that the obese animals may upregulate leptin receptor message in the arcuate in response to increased adiposity and circulating leptin. Acute injections of leptin into the region of the arcuate nucleus of ob/ob mice result in marked decreases in feeding and body weight supporting a role for this region in the regulation of food intake. EXPRESSION OF THE LEPTIN RECEPTOR DURING DEVELOPMENT AND IN THE ADULT MICE. S.-C. Chen¹, M. Nettleton², T. Wang*¹, J. P. Kochan² and R. J. Smeyne¹. ¹Neurogenetics Group and ²Department of Metabolic Diseases, Hoffmann-La Roche Inc., Nutley, NJ 07110.

The cloning of the mouse obesity (ob) gene has made it possible to study the mechanisms of obesity at the molecular level. ob gene appears to encode a signaling factor, leptin, for body weight homeostasis. Interestingly, studies have suggested that decreased sensitivity to leptin may be a more important problem in human obesity. Thus, it is crucial to understand the molecular mechanism involved in leptin signal transduction. Recently, a high affinity receptor (OB-R) for leptin has been identified and cloned by expression cloning from mouse choroid plexus. As a result of alternative splicing, at least two forms of protein with different lengths of intracellular domain were identified. The gene encoding OB-R was subsequently identified and confirmed as the db gene. A single nucleotide mutation causes the inability of the db/db mice to produce the long form OB-R.

We have carried out in situ hybridization to investigate the expression

We have carried out in situ hybridization to investigate the expression and developmental regulation of OB-R gene. Riboprobes derived from different regions of OB-R gene were used in the experiments. With a probe specific to the extracellular domain of OB-R, its message was detected in many adult tissues. These include hypothalamus and choroid plexus in CNS and several peripheral tissues, e.g., kidney, intestine and stomach. In contrast, a much more restricted tissue distribution was observed with a probe that is specific to the long alternative splice variant of OB-R gene. Developmentally, the OB-R gene transcript could be detected in mouse embryo as early as e9.5. Similar tissue distribution patterns were observed throughout development. These results will further our understanding of the sites and molecular mechanisms of leptin in regulating body weight.

METABOLIC ACTIVITY IN THE MIDBRAIN AND FOREBRAIN ASSOCIATED WITH INTESTINAL INFUSIONS OF GLUCOSE VERSUS SALINE IN RAT PUPS. C.B. Phifer*

and A.M. Nance. Louisiana Scholars' College, Northwestern State University, Natchitoches LA 71457.

The nutritive value of diet begins to affect ingestion in rat pups during the second week of life, and pup's first response appears due to preabsorptive signalling in the intestine. Direct duodenal infusions of glucose decrease intake relative to saline infusions, and this inhibition is attenuated by topical anesthesia of the intestinal mucosa. In the present study, [1"C]2-deoxyglucose (2-DG) autoradiography was used to study potential CNS correlates of a response to intestinal nutritive signals

Polyethylene cannulas were implanted in the anterior duodenum. Following 2-DG injections, pups were allowed to ingest milk for 30min. During the first 8min of the test, pups received duodenal infusions of 0.6M glucose or isotonic saline at 0.25%BW/min. Average autoradiograms were made from brain slices of eight pups in each treatment group. Differences in activity were obtained by subtracting one average image from the other average image. Previous analyses revealed effects in the brainstem; the present analysis covered the anterior midbrain andn forebrain areas through the diencephalon.

Absolute differences between brains of glucose- and saline-infused pups were seen in numerous midbrain and forebrain regions, including entorhinal, occipital, parietal and frontal ctx, retrosplenial granular and agranular ctx, medial forebrain bundle, horizontal limb of diagonal band, lateral and medial lemniscus, deep mesencephalic nu, various amygdaloid nu, zona incerta, lateral hypothalamus, caudate putamen and various thalamic nu. These results will be discussed in relation to pathways and regions known or postulated to subserve ingestive behavior and sensory pathways, particularly audition and olfaction. (Support: Louisiana Education Quality Support Fund and Whitehall Foundation.)

SEROTONERGIC MECHANISM OF THE LATERAL PARABRACHIAL NUCLEUS ON NaCl INTAKE INDUCED BY VOLUME DEPLETION. J. V. Menani*, L. A. De Luca Jr and A. K. Johnson. Dept. of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242, USA, Dept. Ciências Fisiológicas, Fac. Odontologia, UNESP, Araraquara, SP, Brazil.

In this study we investigated the effects of injections of serotonergic (5HT) drugs into the lateral parabrachial nucleus (LPBN) on the intake of NaCl and water induced by 24 h water deprivation or 24 h sodium depletion (injection of the diuretic furosemide + 24 h of sodium deficient diet). Rats had stainless steel cannulas implanted into the LPBN. Bilateral LPBN injections of the 5HT antagonist methysergide (4 µg/0.2 µl) increased 0.5 M NaCl intake induced by sodium depletion and 0.3 M NaCl intake induced by water deprivation. Bilateral injections of the serotonergic 5HT_{2A2C} agonist DOI (5 µg/0.2 µI) reduced 0.5 M NaCl intake induced by sodium depletion. Water intake increased after methysergide into LPBN and was reduced after DOI. The specificity of LPBN-5HT blockade on fluid intake was also tested in rats on ad lib food and water by determining effects on the intake of 2% sucrose. Methysergide in the LPBN produced no change in 2% sucrose intake. The results suggest a specific increase in experimentally-induced sodium and water intake by serotonergic antagonism in the LPBN and this may be important for the control of blood

CNS NEURONS REGULATING THE SYMPATHETIC OUTFLOW TO WHITE ADIPOSE TISSUE AS REVEALED BY TRANSNEURONAL LABELING WITH PSEUDORABIES VIRUS, W. S. Warren, M. G. Adkison and T. J. Bartness.* Depts. of Psychology and of Biology, Georgia State Univ., Atlanta, GA 30303.

Siberian hamsters exhibit a decrease in body mass with short photoperiod exposure, an effect due almost exclusively to a decrease in body fat. This decrease in lipid stores is not uniform and seems to be due to a differential drive by sympathetic nervous system (SNS) on white adipose tissue (WAT) pads and consequential differential rate of lipolysis. This effect is achieved via relatively separate innervation of WAT pads by neurons in the SNS chain. We explored the SNS innervation of WAT further by using a viral transneuronal retrograde tract tracer, pseudorabies virus (PRV). PRV was injected into the inguinal WAT (IWAT) pads (108 pfu/µl, 3-5 100nl injections throughout the pad) and hamsters were killed 4-6 days later. Brains, spinal cords and sympathetic chains were removed and processed for immunocytochemical (ICC) identification of virallyinfected neurons. Specific labeling was found in neurons of the sympathetic chain, intermediolateral (IML) horn of the spinal cord, rostral ventrolateral and ventromedial medulla, and the paraventricular and suprachiasmatic nuclei of the hypothalamus. Labeling of the sympathetic chain and IML was unilateral to the injection side, with more uni- than contralateral labeling in the higher CNS areas. These results provide an initial identification of the SNS outflow to WAT.

EVIDENCE FOR VAGAL INVOLVEMENT IN THE PATHOPHYSIOLOGY OF BULIMIA NERVOSA. B.K. Hartman*, P.L. Faris, S.W. Kim, W.H. Meller, N.C. Raymond, and E.D. Eckert. Div. of Neuroscience Research and the Eating Disorders Program. Dept. Psychiatry, Univ. of Minnesota, Mpls, MN 55455
The present study was designed to determine the involvement of the afferent vagus

The present study was designed to determine the involvement of the afferent vagus (see Aicher and Randich; Pain 42:103,1990) in mediating both the altered pain detection (PDT) in bullmia nervosa (Biol.Psych 32:462,1992) and the frequency of binge eating/vomiting. Subjects were thirteen females meeting DSM IV criteria for bullmia nervosa plus the more stringent criteria of at least 7 binge/vomit episodes (betweek). First, the effect of bullmic behaviors on PDT was examined by statistical correlation of weekly measurements of PDT with the time interval since the subject last engaged in a binge/vomit episode. PDT were found to be positively correlated with the time interval since the last binge/vomit episode (z=4.85; p < 0.00001). This finding suggests that PDT (and presumably afferent gastric vagal activity) are dynamically changing across the binge/vomit cycle and are lowest (low agal activity) temporally near to the binge/vomit episode and rise (increase in vagal activity) as the next episode is approached. The second experiment determined vagal involvement in mediating both the bullmic behaviors and the dynamic changes in PDT across the binge/vomit episode with the pullmic behaviors and the dynamic changes in PDT across the binge/vomit episode (z=1.5; p=14). In a double blind study, subjects treated with placebo (n=7) exhibited no significant improvement during a six week study period (ANOVA repeated measures; F(6.5)=1.102; p=.38). In the OND group (n=4) there was a significant decrease in binge/vomit frequency during the double-blind phase (ANOVA repeated measures; F(5.5)=5.9; p=0.01). These results support the hypothesis that afferent vagal hyperactivity is involved in the pathophysiology of bulimia nervosa. Our findings suggest (1) that an increase in spontaneous vagal activity, as indexed by increasing PDT, drives the binge/vomit episodes and (2) not engaging in the pathologic behaviors is associated with a worsening of the physiological abnormalities. Supported by MH 49385.

COOLING BLOCKADE OF THE PARABRACHIAL NUCLEUS ATTENUATES CONDITIONED TASTE AVERSION IN FREELY MOVING RATS. <u>Yuan Wang, David G. Lavond, Kathleen C. Chambers*</u> Psychology Department at University of Southern California, Los Angeles, CA 90089-1061

Permanent or temporary inactivation of the area postrema (AP) causes a malaise which can induce conditioned taste aversions (CTAs). It has been suggested that this malaise interferes with the capability of rats to acquire CTAs induced by LiCl. However, by using cooling to temporarily inactivate the AP, we have demonstrated that a LiCI-induced CTA is attenuated when the AP-lesion-induced malaise is dissociated from a novel food by preexposure to the malaise prior to conditioning. We have found recently that temporary inactivation of the parabrachial nucleus (PBN) also can induce a CTA. The following experiment was designed to determine whether cooling the PBN could attenuate a LiCl-induced CTA if rats are preexposed to cooling prior to conditioning. Twenty-three rats were divided into three groups: Cooling-PBN (n=7), Cooling-Above-PBN (n=8), and No-Cooling (n=8). The PBN of all three groups were preexposed to cooling daily for one week prior to conditioning. On acquisition day, all rats were given access to a 10% sucrose solution for 1 hour. Then the No-Cooling rats were injected with LiCl. Cooling was initiated in those rats assigned to the cooling condition and 5 minutes later LiCl (0.15M, 2ml/kg, i.p) was injected. The PBN was cooled for 1 hour. Two days later, daily extinction trials were initiated. When sucrose solution consumption on acquisition day and extinction day 1 were compared, rats in the Cooling-Above-PBN and No-Cooling groups showed a decrease in the amount consumed whereas rats in the Cooling-PBN group showed no change. These results support the hypothesis that the PBN is necessary for acquisition of LiClinduced CTAs. Supported by USC-FRIF and NIMH 1 R01 MH51197.

HYPOVOLEMIA STIMULATES DRINKING IN BARORECEPTOR-DENERVATED RATS. E.M. Stricker*, A.M. Schreihofer, and A.F. Sved. Department of Neuroscience, University of Pittsburgh, Pittsburgh PA 15260.

Hypovolemia is an established stimulus of thirst and vasopressin secretion. Both responses are thought to be mediated by changes in afferent input to the brain from cardiopulmonary baroreceptors. However, we recently observed that hypovolemia still elicits vasopressin secretion in rats after cardiopulmonary and arterial baroreceptor input to the brain had been eliminated chronically by electrolytic destruction of the nucleus tractus solitarius (NTSX), their brain Therefore, the present experiments sought to stem site of termination. determine whether hypovolemia still elicits drinking in rats with NTSX. Complete loss of cardiac afferent input was confirmed in all NTSX rats by an absence of cardiovascular reflex responses evoked by injection of phenylbiguanide, and by the absence of carotid and aortic baroreceptor reflex responses. Then hypovolemia was produced by injection of 30% polyethylene glycol solution (5 ml, sc); food was not available during the 8-hour test. Control and NTSX rats consumed comparable amounts of water $(6.1\pm2.0 \text{ ml})$, n=13; 7.4 ± 1.1 ml, n=10, respectively), with comparable latencies to drink. Because water intake during hypovolemia underestimates stimulus-evoked drinking due to the inhibitory effects of osmotic dilution, we also examined the intakes of 0.15 M NaCl during hypovolemia in these animals. Again, control and NTSX rats drank comparable amounts of saline in 8 hours (33±6 ml, 30 ± 4 ml, respectively). In neither of these tests did urine volume differ between the two groups. These results indicate that baroreceptor afferent signals arising from the heart and major blood vessels are not necessary for (HL-38786, MH-25140) drinking induced by hypovolemia in rats.

PERIVAGAL CAPSAICIN TREATMENT BLOCKS INCREASED FOOD INTAKE AND BRAIN FOS-LIKE IMMUNOREACTIVITY (FOS-LI) AFTER TREATMENT WITH 2,5-ANHYDRO-D-MANNITOL (2,5-AM). C.C. Horn and M.I. Friedman. Monell Chemical Senses Center, Philadelphia, PA, 19104, USA.

2,5-AM, a fructose analogue, increases food intake and brain Fos-li in vagal afferent pathways. We investigated whether these effects of 2,5-AM are mediated by afferent c-fibers by applying capsaicin to the cervical vagus nerve. Rats were given either perivagal capsaicin treatment (n=9)or sham surgery (n=7)at least 2 weeks before testing. Capsaicin-treated rats did not increase food intake after injection of 2,5-AM (200 mg/kg, i.p.) whereas sham-operated rats did. Furthermore, both groups of rats increased food intake in response to 2-deoxy-D-glucose, which stimulates food intake by a different neural pathway than 2,5-AM. To investigate the effects of capsaicin treatment on brain Fos-li after 2,5-AM, rats in each surgical group were reinjected with either saline or 2,5-AM. Preliminary data suggest that capsaicin treatment reduces Fos-li in vagal afferent pathways, but in a limited fashion. These results indicate that not all brain Fos-li expression after 2,5-AM is related to the effect of 2,5-AM on food intake, and that vagal afferents of the c-fiber variety, mediate the eating response to 2,5-AM. (This research was supported by NIH grants DK36339 and DC00014)

LESIONS OF THE COMMISSURAL REGION OF THE NUCLEUS TRAC-TUS SOLITARII REDUCE FOOD INTAKE AND BODY WEIGHT GAIN IN RATS. W.T. Talman*¹, E. Colombari², J.V. Menani³, and A.K. Johnson⁴. Depts. of Psychology⁴, Pharmacology⁴, and Neurology¹, and the Cardiovascular Center, Univ. of Iowa & VAMC, Iowa City, IA 52242; Dept. of Physiology³, School of Dentistry, Paulista State Univ., Araraquara, SP 14800 and Dept. of Physiology², UNIFESP-EPM, São Paulo, SP 0423-900, Brazil.

Previous studies have shown that lesions of the area postrema and adjacent nucleus tractus solitarii (NTS) alter food intake. We investigated the effects of an electrolytic lesion of the commissural subnucleus of the NTS (commNTS) on body weight, daily food and water intake, and plasma glucose and insulin in adult male Sprague Dawley rats. In the first 6 days after surgery, daily food intake was significantly (p<0.05) reduced in rats with commNTS lesions (7.1 \pm 2.2 g/24h; n=6) when compared with rats with sham lesions (18.1 \pm 1.8 g/24h; n=5). Subsequently, rats with lesions increased food intake, but their intake remained significantly reduced until the 12^{th} postoperative day (11.7 ± 2.9 vs 21.7 ± 0.9 g/24h). A signifireacted until the 12 postoperative day (1.7 ± 2.7 × 3.7 ± 1.7 ± 0.7 g ± 1.1 ± 0.7 g ± 1.0 × 3.8 gm⁻¹ cant reduction in body weight was observed 4 days after commNTS lesion and reached a maximum on the 12th day (283 ± 14 vs 378 ± 12 g). After the 12th postoperative day (283 ± 14 vs 378 ± 12 g). operative day partial recovery of body weight was observed, but weight remained significantly less in rats with lesions when compared with sham operated controls. Food intake and body weight gain in other rats with partial lesions (n=8) of the commNTS or with lesions outside the commNTS did not differ from sham rats. Daily water intake and plasma glucose and insulin were not changed by commNTS lesions. These results suggest that commNTS is involved with mechanisms that control food intake and body weight in rats. THE ROLE OF THE NUCLEUS OF THE SOLITARY TRACT IN TASTE AVERSION AND SODIUM APPETITE USING BRIEF INTAKE TESTS. R. Norgren*, P. Lyuboslavsky, K. Smith, and P.S. Grigson. College of Medicine, Penn State Univ., Hershey, PA 17033.

Six rats received bilateral electrophysiologically-guided electrolytic lesions (30 µA/30 sec) of the gustatory zone of the solitary nucleus (NST), 3 rats received SHAM lesions, and 3 rats served as non-surgical controls. Experiment 1: Rats were given repeated 10-sec access periods (total=30 min) to water plus 6 concentrations of citric acid and QHCl (dehydrated) and water plus 6 concentrations of sucrose and NaCl (rehydrated). Experiment 2: Taste aversion learning (CTA). Water deprived rats were given repeated 10-sec access periods (total=15 min) to 0.3 M alanine, and 15 min later, injected ip with LiCl (0.15 M, 1.33 ml/100g bw). Three taste-LiCl pairings occurred at 72 h intervals. Experiment 3: For NA+ appetite, intake of water and 6 concentrations of NaCl was evaluated across repeated 10-sec trials (total=30 min) 24 h following 2 sc injections of furosemide (7.0 mg/0.7 ml). The results showed that NST lesions (1) disrupted responsiveness to increasing concentrations of sucrose and OHCl, (2) suppressed the expression of a NA+ appetite, but (3) left the CTA intact. Previously, using a consumption test, similar NST lesions permitted expression of an attenuated NA+ appetite. Thus, NST damage may increase the access time required for some taste-guided behaviors. Supported by DC 00240, MH 00653, and DC 02016.

cFOS ACTIVATION OF CATECHOLAMINERGIC NEURONS IN THE DORSAL VAGAL COMPLEX AFTER LICI ADMINISTRATION IN RATS. R.C. Brown, E.A. Baker, L. Rinaman, E.M. Stricker, G.E. Hoffman, and J.G. Verbalis*. Interdisciplinary Program in Neuroscience and Department of Medicine, Georgetown University, Washington, DC 20007, and Departments of Neuroscience and Neurobiology, University

of Pittsburgh, Pittsburgh, PA 15260.

Expression of the immediate early gene product cFos in catecholaminergic neurons was evaluated in the medulla and hypothalamus of rats using double immunocytochemical labeling for cFos and tyrosine hydroxylase (TH) following administration of LiCI (3.0 mmol/kg) given ip as an isotonic (150 mM) solution. One hour after LiCl administration, 61±2% of TH-positive cells in the nucleus of the solitary tract (NTS) were activated as reflected by cFos expression versus 13±4% in controls given an equal volume of 150 mM NaCl (p<0.01). Similarly, in the ventrolateral medulla (VLM) 56±4% of TH-positive cells were activated to express cFos versus 17±6% in the controls (p<0.01). The results in the NTS are analogous to those of previous studies from our laboratories using CCK and food-induced gastric distension, while those in the VLM resemble those produced by CCK but not gastric distension. These data demonstrate relatively similar phenotypic and anatomical profiles of cells in the dorsal vagal complex that are activated to express cFos by LiCl, gastric distension, and CCK administration. Our results therefore suggest that both LiCl and CCK administration may mimic some of the anorexigenic effects of a large gastric distension by activating a common subset of catecholaminergic neurons in the NTS (supported by NIH grants NS28744 and MH25140).

UNILATERAL VAGOTOMY ATTENUATES C-FOS INDUCTION BY CHOLECYSTOKININ AND BOMBESIN IN THE CONTRALATERAL NUCLEUS OF THE SOLITARY TRACT. T.A. Houpi*, S.P. Frankmann, and R.A.

NUCLEUS OF THE SOLITARY TRACT. T.A. Houpt*, S.P. Frankmann, and R.A. Berlin. E.W.Bourne Behav.Res.Lab., Cornell Univ. Med.Coll., White Plains, NY, 10605 and Dept. Psychology, Univ. South. Colo., Pueblo, CO 81001.

The subdiaphragmatic vagus mediates the satiety effects of peripheral cholecystokinin (CCK) at low doses (< 8µg/kg), and of bombesin (BN) in the absence of spinal afferents. Spinal afferents can also mediate the satiety effects of CCK at high doses, and of BN in the absence of the vagus. The nucleus of the solitary tract (NTS) receives vagal and spinal afferent input, as well as descending forebrain input. To determine the relative contributions of the vagus and other inputs in activating the NTS after CCK or BN injections, we examined c-Fos induction in the NTS of unitaterally subdiabhragmatic vagotomized rats (uniVex). NTS of unilaterally subdiaphragmatic vagotomized rats (uniVgx).

Male rats (200g) underwent right or left uniVgx just below the diaphragm and

above the hepatic and celiac branches (n=16), or sham vagotomy (shamVgx;n=8). Five days later, rats received 1 mg Fluorogold (FG) i.p. Ten days after uniVgx, rats

Five days later, rate received CK (8μg/kg), BN (8μg/kg) or saline (1ml/kg) i.p. and were perfused after 1 h. Sections through the NTS were processed for c-Fos and FG immunoreactivity. UniVgx rats showed unilateral FG staining only in the dorsal motor nucleus ipsilateral to uniVgx, verifying axotomy of fibers projecting to the contralateral NTS. Saline induced litte or no c-Fos in the NTS of any rats. In shamVgx rats, CCK and BN induced numerous c-Fos cells in the NTS, and CCK induced more c-Fos in the area postrema (AP) than BN. In uniVgx rats, the c-Fos induced by both CCK and BN was reduced (but not eliminated) in the NTS contralateral to uniVgx; c-Fos in the AP and ipsilateral NTS was not reduced. This confirms the contribution of the vagus in mediating NTS activation by peripheral CCK and BN. The remaining activation of the contralateral NTS may be due to contralateral vagal input, spinal afferent input, or bilateral inputs descending from the forebrain.

NUCLEUS TRACTUS SOLITARIUS LESIONS BLOCK GASTRIC AFFERENT SIGNALS, J.C. Graham, A.M. Schreihofer, E.M. Stricker, and A.F. Sved. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Disruption of vagal afferent transmission from the gut either by gastric vagotomy or capsaicin treatment is known to block oxytocin (OT) release and the inhibition of food intake elicited by cholecystokinin (CCK) injection in rats. The present experiments examined whether these responses would be blocked by lesions of the nucleus tractus solitarius (NTS), the brain stem site to which vagal afferent nerves project. At least 10 days after placement of bilateral electrolytic lesions in the NTS, rats were deprived of food overnight and then were injected with isotonic saline (5ml/kg) or CCK (10μg/kg). Five min later, they were given access to pelleted rat chow for 30 min. Intact rats (n=10) given CCK decreased their food intake by $56\pm4\%$ of control values, whereas in NTS-lesioned rats (n=10) food intake was decreased only by 16±6%. Similarly, CCK-evoked OT release was markedly blunted in NTS-lesioned rats. Together, these results indicate that CCK-sensitive gastric signals are disrupted by NTS lesions in rats. One possible role of these afferents is to signal gastric filling during an ingestive episode, in which case rats with NTS lesions may not inhibit ongoing ingestion appropriately. To test this hypothesis, rats were maintained on a schedule of 30 min access to water per day and then were given a novel, sweet-tasting solution (10% pancake syrup) to drink in place of water. Control rats drank 25 ± 1 ml whereas NTS-lesioned rats consumed significantly more fluid (43 ± 4 ml). Collectively, these results suggest that NTS lesions disrupt afferent signals related to gastric distention that mediate food intake and neurohypophyseal secretion. (Supported by NIH grants HL-38786 and MH-25140, and by a fellowship to JCG from the American Heart Association, Pennsylvania Affiliate.)

556.18

AREA POSTREMA AND MEDIAL NUCLEUS OF THE SOLITARY TRACT LESIONS ATTENUATE THE EFFECTS OF MAMMALIAN BOMBESIN-LIKE PEPTIDE ON FEEDING. F.W. Flynn*. Dept. of Psychology and

Graduate Neuroscience Program, Univ. of Wyoming, Laramie, WY. 82071 Caudal brainstem systems play an important role in mediating the effects of bombesin (BN) on feeding. Within this area, lesions of the area postrema and adjacent nucleus of the solitary tract (AP/cmNST) attenuate the ability of BN to inhibit feeding. BN binds to the gastrin releasing peptide (GRP) and neuromedin B (NMB)-preferring receptors, both of which are found in the AP/cmNST region and would be damaged by lesions. In the following experiments the effects of AP/cmNST and medial NST lesions, on the ability of BN, GRP, and NMB to suppress feeding was tested. Controls, and rats with either AP/cmNST or medial NST lesions were administered 4, 8, or 16 μ g/kg BN, GRP, or NMB and milk intake by non deprived rats, and pellet chow by food deprived rats were measured. Injections of BN and GRP reliably suppressed milk intake in control rats. GRP had no effect on pellet intake in any of the food deprived groups. None of the doses of GRP and only the highest dose of BN suppressed milk intake in rats with AP/cmNST lesions. Medial NST damage produced deficits like those following AP/cmNST lesions and blocked the ability of GRP to suppress milk intake and prevented all but the highest dose of BN to suppress milk intake. None of the doses of NMB tested (up to 128 µg/kg) suppressed milk intake in control rats. The results suggest that damage to GRP-preferring receptors is largely responsible for the inability of BN and GRP to suppress feeding following AP/cmNST and medial NST lesions. (Supported by NIH NS24879 to F.W.F.)

ABLATING THE AREA POSTREMA (AP) ATTENUATES THE DECREASE IN FOOD INTAKE PRODUCED BY 5-CARBOXAMIDOTRYPTAMINE (5-CT) BUT NOT BY α-METHYL5-HYDROXYTRYPTAMINE (α-ME-5-HT). K. J. Simansky* and V. Adipudi. Department of Pharmacology, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129 USA

Peripherally administered 5-hydroxytryptamine (5-HT) reduces food intake by two mechanisms in rats. One involves the 5-HT1-like class of serotonergic receptor, for which the 5-HT analog, 5-CT, is an agonist probe; the other mechanism is mediated by 5-HT2-like receptors, which are probed by α-Me-5-HT. Recently, we reported that lesions in the area postrema (APX) blunted the action of high but not low doses of peripheral 5-HT to reduce food intake (Adipudi and Simansky, AJP, 1995, 269:1314-1320). As a follow-up, we tested the actions of 5-CT (vehicle, 0.015, 0.03, 0.06, 0.12 and 0.24 µmol/kg, i.p.) and α -Me-5-HT (2.0 and 5.0 μ mol/kg, i.p.) to decrease 30-min intake of sweetened mash 4 months after APX. All doses of 5-CT larger than 0.015 µmol/kg reduced intakes in controls (APC); only the highest dose did so in the lesioned rats. Both doses of α -Me-5-HT decreased intake in control and lesioned rats; the groups did not differ. These data demonstrate that the AP, or areas modulated by connections with the AP, mediate inhibitory effects of peripheral 5-HT₁-like stimulation on feeding. In contrast, peripheral 5-HT₂-like stimulation does not recruit AP-related activity during satiation. Supported by MH 41987 to KJS.

DOES AREA POSTREMA ABLATION (APX) AFFECT ACQUISITION OF CONDITIONED FLAVOR PREFERENCE? E. M. Knight, J. D. German and N. J. Kenney* Dept. of Psychology, University of Washington, Seattle, WA 98195.

Hungry rats develop preferences for cue flavors that are associated with the postingestive actions of nutrients during conditioning. It is known that vagal afferents from the digestive tract terminate within the area postrema and subjacent caudal-medial aspect of the nucleus of the solitary tract (AP/cmNTS) and that this brain region is rich in receptors for hormonally-mediated satiety signals originating in the gut. Further, ingestion of a CS+ for a conditioned taste preference elicits Fos expression in this hindbrain region (Emond et al., SSIB, 1995). Taken together, this evidence suggests that the AP/cmNTS may play a role in the learning or display of conditioned flavor preferences

The current study assessed the role of the AP/cmNTS in the acquisition of conditioned flavor preference. Days 30-39 post-surgery, AP/cmNTS-lesioned (APX) and sham-lesioned (SHMX) rats were trained to drink a 0.2% saccharin solution for 30 min/day and chow-restricted to 85% their free-fed post-surgery weight. Rats then received the saccharin solution mixed with either one cue flavor plus 16% Polycose (CS+US) or with another cue flavor with no Polycose (CS-) on alternate days over a 4-day training cycle. On each of the following two days, rats were offered both the CS+ and CS- flavors in a 15-min, 2-bottle choice test. Data for the two test days did not differ and were averaged. SHMX rats consumed 77.3±6.1% of their total test-day intake from the CS+ flavor. APX rats showed a nearly-identical preference for the CS+ flavor (76.1±6.0%). These data suggest that the AP/cmNTS region is not necessary for the acquisition of polysaccharide-based conditioned flavor preferences using a simultaneous conditioning procedure

HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR V

Estrogen regulation of mu- and delta- but not kappa-opioid receptor messenger RNA in the forebrain of female rodents. Vanya Quiñones-Jenab*, Shirzad Jenab, Sonoko Ogawa, Charles E. Inturrisi, and Donald W. Pfaff. The Rockefeller University and Cornell University Medical College, NY, NY, 10021.

Previous studies have suggested that opioids play a role in the

regulation of hormone-dependent reproductive behaviors in the female rat. The present study examined if estrogen treatment alters, the µopioid receptor mRNA levels in certain areas of the forebrain of ovariectomized (OVX) female rats and the $\delta\text{-and}\ \kappa\text{-opioid}$ receptors mRNA levels in the forebrain of OVX female mice using the *in situ* hybridization technique. We observed an increase in the µ-opioid receptor mRNA levels in the ventromedial nucleus of the hypothalamus (VMH) and arcuate nucleus (ARN) after 48 hr of 10 μg of 17-B-estradiol-3-benzoate (EB) treatment, when compared to OVX rats. No effects of estrogen were observed on μ -opioid receptor mRNA levels in the posterior medial nucleus of the amygdala (MeAmyg), hippocampus, and caudate-putamen (CPu). In OVX mice, 48hr-EB treatment increased the δ - but not κ -opioid receptor mRNA levels in the VMH, MeAmyg, and ARN, but not in the CPu . Our results suggest that the estrogenic regulation of μ - and δ -opioid receptor in the CNS may in part be mediated by de novo synthesis of the receptors' mRNA and/or stability of the messages. It is provocative to postulate that the regulation of opioid receptors' mRNA levels may be an important point in the regulation of opioid sensitivity during reproductive behaviors and/or pain control in the rodent CNS(supported by NIH Grant HO05751; NIDA: DA05130, DA00198, DA01457).

PROJECTIONS FROM FOREBRAIN AND MIDBRAIN AREAS TO THE MEDIAN EMINENCE AND NEUROHYPOPHYSIS IN THE FROG RANA PIPIENS. S. Burmeister* and W. Wilczynski. Department of Psychology and Institute for Neuroscience, Univ. of Texas, Austin, TX 78712.

Previous studies utilizing immunocytochemistry have identified several populations of cells that contain neuromodulators that are important in controlling reproductive behavior, such as arginine vasotocin (AVT), gonadotropin releasing hormone (GnRH), as well as tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamine We injected HRP into the caudal-most part of the hypothalamus at the median eminence and neurohypophysis of male frogs in order to determine which such populations of cells project to this area and therefore, may be neurosecretory. HRP filled cells were seen in the anterior preoptic area (aPOA), the magnocellular population of the preoptic area (mgPOA), the suprachiasmatic nucleus (SCN), the dorsal hypothalamus (DH), and more caudally in the ventral tegmental reticular formation. Fibers were seen in the POA, medially ventral to the hypothalamus throughout its extent, as well as in the dorsal and ventral hypothalamus. HRP cells in the DH and POA are similar to populations of TH containing cells, and HRP cells in the mgPOA may be similar to AVT containing cell populations. With these most caudal injections, no cells were seen rostral to the aPOA in regions known to contain LHRH-GnRH in frogs, such as the septal region, or AVT populations in the ventral striatum-accumbens and amygdalar areas. However, the ventral tegmental cells may be similar to chicken II GnRH containing cells. Supported by NIMH grant R01 MH 45696.

THE EFFECTS OF TESTOSTERONE ON TYROSINE HYDROXYLASE IMMUNOREACTIVE CELLS IN THE CNS OF MALE LEOPARD FROGS, *RANA PIPIENS*. <u>J. Chu* and W. Wilczynski</u>. Dept. of Psychology, University of Texas. Austin. TX 78712.

While gonadal steroids are known to control reproduction in vertebrates, and dopaminergic activity is believed to be one of the major neurochemical systems modulating sexual behavior in several taxa, little is known as to how these systems may act upon each other. Tyrosine hydroxylase (TH) is the rate limiting enzyme for the production of dopamine and other catecholamines in the CNS. We investigated how long term testosterone treatment influenced TH immunoreactivity (THir) in cells in the diencephalon of male frogs. Previous neuroanatomical studies indicate that the preoptic area (POA), suprachiasmatic nucleus (SCN), and dorsal and ventral hypothalamus (HYP) are areas that show strong THir labeling. These areas are also believed to be dopaminergic in nature. Adult male leopard frogs were gonadectomized and implanted with either a testosterone filled (N=7) or blank capsule (N=9). After 4 weeks, brains were removed and simultaneously processed for whole mount immunohistochemistry. All THir cells in the POA, SCN, HYP were counted and compared across treatments. Analysis of variance showed T implanted males had significantly more THir cell bodies in all three brain areas compared to castrates (p< 0.01). Planned comparisons showed treatment effect was significant for each brain region: POA (p<0.02), SCN (p<0.05), HYP (p<0.02). Given that the POA and HYP have been implicated as areas directly controlling reproductive behavior, and the SCN controls circadian rhythms, these results give indirect evidence that steroid induced TH expression may increase the production of dopamine in these areas and thus play a role in modulating sexual and seasonal behaviors. EFFECTS OF CASTRATION AND HORMONE REPLACEMENT ON NITRIC OXIDE SYNTHASE IN THE MEDIAL PREOPTIC AREA OF MALE RATS. J. Du, L. A. Lumley and E. M. Hull'. Psychology Department, State University of New York at Buffalo, Amherst, NY 14260. We have shown that the nitric oxide (NO) precursor, L-arginine, enhances

We have shown that the nitric oxide (NO) precursor. L-arginine, enhances dopamine (DA) release in the MPOA and that this enhancement is blocked by a NOS inhibitor (Lorrain & Hull, 1993). The NOS inhibitor also blocked DA release during copulation (Lorrain et al., in preparation), suggesting NO may be the permissive or enhancing factor for DA release in response to a female. Ovariectomy dramatically decreases NOS in female rats' MPOA (Okamura et al., 1994), and castration decreases apparent NOS staining in the penis of male rats (Baba et al., 1994). Since NADPH diaphorase histochemistry (NADPH-d) is the most used marker for

Since NADPH diaphorase histochemistry (NADPH-d) is the most used marker for NOS in the brain (Fang et al., 1994; Matsumoto et al., 1993; Wolf et al., 1992), we examined effects of castration and hormone replacement on NADPH-d in the MPOA of male rats. Two weeks following castration, there was no significant difference in NADPH-d stained neurons in the MPOA among castrated, sham castrated and hormone replaced rats. However, there were fewer NADPH-d stained neurons in the MPOA in one month castrates, compared to sham castrated and hormone replaced rats. Furthermore, no significant difference of NADPH-d activity was found in the paraventricular nuclei of castrated, sham castrated and hormone replaced rats.

We have shown that DA is released in the MPOA of male rats before and during copulation, and is critical for copulation, genital reflexes and sexual motivation. Recent testosterone is permissive for DA release and copulation. Findings of this study suggest that the permissive effects of gonadal hormones on copulatory behavior may be achieved in part by regulating the activity of NOS in the MPOA. NO may be one factor controlled by gonadal hormones that permits or enhances DA release in response to the estrous female. (Supported by NIMH grant, NH-40826 to EMH)

OVEREXPRESSION OF APLYSIA BAG CELL AND ATRIAL GLAND EGG-LAYING HORMONE PRECURSORS. A. Kurosky, E.L. Gorham, Z.-C. Yang, and J.E. Blankenship*. Depts. of Human Biological Chemistry and Genetics and of Anatomy and Neurosciences, Univ. Texas Medical Branch, Galveston, TX 77555

The egg-laying hormone (ELH) of Aplysia is a 36-residue neuropeptide synthesized within a precursor (preproELH) of 271 residues (region 206-241) in the bag cells. A related family of genes express an ELH-related precursor of 173 residues (preproA and preproB) in the atrial gland, an exocrine organ. We have expressed all three precursors including proELH, proA-ELH, and proB-ELH in a pRSET-related bacterial expression system. The prohormones were purified to homogeneity by HPLC. The proteins were characterized by compositional analysis, sequence analysis, and electrospray mass spectrometry. Results from protein analyses were in exact agreement with the predicted sequences obtained from nucleotide sequence analysis of the cDNA clones. Injection of 1 to 10 nmol of proELH into mature Aplysia did not cause egg-laying. ProELH injection was followed by ELH injection (5 nmol) as a control, and in all cases (n=8) egg-laying ensued. Processing of proELH with small aliquots of bag cell extracts demonstrated a predominant cleavage at the tetrabasic site RRKR¹⁸⁴ and also yielded free ELH. Strikingly, the processing of proELH with atrial gland extracts showed a different pattern of processing when compared with processing by bag cell extracts. (Supported by NIH grant NS 29261).

RECIPROCAL CONNECTIONS BETWEEN NEURONS IN THE MEDIAL AMYGDALA OF THE MALE SYRIAN HAMSTER THAT PROCESS CHEMOSENSORY OR HORMONAL SIGNALS. L.M. Coolen* and R.I. Wood Dept OB/GYN, Yale Univ Med School, Box 208063. New Haven. CT 06520.

In the male Syrian hamster, mating is dependent on chemosensory and hormonal stimuli and interruption of either input prevents copulation. The medial amygdaloid nucleus (Me) is a key nodal point in the neural circuitry controlling male sexual behavior because it relays both odor and steroid cues. Me is comprised of two major subdivisions. The anterior subdivision (MeA) receives the majority of chemosensory input from the olfactory bulbs, whereas the posterior subdivision (MeP) contains the majority of steroid receptor-containing neurons. The aim of the present study was to elaborate on the connections linking the two subdivisions of Me. Specifically we tested the hypothesis that reciprocal connections exist between steroid-responsive neurons in the MeP and neurons in the MeA that relay chemosensory information.

To test this hypothesis anterograde (Pha-L) and retrograde (Fluoro-gold; FG) tract

tracers were injected in Me through a single glass micropipette by iontophoresis. Following injections into MeA, sections were stained for Pha-L, FG and androgen receptor-immunoreactivity (AR-IR), to determine if steroid-responsive neurons in MeP have reciprocal connections with MeA. For injections in MeP, sections were stained for Pha-L. FG and Fos-IR induced by chemosensory stimulation, to identify neurons activated by chemosensory cues which are connected with MeP. Following tracer activated by Chemosenson's cues which are connected with IACL From East.

Injections in MeA, AR-IR neurons in MeP retrogradely labelled with FG were in close apposition to fibers and terminals labelled with Pha-L. Moreover, neurons expressing Fos in MeA after chemosensory stimulation projected and appeared to receive projections from the injection site in MeP.

These results demonstrate reciprocal connections between neurons in the chemosensory and the hormonal circuits within Me. They provide anatomical evidence for neural coordination of chemosensory and hormonal cues in the Syrian hamster brain. (Supported by NIH HD-32669).

EFFECT OF CHRONIC ICV INFUSION OF NPY IN LACTATING AND NONLACTATING RATS. B. Woodside* and C. Beaulé. Center for Studies in Behavioral Neurobiology, and Department of Psychology Concordia University, Montréal, Canada.

Neuropeptide Y (NPY) has been implicated in the control of both food intake and the hypothalamic-pituitary-gonadal axis and chronic NPY infusions have been shown to suppress cyclicity in female rats. We investigated the possibility that the increased levels of NPY observed in food restricted lactating rats might contribute to their prolonged period of lactational diestrus by determining the effects of chronic icv NPY infusions on the length of lactational diestrus in ad lib fed lactating rats. NPY or vehicle was infused into the right lateral ventricle via an indwelling cannula attached to an osmotic minipump from Day 12 to Day 19 postpartum at a daily dose of NPY of 14.4µg/rat. To compare the effects of NPY infusions between lactating and cycling animals, virgin females received similar treatments. Consistent with previous reports, NPY infusion resulted in an increase in food intake and bodyweight in virgin females together with a suppression of vaginal cyclicity. Lactating females receiving NPY infusions showed a shorter period of lactational diestrus than vehicle-treated controls. NPY infusions also caused a suppression of milk production and/or letdown as reflected in a reduction in litter growth. It is possible that both of these effects result from the ability of NPY to suppress prolactin release . (Supported by MRC Grant #MA10158 to B.W.)

GONADOTROPIN RELEASING HORMONE MODULATES EXCITABILITY OF SALAMANDER OLFACTORY RECEPTOR NEURONS. H.L. Eisthen*, R.J. Delay, and V.E. Dionne. Boston University Marine Program, Marine Biological Laborator Woods Hole, MA 02543.

The bipolar cells of the terminal nerve extend their fibers into the nasal epithelium and hypothalamic/preoptic area, and contain gonadotropin releasing hormone (GnRH). Although the terminal nerve has generally been considered to serve a sensory function, recent evidence indicates that it may play a role in modulating neuronal activity. In teleost fishes, a branch of the terminal nerve projects to the retina, and the excitability of goldfish retinal ganglion cells has been shown to be modulated by GnRH and other terminal nerve-derived compounds. Although the olfactory and vomeronasal epithelia contain receptors for GnRH, the physiological effect of GnRH on these sensory neurons has received little attention. We are investigating the possibility that excitability of olfactory receptor neurons in an aquatic salamander, the mudpuppy Necturus manulous, is modulated by mammalian GnRH (mGnRH), the form of GnRH that is present in the terminal nerve of amphibits. It lists wholesell native recording from olfertory of the control of th The bipolar cells of the terminal nerve extend their fibers into the nasal epithelium and is modulated by maintainan Girkel (mighty), the form of Girkel that is present terminal nerve of amphibians. Using whole-cell patch recordings from olfactory epithelial slices, we find that a substantial increase in the magnitude of the inward, voltage-activated Na* current is observed within 10 min of application of 10 µM wordinge-activated in a current is observed within 10 min or application or 10 July mGnRH. The magnitude of the Na* current continues to increase for at least 30 min in mGnRH, and the effect is reversible. Under different recording conditions, we have observed that application of mGnRH causes a reversible shift in activation of an outward current. Substitution of Cs* for K* in the intracellular solution eliminates this effect. indicating that GnRH may affect a K* current. The activation profile indicates that this current may be Ca 2+ dependent. We are presently conducting experiments to determine whether mGnRH affects this current directly, or through an indirect effect on Ca 2 conductances. Taken together, these data indicate that GnRH from the terminal nerve modulates excitability of salamander olfactory receptor neurons.

INCREASED STAINING FOR NPY IN THE ARCUATE NUCLEUS OF FOOD RESTRICTED, LACTATING RATS. PERSISTS AFTER REFEEDING A. Abizaid*1, C.-D. Walker2, and B.C. Woodside1. 1Center for Studies in Behavioural Neurobiology, Concordia University and ²Douglas Hospital Research Center, McGill University, Montreal, Canada.

In rats, food restriction from days 8-14 of lactation prolongs lactational diestrus. Neuropeptide-Y (NPY) may play an important role in the central mechanisms prolonging lactational acyclicity since it is known that NPY inhibits LH release in the absence of steroid hormones. Using immunocytochemistry we determined whether 1) food restricted (FR) lactating rats would show an increased number of cells in the ARC showing dense staining for NPY at the end of the food restriction period and 2) if so, how long this effect would persist after refeeding. On Day 2 pp all rats were implanted with cannulae in the right lateral ventricle. Rats were sacrificed on either Day 15 or Day 20 pp, 24hrs after colchicine treatment. To determine whether any differences in NPY staining reflected an influence of nursing underfed pups, in other groups of dams, litters were switched daily between ad lib fed (AL) and FR females between Days15 and 20 pp. After perfusion with saline and paraformaldehyde brains were processed for NPY immunocytochemistry. More cells stained for NPY in FR than AL rats on Day 15 and Day 20 pp(p< .05) in both switched and unswitched litter conditions. These findings suggest that cell bodies within the ARC of food restricted lactating rats continue to show evidence of high levels of NPY five days after the food restriction is terminated. Elevated levels of NPY may play a role in inhibiting reproductive function in food restricted lactating rats.(Supported by Grant #MT 10158 from MRC to B.W.)

STRESS UP-REGULATES PREPROENKEPHALIN (PPE) mRNA

STRESS UP-REGULATES PREPROENKEPHALIN (PPE) mRNA LEVELS IN THE LIMBIC SYSTEM AND HYPOTHALAMUS OF THE FEMALE RAT. C. B. Eckersell*, P. Popper AND P. E Micexych Dept. of Neurobiology and Lab. of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90095.

Estrogen injection causes an early rise in PPE gene expression (peak at 1 hour) in the ventromedial hypothalamic nucleus (VMH) and the posterior dorsal medial amygdala (MeApd) followed by a nadir at 4 hours and a second rise in PPE mRNA which reaches maximal levels at 24 hours. Acute stress has also been shown to increase enkephalin gene expression in the hypothalamus. To investigate the source of PPE mRNA induction in the VMH and MeApd, ovariectomized female rats were given estradiol benzoate (EB; 50 µg in 0.2 ml safflower oil) or the estrogen receptor blocker tamoxifen (TMX; 20 mm Silastic capsule) followed by either an injection of EB or safflower oil vehicle. Animals were sacrificed at the time of injection or 1, 4 or 24 hours later. Brain sections were processed by in situ hybridization for PPE mRNA. Serum glucocorticoid levels were higher at 1 hour in both oil and EB injection groups than at any other time point. EB alone induced a significant increase in PPE mRNA levels in the VMH and MeApd at 1 and 24 hours. In the oil and EB plus TMX treated animals PPE mRNA levels were elevated at the 1 hour time point only. These findings indicate that early increases observed in PPE mRNA levels within the VMH and MeApd may be due to stress which increases glucocorticoid levels rather the direct effect of estrogen. Since it was blocked by TMX, the 24 hour peak in PPE mRNA levels appears to be induced by EB. Supported by NS-21220 and HD-07228.

ACUTE ESTROGEN STIMULATES CHOLECYSTOKININ (CCK) mRNA EXPRESSION IN THE LIMBIC-HYPOTHALAMIC CIRCUIT OF THE FEMALE RAT. P. E. Micevych*, C. B. Eckersell and K. Sarrafzadeh. Department of Neurobiology and Laboratory of Neuroendocrinology, Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90095.

Reproductive behavior in the female rat has been correlated with the estrogenic regulation of CCK in the hypothalamus and the limbic system. Estrogen induces an increase of CCK mRNA in the central part of the medial preoptic nucleus (MPNc) principal portion of the bed nucleus of the stria terminalis (BSTp) and the posterodorsal medial amygdala (MeApd). To determine if a brief exposure to estrogen was sufficient to elevate CCK mRNA levels, ovariectomized rats were treated with nothing; estradiol benzoate (EB; 50 µg in 0.2 ml safflower oil injected s.c.); EB preceded by the antiestrogen TMX (20 mm Silastic capsule implanted s.c.) 48 hours prior to EB injection; or EB followed by TMX (20 mm Silastic capsule and 300µg in 0.15 ml safflower oil injected s.c.) 2 hours after EB. All animals were sacrificed 24 hours after EB injection and tissue was processed for CCK mRNA in situ hybridization histochemistry. Estrogen treatment caused a significant increase in the CCK mRNA levels within the MPNc, MeApd and BSTp as previously reported. This increase was blocked by TMX administration prior to estrogen treatment but was not blocked by TMX treatment 2 hours after estrogen administration. These findings indicate that continuous estrogen exposure is not necessary to stimulate CCK mRNA in the MPNc, BSTp and MeApd. A brief exposure to estrogen initiates a cascade of events that up-regulate CCK mRNA expression and Supported by grant NS-21220 and HD-07228.

ESTROGEN INDUCES AXONAL OUTGROWTH IN THE NUCLEUS RETROAMBIGUUS-LUMBOSACRAL MOTONEURONAL PATHWAY IN THE ADULT FEMALE CAT. V.G.J.M. VanderHorst* and G. Holstege. Department of Anatomy, University of Groningen. The Netherlands.

Anatomy, University of Groningen, The Netherlands.

Recently, a motor pathway has been discovered in the cat which has been postulated to form the final pathway for male mounting (VanderHorst and Holstege, 1996) and female receptive or lordosis behavior (VanderHorst and Holstege, 1995). The pathway originates from the nucleus retroambiguus (NRA), a compact group of interneurons in the caudal medulla, and terminates directly in distinct lumbosacral motoneuronal cellgroups. The question is whether in female cats estrogen has an effect on this NRA-lumbosacral pathway, because only

cats estrogen has an effect on this NRA-lumbosacral pathway, because only females in estrous display lordosis behavior.

Light microscopically, the effect of estrogen on the NRA-lumbosacral and the rubrospinal tracts was studied in 20 cats using wheat germ agglutinin-horseradish peroxidase (WGA-HRP) as a tracer. The rubrospinal pathway served as control. The density of labeled NRA fibers in their target motoneuronal cell groups appeared abundant in estrous and very weak in non-estrous cats, while such differences were not found in the rubrospinal pathway. Electromicroscopical examination of the NRA-semimembranosus motoneuronal projection in 8 cats revealed that labeled terminals in estrous cats were larger and were almost 10 times as numerous than in non-estrous cats. Moreover, in the semimembranosus motoneuronal cell group WGA-HRP labeled growth cones were found in estrous but not in non-estrous cats. Such growth cones appeared to contain growth associated protein (GAP-43). These observations demonstrate that estrogen induces axonal outgrowth of NRA fibers to distinct somatic motoneuronal cell groups, which lends further support to the hypothesis that the NRA is involved in lordosis behavior. The possible mechanisms underlying this outgrowth are discussed.

THE ROLE OF THE CORTICO-MEDIAL AMYGDALA IN HAMSTER SOCIAL ODOR RECOGNITION. A. Petrulis*, M. Schiller, M. Peng and R. E. Johnston. Department of Psychology, Cornell University, NY 14853.

Hamsters, like many mammals, are capable of discriminating a conspecific's sex, species and individual identity on the basis of their odors. Although these abilities appear to be common-place, the neural mechanisms underlying individual discrimination or other forms of recognition have not been well characterized. To investigate this topic further, we have focused on the vomeronasal organ and its projections to the medial and cortical amygdala as a possible neuroanatomical substrate for individual as well as other types of social odor discrimination. Males with complete removal of the vomeronasal organ did not discriminate between individual scents (using a habituation paradigm) on the basis of three of the four odors used. Sham males were able to discriminate using all four odors; males with partial vomeronasal organ damage showed intermediate results. Thus, the vomeronasal organ plays an important but not exclusive role in individual odor discrimination. In contrast, females with lesions to the cortico-medial amygdala were able to individually discriminate two of the same odors used with males. However, females showed impairments in sex odor discrimination attraction and had decreased levels of scent marking. This apparent discrepancy in individual discrimination ability after lesions may be a result of a true sex difference in vomeronasal usage or may indicate that other vomeronasal system target structures are involved. This research was funded by NIH and NSF grants to R.E.J and by a NRSA to A.P.

MEDIAL PREOPTIC AREA LESIONS DO NOT INCREASE HYPOTHALAMIC ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN JUVENILE FEMALE GUINEA PIGS. <u>Deborah H. Olster*</u>, Psychology Department, University of California, Santa Barbara, CA 93106.

Department, Oriversity of Cathoritus, and Barbarda, CA 95100.
Ovariectomized (OVX), juvenile guinea pigs rarely display lordosis following injections of estradiol and progesterone that are behaviorally effective in adults. A previous study has documented a smaller population of estrogen receptor-immunoreactive (ER-IR) cells in the rostral, ventrolateral hypothalamus (VLH) of OVX juvenile, as compared to adult guinea pigs (Olster, 1994). Electrolytic lesions of the medial preoptic area (MPOA) accelerate the maturation of adult-typical lordosis responses to estradiol and progesterone in OVX guinea pigs (Olster, 1995). This study was designed to test the hypothesis that MPOA lesions result in enhanced behavioral responsiveness to estradiol and progesterone in juvenile females, at least in part, by increasing the concentration of ERs in the VLH. Hartley guinea pigs were OVX at 10-11 days of age and received bilateral, electrolytic (1.5 mAMP X 10 sec) or sham lesions aimed at the MPOA 4 days later. At 21 days of age, all animals were transcardially perfused and hypothalamic tissue was processed for ER-immunostaining, using Abbott Laboratories' H222 anti-ER antibody. No significant differences in the number or staining intensity of ER-IR cells in the paraventricular nucleus, arcuate nucleus or VLH were observed in MPOA-lesioned vs. sham-lesioned animals. These data do not support the hypothesis that MPOA lesions enhance behavioral responsiveness to estradiol and progesterone in prepubertal guinea pigs by increasing the concentrations of ERs in the VLH; the facilitation of sexual receptivity following lesion of the MPOA appears to result from other, as yet unknown, mechanisms.

CLONING OF MULTIPLE GENES FOR GONADOTROPIN RELEASING HORMONE (GnRH) IN A SINGLE SPECIES. Richard B. White and R. D. Fernald*. Program in Neuroscience, Stanford University, Stanford, CA 94305-2130.

Recent experiments suggest that multiple GnRH peptides and thus multiple GnRH genes exist in all vertebrate classes. The African cichlid fish Haplochromis burtoni is a unique model for understanding possible functions of alternate GnRHs because it expresses three different forms, each in a distinct brain region. As a first step in studying the possible coordinate regulation of the genes encoding GnRH, we have isolated genomic clones by screening a *H. burtoni* genomic library using DNA probes transcribed from the three distinct GnRH cDNAs previously isolated from this species (White et al. 1995). The clones were then used for Southern blot analysis, which revealed that each gene is present as a single copy. Upstream regulatory sequences of the genes were compared to existing data from salmon, chicken, rat, mouse, and human GnRH genes. The complete sequences of multiple GnRH genes in a single species should provide key information for decoding the phylogenetic relationships between the various GnRH forms that exist in vertebrates.

MOLECULAR CHARACTERIZATION OF A NOVEL EPILEPSY GENE. G.P. Donovan.* L. Ho, and M. Toth. Department of Pharmacology, Cornell University Medical College, New York, NY 10021.

We have identified a mouse gene named *jerky* that, when disrupted by insertional mutation, causes epileptic seizures. Using a multifaceted approach, we examined the function of *jerky* and how its deletion can lead to epileptic seizures. First, we studied the spatial distribution of *jerky* in order to correlate the site of its expression with the seizure focus. We have utilized quantitative RT/PCR and *in situ* hybridization to achieve this. While *jerky* is predominantly expressed in the brain, it can be detected in many other organs. However, the highest expression within the brain was found in the neocortex and especially the hippocampus, which correlates well with the site of seizure initiation. As a secondary approach, we studied the developmental expression of *jerky* and found that expression is highest at postnatal day 5, corresponding to the formation of neuronal synapses. Therefore, *jerky* could play a critical role in maintaining proper neuronal function and suppressing hyperexcitibility. Finally, we examined the molecular functions that jerky protein plays in neurons. Affinity chromatography studies have shown the jerky protein preferentially binds single stranded DNA. In order to delineate the specific sequence(s) to which the jerky protein binds, we have used PCR-based site selection to identify a series of specific single stranded sequences. These sequences were then verified to bind jerky protein by testing in electrophoretic mobility shift assays. Taken together, we suggest that expression of *jerky* is involved in the development and maintenance of neuronal function, especially in the hippocampus, by binding single stranded DNA. Presently, we are focused on the identification of cellular processes (such as DNA replication, repair, and recombination) that may be linked to *jerky* function. Supported by NIH ROINS34151-01A1.

INDUCTION OF FRA-2 BUT NOT FRA-1 mRNA IN HIPPOCAMPAL NEURONS FOLLOWING EPILEPTIC SEIZURES IN RATS: <u>J. Beer*, M. Zimmermann and T. Herdegen</u>. II. Physiologisches Institut, Universität Heidelberg, 69120 Heidelberg, Germany.

Inducible transcription factors (ITFs) are among the first genes expressed in neurons after stimulation. ITFs are thought to play a specific role in coupling neuronal stimulation by regulating the expression of target genes. Dependent on the stimulus (i.e. axotomy or transsynaptic stimulation), different sets of ITFs are transiently or persistently expressed. We investigated the spatiotemporal expression of fos-related antigens 1 and 2 (fra-1 and fra-2) after epileptic seizures with kainic acid, a model for human temporal lobe epilepsy.

Kainic acid was injected i.p. (10 mg/kg in 0.9% saline) into adult male Sprague-Dawley rats. The expression of fra-1 and fra-2-specific mRNA was investigated by in sith lybridization (ISH) after recovery periods of 0.5, 1, 3 and 6 h. Fra-specific oligonucleotides and cRNA were labelled with ³⁵S using terminal deoxynucleotide transferase or the T3/T7 transcription system (Promega, Heidelberg, Germany), respectively. ISH with both types of radiolabelled probes revealed strong expression of fra-2 in the dentate gyrus and moderate expression in the CA-regions of the hippocampus 6 h postinjection. Only minor expression was detected of fra-1-specific mRNA at all times investigated. fra-1 and fra-2 contain the same regulatory elements in their promoter region but not in analogous positions (Foletta et al. 1994, Oncogene 9;3305-3311). We suggest that this may cause differential regulation and consequently different expression patterns of these ITFs.

ACUTE EFFECTS OF C-FOS ANTISENSE OLIGO-NUCLEOTIDE ON HIPPOCAMPAL PARTIAL SEIZURES ELICITED BY ELECTRICAL STIMULATION IN RATS. H. Katsumori^{1,2*}, K. Hashimoto¹, S. Tomitaka¹, N. Narita¹ and Y. <u>Minabe¹</u> Div. of Cortical Function Disorder, Natl. Inst. of Neurosci., NCNP, Tokyo, 187, Japan; Dept. of Pediatr., Tokyo Women's Med. Collage, Tokyo, 162, Japan.

To investigate the role of c-fos in the brain during seizures, we examined the effects of phosphorothioate antisense oligodeoxynucleotides (ODNs) to c-fos mRNA on hippocampus-generated partial seizure model of epilepsy in Wistar male rats. As control, sense and scrambled control ODNs were also tested. Each ODN (10 nmol/10 µl /2 min) was injected into lateral ventricles for consecutive 2 days. 15 hrs after the last injection, electrical stimulations were delivered to assess the effects of each ODN on the two seizure parameters; seizure threshold and afterdischarge duration (ADD). 1 hr after seizures, c-Fos and Jun-B immunohistochemistries of the brain were also performed. The results were obtained as follows: 1) Antisense ODNs decreased ADD selectively and control ODNs failed to change any parameters at tested doses. 2) In antisense ODNs group, ipsilateral c-Fos expression occurred to the stimulation site of dentate gyrus, while Jun-B expression bilaterally. In the major cases of control ODNs groups, c-Fos and Jun-B expression occurred bilaterally. These results indicate that the injection of antisense ODNs selectively inhibit c-Fos expression and c-fos plays some roles in seizure phenomenon. This research was supported by the research grant from the Ministry of Health and Welfare, Japan.

TRANSPOSON MARINER IN THE HUMAN BRAIN: ITS POSSIBLE IMPLICATION IN HUMAN EPILEPTOGENESIS. H. Xie*. M.L. Brines, and N.C. de Lanerolle, Sections of Neurosurgery and Neuroendocrine Program, Yale Univ. Sch. of Med., New Haven, CT.06520

oniv. Sch. of Maci, New Haven, C. 1.00520
mRNA differential display methodology was used to identify genes which are differentially expressed in epileptogenic tissue. We applied this methodology to human hippocampal tissue surgically removed from temporal lobe epilepsy patients and normal autopsy controls. Among the many differentially displayed bands, one band of 320 base pairs was found to be 70% similar in its DNA sequence to the invertebrate transposon mariner. The mariner was first discovered in Drosophila mauritiana due to its ability to mutate the eye color gene. Conservative estimates suggest that transposons are responsible for 0.5-0.1% of mutations within the human genome. We cloned both the genomic copy and the full length mRNA of the human mariner gene. This gene has an open reading frame coding for a transposace of 345 amino acids, contains the characteristic 32 base pair inverted terminal repeats (TR), and the insertion site TA dinucleotide duplication. There are ~60 copies of this gene in the human genome. Northern blot analyses demonstrated an elevated level of mariner transcription in human epileptogenic tissue compared to tissue from autopsy controls. Neither the mariner gene nor its transcripts were detectable in rat, pig or chicken. At the nucleotide sequence level, mariner transposons isolated from human epileptogenic tissue share more than 95% of their nucleotide sequence, while those from normal human genomic DNA share less than 80%. Database search showed that a copy of mariner exists in the T cell receptor gene (TCRB) as well as in the Abelson leukemia oncogene intron 1b. Interestingly, one ITR "signature" of the mariner transposon is located in the human HLA locus in chromosome 6p21.3, which has previously been linked to juvenile myoclonic epilepsy (JME). Further suggestion that mariner may be relevant for neurologic disease is the recent report of spressence within a recombination "hotspot" on chromosome 6p21.3, which has previously been linked to juvenile myoclonic epilepsy. INDUCTION OF TRANSCRIPTION FACTORS IN ABSENCE SEIZURE MODEL MICE Y. Ito*, K. Ishige, M. Aizawa, and H. Fukuda. Department of Pharmacology, College of Pharmacy, Nihon University, Funabashi 274, Japan

The cerebral cortical and thalamic circuitry has been shown to play an important role in the genesis and spreading of absence seizures. We have shown that GABA_B receptors play an important role in y-butyrolactone-induced absence-like seizures (GHB model) and that the increase in nuclear cyclic AMP responsive element (CRE)- and activator protein 1 (AP-1) DNAbinding activities in the cerebral cortex and thalamus is correlated with these seizures. In this study, we compared nuclear CRE-and AP-1 DNA-binding activities in lethargic (Ih/Ih) mice, a genetic model of absence seizures, with those in nonepileptic control mice (+/+). Electroencephalogram recording showed spike and wave discharges spontaneously accompanied by seizure behavior in lethargic mice at 3 weeks of age and older. Nuclear extracts were prepared from various brain regions of age-matched (3 to 6 weeks of age) lethargic and control mice. Gel-shift assay showed that nuclear CRE- and AP-1 DNA-binding activities in the cerebral cortex and modernic were higher than those in control mice. In contrast, in the hippocampus, no difference of these DNA-binding activities was a between lethardic and control mice. These results activities in the cerebral cortex and thalamus in lethargic mice suggest that the increase in nuclear CRE- and AP-1 DNA-binding activities in the cerebral cortex and thalamus is correlated with absence seizures in both lethargic mice and the GHB model Supported by Uehara Memorial Foundation.

SEIZURE-INDUCED EPILEPTOGENESIS AND THE GENERALIZED SEIZURE PHENOTYPE DETERMINE THE PATTERN OF FOS INDUCTION IN MOUSE BRAIN. G.M. Samoriski, D.T. Piekut and C.D. Applegate. Program in Neuroscience, University of Rochester School of Medicine, Rochester, NY 14642.

We have shown that 8 daily consecutive generalized clonic seizures promote reorganizational processes that require time to develop. The evolution of these processes occurs in the absence of continued seizure induction and is manifest predominantly as a change in the behavioral seizure response. The behavioral shift is significantly altered by 2 wks and is characterized by an increase in the probability that the animal will express a "brainstem" seizure. Because the modified seizure susceptibility is defined by a change in the type of motor convulsion that is expressed, the activation of structures selectively involved in the expression of generalized seizure behaviors may be altered in response to subsequent ictal events. Thus, Fos immunohistochemistry was used to evaluate the degree of neuronal activation on the basis of the seizure phenotype and the seizure history. Generalized seizures were elicited in C57BL/6J mice using flurothyl and classified as either "forebrain" or "brainstem". Fos immunoreactivity was then examined 1.5 hrs following either a single generalized seizure, the last of 8 consecutive daily seizures or a retest seizure evoked 2 wks after the last of 8 seizures. The predominant differences in Fos labeling were related to the type of seizure expressed regardless of the seizure history. Furthermore, the different motor components that make up a "brainstem" seizure could not be distinguished by the pattern of Fos labeling suggesting that multiple convulsive behaviors are mediated by one anatomical system. While Fos induction in the ventromedial (VMH) and paraventricular hypothalamic nuclei and hippocampal dentate gyrus was influenced by the seizure history, changes in the degree of Fos labeling in the VMH most closely paralleled alterations in the behavioral response. These data support the concept that separate anatomical systems mediate the expression of the two generalized seizure phenotypes. Also, the VMH may be a point of interaction between the systems and may play a role in seizure-induced neural reorganization. (Supported by NIH grant NS26865)

BEHAVIOR AND FOS ACTIVITY IN AUDIOGENIC SEIZURE-PRONE LONG-EVANS RATS WITH TECTAL GRAFTS. K.C. Ross¹ and J.R. Coleman. Depts. of Psychology¹ and Physiology², Univ. of South Carolina, Columbia, SC 29208.

The goal of this research is to examine a novel model for audiogenic seizure activity with grafting in Long-Evans (L-E) rats. Previous AGS research has utilized mainly albino rat strains. Subjects (n=8) primed for AGS at PND 14 by exposure to 10 KHz tone bursts for 8 m. at 120 dB p.e. SPL were tested for AGS at PND 24 using 120 dB white noise. Subjects were observed as displaying no seizure activity, wild running only, or wild running followed by clonus.

Subjects were lesioned in the right IC and grafts of whole fetal caudal

Subjects were lesioned in the right IC and grafts of whole fetal caudal tecta were implanted in the lesion site following the method of Zrull and Coleman (1991). Subsequent behavioral testing show that the lesion and graft reduced the incidence of clonus, increased observations of no seizure activity, and increased the incidence of wild running alone (pc.000). Onset latency before lesion and graft (M=33.95 s, SD=12.57) was significantly shorter than after lesion and graft (M=38.4 s, SD=12.29; p<.03). Onset duration before lesion and graft (M=22.16 s, SD=9.01) was significantly longer than after lesion and graft (M=18.65 s, SD=12.21; p<.05).

Alternate sections processed for Fos immunochemistry and Nissl stains reveal 14-month graft survival. Host animals display higher stimulus-driven Fos activity in the dorsomedial IC than in other IC sectors and graft.

These data suggest that unilateral lesion and graft alleviate some aspects of seizure activity and identify a focus of Fos expression. The exact role of the graft-host interaction is under further investigation. (Supported by the Deafness Research Foundation and NSF SBR-00285)

LONG-TERM INHIBITION OF CA²⁺/CALMODULIN-DEPENDENT PROTEIN KINASE II ACTIVITY IN A MODEL OF PARTIAL COMPLEX (LIMBIC) EPILEPSY. LD. Kochan¹⁺, S.B. Chum², A.C. Rice² and R.J. DeLorenzo¹⁻². Departments of Pharmacology and Toxicology¹ and Neurology², Medical College of Virginia, Richmond, Virginia 23298.

Status epilepticus (SE) is a severe seizure disorder associated with significant morbidity and mortality and can induce spontaneous recurrent seizures (SRSs). The pilocarpine-induced SE model of limbic epilepsy is a major *in vivo* model used to investigate spontaneous recurrent seizure discharges and has many of the clinical and pathological features of limbic epilepsy. Cal*/Calmodulin-dependent protein kinase II (CaM kinase II) plays an important role in signal transduction. Alteration in the activity of this enzyme has been reported in pathological states including stroke and several models of epileptiform activity. Thus, this study was initiated to investigate changes in CaM kinase II activity associated with persistent plasticity changes, utilizing the well-characterized pilocarpine model of limbic epilepsy. CaM kinase II activity was determined by a measurement of 3 P incorporation into α and β -CaM kinase II subunits. We determined that there is a statistically significant reduction in the α (44%) and β (19%) CaM kinase II subunit autophosphorylation, measured in whole brain homogenates, isolated from epileptic compared to sham control animals 4-6 weeks after pilocarpine-induced SE. To evaluate hippocampal CaM kinase II activity, we prepared hippocampal homogenates from control and epileptic animals at 4-6 weeks after pilocarpine-induced SE. Prolonged seizure activity resulted in a long-term decrease in hippocampal α - and β - CaM kinase II activity by 49 and 35%, respectively. These results indicate that long-lasting decreases in CaM kinase II activity are associated with the persistent seizures observed in the pilocarpine model of limbic epilepsy and suggests that long-term decreases in CaM kinase II activity way contribute to the long-lasting plasticity changes in brain that accompany epileptogenesis. This work was supported by RO1-NS23350.

DIFFERENTIAL EXPRESSION OF THE INDUCTABLE 72-kDa HEAT SHOCK PROTEIN FOLLOWING KAINIC ACID-INDUCED SEIZURES IN IMMATURE AND ADULT RATS. <u>U. Branner ¹, E.F. Sperber ², S.L. Moshé* ² and <u>M.T. Romero ¹. ¹ Department of Psychology, State University of New York at Binghamton, Binghamton, NY 13902; ²Albert Einstein College of Medicine, NYC, NY 10461.</u></u>

The inductible form of heat shock protein (HSP72) is expressed in various areas of the brain of adult rats following kainic acid (KA) seizures (Gass et al., 1995; Armstrong et al., 1995). The level of expression of HSP72 is correlated with the intensity of the seizures and, to some extent, localized to areas susceptible to seizure-induced neurodegeneration.

We have previously reported that the immature brain (5-25 days) appears to be resistant to damage following KA-induced seizures (Sperber et al., 1991). In the present study we compared the immunocytochemical expression of HSP72 in the adult and immature brain (postnatal day 14) following doses of KA which produce status epilepticus in both groups (15mg/kg and 4mg/kg, respectively).

adult and infimature train (positional tay 14) following ookes of KA which produce status epilepticus in both groups (15mg/kg and 4mg/kg, respectively). Preliminary data indicate that HSP72 is extensively induced in the adult brain throughout the hippocampus and other limbic structures following status epilepticus in comparison to adult controls. In contrast, in the immature brain there is little or no expression of HSP72 immunoreactivity following KA-induced scizures or saline injections. These differences between the adult and immature brains are found at 12, 24, and 36 hrs following KA injection. Further studies are necessary to determine whether the immature brain may have an earlier induction of HSP72 which is not detected at the times used in this study. These results further demonstrate the immature rat are resistant to seizure induced damage.

ATTENUATION OF KINDLING-INDUCED DECREASES IN NT-3 mRNA BY THYROID HORMONE DEPLETION. J.B. Rosen*, S.Y. Kim, M.A. Smith, and R.M. Post. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892.

The expression of neurotrophins are known to be altered by amygdala kindling. Because thyroid hormone can regulate the transcription of some neurotrophins, we asked whether thyroid hormone regulates neurotrophin mRNA expression following amygdala kindling.

Rat with electrodes in the basolateral amygdala received PTU in their water, thyroidectomy, T3 in their water, thyroidectomy plus T3 in their water or water only. Ten days after the beginning of the treatments half the rats were kindled daily until they reached one stage five seizure. They were sacrificed 4 hours after this seizure and the brains processed for in situ hybridization for NGF, BDNF and NT-3 mRNA.

In non-kindled rats, thyroid hormone manipulations affected BDNF mRNA in the PVN and pituitary only. There were no effects on basal levels of either NGF or NT-3. The thyroid hormone manipulations had no effect on kindling or on kindling-induced BDNF and NGF mRNA expression. However, the kindling-induced decrease in NT-3 mRNA expression in the dentate gyrus granule cell layer was partially blocked by PTU or thyroidectomy. These effects could be reversed by T3 treatment.

The results indicate that thyroid hormone plays a specific but limited role in the seizure-induced changes of NT-3 mRNA expression found in the dentate gyrus. Additionally, because T3 manipulations did not affect basal levels of NT-3 mRNA, other transcription factors must also regulate the basal levels and kindling-induced decreases of NT-3 gene expression in the dentate gyrus.

CONNEXIN 43 mRNA EXPRESSION IN TWO EXPERIMENTAL MODELS OF EPILEPSY. K. Elisevich*, S. Rempel, K. Jenrow and B. Smith. Epilepsy Research Laboratory, Henry Ford Health Sciences Center, Detroit, MI 48202.

The expression of mRNA for connexin 43, a gap junction protein constituent found in astrocytes, was studied in two experimental models of epilepsy, the electrically kindled rat and the tetanus toxin injected rat. Animals were kindled by electrical stimulation of the amygdala to Racine class 5 seizures and divided into cohorts of three to undergo 3, 6, and 10 such events in total, respectively. Two cohorts of rats received injections of tetanus toxin into the amygdala at strengths of 3 and 9 MLD₅₀, respectively. Features of epileptogenicity were identified electrographically in both cohorts during the first 4 weeks following injection with spontaneous ictal events recorded frequently in the latter cohort. All rats were sacrificed 4, 8, or 10 weeks after electrode or cannula implantation and the epileptogenic area in the region of the amygdala was harvested and pooled by cohort for Northern blot analysis. These were compared with control nonimplanted and implanted tissues. At time points of 4, 8 and 10 weeks, connexin 43 mRNA expression in epileptogenic tissues was found to be decreased or unchanged relative to control cases.

Both experimental models of epilepsy therefore show no connexin 43 mRNA upregulation despite varying degrees of epileptogenicity. Increased gap junction assembly as a substrate underlying epileptogenesis or as a reaction to increased neuronal excitability is unlikely to occur.

ABERRANT EXPRESSION OF GABA, RECEPTOR SUBUNITS IN TOTTERING MICE. S.-C. Liu, B.J. Baumgartner, E.M. Barnes, Jr.,* and M.H. Jalilian Tehrani, Depts. of Biochem. and Mol. Physiol. and Biophys., Baylor Col. of Med., Houston, TX 77030.

The single-locus mutant mouse tottering (tg/tg) displays spike-wave seizures that resemble those in human petit-mal epilepsy. The molecular defect responsible for this abnormality in tg/tg brain is not known. We have recently reported that in comparison to the isogenic background strain (+/+), GABAA receptor function is reduced in tg/tg mouse brain [Tehrani and Barnes (1995) Epilepsy Res. 22, 13-21]. In order to determine whether these alterations can be defined at the level of receptor isoforms, we have examined the expression of GABAA subunit mRNAs by quantitative RT-PCR and compared the data with that obtained by radioligand binding. Paired RT-PCR experiments revealed an elevation of a2- and \$1-subunit mRNA levels in tg/tg cortex, relative to +/+, with no difference in amounts of γ2-subunit transcripts. Biphasic displacement of ³H-flunitrazepam binding by 2oxoquazepam showed that low affinity sites account for 36 ± 7.6 % of the total in +/+ cortical membranes, but $51 \pm 7.5\%$ in tg/tg. This is consistent with evidence that recombinant GABA_A receptors with α2 subunits exhibit low affinity for 2-oxoquazepam. Furthermore, the level of 35S-TBPS binding to membranes from tg/tg cortex represented 73.6 \pm 5.8% of that in \pm +, concordant with reports that receptor isoforms containing \$1 subunits show low binding of 35-TBPS. Thus, our data indicate that an aberrant pattern of GABAA receptor subunit gene expression may contribute to the tottering

Supported by NIH grants NS34253, NS11535, and HL07676.

CEREBELLAR OUTPUT IS REQUIRED TO GENERATE INTERMITTENT FOCAL SEIZURES IN THE MUTANT MOUSE TOTTERING (tg/tg). D.B. Campbell* and E.J. Hess. Department of Neuroscience & Anatomy, The Pennsylvania State University College of Medicine, Hershey, PA 17033.

The neurological mouse mutation tottering (gene symbol: tg) causes ataxia, spike

and wave discharges, and intermittent focal seizures. Previous reports from our laboratory have demonstrated dramatically increased c-fos mRNA expression in cerebellar granule and Purkinje cells during tg/tg intermittent focal seizures, suggesting that cerebellar output via Purkinje cells is involved in the generation of these seizures. We have tested this hypothesis by examining the effect of lesioning tottering mouse Purkinje cells, the only efferents of cerebellar cortex, on the expression of these seizures. The mouse mutation Purkinje cell degeneration (pcd) was used to genetically lesion tottering mouse Purkinje cells by breeding pcd onto was used to generated yestom totering mouse further the tottering mouse line. Although the pcd mutation has not yet been identified, chimera analysis has demonstrated that the mutant gene acts specifically within Purkinje cells to cause the death of all Purkinje cells between postnatal days 15 and 29. Double mutants (tg/tg: pcd/pcd) were generated by +ltg: +lpcd x+ltg: +lpcd matings and the genotypes of all offspring were unequivocally identified by direct molecular analysis. Controls and double mutants were then tested as adults for expression of focal seizures by mild restraint stress, an effective method of inducing seizures in tottering mice. Thirty attempts to induce seizures in each tg/tg: pcd/pcd double mutant have failed: in contrast, tg/tg controls were induced to seize in approximately 50% of trials. Further, c-fos expression in the double to serze in approximately 20% of trials. Further, cycle expression in the doublemutants after restraint stress was completely abolished, suggesting that the lesion not only climinated the overt behavior associated with the seizure but also prevented activation of the brain circuitry associated with the seizures. Thus, removing the cerebellar output eliminated the expression of focal seizures in tentioning in certificial under the corebellum is a critical link in the neural network involved in the generation of 1g/1g focal seizures. Supported by a Klingenstein Fellowship and PHS NS33592.

EFFECT OF SEIZURE TEST ON QUANTITATIVE TRAIT LOCI (QTL) MAPPING IN THE EPILEPTIC EL MOUSE. M.J. Poderycki, J.M. Simoes, M.T. Todorova, and T.N. Seyfried*. Dept. of Biology, Boston College, Chestnut Hill, MA

02167-3811.

The epileptic EL mouse has been studied extensively as a genetic model for complex partial scizures in humans. Seizures in EL mice begin at around 90 days of age through routine handling, but can be induced to occur earlier by repeated rhythmic vestibular stimulation, i.e., tossing or shaking. Several seizure frequency QTL were mapped previously in crosses between EL and non-epileptic strains using various rhythmic stimulation procedures. The genetics of EL is complex, and the presence of these QTL was dependant upon the strain and type of cross used (Rise et al., 1991, Science, 253:669-673; Frankel et al., 1995, Mamm. Genome. 6:830-838). In a backcross to ABP, Ell was mapped to Chromosome 9 near the se locus and El2 was mapped to Chromosome 2 near the Mpm-28 locus. In the present study we evaluated seizure frequencies at 200 days of age in the EL (n=16) and ABP (n=15) strains, their Fl hybrids (n=20) and in the Fl x ABP backcross (n=123). The mice were tested for seizures every other day for 6 tests and were then tested twice per week for an additional 9 tests. The test involved tossing the mice in a mechanical shaker (4 were tested for seizures every other day for 6 tests and were then tested fwice per week for an additional 9 tests. The test involved tossing the mice in a mechanical shaker (4 cm/toss at 5 tosses/sec for up to 30 sec). Over 50% of the EL and F1 hybrid mice seized at least once by tests 2 and 6, respectively, and 100% seized by tests 7 and 10, respectively. ABP mice were largely unresponsive to the testing procedure. Mice in the backcross population seized for the first time at test 3, with 50% and 76% seizing by tests 10 and 15, respectively. The strength of the associations between seizure frequency and Ell (near Se') and Ell (near TSe') and TSE (near TSE') and TSE (sear TSE' number of tests annihistered. For example, the association with 217 weakened as the number of tests increased. Maximum LOD scores as determined by Mapmaker/QTL were 2.9, 1.6, and 1.3 at tests 6, 11, and 15, respectively. In contrast, LOD scores for E12 were 1.0, 4.7, and 4.4 at tests 6, 11, and 15, respectively. These findings suggest that some of the genetic complexity of the EL phenotype may be due in part to genotype-environmental interactions. Supported by the PHS grant (NS 23355) and a grant from the Boston College Research Expense Fund.

ABNORMALITIES IN BENZODIAZEPINE RECEPTORS IN BRAIN ASSOCIATED WITH SEIZURES IN Fyn-DEFICIENT MICE AND EL MICE. Y. Nakamoto*1, T. Miyakawa², T. Yagi³, H. Niki² and M. Yoshii¹. ¹Dept. of Neurophysiol., Tokyo Inst. of Psychiat., Tokyo 156, ²Dept. of Psychol., Fac. of Lett., Univ. of Tokyo, Tokyo 113, and ³Dept. of Neurobiol. Behav. Genet., Natl. Inst. of Physiol. Sci., Okazaki 444, Japan.

Fyn tyrosine kinase deficient mice increase the susceptibility to audiogenic seizures by unknown mechanisms (Miyakawa et al., 1995). In the present study, we have investigated whether benzodiazepine receptors in brain are involved in seizures in Fyn-kinase deficient mice as compared with those in EL mice in which peripheral-type benzodiazepine receptors (PBR) are altered (Nakamoto et al., 1996). Fyn-deficient mice were (2-5 mg/kg, i.p.), an inverse agonist for central-type benzo-diazepine receptors (CBR), than control heterozygous mutant. The drug action did not differentiate EL mice and their control DDY mice. β -CCM in low nM order inhibited [3 H]flunitrazepam binding to CBR in brain tissues less potently (4 0% higher in IC₅₀) in Fyn-deficient mice. The B_{max} of CBR was slightly decreased in Fyn-deficient mice whereas that of PBR, as measured by [3H]Ro 5-4864 binding, showed no significant difference between Fyn-deficient and control mutant mice. The results indicate that abnormalities in GABA_A-benzodiazepine receptors are present in Fyn-deficient mice but not in EL mice.

ALZHEIMER'S DISEASE: TAU AND NEUROFIBRILLARY DEGENERATION

559.1

CHARACTERIZATION OF TAU IN IMR-32 CELLS, R.D. Williams, S.K. Hall, D. Auperin, and M.K. Ahlijanian*, Divisions of Neuroscience and Medicinal Chemistry, Pfizer Central Research, Groton, CT 06340.

Neurofibrillary tangles (NFTs) are one of the classic pathologies associated with Alzheimers Disease (AD) and are comprised of highly phosphorylated tau protein. Hyperphosphorylation limits the association of tau with microtubules and may result in cytoskeletal destabilization and neurodegeneration. PCR experiments demonstrate that IMR32 cells (human neuroblastoma) predominantly express the 3-microtubule binding domain repeat, 0 amino terminal insert, isoform of tau. Treatment of cells with okadaic acid, a protein phosphatase 2A inhibitor (1 µM for 30 min), results in increased immunoreactivity of the antibody AT8, which specifically recognizes phosphorylated Ser202 of tau, in western blots. A corresponding decrease in the immunoreactivity of Tau-1, an antibody which specifically recognizes non-phosphorylated residue 198 in tau, is also observed with okadaic acid treatment does not alter the mobility of tau in SDS-PAGE or the total content of tau, monitored with the antibody HT-7, which recognizes both phosphorylated and non-phosphorylated tau Concomittant treatment with 25 µM staurosporine, a non-selective protein kinase inhibitor, does not alter the phosphorylation pattern of tau. These data demonstrate that IMR32 cells may represent an acceptable whole cell model for assessing the modulation of the phosphorylation state of tau by pharmacological probes. Supported by Pfizer Central Research, Groton.

559.2

INCREASED TAU PROTEIN IN PRIMARY CORTICAL NEURONS EXPRESSING HUMAN Aβ₁₋₁₃ and APP751. Robert K.K. Lee*¹, Richard J. Wurtman*, Benson P.S. Yang* and Rachael Neve*. ¹ Dept. Brain & Cognitive Sci., MIT, Cambridge, MA 02139 and ²Mol. Genetics Lab., McLean Hospital, Harvard Med. Sch., Belmont, MA 02178.

Neurofibrillary tangles are aberrant forms of tau whereas amyloid is derived from the amyloid precursor protein (APP). To determine if APP can regulate tau expression, we amyloid precursor protein (APP). To determine if APP can regulate tau expression, we infected rat cortical neurons (7-10DIV,-10° cells/dish) with replication-defective herpes simplex virus type-1 vectors (HSV; \sim 10° particles /dish) expressing (1) wild-type (WT) or familial AD mutations (FADs) in human APP751 or APP695 (2) A β_{1-2} ; or 3) carboxy-terminal 100 residues of APP (C-100). FADs in APP751 or APP695 were: 717 (G,F or I substituted for V), 692 (G substituted for A) or 670/671 (N,L substituted for K,M). After 36h, cell-associated APP and phosphorylation-independent tau were detected by mAb 22C11 and 5E2 (from Dr. K. Kosik, Harvard Med. Sch.) respectively on immunoblots. APP and total tau levels in control neurons (Ctrl) infected with HSV expressing E.coli βgalactosidase did not differ from uninfected neurons.

APP holoprotein in neurons overexpressing APP751 or APP695 was 1000% that

of Ctrl. FADs in APP751 or APP695 had no significant effect on APP or tau levels relative to their WT counterparts. However, tau was significantly increased (150% of Ctrl) by WT and FADs in APP751, but not in APP695, suggesting that the Kunitz protease inhibitor domain contained in APP751 increases neurite growth

C-100 resulted in neurite dystrophy and decreased total tau levels to 50% of Ctrl after 3 days. In comparison, overexpression of $A\beta_{1:42}$ seemed less toxic and neurons appeared healthy after 5 days of infection. Increased tau and APP (150% and 350% of Ctrl) were also detected in $A\beta_{1-42}$ infectants. Hence, accumulation of intracellular $A\beta_{1-42}$ 42 may contribute to aberrant tau and APP expression. Tau increases caused by APP751 and Aβ₁₋₄₂ will be examined with phosphorylation-dependent antibodies. Our data show that APP751 can regulate tau expression in primary neurons, and also suggest a potential link between amyloid and PHF formation in Alzheimer's disease. (Supported by NIH = MH-28783 & Center for Brain Science and Metabolism Charitable Trust)

THE RISE IN THE CONCENTRATION OF FREE CYTOPLASMIC CALCIUM LEADS TO DEPHOSPHORYLATION OF THE MICROTUBULE-ASSOCIATED PROTEIN TAU. E. Adamec ', M. Mercken , M. L. Beermann , M. Didier and R. A. Nixon. Laboratories for Molecular Neuroscience, McLean Hospital, Belmont, MA 02178.

The effect of a rise in the cytoplasmic concentration of free calcium ([Ca²+],) on

the state of tau protein phosphorylation was studied in rat cortical neurons and mouse cerebellar granule cells in culture. In rat cortical neurons, 1-hour treatment with glutamate, N-methyl-D-aspartate (NMDA), KCl, or a Ca²⁺ ionophore, ionomycin, caused a permanent elevation of [Ca²⁺], On Western immunoblots probed with the phosphorylation-independent antibody LK, the treatment with any of the above mentioned drugs resulted in an appearance of an additional faster moving band. On immunoblots probed with the phosphorylation-dependent antibody tau-1, which recognizes a dephosphorylated epitope, the drug treatments resulted in an increase in the tau-1 immunoreactivity and an appearance of an additional faster moving band. These findings indicate that $[Ca^{2+}]_i$ elevation is associated with dephosphorylation of the tau protein. Administration of 100 nM okadaic acid alone (an inhibitor of phosphatases 1 and 2A) increased the level of tau protein phosphorylation. Administration of okadaic acid together with the above mentioned drugs decreased the drug-mediated dephosphorylation. Pre-incubation mentioned ortugs accreased the ortug-meanated deprosphorylation. Fre-incubation with okadaic acid fully prevented the dephosphorylation. Treatment with cypermethrin (an inhibitor of phosphatase 2B) was without effect when administered either alone, or together with the drugs, or pre-incubated. Similarly, in mouse cerebellar granule cells, glutamate or ionomycin also induced okadaic acidsensitive tau protein dephosphorylation. These findings indicate that, independently of the influx pathway, [Ca²⁺], elevation leads to tau protein dephosphorylation and implicate phosphatase I and/or 2A in the process.

PHOSPHORYLATION OF TAU IN ALUMINUM-INDUCED NEURO-FIBRILLARY TANGLES: TAU-1 AND TAU-5 ARE DIFFERENTIALLY DISTRIBUTED S.M. Singer*, M.A. Norlund and N.A. Muma. Dept. of Pharmacology, Loyola Univ. Chicago Stritch Sch. of Med., Maywood, IL. 60153

In susceptible species, aluminum salts induce neurofibrillary pathology in cortex, We, and others, have several brainstem nuclei and spinal cord neurons. demonstrated the presence of tau and neurofilaments in these aluminum-induced neurofibrillary tangles (Al-NFTs) in rabbits. Using double-label immunocytochemistry and quantitative image analysis we demonstrate phosphorylation-state dependent differences in the presence of tau in Al-NFTs. The area of Al-NFTs is identified based on labeling with an antibody against phosphorylated neurofilaments (SMI31). We compared the colocalization of antibodies directed against tau at phosphorylation state-dependent (tau-1) or independent (tau-5) epitopes with SMI31 to examine tau in the Al-NFTs. The proportion of cell area labeled with non-phosphorylated tau in Al-NFTs was significantly different from total tau in NFTs (N=366 cells, 5 animals, p<0.0001). Multiple regression analyses demonstrated that the amount of tau in the Al-NFT were highly correlated (R=0.91 for tau-1, R=0.93 for tau-5) to tangle size (p<0.0001), area of tau labeling in the cell (p=0.0005 for tau-1, p=0.07 for tau-5) and the area of Al-NFT without tau labeling (p<0.0001). Furthermore, we have found that the amount of tau in the Al-NFT can be predicted by the contributions of (1) tangle without tau labeling (~55%), (2) tangle size (~35%), and (3) area of tau labeling in the cell (~7%). This model suggests that as the area of the cell occupied by the tangle increases, more tau in the tangle is phosphorylated. Our findings suggest that the phosphorylation state of tau is altered during Al-NFT development. A role for aluminum in the pathophysiology of AD remains controversial, however, studies of aluminuminduced neurocytoskeletal degeneration may offer insight to understanding the mechanisms involved in tau and neurofilament perturbations occurring in several neurodegenerative diseases. PHOSPHOPEPTIDE MAPPING OF CAMP-DEPENDENT PROTEIN KINASE AND PAIRED HELICAL FILAMENT KINASE PHOSPHORYLATION SITES IN RECOMBINANT TAU \underline{G} . A. Jicha^{1*}, A. O'Donnel², R. Angeletti², and P. Davies¹ Departments of Pathology¹ and Developmental and Molecular Biology² Albert Einstein College of Medicine, Bronx, NY 10461

We have previously demonstrated that a serine/threonine protein kinase (PHF kinase) that co-purifies with paired helical filaments (PHF) from Alzheimer's disease (AD) brain tissue phosphorylates recombinant tau only after prior phosphorylation with cAMP-dependent protein kinase (PKA). In addition, we have shown that this phosphorylation occurs in the C-terminus of tau. However the precise PHF kinase phosphorylation site(s) and the PKA phosphorylation site(s) that direct this phosphorylation were not identified. Recombinant tau was reacted with either PKA alone or PKA followed by PHF kinase in the presence of $[\gamma^{32}P]$ -ATP. Phosphopeptide mapping of both the PKA phosphorylation sites and the PHF kinase sequential phosphorylation sites was performed using HPLC separations of AP-1, elastase, and trypsin digestions of the phosphorylated recombinant tau. Phosphorylated fragments were identified by scintillation counting, mass spectrometry, and peptide sequencing. Analysis of these phosphorylated fragments provide further support for the novel characteristics of the PHF kinase, allow intepretation of the minimal concensus sequence phosphorylated by the PHF kinase, and further support the role the PHF kinase plays in inducing pathological alterations in tau that contribute to the formation of PHF in AD.

This research was supported by NIH training grant T32GM07288 and NIMH 38623.

A DISSOCIATION OF MITOGEN ACTIVATED PROTEIN KINASE AND TAU HYPERPHOSPHORYLATION IN CORTICAL NEURONS, H. Shayan*, D.T. Ho and T.H. Murphy. Kinsmen Lab, Dept. of Psychiatry, University of British Columbia, Vancouver, Canada V6T 1Z3.

The paired helical filaments (PHFs) of neurofibrillary tangles observed in Alzheimer's disease are produced by the aggregation of the microtubule associated protein tau. PHF-tau is characterized by extensive phosphorylation at specific sites and loss of microtubule binding capacity. Several studies have implicated proline directed kinases such as mitogen activated protein kinase (MAPK) in the in vitro phosphorylation of tau. We examined the requirement of activated MAPK for tau phosphorylation in rat cortical cultures using the okadaic acid induced tau hyperphosphorylation model (Harris et al, 1993). Okadaic acid treatment (0.25 μM) reduced Tau-1 immunoreactivity by 80% as assayed using Western blotting, indicative of tau hyperphosphorylation (Tau-l only reacts with dephosphorylated tau). Treatment of the blots with alkaline phosphatase restored Tau-l immunoreactivity in okadaic acid treated samples, indicating that loss of immunoreactivity was due to hyperphosphorylation of tau at Tau-1 specific sites. Okadaic acid was also shown to double the activity of MAPK based on the electrophoretic mobility shift and phospho-epitope analysis. The pretreatment of cells with 30 μM PD098059 (2-(2'-amino-3'-methoxyphenyl)-oxanaphthalen-4-one), which is a specific inhibitor of MEK-1, the upstream activator of MAPK, suppressed MAPK activation. Under conditions in which MAPK activation was completely blocked, okadaic acid treatment still produced a robust reduction in Tau-I immunoreactivity. These results indicate that activated MAPK is not required for tau hyperphosphorylation in intact neurons. Furthermore, in agreement with previous studies demonstrating that okadaic acid results in disruption of presynaptic vesicle clusters, a profound reduction of synaptic transmission was observed in response to okadaic acid treatment. HUMAN STRESS-ACTIVATED PROTEIN KINASE β (hSAPKβ) PHOSPHORYLATES TAU IN VITRO AND IN VIVO. Y. Kumagae, O.J. Kim, Y. Zhang and C.A. Miller*. Department of Pathology and Neurology. USC School of Medicine, Los Angeles, CA 90033

Phosphorylation of tau plays a role in the formation of paired helical filaments (PHF) in Alzheimer's disease (AD). Several kinases are known to phosphorylate tau. hSAPKβ is a neuron-specific, stressactivated kinase of 45kD belonging to SAPK/JNK kinase family. It colocalizes in neurons containing PHF. We tested whether hSAPKB phosphorylates tau in vitro and in vivo.

Recombinant human tau-40 was incubated with hSAPK β and analyzed on SDS-PAGE. A time-dependent decrease in mobility of tau was maximal by 6 hours suggesting tau phosphorylation by hSAPKβ. In vivo phosphorylation of tau was demonstrated by transiently cotransfecting into CHO cells, human tau-40 cDNA, and a construct of hSAPKB. Expression of tau alone in CHO cells produced two to three bands on Western blots using anti-tau antibody (T14). When hSAPKβ was co-expressed with tau-40, there was an accumulation of tau with decreased mobility

These data suggest hSAPK\$\beta\$ phosphorylates tau in vitro and in vivo Because its expression is in neurons selectively vulnerable in AD, hSAPKB may be relevant to the pathogenesis of PHF in AD. (Supported in part, by the SANKYO Co., NIMH and NIA).

PHOSPHORYLATION OF TAU ON SER 262 BY A MICROTUBULE-ASSOCIATED PROTEIN KINASE. S.M. Jenkins*, and G.V.W. Johnson. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0017.

Site-specific phosphorylation of microtubule-associated proteins (MAPs) plays an important role in modulating the function of these proteins. Recently a protein kinase from embryonic chicken brain with a molecular mass of ~100 kD was found to copurify with MAP-2. Phosphorylation of MAP2 by this kinase completely inhibited microtubule binding (Lopez and Sheetz, JBC 270:12511, 1995). In the present study, the mammalian form of this protein kinase was isolated from a microtubule preparation derived from embryonic and adult rat brain. The 100 kD kinase from rat brain readily phosphorylated both MAP2 and tau as determined by an in-gel kinase assay. In addition, the rat brain protein kinase extensively phosphorylated tau on Ser 262. This was determined by phosphorylation of a peptide encompassing amino acids 257-271 of human tau, and by use of an antibody that selectively recognizes tau when it is phosphorylated at Ser 262 and/or Ser 356 (12E8). The 100 kD rat brain protein kinase was cAMP-independent and inhibited by β -glycerol phosphate, as was the kinase from chick brain. Significantly higher levels of kinase activity were present in embryonic compared to adult rat brain, indicating that the kinase is developmentally regulated. This is intriguing because it has been suggested that inappropriate reexpression of embryonic or juvenile proteins may contribute to Alzheimer's disease pathology. In addition, the phosphorylation state of the kinase apparently modulates its activity. Drewes et al. (1995) recently purified a protein kinase of ~110 kD from bovine brain (MARK). MARK phosphorylated tau on Ser 262, as well as other KXGS sites, and maybe homologous or identical to the rat brain protein kinase Supported by NIH grant AG06569.

INSOLUBLE NFTs FROM ALZHEIMER DISEASE CONTAIN TRANSGLUTAMINASE-CATALYZED GLU-LYS BONDS AS RE-VEALED BY THEIR SENSITIVITY TO A NOVEL ISOPEPTIDASE. D.M. Appelt¹, M.P. Howard², A.G. Loewy², B.J. Balin* 1. Dept. of Pathology and Lab Med¹., Med. Coll. of Penn. and Hahnemann Univ., Phila, PA 19102, and Dept. of Biology², Haverford College, Haverford, PA 19041.

A characteristic in the pathology of Alzheimer's Disease is the accumulation of insoluble protein structures such as neurofibrillary tangles (NFTs) formed from paired helical filaments within dystrophic neurons of the central nervous system. One mechanism by which these tangles may be rendered insoluble is through an enzymatic reaction catalyzed by tissue transglutaminase. Demonstration of the N*-y(glutamic)lysine crosslinks in these insoluble structures is important to verify the role transglutaminase(s) may play in the conversion of soluble proteins into insoluble neuronal matrices. We have identified an isopeptidase from the culture fluid of the bacterium <u>Stenotrophomonas multophila</u> and have demonstrated that it releases crosslinked protein chains from a 'H-labeled acetyl lysine methylamide (ALMA)-casein substrate in which the glu-lys bond has been formed with liver transglutaminase. We have used this isopeptidase to release the crosslinked protein chains from NFTs, resulting in solubilization of these structures previously shown to resist proteolysis and unfolding reagents such as urea, SDS and DTT. Using the ALMA-casein substrate, we have demonstrated the presence of isopeptidase activity in human brain. We are presently testing the hypothesis that the steady state level of glu-lys crosslinked cell matrices is regulated by PHS/NIH AG10160 grant to BJB.

GRADUAL DEVELOPMENT OF Aß-AMYLOID DEPOSITS AND NEUROFIBRILLARY CHANGES: INCIDENCE AND PREVALENCE RATES IN DIFFERENT AGE CATEGORIES.

H. Braak* and E. Braak. Department of Anatomy,
J.W. Goethe University, D-60590 Frankfurt/Main. Germany

J.W.Goethe University, D-60590 Frankfurt/Main. Germany Alzheimer's disease is a relentlessly progressing dementing disorder. Major pathologic hallmarks include extracellular Aß-amyloid deposits and intraneuronal neurofibrillary changes (advanced silver techniques according to Gallyas and Campbell et al. [1]). Initial deposits of both changes develop in anteromedial portions of the temporal lobe. From there, the changes spread in a predictable manner across other cortical areas reflected by stages A-C of Aß-amyloid deposits and I-VI of neurofibrillary changes [2]. Staging reveals that the two changes are by no means normal concomitants of aging. No remissions occur in the course of Alzheimer's disease. Initial neurofibrillary changes develop preferentially in the absence of Aß-amyloid deposits. Stage I cases show the incidence, and stage V-VI cases the prevalence rates of Alzheimer's disease. Advanced age is not a prerequisite for the evolution of the lesions. The arithmetic means of the assigned stages of both the Aß-deposits and the neurofibrillary pathology increase with age. Alzheimer's disease is an age-related, but not an age-dependent disease.

ANALYSIS OF MULTIPLE GENE EXPRESSION IN SINGLE TANGLE BEARING AND NON TANGLE BEARING NEURONS IN ALZHEIMER'S DISEASE.

<u>Ianet E. Cheetham, Nienwen Chow and Paul D. Coleman*</u>. University of Rochester School of Medicine and Dentistry, Dept. of Neurobiology and Anatomy, Rochester, NY, 14642.

In a diseased brain (such as one suffering from Alzheimer's Disease), one cell may clearly be affected whilst an adjacent cell appears healthy or unaffected. Previous technology has allowed us to examine one message at a time at the level of a single cell (in situ hybridization), or multiple messages in a heterogeneous population of cells (northern analysis). We have developed a methodology, to allow us to characterize individual

We have developed a methodology, to allow us to characterize individual cells by ICC using antibodies to identify their neurofibrillary tangle (NFT) bearing status and using a modification of Eberwine et al (1992), to build up a profile of multiple mRNA expression in single, whole, post mortem cells. Fresh postmortem tissue is spread into a layer 1 cell thick and fixed. Tangle bearing neurons are identified using an antibody to a tangle marker and isolated using a micropipette. The mRNA is reverse transcribed and PCR carried out to confirm material is present. A radioactively labeled antisense RNA probe, which is representative of the messages contained in the cell is then amplified. This aRNA is used as a probe for a reverse northern blot, allowing us to profile many genes from one cell at the same time. Different expression profiles between NFT-bearing and NFT-free neurons will be presented. This technology has the potential to be applied to a wide variety of diseases encompassing many different cell types. Supported by grants from the NIA (LEAD AG09016, ADC AG08665, R01

TRANSIENT STRUCTURES FORMED DURING THE DEVELOPMENT OF ALZHEIMER-RELATED A&-AMYLOID DEPOSITS AND NEUROFIBRILLARY CHANGES. Braak* and H. Braak. Department of Anatomy, J.W.Goethe University, D-60590 Frankfurt/Main. Germany

Major pathologic hallmarks of Alzheimer's disease include extracellular and intraneuronal deposits of Aß-amyloid protein and abnormal tau-protein (demonstrated by advanced silver techniques [1]). The pathologic changes appear gradually at specific predilection sites.

Inconspicuous though extensive cloud-like Aß-amyloid deposits with ill-defined boundaries initially develop in anteromedial portions of the temporal lobe. With advance of the disease these precipitations disappear.

Transient forms of neurofibrillary tangles and neuropil threads develop in a subpopulation of CA1 pyramidal cells. These neurons develop conspicuous tangles extending into the tip of the apical dendrite. The change can be recognized first at stage II, is best developed at stage III, and rapidly deteriorates at stage IV [2]. When piercing the stratum lacunosum-moleculare, the altered dendrites develop spindle-shaped dilations filled with argyrophilic material. The varicose segments disappear, leaving no extracellular residues that can be detected at the light microscopic level.

Supported by the Deutsche Forschungsgemeinschaft. [1] Iqbal et al. J. Histotechnol. 16: 335-342, 1993 [2] Braak and Braak, Acta Neuropathol. 82: 239-259, 1991

CONFORMATIONAL AND PHOSPHORYLATED EPITOPES OF TAU IN EARLY ALZHEIMER'S DISEASE. C. L. Weaver, G. A. Jicha, I.J. Vincent*, and P. Davies, Depts. of Pathology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461.

It has been suggested that phosphorylation of tau occurs early in the course of the neurodegeneration of Alzheimer's Disease (AD). We have previously reported that the phosphoepitope recognized by the monoclonal antibody TG3 can be detected in hippocampal pyramidal cells in early cases of AD, prior to the formation of paired helical filaments. It has recently been determined that Alz-50 and a new monoclonal antibody, MC1, require two sequences in tau for immunoreactivity, indicating that au assumes a folded conformation for recognition by these antibodies. MC1 appears superior to Alz-50 in that it does not stain neurons in the normal brain. We have examined a group of early AD cases (Braak stages 1 and 2) with TG3 and MC1 to attempt to determine the temporal relationship between phosphorylation and conformational changes of tau.

Serial sections were cut from formalin fixed tissues on a vibratome. A sequence of consecutive sections were stained with PHF1. Alz-50. TG3, MC1 and MC5. In these early cases, many more neurons are labeled with TG3 and MC1 than with the other antibodies. Many of the CA2 pyramidal neurons stained by MC1 or TG3 dd not have obvious neurofibrillary tangles. The less numerous neurons visualized with PHF1 and MC5 all appeared to contain a neurofibrillary tangle. Additional pairs of adjacent sections were taken along the length of the hippocampus for more detailed studies with TG3 and MC1. Numbers, locations and types of stained neurons were recorded. In general, MC1 appeared to label more neurons than TG3, especially in the CA2, CA4 and dentate gyrus. In some cases, whole fields of neurons were detectable only with MC1. We have tentatively concluded that conformational changes in tau may precede many of the disease related phosphorylations of this protein. Supported by NIMH 38623.

BASAL FOREBRAIN RNA CHANGES IN RELATION TO TAU PROTEIN IN ALZHEIMER'S DISEASE. R. K. Kan, D. S. Morin, L. A. Shaubach, J. N. Einger, R. B. Mitchell, J. R. Day. * and A. Anthony. Department of Biology, Pennsylvania State University, University Park, PA 16802.

Degeneration of the basal forebrain cholinergic system and accumulation of tau are characteristics of Alzheimer's disease (AD). These changes are accompanied by alterations in nucleic acid metabolism and protein synthesis. The present study was designed to examine changes in basal forebrain neuronal RNA metabolism in relation to tau immunoreactivity. Nucleus basalis of Meynert (nbM), medial septal (ms) nuclei and diagonal band of Broca (dbB) from 9 AD patients and 9 age-matched, nondemented controls were removed at autopsy, formalin-fixed, paraffin-processed, serially sectioned at 5µm. Adjacent sections were stained with tau antibody or with Shea's (1970) azure B-RNA procedure. Extent of neuronal loss was quantified at magnification of 50x by averaging the number of cells counted in five fields. All three nuclei from AD subjects exhibited a profound cell loss (p≤0.05) as compared to controls. The amount of neuronal RNA was measured cytophotometrically using a Vickers M85a scanning-integrating microdensitometer. In AD specimens, tau-containing neurons were found to have less RNA than tau-free neurons (p≤0.05). In addition, the mean RNA values of both neuronal population (tau-free and tau-containing neurons) in AD fell well below the control mean (p \leq 0.05). The severity of RNA depletion (in order of percent decline) was nbM (30%) = ms (30%) > dbB(25%). The data indicate that RNA loss occurs in the AD basal forebrain brain and RNA depletion is more pronounced in tau-positive neurons than in tau-negative neurons. These findings suggests that alterations in transcriptional aspects of neuronal metabolism may play a critical role in the pathogenesis of AD. However, whether RNA depletion is primary or secondary to AD pathology, i.e., neurofibrillary degeneration, remain: to be established. This research was funded by The Biology Department at Pennsylvania State University

A SENSITIVE AND HIGHLY SPECIFIC ASSAY FOR PHF PROTEINS. P. Davies*, R. Zinkowski, R. Kohnken, C. Bevona, G. A. Jicha, E. Lane, I.J. Vincent, D. Kerkman and J. DeBernardis. Depts. of Pathology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461 and Molecular Geriatrics Corp, Lake Bluff, IL 60044.

The assay of the concentration of tau protein in cerebrospinal fluid (CSF) has recently been reported as helpful in the diagnosis of Alzheimer's Disease, despite the presence of elevated concentrations of this neuronal protein in CSF from patients with a variety of other diseases. A much more specific diagnostic assay would be the measurement of the abnormal tau of paired helical filaments (PHF). We have identified several antibodies that might be useful for such an assay

Antibodies selected for these assays fall into two categories: those detecting phosphoepitopes present on tau in PHF, and those that react with the specific conformation of tau in PHF. Among the antibodies to phosphoepitopes, several can be rejected because these epitopes are present on tau in normal human brain although unstable in the post mortem period. TG3 is a strong candidate because it recognizes a phosphoepitope which does not appear to be phosphory ated on tau in either autopsy or biopsy brain tissue from normal humans. The monoclonal antibody MC1, like Alz-50, recognizes a conformational epitope formed by bringing together two tau sequences separated by about 300 amino acids: tau in this conformation does not appear to be present at detectable concentrations in the normal brain. Unlike Alz-50, MC1 does not appear to recognize non-tau proteins in the normal brain. Sandwich ELISA formats using a combination of MC1 and TG3 appear to provide very highly specific detection of tau in PHF. Neither recombinant tau, nor tau prepared from biopsy or autopsy brain tissue are not detectable in these formats in concentrations more than 1000 times that of purified PHF. Currently, tau from PHF can be detected in concentrations in the pg/ml range. The utility of these assays in CSF is currently being evaluated. Supported by NIMH 38623

CSE TALLIS INCREASED IN VERY EARLY STAGES OF ALZHEIMER'S DISEASE. <u>D. Galasko*1, J. Brown1, C. Clark², L. Chang³, B. Miller³, R.C. Green⁴, R. Motter⁵, P. Seuben.</u>⁵ ¹Dept. of Neurosciences, UCSD, San Diego, CA 92161; ²Dept. of Neurology, Univ. of Penn. Philadelphia, PA 19104, ³Dept. of Neurology, UCLA, Torrance, CA 90509, ⁴Dept. of Neurology, Emory Univ. Med. Cntr, Atlanta GA 30329, and ⁵Athena Neurosciences, South San Francisco, CA 94080. In 9 studies over the past 3 years, CSF tau was shown to be increased in

patients with Alzheimer's disease (AD) compared to controls. Two studies found a direct correlation between CSF tau and dementia severity, i.e. tau increased cross-sectionally as dementia severity increased. It is not clear how early in AD elevated CSF tau can be found,

increased. It is not clear now early in AD elevated CSF table and be found, since relatively few mild AD patients have been studied. Whether CSF tau increases with normal aging also has not been explored. We therefore measured CSF tau in patients with mild AD (MMSE ≥ 20/30), and in controls (cognitively normal elderly and patients with neurological disorders), and in a group of younger subjects aged 20 - 25. CSF samples were stored frozen until assayed. CSF tau was measured

CSF samples were stored frozen until assayed. CSF tau was measured using a sensitive sandwich ELISA. Tau levels were 509 ± 255 pg/ml in AD and 167 ± 67 in controls. 29 of 36 patients with AD had increased CSF tau levels, exceeding previously determined cut-off point. Increased tau was present even in patients with very mild dementia (MMSE \geq 25). The young normal subjects had CSF tau of 160 ± 78 pg/ml. Among all of the normal subjects, CSF tau did not correlate with age. CSF tau therefore is a sensitive early marker in AD. Tau levels in CSF do not change with

STAGING NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASED BRAIN. D.R. Brady*, C.M. Fleming and K. Hatanpää. Lab. of Neuroscience, NIA/NIH, Bethesda, MD 20892.

Alzheimer's disease (AD) is characterized neuropathologically by neurofibrillary tangles (NFTs) and senile plaques in association cortices of the cerebral cortex. Hyperphosphorylated tau, a microtubule associated protein found normally in the axonal compartment of neurons, is a major constituent of somal NFTs. NFTs are mixed in the cortical mantle with apparently normal neurons devoid of NFTs. However, it has been suggested that the complete tau molecule, including the NH₂-terminus, is only found in early NFTs. Neurons bearing NFTs are mixed in the cortical mantle with apparently normal neurons devoid of NFTs. In order to early NFTs. Neurons bearing NFTs are mixed in the cortical mantle with apparently normal neurons devoid of NFTs. In order to understand how and why NFTs develop, we must first stage the neurons and then focus our attention on that neuronal population that exhibits the earliest signs of NFT formation. The brains of 16 neuropathologically confirmed AD (x age=80.25 \pm 1.3 yrs) and 5 neurologically normal patients (x age=50.4 \pm 8.6 yrs) were obtained postmortem from the LNS Brain Bank (x post mortem delay: AD-8.17 \pm 1.4 hr, normals-17.5 \pm 9.3 hr). Double-labeling with Alz-50 (recognizing the NH₂-terminus of tau) and PHF-1 (recognizing the ser-396 phosphorylation site on tau) antibodies was used to differentiate "early" (Alz-50+) and "mature" (PHF-1+ only) NFTs in temporal lobe. The greatest density of "mature" NFTs were observed in middle and inferior temporal cortices, with the fewest in superior temporal cortex (STC). Conversely, the greatest density of "early" NFTs reside in STC. These results form the basis for in situ hybridization analysis focusing on neurons bearing early NFTs.

ALZHEIMER'S DISEASE; PHOSPHORYLATED NEUROFILAMENT AND PAIRED HELICAL FILAMENT IMMUNOREACTIVITIES IN CSF. J. M. Yuan* and P. Xu. Department of Neurology, First Hospital, Beijing Medical University, Beijing, 100034, China
The definite diagnosis of Alzheimer's disease (AD) requires

histological examination of brain tissue, it is difficult to accept by patients. To establish a specific testing to help the diagnosis is expected. Using monoclonal antibody as the probes, with purified phosphorylated neurofilaments (PNF) and paired helical filaments (PHF) as coated antigens respectively, we established a competitive enzyme-linked immunosorbent assay (ELISA) for PNF and PHF immunoreactive in the CSF. Using this assay, we measured 2 patients with AD, 17 patients with multi-infact dementia (MID), 33 with other neurological disease (ODC), 33 patients with schizophrenia (SCH), and 40 healthy controls (HC). It was found that the levels of PNF immunoreactivity in CSF were no difference in AD, MID, SCH, and HC groups (P>0.05). The levers of PHF immunoreactivity were significantly higher in CSF in AD than in the control groups (P<0.05). The values of PNF/PHF ratio in CSF were significantly lower in AD than controls (P<0.01). Conclusion: (1) There is considerable significance in detection of PHF in CSF to diagnosis and differentiation of the AD. (2) The value of PNF/PHF ratio is also considerable significance to that. (3) Finally, while combinating the levels of PHF immunoreactivity in CSF with the value of PNF/PHF ratio might be developed as a specific diagnosis method of AD. (Supported by Ministry of Health of People's Republic of China)

Several independent groups have demonstrated that cerebrospinal fluid (CSF) tau protein (CSF-tau) is increased in Alzheimer's disease (AD) and that measurement of levels of CSF-tau may be aid in the clinical diagnosis of AD. In the present study, CSF-tau levels were examined in 62 AD patients carrying different genetic risk factors for AD including the apolipoprotein E (Apo E) £4 allele, the α_i -antichymotrypsin (ACT) A* allele and the presenilin-1 (PS-1)1* intronic allele. Further, temporal changes in CSF-tau levels during the progression of AD were surveyed in 17 selected AD cases. The CSF-tau levels were not significantly different between Apo E £4 carriers and non-carriers, ACT A* carriers and non-carriers as well as PS-11* carriers and non-carriers. The CSF-tau levels were quite stable or slightly increased during the progression of AD. None of the genetic risk factors affected the temporal changes in CSF-tau levels. CSF-Aβ protein consisting of 1-42 amino acids (CSF-A β_{1-42}) was significantly reduced in AD patients as compared with that in normal control subjects. The CSF-A β_{1-42} levels were decreased as the disease progressed. The presence or absence of Apo E ε4 allele did not affect the CSF-Aβ levels

ULTRASTRUCTURAL OBSERVATIONS ON PAIRED HELICAL FILAMENTS FORMATION AND THEIR EVOLUTION TO STRAIGHT FILAMENTS IN AGED AND ALZHEIMER'S BRAINS. P. Gómez-Ramos*and M.A. Morán. Dpt. Morfología, School of. Medicine, Autónoma University of Madrid. Spain.

Cytoskeleton changes were studied at both light microscopy (LM) and electron microscopy (EM), in vibratome sections from 2 Alzheimer's and 2 non-demented brains, using the AT8 antibody, which recognizes tau phosphorylated in serines 199 and 202 but does not cross-react with normal tau. Areas containing stained elements were selected at LM, photographed, resectioned and then observed under EM. Neurons which at LM were labeled with granular reaction product loosely distributed throughout the neuron, at the EM showed reaction product not only associated to the nuclear envelope, rough endoplasmic reticulum, poliribosomes and lipofucsin granules but also dispersed throughout the cytoplasm. Neurons which at LM had both granular reaction product and rod-like positive structures, at EM showed, in addition to the above mentioned cytoplasmic staining, bundles of strongly immunostained paired helical filaments. Neurons which at LM showed typical intraneuronal neurofibrillary tangles, at EM exhibited not only cytoplasmic immunostaining but also light or absent immunostaining in straight filaments surrounded by strongly positive bundles of paired helical filaments. These results are discussed in relation to the evolution of the neurofibrillary degeneration. Supported by FISss nº 93/0189, Spain.

GLIA PROTECTS BRAIN TISSUE BY OPPOSING SPREADING DEPRESSION-LIKE DC POTENTIALS. O. Herreras*, J.M. Ibarz, and C. Largo. Dept. Invest., Hospital Ramón y Cajal, Madrid-28034, Spain.

The participation of glia and potassium in spreading depression (SD) and DC potentials have been studied in a model of glial function deprivation in situ by perfusing the gliotoxin fluorocitrate (FC) and/or potassium through a microdialysis fiber in the CA1 area. Extracellular DC potential (V_o), potassium concentration [K⁺]_o, and evoked field activity were monitored. FC caused a rapid impairment of glial function followed by gradual loss of neuronal electrogenic activity and death. SD waves run faster and lasted longer during FC, and the resistance of the st. pyramidale to develop SD was overridden. Cortical waves, that in untreated animals never spread to the CA1, readily reached this area via entorhinal cortex. Membrane potential of glial cells gradually depolarized during FC. When neuronal function decayed, SD waves were smaller and slower, and eventually failed to enter the region of dead neurons around the FC source. A moderate buildup of [K+]o occurred that was accompanied by a sustained negative ΔV_{ov} even after both glia and neurons were disabled. At this time, exogenous potassium still caused negative Vo shifts as in intact tissue. The $[K^*]_{\bar{o}}$ buildup was related to slow DC potentials. Notable differences were found, however, between K^* and V_o shifts in SD. These results indicate that glial cells are not necessary for SD and constitute a functional barrier for SD to spread within the tissue. This may be a major factor of neuroprotection against brain insults causing SD-like potentials. Supp. DGICYT PB1257

GLUT5 MICROGLIAL RESPONSE IN ADULT AND IMMATURE RAT BRAIN FOLLOWING STROKE. K. Li, S. J. Vannucci, F. Maher, F. C. Barone, P. G. Lysko* and I. A. Simpson. NIDDK, Bethesda, MD 20892, SmithKline Beecham, King of Prussia

PA, 19406, Department of Pediatrics, Hershey Med. Ctr.-Penn State Univ. 17033. The GLUTS glucose transporter is expressed in testes, sperm, and epithelial cells of the small intestine where it serves as a fructose transporter. Recently we have found GLUT5 to be expressed in macrophages, neutrophils and microglia where its function has yet to be determined. Microglial expression of GLUT5 was monitored by in situ hybridization and immunohistochemistry at various times of recovery following middle cerebral artery occlusion in the spontaneously hypertensive adult rat (MCAO) and hypoxia/ischemia in the 7 day neonatal rat (unilateral carotid artery ligation, 2.5 hrs: 8% O₂, 37°C). GLUT5, although more prominent in the neonatal rat brain, is diffusely distributed throughout the normal brains, and is located exclusively in microglia. At 1 hr of recovery following the respective insults, no differences in GLUT5 expression were detected between the ipsilateral (ILH) and contralateral hemispheres (CLH) whereas at 3 and 5 hrs a global decrease in GLUT5 expression in the ILH was detected in both models. In the MCAO animals at 48 hrs, the number of microglia and the level of GLUT5 protein and gene expression are dramatically increased throughout the ILH whereas by 5 days GLUT5 is maximally expressed at the borders of the infarct where it remains significantly elevated for at least 15 days. In the neonatal animal, enhanced GLUT5 expression around the infarct for at least 15 days. In the neonatal animal, enhanced GLU15 expression around the infarct begins at 24 hrs and at 3 days is intense in the necrotic hippocampus, the thalamus and cortical infarct. The more rapid GLUT5 response is consistent with accelerated necrosis in the immature brains. The changing expression GLUT5 appears to provide a readily detectable index of microglal migration and activation which should be applicable to other brain injuries. CEREBRAL HYPOXIA-ISCHEMIA IN NEWBORNS RESULTS IN RAPID DEATH OF ASTROCYTES IN STRIATUM: A MECHANISM FOR ISCHEMIC NEURODEGENERATION. LJ Martin*, A Brambrink, C Portera-Cailliau, RC Koehler, JD Rothstein and RJ Traystman, Johns Hopkins Univ. Sch. Med.

The neonatal striatum degenerates following transient hypoxia-ischemia (H-I) by unclear mechanisms. Here, a newborn piglet model of H-I was used to test the hypothesis that damage to astrocytes and abnormalities in the localization of glutamate transporter subtypes accompany striatal neurodegeneration. One-week-old piglets were subjected to 30 min hypoxia (arterial O, saturation 30%) and then 7 min of airway occlusion (O, saturation 5%), producing cardiac arrest, followed by cardiopulmonary resuscitation and return of spontaneous circulation. H-I and sham piglets recovered for 24, 48, or 96 hours (h). Neuronal damage in putamen was 65.7% \pm 36.3% (M \pm SD) at 24 h. 63.5% \pm 32.9% at 48 h. and 78.7% \pm 19.2% at 96 h. mean neuronal densities were reduced 21%, 3.2%, and 44% at 24, 48, and 96 h, respectively. By the TUNEL method, the production of the control of dying putaminal cells (TUNEL-positive nucler/mm) were increased postischemia from a control value of 4.2 ± 4.2 (M \pm SD) to 483.3 ± 350.6 at 24 h, 508.3 ± 205.3 at 48 h, and 147.9 ± 66.7 at 96 h. Glial fibrillary acidic protein (GFAP)-positive cell body densities in the H-1 putamen were reduced 48%-55% at 24-48 h, but were greater than controls by 96 h. Early postischemia, GFAP-positive astrocytes were TUNEL-positive confirming astrocyte death; later postischemia, mitotic figures were GFAP-positive, confirming astrocyte proliferation. By immunocytochemistry, astroglial glutamate transporter protein GLT1 was reduced in the putaminal neuropil at 24 h postischemia, and as GLT1 was depleted in astrocytes later postischemia, neurons became GLT1-positive. In contrast, neuronal glutamate transporter EAAC1 immunoreactivity was maintained early postischemia, but subsequent neuronal loss resulted in lower immunoreactivity. We conclude that rapid astrocytic degeneration is an important consequence of neonatal H-I that could contribute to striatal neurodegeneration through loss of astroglial glutamate transport and resulting excitotoxicity. CONTRIBUTION OF GLIAL METABOLISM DURING A MILD METABOLIC STRESS. W.J. Nicklas* and G.D. Zeevalk. Neurology Dept., UMDNJ-R.W. Johnson Med. Sch., Piscataway, N.J. 08854
Glial cells are relatively resistant to energy impairment requiring prolonged episodes of substrate and O.J. deprivation to cause damage. Little is known of the extent to which glial metabolism is affected during energy impairment and how this might influence events in the neuronal compartment. Our past studies have used an isolated chick retinal preparation to investigate mechanisms associated with energy impairment. Mild energy stress, produced by inhibiting glycolysis with iodoacetate (IOA) for periods up to 45 min, causes an acute toxicity that is predominately NMDA receptor mediated and occurs in the absence of a net efflux of excitatory amino acids (EAAs). Acute toxicity is characterized histologically by selective damage to amacrine and ganglion cells and quantitatively, by GABA release into the medium. In this study, glial metabolism was inhibited with 20µM fluorocitrate (FI-Cit). The selective effect of this compound on metabolism in retinal glial (Muller) cells was verified by following incorporation of radiolabel from "H-acetate and 2-1"-C-glucose into glutamate (Glu) and glutamine (Gln). As predicted, FI-Cit decreased incorporation of "Calbel from glucose into Gln was decreased by 96% (Gln synthesis occurs only in glia), but was only slightly decreased (by 22%) into Glu, (bulk of glucose metabolism to Glu is in the neuronal compartment). These studies suggest that retinal glial cells have properties similar to astrocytes i.e., 1) they preferentially take up and metabolism to Glu is in the neuronal compartment). These studies suggest that retinal glial cells have properties similar to astrocytes i.e., 1) they preferentially take up and metabolism to Glu is in the neuronal compartment). These studies suggest that retinal glial cells have properties similar to astrocytes i.e., 1) they preferentially take up and metabolism to Glu is in the

ASTROCYTIC CLASMATODENDROSIS OCCURS IN HIPPOCAMPAL ORGAN CULTURE AFTER SEVERE ACIDOSIS & ENERGY FAILURE. Richard P. Kraig', P.E. Kunkler, & C.D. Lascola. Department of Neurology, The University of Chicago, Chicago, Il 60637

Excessive acidosis may be a necessary concomitant of brain infarction. During complete ischemia under hyperglycemic conditions, astrocytes become profoundly acidotic (pH₁ 4.3-5.3) while their extraglial space remains at 6.2 pH. Under these conditions, astrocytes undergo clasmatodendrosis (i.e., lose their distal processes) and yet maintain plasma membrane integrity long after loss of high energy phosphates Although clasmatodendrosis was defined in astrocytes almost 90 years ago and its relation to acidosis (and energy failure) was studied 35 years ago, these phenomena remain largely heretical. To begin examining the mechanisms by which this form of astrocytic death develops, we sought to determine if clasmatodendrosis could be seen in hippocampal organ cultures (HOTCs), where identified cells can be followed in space and time. HOTCs were prepared from early postnatal rats and placed on MillicellTM platforms. After more than 21 days *invitro*, cultures were loaded with the fluorescent cytoplasmic marker CalceinTM. Photographs were taken of HOTCs and their surrounding mixed glial cell population (under "normal" Ringer super-fusion) every 5-10 min using computer-based digital imaging strategies. Then, Ringer was changed to an "ischemic" solution consisting of 46 mM Na lactate, 75 mM KCl, 1.0 mM CaCl₂, 1.0 mM MgCl₂, 1.2 mM KH₂PO₄, 1 µg/ml antimycin without glucose at pH 5.3. Process-bearing astrocytes at the edge of the HOTC showed a progressive shortening of distal processes and enlargement of cell bodies consistent with clasmatodendrosis. The latter was also evident in a subpopulation of GFAP-positive astrocytes within HOTCs subsequently immunostained for GFAP

These studies show that astrocytic clasmatodendrosis from acidosis and energy failure can be modeled in vitro using an intact tissue. Thus, the mechanisms responsible for this form of astrocytic death should be amenable to direct examination. (Supported by NS-19108.)

TRANSFERRIN PROTEIN AND mRNA EXPRESSION IN POST HYPOXIC-ISCHEMIC NEONATAL RAT BRAINS. J.R. Connor. S.L. Menzies and C. Palmer* Depts. of Neuroscience & Anatomy and Pediatrics* M.S. Hershey Medical Center, Penn State University, Hershey PA 17033

Pediatrics*, M.S. Hershey Medical Center, Penn State University, Hershey PA 17033

Within 4 hours after hypoxic-ischemic (HI) brain injury in the 7-day old rat (PND7), there is increased stainable iron in the region of tissue injury. Iron when not protein bound is capable of generating free radicals. The response of the iron transport protein, transferrin (Tf), may play a vital role in protecting the brain from damage by binding iron and removing it from the damaged area. In this study, HI brain injury was produced by ligating the R common carotid artery of PND7 rats then subjecting them to 2.25h hypoxia in 8% oxygen. The brains were examined at different time periods post insult. In control animals, Tf mRNA is expressed in choroid plexus and diffusely throughout the rest of the brain at PND 7. By PND 10, Tf mRNA is predominantly in white matter. The normal pattern for Tf mRNA labeling is severely altered by insult. Within 72 hrs of the insult, there are columns of Tf mRNA expressing cells in the cortex on the ischemic side. At the protein level, there is an increase in Tf in astrocytes by 4hrs post insult in those cells with processes surrounding neurons in gray matter. Tf positive astrocytes in columns were still present 3 weeks after the insult. These data indicate the astrocytes are involved in the hypoxic/ischemic response and that involvement includes immediate expression and perhaps uptake of Tf, presumably for removal of iron. Supported by HD30704 (NIH)

RAPID INDUCTION OF PREPROENDOTHELIN-1 mRNA IN BOTH ASTROCYTES AND CEREBRAL ENDOTHELIAL CELLS OF HYPOXIC-ISCHEMIC MOUSE BRAIN. M. C. S. TSANG¹, K. T. Lam², P. T. CHEUNG² and S. K. CHUNG¹. Institute of Molecular Biology, ² Dept. of Pediatric, The University of Hong Kong, Hong Kong. (Spon HKSN)

The endothelin(ET)-1, a potent vasoconstrictor, has been regarded as a neurotransmitter or neuromodulator since ET-1 and its binding sites can be detected in neurons of the central nervous system (CNS) and intra-cerebroventricular infusion of ET-1 can modulate CNS function. Also, it was shown that immunoreactive ET-1 can be detected in the ischemic rat brain, suggesting its possible role in ischemic-related pathogenesis. Here, we study the expression pattern of preproendothelin-1 (PPET-1) mRNA in hypoxic-ischemic young mouse brain which was induced by permanent occlusion of right carotid artery under isoflurane. The animals were then exposed to 8% O₂/ 92% N₂ for 30 mins. The appropriate lesion sites were obtained at 2 hours, 1 and 2 days. At the level of hippocampus of all normal mouse brain, PPET-1 mRNA was detected only in the thalamic neurons and endothelial cells of vessels and capillaries. On the other hand, PPET-1 mRNA was strongly expressed by both the endothelial cells and astrocytes, not only on the ligated side, but also on the non-ligated side of ischemic mouse brain at 2 hour post-insult. The strongest expression was seen in hypothalamus, thalamus and hippocampus with moderate levels in the cortex. One day after insult, the PPET-1 mRNA expression was limited to the CA1 and parietal cortex ipsilaterally. By 2-day post-insult, the PPET-1 mRNA expression level in both astrocytes and endothelial cells was much less than that of 2 hours post-insult. Degenerated neurons did not show any PPET-1 mRNA expression. These upregulation of PPET-1 mRNA by the endothelial cells and astrocytes and their cellcell interaction may play an important role in gliosis and /or changes in blood-brain barrier function associated with post-asphyxial response.

OPTICAL IMAGING OF ACUTE ISCHEMIC INJURY IN HIPPOCAMPAL SLICE CULTURES. A. Barth, . Barth, J. T. Ho, D. W. Hochman, D. W. Newell*. Dept. of Neurological Surgery, Univ. of Washington Sch. of Med., Seattle, WA 98195.

To investigate acute cellular events during ischemic insult, we measured light transmission (LT) changes through organotypic hippocampal slice cultures exposed to increasing periods of anoxia/hypoglycemia (Ax/Hg). Resulting cell death was assessed by propidium iodide fluorescence 48 hours later. During the initial 15 min of ischemic exposure, only a slight LT decrease of 3-5% was observed and all cultures survived. Further ischemia produced marked darkening of the cultures and a sharp LT decrease of 20±4% was measured after 20 min of Ax/Hg, which plateaued then until maximal Ax/Hg exposure of 60 min. This sharp decrease of LT heralded irreversible cellular damage which resulted in complete dying of the hippocampal cultures after 40-50 min of Ax/Hg. Histological examination showed that LT changes during ischemic exposure corresponded to an increase in cell volume suggesting neuronal-glial swelling. These acute changes were completely blocked when the experiments were performed in a low-chloride medium, indicating that transmembrane movements of chloride and sodium ions were involved in cell swelling and LT decrease. We conclude that this optical imaging method is suitable to study and quantify early neuronal and glial swelling associated with ionic fluxes from ischemia and to screen substances which may influence these acute events. PLASMA BUT NOT PACKED RED BLOOD CELLS INFUSED INTO PIG CEREBRAL WHITE MATTER INDUCES RAPIDLY DEVELOPING, MARKED EDEMA. G. Xi*, K.R. Wagner, Y. Hua, G. de Courten-Myers, R.E. Myers Depts. of Neurology and Pathology, Univ. Cincinnati College of Medicine Dept. of Veterans Affairs Medical Center, Cincinnati, OH 45220.

The "toxicity" of blood is hypothesized to be responsible for edema formation and tissue injury following intracerebral hemorrhage (ICH). Recently, we reported that autologous blood infused into cerebral white matter in pigs produced rapidly developing (1 h), marked edema (>10% increases in water contents) adjacent to hematomas (Stroke 34:450-459, 1996). This edema co-localized with interstitial fibrinogen and other plasma protein accumulations despite an intact blood-brain-barrier. Presently, we compared the ability of the blood's plasma and red cell components to induce early edema development.

We infused (2.5 ml) plasma, washed packed red cells (87% hematocrit) or whole blood into the hemispheric white matter of pentobarbital-anesthetized pigs (9-11 kg) over 15 minutes. We monitored blood and cerebral tissue pressures and controlled core temperature, blood gases and pH. We froze brains in situ at 1 to 24 h and determined edema volumes and water contents

Infused plasma from low (but not high)-speed centrifugations of whole blood coagulated and induced rapid (1 h), marked edema in white matter adjacent to and distant from the plasma clots. This edematous white matter was physically changed ("translucent") in appearance due to >10% increases in water contents. No edema was observed at any time point following red blood cell infusions (N=3). In contrast, edema volumes were comparable (at 24 h) with plasma (N=3) and whole blood (N=6) infusions $(6.89\pm1.63~\text{vs}.5.67\pm1.02~\text{cm}^3)$

These results which demonstrate that the plasma and not the red cell component of the blood is responsible for early edema development, provide a new direction for therapeutic approaches to prevent white matter injury following ICH. Supported by NIH NS-30652.

HYPOXIA SENSING MECHANISMS IN HUMAN GLIOMA CELLS

Robert A. Forbes, Paul W., Harris, Stephen L., Facchina, Sandip R. Vaidya, and Ajay Verma Depts. of Neurology and Neuroscience, Uniformed Services Univ. of the Health Sciences. Bethesda, Maryland 20814

Hypoxic gliomas induce neovascularization through the elaboration of vascular endothelial growth factor (VEGF). Hypoxia stimulates VEGF gene expression via transcriptional activation of the VEGF gene as well as an increase in the stability of VEGF mRNA. Sequence specific protein-nucleic acid binding activities figure prominantly in these hypoxia regulated events. The 5' enhancer region of the VEGF gene has recently been shown to contain an octamer homologous to the hypoxia-inducible-factor-1 (HIF-1) consensus recognition element found in other hypoxia sensitive genes such as erythropoeitin. The VEGF mRNA 3'UTR region contains several consensus sequences (AUUUA) known to influence mRNA half-life of other growth factors and cytokines. We have examined the ability of human life of other growth factors and cytokines. We have examined the ability of human U87 glioma cells to respond to hypoxia by elaboration of VEGF immunoreactivity, activation of HIF-1 consensus element binding activity in nuclear extracts, and by the activation of -AUUUA- sequence specific RNA binding proteins in cytoplasmic extracts using gelshift assays. Treatment of glioma cells with 1% oxygen for 12 hrs induces HIF-1 consensus sequence binding in nuclear extracts and stimulates -AUUUA- binding activity in cytoplasmic extracts. Hypoxic cells also show a prominant increase in immunoreactive VEGF. Stimulation of VEGF staining and HIF-1 activation was also elicited by cobalt chloride, an agent which has been shown to mimic hypoxic transcriptional activation in other models. Cobaltous ions were not, however, able to stimulate cytoplasmic RNA binding activity. These results suggest that in human gliomas the hypoxic mechanisms regulating transcription and mRNA stability may use distinct signalling pathways.

CORRELATION OF FIELD RECORDINGS AND INTRINSIC OPTICAL SIGNALS IN HYPOXIC HIPPOCAMPAL SLICES. A.S. Obeidat* and R.D. Andrew, Dept. of Anatomy and Cell Biology, Queen's University, Kingston, Ontario K7L 3N6

Particularly in the cerebral cortex, cell swelling is a serious consequence of ischemia arising from stroke or trauma. Cell swelling can be indirectly assessed by measuring elevated light transmittance (LT) through the brain slice. Conversely, a reduction in LT indicates reduced cell volume (*Neuroscience 62, 371-383,* 1994). Intrinsic optical signals (a large component representing LT) were measured using Axon Imaging Workbench (Axon Instruments). We studied superfused hippocampal slices where O_2 gassing the saline was replaced with N₂ and/or glucose was reduced from 11 to 2 mM for a period of 10 min. LT in the CA1 region and the evoked CA1 field potential were a period of 10 min. LT in the CA1 region and the evoked CA1 field potential were simultaneously recorded. Neither hypoxia (n = 12 slices) nor lowered glucose alone (n = 4 slices) evoked obvious change in LT or in the evoked field at 37.5°C. However in 11 slices deprived of both oxygen and glucose, a dynamic sequence of LT changes and field potential changes occurred across the CA1 region. Between 2 to 4 min of stress, the evoked field potential was lost, immediately prior to the onset of LT elevation in CA1 dendritic regions. LT continued to increase by 50-70% (cell swelling) but by 9-10 min the signal reverted, returning to baseline and then decreasing by 40-60% (shrinkage). At the same time LT increased by 50-68% in the CA1 cell body region. This sequence of dendritic shrinkage/cell body swelling was associated with an irretrievable loss of the evoked field potential in 4 of 5 slices tested. Lowering the temperature to 30°C during

the recovery period following the hypoxia/low glucose insult resulted in a small, partial recovery of the field potential but no obvious changes in LT.

We conclude that during acute ischemic stress, CAI dendrites first swell then rapidly shrink with concurrent cell body swelling that is irreversible. This sequence represents neuronal death as indicated by a permanent loss of the evoked CAI field potential. Induction of the sequence requires both hypoxia and low glucose and once initiated is not significantly affected by lowered temperature.

NEUROPATHOLOGIC OUTCOMES ARE SIMILAR FOLLOWING INFUSION OF PLASMA OR WHOLE BLOOD INTO PIG CEREBRAL WHITE MATTER.

K.R. Wagner*, G. Xi, Y. Hua, G. de Courten-Myers, R.E. Myers.

Depts. of Neurology and Pathology, Univ. Cincinnati College of Medicine;

Dept. of Veterans Affairs Medical Center, Cincinnati, OH 45220.

Several pathophysiologic mechanisms are proposed to be responsible for brain tissue injury following intracerebral hemorrhage (ICH) including the "toxicity" of blood. Previously, we demonstrated marked perihematomal edema and interstitial plasma protein accumulation following whole blood infusions into white matter in pigs (Stroke 34:450-459, 1996). Based on these results, we hypothesized that the blood's plasma component plays an important role in the brain pathologic outcome following ICH.

To test this hypothesis, we infused (2.5 ml) autologous whole blood (N=6) or plasma (N=6) separated by low-speed centrifugation into the frontal hemi spheric white matter of pentobarbital-anesthetized pigs (9-11 kg) over 15 min We monitored blood and cerebral tissue pressures and controlled core temperature, arterial blood gases and pH. We perfusion-fixed brains at 7 or 14 days in situ with formalin and stained cut sections with Luxol fast blue/H&E

In plasma-infused brains fibrin clots comparable to hematomas in whole blood-infused brains occupied the white matter. At 7 days, marked edema continued to be present both adjacent to the mass and in adjoining gyral white matter. Neovascularization was present near the masses' border and macro-phage infiltration was present at the masses' edge. Astrogliosis and myelin pallor were prominent. After 14 days, resorbed masses left fluid-filled cysts surrounded by a large rim of gliotic and atrophic demyelinated white matter.

These results demonstrate that plasma alone is able to produce a neuro-pathologic outcome similar to whole blood suggesting a new therapeutic target to prevent white matter injury following ICH. Supported by NIH NS-30652.

OXYGEN AND GLUCOSE DEPRIVATION-INDUCED SWELLING IN RAT AND HUMAN NEOCORTICAL SLICES. J.L. Werth* and S.M. Rothman. Department of Neurology, Washington University School of Medicine, St. Louis, MO 63110.

Considerable experimental evidence implicates excessive glutamate receptor activation in ischemic neuronal death. We sought to determine if glutamate overload contributes to neurotoxicity in human neocortex. We developed a technique that is amenable to studying human brain tissue obtained from neurosurgical procedures. 400 µm thick brain slices were cut from rat brain and human neocortical biopsies. Tissue impedance was monitored by passing current (4μA, biphasic square wave) between two electrodes and recording the voltage drop across the tissue differentially (Traynelis & Dingledine, J. Neurophys. 61: 927-38). The magnitude of the voltage drop is a function of extracellular space and therefore indicative of cellular swelling. While swelling is not the cause of excitotoxic neuronal death, it is indicative of excessive activation of glutamate receptors. In experiments conducted on brain slices from rat, NMDA induced a 2-5 fold increase in tissue impedance that was blocked by MK801. Oxygen and glucose deprivation (OGD) also increased impedance. Treatment with 5µM MK801 but not non-NMDA receptor antagonist NBQX delayed and lessened the rise in impedance following OGD. Swelling was due largely to Na⁺ influx as lowering extracellular Na+ from 155 mM to 55 mM diminished but did not delay the increase in impedance. In slices from human neocortex, NMDA triggered a rise in impedance that was attenuated by MK801. OGD also led to increased impedance that was delayed by 5µM MK801. The data support the hypothesis that overactivation of NMDA-type glutamate receptors follows OGD in human and rat brain. Supported by grant RO1NS19988 from NINDS.

TIME COURSE OF EDEMA DEVELOPMENT IN THE RABBIT THREE VESSEL OCCLUSION MODEL. M.A. Widmayer.* J.L. Browning, J.M. Keck and D.S. Baskin, Dept. of Neurosurgery, VAMC and Baylor College of Medicine, Houston, TX 77030

In the cat, we have demonstrated that κ -opioid agonists and an AVP V_2 antagonist reduce ischemia-induced edema and improve survival, tissue damage, and neurologic function. Before evaluating the efficacy of these drugs in the rabbit model, we evaluated the time course of development of edema.

Thirty-six SPF, male, NZW rabbits underwent occlusion of 2mm of the right internal carotid, and middle and anterior cerebral arteries (3VO). Six animals were assigned to be sacrificed at either 6, 12, 18, 24, 36 or 48 h post-occlusion. Four mm sections of the brains were immersed in a percoll density gradient to determine specific gravity, and then stained with TTC to assess infarct volume.

Edema and tissue damage were apparent in the right hemisphere by 6h and increased until 24h (p < 0.05, each). Mortality was substantial after 30h. Small sample size resulted in unreliable edema and infarct measurements at the 36h and 48h time points, although there was no additional increase in either measure at the later time points. Therefore, in this 3VO model, sacrifice at 24h is preferable. This research was supported by a VA Merit Review Grant.

A Photothrombotic Stroke Model with Penumbra - Evolution of Perfusion Deficit, Vasogenic Edema and Ischemic Volume WeiGang Gu and Per Wester** Dept Medicine Univ Ume & Sweden

WeiGang Gu and Per Wester*, Dept Medicine, Univ. Umeå, Sweden This study aimed at further characterization of a laser-induced photochemical thrombotic stroke model with a large area-at-risk (Stroke 1995: 26; 444-450), now slightly modified to achieve spontaneous reperfusion. Halothane-anesthetized temperature and blood gas controlled adult male Wistar rats (270-350g) were subjected to a ring-shaped (outer Ø 5.0 mm and 0.35 mm thick) laser-irradiation beam (514.5 nm; 0.9 W/cm²) focused on the somatosensory cortex for 2 min simultaneously with iv. infusion of the photosensitizing dye erythrosin B [17 mg/kg] for 30 s. At different times post-irradiation (p.i.), perfusion deficits were visualised by transcardial carbon black perfusion; cortical water content (wet/dry weight) was measured; and infarction volumes were calculated after transcardial FAM-perfusion and evaluation of multiple coronal sections. A ring-shaped cortical perfusion deficit was observed at 4 hr p.i. which progressively increased at 10 - 24 hr's to reach its maximum at 48 hr's with an almost complete perfusion deficit. At 72 hr's p.i., a spontaneous reperfusion was observed in the area-at risk, which was even more pronounced at 5 and 28 days p.i. Brain water content increased steadily from 4 - 24 - 48 hr's p.i. vs. sham (p<0.01) by ANOVA and post-hoc); at 72 hr's it levelled off and returned to control values at 7 days p.i. Ischemic volume steadily increased from 4 - 10 - 24 hr's to reach its maximum at 48 hr p.i. (p<0.01). At 3 - 7 - 28 days p.i., infarction volume was gradually reduced to less than 50% compared with 48 hr's p.i. (p<0.01). This novel stroke model, now modified by use of a thinner laser ring beam (0.35 instead of 0.50 mm) displays a more delayed ischemic progress in the area-at-risk (penumbra) with late spontaneous reperfusion and a remarkable late tissue recovery.

EFFECT OF INCREASING INTERVALS OF HYPOXIA-ISCHEMIA ON GLUT1 AND GLUT3 GLUCOSE TRANSPORTERS AND INFARCTION IN PERINATAL RAT BRAIN. Susan J. Vannucci, Lisa B. Seaman, Robert M. Brucklacher and Robert C. Vannucci*, Dept. of Pediatrics, Hershey Med Ctr-Penn State Univ., Hershey, PA 17033.

Glucose is the primary fuel for the immature brain and the only fuel able to sustain anaerobic glycolysis. Glucose is transported into brain by the glucose transporter proteins: GLUT1 (55 kDa), blood-brain barrier; GLUT3, neurons; 45 kDa GLUT1, glia. GLUT1 & 3 are low in the 7 day old (P7) rat and limit cerebral glucose utilization. Prolonged (150 min) cerebral hypoxia-ischemia (H/I) in the P7 rat has profound effects on GLUT1 and GLUT3 expression during the early recovery period and produces severe neuronal necrosis/ cerebral atrophy by 30 days. The purpose of this study was to assess the effects of shorter intervals of H/I on GLUT1 & 3 expression and long-term outcome. P7 rats were subjected to right carotid artery ligation followed by 8% O₂ for 60, 90, 120 and 150 min. Brains were analyzed for GLUT1 & 3 mRNA expression at 1, 24, 48 & 7 hrs of recovery. Littermates were analyzed at 30 days for neuropathology. 60 min of H/I produces neuronal damage in 25% of pups; 50% were damaged by 90 min. Both intervals produced increases in GLUT1 mRNA in both hemispheres by 1 hr which normalized by 24 h of recovery, followed by mild reductions in the infarcted. The loss of GLUT3 expression, related to neuronal death, was confined to cortical and hippocampal areas in the affected pups. H/I intervals of 120 and 150 min produced more severe damage in 75-90% of pups, with significant atrophy and cystic cavitation. Neuronal injury was apparent in widespread GLUT3 loss in both groups, whereas GLUT1 loss was not as severe following 120 min. Cerebral H/I at P7 produces increasing neuronal injury with increased duration. The early GLUT183 responses following shorter intervals of H/I may provide insight into neurportection. Supported by HD-30704 & HD-31521, NICHD.

GLUCOSE ANALOGUES IN ISCHEMIC BRAIN SLICES: 3-O-METHYL-GLUCOSE DIFFUSION AND EFFECTS OF LOW GLUCOSE ON THE LUMPED CONSTANT. G.C.Newman*, F.E.Hospod, C.S.Patlak. Depts. of Neurology and Surgery, SUNY at Stony Brook and Northport VAMC, NY.

In an effort to understand glucose metabolism in the ischemic penumbra, we have studied 1) $^{14}\text{C-}3\text{-O-methylglucose}$ (30MG) kinetics and 2) the lumped constant (LC) for $^{14}\text{C-}2\text{-deoxyglucose}$ (2DG), in $450\mu\text{m}$ and in $1050\mu\text{m}$ thick hippocampal slices which spontaneously express features of the ischemic penumbra. 30MG kinetics were analyzed at 5 mM glucose using a model of extracellular (ECS) diffusion with two serial compartments. The lumped constant was calculated in $450\mu\text{m}$ slices using the ratio of volumes of distribution for $^{14}\text{C-glucose}$ (V_d) and 2DG (V_v) after exposure to buffer with glucose between 0.25 and 10 mM

2DG (V_d^{-1}) after exposure to buffer with glucose between 0.25 and $^{9}0$ mM. 30MG kinetics differ dramatically in 450 μ m and 1050 μ m slices. As with $^{14}\text{C-PEG}, ^{3}\text{H}_2\text{O}$ and ^{45}Ca , the ECS diffusion coefficient for 30MG in thick slices is similar to that of bulk solution (5.9±2.1 cm²/sec) while that in thin slices is much smaller (1.8±0.2 cm²/sec), consistent with our hypothesis that brain ECS is non-homogeneous. In addition, the second serial compartment is much larger in 1050 μ m slices (0.14±.08 ml/g) than in 450 μ m slices (0.045±.001 ml/g). Anion exchange chromatography reveals no 30MG phosphorylation, suggesting that glucose transport into an unidentified compartment is selectively increased during ischemia.

an unidentified compartment is selectively increased during ischemia. V_d for ^{14}C -glucose falls much more than V_d for 2DG below 2 mM glucose so that LC increases from 0.3 at 10 mM to 1.2 at 0.25 mM, similar to observations in vivo. SGU decreases from 40 to 5 μ mole/100g/min as glucose is lowered from 10 to 0.25 mM. Thus, brain slices provide an excellent model of cerebral metabolism under conditions of limiting glucose. CONCENTRATION EFFECTS OF ISCHEMIC FACTORS ON HISTOLOGY, ADENYLATES, GLUCOSE UTILIZATION AND ⁴⁵Ca⁻² IN HIPPOCAMPAL BRAIN SLICES. F.E.Hospod*, H.Qi, S. Motwani, S.Trowbridge, G.C.Newman. Dept. of Neurology, SUNY, Stony Brook, NY and VAMC at

Our goal is to understand the neurochemistry of the ischemic penumbra. Our model employs 450 µm thick rat hippocampal slices exposed to buffer with varying hypoxia, pH, K⁺ and glutamate. Brain slices are studied by measurement of histologic injury, adenylates with HPLC, slice glucose utilization (SGU) with ¹⁴C-2DG or ⁴⁵Ca² spaces.

Hypoxia produces a predictable injury that is dependent upon the

degree and duration of O₂ deprivation. Hippocampal regions are sensitive in the sequence CA1>CA2>dentate>CA3>CA4. Increasing histologic injury correlates with reduced adenylates and irreversible accumulation of $^{45}\text{Ca}^{+2}$ in a small compartment. Glutamate, up to $100\,\mu\text{M}$, accumulation of "Ca" in a small compartment. Glutamate, up to 100μM. produces minimal histologic injury or reduction of adenylates despite increased SGU and reversible entry of ⁴⁵Ca" into larger compartments. There is no tissue injury with 8 mM K* despite pronounced uptake of ⁴⁵Ca", while 20 mM K* injures CA1 in a pattern similar to hypoxia. At K* of 40 or 70 mM there is severe tissue destruction with patterns never seen with other ischemic insults, in association with reduced adenylates and irreversible binding of ⁴⁵Ca⁻². Varying pH from 7.4 to 6.2 yields histology similar to hypoxia but with less change in adenylates, inhibited SGU and reduced entry of ⁴⁵Ca⁺² into either the large or small spaces.

Thus each factor produces a unique pattern of tissue response with a complex concentration dependence. Their interactions during ischemia in vivo are likely to be complex and dynamic. We gratefully acknowledge support of grants from VA Merit Review and NIH #NS28429.

THE EFFECT OF GLUCOSE ON BRAIN ATP, LACTATE, AND GLUTAMINERGIC SYSTEM IN THE NEWBORN PIG. M.H. LeBlanc*, X.B. Qian, Z.Cai. Dept.of Pediatrics, University of Mississippi, Jackson, MS 39216

We have shown that glucose worsens hypoxic ischemic brain injury in the 0-3 day old piglet. Using this same protocol 35 piglets were randomly assigned to have their glucose increased to 300 ± 30 SE mg/dl with glucose infusion G, (n=12) or decreased to $67 \pm 16 \text{ mg/dl}$ with insulin I (n=13) or a sham group S (n=10). In the I and G groups at time 0, both carotid arteries were clamped and blood was withdrawn to reduce the blood pressure to two-thirds normal. At time 15 minutes F.O. was reduced to 6%. At time 30 minutes, the brains were frozen in situ in liquid nitrogen, then removed and stored in liquid N2. The shams were anesthetized and their brains were frozen in liquid N_2 using an identical procedure but without inducing hypoxia or ischemia. Brains were homogenized and lactate and ATP were measured enzymatically, CSF amino acids by HPLC and H{3} MK801 binding by Scatchard Analysis. Brain ATP was $1.7\pm.09$ mmoles/kg wet wt. in the S, 0.98 ± 0.09 in the G, and 0.52 ± 0.10 in the I, (all differences statistically significant p<.01). Brain lactate levels were 4.3 ± 1.0 mmoles/kg wet wt. in the S, 29.4 ± 2.6 in the G, and 18.3 ± 1.9 in the I, (all results statistically different p < .01). CSF glutamate was 9.3 \pm 3.6 micro-M in G, 9.6 \pm 3.5 in I, and 2.2 \pm 0.9 in S (G+I>S, p<.05). Glycine was 65 \pm 13 micro-M in G,80 \pm 15 in I and 84 \pm 17 in S (p=ns). MK801 binding showed a K_d of 6.3 \pm 0.4 nM in 6, 6.2 \pm 0.3 in I, and 6.0 \pm 0.6 in S (p=ns), and a B_max of 2.3 \pm 0.2 pMol/mg protein in G (p=ns), 2.6 \pm 0.1 in I (p < .05 vs S), and 2.0 ± 0.2 in S. Although providing additional glucose preserves cellular ATP during hypoxic ischemic brain injury in the newborn pig, it does not change the glutaminergic system, and it worsens outcome by elevating cellular lactate levels above the threshold for cellular injury.

CHANGES IN LABILE ENERGY METABOLITES, REDOX STATE AND INTRACELLULAR PH IN POSTISCHEMIC BRAIN OF NORMO- AND HYPERGLYCEMIC RATS, K.Katsura", J.Folbergrová, and B.K. Siesjó.

Lab. for Exp. Brain Res., Lund Univ. Hosp., S 221 85 Lund, Sweden and
Sec. Dep. of Int. Med., Nippon Medical School, 102 Tokyo, Japan

The present experiments were undertaken to study whether preischemic hyperglycemia, which is known to exaggerate ischemic damage

and to trigger delayed postischemic seizures, affects the bioenergetic state of brain tissue at early (6h) and late (18h) recirculation times. To that end, normo- and hyperglycemic rats were subjected to 10 min of forebrain ischemia, and neocortical tissue was frozen in situ for analyses of labile energy metabolites.

Animals with preischemic hyperglycemia, subjected to 10 min of ischemia and allowed recirculation periods of 6 or 18 hrs, failed to show a reduction of the phosphorylation state of the adenine nucleotide pool, or a rise in tissue lactate content, nor did they show a change in tissue redox state. However, the hyperglycemia led to a rise in phosphocreatine (PCr) content at 6h. Calculations of intracellular pH (pH_i) from the creatine kinase (CK) equilibrium showed a rise in pH_i above normal, a finding which was verified by a limited number of 5,5-dimethyl[2-14C]oxazoline-2,4-dione (DMO) measurements. The preischemic hyperglycemia also blunted the postischemic rise in tissue glycogen content, the results suggesting an inverse correlation

between pH and glycogen content.

The results thus fail to reveal that the hyperglycemia-triggered, masssive exaggeration of ischemic brain damage, which is heralded by generalized seizures after 18-24 hrs of recirculation, is preceded by mitochondrial dysfunction of a degree which affects the bioenergetic state of the redox potential of the tissue. However, the results suggest that the hyperglycemia enhances and/or prolongs the postischemic alkalosis

CNS AXONS FROM VERY YOUNG RATS ARE HIGHLY RESISTANT TO ENERGY DEPRIVATION.<u>R.</u>

FERN* AND B. R. RANSOM Department of Neurology, University

Washington, Seattle, WA 98195.

The neonatal CNS is subject to a variety of metabolic insults including anoxia, ischemia, and hypoglycemia. Although the neonatal CNS is relatively tolerant of these conditions, prolonged CNS ischemia results in severe neurological damage that is typified by lesions of CNS white matter. We have found that white matter from very young rats (P0-P4) is matter. We have found that white matter from very young rats (P0-P4) is highly tolerant to energy deprivation; in particular to joint withdrawal of oxygen/glucose (ie. ischemia), as assessed by changes in the evoked compound action potential recorded from the isolated rat optic nerve. CNS axons from >P4 rats were less tolerant to joint anoxia/aglycemia than they were to aglycemia alone. This may indicate that metabolism of lactate, possible only in the presence of oxygen, may assist the survival of CNS axons during glucose withdrawal after P4. It has been shown previously than astrocytes convert their intracellular glycogen store into extracellular lactate following the withdrawal of glucose and lactate can support action potential conduction in CNS white matter.

2-deoxyglucose (DOG), which will prevent the conversion of glycogen to lactate, reduced the tolerance of CNS axons to aglycemia glycogen to lactate, reduced the tolerance of CNS axons to aglycemia at all ages. Recovery from aglycemia in PO-P4 axons was significantly less in DOG, suggesting that mobilization of glycogen was important for the high tolerance to energy deprivation at this age. The observations that PO-P4 axons can tolerate joint anoxia/aglycemia (where lactate produced from astrocytic glycogen can not be metabolized) but not aglycemia in the presence of DOG (where no glycogen can be utilized) suggests that axons contain glycogen at this age point, which contributes significantly to a hightened tolerance to energy densitystion. THE ROLE OF HYPERGLYCEMIA IN CEREBRAL ISCHEMIC DAMAGE:

M. N. VIVO - IN VITRO STUDY

M.M. Li, R.S. Payne, K.H. Reid^a, J.J. Miller^b, V.G. Iyer^c, M.T. Tseng^a, B.M.

Rigor^a and A. Schurr. Depts. of Anesthesiol, Anat Sci & Neurobiol^b, Pathol^b, and Neurol^c, University of Louisville, School of Medicine, Louisville, KY 40292

Numerous studies have demonstrated a deleterious effect of hyperglycemia on the ischemic brain. In a rat model of chest compression-induced global ischemia, glucose administered 15 min prior to compression induced audiogenic seizures and neuronal damage in surviving rats (Epilepsy Res. in press). This study evaluated the relationship between timing of glucose administration, its blood level just before induction of ischemia and the incidence of audiogenic seizures and neuronal damage.

Fasted (24 h) Long-Evans rats, were divided into two groups based on time of glucose injection (15 min or 120 min prior to chest compression) with 3 glucose glucose injection (15 min or 120 min prior to chest compression) with 3 glucose doses (0, 2, 4 g/kg, i.p.) per group. Procedures for chest compression and testing for audiogenic seizures were as described elsewhere (Brain Res. 689: 159, 1995). Each rat was tested for the presence of audiogenic seizures 24 h post-ischemia and hippocampal slices were prepared 7 days after chest compression (Life Sci.57:2425, 1995). Slices in which a CA1 population spike of > 10 mV (normal PS) was evoked were considered undamaged; those with a PS < 10 mV or no PS were considered damaged. Blood was sampled for glucose determination 3 min pre-chest compression.

CA1 neuronal damage varied with both glucose dose and time of administration 15-min Pre-ischemia glucose normal

Modulation of NMDA toxicity and in vitro ischemic damage by pH and free radical scavengers. K.M. Raley-Susman*, D. Do. M. Monje and S. Cladis, Dept. o. Biology, Vassar College, Poughkeepsie NY 12601

NMDA receptor activation contributes to the damage seen following ischemic insults, via elevations in calcium and exacerbation of free radical production. The receptor function can be modulated by magnesium ions, pH and oxidation state. Thus, manipulation of these parameters may alter the outcome of an ischemic or excitotoxic insult. In this study, we explored the effects of in vitro ischemia or NMDA receptor activation on protein synthesis, morphology and cytoskeletal protein expression in the rat hippocampal slice preparation. We exposed slices from adult rats to either 5 min in vitro ischemia or to 5, 15, 30 min exposure to NMDA $(30, 50, 100, 500 \,\mu\text{M})$. In some experiments, exposures occurred in media of different pH (6.0, 6.5, 8.0). In other experiments, exposures occurred in the presence of ascorbic acid (400, 800 µM, 1.2 mM). Slices were allowed to recover for two hours and then protein synthesis was assayed autoradiographically (3 H-leucine, 4.5 μ Ci/ml) and neurons from 5 μ m methacrylate sections were scored on a morphology scale. In some experiments, CA1 regions were lyophilized, microdissected, homogenized, and extracted proteins were immunoblotted with antibodies against MAP-2 or tubulin. As in our previous work, in vitro ischemia caused a persistent inhibition of new protein synthesis (Raley-Susman and Lipton, Br. Res. 515: 27. 1990), a severe morphological impairment and a specific depletion of MAP2 and tubulin (Raley-Susman and Murata. Br. Res. 694: 92. 1995). Manipulation of pH during this insult did not alleviate the damage (Kaja et al. NS Ab. 21. 1995). In contrast, ascorbic acid attenuated the damage (15-33%) to morphology. Ascorbic acid treatment also alleviated the ischemic depletion of tubulin and MAP-2. NMDA exposure caused a dose-dependent, magnesiumsensitive inhibition of protein synthesis and impairment of morphology.

Acidosis induces necrosis and apoptosis in cultured hippocampal slices P.J. Bergold*1.2, S.I. Moskowitz², R. Li², T.-S. Liu¹, S.B. Lee³, M. Esteban³, H.I. Federoff⁴, K. Tomasellħ, J. Chan³, and D. Ding¹ Depts. of Pharmacology¹, Neuroscience², Biochemistry³, and Neurology³, SUNY-HSCB, Brooklyn, NY 11203; 4Dept. of Neurology, U. of Rochester Medical School, Rochester, NY 14642; 5IDUN Pharmaceuticals, Inc., San Diego, CA 92121

Acidosis, hypoxia and hypoglycemia rapidly and transiently appear after reduction of cerebral blood flow. These metabolic insults, individually or in combination, result in necrotic and apoptotic neuronal loss. We previously demonstrated that transient acidification of intracellular pH from 7.3 to 6.6 induces delayed neuronal loss in cultured hippocampal slices. We now report that a 30 minute acidosis treatment induced both necrosis and apoptosis that was temporally, morphologically, and pharmacologically distinct. Neuronal loss 8 hours after a 30 minute acidosis treatment was largely necrotic while neuronal loss at 16 hours was largely apoptotic. Apoptotic neuronal loss was accompanied by DNA fragmentation and was blocked by inhibitors of protein and RNA synthesis, ectopic expression of the anti-apoptotic gene bcl-2, or an inhibitor of proteases related to interleukin 1B converting enzyme (ICE). Necrotic neuronal loss was unaffected by these treatments. In contrast to the apoptosis and necrosis induced by the 30 minute treatment, a 15 minute acidosis treatment predominantly produced apoptosis. These data suggest that: (1) induction of apoptosis did not depend upon prior induction of necrosis and (2) necrosis has a higher threshold for induction than These data also suggest that acidosis contributes to both necrotic and apoptotic neuronal loss after stroke. Supported by HD31300 to H.J.F and P.J.B.

DNA FRAGMENTATION AND ITS TIMECOURSE IN NORMO VS. HYPOTHERMIC TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. M. Drake* and T. Wieloch, Lab. for Experimental Brain Research, University Hospital, Lund 221 85, Sweden

This study was performed in order to investigate the differences in DNA fragmentation after normothermic- and hypothermic global ischemia, in the hippocampus and the striatum. To study this phenomenon, we used conventional gel electrophoresis after incorporation of ³²P labeled nucleotide at 3'-OH ends on DNA fragments, pulsed-field-gel-electrophoresis and the end-labeling of DNA-fragments in situ (TUNEL). As previously shown by others (MacManus et al, J Cereb Blood Flow Metab, 15, 728-737 (1995)), we observed a similar oligonucleosomal fragmentation pattern of the DNA which peaked at around 48 hours in the striatum and at 72 hours in the hippocampus. Hypothermia completely prevented DNA fragmentation in the CA1 region. The early fragmentation of DNA seen at 24 hours following normothermic ischemia and the residual fragmentation at 24 hours after hypothermic ischemia, emenating from the whole hippocampus is thought to be derived from the hilar neurons which start to degenerate early, and are not protected after hypothermic ischemia. We also observed high-molecular-fragmentation at approximately 50 kb, 300 kb and >600 kb using pulsed-field-gel -electrophoresis.

We conclude that DNA fragmentation at the oligonucleosomal level is prevented in the CA1 neurons and the striatum after an episode of 15 minutes of hypothermic transient global ischemia in the rat. This work was supported by fundings from the Swedish Medical Research Council (grant no. 08644) and NIH (NSO7838).

NEURONAL DAMAGE EVOKED BY GLOBAL HEMISPHERIC HYPOXIA-ISCHEMIA WORSENED BY PROSTAGLANDIN E2 J.A. Thornhill*, E. West and M. Smith, Dept. of Physiology & Sask. Stroke Research Center, Univ. of Saskatchewan, Saskatoon, Sask, Canada

Groups of male, halothane anesthetized Long Evans rats were given intracerebroventricular (icv) injections of prostaglandin E₂ (PGE₂, 200, 400 or 4000 ng) or sterile saline in 4 μ l volumes which caused dose-related increases in colonic temperature but no neural damage. Other groups were given icv PGE, (400 or 4000 ng) or sterile saline followed by the induction of hemispheric hypoxic ischemia (HHI) at the time of the peak febrile response (ligation of the right common carotid artery plus 35 min breathing 12% O₂). Animals given PGE₂ icv plus HHI showed dose related increases in colonic but especially temporalis muscle (brain) temperatures (also evident in their enhanced fever indices, °C x min). In addition, the 4000 ng PGE2 treated group given HHI, showed significantly greater ipsilateral hemispheric neural damage to the HHI insult, especially due to increased hippocampal damage, than the non-febrile, icv saline-treated group given the same HHI insult. The results suggest that the pyrogenic effects of icv PGE2 administration significantly increased the neural damage to HHI from damage observed in the non-pyrogenic saline treated group given the same HHI insult. Supported by the Canadian Heart & Stroke Foundation.

HYPOTHERMIC NEUROPROTECTION IN AGED GERBILS. Corbett*, S. Nurse and F. Colbourne. Basic Med. Sciences, Fac. Med., Memorial Univ., St. John's, NF, Canada A1B 3V6.
Previous studies from this laboratory (Nurse & Corbett, J.Neurosci., 1994, 14: 7726, Colbourne & Corbett, J. Neurosci., 1995, 15: 7250)

have shown that mild intra-or prolonged (i.e. 12-24 hr) post-ischemic hypothermia conveys long lasting (1-6 months) protection against CA l ischemic injury. However, all hypothermia studies have used very young animals (~3-6 months old). Since stroke incidence rises sharply in late middle age and neuronal plasticity and many other factors change with aging, we decided to evaluate the efficacy of hypothermia in 18-20 month old gerbils.

Gerbils were exposed to a 5 min episode of global ischemia or sham occlusion. One group was occluded at a brain temperature of ~32°C. A second ischemic group was maintained at normothermia during occlusion and the first hour of reperfusion. Beginning 1.0 hour after occlusion, these gerbils were gradually cooled to 32°C and maintained at this level for 24 hours before gradual rewarming to 37°C. The third ischemic group was maintained at normothermia during surgery and the first hour of reperfusion.

Both intra and post-ischemic hypothermia provided robust protection (91.6% and 78.2% respectively; p<.001) of hippocampal CA1 neurons when assessed 30 days after ischemia. These data suggest that mild hypothermia may be as effective in old as in young gerbils.

THE COMBINATION OF POSTISCHEMIC HYPOTHERMIA AND DELAYED PBN TREATMENT LEADS TO CHRONIC NEUROPATHOLOGICAL PROTECTION AFTER GLOBAL ISCHEMIA. M.Y.-T. Globus*,

PBN TREATMENT LEADS TO CHRONIC NEUROPATHOLOGICAL PROTECTION AFTER GLOBAL ISCHEMIA. M.Y.-T. Globus*, W.D. Dietrich, I. Valdes, S. Kraydieh, M.D. Ginsberg, R. Busto. Cerebral Vascular Dis. Research Center, Dept. of Neurology, Univ. of Miami Sch. of Med., Miami, FL We recently provided evidence for a delayed excitotoxic process occurring within the CA1 hippocampus with postischemic hypothermia (J Cereb Blood Flow Metab 15:969-968, 1995). We have now tested the hypothesis that delayed free radical reactions also contribute to the lack delayed free radical reactions also contribute to the lack of chronic protection in this experimental setting. Wistar rats underwent 10 min of normothermic (37°C) ischemia (2-vessel). Three ischemic groups were studied: no treatment (n = 4); 3 hrs immediate postischemic hypothermia (30°C) (n = 8); and immediate postischemic hypothermia combined with treatment with the spin-trapping agent N-tert-butyl-alpha-phenylnitrone (PBN) (100 mg/kg, i.p.) on postischemic days 3, 5 and 7 (n = 6). At 2 months, normothermic ischemia led to a complete dropout of CA1 neurons; and postischemic hypothermia alone failed months, normothermic ischemia led to a complete dropout of CA1 neurons; and postischemic hypothermia alone failed significantly to protect the CA1 hippocampus. However, postischemic hypothermia combined with delayed PBN treatment led to significant increases (p < 0.01, ANOVA) in normal CA1 neuronal counts compared to normothermic ischemia. Neuronal counts within the lateral, middle and ischemia. Neuronal counts within the lateral, middle and medial subsectors of the hippocampus in the hypothermic and hypothermic + PBN treatment groups were 23 \pm 7, 18 \pm 7 and 17 \pm 7 (mean \pm SEM) vs. 53 \pm 9, 46 \pm 9 and 32 \pm 13, respectively. The lack of chronic CAl protection with postischemic hypothermia appears to involve both secondary excitotoxic and radical-mediated processes.

ALKOXYL RADICAL AND ARACHIDONIC ACID DAMAGE IN NEUROBLASTOMA CELLS. B. J. O'Neil*, T. R. McKeown. B. C. White

Dept of Emerg. Med., Wayne State Univ., School of Medicine, Detroit MI,48201 Arachidonic acid (ARA) release during cerebral ischemia, and its oxidation during reperfusion produces superoxide. Superoxide is a weak oxidant but can reduce storage protein iron, thereby releasing Fe²⁺, which can act as a transition metal catalyst for lipid peroxidation. This accepted model suggests that arachidonate toxicity occurs by iron-requiring radical mediated damage. We examined this hypothess in a neuronal cell culture model Neuroblastoma B104 cells (NB104) were differentiated into neurons and then exposed for 2 hours either to an alkoxyl radical generated from cumene hydroperoxide (CumOOH) or to ARA in 4 trials. Neuronal damage was assessed by LDH release as a percentage of total LDH (after detergent lysis). A radical scavenger (BHA 100 µM) and iron chelators (DTPA 880 µM) and EHMP 300 µM) were studied for damage inhibition.

GROUPS	Untreated	BHA	DTPA	EMHP
Controls	26 ± 5%	28 ± 7%	10 ± 1%	35 ± 12%
CumOOH 5µM	56 ± 8%	43 ± 21%	$30 \pm 2\%$	19 <u>+</u> 1%
CumOOH 20µM	79 ± 9%	45 ± 29%	$60 \pm 2\%$	25 ± 5%
ARA 10µM	50 ± 5%	37 <u>+</u> 6%	$17 \pm 2\%$	$17 \pm 4\%$
ARA 40µM	79 <u>+</u> 8%	81 ± 2%	$76 \pm 2\%$	58 ± 4%

CumOOH and ARA caused similar dose-dependent damage. BHA, DTPA, and EMHP decreased damage in CumOOH and in 10 µM ARA., however all were ineffective at ARA 40 uM. ARA reaches concentrations near 140 uM during brain ischemia. Our results suggest that higher concentrations of ARA induce membrane damage by unknown mechanisms in addition to iron-requiring radical injury Supported by NIH Grant NS01585-05 and EMF Center of Excellence Award

EVIDENCE FOR AN ASCORBATE-COPPER-PEROXIDE COMPLEX IN LIPID PEROXIDATION. M. R. Emerson, F. E. Samson, and T. L. Pazdernik*. Smith Research Center, Dept. of Pharm., Tox., & Ther., Univ. of Kansas Med. Center, Kansas City, KS 66160

The generation of reactive oxygen species and subsequent free radical damage is implicated in a variety of neuropathologies including ischemia-reperfusion, seizures, and brain trauma. Following these acute brain insults, the delocalization of transition metals (Fe, Cu) into the extracellular fluid may occur. In the presence of H₂O₂ and ascorbate, a radical generating system may be created and induce the formation of oxygen radicals by Fenton-like chemistry leading to a lipid peroxidation cascade and a loss of cellular integrity and function. Using a liposome preparation as a membrane model, we studied the aqueous vs. lipid reactivity of an aqueous, metal-catalyzed radical generating system consisting of ascorbate (330 µM), copper (1.0 µM) and H₂O₂ (10 mM). Cis-parinario acid (6 µM) oxidation was measured to assess lipid peroxidation while salicylate (30 µM) hydroxylation to 2, 5-dihydroxybenzoic acid (2,5-DHBA) was used to assess the aqueous reaction. Both reactions were followed fluorometrically. 2,5-DHBA formation began immediately, was rapid, and stopped within 5 minutes at about 2.75 µM. Cis-parinaric acid oxidation began after a lag of 4-5 minutes and continued until nearly 40% was oxidized at 30 minutes. Maximal salicylate hydroxylation required O₂, while cis-parinaric acid oxidation was more complete in an O2 depleted environment. This data suggests that salicylate hydroxylation occurs through the hydroxyl radical in solution, whereas an ascorbate-copper-peroxide complex mediates lipid peroxidation. This complex may be more important than the hydroxyl radical in the oxidation of biological lipid targets. Furthermore, aqueous antioxidants may not prevent biomembrane damage, while the effectiveness of lipid soluble antioxidants will depend critically on their partition and location in the biomembrane. (Supported in part by DAAH04-95-1-0217 and DAMD17-94C-4045).

NEUROPROTECTIVE EFFICACY OF EBSELEN IN THE RODENT MODEL OF PERMANENT MIDDLE CEREBRAL ARTERY (MCA) OCCLUSION ¹T. Takasago, ²D.I. Graham, ³H. Masayasu and ¹I.M. Macrae*, ¹Wellcome Surgical Institute and ²Dept. of Neuropathology, University of Glasgow, Glasgow G61 1QH, U.K., ³Daiichi Pharmaceutical Co. Ltd., Tokyo, Japan

The neuroprotective efficacy of post-insult treatment with the glutathione peroxidase mimic and free radical scavenger, ebselen, has been investigated in a reproducible model of maintained focal cerebral ischaemia in the rat.

Adult male Fischer 344 rats (277-340 g_s) were anaesthetised (0.8-1.5% halothane in 70% N2O: 30% O2) and ventilated with physiological monitoring throughout. The left MCA was permanently occluded by diathermy, transected, the wound sewn up and the anaesthetic withdrawn. Thirty minutes post occlusion ebselen (10 or 30 mg/kg) or placebo (5mls/kg) was administered by gavage (n=15 per group). A second dose of drug or placebo was administered at 12 hours post-occlusion. At 24 hours, following physiological monitoring, the animal was reanaesthetised and perfusion fixed with FAM for subsequent determination of infarct volume by quantitative histopathology

Post-treatment with ebselen significantly reduced the volume of tissue infarction induced by MCA occlusion. Infarct volume in the cerebral hemisphere was $142\pm 9~\text{mm}^3$ for placebo, compared to $97\pm 8^{**}~\text{mm}^3$ for low dose and $108\pm 7^*~\text{mm}^3$ for high dose ebselen (*p<0.02, **p<0.01, two-tailed t-test with Bonferroni correction). Ebselen had no therapeutic efficacy on the caudate nucleus at either dose. Tissue salvage was confined to the cortex where the volume of infarct was reduced by 36.7% (p<0.01) with the low dose and 27.5% (p<0.01) with the high

These data demonstrate that the potent inhibitory influence of ebselen on free radical damage results in the salvage of a significant volume of cortex, even with delayed oral administration (30 minutes post-insult).

MAINTENANCE OF TURTLE BRAIN ASCORBATE AND GSH LEVELS DURING HYPOXIA-REOXYGENATION. R. Forman, J Kume-Kick* and M. E. Rice. Depts. Physiology & Neuroscience and Neurosurgery, NYU Medical Center, 550 First Avenue, New York, NY 10016.

Anoxia-tolerant turtle brain has exceptionally high levels of the intracellular antioxidant ascorbate, while levels of GSH are similar to those in mammalian brain. Both antioxidants are seasonally regulated in turtle brain, with higher levels in warm-compared to cold-adapted animals. In the present experiments, we addressed how ascorbate and GSH are affected by hypoxia and hypoxiareoxygenation in warm- and cold-adapted turtles. Ascorbate and GSH levels in turtle cerebral cortex, CSF and plasma were determined using HPLC. Warmadapted turtles maintained at room temperature (20° C) were hypoxic for 3 h, with 30 min. reoxygenation in some animals. Cold-adapted turtles maintained at 2°C, were hypoxic for 7 days, with 30 min. reoxygenation in some animals. Normoxic control animals were air-breathing for a period equal to the duration of hypoxia in each group. Brain ascorbate and GSH were unaltered by hypoxia or reoxygenation in both cold and warm-adapted groups. Plasma ascorbate levels were higher in cold-adapted (25-30 µM) compared to warm-adapted groups (15-20 µM), which was opposite from the warm-/cold-dependence of brain ascorbate content. CSF levels in normoxic warm- and cold-adapted animals differed more markedly, with 400-600 µM ascorbate in cold-adapted normoxic controls but only 100-150 µM in warm controls. After 7 days of hypoxia, however, CSF ascorbate levels fell to ~150 µM in coldadapted animals. Levels of GSH in CSF were relatively constant (~100 µM) under all conditions. Maintenance of ascorbate and GSH levels in turtle brain during hypoxia-reoxygenation suggests that antioxidant mobilization and recycling are important factors in preventing oxidative damage in turtle brain. ROLE OF OXIDATIVE STRESS IN ENHANCED VULNERABILITY OF DOPAMINE NEURONS TO ENERGY IMPAIRMENT, G.D. Zeevalk* and Laura Bernard. Neurology Dept. UMDNJ-R W Johnson Med Sch. Piscataway, N.J. 08854 In a previous study we showed that dopamine (DA) neurons in mesencephalic cultures were more sensitive than GABA neurons to a mild energy impairment produced by inhibiting the Krebs cycle enzyme, SDH with malonate (JPET 275, 1995). NMDA receptors played a role in this damage since blocking them during malonate exposure was protective. To further investigate the cellular mediators of damage and potential reason for the greater susceptibility of DA vs. GABA neurons to mild energy stress, the role played by oxidative stress was examined. DA neurons may be more susceptible because of an intrinsic oxidative stress already placed on them due to DA metabolism and oxidation. Several spin trap agents that chelate reactive oxygen species and inhibit lipid peroxidation (PBN, MDL101,002 & MDL, 102,832, gifts of Hoechst Marion Roussel Research Institute, Hoechst Marion Roussel, Inc.) were tested for their ability to attenuate damage due to malonate. Cultures were exposed to 50mM malonate on day 6 in vitro for 24 hr in the presence or absence of the spin trap agents, allowed to recover for 48hr, then assessed for toxicity by simultaneous measurement of the uptake of H-DA & 14°C-GABA Consistent with previous findings, malonate produced a greater loss of DA (68%) than GABA uptake (30% loss). PBN, or either MDL compound, present during malonate exposure, significantly protected both neuronal populations. The MDL compounds were more potent than PBN in providing protection, (maximal protection ~ ImM for the MDL compounds vs 30mM for PBN). Because of the involvement of glutamate receptors in malonate-induced damage, the spin trap agents with an order of potency of MDL102.832 ~ MDL101,002-PBN. To further study the role of oxidative stress in damage caused by energy impairment, cultures were treated with buthionine sulfoxamine (BSO) to prevent

PHENIDONE INHIBITS COMBINED OXYGEN-GLUCOSE DEPRIVATION- AND HYDROGEN PEROXIDE-INDUCED NEURONAL INJURY IN MIXED CORTICAL CULTURES. M.B. Wie H.C.Kim², K.H.Lee¹, J.H.Shin¹, Y.J.Cho², and J.C.Lee. Development Center, Samchundang Pharmaceuticals Inc., C Chunchon 200-160, ²College of Pharmacy, Kangwon National Univ., Chunchon 200-701, Korea. It has been proposed that free radicals derived from arachidonic acid

metabolites stimulate excessive release of excitatory amino acid and neurodegenerative cascade during cerebral ischemia/reperfusion insults.

We examined whether inhibitors of arachidonic acid metabolism exhibit protective effect on combined oxygen-glucose deprivation— and hydrogen peroxide—induced neuronal injury in murine cortical cultures. Mixed cortical cells (14-21 DIV) exposed to oxygen-glucose-deprived media, then placed into oxygenated normal media (Glodberg and Choi,1993). Neuronal injury assessed by measuring LDH release for 20-24 h following oxygen-glucose deprivation. Pretreatment with phenidone (300 μ M), both inhibitor of cyclooxygenase/lipoxygenase attenuated oxygen-glucose cyclooxygenase/lipoxygenase attenuated deprivation-induced neuronal death. However, acetylsalicylic acid (50-500 μ M), cycloxygenase inhibitor and esculetin (10-100 μ M), lipxygenase inhibitor had no effect. Phenidone (30-300 μ M) also inhibited hydrogen peroxide (500 μ M)-induced acute neuronal injury dose-dependently. Blockade of neuronal injury evoked by phenidone disappeared according to the prolongation of oxygen-glucose deprivation time and the saturation extent of anaerobic gas mixture in media. These results suggest that strategy for both inhibition of cycloxygenase and lipoxygenase may beneficial to the neuroprotection from oxygen-glucose deprivation - or oxidative radical induced neuronal injury(Supported by KOSEF 95-0403-19-01-3).

IN ISCHEMIC GERBIL BRAIN AND RETINA, THE INCREASE OF HYDROXYL FREE RADICAL (°OH) IS TIME-RELATED. <u>B. Delbarre*</u>, <u>G. Delbarre and F. Calinon</u>, Faculté de Médecine, 37032 Tours, France.

A study was undertaken to show the relation between time of reperfusion and release of °OH. 6 groups of 5 adult gerbils were used : 3 sham operated (SO), and 3 subjected to unilateral left carotid occlusion (Isc), 60 min followed by 30 min, 4h or 24h of reperfusion. °OH (2,5+2,3DHBA) was determined in left hemisphere and retina by HPLC/Electrochemical (salicylate as scavenger) according to Floyd method (Free Rad. Biol. Med., 2:13-18, 1986). Salicylate (100 mg/kg, i.p.) was administered 10 min before occlusion or SO. Results were given in difference of mean Isc versus SO (Area °OH/Salicylate).

	30 min	4n	2411	
Retina	1.15***	1.20***	1.41***	
Brain	1.29*	1.37**	1.57**	
Bonferroni	test $(n=5)$	n<0.05* n<0	0.01** n<0.001	***

It is not possible to determine level of °OH 48h after IRI because 40 to 60% of gerbils were dead. °OH is significantly increased in IRI. This increase is more important 24h after IRI. These results would suggest that antioxidant drugs could be administered curatively during a long time after IRI. We have shown that the level of glutamate is more important 4h after IRI. The fact that °OH is more important later, 24h after reperfusion, would suggest that glutamate could be responsible for the high level of °OH later after IRI. Bitherapeutic treatment could be administered before and/or after reperfusion.

Increased Hydroxyl Radical Production During Reversible Focal Cerebral Ischemia N. J. Solenski, A. L. Kwan, H. Yanamoto, N. F. Kassell*, J. P. Bennett, K. S. Lee. Departments of Neurology & Neurological Surgery, University of Virginia, Charlottesville, Virginia 22908

Cytotoxic oxygen free radicals may be produced during cerebral

Cytotoxic oxygen free radicals may be produced during cerebral ischemia/reperfusion by several mechanisms. Using a reproducible rat model of focal ischemia/reperfusion, we have measured the *in vivo* time course of cerebral hydroxyl radical production and excitatory amino acid levels.

Anesthetized male Sprague-Dawley rats underwent temporary occlusion of the left middle cerebral artery and reversible bilateral ligation of the carotid arteries. A microdialysis probe was stereotactically placed in either the ischemic core or the perifocal area of the left frontoparietal cortex. Artificial cerebral spinal fluid with 5 mM salicylate was continuously perfused and dialysate samples were collected during 1 hour of baseline, 3 hours of ischemia, and 6 hours of reperfusion time. Samples were assayed by HPLC for 2,3- and 2,5-dihydroxybenzoic acid, and for glutamic and aspartic acids. Cerebral reperfusion was confirmed visually and measured by iodo-[1**C]antipyrine autoradiography. Infarction area was measured histologically.

[**O[antipyrine autoradiography. Infarction area was measured histologically. A statistically significant increase of hydroxyl radical adduct was observed within the perifocal ischemic area. Hydroxyl radical concentration rose in the perifocal area during 3 hours of ischemia and further increased during 6 hours of reperfusion when compared to the ischemic core and to sham controls. (Two-way ANOVA p< 0.05). Preliminary data on the temporal correlation of hydroxyl radical production to excitatory amino acid levels, suggest a high amount of variability during both ischemia and reperfusion in the perifocal area. This *in vivo* study confirms the generation of neurotoxic free radicals during focal ischemia and reperfusion and indicates that this event is most prominent in the perifocal rather than the core of a focal ischemic event. Supported by NS Training Grant # NS 07199–14

A FREE RADICAL SCAVENGER, MDL 101.002, IS NEUROPROTECTIVE IN SEVERAL MODELS OF FOCAL AND GLOBAL ISCHEMIA. D.R. McCarty, M.P. Johnson, N.L. Velayo, C.G. Markgraf, P.A. Chmielewski, J.V. Ficority, H.C. Cheng, S.F. Chaney, T.C. McCloskey, J.H. Kehne, C.E. Thomas and G. Metcali?. Hoechst Marion Roussel Inc., CNS Research, Cincinnati, OH 45215.

Reactive oxygen species generated during brain ischemia are believed to cause free radical chain reactions resulting in cell damage and neurodegeneration. The nitrone spin trap, α-phenyl-tert-butyl nitrone (PBN), has been shown to be efficacious in focal and global ischemia models. A more potent compound, one of a novel class of cyclic nitrone analogs of PBN, MDL 101,002 was investigated. Permanent distal middle cerebral artery (MCA) occlusion in the Spontaneously Hypertensive (SH) rat was achieved by ligating the ipsilateral common carotid artery (CCA), exposing the MCA via craniectomy, and cutting the vessel by electrocautery. In this model, 100 mg/kg MDL 101,002 given i.v. 30 mins postischemia reduced infarct volume by 40%. In Wistar rats, the contralateral CCA was also occluded for 2 or 3 hrs to achieve more consistant infarcts. A 75 mg/kg bolus + 45 mg/kg*h infusion for 6 hrs i.v. beginning at 5 mins postischemia decreased infarct volume 90% with 2 hrs CCA occlusion and 60% with 3 hrs. Proximal MCA occlusion was also performed in Wistar rats by introducing a 3.0 nylon monofilament into the internal carotid artery and advancing it to the origin of the MCA. This monofilament was removed after 3 hrs to allow reperfusion. Doses of 75 mg/kg bolus + 45 mg/kg*h infusion or 40 mg/kg bolus + 26 mg/kg*h infusion for 6 hrs i.v. beginning 30 mins postischemia decreased infarct volumes by 70 or 50%, respectively. Gerbils treated with 100 or 64 mg/kg i.p. 30 mins prior to 5 mins of occlusion of both CCAs exhibited spontaneous locomotor activity at 24 hrs which was comparable to shams. Partial protection was also achieved with a dose of 32 mg/kg. MDL 101,002 is efficacious in animal models of focal ischemia showing histological decreases in damaged tissue, and also producing behavioural improvement in a model of global ischemia. This suggests that neurological damage caused by stroke could be minimized by treatment with free radical scavengers.

EFFECT OF SALICYLATE, AN HYDROXYL RADICAL (°OH) SCAVENGER, ON GLUTAMATE RELEASE IN ISCHEMIC BRAIN AND RETINA OF GERBIL. INFLUENCE OF TIME AFTER REPERFUSION. G. Delbarre*, B. Delbarre and F. Calinon, Faculté de Médecine, 37032 Tours, France.

Salicylate is used as °OH scavenger by R.A. Floyd to determine °OH. What is the effect of salicylate on level of glutamate? Level of glutamate was determined in left hippocampus and retina of gerbil, by HPLC/Electrochemical according to Xu et al. method (Xu, X. et al., J. Liq. Chrom., 9:10, 1986). 12 groups of 5 adult gerbils were used: 6 sham operated (SO), and 6 subjected to unilateral left carotid occlusion (Isc), 60 min followed by 30 min, 4h or 24h reperfusion. Salicylate (100 mg/kg, i.p.) or saline was administered 10 min before occlusion or SO. Results are given in difference of mean Isc/SO (µg/mg of protein).

		30 min	4h	24h	
Retina	Saline	6.86	8.53	5.01	
	Salicylate	2.20***	5.33*	2.60*	
Brain	Saline	6.48	14.05	11.31	
	Salicylate	6.13ns	7.02***	4.58***	

Bonferroni test. (n=5). Salicylate/Saline. p \leq 0.05*, p \leq 0.01**, p \leq 0.01***. Results show that glutamate is increased in IRI. Salicylate significantly reverses this increase. The level of glutamate is more important 4h after reperfusion. Since salicylate prevents the release of glutamate in IRI, it is not possible to determine, on the same ischemic animal, glutamate and "OH when Floyd method is used.

A MICRODIALYSIS STUDY COMPARING HYDROXYL RADICAL PRODUCTION AND DOPAMINE METABOLISM IN VARIOUS RAT MODELS OF CEREBRAL ISCHEMIA. L. Ste-Marie, P. Vachon, L. Vachon and J. Montgomery. Research Centre, Notre-Dame Hospital, Montréal, Québec, Canada.

The goal of our project is to find a model of unilateral global ischemia in the rat brain (Sprague Dawley, n=10) which is highly reproducible with minimal effect on the contralateral side of the brain (control side). A small subtemporal craniectomy was made under anaesthesia and the middle cerebral artery (MCA) was cauterized. Three models of ischemia were compared 1) cauterization of the MCA only 2) MCA cauterized and permanent occlusion of the ipsilateral common carotid artery (CCA) 3) MCA cauterization and both CCA's occluded: permanent occlusion on the ipsilateral side and temporary (30 min) occlusion on the contralateral side. For each of the three models, microdialysis probes were implanted bilaterally in the striatum and infused with Ringer's solution (2µl/min). To investigate OH formation during ischemia, 4-hydroxybenzoate (4HBZ) (400 mg/kg) was injected intraperitoneally at the beginning of the microdialysis. Microdialysate samples were analysed for dopamine (DA), dihydroxyphenylacetate (DOPAC), norepinephrine (NE), homovanillate (HVA) and 3,4-dihydroxybenzoate (34DHBZ) (formed by 4HBZ hydroxylation) by HPLC with electrochemical detection. Preliminary results show that MCA occlusion alone did not augment liberation of DA and metabolites. The third model showed that both sides are affected in different ways: DA and NE increased more on the ipsilateral side, but DOPAC and HVA decreased in the same way. Only the second model showed a non affected response on the control side. At the end of the experiments, the brains were perfused with saline-formaldehyde (10%) and prepared for histological staining (hematoxylin and eosin, cresyl violet). Histological damage will be compared with biochemicals results. (Financial support from the Heart and Stroke Foundation of Canada.)

FREE RADICALS ARE RELEASED IN THE STRIATUM AFTER REOXYGENATION IN A MODEL OF MILD AND SEVERE PERINATAL ASPHYXIA C_Loidl¹, F Capani¹, F. Aguirre², L. Piehl², G. Facorro², T. De Paoli², A Hager² and J. Pecci Saavedra *¹¹¹¹ Inst. de Biología Celular y Neurociencias and LaNAIS-MIE, Fac de Medicina and (²¹) Cátedra de Fisica and LANAIS-RLBM. Fac de Farmacia y Bioquímica. Univ. de Buenos Aires. Argentina.

Biochemical and morphological differences between mild and severe perinatal asphyxia (PA) were demonstrated in the rat striatum and cerebral cortex. Using a model that induces PA at different times of oxygen lack, reactive xygen species (ROS) were measured in an electron paramagnetic resonance (EPR) spectrometer. In term pregnant rats uteri still containing foetuses were taken out by hysterectomy under deep anaesthesia and were placed in a 37°C water bath. The following groups of asphyctic pups were used: slight (10 min of PA), mild (19 min of PA) and severe PA (≥20 min of PA). Controls were obtained by caesarea. Following PA, animals were left to recover at different times of reoxygenation (0, 5, 15 and 30 min). Pups were then sacrificed and in samples of striatum and cortex ROS were trapped by N-t-Butyl-α-Phenylnitrone and analysed with a Bruker ECS 106 EPR spectrometer. Striatal samples showed ROS release in 19 min of PA with 5 and 15 min of reoxygenation groups and the higher detection was observed in the ≥20 min of PA with 5 min of reoxygenation group. ROS release was neither detected in striatal and cortical controls nor in any cortical samples subjected to PA. These results show that free radicals are released in striatum during the short period following mild and severe PA reoxygenation. The quantitative differences detected in both groups could explain the long-term alterations previously observed. Further studies are needed in order to extend the observations to other areas of the CNS

DELAYED TREATMENT WITH THE SPIN TRAP α -PHENYL-N-TERT-BUTYL NITRONE REDUCES INFARCT SIZE FOLLOWING TRANSIENT FOCAL ISCHEMIA IN RATS. Q. Zhao*, M.L. Smith and B.K. Sięsiö. Lab. for Experimental Brain Research, University of Lund, Lund, Sweden

In exploring whether or not α-phenyl-N-tert-butyl nitrone (PBN) can ameliorate ischemic brain damage, 2 h of transient MCA occlusion was induced in Wistar rats by insertion of an intraluminal filament under halothane anesthesia. PBN (Sigma Chemical Co., St Louis, MO, USA) was dissolved in saline and administered i.p. in a dose of 100 mg/kg, repeated 4 times with 12 h interval. Rectal temperature was kept at normal levels during ischemia and for the first 4 h of recirculation. The infarct volume was measured with the 2,3,5-triphenyltetrazolium chloride (TTC) staining technique after 48 h of recirculation. The five groups were: only saline injection (n=16), PBN treatment starting 15 min before MCA occlusion (n=8), or at 1 h (n=10), 3 h (n=11), and 6 h (n=8) after recirculation. In two additional groups: saline treated (n=7) and PBN treatment starting after 1 h of recirculation (n=7), a histopathological analysis of infarct size was made after 7 days of recirculation

Pretreatment with PBN reduced infarct volume to < 50 % of control. A similarly beneficial effect was obtained when the drug was given at 1 or 3 h following recirculation, but not at 6 h.

Microscopical evaluation of infarct volume after 7 days of recovery revealed a significant reduction in infarct volume by 30 %. This reduction was less than that observed after 48 h in TTC-stained brains, suggesting progression of infarct development in the period of 2 to 7 days

These results suggest that free radicals play an important role in the pathogenesis of ischemic cell damage. It may be speculated that continous infusion of PBN, or prolongation of the treatment, might further improve the outcome.

This study was supported by funds from the Swedish Medical Research Council and the National Institutes of Health of the United States Public Health Service.

POLYAMINE-MODIFIED SUPEROXIDE DISMUTASE WITH INCREASED BLOOD-BRAIN BARRIER PERMEABILITY REDUCES ISCHEMIC NEURO-DEGENERATION IN RAT HIPPOCAMPUS. Thomas M. Wengenack*, Geoffry L. <u>Curran</u>, and <u>Joseph F. Poduslo</u>. Molec. Neurobiol. Lab., Mayo Clinic and Foundation, Rochester, MN 55905.

Free radicals are believed to play an important role in cerebral ischemia. Antioxidant enzymes such as superoxide dismutase (SOD) have shown neuroprotective effects in animal models of cerebral ischemia. Experiments using native enzyme have had limited success. Various modifications to increase the half-life or permeability of SOD have also resulted in limited neuroprotective effects. Previous studies in this laboratory have shown that covalent modification of SOD with the polyamine, putrescine, increases its permeability at the BBB. The specific aim of this study was to systemically administer polyamine-modified SOD (pSOD) following global cerebral ischemia in the rat and investigate the effects on the vulnerable CA1 hippocampal pyramidal cells. Transient, global cerebral ischemia was produced in male Wistar rats for 12 min using the 4-VO method. Animals were dosed (i.v.) 1.5 min after reperfusion with either saline, native SOD (5,000 U/kg), pSOD (5,000 U/kg), or enzymatically inactive pSOD (2.1 mg/kg) twice daily for 3 days. Neuroprotective effects were then assessed by counting the number of remaining pyramidal cells in anatomically defined regions of CA1. Rats that received saline had only 1.4 \pm 0.6 neurons/reticle ($\bar{x} \pm SEM$). Native SOD (10.4 \pm 3.0) or inactive pSOD (7.3 ± 2.7) resulted in slightly, but not significantly, more CA1 neurons. Polyamine modified SOD, however, resulted in significantly more CA1 neurons (24.6 \pm 5.9), nearly half that of sham controls (58.6 \pm 0.7). Polyamine modification of SOD and other antioxidant enzymes, as well as growth factors, resulting in increased permeability across the BBB with retained biological activity, may provide a useful tool for the systemic delivery of therapeutic proteins in neurodegenerative disorders. CATALASE ACTIVITY AFTER PERINATAL HYPOXIA-ISCHEMIA IN CU/ZN SOD TRANSGENIC MICE. H. F. Chetkovich, C. Epstein and D. M. Ferriero.* Neonatal Brain Disorders Lab, Dept of Pediatrics and Neurology,

Univ. CA San Fran, San Francisco, CA 94143

Wheras Cu Zn superoxide dismutase (CuZn-SOD) has been shown to be neuroprotective in adult animal models of cerebral ischemic injury, in a model of hypoxic-ischemic injury in neonatal transgenic mice overexpressing CuZn-SOD, there was increased tissue damage. This suggests that there is no concomitant increase in the activity of catalase or glutathione peroxidase in the neonatal brain, resulting in increased hydrogen peroxide concentrations leading to increased tissue damage. To test this hypothesis, we first compared catalase activities in noninjured neonatal CuZn-SOD transgenic mice (TgC) and their nontransgenic CD-1 littermates (WtC). Using a standard colorimetric assay, no significant differences in catalase activity in the cortices (44 ± 2 v. 47 ± 3 U/mg)or hippocampi (62 ± 3 v 58 ± 2) were detected. To address whether enzyme activity changes after hypoxic-ischemic injury, we measured catalase activity in similar groups of animals immediately after hypoxia-ischemia. In this model, the hemisphere ipsilateral to the carotid ligation is injured Again, no significant differences in catalase activity in the cortices or Again, no significant differences in catalase activity in the cortices or hippocampi were seen when comparing ipsilateral to contralateral regions or when comparing ipsilateral damaged regions to controls. Taken together, these findings support the hypothesis that increased hypoxic-ischemic injury in neonatal mice transgenic for CuZn-SOD is due, in part, to increased SOD activity without concomitant increase in catalase activity. Intracellular hydrogen peroxide concentrations in the transgenic neonatal mice may thus reach toxic levels, leading to the increased cerebral tissue injury

Selective vulnerability of the CA1 sector to oxidative injury in organotypic hippocampal culture J.J. Vornov,* A.G. Thomas and Park Depts. of Neurology and Neuroscience Johns Hopkins School of Medicine, Baltimore, MD 21287

We have previously reported that the selective regional vulnerability of the CA1 sector of the hippocampus to global ischemia can be reproduced in organotypic culture. Hippocampal slices from 7 day old rat pups are maintained for weeks. Regional injury is quantified in the living culture with propidium iodide.

Paraquat is an herbicide which produces superoxide by redox cycling within cells. We confirmed the paraquat exposure causes superoxide formation by the reduction of nitroblue tetrazolium to a colored formazan product. This was partially blocked by simultaneous incubation with catalase and superoxide dismutase

Paraquat injury was time and dose dependent. Concentrations that caused submaximal injury consistently produced selective injury in the CA1 region of cultures. The same injury was produced by 3 mM for 5 min, 30 μM for 24 hrs or 3 μM for 5 days. The iron chelator desferoximine significantly decreased injury; the vitamin E derivative Trolox did not. The NMDA receptor antagonist MK-801 protected against brief, but not prolonged exposures to paraquat. Total cellular glutathione was almost completely depleted prior to loss of membrane integrity. There is selective vulnerability of the CA1 region to acute or chronic oxidative stress produced by paraquat. This research supported by an NIH grant NS-01310

HIPPOCAMPAL INJURY FOLLOWING TRANSIENT GLOBAL ISCHEMIA IS REDUCED IN CuZn-SUPEROXIDE DISMUTASE TRANSGENIC MICE.

K. Murakami¹, T. Kondo¹, S. Chen¹¹, E. Carlson², C. J. Epstein², P. H. Chan¹.

CNS Injury and Edema Research Center, Departments of Neurosurgery and Neurology¹, and Pediatrics², University of California, San Francisco, CA

We previously demonstrated that CuZn-superoxide dismutase (CuZn-SOD) transgenic (Tg) mice are highly resistant to cerebral infarction and edema formation following transient focal ischemia and reperfusion. It is, however, formation following transient focal ischemia and reperfusion. It is, however, unclear whether oxygen derived radicals are involved in the pathogenesis of hippocampal injury following transient global ischemia. In order to clarify the role of CuZn-SOD in hippocampal injury, Tg and littermate non-transgenic (nTg) mice were subjected to 5 or 10 min of global ischemia induced by bilateral common carotid artery occlusion (BCCAO) under controlled ventilation. In a preliminary study, we determined that the severity of the hippocampal lesion depends upon the plasticity of posterior communicating artery (PcomA) in transient global ischemia induced by BCCAO. In the present study, we employed the animals with hypoplastic PcomA in the ipsilateral hemisphere. At 1 or 3 d after ischemia, the plasticity of PcomA wassessed followed by explusition of the hippocampal lesion in the hemisphere ipstated in emisphere. At 10 s a dire is scrienta, the plasticity of Fconia was assessed followed by evaluation of the hippocampal lesion in the hemisphere with hypoplastic PcomA using qualitative grading. Plasticity of PcomA was not significantly different between nTg and Tg mice. In the 5 min ischemia group, there was no significant difference in the hippocampal lesion between gloup, there was to significant inherence in the implocamipal resist between Tg and Tg mice at 1 d after ischemia, but nTg mice had significantly more severe lesions than Tg at 3 d (p<0.05). In the 10 min ischemia group, while nTg mice had significantly more severe lesions than Tg at 1 d after ischemia (p<0.05), hippocampal lesions in both nTg and Tg mice were nearly maximized at 3 d. These data suggest that CuZn-SOD may play a protective role in the pathogenesis of hippocampal lesions after transient global instabilities.

Production of extracellular superoxide anion during reperfusion following cerebral ischemia correlates with cerebral infarction. R.H. Fabian', T.A. Kent. Dept. Neurology, and Pharmacol. Toxicol., of the Sch. Med., and the Marine Biomed. Inst., U. Tex. Med. Branch, Galveston, TX 77555-0539.

Superoxide anion production in the brain during and following cerebral ischemia may be important in the pathogenesis of cerebral infarction. Reactive oxygen species concentrations in the brain have been measured during and following cerebral ischemia using various techniques. However, the relationship between reactive oxygen species production and subsequent cerebral injury or infarction has not been determined. In this study, we attempted for the first time to correlate superoxide production during reperfusion as monitored electrochemically using a cytochrome c coated electrode

attempted for the first time to correlate superoxide production during reperfusion as monitored electrochemically using a cytochrome c coated electrode following cerebral ischemia with the appearance of cerebral infarction resulting from the ischemia. Extracellular superoxide anion levels were monitored over the surface of the cerebral cortex in Halothane inhalation anesthetized rats subjected to middle cerebral artery occlusion of various durations followed by monitoring during a period of reperfusion. This was compared to the presence of cerebral infarction after ischemia of various durations as determined by TTC staining of brain slices following sacrifice of the animals with a 24 hour post infarction survival. Currents of cytochrome c coated electrodes were compared to currents of uncoated electrodes as a control. Electrode signal specificity was determined by measuring electrode current during systemic

pared to currents of uncoated electrodes as a control. Electrode signal specificity was determined by measuring electrode current during systemic injections of superoxide dismutase. The results indicate that the average period of ischemia resulting in an increase in superoxide anion concentrations is approximately the same as the average period resulting in significant infarction $\sim 43\pm7.0$ and 49 ± 9.1 min., respectively. These results set the stage for studies to determine whether there is a cause and effect relationship between superoxide anion production and the appearance of cerebral infarction. Supported by a grant-in-aid from the American Heart Association Texas Affiliate, Inc.

VITAMIN E ENHANCES Ca2+-MEDIATED VULNERABILITY OF CEREBELLAR GRANULE CELLS TO ISCHEMIA. V. A. Dyatlov.
D. A. Lawrence and D. O. Carpenter*. Wadsworth Laboratories, NYS Dept. of Health, and School of Public Health, Albany, NY 12201.

Oxidative damage caused by ischemia/reperfusion-induced lipid peroxidation and free radicals might be prevented by vitamin E, an endogenous antioxidant. Suprisingly, our experiments with immature cerebellar granule cells showed that vitamin E (1-10 μM α-tocopherol phosphate) killed postischemic cells. Exposing freshly dissociated cells from the rat cerebellum (2-week-old male pups) to nt ischemia (10-min oxygen and glucose deprivation) resulted in recoveryinduced consumption of cellular anti-oxidants (ascorbic acid, glutathione and α tocopherol) and development of membrane lipid peroxidation measured by the thiobarbituric acid method. The rate of lipid peroxidation of postischemic cells was stimulated by treatment of cells with α -tocopherol. α -Tocopherol dramatically increased the intracellular Ca^{2+} concentration ([Ca^{2+}]), which preceded cell death. Hydrogen peroxide mimicked the effect of vitamin E but was less toxic than α tocopherol phosphate. Dead cells and $[Ca^{2+}]_i$ of viable cells were determined by a two-color fluorescence (7-aminoactinomycin D and fluo-3) from 10,000 cells using a FACScan cytometer. Pre- or cotreatment of the cells with vitamin C and ubiquinol-10 reduced both the α -tocopherol-induced increase in $[Ca^{2+}]_i$ and cell death. The increase in $[Ca^{2+}]_i$ and cell death were also inhibited in the postischemic cells pretreated with the intracellular Ca²⁺ chelator, 1,2-bis-(2-aminophenoxy) ethane-N,N,N',N'-tetraacetic acid acetoxymethyl ester. We believe that after consumption of co-antioxidants, $\alpha\text{-tocopherol}$ is converted to an $\alpha\text{-tocopheroxyl}$ radical, which acts as a toxic prooxidant as cellular bioenergetics deteriorate. This finding has particular importance, because low or physiological concentrations of vitamin E in postischemic cells were sufficient for a potentiation of lipid peroxidation and Ca²⁺-mediated cell killing. Supported by NS 23807 (DOC).

ISCHEMIA: NEUROTRANSMITTERS

ADRENERGIC RECEPTOR mRNA EXPRESSION IN THE RAT CNS AFTER FOCAL ISCHEMIA. S. K. McCune*, J. M. Hill, and P. D. Hurn

Divisions of Neonatology and Anesthesia and Critical Care Medicine, Johns Hopkins University Hospital, Baltimore, MD and Lab of Developmental Neurobiology, NICHD, NIH, Bethesda, MD, 21287.

Adrenergic receptors mediate tissue responses to catecholamines.

Multiple subtypes of adrenergic receptors are expressed in the CNS, each with a unique pattern of distribution. Little is known of the functional significance of these multiple subtypes. Pharmacologic studies after brain injury have suggested that alpha-1 adrenergic receptors may be involved in improved recovery of function. In order to evaluate the subtype of adrenergic receptors that may be involved, alpha-1D, alpha-1B, alpha-2C4, alpha-2C10, beta-1 and beta-2 mRNA expression was evaluated by in situ hybridization after CNS focal ischemia in the adult rat.

Right-sided ischemia was produced by permanent middle cerebral artery intravascular occlusion via insertion of an intravascular suture. The animals were sacrificed 24 hours after injury and receptor mRNA expression was examined by in situ hybridization using oligonucleotide probes specific for each subtype. A diminution of receptor expression was observed in all subtypes in the region of cellular loss. However, a significant increase in alpha-1B receptor mRNA expression was observed in the rim of healthy tissue medially bordering the ischemic lesion.

These results suggest that the alpha-1B adrenergic receptor subtype may be involved in functional recovery after ischemic lesions. Thus, the routine catecholamine surge at birth may be important in protecting against potential perinatal ischemic injury. Supported by NIH grant # NS33668 and # P-30-HD27799

SELEGILINE POST-TREATMENT PROTECTS AGAINST DELAYED NEURONAL DEATH IN GERBIL GLOBAL ISCHEMIA. H. Lahtinen*12, J. Koistinaho¹, R. Kauppinen¹, A. Haapalinna³ and J. Sivenius². A.I. Virtanen Institute¹ and Dept. of Neurology², University of Kuopio, 70211 Kuopio, and Orion Corp., Orion-Farmos³

Occlusion of both common carotic arteries (5 min) of Mongolian gerbil leads to delayed neuronal death of the hippocampal pyramidal cells. This ischemia -induced cell degeneration is first observed in 2-3 days and shares similarities with epileptic cell damage. Selegiline (I-deprenyl), an anti-parkinsonian agent, is a selective MAO-B inhibitor. However, low doses of selegiline have shown to posses rescue-like effects independent of MAO-B inhibition - in different degenerative models. To investigate whether selegiline at low doses could alleviate hippocampal cell death after an ischemic insult, normothermic gerbils underwent a 5-minutes carotic occlusion under halothane anesthesia. Selegiline, $250\,\mu g/kg$ (s.c.), was administered two hours after ischemia and once a day after that. The animals were decapitated three or seven days later for histological analyses. Pyramidal cell degeneration in the CA1 region of the hippocampus was scored (0-3) using Nissl stained sections. The animals treated with selegiline for seven days showed a significantly lower damage score compared with the saline treated animals (1.73 vs. 2.41, p=0.0133). Animals treated for three days showed also milder damage than the saline treated animals (1.67 vs. 2.05, n.s.). In our preliminary experiments, selegiline showed no effect on the cell damage when the treatment started before or immediately after the ischemic insult. mRNA for hsp70 was strongly expressed in the CAI pyramidal cell layer still three days after ischemia but had vanished after seven days. The intensity of the hsp70 signal in the CAI a region correlated negatively to the cell damage score (r=-0.76, p<0.001) showing, that hsp70 does not serve as a marker for neuronal degeneration in this model. Thus, low doses of selegiline administered after the insult seem to protect from or, at least, retard the process of delayed ischemic neuronal death. The neuroprotective mechanism of selegiline remains to be determined.

RAPID CAESAREAN SECTION DELIVERY IS ASSOCIATED WITH BRAIN HYPOXIA IN THE RAT. B. El-Khodor*, A. Gratton and P. Boksa. Departments of Psychiatry and of Neurology & Neurosurgery, McGill University, Douglas Hospital Research Center, Montreal, Canada, H4H 1R3.

Alterations in brain dopaminergic activity has been linked to the pathophysiology of several mental disorders such as schizophrenia. We have previously shown that young adult male rats born by rapid Caesarean section (CS) have increased steady state levels of dopamine (DA) in the nucleus accumbens and striatum and decreased DA in preferable active commendation to the state of the property of the section of t frontal cortex, compared to vaginally born animals. Our group has also shown that birth by CS leads to increased release of mesolimbic DA in response to repeated stress in the adult rat. It is unknown which factors in the CS birth procedure are responsible for these long-term changes in CNS DA transmission. To investigate the possibility that rats delivered by CS may experience early postnatal episodes of hypoxia, we measured levels of brain lactate, a widely accepted measure of CNS hypoxia, at 1, 5 and 30 h after birth in rats born vaginally or by CS. Rats born by CS breathed immediately and spontaneously and exhibited excellent color, muscular tone and activity levels at birth and at all time intervals studied. Rats born vaginally showed elevated levels of brain lactate at 1 h after birth (2313.8±420.7 nmole/g) compared to 5 h (564.6± 144.2 nmole/g) and 30 h (748.0±128.5 nmole/g). Similar to vaginally born controls, rats born by CS showed high levels of brain lactate at 1h after birth (1919.4±302.2 nmole'g). However CS rats maintained significantly higher levels of brain lactate at 5 h (1917.0±195.6 nmole'g) compared to the vaginally born group. By 30 h after delivery, lactate levels in the CS group (631.0±62.5 nmole'g) were similar to values for vaginally born controls. Vaginal birth in humans is accompanied by large increases in plasma catecholamines, which is believed to protect the newborn against hypoxia and promote independent breathing. This increase is absent following CS birth. In our model, rats born by CS showed significantly lower plasma epinephrine (-60%) and no change in plasma norepinephrine, in comparison to vaginally born controls. Our results indicate that biochemical evidence of brain hypoxia can be detected at early times after an apparently innocuous CS birth. This transient hypoxia may contribute to long-term alterations in DA transmission observed following CS birth. Supported by MRCC.

ASYMMETRICAL PROTECTION OF STRIATAL NEURONS FROM ISCHEMIA BY DOPAMINE DEPLETION. Y. B. Ren*, X. D. Li and Z. C. Xu

Dept. of Neurology, Univ. of Tennessee, Memphis. Memphis TN 38163, U.S.A. Spiny neurons in neostriatum are vulnerable to transient cerebral ischemia. It has been suggested that dopamine may play a role in postischemic neuronal damage in neostriatum. The present study investigated the temporal threshold for maximal neuronal damage in rat neostriatum after transient ischemia and the impact of dopamine depletion on ischemic outcome in neostriatum using 4-vessel occlusion method with some modification.

method with some modification.

Male Wistar rats were anesthetized with halothane and fasted overnight before ischemia. The brain temperature was maintained at 37° C during ischemia. Ischemic depolarization (ID) was used as an indication of severe ischemia. Dopamine neurons were depleted with two injections of 6-OHDA (4 µg/2 µl X 2) into the substantia nigra (SN) of either side by random selection. Apomorphine was injected 11 days after SN lesion. Only the rats with contralateral rotation for at least 20 min were selected for transient ischemia 2 weeks after lesion. The animals were sacrificed 24 h effor reperfection. The neuronal damage was evaluated by counting the surprived after reperfusion. The neuronal damage was evaluated by counting the survived neurons in both side of neostriatum on HE staining sections.

neurons in both side of neostriatum on HE staining sections.

Under our experimental conditions, the ischemia that induced ~22 min ID produced about 90% of cell lost in dorsolateral neostriatum. No difference was detected between the left and right striatum. Decrease of ischemic duration (~16 min ID) significantly increased the number of survived neurons (~70% cell lost). In animals after left SN lesioning, no significant difference was found between the number of survived neurons in either side of dorsolateral neostriatum following ischemia of 22 min ID. In contrast, after right SN lesioning, the number of survived neurons in right striatum significantly increased comparing with the left striatum after ischemic insult of the same extent.

Despite the mechanism of this asymmetric protection is not clear at this rount.

Despite the mechanism of this asymmetric protection is not clear at this point, the present study suggests that dopamine may play an important role in postischemic cell injury in neostriatum. Supported by NIH NS33103 and AHA 9400813

POSTISCHEMIC CHANGES OF MEMBRANE PROPERTIES IN CAI PYRAMIDAL NEURONS OF RAT HIPPOCAMPUS IN VIVO. X. Z. Xi*, T. M. Gao and Z. C. Xu Dept. of Neurology, University of Tennessee Memphis, Memphis, TN 38163, U.S.A.

Neuronal hyperactivity caused by excessive glutamate release during ischemia has been postulated to trigger the process of cell death. It is not clear whether the nas been postulated to trigger the process of cell death. It is not clear whether the alterations of synaptic transmission or changes in membrane properties are the major contributor to the pathogenesis of postischemic cell injury. We have found an ischemia-induced postsynaptic potential (i-PSP) evoked from CA1 pyramidal neurons preceding cell death after ischemia. The present study investigated the changes of membrane properties in CA1 neurons following reperfusion.

Male Wistar rats were fasted overnight and anesthetized with 1-2% halothane. The brain temperature was maintained at 37° C during ischemia. Four-vessel cochision was neefformed to induce ischemic desplayation for annexylmately 13.

occlusion was performed to induce ischemic depolarization for approximately 13 min, which consistently produced selective cell death in CA1 region. Membrane properties were compared between morphologically identified CA1 pyramidal neurons before and after ischemia with *n vivo* intracellular recording and staining. In comparison with those before ischemia, spontaneous firing of CA1 neurons

significantly reduced within two days after reperfusion. Hyperactivity as indicated by increasing firing rate was never observed. The rheobase and spike threshold of CA1 neurons were significantly increased after reperfusion. No significant difference was detected in resting membrane potential, spike height and duration,

membrane input resistance and time constant after reperfusion.

These results indicate that the spontaneous activity and the excitability of CA1 neurons are suppressed after transient forebrain ischemia. The i-PSP recorded in CA1 neurons is not associated with a significant modification of membrane properties, suggesting that i-PSP may be due to an increased efficacy of synaptic transmission but not the changes in excitability of the neuron.

ENHANCED RELEASE OF GABA AND TAURINE IN THE MOUSE HIPPOCAMPUS IN ISCHEMIC CONDITIONS. P. Saransaari* and S.S. Oia. Tampere Brain Res. Ctr, Univ. Tampere Medical School, Finland.

The massive release of excitatory amino acids from neural structures during ischemia has been thought to contribute to excitotoxicity and cell death. We studied the releases of both endogenous and preloaded labeled GABA and taurine from mouse hippocampal slices in ischemic conditions in vitro, using a superfusion system. The basal release of both inhibitory amino acids was greatly enhanced in hypoxic, hypoglycemic and ischemic conditions applied from the beginning of the superfusion, ischemia being the most effectual. Potassium stimulation (50 mM K⁺) was still able to potentiate GABA release in hypoglycemia and ischemia. In Ca-free media, the basal release of GABA was slightly increased and potassium stimulation considerably decreased. The basal release was further enhanced in ischemia but potassium stimulation was not significantly different in Ca-free media in normoxic and ischemic conditions. The basal release of taurine was already so substantial in ischemia that subsequent potassium stimulation failed to have an effect. Glutamate receptor agonists did not affect GABA release in standard or ischemic conditions. The NMDA and kainate stimulations of taurine release were not discernible in ischemic conditions but kainate and AMPA still potentiated taurine release in hypoxia. These effects were apparently not receptor-mediated, however. The enhanced release of both GABA and taurine during ischemia could counteract the harmful effects of excitatory amino acids, forestalling perturbation of homeostasis in the hippocampus upon impending hyperexcitation. Supported by the Medical Research Fund of Tampere University Hospital, Finland.

ATP LEVELS AND ADENOSINE EFFLUX FROM RAT HIPPOCAMPAL SLICES DURING HYPOXIA/HYPOGLYCEMIA. J.C. Fowler* and Y. Li. Department of Physiology, Texas Tech University Health Sciences Center, Lubbock, TX 79430. Cellular ATP levels decline and adenosine efflux increases during

Cellular ATP levels decline and adenosine efflux increases during cerebral ischemia in vivo as well as during exposure of rat hippocampal slices to hypoxia/hypoglycemia. It is generally thought that adenosine efflux is proportional to ATP degradation. In addition, ATP depletion is generally inversely related to the degree of recovery of evoked synaptic transmission. We examined recovery of evoked synaptic transmission, cellular ATP levels and adenosine efflux under a number of conditions that after these parameters. a number of conditions that alter these parameters.

Evoked population spikes from slices superfused for 10 minutes in hypoxic/hypoglycemic artificial cerebrospinal fluid (ACSF) that was either Ca⁺²-free or contained Co⁺² (2 mM), MK-801 (10 μM) or TTX (1 µM) exhibited significantly improved recovery. Ca2+-free ACSF, Co2+-and MK-801 block Ca2+ influx. TTX blocks voltagedependent Na⁺ influx. Hypoxic-hypoglycemic ATP levels were significantly spared in the presence of Co⁺², MK-801 or TTX but not in hypoxic/hypoglycemic ACSF lacking Ca²⁺. Hypoxic/hypoglycemic adenosine efflux was unchanged in MK-801, but was reduced in Ca+2-free ACSF or ACSF containing Co+2

In summary, recovery of evoked synaptic transmission and adenosine efflux can be dissociated from changes in hypoxic/hypoglycemic ATP levels. Supported by NINDS NS28027.

NEUROPROTECTIVE ROLE OF THE SEROTONIN 1A

RECEPTOR. P. Banerjee*, T. Adayev, and J.K. Singh. Biol. Doc. Prog. of Grad. School & Dept. Chem., CUNY at Staten Island, NY. A trophic role of the neural serotonin 1A receptor (5-HT_{1A}-R) was suggested in earlier studies, however, a direct demonstration of neuroprotective action of the 5-HT_{1A}-R has not been reported. Our studies demonstrate that the selective 5-HT_{1A} agonist, 8-OH-DPAT, causes inhibition of cell death under stress in the engineered neuronal cells, HN2-5 (hippocampal), as well as in 16-DIV mouse hippocampal neurons. Cell death is initiated by conditions of stress, such as hypoxia or a state of prolonged stress created by continuous culture without feeding. This protection of neuronal cells in each case is eliminated upon pertussis toxin (15 ng/mL) pretreatment and also in the presence of the 5-HT_{1A} antagonist, UH-301 (1 μ M), confirming the involvement of the 5-HT_{1A}-R and a pertussis toxin-sensitive G-protein. Since the HN2-5 cells are completely devoid of Ca²⁺ current, the observed protection cells are completely devoid of Ca²⁺ current, the observed protection could not be solely through a 5-HT_{1A}-R mediated direct or indirect inhibition of Ca²⁺ channels. Possible involvement of the mitogen activated kinase (MAPK) pathway was investigated. Agonist stimulation of the 5-HT_{1A}-R was observed to cause an activation of ERK-1 in both hippocampal neurons as well as HN2-5 cells. Inhibition of the upstream regulator ras by transient expression of dominant negative N17ras caused elimination of the 5-HT_{1A}-R mediated protection of HN2-5 cells during hypoxia. This is the first demonstration of direct neuroprotective action of the serotonin 1A receptor, and our experiments demonstrate that the MAPK pathway, channeled to the nucleus through the kinase ERK-1, is responsible for neuroprotection triggered by the serotonin 1A receptor in neuronal cells.

IMIDAZENIL, A BENZODIAZEPINE PARTIAL AGONIST, PROTECTS GERBIL HIPPOCAMPAL NEURONS FOLLOWING TRANSIENT CEREBRAL ISCHEMIA Laura E. Chadwick, Kelly J. McDonough, and Rochelle D. Schwartz-Bloom* Dept. Pharmacology, Duke University Medical Center, Durham, NC 27710

Benzodiazepines, which enhance GABA-mediated neuronal inhibition, protect hippocampal pyramidal neurons from ischemic injury. We determined whether the benzodiazepine partial agonist, imidazenil (IZ), at non-sedating doses, could produce long-term neuroprotection and prevent working memory deficits induced by ischemia. Gerbils were subjected to 5 min of forebrain ischemia by occlusion of the carotid arteries; IZ (1-6 mg/kg, i.p.) was injected 30 and 90 min later. In a separate experiment, gerbils were trained for 20 sessions on an 8-arm radial maze prior to induction of ischemia. 30 and 90 min later, they were injected with IZ (3 mg/kg, i.p.). Unlike other benzodiazepines, IZ did not produce significant hypothermia or sedation. IZ prevented pyramidal cell death in the CA1 hippocampus 7 days after ischemia in a dosedependent manner. In the long-term experiment, ischemia produced significant deficits in working memory 1 month later. IZ prevented working memory deficits in those gerbils that exhibited complete protection in area CA1 hippocampal pyramidal neurons 35 days following ischemia. There was a significant negative association between the extent of hippocampal area CA1 cell survival and the number of working errors. The neuroprotective efficacy of IZ 7 and 35 days post-ischemia was below that produced by sedating doses of diazepam. Although the lack of sedation produced by IZ may be a clinical advantage in the prevention of ischemia-induced memory deficits and hippocampal cell death long term, diazepam appears to have greater efficacy, possibly due to hypothermia. Supported by NIH grant NS 28791.

ADENOSINE A₁ RECEPTOR MODULATION OF VESICULAR GLUTAMATE RELEASE DURING ANOXIA IN CAT NEURONS OF THE RAT HIPPOCAMPUS. N. Katchman* and N. Hershkowitz, Department of Neurology, Georgetown University School of Medicine, Washington, DC 20007.

Adenosine release following hypometabolic stresses such as stroke and anoxia may serve a neurprotective function. One potential mechanism is through a presynaptic suppression of glutamate release. Adenosine has been shown to effect two sources of synaptic glutamate release, action potential dependent- (excitatory postsynaptic potentials, EPSCs) and independent-release (miniature EPSCs, mEPSCs). We used whole cell patch clamp recording in CA1 pyramidal neurons in the in vitro rat hippocampal slices to examine the role of adenosine in the suppression of both forms of synaptic glutamate release during anoxia . Anoxia was induced by switching perfusion and ambient gas of an interface chamber from a 95%O $_2$ /5%CO $_2$ to a 95%N $_2$ /5%CO $_2$ mixture. As we previously demonstrated anoxia leads to a significant increase in the frequency (280 \pm 70%, n=17) of spontaneous inward currents which have been identified as glutamate-mediated mEPSCs. When slices are preincubated in the adenosine A₁ receptor antagonist, 8-cyclopentyl-1,3-dipropylxanthine (DPCPX) a second larger population of spontaneous inward currents was observed. suppression by glutamate antagonists, tetrodotoxin or by the cutting of the Schaffer collateral pathway indicates that they represent action-potential dependent, glutamatergic EPSCs likely originating from CA3 pyramidal neurons. DPCPX caused the appearance of EPSCs it did not influence the anoxia-induced increase in mEPSC frequency. We have therefore demonstrated that during anoxia increases in extracellular adenosine may contribute to neuroprotection by suppressing action potential-dependent synaptic glutamate release (EPSCs) but not action potentialindependent spontaneous synaptic glutamate release (mEPSCs). (Supported by NIH grant NS32426 and an Epilepsy Foundation of America Research Grant)

PURINE NUCLEOSIDE CONCENTRATION DURING RETINAL ISCHEMIA IN

PURINE NUCLEOSIDE CONCENTRATION DURING RETINAL ISCHEMIA IN RATS S. Roth* J.V. Osinski, A. Toledano, S.S. Park Dept of Anesthesia and Critical Care, University of Chicago, Chicago, Illinois 60637

Adenosine, produced from the decomposition of adenosine triphosphate, is believed to provide protective effects during ischemia. On the other hand, adenosine metabolites may serve as precursors for oxygen free radical formation. The role of adenosine in retinal ischemic injury has not yet been completely elucidated. We sought to determine the time course of formation of adenosine and its purine metabolites during retinal ischemia in rats. Concentrations of adenosine and its purine metabolites during retinal ischemia in rats. Concentrations of adenosine and its purine nucleoside metabolites inosine, hypoxanthine, and xanthine in the retina of ketamine/xylazine-anesthetized rats were measured during retinal ischemia using HPLC. Quantitative measurements were made possible in the small tissue mass through the use of internal standards. Ischemia was induced by ligation of the central retinal artery, and its severity was examined using electroretinography (ERG). In each rat, one retina was ischemic while the other served as a non-ischemic control. Eves were frozen in situ using liquid nitrogen at 1, 5, 10, 20, 30, 60, and 120 min of ischemia. The retina was then removed from the frozen eyes and analyzed. Significant increases in the concentrations of adenosine, inosine, and hypoxanthine in ischemic compared to control retinae were detectable within 1 to 5 min of the onset of ischemia, and within 10 min for xanthine. Increase in adenosine concentration in ischemic relative to control retinae was describable by an exponential function for the first 30 min of ischemia, followed by a plateau. Inosine and hypoxanthine concentrations increased linearly, and xanthine exponentially throughout the measurement period. There was no ERG recovery after 120 min ischemia, nearly complete recovery after 5 min, and intermediate degrees of recovery in the other groups. This study confirmed a possible role of adenosine in retinal ischemia, which may be important during short-term oxygen or blood flow deprivation. However, prolonged ischemia results in ongoing production of xanthine, which by serving as a precursor for oxygen free radical formation, potentially may overwhelm any protective effect of adenosine, and lead to worsening of ischemic damage.

ADENOSINE AT RECEPTOR AGONISTS PREVENT DELAYED NEURONAL DEATH FOLLOWING ISCHEMIA. M.I. Sweeney*, D.S. Arneson and A. Murton. Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, SK, Canada

Adenosine A1 receptor agonists given acutely protect neurons against ischemic death. Recent evidence suggests that endogenous adenosine mediates the cerebroprotective effect of ischemic pre-conditioning. The aim of this study was to determine whether selective A1 agonists also pre-condition the brain to withstand subsequent lethal ischemia. This was tested in in vitro (primary cultures of cerebellar neurons exposed to substrate deprivation plus hypoxia) and in vivo models (unilateral global ischemia in rats). Cell death was quantitated by measuring extracellular lactate dehydrogenase (LDH) in vitro or by counting live cells stained with hematoxylin and eosin in vivo

Incubation of cultured neurons with the A1 agonist cyclopentyladenosine (CPA, 0.1-1µM) during 1 and 3hr of simulated ischemia, or for 1hr at least 24hr prior to simulated ischemia, prevented subsequent cell death. Thus, LDH release, occurring 24hr later, was reduced by 38±6%, 53±4%, 76±9% respectively. I.p. injections of CPA (1mg/kg) given 1 and 24hr before lethal ischemia provided good protection against hippocampal damage. The relative brain damage scores were 3.3±0.5 in control brains, and 1.8±0.6 and 1.0±0.2 after respective CPA injections given 1 and 24hr previously. In all cases, the neuroprotective effects of CPA were antagonized by the selective A1 receptor antagonist dipropylcyclopentylxanthine. These data indicate that activation of an adenosine A1 receptor may be a useful and effective way of preventing the brain against subsequent ischemic damage. Funded by HSF (Sask).

STRIATAL NITRIC OXIDE (NO) PRODUCTION IS ENHANCED IN FOCAL CEREBRAL ISCHEMIA: AN IN VIVO MICRODIALYSIS STUDY. A. Bhardwaj*, F.J. Northington, D.F. Hanley, R.J. Traystman, R.C. Koehler. Johns Hopkins University School of Medicine, Baltimore, MD 21287

We have previously demonstrated that NMDA, AMPA and metabotropic glutamate receptor stimulation enhances hippocampal NO production in vivo. We adapted the microdialysis technique in the rat striatum to measure NO production in the string model of permanent MCA occlusion (n=8). Under controlled conditions of normoxia, normocarbia and normothermia bilateral microdialysis probes were placed in the striatum of halothane anesthetized adult male Wistar rats (250-300 g) and perfused with artificial CSF containing 3μM [14C]-L-arginine. Effluent [14C]-L-citrulline, which was previously shown to be inhibited by nitroarginine was collected every 30 minutes and used as a marker of tissue NO production. In the ischemic striatum, [14C]-Lcitrulline recovery (femtomoles/minute ± S.E.M.) was 537 ± 30 at 3 hours post-ischemia as compared to 356 \pm 26 in the non-ischemic striatum. surgical shams (n=5), [14C]-L-citrulline recovery was not different in the left (350 ± 11) and right (363 ± 27) striatum. Probe placement in the striatum and brain infarcts were confirmed by TTC staining and dissection at 24 hours. These data demonstrate that there is increased conversion of arginine to citrulline indicating increased NO production during permanent focal ischemia.

SATURATION OF A1 RECEPTOR-MEDIATED NEUROPROTECTION BY ENDOGENOUS ADENOSINE IN CORTICAL CULTURES EXPOSED TO OXYGEN-GLUCOSE DEPRIVATION. <u>D. Lobner* and D.W. Choi</u>. Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Experiments in several brain ischemia models have demonstrated that administration of adenosine A1 agonists can reduce neuronal loss. However, contemplation of adenosine agonist administration as a neuroprotective treatment for brain ischemia needs to consider the degree to which adenosine A1 receptors are already activated by release of endogenous adenosine.

In murine cortical cell culture we found that the addition of the A1 receptor agonist cyclohexyladenosine (10 µM) did not affect cell death caused by 50 min oxygen and glucose deprivation, while it did attenuate cell death caused by 5 hr glucose deprivation alone (40% decrease) or 24 hr exposure to NMDA (80% decrease). Adenosine levels endogenously present in the bathing medium at the end of oxygen-glucose deprivation were higher than those found, either after 50 min or at the end, of the glucose deprivation or NMDA exposure. Furthermore, addition of the A1 receptor antagonist 8-cyclopentyltheophylline (10 μM) did potentiate neuronal death induced by oxygen-glucose deprivation, but did not potentiate the death induced by either glucose deprivation or NMDA

These data suggest that endogenous adenosine release is able to saturate the A1 receptor-mediated protective effect in our cell culture model of ischemic brain injury. If such saturation occurs in portions of the ischemic brain in vivo, it could act to limit the neuroprotective gains to be had through administration of exogenous adenosine A1 agonists. Supported by NIH NINDS NS 30337 (DWC)

UPREGULATION OF TYPE I NOS AFTER TRANSIENT FOCAL CEREBRAL ISCHEMIA USING [3H]L-NG-NITRO-ARGININE AUTORADIOGRAPHY H. Hara*1, C. Waeber1, P. L. Huang2, M. C. Fishman2 and M. A. Moskowitz1. Stroke and Neurovascular Regulation Laboratory and ²Cardiovascular

Research Center, MGH, Harvard Medical School, Charlestown, MA 02129.
Changes in regional distribution of nitric oxide synthase (NOS) after transient focal cerebral ischemia in the mouse brain were assessed by quantitative autoradiography using [³H]L-Nº-nitro-arginine ([³H]L-NA) binding in wild-type mice (SV-129) and in mice lacking expression of the neuronal (type I) and endothelial (type III) NOS gene.

[3H]L-NA binding did not change during 3 hr middle cerebral artery (MCA) occlusion in any region. In the early phase after reperfusion (1 - 3 hr), the binding increased by 50 -130% in ipsilateral striatum, amygdala and the MCA region of cortex in SV-129 mice, but was not altered in the ipsilateral anterior cerebral artery (ACA) teritory. No changes were observed in the contralateral striatum, amygdala and cortex. The density of [3H]L-NA binding peaked 3 hr after reperfusion. The dissociation constant (Kd) values in ischemic ipsilateral side did not change 3 hr after reperfusion when compared to contralateral side. The density of binding sites (Bmax) values in ipsilateral side increased 3 to 5 times higher than in contralateral side. The binding in amygdala and MCA area decreased 7 days after reperfusion. In type III mutant mice, but not in type I mutant mice, [3H]L-NA binding also increased 3 hr after reperfusion in the same areas as in wild-

Our data indicate that the rapid up-regulation of neuronal NOS in the ischemic region may play an important role in the early phase after focal cerebral ischemia.

563.16

LOSS OF NITRIC OXIDE SYNTHASE (NOS) POSITIVE NEURONS IN THE NEWBORN BRAIN AFTER HYPOXIA-ISCHEMIA F.J.Northington* A.Brambrink, R.J. Traystman, R.C.Koehler, and L. J. Martin. Dept. of Pediatrics, Anes./Critical Care Medicine, Pathology, and Neuroscience. The Johns Hopkins Medical Institutions, Baltimore, MD 21287.

In adult models of ischemia and excitotoxicity, NOS+ neurons may be spared. In a newborn model of hypoxic-ischemic brain injury, we tested the hypothesis that neurons expressing NOS protein or NADPHdiaphorase (NADPHd) activity would survive in the selectively damaged areas of putamen and somatosensory cortex. 13, 1-2 week old piglets were subjected to 30 minutes (m) of hypoxia followed by 7m of respiratory arrest. After resuscitation, they were survived for 24 (n=4), 48 (n=4), or 96 (n=5) hours (h). 40µ sections of striatum and 48 (n=4), or 96 (n=5) hours (h). 40µ sections of striatum and somatosensory cortex were processed histochemically or immunocytochemically to detect NADPHd or the neuronal isoform of NOS. Positive neurons in 8 fields in the putamen and 4 fields in the cortex were counted in 3 sections from each animal. In both regions, the two methods gave similar results. NOS+ neurons in the putamen (#/mm² \pm SEM, *p<0.01) (Sham(n=5) 30.6 \pm 1.5, 24h 11.4* \pm 6.8, 48h 6.6* \pm 3.7, 96h 3.1*±.8) were vulnerable to injury, with only a subset surviving past 24 hours. There were no differences after 24h. NOS neurons in the cortex, were not reduced in number after injury (Sham 4.3 ± 0.4 , 24h 4.9 ± 0.4 , 48h 1.9 ± 0.9 , 96h 3.1 ± 1.1). In this model, NOS+ neurons in putamen, a primary site of damage, are vulnerable to hypoxia-ischemia. The loss of the NOS protein/diaphorase phenotype occurs within 24h of the insult and is not progressive. If neuronally derived nitric oxide is a mediator in delayed cell death following neonatal hypoxia-ischemia, only a subset of NOS+ neurons are responsible. INDUCTION OF NEURONAL NITRIC OXIDE SYNTHASE EXPRESSION, BUT NOT INDUCIBLE OR ENDOTHELIAL ISOFORMS, FOLLOWING SPREADING DEPRESSION. A.O. Caggiano* and R. P. Kraig. Dept. of Neurology. The University of Chicago, Chicago, IL 60637
Nitric Oxide Synthases (NOS) produce NO, which has important roles in brain

Nitric Oxide Synthases (NOS) produce NO, which has important roles in brain function ranging from glutamate cytotoxicity to LTP. Enhanced expression of the inducible (iNOS) isoform occurs with a variety of stimuli, while enhanced expression of the neuronal (inNOS) and endothelial (eNOS) forms have only been shown to be induced by conditions resulting in cell injury or death. Here we show that nNOS expression can be rapidly and significantly induced following the non-injurious stimulation of spreading depression (SD). Unilateral SD was elicited in 44 Wistar male rats by micro-injection of 0.5M KCI into the left parietal cortex every 9 minutes for 3 hours. After 6 hours or 3 days of recovery brains were processed immunohistochemically with antibodies against nNOS, iNOS and eNOS. Computer based object counting for nNOS and densitometry analysis for iNOS and eNOS quantitated expression. nNOS expression was consistent with previous reports showing punctate and scattered expression filling large processed neurons. Expression was seen in the caudate, putamen, amygdala, lateral hypothalamic group, ventromedial nucleus of the hypothalamus, the median and magnocellular preoptic nucleus, the paraventricular nucleus of the thalamus, the subthalamic nucleus and the dorsal premammillary nucleus. nNOS expression was rapidly (by 6 hours) and significantly (p<0.001) induced in the cortex experiencing SD with a new distribution pattern showing strong expression in small neurons in layers II and III of the primary and supplemental somatosensory cortex, visceral, peririhinal and entorhinal areas. Expression was not induced rostral to -1.0 mm from bregma. Treatment of animals with a single dose of dexamethasone, N_n-nitro-1-arginine methyl ester, phenylephrine or indomethacin significantly reduced the expression of nNOS following SD. Nordhydroguaiaretic acid required longer treatment to reduce expression and mepacrine had no effect. The iNOS and eNOS expression did not change following SD.

These results demonstrate that nNOS expression can be induced by non-injurious stimuli and this new expression may be one mechanism by which plastic changes in brain function and structure are manifest. (Supported by NS-19108)

ENHANCED NO RELEASE FROM CEREBRAL CORTEX AFTER MIDDLE CEREBRAL ARTERY LIGATION IN THE SPONTANEOUSLY HYPERTENSIVE RATS. S. Z. Lin*, A. L. Chiou and Y. Wang. Depts. of Neurosurgery and Pharmacology, National Defense Medical Center, Taipei, Taiwan, 100

We and others previously demonstrated that nitric oxide (NO) can be released from ischemic cerebral cortex after shorterm cerebral ischemia. It has been shown that the NO synthetase is differentially regulated in the spontaneously hypertensive rats (SHR) and in their normal controls (Wistar-Kyoto rats or WKYs). In this study, we compared the NO release in these two strains during ischemic insults. Animals were anethesthetized by urethane. Temporary cerebral ischemia was induced by middle cerebral artery ligation while clamping bilateral common carotids for 40 minutes. Extracellular NO concentration was recorded through a Nafion and porphyrine -coated carbon fiber electrodes and in-vivo chronoamperometry. We found that the peak of NO release from the ischemic cerebral cortex was much higher in the SHRs than in the WKYs. Triphenyltetrazolium chloride (TTC) staining was used to evalulate the volume of infarctions. Similar to the NO release, SHRs had a much greater cortical infarction after shorterm cerebral ischemia than that in WKYs. Taken together, our data suggest that SHRs, compared to WKYs, are more sensitive to the ischemic insults. (This research is supported by a grant from the National Science Council of R.O.C.).

INHIBITION OF NITRIC OXIDE SYNTHASE (NOS) BY 7-NITROINDAZOLE (7-NI) AMELIORATES HYPOXIA-INDUCED DEPLETION OF ATP IN BRAIN SLICES M.T. Espanol, L. Litt*, K. Hasegawa, L.-H. Chang, T.L. James, and P.-H. Chan. University of California, San Francisco, California 94143

Certain central nervous system neurons contain neuronal nitric oxide synthase (nNOS), an enzyme that catalyzes formation of nitric oxide (NO) from L-arginine. Studies by others have shown that nNOS mediates glutamate toxicity presumably because it is calcium-dependent and NMDA-receptor activation causes intracellular calcium entry. We have used an nNOS inhibitor, 7-NI, to ameliorate hypoxia-induced depletion of high energy phosphorus metabolites (PCr and ATP), and reduce adverse histological changes. ³¹P/¹H NMR spectroscopy studies at 4.7 Tesla were conducted in cerebrocortical slices from 7-day old neonatal Sprague-Dawley rats, pretreated for 60 minutes with 1.0-5.0 mM L-Nitro-arginine methyl ester (L-NAME), or 3-10 µM 7-nitroindazole (7-NI). Data were obtained during NOS inhibitor pretreatment, hypoxia, and reperfusion-recovery. During hyperoxia, both L-NAME and 7-NI did not affect levels of ³¹P metabolites. During and after hypoxia (PO₂=0) only brains slices pretreated with ≥9.2 µM 7-NI showed sustained ATP levels and demonstrated full metabolic recovery. Histological scores were significantly higher in the 7-NI studies. In perfused respiring cortical slices, as in the cortex in vivo, NOS-containing neurons modulate hypoxia-induced neuronal injury. ROLE OF NITRIC OXIDE IN ISCHEMIA- EVOKED RELEASE OF [3H] NOREPINEPHRINE IN RAT CORTEX SLICES K.W. Kim. Y. A. Eun, H. R. Lee and K. P. Cho Dept. of Pharmacol., Medical School and Institute for Medical Sciences Chonbuk National Univ. Chonju, 560-182, Rep. of Korea

It has been shown that cerebral ischemia alters brain monoamine metabolism, and brain monoamines are involved in regulating the development of ischemic brain damage. We have examined the ischemia-evoked release of [3 H]NE from the cortical and slices(250 μ M thickness) of the rat loaded previously with the monoamine(15 nM for 15 min). Ischemia was induced by 5 min of deprivation of glucose and additional 5 min of deprivation of glucose and oxygen from Mg²⁺-free Krebs-Henseleit buffer. During ischemic period, significant amount of total [³H]NE was released into the incubation media. This ischemia-evoked release of [³H]NE from cortex slices was attenuated by tetrodotoxin, 1.2 mM MgSO₄, dizocilpine, ketamine, DNQX, or carbetapentane. Ischemia-evoked [³H]NE release was attenuated by oxide synthase inhibitors (L-NAME or 7-nitroindazole) hemoglobin, and methylene blue, potentiated by 8-bromo-cGMP zaprinast, and nitric oxide generator (SNAP). Nisoxetine inhibited the ischemia-induced release of [3H]NE. Omission of Ca²⁺ from incubation media potentiated ischemia-evoked [3H]NE release and the inhibitory effect of blockers for transporter. In conclusion, nitric oxide is involved in ischemia-evoked monoaminea release, and this release is achieved by Ca2+-dependent exocytosis and reversal of transporters, and can be modulated by various neuronal mechanisms (Supported by 1995 Basic Medical Research Fund of Ministry of Education of Korea)

SYMPOSIA

WEDNESDAY AM

SYMPOSIUM. GENE TRANSFER: APPLICATIONS OF VIRAL VECTORS FOR THE STUDY AND TREATMENT OF CNS DISORDERS. L.S. Brady, NIMH & H.J. Federoff, Univ. of Rochester (Chairpersons); M.G. Kaplitt, Rockefeller Univ.; F.H. Gage, Salk Instit.; B.L. Davidson, Univ. of Iowa, X.O. Breakefield, Mass. Gen. Hosp.

The aim of this symposium is to describe recent advances in the use of viral vectors to transfer and express genes in target neurons of the CNS, with emphasis on their application to the study of brain function. M. Kaplitt will describe the use of adeno-associated virus (AAV) vectors to deliver gene products in experimental models of Parkinson's Disease, Alzheimer's Disease, and in neural protection. F. Gage will report on new retroviral and lentiviral vectors used to modify cells to express neurotransmitter and neurotrophic factors. He will describe the use of genetically-modified cells to study functional recovery in experimental models of CNS damage. B. Davidson will describe the use of replicationdeficient adenovirus vectors to study disease in murine models of CNS dysfunction and the ability of the vectors to correct the underlying biochemical defects. X. Breakefield will describe the use of herpes simplex viral vectors to deliver genes for pro-drug activating enzymes in experimental brain tumors. She will present data showing that herpes vectors can be administered via multiple routes to target tumor cells disseminated throughout the brain. H. Federoff will summarize the advances and the limitations in the use of viral vectors to study CNS function.

SYMPOSIUM. BIRD SONG: TWENTY YEARS OF PROGRESS. E.A. Brenowitz, Univ. of Washington (Chairperson); D. Margoliash, Univ. of Chicago; B.A. Schlinger, UCLA; K. Nordeen, Univ. of Rochester; D.F. Clayton, Univ. of Illinois.

Over the past 20 years, the neural system that regulates song

Over the past 20 years, the neural system that regulates song behavior in birds has emerged as an excellent model for study of fundamental issues including sexual differentiation of brain and behavior, sensitive periods in development, hormonal influences on brain function and development, the neural basis of learning and memory, plasticity in adult brains, and the organization of motor circuits. Birdsong is a learned, stereotyped behavior that is sexually dimorphic in many species. The learning, production, and perception of song are regulated by discrete neural circuits. These circuits show considerable morphological and physiological plasticity in adult birds.

This symposium will review progress in this field and identify important directions for future research. Brenowitz will provide a brief overview of the song system. Margoliash will discuss the implications of physiological data, from intracellular to chronic recordings, for understanding the functional organization of the song system. Schlinger will consider the profound influence of sex steroid hormones and their metabolites on development and function of the song system. Nordeen will describe anatomical and synaptic plasticity in the song system at the time of song learning. Clayton will present evidence that differential gene expression is important in determining the degree of plasticity found in the song control system.

EXPRESSION OF THE S182/PRESENILIN I PROTEIN IN NEURONAL CELL LINES. J. Shioi¹, H. Cai¹, N. Tezapsidis¹, H.-C. Li², S. Efthimiopoulos¹, N. K. Robakis s¹.³. Departments of Psychiatry¹ and Biochemistry² and Fishberg Research Center for Neurobiology³, Mount Sinai Medical Center, New York, NY10029, USA.

Many individuals with familial Alzheimer's disease (FAD) have mutations in a chromosome 14 gene termed S182 or Presenilin I (PS-I), whose product has not been identified and its function remains unknown. We prepared affinity purified antibodies against synthetic peptides of the predicted amino acid sequence of PS-I. These antibodies recognized a glutathione S-transferase/PS-I bacterial fusion protein and were used to examine the cellular expression of PS-I. Western blot analysis of N2a neuroblastoma cell extracts detected a single antigen of approximately 50 kDa, in good agreement with the predicted molecular weight of the 467 amino acid protein. Immunoprecipitaion of the 35Slabelled cell extracts also revealed a 50 kDa protein, whose detection was inhibited by the presence of the corresponding antigen peptide during precipitation. Immuno cytochemistry of various cell lines demonstrated that only neural cell lines HS-SY5Y, N2a and NGF induced PC12 cells were well stained with anti PS-1 antibodies, while nonneuronal cell lines, such as C6 rat glioma, fibroblast COS, 293 or CHO, were poorly stained. The staining was specific because it was inhibited by the presence of the competing peptide. In neuronal cells, both cell bodies and extended neurites were equally stained. High magnification showed a cytoskeletal structure-like staining pattern, and a double immunostaining with both anti PS-I and anti-cytoskeletal proteins is under way. These results are consistent with those of Elder et al (1996, J. Neurosci, Res., in press) showing that in tissue sections of mouse central nervous system, PS-I protein is found exclusively in neurons where it is located primarily within cell bodies and dendrites. These data suggest that PS-I is expressed mainly in neurons where it may perform a neuron-specific function. Supported by Grants AG08200 and AG05138.

568.3

EXPRESSION AND SUBCELLULAR LOCALIZATION OF PRESENILIN 1 AND 2, P. M. Mathews, B. Kao, J. L. Yang, X. Qin, J. L. Barnett, A. M. Cataldo, and R. A. Nixon*. Lab. for Molecular Neuroscience, McLean Hospital, Dept. of Psychiatry, Harvard Medical School, Belmont, MA 02178.

In order to study their expression and subcellular localization, we have generated a battery of antibodies against the recently identified chromosome 14 and chromosome 1 gene products (PSI and PS2, respectively) linked to early-onset Alzheimer's disease. Multiple antibodies showed by Western blot analysis an ~50 kDa doublet in murine L-cells stably transfected with a human PS1 cDNA. Immunofluorescence labeling of these cells with a mAb specific for human PS1 localized the overexpressed protein to the ER. In addition to the transfected cells, an ER-like distribution was seen in various human cell lines expressing endogenous levels of PS1 and in pyramidal neurons from both human and monkey cortex. Antibodies against PS2 revealed a similar distribution in pyramidal neurons for this protein. Consistent with the initial report showing the broad distribution of PS1 mRNA, Western blot analysis of multiple human cell lines, of human brain, and of various tissues isolated from monkey has consistently detected PS1. The levels of PS1 immunoreactivity detected in frontal cortex from age-matched control and sporadic Alzheimer's disease cases were found to be similar both by immunocytochemistry and Western blot analysis. In both human and monkey brain, however, Western blot analysis gave evidence for substantial proteolytic processing of PS1 unrelated to the postmortem interval. (AG10916 and F2 NS09848)

Analysis of Presenilin 1 in a Human Neuronal System: Localization in Cell Bodies and Dendrites, D.G. Cook*, J.C. Sung, T.E. Golde, K.M. Felsenstein, B.S. Wojczyk, R.E. Tanzi, J.Q. Trojanowski, V.M.-Y. Lee, and R.W. Doms. Dept. Pathology & Lab. Med., Univ. of Pennsylvania, Philadelphia, PA 19104.

Mutations have been found in two closely related genes located on chromosomes 14 and 1 that cause familial Alzheimer's disease. These genes, Presenilin 1 and 2 (PS1 and PS2), encode novel proteins for which little is known of their function or characteristics of expression.

To gain insight into PSI biosynthesis we have expressed PSI in non-neuronal BHK-21 cells and human neuronal NT2-N cells using the Semliki Forest virus (SFV) vector. PSI was expressed both as a wild type protein, and with antigenic tags (the influenza HA tag was placed near the amino terminus and the Herpes Simplex Virus I gD tag was placed at the carboxyl terminus). For all three forms of PSI, immunoprecipitation showed two primary bands migrating at approximately 43 and 50kDa. Endogylcosidase analyses indicate that PSI is not N or O-glycosylated. Immunofluorescence staining using antibodies against the N-terminus (anti HA), the C-terminus (anti-gD), and the 6th hydrophilic loop of untagged PSI recognized PSI only in permeabilized cells. This strongly suggests that PSI is not expressed on the cell surface. In NT2-N cells, PSI expression was restricted primarily to the cell bodies and dendrites, and co-localized with calnexin, a marker of the rough ER. At the light microscopic level, the A246E mutation did not alter the lacy, reticular expression pattern seen with PSI wt.

did not alter the lacy, reticular expression pattern seen with PS1wt.

The use of SFV to express recombinant proteins in NT2-N cells provides an efficient system to investigate the function of wild type and mutant PS1 in human neuronal cells. Supported by NIH P01 AG 11542.

SUBCELLULAR LOCALIZATION OF PRESENILIN-1 IN CULTURE AND IN THE ALZHEIMER BRAIN. Jorge Busciglio*, Alfredo Lorenzo, Henrike Hartmann. Matthias Staufenbiel+ and Bruce A. Yankner. Dept. Neurology, Harvard Medical School and the Children's Hosnital Roston MA. *Sandra Pharma Ltd. Basel Switzerland

Hospital, Boston, MA. +Šandoz Pharma Ltd., Basel, Switzerland. Missense mutations in presenilin-1 (PS-1) have been shown to cause most cases of familial Alzheimer's disease (FAD). We examined the subcellular localization of PS-1 with antibodies to different regions of PS-1. Transiently transfected COS cells expressing full-length PS-1 showed strong perinuclear cytoplasmic staining which colocalized by double-labeling immunofluorescence with Golgi resident proteins βCOP and 58 kD protein and the ER resident protein BiP. PS-1 immunoreactivity was abolished by preabsorption of the antibodies with the corresponding antigenic peptides. Non-transfected COS cells exhibited a pattern of immunostaining restricted to the ER, suggesting an ER localization of PS-1 when the protein is not overexpressed. PS-1 immunolabeling was observed in neuronal cell bodies and neuritic processes of cultured rat hippocampal neurons. PS-1 immunoreactivity was also detected in oligodendrocytes, astrocytes and neuroblastoma cells. In the Alzheimer brain, PS-1 immunoreactivity was detected in pyramidal neurons of the hippocampal formation and neuronal cell bodies scattered throughout cortical areas, but not in granule cells of the dentate gyrus. PS-1 positive neurons were often seen adjacent and surrounding amyloid plaques, but PS-1 immunostaining was not observed in the plaque cores. Neurons stained with antibodies against phosphorylated tau were also frequently positive for PS-1. These results show that PS-1 is preferentially localized in neuronal populations that are particularly affected in Alzheimer's disease.

568.4

CHARACTERIZATION OF THE PRESENILINS, A NEW CLUE TOWARDS UNDERSTANDING ALZHEIMER'S DISEASE. L. Lévesque, H. Chi, C. Bergeron*, W. S. Trimble, C. Haass, D. Selkoe, P. St George Hyslop and P.E. Fraser. Centre for Research in Neurodegenerative Diseases, University of Toronto, Toronto, Ontario, Canada, M5S 3142.

Presenilins (PS) I and II are part of a new class of proteins which are believed to play an important role in the development of Alzheimer's disease (AD). Missense mutations of these proteins are linked to families with early onset AD. Polyclonal antibodies were raised against different regions of the PS. Examination of neural (PC12) and non-neural cells (Cos and fibroblasts) by confocal microscopy revealed a PS distribution predominantly localized at the endoplasmic reticulum (ER), as well as some overlap with the golgi and nuclear envelop. Some unidentified vesicles were also labelled but no surface staining was detected. COS cells transfected with a c-myc-tagged PS construct showed a similar pattern of expression using either PS or c-myc antibodies. Electron microscopy of monkey cerebellum with immunogoldlabelling appeared often in clusters and seemed to be associated with the ER membrane. Immunofluorescence of primary fibroblast from individuals with selected PS mutations showed no obvious different in PS distribution. Western blots and immunoprecipitation of native or expressed proteins with PS antibodies revealed a predominantly 40-45 kD band which is in agreement with its predicted size. Western blots of the different mutation-bearing fibroblast showed no difference in the level of PS expression. Therefore, mutations of PS does not seem to cause changes in its distribution pattern or its level of expression but may possibly cause functional changes. It is suggested that PS may play a role as protein processing or trafficking which may alter in some familial AD

IDENTIFICATION AND NEURON SPECIFIC EXPRESSION OF THE S182 PRESENILIN I PROTEIN IN HUMAN AND RODENT BRAINS. G. A. Elder', N. Tezapsidis', J. Carter', J. Shioi'*, C. Bouras', H.-C. Li', J. M. Johnston', S. Efthimiopoulos', V. L. Friedrich Jr.² and N. K. Robakis'. Departments of Psychiatry', Molecular Biology², Biochemistry³, The Mt. Sinai School of Medicine, New York, NY; Psychiatry⁴, University of Geneva, Switzerland; Neurosurgery⁵, Albert Einstein College of Medicine, Bronx N.Y.

Many individuals with familial Alzheimer's disease (FAD) have mutations in a gene termed \$182 or presenilin I (PS-I). Presently, the PS-I gene product has been identified but its function remains unknown. Here we report that affinity purified antibodies against the predicted amino acid sequence of the PS-I gene product detected in homogenates of human, mouse and rat brains a single antigen of approximately \$50 kDa. This antigen was also present in several neuronal cell lines. Brain tissue fractionation showed that all PS-I antigen was found in the membrane fraction. In stained tissue sections of mouse CNS, PS-I antigen was found only in neurons and could be located within cell bodies, axons and dendrites. Remarkably, the relative partition among these three compartments varied dramatically. A striking feature of PS-I expression was its intense concentration in some (but not all) dendrites, at levels substantially above those in the parent perikarya. In most of the cerebrum, PS-I staining in axons was very weak or undetectable. By contrast, many axons in portions of the brainstem and in the spinal cord showed marked PS-I immunoreactivity. Similarly, staining of sections from human temporal cortex showed that PS-I was present mainly in neuronal cell bodies and dendrites. These data show that in the CNS, PS-I is expressed mainly in neurons and suggests that this protein may perform a neuron specific function.

EXPRESSION OF PRESENILIN-1 IMMUNOREACTIVITY IN BRAIN AND TRANSFECTED CELLS. J.J. Lah, C.J. Heilman, H.D. Rees, H. Yi, K.E. Miller, S.E. Counts, D.B. Rye, M. Wakai, N.R. Nash, and A.I. Levey*. Dept. of Neurology, Emory University, Atlanta, GA. 30322

Mutations in two closely related genes presentlin 1 (PS1) and presentlin

Mutations in two closely related genes presenilin 1 (PS1) and presenilin 2 (PS2) are responsible for the majority of cases of familial Alzheimer's disease (FAD). Here we examine the PS1 protein by western blot and immunocytochemistry utilizing an N-terminal specific monoclonal antibody. On immunoblots of brain tissue as well as PC12 and COS7 cells transfected with PS1 cDNA, this antibody recognizes a 53kD band, corresponding to the predicted size of the full-length protein. In addition, there is a more abundant polypeptide at 32kD, suggesting that native PS1 is processed into a smaller product. Samples from monkey frontal cortex, hippocampus, septum, thalamus, hypothalamus, striatum, substantia nigra, and cerebellum all revealed the predominance of the 32kD band with no apparent differences in regional abundance. Both bands are present in monkey peripheral tissues, with highest levels in testis and lung, intermediate levels in liver, spleen, salivary gland, and heart, and low or undetectable levels in skeletal muscle and pancreas. Immunocytochemical localization of PS-1 in brain sections shows labeling of neuronal cell bodies, with lower levels in glial cells and blood vessels. Large cortical pyramidal neurons and magnocellular basal forebrain neurons, vulnerable in Alzheimer's disease, express relatively high levels of PS1 immunoreactivity, although many other neuronal populations are also labeled. In transfected cells, immunofluorescent labeling reveals perinuclear and more widespread reticular distributions. Immuno-electron microscopy localizes the N-terminus of PS1 to the cytoplasmic face of discrete intracellular membrane compartments. Studies are in progress to clarify the subcellular localization and to assess the influence of mutations on the processing and localization of PS1.

ABNORMAL BEHAVIOR OF PS-1 IN GEL ELECTROPHORESIS. N. Sahara 1.

A. Yamamoto¹, M. Usami¹, M. Okochi¹, T. Kondo¹, F. Kametani¹, K. Tanaka¹, Y. Yahagi¹, T. Shirasawa² and H. Mori^{*}. ¹⁰Department of Molecular Biology, Tokyo Institute of Psychiatry, 2-1-8 Kamikitazawa, Setagayaku, Tokyo 156, Japan. ²¹Department of Molecular Pathology, Tokyo Metropolitan Institute of Gerontology, Itabashiku, Tokyo 173, Japan.

Presentiin 1 (PS-1) is the main causal gene for familial Alzheimer's disease. We have recently identified *in vitro* PS-1. Using this PS-1, we examined its biochemical property and found the abnormal behavior in gel electrophoresis. A single molecule with the apparent molecular size of 43,000 was identified as freshly synthesized PS-1-467 (the isoform consisting of 467 amino acids) and was found to disappear in one day after incubation at 37°C due to aggregation by its high content of hydrophobic domains. This aggregation changes underwent a formation of an intermediate aggregation with Mr 74,000/100,000 before the final formation of huge-sized aggregation retained at the gel top layer. Thus the 43,000-protein of PS-1-467 was found to be decreased with the reciprocal increase of 74,000/100,000-protein. Failure of identification of PS-1 in the brain may be partly explained by this abnormal property of PS-1.

DEVELOPMENTALLY REGULATED EXPRESSION OF ALZHEIMER-RELATED PRESENILIN GENES (PS-1 AND PS-2) MATCHES NOTCH IN MOUSE BRAIN. O. Berezovskaja, K. Page, MQ. Xia, V. Berezovskij*, W. Wasco, R. Tanzi and B. T. Hyman. Departments of Neurology and Neurobiology, Mass. General Hospital and Harvard Medical School, Boston, MA 02114.

Mutations in the PS1 and PS2 genes are related to early onset Alzheimer disease. The biological functions of the PSs in normal brain and in AD are unknown. One clue is the strong structural homology of PSs with the Celagang gene product sel. 12, which is believed to interact

Mutations in the PS1 and PS2 genes are related to early onset Alzheimer disease. The biological functions of the PSs in normal brain and in AD are unknown. One clue is the strong structural homology of PSs with the C.elegans gene product sel-12, which is believed to interact with lin12, a molecule important during neurogenesis. We studied the pattern of mRNA expression of PS1, PS2, and Notch (the mammalian homologue of lin12) throughout mouse embryogenesis and into adulthood using RT-PCR and in situ hybridization techniques. Strong expression of PSs was observed in embryos which decreased gradually as embryos developed. During early embryosgenesis PS1 and PS2 mRNA were abundantly expressed in the majority of neuroepithelial cells. As embryogenesis continued, high levels of PSs were observed in the ventricular zone, containing precursor cells from which all cell types of the brain originate. Weaker signal was detected at postnatal day 1 and 7; even lower expression of both PSs was observed in an adult mouse brain, where there was very low level cortical expression with somewhat higher expression in the hippocampus and cerebellum. The time course and pattern of expression of PSs parallels that of Notch 1 and Notch 2. These observations suggest that PS could be related to Notch, analogous to the interactions between sel-12 and lin-12; we hypothesize that this role may involve the PSs in cell fate decisions such as neuronal differentiation, synaptogenesis, and/or apoptosis. Supported by NIH grant 3PSO AG 05134.

Two types of monoclonal antibodies against Alzheimer's PS-1 molecule M. Okochi, F. Kametani, M. Usami, N. Sahara, A. Yamamoto, T. Kondo, K. Tanaka, Y. Yahagi T. T. Shirasawa and H. Mori. Department of Molecular Biology, Tokyo Institute of Psychiatry, 2-1-8 Kamikitazawa, Setagaya-ku, Tokyo 156, Japan **Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo 173, Japan

We prepared several antibodies against 3 different domains in PS-1 to see in vivo function of PS-1; at the amino terminal, loop and carboxyl terminal regions of PS-1 as antigen peptides. Immunoprecipitation of PS-1 which were made in vitro using transcription/translational kits with PS-1 cDNA showed virtually a single strong band with Mr 43,000 when three antibodies were used as template. further confirmed in COS cells transfected with PS-1 cDNA. As we had a trouble to conclude PS-1 in brain tissues, we next prepared monoclonal antibodies to the same region of PS-1. Twelve of monoclonal antibodies were established against the same amino terminal antigen. We classified these antibodies into two groups by the following criterion. All 12 monoclonal antibodies precipitated PS-1-467 product. Four monoclonal antibodies precipitated PS-1-374, while 8 monoclonal antibodies hardly detected PS-1-374, though both presenilin molecules shared the same sequence in their amino terminal region. The lack of loop and carboxy terminal regions which are quite downstream from the epitope was found to affect the antigenicity in the amino terminal region. It suggested that both ends interact each other. together with the established mutations in PS-1, the loop structure seemed to play an important role in the structure and functionn of PS-1.

PHOSPHORYLATION AND SUBCELLULAR LOCALIZATION OF THE ALZHEIMER'S DISEASE ASSOCIATED PRESENILIN PROTEINS, C. Haass^{1*}, A. Capell¹, J. Grünberg¹, B. Pesold¹, A. Schindzielorz¹, P. St. George Hyslop², D. J. Selkoe² and J. Walter¹. 'Central Institute of Mental Health, Department of Molecular Biology, J5, 68159 Mannheim, GERMANY. ²Center for Research into Neurodegenerative Diseases, University of Toronto, Toronto, Ontario, CANADA M5S 1A8. ³Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115, USA.

In about 10% of AD cases the disease is inherited as a fully penetrant transpared leaf. (5f. Dp.) the

In about 10% of AD cases the disease is inherited as a fully penetrant autosomal trait. Of the genes involved in familial Alzheimer's disease (FAD), the Presenilin (PS) genes play a fundamental role in causing early onset AD. Here, we report the analysis of post translational modifications of the PS proteins. As shown by in vivo labeling and pulse chase experiments, PS protein do not undergo sulfation or glycosylation. Interestingly, the PS-2 protein was found to be phosphorylated in vivo while little if any phosphorylation was observed for PS-1. The mutant form of PS-2 found in the Volga-German kindred is phosphorylated as well. Phosphorylation of PS-2 proteins was not only observed in transfected COS-7 cells but also in transfected CHO and kidney 293 cells. Phosphorylation of PS-2 takes place exclusively on serines residues. Although several potential recognition sites for protein kinase C (PKC) are present within the sequence of PS proteins, PS-2 is not phosphorylated by PKC. as analyzed by selective stimulation and inhibition of the kinase. By deletion analysis a major site of PS-2 phosphorylation was mapped to its N-terminal half. We also studied the effect of large C-terminal deletions on the subcellular localization of the PS proteins endogenous PS proteins as well as PS proteins overexpressed after transfection of a variety of cDNA clones were detected predominantly within the endoplasmic reticulum (ER) and early Golgi. Deleting the large hydrophilic loop and TM6 which contains a conserved aspartate did not alter the predominant localization of PS proteins within the ER.

The role of S182, a protein mutated in familial Alzheimer's disease, in membrane transport. Thillai Koothan*, M. Maletic-Savatic and R. Malinow. Jones Bldg, Cold Spring Harbor Lab., Cold Spring Harbor, NY 11724.

Missense mutations in S182 protein have been associated with some cases of familial Alzheimer's disease. The S182 gene product is predicted to contain multiple transmembrane domains and resembles an integral membrane protein. We have raised antipeptide antibodies against mouse S182 protein which reacts to both mouse and rat cultured hippocampal neurons. We see no immunostaining in astrocytes. The presence of perinuclear immunofluorescent staining and occasional dendritic punctuate staining indicates S182 protein might be present in the endoplasmic reticulum, Golgi apparatus and dentritic organelles. S182 protein might be involved in the transport of membrane-bound vesicles in the endosome-lysosome apparatus. Antisense oligonucleotides against rat S182 and the fluorescent membrane probe FM1-43 will be employed in cultured rat hippocampal neurons to investigate membrane-bound vesicle transport and exocytosis.

CHARACTERIZATION AND ANALYSIS OF PRESENILIN 2 IN MAMMALIAN CELLS: EFFECTS OF EXPRESSION ON CELL VIABILITY A.C. Crowley, D.E. Merriam, D.M. Kovacs, T.-W, Kim, and W. Wasco*, Genetics and Aging Unit, Department of Neurology, Massachusetts General Hospital-East, Harvard Medical School, Boston MA,

We have recently demonstrated that the expression patterns of PS1 and PS2 in the brain are extremely similar and that mRNA for both proteins is detected primarily in neuronal populations. In addition, we have found that both PS1 and PS2 localize intracellularly to the nuclear envelope, ER and Golgi compartments in transfected mammalian cells (*Nature Med.* 2, 224-229, 1996). These findings indicate that the pathogenic effect of FAD mutations may be initiated by alterations of processes associated with the localization of these proteins within neuronal intracellular membranes. We have continued to characterize the normal expression, processing and subcellular distribution patterns of PS2, and the effects of the FAD-associated mutations. Specifically, truncated and deleted FLAG-tagged expression vector constructs are being utilized to localize the PS2 ER/Golgi localization signals. Using H4 neuroglioma cell lines that have been stabily transfected with constructs that allow for tetracycline-regulated induction of PS2, we have found that the induction of PS2 expression appears to compromise cell viability. We are currently exploring the possibility of PS2 induction of cell death by apoptotic mechanisms. Given that both PS1 and PS2 have been shown to undergo proteolytic processing into two major fragments (Kim et al, submitted), we are also testing for possible correlations between the proteolytic processing and degradation of PS2 and the occurrence of cell death.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: CIRCUITRY AND PATTERN GENERATION IV

569.1

PERIOD INDUCED BY CERVICAL NERVE ROOT STIMULATION, <u>P.C.Su</u>, <u>MD*</u>, <u>S.Pullman</u>, <u>MD</u> Columbia University, The Neurological Institute, 710 W.168th street , NY, NY 10032

Objective:To determine onset, duration and latency of EMG silent period

Objective:To determine onset, duration and latency of EMG silent period (SP) induced by cervical nerve root (CNR) stimulation (sti) compared with SP induced by wrist (W) sti. Background: SP has been used as an investigative tool in motor diseases such as Parkinsonism and dystonia. There is little information about SP induced by CNR. Methods:26 health subjects, age 20 to 65,10 men 16 women, were instructed to isometrically contract opponeus pollicis at 50 percent effort. Surface electrodes were used to record EMG activity. Magnetic sti was applied to C6-7 spinal process for root sti. Electric sti to W was employed in same subject and measurement was compared Result:CNR resulted in a SP immediately following the M response which has latency of 14.1±5.1 mS. Total duration of SP following CNR sti is 97.6±11.4 mS and 112.2±14.3 mS with W sti. Post-sti vs pre-sti EMG amplitude ratio is 2.6 for CNR and 2.1 for W sti. Long spinal reflex (V2) seen in W sti is prominent in 2/3 subject following CNR sti and cannot be identified in 1/3 subject. V2 latency with W sti is 53.1±5.7 mS; 43.7±4.2 with elbow sti and 42.9±5.1 in CNR sti. In the 1/3 subjects where V2 is not discernable from the EMG activity which continued at pre-sti amplitude, there still is a higher EMG rebound at 96±15.3 mS.Conclusion:SP following the M response is most likely due to Renshaw Cell inhibition from antidromic motor impulse because of short latency. V2 may be a polysynaptic suprasegmental response since there are only a small differences in latency when sti was moved from W to elbow and to CNR. In 1/3 subjects, the SP appears to end at V2.This may be either due to decreased inhibition or relatively greater suprasegmental influences breaking through the SP folloing V2 response.

EFFECTS OF INTRATHECAL BACLOFEN ON ANALGESIA AND MOTOR PERFORMANCE IN THE RAT. P. Nance.

University of Manitoba, Winnipeg, Manitoba, Canada R3A 1M4.
Baclofen, a GABAb agonist, is well known as an analgesic and spasticity treatment. An often reported, but poorly documented, clinical side effect of baclofen is the induction of weakness. In the present study, tests of sensory and motor function were performed sequentially to examine the relationship, if any, of baclofen induced analgesia and motor impairment. In a group of four rats, three were cannulated for episodic injection of baclofen and one was not cannulated as a control. The treated animals received one injection per test-day of the following doses of baclofen: 0.5, 1.0, 1.5 μ g. The baclofen was flushed through the cannulae with 10 μ l of saline. nimals were tested three times prior to injection then every 20 minutes for 80 minutes after injection. The testing battery for sensory function included the following: tail flick, hot plate and paw pressure. Motor function was assessed by the inclined plane test and kinematic analysis of swimming. Data from the inclined plane test was not changed by baclofen treatment. However, motor performance on the swimming task was detectable at all doses. Only the hot plate test demonstrated significant analgesia at the highest baclofen dose tested. After baclofen injection, movements were slower and the alternating pattern of foot strokes was observed to change toward a non-alternating gallop style of swim stroke, p<.001. In conclusion, intrathecal baclofen induced changes in motor performance can be observed in sub-analgesic as well as analgesic dosages in the rat. Supported by the Neuroscience Network of Canada.

COMPARISON OF FUNCTIONAL ACTIVATION STUDIED BY WHOLE-BRAIN BOLD- AND CBF-BASED [MRI AND [150]WATER PET DURING SEQUENTIAL FINGER OPPOSITION. S-G. Kim, J.J. Sidtis, S.C. Strother, J.R. Anderson, K. Rehm, K. Ugurbil, D.A. Rottenberg*. Center for Magnetic Resonance Research, Departments of Radiology and Neurology, University of Minnesota, and VA Medical Center, Minneapolis, MN 55455 and 44517.

To compare the spatial patterns of functional activation obtained using fMRI and [15O]water PET during the performance of a simple motor task, five normal volunteer subjects were studied during auditory-cued sequential left-hand finger-to-thumb oppo-sition (1 Hz). All subjects had paired fMRI and [150]water PET scans, three within a two-week period. Functional MRI scans were acquired using a 4 Tesla MR system each subject had three BOLD-based scans and one CBF-based FAIR scan. Thirty-four 5 mm coronal echo-planar images were acquired for whole-brain BOLD studies (TE = 25 ms, TR = 5 s); three contiguous 5 mm slices incorporating M1/S1 and SMA were acquired for CBF-based FAIR studies (TI = 1.4 s, TR = 2.8 s). BOLD and FAIR studies consisted of four control and three task epochs, each lasting one minute. [150]water PET studies consisted of 8-10 alternating baseline-activation scans (90 seconds/scan) separated by eight minutes. We found that contralateral M1/S1, SMA and ipsilateral cerebellum were typically activated in fMRI and PET images. For both PET and fMRI, the Talairach locations of activated foci were reproducible within and between modalities; however, the volume and intensity of individual foci were extremely variable. Inferior cerebellum and the deep gray nuclei were activated in some PET but in no BOLD fMRI studies. The methodological and/or physiological basis of this variability must be understood in order to reliably interpret PET and fMRI functional activation studies. COMPLEXITY IN INDIVIDUAL NEURONS DETERMINES WHICH PAT-TERNS ARE EXPRESSED IN A RING CIRCUIT MODEL OF GAIT GEN-ERATION. D. A. Baxter*, C. C. Canavier, R. J. Butera, J. W. Clark,

TERNS ARE EXPRESSED IN A RING CIRCUIT MODEL OF GAIT GENERATION. D. A. Baxter*, C. C. Canavier, R. J. Butera, J. W. Clark, and J. H. Byrne. Dept. of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225 and Dept. of Electrical and Computer Engineering, Rice University, Houston, TX 77251.

In order to assess the relative contributions to pattern-generation of the intrinsic properties of individual neurons and of their connectivity, we examined a ring circuit composed of four complex physiologically-based oscillators. This circuit produced patterns that correspond to several quadrupedal gaits, including the walk, the bound, and the gallop. An analysis using the phase response curve (PRC) of an uncoupled oscillator accurately predicted all modes exhibited by this circuit and their phasic relationships. The key insights in the analysis were that in a gait pattern, all oscillators are entrained at the same frequency, hence the phase advance or delay caused by the action of each oscillator on its postsynaptic oscillator is the same, and the sum of the normalized phase differences around the ring is equal to an integer. As suggested by several previous studies, our analysis showed that the capacity to exhibit a large number of patterns is inherent in the ring circuit configuration. In addition, our analysis revealed that the shape of the PRC for the individual oscillators determines which of the theoretically possible modes can be generated using these oscillators as circuit elements. PRCs that have a complex shape enable a circuit to produce a wider variety of patterns, and since complex neurons tend to have complex PRCs, erriching the repertoire of patterns exhibited by a circuit may be the function of some intrinsic neuronal complexity. Our analysis showed that gait transitions in a ring circuit do not require rewiring the circuit or any changes in the strength of the connections. Instead, transitions can be achieved by using a control parameter, such as stimulus intensity, to sculpt th

FUNCTIONAL AND MOLECULAR DIVERSITY NEOCORTICAL INTERNEURONES. E. Audinat, B.Cauli, M.C. Angulo, B. Lambolez and J. Rossier*. CNRS URA 2054, ESPCI, 10 rue Vauguelin, 75005 Paris, France,

In the neocortex a large heterogeneity of GABAergic interneurones has been revealed by studying the expression of calcium-binding proteins and neuropeptides but this biochemical diversity bear no clear functional correlates. We have combined whole-cell patch-clamp recording with single-cell RT-PCR to study the expression of calbindin (CA), calretinin (CR), parvalbumin (PV), somatostatin, cholecystokinin, vasoactive intestinal peptide and neuropeptide Y in each recorded interneurone identified by infra-red video microscopy in slices of the rat motor and visual neocortex. The simultaneous amplification of seven different biochemical markers revealed that in 70% of the recorded cells at least one neuropeptide was expressed together with one or two calcium binding proteins. One third of the interneurones were characterized by nonadapting discharges of fast action potentials. All but 2 of the 31 recorded fast spiking cells expressed PV and none of them expressed CR. In half of these cells CA was co-expressed with PV. The remaining two third of the interneurones displayed a marked frequency adaptation of their action potential discharges. Most of these cells expressed either CA or CR which were rarely colocalized. This group of adapting interneurones could be further divided in different functional and biochemical subtypes.

COUNTING THE NUMBER OF SHAL 1 RNA MOLECULES IN IDENTIFIED PYLORIC NEURONS USING QUANTITATIVE SINGLE CELL RT-PCR. D.J. Baro*, R.M. Levini, C.L. Cole, and R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14850.

We study the motor pattern generated by the pyloric network in the stomatogastric ganglion of the spiny lobster. This network contains 14 neurons that fall into six cell types. Each cell type possesses a unique electrophysiological phenotype which defines the cell's role in the network. For example, when and how intensely a cell fires in the motor pattern is partly determined by the transient K⁺ current (I_A), which is distinct in each cell type. We are interested in the molecular basis of IA heterogeneity. Previously we cloned the open reading frame of the lobster *shall* gene and found that it produced an IA in *Xenopus* oocytes. Using a non-quantitative, single cell-reverse transcription-polymerase chain reaction (se-RT-PCR) method we found that the *shal1* gene was expressed in 94% of stomatogastric neurons, but that expression levels varied among cells. We have now developed a quantitative sc-RT-PCR method to determine if variable numbers of *shal1* RNA molecules could account for somatic I_A heterogeneity. Using this method we found significant and reproducible differences in the numbers of *shal1* RNA molecules in each cell type. r example, the PD cell contains 1,087±130 (n=6) shall RNA molecules, while the VD cell possesses 378 \pm 77 (n=5; p<.01). This difference reflects the size of the somatic I_A in each cell: the PD has the largest and the VD the smallest somatic I_A among all pyloric neurons. Presently, we hope to establish whether there is a positive correlation between the number of shall RNA molecules and the maximal conductance of IA in the different cell types. Preliminary data indicates that unlike the other 5 cell types, the number of shall molecules in the AB cell varies significantly among individuals. This is similar to our previous finding in which we demonstrated that the level of shab gene expression was reproducible among individuals in all homogeneous cell types except the AB. OBJECT-ORIENTED TECHNOLOGY ALLOWS UNIVERSAL ACCESS TO NEUROPHYSIOLOGY DATABASES. Daniel Gardner* and Steven M. Erde. Dept. of Physiology and Office of Academic Computing, Cornell University Medical College, New York, NY 10021.

The APLYSIA project is developing data types for queryable storage and entry of neurophysiological datasets, descriptions of identified neurons, and model parameter sets. Allied metadata include: investigator, date, and citation; neurons under study; scalable trace and time markers; query keywords; and experimental conditions. Anticipating parallel ongoing advances in database and multiplatform technology, we deferred implementation, concentrating initial development on specification of a functionally-defined compact yet comprehensive set of neurobiologically useful data types and subtypes. The maturation of object-oriented technologies now permits initiation of an Internet database including data type schema and methods that encompass complex time series and other multimedia abstract data types, data type expandability, universal access, and seamless multiplatform data exchange aiding integration of electrophysiology data from multiple laboratories. Data types are being encoded as C++ objects, made persistent using the Poet object-oriented database management system. Schemes under development for access, query, and entry of data will rely upon the evolving multiplatform object-oriented Java language system. Server-side storage of Java-deliverable methods avoids the need to develop, distribute, or update proprietary client tools. Familiar Web-based tools will combine with Java to shield users from most details of storage or implementation.

COEXPRESSION OF CALRETININ AND VASOACTIVE INTESTINAL PEPTIDE (VIP) IN NEOCORTICAL BURSTING INTERNEURONES. B.Cauli, M.C. Angulo, E. Audinat, B. Lambolez* and J. Rossier, CNRS URA 2054. ESPCI. 10 rue Vauquelin. 75005 Paris, France.

Neocortical inhibitory interneurones are broadly divided in two main groups, interneurones displaying a marked adaptation of their action potential firing, and fast spiking non adapting cells. We have analysed the functional and molecular characteristics of single adapting non pyramidal cells by patch-clamp recordings and multiplex RT-PCR in acute slices of rat neocortex. The simultaneous detection of several biochemical markers (calbindin, calretinin, parvalbumin, neuropeptide Y, vasoactive intestinal peptide, somatostatin and cholecystokinin) and the firing properties revealed a large diversity in this population. However, this protocol has allowed us to characterised a well defined subpopulation of cells. Depolarization of these interneurones evoked an initial high frequency (>50 Hz) burst of action potentials followed by repetitive bursts emitted at low frequency (<20 Hz). RT-PCR indicated coexpression of calretinin and VIP in all these bursting cells. Their morphology was characterised by a bipolar vertically orientated dendritic arborization. Taken together, these results suggest that these bursting interneurones form a homogenous functional population.

A MODEL FOR THE MCN1-ACTIVATED GASTRIC MILL RHYTHM IN THE CRAB, Y. Manor**, F. Nadim*, E. Marder* and M.P. Nusbaum**, *Volen Center, Brandeis Univ, Waltham, MA 02254 and [‡]Dept Neurosci. Univ Penn School of Medicine, Philadelphia, PA 19104.

The gastric mill rhythm (cycle period 7-15 s) in the stomatogastric ganglion of the crab Cancer borealis is elicited by direct activation of the projection neuron MCN1 (Coleman et al., Nature 378, 1995). MCN1 excites most gastric mill network neurons, including DG, Int1 and LG, the latter two of which make reciprocally inhibitory connections. Coleman et al. (1995) suggest that three ingredients are interacting to generate this slow frequency gastric mill oscillation:
(1) presynaptic inhibition of MCN1 terminals by LG; (2) a voltage dependent electrical coupling between regions of the MCN1 arborization and the LG neuron; and (3) the different synaptic time scales of the MCN1 excitatory connections to Int1 and LG.

We present a model that reproduces the main experimental observations. MCN1 DG, Int1 and LG were modeled as Hodgkin-Huxley type neurons. MCN1 consisted of ten compartments, so that the electrically transmitting part of its axon and its transmitting-releasing terminals are spatially separated. Int1 is also inhibited by the pyloric network pacemaker (which produces the pyloric rhythm: period 0.5-2 s), so we added such an inhibition to the model. The model shows that the pyloric rhythm may have a prominent influence on the frequency and the duty cycle of the gastric rhythm. For the model gastric mill rhythm to persist in the presence of the pyloric rhythm influence, we found that it is essential for the inhibitory synapse between the model Int1 and LG to have a graded component, rather than to be merely spike-

NEURAL ANALOGUE OF OPERANT CONDITIONING OF FEEDING BEHAVIOR IN APLYSIA. R. Nargeot* D.A. Baxter and J.H. Byrne. Dept. Neurobiol. and Anat., Univ. of Texas Med. Sch. at Houston, Houston, TX 77030. Previous studies demonstrated that the consumatory feeding behavior in Aplysia (i.e., ingestion, rejection) can be operantly conditioned (Suswein et al., 1986). In particular, successful ingestion of food functions as a reward and thus increases the frequency of ingestion behavior (the operant). Key elements of the central pattern generator (CPG) that mediates consumatory feeding behavior are located in the buccal ganglia. Moreover, the esophageal nerve (E n) has been implicated as a reinforcing pathway. Thus, the isolated buccal ganglia may provide a simple neural preparation that manifests the essential features of this conditioning and that is amenable to analyses of the underlying cellular mechanisms. In this preparation, we monitored the neural correlates of consumatory feeding behavior with extracellular recordings from peripheral nerves, the 12 nerve, the nerve 2.1 and the radular nerve and intracellular recordings from identified cells of CPG for feeding. Tonic electrical stimulation of a nerve 2.3 was used to elicit ingestion-like and rejection-like motor programs, which are distinguished by the amount of overlap between the activities of closer and retractor motor neurons (Morton & Chiel, 1993). Three groups of preparations were examined: (1) a contingent reinforcement group in which the reinforcing stimuli were delivered but were not paired with the ongoing patterned activity; (3) a control group in which the reinforcing stimuli were delivered but were not paired with the ongoing patterned activity; (3) a control group in which no reinforcing stimuli were delivered but were not paired with the ongoing patterned activity; (3) a control group in which no reinforcement group in which the reinforcement paradity higher frequency of ingestion-like patterns (i.e., the reinforced pattern) than either the voke-contro

LIMBIC EPILEPSY AND STRUCTURAL PLASTICITY IN MICE CARRYING A NULL MUTATION OF SYNAPSIN I. Dake Zheng* Lian Li, Lih-Shen Chin, Paul Greengard and James O. McNamara. Department of Medicine, Duke University, Durham, NC27710. Laboratory of Molecular and Cellular Neuroscience, The Rockefeller University, New York, NY 10021.

The cellular and molecular determinants underlying limbic epilepsy are incompletely understood. Synapsin I is a synaptic vesicle protein which has been postulated to modulate neurotransmitter release by controlling the availability of synaptic vesicles for exocytosis. Recent studies have shown that synapsin Ideficient mice exhibited an increased seizure propensity manifested by the striking enhancement of response to electric stimulation (Li et al, PNAS 92:9235, 1995). To further characterize the role of synapsin I in the modifications of neuronal function and structure in the hippocampus, we examined the behavioral and electrophysiological indices of kindling development and kindling-induced sprouting of hippocampal granule cell axons in wild type (+/+), heterozygous (+/-), and homozygous (-/-) mice carrying a null mutation of synapsin I gene. In contrast to wild type littermates, synapsin I-deficient mice exhibit a striking hyperexcitability. Thus the number of amygdala stimulations required to trigger three consecutive clonic motor seizures is significantly less in the -/- mice $(6.0\pm1.0, n=5)$ compared to the +/+ mice $(14.2\pm1.3, n=5; p<0.005)$. The afterdischarge duration is less in the -/- mice for the first nine stimulations, but there is no difference in the subsequent stimulations. Furthermore, the absence of synapsin I in the mutant mice does not impair the kindling-induced sprouting of granule cell axons measured by Timm staining. These findings underscore the powerful influence of synapsin I in controlling the excitability of the mammalian brain, yet kindling-induced structural plasticities are not affected by the null mutation. Seizure-like stimulation produces DNA fragmentation and Poly-ADP-ribose polymerase proteolysis in the immature dentate gyrus. K. Thompson, P. Popper, G. Cole and C. Wasterlain. VHA Medical Center, Sepulveda CA 91343, Dept. of Neurology and Brain Research Institute, UCLA School of Medicine.

We have previously reported severe brain damage from perforant path stimulation in the immature rat both 1 day and 1 month following stimulation. To investigate the acute effects of status epilepticus in the immature brain we have combined histological techniques which show 1) moribund cells 2) DNA fragmentation and 3) proteolysis of the DNA repair enzyme Poly-ADP-ribose polymerase (PARP). Sixteen day old rats under metofane anesthesia were stereotaxically implanted with two bipolar electrodes, one into the perforant path and the second into the ipsilateral dentate gyrus. Awake animals were stimulated with 10 sec trains of a 20 Hz stimulus which was delivered once per minute for 16 hrs. Two hours after stimulation the animals were transcardially perfused with 4% paraformaldehyde. Tissue was processed for H&E staining, in situ end-labeling (ISEL), or immunohistochemical staining. For ISEL staining, fragmented DNA was labeled with biotinylated nucleotide dATP. For immunohistochemistry the tissue was exposed to antibodies directed against the proteolytic fragment of PARP. The biotinylated nucleotides and antibodies were visualized using the ABC peroxidase method. Our results show that neuronal injury is present immediately following perforant path stimulation. The combination of staining techniques shows that hilar damage is present solely in the stimulated hippocampus, with necrotic cells showing eosinophilia but no evidence of DNA fragmentation or PARP proteolysis. Interestingly, the inner layer of the dentate granule cells shows bilateral damage with eosinophilia, ISEL positivity, and immunoreactivity for the proteolytic fragment of PARP. These data suggest that the inner granule cell layer in the immature rat is extremely vulnerable to seizure-like discharge and that these granule cells experience rapid destruction of DNA and DNA repair enzymes Supported by VHA Research Service and by research grant NS13515 from NINDS.

ENOR-TERM ALTERATIONS IN GROWTH FACTOR mRNA EXPRESSION FOLLOWING KAINATE INDUCED SEIZURE ACTIVITY. M. L. Garcia*, V. B. Garcia, E. E. Strehler, P. J. Isackson, and A. J. Windebank. Molecular Neuroscience Program, Mayo Clinic, Rochester, MN 55905 and Jacksonville, FL 32224 USA.

The role of growth factors in preventing cell death both *in vivo* and *in vitro* is well established. Changes in the mRNA of several growth factors are known to occur concurrently with neuronal insults in vivo.

in vitro is well established. Changes in the mRNA of several growth factors are known to occur concurrently with neuronal insults in vivo. However, little is known about the long-term effects of neuronal insults on the expression pattern of growth factor mRNAs. As an assessment of potential effects on long-term growth factor mRNA expression, we have examined the effects of prolonged postictal times on the expression of NGF, BDNF and NT3 following KA-induced seizures. In situ hybridization was performed on tissue from adult male Sprague-Dawley rats sacrificed at various time points following intracranial ventricular injections of KA. Preliminary data indicate changes in all growth factors examined. NGF expression increases within the dentate gyrus and CA1 of the hippocampus ipsilateral to the injection site one week following KA injections. Contralaterally, NGF expression increased within the dentate gyrus, CA3 and CA1 relative to control. BDNF expression increased within the dentate gyrus both ipsi- and contralaterally to the injection site one week following KA injections. BDNF expression increased within CA2 contralateral to injection in and within CA1 ipsilateral to the injection ist. These observations provide evidence that alterations in growth factor mRNA expression occur even after prolonged postictal recovery suggesting a possible role for growth factors in recovery and continued maintenance of surviving neurons within limbic seizure foci (NIH, NS 14304).

RECIPROCAL CHANGES IN GENE EXPRESSION FOR zif268 AND NMDA RECEPTOR SUBUNIT NRI IN THE EPILEPTIC FOCUS AND "INHIBITORY SURROUND" INDUCED BY TETANUS TOXIN IN THE MOTOR CORTEX. F. Liang*, L.D. Le and E.G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717

To reveal the mechanisms underlying epileptogenesis, we studied possible changes in gene expression in rats injected with tetanus toxin (TT, 2-35 ng) in the motor cortex. Immunocytochemistry for Zif268 protein and in situ hybridization histochemistry for NMDA (N-methyl-D-aspartate) receptor subunit 1 (NR1) and AMPA (α -amino-3-hydroxy-5-methylisoxazole-4-propionate) receptor subunit 2 (GluR2) mRNAs were performed. Most of the rats that received 13-35 ng TT exhibited seizure signs and a cluster of increased Zif268 immunoreactivity at the injection site, surrounded by a cortical zone showing decreased Zif268 immunostaining. However, only rats that survived for more than one week after TT injection showed focal NR1 up- and GluR2 down-regulations at the TT injection site. This was surrounded by a zone showing decreased NR1 mRNA levels. Rats surviving for less than 8 days after TT injection showed no clear changes in NR1 mRNA levels, but some showed decreased GluR2 mRNA levels throughout most neocortical areas on the injected side. Cortical areas showing reciprocal changes in gene expression at the injection site and in the surround may correspond to the hyperactive epileptic focus and the hypoactive inhibitory surround, respectively. Based on the present results and our previous report of up-regulation of glutamic acid decarboxylase and down-regulation of Ca²⁺/calmodulin-dependent protein kinase II a gene expression in TT induced epilepsy (Liang and Jones, Soc. Neurosci. Abstr. 20:934, 1994), we propose: 1) that neurochemical segregation of the epileptic focus from other cortical areas may play an important role in the maintenance of seizure activity after TT has been cleared from the brain; 2) a model of epileptogenesis which emphasizes the disturbance of lateral inhibition among neighboring cortical columnar modules. Supported by NIH grant NS21377.

SEIZURES PROMOTE A RAPID TRANSCRIPTIONAL UPREGULATION OF PGHS-2 IN RAT HIPPOCAMPUS, WHICH IS INHIBITED BY THE PAF RECEPTOR ANTAGONIST BN-50730. Marcheselli V.L*.Cinar H.N., Stellingworth M.A., and Bazan N.G. LSU Neuroscience Center and LSU Eye Center, New Orleans, LA.
Seizures promote the account of the Company of the C

Stellingworth M.A., and Bazan N.G. LSU Neuroscience Center and LSU Eye Center, New Orleans, LA.

Seizures promote the accumulation of free fatty acids and diacylglycerols as well as the release of platelet-activating factor (PAF) in brain as a consequence of rapid activation of phospholipases A₂ and C. PAF, an inflammatory mediator, is a transcriptional activator of the immediate-early genes zif-268 and c-fos (Marchesell and Bazan, J. Nerosci. Res. 37:54-61, 1994.). BN-50730, a specific antagonist for the intracellular PAF binding site, inhibits zif-268 mRNA accumulation in brain after a single electroconvulsive shock (ECS). The activation of phospholipase A₃ is a neural inflammatory response by which bioactive lipids become injury signals during repeated seizures (status epilepticus) thus promoting brain damage (Bazan, 1995. Nature 374:501-502.), Prostaglandin H synthase (cyclooxygenase, PGHS), which has a key function in the synthesis of PGE₂, PGF₂, PGD₂, Prostacyclins and thromboxanes, presents two forms in brain tissues: the constitutive type PGHS-1 (COX-1) and the inducible type PGHS-2 (COX-2). Both kainic acid-and ECS-induced seizures promote a rapid increase in PGHS-2 mRNA in rat brain hippocampus which peaks about 3 hrs. However the kainic acid-induced seizures promoted an increase 20-fold larger and more sustained than ECS. Under the same conditions, zif-268 mRNA levels showed a smaller and very transient increase. In vitro transcription studies revealed the mRNA increases occurs through transcriptional gene activation, but not message stabilization. Western blot analysis showed an increase in PGHS-2 protein levels comparable to the mRNA increases. PGHS-1 protein levels did not change with seizures. Pretreatment with BN-50730 by icv injection 15 min before kalinic acid administration or ECS largely inhibited PGHS-2 mRNA and protein accumulation, but did not promote changes in PGHS-1 levels. Distribution studies of PGHS-2 accumulation after seizures in rat brain indicated that hippocampus has

GAP JUNCTION BLOCKADE BUT NOT POISONING OF GLIA BLOCKS SPREADING DEPRESSION IN RAT HIPPOCAMPAL SLICES. C. Largo 1. G.C. Tombaugh², P.G. Aitken². O. Herreras¹, and G.G. Somjen², Depto de

Investigacion, Hospital Ramon y Cajal, Madrid, Spain; ²Dept. of Cell Biology, Duke Univ. Med. Ctr., Durham, NC 27710.

We investigated the role of gap junctions and glial function in the generation and propagation of spreading depression (SD). Waves of SD were triggered by microinjection of concentrated KCl (1.2M) into str. radiatum of CA1 in rat hippocampal slices from a micropipette. DC-coupled recordings of extracellular potential (Vo) were made at the injection site and at a second site approx. Imm distant in str. radiatum or str. pyramidale. In some trials, antidromic population distant in str. radiation of str. pyramidate. In some trials, antidomine population spikes were evoked by stimulating the alveus. Bath application of the gap junctional blocker heptanol (3mM) completely and reversibly prevented the propagation of the SD-related Vo shift without abolishing the Δ Vo at the KCI injection site. Before blockade was complete, SD propagation velocity remained unchanged. Octanol (1mM) had a similar but less reliable effect on SD; EFPSPs and the strength of the strength of the SD in t and antidromic spikes were depressed by both alcohols. In isolated, patch-clamped CA1 neurons, heptanol (3mM) reversibly depressed voltage-dependent Na⁺ currents. Fluoroacetate (5mM), a selective blocker of glial metabolism, virtually abolished synaptic transmission but did not inhibit SD propagation. Moreover, in adomined synaptic transmission but during minor SP propagation. Whelever, if the presence of fluoroacetate, the ability of heptanol to block SD was preserved. These results support the idea that patent gap junctions are required for SD propagation in mammalian brain tissue but that neither synaptic transmission nor intact glial function are essential for SD initiation or propagation.

OPTICAL RECORDING OF THE SPATIAL AND TEMPORAL PATTERNS OF VOLTAGE TRANSIENTS IN RAT HIPPOCAMPAL SLICES

G. Golarai*, J. A. Connor, The Lovelace Institutes, Albuquerque, NM 87108 To determine the functional consequences of synaptic reorganization in the hippocampal circuitry in epilepsy and after lesions, we developed a sensitive method with high spatial resolution to record evoked optical signals from voltage sensitive dyes in acute or cultured hippocampal slices. camera (array size =120X140), was used to capture fluorescent images of slices stained with a voltage sensitive dye (RH795 or di-2-ANEPPS) during a 4 ms exposure to excitation light. The ratio of two images, one taken before, and another at a fixed interval after the stimulation was obtained. Eight to 25 image ratios were averaged. A series of averaged ratio images collected at variable intervals following afferent stimulation, along with simultaneous field potential recordings revealed the spatial and temporal organization of evoked electrical activity. Activation of the perforant path (PP) evoked an optical signal in the stratum moleculare (str. ML) of the dentate gyrus (DG), that lasted for the duration of the electrically recorded field potential (~20 ms, n=17), consistent with depolarization of dendrites in this region. A concomitant depolariza-tion was also recorded optically in the str. Lacunosum ML of the CA1, consistent with parallel activation of the CA1 by the PP fibers (n=4). Optical signals indicating depolarization of the str. Granulosum as well as secondary synaptic potentials in the hilus of the DG and str. Lucidum, Pyramidal and Oriens of CA3 were recorded (n=3). These observations are consistent with previous reports on the organization of synaptic events in the normal hippocampus and suggest that our optical methods are sufficiently sensitive to detect alterations of synaptic events after reorganization of local connections in the hippocampal formation in lesion or epilepsy models.

EPILEPTOGENESIS IN AMYGDALA KINDLING ENHANCES THE DEPRESSION OF EXCITATORY SYNAPTIC TRANSMISSION BY PRESYNAPTIC METABOTROPIC GLUTAMATE RECEPTORS. V. Neugebauer*, N.B. Keele and P. Shinnick-Gallagher. DEPT. OF PHARMA-

DOY, THE UNIVERSITY OF TEXAS MEDICAL BRANCH, GALVESTON, TX 77555-1031.

Metabotropic glutamate receptors (mGluRs) play important roles in certain forms of neuroplasticity and neuropathological disorders. Modulation of excitatory synaptic transmission in the basolateral amygdala by presynaptic mGluRs was

examined in brain slices from control rats and rats with amygdala kindled seizures.

Whole-cell recordings from basolateral amygdala neurons were performed in current-clamp and voltage-clamp. Monosynaptic EPSPs/EPSCs were evoked by

stimulation in the lateral amygdala. Drugs were applied by superfusion.

The group II mGluR agonist L-CCG dose-dependently depressed monosynaptic EPSCs in normal and kindled neurons (EC₅₀: 36 nM and 1.2 nM, respectively). The group III mGluR agonist L-AP4 was less potent in normal and kindled neurons 297 nM and 10.8 nM, respectively). Thus in kindled neurons the affinity of each agonist for its respective mGluR is increased 30 fold. Both agonists also elevated thresholds for synaptically evoked bursting in kindled neurons. Neither L-CCG (up to 10 μM) nor L-AP4 (up to 50 μM) caused membrane currents and changes in current-voltage relationship. The novel mGluR antagonists MCCG (100 $\mu M)$ and MAP4 (100 $\mu M)$ selectively reversed the inhibition by L-CCG and L-AP4 to 61-73 % and 65-81 % of predrug responses, respectively. MCCG and MAP4 (up to 300 µM) themselves did not significantly affect synaptic transmission

The enhanced potency in depressing synaptic activity in the kindling model of epilepsy and the lack of intrinsic activation suggest that the presynaptic group II and group III-like mGluRs might be useful targets for suppression of excessive synaptic activation in neurological disorders such as epilepsy Supported by NIH (NS 24643) and the Deutsche Forschungsgemeinschaft.

GAD-67 STAINED CELLS IN AREA CA1 OF HIPPOCAMPUS ARE MANENTLY REDUCED FOLLOWING PERINATAL HYPOXIA-

INDUCED SEIZURES. CR. Geary*, R. Shanghvi, and FE Jensen. Neurology, Children's Hosp., Harvard Medical School, Boston, MA 02115. We have previously demonstrated that perinatal hypoxia in rats (postnatal day (P) 10-12) results in acute seizures and permanently decreased (postnatal day (P) 10-12) results in acute seizures and permanently decreased seizure thresholds in adulthood. Depth electrode recordings during hypoxia in vivo reveal hyperexcitability in hippocampus and neocortex. Hippocampal slices removed from adult rats with previous perinatal hypoxia show increased excitability under convulsant conditions in vitro in area CA1. To determine whether this hyperexcitability is in part due to decreased inhibitory modulation of CA1 networks, we compared the density of GAD-67 stained cells in area CA1 in adult rats with previous hypoxia-induced seizures at 1810. Pet waters confident at 1870 3 and begins fixed and sessioned (400 pm) cells in area CA in adult rats with previous hypoxal-induced seizules at P10. Rats were sacrificed at P70-75 and brains fixed and sectioned (40µm) for immunocytochemistry. A polyclonal antibody for the GABA synthetic enzyme GAD (GAD-67, Chemicon) was used for immunocytochemistry. The number of GAD stained cells was counted per 500µm² areas in CA1 s. pyramidale and s. radiatum at stereotactically defined planes. Using the pyramidale and s. radiatum at stereotactically defined planes. Using the optical dissector method, the right and left hippocampi were evaluated for 10 previously hypoxic rats and 8 control rats. The mean number of GAD-positive cells was significantly lower in the previously hypoxic adults (23.2 \pm 4.9, n=20) compared to litter mate controls (30.7 \pm 5.9, p<0.001). Furthermore, the number of seizures observed during the hypoxic period at P10 negatively correlated with the number of GAD stained neurons (r=0.5, p<0.002). These results suggest that the chronic hyperexcitability induced the property of the previously the second of the previously that the chronic hyperexcitability induced the property of the previously the property of the previously that the chronic hyperexcitability induced the property of the previously the property of the previously the previously that the property is not predicted by a loss of neurons expensively the previously that the property of the previously that the property of the previously that the previ by perinatal hypoxia is in part mediated by a loss of neurons synthesizing the inhibitory neurotransmitter GABA, and that the more severe seizure activity during the brief hypoxic episode may be related to the loss of these neurons, contributing to long term increases in seizure susceptibility. CHANGES ON SYNAPTOSOMAL GLUTAMATE REGULATION WITH SUBCONVULSIVE DOSES OF

CHANGES ON SYNAPTOSOMAL GLUTAMATE UPTAKE REGULATION WITH SUBCONVULSIVE DOSES OF PENTYLENETETRAZOLE.O.I. Claudio, J.G.Ortiz*, J.Nieves, Dept. of Pharmacology, Univ. of Puerto Rico School of Medicine, P.O. Box 365067, San Juan, Puerto Rico 00936-5067
Previous studies in our laboratory revealed that high-affinity glutamate (GLU) uptake is altered in mice with audiogenic (genetic or induced) or pentylenetetrazole (ptz, 80 mg/kg) seizures. Arachidonic acid (ARA), nitric oxide (NO), protein kinase C and G-proteins have been implicated in the GLU uptake regulation. We administered subconvulsive doses of ptz (40 mg/kg, sc) to examine GLU uptake regulation in the absence of the effects that seizures could have. There was no apparent difference on GLU uptake regulation in synaptosomes from mice injected once (IDxlDay) or three (3DxlDay) doses a day. Similarly, there were no changes in the effects of pertussis or cholera toxin. However, synaptosomes from mice treated once for three days (1Dx3Days) displayed a biphasic effect at 5 µM GLU uptake, but not at 50 µM, when exposed to ARA, a protein kinase C activator. Nitroindazole, a nitric oxide synthase inhibitor, caused a decrease in 5 µM GLU uptake, but increased 50 µM GLU uptake. MCPG, a mGluR antagonist, caused an increase on 50µM GLU uptake, while a biphasic effect was observed on 50µM GLU uptake. These results indicate that GLU uptake regulation appears to be altered by repeated subconvulsive stimuli. (Supported by the NIH/MBRS Program GM S06 08224)

INTRACELLULAR CALCIUM CHELATOR (BAPTA) PREVENTS INTRACELLULAR CALCIUM CHELATOR (BAPTA) PREVENTS
DECREMENT OF INHIBITORY POSTSYNAPTIC CURRENTS IN
DENTATE GRANULE CELLS IN THE HUMAN AND RAT
EPILEPTIC HIPPOCAMPUS. Masako Isokawa*. Brain Research
Institute, Sch. of Medicine, UCLA, Los Angeles, CA 90024-1761.
Intensive activation of the NMDA receptor is reported to temporarily

reduce GABAA receptor-mediated inhibitory currents in the hippocampal dentate granule cells in human epilepsy and in the pilocarpine model of chronic epilepsy (Isokawa, *J. Neurophysiol.* 1996). The present study was designed to further characterize the mechanisms of this response decrement in the GABAA receptor-mediated synaptic transmission. The whole-cell patch clamp recording was conducted in the DGCs in hippocampal slices that were prepared from surgically resected temporal lobe specimens of epileptic patients and from pilocarpine-treated rats with chronic seizures. Inhibitory postsynaptic currents (IPSCs) were electrophysiologically isolated as outward currents at Vm= 0 mV near the reversal potential of glutamate EPSCs, and pharmacologically confirmed as GABAA IPSCs by 10 µM bicuculline methiodide. As previously shown, tetanic stimulation at -30 mV, at which NMDA receptors were activated, reduced IPSC amplitude at 0 mV in all epileptic DGCs. This reduction was APV (50 μ M) sensitive. When 10 mM BAPTA was included in a recording pipette, the decrement of GABAA IPSCs following the tetanic activation of the NMDA current was prevented, indicating that an intracellular calcium increase was responsible for the reduction of the GABAA IPSCs. However, the effect of BAPTA was stronger than that of APV, suggesting that the source of this calcium increase may not be totally exclusive to the opening of the NMDA receptor. Supported by NINDS grants NS02808 and NS31180.

ROLE OF GABAB RECEPTORS IN A GENETIC MODEL OF ABSENCE SEIZURES (GAERS). R. Bernasconi*, P. Mathivet, C. Marescaux and H. Bittiger 1.

Unité INSERM U.398, F-67084 Strasbourg, ¹ Ciba, CH-4002, Basel.

Marescaux et al. (J. Neural Transm. Suppl 35, 37-69, 1992) have shown that GAERS are an isomorphic model of absence seizures and that GABA_B receptors play a central role in the control of absences, implying that the genetic susceptibility of GAERS might reside in an alteration of GABA_B mediated mechanisms. To test this hypothesis we have assessed the kinetics of GABA_B binding sites in membranes prepared from GAERS and from non-epileptic control rats in an agonist and in an antagonist binding assay. Using the agonist ³H CGP 27492 as radioligand we observed a higher affinity of GABA_B receptors in cortical membranes prepared from GAERS compared to controls, whereas the total number of GABAB receptors were similar in both strains. Saturation experiments with the antagonist radioligand 3H CGP 54626 revealed two affinity states of $GABA_B$ receptors. The K_d and B_{max} of both binding sites revealed two artimity states of CABAB receptors. In the Again B_{max} of both ordining sites were similar in cortical and thalamic membranes from GAERS and controls. We also compared the inhibition by the agonist R-(-)-baclofen of antagonist ³H CGP 54626 specific binding to cortical membranes in absence and in presence of Gpp(NHp). Hill numbers (nH) were less than unity suggesting two binding states of GABAB receptors. The IC₅₀ values, the number of binding sites and nH were similar in both strains. Gpp(NH)p shifts were similar in GAERS and in controls suggesting that the interac-DEPUNCIPE SIMILAR IN CARENS and in controls suggesting that the interactions between GABA_B receptors and G-proteins are similar in both strains. We examined the inhibition of ³H CGP 27492 binding by Gpp(NH)p as an index of the allosteric interactions between the binding sites of GABA_B receptor agonists and GTP. The displacement curves revealed two IC₅₀ values implying two different interactions between GABA_B receptors and GTP-binding sites. The binding parameters were similar in both strains a proposition by the allocated interactions. both strains, suggesting that the allosteric interactions betwen GABAB receptors and the GTP-binding sites are similar in GAERS and controls. Taken together, the results of this study suggest that the affinity of GABA_B receptors in GAERS is increased compared to non-epileptic control rats whereas the interactions between G-proteins or GTP-binding sites and GABA_B receptors are similar in both strains.

SLEEP AND WAKING AFTER 8-OH-DPAT GIVEN SYSTEMICALLY AS WELL AS PERFUSED INTO THE DORSAL RAPHE NUCLEUS IN RATS. B. Bjorvatn, K. Hole* and R. Ursin. Dept. of Physiology, University of Bergen, 5009 Bergen, Norway

The 5-HT_{IA} agonist 8-OH-DPAT is reported to increase waking and decrease slow wave sleep (SWS) at 0.375 mg/kg s.c., whereas 0.010 mg/kg s.c. as well as injection directly into the dorsal raphe nucleus (DRN) induced opposite effects. The interpretation has been that stimulation of 5-HT autoreceptors induces sleep, whereas stimulation of postsynaptic receptors induces waking. Both s.c. doses reduced REM sleep whereas DRN injection had no such effect. In cats, perfusion of 8-OH-DPAT (10 μM) in DRN through microdialysis probes increased REM sleep. We investigated sleep and behavior in rats following identical doses s.c. as well as

continuously perfusing 8-OH-DPAT into DRN through microdialysis probes. So far six rats have been stereotaxically implanted with electrodes for EEG/EMG recordings and a guide cannula aimed at the DRN. Each rat was given s.c. injections of saline, 8-OH-DPAT at 0.010 and 0.375 mg/kg in a balanced order blind design followed by 8-OH-DPAT (10 µM dissolved in aCSF) continuously perfused into the DRN. Six days separated the experiments. Microdialysis probes (CMA/12, 1 mm) were inserted and perfusion (1 µl/min) started one hour before EEG/EMG recordings. Histological examinations revealed that the probe was located in DRN in five rats.

8-OH-DPAT at 0.375 mg/kg increased waking initially, SWS-1 and REM sleep were reduced and the effect on SWS-2 was biphasic. Initially SWS-2 was clearly reduced followed by an increase. This dose induced 5-HT behavioral syndrome with flat body posture, hindlimb abduction and increased locomotion. 8-OH-DPAT at 0.010 mg/kg did not change sleep or behavior. Continuous perfusion of 8-OH-DPAT (10 µM) in DRN reduced REM sleep, otherwise no significant changes were seen

In conclusion, stimulation of 5-HT autoreceptors did not increase slow wave sleep. but instead seemed to reduce REM sleep.

SEROTONERGIC CONTROL OF MELATONIN SECRETION: THE ROLE OF 5-HT1A RECEPTORS, P.J. Nathan, G.D. Burrows, S.Y. Chai*, T.R. Norman. Dept. of Psychiatry, University of Melbourne, Austin and Repatriation Medical Centre Melbourne, VIC 3084, Australia.

Melatonin (MT) is a hormone secreted from the pineal gland. The nocturnal rise in MT occurs by activation of β_1 -adrenergic receptors in the pineal gland. α_1 adrenoceptors have also been shown to modulate MT secretion, by potentiating the effect of β_1 -adrenoceptors. Although MT is synthesised from serotonin (5-HT), the role of serotonergic receptor subtypes in the control of melatonin production is not clear. We investigated the effect of some full (S-20499 & flesinoxan), partial (buspirone and ipsapirone) and indirectly acting 5-HT receptor agonists (d-fenfluramine & paroxetine), on day- and night-time MT in male rats. d-Fenfluramine and paroxetine (20mg/kg) were the only drugs that increased daytime MT (p<0.01). At night, d-fenfluramine and flesinoxan significantly increased melatonin at 20mg/kg (p<0.01). S(+)-20499 on the other hand significantly increased MT at both 10 mg/kg (p<0.01) and 20 mg/kg (p<0.001). The fact that only the indirectly acting agonists increased day-time melatonin suggests that acutely increasing 5-HT availability (in the pineal gland or an extra pineal source). increases MT. At night, all 5-HT agonists tended to produce a dose related increase in MT. d-Fenfluramine significantly increased MT at 20 mg/kg, further supporting the hypothesis that increasing the availability of 5-HT. stimulates both day- and night-time MT secretion. However both S(+)-20499 and flesinoxan significantly increased nocturnal MT, suggesting a role for 5-HT_{1A} receptors in the regulation of MT secretion. The fact that the latter drugs had no effect during the day would suggest that a functionally coupled β_1 -adrenergic receptor may be required for the effect of 5-HT_{1A} receptor stimulation to be mediated. The mechanism by which 5-HT_{1A} receptors increase MT may be similar to that of α_1 adrenoceptors (i.e potentiation of the β_1 -receptor response). (Funded by Servier)

REGULATION OF SEROTONIN REUPTAKE TRANSPORTER (SERT) mRNA EXPRESSION BY ESTROGEN (E) AND PROGESTERONE (P) IN RHESUS MACAQUES. M. Pecins-Thompson, N.A. Brown, C.L.Bethea* Div. of Repro. Sci., Oregon Regional Primate Center, Beaverton, OR 97006

Ovarian steroids regulate prolactin secretion and modulate mood. Both prolactin and mood are regulated by serotonin neurons which we have found contain nuclear receptors for steroid hormones. This study examined the effect of E±P on the expression of mRNA for SERT in monkeys using *in situ* hybridization. A recombinant subclone of the 5' cytoplasmic domain of the human SERT was generated with a 253 bp insert. The subclone was generated by RT-PCR using the human SERT cDNA (gift from R.D. Blakely) and primers based on published sequence. Monkeys were ovariectomized (OVX)-control, E treated (28 days) and E+P treated (14 days E + 14 days E+P). Perfusion fixed midbrain sections containing the dorsal raphe (10μ) were hybridized at 50°C with 35 S antisense cRNA. After a final wash in 0.1X SSC at 60°, sections were apposed to β -max film for 3 days. Adjacent sections were immunostained for serotonin to confirm the location of the dorsal raphe. Densitometric analysis of autoradiographs with graylevel thresholding was performed at 5 levels of the dorsal raphe. The number of pixels exceeding background in defined areas was obtained (pixel number) and normalized by the total number of pixels counted (pixel fraction). Average pixel number was $22,280 \pm 3517$, $15,227 \pm 1714$, $14,827 \pm 2042$ for ovx, E and E+P treated groups, respectively. There was a 32% and 33% decrease in SERT mRNA signal represented by pixel number in E and E+P treated macaques compared to controls (ANOVA, p< 0.05). These data indicate that E with or without P reduces SERT mRNA expression which could result in an overall increase in serotonin neurotransmission. Supported by HD17269, HD18185, DK9098, RR00163.

SUPPRESSION OF MILK DRINKING IN RATS DUE TO ENHANCED SEROTONERGIC NEUROTRANSMISSION. <u>S. K. Hemrick-Luecke*</u>, D. C. Evans and R. W. Fuller. Lilly Research Labs., Eli Lilly and Co., Lilly Corporate Center., Indianapolis, IN 46285.

Serotonin (5HT) neurons are postulated to be involved in the regulation of food intake. The combination of fluoxetine, a selective 5HT reuptake inhibitor, and L-5HTP, a 5HT precursor, results in greater increases in extracellular 5HT concentrations than either fluoxetine or L-5HTP alone extracellular 5HT concentrations than either fluoxetine or L-5HTP alone (Fuller et al., J. Pharm. Pharmacol. 48:68, 1996). In these experiments, fluoxetine (10 mg/kg, ip) or L-5HTP (20 mg/kg, ip) alone had no effect on milk drinking at 1 hr, while the combination decreased the ratio of sweetened, condensed milk drinking by 50%. The combination of 5HT reuptake inhibitors and 5HT_{1A} antagonists has also been reported to result in enhanced extracellular 5HT concentrations as compared to 5HT reuptake inhibitors alone (Fuller et al., 1996; Hjorth, J. Neurochem. 60: 776, 1993). Neither fluoxetine (10 mg/kg, ip) nor WAY100,635 (1 mg/kg, ip), a 5HT_{1A} antagonist, alone had an effect on milk drinking at 1 hr. The combination of fluoxetine and WAY100,635, however, decreased the ratio of milk drinking by 56%. Another 5HT_{1A} antagonist. 1 hr. The combination of fluoxetine and WAY100,635, however, decreased the ratio of milk drinking by 56%. Another 5HT_{1A} antagonist, S-(-)-206130, at 5 mg/kg, ip, also had no effect alone on milk drinking, while the combination of fluoxetine and S-(-)-206130 decreased milk drinking by 48% at 1 hr. The 5HT-releasing drug, d-fenfluramine, dose-dependently inhibited milk drinking at 1, 3 and 10 mg/kg ip (25%, 82% and 97% respectively) at 1 hr. D-Norfenfluramine, a metabolite of d-fenfluramine which is also a 5HT releaser, dose-dependently decreased milk drinking at 1, 3 and 10 mg/kg, ip (55%, 96% and 97% respectively) at 1 hr. These results suggest that decreases in milk consumption may be a functional response to enhanced serotonergic neurotransmission. a functional response to enhanced serotonergic neurotransmission.

Chronic Fluoxetine Reduces Serotonin Transporter mRNA and 5-HT,_B mRNA in a Sequential Manner in the Rat Dorsal Raphe Nucleus. <u>J. F. Neumaier*, D. Root, and M. W. Hamblin.</u> Harborview Medical Center, GRECC, SVAMC, Department of Psychiatry and Behavioral Sci., University of Washington, Seattle, WA 98104.

Depression has been associated with reduced serotonergic neurotransmission. SSRI antidepressants increase stimulated serotonin neurotransmission. SSRI antidepressants increase stimulated serotonin release and may do so by downregulating presynaptic terminal autoreceptors. We previously found increased 5-HT_{1B} mRNA in dorsal raphe nucleus (DRN) in learned helpless rats, and hypothesize that fluoxetine may protect against LH by reducing 5-HT_{1B} terminal autoreceptor synthesis. To test this hypothesis we measured the level of presynaptic 5-HT_{1B} mRNA in the DRN (a major source of serotonin projections to the forebrain) and other postsynaptic (nonserotonergic) regions that also express 5-HT_{1B} mRNA following subchronic fluoxetine treatment. This was compared to serotonin transporter (SERT) mRNA, which codes for fluoxetine's initial site of action.

Male rats were treated parenterally with fluoxetine or saline for 4-21

Male rats were treated parenterally with fluoxetine or saline for 4-21 days prior to sacrifice and determination of 5-HT_{1B} and SERT mRNA by in situ hybridization. Fluoxetine produced a time-dependent and reversible reduction in DRN 5-HT_{1B} mRNA levels while other brain regions showed no significant changes. SERT mRNA was only temporarily reduced, and returned to sham values by 21 days. This time course study may help explain previous contradictory results regarding the effect of fluoxetine on SERT mRNA levels in DRN, and is relevant to hypotheses of initial and adaptive changes in gene expression following SSRI antidepressant treatment. These data support the hypothesis that increased 5-HT_{1B} autoreceptor activity may be important in animal models of depression and antidepressant action.

REGULATION OF PERIPHERAL 5-HT, A RECEPTORS IN MAJOR DEPRESSION: AN IN VITRO MODEL. S. J. Garlow*, Dept. of Psychiatry and Behav. Sci., Emory Univ. Sch. of Med., Atlanta, GA 30322.

Sch. of Med., Atlanta, GA 30322.

One of the most consistent peripheral phenotypes of Major Depression is an increase in the B_{max} of the 5-HT_{2A} receptor on platelets. The other consistent platelet phenotype of depression is the decrease in B_{max} for the serotonin transporter (5-HTT). The factors that regulate the numbers of 5-HT_{2A} receptors on platelets is not known. The hypothesis tested in this project is that the numbers of 5-HT_{2A} receptors on platelets is determined by the rate of transcription of the 5-HT_{2A} receptor gene in megakaryocytes. Megakaryocytes are the nucleated cells from which platelets are derived. A series of soluble factors are being tested for their ability to affect the rate of transcription of the 5-HT_{2A} receptor gene in megakaryocytes. A second hypothesis tested in this project is that the same factor that causes the increase in the B_{max} of the 5-HT_{2A} receptor also causes the decrease in the B_{max} of the 5-HTT. These experiments are a prelude to studying the regulation of transcription of the 5-HT_{2A} receptor and 5-HTT in depressed patients.

5-HT_{2C} RECEPTOR ACTIVATION MODULATES MELATONIN PRODUCTION IN RAT PINEAL GLAND <u>L. Steardo*, P. Monteleone, M.R. Carratù, D. Ancona, V. Cuomo</u>. Institute of Pharmacology, School of Medicine, University of Bari. Italy.

5-HT receptors have been detected on the rat pinealocyte membranes; however, at present the precise role played by serotonin in the in vivo regulation of rat pineal gland activity remains still not identified. The present investigation has been performed to evaluate the effect of the 5- HT_{2C} agonist, mCPP (meta-chlorophenylpiperazine), on the synthesis of melatonin in rat pineal gland. In comparison to saline, mCPP (0.5 and 2.5 mg/kg, i.p.) increases the nocturnal rise of both pineal Nacetyltransferase (NAT) activity and melatonin-content (p<0.001), whereas it has been not able to influence the biosynthetic activity of the gland during the day. Furthermore, mCPP has potentiated the increase of the NAT activity and melatonin production provoked by β₁ stimulation (isoproterenol 1 mg/kg, i.p.) induced during the day (p<0.001). The findings suggest that the 5-HT_{2C} receptor stimulation is a part of the physiological mechanism involved in the modulation of rat pineal activity.

DOPAMINE D1 AND SEROTONIN 5HT-2A/2C RECEPTOR SYNERGISTIC STIMULATION OF *c-fos* AND *zif 268* mRNA IN THE STRIATUM. RF Paletzki * and C R Gerfen. Lab of Neurophysiology, NIMH, Bethesda, MD 20892.

The output of the basal ganglia is determined by the relative activity of the "direct" and "indirect" pathways from the striatum to the substantia nigra. Striatal neurotransmitter systems modulate these pathways in a variety of ways, in some cases through the distribution of receptor subtypes with different signal transduction effects on functionally distinct subpopulations of striatal neurons. For example, dopamine D1 and D2 receptor subtypes, which are segregated to direct and indirect output pathway neurons oppositely affect these pathways due to the respective facilitation and inhibition of adenylate cyclase. The multiplicity of serotonin receptor subtypes provide other patterns of modulation of striatal output pathways. The SHT-2A/C receptor subtype is expressed by select subsets of both direct and indirect striatal output neurons. This serotonin receptor subtype was studied with quantitative in situ hybridization histochemical localization of the induction of the mRNAs encoding the immediate early genes c-fos and zif268 following treatment with 5HT-2A/2C agonists and antagonists alone and in combination with the dopamine D1 receptor agonist SKF38393 in rats with unilateral striatal dopamine depletion. The 5HT-2A/2C agonist m-CPP (1 mg/kg) did not have an affect on basal immediate early gene mRNA levels in striatum. D1 receptor mediated induction of mRNAs encoding both c-fos and zif268 in direct projection neurons was evident in the dopamine depleted striatum of animals treated with SKF38393 (2 mg/kg) alone. The level of this induction was further increased with combined SKF38393 and m-CPP treatment. These results demonstrate an interaction between D1 dopamine and serotonin 5HT-2A/2C receptors (supported by the NIH).

SPECIES- AND TISSUE-SPECIFIC DIFFERENCES IN TRYPTOPHAN HYDROXYLASE K.E. Vrana", J.W. Haycock', C.A. Stockmeier', and S.C. Kumer. Dept. of Physiology and Pharmacology, Bowman Gray Sch. of Med. Medical Center Blvd., Winston-Salem, NC 27157; 'Dept. of Biochem. And Mol. Biol., LSU Medical Center, New Orleans, LA 70119; 'Dept. Of Psychiatry, Case Western Reserve University, Cleveland, OH 44106.

Tryptophan hydroxylase subserves disparate functions in the brain and in the pineal gland, where it mediates serotonin and melatonin biosynthesis, respectively. Whereas some differences in the biochemical characteristics of raphe and pineal TPH have been reported, both enzymes appear to be encoded by the same mRNA sequence. In the present studies, we report immunochemical differences in TPH from rat and human dorsal raphe and pineal gland using blot immunolabeling with four different antibodies that recognize TPH. TPH immunoreactivity from the four sources was present as a 50-55 kDa band, although the apparent MW of human pineal TPH was several kDa lower than that of the other three. Each of the antibodies produced a different pattern of reactivity with TPH from the four sources: WH3, a mousmonoclonal, was raphe TPH-preferring; a rabbit polyclonal was rat pineal TPH-preferring; and PH8, another mouse monoclonal, was relatively pan TPHspecific. In addition, although TPH activity (with Trp as substrate) appeared to be substantially higher in homogenates of rat pineal gland as compared with rat dorsal raphe, dilution/mixing experiments indicated that endogenous inhibitors in the dorsal raphe homogenates were, in large part, responsible for this difference. These immunochemical results provide further evidence for differential posttranslational processing of TPH in dorsal raphe and pineal gland. [Supported by GM38931 (K.E.V.), MH00967 and NS25134 (J.W.H.), MH45488 (C.A.S.), and T32DA07246 (S.C.K.)]

CELL-SPECIFIC GLUCOCORTICOID REGULATION OF TRYPTOPHAN HYDROXYLASE MRNA LEVELS IN THE BRAIN. Michael S. Clark* and Andrew F. Russo.

Department of Physiology and Biophysics. University of Iowa. Iowa City. IA 52242.

A potential target of glucocorticoid modulation of mood and sleep patterns is the enzyme tryptophan hydroxylase (TPH); which is required for the synthesis of serotonin in the raphe nuclei, and melatonin the pineal gland. We have used a sensitive competitive RT-PCR assay to examine the effect of glucocorticoid treatment on TPH mRNA levels in the rat brain. Chronic treatment increases TPH mRNA levels by 16-fold in the pineal, while decreasing them 6-fold in the raphe nuclei. Using a model serotonergic cell line, we show that glucocorticoids are capable of directly repressing TPH mRNA levels. Hence, glucocorticoids can potentially alter serotonin and melatonin biosynthetic capacity by cell-specific modulation of the TPH gene.

POTASSIUM CHANNELS: PHYSIOLOGY, PHARMACOLOGY, AND MODULATION

572.1

A HERG-LIKE K † CURRENT IN PROLIFERATING MYOBLASTS BEFORE FUSION

E. Wanke*, A. Arcangeli^, M. Olivotto^, L. Faravelli and R. Bonecchi. Dept. of Gen. Physiology and Biochemistry, Univ. of Milan, Via Celoria 26, I-20133 Milano and ^lnst. of Gen. Pathology, Univ. of Florence, Vle. Morgagni 50, I-50134 Firenze, ITALY.

A novel inactivating inward-rectifying current $(I_{\rm IR})$, described in murine and human neuroblastoma cells (Arcangeli et al., 1993 J.Cell Biol. 122:1131; Arcangeli et al., 1995 J.Physiol., 489:455-471, 1995), turned out to be biophysically and pharmacologically similar to the heart current $I_{\rm KI}$ and to the currents expressed in occytes after injection of HERG cDNA. Here we show that a HERG-like current is expressed also in myoblasts derived from young mouse muscles. Hindlimb muscle was dissected from 1 to 2-week-old animals. Satellite cells in culture were obtained after incubation in 80% DMEM, 20% FCS, 10 μ M/ml insuline, 2 mM glutamine, 10 ng/ml EGF and 50 ng/ml bFGF. The percentage of cells displying the $I_{\rm RR}$, the anomalous rectifier current $(I_{\rm KI})$ or both is 25/40/35% respectively, during proliferation of myoblast. The $I_{\rm IR}$ current tend to disappear being substituted by $I_{\rm KI}$ after differentiation and fusion to form myotubes. Very rarely a small fraction of $I_{\rm IR}$ was found in myotubes. The various currents were pharmacologically isolated with Cs' (5mM) which is a blocker of all inward rectifier currents and E-4031 which is considered selective for HERG-like currents. These findings suggest that, at certain stages of cell differentiation, a novel type of inward rectifying channel is expressed, whose biophysical properties could coincide to those encoded in oocytes by the HERG gene. In conclusion our findings should help to understand not only the physiological role of the novel channel but also its linkage to the proliferating phase of normal and cancer cells.

ACTIVATION AND INHIBITION OF THE G PROTEIN-ACTIVATED K* CHANNEL, GIRKI, BY DIFFERENT TYPES OF METABOTROPIC GLUTAMATE RECEPTORS. <u>Dahlia Sharon</u>, <u>Dmitry Vorobiov and Nathan Dascal*</u>. Dept. Physiol. Pharmacol., Sackler Sch. Med., Tel Aviv University, Ramat Aviv 69978, Israel.

Metabotropic glutamate receptors (mGluRs) control intracellular signaling cascades through activation of G proteins. The inward-rectifying K+ channel, GIRK, is activated by the βγ subunits of Gi proteins and is widely expressed in the brain. We investigated whether an interaction between mGluRs and GIRK is possible, using Xenopus oocytes expressing mGluRs and a cardiac/brain subunit of GIRK, GIRK1. Adenylyl cyclase-inhibiting mGluRs (types 2, 3, 4, 6 and 7) activated the GIRK1 channel. This is consistent with the activation of GIRK1 by Gi coupled receptors. In contrast, phospholipase C-activating mGluR1 and mGluR5, presumably coupled to Gq, inhibited the channel's activity. This inhibition was suppressed by a protein kinase inhibitor, staurosporin, and thus appeared to be mediated by a protein kinase, possibly protein kinase C. These modulations could be involved in the mGluRs' effects on neuronal excitability in the brain. Inhibition of GIRK1 by phospholipase C-activating mGluRs bears upon the problem of specificity of G protein - GIRK1 interaction, explaining why receptors coupled to Ga are inefficient in activating GIRK1.

The concentration of K* in the interstitial fluid is subjected to transient changes in the course of normal functioning of densely packed central neurons. We have studied the reaction of acutely isolated pyramidal neurons to the step-like elevation of the external K*. In many cases the shift in external K* from O- 2 mM to 2-20 mM was followed by the slow development of the current which had inward direction when measured at negative holding voltages from -120 to -50 mV. This current was clearly additive to the "normal" quick leakage component. The amplitude of the slow current (but not its kinetics) was determined by the K* concentration. External Na* strongly influenced the kinetics and to a smaller extent the amplitude of this current: with the increase in the external Na* from 0 to 150 mM the current was becoming larger and substantially slower. Thus, the time constant of activation of this current was around 80 ms when measured at external [K*] = 20 mM and [Na*] = 20 mM and 120 ms at 20 mM and 150 mM. respectively (isotonic K phosphate inside). The development of this current was due to the increase in K* and, to a smaller extent, in Na* permeability of the membrane. We suggest that the K* - activated inward rectifier may serve as a sensor of external K* concentration subjected to transient changes in the course of functioning of the central neurons.

ATP-SENSITIVE K⁺ CHANNELS ARE MODULATED BY CYTOPLASMIC pH AND LACTATE IN RAT CEREBRAL CORTICAL NEURONS. Z.-Q.TONG*, P.SU and F ZOU. Dept.of Physilo.,First Military Medical Univ., Guangzhou 510515,P.R.Chian

Recent studies have proved that increase of K-ATP channels activity could protect hypoxic-ischemic brain damage. Nevertheless, the absence of intracellular ATP concentration in hypoxic-ischemic damage, in vivo is not enough to active K-ATP channels, which suggested some metabolic substances, such as H+ and lactate, maybe modulate K-ATP channels. The effects of pH and lactate on K-ATP channels activity have been studied on inside-out membrane patches of neurons acutely dissociated from rat. The pipette filled with 140mM KCl solution and bath solution was identical (with 1 mM EGTA, pH 6.0,7.3 or 8.0). The results were as follows: (1) Open probability (Po) and mean open times of K-ATP channels were 0.275 ± 0.068 , 0.056 ± 0.01 , 0.011 ± 0.003 and 12.7 ± 6.4 ms. 4.3 \pm 2.2 ms, 3.2 \pm 1.8 ms observed in pH 6.0, 7.3 and 8.0, respectively .holding potential at 60 mV(n=10,p<0.05 compared each other). The cytoplasmic ATP levels had an IC50 for inhibiting Po of K-ATP channels approximately (mM): 2.5 \pm 1.4 , 0.124 \pm 0.023 and 0.085 \pm 0.019 in various pH (n=6,p<0.05). (2) Po and mean open time of K-ATP channels were dependent on the cytoplasmic lactate levels, which were 0.060 ± 0.012 , 0.153 ± 0.043 , 0.265 ± 0.073 , 0.299 ± 0.098 and $15.6 \pm 3.4 \text{ ms.} 20.5 \pm 5.8 \text{ ms.} 56.7 \pm 11.2 \text{ ms.} 95.7 \pm 20.8 \text{ ms.}$ in 5,10,20 and 30 mM lactate ,respectively. An IC50 of ATP were 1.2 \pm 05 mM in 20 mM lactate (3)Single channel currents often became multichannel activities in pH 6.0 or 20 mM lactate levels .The results demonstrated that K-ATP channels activity related to cytoplasmic pH and lactate ,easily evoked in acid condition with lower sensitivity to ATP concentration, which maybe involved mechanism of protection of hypoxic-ischemic brain damage

BAPTA POTENTIATES CA²⁺ DEPENDENT AHPS WITHOUT ALTERING ASSOCIATED CA²⁺ SIGNALS IN CA1 HIPPOCAMPAL NEURONS IN RAT BRAIN SLICES. B.S. Jahromi*¹, L. Zhang¹, P.S. Pennefather¹^{1,3}, M. Tymianski¹, M.P. Charlton¹² and P.L. Carlen¹². Playfair Neuroscience Unit¹, Toronto Hospital Research Institute and Depts. of Physiology² and Pharmacy³, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

We have shown previously that intracellular application of the fast calcium chelator BAPTA potentiates the Ca*-dependent slow afterhyperpolarization (sAHP) and underlying K* current (I_{sAHP}) in rat CA1 cells. Here we examined whether this potentiation of AHP by BAPTA is associated with altered intracellular Ca*-dynamics. Using whole-cell patch-clamp techniques, depolarizing pulses were used to generate AHP's in hippocampal CA1 neurons of acute rat brain slices. The resulting sAHP or I_{sAHP} was recorded in tandem with evoked Ca*- transients by inclusion of fluo3 or calcium green (2-5µM) in the patch pipette solution. The observed cell body Ca*- fluorescence signals took a time course similar to that of the I_{sAHP}, in accordance with data published elsewhere (Knöpfel et al., 1992). Addition of 1 mM BAPTA + 0.1 mM CaCl₂ to the intracellular dialysis solution caused potentiation and an alteration of the I_{sAHP} time course. However, simultaneously measured Ca*- signals were not significantly different from those recorded in the absence of BAPTA. Possible interpretations involving the buffered diffusion of Ca*-, localization of AHP channels, and limitations of the Ca*- imaging method will be presented.

Functional effects of the weaver mutation on GIRK2 function in Xenopus oocytes and in cerebellar granule cells. P.A. Slesinger', N. Patil', Y.N. Jan and L.Y. Jan. HHMI and Dept. of Physiology, Univ. of California, San Francisco, San Francisco, CA 94143. Department of Genetics, Stanford University School of Medicine, Stanford, CA 94305.

A mutation (G156S) in the putative pore region of a G protein-gated inwardly rectifying K' channel, GIRK2, has been identified in the weaver mouse (Nature Constited 1, 126, 1969), packets and bupper the mouse the medicine which

A mutation (G156S) in the putative pore region of a G protein-gated inwardly rectifying K' channel, GIRK2, has been identified in the weaver mouse (Nature Genetics 11, 126, 1995); an ataxic and hyperactive mutant mouse in which neurons in the cerebellum and substantia nigra are developmentally impaired and subsequently die. We our interested in determining the mechanism by which mutant GIRK2 w channels lead to the weaver phenotype. We found previously that the expression of GIRK2 w channels in oocytes forms G protein-activated inwardly rectifying channels that lose their selectivity for K' and Na', whereas the co-expression of GIRK1 with GIRK2 w appears to form heteromeric channels with reduced channel activity (Neuron, 16:321, 1996). These results suggest that the effect of the weaver mutation on neuronal function would depend on the relative expression levels of other GIRK subunits To test the hypothesis that GIRK1 and GIRK2 w heteromeric channels are non-functional, we have examined the expression of dimers in oocytes. The GIRK1-GIRK2 dimer but not the GIRK1-GIRK2 w dimer shows large receptoractivated inwardly rectifying K' currents. To determine whether the weaver mutation leads to a gain of function (Na' permeability) or loss of function (nonfunctional heteromeric channels) in cerebellar granule cells, we have begun to record G protein-activated inwardly rectifying K' currents from wild-type and weaver granule cells. In wild-type granule cells grown in vitro, intracellular perfusion with 200 μM GTP/S activates an inwardly rectifying K' current which can be blocked by 500 μM GTP/S activates an inwardly rectifying K' current which can be blocked by 500 μM GTP/S activates an inwardly rectifying K' current. We are now examining the GIRK currents in weaver granule cells and using immunohistochemistry to determine the subcellular distribution of GIRK2 and GIRK1 channel proteins in cultured granule cells. CLONING AND CHARACTERIZATION OF A MODULATORY ELEMENT FOR POTASSIUM CHANNELS. Fuxiong Lu, Dengfeng Xia, Zhengxing Qu, David H Solomon* Department of Pharmacology. College of Physicians and Surgeons of Columbia University, New York, NY 10032.

Calcium-activated potassium (K_{C_a}) channels play an important role in a wide variety of physiological processes. Previous studies indicated that K_{C_a} channels are modulated by the cAMP dependent protein kinase (A. Carl et al. Am. J. Physiol. 261, C387, 1991), protein kinase C and protein phosphatase (P. Reinhart & B. Levitan. J. Neurosci. 15, 4572, 1995). Although regulation of potassium channel activity by N-terminal modulation has been extensively studied at the molecular level, the effect of C-terminal modulation on its activity is poorly understood. In an effort to search for intracellular proteins that can bind to the COOH-terminus of K_{C_a} channels and modulate their activity, we used the yeast two-hybrid system to screen proteins that associate with the COOH-terminus of this channel. PCR products encoding the cytoplasmic COOH-tails of two Aplysia K_{C_a} channels were subcloned into a yeast expression vector and fused with the GAL4 DNA binding domain. An Aplysia cDNA library was constructed into a vector containing the sequence encoding the GAL4 activation domain. The target constructs were cotransfected with the cDNA library into yeast cells. One clone obtained by this procedure, clone L6, contained a 1.2 kb cDNA. A 2.6 kb full-length cDNA of clone L6 was obtained and sequenced. Southern blot analysis suggests this is a unique gene. A search of protein sequence databases with BLAST revealed similarity of the NH, terminal 481-amino acids of Aplysia L6 to regions found in a phosphotyrosine independent ligand p62B for the Lck SH2 domain, a neuronal acetylcholine receptor, and dystrophin. It is postulated that this new protein may modulate K_{C_a} channel activity by associating with the C-terminus of the channel. We are functionally studying, by co-injection of L6 mRNA into X_{C_a} channels.

GATING OF BK CHANNELS CAN BE INDEPENDENT OF CALCIUM OR VOLTAGE. <u>Brad S. Rothberg* and Karl L. Magleby</u>. Department of Physiology and Biophysics, University of Miami School of Medicine, Miami, FL 33101.

and Biophysics, University of Miami School of Medicine, Miami, FL 33101.

Large conductance calcium-activated K* (BK) channels are activated by membrane depolarization and micromolar levels of intracellular Ca²*. In order to study the interaction between Ca²* and voltage in the channel gating mechanism, currents were recorded from single BK channels using the patch clamp technique from inside-out patches of membrane excised from cultured rat myotubes. The intracellular surface of the patch was exposed to bathing solutions containing free Ca²* at concentrations ranging from 0.3 nM to 1000 μM. At each [Ca²¹], currents were recorded at several different membrane potentials (V_m's) ranging from -80 to +120 mV. Analysis was limited to data

during the normal mode, which includes 96% of the open and shut intervals. Very low levels of activity were observed at $[Ca^2^+] < 30$ nM (open probability $(P_o) < 5 \times 10^5$ at +30 mV). This activity appeared to be Ca^{2^+} -independent, since increasing the free $[Ca^{2^+}]$ 100-fold (from 0.3 to 30 nM) did not significantly increase P_o at a given V_m , although the P_o was increased at these $[Ca^{2^+}]$ by depolarization. Therefore it appears that the gating mechanism contains V_m -dependent transitions which are Ca^{2^+} -independent for $[Ca^{2^+}] < 30$ nM. Changing V_m in the negative direction decreased P_o , and this decrease leveled off at a minimum value which depended on the $[Ca^{2^+}]$. Therefore some gating transitions may be V_m -independent.

transitions may be V_m -independent. A fit to the data projected a $V_{0.5}$ (V_m resulting in half-maximal activation) of about +165 mV as $[Ca^2] \to 0$ and about -75 mV as $[Ca^2] \to \infty$. The effective gating charge (estimated from single Boltzman fits) appeared to be Ca^{2^+} -independent over the examined range of $[Ca^2]$'s. Supported by grants from the NIH and Muscular Dystrophy Association to K.L.M.

h-CURRENT MODULATION BY NOREPINEPHRINE, DOPAMINE, HISTAMINE AND CYCLIC-AMP ANALOGUES IN RAT HIPPOCAMPAL NEURONS J.F. Storm*, T. Winther & P. Pedarzani, ** Inst. of Neurophysiol. University of Oslo, Norway, and *Dept. Molec. Biol. Neur. Signals, Max-Planck Institute for Experimental Medicine, Göttingen, Germany. Norepinephrine, acting via cyclicAMP (cAMP), enhances the hyperpolarizationactivated cation current I_h (=I_O) in hippocampal neurons, in a protein kinase A(PKA)-independent manner (Pedarzani & Storm, *PNAS* 92: 11716-20, 1995), thus causing depolarization. We now report that three other transmitters acting via cAMP, serotonin (5-HT), dopamine (DA) and histamine (HA) have a similar effect on I_h . Furthermore, the cAMP-analogue Rp-cAMPS occludes the I_h modulation by these monoamines, suggesting a direct nucleotide action on the In was activated by hyperpolarizing voltage steps during wholecell recording from CA1 pyramidal cells (n = 55) in slices from young rats. 5-HT (10-30 $\mu M),\; DA$ (10-30 $\mu M),\; HA$ (10-30 $\mu M)$ or the β -adrenergic agonist isoproterenol (Iso, 1-5 $\mu M)$ enhanced $I_h,\; and\; caused\; an inward shift in the$ holding current at negative voltages where Ih was activated. (5-HT was applied holding current at negative voltages where I_h was activated. (5-H was applied in the presence of a blocker of $5HT_{1A}$ receptors). In cells loaded with intracellular Rp-cAMPS (500 μ M in the pipette), I_h was large and Iso, 5-HT, DA or HA caused no further increase in I_h (n=4-5 for each), nor the corresponding inward shift in the holding current at negative potentials (n=4 for Iso). These data suggest that Rp-cAMPS can enhance I_h in a manner similar to cAMP, thus occluding the effect of the monoamines. A similar action of Rp-cAMPS (known as a PKA inhibitor), and cAMP, both enhancing In, suggests a direct cyclic nucleotide effect on the h-channels, as previously shown in heart SA node (DiFrancesco & Tortora, *Nature* 351:145-47, 1991). These results further suggest a convergent modulation of In by several transmitters involved in brain state control and arousal [Supported by NFR].

EFFECT OF ANOXIA AND METABOLIC INHIBITION ON MEMBRANE POTENTIAL AND K⁺ CHANNELS IN PYRAMIDAL CELLS IN RAT BRAIN SLICE. <u>L. Hyllienmark and T. Brismar*</u>. Dept Clinical Neurophysiology, University Hospital, S-58185 Linköping, Sweden.

University Hospital, S-58185 Linköping, Sweden. Metabolic inhibition or anoxia causes hyperpolarization due to an increase in membrane K^+ conductance. The aim of the present study was to analyse this mechanism in pyramidal cells and to elucidate the type of ion channel involved. Brain slices (300 μ m) were obtained from 10 to 19 days old rats and individual cells were visualized with infra-red differential contrast microscopy. Whole-cell recordings were performed on pyramidal cells from the CA1 field in the hippocampus with patch-clamp technique (1-3 MOhm pipettes). Slices were perfused with Ringerglucose solution and in most experiments 300 nM tetrodotoxin. Anoxia was induced by switching the aerating gas from 95%O2-5%CO2 to 95%N2-5%CO2. The resting potential (E) was -56.0 ± 0.22 mV ($n\!=\!171$, mean. SEM). Anoxia caused hyperpolarization which appeared with a latency of about 4 min and reached a maximum of -3.4 ± 0.42 mV ($n\!=\!16$) after 8 minutes. Addition of the metabolic inhibitor dinitrophenol for two minutes changed E by -3.9 ± 0.76 mV ($n\!=\!59$). The hyperpolarization was accompanied by an incresed K+ conductance at resting potential which could be blocked by tolbutamide but not by glibenclamide or addition of intracellular ATP. The effect of metabolic inhibition could partly be inhibited of cadmium suggesting that an increase in intracellular Ca2+ may be involved. In addition, metabolic inhibition and anoxia caused a decline in the A-current.

In conclusion, the short-term effects of anoxia or metabolic inhibition in pyramidal cells in brain slices are similar and resembles those previously described in cultured cells. Although the hyperpolarization and incresed K^{+} conductance at resting potential were mediated by a tolbutamide-sensitive channel it was not of a classical ATP-sensitive type.

Supported by the Swedish Medical Research Council (project no. 14x-4255).

572.10

CALMODULIN (CaM) AND CaMK MODULATE COEXISTING Kv1.3 AND INTERMEDIATE-CONDUCTANCE K_{cs} CHANNELS IN A SIMILAR MANNER. M.C. Chang and L.C. Schlichter*, Dept. of Physiology, Univ. of Toronto, and Playfair Neurosci. Unit, Toronto Hospital, Toronto, ON MST 288 Canada.

Voltage-activated (Kv1.3), and intermediate-conductance (IK) $K_{\rm Ca}$ channels are present in lymphocytes and some CNS neurons. In the immune system, Kv1.3 and $K_{\rm Ca}$ are involved in T lymphocyte activation, proliferation and volume regulation, partly by regulating ${\rm Ca}^3$ signalling. In some CNS neurons, similar IK channels may produce after-hyperpolarizations, and Kv1.3 may contribute to repolarization of specific neurons. Several enzymes that are important for T-cell activation lie downstream of the ${\rm Ca}^3$ entry: calmodulin (CaM), calcineurin (a CaM-dependent phosphatase that is highly expressed in lymphocytes and CNS neurons), and ${\rm Ca}^3$ /CaM dependent-protein kinases, of which T cells express CaMKII, and CaMK-Gr (IV). We investigated a possible regulatory loop whereby ${\rm Ca}^3$ entry, which requires K' channel activity, feeds back to up-regulate the function of those K' channels. Whole-cell Kv1.3 and IK ${\rm K}_{\rm Ca}$ currents were measured in mitogen-stimulated human T lymphoblasts. Three membrane-permeant CaM antagonists (trifluoperazine, W-7, calmidazolium) dose-dependently reduced both currents, and, as expected for competitive binding, excess internal CaM significantly relieved this inhibition. To test for involvement of CaM kinases, intext T lymphoblasts were treated with Kh-62 (originally developed as a CAMKII inhibitor), before establishing whole-cell recordings: both K' currents were significantly inhibited. Thus, CaM and CaMK appear to regulate both IK ${\rm K}_{\rm Ca}$ and Kv1.3 channels, and would be expected to promote channel activity after ${\rm Ca}^2$ rises during real activation. A broader implication is that a transient ${\rm Ca}^3$ elevation, which can persistently activate ${\rm CaMK}$, may produce long-term regulation of ion channels. In this, there may even be parallels between mechanisms underlying neuronal memory (e.g. LTP, LTD) and immune cell memory. Supported by MRC, OGS, Canada.

INVERTEBRATE LEARNING AND BEHAVIOR V

573.

LONG-TERM MEMORY OF OPERANT CONDITIONED BEHAVIOUR IN LYMNAEA. K. Lukowiak*, G. Spencer, T. Inoue, R. Cotter and N. Syed. Neuroscience and Respiratory Research Groups. University of Calgary, Calgary, Alberta, T2N 4N1 and Arabian Gulf University/CMMS, Manama, Bahrain.

Lymnaea are bimodal breathers being able to respire either through their skin or when at the surface via a rudimentary lung (aerial respiration). Aerial respiratory behaviour increases significantly when the animal is in an hypoxic environment. This aerial respiratory behaviour can be operantly conditioned by the contingent presentation of a tactile stimulus to the respiratory orifice, the pneumostome, each time the snail attempts to breathe in the hypoxic pond water. A training period of 0.5 h per day, twice daily for 2.5 days results in learning which persists for up to 1 week. A second group of animals (N=15) received a similar initial 2.5 day training regime but were then retrained at one week intervals for 3 more weeks. This group thus received 8 training sessions over a 4 week period (spaced training group). Learning in this group was found to persist for up to one month. In a third group of animals (N=15) the same number of training sessions (8) were given, but over only a 4 day period, (massed training group). In this massed training group learning did not persist for one month. Yoked Control animals (N=15 to both spaced and massed regimes) neither exhibited significant changes in their aerial respiratory behaviour during their "training period", nor did they exhibit any retention of learned behaviour when tested at a one week interval. Supported by MRC (Canada)

BEHAVIORS OF THE GILL IN FREELY--MOVING APLYSIA CALIFORNICA. <u>J.L. Leonard</u>*, Mark O. Hatfield Marine Science Center, Oregon State Univ., Newport, OR 97365 and Marine Biological Laboratory, Woods Hole, MA 02543.

The neural control of movement in the Aplysia gill has been an important model system for the study of behavioral plasticity. Many studies have used reduced preparations and/or restrained intact animals to examine the physiological mechanisms of behavioral phenomena identified in freely-moving animals. The behavior of the siphon has often been used to infer gill behavior in intact Aplysia. In in vitro preparations siphon movement is not necessarily a good predictor of gill movement (Mpitsos and Lukowiak 1985; Schaefer and Brownell 1986). To better understand the behavior of the gill under "normal" conditions, the right parapodium was surgically removed from Aplysia weighing from 19-300 g and both spontaneous and evoked behaviors of the gill recorded on videotape. The most surprising result was the variety of patterns of spontaneous gill and mantle organ contractions. In intact but restrained Aphysia, gill movements such as the SGM or LUM seen associated with INT II activity in in vitro preparations, are reliably associated with the "stereotyped" Pumping behavior (Pinsker 1982-3; Leonard and Lukowiak 1986; Leonard et al. 1989). This was not the case in hemiparapodectomized (HPX) Aplysia. In HPX animals spontaneous LUMs occurred in several contexts; a) with contractions of the siphon, mantle and parapodia, the classic Pumping; b) preceeding contraction of other mantle organs the "gill-first" pumping; and c) alone, without contraction of other mantle organs. Similarly, contractions of the siphon were often observed that were not followed or accompanied by gill movements, and on occasion, coordinated contractions of siphon, mantle and parapodium were not accompanied by detectable gill contraction. The types of gill movements seen in HPX animals were consistent with those described previously (Leonard et al. 1989), with the addition of a new Act, Quiver. Supported by an NIH grant (NS-08437) to L.B. Cohen.

CONTRIBUTION OF MONOSYNAPTIC EPSPS FROM LE SIPHON SENSORY NEURONS TO MEDIATION AND HABITUATION OF THE GILL- AND SIPHON WITHDRAWAL REFLEX IN APLYSIA. R.D. Hawkins* and L. Frost. Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032

Monosynaptic connections from LE siphon sensory neurons to motor neurons are thought to contribute to the gill- and siphon-withdrawal reflex in Aplysia and its modification during simple forms of learning. However, other sensory neurons and interneurons are also thought to contribute (Hawkins & Frost, 1995). To estimate the relative contribution of monosynaptic EPSPs from LE neurons, we compared them to the complex PSP produced in LFS siphon motor neurons by tactile stimulation of the siphon. In rested preparations, the monosynaptic EPSP was $34.5 \pm 5.1\%$ of the amplitude and $6.6 \pm 1.8\%$ of the area of the complex PSP (n = 15). Siphon stimulation produced 2.6 ± 0.7 spikes in an LE cell when it was within the cell's receptive field ("on-field"). Following 5 siphon stimulations at 5 min intervals, which produces behavioral habituation in this preparation (Hawkins et al., 1990), the area of the complex PSP was significantly reduced (81 \pm 9%, n = 12, p < .05). There was no change in the number of spikes in on-field LE neurons, but the area of monosynaptic PSPs from those neurons was significantly reduced (43 ± 10%, n = 7, p < .01). By contrast, the area of monosynaptic PSPs from off-field LE neurons was not changed (n = 5). In preliminary experiments (n = 5) we have obtained quantitatively similar results when recording from the motor neuron LDG1, which mediates most of the gill-withdrawal reflex in this preparation (Hawkins et al., 1992). These results suggest that monosynaptic EPSPs from LE siphon sensory neurons make a substantial contribution to the gill- and siphonwithdrawal reflex and its modification during habituation. Supported by NIMH.

INDIRECT AND DIRECT EFFECTS OF 5-HT ON SENSORIMOTOR SYNAPSES IN *APLYSIA*. X. Liao* and E.T. Walters. Dept. Integrative Biology, Univ. Texas - Houston Medical School, TX 77030.

We are testing whether 5-HT application to Aplysia ganglia activates modulatory neurons that facilitate synapses between pleural sensory neurons (SNs) and pedal motor neurons. Six of 8 connections measured in 5 μM 5-HT in artificial seawater (ASW) showed facilitation, to a mean for the entire group of 169% of their pre-5-HT values. Surprisingly, only 1 of 9 connections measured in 5-HT medium containing elevated divalent cation levels ("hi-di" solution - 2.2 X Mg²⁺ and 1.25 X Ca²⁺) was facilitated (to 106%), while the group mean was depressed to 88% of baseline. Long-term treatment was conducted 4 hr after dissection with 2 hr application of 5 μM 5-HT. Connections were tested before and 1 d after treatment. Treating with 5-HT in ASW caused significant long-term facilitation (LTF)(from 7.7 to 11.3 mV, n=12 ganglia). Untreated controls showed no change (from 7.5 to 7.5 mV, n=10). Treatment with 5-HT in hidi caused no significant change (from 9.4 to 8.2 mV, n=10). Similarly, treatment with 5-HT mixed with 60 µM TTX, resulted in mean EPSP depression in 4 of 6 ganglia, while TTX alone had no obvious long-term effect (n=4). Initial results (n=2) showing that hi-di solution does not block 5-HT facilitation in 3 d old dissociated cell cultures, suggests that blocking effects of hi-di are not due to direct actions on 5-HT pathways in SNs. Interestingly, hi-di fails to block LTF in ganglia treated with 5-HT 3-5 d after CNS dissection (22 of 24 connections facilitated, from a mean of 6.9 to 11.5 mV). Our results show that 5-HT applied to ganglia produces complex facilitatory effects, and suggest that axon injury may cause a delayed increase in the responsiveness of SNs to 5-HT.

Rp-cAMPS BLOCKS THE AXOTOMY-INDUCED INCREASE IN EXCITABILITY AND GROWTH OF ISOLATED APLYSIA SENSORY NEURONS IN CELL CULTURE. S. S. Bedi* and D. L. Glanzman, Department of Physiological Science, UCLA, Los Angeles, CA 90024.

Axotomy of Aplysia sensory neurons in dissociated cell culture induces long-term changes in these cells which resemble those induced by repeated applications of the modulatory neurotransmitter serotonin (5-HT). Among these changes are hyperexcitability (Salim and Glanzman, Soc. Neurosci. Abstr. 21:1267, 1995) and increased neurite outgrowth. Serotonin's long-term effects on sensory neurons are mediated by activation of the cAMP second messenger pathway. To determine whether the long-term effects of axotomy are also mediated by cAMP-dependent intracellular signals, we axotomized cultured sensory neurons in the presence or absence of Rp-cAMPS, a specific inhibitor of protein kinase A (PKA).

The excitability of isolated sensory neurons in culture was tested and the number of branch points on their neurites quantified. Then some of the sensory neurons were axotomized. Twenty-four hr later the excitability of the neurons was retested and their neurites re-inspected. Axotomized neurons left in normal cell culture medium exhibited significantly greater excitability and neurite outgrowth, as indicated by an increase in the number of branch points on their neurites, than did unaxotomized (control) sensory neurons. By contrast, axotomized sensory neurons placed into cell culture medium containing Rp-cAMPS (500 µM) did not exhibit an increase either in excitability or outgrowth when examined 24 hr after axotomy. Interestingly, Rp-cAMPS also blocked the more modest increase in excitability and outgrowth observed in control cells left in normal medium for 24 hr. Our results indicate that injury stimulates cAMP-dependent gene transcription in Aplysia sensory neurons and provide further support for the idea (Walters and Ambron, 1995) that the cellular pathways activated by injury and those activated by 5-HT in sensory neurons overlap. 5-HT ENHANCES SPONTANEOUS ACTIVITY OF ISOLATED NERVES AND INCREASES EXCITABILITY OF APLYSIA SENSORY NEURON AXONS. <u>I.D. Gunstream*, G.A.Castro, and E.T. Walters.</u> Dept. Integrative Biology, Univ. Texas - Houston Med. School, TX 77030.

Strong, noxious stimulation of *Aplysia* is likely to damage peripheral nerves and trigger the release of 5-HT at various sites (see Walters & Ambron, *Trends Neurosci.* 18:137, 1995). To begin to test whether 5-HT directly modulates peripheral axons following nerve injury, we examined the effects of 5-HT on extracellularly recorded activity from a segment of peripheral nerve p9 severed from both the tail and CNS. In every case, isolated segments showed some spontaneous activity that persisted for the duration of the experiment (up to 2 d). Application of 10 µM 5-HT increased spontaneous activity in 8 of 8 isolated nerves tested. Clear increases in activity were seen for doses of 1-250 µM (n=2 preparations). Enhanced activity was also seen after 5-HT application to surgically desheathed segments (n=2). 5-HT did not cause obvious enhancement of activity in central (pleuroabdominal) connectives. Selective application of 5-HT to nerve p9 while attached to the CNS never activated pleural sensory neurons (SNs). However, local application of 5-HT to nerve p9 increased the activity evoked by a 1-s nerve shock in 3 of 3 cells tested (from 11.4 to 17.6 spikes), under conditions (2 µM external Ca²⁺) expected to reduce Ca²⁺-dependent release of endogenous modulators. 2-hr nerve application of 10 µM 5-HT does not appear sufficient to induce long-term hyperexcitability of pleural SN somata (n=5) or to enhance hyperexcitability induced by nerve crush (n=4). Peripheral 5-HT may enhance SN injury discharge and activate axons of neurons that have widespread modulatory effects (see Liao & Walters, this volume). LONG-TERM HYPEREXCITABILITY OF *APLYSIA* SENSORY NEURONS FOLLOWING cAMP INJECTION: INVOLVEMENT OF Ca²⁺ AND OTHER SIGNALS. <u>M.R. Lewin and E.T. Walters*</u>. Dept. Integrative Biology, Univ. of Texas - Houston Medical School, TX 77030. One d after injection of cAMP into *Aplysia* sensory neurons (SNs) K⁺

One d after injection of cAMP into Aplysia sensory neurons (SNs) K⁺ currents in the cell soma are depressed (Sholz & Byrne, Science 240:1664, 1988) and apparent synaptic growth occurs (Nazif et al., Brain Res 539:324,1991). Because of likely overlap of injury and memory signals (Walters, Biol. Bull. 180:241,1991) and because impalement/injection procedures cause potentially significant cellular damage, we are testing the possible involvement of injury-related signals in triggering long-term hyperexcitability during pressure injection of cAMP and fast green (FG) dye into pleural SN somata. One d after cAMP injection, 289 spikes were evoked in SN somata by a 1-s depolarizing test pulse at 2.5X threshold (n=6 ganglia and 24 cells). This significantly exceeded the number of spikes evoked 1 d after injecting 1) cAMP and the Ca²⁺-chelator BAPTA (16.5 spikes, n=7 ganglia and 25 cells), 2) cAMP and BAPTA while extracellular Ca²⁺ was reduced by 5000X (13.9 spikes, n=9 ganglia and 37 cells), or 3) FG alone (15.5 spikes, n=8 ganglia and 57 cells) (p<.01 in each case). The attenuation of hyperexcitability by BAPTA injection and low extracellular Ca²⁺ suggests that concomitant Ca²⁺ transients contribute to long-term effects of cAMP signals. FG-injected cells were more excitable than uninjected cells in the same ganglia (15.5 vs 6.2 spikes, p<.002), suggesting that this dye or other aspects of injection can also induce persistent responses. The relatively low excitability seen after FG injection in low extracellular Ca²⁺ (6.8 spikes, 4 ganglia and 37 cells) suggests that other (injury-related) signals may also be Ca²⁺ dependent. Supported by NiH grant MH38726 to E.T.W.

ROLE OF PROTEIN KINASES IN UBIQUITIN-MEDIATED TURNOVER OF C/EBP DURING LONG-TERM FACILITATION IN APLYSIA SENSORY NEURONS. N. Yamamoto*, A.N. Hegde, D.G. Chain and J.H. Schwartz. Center for Neurobiology & Behavior, Columbia University, New York, NY 10032.

Rapid induction of mRNA encoding the transcription factor ApC/EBP is necessary for long-term facilitation (LTF) of the sensory-to-motor synapses that mediate defensive reflexes (Alberini et al., Cell 76:1099, 1994). We found that DNA-binding activity of ApC/EBP protein is maximal at 3 h after beginning sensitization treatment in vivo, and then falls to basal levels by 6 h, indicating that the transcription factor acts during a critical time period. To examine the molecular mechanism of the turnover of ApC/EBP, we incubated recombinant ApC/EBP with Aplysia nervous tissue extracts. The protein was rapidly degraded. The proteolysis depended on the presence of ATP and proteasomes, and gave rise to multiple ubiquitin ladders as intermediate products. The degradation occurred only in nervous tissue, suggesting some tissue-specific factor is required. This ATP-ubiquitin-proteasome-mediated degradation was enhanced by phosphatase inhibitors, suggesting that the factor is a protein kinase. From studies with various kinase specific inhibitors, we found that both MAP kinase (MAPK) and protein kinase C (PKC) are necessary for the degradation of ApC/EBP. In addition, we have evidence that activation of ApC/EBP (DNA binding) requires direct phosphorylation by MAPK, which is activated by PKC. These results suggest that MAPK and PKC regulate both activation and turnover of ApC/EBP. (Supported by NIH grants MH48850 and MH00921 [JHS])

INHIBITORS OF PROTEASOMES BLOCK LONG-TERM FACILITATION IN APLYSIA. D.G. Chain*, S. Schacher, A.N. Hegde, A. Casadio, A.L. Goldberg and J.H. Schwartz. Center for Neurobiology & Behavior, Columbia University,

and J.H. Schwarz. Center for Neurobiology & Benavior, Columbia University, NY, NY 10032 and Harvard Medical School, Boston, MA 02115.

The cAMP-dependent protein kinase (PKA) becomes persistently activated during long-term facilitation (LTF) in Aplysia sensory neurons (SNs). Persistence OFKA results from proteolysis of its regulatory (R) subunits that are degraded in tissue extracts by the ubiquitin system (Hegde et al., PNAS 90:7436, 1993). tissue extracts by the ubiquitin system (Hegge et al., PMA3 9):7436, 1993). Down-regulation of R is a nervous system-specific process dependent on factors that modulate proteasomes (Hegde et al., Soc. Neurosci. Abs. 20:1072, 1994; Chain et al., J. Neurosci. 15:7592, 1995). We have characterized the proteasomes biochemically and used inhibitors to establish whether they have a critical role in LTF. We tested the action of a transition-state peptide aldehyde inhibitor, N-Carbobenzyl-leu-leu-leunorvalinaldehyde (MG115) by monitoring the hydrolysis of fluorogenic peptide substrates using purified proteasomes. We found that MG115 blocks chymotryptic activity by > 90%. We tested MG132 (N-Carbobenzyl-leuleu-leu-leucinaldehyde), a more potent, closely-related structural analog, in cell-culture. SNs and motor neurons reestablish connections after 4 days and undergo LTF after repeated applications of 5-HT (Montarolo et al., Science 234:1249, 1986). The amplitude of the EPSP was recorded for each culture before and 24 h after 5 applications of control solution at 20 min intervals followed by 22 h treatment with MG132 alone, 5 applications of 5-HT at 20 min intervals followed by 22 h treatment with the inhibitor alone, or 5 applications of 5-HT alone. A one-factor Anova indicated a significant effect of the treatment (DF=2,17; F+13.725; p<0.001). Multicomparison tests (Dunnett's) indicated that 5-HT significantly increased the amplitude of the EPSP compared to the MG132 significantly interasted the amplitude of the EF3* compared to the MO312 returnent (T=3.88; p.0.01). Treatment with MG132 after 5-HT evoked a change not significantly different from treatment with MG132 alone (t=0.55). These results suggest that degradation by proteasomes has an important function in the maintenance of LTF. (Supported by NIH grants NS29255 and MH00921 [JHS])

MUTATION IN MAP KINASE PHOSPHORYLATION SITES BLOCKS LEARNING-RELATED INTERNALIZATION OF apCAM IN APLYSIA SENSORY NEURONS. C.H. Bailey*, B.-K. Kaang, M. Chen, and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032, & Inst. Mol Biol. & Genetics, Seoul Natl. Univ., Korea.

The synaptic growth that accompanies 5-HT-induced long-term facilitation of the sensory-to-motor connection in dissociated cell culture is associated with a down-regulation of cell adhesion molecules (apCAMs) on the surface membrane of the sensory neuron (Mayford et al., 1992). Down-regulation is achieved by activation of the endosomal pathway leading to internalization and apparent degradation of apCAM (Bailey et al., 1992). Of the two apCAM isoforms (membrane bound and GPI-linked), only the transmembrane form is internalized. Thus, a 1 hr exposure to 5-HT leads to a 68% decrease in the density of goldlabeled complexes bound to the transmembrane form at the surface membrane and a 24-fold increase in its internalization. The selective internalization of the transmembrane form highlights the potential regulatory significance of its intracellular domain, which contains a PEST sequence (thought to target degradation) and two consensus sites for MAP kinase phosphorylation. To explore further the functional role of the intracellular domain, we have overexpressed specific epitope-tagged deletion and mutant transmembrane constructs and find both 5-HT-induced down-regulation at the surface membrane and internalization can be blocked by removing either the entire cytoplasmic tail; or the region containing PEST or by simply substituting alanine for threonine in the two MAP kinase consensus sites. These data suggest phosphorylation by MAP kinase may be important in the learning-related internalization of apCAMs.

FUNCTIONAL ORGANIZATION OF THE AMPHIBIAN OPTIC TECTUM G. Roth*, U. Dicke and M. Wallstein. Brain Research Institute, University of Bremen, PO Box 330440, 28334 Bremen, Germany.

Tracer injections and intracellular labeling with Biocytin (Sigma) reveal 3 types of tectal projection neurons in salamanders. The 1st type arborizes predominantly in the superficial layer of retinal afferents containing information about contrast. The axon descends to the contralateral medulla; no ascending projections exist. The 2nd type arborizes in the *intermediate* layer of retinal afferents containing information about motion. The axon descends *ipsilaterally* and *laterally* inside the medulla; ascending axons project bi- or ipsilaterally to pretectum and thalamus. The flat dendritic tree of the 3rd type arborizes in the deep layer of retinal afferents containing information about ambient illumination and in the efferent fiber layers. Ascending projections are the same as in the 2nd type; the descending axon runs in the medial ipsilateral medulla. Tracer studies in various species of frogs reveal essentially the same types of projection neurons. In salamanders and frogs, interneurons have small dendritic trees arborizing in one or more of the retinal layers. Intracellular recording and labeling reveals extensive electrical coupling among different types of neurons. Projection neurons show excitatory or excitatory-inhibitory responses at short latencies (7.6 ms on average) at electrical stimulation of the optic nerve, while interneurons respond at

longer latencies (33.4 ms) mostly with inhibition or excitation-inhibition.

Experiments using polyclonal primary antibodies against GABA and glycine Experiments using polyclonal primary antibodies against GABA and glycine (Sigma, Chemicon) and a monoclonal primary antibody against glutamate (Sigma) suggests that most projection neurons are exclusively glutamatergic, while a small number appears to contain GABA and/or glycine in addition. Many tectal interneurons, in addition to glutamate, contain GABA or GABA/glycine.

The 3 types of projection neurons plus subtypes of interneurons constitute 3 tectal bacteries are prize declarated white it limitation. The neurons of internet.

TEMPORAL RELATIONS BETWEEN RESPONSES IN VISUAL CORTICAL AREAS AND SUPERIOR COLLICULUS OF THE CAT. A.K. Engel* and M. Brecht. Max-Planck-Institut für Hirnforschung. 60528 Frankfurt, Germany

The functions of cortex and superior colliculus (SC) are intimately related in mammals. Corticotectal projections originate from almost the en-tire neocortex and collicular feedback is provided via thalamic structures. Here, we have aimed at testing the hypothesis that temporal codes may be important for the corticotectal interplay. To this end, we applied correlation analysis to visually evoked multiunit responses that were simultaneously recorded from superficial SC layers and from visual cortical areas 17, 18, PMLS and PLLS in anesthetized cats. We frequently observed temporal correlations between responses in these cortical areas and the SC. Many of the correlograms showed broad peaks (width >20 ms) but occasionally also narrow peaks were seen. In addition, we frequently observed oscillatory side peaks indicating rhythmic firing at frequencies between 5-80 Hz. Corticolectal interactions were similar for all cortical areas studied. These interactions occurred mainly for cells with overlapping receptive fields and tended to be weaker than those observed within the cortex. In addition, corticotectal interactions did not occur at 0-time lag but systematic phase shifts were observed, the cortical units leading 0-25 ms over collicular responses. Furthermore, our data indicate that the incidence of corticotectal synchrony is correlated with the occurrence of synchrony chrony between the cortical areas. Our data demonstrate for the first time that the corticotectal pathway affects spike timing in the SC. Thus, SC neurons might be able to "read" relations within cortical populations defined by synchronized firing. TEMPORAL CODING IN THE CAT SUPERIOR COLLICULUS M. Brecht* W. Singer and A.K. Engel. Max-Planck-Institut für Hirnforschung, 60528 Frankfurt, Germany

Evidence is accumulating that synchronous firing of neurons plays an important role for visual information processing. Recent work on the visual cortex has suggested that correlated activity may serve for the integration of activity into coherent representational states and for the selection of distributed responses for further joint processing. Since population coding is also assumed to be important for sensorimotor transformations carried out in the superior colliculus (SC), we have now studied temporal relationships between spatially separate neurons in the tectum. Using arrays of multiple electrodes, we have recorded from superficial layers of the SC in anesthetized and paralyzed cats. Responses to visual stimulation were subjected to correlation analysis. Our results demonstrate that neurons in the SC can readily synchonize their activity. Synchronized activity was observed for neurons with overlapping as well as nonoverlapping receptive fields and occurred over distances of several millimeters. Correlograms showed both narrow as well as broad peaks (width >20 ms) that were centered around 0 ms phase shift. In many cases, the interactions were accompanied by oscillatory components of varying frequency (5-80 Hz). In a number of cases, we have obtained preliminary evidence that the interactions depend on the configuration of visual stimuli. Taken together, the data are compatible with the notion that synchrony may be important for processing in the SC and may allow the selection of stimulus-specific motor responses from spatially nondiscrete activity patterns. Supported by the MPG, by the Heisenberg Program of the Deutsche Forschungsgemeinschaft and by the Minna-James-Heineman Foundation.

MODELING THALAMUS AS A PREDICTIVE COMPARATOR W. Softky* Mathematical Research Branch, NIDDK, NIH

This work proposes that the combined influences of cortical/reticular (nRT) feedback to a thalamic "relay" cell may provide it with a very specific contextual signal—an inhibitory prediction of the cell's imminent sensory input—and that under normal sensory conditions the cell acts as a comparator, conveying to cortex approximately the difference between the prediction and the actual sensory input. Such predictive inhibition would implement several useful features: nonlinear reduced-redundancy coding in space and time; compensation for feedback's inevitable delays; and refining the brain's represenation by emphasizing its mistakes. This preliminary test evaluated whether a relay cell could transmit both signs of prediction error by means of its two known spiking patterns, single (tonic) spikes and post-inhibitory-rebound bursts. Reverse-correlations $(\pm \tilde{3}00~ms,$ below) of random excitatory and inhibitory input to a simulated thalamic cell showed, over a wide range of firing rates, that on average tonic spikes signalled excess excitation and reduced inhibition in the preceding 30-100 msec, while bursts signalled approximately the opposite. These simulations predict that the receptive fields reconstructed from bursts vs. from spikes should be different and-in the postulated case of predictive inhibitionextra-classical spatiotemporal patterns, such as motion extrapolation.

MECHANISMS UNDERLYING THE GENERATION OF THE SLOW AFTERHYPERPOLARIZATION (AHP) IN PERIGENICULATE (PGN) NEURONS AND ITS ROLE IN SYNCHRONIZED OSCILLATIONS. U. Kim^{*}, T. Bal, and D.A. McCormick. Sec. Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510

During the generation of spindle waves in vitro perigeniculate neurons progressively hyperpolarize and this appears to contribute to the "waning" of these synchronized oscillations. Intracellular recordings in PGN neurons revealed that this afterhyperpolarization was associated with a reduced responsiveness to barrages of EPSPs arising from burst firing in LGNd thalamocortical cells, as well as a decreased ability of a burst of activity in thalamocortical cells to generate a burst of activity in thalamocortical cells to generate a burst of action potentials in PGN neurons. This afterhyperpolarization appears to be generated through intrinsic mechanisms since the generation of a single burst of action potentials (500-600 Hz) induced by an intracellular injection of a depolarizing current pulse (50-100 msec) is followed by a slow AHP of about 1 sec in duration. The induction of repetitive burst discharges at the frequency of 5-10 Hz augments the amplitude and duration of AHP up to 5-10 sec.

The AHP was found to have multiple components, including a voltage-dependent rectification of the membrane (including activation and de-activation of the persistent sodium current), a Ca²⁺-activated K⁺ current, and possibly a Na⁺-dependent K⁺ current. Intracellular injection of depolarizing and hyperpolarizing ramps resulted in the generation of apparent inward rectification at depolarized membrane potentials. Block of the persistent Na⁺ current with TTX reduced this rectification, but did not abolish it. The slow AHP following repetitive depolarizing current pulses was associated with an increase in membrane conductance, its equilibrium potential was shifted to more positive levels with increases in [K⁺]₀ and was abolished following the abolition of action potentials with TTX. These results suggest that is may be mediated in part by a Na⁺ and/or Ca²⁺-dependent K⁺ current. Supported by NIH and the Klingenstein Fund.

LATERAL INHIBITION IN THE PERIGENICULATE NUCLEUS OF THE FERRET. M. V. Sánchez-Vives* and D. A. McCormick. Sec. Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06510.

The GABAergic neurons of the perigeniculate nucleus (PGN) form reciprocal connections with thalamocortical cells of the LGN and with other PGN neurons. These reciprocal interconnections allow for the generation of both normal (e.g. spindle waves) and abnormal (e.g. spike-and-wave seizures) patterns of activity, probably depending upon lateral inhibition within the PGN. Here we demonstrate that activation of PGN neurons with the local application of glutamate typically results in IPSPs that exhibit reversal potentials of around -78 mV and are blocked by the GABAA receptor antagonists bicuculline and picrotoxin. In addition, PGN neurons also possess GABAB receptors and lateral inhibition can generate slow IPSPs that may be mediated by these receptors.

Local application of bicuculline results in a marked prolongation of rebound bursts of action potentials and the rebound LT Ca²⁺ spike in PGN neurons in normal and TTX containing solution, respectively. These results suggest that the activation GABA_A receptors strongly regulates the duration of burst discharges in PGN neurons. However, the burst prolongation induced by picrotoxin is always much weaker, even when it is effective in blocking IPSPs and the response to muscimol. These observations suggest that this effect of bicuculline is mediated by an unusual GABA_A receptor in PGN cells or due to an uncharacterized effect of bicuculline on a membrane conductance out of the GABA recentor complex.

A RETINOGENICULATE PATHWAY EXPRESSES THE α SUBUNIT OF CAM II KINASE IN THE PRIMATE. <u>D.J. Calkins' and S.H.C. Hendry.</u> Krieger Midd(Prin) Institute. Debye Hopking University. Beltimore, MD 21218.

Mind/Brain Institute, Johns Hopkins University, Baltimore, MD 21218. Neurons in the intercalated regions ventral to each magnocellular (M) and parvocellular (P) layer of the primate lateral geniculate nucleus (LGN) are differentiated from M and P neurons by immunoreactivity for the α subunit of type II calmodulin-dependent kinase (Cam II kinase). These intercalated neurons provide multiple direct pathways to the primary visual cortex and, like the M and P pathways, are likely to transmit visual information from the retina. However, whether the intercalated neurons are postsynaptic to one or more types of retinal ganglion cell, and whether these also are differentiated by Cam II kinase immunoreactivity, is unknown. Immunostaining for the α subunit of Cam II kinase in wholemounts and vertical sections of Macaca mulatata retina revealed labeled amacrine cells, with a corresponding band of dense immunoreactivity along the border between the IPL and ganglion cell layer (GCL). A weaker band was also present in the middle IPL that could indicate additional populations of labeled amacrine reals. The intensely labeled ganglion cells had broad dendritic trees stratifying narrowly over the GCL. These cells, some with dendritic trees stratifying narrowly over the GCL. These cells, some with dendritic trees stratifying narrowly over the GCL as parsely and resembled γ ganglion cells, but whether they comprise only a single type is undetermined. Ganglion cells axons were also intensely labeled, as were axon terminals in LGN confirmed by electron microscopy to be presynaptic to α Cam II kinase labeled dendrites of intercalated neurons. These results are consistent with one or more retinogeniculocortical pathways immunoreactive for Cam II kinase that originate in large-field ganglion cells distinct from the "parasol" and "midget" ganglion cells underlying the M and P pathways. HISTAMINE INHIBITS PERIGENICULATE NEURONS THROUGH ACTIVATION OF A CI CONDUCTANCE. K. Lee* and D.A. McCormick. Section of Neurobiology, Yale Univ. Sch. Med. New Haven, CT 06510.

The nucleus reticularis thalami (nRt) and its visual counterpart, the perigeniculate nucleus (PGN), is innervated by histaminergic fibers presumably arising from neurons in the tuberomammillary nucleus of the hypothalamus. Local application of histamine to the PGN neurons in the ferret geniculate slice maintained in vitro resulted in a decrease in input resistance and a slow membrane depolarization or hyperpolarization towards about -73 mV, depending on resting membrane potential. These responses were not abolished by blockade of synaptic transmission with local application of tetrodotoxin, indicating that they are direct postsynaptic actions. Voltage clamp analysis revealed that the membrane potential change induced by histamine or the $GABA_A$ agonist muscimol was associated with a current that reversed around -73 mV when recorded with either 2 M potassium acetate or 3 M cesium acetate-filled electrodes. When cells were loaded with Cl by recording with 3 M potassium chloride-filled electrodes, the reversal potential of histamine and GABA responses both shifted to a similar extent to more depolarized membrane potentials. These results strongly suggest that activation of histaminergic receptors in the GABAergic PGN/nRt neurons results in an increase in a chloride, but not a potassium, conductance. Interestingly, application of histamine to the PGN could halt the generation of spindle waves, indicating that increased activity in the tuberomammillary histaminergic system may play a functional role in dampening thalamic oscillations through increases in Cl' conductance in PGN cells. Supported by NIH and the Klingenstein Fund.

MUSCARINIC RECEPTOR-MEDIATED RESPONSES IN THALAMIC LOCAL INTERNEURONS. J. J. Zhu, D.J. Uhlrich, and W.W. Lytton. Neuroscience Training Program and Depts. of Anatomy and Neurology, University of Wisconsin Medical School and the Wm. S. Middleton VA Hospital, Madison, WI 53706

Thalamic cells, including local interneurons, have both bursting and tonic firing modes. Many neurotransmitters switch firing modes in thalamocortical and thalamic reticular cells, reflecting behavioral state transitions. We wanted to determine whether these neurotransmitters have similar effects on thalamic local interneurons.

We studied muscarinic receptor-mediated effects on identified local interneurons (n=53) in the adult rat lateral geniculate nucleus slice. As expected, a brief application of a muscarinic agonist, methacholine (Mch), induced a hyperpolarization due to an increase a K* conductance. However, with the whole-cell recording configuration, this was often followed by a slow depolarization. Both muscarinic responses, which were accompanied by a decrease in input resistance, were insensitive to TTX and blocked by gallamine, suggesting the direct involvement of the M2 receptor. The depolarization was selectively suppressed when high concentration EGTA was included in the patch electrode solution, suggesting a Ca²*-mediated event, and voltage clamp analysis revealed that the depolarization was due to an increase in two Ca²*-dependent conductances, f_h and f_{can} . Interneurons, when hyperpolarized or at rest, assume the burst mode of firing. Mch application switched them into the tonic firing mode. Computer simulation demonstrated that this switch from bursting to tonic mode could be explained by a combination of the decreased input resistance and the pre-activation of f_{can} preempting the initial burst response. Our study provides a possible cellular mechanism for different firing modes observed in thalamic local interneurons in different behavioral states. Supported by NEI, NINDS, and the VA

FUNCTIONAL ACTIVATION OF LATERAL GENICULATE NUCLEUS AND PRIMARY VISUAL CORTEX DURING VISUAL IMAGERY IN HUMAN BRAIN, T. Kato, W. Chen, X.-H. Zhu, D. Tank[#], S. Ogawa[#] and K. Ugurbil*, CMRR, University of Minnesota, School of Medicine, Minneapolis, MN 55455, #Lucent Technologies Bell Labs, Murray Hill, NI 07974, USA.

**Lucent Technologies, Bell Labs, Murray Hill, NJ 07974, USA.

Whether visual imagery process is subserved by the similar neural substrate as visual perception is one of the major controversies in visual neuroscience. Our goal in this study was first to demonstrate that the LGN activation in the human brain can be robustly detected during visual perception using fMRI with blipped EPI at high (4 Tesla) magnetic fields, subsequently to examine if V1 and the LGN activation are both present during visual mental imagery tasks and finally to study the relationship between the visual imagery patterns and the V1 activation. The flashing light created by a goggle was used for visual perception task. Five visual imagery tasks were designed for this study. Each task involved different view field and spatial resolution of imagined picture and memory. The activation in V1, LGN and pulvinar was detected during visual perception task using fMRI. The results showed a coupled relationship between the LGN and V1 activation. Most visual imagery experiments also showed the activation in V1, LGN, and pulvinar. Inferior pulvinar was more involved in visual perception and lateral and medial pulvinars were more involved in visual imagery. Our results demonstrated that activated location in V1 areas during visual imagery tasks depend on the view size, fine details (or spatial resolution) of imagined pictures and the ability to recall and recreate imagined pictures. It was also demonstrated for the first time that the LGN was activated during visual imagery processing in human brain together with V1 and pulvinar activation. These data suggest that both the LGN and V1 involves in visual perception and visual imagery processing and that other thalamic nuclei such as the pulvinar also contributes to the processing of mental visual imagery issual imagery.

LUMINANCE CHANGES ACTIVATE THE LATERAL GENICULATE NUCLEUS IN THE HUMAN BRAIN. B. Gulyás* J. Larsson and P. E. Roland. Division of Human Brain Research, Department of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

With the purpose of exploring the brain structures activated by changes in luminance levels under Ganzfeld viewing conditions, we measured regional cerebral blood flow (rCBF) changes in ten male volunteers with positron emission tomography (PET) and 150-butanol, as the tracer, while the subjects performed a visual detection task. During the task the luminance level of the isochromatic Ganzfeld visual scene gradually changed in either direction (brighter or dimmer). The subjects had to press a response key when they detected the change. In the reference condition, no luminance changes were present in the response key at the same rhythm as in the experimental condition. Significant changes in rCBF levels were determined with 3-D cluster analysis (Roland et al. Human Brain Mapping 1(1993): 3-19).

During luminance detection, there was activation in the lateral geniculate nucleus (LGN) (HBA [Roland et al., Human Brain Mapping 1(1994):173-184] coordinates: x = 24, y = -25, z = -2 mm), as well as in extrastriate visual cortical regions (lateral occipital gyri, lingual and fusiform gyri), and the temporal and prefrontal cortex.

The present findings are in line with earlier observations on the neuronal role of LGN cells in primates in luminance detection, and demonstrate, for the first time, that activation in the human LGN can be shown with a functional brain imaging technique, in combination with a high performance computerised brain atlas system.

IMAGING CALCIUM TRANSIENTS IN RELAY NEURONS IN THALAMIC SLICES REVEALS BOTH LOW—AND HIGH-THRESHOLD CALCIUM CHANNELS IN THE SOMA AND PROXIMAL DENDRITES. Q. Zhou*, DW. Godwin, D.O Malley and P.R.Adams, Dept. Neurobio. SUNY Stony Brook, NY 11794.

Thalamic relay neurons respond to sensory inputs in one of two modes, burst or tonic, which partially depend on the underlying Ca²* currents. Because synaptic inputs to relay neurons may segregate upon relay cell dendrites, the location of voltage-gated Ca²* channels may influence the effectiveness of synaptic inputs. Ca²* transients in thalamic relay neurons in brain slices of postnatal (10 to 21 day old) rats were examined using confocal imaging and the fluorescent indicator calcium green dextran. Electrical activity was controlled by whole cell recording. In response to a ramp depolarizing current injection, we observed Ca²* transients in relay cells in two membrane potential ranges: one at relatively hyperpolarized values corresponding to the burst firing mode where both low- and high-threshold Ca²* channels are active, and the other at more depolarized values corresponding to the tonic mode where Ca²* influx through high-threshold Ca³* channels are active, and the other at more depolarized values corresponding to the tonic mode where Ca³* influx through high-threshold Ca³* channels dominates. These Ca²* transients have been observed in the cell body and throughout the part of the dendritic field examined so far (up to 100 µm from the soma, including branches up to the fourth order). At different low firing frequencies (up to 5 Hz for Na² action potentials, 3 Hz for LTS), individual Ca³* transients of constant sizes corresponding to single Na² action potentials or LTS can be seen throughout the dendritic field. At higher firing rates, e.g., in the range of spindle-wave activity, the signals became larger and merged. The location of the Ca³* currents underlying these Ca⁵* transients was examined using voltage protocols to selectively activate either low- or high-thres

LOCALIZATION OF GLUTAMATE IN THE RELAY NEURONS OF CAT LATERAL GENICULATE NUCLEUS Qilin Cao, Zhonghao Liu, Dahua Liu, Neugang Liu, Department of Anatomy and Neurobiolgy Hunan Medical University, Changsha 410078, P.R. China

The geniculocortical pathway in cat has been studied thoroughly morphologically and physiologically, and is composed of at least three channels (Y.W). The transmitters used by the pathway and the variation of the trasmitters used by the different channels however, remained to be elucidated in present study, the immunogold silver staining(ICSS) technique combined to the retrograde tracing methods, was used in 6 adult cat lateral geniculate nucleus(LGN) to analysize the distribution of Glutamate-containing neurons and to determine the locolization of Glutamate in the relay cells of cat d.GN. The glutamate-immunoreactive(Glu-ir) neurons distributed in all three laminaes (A, A1 and C.) of cat d.GN and can be divided into small, medium and large cells. Laminae C contained only small Glu-ir neurons, while laminae A and A1 had all the three types of Glu-ir neurons. Following the HRP injection into the primary visual area(area 17), the retrograde labeling neurons distributed in laminae A and A1 and and C.) of can consisting with the previous studies. The results of double-labeling study showed most HRP labeling neurons were also Glu-immunoreactive, and the double-staining neurons were composed of a large proportion of large double-staining neurons increases from media to lateral parts of the laminae A and A1 our result indicates most relay cells of cat GLGN are Glu-immunoreactive, and suggests the Glu are one of the major transmitters in the geniculocortical pathway in cat. THE ROLE OF THE BASAL GANGLIA IN MEMORY: EVIDENCE FROM PATIENTS WITH PARKINSON'S DISEASE AND HUNTINGTON'S DISEASE W.J. Lombardi*, K. Marder, E.D. Louis, D. Thorne, L.J. Côté, and Y. Stern. Department of Neurology, Columbia University, New York, NY 10032.

Nondemented patients with Parkinson's disease (PD) and Huntington's disease (HD) have a qualitatively similar memory disorder characterized by a recall deficit accompanied by normal recognition memory. This recall deficit is presumed to reflect the contributions of frontal-subcortical circuits to memory performance. If the structures of the basal ganglia play a unique role within these circuits, it should be possible to demonstrate some differences in memory performance among patients with different types of basal ganglia dysfunction. We provide evidence for such a dissociation between PD and dystinction. We provide evidence for such a dissociation between PD and HD patients using the proactive interference paradigm. Subjects studied a target list of word pairs (e.g., VIOLIN-MUSIC), some of which had been preceded by an interfering pair (e.g., VIOLIN-STRING) on a previous list (the interference condition) and some of which had not (the control condition). HD patients and normal subjects recalled fewer interference than control word pairs. PD patients, however, recalled an approximately equal number of pairs from the interference and control conditions. The proactive interference effect appears to occur in subjects with normal basal ganglia function as well as in subjects with an imbalance of basal ganglia pathways favoring those which decrease basal ganglia output (HD). Proactive interference does not appear to occur in subjects with an imbalance of basal ganglia pathways favoring those which increase basal ganglia output (PD). These data suggest that the basal ganglia play an important role in the memory processes which give rise to interference phenomena

CALLOSAL AND CORTICAL CONTRIBUTION TO PROCEDURAL LEARNING. E. de Guise¹, A. Quattrini², I. Papo², M del Pesce², N. Foschi² and M. Lassonde 1*.1-Groupe de Recherche en Neuropsychologie Expérimentale. Univ. de Montréal, Qué., Canada. 2- Centro dell'Epilessia, Ospedale Torrette, Ancona, Italia.

The present study thus examined whether callosotomized (CS) and acallosal subjects (AS) could learn a visuomotor skill that involved a motor control from either both or only one hemisphere. Eleven adult patients, five CS and six AS, were examined in this study. Five of these patients had frontal epileptic foci and three had temporal foci. Furthermore, one of the AS had a bilateral prefrontal atrophy consecutive to surgical removal of an orbito-frontal kyst. The performance of these experimental subjects was compared to that of eleven control subjects, matched for age and I.Q., on a modified version of a serial reaction time task (Nissen and Bullemer, 1987). On each trial, a light appeared at one of four locations. Subjects were instructed to press the one key, out of a set of four keys, that was directly below the light. For the bimanual (interhemispheric) condition, subjects rested the middle and index fingers of both hands on the four keys. In the unimanual (intrahemispheric) condition, subjects rested the index, middle, third and little fingers of one hand on the four keys. In each condition, the subjects received 16 blocks of 100 trials. Each block comprised 10 repetitions of a 10-trial sequence. None of the experimental subjects learned the task in the bimanual, interhemispheric, condition. Patients with frontal epileptic foci or orbito-frontal damage (n=6) also failed to learn the task in the unimanual condition when they were using the hand controlateral to the damaged hemisphere. All other subjects, including the CS and AS with temporal foci, learned the visuomotor skill as well as their controls in the unimanual condition. These findings indicate that the corpus callosum and the frontal cortical areas are important for procedural learning of a visuomotor skill and question the widespread conception of a predominantly subcortical involvement in procedural learning

DISSOCIATING THE ROLES OF THE BASAL GANGLIA AND FRONTAL LOBES IN HABIT LEARNING B.J. Knowlton* L.R. Squire and J. Mangels² Dept of Psychology, UCLA, Los Angeles CA 90095, ¹Depts of Psychiatry and Neurosciences, UCSD and VAMC San

Diego 92161 and ²Dept of Psychology, UC Berkeley, CA, 94720. Patients with Parkinson's disease (PD) and amnesic patients exhibit a double dissociation between performance on a nondeclarative probabilistic classification task and performance on a declarative memory test for the training episode. These results demonstrate the existence of independent systems for declarative memory and gradually formed associations akin to habit learning. The former depends on medial temporal lobe structures while the latter appears to depend on the basal ganglia. However, frontal lobe dysfunction present in PD may have impaired habit learning in these patients. To test this possibility, 10 patients with frontal lobe damage were tested on the probabilistic classification task. They performed as well as control subjects. There was also a significant interaction between the performance of the frontal patients and PD patients across 150 trials, with frontal patients learning more rapidly. Finally, performance was uncorrelated with severity of frontal signs in frontal patients, yet was correlated with PD symptom severity in PD patients. These results suggest that habit learning depends on the basal ganglia and that cognitive deficits in PD and frontal lobe dysfunction are dissociable. INTACT PRIMING FOR NOVEL LETTER STRINGS IN AMNESIA. S.Hamann* and L.R. Squire. VA Med Ctr. and Dept. of Psychiatry and Neurosciences, UCSD, La Jolla, CA 92093. Recent studies have challenged the idea that priming for ostensibly novel stimuli such as pseudowords (REAB) reflects the creation of new representations. Priming for such stimuli could instead reflect the activation of familiar memory representations that are orthographically similar (READ), and/or the activation of familiar subparts of stimuli (component letters). We tested this possibility in 3 experiments that assessed perceptual identification priming and recognition for novel and familiar letter strings in amnesic patients and control subjects. Priming for words (READ), pseudowords (REAB), and orthographically illegal nonwords (KXZL) was fully intact in the amnesic patients following a single exposure, whereas recognition was impaired for the same items. Thus, priming can occur for stimuli that are unlikely to have preexisting representations and that are dissimilar to real words. Words and pseudowords exhibited twice as much priming as illegal nonwords, suggesting that activation may contribute to priming for words and wordlike stimuli. Two additional results suggested that the priming effect for illegal nonwords must result from the formation of new perceptual associations among the component letters of each nonword rather than the activation of individual letter representations. First, robust priming was demonstrated when conditions allowed the formation and use of new perceptual associations but prevented any contribution to priming from activation of component letters (by including the same letters in the primed and baseline lists: study: KXZL; primed: KXZL, baseline: LZXK). Second, no priming occurred when only activation of individual letters could contribute to the priming effect (study: KXZL; primed: LZXK, baseline: DJRQ). In summary, the results demonstrate that priming following a single exposure can depend on the creation of new perceptual representations for novel letter strings. This process does not depend on the brain structures important for declarative memory that are damaged in amnesia. Support: Dept. of Veterans Affairs and NIMH Grant MH24600.

DISSOCIABLE CONCEPTUAL PRIMING PROCESSES: EVIDENCE FROM ALZHEIMER'S DISEASE C. J. Vaidya*, J. D. E. Gabrieli, K. L. Lange, and D. A. Fleischman. Dept. of Psychology, Stanford University, Stanford, CA 94305; Dept. of Neurological Sciences, Rush-Presbyterian St. Luke's Medical Center, Chicago, IL

We report a neuroanatomical dissociation between two forms of conceptual implicit memory. Past studies of patients with Alzheimer's disease (AD) have shown impaired conceptual priming using tests that require generation of responses based upon knowledge of semantic-category relations (category association: e.g., FRUIT-APPLE, name the first FRUIT that comes to mind), and conceptual associations between words (word association: e.g., SALT-PEPPER, SALT-? say the first word that comes to mind). Studies with normal participants have shown functional dissociations between these two forms of conceptual priming, using manipulations such as divided attention (reduces category- but not word-association priming) and semantic processing. Semantic processing enhances priming for strongly related category-exemplar pairs, but not for strongly associated words. Thus, distinct conceptual processes may underlie priming of strongly related stimuli, in category association and word association tests. We hypothesized that AD patients will show intact priming on word association using strong word-associates, and impaired priming on category association using strong category-exemplar pairs. Indeed, AD patients showed normal word-association priming, but impaired category-association priming. Our findings differ from past studies of word-association priming in AD because those studies included stimuli that were moderately associated and did not distinguish between category-exemplar and other kinds of word associates. Thus, conceptual priming is impaired in AD only to the extent that response-generation depends on unitized impaired conceptual priming using tests that require generation of responses based intact in AD to the extent that response-generation depends on unitized representations, such as strongly associated words.

RECOGNITION JUDGMENTS: NO EVIDENCE FOR A CONTRIBUTION FROM IMPLICIT MEMORY. P.J.Reber* and L.R.Squire. Departments of Psychiatry and Neurosciences, UCSD and VA Medical Center, San Diego, 92161

Nondeclarative (implicit) memory for previously seen stimuli does not depend on the brain structures that support declarative memory. However, questions have been raised about whether the two kinds of memory operate fully independently, and specifically, whether implicit memory can support recognition judgments. Dorfman et al. (1996) reported that patients receiving ECT improved their recognition performance when they were encouraged to relax their criteria for endorsing test items as familiar. It was suggested that implicit memory helped patients make recognition judgments, because they could use information about the familiarity of the test items. We adopted this paradigm for a study of amnesic patients. Subjects studied a list of 72 words and, after a 5 min. delay, took two yes/no recognition tests in sequence. The instructions encouraged either a 'Low' or 'High' criterion for test item endorsement. The Low-criterion recognition test encouraged subjects to say 'yes' if the word was "at all familiar," and the High-criterion test instructed subjects to say 'yes' only when they were relatively certain the word had been presented. In accordance with the instructions, the amnesic patients endorsed more items in the Low-criterion test. However, their recognition performance was identical in the two conditions by percent correct or d' measures. Three control groups tested at different study-test delays (5 min., 1-2 d. or 1 w.) exhibited poorer performance at longer delays but, like the amnesic patients, performed the same on both tests. The findings of Dorfman et al. may be specific to patients tested one hour after ECT. Improved performance in the Low-criterion test may reflect a partial lifting by instructions of a meta-memory deficit (or confusion) present after ECT but not present in stable amnesia. Our results provide no evidence that the intact implicit memory of amnesic patients can contribute to recognition memory performance, consistent with previous reports (Haist, Shimamura & Squire, 1992) These results suggest that implicit memory is encapsulated and separate from from declarative memory. BEHAVIORAL AND FUNCTIONAL NEUROIMAGING EVIDENCE FOR PRESERVED CONCEPTUAL IMPLICIT MEMORY IN GLOBAL AMNESIA. J.D.E. Gabriel*. E.V. Sullivan, J.E. Desmond, G.T. Stebbins, C.J. Vaidya, M.M. Keane, A.D. Wagner, M.M. Zarella, G.H. Glover, and A. Plefferbaum. Depts. of Psychology, Psychiatry, and Radiology, Stanford University, Stanford, CA 94305, Dept. of Neurological Sciences, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612, Memory Disorders Research Center, Boston VA, Boston, MA 02130, and Dept. of Psychology, Wellesley College, MA 02181.

Studies with amnesic patients and normal subjects have provided evidence for functional and anatomic dissociations between the memory systems that mediate performance on explicit memory tasks (recall, recognition) and implicit memory tasks (repetition priming). Functional neuroimaging studies have revealed multiple neocordical memory systems that appear to mediate distinct forms of repetition priming. In our prior functional magnetic resonance imaging (IMRI) studies, subjects judged whether words referred to abstract or concrete concepts. Judgments for repeated relative to initial presentations of words yielded shorter response latencies and reduced activity in left inferior prefrontal cortex (LIPC). The present study tested the hypothesis that the reduced LIPC activation when performing abstract/concrete judgments on repeated words. In the behavioral study, 14 patients with global amnesia (7 with alcoholic Korsakoff's syndrome, 7 with other etiologies) and 14 control subjects (7 alcoholic, 7 normal) made abstract/concrete judgments on repeated words. In the behavioral study, 14 patients with global amnesia (7 with alcoholic Korsakoff's syndrome, 7 with other etiologies) and 14 control subjects (7 alcoholic, 7 normal) made abstract/concrete judgments on two lists of words, followed by either an implicit memory test (abstract/concrete judgments for repeated and novel words) or an explicit recognition memory test. The amnesic patients showed a normal gain in speed o

DISSOCIATION BETWEEN TWO FORMS OF CONCEPTUAL IMPLICIT MEMORY IN ALZHEIMER'S DISEASE: ROLE OF ATTENTION. N. Askari*, C.J. Vaidya, B. Jacobson, S.L. Thompson-Schill, K.L. Lange, D.A. <u>Fleischman, I.D.E. Gabrieli</u>. Dept. of Psychology, Stanford, University, Stanford, CA 94305 and Dept. of Neurological Sciences, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612.

Patients with Alzheimer's Disease (AD) typically show preserved priming on some perceptual implicit memory tasks (e.g., perceptual identification and picture naming) but reduced priming on conceptual implicit memory tasks (e.g., category exemplar generation). In a previous report, however, we found a dissociation between forms of conceptual priming in AD: impaired priming on a test that requires the 'generation' of a response (e.g., category generation: "name 8 types of VEGETABLES") but intact priming on a test that requires the 'identification' of an item (e.g., category verification: "Is this a type of vegetable?, LETTUCE). In the present report, this dissociation was replicated with a larger sample of AD patients (AD, N=36; NC, N=36). We hypothesized that AD patients may be impaired on conceptual priming tests that are more demanding of attentional capacity (e.g., category generation), but intact on tests that are less demanding of attentional capacity (e.g., category verification). To test this hypothesis, college students performed these two tasks under divided or focused attention conditions. Dividing attention reduced priming or category generation but not on category verification, thereby paralleling the dissociation found in AD patients. Thus, it appears that the conceptual priming deficits seen in AD patients may be attributable, at least in part, to reduced attentional capacity in AD. Supported by NIA.

NEUROPHYSIOLOGICAL (ERP) CORRELATES OF ENCODING AND RETRIEVAL FROM VERBAL EPISODIC MEMORY. J. A. Mangels*, T. W. Picton, and F. J. M. Craik, Rotman Research Institute, Baycrest Centre for Geriatric Care, North York, Ontario, Canada M6A 2E1.

The frontal lobes play an important role in strategic, attentionally controlled processes related to the encoding and retrieval of episodic memories. Recent neuroimaging studies (PET) indicate this role is functionally lateralized. Episodic encoding differentially activates left prefrontal cortex, whereas episodic retrieval differentially activates the prefrontal cortex.

differentially activates right prefrontal cortex.

To assess the time course of neural activity during encoding and retrieval, we recorded event-related potentials (ERPs) from 46 electrodes as subjects studied and recognized words. During encoding, subjects studied words under full attention or while performing a secondary task (divided attention). The secondary task required subjects to make motor responses to tones presented in either a predictable pattern ("easy") or a random sequence ("difficult"). During retrieval, subjects classified items depending on whether recognition was accompanied by conscious recollection of the study-episode ("remember") or whether recognition was based only on the familiarity of the stimulus ("know"). In all encoding and retrieval conditions, the N180 observed over occipito-temporal sites was larger over the left hemisphere and may reflect processes associated with the automatic identification of verbal stimuli. From 400 to 2400 msec, a sustained positive wave emerged maximally over prefrontal sites. This frontal positivity was lateralized to the left hemisphere are encoding and right hemisphere arterieval and was modulated by attention at encoding and right hemisphere arterieval and was modulated by attention at encoding and play successful recognition at retrieval. Specifically, frontal positivity was evident in the full attention and "easy" divided-attention encoding conditions, but was not apparent in the "difficult" divided-attention condition. Frontal positivity also was associated with correctly recognized words, but not with new words. "Remember" responses were further differentiated by a centro-parietal positive wave (P650) that was larger than that observed for "know" or "new" responses.

575.11

LEFT MEDIAL TEMPORAL ACTIVATION DURING VERBAL EPISODIC MEMORY CONSOLIDATION: A FUNCTIONAL MRI STUDY. J. R. Binder*, P. S. Bellgowan, J. A. Frost, T. A. Hammeke, J. A. Springer, S. M. Rao, and R. W. Cox. Dept. of Neurology, Medical College of Wisconsin, Milwaukee, WI 53226. Functional imaging studies of declarative memory have only rarely demonstrated

Functional imaging studies of declarative memory have only rarely demonstrated activation of the medial temporal lobe. We hypothesize that this is because these memory systems are "on" under most circumstances, making it difficult to elicit activity contrasts. This idea was tested by contrasting activation during an episodic verbal encoding task with either a "rest" state or a perceptual "distractor" task that lacked distinct, verbally encodable episodes. Whole-brain, echoplanar functional magnetic resonance imaging was performed at 1.5T in 30 normal subjects. In the semantic decision task, subjects heard spoken nouns and pressed a button if a word met specified semantic criteria [Binder et al., Arch. Neurol. 1995]. This was compared to either a "rest" state or to a tone decision task in which subjects heard tone sequences and responded to specified target sequences. Individual maps of the difference between conditions in each voxel, represented as a t statistic, were resampled in stereotaxic space and spatially averaged across subjects. Averaged t values with a voxel-wise probability of p<00001 were considered significant. Activation occurred in the left inferomedial temporal lobe during the semantic decision task in comparison to the tone decision task. This region included the middle portion of the fusiform gyrus, adjacent collateral sulcus, anterior and middle portions

Activation occurred in the left inferomedial temporal lobe during the semantic decision task in comparison to the tone decision task. This region included the middle portion of the fusiform gyrus, adjacent collateral sulcus, anterior and middle portions of the parahippocampus, and anterior hippocampus up to but not including the amygdala. No significant activation occurred in the right inferomedial temporal lobe. There was also activation in the left retrosplenial cortex. No significant activation

amygdala. No significant activation occurred in the right inferomedial temporal lobe. There was also activation in the left retrosplenial cortex. No significant activation was observed in these areas when the semantic decision task was compared to "rest." These results suggest that the left medial temporal memory system is relatively active during semantic-level processing of verbally encodable episodes, and that this state description also applies to the condition called "rest." This left medial temporal area is less active during perceptual-level processing of non-verbally encoded material. (Supported by NIH NS33576.)

DISSOCIATION OF MEDIAL TEMPORAL LOBE STRUCTURES INVOLVED IN ENCODING AND RETRIEVAL: AN FMRI STUDY, J. B. Brewer*, J. E. Desmond, G. H. Glover, and J. D. E. Gabrieli, Neuroscience Program, Depts. of Psychology and Radiology, Stanford University, Stanford, CA 94305.

The medial temporal region is essential for the formation of declarative memories in humans and other primates. Animal studies have provided evidence that different components of the medial temporal region make distinct contributions to declarative memory performance. The present study used functional magnetic resonance imaging (fMRI) to examine whether different components of the medial temporal region make distinct contributions to human memory. Subjects performed retrieval and encoding memory tasks. In the retrieval task, subjects discriminated between visually presented words that corresponded to studied ("OLD") and unstudied ("NEW") line drawings. Functional data were acquired at 1.5 T using a gradient echo spiral sequence sensitive to T2* (TR/slice=90; total TR=720; TE=40; flip angle=65"). Eight alternating blocks of 20 words were used. Half consisted of 18 OLD and 2 NEW items where subjects responded to OLD items, and half consisted of 18 NEW and 2 OLD items where subjects responded to NEW items. Functional data analysis using the cross-correlation method described by Friston et al. [Human Brain Mapping, 1994] revealed in 5 subjects increased activation in the subiculum region of the hippocampus when subjects were responding to OLD relative to NEW items. In the encoding task, subjects saw 50 color photographs, 25 indoor and 25 outdoor, arranged in12 alternating blocks. Blocks of 8 novel pictures were alternated with blocks of 2 pseudorandomly repeating familiar pictures. Subjects were instructed to respond to indoor photographs. In 5 subjects, there was greater activation in the parahippocampal grous during viewing of novel versus repeated pictures. These results demonstrate the potential of fMRI to resolve activity in the closely spaced structures of the hippocampal grous during viewing of novel versus repeated pictures.

MEDIAL TEMPORAL PATHOLOGY AND GLOBAL ANTEROGRADE AMNESIA DURING CHILDHOOD. F. Vargha-Khadem¹, A. Connelly², K.E. Watkins¹ W. Van Paesschen². M.Mishkin³ and D.G. Gadian². ¹Neurosciences and ²Radiology and Physics Units, Institute of Child Health, London WC1N 1EH, UK and ³NIMH, NIH, Bethesda MD 20892 USA. (SPON: European Brain and Behaviour Society)

Combined magnetic resonance (MR) and neuropsychological findings are presented for three adolescents with profound amnesia due to medial temporal damage sustained in one case at age 9, in a second at age 4, and in the third at birth. With the advent of quantitative MR techniques, such cases provide an unusual opportunity to determine not only which specific medial temporal-lobe structures are critical for memory functions but also when they become critical. MR imaging and spectroscopy were carried out on a 1.5T clinical imaging system. The protocol included acquisition of 3-D data sets for volumetric analysis of the hippocampi, T2 maps through the hippocampi, and ¹H spectra of 2x2x2 cm cubes centred on the medial regions of the temporal lobes. Neuropsychological evaluations showed normal immediate memory but impaired long-term memory for both verbal and nonverbal material in all three cases. The amnesic syndrome was as pronounced in the perinatal case as in the others. All three cases had bilaterally elevated hippocampal T2 values and bilaterally small hippocampal volumes. In contrast, magnetic resonance spectra were normal or displayed only mild unilateral abnormalities, suggesting that bilaterally symmetrical pathology was largely confined to the hippocampal formation. The results not only confirm the importance of this structure for long-term memory but also suggest that, even when reorganizational capacity of the brain is at its peak, no other structure can compensate for damage to this one

A PET STUDY OF SIMPLE FINGER MOVEMENTS INSTRUCTED BY AUDITORY, SOMATOSENSORY, VISUAL AND INTERNAL CUES. RA Weeks*, M-J Catalan, M Honda and M Hallett. Human Motor Control Section, NINDS, NIH, Bethesda, Maryland, USA.

Externally guided movements have been shown to activate premotor areas. We sought to determine whether the pattern of cerebral activation is dependent upon the modality of sensory instruction during choice reaction finger movements with visual, auditory and somatosensory instructions and comparisons with internally generated movements.

We measured rCBF in 16 healthy volunteers after bolus intravenous injection of $\mathrm{H}_2^{15}0$. 4 movement and 4 control scans were performed in each subject. Data was analysed using subtraction techniques and statistical parametric mapping. Both within condition and between condition comparisons were made at Omnibus significance levels of p<0.001.

Within condition analysis revealed that all movements activated the contralateral sensorimotor cortex, premotor, supplementary motor and ipsilateral cerebellar areas. Between condition analysis showed there were no statistical differences in the cortical motor areas activated by the three externally instructed conditions. Internally generated movements were associated with increased activation in the contralateral anterior SMA and bilateral parietal areas when compared to the external tasks. The somatosensory task showed increased activation in the ipsilateral thalamus when compared to all other movements and may be related to attentional mechanisms.

Internally generated movements showed increased contralateral anterior SMA activity, while externally instructed finger movements regardless of modality of instruction are associated with similar patterns of cortical motor activation.

GAZE DIRECTION MODIFIES HUMAN MOTOR CORTICAL HAND REPRESENTATIONS. J. N. Sanes*, J. P. Donoghue, B. Siewert, R. R. Edelman, S. Warach, Dept. Neuroscience, Brown University, Providence, RI 02912, Depts. Neurology and Radiology, Beth Israel Hospital, Harvard Medical School, Boston, MA 02115.

Direction of gaze influences neuronal discharge in primate parietal and frontal cortical areas involved in controlling arm movements suggesting that neuronal registration of gaze with limb motor output occurs broadly across cerebral cortex. The current work investigated whether gaze angle affected activation patterns in human cortex during performance of sequential finger movements. With the BOLD EPI method (Siemens 1.5 T MR system), we obtained functional MR images (TR = 2 s) while subjects alternated between 30 s periods of repetitive finger movements using the right dominant hand and no finger movements. Subjects lay supine in the MR system with their right arm positioned next to the right side. Gaze was actively maintained leftward, centrally or rightward. Regions activated by finger movements were determined using cross-correlation statistics. Gaze angle modified activation patterns in contralateral primary motor cortex, lateral and medial premotor cortex, and parietal areas. In each cortical region, the least activation occurred when subjects directed gaze leftward, with significant increases in the number of activated voxels when subjects looked centrally or rightward. Activation greater than that obtained during leftward gaze was nearly equivalent during central and rightward gaze. These data demonstrate that gaze can immediately shift brain activation patterns occurring in multiple motor cortical areas during performance of hand movement and suggest that primary and non-primary motor cortical areas are influenced by gaze signals. The results provide further support for dynamic interactions between gaze signals and neural mechanisms encoding somatic motor mappings. Support: NIH AG10634, NS01634, NS25074: McDonnell-Pew Program in Cognitive Neuroscience; and Harcourt General Charitable Trust.

FUNCTIONAL NEUROANATOMY ASSOCIATED WITH PERFORMANCE OF HETEROGENEOUS FINGER MOVEMENT SEQUENCES. S. M. Rao*, K. Y. Haaland, D. L. Harrington, A. C. Rosen, J. A. Bobholz, S. J. Woodley, T. A. Hammeke, S. A. Fuller, J. M. Cunningham, J. R. Binder and R. W. Cox. Department of Neurology, Medical College of Wisconsin, Milwaukee, WI 53226.

Cognitive-motor theory contends that voluntary, sequential movements are governed by motor programs thought to be hierarchical in nature. The duration of Cognitive-motor theory contends that voluntary, sequential movements are governed by motor programs thought to be hierarchical in nature. The duration of motor programming prior to movement is affected by many characteristics of the action, including sequence complexity. In this whole-brain echoplanar 1.5T FMRI experiment, we systematically manipulated sequence complexity to better understand the functional neuroanatomy underlying planning and controlling of sequential events. Ten right-handed volunteers performed right finger keypresses in response to 5-digit sequences (1=index, 2=middle, 3=ring) presented visually. One condition involved repetitive sequences (1111, 2222, or 3333) and the remaining seven conditions used heterogeneous sequences varying systematically in the number of transitions (2-4) and postures (2-3). Functional images were generated using a cross-correlation technique, burred (4 mm FWHM), coregistered with high resolution anatomic images, and converted to stereotaxic space. Paired t-tests (t [9]=3.7, p < 0.005) were used to subtract the functional images derived from the repetitive sequence conditions from those generated from each of the 7 heterogeneous sequence conditions on a pixel-by-pixel basis. Mean reaction time to the first keypress and the total activated brain area (heterogeneous minus repetitive conditions) increased significantly as a function of sequence complexity. This increased activity was observed primarily in the posterior parietal, extrastriate, and lateral premotor areas bilaterally, and in the left lateral cerebellum (contralateral to the side of movement). We conclude that these train regions are critical in the translation of an external visuospatial stimulus into heterogeneous movement sequences. Our findings are in contrast to previous functional interest activities between the sequences and the sequences are in contrast to previous functional interest activities between the contrast of the contrast of the previous described interested activities.

brain regions are critical in the translation of an external visuospatial stimulus into heterogeneous movement sequences. Our findings are in contrast to previous functional imaging studies demonstrating increased activation within the supplementary motor area (SMA) during the performance of memorized finger sequences. These results suggest that the SMA is activated only during the performance of internally generated sequences held in working memory. (Supported by NIH P01-MH51358.)

MULTI-MODALITY CEREBRAL ACTIVATION IN MOTOR FUNCTION BY PET AND MEG. J.R.Pedersen¹, P.Johannsen², K.Særmark¹, and A.Gjedde*² Biomagnetic Group, Physics Dept, The Technical University of Denmark, Lyngby, 1, PET Centre, Aarhus University Hospitals, Aarhus, Denmark.2

We report the use of positron emission tomography (PET) to fix the location of magnetoencephalography (MEG) locations of cerebral activity. MEG is the direct measurement of magnetic fields created by electrical activity of populations of neurons. It has excellent temporal resolution but uncertain spatial resolution. To map cerebral activation in voluntary movement of the right index finger, we applied PET to evaluate the location and MEG to evaluate the temporal sequence. MEG signals were recorded in 35 channel positions, using a 7-channel, second order gradiometer SQUIDsystem. Data was collected from 1s before to 2s after the movement. The "inverse problem" was solved using the MUSIC-algorithm. The PET data were co-registered to the individual MRI and the Talairach co-ordinate system. Voluntary movements followed rest in three scans each. A t-statistic [2] was applied to the subtracted PET images (FWHM = 18mm). For t>4.30. the change in cerebral blood flow was significant at p<0.05. PET showed significant activation in SMA, pre-motor and motor cortex. The MEG sources were placed within 1 cm of the PET positions. A non-significant PET peak in the left middle frontal gyrus, (x=-31,y=46,z=21; t=3.16) coincided with MEG and was active 800-200 ms before the movement. The study points to a center in the left middle frontal gyrus, involved in the early planning of voluntary finger movements (MRC of Denmark).

FRONTAL LOBE INVOLVEMENT IN THE SPONTANEOUS EMERGENCE OF ANTICIPATORY VISUOMOTOR BEHAVIOR, S.L. Bressler*, G.V. Wallenstein, I.A.S. Kelso. Program in Complex Systems & Brain Sciences, Florida Atlantic University, Boca Raton, FL 33431.

The dynamics of a visuomotor coordination task show that simple reactive behavior spontaneously shifts to synchronized behavior as the rate of stimulus presentation is increased, even though the inter-stimulus interval remains sufficient to allow reactive behavior (Engstrom, Kelso & Holroyd, in press). Behavior is attracted to a synchronized state as the perception of a rhythmic pattern in the stimulus train allows anticipation of each succeeding stimulus.

Ten subjects performed sixty runs of the task, flexing the right index finger in coordination with an LED stimulus. In each run, ten stimuli (called a plateau) were presented at rates stepped from 0.167 to 2.0 Hz. Behavior was strictly reactive at the lowest rates (mean RT=298±194 ms; minimum=78 ms), but at 1.25 Hz and above became quasi-synchronized, showing a mixture of anticipatory and reactive flexions.

To monitor the topography of brain electrical activity as synchronized behavior emerged, EEGs were recorded at 61 scalp sites. Fourier analysis revealed maximal spectral power at the frequency corresponding to the rate of stimulus presentation and movement in each plateau. Maps of the topographic distribution of spectral power at this frequency were plotted for each plateau. Separate maps were made for reactive and anticipatory types of behavior for plateaus with both types.

During reactive behavior, the maxima of significant power spectral density occurred at left central and antero-central sites (contralateral to motor output). During anticipatory behavior, additional maxima occurred at frontal sites, the power being significantly greater than during reactive behavior in the same plateaus. Selective frontal involvement in anticipatory behavior supports a role for frontal cortex in the generation of movement based on expected events, particularly when they induce an internalized temporal pattern. Supported by NIMH Grants MH42900 & MH19116.

THE ROLE OF THE RIGHT PREMOTOR CORTEX AND SMA IN THE COORDINATION OF BIMANUAL MOVEMENTS. N. Sadato*, Y. Yonekura, A. Waki, H. Yamada and Y. Ishii. Biomedical Imaging Research Center, Fukui Medical School, Fukui, Japan

Previous electrophysiological study showed that SMA is required for the synchrony of bimanual movements and for the bimanual coordina-tion of parallel movements (Pascual-Leone, et al. Neurology 44:A329, 1994). To obtain better understanding of cortical representation of the bimanual coordination, we measured regional cerebral blood flow with O-15 water and PET. We studied 12 right handed normal volunteers. A complete session consisted of 3 rest scans, 6 scans with acoustically paced (1 Hz), bimanual sequential movements, mirror or parallel version of the equence. To determine if the cortical representation of bimanual co-ordination is sequence dependent, other 9 volunteers were recruited. Each subject performed acoustically paced abduction-adduction move-ment of the index finger; right only, left only, mirror and parallel version were performed twice. The right dorsal premotor area extending to the right anterior SMA showed significantly larger activation during parallel sequential movement compared to the mirror sequential movement (p < 0.05 with correction for multiple comparisons). With lesser degree, the same areas were activated by parallel abduction-adduction movement significantly greater than by the mirror version. The right dorsal premotor area and SMA are related to the bimanual coordination of parallel movements.

EQUIVALENT ELECTRICAL DIPOLE MODELING OF HUMAN MOVEMENT-RELATED CORTICAL POTENTIALS FOR FINGER, FOOT AND MOUTH MOVEMENTS. Ina M. Tarkka*1, Garrett W. Milliken2 and Dobrivoje S. Stokić2 Department of Neurosurgery, University of Texas-Houston Medical School, and ²Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030.

Self-paced voluntary movements are reflected in scalp-recorded movement-related cortical potentials (MRCP). In an attempt to delineate which of the MRCP components reflect cortical somatotopic organization, noninvasive equivalent electrical dipole modeling of MRCP data derived from movements of the right index finger, right foot, and mouth was performed. Generator locations for MRCPs were identified in each of the 8 healthy volunteers. EEG was recorded with 30 Ag-AgCl electrodes placed on the scalp (bandwidth DC-50 Hz). MRCPs were created by averaging according to the onset of the rectified surface EMG of the active muscle (400 ms pre- and 300 ms post-onset). Individual wave forms consisted of 60-80 sweeps. Models for both grand average and individual data were developed for each movement type using Brain Electrical Source Analysis software with a 4-shell spherical head model and individual head radii. The spatio-temporal models covered the activation profile of different brain regions throughout the 700 ms window. MRCP of the index finger movement was sufficiently explained by 8-dipole model, unilateral foot movement by 5-dipole model and pucker of the mouth by 7-dipole model. Residual variances of all the models were below 6%. Superimposition of dipole coordinates on a stereotaxic atlas identified active regions in the cerebellar cortex, thalamus and supplementary motor area. These general regions were common for the three movement types but the primary sensory and primary motor cortical areas, active for about 300 ms, showed distinct somatotopic organization. This work was supported in part by the Vivian L. Smith Foundation for Restorative Neurology, Houston, and in part by NCMRR (NIH) grant #T32 HD 07465 (GWM).

COHERENT BILATERAL ACTIVITY OF THE HUMAN PREMOTOR AND SENSORIMOTOR CORTEX DURING INTERNALLY- AND EXTERNALLY-CUED FINGER MOVEMENTS C. Gerloff*, J. Hadley, J.M. DeLeo, J. Classen, C. Toro and M. Hallett Human Motor Control Section, Medical Neurology Branch. NINDS, National Institutes of Health, Bethesda, MD 20892, U.S.A

EEG coherence analysis can be used to assess functional cooperativity of different cortical areas. We investigated EEG coherence patterns during metronome- and self-paced finger movements in 8 normal subjects.

EEG was recorded during 4 task conditions from 28 scalp electrodes. The 4 conditions were continuous metronome-paced finger extensions at 2 Hz (right hand), self-paced movements at the same rate (right hand), listening to the metronome without moving, and neither metronome sound nor movement. For coherence analysis, the EEG was segmented into epochs of 2048 ms, and the normalized crosspower-spectra were computed for each condition, all electrode pairs, and different frequency bands (alpha:8-12.9, beta1:13-20.9, beta2:21-30.9, gamma:31-50 Hz). Taskrelated coherence was obtained by subtraction of task and respective rest conditions. Multiple t-tests and Bonferroni correction were used for significance testing

For all frequency bands, task-related increases of coherent EEG activity were maximal in electrode pairs overlying the left and right lateral and the mesial centroparietal cortex. For these regions, coherence was generally higher during internally- than during externally-cued movements. Maximum differences were found in the beta bands in electrode pairs C3-C4, C3-CP4, C3-CPz, C3-Pz, Fz-TP7, FCz-TP7, FCz-CPz, FCz-Pz, FCz-C4, FCz-CP4, Fz-P4, Fz-C4, C4-FC4 (p<0.05).

These results indicate (1) a highly bilateral, synchronized cortical processing for unilateral finger movements, and (2) a higher demand for functional cooperativity between lateral and mesial premotor and sensorimotor areas with internal pacing

POSTERIOR CORTICAL AREAS MEDIATE BIMANUAL COORDINATION OF VISUALLY INSTRUCTED MOVEMENTS: PRE- AND POST-OPERATIVE STUDY OF A SPLIT-BRAIN SUBJECT. J.C. Eliassen*†, K. Baynes† and M.S. Gazzaniga§ Center for Neuroscience, University of California, Davis SDepartment of Psychology, Dartmouth College, Hanover NH

Callosotomy patients provide a unique population for the study of two-handed coordination. The corpus callosum allows for the smooth coordination of two handed movements. In its absence subjects coordination of two handed movements. In its absence subjects coordinate the two arms poorly via subcortical pathways or by using visual guidance. We followed a patient through two stage callosotomy testing her on two handed line-drawing tasks. Before surgery she exhibited spatial coupling, the tendency of one arm to adopt the other's movement characteristics when executing dissimilar trajectories. Spatial coupling persisted following anterior callosotomy

but significantly diminished after posterior section.

Additionally, before surgery RT's and movement times (MT's) for bimanual movements were greater when the subject made two different movements than when making identical movements. The RT and MT differences persisted after anterior callosotomy but vanished following posterior callosotomy.

This suggests that the posterior callosum mediates the integration of

spatial information for bimanual movements during both the planning and execution stages of visually instructed bimanual arm movements. Supported by NIH/NIDCD grant R29 DC00811 to K.B. and NIH/NINDS grant PO1 NS 17778-14 and the McDonnell-Pew

DIRECTIONAL MODULATION OF MOTOR CORTEX PLASTICITY INDUCED BY SYNCHRONICITY OF MOTOR OUTPUTS IN HUMANS. Leonardo G. Cohen*. Christian Gerloff, Lala Faiz, Norimichi Uenishi, Joseph Classen, Joachim Liepert and Mark Hallett, Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

Synchronous movements (SM) of hand and shoulder can trigger motor plasticity (Soc. Neurosci. Abstr. 21:517). The purpose of this study was to determine if plasticity of a motor representation is directionally modulated by the interaction with other body parts involved in a synchronous task. We studied plastic changes associated with (a) SM of hand and shoulder, (b) SM of hand and mouth, (c) unskilled and (d) skilled asynchronous movements of hand and shoulder, and (e) of hand

alone. Five groups of 8-11 subjects each participated in this study. Abductor pollicis brevis (APB) was mapped twice a day using transcranial magnetic stimulation before and after training in one of the 5 tasks. In each mapping session, we determined motor thresholds, maps, and centers of gravity (COG).

Training resulted in improved performance in tasks a, b, and d. Motor thresholds did not change in any condition. Motor maps were larger in tasks involving skill acquisition (a, b, d), but not in those involving unskilled movements (c, e). APB COG moved laterally with hand-mouth training (b) and medially with hand-shoulder training (a) but remained unchanged in other conditions. We conclude that training can induce directionally selective plasticity in the adult human motor cortex and that synchronous engagement of different body parts is a powerful trigger for this type of plasticity.

MOTOR CORTEX MAY DRIVE THE MOTONEURON POOL DURING SUSTAINED CONTRACTION S. Salenius*, K. Portin, R. Salmelin, M. Kajola, R. Hari. Brain Research Unit, Low Temperature Laboratory, Helsinki University of Technology, FIN-02160 Error, Fillordy, 02150 Espoo, Finland.

We recorded cortical rhythms with a Neuromag-122TM whole-scalp neuromagnetometer, during weak sustained contractions of the right and left first interosseus muscles from 8 healthy right-

We found coherence between cortical and motor unit rhythmicity in all subjects at frequencies ranging from 14 to 33 Hz. Sources coherent with EMG were identified in contralateral motor cortices. Averaging with respect to EMG bursts also revealed clear responses responses in the motor cortex. The strongest MEG responses preceded the peak of the EMG burst by 10 and 30 ms. Cooling the skin over the interosseus muscle to about 15 °C prior to contraction increased the time-lag between MEG and EMG by 7–10 ms.

These results implicate that motor unit activity is modulated by cortical activity at frequencies of 14–33 Hz and that the motor cortex may drive the spinal motoneuron pool during sustained

USE-DEPENDENT MODULATION OF MOVEMENT REPRESENTATION IN THE HUMAN MOTOR CORTEX. J Classen*, J Liepert, M Hallett, and LG Cohen. Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, U.S.A.)

In animals, movement representations in the primary motor cortex can be reshaped by various manipulations. In the present study we investigated whether movement representations in the human motor cortex can be modulated by repetition of simple motor actions. In nine right-handed healthy volunteers (Ss) focal transcranial magnetic stimulation (TMS) over the motor cortex induced isolated, consistent, and reproducible healthy volunteers (Ss) focal transcranial magnetic stimulation (TMS) over the motor cortex induced isolated, consistent, and reproducible movements of the thumb at a stimulation intensity of 5 % above relaxed motor threshold. The coil and head position were held stable by an aluminium frame. Thumb movements were recorded with miniature accelerometers fixed to the proximal phalanx, and quantified using the first-peak acceleration (FPA) in the axes of the principal movement plane. A baseline movement vector was calculated by averaging FPAs obtained over 10 min of TMS at 0.1 Hz. Training consisted of brisk repetitive thumb movements (1 Hz for 30 min) in a direction opposite to that induced by TMS. Posttraining, TMS (0.1 Hz for 40 min) induced movements with a direction opposite to training a direction opposite to training direction opposite to pretraining movements and similar to training movements. FPA vectors were calculated and their angular deviations from the baseline FPA-vector determined. FPA vectors changed in the direction of training (P<0.001) and returned to near baseline value after

This study provides direct physiological evidence of plasticity of move-ment representation in the human motor cortex.

REORGANIZATION OF DOMINANT HAND MOTOR FUNCTION ASSOCIATED WITH ARTERIOVENOUS MALFORMATION A FUNCTIONAL MRI STUDY J. R. Meyer *, D.R. Gitelman, J Schweitzer, C. Callahan, T. Parrish, H. Baiger, E.J. Russell, M.M. Mesulam, Northwestern University Medical School, and Northwestern Memorial Hospital, Chicago Illinois

Brain lesions early in development lead to functional reorganization as an expression of plasticity, but the evidence for this in the human brain has so far been mostly indirect. We present an fMRI study consistent with reorganization of motor function in a 20 y. o. right-handed male with a left hemispheric precentral AVM that appears to involve the motor area for the hand.

appears to involve the motor area for the hand.

fMR1 of motor function was performed using a 1.5T Siemens Vision MR scanner
with 25mT/m gradients. Multi-slice, single shot, blipped-EPI was performed centered
on the motor cortex,parallel to the ac-pc line while the subject performed a finger
tapping task with each hand. Analysis of fMR1 data was performed using SPM-95
software for correction of motion and statistical analysis, and AVS software was used
for image overlay, image segmentation, scalp editing and volume rendering. Time
series analysis with rest vs. active tapping was performed. Functional data was
overlayed on high resolution volume rendered images.

With movement of the left hand localized activation was seen in the contralateral

With movement of the left hand, localized activation was seen in the contralateral sensory-motor cortex. Movement of the right hand demonstrated localized activation in the ipsilateral sensory-motor cortex, as well activation medially in area 6 bilaterally. Right hand movement did not lead to significant activation in the contralateral motor cortex (i.e., the region of the AVM) but some activation was seen in the sensory cortex lateral to the AVM.

In the sensory corex latera to the AVM.

These observations are consistent with a reorganization of dominant (right) hand function within the left and right hemispheres. The potential advantage of fMRI in studying reorganization is that it gives a much more comprehensive picture of the full anatomical re-mapping of the target function. Correlation with intra-operative corticography is still necessary in this patient to exclude the possibility of movement-induced activation of left motor cortex that may have been obscured by feet blood flow within ac AVM. fast blood flow within an AVM.

INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-5 EXPRESSION IS INCREASED WITH SCHWANN CELL DIFFERENTIATION. H-L. Cheng* and E.L. Feldman. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

The IGF family of ligands, receptors and binding proteins are essential for normal nervous system development and instrumental in nervous system regeneration. We have reported that Schwann cells (SCs) express insulin-like growth factor binding protein-5 (IGFBP-5). IGFBP-5 is enhanced during differentiation in multiple cell types and may play a role in the maintenance of a differentiated phenotype. In the presence of cAMP analogues, we have observed morphological differentiation of SCs and expression of myelin proteins. In the current study, we examined the levels of IGFBP-5 produced by SCs upon differentiation with cAMP. SCs were incubated in serum free media in the presence or absence of 1 mM 8-bromo cAMP and/or 10 nM IGF-I. Conditioned media were collected, concentrated, and proteins were separated by SDS-PAGE followed by IGFBP-5 immunoblotting. As in our previous experiments, we observed that secreted IGFBP-5 was degraded in the absence but experiments, we observed that secreted IGFBP-3 was degraded in the absence but protected in the presence of IGF-1. ImM 8-bromo cAMP significantly enhanced the expression of IGFBP-5 in the presence of 10 nM IGF-1. Forskolin and dibutyryl cAMP had similar effects to 8-bromo cAMP and enhanced IGFBP-5 expression in SC conditioned media in the presence of IGF-1.

To determine if the effects of cAMP on IGFBP-5 protein expression was secondary to the IGFBP-5 protein expression was secondary.

to enhanced IGFBP-5 gene expression, Northern analysis was performed using RNA isolated from SCs cultured under the same conditions as the immunoblot experiments. IGF-I had no effect on IGFBP-5 gene expression, however, addition of cAMP increased IGFBP-5 gene expression 5 fold. In summary, we believe terminal SC differentiation is augmented by the ability of SCs to secrete IGFBP-5, which, in turn, may bind SC basement membrane and increase local IGF-I bioavailability.

ANTIOXIDANTS SUPPORT MYELINATION OF DRG AXONS IN FULLY DEFINED MEDIA IN VITRO. A. J. Windebank* and Molecular Neuroscience Program, Mayo Clinic, Rochester, MN 55905 USA.

Dorsal root ganglion neurons myelinate when cultured in medium containing serum and ascorbic acid. Ascorbic acid plays a key role in the development of basement membrane and myelination does not occur without it. B27 is a defined serum substitute that contains antioxidants such as catalase and $\alpha\text{-tolcopherol}$ (vitamin E) but does not contain ascorbic acid. Our studies looked at effects of B27, catalase and vitamin E on myelination. Catalase and vitamin E were tested individually in both N2 serum-free and serum-containing media. DRG neurons were cultured for 4 weeks in collagen-coated ACLAR plastic dishes and myelin was stained with Sudan black. Myelination was observed in cultures containing B27 without the addition of ascorbic acid. Vitamin E induced myelination in medium-containing serum but not in N2 serum-free medium. Catalase did not induce myelination with or without serum. These results indicate that vitamin E plays a major role in the ability of B27 to induce myelination. This is the first demonstration of myelination in fully defined media in vitro and confirms the critical importance of antioxidants in myelination (NIH, NS 14304).

CULTURED MICROGLIA EXHIBIT IMPORTANT ASPECTS OF THE "RESTING" MICROGLIAL PHENOTYPE IN SERUM-FREE, ENDOTOXIN-FREE MEDIA. C.J.M. Kane*, I.R. Niesman. W. Chen. Z.Q. Yang and S.A. Gilmore. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Cultured CNS microglia are useful for modeling the interaction of microglia with neurons. However, the established methods of microglial culture are limited to proliferating, ameboid cells expressing MHC class III, complement receptor 3, and ED1 antigen. This cellular phenotype resembles activated microglia at sites of pathology. Understanding the induction of microglial activation in CNS disease has been thwarted by the absence of a routine method for culture of "restino" microglia. the absence of a routine method for culture of "resting" microglia.

A method was developed to culture microglial cells expressing

A method was developed to culture microglial cells expressing important aspects of the resting microglial phenotype associated with ramified microglia. Primary cultures of mixed glia were prepared from the cerebrum, cerebellum, or spinal cord of one-day old Charles River CD rats. The loosely attached microglia were separated from subconfluent cultures by orbital shaking. The microglial cells were plated on uncoated glass chamber slides in DMEM + 10% FBS. After 24 hrs, the culture medium was replaced with serum-free, endotoxin-free medium. The majority of *Griffonia simplicitolia* lectin-labeled microglial cells extended ramified processes and the rate of microglial mitosis was markedly decreased within 24 hrs. Immunocytochemistry revealed decreased expression of MHC class II, complement receptor 3, and ED1 antigen. Thus, microglia can be cultured routinely under conditions that eliminate activation signals and promote expression of a cellular phenotype similar to that of resting, ramified microglia *in vivo*. This *in vitro* model of "resting" microglia permits cellular and molecular analysis of the mechanisms of microglial activation and analysis of constitutive interactions between resting microglia and neurons. (NIH AG12411).

TAU PROTEIN HAS A KEY ROLE IN EXTENSION FORMATION OF CULTURED OLIGODENDROCYTES. P. LoPresti* and G. Dawson Dept. Pediatrics, University of Chicago, Chicago, II. 60637.

The Microtubule-Associated Protein (MAP) tau was found in cultured oligodendrocytes (OLGs) from adult brain (LoPresti et al, Proc Natl

Acad Sci USA 92,10369-10373; 1995). In these cells, tau and its mRNA were present in OLG soma, processes and tips. In addition, Western blot analysis detected as many as 8 tau isoforms. In this study we address the question of the role of tau in neonatal oligodendrocytes. By Western blot analysis, we have examined the electrophoretic pattern of tau both in CG4 cells and in neonatal rat OLGs. In both CG4 cell line and primary OLG cultures, we detected a similar electrophoretic pattern of tau. We found that 3 tau isoforms were present in both undifferentiated CG4 cells and freshly isolated OLGs, however tau protein levels increase both in differentiated CG4cells and in one-week old cultured neonatal OLGs. By using tau antisense oligonucleotides (50uM) in neonatal OLGs, we founded almost complete inhibition of extension formation. As a control, sense-treated or untreated OLGs show the same extent in the length of processes. Western blot analysis of tau antisense treated OLG cultures showed absence of any detectable levels of tau protein.

The above findings suggest that a) tau protein is upregulated during active process formation during myelination and that b) suppression of tau protein will prevent extension in OLGs. (This work was supported by Children's Research Foundation Grant to P.L. and HD-06426 to

THE EXPRESSION, REGULATION, AND FUNCTIONS OF HIPPOCAMPAL SPECIFIC METALLOTHIONEIN ISOFORM. M. Baxi, M. Hiramatsu, I Ahmad, H. El Refaey, G. Helal, F.M. Hamada, R. Hao, R.F. Pfeiffer, P Rojas, D.R. Cerutis, and M. Ebadi. Depts. of Pharmacology, Cell Biology and Anatomy, and Neurology Univ. of Neb. Coll. of Med., Omaha, NE 68198-6260, Inst. for Life Support Techn., Yamagata, Japan; and Dept. of Neurology, Univ. of Tennessee, Memphis, TN 38163

Metallothionein (MT), first described in the brain in our laboratory (M. Itoh M. Ebadi, and S. Swanson, J. Neurochem. 41:823-829, 1983), is now known to consist of four similar but distinct isoforms, designated as MT I - MT IV MTs I and II are present in glial and ependymal cells, and MT III which is found in high concentration in the hippocampus is found mostly, but not solely, in neurons. The zinc containing neurons in the brain are a subclass of the glutamatergic neurons, which are found predominantly in the telencephalon, and are viewed as an endogenous modulator of ligand- and voltage-gated ion channels. In this communication, we report that the hippocampal MT and its MT mRNA are synthesized on a continuous basis and hence may play a role in regulating the transport, accumulation, and compartmentation of zinc in the hippocampus. In addition, since MT is able to regulate the intracellular redox potential, we have taken a group of experiments to learn the role of MT in oxidative stress. By using electron spin resonance spectrometry (ESR) we have shown that 6hydroxydopamine induces hydroxyl radicals and superoxide anions and dramatically enhanced MT mRNA in several brain areas, but especially in the hippocampal subfields. The results of these studies are interpreted to suggest that MT plays a major role in the defense against oxidative reactions, especially in the areas of brain possessing high concentrations of zinc. (Supported in part by a grant from USPHS-NS34566).

MICROGLIAL CELLS IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES REGAIN A RESTING STATUS FOLLOWING INITIAL ACTIVATION. N.P. Hailer*, J.D. Järhult, R. Nitsch, Humboldt University Clinic (Charité), Institute of Anatomy, D-10098 Berlin, Federal Republic of Germany. Numerous studies indicate that neurons in organotypic hippocampal slice cultures (OHSC) preserve morphological and physiological features of the in vivo-situation, however, there is little knowledge about the properties of microglial cells under these in vitro-conditions. We therefore addressed the question whether microglial cells in OHSC are initially activated following explantation but return to a resting state during in vitro-cultivation. Thus, we analyzed a) microglial cell morphology, b) microglial cell distribution, and c) expression of integrin adhesion molecules as putative markers of microglial activation at 0, 3, 6 and 9 days after explantation. Hippocampal slices fixed immediately following explantation showed only resting microglial cells, mainly located in the paraventricular regions. After 3 days in vitro (div) OHSC surfaces were covered by activated microglia, whereas intermediate layers of OHSC showed activated morphology with ovaloid cytoplasm and no or merely few cytoplasmic processes, after 6 div, however, an increasing degree of ramification could be observed. After 9 div microglial intermediate layers had almost regained the morphological appearance of resting cells with filigrane cytoplasmic processes extended in all directions. The intermediate layers had almost regained the morphological appearance of resting cells with filigrane cytoplasmic processes extended in all directions. The intermediate layers had almost regained the morphological appearance of resting cells with filigrane cytoplasmic processes extended in all directions. The integrin adhesion molecules LFA-1 and VLA-4 were expressed on most microglial cells with activated morphology, as verified by co-localization with double immunofluorescence labeling for LFA-1 or VLA-4 w

MICROGLIAL CELLS AND ASTROCYTES INCORPORATE DEGENERATING PERFORANT PATH AXONS IN THE RAT DENTATE MOLECULAR LAYER FOLLOWING ENTORHINAL LESION Bechmann, L and Nitsch, R.\$ Humboldt University Clinic (Charité). Institute of Anatomy, D-10098 Berlin, Germany
Entorhinal lesion results in anterograde degeneration of axons normally terminating in the outer portions of the dentate molecular layer. This is accompanied by an activation of microglial cells and astrocytes which play a key role in various neurodegenerative disorders. In order to further analyze the involvement of glial cells in mechanisms of hippocampal reorganisation following lesion, we studied the process of phagocytosis of degenerating axon terminals by activated microglial cells and astrocytes. Crystals of a rhodamine- and biotin-coupled dextran-amine (Min-Ruby; allowing for light double- and confocal-fluorescence as well as electron microscopical analysis) were stereotaxically placed in the entorhinal cortex of adult rats. This resulted in staining of the entire perforant path including terminal branches in the middle and outer dentate molecular layer and which was stable at least until 20 days following application. One day after, animals received an electrolytic entorhinal cortex lesion. Microglial cells were detected by means of lectin staining (GSI-B4) or an antibody against a microglial cell surface protein (MUC-102) while astrocytes were immunostained for GFAP. all visualized using FITC-fluorescence. Following lesion, typical axons and their boutons were no longer visible but the rhodamine was arranged in characteristic granules. Double fluorescence for both rhodamine and FITC unraveled microglial cells which exhibited typical characteristics of activation, i.e., a round shape and the lack of ramification by one day and astrocytes at least by four days post lesion (dpl) to be associated with these granules. High power double fluorescence and confocal microscopy 2 dpl detected rhodamine granules signifying degenerating entorhinal axons to be contai

HUMAN FETAL ASTROCYTES EXPRESS FIBRONECTIN NON-SPECIFICALLY IN VITRO AND SOLELY AT THE BLOOD-BRAIN BARRIER IN VIVO. D.M. Kerkovich*, K.M. Weidenheim, W.D. Lyman. Path. Dept., Albert Einstein Coll. Med., Bronx, NY 10461.

Until recently, fibronectin was believed to be absent in the central nervous system (CNS) with the exception of basement membranes (BM) surrounding blood vessels and in the pia mater. BM fibronectin is a produced by endothelial cells and, in the pia, by fibroblasts. In vitro, however, enriched cultures of rat and mouse astrocytes can express fibronectin. In this study, we examined whether human fetal astrocytes synthesize and secrete fibronectin. We have addressed this question using Western blot analysis and single- and double-label immunocytochemistry of enriched astrocyte cultures from 16 to 24 week human fetal CNS Fibronectin expression was also examined in vivo by immunohistochemical staining of frozen tissue sections. Furthermore, we utilized a novel co-culture model of the human blood-brain barrier (BBB) to examine fibronectin expression. Results showed that greater than 50% of GFAP+ astrocytes in culture expressed fibronectin whereas, in vivo, fibronectin positivity was only detected in profiles consistent with astrocyte foot processes abutting the abluminal surface of microvessels. This localization of staining was also found in the BBB model (Supported in part by USPHS grants MH 47667 and MH 46815)

SYNAPTIC ACTIVITY-DEPENDENT COMMUNICATION BETWEEN NEURONS AND ASTROCYTES . G. Carmignoto*, L. Pasti and T. Pozzan. Dept. of Biomedical Sciences, University of Padova. 35127 Padova, Italy. Glutamate and neuronal stimulation can trigger [Ca²+], oscillations and waves

in cultured astrocytes and, when repetitively applied, long-term changes in their [Ca²⁺], oscillation frequency. Oscillating astrocytes can, in turn, signal back to neurons by increasing their [Ca²⁺],. The occurrence of similar phenomena in the brain would suggest the involvement of astrocytes as active cells in the astrocyteneuron networtk. We, therefore, used acute brain slice preparations and confocal fluorescence microscopy to monitor the spatio-temporal features of [Ca²⁺], changes in hippocampal and visual cortical astrocytes after loading with Indo-1. We found that, similarly to cultured astrocytes, the frequency of oscillations in astrocytes in situ increased upon repetitive activations of mGluRs by t-ACPD (5- $30\mu M)~(0.75\pm0.04$ and 1.38 ± 0.01 peaks/min at the 1st and 3rd stimulation, respectively; mean change $102\pm18~\%$; p> 0.001; n= 52). Electrical stimulation of presynaptic afferents at 0.2 Hz (100-200 msec train at 20-50 Hz; 100 pA) induced [Ca²⁺]_i oscillations in astrocytes sorrounding stimulated neurons. Repetitive [Ca²⁺]_i increases could occur at discrete loci along astrocyte processes. An identical stimulus applied several minutes after the first induced in 10 of 21 cells a significant increase in oscillation frequency indicating that neuronal stimulation can induce long-term changes in the astrocyte response. Glutamate released at the synapse can, therefore, trigger [Ca²⁺], elevations in both postsynaptic neurons and astrocytes. These observations suggest the existence of a synaptic-like form of communication between synaptic terminals and astrocyte processes and prompt the evaluation of a new aspect in the study of brain's plasticity. TISSUE PLASMINOGEN ACTIVATOR MEDIATES MICROGLIAL ACTIVATION VIA A PROTEASE-INDEPENDENT MECHANISM. A. D. Rogove*, S. Strickland and S. E. Tsirka. Department of Pharmacology State University of New York at Stony Brook, Stony Brook, NY 11794

The serine protease tissue plasminogen activator (tPA) has been shown to mediate the activation of microglial cells. The participation of tPA in microglial activation was found to be independent of the conversion of plasminogen to plasmin. To further elucidate the mechanism by which tPA mediates microglial activation, microglial cells in primary mixed cortical cultures prepared from mice deficient in tPA (tPA *) were tested for their ability to activate in response to the addition of lipopolysaccharide (LPS) to the culture media. The activation microglia addition in prophysactianae (LPS) to its culture media. The advancement of its cultures from tPA* mice was incomplete (only 19% of the microglia were partially activated, compared to complete activation seen in 84% of microglia in cultures from wild-type mice). Furthermore, the addition of either rtPA or rtPA irreversibly inactivated with the protease inhibitor PMSF (rtPA/PMSF) to tPA+cultures prior to LPS addition restored the ability of microglia in these mixed cortical cultures to respond to LPS to nearly wild-type levels (70% and 71% of the microglia were completely activated in tPA⁺ cultures supplemented with rtPA and rtPAPMSF, respectively). These results demonstrate that tPA affects microglial activation in a protease-independent manner and defines the first physiological

role of tPA which is independent of its proteolytic activity.

ELECTROPHYSIOLOGICAL HETEROGENEITY OF ASTROCYTES. G.M McKhann II, R. D'Ambrosio and D. Janigro. Dept. of Neurosurgery, Univ. of Washington, Seattle, WA 98104
Astrocytes have traditionally been thought of as a relatively homogeneous

population of cells characterized by a negative resting membrane potential (RMP) and low input resistance due to high potassium permeability. However, in situ recordings from hippocampal and corpus callosum slice astrocytes have revealed a wide range of RMP. Additionally, astrocytes from different areas of the central nervous system have been shown to exhibit regional variations in ion channel expression and intercellular gap junction coupling. We hypothesized that astrocytes within a single brain region constitute a heterogeneous population of cells. Utilizing whole cell and gramicicdin-perforated patch clamp recordings from cultured rat neocortical astrocytes, we found that these cells exhibit a bimodal distribution of RMP (range -20 to -84). RMP did not depend on the recording configuration (whole cell vs. perforated), cell proliferation, cell differentiation, or time in culture. Cells could be divided into "hyperpolarized" cells (HC, RMP<-60 mV) and "depolarized" cells (DC, RMP>-60 mV). HCs were characterized by a higher membrane conductance (43.9±0.14 nS) and a nearly linear I-V profile DCs had a lower membrane conductance (25.3±0.14 nS) and displayed inward rectification. Pair recordings from adjacent cells suggested that DCs and HCs are often electrically coupled. The ion current profile as well as the pharmacological properties of a given cell were often dynamic, depending on the degree of intercellular coupling with other astrocytes. The heterogeneity of astrocyte ion current mechanisms may allow for specialized regulation of the extracellular environment in different areas of the central nervous system. Supported by NIH NHLB 51624 and NS 07144.

CALCITONIN GENE RELATED PEPTIDE-IMMUNOREACTIVITY (CGRP-IR) EXPRESSION IN HIPPOCAMPAL CAI NEURONS FOLLOWING ISCHEMIA MAY SUPPRESS INFLAMMATORY IMMUNE RESPONSES TO DYING PYRAMIDAL CELLS. K. Bullochi*, T.A. Milner, L.P. Reagan, N.G. Weiland, G. Buzsaki, M. Hsu, and B.S. McEwen, Lab Neuroendocrinol, Rockefeller U.): Dept Neurol& Neurosci, Cornell U. Med Col, New York, NY 10021 (2)
Center Mol Behav Neurosci., Rutgers U., Newark, NJ 07102.
We have shown that CGRP derived from hilar mossy cells is increased in the

inner molecular layer of the dentate gyrus after adrenalectomy and colchicine destruction of granule neurons (Bulloch et al. NeuroReport V.7 in press). Moreover, GCRP contains cellular immune responses in specific organs such as the thymus (Bulloch et al Ann NY Acad Sci.V.741,p.126,1994). Given the immunoregulatory role of this peptide, we have continued to characterize the distribution of CGRP in another model of insult, ischemia. Following the rat four vessel occlu sion model of ischemia, CGRP-immunoreactivity (ir) was found in a distinct band of cells distributed diffusely within the CA1 pyramidal cell layer and in varicose fibers within the CA2 pyramidal cell layer. Control rats showed no CGRP-ir within these regions. Sections double-labeled for CGRP and nitric oxide synthase, or calbindin, or parvalbumin, showed that CGRP co-localized with calbindin in some neurons. Electron microscopic analysis of the ischemic CA1 region showed that CGRP-ir is primarily found in terminals containing small clear vesicles which form symmetric synapses (inhibitory type) with the perikarya and large dendrites. some identified as originating from pyramidal cells. Together, these data indicate that in addition to impaired pyramidal cells, CGRP-ir was primarily localized to axon terminals of basket cells in response to ischemia. Moreover, in conjunction with our previous studies, these findings also support a discrete regional immuno-regulatory role for CGRP following CNS trauma. LYMPHOCYTIC MENINGOENCEPHALOMYELITIS INDUCED BY TRANSGENIC

LYMPHOCYTIC MENINGOENCEPHALOMYELITIS INDUCED BY TRANSGENIC EXPRESSION OF TNF-α in THE CNS. A. K. Stalder*, A. Pagenstecher, L. L. Campbell. The Scripps Research Institute, Dept. of Neuropharmacology, La Jolla, CA 92037. TNFα is a proinflammatory cytokine that may play a role in many inflammatory CNS disorders e.g. bacterial meningitis, HIV encephalopathy and MS. To study the mechanisms by which TNFα may contribute to the clinicopathological alterations in these disorders, we used a transgenic (tg) approach to target expression of TNF α to astrocytes using a GFAP/TNF α fusion gene. Two GFAP-TNF α lines were established in which TNF α mRNA expression was demonstrated predominantly in the brain stem cerebellum and spinal cord (GT-8 line), or throughout the brain and the spinal cord (GT-8 line). 2 line). A profound phenotype developed in both lines which differed for each. The GT-8 line showed a progressive development of ataxia with muscle spasms and hind-limb dysfunction, while the GT-2 had sudden onset of total paralysis affecting the lower body. In the brain and spinal cord from tg mice, significant pathological changes were present that overlapped with areas of TNFα expression. In the GT-2 line, extensive meningoencephalomyelitis with predominantly lymphocytic infiltrates, was seen in the spinal cord and cerebellum. The GT-8 line showed focal perivascular and meningial infiltrates in the neocortex, cerebellum and pons. In both lines, tissue damage was evident in both gray and white matter regions of the spinal cord and brain and overlapped with the mononuclear infiltrates. Furthermore, areas of hemorrhage were observed within the infiltrates suggestive of vascular injury. Pronounced astrocytosis was found around the infiltrates, Apoptosis is a well described effect of TNFa, we analyzed for apoptosis in the CNS. Apoptotic nuclei were rarely if at all present in the CNS tissue from wild type mice. In contrast, in the CNS tissue of GFAP-TNF α mice, numerous apoptotic nuclei were observed surrounding, and to a lesser extent within the mononuclear infiltrates. These findings indicate that overexpression of TNF α in the CNS promotes the recruitment and infiltration of mononuclear cells, in which the resultant lymphocytic recruitment and infinition of infolionic race tens, in which the resolutin typiphic vice meningoencephalomyelitis, together with increased apoptosis, leads to extensive neural tissue destruction, and likely underlies the observed phenotype of these GFAP-TNF α tg mice. These tg mice should be a valuable tool to further define the mechanics of TNF α actions in the CNS. Supported by USPHS grant MH 50426.

VAGOTOMY DELAYS, BUT DOES NOT BLOCK LPS-INDUCED Sheba M. J. MohanKumar, P. S. MohanKumar and S. K. Quadri*

Neuroendocrine Research Laboratory, Department of Anatomy and Physiology, Kansas State University, Manhattan, KS 66506.

Lipopolysaccharide (LPS) has been reported to induce a number of central effects including sleep, fever, anorexia, analgesia etc. The mechanisms by which LPS produces its central effects are unclear. This study was done to investigate the possibility that LPS-induced fever is mediated through the vagus nerve. Sub-diaphragmatic vagotomy was performed in adult male Sprague-Dawley rats, followed 2 h later by an intraperitoneal injection of saline or LPS in saline (10µg/kg BW). Rectal temperature (°C) was monitored at half-hour intervals for 5 h. Saline treatment produced no significant changes in rectal temperature either in sham-operated or in vagotomized rats. LPS treatment increased (p<0.05) rectal temperature in sham-operated rats from 37.1 ± 0.2 to 37.9 ± 0.2 within 1 h and kept it elevated for 4 h. A similar LPS treatment did not produce a significant increase in rectal temperature in vagotomized rats (from 37.1±0.3 to 38±0.3) until 2 h after treatment, after which the temperature remained elevated for 3 h. The delay in fever induction in vagotomized rats indicates that the immediate stimulus for LPS-induced fever is transmitted to the central nervous system through the vagus, whereas another mediator, possibly interleukin-1, is involved in the delayed increase in temperature such as that observed in vagotomized animals.

INTERLEUKIN-12 GENE EXPRESSION IS INDUCED IN THE CNS AND IN CULTURED ASTROCYTES AND MICROGLIA BY LPS. I.L. Campbell*, C-S Chiang, N.C. Yu, F.E. Bloom and A.K. Stalder. Dept. of Neuropharmacology, The

Scripps Research Institute, La Jolla, CA, 92037
Interleukin-12 (IL-12) plays a central role in the regulation of cell-mediate immunity and is implicated in antiviral and antitumor host responses in the CNS as well as in the pathogenesis of the autoimmune demyelinating disorders EAE and MS. Here we examined whether the IL-12 p35 and p40 genes that encode the subunits of the biologically active IL-12 heterodimer can be induced in the brain following peripheral LPS administration. Mice were injected ip with either a single or two staggered sub-lethal doses of LPS and IL-12 p35 or p40 mRNA levels analyzed in the brain by RNase protection assay (RPA). Expression of IL-12 p 35 mRNA was constitutive, the levels of which did not alter following either LPS treatment protocol. In contrast, IL-12 p40 mRNA was not detectable in brain from control mice or mice given a single injection of LPS. However, significant induction of IL-12 p40 RNA was seen in mice given two LPS injections. Analysis of IL-12 p40 RNA expression by in situ hybridization revealed positive cells with the morphological appearance of microglia and astrocytes, scattered throughout the brain parenchyma. To confirm the possibility that microglia and astrocytes express the IL-12 p40 gene, purified cultures of these cells were prepared, treated with LPS and IL-12 p40 RNA levels assessed. No detectable IL-12 p40 mRNA was found in control cultures. However, following exposure to LPS, significant induction of IL-12 p40 mRNA occurred in both astrocytes and microglia. Taken together the 12 P40 mRNA occurred in own astrocytes and microgial. Tasken together infindings indicate IL-12 gene expression can be activated in the brain, with microglia and astrocytes likely providing a significant local source for production of this cytokine. Localized production of IL-12 may have a significant impact on the development of cell-mediated immunity within the CNS. Supported by USPHS grants MH 50426 and MH 47680.

LEUKEMIA INHIBITORY FACTOR CAN ACT AS AN ANTI-INFLAMMATORY CYTOKINE. L. R. Banner*†, C. J. Woolf‡ Steve Poole‡ and P.H. Patterson†, †Biology Division 216-76, Caltech, Pasadena, CA 91125 and [‡]Dept. of Anatomy, University College London, London WC1E 6BT.

The neuropoietic cytokine leukemia inhibitory factor (LIF) plays a role in the response to injury in both the peripheral and central nervous systems. To test whether LIF regulates neurogenic inflammation, we have studied its role in adjuvant-mediated inflammation. Intraplantar injection of complete Freund's adjuvant (CFA) produces an inflammatory response characterized by local swelling, sensory hypersensitivity and a rapid up-regulation of IL-18 and NGF, followed by substance P and CGRP in sensory neurons. We find that LIF mRNA levels in the footpad increase following either CFA or IL-1 injections. Intraplantar injection of LIF results in a decrease in IL-1 protein, suggesting that LIF may down-regulate the inflammatory response. Further evidence comes from results obtained with LIF knockout mice. Intraplantar CFA injection in these mice yields a significant increase in inflammatory edema over that seen in wild type mice. Moreover, peak IL-1 levels in plantar skin of wild type mice are lower and return to baseline faster than in mutant mice. These results provide evidence for an anti-inflammatory role for LIF during peripheral inflammation.

INTERLEUKIN-1 RECEPTOR ANTAGONIST ATTENUATES INFLUENZA-VIRUS-INDUCED EFFECTS ON INGESTIVE BEHAVIOR. Dept. Pharmacology, Louisiana State Univ. Med. Ctr., Shreveport, LA 71130

As infection with influenza virus develops, animals display fever, As infection with immeriza virus develops, aiminas usipay fever, decreased exploratory and feeding behavior, and loss of body weight. These responses may be mediated by cytokines, specifically by interleukin-1 (IL-1). We assessed the effects of a naturally occurring IL-1-receptor antagonist (IL-1ra) on food and milk intake in mice injected with IL-1, lipopolysaccharide (LPS), or inoculation with influenza virus (PR8 H1N1).

IL-1ra significantly attenuated the reductions of the ingestion of sweetened condensed milk in a 30-minute period following intraperitoneal (ip) injection of IL-1α or IL-1β (100 ng), but only attenuated that caused

(ip) injection of IL-1 α or IL-1 β (100 ng), but only attenuated that caused by LPS (1-5 µg ip). In the influenza virus infection model, mice were inoculated intranasally with a lethal or sublethal doses of the virus or vehicle and were either given repeated injections of IL-1ra, or IL-1ra or vehicle was delivered by subcutaneous osmotic minipumps. The IL-1ra treatment did not reverse the effects of the virus infection on body weight, 23-hour food pellet intake, or milk intake. However, in several experiments, IL-ra significantly attenuated the reductions in body weight, food intake and milk ingestion. In most experiments, there was also a significant decrease in mortality caused by lethal doses of the virus. It is concluded that the IL-1ra treatment may attenuate some aspects of sickness behavior, suggesting that IL-1 may mediate some of the effects of infection with influenza virus on ingestive behavior.

THE INTERLEUKIN-1-RECEPTOR ANTAGONIST FAILS TO ALTER THE NEUROCHEMICAL AND HPA RESPONSES TO LPS Adrian J. Dunn and Rhonda F. Brown* Dept. Pharmacology, LSU Med. Ctr., Shreveport, LA 71130

Endotoxin (LPS) administration stimulates the secretion of interleukin-1 (IL-1). LPS and IL-1 both activate the hypothalamo-pituitary-adrenocortical (HPA) axis and increase cerebral catecholamine and indolamine metabolism. The responses to LPS and IL-1 are remarkably similar with peak responses in plasma ACTH and corticosterone and in the norepinephrine catabolite, MHPG, around 2 h, and elevations of brain tryptophan and 5-hydroxyindoleacetic acid (5-HIAA) somewhat later. The results are not compatible with the simple hypothesis that IL-1 mediates these responses to LPS, because peak IL-1 production after LPS does not occur until around 2 hours, so that the responses to LPS ought to be delayed more than is actually observed.

the delayed more than is actually observed.

The HPA and neurochemical responses to LPS were examined using doses of the IL-1-receptor antagonist (IL-1ra) more than adequate to block responses to administered mouse IL-1B. We failed to observe statistically significant attenuation of the neurochemical or HPA responses to LPS 1-6 h following injection of low doses of LPS (1-5 µg IP), although slight attenuations were observed at 4 and 6 h in one experiment. Icv doses of IL-1ra up to 200 µg failed to attenuate the responses to IP LPS at 1-2h, but occasionally produced a small attenuation at 4h.

In-1ra up to 200 gg fathed to attenuate the responses to IP LPs at 1-2n, but occasionally produced a small attenuation at 4h.

We conclude that although IL-1 probably contributes to the HPA and neurochemical responses to LPS, it is not the only factor, and probably not the major one. Moreover, LPS does not activate the HPA axis or neurochemical changes solely by inducing IL-1 synthesis within the brain.

LIPOPOLYSACCHARIDE, BUT NOT TURPENTINE INDUCES EXACERBATED FEVERS IN TNF DOUBLE RECEPTOR KNOCKOUT MICE. L. R. Leon, W. Kozak, J. Peschon, and M. J. Kluger*. The Lovelace Institutes, Albuquerque, NM 87108 and Immunex Research Corporation, Seattle, WA 98101.

Kluger*. The Lovelace Institutes, Albuquerque, NM 87108 and Immunex Research Corporation, Seattle, WA 98101. Tumor necrosis factor- α (TNF- α) is capable of causing fever, lethargy, body weight loss and anorexia in several species. Under several experimental conditions, TNF- α has endogenous cryogenic or antipyretic properties; that is, it reduces fever.

We used TNF double receptor (TNFR) knockout mice to examine the affect of paripheral injections of lipopolysaccharide (LPS) or

We used TNF double receptor (TNFR) knockout mice to examine the effect of peripheral injections of lipopolysaccharide (LPS) or turpentine on fever, lethargy (motor activity), body weight and food intake. Body temperature and motor activity of mice was measured using biotelemetry. TNFR knockout mice injected ip with a high dose (2.5 mg/kg) of LPS developed exacerbated fevers compared to wildtype mice. This enhancement was seen during the early (3-15h), but not late phase (16-24h) of fever to this dose of LPS (ANOVA, Scheffe, p < 0.05). Motor activity, body weight and food intake were similarly depressed in both groups of mice to the high dose of LPS. A low dose of LPS (50 μg/kg, ip) or turpentine (100 μl/mouse, sc) induced similar fevers, lethargy, loss of body weight and anorexia in TNFR knockout and wildtyne mice.

induced similar fevers, lethargy, loss of body weight and anorexia in TNFR knockout and wildtype mice. These results support the hypotheses that (1) endogenous TNF- α is a key inhibitor of the febrile response to a high dose of ip injected LPS, but not a low dose of ip LPS or sc turpentine, and (2) endogenous TNF- α is not a key mediator of the lethargy, loss of body weight or anorexia induced to ip injected LPS or sc turpentine in mice. Research supported by NIH A127556.

ANTIPYRETIC ROLE OF ENDOGENOUS BRAIN MELANOCORTINS DURING FEVER. <u>I.B. Tatro*1, M.L. Entwistle¹, I.D. Alvaro², R.S. Duman², S. Sharma³, V.L. Hruby³, and O.-H. Huang¹. ¹Endocrine Div., New Eng. Med. Ctr./Tufts Univ. Sch. Med., Boston, MA 02111; ²Lab. Mol. Psych., Yale Univ. Sch. Med., New Haven, CT, 06508; ³Dept. Chemistry, Univ. Arizona, Tucson, AZ 85721.</u>

Bacterial infection causes fever, an adaptive but potentially self-destructive response, in the host. Exogenous melanocortin (α -MSH-related) peptides are antipyretic, and forebrain structures important in thermoregulation are innervated by MSH-containing neurons and contain melanocortin receptors (MCR). To test the hypothesis that endogenous central melanocortins exert antipyretic effects during fever, we tested the effect of intracerebroventricular (icv) injection of a novel synthetic MCR antagonist (MCR-Ant) in endotoxin-challenged rats. In vitro, MCR-Ant inhibited α -MSH-induced adenylate cyclase activation in heterologous cells expressing either rat MC3 or rat MC4 (the major MCR subtypes expressed in brain; IC50 = 1 nM for each), but showed no intrinsic agonism. Rats received E. coli lipopolysaccharide (LPS, 25 ug/kg) or saline ip, followed 30 min later by 4 μ L (168 pmol) MCR-Ant or saline, icv. Body temperatures (T_b) were monitored for 8 hr. LPS fevers were 77% greater in MCR-Ant-injected rats (11.4 \pm 1.1, N=11; vs. 6.4 \pm 0.9 °C.hr, N=12; area under curve for Tb rise)(p<.01). Effect of MCR-Ant was negligible in control rats. The results suggest a protective antipyretic role of central MSH neurons during infection. Support: NIH MH44694, DA08227, DK17420.

NEURAL-IMMUNE ABNORMALITIES IN DEPRESSED PATIENTS AND HEALTHY CONTROLS, G.R. Heninger*, L.H. Price, R. T. Malison, and G. H. Pelton, Dept. of Psychiatry, Yale University, New Haven, CT 06510. Immune abnormalities have been demonstrated in patients with depression, but their role in pathogenesis is unknown. METHODS: In order to evaluate possible abnormalities in immune mediated neuroendocrine function in patients with depression, we have administered, in a placebo-controlled manner, a 5 min. i.v. infusion of the potent immune stimulant, lippopolysaccharide (LPS), 2 ng/kg to 6 depressed patients (DP) and 6 healthy controls (HC). Before and after the LPS or placebo infusion, repeated measures were made of subjective symptoms, body temp., blood leukocytes, IL-1 beta, IL-6, TNF alpha, C-reactive protein, alpha 1-acid glycoprotein, haptoglobin, ACTH, cortisol, and growth hormone (GH). RESULTS: LPS produced reliable and robust increases in all the measures listed above. In comparison to the HC, the DP had a 60% reduction of subjective reports of chills and body temp, but total leukocytes were doubled at early time points. There was a trend for the IL-6 and TNF-alpha responses to be lower in DP, but the response of C-reactive protein and haptoglobin tended to be higher. The ACTH, cortisol, and GH response to LPS of DP were reduced to less than 20%, 50%, and 25% of the response of HC respectively. CONCLUSION: Depressed patients have a blunted symptomatic, body temp., and neuroendocrine response to LPS in the face of a normal or increased immune response. The data is consistent with the hypothesis that a chronic hyper immune state in depression leads to downregulation of the central nervous System response to immune stimulation. (Supported by the Stanley Foundation).

OCULOMOTOR SYSTEM: SACCADES

579.1

ACTIVITY OF PREFRONTAL NEURONS DURING MEMORY-GUIDED EYE MOVEMENT AND FIXATION. R.G. Erickson*. LNP, NIMH,

Cortical neuronal responses during delayed response tasks have previously been proposed to reflect either working memory or motor planning. To determine how primates execute memory-guided as opposed to visually-guided eye movements I hypothesized that parts of the prefrontal cortex serve as a selective relay allowing stored rather than current sensory information to be sent to motor areas. As a test, extracellular recordings were obtained from prefrontal cortex along the principal sulcus of rhesus monkeys trained to perform memory-guided eye movements followed by memory-guided ocular search in total darkness. Three types of randomly interleaved trials were used to require eye movements and fixation guided by either spatial memory in complete darkness, memory for one of multiple visible targets, or in response to movement of a single visible target. In a sample of 102 cells from one monkey, two predominant activity patterns were observed. First, when significant modulation of delay-period activity occurred on spatial memory trials (18 cells), the activity did not depend upon presence or absence of a visible cue at the intended saccadic target zone. In addition, the delay-period activity invariably ended with saccade execution and response modulation did not persist during a subsequent period of memory-guided search (18 of 18 cells). Second, a larger group of cells (42) had significant modulation of activity during memory-guided fixation without significant modulation of delay-period activity, but no cells exhibited modulation which persisted through both phases of the task.

These data suggest that both remembered and current sensory information is available to prefrontal 'delay' and 'memory-fixation' neurons and is selectively accessed as part of the process of selecting a particular response. The results do not support the hypothesis that prefrontal cells actually store spatial memories.

DISSOCIATION OF TARGET SELECTION FROM SACCADE PLANNING IN MACAQUE FRONTAL EYE FIELD. N.P. Bichot*, K.G. Thompson & J.D. Schall. Department of Psychology, Vanderbilt University, Nashville, TN 37240 To determine if target discrimination in macaque frontal eye field (FEF) is

To determine if target discrimination in macaque frontal eye field (FEF) is contingent on saccade planning, the activity of FEF neurons was recorded in two monkeys during blocked GO and NOGO visual search trials. In the GO search task, the monkey was rewarded for directing gaze to the salient oddball target among distractors distinguished by color. In the NOGO search task, a cue to withhold saccades was presented 500 ms before the appearance of the search display, and the monkey was rewarded for maintaining fixation on a central fixation point for up to 1000 ms.

To account for possible saccade planning even during successful NOGO trials, we analyzed the eye movements made by the monkeys within a 500 ms time window after they were rewarded for maintaining fixation. The monkeys made saccades to the oddball after reward in less than 15% of NOGO trials during recordings from 20 out of 22 cells. The lack of saccade planning was reflected by an attenuation of visual responses in NOGO trials compared to GO trials, similar to what had been observed by Bushnell and Goldberg (J. Neurophysiol. 46:773-787) during visual detection. The evolution of activity signalling target location was characterized with an analysis based on Signal Detection Theory. In the GO task neural activity evolved to signal target location at a consistent time after stimulus presentation and did not predict when the eyes would move (Thompson et al., Soc. Neuro. Abs. 21:1270). In the NOGO task, for the majority of neurons, activity evolved to signal the location of the oddball stimulus to a comparable degree and over a similar timecourse. Thus, the selection of a salient visual stimulus by FEF neurons is not contingent on saccade production but rather may reflect the outcome of an "automatic" bottom-up visual selection process. (Supported by F32-EYO6495, McDonnell-Pew and R01-EYO8890)

NEURAL BASIS OF SACCADE REACTION TIME: FRONTAL EYE FIELD D.P. Hanes* & J.D. Schall. Department of Psychology, Vanderbilt University, Nashville, TN 37240

Understanding the neural basis of the duration and variability of reaction times (RT) is a central problem of cognitive neuroscience. Many conceptual models have been proposed to account for the distribution of RTs. One class of models utilizes a decision process in which a response is initiated when a growing signal reaches a threshold. By stochastically varying either the rate of the growth (variable rate model) or the threshold that triggers the movement (variable threshold model) RT distributions are generated. Physiological approaches that test such models are essential for understanding the processes that regulate movement initiation. We have been investigating these decision processes using a countermanding task that manipulates a subject's ability to inhibit a saccade during different stages of its preparation. Cells with movement-related activity were recorded in the frontal eye fields of two rhesus monkeys performing the countermanding task. In 23 of 25 cells, the discharge level 10-20 ms before the saccade did not vary with saccade latency (SL). Also, the rate of growth of the activity significantly declined with increasing SL in 22 of 25 cells. Both of these results are predicted by the variable rate, but not the variable threshold model. If the variable rate model is correct, the level of neural activity on successfully inhibited trials should not reach the critical threshold level. In 19 of 25 cells the neural activity when monkeys withheld saccades was significantly less than the threshold level. We implemented a simple mathematical model to further test the variable rate model. The parameters of the model were derived directly from corresponding measures of activity of individual neurons. In 15 of 22 cells the mean of the model SL distribution was not different from the actual SL distribution. In 9 of 22 cells the both the mean and the shape of the distributions were not different. (Supported by R01-MH55806 & F31-MH11178)

ACTIVITY DURING INTERRUPTED SACCADES OF ROSTRAL SUPERIOR COLLICULUS NEURONS PROJECTING TO THE OMNIPAUSE REGION. N. J. Gandhi* and E. L. Keller. Graduate Group in Bioengineering, UCSF, San Francisco and The Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115.

Neurons found in the deeper layers of the rostral third of the superior colliculus (SC) are active during fixation and inhibited during large saccades. An anatomic study has reported that the rostral SC projects to omnipause neurons (OPNs), and previous physiological studies have shown that stimulation of the rostral SC during large saccades produced interrupted saccades similar to those produced by OPN stimulation.

These findings suggest that the rostral SC provides an input signal to the OPNs that may be critical in controlling and ending saccades. To clarify the role of the rostral SC projections to the OPNs in saccade control, we stimulated the region of the OPNs to test for antidromic activation of SC neurons and recorded neural activity in the rostral SC during saccades interrupted by OPN stimulation. We specifically wished to

determine if rostral SC neurons were reactivated during the period of interruption.

The probability of antidromic activation from the OPN region was greatest for the most rostral SC neurons (0.7) and decreased linearly to 0.2 for the caudal SC. A resumption of discharge in rostral neurons was rarely observed during the interrupted period. Reactivation of these neurons occurred prior to or after the end of the resumed saccade. For truncated movements, however, resumed activity was observed at the time of truncation. Therefore, neurons in the deeper layers of the rostral SC partially reflect the eye perturbations induced by OPN stimulation and may contribute to the control of OPNs and saccade termination, but their discharge profiles are not nearly as tightly coupled to saccadic termination as the latter group of cells. The fact that rostral SC neurons do not resume discharging during saccadic interruption may help to explain why interrupted saccades are normally orthometric, when control theories with a resetable neural integrator would predict hypometric errors. A NEW MODEL OF THE SACCADIC SYSTEM: II. DIRECTIONAL DRIVE BY THE SUPERIOR COLLICULUS. P. Lefèvre*, C. Quaia, L.M. Optican, LSR, National Eye Institute, NIH, Bethesda, MD 20892

The intermediate layers of the superior colliculus (SC) are believed to be responsible for controlling saccades. Three types of neurons contribute to this control: burst neurons that burst during saccades; fixation neurons that pause during saccades; and buildup neurons that begin firing before, and can burst during saccades. The locus of activity in the SC is retinotopically mapped, and the locus of the active burst cells seems to encode the amplitude and direction of the movement. The activity of the buildup neurons is initially localized to the same place, but during the saccade it appears to spread in a rostral direction.

These findings have led to models of the SC that propose that the locus of active

burst neurons determines the desired ocular displacement, and the spatial distribution of activity among the buildup neurons forms the displacement integrator of the feedback controller. However, experimental data from Aizawa and Wurtz (1994) show that muscimol lesions in the intermediate layers of the SC lead to curved saccade trajectories that attempt to "go around" the site of the lesion. This would not be possible if the displacement integrator were in the SC, as damaging the integrator would eliminate the brain's knowledge of where the eye is currently. This would lead to an incorrect estimate of the motor error, and an inappropriate saccade.

In the new model proposed here, the burst neurons determine the desired ocular displacement, and the buildup neurons provide a directional drive to the brain stem. The saccade starts when the interaction between the burst and fixation neurons turns off the brain stem omnipause neurons. A novel feature of the new model is that the integrator is in the cerebellum, not the SC. Thus, the end of the saccade is controlled by the cerebellum. If the cerebellum is lesioned, saccades eventually stop because the collicular fixation neurons reactivate

FUNCTIONAL INTERACTIONS BETWEEN THE TWO FUNCTIONAL INTERACTIONS BETWEEN THE TWO FRONTAL EYE FIELDS IN MONKEY. J. Schlag, P. Dassonville, M. Schlag Rey and M. S. Letinsky*. Brain Research Institute, Depts. of Neurobiology and Physiology, UCLA, Los Angeles, CA 90095.

Movement cells in the FEF discharge before and during purposeful saccades of particular direction and amplitude. At the same time, cells that encode a different saccade vector are silent. What prevents different populations of saccade-related cells from issuing competing commands? That is: why do oculomotor centers always seem to agree on the next orientation of gaze? To study the mechanism of this remarkable cooperation, we have recorded from one FEF in trained monkeys while saccades were evoked by electrically stimulating the other FEF. The preferred saccade vectors of cells at both the recording and stimulation sites were first determined. When the vectors were different, the cells were either unaffected (51%) or inhibited (49%) by the contralateral stimulation Reciprocally, in all 14 cases in which the cells in both FEFs had similar vector preferences, the stimulation produced an excitation in the contralateral cells. These results are comparable to those found earlier in studying the effects of FEF stimulation on burst cells in the superior colliculus (Schlag-Rey et al., J. Neurophysiol., 1992, 67: 1003). We suggest that the winner-take-all phenomenon in oculomotor structures is implemented by connections such that cells that command similar movements mutually excite each other while silencing cells that would produce conflicting movements. (Supported by USPHS grants EY05879 and EY02305).

A NEW MODEL OF THE SACCADIC SYSTEM: I. SEPARATE MODULES FOR SPECIFYING DIRECTION AND DURATION L.M. Optican*, C. Quaia, P. Lefèvre, LSR, National Eye Institute, NIH, Bethesda, MD 20892.

Saccades rapidly change the orientation of the eye in the head, despite the viscous and elastic forces of the extraocular muscles and orbital tissues. This requires a pulse-step of innervation. Existing models focus on generating the pulse of innervation, and obtain the step of innervation by integrating that pulse

Robinson (1975) proposed a closed-loop feedback controller that generated the pulse simply as a function of the dynamic motor error (difference between desired and current eye orientations). Models based on this feedback controller obtain burst neuron activity as a nonlinear function of either horizontal or vertical motor error. Experimental results, however, reveal that the activities of brain stem burst neurons have directional tuning curves with a wide range of preferred on-directions. Thus, the input to the burst neurons can not come from a decomposition of the motor error into horizontal and vertical components, but must come from a vectorial error. However, a vectorial error feedback loop would always generate horizontal and vertical components of the same duration, whereas saccades can have components of different durations. Without a vectorial motor error feedback loop, the duration of the pulse must be determined elsewhere. Only lesions of the cerebellum result in hypermetric saccades, which are, essentially, saccades that do not stop when they should. We infer from this that the cerebellum plays a crucial role in ending the saccade.

These three abstracts present a new approach to modeling the saccadic system that uses a distributed representation of neurons whose activity more closely matches the experimentally observed behavior of neuronal populations in the brain stem, superior colliculus, and cerebellum. A model based on this distributed approach generates the saccadic pulse through the interaction of a collicular mechanism providing a directional drive, and a cerebellar mechanism controlling duration

A NEW MODEL OF THE SACCADIC SYSTEM: III. FEEDBACK CONTROL OF DURATION BY A SPATIAL INTEGRATOR IN THE CEREBELLUM. C. Quaia*, P. Lefèvre, L.M. Optican, LSR, National Eye Institute, NIH, Bethesda, MD 20892.
Lesions of the cerebellum result in permanent dysmetria of saccades, in most cases

a hypermetria. The hypermetric saccades, although larger, are slower than normal. This leads us to the inference that the cerebellum contains the saccadic integrator and contributes to the dynamics of the saccade. We infer from recording studies of the vermis and fastigial nuclei that the saccadic integrator may be represented by a wave of activity that moves through the fastigial nuclei during a saccade. The output of the fastigial nuclei is responsible for accelerating the eye at the beginning of the saccade, and stopping the eye at the end of the saccade by inactivating the drive to the motor neurons. Thus, a saccade can cease even though an input to the burst neuron remains, and the pontine omnipause neurons have not been reactivated

One consequence of the fastigial output is that the activity of individual motor neurons is shut down abruptly, in a process we call dynamical derecruitment. This derecruitment allows the total drive of the oculomotor neurons to decrease gradually, even though experimental evidence shows that the burst on individual motor neurons shuts off abruptly

One advantage of a dual controller for the saccadic system is that it provides redundancy. If either the cerebellum or the superior colliculus is lesioned, saccades are still possible. However, they will show deficits associated with the loss of the damaged part of the system. In the case of cerebellectomy, saccades will be too large. This hypermetria results from the longer duration of the saccade, which only stops when the fixation neurons in the SC come back on, and turn on the pontine omnipause neurons. In contrast, lesions of the SC lead to errors in the initial direction of a saccade, and lower saccade velocity. The final eye position, however, would be correct, because of the cerebellar output.

DEMONSTRATION OF SACCADE-RELATED SINGLE-UNIT ACTIVITY IN THE DORSOLATERAL PONTINE NUCLEUS (DLPN) OF THE RHESUS MONKEY. P. Thier*¹, P. W. Dicke¹, S. Barash², U. Ilg¹. Sektion Visuelle Sensomotorik, Neurologische Universitätsklinik, 72076 Tübingen, Germany and The Weizmann Institute, 76100 Rehovot, Israel.

The DLPN is connected to saccade-related regions, but saccade-related neuronal activity has not been reported in the DLPN. The DLPN receives strong input from cortical area LIP and the FEF, and it projects to vermal lobules VI,VII. The involvement of all these areas in saccades is well established. Nevertheless, only pursuitrelated activity, not saccade-related activity, has been reported in the DLPN. The question, whether saccade-related activity exists in the DLPN is particularly interesting in view of current thinking about cortical contributions to goal-directed eye movements, which favors the dichotomy of a cortico-pontine pathway for smooth-pursuit eye movements and a cortico-tectal pathway for saccades.

We have started to record single-units from the DLPN of a rhesus monkey trained to execute saccades to remembered locations (..memory saccade task"). So far, we have recorded from 50 single-units, we would provisionally assign to the DLPN. based on their locations relative to conspicuous electrophysiological landmarks such as the oculomotor nuclei and additional information derived from MRI scans. Out of these, 8 exhibited clearcut directionally selective saccade-related responses, characterized by strong pre- or perisaccadic bursts of discharge. In several cases, these bursts were preceded by a tonic increase of activity in the ..memory period", in which the monkey was required to memorize the spatial location of the peripheral target in the absence of visual information. These preliminary electrophysiological observations strengthen the hypothesis of a cortico-pontine pathway for saccades. which involves the DLPN, and bypasses the classical cortico-tectal pathway for

EFFECT OF DORSAL CEREBELLAR VERMAL LESIONS ON SACCADES AND PURSUIT IN MONKEYS, M. Takagi, D.S. Zee*,

Tamargo. Neurology Dept., Johns Hopkins Hospital, Baltimore, MD, 21287.

We investigated the effect of aspiration of the dorsal cerebellar vermis (predominantly lobules 6 and 7) on saccades and pursuit in three rhesus monkeys. We analyzed immediate effects, on saccade accuracy and dynamics (velocity and acceleration) to target steps, and on pursuit initial acceleration and steady-state gain to step-ramp stimuli. We also measured saccade and pursuit adaptive capabilities using double step paradigms (position steps for saccades and velocity steps for pursuit).

Saccades: In most cases saccades became hypometric postop, (82% on average). Only one monkey showed a transient hypermetria, for leftward saccades. In som cases saccade dynamics were also altered, especially changes in acceleration and deceleration, but these did not necessarily correlate with changes in accuracy. Saccade gain adaptation (to a decreasing double-step stimulus, preop value about 10-15% decrease after 200 trials) was abolished in two monkeys, and impaired (50% of preop value) in a third.

Pursuit: Pursuit initial acceleration (avg accel in first 100ms of smooth tracking) was decreased in all monkeys (76% of preop). Steady-state tracking gains were also slightly decreased (92% of preop). Pursuit adaptation (to a double-step stimulus, target velocity doubled or halved at the onset of smooth tracking) was also impaired in all monkeys (78% of preop value for increasing paradigm and 52% for decreasing paradigm).

These results implicate the dorsal cerebellar vermis directly in both immediate

(online) and in adaptive control of saccades and pursuit. They also suggest that cerebellar cortex alone has an important role in saccade and pursuit adaptation. Supported by NIH EY01849.

SACCADIC GAIN ADAPTATION IS JUST THAT. J. Wallman*, A. F. Fuchs† and M. Pong†. Biology Dept., City College and Graduate School, CUNY, NY, NY 10031 and †Dept. of Physiol. & Biophysics, Univ. of Washington, Seattle, WA 98195

The brain maintains the accuracy of saccadic eye movements by adjusting their amplitudes relative to the distance of the target (the saccadic gain) based on the errors of recent saccades. Thus, in the classic paradigm, if one arranges for saccades to land beyond the target (by surreptitiously moving the target during the saccades). the saccade gain decreases over a few hundred saccades. We suppose that this saccadic gain adaptation occurs at the motoric level and uses a visual error signal. However, the error signal might be motoric (the brain noting whether the corrective saccades are in the same or opposite direction as the preceding primary saccade) Also, the gain change might simply reflect a remapping of visual space in the CNS. We tested these possibilities by two experiments in humans and rhesus monkeys

To test whether the error signal is motoric, we used a paradigm suggested by Deubel. During the primary saccade to an initial target step, we stepped the target backward only briefly, so that fewer than 10% of corrective saccades were backward (~200 msec). The saccadic gain decreased over a few hundred saccades, even though most of the corrective saccades were forward by the end of the adaptation. Therefore, corrective saccades do not guide the direction of saccadic gain adaptation.

To test whether the gain adaptation involves visual remapping, we decreased the gain of 10° horizontal saccades by adaptation according to the classic paradigm described above, and then tested them to targets in retinal positions unused during the adaptation procedure, by having targets make a double step-the first vertical and the second horizontal-before the first saccade is made. The adapted gain transfers to 10° horizontal saccades made to these new locations.

We conclude that saccadic gain adaptation involves an error signal that is visual, not motor, but the adaptation is motor, not visual.

THREE-DIMENSIONAL ORGANISATION OF SYNAPTIC VESICLE ENSEMBLES IN RAT HIPPOCAMPUS IN RELATION TO SYNAPTIC EFFICACY, D.A.Rusakov*, M.G.Stewart, H.A.Davies, G.Richter-Levin and T.V.P.Bliss. (SPON: Brain Research Association). Dept. of Biology, The Open University, Milton Keynes MK7 6AA, UK; Dept. of Psychology, Univ. of Haifa. 31905 Israel; National Institute for Medical Research, London NW7 1AA, UK

The spatial organisation of synaptic vesicles (SVs) in pre-synaptic boutons is believed to play a functional role in synaptic transmission. Visible groupings of SVs in excitatory synapses from area CA1 of rat hippocampus were examined in an electron microscopic study. In each animal, 50-90 single section micrographs of synapses were sampled randomly. Euclidean co-ordinates of each SV and of related active synaptic zone (AZ) edges were transported to a data base. The data were used in order: (i) to establish the probabilities of SV-AZ distance classes, including stereological estimation via analytical unfolding; (ii) to estimate frequencies of the positioning of SVs with respect to AZs within synaptic boutons. In several synapses, the organisation of SV ensembles in space was reconstructed and visualised via a serial section study

Analysis of SV co-ordinates has revealed two distinct sub-population of synapses, one with relatively high, and one with low, accumulation of SVs in the proximity of AZs. A phenomenon showing the lower occurrence of SVs in the centre, compared to the edges, of AZs has also been discovered.

The results provide insights into the possible molecular machinery of synaptic transmission where SV-AZ distance reflects the probability of recruitment of a SV for mediator release. The second stage of the study will compare SV ensembles contralaterally within the paradigm of long-term potentiation induced in one hemisphere of the rat hippocampus

SYNERGISTIC ACTION OF GABA-A AND NMDA RECEPTORS IN THE NEONATAL RAT HIPPOCAMPUS.

Y. Ben-Ari *, R. Khazipov, I. Khalilov, & X. Leinekugel

INSERM Unite 29, 123, Bd de Port-Royal, Paris, 75674, FRANCE
In the neonatal hippocampus, GABA acting via GABA-A receptors has a depolarizing action because of elevated intracellular Cl-J We have used now non dyalizing patch-clamp recording technique and confocal microscopy to study the interactions between GABA and glutamate mediated currents in neonatal hippocampus. Our observations can be summarized as followings: 1) Electrical stimulation of stratum radiatum evoked 3.9±1.2 spikes in cells-attached recordings from pyramidal cells (n=13). The AMPA-R antagonist CNQX (10μM) did not modify significantly the response, whereas D-APV (50μM) reduced it to 1.3±0.2 spikes, that were blocked by further application of bicuculline (10µM). This suggests that GABA-A and ceptors mediate most of the excitatory synaptic transmission in neonatal slices, whereas AMPA-Rs are quiscent; 2) GABA-A agonist isoguvacine attenuated the voltage-dependent Mg-block of single NMDA channels recorded in cell-attached configuration; 3) Isoguvacine also augmented the calcium influx through NMDA channels as visualized with confocal microscopy in neurons loaded by Fluo-3AM. We conclude that in neonatal hippocampus, GABA is the principal "fast" acting excitatory transmitter. GABA activates NMDA receptor by removing Mg-block, i.e. it plays the role conferred to AMPA-R in adult. This synergistic action underlies a novel form of LTD that prevails at this early stage (see McLean et al.) and probably other roles subserved by GABA and glutamate receptors in

A NOVEL LONG TERM DEPRESSION IN THE NEONATAL RAT HIPPOCAMPUS REQUIRING SYNERGISTIC ACTIVATION OF GABA $_{
m A}$ AND NMDA RECEPTORS

H.A. McLean, O. Caillard, Y. Ben-Ari, A. Maillart* and J-L Gaiarsa INSERM Unité 29, 123 Bd de Port Royal, Paris 75674, France.

During the first 4 days of postnatal life (P0-P4), GABA provides the main excitatory drive in the CA3 region of the rat hippocampus. At same time, GABA provides sufficient membrane depolarization for $\rm NMDA\text{-}R$ activation (see abstract: Ben-Ari et al). We have discovered that this $\rm GABA_A$ / $\rm NMDA$ synergy underlies a novel form of tetanic LTD expressed by $GABA_A$ -R (LTD $_{GABA-A}$). Tetanic stimuli (TS; 100 Hz, 1 second) delivered to the stratum radiatum in the presence of CNQX (10 uM) induced a sustained (> 60 min) depression of the peak amplitude and the initial slope of monosynaptic GABAA postsynaptic potentials (PSPs) to and 49% of control values respectively. Tetanic LTD_{GABA-A} requires: (1) membrane depolarization during TS mediated by GABAA-R as LTD_{GABA-A} was prevented by either voltage clamping cells at -60 mV during TS (n=5) or by bath application of bicuculline (10 µM) during TS (n=6); (2) activation of NMDA-R as LTDGABA-A was prevented by bath application of D-APV (50 μM) during TS (n=5); (3) an increase in intracellular calcium levels as LTD_{GABA-A} was prevented by loading cells with BAPTA (50 mM) (n=5). Furthermore, bath application of NMDA (30µM) at potentials more positive than -40 mV induced sustained (>45 min) decreases in both the amplitude and initial slope of GABA A PSPs to 63% and 56% of control values respectively. LTDGABA-A is a novel form of synaptic plasticity demonstrating that synergistic actions of GABA and NMDA receptors have important functional consequences in the developing hippocampus. ADENOSINE A2 RECEPTORS UPREGULATE THE POSTSYNAPTIC AMPA COMPONENT IN HIPPOCAMPAL LTP.

D.J._Mogul*_&.K., Kessey. Depts. of Biomed Engineering & Neurobiol. Northwestern University, Evanston, IL 60208 USA

Increases in neuronal firing elevate levels of extracellular adenosine in the brain. We examined the role of A2 receptors in both normal synaptic transmission and tetanus-induced long-term potentiation (LTP) in rat hippocampal slices. Extracellular postsynaptic field potentials (EPSP) recorded in stratum radiatum of CA1 were measured in response to presynaptic stimulation of the Schaffer collaterals. Addition of the A2 agonist DPMA increased the EPSP evoked by low frequency test pulses (0.033Hz). DPMA had no effect on paired-pulse facilitation suggesting that the effects were not presynaptic. Consistent with this, DPMA did not affect the NMDA component of the EPSP but selectively increased the AMPA component. The $\mathrm{A_2}$ antagonist DMPX blocked or significantly reduced the induction of tetanus-induced LTP (100Hz; 1s) but had no effect on LTP maintenance when the A2 antagonist was perfused after LTP induction in control solution. Furthermore, LTP induction normally blocked with the NMDA antagonist AP5 could be induced by concurrent A2 activation. However, this induction was occluded by a train of saturating tetani applied prior to AP5 and DPMA indicating the two potentiations were acting via a convergent pathway. These results suggest that A2 receptors may play an important role in the modulation of hippocampal transmission and LTP by regulating postsynaptic AMPA receptor-channels. Supported by the NIH (NINDS NS31764) and the Whitaker Foundation.

12-HYDROPEROXYEICOSATETRAENOIC ACID INDUCED THE LONG-TERM POTENTIATION IN RAT HIPPOCAMPAL CA1. M. Nishiyama*1, N. Hori², T. Watanabe¹, T. Hori¹, K. Suzuki³, E. Maru³ and T. Shimizu⁴ ¹Div. of Neurosurg.. Inst. of Neurol. Scis., Tontori Univ. Sch. of Med. Yonago 683, ²Dept. of Pharmacol., Kyushu Univ., Fac. of Dent., Fukuoka 812, ³Dept. of Physiol., Nippon Med. Sch., Tokyo 113, ⁴Dept. of Biochem., Fac. of Med., Univ. of Tokyo, Tokyo 113, Japan.

We previously demonstrated that at least two distinct receptors for 12-hydroperoxyeicosatetraenoic acid (12-HPETE) existed in the canine hippocampus and that 12-lipoxygenase translocated in the synaptic area, according to the enhancement of synaptic potential by seizure in vivo. In this report, we confirmed these results by using brain slices in vitro. Intracelluar response (EPSP), population spikes and population EPSP (pEPSP) induced by Schaffer collateral stimulation were recorded from the pyramidal cell, cell layer and the dendric trees in CA1 area, respectively. Spike potentiation, induced by tetanic stimulation is remarkably augmented by the pretreatment of 100 nM 12-HPETE($267.8\pm44.0\%$, n=8) and 500 nm 12-HPETE($267.8\pm44.0\%$, n=8). nM arachidonic acid (197.0 $\pm18.5\%,~\text{n=8}),$ as compared with control ones (144.0 \pm 10.1%, n=16). 12-HPETE (100 nM) itself induced LTP-like potentiation (pEPSP: $196.0 \pm 31.6\%$, n=10; EPSP: $162.3 \pm 7.4\%$, n=4), which were not blocked by 50 μ M APV. Furthermore, 12-HPETE did not affect the impedance of postsynaptic membrane, or enhance the postsynaptic responses to iontophoretically applied quisqualate and NMDA. Theta burst stimulations also induce the LTP (pEPSP: 150.9 $\pm 9.5\%$, n=8; EPSP: 148.8 $\pm 22.3\%$, n=4) without the enhancement of postsynaptic glutamate responses. Thus, 12-HPETE is suggested to be one of retrograde messengers, which predominantly acts in the presynaptic site, playing a critical role in the synaptic plasticity

580.4

DEFICIENCY IN INDUCTION BUT NORMAL EXPRESSION OF LTP IN HIPPOCAMPAL SLICES FROM YOUNG RATS. <u>D. Liao* & R. Malinow</u>, Cold Spring Harbor Laboratories, Cold Spring Harbor, NY11724 and *Dept. of Physiology & Biophysics, U. of Iowa, Iowa City, IA52242.

We have investigated the developmental changes of LTP in the CA1 region of hippocampal slices from rats of postnatal day 4-14. Consistent with previous results, we found that tetanus-induced LTP in field recordings is diminished in slices from younger animals (n=30, p<0.01). Tetanus-induced LTP in whole-cell current-clamp recordings is also diminished in younger animals (n=20, p<0.02). However, robust LTP can be induced in young animals if sufficient postsynaptic depolarization is directly provided by the recording electrode with a pairing protocol (average age = 7.3 days; n=12, p<0.01). In whole-cell current-clamp recordings, we found a positive correlation between the number of action potential spikes during tetanus and age of animal (n=25, p<0.05), and a positive correlation between the amount of potentiation and the number of spikes (n=19, p<0.04). Several measures of synaptic function also suggest that synaptic density is lower in younger animals. These results indicate that the smaller LTP in field and whole-cell current-clamp recordings are due to insufficient postsynaptic depolarization during LTP induction rather than a defect in expression mechanisms.

Metabotropic glutamate receptor antagonists inhibit both NMDA receptor-dependent and independent LTP in the dentate gyrus *in vivo*. D. Manahan- Vaughan and K.G. Reymann*, Federal Institute for Neurobiology, Brenneckestr. 6, D-39118 Magdeburg, Germany.

This study examined the role of metabotropic glutamate (mGluR) receptors in NMDA receptor-dependent and -independent long-term potentiation (LTP). The group 1 mGluR antagonist (S)-4-carboxyphenylglycine (4CPG), and the group 1 and 2 antagonist (RS) - α -methyl 4-carboxyphenyl-glycine (MCPG) were used. D (-)-2-amino-5-phosphonopentanoic acid (AP5) was used to confirm the NMDA receptor contribution in the LTP recorded.

Male wistar rats underwent implantation of stimulating and recording electrodes into the granule cell layer of the dentate gyrus (DG). Following 5 days recovery, the field excitatory post-synaptic potential slope function (fEPSP) and population spike amplitude (PS) were measured from freely moving animals. Drug concentrations used were 4 -30 mM 4CPG, 20 mM AP5 and 200 mM MCPG in an injection volume of 5 µl. Drugs were applied 30 min before tetanus via a cannula implanted the lateral cerebral ventricle.

200 Hz tetanisation produced an LTP of fEPSP and PS which was inhibited by pre-tetanus application of AP5. MCPG completely inhibited LTP by 2h post-tetanus. A similar effect, which was dose-dependent, was obtained with 4CPG. Neither drug had an effect on baseline when compared with vehicle injected controls. LTP induced by 400Hz tetanisation was not inhibited by AP5. However MCPG and 4CPG inhibited the development of this LTP by 2h. These results support a role for mGluRs in both NMDA receptor-dependent and -independent LTP, and implicate group 1 mGluRs in these phenomena.

DISSOCIATION OF LTP OF AMPA AND NMDA RECEPTOR-MEDIATED SIGNALS: EVIDENCE FOR GLUTAMATE SPILL-OVER AND PRESYNAPTIC CONTRIBUTION TO EXPRESSION OF LTP. <u>Dimitri M. Kullmann* & Fredrik Asztely</u>, Dept. Clinical Neurology, Institute of Neurology, Queen Square, London WC1N 3BG, United Kingdom.

Is LTP of NMDA receptor-mediated signals always accompanied by LTP of AMPA signals? To prevent induction of conventional LTP we first dialysed 25 CA1 pyramidal cells from guinea pig hippocampal slices for 45 minutes with whole-cell pipettes containing 5 mM BAPTA. Pure NMDA receptor-mediated EPSCs were elicited by holding the cells at +40 mV in 0 μ M DNQX, and stimulating two pathways at 0.1 Hz. Tetanic stimulation (2 x 50 pulses, 100 Hz) while holding the cells at -80 mV caused a small potentiation when compared to the control pathway at 25 minutes (11 \pm 5 %, mean \pm 5.E.M., p = 0.033, paired t test). In 17 other slices we simultaneously recorded AMPA receptor-mediated signals with whole-cell and extracellular field electrodes. We elicited LTP of the field EPSPs with two 100 pulse 100 Hz tetani (54 \pm 5 %, p < 10 6). By clamping individual pyramidal cells at +30 mV during the tetani, LTP of the AMPA EPSCs was prevented (1 \pm 6 %, p = 0.870). In contrast, when the NMDA component was subsequently compared to the control pathway, it was again significantly potentiated (14 \pm 6 %, p = 0.036). Tetanic LTP of NMDA EPSCs can thus be elicited under conditions designed to prevent LTP of AMPA signals. We propose that NMDA receptors sense glutamate spill-over from terminals which are presynaptic to neighboring cells. LTP at these synapses potentiates presynaptic glutamate release, causing an increase in the NMDA signal, but not in the AMPA signal because of the lower affinity of AMPA receptors. This explains (i) differential potentiation of AMPA and NMDA signals; (ii) increased quantal content with LTP; (iii) greater variability of AMPA than NMDA components of EPSCs; and (iv) the observation that pure NMDA EPSCs can be elicited with minimal stimulation. (Supported by the MRC and the Wellcome Trust)

TETANIC LTP OF NMDA RECEPTOR-MEDIATED EPSCS IN CA1 IS ASSOCIATED WITH AN INCREASED RATE OF DEPRESSION BY MK-801. Gül Erdemli* & Dimitri M. Kullmann, Dept. Clinical Neurology, Institute of Neurology, Queen Square, London WC1N 3BG, United Kingdom

Manabe & Nicoli (Science 265:1888, 1992) looked for presynaptic expression of LTP in CA1 by measuring the rate at which the use-dependent blocker MK 801 depressed NMDA receptor-mediated EPSCs. Prior induction of LTP by pairing low-frequency stimulation with postsynaptic depolarization had no detectable effect on the rate at which the EPSCs decayed with repeated stimulation, implying no change in the opening probability of NMDA receptors Pairing-induced LTP is however associated with very little potentiation of the NMDA component. We have therefore repeated these experiments with tetanic LTP, since this has been reported to be associated with an increase in the MDA component. We elicited EPSCs in CA1 pyramidal cells of guinea pig hippocampal slices (holding potential -80 mV). Tetanic LTP was elicited in one pathway (2 x 100 pulses at 100 Hz) while holding the cells at 0 mV. Non-NMDA receptors were subsequently blocked by DNQX (10 μM), and the cells held at +40 mV. When compared to the control pathway, the NMDA component was also potentiated, although less than the non-IMDA component (21 ± 9 % and 63 ± 11 %, respectively, means ± s.E.M.; n = 25). MK-801 (40 μ M) caused a faster decay of successive NMDA receptor-mediated EPSCs in the tetanized pathway than in the control pathway (difference in single exponential time constants: $20 \pm 8 \%$, p < 0.02). Our results support an increase in glutamate release probability. To explain the apparent disagreement with Manabe & Nicoli (1992), we propose that much of the NMDA signal arises from spill-over of glutamate from terminals which are presynaptic to neighboring cells. Tetani, but not pairing, induce LTP at these synapses, increasing the spill-over, and explaining the larger potentiation of the NMDA receptor-mediated signals and faster decay with MK-801. (Supported by the MRC)

2-DEOXY-D-GLUCOSE (2DG) CAUSES A RAPID BUT REVERSIBLE INCREASE IN CYTOPLASMIC $[{\rm Ca}^{2^+}]$ IN HIPPOCAMPAL NEURONS. K. Krnjević*, I. Medina and Y. Ben-Ari. INSERM Unité 29, 123 bd Port Royal, 75014 Paris, France

In view of the very predictable sustained potentiation of EPSPs produced by 2DG in CA1 neurons (Tekkök and Krnjević, J. Neurophysiol., 74: 2763, 1995) - and evidence that like other types of LTP, 2DG-induced LTP is Cadependent (Tekkők and Krnjević, this meeting) - we were interested in possible changes in [Ca²⁺] produced by temporary applications of 2DG. As in the previous experiments, 2DG (10 mM) was substituted for glucose

in the ACSF. Changes in intracellular calcium concentration [Ca² estimated by measuring Fluo-3 fluorescence using confocal scanning microscopy. Fluo-3 was loaded in two ways: 1) by local external application of 1 µM Fluo-3 AM in CA1 pyramidal layer; 2) by loading of 10 µM Fluo-3 whole-cell patch micropipette.

In all experiments, whether on cultured hippocampal neurons (at room temperature) or in slices (kept near 30°C), from Wistar rats at 5, 15 or 30 days, 2DG applications lasting 5-12 min induced without fail a marked increase in fluorescence of CA3 and CA1 pyramidal neurons. The change was always detectable within 1-2 min. It usually reached a plateau near the end of the 2DG applications and persisted for at least 10 min subsequently. In 4 CA1 cells (in slices at P30), further washing with glucose-containing ACSF for

CALCH'S (in sites at 750), in their washing wing gutose-containing ACSF for a total of 30 min led to full return of fluorescence to the initial baseline. Major suppression of inward currents by TTX, Cd^{2+} and CNQX did not prevent the rise in $[Ca^{2+}]_i$. In preliminary tests, this effect of 2DG appeared to be reduced by dantrolene but not by thapsigargin (both 10 μ M). We conclude that 2DG consistently raises [Ca] i of hippocampal neurons and that this may be the intracellular signal that initiates the 2DG-induced LTP.

2-DEOXYGLUCOSE (2DG)-INDUCED LTP IN HIPPOCAMPAL CAI NEURONS REQUIRES Ca^{2+} RELEASED FROM INTERNAL STORES. S. Tekkök* and K. Krnjević Anaesthesia Research and Physiology Depts., McGill Univ., Montréal, PQ H3G 1Y6 Canada.

In hippocampal slices from Sprague-Dawley rats, a temporary block of glycolysis by 2DG is followed by a sustained increase in EPSPs (2DG LTP) (Tekkők and Krnjević, J. Neurophysiol. 74:2763, 1995). To investigate a possible role of Ca²⁺ in 2DG LTP, the effects of 2DG on EPSPs were tested in slices exposed to Ca²⁺-free media (at 33° C). When 8 slices were perfused in sinces exposed to Ca -- free media (at 35 C). When a sinces were perfused for 25 min with Ca²⁺-free ASCF (in 6 cases with 100-200 μM EGTA added), and then for 13 min with Ca²⁺-free ACSF containing 10 mM 2-DG instead of glucose, the return to standard ASCF was followed by the usual 2DG LTP—the slope of the afferent volley-EPSP (V-E) relation increased by 88 ± 10.5 % (SEM). But after Ca²⁺-free treatment for 77 min, similar 13 min applications of 2DG caused only a very small LTP (V-E slope increased by 17 ± 7.3 %, n=6, P<0.05). To control for a possible loss of synaptic plasticity after prolonged Ca²⁺-free perfusion, 5 slices were perfused with Ca²⁺-free medium for 90 min, and then with standard ACSF for 60 min before the 2DG application: there was a 2-DG LTP by 34 %, indicating substantial conservation of synaptic plasticity. In similar experiments on NMDAR-mediated EPSPs, 25 min of Ca²⁺-free perfusion did not prevent a large 2DG LTP (V-E slope increased by 96 ± 9.9%, n=2). But after longer Ca²⁺-free

treatment, NMDAR-mediated EPSPs failed to recover from 2-DG effect (n=6). These results suggest that Ca²⁺ is required for the induction of 2-DG LTP; but the necessary Ca²⁺ probably comes from an internal stores which is not These results suggest that Ca is required to the induction of 2-10 E11, but the necessary Ca^{2+} probably comes from an internal stores which is not readily depleted by Ca^{2+} -free perfusion.

LTP DEVELOPMENT IS RESTRICTED TO TETANIZED SIDE IN HIPPOCAMPUS. <u>Janea Mack and Sanika Chirwa*</u>. Physiology. Meharry Medical College, 1005 DB Todd Blvd, Nashville, TN 37208

The objective of the present study was to characterize the use-dependent changes in synaptic efficacy occurring across ipsilateral and contralateral CA1 synapses following paired-pulse (interpulse intervals, 30 msec at 0.01 Hz, for 5-10 pairs) or brief tetanic stimulation (100 Hz, 1 sec; 3 trials given at 5 sec intervals) applied to ipsilateral CA3 afferents. For this purpose, 5 male guinea pigs (gp) weighing 150-200 g, anesthetized with urethane (1500 mg/kg IP) had small access holes made in the skull to allow for stereotaxic placement of a stimulating electrode in ipsilateral CA3 region. Similarly, an electrode was positioned in the ipsilateral and in the contralateral CA1 dendritic regions to record field EPSPs. Subsequently, the CA3 afferents were activated (0.02 Hz) to elicit CA1 dendritic field EPSPs (0.5-1.0 mV). It was found that both paired-pulse facilitation (4 of 5 gp) and LTP (3 of 5 gp) were readily induced in the ipsilateral CA1 dendrites. In contrast, LTP development did not occur in the contralateral CA1. In addition, the contralateral CA1 exhibited no change (4 of 5 gp) or some depression (1 of 5 gp) to paired pulse stimulation. These results suggest that development of synaptic LTP across ipsilateral CA1 synapses does not co-occur with LTP across the contralateral CA1. synapses does not co-occul with LFF across the contralactal CAT synapses. This attribute may be important in determining bi-directionality during spatial navigation, as LTP in the hippocampus appears to be involved in this process. Supported by AID Grant HNE-5053-G-00-5093-00, NIH RCMI Grant G12-RR03032 and NIH NIGMS Fellowship 5-F31-GM17065-02.

ISCHEMIA: MECHANISMS

581.1

NITRIC OXIDE AND PEPTIDE GROWTH FACTORS DIRECTLY MODULATE PROTEIN KINASE C ACTIVITY. M. TenBrocke, L. Kue, R. P. Lisak*, and K. Maiese. Dept. of Neurology, Center for Molecular Medicine, Wayne State University School of Medicine, Detroit, MI, 48201

Both the protective ability of peptide growth factors and the neuronal degeneration following exposure to nitric oxide (NO) are dependent upon the pharmacological down-regulation of the signal transduction pathways of protein kinase C (PKC) (Maiese, et al. J Neurosci Res 36: 77-87, 1993; Maiese, K. and Boccone, L. J Cereb Blood Flow Metab 15: 440-449, 1995). In primary hippocampal neurons, we characterized the ability of NO and the trophic factors, basic fibroblast growth factor (bFGF) and epidermal growth factor (GGF), to directly regulate the cellular activity of PKC. PKC activity was measured by a commercial P³² enzyme assay and results were expressed to the NO generators sodium nitroprusside (300µM) and SIN-1 (300 µM) for 5 minutes and PKC activity was assessed at 2, 6, and 24 hours post NO exposure. PKC activity was assessed at 2, 6, and 24 hours post NO exposure. PKC activity rapidly increased over baseline within 2 hours (31±8%) and gradually returned to baseline at 6 hours (19±8%) and 24 hours (4±5%) following NO administration (n=13, p<0.001). Treatment with the phorbol ester phorbol 12-myristate 13-acetate (PMA) at a neuroprotective concentration of 1µM down-regulated PKC activity by 88±5% in normoxic cultures and actively reversed the NO induced increase in PKC activity by 79±6% (n=6, p<0.001). In contrast, bFGF and EGF individually reduced PKC activity over baseline by 26±5% and 54±11%, respectively (n=8, p<0.001). In contrast, bFGF and EGF individually reduced PKC activity three pharmacological inhibition of PKC activity directly antagonizes NO induced elevations and that the peptide growth factors actively down-regulate PKC activity during NO toxicity. These results suggest that NO toxicity and neuroprotection by bFGF and EGF are directly linked, in

581.2

PEPTIDE GROWTH FACTORS ACTIVELY REVERSE NITRIC OXIDE INDUCED PROGRAMMED CELL DEATH. K. Maiese*, I. Kue, and M. TenBroeke. Dept. of Neurology, Center for Molecular Medicine, Wayne State University School of Medicine, Detroit, Mi, 48201
Peptide growth factors, and the subsequent signal transduction pathways that they modulate, are neuroprotective during nitric oxide (NO) induced neurodegeneration (Maiese, K. and Boccone, L. J. Cereb Blood Flow Metab 15: 440-449, 1995). Yet, the molecular mechanisms of neuronal protection are not well defined. In primary hippocampal neurons, we characterized the role of programmed cell death (PCD) during administration of NO and the peptide growth factors basic fibroblast growth factor (FGF) and epidermal growth factor (EGF)wear condensation and DNA fragmentation was considered consistent with PCD and was documented by hematoxylin and eosin stain, terminal-deoxynucleotide transferase-mediated dUTP-digoxigenin nick end-labeling, and transmission electron microscopy. NO toxicity was achieved with the administration of the NO generators sodium nitroprusside (300 µM) and SIN-1 (300 µM). Induction of PCD following NO exposure alone was both robust and rapid with neurons positive for PCD increasing from 20±4% (0 minutes) to 50±5% (60 minutes) and to 75±6% (24 hours). Consistent with PCD. NO induced neuronal degeneration was reduced from 79±6% to 28±5% by the inhibition of either transcriptional or translational protein synthesis confirmed by an \$3.59 methonine assay. Basic FGF (10 ng/ml) or EGF (10 ng/ml) administered 24 hours prior to NO exposure increased neuronal survival from 30±5% (NO only) to 68±4% (EFGF) and to 32±4% (EFGF) [-10, p<0.001). In addition, the peptide growth factors actively decreased PCD expression over a 24 hour period from 80±7% (NO only) to 30±4% (EFGF) and to 32±4% (EFGF) [-10, p<0.0010). Assessment of protein synthesis during trophic factor administration revealed a reduction in NO induced protein synthesis by both bFGF and EGF of approximately 20%. Thus, NO in

NEURONAL NITRIC OXIDE SYNTHASE (NOS) INHIBITION ATTENUATES ISCHEMIC EXCITATORY NEUROTRANSMITTER RELEASE.

R Kahn, M Panah, S Kiffel, J Weinberger*, Departments of Anesthesiology and Neurology, The Mount Sinai Medical Center, New York, NY 10029.

Nitric oxide (NO) is an important modulator of excitatory neurotransmitter release (ENR) during cerebral ischemia/reperfusion (ISC/R). In this study, we

examined the role of specific neuronal NOS inhibition (nNOSI) on ENR and GABA release during global cerebral ISC/R using the novel nNOSI 7nitroindazole (7-NI).

Microdialysis probes were stereotaxically inserted into the striatum of 24 Sprague-Dawley rats. Dialysates were analyzed by HPLC for neurotransmitter release. Rats received 0, 5, 10 or 20 mg/kg 7-NI iP. Global forebrain ischemia was induced for 15 minutes (ISC). ENR continued to be measured in 15 minute epochs for one hour during reperfusion (R1-R4)

Large increases in glutamate (GLU), glycine (GLY), GABA, and aspartate (ASP) occurred during ISC, which returned to basal levels during reperfusion. 7-NI administration resulted in a dose-dependent attenuation of GLU release during ISC/R. Significant decreases in GLY release as well as a more rapid return to basal levels were observed with nNOSI compared to placebo. Although trends towards decreases in ASP and GABA release with nNOSI were observed, these differences were not statistically significant.

Previous studies using non-specific constitutive NOSI did not demonstrate

differences in ENR during ischemia and did demonstrate increases in ENR during reperfusion. This nNOSI mediated attenuation of GLU and GLY release as well as the avoidance of sustained GLY release during reperfusion may help elucidate the role of NO in ischemic damage in the striatum 1, Stroke 1995;26:298-304.

INDOMETHACIN ATTENUATES INCREASES IN iHSP 70 FOLLOWING GLOBAL CEREBRAL ISCHEMIA IN PIGLETS, T.C. Beasley * 1,F. Bari^{1,3},C. Thore*, T. Louis*, N. Thrikawala*, and D. W. Busija*, 'Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157, 'East Carolina Medical School, Greenville, NC 27858, and ³Albert Szent-Györgyi Medical University, Szeged, Hungary.

Changes in protein metabolism following ischemia may determine the course of brain damage and/or recovery. In anesthetized, newborn pigs, we investigated indomethacin modulation of ischemia related changes in inducible heat shock protein 70 (iHSP 70) levels in brain. Total global ischemia was produced for 5-10' by raising intracranial pressure. Cessation of blood flow was verified visually and by microsphere technique. iHSP 70 levels were evaluated by western blotting and localized by immunohistochemistry Silver staining demonstrated moderate neuronal necrosis following 5' ischemia compared to time-control tissue while 10' ischemia resulted in extensive neuronal necrosis. Western blotting revealed a significant (p<0.05) elevation in neuronal necrosis. Western blotting feveraled a significant (ps. 0.5) elevation in iHSP 70 levels after 6 hours of reperfusion over time control samples in hippocampus (195±69%, n=8), cerebellum (136±45%, n=7), and cerebral cortex (111±39%, n=6). iHSP 70 immunoreactivity (IR) was observed primarily in neurons. Ischemia also increased glial fibrillary acidic protein (GFAP) IR of astrocytes. Administration of 5 mg/kg indomethacin (i.v.), prior to ischemia attenuated the ischemia-induced increase in iHSP 70 observed in the hippocampus and cerebral cortex (89±30% and 7±30%, respectively n=5, control of the protection of pc0.05 compared to ischemia). Similarly, indomethacin administration reduced the extent of GFAP(+) IR. Indomethacin pretreatment had no apparent effect on the iHSP 70 increase in the cerebellum (186±65%, n=5, p<0.05). We conclude that indomethacin pretreatment attenuates ischemia-induced increases in iHSP 70 and GFAP in hippocampus and cerebral cortex. Supported by NIH grants HL30260, HL46558, and HL50587.

ANISOTROPY IN APPARENT DIFFUSION COEFFICIENT (ADC) IN THE EARLY HOURS FOLLOWING FOCAL CEREBRAL ISCHEMIA. A.D. Perez-Trepichio,

ANISOTROPY IN APPARENT DIFFUSION COEFFICIENT (ADC) IN THE EARLY HOURS FOLLOWING FOCAL CEREBRAL ISCHEMIA. A.D. Perez-Trepichio, A.W. Majors, Y. Wang, A.J. Furlan, T.C. Ng, S.C. Jones*. Cerebrovascular Research Laboratory, Cleveland Clinic Foundation, Cleveland OH 44195.

Diffusion-weighted imaging (DWI) has enormous potential in the early detection of brain ischemic insult. We studied the contribution of the direction of the diffusion-sensitizing gradient pulses in the ADC in rat focal cerebral ischemia. Seven Sprague-Dawley rats were anesthetized (isoflurane, N₂O, O₂) and underwent permanent direct occlusion of the right middle cerebral artery and both common carotid arteries. MR-DWI were obtained with a GE 4.7 Tmagnet (TR=1500 ms/TE=35 ms; Slice thickness 2 mm; 2 slices, b=0, 261, 586 and 1042 sec/mm²). ADC images with an acquisition window of 101 ± 33 min (mean ± sd) from stroke onset were generated. Mean ADC values (± sd) in the x (medial-lateral), y (dorsal-ventral), z (rostral-caudal) axis in the core of the hypointense area on the right ischemic cortex (RIC) and the left homologous area (LHC) are shown in the Figure (RIC vs LHC, p<0.01, n=7, RMANOVA). Expectedly, each ADC is lower on the ischemic side. The percent decreases (RIC)LHC) in a Changes in ADC during ischemia depend on the direction of the sensitizing gradient. It is possible that the z axis is particularly sensitive to the cortical columnar neuroarchitectural organization of the cerebral cortex. These results suggest that anisotropic changes of water diffusion occur in ischemia and that the utilization of ADC can better demonstrate the damaged area following focal cerebral ischemia in gray matter.

EFFECTS OF CEREBRAL ISCHEMIA ON PROSTAGLANDIN (PG)-INDUCED VASODILATION IN PIGLETS

D. Busija²⁺, F. Bari, ^{1,2} R. Errico, ¹ and T. Louis, ³ Bowman Gray Sch. of Med., Winston-Salem, NC 27157, ²Albert Szent-Györgyi Med. Univ., Szeged, Hungary H-6720, and ³East Carolina Univ. Sch. of Med., Greenville, NC 27858

Prostaglandins are important regulators of the cerebral circulation, but effects of ischemia on PG-induced dilation are unclear. We examined the effects of iloprost, a stable prostacyclin analog, and PGE2 on cerebral arterioles prior to ischemia, and 1, 2, and 4 hours following 10 minutes of total, global ischemia. Baseline arteriolar diameters in piglets were $\sim 100 \ \mu m$. Ischemia was induced by increasing intracranial pressure. Topical application of iloprost dilated arterioles by 10±0.3% at 0.1 μ g/ml and by 21±3% at 1 μ g/ml, and ischemia reduced dilation at 1 hour to $3\pm1\%$ and $8\pm1\%$ for 0.1 and 1 μ g/ml, respectively (n=6). However, arteriolar dilation returned towards normal over 2-4 hours. In contrast, PGE₂-induced dilation was unaffected by ischemia (n=6) In control animals, we found that glibenclamide, an inhibitor of ATPsensitive K+ channels (KATP), blocked arteriolar dilation to iloprost (n=6) but not PGE₂ (n=4). Finally, administration of indomethacin (5 mg/kg) prior to ischemia preserved dilation to iloprost (n=5). We conclude that transient changes in vascular reactivity to iloprost are caused by impaired KATP function following ischemia, and that reduced responsiveness to iloprost can be prevented by prior treatment with indomethacin. Supported by HL-30260, HL-46558, and HL-50587

Modulation of heat shock factor proteins by glutamate receptor antagonists in focal cerebral ischemia. <u>Stephen L. Minger*, James Geddes, Mary Holtz, Su-</u> san Craddock and L. Creed Pettigrew. Department of Neurology and Sanders-Brown Center on Aging, University of Kentucky, Lexington, KY. Heat shock proteins, molecular chaperones that function as markers of neu-

ronal stress, are induced following experimental brain injury or neurodegenerative disease. We examined whether glutamate receptor antagonists could erative disease. We examined wrighter glutantate receptor arragonists could modulate neuronal injury responses that occur in the wake of permanent focal cerebral ischemia. Male spontaneously hypertensive rats pretreated with either 30 mg/kg NBOX (i.p., 30 minutes prior).10 mg/kg CGS 19755 (i.v., 5 minutes prior) or saline were subjected to tandem common carotid and middle cerebral arterial (CCA-MCA) occlusion. After 24 hours, only CGS 19755 pretreatment significantly reduced infarct volume, whereas both NBOX or CGS treatment significantly reduced infarct volume, whereas both NBQX or CGS 19755 ameliorated cytoskeletal proteolysis and calpain activation (Minger et al., 1996. Stroke. 26, 191). In ischemic controls, expression of heat shock proteins (hsp) -72 and -32, well-characterized markers of neuronal stress, were detected only after 24 hours of CCA-MCA occlusion. Hsp72 immunoreactivity was observed in discrete neuronal populations in healthy tissue outside the infarct, with hsp32 immunoreactivity restricted to glia surrounding the infarction border. Pretreatment with either glutamate receptor antagonist, however, significantly altered the distribution and temporal expressions of both heat check proteins effect feed isothopia. pression of both heat shock proteins after focal ischemia. Large numbers of hsp72 immunoreactive neurons were now detected within the infarct after 24 hsp72 immunoreactive neurons were now detected within the infarct after 24 hours, whereas cellular hsp32 expression was induced after 6 hours and a shift from exclusively glial to mixed neuronal and glial hsp32 expression was observed after 24 hours in the infarcted cortex. These studies are among the first to report that glutamate receptor antagonism modifies both the distribution and cellular pattern of heat shock protein expression following ischemia. SERIAL DIFFUSION (DWI) AND PERFUSION MR IMAGING (PI) IN ACUTE STROKE PATIENTS DEMONSTRATES REMARKABLE VARIABILITY IN THE EVOLUTION OF TISSUE INJURY IN

LH Schwamm, AG Sorensen, W Copen, G Gonzalez, W Koroshetz*, Neurology and Radiology, Massachusetts General Hospital, Harvard Medical School, Boston MA 02114.

PI traces the entry of an intravenous bolus of contrast to non-invasively blood volume as well as kinetic characteristics related to blood flow. DWI identifies regions of lowered water diffusion occurring when ATP levels fall. PI/DWI images localize decreased perfusion and early ischemic tissue changes in acute stroke patients (Radiology 1996). The evolution of ischemia and ischemic tissue injury has been determined using these techniques in animal stroke models.

We performed serial PI/DWI and conventional MR imaging in 8 patients with presumed

embolic strokes. Each patient received up to 5 studies over the first 3 days after stroke onset. The initial scan was always performed within 3-12 hours of symptom onset and a final scan at 7 days. The studies in these patients highlight the remarkable variability and relative slowness in the evolution of clinical stroke and ischemic tissue injury. Within regions of abnormal blood flow (abnormal PI), it was common to find early ischemic tissue changes (abnormal DWI) continue to develop 12-36 hours after stroke onset (6/8 patients). In general, regions that became abnormal on DWI progressed to completed infarction, whereas regions abnormal on PI demonstrated significant variability in the progression to infarction. Improved perfusion occurred over a wide range of times during the study in some patients (5 hours-4 days), and not at all in others.

These data demonstrate that ischemic stroke can be a prolonged and dynamic process in humans. Brain regions that eventually infarct may remain normal on DWI (preserved ATP levels) for hours after stroke onset, before progressing to infarction. The MRI-defined "time window" of reversible brain injury (i.e., abnormal PI without abnormal DWI) is much longer in humans than has been published in studies of animal stroke models.

SERIAL DIFFUSION MAPPING OF SPREADING DEPRESSION LIKE

SERIAL DIFFUSION MAPPING OF SPREADING DEPRESSION LIKE DEPOLARIZATIONS IN NORMO- AND HYPERGLYCEMIC RATS T. Els. J. Röther, C. Beaulieu, A. de Crespigny, D. Kunis. M. Moseley, Lucas MRS Imaging Center, Dept. of Radiology, Stanford University Medical School, Stanford, California, USA We investigated the hypothesis, that hyperglycemia influences the initiation and propagation of spreading depression like periinfarct ischemic depolarizations (SD) in focal cerebral ischemia of rats. Rats (n=6) were rendered hyperglycemic by a single i.p. injection of streptozotocin (60mg/kg BW) 36 hours before induction of focal cerebral ischemia using the intraluminal suture model. Results of control rats (n=7) were previously published (Röther et al., JCBFM 1996;16:214-220) and re-evaluated according to a standardized protocol. The initiation and propagation of intraliminal suture moder. Results of control rats (i=2) were previously published (Röther et al., *JCBFM* 1996;16:214-220) and re-evaluated according to a standardized protocol. The initiation and propagation of remotely induced focal ischemia and periinfarct SD was monitored using ultrafast diffusion weighted MR imaging. Maps of the apparent diffusion coefficient (ADC) were calculated. SD related transient ADC decreases were followed with a temporal resolution of 12-18 sec. Hyperglycemic rats revealed a significant prolongation of the latency time between induction of ischemia and start of the ADC decrease as compared to controls (3.7±1.2 min. vs. 1.5±1.3 min.; p=0.04). The time to the maximal ADC decrease was significantly increased in hyperglycemic rats (5.1±1.8 min. vs. 2.8±0.7 min.; p=0.01). Transient ADC decreases occurred in the periinfarct tissue of both experimental groups that represent extra- / intracellular water shifts during SD. Hyperglycemic rats showed significantly faster recovery of transient ADC declines in the area adjacent to the ischemic core (4.72±1.29 min. vs. 7.3±2.66 min. in controls, p=0.026). Tissue perfusion as assessed by dynamic contrast enhanced susceptibility MRI did not reveal significant differences between the two groups. Conclusions: 1) Hyperglycemia delays the anoxic depolarization after focal ischemia and 2) supports a faster repolarization in severely mal-perfused areas indicating the increased demand of energy in the ischemic core and periinfarct tissue

DIMENSIONAL COMPLEXITY OF THE EEG IN A CASE OF SUBCORTICAL STROKE M. Molnár*a, Gy. Gácsb, J. E. Skinnerc, G. Ujvária and G. Karmosa

^aInstitute for Psychology, Hungarian Academy of Sciences, Budapest, H-1394 Hungary

bPeterfy Hospital, Budapest, Hungary

'Tott's Gap Medical Research Laboratories, Bangor, USA

The application of recently developed methods of chaos theory makes it possible to use deterministic measures to the analysis of time series such as the EEG. By these means inferences can be drawn as to the complexity of the generator producing the analyzed signal. Consequently, the functional integrity of the cortical areas where the analyzed EEG was recorded from can be assessed. The case of a 62 year old female patient is described who suffered embolism from the heart in the area of the right internal capsule and lentiform nucleus - as shown by CT scan - causing left sided faciobrachial hemiparesis. The EEG was recorded by 22 scalp electrodes in "eyes open" and "eyes closed" conditions. A low dimensional area was seen in the right parietal area the size of which changed dynamically corresponding to the different recording conditions. Conventional analysis of the EEG (power spectra) revealed no apparent slow activity in the same region. It is suggested that the observed low dimensional EEG activity was probably caused by the ischemic damage of the thalamocortical projection system on the same side. The non-linear methods of analysis may in cases be more sensitive to detect pathology than the conventionally used procedures.

581.10

INCREASED PLASMA LIPID PEROXIDATION IN PATIENTS WITH STROKE. M.C. Polidori, W. Koroshetz, B. Frei, G. Rordorf and M.F. Beal. Neurology Service, Massachusetts General Hospital, Boston, MA 02114 and Boston University, Boston, MA Cerebral ischemia followed by reperfusion, may stimulate lipid

peroxidation. We measured cholesterol ester hydroperoxides (CE-OOH) in 10 patients with lacunar stroke (6M, 4F, 76±9.7 yo) and 19 patients with large cortical infarcts (16M, 3F, 64.4±16.8 yo) diagnosed on the basis of the TOAST subtype classification system. Four plasma samples were obtained from each patient every other day. Lipid peroxidative damage was measured with a sensitive and selective HPLC assay with chemiluminescence detection. The neurological deficit was monitored in all patients with daily administration of NIH Stroke Scale and Glascow Coma Scale. We found higher levels of CE-OOH (nmol/l) in the plasma of the cortical stroke patients with respect to lacunar stroke patients at all cortical stroke patients with respect to facunar stroke patients at an timepoints. There was a strong positive correlation between the levels of lipoperoxides and the NIH Stroke Scale scores (r2=0.7, p<0.002) and a negative correlation between CE-OOH concentrations and Glascow Coma Scale scores (r2=-0.7, p<0.003), both at the 7th day from the stroke onset. Levels of plasma CE-OOH are an excellent biological marker of clinical outcome in stroke. Supported by NS108288.

Antimyoclonic effects of riluzole and benzamide in posthypoxic myoclonus. A.G. Kanthasamy, T.O. Vu, A. Tran and D.D. Truong,* Parkinson & Move. Disord. Lab., Dept. of Neurology, Univ. of California, Irvine, CA 92717.

Since neuronal overexcitation has been linked to neurological consequences in posthypoxic conditions, our previous study using nitric oxide synthase inhibitors (L-NAME and 7-nitroindazole) demonstrated that nitric oxide plays a neuromodulatory role in posthypoxic myoclonus. In the present study, to further confirm that a nitric oxide cascade is involved in posthypoxic myoclonus, compounds that intervene in upstream and downstream events of nitric oxide synthase activation, namely riluzole (glutamate release inhibitor) and benzamide (inhibitor of poly-ADP-ribosesynthetase), were tested in a cardiac arrest-induced posthypoxic animal model of myoclonus. The test compounds were administered to cardiac arrested rats and audiogenic myoclonus was quantitated for 3 hr. Riluzole (4-12 mg/kg i.p.) dose-dependently attenuated myoclonus and higher doses produced a rapid and long lasting response persisting for more than 3 hr. Preliminary histological examination of riluzole-treated animals showed decreased neuronal damage in the cortex, basal ganglia and hippocampus as compared to untreated cardiac arrested rats. Also, benzamide at 75 and 150 mg/kg, i.p. significantly (p<0.01) attenuated audiogenic myoclonus. Taken together with data showing antimyoclonic effects of several serotonergic agents, the results suggest that nitric oxide-mediated neuromodulation of serotonergic system may be involved in the pathophysiology of posthypoxic myoclonus. Further mechanistic studies underway to explore the interaction between nitrergic and serotonergic systems.

CELL DIFFERENTIATION AND MIGRATION IX

582.1

MECHANISMS OF ANTERIOR PITUITARY CELL TRANSDIFFERENTATION. S.A. DeRiemer*, Division of Biomedical Sciences, Meharry Medical College

Somatotrophs from the adult rat anterior pituitary gland transdifferentiate into mammotrophs via a dual hormone secreting mammosomatotroph intermediate. This process, which may occur in vivo during the normal pregnancy/lactation cycle of females, can be induced in vitro by addition of serum or a partially purified serum factor to FACS purified somatotrophs. Two sets of experiments have been carried out to extend these findings: 1) Characterization of other possible inducers which has identified a soluble factor released by rat pituitary and human epidermal fibroblasts and 2) Analysis of the mechanism of the phenotypic respecification which has identified changes is the pattern of tyrosine phosphorylated proteins. Methods Mixed populations of pituitary cells were prepared by percoll density gradien centrifugation of cells dissociated from adult male or female Sprague-Dawley rats Cells were cultured in serum free defined medium with or without the addition of hormones/growth factors or fibroblast condictioned medium for up to 2 weeks. The extent of transdifferentiation was assayed by immunocytochemistry or reverse hemolytic plaque assay with PRL and GH antisera (NIDDK). Western blots were probed with anti-phosphotyrosine antibodies to monitor phosphorylation Results: Mixed cultures had previously been shown to have a lower response to serum than FACS purified cells. Panning to remove fibroblasts prior to plating increased the response to serum. Fibroblast conditioned medium could substitute for serum addition and human epidermal fibroblast conditioned medium was as effective as medium conditioned by pituitary fibroblasts. Incubation with 10% horse serum or fibroblast conditioned medium for 15 min. -24 hrs induced increased tyrosine phosphorylation of at least two proteins of Mr. 75 kd and 56 kd. Supported by RCMI (5-G12-RR03032); MBRS (2-SO6-GM-08037); and MRCE (HRD-92-55157.

A MORPHOLOGICAL AND BIOCHEMICAL CHARACTERISATION OF PITUITARY ADENYLATE CYCLASE ACTIVATING PEPTIDE (PACAP) INDUCED NEURONAL DIFFERENTIATION OF PC12 CELLS A. P. Barrie, G. Ballantyne, J. N. Brown and J. M. Allen*
Division of Biochemistry and Molecular Biology, Clasgow
University, Glasgow G12 8QQ, U.K.

When exposed to Nerve Growth Factor (NGF) PC12 cells differentiate into a sympathetic neuronal phenotype and have been used to map in detail the NGF induced MAP kinase cascade.

Receptors for PACAP have been found on these cells, and we find that a low concentration of PACAP (5nM) induces the cells to differentiate into

a neuronal phenotype distinct from that of NGF. In morphological studies, TRITC-phalloidin staining of actin filaments, shows that whereas NGF treated cell neurites have many branches and filopodia the PACAP treatment results in longer, less

branched neurites with fewer filopodia.
Western blotting shows that PACAP unlike NGF does not induce

expression of the growth cone protein, GAP-43.

The effect of PACAP on MAP kinase activation was measured and compared to the response of NGF. PACAP (5nM) causes a prompt increase in MAP kinase activity which remains elevated for at least 1 hr after stimulation. In contrast to NGF, the PACAP response is independent of ras, and comparable stimulations are seen in ras negative and wild type PC12 cells. The effects of various kinase inhibitors on the PACAP stimulation will be shown.

Supported by grants from the Wolfson and Wellcome Trusts.

CONNEXIN43 TRANSFECTION DELAYS NEURONAL DIFFERENTIATION OF PC12 CELLS. A.F. Andrade-Rozental, R. Rozental, M. Urban, M. El-Sabban and D.C. Spray. Dept. Neurosci., A. Einstein Coll. Med., Bronx, NY 10461, Inst. Biophys. "Carlos Chagas Filho", Fed. Univ. Rio de Janeiro, Brazil.

We have shown that there is a reciprocal relationship between electrotonic coupling via gap junctions and expression of neuronal phenotype during differentiation (Dev. Biol. 167: 350, 1995). However, whether this temporal relation implies functional connection remained to be determined. To investigate this relationship, we have used PC12 cells, a rat pheochromocytoma cell line which can differentiate into neurons. Specifically, we evaluated whether constitutive expression of Cx43, a Cx-type expressed in immature neuroblasts (see Rozental et al.), prevents the differentiation of PC12 cells treated with NGF (50 ng/ml). We have used molecular biological immunocytochemical and electrophysiological techniques. Clonal sublines were established from the parental population. Among the clones selected, we have concentrated on two termed "D" and "J". The "D" clone expressed low incidence of dye coupling (LY; 20%) and g_i (200 -2000 pS). By contrast "J" clone was virtually uncoupled and fully differentiated; this clone when transfected with Cx43 ("J"-Cx43; 60% coupled by LY) did not undergo pronounced differentiation. We show an inverse relationship between differentiation and strength of coupling such as "J" clones "D" clones >>> stably transfected "J"-Cx43. These results support the hypothesis that intercellular coupling modulates neuronal differentiation.

582.5

IDENTIFICATION AND CLONING OF GENES REGULATED BY NERVE GROWTH FACTOR M. Grønborg, M. Lauritzen* and S. Gammeltoft, Dep. of Biochemical Chemistry, Glostrup Hospital, DK-2600 Glostrup

Nerve Growth Factor (NGF) induces growth arrest and neurite outgrowth in PC12 rat pheochromocytoma cells, whereas other growth factors such as Epidermal Growth Factor (EGF) and Insulin-like Growth Factors (IGFs) support survival and stimulate growth. NGF-induced genes includes the immediate early genes (IEGs), which encode transcription factors like c-fos, NGF-IA, NGF-IB and c-myc. The products of the IEGs are thought to be involved in regulating expression of genes, which are associated with the neuronal phenotype such as various neurofilaments, peripherin, GAP43 and transin. However, IEGs known to be regulated by NGF presently are also induced by EGF and IGFs indicating. that although they are essential, they are not sufficient for neuronal differentiation. In order to identify new early genes involved in neuronal differentiation, we have analyzed gene expression in PC12 cells before and after 2 hr of NGF stimulation by differential PCR-display. A total of 10 bands potentially representing NGFregulated mRNAs have been observed. These have been cloned and sequenced and represents both known genes encoding thrombospondin, the LDL receptor and cytokeratin in addition to sequences with unknown functions. Characterization of expression pattern of the unknown sequences and their functional significance during neuronal differentiation are in progress

PROTHROMBIN SYNTHESIS IN HUMAN NEURONS IS REGULATED BY RETINOIC ACID. <u>V.B. Mahajan, D.D. Cunningham*</u>. Dept. of Microbiology and Molecular Genetics, University of California, Irvine CA 92717.

In neuronal culture systems thrombin influences growth cone collapse, neurite retraction, viability and differentiation while thrombin inhibitors reduce synapse elimination and cell migration. Although prothrombin mRNA has been detected in the CNS, it remains uncertain whether an endogenous, regulated source of thrombin protein is available in the brain to activate thrombin receptors. In this study, prothrombin synthesis was demonstrated in cultured human retinoblasts (Ad12Her10) and in a human neuroblastoma (SK-N-SH) cell line. Antiprothrombin antibody was incubated with conditioned medium from cells labeled labeled with [35]-methionine and [35]-cysteine. Following SDS-PAGE of immunoprecipitates, a 72 kD band was detected by autoradiography. This band corresponded to the molecular weight of prothrombin and an identical band isolated from human liver cells (HepG2). Furthermore, the 72 kD band was specifically eliminated when excess, unlabeled prothrombin was added to conditioned medium. To exclude the possibility that the band was a complex formed by serum-derived thrombin with labeled thrombin inhibitors, hirudin was added to the conditioned medium; hirudin is a potent inhibitor of thrombin and prevents the formation of thrombin complexes. Even with hirudin treatment, the 72 kD band remained intact. To investigate the regulation of prothrombin synthesis and secretion, factors important during neurodevelopment were screened. Interestingly, application of retinoic acid caused a rapid time and dose dependent decrease in prothrombin synthesis and secretion. Recognized as a potent regulatory and differentiating factor during development, retinoic acid mediates effects opposite to those of thrombin such as neurite extension. Thus, brain-synthesized prothrombin may serve as a developmentally regulated source of thrombin in the nervous system. (Supported by NIH Grant AG 00583)

582.4

EXPRESSION OF UBIQUITIN GENES IN PC12H CELLS INDUCED BY NGF TREATMENT.

R. Ohtani-Kaneko*, K. Takada(1), M. Asahara(2), K. Kakuta(3), M. Hara, M. ligo, K. Ohkawa(1), H. Yokosawa(4), K. Hirata. Dept. of Anatomy, St. Mariannna Unix Sch. of Med., Kawasaki, Japan 216. Faculty of Pharmacological Science. Hokkaido Univ. Sapporo, Japan.

Ubiquitin is a highly conserved 76 amino acid protein, functioning in a variety of cellular activities. Recently, ubiquitin has been suggested to be involved in neuronal differentiation. Takada et al. (*94) showed that levels of high molecular weight (HMW) ubiquitin-protein conjugates were increased in PC12h cells after NGF treatment and that inhibition and promotion of neurite outgrowth resulted in blockade and induction, respectively, of HMW ubiquitin-conjugates. Furthermore, we found that the level of monoubiquitin was decreased and that of multi-ubiquitin chains was increased in water-soluble nuclear extract of NGF-treated PC12h cells. All these results suggested the possibility that ubiquitination, making multi-ubiquitin chains on target proteins to form HMW ubiquitin-protein conjugates, was induced by

In the present study, we investigated effects of NGF on gene expression of ubiquitin. Ubiquitin genes have been cloned in various species which are divided into three types depending on the number of repeated ubiquitin. We compared NGF-induced changes in expression of these three ubiquitin genes by Northern hybridization, using an porcine ubiquitin coding region probe.

EFFECTS OF BONE MARROW STROMAL CELLS ON NEURONAL DIFFERENTIATION OF NEUROBLASTOMA CELLS. L. H. So, K. O. Lai, N. Y. Ip and M. F. Leung*. Dept. of Biology, Hong Kong Univ. of Science & Technology, Hong Kong.

Science & Technology, Hong Kong.

Bone marrow stromal cells have been shown to play an important role in the proliferation and differentiation of hemopoietic cells. The effect of bone marrow stromal cells on the growth regulation of other cell types is not clear. In human, it has been shown that malignant neuroblastoma cells can metastasize into bone marrow. The neuroblastoma cells isolated from the affected bone marrow can attach to the stromal cell layer to grow and extend neurite outgrowth. To study the effects of bone marrow stromal cells on the growth and differentiation of neuroblastoma, we have isolated bone marrow stromal cells from cultured bone marrow of Phase-bright cell bodies and neurite extensions leukemia patients. typical of neuronal cells were observed in PC-12 and IMR-32 cells after treatment with either conditioned medium or cellular protein extracts of the bone marrow stromal cells. Co-culture of bone marrow stromal cells and neuroblastoma NG108-15 cells also resulted in neuronal phenotype. A stromal cell line developed by mutageniting the primary stromal cells with N-methyl-N'-noitrosoguanidine resulted in a more pronounced effect in inducing neuronal differentiation. Our findings suggest that in addition to their roles in hemopoietic cells development, bone marrow stromal cells may also affect neuronal differentiation.

Neural Crest Derived Frontonasal Mesenchymal Cells May Provide Retinoid Signals To Regulate Olfactory Pathway Morphogenesis. Raymond M. Anchan* and Anthony-Samuel LaMantia. Department of Neurobiology, Duke University Medical Center, Durham, N.C. 27710

Our recent observations suggest that the olfactory epithelium and bulbs do not develop in PAX-6 mutant (small eye-sey/sey) mice due to a failure in retinoic acid (RA) signaling from the frontonasal mesenchyme. This embryonic mesenchyme is a mosaic of cells including a GAP-43 immunoreactive subpopulation that is absent in sey/sey mice. We asked whether these GAP-43 immunoreactive cells have characteristics that imply they are neural crest derived and produce RA. If so, their absence in sey/sey mice may reflect migratory anomalies of the cranial neural crest reported previously in sey/sey rats (Matsuo et al., (1993) Nat Genet: 299). Frontonasal mesenchymal cells in the mouse express neural crest associated molecules including the low-affinity nerve growth factor receptor, cellular RA binding proteins, and NCAM. Some of these antigens are coexpressed by GAP-43 immunoreactive cells. Using an RA responsive indicator cell assay, we correlated RA signaling with populations of GAP-43 immunoreactive cells. Next we compared RA responses elicited by explants of various mesenchymal regions from different age embryos. At early stages RA signals generated by mesenchyme from either the branchial arch or optic stalk are at least 2X greater than that from frontonasal mesenchyme. At later stages RA signaling from the olfactory epithelium mesenchyme increases. Thus changes in RA signaling coincide with cranial crest migration. It is therefore possible that a distinct population of neural crest derived RA-producing cells migrates to the frontonasal mesenchyme and subsequently provides local RA signals essential for olfactory pathway formation. Supported by NRSA 1 F32 DC00244-01 to R.M.A. and NIH HD29178 to A-S.L.

THE UBIQUITOUS EXPRESSION OF A PERLECAN- RELATED PROTEOGLYCAN WHICH ACTIVATES FIBROBLAST GROWTH FACTORS IN NEURAL DEVELOPMENT. S. J. Joseph., M. D. Ford, V. Nurcombe* and U. Greferath. Dept. of Anatomy and Cell Biology, Univ. of Melbourne, Parkville, Vic. Australia, 3052.

A heparan sulfate proteoglycan, called BRM (brain regulated molecule), was isolated through its ability to potentiate neural cell responses to either FGF-1 or FGF-2 (1). Amino acid sequence of the core protein of BRM is homologous to the large proteoglycan, Perlecan . However, BRM has a significantly smaller core protein of 45 kD as compared to the 400 kD Perlecan core. Analysis of an embryonic mouse neuroepithelial cell line indicated that a 96 bp cDNA probe homologous to both Perlecan and BRM detected Perlecan at 12.6 kb, as well as novel transcripts at 6.5 and 3.5 kilobases. The latter species appears by virtue of its size and abundance to be the BRM transcript. In addition polyclonal antibody specific to BRM detects a single species at 290 kD, whereas a polyclonal anti-Perlecan antibodies cross-reacts with BRM as well as detecting native Perlecan and three other variant isoforms. These results suggest that Perlecan variants exist on an RNA and protein level, and that BRM is a homologous variant of Perlecan which is differentially glycosylated in a manner that confers specific function. Immunohistochemical studies reveal a differential staining pattern for BRM as compared to Perlecan; BRM is highly expressed in neuroepithelial cells through-out embryonic neural development. The BRM antibody also detects a single species in various tissues of adult mouse, and has recently been shown to have a broad distribution. This ubiquitous proteoglycan is found in the extracellular matrix of several tissues and is expressed by various epithelial cells . This proteoglycan, which plays a critical role in neural development appears to have a function in many different tissues. 1. Nurcombe et al. (1993). Science, **260**, 103-106.

THE ROLE OF CALCIUM CHANNELS IN CHROMAFFIN CELL DIFFERENTIATION BY LOW FREQUENCY MAGNETIC FIELD STIMULATION (LFM).

Consuelo Morgado-Valle¹, Leticia Verdugo-Díaz² and René Drucker-Colín^{1,2}*

¹ Instituto de Fisiología Celular, and ²Departamento de Fisiología, Facultad de Medicina, UNAM, México.

Adrenal chromaffin cells have an endocrine phenotype and secrete adrenaline. When these cells are cultured with nerve growth factor (NGF) differentiate into a neural-like phenotype with a conspicuos neurite-outgrowth and preferentially secrete noradrenaline. The exact mechanism of differentiation is not well understood, since multiple events are involved. One such mechanism may be related to calcium movements across the plasma membrane, through voltage-dependent calcium channels. In this work we have studied the role of calcium channels in the differentiation process, while comparing NGF and LFM field stimulation as the differentiation stimuli. Chromaffin cells were cultured in the presence or absence of NGF or under LFM stimulation of 7 Gauss during 7 days (4hrs/day). We tested L and N type calcium channel blockers (Nifedipine 0.1 and 0.3 uM, o-conotoxin 0.5 and 1 uM) and L- type channel agonist Bay K 8644 (5 uM), to determine the participation of calcium ions in the mechanism of neurite outgrowth. In another set of experiments we tested K+ induced noradrenaline release in nifedipine cultured chromaffin cells, with or without LFM field stimulation.. Our results indicate that there is a significant inhibition of neurite outgrowth when cells are cultured in presence of chronic nifedipine only in cells stimulated with LFM field (p<0.001). ω -conotoxin a potent Ntype calcium channel blocker did not affect neurite outgrowth of cells neither in the presence of NGF or LFM High K+ induced noradrenaline release, is not affected when cells are cultured in the presence of chronic nifedipine with NGF, LFM field or both. These results suggest that L-type Ca²⁺ channels are involved in chromaffin cell differentiation induced by LFM stimulation

EFFECTS OF ACETYLCHOLINE AND ITS ANALOGUES ON MEDIAL SEPTAL NEURONS IN PRIMARY CULTURE, R.L. Kenigsberg* and Y. Hong, Centre de Beacheach, Pediatrians, Having Ste Justine, Mostéal, Quidhea, Canada, MATLICS.

Recherche Pediatrique, Hôpital Ste-Justine, Montréal, Québec, Canada H3T 1C5
Although forebrain cholinergic cell loss has been documented to be associated with learning and memory deficits in aging and Alzheimer's disease, cholinergic replacement therapy does not appear to sufficiently prevent intellectual decline. Furthermore, the roles of acetylcholine (ACh) in the basal forebrain are actually not fully understood. We thus recently examined the effects of ACh and its analogues on the survival and differentiation of cholinergic and GABAergic neurons derived from an important basal forebrain cholinergic nucleus, the medial septal nucleus from fetal rat brain (embryonic day 17) maintained in culture. After the cells were cultured in serum-free chemically-defined media in the presence of muscarinic or nicotinic receptor agonists or antagonists for 7 days, the cells were harvested and choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) activities measured by radiometric assays. We found ACh to markedly elevate both ChAT and GAD activities without altering general cell survival. These effects were mimicked by bethanechol (muscarinic agonist) as well as nicotine. Surprisingly, pirenzepine (M₁ antagonist) also increased ChAT activity, although it did not affect GAD. When glia were eliminated from these cultures by treating with the antimitotic 5fluorodeoxyuridine (10.5), the cholinergic response was significantly attenuated while the induction of GAD was unaltered. Furthermore, exclusion of glia from these cultures did not change the effects of pirenzepine on either neuronal cell type. These results suggest that activation of cholinergic receptors (both M and N) up-regulates medial septal neuronal maturation and glia are implicated in these effects on cholinergic but not GABAergic neurons. The pirenzepine-induced increase in ChAT implicates a differential distribution of M1 receptors on some groups of cells, such as the GABAergic neurons for example. (Supported by MRC of Canada)

PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING VI

583.1

THE EFFECT OF VARIOUS SUBSTRATES ON THE ORIENT ATION OF CHICK DRG NEURONS IN APPLIED ELECTRIC FIELDS M. E. McGinnis*, B. A. Green, E. L. Tuck, O. Jarrett, and B. Livingston. Biology Department, Spelman College, Atlanta, GA 30314-4399.

The orientation of neurons in an electric field is a well described phenomenon. Neurites usually extend toward the cathode of an electric field, resulting in asymmetric distribution of neurites. The purpose of this study is to compare the behavior of neurons grown on various substrates when placed in electric fields. Adhesion and motility of growth cones are highly dependent on both specific and nonspecific characteristics of the substrate molecules. Redistribution of the cellular receptors for these molecules in electric fields may be one of the mechanisms for the galvanic effect.

DRG neurons from 8.5 - 9 day old chick embryos were isolated and seeded onto glass coverslips coated with various substrates such as glass, collagen type IV, laminin, fibronectin, and matrigel. These coverslips were then placed in chambers for applying uniform DC electric fields. The orientation, length, and point of origin of neurites were determined from high resolution video images. Quantitative measures of orientation were determined for a range of field strengths (1.0 mV/mm – 100 mV/mm). The resulting dose response curves were compared for the different substrates.

CLONING OF HUMAN NEOGENIN ANIG SUPERFAMILY PROTEIN RELATED TO DCC

J. Vielmetter*, X. Cheng, K. Yamakawa, R. Lane, F. Miskevich, J. Korenberg, and W. J. Dreyer, Division of Biology, California Institute of Technology, Pasadena, CA 91125

Neogenin is a cell surface protein belonging to the immunoglobulin (Ig) superfamily and was first characterized in the chicken. Neogenin's structure deduced from its amino acid sequence is predicted to be composed of four Ig domains followed by six fibronectin type III (FnIII) domains, a transmembrane domain and an alternatively spliced intracellular domain. Neogenin shares this domain structure with the human tumor suppressor molecule Deleted in Colorectal Carcinoma (DCC). Neogenin also shares a significant sequence similarity with DCC, and both molecules therefore define a subgroup of the Ig superfamily proteins that is structurally distinct from other Ig molecules such as for example N-CAM, Ng-CAM, Bravo/Nr-CAM, axonin, and contactin. Expression studies in the chicken embryo using a monoclonal antibody against chicken neogenin have revealed that neogenin expression correlates with the onset of neuronal differentiation. We have now cloned the human homolog of neogenin. Human and chicken neogenin share over 90% similarity and are both alternatively spliced in identical regions in the intracellular domain. Human neogenin is expressed in the human embryonic and adult brain and maps to the chromosomal location 15q22.2-22.3 as determined by fluorescence insitu hybridization (FISH). Neogenin maps within a gene locus associated with the Bardet Biedel syndrom, a genetic defect causing severe mental retardation, obesity and several other defects. The cloning and sequencing of human neogenin not only proves that neogenin and DCC are paralogs and not species homologs but also allows to determine genetic linkage of neogenin to known or Supported by NEI yet unknown genetic defects in humans.

NEUROTRIMIN, A MEMBER OF A SUBFAMILY OF NEURAL CELL ADHESION MOLECULES, PROMOTES HOMOPHILIC ADHESION AND NEURONAL OUTGROWTH. O. D. Gil*, G. Zanazzi, A. Struyk, and J. Salzer. Department of Cell Biology, New York University Medical Center, New York, NY 10016.

Several cell adhesion molecules of the immunoglobulin superfamily (IgCAMs) have been implicated in the development of specific neuronal projections. Neurotrimin (Ntm) is a member of a differentially expressed subfamily of IgCAMs that also includes the opioid binding cell adhesion molecule (OBCAM) and the limbic system associated membrane protein (LAMP). These proteins have three Ig-like domains and are attached to the plasma membrane via a glycosyl-phosphatidylinositol (GPI) anchor. To characterize the function of Ntm, we generated a soluble recombinant chimera in which Ntm is fused to a human Fc domain (Ntm-Fc). We also expressed a myc-tagged Ntm in CHO cells and observed that Ntm accumulates at sites of cell contact. In addition, Ntm-Fc binds to Ntm expressing CHO cells but not to control cells transfected with the vector alone. Ntm-Fc also binds extensively to E-15 dorsal root ganglia (DRGs) primary neurons which express high levels of Ntm but not to E-21 superior cervical ganglia (SCGs) primary neurons which do not. The binding of Ntm-Fc to DRGs and to transfected cells was eliminated by pretreating the cells with PIPLC which specifically cleaves GPI anchored proteins. In neurite outgrowth assays, Ntm-Fc absorbed onto a nitrocellulose coated coverslip promotes the outgrowth of DRGs but not of SCGs. Taken together, these results indicate that Ntm mediates homophilic interactions that may be important in the formation of specific neuronal circuits by promoting adhesion and neurite outgrowth. Supported by NIH grant RO1NS33165 and NS26001.

RECOMBINANT FRAGMENTS OF Ng-CAM WITH DIFFERENT EFFECTS ON CNS AND PNS NEURITE GROWTH. S. Chikramane, D.R. Friedlander and M. Grumet*. Depts. of Pharmacology and Neurology, NYU Medical Center, 550 First Avenue, New York, NY 10016.

Ng-CAM is a cell adhesion molecule expressed on neurons and Schwann cells and is one of the most potent promoters of neurite growth in culture. To assess its potential use as a promoter of axonal regeneration in vivo, specific domains of Ng-CAM were analyzed for their stimulation of neurite outgrowth in vitro. Recombinant baculovirus proteins representing the 6 lg domains (Ng16), the first 3 lg domains (Ng13) and the 80 kD subunit that normally occurs in vivo (Ng80) were produced and isolated without denaturation. Dissociated DRG neurons extended processes on substrates coated with each recombinant protein. Neurite extension was highest for Ng16 and at levels comparable with purified Ng-CAM. Second was Ng13, and Ng80 was third. These observations suggest that the 135 kD is more potent than the 80 kD subunit in stimulating neurite outgrowth of DRG cells.

Dissociated neurons from CNS tissues including spinal cord, retina and optic tectum extended neurites on substrates coated with Ng16 at levels comparable to those elicited by purified Ng-CAM. In contrast, minimal neurite extension was observed on Ng80, and intermediate levels on Ng13. When explants or reaggregates were placed on these substrates, numerous very long processes extended on Ng16. In sharp contrast, only few, short neurites extended on Ng13 or Ng80, although a meshwork of neurites was present at the explant boundary. Given that dissociated cells extend neurites on Ng13, the lack of neuritic extension from explants on Ng13 may be due to a choice by neuronal growth cones to remain in the cellular environment rather than extending on Ng13. The superior activity of Ng16 suggests that multiple domains in Ng-CAM are required for optimal stimulation of neurite outgrowth and that Ng16 may have application as a promoter of axonal regeneration. Supported by NSF IBN-9310731 and Acorda Therapeutics, Inc.

TERMINAL FIELD FORMATION BY THE DORSAL P NEURON IN THE LEECH: THE ROLE OF INTERACTIONS BETWEEN SIBLING PROCESSES

H. Wang* and E. R. Macagno, Dept. Biol. Sci., Columbia University, New York, NY 10027

University, New York, NY 10027

Pressure-sensitive (P) neurons in the leech CNS form terminal fields in the body wall of the animal early in embryogenesis. A characteristic of these terminal fields is that individual branches form arbors that do not overlap with one another, a property that has been called self-avoidance. For dorsal P neurons, the major field comprises six subfields that are established by six first-order branches and the higher order branches they produce. Time-lapse studies indicate that sibling processes from neighboring subfields have frequent but transient overlaps that last several minutes, the overlapping processes then retracting. Analysis of 3D images obtained from serial optical sections using a deconvolution algorithm suggest that at least half of such overlaps do not include direct contact of the respective processes. However, mechanically detaching parts of the terminal field induces the invasion of the processes from neighboring subfields within 24 hours. We are currently using a laser microbeam to investigate this further. These results imply that there are very strong growth-inhibiting interactions between sibling processes, but that they do not necessarily involve direct contact. Supported by NIH Grant NS-34545.

IDENTIFICATION OF A PEPTIDE SEQUENCE INVOLVED IN HOMOPHILIC BINDING IN THE NEURAL CELL ADHESION MOLECULE L1. X. Zhao* and C.-H. Siu. Banting and Best Department of Medical Research, University of Toronto, Toronto, Ontario M5G 1L6, Canada.

L1 plays an important role in neural development and has been implicated in X-linked hydrocephalus and related neurological diseases. The extracellular region of L1 contains six immunoglobulin (Ig)-like domains, followed by five fibronectin type III-like repeats. We have previously demonstrated that the second Ig-like domain (Ig2) of L1 contains both homophilic binding and neuritogenic activities (Zhao and Siu, 1995, J. Biol. Chem. 270:29413-29421). Two Hydrocephalus/-MASA syndrome-related mutations (R184Q and H210Q) have been mapped to the Ig2 domain. The R184Q mutation led to a complete loss mapped to the 1g2 domain. The R184Q mutation led to a complete loss of both homophilic binding and neuritogenic activities, while the H210Q mutation resulted only in a partial loss, suggesting that Arg184 might play an important role in L1 homophilic binding. Oligopeptides corresponding to sequences flanking Arg184 were synthesized, and their effects on L1 homophilic binding and neuritogenic activities were examined. The peptide PL1-2A corresponding to the sequence between His-178 and Gly-191 inhibited both Ig2 fusion protein and L1-mediated cell-cell adhesion, while several control peptides and peptide analogs cell-cell adhesion, while several control peptides and peptide analogs had no effect. When neural retinal cells were cultured on a monolayer of L1 transfected cells, peptide PL1-2A was a potent inhibitor of L1-induced neurite outgrowth. Taken together, these results indicate that the homophilic binding site of L1 resides within the sequence HIKQDERVTMGQNG of Ig2.

A NOVEL CADHERIN-RELATED MOLECULE IS REGULATED BY SYNAPTIC ACTIVITY AND IN THE DEVELOPING CENTRAL NERVOUS SYSTEM. K.I. Andreasson*, C.A.Barnes and P. F. Worley. Depts of Neurology and Neuroscience, Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205 and Depts of Neurology, Psychology and Div. of Neural Systems, Univ. of Arizona, Tuscon, AZ 84724.

We have utilized differential cDNA cloning to identify genes rapidly regulated by activity in the rat hippocampus. One of the cDNAs isolated has an open reading frame that encodes a predicted protein which shows some homology to the family of protocadherins. mRNA for IEG8 is regulated by a variety of activity-dependent stimuli. Two hours following a maximal electroconvulsive seizure, expression is induced by Northern analysis and *in situ* hybridization in the dentate gyrus and amygdala, peaks at four hours and is back to baseline at 12 hours. In chronically implanted animals, IEG8 mRNA was strongly induced in hippocampal granule cells ipsilateral to high frequency LTP stimulus two hours after stimulation. This induction requency LTP stimulus two nours are stimulation. This induction was eliminated with pretreatment of the animals with MK-801. During fetal and post natal development, IEG59 is expressed in discrete patterns in developing cortex and spinal cord. These findings suggest a role of cadherin-related molecules in synaptic and developmental plasticity. Supported by MH53608, AG9219, and HD00992.

AND STEREOTYPED PATHFINDING BY

SELECTIVE AND STEREOTYPED PATHFINDING BY A DEVELOPMENTALLY MALLEABLE MOTOR NEURON IN THE MEDICINAL LEECH. J. Jellies*, T.M. Harik and B.M. Campbell. Department of Biological Sciences, Western Michigan University, Kalamazoo, MI 49008.

The neurons innervating the heart tubes in *Hirudo medicinalis* (the heart excitors, HE's) exhibit transient overgrowth of peripheral projections followed by loss of supernumerary terminals after innervation of the heart. The emerging heart muscle exerts a local influence over the peripheral terminals as well as a retrograde influence on recruitment of the HE's into the central motor circuit divine phythrips activity. on recruitment of the HE's into the central motor circuit driving rhythmic activity (Jellies & Kopp, *Invert. Neurosci.* 1995, 1:145). As initial steps to investigate the heart-derived signals and their influence over HE development we have; 1) used intracellular labeling and immunohistology to examine the earliest choices of HE growth cones in situ, 2) confirmed the specificity of heart innervation by retrograde Dil tracing, and 3) begun to examine HE outgrowth using muscle-neuron co-culture. In the heart system, pathfinding and target selection seem to be distinct events and the initial overgrowth of HE axons is not random. HE growth cones all exit an existing pathway at stereotyped locations and pioneer longitudinally-directed arbors, including those that will be subsequently lost. Just after emergence of the heart, the HE makes very close appositions with it as evidenced by retrogradely labeled HEs following Dil injections into the embryonic heart. In adults, focal Dil injections into heart muscle in 14 segments labeled the HEs (and no other neurons) in 8 ganglia and no neurons in 6. Thus, while ultimate target choice is highly specific, the specificity of initial outgrowth does <u>not</u> play a direct role in target recognition or choice. Innervation of the outgrowth does not pay a direct role in target recognition or choice, innervation of the heart arises not from target-dependent pruning of random projections but rather by virtue of a heart-derived influence that induces a distinct change in phenotype. We have begun to examine this by culturing denervated segments of heart muscle with CNS ganglia. To date, both heart muscle and regenerating axons adhere well to a polylysine substrate on glass, survive in L-15 medium, and exhibit profuse outgrowth after 3-5 days. We are currently examining this outgrowth for evidence of reinnervation and specificity. Supported by NSF 9609701 and a Sloan Foundation Fellowship (JI).

DIFFERENTIATION OF NEURONAL PROCESSES DETERMINES THEIR RESPONSE TO INHIBITORY ENVIRONMENTAL CUES. A. Shibata*, M.V. Wright, and S.B. Kater. + Department of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523; [†]Department of Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, Utah, 84132.

University of Utah School of Medicine, Salt Lake City, Utah, 84132.

Mammalian CNS neurons develop into polarized cells with distinct axonal and dendritic processes. Hippocampal neurons initiate undifferentiated minor processes, one of which becomes the axon (1.5 days in vitro (DIV)) and the rest mature into dendrites (after 4 DIV) (Dotti et al, 1988). Axons and dendrites are unique in many ways including their morphology, cytoskeletal organization, and mRNA content. Studies on other cell types have shown that inhibitory cues found on oligodendrocytes inhibit axonal outgrowth. The response of dendrites and axons from the same neuron to oligodendrocytes is not known. Based on the intrinsic differences between axonal and dendritic processes, we tested the idea that dendrites and axons of rat hippocampal neurons behave differently when encountering oligodendrocytes.

neurons behave differently when encountering oligodendrocytes.

We have developed a high resolution culture system in which primary cultured oligodendrocytes (and control 3T3 fibroblasts) are presented to the growth cones of minor processes, dendrites, or axons of rat hippocampal neurons. Our studies show that axonal growth cones of neurons cultured for 1 or 6 DIV collapse upon encountering oligodendrocytes 88.5% (n= 26) and 93.3% (n=15), within an average of 12.2 min and 9.1 min, respectively. Similarly, the majority (65.4%, n=26) of minor processes collapse within ~11.3 min. after contacting oligodendrocytes. In contrast, processes compise within ~11.3 min. after confacting offgodendrocytes. In contast, only 17.4% (n=23) of MAP2-positive dendrites of hippocampal neurons cultured for 6 DIV collapse when encountering oligodendrocytes. These results suggest that as minor processes differentiate into axons and dendrites, dendrites appear to become unresponsive to oligodendrocytes whereas axons remain sensitive to this inhibitory environmental cue. Taken together the data reveal several previously unrecognized points including that collapse of growth conces following contact with oligodendrocytes is by no means an obligatory reaction.

DOES GRASSHOPPER SEMAPHORIN-1 INDUCE COLLAPSE OF NEURONAL GROWTH CONES IN VIVO? J. Wong, W. Yu. and T. P. O'Connor. Dept. of Anatomy and Zoology, Vancouver B.C., Canada. Members of the semaphorin/collapsin family of transmembrane and Members of the semaphorin/collapsin family of transmembrane and secreted proteins have been proposed to act as growth cone guidance signals in vertebrates and invertebrates. A number of studies have indicated that these molecules inhibit neurite outgrowth and stimulate growth cone collapse in vitro. Whether these molecules have similar functions in vivo is uncertain. We have used the developing grasshopper limb bud (Shistocerca gregaria) to study the effects of grasshopper semaphorin 1 (G-Sema 1) in vivo. In the embryonic limb-bud, neurons of the subgenual organ (SGO) contact and fasciculate with a pathway pioneered by the Ti 1 neurons. Elimination of the Ti 1 pathway by heat shock (Klose and Bentley 1989, Science 245:897) causes arrest of the proximal extension of the SGO growth cones. Since semaphorins have been implicated to have growth inhibitory properties, we examined the possibility that the arrest/collapse of the SGO axon is mediated by a band of epithelial cells expressing G-Sema 1. Using fluorescence double-labeling, we demonstrate that SGO axons extend into the band of Glabeling, we demonstrate that SGO axons extend into the band of G-Sema I expression by 42% of embryonic development. At this stage, the SGO neurons are typically within filopodial reach of the Ti I neurons. In the absence of the Ti I pathway, the proximal extension of the SGO growth cones is arrested within the band of G-Sema I expression. In addition, the growth cones do not display a collapsed phenotype, and typically extend to the proximal border of the G-Sema I expressing band. These results suggest that inhibition of growth cone extension in vivo may be due to signals other than growth cone collapse.

CORTICO-EFFERENT PLASTICITY IS REGULATED BY MYELIN ASSOCIATED NEURITE GROWTH INHIBITORS IN THE ADULT RAT. G.L. Tillotson*, M.K. Schulz, L. Schnell and M.E. Schwab. Dept. of Neurology, Hines VA Hospital/Loyola University, Maywood, IL, 60153, USA; Dept. of Anatomy and Cell Biology, Odense University, Denmark and Brain Research Institute, University of Zürich, Zürich, Switzerland.

Following unilateral cortical lesions in neonatal rats, the spared unablated hemisphere is known to demonstrate remarkable neuroanatomic plasticity in corticoefferent connectivity. This same type of structural plasticity is not seen after similar lesions in adult rats. One possibility for the lack of such a plastic response in the adult CNS may be the presence of myelin associated growth inhibitory proteins NI 35/250. These proteins have been found to play a crucial role in preventing fibers from regenerating in adult rat spinal cord lesions (Schnell et al., Nature 367:170, 1994). The aim of this study was to determine if blocking these inhibitory proteins by the application of the specific antibody IN-1 would enhance cortico-efferent plasticity in adult rats

6-8 week old Lewis rats underwent unilateral aspiration lesion of the sensorimotor cortex. Animals were then treated with either IN-1 antibody or a control antibody. After a survival period of 12 weeks, the spared sensorimotor cortex was stereotaxically injected with the anterograde tracer biotinylated dextrane amine (BDA), and cortico-efferent fibers were analyzed. We found an increase in BDA positive fibers crossing the midline at the level of the corpus callosum in animals treated with IN-1 antibody, as compared to controls. These results indicate that myelin associated neurite inhibitory proteins play an important role in regulation of cortico-efferent plasticity in the adult. Fiber distributions at subcortical levels including thalamic and pontine nuclei are currently under investigation

MYELIN-ASSOCIATED GLYCOPROTEIN (MAG) INDUCES COLLAPSE OF HIPPOCAMPAL AXONAL GROWTH CONES. S.B. Kater, P. E. Braunt, S. David~, L. McKerracher~ and A. Shibata# Dept. of Neurobiology and Anat., Univ. of Utah Sch. of Med., Salt Lake City, UT; +Dept. of Biochm, McGill Univ., Montreal CA; ~Cent. for Res.in Neuroscience, Montreal Gen. Hosp.Res. Inst., Montreal, CA; #Dept. Anat. and Neurobiology, Colorado State Univ., Ft. Collins, CO.
Both during development and in the mature mammalian CNS the outgrowth of

Both during development and in the mature mammalian CNS the outgrowth of neuronal processes is constrained by inhibitory environmental signals. Molecules on oligodendrocytes appear in large part responsible for the inability of adult axons to regrow following injury. Two molecules associated with oligodendrocytes are reported to contribute to inhibitory activity: NI-35 NI-250 and MAG. The native and recombinant MAG have been shown to inhibit neurite initiation in vitro (McKerracher et al, 1994, Mukhopadhyay et al. 1994) although its ability to inhibit elongating growth cones is unknown. Previously, inhibitory activity of particular substrates has been determined by their ability to elicit growth cone collapse in vitro. In a preceding abstract we employed a growth cone collapse assay to shown that axonal growth cones are inhibited by oligodendrocytes which expresses MAG and GAL-C in culture. abstract we employed a growth cone contapse assay to shown that axonal growth cones are inhibited by oligodendrocytes which expresses MAG and GAL-C in culture. Here, we utilized the same growth cone collapse assay to evaluate the inhibitory activity of MAG to cultured CNS neurons. Axonal growth cones of rat hippocampal pyramidal neurons were presented the with MAG coated polystyrene beads. Our results reveal that MAG coated beads (N=15) cause 10X more collapse (73%) of axonal growth cones than do uncoated beads (N=14). During collapse the growth axona grown cone brand outlocated ecast (N=1). During conapse the grown cone becomes phase dark, losing an average of 80% of its lamellipodial surface area within approximately 25+/- 0.5min after initial contact. Unlike NI-35, this collapse response is not mediated through signaling by intracellular Ca2+. Axonal growth cones loaded with Fura-2AM showed no significant changes in intracellular Ca2+ levels preceding, during, or following the time of collapse (N=6). These results show that MAG, as a substrate bound molecule, inhibits axonal elongation of CNS neurons tin a manner similar to oligodendrocyte -induced collapse.

LESION-INDUCED SPROUTING OF CORTICOSPINAL FIBERS IS STRONGLY INCREASED IN MYELIN-FREE RAT SPINAL CORD. Michaela Thallmair, Patrik Vanek, Martin E. Schwab and Josef P.Kapfhammer* Brain Research Institute, University of Zürich, August-Forel-Str. 1, 8029 Zürich, Switzerland, § Department of Anatomy, University of Freiburg, Germany

Myelin and its associated neurite growth inhibitors play a crucial role in preventing fibers from regeneration in adult rats (Schnell et al., Nature 367:170, 1994). An inverse regional distribution of myelin and GAP-43, a putative marker for axonal growth and plasticity, has been described in normal rats (Kapfhammer and Schwab, JCN 340:194, 1994); Regions in the mature CNS which are only lightly myelinated retain a high expression of GAP-43 and in parallel high capacity for sprouting and regrowth. After suppression of myelination in the lumbar spinal cord by neonatal Xirradiation GAP-43 expression was strongly enhanced (Kapfhammer and Schwab, Eur. J. Neurosci, 6:403, 1994). This increased GAP-43 expression correlated with enhanced sprouting of primary afferents after dorsal root lesions (Schwegler et al., J.Neurosci.15:2756, 1995). These findings suggest that myelin and its inhibitors

restrict sprouting and structural plasticity in the adult CNS.

To further investigate the physiological role of myelin-associated neurite growth inhibitors unilateral pyramidotomies were performed in X-irradiated and normal 3-4wk old rats. Sprouting was investigated using WGA-HRP or BDA. We found that collateral sprouting of unlesioned fibers was increased in the myelin-free parts of the spinal cord as compared to controls: Fibers crossed the midline and terminated in the denervated area. We obtained similar results in pilot-experiments in which specific antibodies (IN-1) against the neurite growth inhibitors NI-35/250 were applied. This supports our hypothesis that myelin and its associated neurite growth inhibitors contribute to the restriction of collateral sprouting and plasticity in the adult CNS.

Two new chondroitin sulfate proteoglycans (CSPGs) in the developing chick nervous system W. Halften; Dept. of Neurobiology; University of Pittsburgh

Two CSPGs were detected in the developing chick brain. Immunostaining shows that the 4C10 antigen is present in CNS but not PNS. The antigen is particularly abundant in white matter of the spinal cord, axonal tracts in the brain, the optic fiber layer and the plexiform layers of the retina. The antigen is present in embryonic but not in posthatched chick CNS. In western blots, the 4C10 antigen appears as a broad smear with a MW of 300kD. After chondroitinase treatment, the immunoreactiv sinal decreases to two sharp bands with molecular weights of 90 and 45kD. Under reducing conditions, a single band at 45kD is detected, suggesting that the core protein of the CSPG exists as a disulfide-linked dimer with subunits of 45kD. The second CSPG (1D10 antigen) has a very restricted distribution. It is abundant in the optic nerve from the optic disc to the onset of the diencephalon, on the surface of macrophages and in the amnion. The expression of the antigen is restricted to only embryonic tissues. The molecular weight of the antigen is 300kD with a core protein of 70kD.

THE DSD-1 EPITOPE REPRESENTS A CHONDROITIN SULFATE MODIFICATION EXPRESSED ON DSD-1-PROTEOGLYCAN AND PROMOTES NEURITE OUTGROWTH OF HIPPOCAMPAL NEURONS

PROMOTES NEURITE OUTGROWTH OF HIPPOCAMPAL NEURONS

Mandl, and A. Faissner⁴, Dept. for Neurobiology, University of Heidelberg,
D-69120 Heidelberg, Germany; ¹ Dept. of Biochemistry, Kobe
Pharmaceutical University, J-658 Kobe, Japan
The chondroitin sulfate (CS) proteoglycan (PG) DSD-1-PG has been
identified with the monoclonal antibody (mAb) 473HD. The results of
digestion experiments with glycosaminoglycan (Gag) lyases suggest that
the epitope of the mAb 473HD is composed of a dermatan (DS)/CS C
hybrid (designated DSD-1 for germatan gulfate dependent). DSD-1-PG is
expressed by immature glial cell in a developmentally regulated fashion and hybrid (designated DSD-1 for dermatan sulfate dependent). DSD-1-PG is expressd by immature glial cell in a developmentally regulated fashion and Western blot analysis of mouse brain extracts documented maximal expression during early postnatal stages. When coated as substrate, DSD-1-PG promotes neurite outgrowth of embryonic day 18 (E18) hippocampal neurons and the DSD-1 epitope is required for this effect, which suggests functional relevance of a particular Gag in neuronal process outgrowth. Therefore, the structural characterization of DSD-1 was attempted. Pharmacological agents which block sulfation abolished the epitope in the DSD-1-PG expressing oligodendroglial Oli-neu precursor cell line, as shown by immunoprecipitation and immunocytochemistry. This conclusion is consistent with competition ELISAs using several CS of similar structure, but distinct sulfate composition. In order to advance the purification of the DSD-1 structure, various CS carbohydrates were enriched on a 473HD DSD-1 structure, various CS carbohydrates were enriched on a 473HD column by affinity chromatography. The retained eluates proved functionally active, while the flow through was not efficient in a neurite outgrowth test. These results indicate that the DSD-1 Gag by itself might be a neurite outgrowth promoting factor. (Supported by DFG (Fa 159/5-1,2,3) and H.-L.-Schilling Stiftung)

DYNAMIC MICROTUBULES ARE REQUIRED FOR GROWTH CONE TURNING TO AVOID SUBSTRATUM-BOUND CHONDROITIN SULFATE PROTEOGLYCAN. J. F. Challacombe*, D. M. Snow and P. C. Letourneau. The University of Minnesota, Dept. of Cell Biology and Neuroanatomy, Minneapolis, MN 55455.

We previously examined the organization of actin filaments (AFs) and stable we previously examined in organization to actin materias (viz.) and states and dynamic microtibules (MTs) in growth cones turning to avoid substratum-bound chondroitin sulfate proteoglycan (CSPG) (Challacombe, et al., 1995, Soc. Neurosci. Abs. 21:13). Using cytochalasin B, we showed that intact AF bundles are necessary for the MT reorientation that is crucial for growth cone

In the present study, E9-11 chick sensory neurons were exposed to low concentrations of the MT-specific drugs taxol and vinblastine (VB) to reduce MT dynamics. Growth cones migrating on fibronectin were monitored by phase contrast video microscopy as approached and contacted CSPG borders. In contrast to controls, taxol- and VB-treated growth cones did not turn to avoid CSPG. Instead, they either stopped, retracted or sidestepped laterally along the border. When the drugs were washed out, normal turning behavior resumed. Following fixation of recorded growth cones, dynamic and stable MTs were immunofluorescently labeled and imaged with a laser scanning confocal microscope. In untreated growth cones and in those exposed to MT-specific drugs that were subsequently washed out, dynamic MT ends extended farther toward the leading margin than stable MTs. In growth cones exposed to low concentrations of taxol and VB, the labeling of dynamic and stable MTs were nearly coincident, and dynamic MT ends did not extend as far distally. Based on the effects of taxol and VB on growth cone behavior, and on the organization of dynamic and stable MTs, we propose that dynamic extension of MT ends toward the leading edge is necessary for growth cone turning to avoid CSPG. TENASCIN/CYTOTACTIN (TN-C) EXPRESSION IN THE **GYRUS** DENTATE AFTER UNILATERAL ENTORHINAL CORTEX LESION.

T. Deller¹*, C. A. Haas¹, T. Naumann¹, A. Joester², A. Faissner², and M. Frotscher¹. Anatomical Institute, Univ. of Freiburg, F.R.G. (1), Department of Neurobiology, Univ. of Heidelberg, F.R.G. (2).

Unilateral entorhinal cortex lesion (ECL) induces a massive sprouting response in the denervated outer molecular layer of the rat dentate gyrus. Recent in vitro data suggest, that the glial derived extracellular matrix protein TN-C could be involved in these axonal growth processes. The expression of TN-C was analyzed in the dentate gyrus of adult rats 2, 6, 10, 14d, 4wks, and 6 months after ECL using immunocytochemistry and in situ hybridization. TN-C immunoreactivity increased throughout the denervated outer molecular layer by day 2, reached a maximum around day 10, and was back to control levels by 4 weeks. Using electron microscopy, single intensely TN-C-immunoreactive cells could be identified as reactive astrocytes that phagocytose degenerated terminals. In situ hybridization for TN-C mRNA revealed cellular profiles in the denervated zone, most likely astrocytes. These data suggest that glial derived TN-C is involved in axon growth in vivo and indicate that neuron-glia interactions are essential for the sprouting response after ECL (supported by the DFG).

ACTIVITY-DEPENDENT REGULATION OF NEURON-SPECIFIC GROWTH-ASSOCIATED GENES: ROLE OF PROTEOGLYCANS. W. Wang and K.E. Dow*, Dept. of Pediatrics,

Queen's University, Kingston, Ontario Canada K7L 2V7.

Excitatory amino acid (EAA) neurotransmitters have been shown to play important roles as molecular signals influencing the structure of neurons during development. We have previously provided evidence that EAA agonists induce the synthesis and release of proteoglycans (PGs) with neurite-promoting activity from fetal hippocampal neurons (Sugiura and Dow, Dev. Biol. 1994; 164:102). In the present studies, we analyzed the regulation by EAA receptor activation of the expression of the neuron-specific growth-associated genes T α 1 α -tubulin $(T\alpha 1)$, microtubule-associated protein-2 (MAP-2), growth-associated protein-43 (GAP-43) and two developmentally regulated PGs, cerebroglycan and neurocan, and correlated this expressions. sion with morphological indicators of growth.

Primary cultures prepared from E19 rat hippocampal neurons were exposed to glutamate (100 μ M) for 5 minutes and mRNA levels were quantitated by competitive reverse transcription polymerase chain reaction (RT-PCR). Neurite growth was also quantitated by morphological assessment at different time points following exposure. Exposure to glutamate resulted in 2.0-, 1.5- and 2.2-fold increases in Tα1, MAP-2 and GAP-43 mRNA levels respectively, which peaked at between 8 and 12 hours following exposure (p < 0.05 vs control) and increases in neurite growth measured at 48 hours following exposure (p < 0.05 vs control). Heparin inhibited the glutamate-induced induction of Tα1, MAP-2 and GAP-43 mRNA expression and ineurite growth when added to culture medium at 25 µg/ml following glutamate exposure while chondroitin sulphate had no effect. Exposure to glutamate produced a 3.6-fold increase in mRNA levels of the integral membrane heparan sulphate PG (HSPG) cerebroglycan (p < 0.05 vs control) while mRNA levels of neurocan, a developmentally regulated CSPG, were not significantly altered. These studies suggest that neuronal HSPGs regulated by activation of EAA receptors may mediate autocrine growth responses.

583.18

OKADAIC ACID AFFECTS SUBSTRATE DEPENDENT NEURITE OUTGROWTH J.Viti* and C. Lagenaur. Dept. of Neurobiology, Univ. of Pittsburgh Pittsburgh PA 15261.

Phosphorylation events within the neuron are thought to be important mediators of neurite outgrowth. We have shown that okadaic acid, a serine/threonine phosphatase inhibitor, can significantly alter neurite outgrowth and morphology. When okadaic acid is added to mouse cerebellar granule cells cultured on purified N-CAM, growth cones disappear and the cells produce multiple processes along the cell body. The effect is substrate-dependent. Using time-lapse cinematography, okadaic acid was shown to cause complete neurite retraction within 20 min. Over the course of several hours, new neurite-like structures(without growth cones) formed around the cell body. Vesicular transport was seen along these processes. Double labeling experiments showed that these processes induced by okadaic acid have a core of tubulin in their center surrounded by a thin sheet of actin This is the same pattern seen in normal neurites. Also, taxol, a drug which stabilizes tubulin and does not allow it to depolymerize, causes these neurons to produce multiple processes around their cell bodies. These experiments suggest that the structures induced by okadaic acid are neurites and that okadaic acid is somehow acting on the polymerization state of tubulin. KN-62, an inhibitor of calcium/calmodulin protein kinase II, was shown to attenuate the effect of okadaic acid, suggesting that this class of kinases might be might play a role in substrate dependent neurite formation. Supported by NIH grant EY 05308

DIFFERENTIAL RESPONSE OF NEURONS TO TENASCIN SPLICE VARIANTS, S. Meiners, S. Y. Ho, and H. M. Geller*. Dept. of Pharmacology, Robert Wood Johnson Medical School-UMDNJ, Piscataway, NJ

Tenascin-C (TN) is a 6-armed multidomain extracellular matrix (ECM) protein which has been implicated in the regulation of neurite outgrowth both during development and after injury. Each arm of TN is a polypeptide of 220-320 kDa, depending on species and alternative RNA splicing. The largest (HxB.L) and smallest splice (HxB.S) variants differ in that the former contains several fibronectin type III (FN-III) domains which are missing in the latter. We compared neurite outgrowth on baby hamster kidney (BHK) cells transfected with HxB.L or HxB.S (the generous gift of Dr. Harold P. Erickson, Duke University of Medicine). Outgrowth was significantly higher on cells transfected with HxB.L and significantly lower on cells transfected with HxB.S in comparison to outgrowth on control, untransfected cells.

To determine whether the splice variants exerted their effects in a substratebound or a soluble form, HxB.L and HxB.S were isolated from the conditioned media of transfected cells, added to cultures of untransfected BHK cells for $24\ hr$, and then washed away. Under these conditions, both HxB.L and HxB.S bound to the surface of BHK cells and promoted neurite outgrowth, although bound HxB.L was a somewhat better growth substrate than bound HxB.S. In contrast, soluble HxB.S inhibited neurite outgrowth in a dose-dependent manner, whereas soluble HxB.L failed to inhibit outgrowth. These results indicate that the effect of TN on neurite outgrowth is a function of splice variants, as well as the form of conformation of those splice variants.

This work was supported by NIH Grant NS 25168 to H. G. and by NJ Governor's Council Advanced Research Fellowship P2MF6C to S. M.

Isolation of a Drosophila Eph receptor protein tyrosine kinase expressed in the nervous system. A.L. Scully¹, M. McKeown², R. Dyck*¹, J.B. Thomas¹, 1) Molecular Neurobiology Laboratory, 2) Molecular Biology & Virology Laboratory, The Salk Institute, P.O. Box 85800, San Diego, CA 92186.

We are examining the role of receptor protein tyrosine kinases (RPTKs) in axon pathfinding during development. In order to identify *Drosophila* RPTKs which may be involved in neuronal pathfinding, we carried out a PCR-based screen using degenerate primers to two conserved regions within the kinase domain of RPTKs (Lai and Lemke, Neuron 6, 691-704). One of the kinase domains identified in the screen shows similarity to the Eph subfamily member Cek7 and its homologues in rat and mouse, Rek7 and Bsk. Sequence analysis of a full-length cDNA confirms that it shares significant sequence homology to Cek7/Rek7/Bsk within both the kinase and extracellular domains. We have thus tentatively named this *Drosophila* RPTK Dek. Rek7 has been shown to be expressed on subsets of developing axons within the brain and eye (Winslow et al., Neuron 14, 973-81). In situ hybridization of dek cDNA probes to embryos reveals a pattern of expression restricted to the CNS during the period of axon elongation. We are currently screening for mutations in dek and expressing dominant negative forms of the protein in order to elucidate its possible role in axon guidance. Supp. by NIH grants and a Pew Scholars Award from Pew Memorial Trusts to John B. Thomas.

ELF1 SPECIFICALLY REPELS TEMPORAL RETINAL AXONS IN VITRO. GC Friedman*1, T McLaughlin1, MJ Hansen2, M Nakamoto2, DDM O'Leary1, JG Flanagan2. 1 The Salk Institute, La Jolla, CA; ²Harvard Med Sch, Boston, MA.

Elf1, a ligand for the Eph receptor tyrosine kinase Mek4, is expressed in a gradient along the rostrocaudal axis of the chick optic tectum during formation of the retinotectal map, being high caudally and low rostrally. Mek4 is expressed in a complementary gradient along the temporal/nasal axis of the retina, suggesting that the interaction of Elf1 and Mek4 is involved in targeting of retinal axons to their appropriate termination zones in the tectum.

We have used the membrane stripe assay to investigate the response of retinal axons to membranes containing Elf1. Membranes from 293T cells transfected with an Elf1 expression construct and untransfected 293T cells were pooled 2 days after transfection, and membrane fractions were collected from each. In second set of experiments tectal membranes were collected from E10 embryos which had been infected at st. 11 and st. 14 with a replication competent retrovirus containing the Elf1 cDNA. Exogenous expression of Elf1 was confirmed with a Mek4-AP fusion protein; transfected 293T cells and infected rostral tecta had high levels of Mek4-AP staining which was absent in the untransfected 293T cells and uninfected rostral tectum. Alternating lanes of transfected and untransfected 293T cell membranes were prepared and explants from temporal or nasal retina were laid down perpendicular to the lanes. Temporal axons showed a strong growth preference for the untransfected lanes, whereas nasal axons showed no preference. Temporal axons also showed a preference for membranes from uninfected rostral tecta versus Elf1 infected rostral membranes, whereas nasal axons again showed no preference. In addition, temporal axons grew well but showed no preference when given a choice between membranes from Elf1 infected rostral tecta and normal caudal tecta, indicating that Elf1 acts as a repulsive molecule. These results support the hypothesis that Elf1 can regulate the topographic targeting of retinal axons in vivo. (Supported by R01 EY07025, R01 HD29417, F32 EY06550)

584.5

NT-3 and trkC expression patterns suggest their role in the development of corticospinal axon projections to the brainstem and spinal cord. K.T. Yee.* and D.D.M. O'Leary Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037. Previous work has demonstrated that layer 5 neurons innervate midbrain, hindbrain and spinal target sites by collateral branches that develop de novo from primary corticospinal axons. Unidentified target-derived diffusible tropic activities appear to regulate this innervation process. Recent evidence has shown that the neurotrophic factor NT-3 can enhance corticospinal axon sprouting in the spinal cord during development or following lesion and can induce turning of cortical neurites in vitro. Given these findings, we were interested in examining whether NT-3 may be involved in mediating target innervation in the corticospinal pathway during normal development.

To address this, we have assessed the expression of NT-3 and the

corticospinal pathway during normal development.

To address this, we have assessed the expression of NT-3 and the distribution of its primary receptor, trkC, within the developing corticospinal pathway in rats using in situ hybridiztion for NT-3 mRNA (gifts from W. D. Snider and K.-F. Lee) and immunohistochemistry against trkC (Santa Cruz Biotech, Inc.). At postnatal day 1, NT-3 mRNA is expressed by several corticospinal target areas (eg., superior colliculus, dorsal column nuclei and spinal intermediate gray) and trkC is expressed along the corticospinal tract and by layer V cortical neurons. A proportion of the trkC expressing cells could be labeled following injections into the pyramidal decussation indicating that at least some corticospinal neurons are trkC positive. Since the spatial and temporal expression of NT-3 and are trkC positive. Since the spatial and temporal expression of NT-3 and its primary receptor correlates with corticospinal target innervation, it is possible that NT-3 may play a role in directing collateral extension into certain target regions of corticospinal axons and/or may be important for their maintenance into maturity

TYROSINE PHOSPHORYLATION OF NILE/L1 BY THE EPH KINASE CEK5 A.H. Zisch, L.D. Chong, W.B. Stallcup, J.A. Holash, H. Voshol", M. Schachner" and E.B. Pasquale*. The Burnham Institute, La Jolia CA 92037, USA and *ETH, CH-8093 Zurich, Switzerland.

NILE/L1 is a transmembrane cell adhesion molecule of the immunoglobulin superfamily that has been implicated in neurite outgrowth and neuronal migration. Binding of ligands to NILE/L1 results in the activation of intracellular signaling pathways, in some cases through the association of NILE/L1 with kinases. For example, NILE/L1 interacts in cis with FGF receptor 1 and complexes with cytoplasmic serine/threonine kinases. Recently it was demonstrated that crosslinking of Ng-CAM, the putative chick homologue of NILE/L1, on the surface of chick primary neurons leads to tyrosine phosphorylation of the cytoplasmic domain. Here we address whether NILE/L1 is a target of receptor tyrosine kinases of the Eph tamily, since the Eph kinases are highly expressed during development of the nervous system. In vitro kinase assays showed that the recombinant cytoplasmic domain of L1/NILE is phosphorylated on tyrosine by the Eph kinase Cek5. To determine LI/NILE is phosphorylated on tyrosine by the Eph kinase Cets. To determine whether NILE/L1 can be phosphorylated on tyrosine by CekS in vivo, we used the rat glioblastoma cell line B28 stably transfected with NILE/L1. Additional transient transfection with Cek5 cDNA led to expression of Cek5 in its phosphorylated. presumably activated form. Biochemical analysis of NILE/L1 by immunoprecipitation and immunoblotting with anti-phosphotyrosine antibodies revealed tyrosine phosphorylation of NILE/L1 in Cek5 transfected cells, but not in control transfectants. As NILE/L1 and Eph kinases co-localise in certain regions of the brain, such as the molecular layer of the cerebellum, we hypothesis crosstalk between NILE/L1 and Eph kinases also occurs in vivo and aiters phosphorylation-dependent functional properties of NILE/L1. CONTROL OF TOPOGRAPHIC RETINAL AXON MAPPING BY ELF-1 M. Nakamoto, H-J. Cheng, A.D. Bergemann, M.J. Hansen, D. Van Vactor*, C.H. oon, and J.G. Flanagan. Dept. of Cell Biology, Harvard Medical School, Boston,

Topographically organized patterns of neuronal connectivity are found throughout the nervous system. The retinotectal projection is a particularly wellstudied system, in which temporal retinal axons project to anterior tectum and nasal retinal axons to posterior tectum. As first proposed by Sperry in the 1940s, these topographic maps are believed to be established by complementary labels in gradients across pre- and post-synaptic fields. However, molecular identification of the position-specific labels had long been an elusive goal.

the position-specific facels raid only occid in clusive goal.

Recently, we cloned ELF-1 (Eph ligand family-1), detected as a ligand for Eph family receptor tyrosine kinases, by a novel method using a soluble receptor with an alkaline phosphatase tag to detect the ligand in embryos. We find matching gradients in RNA expression for ELF-1 in the tectum, and its receptor Mek4 in the retina. Ligand-receptor interactions detected with alkaline phosphatase fusions of ELF-1 and Mek4 also reveal gradients, and provide direct evidence for molecular complementarity of gradients in reciprocal fields. To address the function of ELF-1 in vivo, we altered the expression pattern of ELF-1 in the developing tectum using retrovirus vector. In those embryos, patches of ectopic ELF-1 expression are superimposed on the endogenous anterior-posterior gradient. Temporal retinal axons avoid the ectopic ELF-1 patches and project to positions more anterior than th topographically normal locations, while nasal axons do not show obvious topographicary formal rocations, while hasha axons our off show working abnormality. These results indicate that ELF-1 and Mek4 could be topographic mapping molecules of the type predicted by Sperry.

ELF-1 is a member of Eph ligand family, which consists of at least seven members, and current experiments indicate other Eph ligands have comparable roles

in establishing the spatial pattern of the nervous system (Supported by HD29417 and DK45580)

EFFECTS OF NEUROTROPHINS ON RETINAL NEURONAL OUTGROWTH, J. Atkinson*, M.K. Panni and R.D. Lund. Dept. of

OUTGROWTH. J. Alkinson*, M.K. Panni and R.D. Lund, Dept. of Pathology, Inst. of Ophthalmology, 11-43 Bath Street, London, ECIV 9EL, UK. Developing retinal axons follow a stereotypical course towards subcortical visual centres, which on arrival they must recognise. Transplantation studies suggest that local substrate cues close to the surface of the brainstem and diffusible factors emanting from the target region are important. One group of diffusible factors is the neurotrophin family, whose receptors have been found to be expressed in both the developing as well as the adult visual system.

In this study, both brain derived neurotrophic factor (BDNF), and neurotrophin 4 (NT4) were shown to promote neurite outgrowth from embryonic mouse retinal explants (E12-14) grown on laminin in vitro, whereas neurotrophin 3 (NT3) showed no neurite promoting activity. When cultured in the presence of an antimitotic agent such as cytosine arabinoside, outgrowth was unaffected in BDNF-containing cultures but was significantly diminished in NT4-containing cultures, suggesting a possible role for glial cells in NT4-promoted retinal outgrowth. We have cotransplanted embryonic mouse retina (E12-14) with specific

possible role for glial cells in NT4-promoted retinal outgrowth. We have cotransplanted embryonic mouse retina (E12-14) with specific neurotrophin producing fibroblasts into the cortex of neonatal rats in order to assess a role of these molecules in developing retinal ganglion cells. Transplanted retinal ganglion cells showed directed outgrowth towards BDNF producing fibroblasts but not towards NT3 and NT4 producing fibroblasts. These results indicate that NT3 does not seem to promote retinal outgrowth, NT4-induced outgrowth is likely to be dependent on the environment whereas BDNF is equally effective in vitro and in vivo in promoting and environment retinal axons.

and in vivo in promoting and guiding developing retinal axons.

We would like to thank Dr. F.H.Gage for providing the BDNF producing fibroblasts and Dr. E.Arenas for providing the NT3 and NT4 producing fibroblasts. This work was supported by Action Research and MRC, UK.

THE NEUROTROPHINS NT-3, BDNF AND NT-4, BUT NOT NGF, ENHANCE NEURITE TURNING IN AN APPLIED ELECTRIC FIELD. <u>L. Sangster, R. Stewart, R. Zietlow and C.D. McCaig*</u> Department of Biomedical Sciences, University of Aberdeen, Aberdeen, Scotland, AB9 1AS.

Endogenous electric fields exist in embryos and their disruption results in abnormal neuronal development. In vitro applied electric fields affect the direction of neurite growth. Neurotrophins also influence nerve growth, both in vivo and in vitro. Electric fields and neurotrophins coexist in embryos thus interactions may occur. We have investigated whether or not neurotrophins can alter the effects of an applied electric field on neurite growth.

A d.c. electric field (150mV/mm) applied for 5 hours affected the growth of disaggregated cells from the neural tube of stage 20 Xenopus laevis. Neurites responded to the field by turning to grow cathodally. Exposure of neurites to neurotrophin 3 (NT-3; 50ng/ml), brain-derived neurotrophic factor (BDNF; 100ng/ml) or neurotrophin 4 (NT-4, 100ng/ml) lowered the threshold field strength necessary to elicit a turning response to 100mV/mm. Only BDNF enhanced cathodal orientation at 150mV/mm, with neurites turning three times as far as in the field alone. Concomitant exposure of neurites to BDNF and NT-3 did not enhance the effect of either alone. Neurite turning did not occur in a field of 100mV/mm in the presence of 50ng/ml nerve growth factor (NGF).

Xenopus growth cones release acetylcholine (ACh) spontaneously. This is enhanced by both NT-3 and BDNF. Nicotinic ACh receptor antagonists abolish field-induced cathodal turning, thus ACh release may be crucial for this response. These neurotrophins may enhance cathodal turning because they enhance ACh release.

Interactions in vivo, where neurotrophins and electric fields coexist, would increase the efficacy of endogenous electric fields as modulators of nerve growth. Supported by the Wellcome Trust.

OVEREXPRESSION OF C-SRC AND N-SRC IN THE DEVELOPING XENOPUS RETINA DIFFERENTIALLY IMPAIRS AXONOGENESIS T. L. Worley* and C. E. Holt. University of California, San Diego, Dept. of Biology 0366 La Jolla CA 92093.

L. Worley¹ and C. E. Holt. University of California, San Diego, Dept. of Biology 0366, La Jolla, CA 92093.

To study the role of the cytoplasmic tyrosine kinases c-src and its neuronal splice-form n-src in the development of the vertebrate retina and retinal projection, Xenopus retinal precursors were transfected in vivo with constructs expressing pp60°-Src, pp60°-Src, or constitutively active mutants of c-src and n-src. The phosphotyrosine labeling intensity of all transfected retinal cells was significantly increased compared to untransfected cells, (indicating that the constructs were enzymatically active), and was greatest in cells expressing deregulated n-src. A comparison of the distribution of transfected retinal cell types showed that the expression of either the c-src or n-src deregulated constructs inhibited photoreceptor differentiation to similar degrees, but did not influence other retinal cell fate decisions. In contrast, the extension of axons from transfected retinal ganglion cell and forebrain neurons was severely impaired in cells expressing deregulated n-src. Transfected retinal axons that did elongate were observed in whole-mount preparations to correctly navigate through the contralateral optic tract to the optic tectum. These results suggest that c-src and n-src may play a similar role in photoreceptor differentiation, however; the differences observed between c-src and n-src expressing cells in the intensity of phosphotyrosine labeling and the ability of transfected neurons to extend axons indicates that c-src and n-src also have distinct activites in vivo. This work was supported by NIH #NS23780 (C.E.H.).

GENETIC ANALYSIS OF *Netrin* GENES IN DROSOPHILA: NETRIN-A AND NETRIN-B FUNCTION TO GUIDE COMMISSURAL AXONS IN THE CNS AND MOTOR AXONS IN THE PERIPHERY. Jennifer L. Doyle, Kevin J. Mitchell. Barry S. Dickson, and Corey S. Goodman*. HHMI, Dept. of Molec. and Cell Biology. Univ. of California, Berkeley 94720.

The vertebrate netrins (netrin-1 and 2) and their *C. elegans* homologue

The vertebrate netrins (netrin-1 and 2) and their *C. elegans* homologue UNC-6 are bifunctional, chemotropic guidance molecules that are expressed at the ventral midline of either the spinal cord or the whole animal, respectively. In collaboration with the Tessier-Lavigne lab, we cloned two tandem *Netrin* genes in *Drosophila* (*Jonetinha* and *D-netrinB*). Both *Netrin* genes are expressed at the midline of the developing CNS, although each is also expressed by different subsets of lateral neurons. In addition, both *Netrin* genes are expressed in peripheral tissues in different subsets of muscles and patches of epidermis. We generated a small deficiency which deletes both *Netrin* genes. In embryos doubly mutant for both *Netrin* genes, the commissures are partially missing or thinner. We have been able to rescue this double mutant phenotype by expressing either Netrin-A or Netrin-B along the midline as driven by the *slit* promoter, suggesting that the function of the two genes is redundant at the midline. In the double mutant we also find striking defects in the projections of motor axons; in particular, the distal path of the intersegmental nerve (ISN) is aberrant. In order to further test the functions of the netrins, we ectopically expressed both genes using the GAL-4/UAS system of tissue-specific transcriptional activation. Pan-neural expression of either gene causes severe disruption of both CNS commissural and longitudinal tracts. Ectopic expression throughout the developing somatic musculature results in misrouting of the ISN. This genetic analysis suggests that the two Netrins function as attractants and repellents during axon guidance in both CNS and periphery in Drosophila. Supported by NIH/NRSA # T32-GMO7048-21 to JLD and NIH/NINDS #5 R01 NS18366 to CSG.

NONRECEPTOR TYROSINE KINASES pp60^{C-SRC} AND p59^{FYN} AS MEDIATORS OF AXONAL GUIDANCE IN THE DEVELOPING OLFACTORY PATHWAY. W.R. Morse, J.G. Whitesides, P. Morell*, A.-S. LaMantia and P.F. Maness. Dept. Biochemistry, Univ. North Carolina Sch. of Med., Chapel Hill, NC 27599 & Dept. Neurobiology, Duke University Sch. of Med., Durham, NC 27710.

pp60c-src and p59/m are src-family nonreceptor tyrosine kinases that are essential components of L1- and NCAM-mediated signaling pathways leading to neurite outgrowth. Immunofluorescent localization of pp60c-src, p59/m and the neural cell adhesion molecules NCAM and L1 at embryonic day 11.5 in the mouse shows their coexpression along nascent olfactory axons in the lateral cranial mesenchyme. We have examined the behavior of NCAM-immunoreactive olfactory axons in fym-minus and src/fym-minus mice as they exit the olfactory epithelium, fasciculate into a single nerve and project toward the forebrain. Mutant mice display altered axonal trajectories, as determined by the direction of growth and number of single axons and fascicles exiting the epithelium. These axons may therefore be defective in some mechanism of axon guidance or fasciculation. Nonetheless, mutant olfactory axons do ultimately reach the forebrain vesicle. Defects in axonal trajectories in src/fym doubly null mutant mice are somewhat more severe than in fymminus mice, suggesting that src and fyn can partially compensate for one another during olfactory axon outgrowth. We are currently evaluating L1 and NCAM-mediated fasciculation of axons from olfactory explants in vitro as a potential mechanism requiring src and fyn tyrosine kinases. Our current in vivo observations suggest that src and fyn contribute to axon guidance during initial assembly of the olfactory pathway. This work was supported by NIH grant NS26620.

POTENTIAL ROLES OF NETRIN-1 DURING AXONOGENISIS IN THE ZEBRAFISH EMBRYO. J. D. Lauderdale*, M.C. Halloran, N. M. Davis, and J. Y. Kuwada. Dept. Biology, Univ. Michigan, Ann Arbor, MI 48109-1048

During embryogenesis, pioneer neurons project growth cones that follow stereotyped, cell-specific pathways to reach specific, often distant, targets. These growth cones often follow extracellular directional cues. Netrin may be one such guidance cue. Netrins are secreted, laminin-related molecules. Netrin/UNC-6 acts as a bifunctional guidance cue for developing axons in the nematode (Hedgecock et al. 1990, Neuron 4:61; Wadsworth et al., 1996, Neuron 16:35). In vertebrates, explant studies have shown that chick netrin-1 can act as a chemoattractant for ventrally directed commissural axons (Serafini et al., 1994, Cell 78: 409; Kennedy et al., 1994, Cell 78:425; Shirasaki et al., 1995, Neuron 14:961) and as a chemorepellent for dorsally directed trochlear motor axons (Colamarino and Tessier-Lavigne, 1995, Cell 81:621). These data suggest that netrin-1 may act as a bifunctional guidance cue for developing axons in the embryonic vertebrate nervous system. In order to elucidate the in vivo function of netrin in vertebrates, we cloned a zebrafish homolog of chick netrin-1 and examined the relationship of netrin mRNA expression to identified growth cones and axon tracts during early axonogenisis in the zebrafish embryo. In the brain, epiphysial growth cones project ventrally along a dorsoventral stripe of cells expressing netrin in the diencephalon. In contrast, axons which form the tract of the posterior commissure, including the ventrally directed nucPC axons, extend in a region of the diencephalon bordered by cells expressing netrin. Spinal cord commissural axons extend ventrally along cells expressing netrin. In the somites, the muscle pioneer cells, an intermediate target for the primary motor neurons, express netrin. These data suggest that netrin may be involved in guiding several different types of growth cones. We are currently manipulating netrin expression in vivo and examining which growth cones respond to ectopically expressed netrin. LEECH NETRIN IS EXPRESSED IN SPECIFIC CENTRAL NEURONS AND VENTRAL MUSCLE CELLS. G. O. Aisemberg', W.-B. Gan, V. Y. Wong, T. R. Gershon and E. R. Macagno. Dept. of Biological Sciences, Columbia University, New York, NY 10027.

A member of the netrin family of axonal guidance proteins was cloned and characterized in the leech *Hirudo medicinalis*, an organism in which neuronal function and development can be addressed at the level of single, identified neurons. Leech netrin (Hm-netrin) mRNA was detected in both embryos and adults by *in situ* hybridization, in a specific subset of central neurons of the midbody, beginning at the early period of gangliogenesis. These Hm-netrin-producing neurons include the Bipolar cells, a pair of transient neurons that may be involved in marking pathways in the longitudinal connective nerves. Hm-netrin is also detected in a band of ventral muscle cells segmentally repeated along the midbody.

To further characterize this extracellular protein in the leech system, a polyclonal antibody against *E. coli*-expressed Hm-netrin was raised and affinity-purified. This antibody was used to localize the Hm-netrin protein, a putative diffusible factor, in the leech embryo.

Funded by NIH Grant #NS-34545.

IMMUNOHISTOCHEMICAL LOCALIZATION OF NETRIN-1 EXPRESSION IN THE EMBRYONIC CHICK NERVOUS SYSTEM. EXPRESSION IN THE EMBRYONIC CHICK NERVOUS SYSTEM.

Evidence suggests that netrin-1 participates in

Evidence suggests that netrin-1 participates in axon guidance mechanisms, particularly those which determine whether developing axons grow toward or away from the floor plate. Explanted, embryonic, spinal cord floor plate releases a substance(s) that acts as a chemoattractant for commissural spinal axons and a chemorepellent for trochlear motor axons. Cells engineered to express netrin-1 motior axons. Cells engineered to express netrin-1 mimic both of these effects. Moreover, netrin-1 mRNA is expressed in the floor plate *in vivo* during stages of development in which these and many other axons are extending. We prepared antinetrin-1 polyclonal antisera to study netrin-1 protein expression in the embryonic chick nervous system. Netrin-1 immunoreactivity was detected in system. Netrin-1 immunoreactivity was detected in several regions including: 1) the floor plate of the brain and spinal cord, 2) the retina, and 3) particular pathways travelled by extending axons. Notably, netrin-1 immunoreactivity was not detected in the spinal cord floor plate until after the arrival of the first commissural axons. NETRIN DEPENDENT- AND INDEPENDENT-FLOOR PLATE CHEMOATTRACTION AND CHEMOREPULSION OF DEVELOPING

NETRIN DEPENDENT. AND INDEPENDENT.FLOOR PLATE CHEMOATTRACTION AND CHEMOREPULSION OF DEVELOPING AXONS IN THE MAMMALIAN BRAIN. R. Shirasaki¹, C. Mirzayan², M. Tessier-Lavigne² and F. Murakami¹.*.¹ Dept. Biophys. Engineering, Fac. Engineering Science., Osaka Univ., Toyonaka, Osaka 560, Japan. ²Howard Hughes Medical Inst., Dept. Anatomy, UCSF. CA 94143-0452. Previous studies by our laboratories and others have shown that the floor plate (FP) attracts spinal cord, metencephalic (Met), and myelencephalic (My) alar plate (AP) axons, but repels mesencephalic (Mes) basal plate (BP) and AP axons in the rat embryo (Nature 336, 1988; Cell 81, 1995; Neuron 14, 1995; Neuron 14, 1995). They have also shown that netrin-1 attracts spinal cord and Met AP axons and repels trochlear motor axons (Cell 78, 1994; Neuron 14, 1995; Cell 81, 1995), but molecules responsible for chemoattraction and chemorepulsion of other types of axons remain largely unknown. Here we examined whether netrin-1 can mimic FP chemotropic activities toward My and Mes axons. Aggregates of netrin-1-secreting COS cells attracted both MyAP and MesAP axons in the same manner as FP explants. These axons expressed the TAG-1 glycoprotein in vitro. Together with our previous findings that Mes, My and Met commissural axons express TAG-1, these results suggest that netrin-mediated chemoattraction operates for commissural axon guidance at all these levels of the brain. Regarding FP chemorepulsion, we found that FP at all axial levels repels two types of MesBP axons: tyrosine hydroxylase-positive axons and dorsally-directed axons in the rostral MesBP (likely those that form the posterior commissure). Neither of these classes of axons was repelled by recombinant netrin-1 secreted by aggregates of transfected 293 cells, under conditions where trochlear motor axons were repelled. Together, these results suggest that, although netrin-1 can function as a common chemoattractant for ventrally-decussating CNS axons, FP chemorepulsion of MesBP axons may involve diffusible molecul

DELETED IN COLORECTAL CARCINOMAS (DCC) ENCODES A NETRIN RECEPTOR. K. Keino-Masu^{1,2}, M. Masu I, E. D. Leonardo I, L. Hinck I, and M. Tessier-Lavigne I Howard Hughes Medical Institute, Dept. of Anatomy, University of California. San Francisco, CA 94143-0452. ²Dept. of of California, San Francisco, CA 94143-0452. ²Dept. of Physiology, National Defense Medical College, Saitama, Japan. Floor plate cells at the ventral midline of the developing spinal

cord express a chemotropic factor, netrin-1, which promotes the outgrowth of commissural axons and attracts these axons *in vitro*. Netrin-1 is a homologue of the *C. elegans* protein UNC-6, which is required for circumferential migrations of axons and cells in the nematode. To investigate the mechanisms through which netrin-1 nematode. To investigate the mechanisms through which netrin-produces its actions, we analyzed two genes, deleted in colorectal carcinomas (DCC) and neogenin, which are vertebrate homologues of unc-40, a gene that is involved in unc-6 dependent migrations in C. elegans. These genes encode transmembrane proteins that are members of the immunoglobulin gene superfamily. We have found that DCC is abundantly expressed in commissural neurons in the developing rat spinal cord, and that its protein product is expressed on commissural axons and binds netrin-1. Moreover, an antibody against the extracellular portion of DCC blocks netrin-dependent against the tradectular portion of DCC blocks internependent outgrowth of commissural axons in vitro, without effect on netrin-independent outgrowth. These results implicate DCC as a receptor or a component of a receptor that mediates attraction by netrin-1. Supported by the Howard Hughes Medical Institute, the American Paralysis association, and Jane Coffin Childs fellowship.

CHANGE OF GROWTH CONE RESPONSIVENESS TO FLOOR PLATE-DERIVED CHEMOATTRACTANT AFTER CROSSING THE FLOOR PLATE. R. Katsumata. R. Shirasaki. N. Yamamoto* and F. Murakami. Dept. Biophys. Engineering, Fac. Engineering. Sci., Osaka University, Toyonaka, Osaka 560, Japan.

Murakami, Dept. Biophys. Engineering, Fac. Engineering. Sci., Osaka University, Toyonaka, Osaka 560, Japan.

A variety of ventrally decussating commissural axons in the vertebrate central nervous system are guided toward the ventral midline by floor plate (FP)-derived chemoattractant(s) (Shirasaki et al., Neuron 14, 1995; Tamada et al., Neuron 14, 1995). If the growth cones of these axons follow a concentration gradient of chemoattractant, one would expect them to stall at the FP where chemoattractant concentration is maximal. However, during development the axons continue to grow past the FP. One possible explanation for this is a change of the growth cone responsiveness to FP-derived chemoattractant during migration through the FP. A prediction from this theory is that commissural axons would show no reoriented growth toward the FP once having crossed it. Here we tested this by culturing rhombomere-1 segment from embryonic day 13 rat for 2 days in collagen gel, either in the absence or presence of an ectopic FP explant placed on one side. In control preparations, commissural axons grow beyond the midline FP from both sides. When an ectopic FP explant was cultured next to the strip on one side, the axons on that side showed reoriented growth toward the explant, demonstrating chemoattractive activity of the ectopic FP toward the ipsilateral axons. However, the axons growing from the opposite side ignored the ectopic FP. When the midline FP was removed from the strip, axons growing from the contralateral side showed reoriented growth toward the ectopic FP. Together, these results suggest that growth cones of commissural axons change their responsiveness to FP-derived chemoattractant during their migration through the FP. Such a change may account for why commissural axons are not detained at the ventral midline FP in vivo. (Supported by Grant-in-Aid from the Monbusho, Japan.)

GRADED EXPRESSION OF NETRIN PROTEIN IN THE EMBRYONIC SPINAL CORD. T.E. Kennedy*, L. Hinck*, S. Colamarino*, C. Mirzayan*, S. Faynboym*, W. Marshall*, M. Tessier-Lavigne*, ¹Howard Hughes Medical Institute, University of California, San Francisco, ¹Depts. of Anatomy, ²Biochemistry and Biophysics, SF, CA, 94143.

Gradients of molecular cues have been proposed to guide growing axons during neural development. In the embryonic spinal cord, commissural axons pioneer a circumferential pathway to the floor plate at the ventral midline. Floor plate cells secrete a factor(s) that promotes the outgrowth of these axons and attracts them in vitro. Two proteins purified from embryonic chick brain, netrin-1 and netrin-2, possess outgrowth promoting and chemotropic activity like floor plate cells. In the chick, netrin-1 mRNA is expressed at high levels in the floor plate region, whereas netrin-2 mRNA is expressed more widely in the ventral spinal cord but is absent from the floor plate. We have raised antibodies that recognize netrin-1 and netrin-2. These antibodies reveal graded distribution of netrin protein in the embryonic spinal cord during the initial period of commissural axon extension. The antibodies also block the ability of floor plate cells to promote the outgrowth of commissural axons *in vitro*. These results support the hypothesis that a gradient of netrin protein directs the growth of commissural axons to the ventral midline of the developing spinal cord.

VERTEBRATE HOMOLOGS OF C. ELEGANS UNC-5 ARE CANDIDATE NETRIN RECEPTORS. L. Hinck¹, E. D. Leonardo¹, M. Masu¹, K. Keino-Masu^{1,2}, T. Serafini^{1*} and M. Tessier-Lavigne¹ ¹Howard Hughes Medical Institute, Dept. of Anatomy, University of California, San Francisco, 94143. ²Dept. of Physiology, National Defense Medical College, Saitama, Japan.

Growth cones are guided to their targets in the embryonic nervous system

in part by diffusible attractants and repellents. Netrin-1 is a diffusible factor which acts bifunctionally to attract and to repel different classes of axons in vertebrates. Genetic analysis in C. elegans has identified a netrin-1 homolog, UNC-6, which functions in axon guidance, and a transmembrane protein, UNC-5, which is a candidate receptor for repulsive actions of UNC-6. We report the identification of two vertebrate homologs of UNC-5, termed UNC5H-1 and UNC5H-2, which, like UNC-5, possess in their extracellular domains two immunoglobulinlike domains and two thrombospondin type-1 repeats. *In situ* hybridization analysis reveals that *Unc5h-1* mRNA is expressed in the embryonic spinal cord, thalamus and cortex, whereas *Unc5h-2* mRNA is expressed in developing sensory structures including the optic cup, otic vesicle and nasal epithelium, as well as in restricted domains in the developing midbrain and diencephalon. Expression of the two UNC-5 homologs was also detected by Northern analysis in the adult, in both neural and non-neural tissues. Transfected cells expressing UNC5H-2 bind netrin-1, supporting the hypothesis that UNC5H-2 is a netrin receptor.

Supported by the Howard Hughes Medical Institute, the American Paralysis Association and a Jane Coffin Childs fellowship.

ANTIBODIES RAISED TO COLLAPSIN-1 BLOCK A SENSORY AXON REPELLENT ACTIVITY SECRETED FROM VENTRAL SPINAL CORD EXPLANTS. lain.Shepherd*, Yuling Luo and Jonathan Raper. Department of Neuroscience, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104
During embryogenesis different classes of DRG primary sensory neurons extend

Central projections to specific dorso-ventral locations in the developing spinal cord. Between E3.5 and E8.5 the pattern of projection of muscle and cutaneous central sensory afferents is identical. Initially these afferents are restricted to the dorsal funculae and then subsequently they are restricted to the dorsal cord gray matter. Only at E8.5 do muscle afferents begin to diverge from cutaneous afferents and project into ventral cord gray matter.

Previous studies have shown that ventral spinal cord explants secrete a sensory neurite repellent factor. To test whether this ventral cord repellent activity is due to collapsin-1 we have raised rabbit antibodies to recombinant chick collapsin-1 protein. These antibodies i) recognize collapsin-1 on western blots ii) block collapsin-1 function in an in vitro growth cone collapse assay iii) block the ventral spinal cord sensory neurite repellent activity.

We have also carried out a series of in vitro experiments investigating the sensitivity of muscle and cutaneous sensory growth cones to collapsin-1. We have found that growth cones of chick E7 DRG neurites are equally sensitive to collapsin-1 when cultured in NT-3 or NGF supplemented media. However in E10 DRG cultures NT-3 dependent muscle sensory neurite growth cones are partially insensitive to collapsin-1.

These results support the hypothesis that collapsin-1 helps confine central sensory afferents to the dorsal cord during early stages of embryogenesis. We suggest that initially all central sensory afferents are collapsin-1 sensitive. Only at later stages, coinciding with the onset NT-3 dependence, do muscle sensory afferents become insensitive to collapsin-1 allowing them to project into ventral cord.

This work was sponsored by grants from the NINDS and NINCDS to JAR.

585.3

IDENTIFICATION AND CHARACTERIZATION OF CHICKEN COLLAPSINS 3, 4 AND 5. Leonard Feiner, Yuling Luo*, and Jonathan A. Raper. Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia, PA

In order to achieve the exquisitely complex connectivity found in the nervous system, the axons of newly born neurons navigate unerringly to their appropriate targets. This feat is accomplished by growth cones which respond to cues in the local environment which can be permissive, attractive or repulsive. Collapsin-1 is a glycoprotein that appears to be a repulsive cue for the growth cones of dorsal root ganglion cells but not retinal ganglion cells. We have cloned the entire open reading frames of three related proteins, collapsin-3, collapsin-4 and collapsin-5 by screening an E10 chicken library with partial sequences isolated by PCR. Collapsin-3 is the chicken homolog of mouse semaphorin E, while collapsin-4 and collapsin-5 are novel family members. All of these putative proteins contain a N-terminal semaphorin domain followed by a immunoglobulin domain. Collapsin-3 and collapsin-5 appear to be secreted proteins while collapsin-4 contains a transmembrane region followed by a 100 amino acid C-terminal region with no

known homology.

We have begun to study the patterns of collapsin-3 mRNA distribution by in situ hybridization in both whole mounts and sections of chicken embryos. Collapsin-3 is expressed in dynamic patterns in the spinal cord and hindbrain as well as in non CNS tissues such as cardiac and renal primordia. Within the spinal cord, collapsin-3 is initially expressed during E3 and E4 in the roof plate, floor plate and notochord. By E6, spinal cord expression becomes restricted to a medial subpopulation of motor neurons. In the hindbrain, expression is found in the cranial ganglia of nerves V and VII and in their exit points in rhombomeres 2 and 4. We are now testing recombinant collapsin-3, 4 and 5 for collapsing activity on a variety of growth cones in culture.

IDENTIFICATION OF THE HOMOLOGUE OF CHICK COLLAPSIN-2 IN THE MOUSE. Michael J. Renzi and Jonathan A. Raper*. Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

The growth cone responds to a number of guidance cues during its complicated trek through the developing nervous system. Both attractive and repulsive in nature, these guidance cues help to assure that the appropriate connections are made between neurons and their targets. Collapsin-1 is a diffusible glycoprotein that has been shown to collapse sensory growth cones in an *in vitro* assay, suggesting that it acts as a repellent. It is a member of the semaphorin/collapsin family of proteins. Collapsin-2 is 50% identical to Collapsin-1 and contains a semaphorin

domain, an immunoglobulin domain, and a carboxy-terminal basic region.

We have identified a partial mouse cDNA 85% homologous to chick collapsin2. The 3' portion of this cDNA was isolated from an E10 mouse cDNA library.

PCR was performed on cDNA from the same age mice to identify a clone which includes the 5' region and overlaps the library clone. Together these two clones comprise 93% of the expected mouse collapsin-2 coding sequence. We are currently probing sections with a digoxigenin labeled RNA probe to determine the distribution of mouse collapsin-2 RNA during development. We are also isolating genomic clones in an effort to further characterize this molecule.

This work was sponsored by grants from the NINDS and NINCDS to JAR.

STRUCTURE-FUNCTION ANALYSIS OF THE REPELLENT AXON GUIDANCE MOLECULE COLLAPSIN-1. Adam M, Koppel* and Jonathan A. Raper. Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Axon pathfinding during development depends on both attractive and repulsive signaling cues that act upon migrating growth cones. Collapsin-1, a chick brain glycoprotein, could be such a repulsive guidance cue. Collapsin-1 induces the collapse and paralysis of sensory, but not retinal, growth cones in an *in vitro*

The protein sequence of collapsin-1 predicts several structural domains, including an amino-terminal signal sequence, a semaphorin domain followed by a C-2 type immunoglobulin loop, and a carboxy-terminal basic (positively charged) region. Another collapsin family member, collapsin-2, has identical structural domains but does not induce collapse of sensory neuronal growth cones in our functional assay.

To study the functional roles of these putative structural domains, several

deletion and chimeric (collapsin-1—collapsin-2) mutants of collapsin-1 were constructed with a carboxy terminal mye tag, cloned into a mammalian expression vector, and expressed in a mammalian cell line. These mutant proteins, detected on western blots with anti-mye and anti-collapsin-1 antibodies, were assayed for We found that 1) the carboxy-terminal basic region is not essential for activity.

2) the immunoglobulin loop is not essential for activity; 3) the collapsin-1 sequence at the amino-terminal end of the semaphorin domain is necessary for

Additional chimeric constructs are being produced to further define the regions of collapsin-1 sequence required for its activity and specificity.

A COLLAPSIN-1 BINDING PROTEIN IS EXPRESSED ON BOTH THE GROWTH CONES AND AXONS OF DRG. Hiroaki Kobayashi, Shigeru Saito*. Adam M. Koppel, and Jonathan A. Raper. Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia, PA 19104. Collapsin-1 (coll-1) is a secreted glycoprotein that is expressed in the nervous

system during development and is thought to act as a repellent guidance cue for growth cones. All cultured E7 DRG growth cones collapse in response to coll-1. At E7 in vivo, coll-1 mRNA is expressed in the dorsal gray matter of the spinal cord. It could help to confine DRG axons to the dorsal funiculi and prevent premature entry of DRG axon collaterals into the cord. The receptor for coll-1, although not yet identified, should be expressed on coll-1 sensitive DRG growth

To investigate the distribution of coll-1 receptors in vivo, a recombinant collapsin-1-alkaline phosphatase fusion protein (Coll-1-AP) was made to use as a probe. To test its specificity, DRG and retinal explants were incubated with Coll-1-AP. AP signal was observed along the entire length of DRG axons including the growth cones. Retinal growth cones do not respond to coll-1, and no staining was detected on retinal axons or growth cones. These observations suggest that the Coll-1-AP probe detects a cell surface coll-1 binding protein that could be a receptor. Specificity was further shown by the fact that excess unlabeled coll-1 competes with the binding of Coll-1-AP to DRG axons. The Coll-1-AP construct

may be useful in identifying a coll-1-receptor.

This work was sponsored by grants from the NINDS and NINCDS to JAR.

COLLAPSIN-1 DELAYS THE GROWTH OF SENSORY AFFERENTS INTO THE DORSAL SPINAL CORD. K. Sharma*, Y. Luo, J. Raper, and E. Frank, Depts. of Neurobiology, Univ. Pitt. Med. Sch., Pittsburgh, PA 15261 and Univ. Penn. Med. Sch., Philadelphia, PA 19104.

During development, sensory axons from DRG grow to the spinal cord and project rostro-caudally within the future dorsolateral funiculus for 1-2 days before they begin to sprout collaterals into the dorsal horn. What prevents these axons from growing into the dorsal horn prematurely, during this waiting period? Recently, collapsin-1 mRNA was found not only in the ventral cord, but also dorsally, near the dorsal root entry zone, at stages shortly before and during the waiting period (st 25 - 31 in chick embryos). Because collapsin-1 can block the growth of sensory axons in culture, we tested if it could delay the normal ingrowth of sensory axons when applied exogenously at the end of the waiting period.

Spinal cord explants with attached DRG were made from st 30 chick embryos, embedded in agarose, and kept in culture for 2 days. At st 30, no afferents have grown into the dorsal horn, but after 2 days in culture extensive ingrowth has occurred. Muscle spindle afferents, revealed by staining for trkC, project ventrally through the medial dorsal horn while trkA-positive afferents arborize in the lateral dorsal horn. Injection of recombinant collapsin-1 into the ventral horn at the time of culture blocked the growth of both trkA+ and trkC+ sensory collaterals into the dorsal horn for the 2 day culture period. Thus if the collapsin-1 mRNA seen in dorsal cells reflects the presence of functional protein, it could explain why sensory afferents wait.

Although the inhibitory effects of collapsin-1 on trkA+ axons was expected, we were surprised to find that trkC+ axons were similarly affected. Earlier studies reported that sensory neurons grown in NT-3, which would select for trkC+ cells, were not inhibited by semaphorin-3, the mammalian homolog of collapsin-1. A possible explanati

COLLAPSIN-1 SPECIFICALLY ARRESTS CEREBELLAR MOSSY FIBER GROWTH CONES IN VITRO. D.H. Baird*, S. Rabacchi, B. Kruk, J.M. Solowska. Dept. of Neurobiology and Anatomy, Medical College of Pennsylvania and Hahnemann Univ., Philadelphia, PA 19129.

Cerebellar granule neurons are known to specifically arrest the extension of their mossy fiber afferents (the "stop-growing signal"), but the molecular basis of this effect is unknown. To determine if members of the collapsin/semaphorin family of proteins might contribute to this growth arrest, we applied purified, recombinant collapsin proteins to cultured mossy fiber growth cones from the basilar pontine nuclei of new born mice. Pontine mossy fibers innervate the cerebellar cortex postnatally during the period when granule neurons and Purkinje cells are maturing. When added to the culture medium at 1-5 ng/ml (final), collapsin-1 interrupted neurite elongation and collapsed growth cone lamellae within 1 min. Filopodia persisted, but became static. Theses effects were observed in 15/19 growth cones that extended rapidly prior to collapsin application. Neurite retraction was observed in some case. Sometimes growth cones recovered and advanced after collapsin-1 application, but recovery was not seen until at least 2 h post collapsin-1, and recovery was faster at lower concentrations. Collapsin-2 at an effective concentration twice that of collapsin-1 had little or no effect on growth cone motility in 17 rapidly advancing growth cones. In a second type of assay, collapsins or control materials were applied to cultured mossy fibers for 40 m. The cultures were fixed, and growth cone areas were measured. Collapsin-1 at about 5 ng/ml reduced growth cone areas by 40-50%, a highly significant result. These results indicate that collapsin-1 might play a role in the pathfinding and targeting of mossy fibers, including the stop-growing signal. Collapsins were generously provided by Y. Luo and J. Raper. Supported by NS33214 and HD07467.

GENETIC ANALYSIS OF DROSOPHILA SEMAPHORIN I FUNCTION DURING GROWTH CONE GUIDANCE.

H-H. Yu, H. Araj, S. Ralls, and A.L. Kolodkin*, Dept. of Neuroscience. Johns Hopkins University School of Medicine, Baltimore, MD 21205

The semaphorins are a large family of related secreted and transmembrane proteins, several members of which are likely to function membrane proteins, several members of which are likely to function during neurodevelopment to inhibit or repel neuronal growth cones. These include the secreted proteins Semaphorin III in vertebrates and Drosophila semaphorin II, and the transmembrane protein Grasshopper Semaphorin I. Functional analysis of these semaphorins has thus far addressed the role they play in the generation of peripheral neuronal pathways, however the selective expression of these and other semaphorins in the central nervous system (CNS) suggests that semaphorins may also play a role in the establishment of central pathways.

We have undertaken a functional analysis of the transmembrane semaphorin D-sema I during embryonic neuronal development to address

semaphorin D-sema I during embryonic neuronal development to address semaphorin function in CNS development. D-sema I shares with other semaphorin function in CNS development. D-sema I shares with other semaphorins a 500 amino acid extracellular semaphorin domain, contains a single transmembrane domain, and has a small cytoplasmic domain. D-sema I is expressed in the CNS at the time when axon pathways begin forming and continues throughout embryogenesis, suggesting a role for D-sema I in the generation of CNS pathways. To gain insight into the role played by D-sema I in this process, we have taken a genetic approach, examining loss-of-function mutations in d-sema I for defects in selective fasciculation. We have also used transgenic strategies to complement these studies by ectopically expressing D-sema I on a variety of embryonic tissues. These studies will allow us to determine the role played by this transmembrane semaphorin in embryonic growth cone played by this transmembrane semaphorin in embryonic growth cone guidance

SEMAPHORIN EXPRESSION IN THE DEVELOPING MAMMALIAN BRAIN. SEMARTHORIN EAT RESIDENT IN THE VILL STATE ABOVE AND A SECOND OF Physiology Oxford OX1 3PT, UK and ²Max Planck Institute for Brain Research, Frankfurt 60528, Germany.

During development, many axons have to navigate over considerable distances and through a variety of cellular environments in order to reach their appropriate

and through a variety of cellular environments in order to reach their appropriate targets. In this endeavour, they are guided by a combination of attractive and, as is becoming increasingly apparent, repulsive cues. We have examined the expression of five members of the semaphorin family of proteins, which have been implicated in several aspects of inhibitory or repulsive guidance mechanisms.

To determine the patterns of semaphorin expression during development of the thalamocortical pathway, we performed in situ hybridizations on coronal and sagittal sections from rat brains between E15 and P7. The tissue was embedded in paraffin. cut at 10µm and processed using ³⁵S-labelled RNA probes specific for semaphorins B, C, D, F and G, as described previously (Püschel et al., 1992).

All five semaphorins were detected during this developmental period and each manifested unique expression domains, examples of which are given below. SemD

manifested unique expression domains, examples of which are given below. SemD was expressed in the basal telencephalon from the earliest ages examined (E15-E17) at a time when thalamocortical and early corticofugal fibers coestablish the internal capsule (IC). It was also transiently expressed in the thalamic reticular nucleus (E17-P2) and the PRNIC region (E17-P0). Transcripts for sem B. C, F and G were detected in the developing cortical mantle throughout embryonic development in complementary and partially overlapping patterns - but *excluding* the intermediate zone and accumulating WM, through which many long-range axons are growing. In contrast, during postnatal development, the WM was heavily labelled with probes for semF and G. In the subplate, four out the five semaphorins were detected, and each followed a distinct timecourse of expression. Taken together these results document a high degree of specificity in the spatial and temporal expression patterns of semaphorins and support their possible instructive role in axon elongation, branching and synapse formation.

CLONING AND ANALYSIS OF THREE ZEBRAFISH SEMAPHORINS. M.C. Halloran*, C.S. Yee, S.M. Severance, and J.Y. Kuwada, Dept. of Biology, Univ. of Michigan, Ann Arbor, MI 48109

The semaphorin/collapsin gene family encodes putative repulsive axon guidance molecules, including both secreted and transmembrane proteins, all of guidance molecules, including both secreted and transmembrane proteins, all of which share a conserved sema domain of about 500 amino acids (Kolodkin, 1996, Trends Cell Biol. 6:15). Several members of this family have been identified in chicken (Luo et al., 1995, Neuron 13:1131), mouse (Messersmith et al., 1995, Neuron 14:949; Puschel et al., 1995, Neuron 14:941), human (Messersmith et al., 1995), and insects (Kolodkin et al., 1993, Cell 75:1389). Chick collapsin-1 and mouse semaD inhibit specific axon outgrowth in vitro, however no function or activity has been described for the other vertebrate semaphorins. As a first step toward elucidating their in vivo function, we have initiated the cloning and analysis of these genes in the zebrafish. A zebrafish homolog to chick collapsin-1 has been characterized previously (Yee et al., 1995 Soc. Neurosci. Abstr. 21:293), and we have now isolated three additional zebrafish semaphorins.

SemaZ-VI shares 71% amino acid identity in the sema domain to chick collapsin-2. Whole mount in situ hybridization shows semaZ-VI expression in collapsin-2. Whole mount in situ hybridization shows semaZ-VI expression in the floor plate underlying the midbrain and the posterior hindbrain, in two the floor plate underlying the midbrain and the posterior hindbrain, in two regions of the diencephalon, in the hindbrain, in sensory ganglia, and in the notochord. In the cyclops mutant, semaZ-VI expression in the floor plate and diencephalon is absent, while expression in other structures is unaffected. SemaZ-V shares 53% amino acid identity to chick collapsin-5 in the sema domain, and is expressed in the developing somites and in a midbrain nucleus. SemaZ-IV encodes a transmembrane protein sharing 44% amino acid identity with mouse semaC. It is expressed in the dorsal spinal cord and hindbrain, in a subset of calls in the vertex legislar cord, in the branchial scales and in the subset of cells in the ventral spinal cord, in the branchial arches, and in the tectum. The unique and specific expression patterns of these genes, and their identity as semaphorin family members suggests they play important roles during zebrafish development. CLONING AND EXPRESSION OF TWO NOVEL MURINE SEMAPHORIN FAMILY MEMBERS L. Zhou.*S.I. Lentz F.A. White, D.E. Wright, and W.D. Snider, Dept. of Neurology, CSNSI, Washington Univ., St. Louis, MO, 63110.

Semaphorins are a very large family of molecules found in both vertebrates and invertebrates, the prototypical members of which are thought to be important for axon guidance. All family members have a characteristic 500 amino acid (AA) extracellular "semaphorin" domain which has a novel molecular structure. Most reported chick and murine homologues contain an IgG domain C-terminal to the Sema domain. At the N-terminal region these molecules contain a signal sequence and are thought to be secreted. We have previously described SemaX (here called Sema9), a novel Sema family member with 30-40% identity at the AA level in the Sema domain to previously published mouse homologues. We now report full length sequence of this new Sema family member. Sema9 shares considerable homology to Sema1 (SemaIII, SemaD) near the 3' end but diverges at the 5' end. Importantly, Sema9 has a molecular structure different than most vertebrate Semas in that it contains a transmembrane

domain. We also now report partial sequence for Sema10, another novel murine Sema with approximately 25% identity at the AA level to other Sema family members. In order to gain insights into potential functions of Sema9 and Sema10, we have compared expression of these molecules to other Sema in multiple regions of the developing and mature nervous system. Sema9 mRNA is widely expressed in the periphery (E9.5-PN-1) in patterns clearly distinct from Sema1 and Sema5 (SemaE). Interestingly, Sema9 is intensely expressed by non-neuronal cells as well as neurons in both dorsal root ganglion and spinal cord. Within the CNS, Sema9 has distinctly different expression patterns in several regions compared to Semal and Sema5. Sema10 also has novel expression patterns. In particular, Sema10 exhibits expression in peripheral and optic nerves and diffuse expression in spinal cord and sensory ganglia at embryonic stages. In addition, Sema10 is expressed in specific CNS cranial nuclei during development. Our findings of two additional Sema family members with expression patterns clearly distinct from any previously reported members underscore the diversity and complexity of this family of molecules in mammals. A STUDY ON A NOVEL MEMBER OF MOUSE SEMAPHORIN GENE FAMILY. S. INAGAKI', T. FURUYAMA', N. MIYAZAKI', S. SHIMADA', K. INOUE, Y. MINAMI, MASAYA TOHYAMA', ¹Dept. of Neurobiol., School of Allied Health Sci., ²Dept. Anatomy & Neuroscience, Faculty of Medicine, Osaka University, Suita-shi,

Invertebrate semaphorin I (Sema I) and its related proteins, chick collapsin and mouse Sema ||| contribute to the proteins, chick collapsin and mouse sema @ contribute to the axon guidance by their repellent actions. We have identified a novel member of the semaphorin gene family (M-Sema F) from the mouse brain. This member encodes a Sema domain which is similar among Sema !- @ followed by a single putative immunoglobulin-like domain, a transmembrane domain, and a proline-rich intracellular domain. In situ hybridization histochemistry displayed the expression of the mRNA from early to late embryos throughout the brain and spinal cord. But the expression decrease as animals grow and was restricted to the forebrain, tectum and several brain regions, and only weak expression was seen in the adult. The expression was detected in the embryo In addition to the nervous tissue, some other tissues such as the lung and kidny. These suggest that this molecule is a novel transmembrane member of the semaphorin gene family of the vertebrate which may function in forming the neuronal network during development, although it is not known whether this molecule functions in the same fasion in the nervous system as Sema II functions as repulsive guidance cues to sensory nerve.

MOLECULAR CLONING AND CHARACTERIZATION OF NOVEL SEMAPHORINS

T. Kimura, S. Tojo* and K. Kikuchi Sumitomo Pharmaceuticals Research Center. Konohana Osaka 554, Japan

Semaphorins are large family of proteins implicated in neuronal guidance during development. Although more than ten semaphorin genes have been cloned, only a few have been functionally analyzed. Northern analysis, however, has shown that some semaphorins are expressed in neonatal or matured animals as well as embryos(Neuron 14,941-948(1995), FEBS Lett. 370,269-272(1995), and our unpublished data). This prompted us to study function of semaphorins in matured animal. Our computer analysis identified more than twenty semaphorin-related sequences in EST database of infant or adult brain cDNA library. Using the sequence data, we cloned three new members of semaphorin genes from adult rat cDNA library(semaW, Y, Z). They were expressed mainly in adult. And the expression pattern was very characteristic in adult rat. That is, semaW was expressed in cerebrum, cerebellum and lung, semaY in cerebellum and muscle, and semaZ in cerebrum, cerebellum and spinal cord. These results suggest that the semaphorins would, if any, have some function other than axon guidance in adult nervous system, in which neural network has been established. We are presently analyzing expression distribution of these semaphorins in more detail by in situ hybridization and immunohistochemistry.

DO SEMAPHORINS ACT AS GUIDANCE MOLECULES FOR AFFERENT AND EFFERENT PROJECTIONS IN THE DEVELOPING CEREBRAL CORTEX? D. Bagnard¹, H. Betz², M. Götz*¹, A.W. Püschel² and J. Botz¹. l'INSERM U.371 Cerveau et Vision, 69500 Bron, France; ²Max-Planck-Institut für Himforschung, Abt. Neurochemie, 60528 Frankfurt, Germany.

Previous tissue culture studies provided evidence for the existence of diffusible and membrane-associated guidance factors which control the formation of reciprocal connections between thalamus and cortex during corticogenesis (for review see Bolz et al., TINS 16, 310, 1993). The molecular nature of these factors is not known. In the developing spinal cord it has been shown that members of the semaphorin gene family act as repellent signals during the navigation of sensory and motor axons towards their peripheral targets. Based on their homology to chicken collapsin and grasshopper semaphorin I several distinct cDNAs (semA semG) have been cloned from mouse cDNA libraries (Püschel et al., Neuron 14, 941, 1995). We are studying whether semaphorins might also exert an effect on growing thalamic and cortical axons. For this we employ various in vitro systems to examine the influence of soluble and membrane-bound semaphorins on growth cone navigation and axon elongation. Application of conditioned medium from 293 cells transfected with Sem D caused a collapse in 54% of cortical growth cones and 51% of thalamic growth cones. In contrast, after addition of medium from nontransfected 293 cells or from 293 cells transfected with Sem E, only 20-24% of cortical and 9-23% of thalamic growth cones were in a collapsed state. In cocultures with aggregates of 293 cells transfected with a Sem D expression vector and either thalamic or cortical explants in a 3 dimensional plasma matrix, axons extending from the explants were deflected from the cell aggregates. These results suggest that at least one member of the semaphorin gene family can orient the rowth of thalamic and cortical axons. (Supported by INSERM and DFG grant Pu102/4-1 to A.W.P.).

MEMBRANE-ASSOCIATED MOLECULES REGULATE THE FORMATION OF LAYER-SPECIFIC CORTICAL CIRCUITS. V. Castellani and J. Bolz *. INSERM U.371 Cerveau et Vision, 69500 Bron, France.

Axon collaterals of pyramidal cells make stereotyped connections within some of the 6 cortical layers. In our previous experiments we examined the branch formation of axons extending from cortical explants prepared from E16 rats (which contain neurons destined for layer 6) on membrane substrates prepared either from layer 6, or from layer 5, or from layers 1-4 of young postnatal rats. We observed that axons emitted more collaterals on membranes from their target layers (layer 6 and layers 1-4) than on membranes from layer 5, their non-target layer (Castellani et Bolz, Neurosci. Abstr. 1995). We now examined the behavior of axons from cells in the superficial cortical layers. For this we prepared explants of the ventricular zone at E19, the time at which cells of the deep cortical layers have migrated out into the cortical plate. Axons of cells destined for layers 2/3 branched about 2 times more often on membranes from layer 5 or from layers 1-4 than on membranes from layer 6. Our finding that layers 2/3 cells exhibit many axonal branches on membranes from layer 5, a target layer, as well as on membranes from layers 1-4, a mixture of target and non-target layers for this set of axons, suggests the existence of sprouting factors in the target layers. To address this issue further, for layer 6 cells we mixed membranes from their target and non-target layers. We observed an equal amount of axon collaterals on the mixed membrane substrates as on membranes from the target layers alone. In addition, heat-inactivation strongly decreased axonal branching on target layers, but had no effect on non-target layers. This suggests that membrane-associated molecules restricted to individual layers induce collateral branch formation of specific sets of axons. Moreover, cortical axons in vitro express their layer-specific branching behavior at very early developmental stages, before the neurons have migrated into their final position in the cortex. (Supported by INSERM).

REPULSION OF SPINAL COMMISSURAL AXONS BY A DIFFUSIBLE FACTOR FROM THE ROOF PLATE <u>A. Augsburger, A. Schuchardt, S. Hoskins and J. Dodd*</u> Dept. Physiology & Cellular Biophysics, Columbia University, New York, NY 10032.

The earliest spinal commissural (C) neurons in the rat differentiate close to the roof plate (RP) at the dorsal midline of the spinal cord. C axons extend in a ventral direction, away from the RP. Upon reaching a point approximately half way down the dorsoventral axis of the spinal cord, C axons alter their trajectory and project ventro-medially towards the floor plate (FP), apparently under the influence of diffusible chemoattractants, the netrins. Because the initial ventral extension of C axons occurs in the absence of FP-derived signals, we have examined the possibility that the direction of initial axon growth is influenced by repellant signals from the RP. To test this we have assayed the effects of RP tissue on the growth of C axons. Explants of dorsal neural tube containing C neurons were grown in collagen gel in the presence of netrin-1 or FP-conditioned medium, under which conditions C axons identified by TAG-1 expression, projected into the collagen gel. When E11 or E13 RP was positioned ~150 μm from the ventral edge of the dorsal explant ventrally directed C axons stopped growing or altered their direction of extension, to avoid the RP explant. RP tissue repels C axons but not several other classes of central and peripheral axons. The RP-derived repellant activity is not mimicked by several other tissues of neural and non-neural origin. These studies suggest that the dorsoventral trajectory of C axons in the spinal cord is controlled initially by a RP-derived repellant and subsequently by a FP-derived chemoattractant NIH: NS 27113 to JD. NIH: T32-AG00189 (AS).

ROLE OF HB-GAM (HEPARIN-BINDING GROWTH-ASSOCIATED MOLECULE) IN PROLIFERATION ARREST AND ITS ASSOCIATION WITH THE DIFFERENTIATING NEUROMUSCULAR SYSTEM. E.Szabat, L. Ahtee and H.Rauvala. Lab. of Molecular Neurobiology, Institute of Biotechnology, University of Helsinki, Finland HB-GAM is a secretory, extracellular matrix-associated protein that was isolated

HB-GAM is a secretory, extracellular matrix-associated protein that was isolated be sreening for proteins that enhance neurite outgrowth in perinatal rat brain neurons. In the present study we have investigated the possible role of HB-GAM in cell proliferation in the developing limb of the rat. Exogenously added recombinant HB-GAM was found to inhibit the proliferation of mesenchymal and epithelial cells in cultured limb buds, as demonstrated by bromodeoxyuridine incorporation and by staining for proliferating cell nuclear antigen. The inhibitory effect of HB-GAM on cell proliferation was reversed by heparin, suggesting that HB-GAM may bind to heparin-type carbohydrate epitope that is required for cell proliferation in the developing limb. In agreement with the putative role in proliferation arrest, endogenous HB-GAM of the developing limb was found to be expressed in a proximal-to-distal pattern. Furthermore, HB-GAM was associated with the muscle surface as demonstrated in double-immunostaining of HB-GAM with desmin and myosin heavy chain proteins. Coinciding with the onset of synapse formation, HB-GAM was found in patches on the muscle cell surface in close proximity to nicotinic acetylcholine receptor clusters.

PROTEIN AND GENE EXPRESSION FOR TRANSGLUTAMINASE (TG) IN DEVELOPING MOUSE MUSCLE. E. J. Gregory, D. L. Steigerwalt, M. N. Zoubine, B. A. Citron, B. W. Festoff* Neurobiology Research Lab, VA Medical Center, Kansas City, MO: and Department of Neurology, University of Kansas Medical Center, Kansas City, KS

TG catalyzes the Ca+* dependent cross-linking of proteins via the y-carboxamide group of glutamine residues and the e-amino group of lysine. TG is

TG catalyzes the Ca++ dependent cross-linking of proteins via the y-carboxamide group of glutamine residues and the e-amino group of lysine. TG is important in neural development, having a biphasic increase in activity: the first embryonic then postnatal, coincident with neural apoptosis. TG is implicated in formation of the apoptotic body, but it also has a role in tissue stabilization, since the resulting isopeptide after cross-linking is stable and resistant to proteolysis. Our model of synapse formation and maintenance at the neuromuscular junction (NMJ) led us to study clotting cascade components and related molecules in development. In this study, we analyzed protein (cytosolic and particulate fractions) and gene expression of TG in developing murine skeletal muscle from embryonic through postnatal times. TG activity was determined by the incorporation of radioactive putrescine into dimethylcasein. RT-PCR was performed using synthesized 3' and 5' oligonucleotide primers based on known TG sequence. Cytosolic TG specific activity increased significantly from E14, but with a much shorter duration, decreasing just prior to birth and remained constant through P30. Particulate TG also increased significantly from E14, but with a much shorter duration, decreasing just prior to birth and remained constant through P30. RT-PCR showed increased TG mRNA levels from birth to P15 with lower levels at P30. Peak cytosolic TG activity coincides with NMJ formation and previous work in this lab led us to hypothesize a role for TG in synapse stabilization. Murine polyneuronal synapse elimination occurs from birth to P15, coinciding with the dramatic decrease in cytosolic TG, when its role in synapse stabilization and other cellular stabilization processes may be diminished. Supported by the Marion Merrell Dow Foundation/SEP and the Medical Research Service of the Dept. of Veterans Affairs.

EVIDENCE THAT S-LAMININ/LAMININ-β2 HAS A DIRECT ROLE IN SYNAPTIC REGULATION OF SCHWANN CELLS *IN VIVO* AT THE NEUROMUSCULAR JUNCTION. <u>Bruce L. Patton* and Joshua R. Sanes.</u>

Dept. Anatomy & Neurobiology, Washington Univ Sch. Med., St. Louis, MO 63110.

The synaptic basal lamina (BL) of the vertebrate neuromuscular junction promotes pre- and postsynaptic differentiation and contains specialized components. *In vitro*, recombinant forms of one such component, S-laminin/laminin- β 2, cause neurites extending from motoneurons to stop and differentiate into presynaptic terminals. In "knockout" mice lacking laminin-β2, nerve terminal differentiation is impaired, consistent with *in vitro* results (Noakes et al., 1995, Nature 374:258). In addition, Schwann cell processes, which normally cap nerve terminals, invade the synaptic cleft in the laminin-[22] mutant thus enwrapping presynaptic terminals. Our initial interpretation of the aberrant Schwann cell behavior was that Schwann cells were reacting to defective nerve terminals. This hypothesis is consistent with some neuromuscular pathologies in which nerve terminals become enwrapped by the terminal Schwann cell. However, we later found that recombinant lamininin-\(\beta \) inhibited the migration of Schwann cells in vitro (Patton et al., 1995, Soc. Neurosci. Abst. 323.3). This suggested that one function of laminin-β2 in vivo is to actively inhibit Schwann cell invasion of the synaptic cleft. To test this idea, we examined denervated control and laminin-β2 mutant muscles by EM. As expected, Schwann cells remained at synaptic sites after the axon had degenerated. However, in controls, only 5% of the synaptic BL was directly contacted (<70 nm) by a Schwann cell process. In contrast, close contact was increased 10-fold in mutants, averaging 50% of the total cleft. Thus laminin-β2 appears to inhibit Schwann cells from establishing intimate contact with the synaptic BL even in the absence of axons. Interestingly, in ganglia and spinal cord as well as in muscle, pathologic detatchment of synapses involves enwrapping of nerve terminals by their associated glial cells. The usual interpretation is that deprived nerve terminals first withdraw from their postsynaptic contact and are secondarily enwrapped. Our results raise the possibility that in some cases a change in postsynaptic structure regulating glial cell behavior is more directly responsible. (Supported by NIH.)

THE SCHWANN CELLS AND THE NEUROMUSCULAR SYSTEM. L. Koenig*, J. Chapron, S. de la Porte, K.X. Zhang, G. Eschers and H. Chneiweiss²⁰. University Bordeaux II- CNRS URA 1226 - France. Institut Anatomie Lausanne - Suisse. Institut Anatomie Lausanne - Suisse.

At the neuromuscular junction (NMI), nerve terminal, Schwann cell and muscle cell are juxtaposed during cell differentiation and synaptogenesis. We investigated in vitro the influences of Schwann cells (S) on motoneurons (MN) outgrowth and synaptogenesis.

For MN outgrowth: when motoneurons were cultured for 48 h in presence of S or conditioned medium (CM) by S, the axon outgrowth increases by 16-fold, that as to be compared to the 3-4-fold increase produced by basal lamina components. We will compare the effect of GDNF (glial cell line derived neurotrophic factor) and CM by S cells on the axon outgrowth.

For synaptogenesis, we analyzed the appearance and maturation of synaptic narkers: i) When Schwann cells or CM were added to muscle-nerve cocultures, we observed a modest increase in the number of membranes acetylcholine receptor (AChR) (10%), but a large increase of AChRs clusters (85% with S and 40-50% with CM). Thus, the Schwann cells release factor(s) which induce AChRs clustering, 2) Synaptic maturation results in a switch of synaptic cholinesterase from AChE-BChE complex to AChE. S are involved in this phenomena. Indeed, addition of S or CM to muscle-neuron co-cultures in this phenomena, Indeed, addition of S or CM to muscle-neuron co-cultures induced a regression of BChE, as in adult NMJ. This effect is inhibited by the 6.17 antibody which recognizes a molecule synthetized by S. Thus, in addition to the neuronal factors CGRP, ARIA/heregulin, agrin, which control the synthesis, maturation and accumulation of AChRs, Schwann cells synthesize factor(s) involved in maturation of synaptic cholinesterases.

By acting on motor-axon outgrowth, AChRs clustering and synaptic cholinesterases maturation. Schwann cells play a key role in the neuronary action of synaptic system.

Agrin Function is Required for Pre- and Postsynaptic Differentiation at Neuromuscular Junctions in vitro. J.L. Bixby*, M.A. Rüegg[±] and J.A. Campagna. Dept. Mol. & Cell. Pharm., Univ. Of Miami, Miami FL 33101 and [†]Dept. of Pharm., Biozentrum, Basel, Switzerland

Agrin is a heparin sulfate proteoglycan; multiple isoforms are synthesized by both muscle and nerve. Neural agrin is likely to induce aggregation of acetylcholine receptors (AChRs) and other postsynaptic proteins during synapse formation at the neuromuscular junction (NMI) (Reist *et al.*, Neuron 8, 865; Bowe and Fallon, Ann. Rev. Neurosc. 18, 443). We have previously shown that either neural or muscle agrin, when heterologously expressed, has those properties predicted for a motoneuronal "stop signal" (Campagna et al., Neuron 15, predicted to a indonlemental stop signal (campagna et al., Neuron 15, 1371, 1995). To test the hypothesis that agrin's activities on motoneurons are important for presynaptic differentiation in vitro, we used an agrin antibody to disrupt agrin function in chick ciliary ganglion (CG) neuron/myotube cocultures (e.g. Bixby, J. Neurobiol. 26, 262, 1995). In cocultures grown in the presence of 200 µg/ml antiagrin IgG, both AChR clustering and clustering of the synaptic vesicle protein synaptotagmin (syt) were inhibited. Syt clustering was still abrogated in the presence of 100µg/ml blocking antibody, while the postsynaptic clustering of AChRs, heparan sulfate proteoglycan, and s-laminin was retained. These results demonstrate that agrin function is required for clustering of postsynaptic proteins at nerve-muscle contacts *in vitro*. Coupled with the observations that agrin can be <u>sufficient</u> to induce syt clustering, our results also suggest that agrin is directly involved in the induction of presynaptic differentiation, at least in vitro. RAT NEUROMUSCULAR JUNCTIONS GAIN TERMINAL SCHWANN CELLS DURING POSTNATAL DEVELOPMENT. F.M. Love* and W.J. Thompson Department of Zoology, The University of Texas, Austin, TX 78712.

Rat neuromuscular junctions undergo synaptic rearrangements in early postnatal development leading to the innervation of each muscle fiber by a single motor neuron. Recent experiments have suggested that terminal Schwann cells (SCs) influence the growth of nerve terminals and the innervation of endplates. We have. therefore, examined how the number of terminal SCs at neuromuscular junctions changes between birth and adulthood. SCs were labelled with antibodies to S100 nerve terminals and axons were labelled with antibodies to neurofilament and synaptophysin, and nuclei were labelled with DAPI. The number and position of SC nuclei were determined by the colocalization of DAPI and \$100 labels. All nerve terminals were covered by \$C processes at all ages examined. However, at birth, \$C somata were present over only about one-half of the endplates in soleus and two-thirds of those in EDL. In most cases where a \$C soma was absent from the thirds of those in EDL. In most cases where a SC soma was absent from the terminal, one was present along the preterminal axon. The SC processes which cover the terminal, therefore, are extensions of these preterminal SCs. After postnatal day 7, all junctions had overlying SC somata. During the period from birth to adulthood, the average number of terminal SC somata increased from 0.4 to 2.6 in soleus and from 0.9 to 3.4 in EDL. As the number of SC nuclei atop the terminals increased, the number along the preterminal axons declined. Taken together, these observations suggest that during development SCs migrate along preterminal axons to cover the nerve terminals. Moreover, as the number of SCs at an endplate increases, the proportion of the endplate area occupied by an individual SC decreases. This change in the number and morphology of terminal SCs shows that SCs and nerve terminals rearrange their contacts at the developing neuromuscular

SCHWANN CELLS AT THE NEUROMUSCULAR JUNCTION AND THEIR ROLE IN THE MAINTENANCE OF SYNAPTIC INTEGRITY T.T. Trachtenberg* and W.J. Thompson, Department of Zoology, The University of Texas, Austin, Texas 78712.

Schwann cells (SCs) at neuromuscular junctions (nmjs) behave during nerve sprouting in a manner that suggests that these cells play a major role in inducing and guiding nerve growth. The role of SCs at unperturbed nmjs, however, is largely unknown. We have begun to examine the influence of terminal SCs on the maintenance of synaptic integrity at nmjs by disturbing the morphology and position of these cells. To induce changes in terminal SC morphology and position, we have transplanted foreign nerves over the surface of normally innervated soleus muscles. In these preparations, SCs growing from the transplant interact with terminal SCs at nmjs, resulting in the morphological disruption of affected synapses terminal SCs at miny, resulting in the morphological unsymbol of artected synapsis manifest as a smaller and fragmented nerve terminal arborization. Muscless were stained with antibodies to neurofilament and synaptophysin to label axons and nerve terminals and either anti-S100 to label SCs or bungarotoxin to label acetylcholine receptors (ACfiRs). In muscles in which the SCs and the nerve terminals were stained, we were able to identify remodeled endplates at which the SCs growing out of the transplant had interacted with and induced the migration of the terminal S In preparations employing bungarotoxin we were able to identify remodeled endplates in which portions of the AChR plaque were no longer covered by a nerve terminal. Some of these deserted AChR patches were fragmented in appearance, suggesting that these receptors were being lost. These data suggest that the integrity of an endplate is dependent on the maintenance of its terminal SCs and that the displacement of terminal SCs or their processes is followed by the loss of the underlying nerve terminal, resulting in the presence of bare patches of AChRs. These results may provide a mechanism by which transplanted, foreign nerves compete with the original nerve for the innervation of existing synaptic sites (Bixby & Van Essen, Nature 282: 726-728). This work was supported by a grant from the NIH.

FORMATION AND ELIMINATION OF NEUROMUSCULAR JUNCTIONS DIRECTLY OBSERVED IN LIVING FROGS (XENOPUS LAEVIS). Albert A. Herrera,* Neurobiology Program, Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

The pectoral muscle (supracoracoideus) of early postmetamorphic Xenopus laevis is being used as a preparation in which myogenesis and the formation, elimination, and maturation of neuromuscular junctions can be directly observed and manipulated. There are about 800 fibers in the adult muscle, most of which are innervated at two widely separated sites. Starting at a stage when only 10% of these fibers have developed, muscles are surgically exposed and stained with the vital fluorescent dye RH414 and other synapse-specific markers. *In vivo* observation of identified cells repeated at 1-4 week intervals reveals the following. 1) Fibers are innervated as soon as they appear, with well-formed synaptic contacts seen on fibers that are still enlarging by myoblast fusion. 2) One or more additional junctions is added soon after the first junction, usually at a distant location. 3) New junctions are formed by nodal or terminal sprouts that arise from axons supplying nearby fibers. 4) Elimination of focal polyneuronal innervation is seen as regression of established synapses in junctions that are apparently multiply innervated. 5) Following such synapse elimination, surviving nerve terminals in the same area enlarge by extension of growth cones, but abandoned synaptic sites are not reoccupied. 6) Growth in muscle fiber and body size is accompanied by the elaboration of many new junctional branches, with synaptic size increasing 20-50 fold. 7) At the earliest stages, each muscle has the full complement of 2-3 muscle spindles.

A variety of molecular probes and focal lesions are being used to study these processes in identified, repeatedly observed junctions and to test hypotheses for underlying mechanisms. Supported by the NIH (NS24805).

NEUROMUSCULAR JUNCTION FORMATION DURING NORMAL DEVELOPMENT: A REFLECTED LIGHT CONFOCAL STUDY OF THE POSTSYNAPTIC MEMBRANE. MJ.Marques. CC.Nelson and J.W. Lichtman. Dept of Anatomy & Neurobiol., Washington Univ. Med. Sch., Saint Louis, MG 63110.

Developmental changes at the neuromuscular junction were studied by making reflected light confocal reconstructions of the acetylcholine receptor rich postsynaptic nembrane. Sternomastoid muscles from embryonic day 17 (E17), postnatal day 2 to 21 (P2 to P21) and adult mice were fixed and their AChRs stained with α -bungarotoxin-biotin-avidin-HRP. Using a confocal microscope (Noran Odyssey) the muscles were observed under epi-illumination with a 100X, 1.4NA oil objective. The structural findings obtained with this technique were superior to those we obtained with fluorescenctly tagged α-bungarotoxin also using confocal microscopy. Because the HRP reaction product at the postsynaptic membrane shows specular reflectance, only light coming from the relatively untilted regions of the membrane is collected by the objective. Thus, junctional folds appear as dark bands whereas the tops of the folds are bright. Typically, in adults, the folds run parallel to each other and roughly orthoganol to the long axis of the primary synaptic cleft. Much flatter endplates with no clefts were typical for the earliest ages (E19 to P2), where the postjunctional membrane shows a mosaic of wide irregularly distributed receptor areas. Beginning at P4. receptor regions with different heights were observed within the same endplate, nascent folds were seen in the deeper areas while loose receptor spots irregularly distributed and less reflective were seen at the more superficial areas. From our studies Reflected light confocal microscopy thus seems to be a useful approach for the study of the topography of the postsynaptic membrane Supported by grants from FAPESP and the NIH

DEVELOPMENTAL REGULATION OF \$\beta\$-AMYLOID PROTEIN PRECURSOR DURING NEUROMUSCULAR SYNAPTOGENESIS.

M. Akaaboune*, B. Allinquant, P. Mailleux and D. Hantaï. INSERM U.153 and CNRS URA 1414, F-75005 Paris.

β-amyloid protein precursor (APP) is a transmembrane glycoprotein present in numerous tissues and especially in the central and peripheral nervous system. In this work we have examined the expression of APP in the developing skeletal muscle of the mouse using Western blotting and immunocytochemistry with confocal microscopy. Using anti-APP polyclonal antibodies directed against different domains of the molecule, we have found that APP isoforms are present in increasing amounts from embryonic day 16 to postnatal day 5 and then decrease progressively to reach low levels observed in the adult. antibody against the 695 isoform of APP detected a 94 kDa band that appeared in the adult skeletal muscle, whereas isoforms of higher molecular weights were decreased. Immunocytochemistry revealed that APP was localized in the cytoplasm of myotubes at embryonic day 16 and became gradually concentrated at the neuromuscular synapse from birth to adulthood. confocal laser microscopy analysis showed that APP became increasingly colocalized with acetylcholine receptor from birth onward. Taken together, these results show that APP is regulated as neuromuscular development proceeds and suggest a role for APP in synaptogenesis. This work was supported by AFM.

RECONSTITUTION OF AVIAN ACETYLCHOLINESTERASE ON TO THE FROG NEUROMUSCULAR SYNAPSE. <u>Susana G. Rossi, Richard L. Rotundo, and Lili Anglister</u>*, Depts. of Cell Biology and Anatomy, Univ. of Miami Sch. of Med. Miami, FL 33101, and Anatomy and Cell Biology, Hebrew Univ. Hadassah Med. Sch. Jerusalem, Israel.

The highly organized pattern of acetylcholinesterase (AChE) molecules at the neuromuscular junction (NMJ) suggests the existence of specific binding sites for their precise localization. The predominant AChE isoform localized at NMJs is the asymmetric A12-AChE which is tightly linked to the extracellular matrix via its collagen tail. To test the hypothesis that a specific array of target molecules exists for directing attachment of newly synthesized enzyme, we "transplanted" immunoaffinity purified globular (G4/G2) and asymmetric (A12) AChE forms from quail muscle cultures to frog (Rana pipiens) NMJs. Frozen sections of adult frog muscles, or empty basal lamina sheaths of the muscles, were incubated overnight with purified AChE forms under conditions that allowed a gradual decrease of ionic strength. Frog NMJs were localized using Rh-aBTX and the quail AChE was localized using avian-specific mAb 1A2. There was no detectable binding above background levels of the globular avian G4/G2 AChE to frog NMJs, whereas more than 80% of the frog NMJs bound the quail enzyme when incubated with A12-AChE form. These results indicate that specific binding sites for A12-AChE exist at the NMJ and are organized to form a "molecular parking lot" in which the AChE molecules can be inserted and removed as required. Supported by grants from the NIH to R.L.R. and Israel Acad.of Sci. to L.A.

ULTRASTRUCTURE OF THE DEVELOPING NEUROMUSCULAR JUNCTION IN <u>DROSOPHILA</u> EMBRYOS. <u>M.B.Rheuben*</u>, <u>M.Yoshihara, and Y.Kidokoro.</u> Dept. of Anatomy, Michigan State Univ., E. Lansing, MI 48824, and Inst. for Behavioral Science, Gunma Univ. Sch. of Med., Maebashi 371, Janan.

The development of neuromuscular junctions on embryonic abdominal muscle was examined using scanning and transmission electron microscopy. Around 16.5 hrs AEL, during a stage designated as the "prevaricosity period" from confocal observations (Yoshihara et al, in preparation), the axons the nerve entry point (NEP) on the muscle fiber, and partial retraction of the long, exploring filopodia occurs. Contacts of an axon terminal with the muscle fiber in this region include synaptic components: a flat apposition with the muscle fiber membrane and a presynaptic dense body surrounded by a cluster of vesicles. Postsynaptic folds of the muscle are lacking. Peripheral glial processes end within the NEP. The first, smaller than normal, miniature endplate currents are observed during this period (Kidokoro and Nishikawa, 1994). Around 19 hrs AEL the enlarged regions of the axons of the "prevaricosity" condense, and constrictions divide them into several varicosities at the NEP. Each varicosity might contain 4 to 9 well-formed active zones. In Type I junctions, the postsynaptic membrane becomes more obviously electron dense, and cavities form beneath it, separating a thin layer of muscle close to the terminal. These thin layers, as well as outgrowths from the muscle fiber, form the subsynaptic reticulum, which, by hatching, only consists of one or two lamellae in Type I varicosities. By 16 hrs multiple axon types, having vesicles with differing structures, are present on the dorsal muscles, and by hatching both Type I and Type II varicosities can be distinguished. Regulation of Synaptotagmin Gene Expression During Neuromuscular Synaptogenesis in vivo. <u>I.A. Campagna*, David Prevette*</u>, R.W. Oppenheim², <u>I.L. Bixby.</u> Dept. of Mol. & Cell. Pharm., Univ. Of Miami, Miami, FL 33101 and *Neurobiology & Anatomy, Bowman Gray School of Med., Winston-Salem, N.C., 27157.

During neuromuscular synaptogenesis, signals from motor neurons regulate the synthesis and the assembly of postsynaptic elements. Similarly, it has been hypothesized that signals from target muscles regulate synthesis and assembly of presynaptic components in motor neurons. The synaptotagmins (syts), a family of synaptic vesicle proteins, are differentially regulated during development of peripheral motor neurons, and upregulation of syt I mRNA is temporally correlated with target innervation (Lou and Bixby, Mol. Cell. Neurosci. 6, 252, 1995). To test the generality of these observations, and to test the hypothesis that upregulation of syt mRNA is causally related to target contact, we examined the expression of syt I and syt II mRNAs in motor neurons of the chick lumbar spinal cord using in situ hybridization. Ventral horn motor neurons upregulate syt I mRNA at the the time when axons are making contact with peripheral targets (E5-E6). Syt I mRNA is downregulated after synaptogenesis (E15-E20), and syt II mRNA is upregulated. Unilateral limb removal (Oppenheim et al., J. Comp. Neur., 177, 87) largely prevents the early increase in ipsilateral syt I gene expression. These results suggest that target contact induces the developmental upregulation of syt I in spinal motor neurons, and that a later stage of synaptic maturation results in changes in syt isoform expression. Supported by NSF grant IBN 9309526.

MUSCARINIC RECEPTOR-DEPENDENT DAG PRODUCTION IN SKELETAL MUSCLE REQUIRES Ca** INFLUX THROUGH VSCCs Rosely O. Godinho and Richard L. Rotundo*, Department of Cell Biology and Anatomy, Univ. of Miami Sch. of Med. Miami, FL 33101.

The synthesis and assembly of acetylcholinesterase (AChE) requires Ca++ influx through L type channels and diacylglycerol (DAG)-dependent PKC activation. Previous experiments from our lab showed that DAG production in skeletal muscle can be stimulated through muscarinic receptors (mAChR) To study the interaction between membrane depolarization/ Ca^{++} influx and mAChR activation, we examined the effects of Ca++ channel agonist (Bay-K 8644) and antagonist (nifedipine) on DAG production induced by mAChR activation. Electrical stimulation of myotubes resulted in an 80% increase in DAG. This effect was mimicked by 1 µM veratridine and 50 nM Bay-K, but inhibited by 10 µM nifedipine. Stimulation of mAChR with Oxotremorine-M produced a 750% increase in DAG that was blocked by nifedipine. Our results indicate that both membrane depolarization and mAChR activation are necessary to increase DAG production in cultured myotubes. Immunofluorescence studies using anti-rat mAChR antibodies showed that M1 mAChRs are present on cultured myotubes as well as restricted to the neuromuscular junction of adult skeletal muscle where they co-localize with nAChRs. We suggest that concurrent activation of both nAChRs and mAChRs at the neuromuscular junction are involved in DAG production and PKC activation leading to the regulation of AChE synthesis and assembly. Supported by the FAPESP and NIH/FOGARTY (ROG) and NIH (RLR).

LOCALIZED MEMBRANE DEPOLARIZATION REGULATES ACETYLCHOLINESTERASE mRNA LEVELS IN MYOTUBES A.E. Vazquez*, S.G. Rossi and R.L. Rotundo. Dept. of Cell Bio. and Anat., Univ. of Miami Sch. of Med., Miami, Fl. 33136

In skeletal muscle, acetylcholinesterase (AChE) protein as well as mRNA are highly concentrated at neuromuscular junctions. To study mechanisms responsible for the local regulation of expression, we examined the effects of localized membrane depolarization or sodium channel block on the levels of AChE mRNA in quail muscle cultures. RNase protection experiments indicate that 5 µM tetrodotoxin increases the AChE mRNA levels while treatment with 20 nM scorpion venom or 1-10 µM veratridine decrease AChE mRNA levels with respect to control. Localization of AChE mRNA by in situ hybridization allows identification of individual nuclei expressing the AChE gene (AChE mRNA+ nuclei). Tetrodotoxin increases the number of AChE mRNA+ nuclei, whereas scorpion venom treatment decreases the number of AChE mRNA+ nuclei relative to untreated controls. Detection of AChE mRNA+ nuclei in experiments where only a portion of the muscle fibers were exposed to the drugs, while the other portion was maintained in normal medium, show that each nuclei responds to signals originating specifically on the overlying region of the plasma membrane. These studies suggest that localized membrane depolarization can be responsible for regulating AChE mRNA expression in the underlying nuclei. Supported by grant from the NIH to R.L.R.

NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS VIII

NEUROFIBROMIN NEGATIVELY REGULATES NEUROTROPHIN SIGNALLING IN EMBRYONIC SENSORY NEURONS. K. S. Vogel, M. El-Afandi, L. Klesse, and L. F. Parada*. Center for Developmental

M. El-Alandi, L. Klesse, and L. F. Parada*. Center for Developmental Biology, U.T. Southwestern Medical Center, Dallas, TX.

Neurofibromin, the product of the neurofibromatosis type 1 (NF1) gene, negatively regulates p21 ras signalling through its GTPase-activating protein (GAP) domain. To understand how neurons acquire dependence on neurotrophins that signal through its receptors and the ras pathway, we compared survival of sensory and sympathetic neurons isolated from NF1 mutant and wild-type mouse embryos. We have shown that neurons that lack neurofibromin survive in the absence of neurotrophins and that mutant neurons isolated prior to target contact fail to acquire neurotrophin dependence in vitro. To determine whether neurofibromin acts as a negative regulator of p21 ras in embryonic neurons, we introduced Fab fragments of a function-blocking anti-ras antibody into NF1 mutant and wild-type trigeminal and DRG neurons. Anti-ras antibodies block the survival of both NF1 mutant and wild-type sensory neurons: these neurons can be rescued by NGF. In the presence of anti-ras Fab fragments, NF1 mutant neurons are ten times more sensitive to the rescue effects of NGF than are wild-type neurons. Our results are consistent with a model wherein p21 ras signalling may occur constitutively in the absence of neurofibromin in neutropoin sensory neurons. To explore further the role of neurofibromin in neurors memory smalling, we are examining the survival of neurons isolated from embryos mutant for both neurofibromin and trk receptor or neurotrophin genes. Supported by NIH Grant# 1-R01-NS34296-01.

REGULATION OF MuSK EXPRESSION IN SKELETAL MUSCLE DURING DEVELOPMENT AND AFTER INJURY.
D. C. Bowen, J. S. Park, G. D. Yancopoulos, R. M. Lindsay, D. J. Glass, P. S. DiStefano* Regeneron Pharmaceuticals, Tarrytown, NY.

The receptor tyrosine kinase, MuSK (Muscle Specific Kinase), has recently been shown to be a required component of the signaling receptor complex for agrin and to be necessary for neuromuscular junction (NMJ) formation in vivo. To understand better the mechanism junction (NMJ) formation in vivo. To understand better the mechanism by which MuSK activation leads to NMJ formation, we are investigating the regulation of MuSK expression during development in the embryo and during atrophy in the adult. We find that MuSK is expressed in skeletal muscle early in development and becomes concentrated at the motor endplate by birth. In the adult, full-length MuSK is precisely colocalized with acetylcholine receptors (AChRs) while MuSK mRNA is expressed exclusively by subsynaptic nuclei. Although substantial MuSK immunoreactivity remains concentrated at the motor endplate after denervation or limb immobilization, MuSK mRNA becomes expressed throughout the myofiber under these conditions. Finally, we have examined the distribution of MuSK on the surface of cultured myotubes and find that after treatment with agrin, MuSK becomes concentrated at the site of AChR clusters. Experiments are currently underway to determine the relationship between the expression of full-length MuSK and that of other components of the NMJ.

PROPOSED ROLE FOR NARIA IN SKELETAL MUSCLE DEVELOPMENT. T. Mason*, Y. Kuo, X. Yang and L. Role. Department of Neurology; Center for Neurobiology and Behavior, Columbia University,

P&S, 722 W 168th St. NY, NY 10032

The neuregulins represent a family of related proteins which are potential ligands for erbB3 and erbB4. They exist in multiple isoforms, sharing a common epidermal growth factor (EGF) domain. Neuregulins function to activate acetylcholine receptor gene (AChR) expression and to induce Na* channel formation in cultured chick muscle (Fischbach and colleagues; Cell, 72: 801; JNeurosci, 13: 2118). Recently, we have described a novel neuregulin splice variant which lacks an immunoglobulin-like domain in its N-terminus, termed nARIA (unpublished work of Y.K., L.R. and X.Y.). PCR, Northern, and in situ hybridization demonstrate that nARIA is the predominant form of neuregulin expressed in both visceral and

somatic motoneurons early in synaptogenesis (X.Y., Y.K., L.R.; in prep.).

Using a nARIA isoform-specific antibody, protein can be detected in nerve fibers within skeletal muscle. To investigate a potential role of nARIA in nerve-muscle interactions, we have examined the effects of recombinant nARIA on a mouse cell line, Sol8. Sol8 cells provide a system in which one can study the maturation of skeletal muscle, including the transition from myoblasts to myotubes and the expression of mature, epsilon subunitreporting to the expression of matter, expression and the expression in matter, expression, involving AChR subunits and myogenic transcription factors, among others. Treatment of undifferentiated Sol8 cells with recombinant nARIA and analysis of mRNA by Northern blot reveals changes in the levels of several AChR subunit mRNAs. These results suggest that nARIA may play an important role in the early development of vertebrate skeletal muscle. (Supported NS29071 to L.R.; NSAD to Neurol).

THE RECEPTOR TYROSINE KINASE, MuSK, IS REQUIRED FOR NEUROMUSCULAR JUNCTION FORMATION IN VIVO, AND IS A COMPONENT OF A RECEPTOR COMPLEX FOR AGRIN.

D. J. Glass, T. M. DeChiara, D. C. Bowen, T. N. Stitt, C. Radziejewski, I.-A. Bruno, T. E. Ryan, D. R. Gies, S. Shah, S.I. Burden², P. S. DiStefano, D. M. Valenzuela, and G. D. Yancopoulos*. Regeneron Pharmaceuticals, Tarrytown NY; ²Skirball Institute, NYU, NYC, NY

Formation of the neuromuscular junction requires a series of inductive interactions between growing motor axons and differentiating muscle cells, culminating in the precise juxtaposition of a highly specialized nerve terminal with a complex molecular structure on the postsynaptic muscle surface. The receptors and signaling pathways mediating these inductive interactions have not yet been characterized. We have isolated a novel receptor tyrosine kinase, MuSK, (Muscle Specific Kinase), which is localized at the motor endplate in skeletal muscle, and which is up-regulated upon denervation. We have further generated mice with a targeted disruption of the gene encoding MuSK. Neuromuscular junctions do not form in these mice, suggesting a failure in the induction of synapse formation. Agrin is a nerve-derived factor that can induce molecular reorganizations at the motor endplate, but the mechanism of action of agrin remains poorly understood. We demonstrate that: myotubes obtained from MuSK(-/-) mice fail to cluster AChRs in response to agrin stimulation; agrin acts via a receptor complex that includes and requires MuSK; and that agrin-induced activation of MuSK additionally necessitates a myotube-specific accessory component (MASC).

AGRIN 4,8 STIMULATES TYROSINE PHOSPHORYLATION OF MUSK IN DENERVATED SKELETAL MUSCLE IN VIVO. <u>P.S. DiStefano, T.N. Stitt, T. Daly, G. Elove, D.M. Valenzuela, G.D. Yancopoulos, R.M. Lindsay*, D.J. Glass.</u> Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

We have previously demonstrated that the receptor tyrosine kinase, MuSK, is up-regulated in skeletal muscle as a result of denervation or limb immobilization. Furthermore, MuSK is a signal transducing molecule necessary for the acetylcholine receptor-clustering actions of agrin. To determine whether agrin could activate MuSK in vivo and potentially affect the integrity of skeletal muscle, purified soluble recombinant human agrin isoforms (agrin 4,8 and agrin 4,0) were injected into rats with unilateral hindlimb denervation. Agrin was infused either into the femoral artery or into the jugular vein and muscles were assayed for tyrosine phosphorylation of MuSK by Western blot techniques. Intra-arterial infusions of agrin 4,8, but not agrin 4,0 (3 mg/kg) caused a time-dependent phosphorylation of MuSK, peaking at 2 hr. The response was only observed in denervated muscles. Intravenous injections (3-15 mg/kg) resulted in MuSK phosphorylation only in denervated muscles. Pharmacokinetic analyses using 1251-agrin isoforms showed a rapid initial clearance and an elimination half life of ~3 hr for agrin 4,8. The results illustrate the selective responsiveness of denervated skeletal muscle to agrin.

CALBINDIN-D_{28k} AND PARVALBUMIN LOCALIZATION IN HIPPOCAMPAL ORGANOTYPIC CULTURES. M.E. Morris*, S. Hefft, D. Muller and K.G. Baimbridge. Dept. of Pharmacology, Centre Médical Universitaire, Université de Genève, CH-1211 Genève 4 and Dept. of Physiology, University of British Columbia, Vancouver BC, Canada V6T 1Z1.

In order to assess the presence, distribution and potential function of calbindin-D_{28k} (CaBP) and parvalbumin (PV) immunohistochemical staining of hippocampal organotypic cultures was carried out at different stages of development and correlated with electrophysiological recording in slices from 7 and 12 day postnatal rats (P7 & P12), cultured for 7 to 28 days (D7-28). At P7-D7 there is significant CaBP staining in dentate granule cells, mossy fiber projections, reactive astrocytes in the dentate and edges of the slice, and interneurons and pyramidal cells of CA1. PV staining is remarkably strong in pyramidal cell layers and weaker in the dentate. At P7-D8-14 CaBP staining of interneurons and superficial neurons of the more clearly defined pyramidal cell layers becomes prominent, with greater density in ventral cf. dorsal hippocampus; staining for PV remains strong. For P7-D21-28 and P12-D18 cultures CaBP and PV staining is present but attenuated. Exposure of P7-D7 slices to bFGF (50 ng/ml) during culture markedly depressed PV but spared CaBP expression. In both P7-D7 and D8-14 cultures paired pulse facilitation and inhibition, and LTP and LTD of extracellular CA1 EPSPs could be observed. Although expression of CaBP resembles in vivo development, that of PV is considerably enhanced. The early presence and distribution of CaBP and PV in interneurons correlates with evidence for the excitatory role of GABAergic neurons in synaptogenesis and suggests that the Ca-binding proteins may be playing a significant role in buffering and translocation of Ca²⁺. EXPRESSION OF CNTF RECEPTOR α IN RAT BRAIN NEUROEPITHELIUM CLOSELY CORRELATES WITH NEUROGENESIS. M.-Y. Lee, H.-D. Hofmann, B. Heimrich* and M. Kirsch, Catholic University Medical College, Seoul. Korea and Institute of Anatomy I, Freiburg, Germany.

Institute of Anatomy I, Freiburg, Germany. The involvement of CNTF receptor α in the regulation of central nervous system development is suggested by several lines of evidence including its early expression in the proliferating neuroepithelium. To investigate the relation of CNTFR α expression to the proliferation and differentiation of neuronal precursor cells we have studied the distribution of receptor mRNA in proliferative zones of the embryonic and postnatal rat brain by non-radioactive in situ hybridization.

At embryonic day 16 (E16) the entire neuroepithelium surrounding the ventricles was strongly labeled. During further development expression of CNTFRα became increasingly restricted to specific areas of the ventricular zone. CNTFRα became were never detected in other proliferation zones (subventricular zone, cerebellar external germinal layer) or in areas of precursor cell migration. In the neuroepithelium of the lateral ventricles CNTFRα expression started to cease around birth and only a small area close to the olfactory ventricle remained labeled until P14. In the third ventricle expression was restricted to the most dorsal habenular neuroepithelium at P3. CNTFR expression in the neuroepithelium of the fourth ventricle ceased already at late embryonic stages except at the edge of the lateral recess. The aqueductal neuroepithelium also showed a very distinct expression pattern and the most dorsal part of the tectal recess remained labeled until P10. Thus, the temporal and spatial distribution of CNTFRα mRNA in the neuroepithelium closely correlated with previously described patterns of persisting neurogenesis in the neuroepithelium itself and in the neighbouring subventricular zone. This was comfirmed by comparing CNTFRα in situ hybridization with BrdU immunocytochemistry. Our results suggest that CNTFRα plays a role in the regulation of neurogenesis in the ventricular and subventricular zone, although it is not generally expressed in proliferating neuronal progenitors. EXPRESSION PATTERNS OF BONE MORPHOGENETIC FACTOR RECEPTOR mRNAs IN THE DEVELOPING AND ADULT RAT BRAIN S. Söderström, H. Bengtsson and T. Ebendal*. Department of Developmental Neuroscience, Uppsala University, Biomedical Center, Box 587, S-751 23 Uppsala, Sweden.

In addition to neurotrophins, members of the superfamily of transforming growth factors (TaF)-β, such as activins, bone morphogenetic factors (BMPs) and glial cell line-derived neurotrophic factor (GDNF), have been suggested to regulate developing neurons. Human recombinant GDNF stimulates survival and fibre outgrowth in chicken embryo sympathetic and ciliary ganglionic neurons. Molecular cloning of serine-threonine protein kinase receptors from peripheral ganglia and retina of the chicken embryo shows the presence of several different types II and I receptors likely to mediate neurotrophic effects. In situ studies have shown that the type II and type I receptors in developing and adult rat brain are expressed in different, developmentally regulated patterns. Only partial overlap in distribution was found among type II (ActR-II. BMPR-II) and type I receptors (ActR-I, ActR-IB, BMPR-IA, BMPR-IB and TβR-I), suggesting that complex interactions between ligands and receptors may mediate trophic signals in CNS. Preliminary in situ results show that some ligands among activins, BMPs and the growth/differentiation factors (GDFs) known to bind and activate serine/threonine kinase receptors, are expressed in the brain parenchyma, whereas other ligands appear to be expressed mainly in meninges and the vasculature of CNS.

DEVELOPMENTAL REGULATION OF CILIARY NEUROTROPHIC FACTOR RECEPTOR IN EMBRYONIC CHICK HEART. X. Wang and S. W. Halvorsen*, Dept. Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260.

Ciliary neurotrophic factor (CNTF)/growth promoting activity (GPA) are members of the neurokine family of factors that have extensive effects on a wide variety of neuronal and glial populations. Yet, outside of the nervous system there is a limited response to CNTF due to the low level of expression of the CNTF receptor a subunit. In the peripheral nervous system chick parasympathetic neurons are exquisitely sensitive to the neurotrophic effects of CNTF. We have begun to examine the interaction of avian parasympathetic neurons with their targets of innervation. Surprisingly, we found, using Northern blot analysis, that the embryonic chick heart expresses significant levels of mRNA for the CNTF receptor a subunit. The cardiac mRNA is the same size as that detected in chick embryonic ciliary ganglia and brain (~2.7kb) and was seen as early as embryonic day 3 (e3). The levels of expression were 2 to 3-fold greater in atria than in ventricles at e15. Further, we found that the expression of CNTF receptor mRNA was developmentally regulated in both atria and ventricles, with levels at e11-13 as much as 4 to 5-fold greater than those at e3. E11-13 is a critical period in cardiac development when functional parasympathetic synaptic activity begins to appear suggesting that cell-cell interactions may regulate CNTF receptors. The relative contribution from cardiomyocytes compared with cardiac ganglion neurons to this receptor signal has not been determined. In conclusion, the finding that the regulation of CNTF receptors occurs at a time of synaptogenesis provide a means for using this chick model for elaborating the molecular mechanisms of controlling neurokine responses and understanding their physiological role in a defined cell population (Supported by grants NIII R55-NS30232 and AIIA-NYS Affiliate #940021)

HIGH POTASSIUM INCREASES SURVIVAL MOTONEURONS FROM CHICK EMBRYO SPINAL CORD THROUGH A CALMODULIN DEPENDENT MECHANISM. J.X. Comella*, R.M. Soler, J. Egea, E. Giné. C. Sanz-Rodriguez. Unit of Molecular Neurobiology, Dept. Cièncie4s Mèdiques Bàsiques, Univ. Lleida, E-25198 LLEIDA, Spain.

During development most neuronal populations undergo a process

During development most neuronal populations undergo a process usually referred to as naturally occurring cell death. For motoneurons (MTNs) of the lumbar spinal cord of chick embryo, this process takes place in a well defined period of time, between embryonic days 6 and 10. For their survival, neuronal populations depend on the availability of specific neurotrophic factors derived from their innervation target tissue. It is known that an increase in the intracellular calcium levels allows to maintain cultures of neuronal populations in spite of the absence of neurotrophic factor. This can be achieved by increasing the extracellular potassium concentration that in turn depolarizes the cytoplasmic membrane and voltage-dependent calcium channels open. We have found that the same phenomenon can be induced in MTNs by adding 30 mM potassium to the culture media. Survival is dependent on extracellular calcium since addition of the calcium chelator EGTA blocks the potassium effect. By using FURA-2 intracellular calcium measurements it can be demonstrated that potassium increases chronically the concentration of calcium from a resting value of ca. 50 nM to 150 nM value in depolarized MTNs. We have observed that calcium is able to specifically activate the ras/MAPK pathway and this activation is mediated in some point by calmodulin since specific inhibitors (W13) but not the inactive chemically-related analogue (W12) blocks, both survival effects and activation of the ras/MAPK pathway.

REK-4 RECEPTOR EXPRESSION IS DEVELOPMENTALLY REGULATED IN THE RODENT FOREBRAIN. R.M. Cassidy*, P.L. Holst¹, G.M. Fox¹, and L.F. Kromer. Dept. of Cell Biology & Interdisciplinary Program in Neurosci., Georgetown Univ. Med. Ctr., Washington, DC 20007 and Amgen, Inc., Thousand Oaks, CA

Recently Cek-4 & 5, members of the Eph-related tyrosine kinase receptor subfamily, have been implicated in the development of topographic retinotectal projections. In the present study, in situ hybridization procedures were used to evaluate the embryonic (E18), postnatal (P0, P3, P14), and adult expression of a rat homologue of the postnatal (PO, P3, P14), and adult expression of a rat nomologue of the Cek-4 receptor, Rek-4. At E18 there is extensive expression of Rek-4 in neuroepithelium within the ventricular and subventricular zones of the lateral ventricles. Migrating neuroblasts and neuroblasts within the cortical plate and developing pyramidal cell layers of the hippocampus, piriform, and insular cortices also exhibit a high hybridization signal. At birth and during early development (P0-3), there is continued expression of Rek-4 in the germinal zones, in hippocampal and dentate granule cells, and within specific neocortical nippocampat and dentate gradule certs, and within spectric redoctivities lamina. By P14 there is a global reduction in Rek-4 expression in all forebrain regions with heavily labeled neurons most frequently observed in the piriform cortex and hippocampus. In the adult, Rek-4 expression is uniformly reduced in all forebrain areas, including the These observations suggest that Rek-4 mRNA is nippocampus. These observations suggest that Rek-4 linkNA is expressed at high levels in many forebrain regions during neurogenesis, neuronal migration, and axonal growth, with a rapid postnatal down-regulation to very low levels in the adult. BRIEF EXPOSURE TO NEUROTROPHINS INCREASES THE CHOLINE ACETYLTRANSFERASE ACTIVITY OF CULTURED SEPTAL NEURONS IN A CALCIUM- DEPENDENT MANNER. D. Nonner, E.F. Barrett* and J.N. Barrett. Dept. Physiology & Biophysics. Univ. Miami Med. School, P.O. Box 016430. Miami FL 33101.

Previous studies have shown that week-long exposures to nerve growth factor (NGF) or brain-derived neurotrophic factor (BDNF) increase the activity of choline acetyltransferase (ChAT) in basal forebrain cholinergic neurons. Since in other cells neurotrophins (NTs) cause phosphorylation of their trk receptors within a few minutes, we tested whether brief exposure to NTs might be sufficient to elevate ChAT activity.

Embryonic (E15) rat septal neurons grown for 7 days in medium lacking exogenous neurotrophins were exposed to NGF, BDNF, NT-3 or NT-4 (each at 100 ng/ml) for 15-60 min, after which NTs were washed out and replaced with control medium. After 12 hr ChAT activities in NT-treated cultures were ≥50% greater than those in sister cultures never exposed to NT, and the increase persisted for at least 24 hr. This NT-induced increase in ChAT activity was not mediated by increased neuronal survival, but did require the presence of extracellular Ca2+ during NT exposure. Consistent with a role for Ca2+ in this response, NT exposure produced a transient increase in intracellular [Ca²+], a subpopulation of fura-2-filled septal neurons. The NT-induced increase in ChAT activity was blocked by the tyrosine kinase inhibitors K252a (2 µM), K252b (5 μ M) and genistein (20 μ M).

These results suggest that brief exposure to NTs can produce prolonged changes in ChAT activity, and that the signalling pathway requires Ca* and kinase activity of trk receptors. Supported by NS 12207. Neurotrophins kindly supplied by Regeneron Pharmaceuticals.

QUANTITATIVE ANALYSIS OF THE INFLUENCE OF NEUROTROPHINS ON THE CELL-CYCLE PARAMETERS OF MOUSE CORTICAL PRECURSOR CELLS, C. Dehay, A. Shering V. Cortay, P. Savatier** and H. Kennedy. INSERM U371, 18 avenue du Doyen Lépine 69675 Bron, FRANCE and *Ecole Normale Supérieure, 46 allée d'Italie, 69364 Lyon Cedex 07 FRANCE.

The influence of neurotrophins BDNF, bFGF, EGF, NT3 and NT4 was studied in dissociated cell cultures of $\hat{E}14$ embryonic cortical precursors. Proliferation and cell cycle parameters were studied by means of BrdU incorporation by cells in S phase following a 3 hours exposure. The total cycling population (i.e. the growth fraction: GF) was revealed by PCNA (proliferating cell nuclear antigen) immunostaining. The cell-cycle parameters were estimated (1) with FACS analysis which when using BrDU and propidium iodide double labelling allows estimation of the absolute duration of the different phases of the cell-cycle and (2) with immunocytochemistry by means of the labelling index (LI) calculation. The LI corresponds to the proportion of BrdU positive cells (ie cells in S phase) with respect to the total cycling population (PCNA imunoreactive cells). Variations of the LI value reflect modifications of the cell-cycle kinetics so that low values of LI reflect low rates of division due to long cell-cycle duration whereas high LI values indicate fast rates of cell division with shorter durations of cell cycle time. We found that in presence of bFGF (50ng/ml during 48 hours), there is an increased proliferation of mouse cortical precursors. This is accompanied by higher values of LI and GF indicating that bFGF promotes cortical proliferation by shortening the cell cycle and by influencing the mode of division. The increase in GF indicates that bFGF inhibits differentiation by inducing the precursors to retain their proliferative abilities. Similar but less pronounced effects were obtained when EGF (50ng/ml) was added to the culture medium for 48 hours. NT3, NT4 and BDNF failed to influence cortical cell proliferation

FLOOR PLATE NEUROEPITHELIUM HAS BINDING SITES FOR GROWTH REGULATOR, VASOACTIVE INTESTINAL PEPTIDE. I. M. Hill*, P. Gressens, G. W. Glazner and D. E. Brenneman. Lab. of Dev. Neurobiol. NICHD, NIH, Bethesda, MD 20892; Service de Neuropediatrie, Hopital Robert-Debre, Paris, France.

The trophic actions of VIP in CNS cultures occur indirectly through the vasoactive intestinal peptide (VIP)-induced release of several glial factors, including activity dependent neurotrophic factor (ADNF). In the mouse, VIP is an important regulator of growth during embryonic days (E) 9-11. Since VIP binding sites are restricted to the nervous system during this period, the VIP-induced coordinated growth of brain and body suggests that the growth-regulatory functions of VIP are indirect. Furthermore, VIP-stimulated growth has been shown to occur through the action of the endogenous factor, ADNF. Here we describe the regional localization of VIP binding sites in the neural tube of the E9 mouse embryo examined with 135I-VIP and in vitro autoradiography. Moderately dense VIP binding was seen throughout the neural tube. High densities of VIP binding were seen along the floor plate and ventral midline neuroepithelium and were especially evident in the midbrain, hindbrain and spinal cord. The high density of VIP binding sites along the extent of the floor plate of the neuraxis, the center governing tissue organization during this period of development, suggests that VIP regulates the release of diffusible signals that are secreted from this region and coordinate early morphogenic events. The floor plate is composed exclusively of macroglia in the rat. This is consistent with the hypothesis that VIP-regulated growth is mediated through ADNF and other factors released from the floor plate glial cells

GESTATIONAL METHYLMERCURY EXPOSURE ALTERS NEUROTROPHIN-AND NEUROTRANSMITTER- STIMULATED PHOSPHOINOSITIDE (PI) HYDROLYSIS IN NEONATAL RATS. S. Barone, Jr.*, T.M. Freudenrich and W.R. Mundy. Neurotoxicology Division, NHEERL, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711.

Neurotrophin-induced signal transduction mediated through the trk receptors has been implicated in neuronal growth, differentiation, and survival. In this study we have examined changes in the ontogeny of agonist-stimulated PI hydrolysis as a possible mechanism for the neuropathology resulting from exposure to the developmental neurotoxicant, methylmercury (CH,Hg). Long-Evans dams were dosed p.o. on gestational days 6-15 with 0 or 2 mg/kg CH,Hg dissolved in saline. Pups were sacrificed and regional were performed on postnatal days (PND) 1, 4, 10, 14, and 21. Agoniststimulated PI hydrolysis was measured as the accumulation of inositol phosphates (IP) in brain slices from cortex and cerebellum. In control slices (PND 4), the neurotrophins NT-3 and BDNF (1-1000 ng/ml) stimulated IP accumulation in a concentration-dependent manner with an EC₅₀ of 400 ng/ml and a maximum stimulation of 250% of basal. NGF was effective only in the cortex with maximum stimulation of 150%. Carbachol-, norepinephrine-, and neurotrophin-stimulated PI hydrolysis was greatest on PND 1-4, and decreased with age in both brain regions. Neurotrophins did not stimulate IP accumulation above basal levels after PND 10. CH₃Hg had no effect on Norepinephrine-, NT-3-, or BDNF-stimulated IP accumulation at any age in the cerebellum. In the cortex, carbacholstimulated IP accumulation was decreased in PND 1 compared to controls. NT-3stimulated IP accumulation was decreased on PND 1, and increased on PND 14 compared to controls. NGF-stimulated IP accumulation, which was not above basal levels in control animals on PND 14-21, was increased on PND 10-21 in CH₃Hg exposed rats. These results suggest that gestational exposure to CH₃Hg alters the signal transduction cascade associated with neurotransmitter and neurotrophin receptors in the cortex

IMMUNOREACTIVITY OF HIGH-AFFINITY NEUROTROPHIN RECEPTORS (TRK-A, TRK-B AND TRK-C) IN CAT VISUAL CORTEX DURING POSTNATAL DEVELOPMENT. O. Gu*, Y. Li and M. Cynader. Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, BC, Canada V5Z 3N9.

Recently, it has been shown that neurotrophins are involved in visual cortex development and activity-dependent plasticity. To further explore the role of neurotrophins in the developing visual cortex, we investigated the localization and distribution of the high-affinity neurotrophin receptors trkA, trkB and trkC in the primary visual cortex of cats aged at 2, 4, 6, or 12 weeks, and in adult animals. TrkA, trkB, and trkC, were visualized in cortical sections with specific polyclonal antibodies using immunocytochemical techniques. Each of these high-affinity neurotrophin receptors showed unique and selective laminar distribution patterns, and the immunoreactivity associated with all three receptors declined during postnatal development. At all ages examined, trkB-related immunoreactivity was always stronger than that associated with trkA and trkC. While trkB-related immunoreactivity was found to be still abundant in adult visual cortex, immunoreactivity associated with trkA and trkC was reduced to a minimum at this age. Immunoreaction product for all three receptors was primarily associated with neuronal somata and dendrites, especially those of pyramidal neurons. However, immunoreactivity related to trkB also was found within glial cells at 6 weeks of age, and immunoreactivity of trkC was mostly localized in axons in adult visual cortex. In conclusion, since trkA, trkB and trkC are the primary targets of different neurotrophin family members, our results suggest that each neurotrophin family member may play a specific role in the development and maintenance of neuronal structures in the visual cortex.

TrkB-LIKE IMMUNOREACTIVITY IS NOT EVIDENT ON GENICULOCORTI-CAL AFFERENTS IN LAYER IV OF KITTEN VISUAL CORTEX. M.A. Silver*, M.J. Radeke', S.C. Feinstein', and M.P. Stryker'. W.M. Keck Center for Integrative Neuroscience and Neuroscience Graduate Program, Univ. of California. San Francisco, CA 94143; and Neuroscience Research Institute and Dept. of Molecular. Cellular, and Developmental Biology, Univ. of California, Santa Barbara 93106.

Delivery of neurotrophic factor ligands of TrkB locally to primary visual cortex has

been shown to have effects both on geniculocortical afferents, causing desegregation of ocular dominance columns (NT-4/5 and BDNF, Cabelli, et al., Science, 1995), and on geniculate cell bodies, preventing changes in size following monocular deprivation (NT-4/5, Riddle, et al., Nature, 1995). These results suggest that the

deprivation (NT-4/5, Riddle, et al., Nature, 1995). These results suggest that the terminal branches of geniculocortical afferents in layer IV of the cortex may express TrkB, the high affinity receptor for NT-4/5 and BDNF.

To investigate this possibility, we have labeled geniculocortical afferents by injections of the anterograde neuronal tracer Phaseolus vulgaris leucoagglutinin (Pha-L) into the dLGN of 28 day old kittens. After a 12 day survival, brain regions of interest were processed for double label immunofluorescence using an antibody to Pha-L and either an antibody raised against amino acids 23-36 of the extracellular domain of the TrkB protein (anti-TrkB23) or one directed against amino acids 606-619 of the tyrosine kinase domain of the full length isoform (anti-TrkB.FL.).

TrkB-like immunoreactivity was present in many cortical neurons and in the cortical neuropil both in punctate and diffuse distributions. It was also observed in the medial septal nucleus and the diagonal band of Broca. The geniculocortical afferents in layer IV of the cortex were not labeled above the background of the afferents in layer IV of the cortex were not labeled above the background of the cortical neuropil, even though TrkB protein has been reported to be present on neurons within the LGN (Cabelli, et al., Soc. Neurosci. Abs., 1994). Neither punctate nor diffuse TrkB-like immunoreactivity was specifically associated with these afferents. These results suggest that the effects of NT-4/5 and BDNF on development and plasticity of geniculocortical afferents are probably not due to their direct actions on these afferents. Supported by NIH EY02874, NIH EY10739, and HHMI.

587.19

IN VITRO EXPRESSION OF FIBROBLAST GROWTH FACTOR RECEPTORS IN THE DEVELOPING CEREBRAL CORTEX <u>D.McLaughlin*</u>, <u>J.A.Clausen and D.J.Price</u>, Dept. of Physiol., Univ. Med. Sch., Teviot Place, Edinburgh EH8 9AG,

There are et least nine fibroblast growth factors (FGF1-9) and four FGF receptors (FGFR1-4). FGF-2 is expressed by the neuroepithelium of the developing telencephalon and promotes the proliferation and migration of cortical cells. It may maintain cortical cells in an immature state until neurotrophin 3 (NT-3) initiates cell differentiation. Later, FGF-2 may promote the

survival of cortical and/or subplate neurons.

In this study we first examined the distributions of FGFR1,2 in the developing cortex in vivo. Immunohistochemistry revealed the presence of these receptors throughout the wall of the developing telencephalon, from ventricular zone to cortical plate, with enhanced expression in the subplate. We then dissociated the developing cortex, and studied expression of FGFR1,2 in vitro. We added a range of neurotrophic factors to dissociated embryonic day 15 cortex. FGF-1 and FGF-2 (100pg/ml), NT-3 and NT-4/5 (10ng/ml) maintained FGFR1,2 expression in vitro

We conclude that FGFR1,2 may be involved at several stages of cortical development, and that the level of expression of the receptors may be influenced by growth factors including the neurotrophins and the FGFs themselves.

TRKB RECEPTORS LOCALIZE TO PATCHES IN DEVELOPING STRIATUM. L.C. Costantini, S.C. Feinstein, M.J. Radeke, and A. Snyder-Keller, Wadsworth Center, NYS Dept. of Health, Albany, NY, and Neuroscience Research Institute, U.C. Santa Barbara, Santa Barbara, CA.

The compartmentalized expression of neurotransmitters and neuropeptides in developing striatum begins prenatally at embryonic day 19 (E19), when dopamine (DA) afferents cluster into patches which coincide with patches of substance P (SP)-expressing striatal neurons. To investigate the role of growth factors in the initial formation of striatal patch vs. matrix, we examined the spatial and temporal expression of trkB receptors using immuno-histochemistry. Polyclonal antibodies against the C-terminus (Santa Cruz; residues 794-808), or specific for the tyrosine kinase domain (residues 606-619), revealed dense patches of immunoreactivity in the developing striatum: trkB+ cells and fibers were localized to patches beginning at E19, and co-localized with DA fibers and SP+ neurons. This patchy distribution persisted through postnatal day 10, then became more uniform, with the exception of a small population of densely-labeled cells. Antibodies raised against the extracellular domain (residues 23-36), which recognize all known isoforms of trkB, showed high expression of trkB in fiber bundles coursing through the immature striatum. Glutamate receptors (GluR1 and GluR2/3 AMPA-type and NMDA-type) were also clustered in developing striatum, co-localizing with patches of trkB+ and SP+ cells, and DA fibers. A concentration of these receptors on neurons of the developing patches may indicate a convergence of growth factors and afferent innervation onto future patch cells that may regulate the phenotypic differentiation of patch vs. matrix cells of the striatum. Specific effects of perinatal manipulation of afferents on the development of these receptors are currently being investigated. Supported by MH 46577 (A.S.K.) and EY 10739 (S.C.F.).

EXPRESSION AND LOCALISATION OF THE FOUR FIBROBLAST GROWTH FACTOR RECEPTOR TYPES IN THE HUMAN FETAL MUSCLE AND HEART

M.G. Ennas, L. Balaci, V. Sogos, S. Laconi, M. Presta and F. Gremo* Medical School, Cagliari, Brescia (Italy)

Basic fibroblast growth factor (bFGF) has been shown to stimulate proliferation and to depress differentiation of myogenic cells. It exerts its action through stimulation of high and low affinity receptors, whose presence however has never been extensively investigated in the human immature muscle. Thus, we studied the expression and localisation of the four types of high affinity, tyrosine-kinase FGF receptors (FGFRs) and of low affinity FGF binding molecules perlecam and syndecam in the embryonic and fetal skeletal and heart muscle. In brief, samples were dissected out from 8-18 week old human embryos and tissues processed for Northern and Western blot analyses as well as for immunocytochemistry. Nonnern and western biot analyses as well as for infinitiocytocierismism. Results showed that in the developing muscle mRNAs for FGFR1, FGFR3 and FGFR4 were expressed, but a progressive decrease in their content paralleled fetal maturation. In accord with it, in the human adult muscle no specific mRNA was detected. Double staining with antibodies directed against the different FGFRs and against markers of myotubes/myofibers maturation confirmed a relative abundance of FGFR3 and FGFR4 in more immature myotubes. Moreover, a different distribution of the two receptors within fibres was observed. In adult muscle, only a few FGFRs were present associated to the connective sheath. Immunostaining of samples of dystrophic muscles suggested an increase of specific FGFRs in regenerating tissue.

(Supported by Telethon-Italy and Regione Autonoma Sardegna Grants to F.G.; L. Balaci was a recipient of a Telethon fellowship).

NEURONAL DEATH: OXIDATIVE STRESS

CHARACTERIZATION OF APOPTOTIC PROTEASE ACTIVITY IN ISCHEMIC BRAIN TISSUE BY TWO-DIMENSIONAL PROTEIN ELECTROPHORESIS. S. Massa* and M.W. Sganga. Dept. of Neurology, Veterans Administration Medical Center and University of California, San Francisco 94121.

Activation of specific proteases plays a major role in a cell's comittment to undergo efficient self-destruction after subnecrotic injury. We have used in vivo and in vitro models of such cellular injury combined with large format two-dimensional electrophoraes to examine the pact translational assessment. electrophoresis to examine the post translational processing and proteolytic degradation of neuronal proteins important to the apoptotic program. Proteins were extracted from primary cultured neurons metabolically labelled with 35-S-methionine. These normal proteins were then exposed to enzymes generated by either cultured neurons undergoing potassium shift-induced apoptosis or cortical and hippocampal tissue from gerbils which had experienced global ischemia. dimensional analysis revealed several major and minor protein components which were degraded by activated proteases or otherwise modified post-translationally. Studies using specific inhibitors have identified several of the processing events to be dependent on ICE-related proteases in particular. identification of cell death-specific proteases, modifiers and their substrates will provide targets for therapy which may decrease the extent of neuronal injury caused by stroke-related ischemia. Supported by grants from UCSF and the VA.

PRETREATMENT WITH THE PLATELET - DERIVED GROWTH FACTOR - BB AMELIORATES THE DELAYED NEURONAL DEATH FOLLOWING FOREBRAIN ISCHEMIA IN RATS. K. Iihara, T. Tsukahara*, M. Sakata, H. Yanamoto, T. Taniguchi, and N. Hashimoto. Dept. of Cerebrovascular Surg., National Cardiovascular Center, Osaka 565 : Dept. of Neurosurg., Maizuru Municipal Hospital, Kyoto 625 ; Dept. of Neurosurg., Maizuru Univ., Kyoto 607: Japan

Our previous study demonstrated that ischemia induces the expression of the platelet-derived growth factor (PDGF) -B chain, but not -A chain, first in neurons and later in Our previous study demonstrated that ischemia induces the expression of inclipated-derived growth factor (PDGF) - B. chain, but not -A chain, first in neurone and later in brain macrophages in both mRNA and protein levels after focal ischemia in rat brain (lihara et al., J CBF Metab 14, 818, 1994). Recently, we have shown the induction of PDGF \(\beta\) -receptor in focal ischemia and suggested the importance of the coordinate expression of the B chain and the B-receptor in the neuronal survival, glial response and accumulation of the bain macrophages in the ischemic brain (lihara et al., J CBF Metab 16, 1996 in press). Here we demonstrated that pretreatment with PDGF-BB, but not-AA, ameliorates the delayed neuronal death (DND) following forebrain ischemia in rats. Intraventricular cannula connected to osmotic minipump was placed using stereotaxic apparatus on male Wistar rats two days before the operation. Rats subjected to ischemia were divided into subgroups with infusion of 2µg of; a) PDGF-AA, b) PDGF-BB, c) albumin, (n=7) respectively. Forebrain ischemia was induced on Wistar rats by transient occlusion of bilateral carotid arteries together with lowering the blood pressure to 50 mmHg. On day 7 post ischemia, rats were sacrificed and the number of survived CA1 symanidal neurons was counted on histological specimen. Pretreatment with PDGF-BB significantly increased the number of survived CA1 subfield (P<0.001) as compared with albumin group. In contrast, PDGF-AA showed no protective effect on the DND. This suggests that PDGF-BB, but not PDGF-AA, has neuroprotective action in the ischemic brain.

Table. Survived Neurons in the CA1 (cell counts/mm) (P<0.001)

CLONING OF A SERINE PROTEINASE INHIBITOR FROM THE BOVINE BRAIN AND ITS CHARACTERIZATION. M. Nishibon*, N. Nakaya, M. Kawabata, N. Adachi and K. Saeki. Dept. of Pharmacology, Okayama Univ. Med. School Okayama 700, JAPAN.

A growing evidence suggests that serine proteinases such as thrombin and tissue-type plasminogen activator may be involved in the processes of neuronal degeneration, repair and cell death. Serine proteinase inhibitor (serpin) is one of the counter molecules of the action of proteinase. Previously we purified a novel serpin B-43 from the bovine brain. In the present study, we cloned B-43 cDNA and investigated the biochemical feature of the recombinant protein. Moreover, we examined the effect of transient ischemia on the expression of B-43-like immunoreactivity in the rat hippocampus. The bovine B-43 cDNA was cloned from bovine brain cDNA library. The length of the cDNA was 1338 bp. It encoded 378 amino acids, and the mW of the protein was estimated to be 42.6 kDa. which is consistent with that of the native B-43 purified from the bovine brain. A homology search revealed that B-43 belongs to the ovalbumin branch of the serpin superfamily. The sequence of the reactive site of B-43 was estimated to be Arg-Cys on the basis of the alignment of the amino acid sequence of B-43 to some members of the serpin superfamily . B-43 was the most homologous to PI-6/mSP-3. Northern blot analysis showed that the size of the transcript was 1.4 kb and that there was marked variation in the expression of B-43 among the brain regions. [35S]-labeled B-43 protein synthesized in vitro formed complexes with thrombin, trypsin and α -chymotrypsin, but not with urokinase or plasmin. After transient forebrain ischemia induced by four vessel occlusion, the expression of B-43 was increased in the pyramidal cells of CA1-CA3 in the rat hippocampus These results suggest that B-43 might be involved in the processes of neuronal degeneration through the inhibition of serine proteinases in the brain.

CYCLIN D1 IS UPREGULATED IN REGIONS OF NEURONAL DEATH DURING ISCHEMIA, EPILEPSY AND IN A DEVELOPMENTAL MODEL OF NEURONAL DEATH. S. Timsit, S. Rivera, N. Chevassus Au Louis, E. Tremblay,* F. Guischard, P. Ouaghi, Y. Ben-Ari and M. Khrestchatisky. Université René Descartes, ParisV, INSERM U-29, 123, Bd Port-Royal, 75014 Paris France.

Cyclins D play a key role in the G1 phase of the cell cycle. They have also been involved in programmed cell death in cultured neurons. To investigate the potential role of cyclins D in selective and delayed cell death we have studied the expression of cyclins D1, D2, D3 in two well known models of in vivo pathological neuronal death: transient global ischemia and intra-amygdaloid kainate injections causing status epilepticus. In situ hybridization with cyclin D1, D2 and D3 probes revealed a specific upregulation of cyclin D1 in regions of ischemia-induced neuronal death as assessed by TUNEL method: namely the hilus at 48 hours, followed by the CA1 region of the hippocampus at 72 hours and the cortex at 96 hours. Cyclin D1 was also upregulated in the CA3 region starting 16 hours after kainate injection. Parallel induction of cyclin D1 was observed by immunohistochemistry in ischemia. Neither cyclin D2, nor cyclin D3 mRNÁ were increased in the hippocampus of ischemic or epileptic rats. The cyclin D1 upregulation in regions of neuronal death was not restricted to the hippocampus. Furthermore, cyclin D1 expression was also observed postnatally in visual diencephalic regions after experimental lesion of the occipital cortex. Our data show for the first time that cyclin D1 is upregulated *in vivo* in regions of neuronal death in a variety of structures and regardless of the model utilized. ANTIOXIDANTS REDUCE DELAYED RETINAL CELL DEATH INDUCED BY ISCHEMIA OR HYPOGLYCEMIA-LIKE CONDITIONS A. C. Rego and C. R. Oliveira* Center for Neurosciences of Coimbra, Department of Zoology and Faculty of

ISCHEMIA OR HYPOGLYCEMIA-LIKE CONDITIONS A. C. Rego and C. R. Oliveira* Center for Neurosciences of Coimbra, Department of Zoology and Faculty of Medicine, University of Coimbra, 3000 Coimbra, Portugal Cell death upon ischemia is frequently associated with the alteration of cell function, involving an increased release of excitatory amino acids, the alteration of Ca²⁺ homeostasis and the reduction of cellular ATP. Our aim was to analyze the survival of retinal cells after incubation for a short period with hypoxia, hypoglycemia or ischaemia inducers, and further examine the effect of antioxidants. Co-cultures of retinal cells were incubated, for 15 min, in the presence of ascorbate/Fe²⁺ at pH 6.5 (oxidative stress), oligomycin and cyanide (hypoxia), iodoacetic acid (hypoglycemia) or in the presence of hypoxia and hypoglycemia inducers (ischemia). The viability of retinal cells was analyzed by determining the LDH leakage to the culture medium (in % of total), for up to 24 hours. The release of LDH in cells submitted to oxidative stress increased steadily up to 8 hours, with values of 11.86±1.45 %. LDH leakage after hypoglycemia-like conditions increased significantly from 4 hours to up to 10 hours, with values of 21.42±1.05 %, whereas LDH leakage after ischemia-like conditions increased significantly from 4 hours to up to 24 hours (42.83±3.9 %). Pre-incubation with 20 μM vitamine E or 10 μM idebenone completely prevented the cell death that occurred after oxidative stress. Cell death occurring after hypoglycemia was completely reduced for up to 10 hours in cells pre-treated with vitamine E, but only partially reduced upon pre-incubation with idebenone. Nevertheless, cell death following sichemia-like conditions (10-12 hours incubation) was only significantly reduced upon pre-incubation and maintenance of the antioxidants. These data indicate that the pattern of retinal cell death depends on the extent of metabolic depletion and that the antioxidants vitamine E and idebenone can reduce cell death, suggesting

hypoglycemia or ischemia conditions.

TISSUE INHIBITOR OF METALLOPROTEASES 1 (TIMP-1) IS AN IMMEDIATE EARLY GENE UPREGULATED IN EPILEPSY AND ISCHEMIA S. Rivera*, S. Timsit, E. Tremblay, E. Prats, P. Ouachi Y. Ben-Ari and M. Khrestchatisky. Université René Descartes, Paris V. INSERM U-29, 123 Bld. Port Royal, 75014 Paris, France.

TIMP-1 is a secreted glycoprotein of the extracellular matrix (ECM) that inhibits type IV collagenases which have been largely implicated in the destruction of matrix leading to tissue degeneration. We have studied by insitu hybridization and immunohistochemistry the expression of TIMP-1 in the brain of epileptic and ischemic rats using kainate (KA) intraperitoneal (ip) and intraamygdalar (ia) injections and the 4-vessel occlusion model of global ischemia. An early (1 h) transient increase in mRNA expression occurred in the granule reurons of the dentate gyrus in both epileptic and ischemic hippocampi. Such increase was not blocked by pretreatment with cycloheximide, which in contrast inhibited Fos protein induction in the same animals. The increase in mRNA levels, that peaked around 4-8 h, was followed by an increase of TIMP-1 protein in the cell bodies of the dentate gyrus granule cells and in their axons and dendrites. At later time points (16-72 h), in epileptic animals, astrocytes also exhibited a dramatic induction of TIMP-1 mRNA levels. TIMP-1 mRNA was particularly high at 72 h in the vulnerable CA3 and CA1 hippocampal subfields of KA ia-injected and ischemic animals respectively. In conclusion, TIMP-1 is regulated by neuronal activity, behaves like an immediate early gene, is expressed by neurons and astroglia, and may be related to excitotoxic neuronal death. Ongoing in vitro studies using TIMP-1 antisense oligonucleotides in cultured neurons should provide information on the potential role of TIMP-1 in neuronal protection. Anontosis Depends on Severity and Duration of Hypoxia in Cultured Neocortical Neurons Kenneth Banasiak, Alia Bazzy-Assad and Gabriel G. Haddad . Department of Pediatrics section of Respiratory Medicine, Yale University School of Medicine, New Haven, CT 06520 Various animal models of cerebral hypoxia-ischemia have shown evidence of neuronal apoptosis. However, it is not clear as to whether neuronal apoptosis is the direct result of hypoxia or whether other substances released during in vivo hypoxia-ischemia mediate this process. We hypothesized that hypoxia can directly induce neuronal apoptosis and that the duration and severity of hypoxia may after the time course of apoptosis. Since apoptosis implies a genetically controlled mechanism, we examined the time course of expression of bel-2 and p53 proteins (genes implicated in apoptosis and cell cycle control) in neurons cultured under various hypoxic conditions. Rat neocortical neurons were cultured under conditions of 21% O₂/5% CO₃ for 7 to 10 days. After this period, culture plates were placed in an incubator with levels set at 0.1%, 1%, and 3% O₂ with 5%CO₂. Plates were removed at 24 hour intervals for TUNEL stain, immunofluorescence staining for p53 and bcl-2, and protein extraction for Western blotting of p53 and bcl-2. When≥ 70% of the neurons exhibited positive TUNEL staining, the remaining plates were collected for DNA extraction and gel electrophoresis to detect DNA fragmentation Under all hypoxic conditions, positive TUNEL stain and DNA fragmentation were observed in vitro. However, these alterations were seen after a shorter period of hypoxia when the stress was more severe $(0.1\%\ O_2, \sim 48 hrs; 1\%\ O_2 \sim 72 hrs; 3\%\ O_3, \sim 72\ hrs)$. Time dependent increases in p53 and bcl-2 proteins were also observed on immunofluorescence staining and Western blot. These increases followed the same pattern as that of TUNEL staining and DNA fragmentation. We conclude that hypoxia can directly induce apoptosis in cultured rat neocortical neurons. The duration and severity of hypoxic exposure appears to affect the time course of neuronal apoptosis. In addition, there appears to be an increase in p53 and bcl-2 proteins in hypoxia-induced neuronal apoptosis. These gene products have been implicated in cell cycle control and alteration of there expression suggests a link between hypoxia-induced apoptosis and cell cycle control NIH #HD32573

MUSCARINIC RECEPTOR SUBTYPE DETERMINES VULNERABILITY TO OXIDATIVE STRESS IN COS-7 CELLS. J.G. Strain, and J.A. Joseph*. USDA-Human

Nutrition Research Center on Aging at Tufts University, Boston, MA 02111.

Previous research has suggested that there may be increased selective vulnerability (SV) to oxidative stress (OS) among central neuronal regions in aging, and that OS SV may be important in determining regional differences in neuronal aging. In an effort to assess whether one factor determining OS SV might involve qualitative/quantitative differences in receptor subtypes in various neuronal populations, we exposed COS-7 cells transfected with one of five muscarinic receptor subtypes $(M_1-M_1, AChR)$ to low concentrations of H_2O_2 (0, 300 or 500 μ M for 30 minutes in growth medium) and examined intracellular Ca²⁺ levels prior to and following 500 μM oxotremorine (oxo). Fluorescent imaging was used to visualize intracellular Ca^{2*} changes in individual Fura II-loaded cells. No consistent differences were observed in baseline (pre- oxo) Ca^{2*} levels or oxo-stimulated increases among the various MAChR subtypes either in the presence or absence of H₂O₂. However, following H_0O_2 exposure the number of cells responding to oxo, as well as the ability of the cells to clear excess Ca^{2*} (i.e., Ca^{2*} recovery time, $Ca^{2*}RT$) following oxo stimulation varied as a function of transfected MAChR subtype. The percent of cells showing the greatest decreases in responding to oxo were those transfected with the M1 (500 μ M H₂O₂, 30%) and M₂(45 %) subtypes while M_{1,4} and , cells showed no significant decreases with H₂O₂. However, M₃ transfected cells showed decreases in Ca²RT following H₂O₂ (25-30%). Assessments are presently being carried out to discern the factors (e.g., signal transduction, G-protein coupling) that may determine OS SV among these (MAChR) and other (doparnine, D₁, D₂ etc.,) receptor subtypes. However, these findings suggest that receptor subtype differences in various neuronal populations may determine OS SV in various neuronal regions. These differences are expressed as selective regional declines in aging. (Supported by USDA Intramural)

DOPAMINE TOXICITY AND THE PROTECTIVE EFFICACY RECOMBINANT ANTI-OXIDANT ENZYMES. S. Duffy and T.H. Murphy*. Dept.

of Psychiatry, University of British Columbia, Vancouver, CANADA V6T 1Z3
Oxidation of dopamine(DA) results in formation of several pro-oxidant neurotoxins, including H2O2 and DA quinones, suggesting that aberrant DA oxidation may contribute to the degeneration of dopaminergic neurons observed in Parkinson's Disease. Conversely, up-regulation of antioxidant enzymes may provide protection. Thus, we are examining the mechanisms of DA toxicity in Human Embryonic Kidney (HEK 293) and N18 RE105 neuronal cell lines, and the possible protection conferred by transfecting these cells with plasmids encoding the antioxidant enzymes quinone reductase (QR) and glutathione S-transferase (GST) (resulting in overexpression) These enzymes may be particularly efficacious because of their possible role in DA quinone detoxification; moreover, QR and GST activity can be induced pharmacologically, making them possible targets for therapeutic intervention. DA (10-100 µM) produced a dose-dependent toxicity as revealed by lactate dehydrogenase and β-galactosidase assay (measures of toxicity in total cells and transfected cells respectively). In N18 cells, this effect was largely ameliorated by extracellular addition of the H2O2 metabolizing enzyme catalase or the iron chelator desferroxamine, but not monoamine oxidase inhibitors, indicating toxicity mediated by H₂O₂ (from DA auto-oxidation) with subsequent iron-dependent production of hydroxyl radicals (OH). Transfection of QR and GST plasmids resulted in enhanced enzyme activities (3-7 fold); however, this overexpression did not provide significant protection against extracellular DA (OH'-mediated toxicity) in either cell line. To examine toxic effects of intracellular DA, HEK cells were transfected with a DA transporter cDNA. This greatly potentiated DA toxicity, indicating that intracellular accumulation is also deleterious. The mechanisms involved and effects of QR and GST overexpression on the toxicity of intracellularly accumulated DA remain to be determined. Supported by Heart and Stroke Foundation of BC and Yukon.

NERVE GROWTH FACTOR POTENTIATES FREE RADICAL-MEDIATED NEURONAL NECROSIS IN STRIATAL CELL CULTURES F.C. Park* ILO Jou, and B.I. Gwag. Dept. of Pharmacology, Ajou Univ. School of Medicine, Suwon 442-749, Korea.

Extensive evidence supports that neurotrophins protect central neurons against various injuries including programmed cell death or apoptosis. Recently, we reported that neurotrophins (e.g. BDNF, NT-3, and NT-4/5) potentiated certain forms of neuronal necrosis induced by exposure to NMDA or oxygen-glucose deprivation (Koh et al., 1995. Science 268:573-575). BDNF also increased neuronal necrosis induced by exposure to FeClo or buthionine sulfoximine (BSO) in cortical cell cultures (Gwag et al., 1995, neuroreport, in press.). However, NGF effect was not observed due to absence of functional receptors, trkA. The present study was performed to address effect of NGF on neuronal apoptosis and necrosis.

To test this, we prepared rat striatal cultures known to express trkA receptors and respond to NGF. Neuron-glia cocultures (DIV 13-15) exposed to 5 \(\true{m}\) M FcClo or 100 \(\true{m}\) M BSO produced mild neuronal death 24 hr later. Pretreatment with 100 ng/mL NGF caused rapidly-evolving expansion of neuronal cell bodies about 4 hr following exposure to FcClo or BSO, and markedly increased the resulting neuronal death observed 24 hr following the oxidative stress. This necrosis potentiation by NGF was prevented by inclusion of 1 \(\true{m}\) g/mL cycloheximide a protein synthesis inhibitor, as well as 100 \(\true{m}\) M trolox, an antioxidant, suggesting that NGF may potentiate free radical-induced neuronal necrosis through mechanisms involving synthesis of new proteins.

Neuron-rich stratal cultures (DIV 7) deprived of serum undergo neuronal apoptosis characterized by cell body shrinkage, chromatin treatment with NGF did not attenuate neuronal apoptosis induced by serum deprivation. Absence of neuroprotection by NGF against the neuronal apoptosis induced by a graduate research fund from Ajou University S

HYDROXYNONENAL MAY MEDIATE APOPTOTIC NEURONAL DEATH INDUCED BY TROPHIC FACTOR WITHDRAWAL AND OXIDATIVE INSULTS. I. Kruman. O. Guo. A. J. Bruce, D. E. Bredesen, W. R. Markesbery*, and M. P. Mattson. Sanders-Brown Research Center on Aging and Department of Anatomy & Neurobiology, University of Kentucky. Lexington, KY 40536. La Jolla Cancer Res. Foundation, La Jolla. CA 92037.

Lexington, KY 40546. La Joila Cancer Res. Foundation, La Joila, CA 92037. Oxidative stress can induce apoptosis in a variety of cell systems. In PC12 cells withdrawal of trophic factor support (WTFS) and amyloid β -peptide (A β) induce apoptosis, and the cell death can be prevented or delayed by administration of antioxidants. We have found that WTFS and A β induce oxidative stress in PC12 cells and primary embryonic rat hippocampal neurons: the oxidative stress precedes neuronal death and antioxidants protect the neurons from death. 4-hydroxynonenal (HNE) is a relatively stable aldehydic product of lipid peroxidation that he been linked to several different disease processes including tion that has been linked to several different disease processes including atherosclerosis and liver toxicity.

We report here that: (1) HNE can induce apoptosis of PC12 cells and We report here that: (1) HNE can induce apoptosis of PC12 cells and hippocampal neurons in a concentration-dependent manner. (2) A\(\beta \) and other oxidative insults induce lipid peroxidation. HNE production, and conjugation of HNE to multiple cellular proteins. (3) Expression of Bc1-2 protects PC12 cells against apoptosis induced by HNE. High concentrations of HNE induce necrosis rather than apoptosis and this death is not prevented by Bc1-2. HNE may promote neuronal damage and death by impairing ion-motive ATPases and disrupting calcium homeostasis (see Mark et al., this meeting). Moreover, HNE may induce further oxidative stress in neurons by causing gluathione depletion. We have found that gluathione-ethyl ester protects cultured neurons against AB toxicity. WTFS, and HNE toxicity. A better understanding of the chemistry and cellular bioactivities of HNE may lead to the development of novel compounds that protect neurons from degeneration in the myriad of neurodegenerative conditions in which oxidative stress and apoptosis play roles. SELECTIVE DEGENERATION OF NEURONS and OLIGODENDROCYTES BY OXIDATIVE STRESS: INVOLVEMENT OF NF-kappa B. K.-Y., Park*, E.C., Park, I.L.O., Jou, and B.J. Gwag Dept. of Pharmacology, Ajou Univ. School of Medicine, Suwon 442-749, Korea.

Cocultures of neurons and glia exposed to 10-50 \(\mu \) M ferrous chloride (FeCl2) or 0.1-1 mM buthionine sulfoximine (BSO) undergo neuronal degeneration over 24 hr. The oxidative stress also induced death of oligodendrocytes in the absence of detectable astrocyte injury. The degeneration pattern of neurons and oligodendrocytes is similar to necrosis involving cell body swelling. This degeneration pattern correlates well with localization of NF-kB. Cytoplasm of neurons and oligodendrocytes were immunolabeled with antibodies specific to NF-kB Ilowever, NF-kB immunoreactivity was barely detectable astrocytes. Considering the potential role and localization of NF-kB is jossible that neurons and oligodendrocytes exposed to Fe* or BSO may degenerate through mechanisms involving activation of NF-kB. In support of this, FeCl2 treatment induces translocation of NF-kB from cytoplasm to nucleus in cortical neurons and oligodendrocytes prior to death. Inclusion of 100 \(n \text{M} \) trolox, an antioxidant, or pyrrolidine dithiocarbamate (PDTC), an inhibitor of NF-kB, blocks nuclear translocation of NF-kB. In addition, trolox or PDTC blocks the free radical-induced swelling of cell bodies and cell death. In contrast, the same treatment with PDTC or trolox does not block excitotoxic neuronal death induced by exposure to 15 \(\mu \text{M} \) MNDA or 40 \(\mu \text{M} \) M kainate. These results suggest that NF-kB activation is a critical step to the free radical-mediated cell death in central nervous system.

SURVIVAL FACTOR-INSENSITIVE GENERATION OF REACTIVE OXYGEN SPECIES INDUCED BY NEURONAL APOPTOSIS IN CULTURED CELLS. T. Satoh. N. Sakai. Y. Enokido. Y. Uchiyama. and H. Hatanaka. Div. of Protein Biosynthesis, Institute for Protein Research, Osaka Univ., 3-2 Yamadaoka, Dep. of Anatomy, Med. Sch. of Osaka Univ., 3-1 Yamadaoka, Suita, Osaka 565, Japan.

ROS (Reactive oxygen species) play a key role in not only several pathological, but also physiological events in the nervous system. We performed confocal and flow cytometry with a ROS-specific fluorogen, 6carboxy-2',7'-dichorodihydrofluorescein diacetate, di(acetoxymethyl ester) (C-DCDHF-DA) to investigate the involvement of ROS in neuronal apoptosis. For flow cymetry, the total number of events was 5,000 per sample. The samples were gated to obtain data from viable cells stained with C-DCDHF -DA (T. Satoh, et al, Neurosci. Lett. 201 (1995) 119-122). Serum deprivation decreased the viability to about 40 and 50% of that of PC12 cells and cortical neurons, respectively, incubated in the presence of serum. In the presence of NGF, cAMP analog and insulin, the number of viable PC12 cells recovered to the same level as the control. Bcl-2 blocked serum deprivation-induced apoptosis in PC12 cells. In rat cortical neurons, EGF completely prevented serum deprivation-induced apoptosis. In PC12 cells, serum deprivation significantly increased the level of ROS. However, NGF, cAMP analog, insulin and Bcl-2, which prevented apoptosis, did not affect the upregulation of ROS induced by serum deprivation. Also, in rat cortical neurons, serum deprivation increased the level of ROS. EGF, which prevented apoptosis, did not affect the increase of ROS. These data suggest that survival factors rescue the serum deprivation-induced apoptosis independently of ROS production.

NEUROPROTECTION OF ORGANOTYPIC SLICE CULTURES AGAINST OXIDATIVE STRESS-INDUCED CELL DEATH AS ASSESSED BY DIFFERENT VIABILITY ASSAYS. T. Skutella^{1*}. A. Scheidereiter¹, R. Nitsch¹, and C. Behl², Humboldt University Clinic (Charite), Institute of Anatomy, D-10098 Berlin¹ and Max-Planck Institute of Psychiatry Clinical Institute of Anatomy. Munich², Germany

The entorhinal-hippocampal system is one major target in neurodegenerative disorders such as Alzheimer's disease in which a role of oxidative stress-induced cell death has been implicated. Antioxidants such as vitamine E and ß-estradiol scavenge free radicals, prevent the peroxidation of membrane lipids and therefore may protect neurons against oxidative challenges. To study if these antioxidants do effectively protect hippocampal neurons maintained in their organotypic organization, hippocampal slice cultures from adolescent rats were employed. Using this cellular system, hydrogen-peroxide (H_2O_2) -, glutamate- and β -amyloid induced cell death as paradigms of oxidative stress-induced neurodegeneration were studied. Viability of neurons and glial cells in various hippocampal regions was determined using the fluorescent DNA dye propidium iodide. Early changes and impairments in mitochondrial activity were analysed using the MTT test. Furthermore lactate dehydrogenase release served as an indicator for cellular degeneration. A potent antioxidant effect in hippocampal tissue is reported Supported by the DFG: Ni 344/2-1 and SFB 507/C1

ESTROGEN PROTECTS AGAINST HYDROGEN PERIOXIDE TOXICITY IN DIFFERENTIATED NT-2 CELL CULTURES. K.L. Rogers*, C.A. Singer, and D.M. Dorsa. Departments of Pharmacology and Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195 and the VA PSHCS, Seattle, WA 98108 Trophic effects of estrogen on neuronal survival and differentiation are

Washington, Seattle, WA 98195 and the VA PSHCS, Seattle, WA 98108 Trophic effects of estrogen on neuronal survival and differentiation are well-described. We have noted neuroprotective effects of estrogen against glutamate toxicity in primary cortical cultures, and others have reported neuroprotection against serum deprivation and hypoglycemia in cell lines. We now present data addressing the mechanism of estrogen neuroprotection using the human NT-2 cell line terminally differentiated into a neuronal phenotype with retinoic acid treatment. Oxidative stress induced by hydrogen peroxide (H₂O₂) results in a dose- and time-dependent cell death of NT-2 neurons, quantified by measuring release of lactate dehydrogenase (LDH). Estrogen pretreatment decreases LDH release following H₂O₂ exposure. The proto-oncogene BCL-2 is thought to regulate cell survival and BCL-2 protein levels seen on immunoblots with the OM-11 antibody are upregulated with differentiation in the NT-2 cultures. Estrogen treatment results in further upregulation, suggesting that enhanced expression of BCL-2 is a possible component of estrogen neuroprotection. The cultures appear to express estrogen receptor, as demonstrated by immunoblotting with the H-222 estrogen receptor, as demonstrated by immunoblotting with the H-222 estrogen receptor antibody. Since BCL-2 has been shown to reduce oxidative stress and prevent cell death following glutathione deprivation, these data suggest an estrogen regulation of BCL-2 could serve to reduce free radical-related toxicity. A possible direct antioxidant effect of the neurosteroid estrogen regulation of genomic determinants of neuron survival. Supported by NARSAD Young Investigator Award to K.L.R., a Molecular Neurobiology Training Grant to C.A.S. and ADRC Grant AG05136 to D.M.D.

NEURONAL DEATH: EXCITOTOXICITY

589.1

BRAIN MATURITY AND SELECTIVE GLUTAMATE RECEPTOR SUBTYPE ACTIVATION INFLUENCE EXCITOTOXIC NEURONAL DEATH MORPHOLOGY ALONG AN APOPTOSIS-NECROSIS CONTINUUM. C Portera-Cailliau*, DL Price, and LJ Martin. Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Glutamate excitotoxicity is a clinically relevant process that results in selective neuronal death by mechanisms which remain unclear,

Glutamate excitotoxicity is a clinically relevant process that results in selective neuronal death by mechanisms which remain unclear. Cell death has been traditionally classified as apoptotic or necrotic based on biochemical and morphological criteria. Necrotic morphologics and apoptotic DNA laddering can co-exist following excitotoxic and ischemic insults to the adult rat brain, suggesting that apoptosis and necrosis may not be mutually exclusive modes of cell death in the nervous system. We tested the hypothesis that neuronal maturity and selective activation of glutamate receptor subtypes influence the morphological phenotype of neuronal death in vivo, along an apoptosisnecrosis continuum. Neuronal death caused by excitotoxin injections into the newborn and adult rat forebrains was assessed with respect to degenerative neuronal morphologies and DNA fragmentation patterns. In both cases, death of neurons exhibiting a variety of morphologies was observed, but unequivocal apoptosis occurred only in the immature brain. Neuronal death in developing and adult brains was characterized ultrastructurally by highly ordered but distinct sequences of subcellular organelle abnormalities, and by similar DNA laddering patterns. In the adult brain, NMDA and non-NMDA receptor-mediated neurotoxicities approximated necrosis and apoptosis, respectively. We conclude that neuronal death phenotype varies along an apoptosis-necrosis continuum, rather than through two distinct, independent cell death pathways. Supported by NIH grants AG05146, NS 20471, NS 10580.

589.3

GLUTAMATE INDUCES THE FORMATION OF HIGH MOLECULAR WEIGHT DNA FRAGMENTS CHARACTERISTIC OF APOPTOSIS IN CEREBELLAR GRANULE CELLS. R. E. Paulsen*, H. R. Holte, A.-B. Kolstø, and O. J. Marvik. Biotechnology Centre of Oslo, University of Oslo, N-0316 Oslo, Norway.

Glutamate induces cell death when released during ischemia in the brain in vivo or when added to cultured neurons in vitro. A slow component of the cell death is due to Ca^{2r} influx following activation of the NMDA subtype of glutamate receptors. Several observations suggest that Ca^{2r} may activate endonucleases, leading to the formation of high molecular weight DNA fragments characteristic of apoptosis.

We have investigated glutamate (100 μ M)-induced cell death in cerebellar granule cells in culture. In our assay >95 % protection was observed after 24 hours with the noncompetitive NMDA receptor antagonist MK801 (1 μ M), and partial (30 %) protection was observed with the non-NMDA receptor antagonist CNQX (1 μ M). A time-dependent formation of two classes of high molecular weight DNA fragments (~50 and >680 kbp) was observed using pulse-field gel electrophoresis and quantitative detection of the fragmented DNA with DNA-specific antibodies. The highest level of >680 kpb fragments was seen at 8-12 hours, whereas ~50 kbp fragments increased steadily from 6 to 30 hours following glutamate treatment. MK801, but not CNQX, protected completely against the formation of these fragments.

THE ALIAMIDE PALMITOYLETHANOLAMIDE BUT NOT ANANDAMIDE PROTECTS CENTRAL NEURONS FROM EXCITOTOXIC INJURY IN A DELAYED POSTGLUTAMATE PARADIGM. S.D. Skaper*, A. Buriani, R. Dal Toso, L. Petrelli, S. Romanello, L. Facci and A. Leon. Researchlife S.c.p.A., 31033 Castelfranco Veneto, Italy.

N-Acylethanolamides, like palmitoylethanolamide (PEA), and N-acylphosphatidylethanolamides accumulate in conditions involving tissue degenerative changes, including ischemia. Excitatory amino acid receptors are known to stimulate the synthesis of N-acylethanolamides and N-acylphosphatidylethanolamides in cultured central neurons. Interestingly, it has recently been demonstrated that mast cells express a peripheral-type cannabinoid receptor (CB2) that recognizes PEA (ALIAmides) and downmodulates activation of these cells in vitro (Facci et al., PNAS, 1995). Here we report that PEA, but not the cognate N-acylamide anandamide (the ethanolamide of arachidonic acid), protects cultured mouse cerebellar granule cells against glutamate toxicity in a delayed postglutamate paradigm. PEA reduced this injury in a concentration-dependent manner and was maximally effective when added 15 min after a 5-min glutamate challenge. Cannabinoids, which like PEA are functionally active at CB2 on mast cells, also reduced neuronal loss in this delayed post glutamate model. The PEA and cannabinoid neuroprotective effects were antagonized by the putative brain CB1 receptor agonist anandamide. Anandamide was also found to antagonize the functional effects of PEA and cannabinoids on mast cells (Facci et al., PNAS, 1995). Cerebellar granule cells expressed CB1 and CB2 mRNA, and two cannabinoid binding sites were detected in cerebellar membranes. Activation of CB2-like receptors by endogenous N-acylethanolamides may serve to downmodulate deleterious cellular processes following pathological events or noxious stimuli in both the nervous and immune systems, thus the acronym autacoid local injury antagonism (ALIA) for this mechanism.

589.4

GLUTAMATE KILLS DEVELOPING CEREBELLAR GRANULE CELLS BY OXIDATIVE STRESS INDEPENDENT OF RECEPTOR ACTIVATION. A. Leon*, G. Marcolongo°, M. Fabris and S.D. Skaper. Research*life* S.c.p.A., Castelfranco Veneto 31033 and ° Monselice 35043, Italy.

Glutamate (Glu) is thought to serve as the major excitatory neurotransmitter in the CNS, stimulating both NMDA and non-NMDA receptors. While activation of NMDA receptors participates in a variety of physiological processes, excessive Glu receptor stimulation has been implicated as the proximate cause of neurodegeneration in several types of brain insults, including hypoxia, ischemia and trauma. During episodes of metabolic compromise, such as hypoxia and ischemia, extracellular Glu levels rise. It is not clear how acute excitation alone could account for the delayed and progressive neuronal degeneration observed in the pathologies in which Glu is implicated. Glu, by inhibiting cystine uptake, may cause neuronal death due to accumulation of cellular oxidants (Murphy et al., FASEB J, 1990). Using a homogeneous population of mouse cerebellar granule neurons, we now show that Glu concentration-depenently (LC₅₀: 2 mM) produces cellular toxicity at a stage (36-48 hr in vitro) prior to development of an excitotoxic response. Glu cytotoxicity was preceeded by a loss of intracellular GSH levels, and was prevented by cystine and cell permeant GSH esters, but not by NmDA and non-NMDA receptor antagonists. A novel series of antioxidants (ALOX) were also potently cytoprotective. The Glu receptor subtype agonists NMDA, kainate and AMPA, which do not inhibit neuronal cystine uptake, were not neurotoxic. Inhibition of cystine uptake by elevated concentrations of extracellular Glu in chronic-progressive brain insults might limit the ability of neurons to maintain redox homoostasis. Therapies directed against free radical attack may be beneficial in prevention of that injury.

PROTECTIVE ROLE OF CALCIUM-BINDING PROTEINS IN DIFFERENTIATED NEUROBLASTOMA CELLS EXPOSED TO EXCITATORY AMINO ACIDS. B. Fellay, C. D'Orlando, B. Schwaller, V. Gotzos, B. Schneider and M.R. Celio*. Institute of Histology and General Embryology, University of Fribourg, CH-

Those troops are determined by the state of overstimulation may disturb the Ca²⁺ homeostasis leading to an abnormal prolonged increase of its intracellular concentration. Various reports claim a protective role of calcium-binding proteins (CaBPs) in these pathologies. We tested the capacity of the CaBPs calretinin (CR) and parvalbumin (PV) to buffer Ca²⁺ and to protect nerve cells. For this, we first transfected P19 mouse embryonal carcinoma cells with CR or PV cDNA. This cell type has the capability of differentiating into neuron-like structures expressing functional glutamate receptors upon exposure to retinoic acid. The presence of the CaBPs in cloned, transfected cells was verified by immunohistochemical staining and immunohiots. After EAA exposure, [Ca²⁺]_i measured using the ratiometric dve fura-2 showed an initial rise in both transfected and control ratiometric dye fura-2 showed an initial rise in both transfected and control P19 cells from 60 to 400 - 500 nM. $[{\rm Ca^{2+}}]_i$ decreased in transfected cells to 150 - 200 nM within 5 min, while it remained at the initial high level in control cells. The survival rate of CR-transfected P19 cell clones, compared with that of control cells, was measured using the lactate dehydrogenase assay. The results indicate a protective effect of CaBPs within the first hour following EAA stimulation of P19 cells. This protection is transient and fails to rescue cells after prolonged stress. In a second set of experiments we transfected with CR the N18RE-105 neuroblastoma-embryonic retina hybrid cell line which also show a Ca²⁺-dependent, delayed cell death induced by glutamate. Preliminary results confirm a protective role of this CaBP also in this experimental paradigm. Thus, CaBPs may help to delay cell death after EAA stimulation. DEPRENYL PROTECTS DOPAMINE NEURONS FROM EXCITOTOXIC CELL DEATH. C. Mytilineou*, P.M. Radcliffe, E.T. Kokotos Leonardi, P. Werner and C.W. Olanow. Department of Neurology, Mt. Sinai Sch. of Medicine, New York NY 10029

L-Deprenyl (selegiline), a MAO B inhibitor, protects several types of neurons from axotomy or neurotoxins by a mechanism independent of MAO inhibition (Finnegan et al., 1990; Tatton and Greenwood, 1991; Ansari et al., 1993). In this study we examined the effect of deprenyl on dopamine (DA) neurons challenged according to a paradigm that results in excitotoxic cell death. Mesencephalic cultures from E14 rat embryos were subjected, beginning on the 5th day in vitro, to 4 daily complete changes of feeding medium. Complete medium change results in increased extracellular glutamate and neuronal death, which is prevented by blocking glutamate receptors (Driscoll et al., 1993). Medium changes in mesencephalic cultures caused a 41±7% loss of tyrosine hydroxylase-positive (TH+) neurons and 65±5% reduction in [H]DA uptake and these effects were completely prevented by the NMDA receptor blocker MK-801 (10µM). At a concentration of 50µM, deprenyl prevented the loss of DA neurons (surviving TH+ cells: 107±12 of control). The loss in [H]DA uptake was also attenuated by deprenyl (31±3% reduction; p<0.001 compared to controls). The protective effect of deprenyl was dose dependent between 0.5 and 50µM. Pargyline, a potent MAO inhibitor, had no effect suggesting that protection by deprenyl was independent of MAO inhibition. Deprenyl also protected DA neurons from direct exposure to NMDA. Exposure to 200µM NMDA for 30 min. caused 25±3% loss of TH+ neurons and 46±6% loss in [°H]DA uptake. Deprenyl completely prevented the loss of TH+ neurons and protected from loss in DA uptake (17±1% reduction; p<0.01 compared to NMDA alone). Deprenyl had no inhibitory effect on NMDA receptor binding indicating that neuroprotection occurs at a point beyond the activation of glutamate receptors. APOPTOSIS OF HIPPOCAMPAL INTERNEURONS AFTER AMYGDALA KINDLED SEIZURES. L.X. Zhang*, X.L. Li, S.R.B. Weiss, R.M. Post and M.A. Smith. Biological Psychiatric Branch, NIMH, Bethesda, MD 20982.

Seizure induced neuronal damage may involve both excitotoxic and apoptotic (Programmed cell death) mechanisms. Apoptosis of neurons has been reported after kainate-induced seizures, but it is difficult to determine the role of seizure activity itself in seizure-associated cell death when convulsant drugs are used because damage that might be caused by seizure activity can't be because damage that might be caused by seizure activity can't be distinguished from damage caused by direct neurotoxic action of the drugs. Therefore, in the present study, we used a kindled seizure model in which electrical stimulation of the basolateral amygdala induces cell loss most notably in the hilus of the dentate gyrus. To identify which cells might be undergoing apoptosis, we labeled the 3' end of DNA fragments with digoxigenin nucleotides using terminal transferase (ApopTag, Oncor). We found that the number of ApopTag-positive cells increased 41.5% after one kindled seizure and 95.9% after 20 seizures compared to sham controls. The ApopTag-labeled cells appeared to be mainly interneurons of the hippocampal formation. Preferential vulnerability of GABAergic interneurons is consistent with previous studies on seizure-induced cell loss. Our present results, coupled with our previous observation that the apoptosis-related protein, BAX, is induced in the hippocampus by seizures, suggest that apoptosis of GABAergic interneurons may lead to dysinhibition in the hippocampus and result in the increased seizure activity.

HEAT SHOCK DOES NOT PREVENT APOPTOSIS IN CULTURED CEREBELLAR GRANULE CELLS. K. Sato*, H. Saito, and N. Matsuki Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, The University of Tokyo, Bunkyo-ku, Tokyo, 113

We have shown previously that heat shock attenuates serum deprivationinduced neuronal death via production of HSP70. But it remains uncertain whether heat shock is also protective to apoptosis. Differentiated cerebellar granule cells undergo apoptotic cell death when deprived of depolarizing concentration of extracellular potassium in culture. Here we investigated the effect of heat shock on low potassium-induced apontosis and glutamate toxicity. Cerebellar granule cells isolated from 8-day-old postnatal rats were plated at the density of 4×10^5 cells/cm² and cultured in the presence of 25 mM of potassium and 10 μM of AraC. After 7 days in vitro, cells were heat shocked (43 °C 30 min) and exposed to low potassium medium (5 mM) or glutamate containing medium (1-1000 µM) 24 hr after the heat shock. Cell viability was evaluated by measuring LDH release and MTT assay after 24 hr Heat shock significantly protect cultured cerebellar granule cells from glutamate toxicity but had no effect on low potassium-induced apoptosis. These results suggest that the heat shock does not prevent apoptotic neuronal death

KAINATE-INDUCED NEUROTOXICITY IS ATTENUATED IN SOD-TG MICE. H.Hirata* and J.L. Cadet, Neuropsychiatry Section, Neuroscience Branch, NIDA/NIH, P.O. Box 5180, Baltimore, MD 21224.

Peripheral administration of kainic acid (KA) can cause cell death in the hippocampus of rodents. This cell death is thought to involve oxidative stress and to occur through an apoptotic process because it involves DNA fragmentation. In the present study, we have begun to investigate KA-induced neurotoxicity in SOD-Tg mice. Low or medium dose (15 or 30 mg/kg, i.p.) of KA did not induce apoptotic cell death in the hippocampus in every group. However, a higher dose (45 mg/kg, i.p.) of KA killed 6 of 13 (46% wild-type mice, 2 of 9 (22%) heterozygous SOD-Tg mice but none of the homozygous SOD-Tg mice died. These results show that SOD-Tg mice are protected against the lethality of KA. These results suggest that superoxide radicals are involved in the toxic effects of the drug. Ongoing studies are evaluating if the SOD-Tg mice are also protected against apoptotic changes seen in the hippocampus of wild-type mice by using in situ nick translation technique

KAINIC ACID INJURY OF THE RAT HIPPOCAMPUS INDUCES ENHANCED EXPRESSION OF APOLIPOPROTEIN D IN NEURONS DESTINED FOR CELL

Wei Yi. Ong and Shutish C. Patel

Department of Anatomy, National University of Singapore, Singapore and
Neurobiology Research Laboratory, VA Connecticut Healthcare System
(Newington) & Department of Neurology, UCONN Health Center, Farmington, CT.

Apolipoprotein D (apo D), a member of the lipocalin superfamily of transporters for small hydrophobic ligands, has been implicated in the transport of cholesterol, progesterone, arachidonic acid and heme-related molecules such as bilirubin. ApoD is widely expressed in neural and peripheral tissues but its physiological role(s) are poorly understood. High levels of apoD expression have been found in the regenerating rat sciatic nerve, suggesting that it may play a role in the repair process during nerve injury. Here we report our findings on the expression of apoD in the rat hippocampus following kainic acid (KA)-induced excitotoxic injury. Using an anti-rat apoD antibody and biotin-avidin enhanced immunocytochemistry, we observed that in the normal rat brain, there was little apo D expression, restricted mainly to scattered astrocytes and to perivascular fibroblasts. In contrast to control rat brain, KA injected rats showed apoD immunoreactivity in the pyramidal neurons of the affected CA fields 24 and 48 hours after injection of the excitotoxin, at a time when there was no histological evidence of cell death. ApoD immunoreactivity peaked by day 3 coincident with neuronal cell death and declined thereafter reaching very low levels by day 7.

Besides pyramidal neurons, apoD immunoreactivity was also observed in a small number of reactive glial cells in the affected CA fields, but not in the vascular compartments at any time point. We conclude that following excitotoxic injury with KA, apoD is induced in hippocampal pyramidal neurons destined for cell death. [Supported by grants from the National University of Singapore (RP920367) and the National Institutes of Health (NS34339)].

REGIONAL LOCALIZATION OF KAINIC ACID-INDUCED GELATINASE EXPRESSION. W. Zhang* and P. E. Gottschall. University of South Florida, Department of Pharmacology and Therapeutics, Tampa, FL 33612-4799

or South Florida, Department of Pharmacology and Therapeutics, Tampa, FL 33612-4799

Evidence from *in vitro* studies implicate a role for matrix metalloproteinases (MMPs) in several neuronal functions, including differentiation during development, neurite extension, and possibly neuronal degeneration. Few reports have documented the expression of these enzymes in the brain *in vivo*. In this study, neuronal degeneration was induced in Sprague-Dawley rats by systemic administration of kainic acid (10 mg/kg). Rats were subsequently divided into convulsive and nonconvulsive groups, after observing their behavior in reaction to the drug. Animals were sacrificed 6, 12, 24, 72, and 168 h (7 days) after injection of kainic acid. Gelatinase A (MMP-2) and gelatinase B (MMP-9) were extracted from brain regions in buffer containing 1% Triton-X-100, partially purified using gelatin-sepharose, and assayed by standard gelatin-zymography. Without treatment, both enzymatic activities were expressed differentially in various brain regions with highest levels in the hippocampus and the lowest in the cerebellum, although MMP-2 was expressed at 10-20-fold higher levels compared to MMP-9. In regions from convulsive rats, gelatinase B activity was dramatically elevated 12 h after injection (8.1-fold hippocampus, 7.7-fold diencephalon, 7.2-fold striatum, 5.7-fold frontal cortex, 5.5-fold cerebellum, 2.6-fold midbrain). Gelatinase A activity was induced more than 2-fold in hippocampus, diencephalon and striatum, to a lesser extent in frontal cortex and midbrain, and unchanged in cerebellum 72 h after injection. Neither gelatinase activity was altered in any brain region from non-convulsive rats. These data demonstrate that gelatinase A and B are differentially expressed with respect to time after kainate injection and suggests that they are regulated by convulsion-associated mechanisms and degeneration. ASTRESSIN, A NOVEL CRF ANTAGONIST, PROTECTS AGAINST EXCITOTOXIC CELL DEATH. H. L. Maecker*, A. Desai, S. M. Brooke, R. M. Sapolsky, J. Rivier, and W. Vale. Department of Biological Sciences, Stanford University, Stanford, CA 94305-5020 and The Salk Institute, La Jolla, CA 92186-5800.

In the current study, the neuroprotective potential of a novel and potent CRF antagonist, Astressin, against kainic-acid induced excitotoxic seizures was measured. Initially, 22 control and 21 Astressin-treated rats were subjected to 10 mg/kg systemic kainic acid, i.p. Ten minutes prior to and 30 minutes following the insult, the rats were injected stereotactically with either saline or 25 ug Astressin into the lateral ventricle. Three days post kainic acid injection, rats were perfused, their brains fixed, sectioned, and stained for quantification of hippocampal lesions. Astressin-treated rats exhibited a highly significant reduction of total hippocampal damage, as well as a reduction in damage incurred in all hippocampal fields (p<0.001). Next, the neuroprotective potential of Astressin administration AFTER excitotoxic insult was assessed. Twelve control and twelve Astressin-treated rats were injected i.p. with 10mg/kg of kainic acid. Thirty minutes following the excitotoxic insult, the rats were stereotactically infused with either saline or 50 ug Astressin. Three days post-insult the rats were perfused and brains were prepared for lesion quantification. Astressin was again shown to have significant neuroprotective effect (p<0.001), reducing total hippocampal damage by 70%. The magnitude of protection afforded by Astressin was greater than any reported protection provided by other CRF Antagonists to date. These findings confirm the protective potential of CRF Antagonist use even when administered after excitotoxin exposure. Further, this study suggests the therapeutic potential of the novel and potent antagonist, Astressin, against neurological insult.

DNA REPAIR AND APOPTOSIS AS RESPONSE TO GENOTOXICITY DURING NEURONAL DIFFERENTIATION. G. Brescia°, G. Assennato° and P. Corsi*. *Istituto di Fisiologia Umana, °Istituto di Medicina del Lavoro, Facoltà di Medicina e Chirurgia, 70124 Bari, Italy.

Chirurgia, 70124 Bari, Italy.

Recently attention has been focused on the role of genotoxic stress in apoptosis and in the age-related failure of several cellular cellular cellular servicities.

With the primary objective of investigating on a possible agerelated response to genotoxic stress, the DNA repair activity, the markers of cytotoxicity and the apoptosis have been evaluated in neuronal cortical cultures after UV exposure.

At 7, 14 and 21 days in vitro we measured the Unscheduled DNA

At 7, 14 and 21 days in vitro we measured the Unscheduled DNA Synthesis (UDS), LDH release and the number of apoptotic cells immuno-positive to the TUNEL reaction. Moreover the levels of the two proteins involved in the cellular responses to genotoxic stress, in apoptosis and in the DNA repair, namely p53 and GADD45, were also analyzed.

Our experimental findings suggest that decreased performance of DNA repair activity is associated to the degree of cellular differentiation and to ageing, and results in increased cytotoxicity and apoptosis.

SUBCELLULAR DISTRIBUTION OF GAPDH IN ARA-C INDUCED CEREBELLAR GRANULE CELL APOPTOSIS

P.A. Saunders*, R. Ishitani@ E Chalecka-Franaszek and D.-M. Chuang Sect. Molecular Neurobiol., Biol. Psychiatry Branch, NIMH, NIH Bethesda MD 20892, @ Josai U., Sakado, Saitama 350-02, Japan. We have discovered that cytosine arabinoside (AraC) induced apoptosis of cerebellar granule cells increases a 38 kd protein band on

We have discovered that cytosine arabinoside (AraC) induced apoptosis of cerebellar granule cells increases a 38 kd protein band on SDS-PAGE identified as glyceraldehyde-3-phosphate dehydrogenase (GAPDH) EC 1.2.1.12 (Ishitani et al, this volume) Oligonucleotides antisense to GAPDH mRNA afford significant protection to freshly plated granule cells against AraC cytotoxicity, while randomized antisense oligonucleotides are ineffective. To prove unambiguously that the 38 kd band is GAPDH, we have examined Western blots from control and AraC treated granule cells with a monoclonal antibody against GAPDH. A single 38 kd immunoreactive band (ir-GAPDH) was observed to be increased in the 200,000 x g pellets of sonicated cells treated with AraC. We used differential centrifugation to find which subcellular components are affected. Treated and untreated cells were sonicated in 0.32 M sucrose and sequentially centrifuged at 1000, 20,000, and 200,000 x g to obtain crude nuclear, mitochondrial, microsomal, and cytosolic fractions. ir-GAPDH was strongly increased in the 1000 and 20,000 x g pellets, unchanged in the 200,000 x g pellets, and markedly decreased in the cytosol of AraC treated cells. The dehydrogenase activity of GAPDH did not increase in parallel to the immunoreactivity. These observations suggest that GAPDH levels change in specific organells during apoptosis for reasons which are separate from its function as a glycolytic enzyme. (supported by NIMH/NIH)

GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE (GAPDH) ANTISENSE OLIGODEOXYNUCLEOTIDES PROTECT AGAINST CYTOSINE ARABINOSIDE-INDUCED APOPTOSIS IN CULTURED CEREBELLAR NEURONS. R. Ishitani*1 and D.-M. Chuang². 1)Group on Cellular Neurobiology, Josai Univ., Saitama 350-02, Japan. 2)Sect. Molecular Neurobiol., BPB, NIMH, MD 20892, U.S.A.

Cytosine arabinoside (AraC) is a antimetabolite that kills proliferating cells by inhibiting DNA synthesis and also is an inducer of apoptosis. We recently reported that age-induced apoptotic cell death of cultured cerebellar granule cells (CGC) is directly associated with overexpression of a particulate 38-kDa protein, identified by us to be GAPDH. We here show that the AraC-induced neuronal death of immature CGC in culture is effectively delayed by actinomycin-D (Act-D), cycloheximide or aurintricarboxylic acid. Furthermore, two GAPDH antisense, but not their corresponding sense, oligodeoxyribonucleotides markedly arrested AraC-induced apoptosis. Prior to AraC-induced neuronal death. GAPDH mRNA levels increased by an approximately 2.5-fold and this mRNA accumulation was blocked by Act-D and the GAPDH antisense (but not sense) oligonucleotide. Thus, the present results show that GAPDH over-expression is involved in AraC-induced apoptosis of CGC.

590.4

OVER-EXPRESSION OF GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE (GAPDH) IS INVOLVED IN LOW K⁺-INDUCED APOPTOSIS, BUT NOT NECROSIS, OF CULTURED CEREBELLAR NEURONS. K. Sunaga¹, M. Tanaka², N. Katsube^{*2}, H. Aishita², D.-M. Chuang³ and R. Ishitani¹. 1)Group on Cellular Neurobiol., Josai Univ., Saitama 350-02, Japan. 2)Ono Pharmaceuticals, Osaka 541, Japan. 3)Sect. Molecular Neurobiol., BPB, NIMH, MD 20892, U.S.A.

D'Mello et al. have reported the induction of apoptosis in cerebellar granule cells (CGC) by lowering K+ to 5 mM in We found that exposure of CGC to low culture medium. potassium (K+) for 24 hr induced not only apoptosis but also necrotic damage. Treatments with actinomycin-D (Act-D) and GAPDH antisense (but not sense) oligodeoxyribonucleotides attenuated low K+-induced neuronal death by approximately Morphological inspection revealed that, like Act-D GAPDH antisense oligonucleotides preferentially blocked low K+-induced apoptosis with little or no effect on necrotic damage. The levels of GAPDH mRNA and protein were markedly increased in a time-dependent manner following low K⁴ exposure. This GAPDH mRNA and protein up-regulation was blocked by the GAPDH antisense oligonucleotide. results suggest that GAPDH over-expression participates in low K⁺-induced apoptosis of CGC.

NEUROPROTECTIVE EFFECTS OF LITHIUM IN S. Nonaka^{1,2}. CEREBELLAR GRANULE CELLS. X -M Gao¹ Katsube² and D.-M. Chuanq^{1*} 1)Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892, U.S.A. 2)Minase Research Institute, Ono

Pharmaceutical Co., Ltd., Mishima-Gun, Osaka 618, Japan.
Lithium is the most commonly used drug for the treatment of manic depressive illness. We have studied its neuroprotective actions against various insults in cultured cerebellar granule cells (CGC) of rats. We have shown that carbamazepine and phenytoin induce apoptosis of CGC by a NMDA reversible mechanism. Here we found that lithium (3-10 mM) dose-dependently protected against carbamazepine (200 μ M) and pnenytoin (20 μ M)-induced neurotoxicity assessed by morphological inspection, MTT metabolism and DNA fragmentation. These protective effects are not prevented by RNA and protein synthesis inhibitors or inclusion of myo-inositol, suggestive of a mechanism independent of inositol monophosphatase blockade. Lithium also significantly protected against CGC apoptosis induced by aging of the cultures. Moreover, lithium rescued death of CGC exposed to low KCI (5 mM), confirming a previous report (D'Mello et al., 1994). Additionally, we found that glutamate (100 μ M) and sodium nitroprusside (SNP, 30 μ M)-induced CGC death was associated DNA fragmentation. Lithium had marginal protection was associated bind fragmentation. Ethium had marginal protection against glutamate toxicity but no effect on SNP toxicity. Thus, lithium has a wide spectrum of neuroprotective effects which may provide a new avenue to study the underlying therapeutic mechanism of this drug.

ADENOSINE MODULATES NEURONAL SURVIVAL IN PURIFIED AVIAN RETINAL CULTURES. R.Paes-de-Carvalho* and G.A.Maia. Dep. Neurobiology Federal Fluminense University, Niterói, RJ 24001-970, Brazil

Adenosine (ado) has been characterized as a neuroprotective substance released during hypoxia and ischemia. The effects of ado are believed to be mediated by the modulation of cyclic AMP levels and inhibition of excitatory neurotransmitter release induced by activation of specific cell surface receptors. Previous work showed specific ado uptake and release in cultured chick retinal neurons. Here we show that ado regulates the survival of chick embryo retinal neurons and photoreceptors grown in purified cultures. Dissociated cells from retinas of E8 embryos were diluted in medium 199 containing 1% Fetal calf serum, 2 mM glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin, plated in dishes pre-treated with poli-l-ornithine (8X 10° cells/dish), and incubated at 37°C in 5%CO₂/95% air. The drugs were added after 18 hs of culture and mantained for 48 hs. In some cases, the medium was changed and the drugs re-added. After further incubation for 72 hs, the cells were fixed and their number estimated by counting 10 fields of 0.114 mm² using an inverted microscope. The change of medium induces a cell death of 48.5 ± 7% in these cultures, an effect that is reduced when the cultures are incubated with NBI (5µM), an ado uptake that is reduced when the cultures are incubated with NoI (SIJIII), an add uptake blocker (12.4 \pm 0.4%), ado (100µM) plus EHNA (10µM), an ado deaminase inhibitor (0 \pm 0.5%), or CGS21680 (20µM), an A_2 ado receptor agonist (28.7 \pm 3.5%), but not by CHA (10µM), an A_1 receptor agonist (52 \pm 6.4%). In cultures mantained without changing the medium, NBI promotes an increase in cell number of 26.2 \pm 3% and in the number of photoreceptors of 47.1 \pm 7.4%. The addition of ado deaminase (0.5U/ml) promotes a cell death of 40 \pm 5%, an effect blocked by EHNA. The results suggest a role for extracellular ado on the regulation of neuronal survival and differentiation in the developing retina. Financial support: CNPq and CEG-UFF

MODULATION OF APOPTOSIS AND REPAIR OF DNA DAMAGE IN NEURONS BY CYCLIC AMP G.T. Gobbel* and P.H. Chan CNS Injury and Edema Res. Center & Brain Tumor Res. Center, Dept. of Neurol. Surgery, Univ. of California, San Francisco, CA 94143 DNA damage may contribute to the neuronal injury that accompanies

various neurological disorders, but little is known concerning how neurons respond to DNA damage. Rat cortical neurons die by apoptosis following DNA damage induced by x-rays and repair DNA damage more slowly than other cells such as astrocytes. Because damage more slowly than other cells such as astrocytes. Because cAMP can increase the rate of rejoining of DNA strand breaks in some cells, we tested the effect of cAMP on apoptosis and rejoining of DNA strand breaks in neurons following x-irradiation. Cortical neurons isolated from rat embryos at day 15-17 of gestation were treated with dibutyryl cAMP (0.25-1 mM) for 3 days and then irradiated with 4-8 Gy of x-rays. Treatment with cAMP did reduce the number of apoptotic cells following irradiation as detected by nuclear fragmentation using Hoechst dye. However, unlike astrocytes, cAMP treatment significantly decreased the rate of double-strand break rejoining using Hocenst dye. However, timike astrocytes, CAMP treatment significantly decreased the rate of double-strand break rejoining following 32 Gy as measured by pulsed-field gel electrophoresis. The association between slower DNA repair and reduced apoptosis did not appear to be due to a reduction in ADP-ribosylation and sparing of NADH and ATP; treatment with 0.5-5 mM benzamide to inhibit ADP-ribosylation and sparing of NADH and ATP; treatment with 0.5-5 mM benzamide to inhibit ADP-ribosylation. ribosylation increased the number of neurons induced by radiation to undergo apoptosis. We conclude that cAMP does not reduce apoptosis by increasing the rate of DNA repair and that depletion of NADH and ATP due to ADP-ribosylation does not account for radiation-induced neuronal apoptosis. Supported by NIH Grant CA 13525.

ANTI-APOPTOTIC IMPACT OF ATP AND ADENOSINE IN THE CULTURED RAT CEREBELLAR GRANULE CELLS. H. Amino*, H. Saito and N. Nishiyama. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo. 113 Japan.

Recent data suggested that nucleosides and nucleotides act not only as neurotransmitters and/or neuromodulators but also as neurotrophic factors in the nervous system. Therefore, we studied the effects of exogenously applied ATP and adenosine (Ado) on neuronal apoptosis. Cultured cerebellar granule cells, isolated from 8-day-old postnatal rat and grown *in vitro* for 6-7 days in medium with depolarizing concentration of extracellular potassium (K*, 25 mM), die by apoptosis when concentration of K* was lowered to 5 mM. Lactate dehydrogenase (LDH) assay revealed that approximately half of neurons died by exposure to low K* medium for 30 hours. Treatment of neurons with ATP (1-1000) μM) and Ado (0.1-100 μM) significantly prevented low K⁺-induced apoptosis in a concentration-dependent manner. Both ATP (1000 μ M) and Ado (100 μ M) protected more than 90 % of neurons from death. In contrast, UTP (1-1000 μ M) did not have such an effect. Moreover, ionotropic P_2 -purinergic receptor agonist, α . β -methylene Moreover, fortoropic P_2 -purinterigic receptor agonts, P_2 -interiprent ATP (1-1000 µM) mimicked the anti-apoptotic effect of ATP. These results suggest that extracellular ATP and Ado protect neurons from apoptosis via the G-protein-coupled P_1 - and ionotropic P_{2x} - and/or G-protein-coupled P_{2y} -purinergic receptors and that they might be involved in the regulation of development of the nervous system and in the pathophysiology of neurodegenerative disorders.

590.8

CYCLIC AMP PREVENTS PROGRAMMED CELL DEATH OF CULTURED RAT CEREBELLAR GRANULE CELLS. J.Y. Chang*, J.Z. Wang. and V.V. Korolev Dept. of Anatomy, Univ. Arkansas for Med. Sci. Little Rock, AR 72205

Cultured cerebellar granule cells undergo programmed cell death when they are deprived of depolarizing KCl. We have performed a series of experiments to correlate the structural and biochemical changes in this process of cell death. The change of total protein level, protein synthesis rate, RNA synthesis rate, and mitochondria activity during the first 48 hours of KCl removal were determined. Further experiments indicate that the cAMP analog CPT-cAMP can prevent the cell death in a dose-dependent manner, with the maximal effect seen a 500 µM. Approximately 70% of cells can be saved with this concentration of CPT-cAMP for at least 6 days. The attempt to plate down cerebellar granule cells in CPT-cAMP (without depolarizing KCI) for long term culture was unsuccessful. While CPT-cAMP significantly slow down initial cell death, the viability was similar to those in low KCI alone a week after plating. Pituitary adenylate cyclase activating polypeptide (PACAP) increased the intracellular cAMP levels of these cells in a time- and dose-dependent manner. This agent can prevent the decrease of cAMP and cell death induced by KCl withdrawal. These results suggest that PACAP could function as neurotrophic factor for cerebellar granule cells <u>in vivo</u>. (Supported by NIH NS32253)

Natriuretic Peptides Prevent the Death of Trophic Factor-Deprived PC12 Cells and Promote the Survival of Basal Forebrain Cholinergic Neurons. S.E. Farinelli*, W.J. Friedman and L.A. Greene. Dept. of Pathology and Ctr. for Neurobiology and Behavior, Columbia University, New York, NY 10032.

We have shown previously that nitric oxide prevents the death of trophic factor-deprived PC12 cells and primary sympathetic neurons by increasing intracellular cGMP. Since natriuretic peptides exert their biological actions by activating a receptor-linked guanylate cyclase, we proceeded to test these peptides for their ability to protect PC12 cells following removal of trophic support. Both atrial natriuretic peptide (ANP) and brain natriuretic peptide (BNP) at 10 nM promoted complete survival for at least one day following removal of serum from naive PC12 cells while only 35% of the untreated cells remained alive. These peptides also provided complete protection for three days to neuronally-differentiated PC12 cells following withdrawal of NGF in serum-free medium while only 40% of the untreated cells survived. C-type natriuretic peptide (CNP) also significantly increased survival in these paradigms. Addition of the cGMP phosphodiesterase inhibitor dipyridamole increased both the potency and the duration of the effects of the peptides, suggesting that the peptides act by increasing cGMP.

Since natriuretic peptide receptors are expressed in the brain during perburgic development, we investigated whether. Here periods contactives and the during perburgic development, we investigated whether. Here periods active provides and the during perburgic and personnel we investigated whether. Here periods active provides and the during perburgic and personnel we investigated whether. Here periods active personnel we investigated whether. Here periods active personnel we investigated whether. Here personnel personnel personnel personnel personnel personnel personnel personnel personnel personnel personnel personnel personnel personnel p

suggesting triat the peptides act by increasing cGMP. Since natriuretic peptide receptors are expressed in the brain during embryonic development, we investigated whether these peptides might exert a trophic effect on primary neurons cultured from various brain regions. Addition of 100 nM CNP at the time of plating to cultures of basal forebrain from E16 rats, resulted in a 50% increase in the number of cholinergic neurons surviving at one week.

Taken together, the data surgest that netriviatio pentides may provide.

Taken together, the data suggest that natriuretic peptides may provide trophic support for certain responsive neuronal populations during development of the CNS. (Supported by grants from the NINDS).

DOPAMINE-INDUCED CA2* DISREGULATION IN PC-12 CELLS. J.G.Strain G.Cao* and J.A.Joseph. USDA-Human Nutrition Research Center on Aging at Tufts University, Boston, MA. Previous research has suggested that the initial effects of free radical neurotoxic insult involve large increases in intracellular Ca2* and ultimately, cell death. It has been postulated that the neurotoxic effects of DA may involve autooxidation and reactive oxygen species (ROS) generation. However, the exact role of DA in cellular Ca2* disregulation has not been specified. Thus, PC-12 cells were exposed to 1 mM dopamine (DA) for 30 minutes in growth medium alone (control) or containing various concentrations of either the calcium channel antagonists(CCA) nifedipine or conotoxin or the antioxidants (ANTOX), Trolox or PBN. Fura-II and fluorescent imaging analyses were used to visualize intracellular Δ Ca2* in individual cells following depolarization with 30 mM KCl. Results showed that while initial Ca2* levels in the cells and the rise in free intracellular Ca2* following depolarization were not affected by DA, there was a significant decrease in the ability of the cells to clear excess Ca2* following depolarization (Ca3*R). Both PBN and conotoxin partially antagonized DA-induced Ca2*R deficits, but not Trolox or nifedipine, suggesting that ROS initiated by DA autooxidation can have significant cytotoxic effects on Ca2* homeostasis, which are only selectively antagonized by ANTOX or CCA. (Supported by USDA Intramural)

ELEVATED INTRACELLULAR Ca²⁺ UNDERLIES THE PRODUCTION OF 50-600 kbp DNA FRAGMENTS DURING APOPTOTIC ROD CELL DEATH. D.A. Fox*.

A.T. Poblenz, M.L. Campbell and L. He. University of Houston, College Optometry and Dept. of Biochemistry, Houston, TX 77204.

Electron microscopy studies show apoptotic rod and bipolar cell death in rats exposed to lead during development. This was temporally correlated with the production of 50, 300 and 600 kbp DNA (HMW) fragments and elevated intracellular Ca2+ ([Ca2+]i). Therefore, in vitro studies examined the role of [Ca²⁺]_i in producing DNA condensation and genomic DNA fragmentation. Dark- or light-adapted rat retinas were incubated (15 min) in Ringer's buffer with 0-2.0 mM free Ca²⁺ with or without chemical agents that elevated [Ca²+];: IBMX, dibutyryl cGMP, ouabain and/or Pb²+. The occurrence of HMW fragments and ladders were examined using field-inversion and conventional gel electrophoresis, respectively. DNA condensation was viewed with acridine orange staining (AO). Retinas incubated in all buffers without Ca2+ exhibited a minimal amount of HMW fragmentation and apoptotic rods. In the presence of Ca²⁺, HMW fragments were differentially and significantly enhanced with all agents while AO revealed the selective occurrence of and significant increase in the number of apoptotic rods. Ladders or necrosis were not observed. These results demonstrate that selective rod apoptosis can be produced in vitro by elevating [Ca²⁺]_i and that fragmentation of genomic DNA is a multi-step process potentiated by Ca²⁺. These results suggest that Ca²⁺ overload may be responsible for the apoptotic rod (and bipolar) cell death seen during developmental lead exposure. Supported by NIH Grant ES03183.

USE DEPENDENT PURKINJE CELL DEATH CAN BE RETARDED BY A BATH APPLIED SHORT HEPARIN-LIKE PROTEIN. M. Sugimori* and R. Llinás, NYU Medical Center, Dept. Physiology & Neuroscience, 550 First Ave., NY, NY 10016.

Neuronal death, to include only individual dendritic branches, was reported for Purkinje cell dendritic trees in guinea pig cerebellar slices following glutamic acid electrophoresis. The results indicated that such events were generated by secondary release of calcium from intracellular stores, probably via the activation of an IP3 receptor, as they were blocked by the intracellular injection of heparin, an IP3 receptor blocker (Sugimori et al., <u>Soc. Neurosci Abst.</u> 21,793.10, 1995). Using Fura II, calcium imaging of Purkinje cell in a somatic patch clamping paradigm demonstrated that bath application of a short heparin-like protein (enoxaparin) which, as regular heparin may block the IP3 receptors, produced a reduction of the secondary release of intracellular calcium to glutamic acid iontophoresis. It also produced a partial reversal in the dendritic death march if the added following glutamate administration. In addition, the electrophysiological deterioration that accompanies increased [Ca]i was also markedly reduced. The results suggest that cell death, as related to increased intracellular calcium concentration following an acute excitotoxin events may be reduced by extracellulary applied IP3 blockers. PROMOTION OF NEURONAL CELL SURVIVAL BY 6R-TETRAHYDRO-BIOPTERIN. K. Koshimura*, J. Tanaka, Y. Murakami and Y. KATO. First Division, Department of Medicine, Shimane Medical University, Izumo, 693, Japan.

Recently, we have reported that 6R-tetrahydrobiopterin (6R-BH4), a natural cofactor for aromatic L-amino acid hydroxylases and nitric oxide synthase (NOS), activates voltage-dependent Ca2+ channels in rat neurons independently of its cofactor activity. Several lines of evidence suggest that Ca2+ channel activationinduced increase in intracellular Ca2+ concentration enhances neuronal cell survival. In the present study, we investigated the effect of 6R-BH4 on neuronal cell survival using differentiated PC12 cells. 6R-BH, activated Ca2+ channel activity as estimated by 45 Ca 21 uptake, which was sensitive to nicardipine (1 μ M), an inhibitor for L-type Ca 21 channels, but resistant to α -methyl-p-tyrosine (α-MT, 1 mM), an inhibitor for tyrosine hydroxylase, and L-nitroarginine (LNA, 0.1 mM), an inhibitor for NOS. The effect of 6R-BH4 on Ca2+ channels was abolished by Rp-cAMPs (1 mM), an inhibitor for protein kinase A, and mimicked by 8-bromo-cAMP (1 mM). After 5 day-culture in the absence of serum and NGF, viable cell number estimated by MTT assay was decreased to one fifth of the number of cells cultured in the presence of serum and NGF. Addition of KCI (50 mM) increased viable cell number cultured in the absence of serum and NGF. 6R-BH₄ (10⁻⁷- 3x10⁻⁵ M) dose-relatedly increased viable cell number The effect of $6R-\dot{B}H_4$ on cell survival was inhibited by nicardipine (1 μ M) and Rp-cAMPs (1 mM) but persisted in the presence of α-MT (1 mM) and LNA (0.1 mM). Addition of 8-bromo-cAMP (1mM) increased number of viable cells cultured without serum and NGF. These results suggest that 6R-BH, promotes survival of differentiated PC12 cells by activating L-type Ca2+ channels via cAMP-protein kinase A pathway indepedently of its cofactor activity.

CALCINEURIN INHIBITORS BLOCK APOPTOTIC SIGNAL TRANSDUCTION IN CEREBELLAR GRANULE CELLS. C. Galli, O. Meucci^, A. Mascia, M.T. Ciotti, Mercanti D., M. Hribal, L. Milazzo, R. Possenti*, Inst. of Neurobiology CNR, Via K. Marx 43, 00137 Rome, Italy. Dept. of Pharmacol. Physiol. Sciences, Univ. of Chicago, Chicago, Illinois

We have previously shown that the drop of intracellular calcium is the first step in the signal transduction of the apoptotic message triggered by lowering extracellular potassium in cerebellar granule cells (J. Neurosci, 15, 501-508,1995). We have also described (Soc. Neurosci, Ab.793.9, 1995) the hyperphosphorylation of a 120 kDa acidic protein occurring in the first hours of the apoptotic process. In this report we demonstrate that the hyperphosphorylation is caused by the decrease of intracellular calcium. In order to identify the enzymes involved in the calcium signalling of apoptosis we screened a series of protein kinase and phosphatase inhibitors and found that type II pyrethroids, which are specific inhibitors of calcineurin, protect cerebellar granule cells from apoptosis. We found that both deltamethrin and cypermethrin abolished the observed hyperphosphorylation of p120. One related compound, allethrin, which lacks any inhibitory action on calcineurin, was completely ineffective in preventing inhibitory action on calcineurin, was completely meffective in preventing apoptosis and the associated p120 hyperphosphorylation. Moreover we found that treatment with type II pyrethroids, but not with allethrin is able to restore physiological calcium levels in neurons deprived of high potassium. This effect was mediated by an increased influx of calcium from extracellular compartment. These findings suggest that pyrethroids by inhibiting calcineurin cause an increase of calcium which is sufficient to block the hyperphosphorylation of p120 and the following apoptotic cascade. Pyrethroids as deltamethrin or cypermethrin were also able to prevent apoptosis in neuronal PC12 deprived of NGF but not in naive PC12 deprived of serum suggesting that passage from a non-neuronal phenotype to a neuronal phenotype is accompanied by an involvement of calcineurin in apoptotic message. by an involvement of calcineurin in apoptotic message

DANTROLENE INHIBITS GT1-7 NEURONAL DEATH INDUCED BY MULTIPLE AGENTS. H. Wei, W. Wei and D.C. Perry*. Dept. of

Pharmacology, George Washington University, Washington D.C. 20037.

Dantrolene inhibits release of Ca²⁺ from the endoplasmic reticulum via ryanodine receptor channels. The ability of dantrolene to inhibit neuronal death induced by multiple agents was investigated in GT1-7 hypothalamic neurosecretory cells. Cells were treated with serum deprivation, ionomycin (3 µM), A23187 (4 µg/ml), thapsigargin (50 nM) or caffeine (10 mM), alone or after 30 min pretreatment with dantrolene (120 μM). Cell viability was determined by the trypan blue exclusion assay. Viability decreased after 24 treatment with serum deprivation (37%), ionomycin (47%), A23187 (57%), thapsigargin (61%) or caffeine (59%). With dantrolene pretreatment, cell viability significantly increased to 68%, 80%, 79%, 93% or 90% respectively (P<0.01 except A23187). Cells treated with thapsigargin or caffeine were demonstrated to die by an apoptotic mechanism. The effect of these agents on cytosolic Ca²⁺ ([Ca²⁺]₁) in GT1-7 cells was studied using the flourescent calcium dye Fura-2/AM. Caffeine did not induce elevation of [Ca²⁺], Ionomycin, A23187 and thapsigargin all significantly increased [Ca²⁺], to 437%, 1035% and 231% of control, respectively (P<0.05). Pretreatment with 120 µM dantrolene for 30 min decreased the stimulated [Ca2+] levels to 366%, 539% and 169% of controls respectively (P<0.05 for A23187 and thapsigargin) These results demonstrate that dantrolene can inhibit GT1-7 cell death induced by multiple agents, but that its protective effects may not always be due to inhibition of increases in cytosolic Ca2+ concentrations. Supported by the Souer Stroke Fund.

ALTERED ER SIGNALING AS REVEALED BY ENHANCED EXPRESSION OF THE BIP/GRP78 GENE DURING PROGRAMMED NEURONAL CELL DEATH

T. Koike*, K. Nakayama, S.Tanaka, and C. Mitsui Graduate Program in Biological Sciences, Hokkaido University, Faculty of Science, Sapporo

By utilizing neuronal PC12 cells as a model, we have searched genes up-regulated during their cell death, and found that expression of the BiP/GRP78 gene among the HSP70 family genes is markedly enhanced during neuronal death following NGF deprivation(Aoki et al., submitted). The BiP/GRP 78 induction is suppressed under depolarizing conditions with elevated K+ or by treatment with cAMP. The BiP induction also occurred in cultured rat SCG neurons following NGF deprivation. We have previously reported that SCG neurons treated with an excessive dose of the Ca2+ chelator BAPTA-AM, underwent apoptosis (Nakayama and Koike, 1995). Under these conditions, we found that the BiP /GRP78 gene expression is greatly induced. Thapsigargin (TG), an inhibitor for Ca²+ ATPase in ER also caused similar enhancement, suggesting that depletion of Ca²+ from ER stores plays a role in its induction. Moreover, fura-2 measurements indicated a decrease in basal [Ca²+]i levels during cell death following NGF withdrawal along with significant reduction of TG-induced Ca2+ release form ER stores Since TG itself is not toxic to SCG neurons, it is unlikely that the BiP/GRP 78 induction itself causes neuronal death. We propose that an alteration in ER signaling occurs in parallel with other cell death cascades, leading to altered processing of secretory proteins from ER that are necessary for maintenance of synaptic integrity of neurons.

POTENTIATED NECROTIC DEATH BY NGF IN A GLUCOSE-DEFICIENT ENVIRONMENT. J.H. Hong, S.H. Lee, H.J. Kang, K.M. No, S.Y. Chang and J.M. Chung*. Dept. of Biology, Ewha Womans University, Seoul, Korea 120-750.

It is widely believed that nerve growth factor (NGF) may serve as a therapeutic agent for many types of neuronal diseases One of the mechanisms suggested to explain the protective role of NGF is that the trophic factor can prevent the increase of intracellular calcium (Ca) ions which might be responsible for neural death. To examine whether the Ca hypothesis works even under a pathological condition, we applied NGF to PC12 cultures deprived of glucose and examined the effect of NGF on cell death. Here NGF rather promoted cell death under a glucose-deprived condition. Changes in chromatin morphology and patterns of DNA fragmentation showed that cell death induced by NGF was necrotic. The NGF-induced necrotic death occurred in a manner dependent on extracellular Ca. Also nifedipine (1-10nM) and ryanodine (0.1-10nM) could partially block the cell death. All these suggest that NGF might potentiate cell death by increasing intracellular Ca in cells deprived of glucose. However, the coapplication of nifedipine and ryanodine could not block the death completely. It is, therefore, possible that NGF induces necrotic death via 2 separate pathways, a Ca-dependent, and a Ca-independent ones, in a hypoglycemic condition. (Supported by Ewha Research Grant to JMC)

REGENERATION: FUNCTIONAL RECOVERY

591.1

TIME COURSE OF OPTIC NERVE REGENERATION IN THE LIZARD, CTENOPHOROUS ORNATUS. N. Tran. S.A. Dunlop*. J.M. Papadimitriou and L.D. Beazley. Department of Zoology and Department of Pathology, The University of Western Australia, Nedlands 6907, Australia.

We have recently shown in lizards that, as in frogs, the optic nerve can regenerate. In lizards at one year after optic nerve crush, optic axons had re-grown along essentially normal pathways to reach retino-recipient centres; approximately two thirds of retinal ganglion cells had survived axotomy, a proportion similar to that in frog. However, unlike frog in which visuomotor function is restored, lizards appeared blind on the operated side and failed to exhibit feeding behaviour or startle responses. This lack of visually elicited behaviour was found to be correlated with a failure of axons to form a retinotopic map within the optic tectum. In frog, regenerating axons reach the tectum within 3-4 weeks and visually evoked responses can be recorded shortly thereafter. Here, we have examined the time course of optic nerve regeneration in the lizard to determine whether there was a delay compared to frog, delayed innervation might have resulted in an inability of regenerating axons to re-establish a retinotopic map. Animals received unilateral optic nerve crush and at monthly intervals up to 1 year were perfused with 4% paraformaldehyde. Crystals of the carabocyanine dye Dil were placed across the entire optic disk. Brains were kept at 37°C for 6 weeks to allow for transport, embedded, sectioned coronally at 100µm and examined using a fluorescence microscope. At all stages examined, the crush site persisted macroscopically as a translucent region indicative of reduced myelination and the nerve between the eye and the crush site was heavily labelled. By one month, a minority of axons had crossed the crush site, reached the optic tectum and spread across it; the low proportion of regenerated axons allowed individual terminals to be identified. By 2 months, the projecti

ABNORMAL SENSORY REINNERVATION OF MYSTACIAL GUARD HAIRS IN LONG TERM CHRONIC CONSTRICTIVE INJURY (CCI) OF THE INFRAORBITAL NERVE (ION) IN RATS. B.L. Munger*1, G. B. Bennett?, & B. P. Vos³, 1Dept. Anat. & Physiol., U. Tasmania, Hobart, Tas., Aust. 7005; 2NAB, NIDR, NIH, Bethesda, MD 20809; 3Lab. Anesth., Dept. Med., U. Antwerp, Belgium. Experimentally produced painful peripheral neuropathies result from a variety of physical injuries to peripheral neuropathies result from a variety of physical injuries to peripheral neuropathies result from a

variety of physical injuries to peripheral nerves following the initial description by Bennett and Xie of CCI in sciatic nerves of rats (Pain description by Bernett and Are of Cell in Schall nerves of that (Fain 33:87, 1988). The present study compares the early and long term effects of CCI to the ION (Vos et al, J. Neurosci. 14:2708, 1994) with lesions in the sciatic nerve (Munger et al, Exp. Neurol. 118:204, 1992). Rats were anaesthetised with Nembutal and two ligatures were placed around the ION with mild tension. The rats were killed with an overdose around the ION with find tension. The lats were knied with an overalous of Nembutal following behavioural observations at early postoperative days 1-15 and long term days 15-130. Sections of mystacial skin were fixed in formalin and serial paraffin sections stained with silver. The early pathology in the ION was identical to that seen in Bennett's model (Munger et al). The large diameter axons degenerated with preservation of many Aδ and C fibres. The animals at 130 days persisted in demonstrating behavioral evidence of abnormal sensibility of mystacial skin. The animals at 130 days had abnormal sensory reinnervation of guard hairs identical to rats that had ION's cut or crushed (Munger and Renehan, JCN 283:169, 1989). The normal palisade of lanceolate terminals was absent and only simple terminals resembling free nerve endings could be found. The abnormal sensory re-innervation may account for persistent (long term) behavioural changes consistent with abnormal sensibility of reinnervated mystacial skin (Vos et al 1994).

FUNCTIONAL GAP JUNCTIONS COUPLE MOTOR NEURONS IN DEVELOPMENT AND REINNERVATION. R.J. Balice-Gordon*, A. Pereda*, & M.J. Pinter*. ¹Dept. Neurosci., Univ. Penn. Sch. Med., & ¹Dept. Neurobiol. & Anat., Med. College of Penn., Philadelphia, PA. During development and adult reinnervation, neuromuscular junctions undergo a period of activity dependent synaptic plasticity, resulting in the loss of multiple motor neuron inputs and continuing until a single input remains. We have found that motor neurons are coupled by gap junctions during these times. Dye fills in mouse spinal cord slices and immunostaining with connexin specific antibodies shows that from E14 to birth, ca. 80% of the motor neurons in the mouse ventral lumbar spinal cord are coupled by gap junctions. The shows that from E14 to birth, ca. 80% of the motor neurons in the mouse ventral lumbar spinal cord are coupled by gap junctions. The percentage of coupled motor neurons declines rapidly after birth; by P10, as in adults, few if any dye coupled or immunopositive motor neurons are detected. From E10 to E14, ventral ventricular zone cells are dye coupled as well as immunopositive for connexins. We are using time lapse video microscopy to determine whether dye coupled neurons populate the same motor pools in the ventral horn.

Following nerve damage, intracellular dye fills and immunostaining show that gap junctional coupling among motor neurons is transiently re-expressed. In adult cat spinal cord 3 weeks after nerve damage, clusters of 4 to 6 motor neurons are labeled following Neurobiotin injection of a single identified motor neuron. Similar injections in normal adults yield single labeled motor neurons. In adult mouse

injection of a single identified motor neuron. Similar injections in anormal adults yield single labeled motor neurons. In adult mouse spinal cord, motor neurons show peak connexin expression 2 to 3 weeks following nerve damage. Five to 6 weeks after damage, little if any expression is detected. Transient gap junctional coupling among developing and axotomized motor neurons may mediate electrical or metabolic signation that is important for the formation and refinement. metabolic signaling that is important for the formation and refinement of synaptic connections. This work was supported by grants from the NIH and Spinal Cord Research Foundation.

INCREASING THE SPECIFICITY OF REGENERATING MOTOR NERVES C.M. Neumann, T.M. Brushart*, and T. Gordon*, Dept Pharmacol., Div. of Neurosci., Univ of Alberta, Edmonton, Canada T6G 2S2 and Depts of Orthopaedics and Neurology, Johns Hopkins Hosp., Baltimore, Maryland 21287

Using the rat femoral nerve model, we looked at the specificity of regenerating motor neurons. Although it has been shown that motor neurons in juvenile rats will preferentially reinnervate the motor rather than the sensory branch of the femoral nerve, there is little preferential motor reinnervation in the adult rat. We sought to determine whether the specificity of regenerating adult rat motor neurons could be induced by enhancing axonal growth by either 20 Hz stimulation, or direct current stimulation. Using adult Sprague Dawley rats, we cut the left femoral nerve, and then repaired it using microsurgical technique. The rats were subjected to one of three conditions: 1) normal cage activity, 2) 20 Hz stimulation, or 3) direct current stimulation for 2 weeks, 24 hrs/day. The motor neurons that regenerate axons through the motor and sensory branches of the repaired femoral nerves were retrogradely labelled by applying horseradish peroxidase to the motor branch of the femoral nerve, and fluorogold to the sensory branch. Rats were sacrificed by perfusion with 4% paraformaldehyde. The spinal cord was cryosectioned, and the labelled motor neurons were counted. We found that, while direct current did not enhance the specificity of regenerating motor axons for the motor branch at 2 weeks, 20 Hz stimulation significantly increased this specificity at 2 weeks (58% motor, 31% sensory p<0.01) as compared with normal cage activity (49% motor, 40% sensory p>0.01). We conclude that 20 Hz stimulation may be beneficial to functional recovery following a peripheral motor nerve injury by enhancing appropriate connectivity. Long term studies presently underway aim to determine whether the specificity will increase with time, and whether this is due to the pruning of misdirected sprouts from the sensory branch. Supported by AHFMR, Canadian MRC and NCE

SPROUTING OF PRIMARY AFFERENT FIBERS AFTER SPINAL CORD TRANSECTION. N.R. Krenz* and L.C. Weaver. Neuroscience Program, Robarts Res. Inst. & University of Western Ontario, London, Ont., Canada.

Spinal cord injury above mid-thoracic levels often results in hyperreflexive sympathetic regulation of arterial pressure. Sprouting of primary afferent fibers into regions containing sympathetic preganglionic neurons (SPNs) or interneurons may be responsible for this autonomic dysreflexia. Myelinated and unmyelinated afferent fibers were assessed in control rats and rats 7 and 14 days after spinal cord transection (SCT) at the 6th thoracic segment. Myelinated afferents were identified by immunofluorescence for cholera toxin B (CTB), which was transported from muscle to the cord. In lumbar, but not thoracic cord, CTB-containing fibers were more dense in laminae III and IV at both 7 and 14 days after SCT, compared to controls. This sprouting likely contributes little to dysreflexia, because it occurs in lumbar regions that contain few SPNs, but not in the thoracic cord that contains the majority of SPNs. The unmyelinated fibers were immunolabelled for calcitonin gene-related peptide (CGRP). The area of CGRP fibers in laminae III and IV increased at all cord segments at 14 but not 7 days after SCT. Moreover, 14 days after SCT, CGRP fibers sprouted in dorsal root ganglia rostral and caudal to SCT, CGRP fibers around the SPNs increased above SCT and in lumbar segments at 14 but not 7 days after SCT. CGRP fibers around SPNs did not differ from controls in segments T6-13. In conclusion, unmyelinated primary afferent fibers sprout in the dorsal root ganglia and throughout thoracic and lumbar dorsal horn after SCT. The CRGP fibers that increased around the SPNs after SCT do not extend from the dorsal born and probably are not primary afferents. Sprouting of CGRP fibers may contribute to autonomic dysreflexia. COMPENSATORY NEUROGENESIS IN THE DENTATE GYRUS OF ADULT RATS. E. Gould* and P.Tanapat. Lab. of Neuroendocrinology, Rockefeller Univ., New York, NY 10021. In general, replacement of neurons following cell death is not a

feature of the adult mammalian brain. Our previous studies have shown that both naturally occurring developmental cell death, as well as adrenalectomy-induced cell death in adulthood, are accompanied by increased granule cell proliferation in the dentate gyrus (Gould, 1994). These findings suggest that granule cell death stimulates the production of new granule neurons in this system. In order to directly investigate this possibility, we used ³H-thymidine autoradiography, immunohistochemistry for cell-specific markers and in situ DNA end labeling to examine the effects of lesioning the granule cell layer on the degeneration and proliferation of cells in the dentate gyrus of adult rats. Lesion of the granule cell layer with ibotenic acid resulted in a greater than sixfold increase in the number of 3H-thymidine labeled cells in the dentate gyrus. The vast majority of these ³H-thymidine labeled cells (~80%) possessed the morphology of immature granule neurons, i.e., medium-sized, round or oval cell bodies, and were not immunoreactive for vimentin, a marker of immature glia. In situ DNA end labeling demonstrated that the degenerating cells were distinct in morphology and location from the ³H-thymidine labeled cells. These results suggest that signals produced by dying granule cells stimulate granule cell progenitors to proliferate and potentially repopulate the damaged area Supported by a NARSAD Young Investigator Award and MH52423 to

591.9

FUNCTIONAL RECOVERY AFTER SEPARATION OF FASCICLES IN TUBULAR REPAIRS OF GAP INJURED NERVES . M.R. Wells*, U. Vaidya, B.H. Hallas, A. Bosak, S. Tierney, and P. Jakovina. N. Y. College of Osteopathic Medicine, Old Westbury, N.Y. 11568-8000

It has been suggested that tubular repairs of peripheral nerves with short gap injuries can produce a functional recovery similar to nerves repaired by direct suture of the proximal and distal stumps. In the direct suture repair, the appropriate matching of fascicles appears to be important in the eventual recovery of function. In the present study, we have compared functional recovery after gap injuries of the rat sciatic nerve which were repaired either with a single tube or two smaller tubes in which two major fascicles of the nerve were matched. Twenty female, Sprague-Dawley rats received 8 mm gap injuries of the sciatic nerve which were repaired with either a single silicone tube (2 mm I.D., n=10) or two smaller tubes (1 mm I.D., n=10). For the double tube repair, the proximal and distal ends of the major tibial fascicle was placed in one tube, while the remaining fascicles were sutured into the other tube. A group of three animals which received only a sciatic nerve crush at the level of repair was also included for comparison. Functional recovery was followed over time using the sciatic functional index (SFI) and hindlimb extension pressure over a period of nine weeks. Animals in which repairs were made with two tubes had a significantly better recovery over the course of the experiment (SFI, p<0.04) compared to animals in which nerves were repaired with a single tube. However, the recovery was clearly poorer than with crush injured nerves. The results demonstrate that fascicular matching can also improve the functional outcome of tubular nerve repairs. It may also be implied that inappropriate choices by regenerating axons may be detrimental to recovery in tubular repairs.

REGROWTH AND REDIRECTION OF VASOPRESSIN- AND OXYTOCIN-CONTAINING FIBERS AFTER ABLATION OF THE NEUROHYPOPHYSEAL TRACT IN SHEEP. M.J. McKinley*, M.E. Giles and B.J. Oldfield. Howard Florey Institute of Experimental Physiology and Medicine, University of Melbourne, Parkville, Australia.

An immunohistochemical study was made of brains of sheep in which the hypothalamo-neurohypophyseal tract (HNT) had been ablated. Two electrodes were implanted into the HNT of 6 adult Merino cross-breed ewes while they were under the influence of general anesthesia induced by intravenous Na thiopentone (19 mg/kg) and maintained by halothane/oxygen inhalation. The HNT was ablated by passage of radiofrequency current across the tips of the electrodes. After 1-4 months, these sheep, as well as 4 normal ewes, were killed by intravenous injection of Na pentobarbital (100 mg/kg). Immunohistochemistry was used to identify the presence of oxytocin and vasopressin in cells and fibers in the diencephalon of these animals. In all 6 sheep with HNT lesions, a dense fiber tract was observed in which oxytocinand vasopressin-containing fibers extended medially, then rostrally from the supraoptic nucleus across the base of the brain and optic chiasm to the lamina terminalis. A particularly dense array of these oxytocin- and vasopressir containing varicose fibers surrounded the blood vessels in the vascular plexus of the organum vasculosum of the lamina terminalis, where the blood-brain barrier is lacking due to the presence of fenestrated capillary endothelium. Such fibers were not observed in the normal sheep. Sheep with HNT lesions also exhibited many more fibers extending to the lateral walls of the third ventricle and contacting the cerebrospinal fluid (CSF) than did controls. These results show that after ablation of the HNT, axons from hypothalamic magnocellular neurons can grow to new sites in the brain where it is possible that oxytocin and vasopressin may be released into the blood-stream or CSF Supported by an Institute Block Grant to the Howard Florey Institute by the

National Health and Medical Research Council of Australia

COMPENSATORY REINNERVATION FOLLOWING UNILATERAL LESION OF THE OLIVOCEREBELLAR TRACT IN THE RAT. M. Zagrebelsky, F. Rossi*, M.E. Schwabs, P. Strata, Dept. of Neuroscience, University of Turin, I-10125 Turin, Italy; §Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland.

Functional recovery following brain injury depends upon the formation of new topographically organised projections. We have studied the reorganisation of the olivocerebellar projection following deafferentation of a hemicerebellum by unilateral otrocereoenar projection following deariferentiation of a nemicereoenum by unliateral section of the inferior cerebellar peduncle in newborn rats (P1). The normal olivocerebellar system shows a very precise topographical organisation in which climbing fibre stripes and zebrin II defined Purkinje cell bands align. Within less than 24 hours following the lesion olivocerebellar fibres from the intact side give rise to sprouts that grow across the cerebellar midline in the deafferented hemicerebellum. There the transcommissural axons restore the original pattern of calcitonine gene-related peptide (CGRP)-positive climbing fibre stripes within a few days. Furthermore in the deafferented hemicerebellum of adult rats, lesioned at birth, the alignment between climbing fibre stripes and zebrin II defined Purkinje cell bands is fully and precisely restored. These results show that a high degree of target specificity is attained by this reinnervation process. The extent of reinnervation of the deafferented hemicerebellum gradually declines if the lesion is performed in older animals and it is absent after postnatal day ten (Sherrard and Bower, 86). This phenomenon parallels the progressive myclination of the white matter with the appearance of myelin-associated neurite growth inhibitors (Caroni and Schwab.'88). To establish whether the transcommissural reinnervation can be obtained also in older lesioned rats we neutralised the myelin-associated neurite growth inhibitors by the application of a specific blocking antibody (IN-1; Caroni and Schwab, '88). First results show that lesions at postnatal day 15 induce sprouting and transcommissural reinnervation of the deafferented hemicerebellum by climbing fibres if the activity of the myclin-associated neurite growth inhibitors is blocked. GAIT ANALYSIS AS A MEASURE OF FUNCTIONAL RECOVERY AFTER NERVE GAP INJURIES.

Jakovina, and M.R. Wells.

N. Y. College of Osteopathic Medicine, Old Westbury

The detection of functional recovery after gap injuries of the sciatic nerve is problematical since the commonly used sciatic functional index recovers poorly or not at all in this model. In the present experiment, we have examined the use of a gait analysis technique to detect functional deficits produced by nerve gap injuries and subsequent recovery. Sprague-Dawley rats received an 8 mm gap injury of the sciatic nerve repaired with a silicone tube or two tubes in which nerve fascicles were matched (see Wells, M.R. et al. in this volume). A group of animals which received only a sciatic nerve crush was also included for comparison. Gait patterns of the affected legs were measured using a Peak Performance computer system. Walking patterns were digitized using reflective markers placed on the hip, knee and ankle joints and on the foot. Initial parameters examined included stride length, vertical displacement of the foot and ankle, and range of motion of the ankle and knee. All of the parameters examined were significantly altered by the nerve injuries over the course of the experiment. The severity of deficits expressed generally increased with time before Measurements of stride length and vertical displacement of the foot and ankle appeared to recover to normal values by 9 weeks after injury, while the range of motion of the ankle and knee showed an incomplete recovery which differed with the type of nerve injury. Of the parameters measured, the ankle range of motion appeared to be the best indicator of recovery. The data suggest that the analysis of gait parameters may be a useful behavior-based technique for detecting deficits and functional recovery in nerve gap injury models.

CHARACTERISTICS OF DYSFUNCTION FOLLOWING SPINAL INJURY

CHARACTERISTICS OF DYSFUNCTION FOLLOWING SPINAL INJURY IN LARVAL LAMPREYS. V. Pate, L. Guan, T. Kiemel, J. Presson*, A. H. Cohen, Dept. of Zoology, University of Maryland, College Park, MD 20742.

The larval lamprey is known to recover function after spinal injury. Axons regrow, reconnect and can restore some function within the context of locomotion. We show that although there is considerable regeneration, 27 weeks after lesioning there can also be significant dysfunction following spinal crush at the mid-body level. Dysfunction is defined as abnormal movement during swimming not seen in sham operated controls. We begin to characterize abnormalities from electromyograms recorded in the whole animal. We use two measures of axonal regeneration: correlated spike activity across the lesion site.

normalities from electromyograms recorded in the whole animal. We use two measures of axonal regeneration: correlated spike activity across the lesion site in the isolated spinal preparation, and conduction of electrical activity across the lesion in both rostral to caudal and caudal to rostral directions.

Most, but not all, animals display some dysfunction. The major form of dysfunction relate to initiation, termination or maintenance of locomotion either when induced by tail pinch or when spontaneously initiated. Some animals exhibit a pattern of inhibition between the rostral and caudal segments; when one is active, the other is not. In the extreme, one may immediately silence the one is active, the other is not. In the extreme, one may immediately silence the other. There can also be problems in termination of swimming, with, for example, the caudal segments continuing until the rostral are stimulated by head strokes. There can also be problems in maintaining a unified frequency above and below the lesion. The swimming can have episodes of two clear frequencies of large amplitude bursting, which may or may not be accompanied by phase locked bursting. The two frequency bursting can be associated with significant evidence for regeneration of the intersegmental coordinating fibers, suggesting that the brain was driving the rostral and caudal segments at frequencies that the fibers were unable to coordinate. In most cases in which dysfunction was seen, there was clear evidence for regenerated fibers crossing the lesion site. Supported by NIH NS16803 to AHC; VP was supported by Howard Hughes

LOCOMOTOR PERFORMANCE IN ADULT MONODELPHIS DOMESTICA (S. AMERICAN OPOSSUM) FOLLOWING COMPLETE SPINAL TRANSECTION AT ONE WEEK POSTNATAL AGE. N. R. Saunders* G. W. Knott, P. Kitchener, K. Lomasney, J. G. Nicholls and T. Smith. Department of Anatomy & Physiology, University of Tasmania, GPO Box 252C, Hobart, 7001,

Australia. Neonatal Monodelphis have previously been shown to recover and develop apparently normal locomotor performance following complete spinal cord transection (Saunders et al., 1995, Clin. Exper. Pharm. & Physiol., 22, 518-526; Soc. Neurosci. 21, 506.2). The behavior of these animals when adult has now been assessed using standard tests (eg Kunkel-Bagden et al., 1993, Exper. Neurol. 119, 153-164) including those recommended by the American Paralysis Association (1990, Exper. Neurol. 107, 113-117): placing, climbing an inclined beam, runways (wide runways and grids) footprint analysis and swimming. Spinal cords of litters of 6 to 8 day old Monodelphis conditions. In 2 presented animals. tootprint analysis and swimming. Splital cross of mices of vide of any old monitolerpin were crushed in anaesthetised animals under sterile conditions. In 12 operated animals killed 0-24h after crushing, the cord was shown to be completely severed; 10 animals from 3 litters survived to adulthood. These were compared with 5 unoperated littermates. Only small differences were found in some parts of the footprint analysis (printlength, P-0.005 and toe spread, P-0.04, were significantly smaller than for controls). There were no significant differences in the time to climb and errors made while climbing a 45° angle pole; similarly there were no significant differences in crossing a 1.5 cm or 3.5 cm grid. It is concluded that *Monodelphis* that have had their spinal cords severed in the first week of life, develop to a remarkably normal extent with respect to locomotor ability. Nerve impulse conduction across the site of injury and pathway tracing in spinal cords of the operated animals are currently being investigated.

OPOSSUMS DEVELOP SOME STEPPING AFTER SPINAL CORD TRANSECTION (TX) ON POSTNATAL DAY (PD) 8 BUT DEVELOP NORMAL LOCOMOTION AFTER TX ON PD5. D.M. Basso*, J.R. Terman X.M. Wang, G.F. Martin, J.C. Bresnahan. Dept. Cell Biology, Neurobiology and Anatomy. The Ohio State University, Columbus, OH 43210.

Spinal cord (SC) TX made in PD5 opossums (Didelphis virginiana) results in reconstitution of the cord and growth of supraspinal axons through the lesion (Wang et al '96). Growth through the lesion is reduced when SC TX is made later in development. The motor efficacy of these regenerated and/or late growing axons is currently unknown. Thus, we tested the motor behavior of adult opossums with varying degrees of axonal growth through SC TX as compared to adults with TX

Opossums had complete mid-thoracic TX as neonates on PD5 (n=6), 8 (n=7), 12 (n=2), 19-40 (n=10) or as adults (6 mo; n=3). Age-matched, unlesio animals served as controls (n=3). All animals were tested at 6 mos. for open field loco-motion using the Basso, Beattie, Bresnahan Rating Scale. tree climbing, stair descent, and reflexes. All opossums lesioned as neonates were le to support their weight or step with the hindlimbs, whereas those with TX as adults demonstrated no locomotor recovery. Locomotion in the PD5 group (gp) was nearly normal (x±sd: 20± 0.84), not significantly different from controls (21 \pm 0; p>0.05) and notably better than in those lesioned at PD8-40 (11 \pm 0.79) p<0.001). Retrograde labeling from below the TX in PD5 and 8 animals showed a decrease in number but not distribution of labeled neurons in the brainste indicating that the same brainstem nuclei supported axonal growth in both gps. This suggests that the development of normal locomotion after TX may not be due solely to plasticity of supraspinal systems. Enhanced locomotor performance for the PD5 vs 8 gps may be due to plasticity of ascending and/or propriospinal systems. (Supp. by NS10165, 25095 and APA BB2-9302).

REGENERATION AND RECOVERY OF SENSORY EVOKED LOCOMOTOR BEHAVIOR FOLLOWING CRUSH INJURY OF THE TRIGEMINAL NERVE IN LARVAL LAMPREY. K. Philbrick, J.L. Calton*, A.D. McClellan, Biol. Sciences, Univ. Of Missouri, Columbia, MO 65211.

In the present study, the right trigeminal nerve was crushed in larval lamprey (<u>Petromyzon marinus</u>), and animals were tested at weekly intervals for recovery of the trigeminal sensory-evoked escape response. After various recovery times (0-12 wks.), anatomical regeneration of sensory and motor components of the trigeminal nerve were examined by application of HRP to the rostral part of the head. In some cases, muscle recordings were used to determine if regeneration of the sensory component of the trigeminal nerve was functional.

Behavioral recovery. In normal animals, tactile stimulation of the head elicits an escape response consisting of head flexion away from the stimulus, followed by swimming. During the first week following nerve crush, tactile stimulation ipsilateral to the crush did not elicit escape responses. By 3 weeks post-crush (PC), head flexure and escape activity could be elicited in about 52% of the animals. By 7 weeks PC, all the nerve crushed animals responded normally to tactile stimulation ipsilateral to the crush

Anatomical regeneration. In normal animals, HRP application to the head labels trigeminal motorneurons (nVm), axons of the descending tract (dV), some medullary dorsal cells (Dcm), and some spinal dorsal cells (Dcs). Following nerve crush, there was a gradual increase in labeling in nVm and dV ipsilateral to the crush with increasing recovery time. However, it appears that relatively few dV fibers are required for behavioral recovery, as recovery of this trigeminal component was only partial at 12 weeks PC.

In summary, sensory and motor components of the trigerminal nerve in lamprey regenerate following a crush injury. Behavioral recovery of the trigerminal sensory-evoked escape response is presumably mediated by restoration of synaptic connections between trigeminal afferents and brain neurons, such as reticulospinal neurons.

ARE SUPRASPINAL AND PROPRIOSPINAL AXONS WHICH GROW THROUGH THE LESION AFTER TRANSECTION OF THE THORACIC CORD IN DEVELOPING OPOSSUMS MAINTAINED IN THE ADULT ANIMAL X.M. Wang, D.M. Basso, J.C. Bresnahan, J. R. Terman and G.F. Martin*. Department of Cell Biology, Neurobiology and Anatomy, The Ohio State University, Columbus, Ohio 43210.

When the thoracic cord of the opossum, <u>Didelphis virginiana</u>, is transected at postnatal day (PD)5 and injections of Fast Blue (FB) are made caudal to the lesion 30-40 days later, labeled neurons are present rostral to the lesion in each of the supraspinal nuclei and spinal laminae labeled by comparable injections in unlesioned, age-matched controls. In the present study we asked whether axons which grow through the lesion during development are still present in the adult animal. The thoracic cord of 3 anesthetized pups was transected at PD5, as in the previous study, but they were maintained until adulthood before being anesthetized again and subjected to injections of FB caudal to the lesion site. After a 5-7 day survival, each animal was sacrificed and perfused so that its spinal cord and brain could be removed and sectioned for fluorescence microscopy. In all cases, neurons were labeled rostral to the lesion in each of the supraspinal and spinal areas labeled by comparable injections in non-lesioned, age-matched controls. Three additional cases lesioned at PD5 were subjected to injections of Fluoro-Ruby into either the red nucleus or the medullary reticular formation as adults. In all cases, labeled axons were present caudal to the lesion. We conclude that supraspinal and propriospinal axons which grow through lesions of the thoracic cord during early development in opossums are still present at maturity. Behavioral analyses of the animals used for this study suggested that use of the hindlimbs in locomotion was comparable to that in non-lesioned, age-matched controls. (Supported by NS-25095 and 10165).

COMPARISON OF CONDUCTION IN CHRONIC AND ACUTE CHEMICALLY-INDUCED DEMYELINATED SPINAL CORD AXONS. O. Hormou', K. Hashi', I. D. Duncan', and J. D. Kocsis'. 'Dept. of Neurosurgery, Sapporo Med. Sch., Sapporo, Japan. 064, 'Dept. of Medical Sciences, Sch. of Veterinary Med. Univ. Wisconsin, Madison, WI. 53706-1102. 'Dept. of Neurology, Yale Med. Sch., New Haven, CT. 06510; and VAMC. West Haven, CT. 06516

The conduction properties of the chronically-demyelinated axon of taiep rats, acute chemically-induced demyelinated axon (ethidium bromide with X-irradiation; EB-X), and normal Wistar (control) rats were studied in in vitro. The taiep rat has a new inherited disorder where myelination is attempted, but there is progressive demyelinis lost by about 12 months. The oligodendrocytes in the taiep rat are characterized by accumulation of microtubles in their cytoplasm; it has been proposed that this microtuble defect in oligodendrocytes results in disruption of normal myelination. In contrast to the chronic demyelination mutant model, the EB-X model is used as an acute chemically-induced focal demyelination model which has a relatively punctate glial-free region of spinal white matter with demyelinated axons lasting for several weeks. The conduction velocity of axons in both the taiep and EB-X dorsal column axons was reduced. Although the taiep rat axons display refractory periods similar to that of control rats, the ability to sustain high frequency discharges was reduced. In contrast, axons from the EB-X rat had longer refractory periods and had a reduced ability to follow high frequency stimulation. Pharmacological and morphological membranes and differences in ion channel organization on the axonal membranes and differences in the extra-axonal environment in the taiep and EB-X rat spinal cords. These results suggest that unlike acutely demyelinated axons which display marked frequency-dependent conduction block, chronically demyelinated axons of the taiep rat spinal cord develop compensatory mechanisms to stabilize a

REGENERATION AND PROLIFERATION OF HIPPOCAMPAL NEURONS IN CULTURE, <u>G.J. Brewer</u>, and <u>M.S. Evans</u>. Southern Illinois Univ. Sch. Med., Springfield, IL 62794.

Adult mammalian CNS neurons are thought to be terminally differentiated and postmitotic. We have recently developed techniques for isolation of neurons from any age adult rat hippocampus (Soc. Neurosci. Abs. 21:673.8). A density gradient is used to isolate spherical remnants of neurons in high yield from debris and inhibitory oligodendrocytes. Axons and dendrites regenerate in the majority of cells over several days in serumfree NeurobasalA/B27 medium. Neuronal identity is inferred from electrophysiology, immunoreactivity for neurofilament, MAP2, tau, neuron-specific enolase, and synaptic like vesicles by EM. Nestin is an intermediate filament protein known to be expressed in neuroepithelial stem cells (Lendahl etal., Cell 60:585). Nestin immunoreactivity is detected in isolated embryonic hippocampal neurons which declines during several days of differentiation in culture. In contrast, isolated adult neurons are initially nestin-negative. During the course of regeneration in culture, adult neurons increase nestin immunoreactivity for a few days and then lose it. With 5 ng/ml FGF2, a fraction of these neuron-like cells begin to proliferate after 3 days in culture. Proliferation occurs in cells with short processes as judged by incorporation of BrdU, time lapse photography and total cell numbers. These studies suggest that adult CNS neurons retain large regenerative and proliferative potential, and that the brain environment is growth restrictive. (Alzheimer Association and NIA Pilot)

FUNCTIONAL CHARACTERIZATION OF ADULT RAT HIPPOCAMPAL NEURONS IN CULTURE, M. S. Evans* and G. J. Brewer. Southern Illinois Univ. Sch. of Med., Springfield, II. 67794

We have recently developed methods for culturing neurons from adult rat hippocampus. In order to determine whether adult cultured neurons have normal electrical properties we have studied cultures from rats of three age groups: 1) embryonic, 2) 10 months, and 3) 35 months old. Cells were selected for study by their appearance in phase contrast optics. Neurons had a polarized morphology, usually with a large branching apical dendrite and small basal dendrites. In whole-cell recording the mean resting potentials were almost identical in the three age groups. All neurons had nonlinear current-voltage relationships, indicating the presence of voltage-sensitive ion channels. Most neurons had a strong voltage-sensitive inward current followed by voltage-sensitive outward currents, and fired a single action potential. Tetrodotoxin blocked the voltage-sensitive inward current. Cells with a glial morphology had linear current-voltage curves and did not fire action potentials. Our results indicate that adult cultured neurons have a clearly neuronal electrophysiological phenotype

SKIN BLISTER METHOD TO STUDY REINNERVATION OF HUMAN EPIDERMIS

W.R. Kennedy, M. Nolano, C.K. Knox*, G. Wendelschafer-Crabb University of MN, Minneapolis, MN 55455 and Minnesota Datametrics Corporation, St. Paul, MN 55126

Skin blisters of 2-3 mm are made on forearm skin by application of negative pressure. The blister roof is removed and stained immunohistochemically for the neuronal marker protein gene product 9.5 and other markers of epidermis and nerves. The roof, which contains keratinocytes and epidermal nerves, separates from the underlying dermis at the dermal-epidermal basement membrane. Nerves are counted by computer analysis of confocal images. Immunohistochemical staining of skin biopsies from the blister site and adjacent skin shows that the regenerated epidermis exceeds normal thickness by 4 days. Regenerating nerves with growth cones begin to enter the new epidermis on day 4. Nerves in skin surrounding the blister lean toward the blister and develop branches with growth cones. Some nerves entered the upper epidermal cell layers by day 9. Quantitation of regenerated nerves is possible from a second blister or from biopsy sections. The method will be useful for diagnosis or staging of polyneuropathy or local nerve injury, studying the effect of substances on nerve regeneration in a rapidly healing superficial wound and judging potential response to therapeutic trials.

CULTURE OF VIABLE NEURONS FROM POSTMORTEM ADULT RATS, <u>DQ McManus* and GJ Brewer.</u> Southern Illinois Univ. Sch. of Med., Springfield, IL 62794

Live neurons from postmortem patients may help to better understand age related neurologic disease. To explore this possibility, adult rat brain tissue was dissected from in situ frontal cortex at 0, 1 and 2 hours after death. After anesthesia and decapitation, the skull was resected to expose and remove frontal cortex. Between time points the skull was replaced over the brain. The decapitated head with remaining brain was kept humidified in a covered container exposed to ambient air at approximately 21 °C. At the next time point the skull was lifted off, the frontal cortex sample was removed, and the head with remaining brain tissue was manipulated as described above. The brain tissue was processed for each time point as previously described using serum-free medium B27/Neurobasal, GJ Brewer, Soc. Neurosci. Abs. Successful neuronal cultures were obtained at all Total isolated viable cells declined only 30% from <u>21:673.8 (1995)</u>. three time points. freshly isolated (7,900 cells/mg tissue) to 2 hours postmortem (5,600 cells/mg tissue). After 5 days in culture, the yield of neurons dropped from 65% to 25% of total live cells isolated from 2 hours postmortem brain tissue. Cells with neuron-like morphologies by phase contrast were recognized by antibodies to neurofilament, tau, and MAP2. Selective GFAP staining was observed for other astrocytic cell types, but not for neuronal cell types. Neurons cultured from 1 and 2 hours postmortem brain appeared similar to freshly isolated neurons. (Alzheimer's Association and Mr. & Mrs. Malan's research gift)

591.20

AN IN VIVO MICRODIALYSIS STUDY OF THE CORRELATION BETWEEN THE REGENERATION OF 5-HT FIBERS, THE RELEASE OF 5-HT, AND LOCOMOTION.

OF 5-H1, AND LOCOMOTION.

C. GERIN*, A.PRIVAT, INSERM U-336, C.C.106, Univ. Montpellier II, Pl. E. Bataillon, 34095 Montpellier Cedex05, France.

The release of 5-HT from raphe-spinal cord terminals in the ventral horn is correlated to locomotor activity (Gerin et al., 1994;

Gerin et al., 1995). In order to appreciate the functional parameters of regenerating serotonergic fibers, a microdialysis probe was stereotaxically implanted ipsilaterally in the ventral horn of hemilesioned rats. The concentration of 5-HT in the ventral horn was analyzed with an HPLC-ED system. The animals were submitted to motor test performances (inclined grasp, beam walk, and treadmill run). The microdialysis test session was divided into three parts: rest (90 min). Treadmill run (60 min), post-exercise (90 min). Microdialysate samples were collected at fifteen minute intervals. The animals were sacrificed 40 days after permanent implantation of the probe and the spinal cord was sectioned for histological analyses (location of the probe, and extension of the lesion) and for immunocytochemical detection of the 5-HT and GFAP

Motor performances and the time course of recovery were both correlated with the extension of the lesion. The locomotor scores are correlated to the concentration of 5-HT measured at rest on days 8, 16-20, 32-36. Thus, after a complete recovery of the locomotor function, 5-HT concentrations tend to be similar to those measured in control animals Supported by IRME and AFM.

GDNF TRIGGERS THE OUTGROWTH OF FETAL VENTRO-MESENCEPHALIC GRAFTS FROM NIGRA TO STRIATUM IN THE 6-OHDA LESIONED RATS. Y. Wang*, L. T. Tien and B. J. Hoffer, Dept. of Pharmacology, National Defense Medical Center, Taipei, Taiwan and Dept.
Pharmacology, Univ. Colorado Health Sciences Center, Denver, CO. 80262
Previous reports have indicated that grafting of fetal ventro-

mesencephalic (VM) tissue to the nigra region of unilaterally 6-OHDAlesioned animals, in conjunction with kainate injection between nigra and striatum, restores nigrostriatal tyrosine hydroxylase immunoreactivity. Glial cell line derived growth factor (GDNF), a potent trophic factor for dopaminergic (DA) neurons, has been found to be upregulated by kainate. In this experiment, we investigated the bridging effect of GDNF injection on intra-nigral transplants. Adult Sprague-Dawley rats were anesthetized and unilaterally injected with 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle. The completeness of lesions was tested by measuring methamphetamine -induced rotations. One to two months after 6-OHDA administration, fetal VM tissues were grafted in the lesioned nigral area followed by injection of GDNF 100 μ g, along a tract from nigra to striatum Animals receiving transplantation and GDNF injection showed a significant decrease in rotation one to three month after grafting. Immunocytochemical studies indicated that tyrosine hydroxylase -positive neurons and fibers were found in the nigra and striatum, respectively, after grafting. No effects of similarly injected BDNF were seen. These results indicate that fetal nigral transplantation and GDNF injection may restore the nigrostriatal DA pathway in the Parkinsonian animals and supports the trophic activity of GDNF on midbrain DA neurons. This research is supported by grants from the National Science Council of R.O.C and USPHS of U.S.A

TIME-COURSE AND SPECIFICITY OF EFFERENT GROWTH FROM NEURAL GRAFTS PLACED INTO THE NEONATAL STRIATUM. K. Wictorin*, M. Olsson, M. A. Gates, K. Bjerregaard, K. Campbell and A. Björklund. Wallenberg Neuroscience Center, Lund, Sweden.

When embryonic striatal tissue is implanted into the lesioned adult rat striatum, efferent projections are formed into the adjacent globus pallidus (GP), but not much further into the host. It is well known from other transplantation models that the neonatal brain serves as a permissive host environment for fibre growth from implanted cells. In the present study we implanted embryonic (E 13.5-14) tissue derived from the mouse lateral ganglionic eminence (LGE) into the postnatal day (P) 3 rat striatum, and used a mouse specific antiserum (M6) to study the time-course of the efferent growth. At 5 days post-grafting efferent fibres had grown through the GP and into the entopeduncular nucleus. By 7 days the outgrowth had reached into the most rostral aspect of the substantia nigra (SN), and by 11 days this structure was densely innervated. In separate animals this outgrowth was compared to that occurring from grafts of tissue from either the cerebral cortex (CC) or rhombencephalic lip (RL) placed into the P1 striatum. Whereas the LGE implants specifically innervated above all the GP and SN, the CC tissue extended dense projections into certain thalamic nuclei and also grew further into the brainstem. The RL grafts did not provide any significant outgrowth away from the striatal implant site.

This study demonstrates the permissive nature of the neonatal brain for outgrowth from embryonic implants also in the striatal grafting model. The outgrowth follows a distinct time-course which is compared to that of normal striatal development. The efferent growth is highly specific and dependent on the type of tissue that is implanted. Supported by the Swedish MRC, the Kock and Wiberg Foundations.

A RAT MODEL OF L-DOPA-INDUCED DYSKINESIA: NEUROCHEMICAL CHANGES IN THE BASAL GANGLIA AND INTRASTRIATAL TRANSPLANTS. M.A. Cenci. C.S. Lee and A. Björklund*. Wallenberg Neuroscience Centrum, Sölvegatan 17, 223 62 Lund, Sweden.

The development of dyskinesia is one of the major drawbacks of long-term L-DOPA

treatment in Parkinson's disease, and the mechanisms underlying this adverse side-effect are largely unknown. We have developed a rat model of L-DOPA-induced dyskinesia which is suitable for studies aimed at elucidating the pathophysiology of

dyskinesia which is suitable for studies aimed at elucidating the pathophysiology of this phenomenon, or at testing possible remedies to it.

Rats sustaining unilateral injections of 6-hydroxydopamine (6-OHDA) in the mesostriatal dopamine pathway received daily injections of L-DOPA (8 mg/kg L-DOPA plus 15 mg/kg benserazide i.p.) for 21 days. During this period, part of the rats gradually developed abnormal involuntary movements, which appeared 20-120 min after each L-DOPA dose, and were classified in four groups (orolingual movements, limb during in the control of the property of the control of the alter each L-DOFA dose, and were classified in four groups (orningar inovernents, limb dyskinesia, axial dystonia, hyperlocomotion), as well as quantified daily in a scale from 0 to 4. An in situ hybridization analysis of neurotransmitter-related mRNA expression in the basal ganglia of L-DOPA-treated rats revealed that levels of preproenkephalin (PPE) mRNA, glutamic acid decarboxylase (GAD67) mRNA, and prodynorphin (PDyn) mRNA in the dopamine-denervated caudate-putamen, as well as GAD67 mRNA expression in the globus pallidus ipsilateral to the 6-OHDA lesion, were positively correlated with the rats' cumulative dyskinesia scores. However, among the latter markers, only striatal PDyn mRNA expression was clearly treatmentdependent (3 times higher in the L-DOPA treated group than in non-treated lesion-only

Intrastriatal transplants of fetal ventral mesencephalic tissue dramatically reduced the severity of L-DOPA-induced dyskinesia and abolished the associated neurochemical changes (i.e. hyperexpression of mRNAs encoding for PPE, PDyn and GAD67). In addition, the transplants prevented the development of abnormal involuntary movements upon increasing L-DOPA doses in non dyskinesia-prone rats. supp. by Tore Nilsson and Ake Wiberg Foundations

GRAFT-DERIVED DOPAMINERGIC INNERVATION OF STRIATAL INTERNEURONS B. Rajakumar, A.W. Hrycyshyn*, N. Rajakumar and B.A. Flumerfelt. Departments of Anatomy & Cell Biology and Psychiatry, University of Western Ontario, London, Ontario, Canada, N6A 5C1

Intrastriatal grafting of embryonic dopaminergic (DA) cells is widely employed as an alternative treatment in Parkinson's disease. It is believed that functional restoration is achieved partially through reinnervation of the host by the grafted DA neurons. In this study, it was hypothesized that the graft-derived DA neurons re-establish normal synaptic contacts with somatostatin-, parvalbumin-, calretinin- and acetylcholine-containing interneurons of the host striatum. Unilateral substantia nigra lesions were made by stereotaxic injection of 6-hydroxydopamine in adult rats. The extent of the lesions was assessed using rotational behaviour following amphetamine injection. Suspensions of ventral mesencephalic cells from 14-15 day old embryos were stereotaxically grafted into the DA depleted striatum. Three months postgrafting, animals with rotational recovery were perfusion-fixed with a solution containing 4% paraformaldehyde, 0.08% glutaraldehyde and 15% picric acid. Vibratome sections were doubleimmunolabeled using cobalt-intensified DAB and DAB as the chromogens for interneurons and DA terminals respectively. Light microscopic observations revealed close apposition between DA fibres and striatal interneurons. Ultrastructural examination revealed numerous appositions between graft-derived DA terminals and dendrites and somata of all four types of interneurons. Moreover, graft-derived DA terminals made synaptic contact with dendrites of cholinergic interneurons similar to that seen in normal animals. [Supported by MRC Canada].

HETEROGENEOUS INTEGRATION OF GLIA FROM PHYLOGENETICALLY DIVERSE REGIONS OF THE MURINE EMBRYO AFTER TRANSPLANTATION TO THE NEONATAL RAT.

Monte A. Gates*, Martin Olsson, Kristoffer Bjerregaard and Anders

Björklund Department of Medical Cell Research, Univ. of Lund, Sweden

Glial cells support neuronal migration and growth during central

nervous system (CNS) development. Recent studies show that this support can be regionally specified, so that glia from particular areas of the developing CNS best promote the migration and/or growth of specific groups of neurons. The idea, then, that glia from various regions of the

developing CNS are heterogeneous seems possible.

In the present study, dissociated cells from the embryonic day 14 (E14) mouse cerebral cortex (CC), ventral mesencephalon (VM), or rhombencephalic lip (RL) were transplanted to a site between the substantia nigra (SN) and neostriatum of postnatal day 1 (P1) rats, and the integration of donor glia revealed via immunocytochemistry using the murine- specific, glial antibody M2. While the distribution of glia from the donor VM was restricted to the internal capsule, globus pallidus and SN of the host, glia from CC and RL regions were additionally distributed throughout much of the adjacent thalamus. Such heterogeneous integration reflects a variability in the potential for glial cells to integrate across brain regions and suggest a regional diversity in the responses of glia to the milieu(s) of the CNS. Beyond an interesting developmental phenomenon, the potential for glia to integrate across CNS regions seems relevant to current cell replacement paradigms where the integration of donor glia may affect the migration and growth of their neuronal counterparts. Currently, we are grafting similar donor cells into other loci of P1 rats to determine the potential for additional heterogeneous responses by phylogenetically diverse glia. NIGRAL MICROTRANSPLANTATION TO THE CAUDATE -PUTAMEN UNIT OR NUCLEUS ACCUMBENS: CORRELATION OF SENSORIMOTOR BEHAVIORS AND DOPAMINE CONTENT AS MEASURED BY IN VIVO NOLTAMETRY. G.Falkenstein*, C.Rosenthal*, T.Reum*, A.Marburger*, M.Samii*, R.Morgenstern*, G.Nikkhah** / ** Neurosurgical Clinic, Nordstadt Hospital, Haltenhoffstr. 41, D-30167 Hannover, ^* Institute of Pharmacology and Toxicology, Medical Faculty (Charité), Humboldt-University at Berlin, D-10098

The aim of the study was to further elucidate mechanisms of graft induced behavioral recovery. We approached this issue in a comparative study including a) a wide spectrum of tests for complex sensorimotor behavior and b) electrochemical measurements for graft derived reconstitution of striatal dopamine levels.

Three groups of unilaterally 6-OHDA lesioned rats received the same total amount (1,5 µl) of cell-suspension (200,000 cells/µl) derived from E14 ventral mesencephalon. In two groups the grafts were implanted into the caudate-putamen unit (CPU), distributed either over two deposits in one tract or over six deposits in three tracts. The third group received two deposits in one tract into the nucleus accumbens (NAc). The comparative study assessed spontaneous (such as disengage behavior, skilled forelimb use, side-stepping and -falling) and drug induced rotational behavior. Preliminary behavioral results indicate good graft survival, e.g. amphetamine-induced rotation was completely compensated two weeks after the transplantation as seen with intrastriatal grafts. In addition, intrastriatal grafts lead to a partial recovery in stepping behavior as well as in skilled forelimb use, which was not observed in the NAc-grafted group. Studies on long-term behavioral effects and in vivo voltametric measurements of dopamine levels are in progress and will be reported at the meeting

ALTHOUGH ADRENAL MEDULLA GRAFTS PLACED INTO THE LATERAL VENTRICLE, GROW BETTER THAN THOSE PLACED INSIDE THE DOPAMINE DENERVATED STRIATUM, THEIR CONSEQUENCES OVER THE FUNCTIONAL DISTURBANCES ARE EQUIVALENT. V. Anaya-Martínez, E. Montiel-Flores, J. Espinoza-Villanueva, M. R. Avila-Costa, N. Manzano-León, L. Colín-Barenque and F. García-Hernández*. Neurosciences. ENEP Iztacala. UNAM. Ap 314. Tlalnepantla, México, 54090.

When grafted into the dopamine denervated striatum, adrenal medullary tissue exhibits poor survival rates, which may limit its capability for reducing motor disturbances. In this study we correlated the reduction of motor deficits with the grafting site and graft survival. Male Wistar rats, exhibiting apomorphine (0.25 mg/Kg) induced rotation (more than 200 turns in 30 min), after the unilateral injection of 6-OHDA into the medial forebrain bundle, were grafted with fetal adrenal medullary tissue as follows: Group 1 (n=9): received 1µl placed into the ipsilateral lateral ventricle, Group 2 (n=8): received 1 μl placed inside the ipsilateral striatal parenchyma and Group 3 (n=9); received 5 ul also inside the ipsilateral striatal parenchyma. Apomorphine induced rotation was tested again 15, 30, 45 and 60 days after grafting, term after which all rats were sacrificed for histological analysis of tyrosine hydroxylase (TH) immunostained serial sections of the striatum where the transplant was found. With the aid of a computer assisted system, the volume of the prevailing transplanted tissue was established as well as the number and size of the TH immunoreactive cells within the graft. Our results show that although ventricular grafts exhibited a modest loss of the original graft volume and abundant and bigger TH immunoreactive cells, the reduction of apomorphine induced rotation was the same as in intrastriatal grafts, who had only a few and small TH immunoreactive cells, with high loss of the original transplant volume

INTRASTRIATAL INJECTION OF ADENOVIRUS EXPRESSING TYROSINE HYDROXYLASE ATTENUATES ROTATIONAL BEHAVIOR IN 6-OHDA RATS BY PREVENTING AGONIST-INDUCED SENSITIZATION. S. Gancher*, L. Muldoon, M. Pagel, and B. Davidson. Department of Neurology, Oregon Health Sciences University, Portland Oregon 97201

In rats with unilateral 6-OHDA lesions, the intracerebral inoculation of recombinant viruses containing the gene for tyrosine hydroxylase (TH) has been shown to attenuate drug-induced rotational behavior. After 6-OHDA lesioning, rats were treated with six daily injections of apomorphine (0.1 mg/kg), resulting in a significant increase in contralateral rotations which reflected behavioral sensitization. After intrastriatal inoculation of recombinant adenovirus containing the gene for human TH (1µl, 109 particles/µl) and a three week recovery, the response to apomorphine fell to levels first observed with initial apomorphine exposure and remained unchanged over six daily apomorphine injections. A group of rats were similarly treated with apomorphine, received intrastriatal injections of vehicle, and allowed to recover for six weeks prior to repeated administration of apomorphine. These rats also exhibited a response which was initially reduced, but which then did increase following subsequent daily apomorphine treatments. These results suggest that a) sensitization to apomorphine in 6-OHDA rats is extinguished over several weeks without treatment, and b) replacement of TH into the striatum results in an attenuated response to apomorphine by interfering with the development of sensitization. These finding suggest that in this model, sensitization to agonist-induced rotational behavior depends on the extent of dopamine depletion. (Supported by NINDS KO81539 and VA Merit Review).

CHARACTERIZATION OF IN VIVO SURVIVAL OF EMBRYONIC DOPAMINERGIC CELLS AFTER SELECTIVE SORTING USING A FLUORESCENT NEUROTENSIN DERIVATIVE. A.F. Sadikot*, M. Alonso-Vanegas, M.P. Faure, K. McDonald and A. Beaudet. Montreal Neurol. Inst., Univ. McGill, 3801 University St., Montreal, QC, Canada H3A 2B4.

Current methods for transplantation of embryonic midbrain result in delivery of a heterogeneous population of cells containing dopaminergic neurons, gabaergic neurons, glia, and mesenchymal elements. The fact that dopaminergic neurons of the midbrain are selectivey endowed with high affinity receptors for neurotensin (NT) (Szigethy et al, '89), has allowed us to selectively tag embryonic DA cells with fluo-NT and sort these neurons from other cell types by flow cytometry (Faure et al, '94; '96). Rat mesencephalic cells were harvested at embryonic day 15, mechanically dissociated, cultured for 7 days, and then labelled with fluo-NT. DA cells were then separated from other cell types using a fluoresence activated cell sorter (FACS). 5 µl of a solution containing 10, 000 cells/µl of Hanks balanced salt solution was then stereotactically transplanted into the dopaminedenervated adult rat striatum. In a control group, comparable numbers of unsorted embryonic cultured cells were transplanted into the dopamine-denervated adult rat striatum. At one month after transplantation, animals were perfused with aldehydes and processed for immunohistochemistry for tyrosine hydroxylase as a marker for dopaminergic cells. Sorted cells were noted to survive and grow processes resulting in partial reinnervation of the denervated striatum. By comparison, unsorted DA cells showed more exuberant cell processes and greater density of striatal reinnervation. Our results suggest that cell sorting of embryonic DA cells is feasible, and DA cells survive the process of fluo-NT labeling and FACS separation in a condition that allows for subsequent cell survival in vivo. Evtouchenko, R. Guzman, R.W. Seiler, J. Zimmer and C. Spenger. Dept. of Neurosurgery, University of Bern, Bern, Switzerland. *Dept. of Anatomy and Cell Biology, University of Odense, Odense, Denmark

Adult Sprague-Dawley rats received unilateral injections of 6-hydroxydopamine into the nigrostriatal bundle, and the completeness of the lesions was assessed by Damphetamine-induced rotations. Rotating animals were randomly divided into a control group (sham operation), a group intrastriatally grafted with fresh cell suspension from fetal (E13) ventral mesencephalon and a group intrastriatally grafted with 7 days old free floating roller tube (FFRT) cultures derived from fetal (E13) ventral mesencephalon. Post-operative evolution in rotational behaviour was evaluated at several time points post-transplantation (p.t.), and long-term survival of tyrosine hydroxylase-immunoreactive (TH-ir) neurons was assessed in serial sections of the grafted brains (12 weeks p.t.).

Three, 5 and 9 weeks post-grafting rats grafted with fresh cell suspensions (N=9) showed an average reduction in D-amphetamine-induced rotations of 50%, 101%** and 121%*** and rats grafted with cultured tissue (N=9) an average reduction of 73%**, 103%*** and 104%***, respectively (**=p<0.01;***=p<0.001). Shamoperated animals displayed no significant changes in rotational behavior in the same period. Histological examination of the grafts revealed similar numbers of TH-ir neurons in suspension grafts (mean \pm SEM = 756 \pm 99, N=9) compared to tissue culture grafts (mean ± SEM = 728 ± 92, N=9).

In conclusion, the similar extent to which culture grafts survive and are effective as compared to fresh suspension grafts illustrates the feasibility of effective in vitro maintenance of fetal nigral tissue prior to transplantation.

In Parkinson's disease, dopaminergic cells of the substantia nigra degenerate, disrupting the nigrostriatal pathway. One approach to replace these lost neurons is to transplant mesencephalic tissue into the striatum. In an attempt to improve survival of transplanted dopaminergic neurons, we have pretreated the graft with the dopaminotrophic factor glial cell line-derived neurotrophic factor (GDNF). Mesencephalic grafts from fetal Fischer 344 rats (E14-E15) were pre-incubated in GDNF (1 µg/µL) or the control protein, cytochrome c (1 µg/µL), and transplanted into the striatum of adult hosts that had been previously lesioned by receiving medial forebrain bundle injections of 6-hydroxydopamine. Host rats received intrastriatal injections of GDNF or cytochrome c (10 μg each) adjacent to the graft at ten days and four weeks postgrafting. The animals were tested for apomorphine-induced rotation behavior, and were perfused for immunohistochemical analysis of transplant morphology at six weeks postgrafting. GDNF and cytochrome c treated groups both showed significant motor improvement. Morphological evaluation revealed that the GDNF-treated grafts were larger than control grafts. Additionally, tyrosine hydroxylase (TH) immunohistochemistry and image analysis showed a significantly higher staining density in the transplanted area, indicating better innervation, and further analysis revealed significantly larger TH-positive cells in the GDNF transplants than in controls. This experiment supports the positive effects of GDNF on dopaminergic cells, and suggests that transplantation in conjunction with neurotrophin application could be a successful treatment strategy. TIRILAZAD MESYLATE INCREASES S EMBRYONIC DOPAMINERGIC NEURONS IN SHRVIVAL. OF

A. Othberg, M. Keep*, P. Brundin¹ and O. Lindvall.

Section of Restorative Neurology, Department of Clinical Neuroscience,
Section of Neuronal Survival, Department of Physiology and Neuroscience,
Wallenberg Neuroscience Center, S-221 85 Lund, Sweden.
The survival of embryonic dopaminergic neurons of rat or human origin after
grafting to the striatum is low (5-20%). Transplantation of tissue from at least
3-4 embryos per side is therefore needed to obtain therapeutic improvement in a patient with Parkinson's disease. For the further development of neural transplantation into a clinically useful treatment for a larger number of patients, the survival of grafted dopamine neurons has to be increased. Lazaroids are compounds which have been shown to improve survival of rat dopamine neurons in cell culture and after grafting to the rat brain (Nakao et al., Proc. Natl. Acad. Sci. USA. 1994, 91:12408-12), probably by inhibiting lipid peroxidation. The only lazaroid approved for human use is tirilazad mesylate (Freedox, Pharmacia-Upjohn). To determine if tirilazad has the utility shown (Precox, Pharmacar-Opjoint). To determine it utilizate has the durity shown for other lazaroids, it was used here in cultures of rat ventral mesencephalon (VM), and in rat and human VM suspensions, which were treated the same way as in clinical transplantations. After 7 days in culture, we observed a 2.4-fold higher number of surviving tyrosine hydroxylase-positive, presumed dopaminergic, cells with 0.3 µM tirilazad as compared to control. The viability studies showed significantly faster decline of the number of surviving neurons in control compared to tirilazad over time up to 30 hrs. These results show that tirilazad has neuroprotective effects on embryonic VM neurons similar to those of other lazaroids. Trilazad should therefore be useful to improve graft survival in clinical transplantations, thereby reducing the amount of embryonic tissue required to induce significant symptomatic relief in patients with Parkinson's disease. Supported by the Swedish Medical Research Council.

THE IMPORTANCE OF DISSECTION MEDIUM AND LAZAROIDS FOR CELL SURVIVAL AT GRAFTING I. Strömberg, L. Björklund, L. Evtouchenko, and C. Spenger. Dept. of Neurosci, Karolinska Institutet, Stockholm, Sweden, Dept. of Neurosurg. Univ. Hosp. of Bern, Switzerland The trials of grafting catecholamine tissue to patients suffering from

Parkinson's disease have reached the point that increased cell survival is needed to enhance graft efficacy. Animal experiments have been focused on trophic factors in this issue, but another approach to yield better survival might be to remove some of the toxic mechanisms which occurs during the dissection and transplantation procedures. In this study we have examined the effect of lazaroid U-74006F, which may inhibit oxidative stress by reducing free radical formation. The intraocular grafting model has been used where fetal ventral mesencephalon has been implanted to the anterior chamber of the eye. During dissection either Hanks' balanced salt solution (HBSS) or Dulbecco's modified Eagle medium (DMEM) has been used and a preincubation in U-74006F at 0.3 μ M for 15 min prior to transplantation was performed. Weekly injections of U-74006F was performed for two weeks and cell counts of tyrosine hydroxylase (TH) positive neurons were performed at 3 weeks. Control grafts were treated with either HBSS or DMEM. TH-immunohistochemistry revealed that grafts dissected and treated with DMEM possessed twice as many neurons s that found in HBSS treated grafts. Injections of 5 μl of 3 μM Ú-74006F diluted in DMEM revealed insignificant increase in TH-positive neurons. A 10-fold increase in the doses of U-74006F significantly increased the neurons from 333±56 cells in DMEM treated controls to 812±188 TH-positive neurons after lazaroid treatment. In conclusion, both the selection of dissection medium and the treatment with lazaroids seems to be important to enhance the cell survival.

IN VIVO EVALUATION OF ADENOVIRAL VECTOR CONTAINING THE DOPAMINE D. RECEPTOR GENE IN RAT AND MOUSE STRIATA. DOPAMINE D. RECEPTOR GENE IN RAL AND MOUSE STRALA. IL. Umegaki, H. Ikari, J. Chernak, J. Hengemihle, G. Roth, D. Ingram.* Gerontol. Res. Ctr., Natl. Inst. Aging, NIH, Baltimore, MD 21224: Dept. Geriatric Med., Nagoya Sch. Med., Nagoya, JAPAN. Decline in striatal dopamine D₂ receptors (D₂R) is observed in mammalian aging as well as in neurodegenerative diseases Such as

Huntington's disease and late-stage Parkinson's disease. To assess the feasibility of gene transfer of D₂R, we (Ikari et al., *Mol. Brain Res.* **34**:315, 1995) constructed a replication-deficient adenoviral vector containing rat D₂R cDNA (AdCMV.DopD₂R). Applying an apomorphine-induced rotational model, we assessed the function of AdCMV.DopD.R in vivo. Starting 4 wk after injection of AdCMV.DopD2R into rat striatum, we observed the predicted contralateral rotational behavior. To determine how this behavior was coupled to receptor expression, we performed autoradiography with the D₂R-specific ligand, [1²⁵I]iodosulpride. Densitometric evaluation showed an increase of ligand binding in vector-injected sites that peaked at day 5 and declined to basal levels by 3 weeks after injection. Thus, small, undetectable increases in D₂R may affect rotational responses or it may be delayed or dependent on factors other than D₂R levels, which we are now examining. To assist in this approach, we have injected AdCMV.DopD2R into mouse striatum, the smaller size of which may allow a relatively greater increase over endogenous D2R levels than in rats. We have confirmed increased ligand binding and apomorphineinduced rotational behavior in this mouse model

PREINCUBATION WITH GROWTH FACTORS IMPROVES SURVIVAL OF EARLY MESENCEPHALIC GRAFTS IN HEMIPARKINSONIAN RATS. D.J.Zastrow*, W.M.Zawada, E.D.Clarkson, F.Adams, P.Bell, and C.R.Freed Div. Clin. Pharmacol., Univ. Colorado School of Medicine, Denver, CO 80262.Poor survival of transplanted embryonic dopamine (DA) neurons in patients

with Parkinson's disease limits the usefulness of this evolving therapy. We have previously shown that apoptosis is in part responsible for the loss of DA neurons in vitro. Programmed cell death in DA neurons can be reduced by GDNF or a combination of IGF-I and bFGF. In an effort to improve the survival of DA neurons in grafts, we have transplanted tissue strands from E15 rat ventral mesencephalon into 6-OHDA-lesioned rats. Each freshly obtained embryonic tissue strand was prepared from 1/2 of a ventral mesencephalon and incubated for 2 hrs on ice in L-15 medium containing GDNF (100 ng/ml), IGF-I (1500 ng/ml), and bFGF (150 ng/ml) and controls in L-15 alone. Tissue strands were grafted immediately following incubation and animals were sacrificed either 1 or 7 days post-transplant. Dopamine neurons were identified by tyrosine hydroxylase immunoreactivity. Growth factor pretreatment improved DA neuron survival by 55% in grafts after 1 day in vivo and by 57% after 7 days in vivo. To further enhance DA neuron survival in vivo by methods aimed at preventing apoptosis, we have studied in vitro the effects of inhibitors of cysteine proteases and calpain (putative mediators of apoptosis). Cultures from dispersed mesencephalon were grown for 3 days in serum-enriched medium. Ac-YVAD-chloromethylketone, an inhibitor of interleukin-1 β converting enzyme, at 1 μ M and 10 μ M improved survival of DA neurons by 24% and 31%, respectively. Calpain inhibitor I (1 μ M) rescued 40% of DA neurons. This inhibitor was toxic to cultures at concentrations of $\geq 10 \mu M$. Prevention of apoptotic cell death with growth factors and protease inhibitors may improve the viability of DA neurons grafted for Parkinson's disease. Supported by NS 18639, GM 07063, and the Natl. Parkinson Foundation.

SIMULTANEOUSLY COGRAFTED STRIATAL TARGET TISSUE ENHANCES NEURITE OUTGROWTH AND NEURON VIABILITY OF GRAFTED MESENCEPHALIC DOPAMINE NEURONS <u>C.E. Sortwell'*</u>, <u>T.J. Collier²</u>, <u>B.C.</u>

NEURITE OUTGROWTH AND NEURONS CL. Sortwell*. TJ. Collier², B.C. Blanchard¹ and J.R. Sladek. Jr.¹ Department of Neuroscience, Chicago Medical School, North Chicago, IL. 60064 and ²Department of Neuroscience, Chicago Medical School, North Chicago, IL. 60064 and ²Department of Neuroscience, Chicago Medical School, North Chicago, IL. 600612. Trophic factors derived from target striatum are crucial for nigrostriatal pathway formation and maintenance. Evidence collected in vitro demonstrates that striatal cells may be capable of exerting both a trophic effect on dopamine (DA) neurons survival and a tropic effect on neurite extension. However, previous in vivo studies have demonstrated only a tropic effect of cografted striatum on grafted DA neurons. The aim of the present study was to characterize the tropic and/or trophic effects of striatal cografts on grafted mesencephalic DA neurons. Unilaterally, 6-OHDA-lesioned male, Fischer 344, rats were grafted with either an embryonic (E15) mesencephalic cell suspension alone or with both mesencephalic and striatal cell suspensions (E15) mixed or seperate conditions) to the striatum. Lesioned rats receiving no graft served as controls. Rotational assessment was conducted following amphetamine challenge at 1 week prior, and 4 and 8 weeks following grafting. After behavioral assessment, rats were immunostained using antisera directed against tyrosine hydroxylase (TH) and analyzed histologically. Results confirm previous findings of striatal tropic effects where DAergic fiber outgrowth is enhanced when striatum is separately cografted and T11 rich patches are observed within mixed striatal and mesencephalic cografted with striatal cells contained 2 and 3-fold higher cell counts of DA neurons. Mesencephalic cell suspension grafts that were mixed with striatal cells or separately cografted with striatal cells contained 2 and 3-fold higher cell counts of DA neurons. Respectively, than solo mesencephalic grafts. Separate cografts appeared to induce enhanced behavioral recovery whe

CO-GRAFTS OF MUSCLE CELLS AND MESENCEPHALIC TISSUE INTO HEMIPARKINSONIAN RATS: BEHAVIORAL AND HISTOCHEMICAL EFFECTS. F.G. Kaddis', E.D. Clarkson and C.R. Freed, Depts. of Medicine and Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262.

Conditioned medium from muscle cell cultures (MC-CM) has been shown to increase the expression of tyrosine hydroxylase (TH) in rat mesencephalic cultures (Iacovitti et al. Molec. Brain Res. 16:215, 1992). To see if muscle cells can improve embryonic midbrain transplants in a rat model of Parkinsons disease, we have tested the effects of MC-CM on embryonic mesencephalic and striatal cultures and then co-transplanted newborn rat muscle cells along with embryonic dopamine cells into denervated rat striatum. Results showed that: (A) MC-CM increased the number of TH neurons in ED15 midbrain cultures but did not stimulate the expression of TH in ED15 striatal cultures, (B) co-transplants of muscle cells with ED15 mesencephalic cells improved striatal reinnervation and more rapidly reversed circling behavior to methamphetamine than ED15 mesencephalic tissue grafts alone.

IPSILATERAL CIRCLING TO 5 MG/KG METHAMPHETAMINE, RPM

Pre-Grafting		Months Post-Grafting

INCREASED DOPAMINERGIC ACTIVITY CAUSED BY STRIATAL INJURY IS ASSOCIATED WITH AXONAL SPROUTING. G.T. Liberatore', D.I. Finkelstein', J.Y.F. Wong', M.K. Horne', G.A. Donnan' and D.W. Howells'*. Departments of Medicine and Neurology, University of Melbourne, Austin and Repatriation Medical Centre (Austin Campus), Heidelberg, Victoria 3084, Australia and ²Department of Anatomy, Monash University, Clayton, Victoria 3168, Australia.

We have previously shown that striatal injury causes activation of the nigro-striatal dopamine system. This response is characterised by stimulation of pre-synaptic dopamine activity (increased tyrosine hydroxylase activity, increased concentrations of dopamine and its metabolites and increased density of pre-synaptic dopamine uptake sites) with an accompanying down regulation of the density of the predominantly post-synaptic D_1 and D_2 dopamine receptors. This response could be due to either, increased activity within existing dopamine terminals and/or branching and sprouting of new dopamine terminals within the striatum. To investigate the latter, normal and 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine treated male C-57 black mice were anaesthetised and the left striatum lesioned using a Scouten wire knife. Counting silver stained axons and their branches demonstrated that striatal injury causes axonal sprouting one month post damage. Injection of dextran-biotin into the substantia nigra and then monitoring its transport into the striatum, shows that some of this neuronal sprouting is of nigral origin. Tyrosine hydroxylase immunohistochemistry, on alternate sections, demonstrates that a proportion of this sprouting is dopaminergic. A better understanding of these processes and their regulation may play a important role in improving treatment of Parkinsons disease

Research is funded by the AHMRF and NH&MRC.

TRANSPLANTS OF FETAL VENTRAL MESENCEPHALIC TISSUE INTO THE MIDBRAIN ATTENUATE DI AGONIST-INDUCED ROTATIONAL BEHAVIOR, D.M. Yurek* and J.A. Coopei . Depts. of Surgery/Neurosurgery and Anatomy & Neurobiology, Univ. of Kentucky College of Medicine, Lexington, Kentucky 40536.

The function of dopamine release within the substantia nigra pars reticulata (SNR) is not clearly understood despite the long-standing evidence that dopamine is somatodendritically released. Somatodendritic release of dopamine may serve an autoregulatory function for dopaminergic neurons and may also regulate the activity of striatonigral neurons, which are known to have receptors of the D1 subtype on nerve terminals located within the SNR. We recently demonstrated that rotational behavior elicited by SKF 82958 is effectively blocked by intranigral administration of the D1 receptor antagonist, SCH 23390, which suggests that dopamine release within the midbrain contributes to rotational behavior induced by dopaminergic drugs.

In this study young adult rats were given unilateral 6-hydroxydopamine lesions and cannula were implanted to allow for the administration of dopaminergic drugs into the SNR ipsilateral to the lesion. Rotational behavior was tested after administration of the following drugs: SKF 82958, 7.0 µg intranigral or 0.01 mg/kg (s.c.); quinpirole, 10.0 μg intranigral or 0.2 mg/kg (s.c.); and amphetamine 5.0 mg/kg (i.p.). Animals did not show significant rotational behavior to intranigral administration of quinpirole. One week after rotational testing was completed animals received midbrain transplants of fetal mesencephalic tissue; transplants were targeted for the dorsolateral aspect of the SNR. Retests for rotational behavior began weeks posttransplantation. Animals receiving midbrain transplants showed significant reductions in rotational behavior after intranigral or s.c. administration of SKF 82958. Midbrain transplants did not significantly reduce rotational behavior elicited by quinpirole (intranigral or s.c.) or amphetamine. This research was supported by USPHS NS 29994.

UNILATERAL FETAL MESENCEPHALIC GRAFIS IN NON-LESIONED RATS REDUCE THE RATE OF HIGH AFFINITY DOPAMINE UPTAKE IN THE CONTRALATERAL STRIATUM: AN IN VIVO VOLTAMMETRIC STUDY. A. Marburger, R. Morgenstem *, D. Schönfuß, N. Drandarevski and T. Reum, Inst. Pharmacol. and Toxicol., Medical Faculty (Charité), Humboldt University at Berlin, D-10908 Berlin, Germany

Fetal mesencephalic grafts as a potential alternative treatment in Parkinsons' disease have been examined very thoroughly in the last decade. The graft-induced recovery of motor dysfunctions in the 6-OHDA model of Parkinsonism is generally related to the survival of dopamine (DA) in the denervated striatum. However, there is growing evidence for further effects of the graft involving the contralateral side in the complex event of functional recovery. Recently we showed that fetal grafts in previously 6-OHDA lesioned rats induce a reduction of DA reuptake mechanisms in the contralateral striatum in vivo and in vivo.

In order to see whether these effects are independent of a previous lesion and whether they are occurring in the grafted striatum as well, we examined the extracellular DA elimination in non-tesioned but grafted rats with fast cyclic voltammetry. Rats were grafted with solid fetal midbrain intracerebroventricularly (i.e.v.) and with intrastriatal cell suspensions. Extracellular DA clearance was measured after electrical stimulation of the medial forebrain bundle before and after treatment with the high affinity DA uptake where calculated with the aid of a kinetic model.

In i.e.v. grafted animals, both in the ipsi- and contralateral striatum the rate of high affinity DA uptake were calculated with the aid of a kinetic model.

In i.e.v. grafted animals, both in the ipsi- and contralateral striatum the rate of high affinity DA uptake were calculated with the aid of a kinetic model.

EFFECTS OF CHRONIC ALCOHOL CONSUMPTION AND AGING ON PROENKEPHALIN mRNA. M.J. Druse-Manteuffel and N.F. Tajuddin. Mol. Cell. Biochemistry Dept., Loyola U. Chicago, Stritch School of Medicine, Maywood, IL 60153

Previous studies from this laboratory demonstrated age-related changes in the dopaminergic system in both nigrostriatal and mesocorticolimbic brain areas. As an extension of our prior work, we examined the effects of aging and chronic alcohol consumption on the expression of the gene encoding proenkephalin (PE). In situ hybridization histochemistry was used to detect PE mRNA in the striatum, nucleus accumbens and frontal cortex. PE mRNA was detected using an ³⁵S-labeled synthetic oligonucleotide probe, corresponding to the 48 base pairs, complementary to bases 388 to 435 of PE mRNA (Yoshikawa et al., 1984; Hammer et al., 1993). PE mRNA was quantitated in 5 and 24 month male Fischer 344 rats that consumed a control or ethanol-containing liquid diet for 6 weeks

The results of these studies demonstrated an age-related decline in PE mRNA levels in both the rostral striatum and in the nucleus accumbens. There was also an ethanol-associated decrease in PE mRNA at 5 months. No age- or ethanol-associated changes were detected in the frontal cortex.

RESPONSE OF BASAL FOREBRAIN NUCLEAR FACTOR KAPPA B TO HYPEROXIA IN VIVO. T. Toliver*, L. Tong, D. Rassin and J.R. Perez-Polo. Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX

We previously reported that DNA-binding levels of nuclear factor kappa B (NFxB) are altered in the aged rat basal forebrain and hippocampus. We propose that age-associated oxidative stresses contribute to altered NFkB activity with aging. In order to test the hypothesis that NFKB responds to oxidative stress in vivo, we exposed rats to 100% oxygen under isobaric conditions for various amount of time. Analysis of nuclear NFkB DNA-binding activity by electrophoretic mobility shift assay and protein levels by western blot analysis demonstrates that basal forebrain levels of NFkB were unaffected following 6 hours of hyperoxia, significantly decreased following 12 and 24 hours of hyperoxia, and restored to almost normal levels following 48 hours of hyperoxia. The data suggest that NFxB in basal forebrain responds to oxidative stress, perhaps to alter gene transcription in an attempt to promote survival under oxidative stress. CHANGES IN AP-1 DNA BINDING ACTIVITY IN THE RAT DURING HYPEROXIA-INDUCED OXIDATIVE STRESS. L. Tong*, Tracy Toliver and J.R. Perez-Polo. Dept. of HBC&G, UT Med. Branch, Galveston, TX 77555-0652

Oxidative stress appears to contribute to aging-associated neurodegenerative diseases such as Alzheimer's disease. The AP-1 transcription factor is made up of a family of regulatory proteins that are activated by oxidative stress. The purpose of the present study is to examine the AP-1 DNA binding activity and its component proteins in the rat brain under oxidative stress induced by hyperoxia. Young male Fischer-344 rats were exposed to 100% oxygen under isobaric conditions for various times. After hyperoxic treatments, the brains were dissected, and nuclear protein extracts were prepared. The AP-1 DNA binding activities in different brain regions were analyzed by electrophoretic mobility shift analysis (EMSA). The participating protein species were identified by supershift and Western blotting. There were elevated AP-1 DNA binding activities in hippocampus and basal forebrain induced by hyperoxic treatment, followed by a restoration to near control levels. These results suggest that AP-1 signaling is involved in brain responses to oxidative stress. Supported in Part by NINDS-NS18708. This is publication 60A from USPHS grant P01 AG10514 awarded by NIA.

EFFECTS OF OXIDATIVE STRESS ON SYNAPTIC MEMBRANE Ca2 + TRANSPORTERS: IMPLICATIONS FOR BRAIN AGING. M.L. Michaelis*.

TRANSPORTERS: IMPLICATIONS FOR BRAIN AGING. M.L. Michaelis*,

J. Huschenbett, and A., Zaidi. Dept. of Pharmacology/Toxicology & Ctr.
Neurobiol./Immunol. Res., Univ. of Kansas, Lawrence, KS 66045.
The plasma membrane Na*/Ca** exchanger and Ca** † -ATPase are
critical for [Ca**], regulation, and the kinetic properties of these systems
change in aged rat brain. Such age-related changes could be due to
oxidative modification of Ca** transporting proteins as a result of chronic
oxidative stresses and accumulation of oxidized proteins. These studies
were undertaken to determine the sensitivity of these neuronal Ca** transporters to in vitro exposure of synaptic membranes to oxidizing conditions.
We initially tested the effects of thou againstitutes. AAPH and ACVA agents We initially tested the effects of two azo-initiators, AAPH and ACVA, agents that generate peroxyl free radicals via thermal decomposition, thus permitting one to calculate the amount of free radicals produced under controlled conditions. AAPH, the more hydrophilic agent, produced 15 - 70% inhibition of exchanger activity across AAPH concentrations estimated to generate 6 to 60µM free radicals. When the lipophilic agent ACVA was tested, inhibition ranged from 30 - 95% at 6µM to 60µM concentrations. The Ca² *-ATPase was even more sensitive to exposure to these free radical generating systems, showing nearly complete loss of activity with ~20:M free radicals generated by AAPH and 5:M free radicals by ACVA. These results radicals generated by AAP and 3.4m the radicals by ACVA. These results suggest that generation of free radicals within the membrane disrupts the activity of both Ca^{2+} transporters more strongly. Studies in which a xanthine/xanthine oxidase system was used to generate superoxide revealed that the Ca^{2+} -ATPase is also very sensitive to the presence of this free radical. Ongoing studies are examining the effects of $\rm H_2O_2$ and peroxynitrite on the activity of these $\rm Ca^{2^+}$ -regulating systems. (Supported by Alz. Dis. Assoc., AG12993, and Higuchi Biosciences Ctr., U. of KS).

REGIONAL LEVELS OF 8-OHDG, A MARKER OF OXIDATIVE DAMAGE TO DNA, IN RAT BRAIN AND THE LACK OF EFFECT OF CHRONIC L-DOPA TREATMENT. D.M. Togasaki*, M.K. Shigenaga, V. Jackson-Lewis, S. Przedborski, Dept. of Neurology, Columbia University, New York, NY, and Dept. of Molecular and Cell Biology, University of California, Berkeley, CA.

Oxidants may injure nigrostriatal neurons in Parkinson's disease by attacking cell constituents, including nucleic acids. L-Dopa might exacerbate this injury by elevating oxidative stress. 8-Hydroxydeoxyguanosine (8-OHdG) is a product of oxidative damage to deoxyguanosine (dG) residues in DNA; it can be assayed with HPLC methods. We measured 8-OHdG (normalized with the levels of dG) in five brain regions of male Sprague-Dawley rats (n=3-4/group) injected twice daily for 40 days with L-dopa methyl ester/benserazide (50 and 12.5 mg/kg in 0.9% saline, i.p.) or vehicle. Rats were sacrificed 24 hours or seven days after the last injection, and total cellular DNA from each region was isolated, digested, and analyzed. Biogenic amines and their metabolites were also measured. There are differences in the amount of 8-OHdG in various brain regions. The substantia nigra contains the largest amount (14.4 \pm 1.8 μ moles 8-OHdG/mole dG, mean \pm SEM), followed by the striatum (12.1 \pm 1.4), the frontal cortex (10.5 \pm 0.8), the hippocampus (9.4 \pm 0.8), and the cerebellum (8.8±0.6). The nigral level is significantly greater than the levels in cortex, hippocampus, and cerebellum. L-Dopa treatment has no effect, nor does the longer washout time. The level of 8-OHdG shows a positive correlation with the amount of serotonin in these areas, suggesting an association between serotonin levels and oxidative damage. There is no correlation between the levels of 8-OHdG and dopamine or its metabolites. The lack of effect of L-dopa upon 8-OHdG levels may be due to: normal rats might be able to compensate for additional levodopa; the additional 8-OHdG formed may be too low to be measured; prolonged treatment might be necessary; damage might be selective for mitochondrial DNA. TAURINE-DOPAMINE (DA) INTERACTIONS IN THE STRIATUM. B. Eppler*, D.R. Wallace, M.A. Pelleymounter, R.M. Booze, S.C. Liu and R. Dawson, Jr. Dept. of Pharmacodynamics, Univ. Florida, Gainesville, FL 32610, Dept. Pharmacology, Univ. Kentucky, Lexington, KY 40536 and Dept. Neurobiology, Amgen, Inc, Thousand Oaks, CA 91320

Taurine is a sulphur containing amino acid that is involved in both neuromodulatory and antioxidant functions and may interact with the CNS DA system. The aim of the present series of studies was to examine age-related changes in striatal taurine content and investigate some potential interactions between taurine and the DA system

Aged (26 months) and adult (5 months) male Long-Evans rats were behaviorally tested using the Morris water maze task and then were sacrificed for the determination of brain taurine by HPLC. Additional experiments assessed the ability of taurine and related amino acids to inhibit $FeCl_3$ stimulated DA oxidation using an assay for quinone formation. DA receptor binding (D3 subtype) was determined in the presence and absence of 20 mM taurine using [3H]-7-OH-N,N-di-n-propyl-2-aminotetralin (DPAT) in striatal membrane preparations oxidatively damaged with the combination of 200 μ M DA and 100 μ M FeCl₃. Finally, the *in vivo* effects of depleting brain taurine in adult Sprague-Dawley rats with 1% β-alanine were assessed on striatal [3H]-DPAT binding.

Striatal taurine content was depleted (p < 0.05) in learning impaired aged rats (n = 8) compared to adult rats (n = 8). Aged rats that were unimpaired behaviorally (n = 7) did not differ significantly in striatal taurine content from the adult controls. Taurine content was not altered in the hippocampus or temporal cortex of aged rats. Taurine was found to significantly inhibit iron-stimulated DA oxidation and protect D3 receptors from oxidative damage. Treatment with β -alanine caused a 25% increase in striatal D3 receptors and D3 receptors have been reported to increase in aging.

Collectively, these findings suggest that taurine may protect vulnerable striatal neurons from age-related oxidative damage. (Funded by grants from Taisho Pharmaceutical Co., Ltd. and NIH AG10747, AG10836 and AG 00242.)

EXTRACELLULAR SPACE DIFFUSION PARAMETERS IN THE RAT BRAIN DURING AGEING. E. Syková*, T. Mazel and T. Roitbak. Dept. Neurophysiol., Inst. Exp. Med. ASCR, Prague 4, Czech Republic

The changes in extracellular space (ECS) diffusion parameters influence non-synaptic transmission and intercellular communication in the CNS. The morphological changes during ageing, including cellular loss, astrogliosis. demyelination and swollen astrocyte processes, may result in changes in ECS diffusion parameters, such as the ECS volume fraction α (α = ECS volume / total brain volume) and ECS tortuosity λ = (D/ADC)^{1,2}, where D is the free diffusion coefficient and ADC is the apparent diffusion coefficient in the brain. We studied the diffusion parameters in vivo by the real-time iontophoretic method using TMA+-selective microelectrodes. Measurements were done in the cortex, corpus callosum (white matter, WM) and hippocampus of ageing rats (aged 26-32 months). The α in senescent rats (n = as significantly lower than in young adults (n = 25) (all values are expressed as mean±S.E.; data from young adults are given in parentheses). in the cortex α =0.18±0.003 (0.21±0.003), in the WM α =0.15±0.004 (0.19±0.004), in the pyramidal cell layer of the CA1 region of hippocampus (CA1pyr) α =0.09±0.005 (0.12±0.004) and in CA1 stratum radiatum (CA1rad) α =0.13±0.006 (0.16±0.008). Tortuosity λ was significantly lower in the cortex, where $\lambda = 1.51 \pm 0.02$ (1.60 ± 0.01), but it was significantly higher in CA3rad, where $\lambda = 1.49 \pm 0.02$ (1.41 ± 0.02). We conclude that significant changes in ECS diffusion parameters which accompany morphological changes during ageing can contribute to impairment of signal transmission, greater susceptibility to anoxia, changes in behavior and memory impairment. OXIDATIVE STRESS PROMOTES MITOCHONDRIAL IRON SEQUESTRATION IN CULTURED ASTROGLIA. L. Bernier*, G. Bernatchez and H.M. Schipper. Lady Davis Institute, Jewish General Hospital, and Department of Neurology and Neurosurgery, McGill University, Montreal, Canada H3T 1E2

Cysteamine (CSH) induces the appearance of iron-rich, peroxidasepositive cytoplasmic granules in cultured rat astroglia, which are identical to those which progressively accumulate in the aging subcortical brain. Both in situ and in culture, these glial inclusions derive from degenerate mitochondria in the context of a generalized cellular stress (heat shock) response. In the present study, we demonstrate that CSH up-regulates transcription of heme oxygenase-1 (HO-1) in cultured astroglia followed by the sequestration of nontransferrin bound, non-heme 55Fe by the mitochondrial compartment. CSH-induced HO-1 expression can be blocked by iron chelators (deferroxamine, phenanthroline) and protein synthesis inhibitors, and mitochondrial iron trapping is recapitulated by H2O2 or menadione exposure. Our findings indicate that oxidative stress is the mechanism responsible for CSH-induced sequestration of non-heme, non-transferrin bound iron in astroglial mitochondria. CSH-stressed astroglia may serve as a useful model to investigate mechanisms of iron sequestration in the normal senescent brain, in Parkinson's disease, and in other aging-related neurodegenerative disorders

INDUCTION OF NITRIC OXIDE SYNTHASE IN MOTONEURONS OF THE AGED RAT SPINAL CORD. K. Kanda*, S. Asaki and E. Nomoto. Dept. of Central Nervous System, Tokyo Metropol. Inst. of Gerontol., Tokyo 173, Japan.

Loss of motoneurons with advancing age has been shown in both human and experimental animals. However, underlying mechanisms for motoneuronal death in the aged remains unclear. It has been proposed that the survival of motoneurons is maintained by neurotrophic factors. Recently, it has been suggested that nitric oxide is involved in motoneuronal cell death induced by deprivation of trophic factor. We examined in the present experiments if nitric oxide synthase (NOS) was induced in motoneurons in aged rats.

Experiments were performed on male Fischer rats which had been raised

Experiments were performed on male Fischer rats which had been raised under the specific pathogen free condition. The animals (three age groups:15-17, 24 and 29-30 months old) were anesthetized with Nembutal (50 mg/kg, ip), and perfused transcardially with a cooled fixative (1.25% glutalaldehyde and 1% paraformaldehyde in phosphate buffer, pH 7.6). The lumbar spinal cord was removed and immersed in 30% sucrose in phosphate buffer overnight. Serial sections were cut and stained with histochemistry for reduced nicotinamide dinucleotide phosphate diaphorase (NADPH-d). NADPH-d positive cells in the ventral horn of L4 to L6 were counted. In some rats, Fluorogold was injected into the sciatic nerve 8 days before perfusion to identify motoneurons.

the sciatic nerve 8 days before perfusion to identify motoneurons.

Motoneurons in the lumbar spinal cord of young rats were not stained for NADPH-d under the present experimental conditions. On the other hand, NADPH-d positive, large neurons, which were presumably alpha motoneurons, were found in the ventral horn of aged rats. The number of such NADPH-d positive neurons was increased with advancing age from 24 months to 29-30 months. Appearance of NADPH-d positive motoneurons seems to coincide with motoneuronal loss, and it appeared that the both phenomena advanced similarly. The findings in the present study suggest that expression of NOS plays an important role in cell death of motoneurons in the aged rat. important role in cell death of motoneurons in the aged rat. NITRIC OXIDE SYNTHASE PROTEIN IMMUNOREACTIVITY (NOS-IR) IS ALTERED IN CRANIAL MOTOR NUCLEI IN RESPONSE TO INJURY AND AGING IN F344 RATS. R.L. Benton*, P. Grammas¹ and J.M. Jacob. Depts. of Anat. Sci. and ¹Pathology, Univ. of Oklahoma HSC, Oklahoma City, OK 73190.

Nitric oxide (NO), a freely diffusible molecule, has been implicated in a variety of neuromodulatory and neurotoxic functions in the nervous system. Both aging and peripheral nerve injury result in a multitude of physiological, morphological and biochemical changes in the perikaryon. The objective of this study is to investigate the effect of age and nerve injury on NOS expression in motor neurons and blood vessels of the facial injury on NOS expression in motor neurons and blood vesses of the factal nucleus (CN VII). Injured motor neurons were labeled with the retrograde tracer FluoroGold; animals were killed 1, 3 or 7 days following transection of the facial nerve. Using polyclonal antibodies directed against the three isoforms of NOS (inducible NOS, endothelial NOS, brain NOS), the distribution of protein immunoreactivity (IR) was determined. Our results indicate that NOS-IR is differentially expressed in motor neurons and blood vessels. iNOS-IR is re-expressed within brain microvessels located in CN VII nucleus of old (24 mo) unoperated rats whereas no iNOS-IR is present in mature (6 mo) rats. There is no basal iNOS-IR or bNOS-IR in motor neurons of either age. eNOS-IR is restricted to microvessels and is unchanged with age. Axotomy results in the induction of iNOS-IR and bNOS-IR in cranial motor neurons. Aging and injury differentially affect the expression of specific isoforms of NOS and may be consistent with a neuroprotective role for NO.

AGE-RELATED CHANGES IN THE RHESUS MONKEY: ASSOCIATION OF INFLAMMATORY PROTEINS AND AMYLOID MITH COGNITION, J.A. Sloane, M.F. Pietropaolo, D.L. Rosene, M.B. Moss, B.L. Martin-Razzaboni*, T. Kemper and C.R. Abraham. Depts. Pathology, Biochemistry, Neurology, Medicine, and Anatomy and Neurobiology, Boston Univ. Sch. of Med., Boston, MA 02118.

In order to assess whether amyloid plaque accumulation can account for age-related cognitive impairment that begins at about 20 years of age, we measured plaque density in the brains of rhesus monkeys 5 to 31 years old. Amyloid plaques accumulate with age, starting at 25 and escalating at 30 years of age. Although both cognitive dysfunction and plaque number increase with age, amyloid plaques do not appear to be related to the cognitive dysfunction observed. Some of the oldest monkeys with severe cognitive impairment had few amyloid plaques while others with only mild cognitive impairment had abundant plaques. As an alternative potential mechanism for age-related cognitive decline, we examined cerebral white matter, in which we have previously observed dramatic morphological alterations, for the presence of inflammatory changes. Using western blotting and immunohistochemical techniques, we found increased activation of microglia and astrocytes with age. It appears that upregulation of inducible nitric oxide synthase (iNOS), an inflammation-related enzyme produced principally by activated astrocytes and microglia, occurs earlier in age than plaque accumulation. Furthermore, our preliminary results suggest iNOS expression may correlate with age-related cognitive impairment. (Supported by NIH grant PO1-AG00001)

ALTERATIONS OF MN-SUPEROXIDE DISMUTASE (MN-SOD) AND β-AMYLOID PRECURSOR PROTEIN (βAPP) GENE EXPRESSION WITHIN SPECIFIC CELL TYPES IN THE AGED LONG-EVANS RAT. E. Skiba, K. Sugaya, D. Bryan, D. Personett, S.J. Xu*, M. M. Nicolle, M. Gallagher and M. McKinney Mayo Clinic Jacksonville, Jacksonville, FL 32224 and University of North Carolina, Chapel Hill, NC 27599

Our laboratories are investigating candidate gene expression in an aging rat model in which spatial learning is quantitated in a water maze. We have previously reported that hippocampal Mn-SOD, β APP and glial fibrilliary acidic protein (GFAP) mRNA levels are correlated with memory impairment in these animals, suggesting the existence of oxidative stress and glial activation. In the present study, we address which types of cells are involved in these alterations we found in this animal model. Mn-SOD and \$APP gene expression in astrocytes, microglia and cholinergic cells were investigated using in situ hybridization (ISHH) combined with immunostaining for GFAP, CD2 (OX-42) and choline acetyltransferase (ChAT), for each of these cell types, respectively. BAPP mRNA in Mn-SOD immunopositive cells was also examined by this technique. Neurons appeared to be the major sites of alteration of Mn-SOD mRNA in the aged hippocampus. Hippocampal neurons, including scattered cells in the hilus, exhibited strong Mn-SOD immunoreactivity and expressed high levels of βAPP mRNA. In GFAP-immunostained material, hilar cells expressing high β APP mRNA levels appeared to be surrounded by astrocyte processes. Cholinergic cells of the basal forebrain had higher Mn-SOD mRNA expression and (probably) stronger Mn-SOD immunoreactivity than surrounding non-cholinergic cells. OX-42 positive microglia were prominent in the both basal forebrain and hippocampus. These results indicate that in the aging brain glial activation may be a source of neuronal oxidative stress and that neurons may respond to such stress by elevating their levels of Mn-SOD, and/or BAPP.

593.12

GLUCOCORTICOID RECEPTOR (GR) MRNA EXPRESSION IN ASTROCYTES AND MICROGLIA IN THE AGED RAT BRAIN. D. Bryan, K. Sugaya, D. Personett, E. Skiba, S.J. Xu, M. Gallager and M. McKinney* Mayo Clinic Jacksonville, Jacksonville, FL 32224 and University of North Carolina, Chapel Hill, NC 27599

Our laboratories are investigating candidate gene expression in an aging rat model in which spatial learning is quantitated using a water maze. We reported global glial activation and BAPP mRNA elevation in learning-impaired Long Evans rats. Adrenal steroids are known to regulate protein synthesis, and age-related effects on glia have been reported. Glucocorticoids are also known to regulate BAPP mRNA expression in hippocampal neurons. Thus, glucocorticoids may be factors in the alterations in gene expression we observed in this aging animal model. In the current study, we examined GR type I and II mRNA expression in astrocytes and microglia, by using in situ hybridization histochemistry (ISHH) combined with immunohistochemistry for GFAP and CD2 (OX42) in the same brain sections, respectively. We observed expression for both types of GR mRNA in hippocampal neurons, astrocytes and microglia. These data indicate that ISHH combined with immunohistochemistry for glia can be used to address the involvement of adrenal steroids in the alteration of neuronal or glial gene expression in the aging brain.

ASTROCYTES IN THE AGED RAT SPINAL CORD FAIL TO INCREASE GFAP mRNA FOLLOWING SCIATIC NERVE AXOTOMY. S.A. Gilmore*, T.J. Sims and C.J.M. Kane. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Marked changes in the astrocyte population in the brain occur with aging and are paralleled by increase in the levels of astrocyte glial fibrillary acidic protein (GFAP). Aging also alters the astrocyte response to injury, but the nature of these changes is not clear due to the diversity of models employed. This study was designed to: (1) establish whether astrocytic changes similar to those in the brain occur with aging in the spinal cord, and (2) define the effect of aging on the astrocytic responses following a non-invasive injury to the spinal cord. The levels of GFAP mRNA were quantified in the lumbar spinal cord of young (2 month old) and old (8, 11 and 17 month old) Charles River CD rats by Northern hybridization and densitometry. The level of GFAP mRNA was increased 0.4-flod (p<0.01) in rats 28 months old compared to rats 2 months old; there was no difference between rats aged 8, 11 or 17 months. Non-invasive injury was performed by axotomy of the sciatic nerve with analysis at 4 days post-injury. The lumbar cord of young rats responded with a 0.5-fold increase in GFAP mRNA levels compared to uninjured controls (p<0.001). In contrast, the levels of GFAP mRNA in the aged cord following axotomy remained unchanged compared to age-matched, uninjured controls. Immunohistochemical analysis of GFAP in the lumbar cord paralleled the changes in GFAP mRNA. Thus, astrocytes in the spinal cord exhibited increased expression of GFAP mRNA with aging; and in contrast to young rats, the levels of GFAP mRNA in aged rats did not increase in response to injury. (Supported in part by NIH AG12411).

NEUROGLIA AND MYELIN IV

Immunohistochemical Localization of Transferrin Binding Protein in the Avian Retina Sa Sun Cho* Amold G. Hyndman, John J. Lucas. Dept. of Anatomy, Seoul National Univ. College of Med., NJ 08855, USA: ²Dept. of Biological Science Rutgers Univ., Piscataway, NJ 08855, USA: ²Dept. of Biochemistry and Molecular Biology, State Univ. NY Health Science Center, Syracuse, NY 13210, USA

Transferrin binding protein(TfBP) is a glycoprotein purified from the chick oviduct that exhibits transferrin binding activity. Recent work has shown TfBP is a previously described heat shock protein 108(HSP 108). Antiserum to TfBP has been found to selectively label oligodendrocytes in the avian brain(Brain Res 674:15, 1995). The aim of this study was to examine TfBP immunoreactivity in the avian retina using immunohistochemical methods. A strong immunostaining was evident in the small cells in the avian retina. The immunoreactive cells were interposed between ganglion cells in the 8th layer and occurred along the nerve fibers in the 9th layer of In the whole mount preparation, TfBP-labeled cells displayed the unique morphological features of brain oligodendrocytes: the fine processes that extended radially from the perikarya could be traced to terminals located around or along optic nerve fibers. These immunoreactive cells were distributed throughout the retina with diminishing toward the periphery of the retina. A diffuse staining at lower level was also visible in the inner segment of the photoreceptor layer. Given the fact that the avian retina has myelin in the 8th and 9th layers, the distribution and morphology of TfBP-immunoreactive cells observed in this study suggests strongly that TfBP-labeled cells are retinal oligodendrocytes responsible for production and maintenance of myelin in the avian retina.

IRON AND MANGANESE UPTAKE IN GLIAL CELL CULTURES FROM HYPOTRANSFERRINEMIC MICE. A. Takeda*. A. Devenyi. and J. Connor Depts. of Neruoscienc & Anatomy, and Pediatrics Penn State University School of Medicine, Hershey PA 17033

Hypotransferrinemic (Hp) mice are normally occuring mutants with a splicing defect in the transferrin (Tf) gene. The resulting phenotype expresses <1% of the normal plasma circulating levels of Tf. Consequently, this animal offers the opportunity to examine the role of Tf in iron distribution to cells. In this study, we use mixed glial cultures from Hp mice and unaffected wild type controls to determine the contribution of Tf known to be produced and secreted by glial cells in culture to iron uptake by glial cells. The mice expressing the Hp mutation are pale compared to unaffected filtermates and can be identified at birth. For the tissue culture analysis, the brains of Hp and unaffected animals were removed within 2-3 days of birth and mixed glial cultures were prepared according to standard procedures. The cultures were established in 10% fetal calf serum for 7 days. Subsequently, the cultures were changed to a defined, serym-free. Tf containing or Tf-free medium for 1 day followed by addition of 9 FeCl3 to the medium for 3.6 or 24 hrs. In the absence of Tf. iron uptake was elevated in both normal and Hp mice at 3 and 6 hrs but not at 24 hrs. The amount of iron uptake in the Hp mouse mixed glial cultures was 2-10X higher than in the normal mice over a 3 hr incubation period. The absence of Tf in the medium of the Hp mouse cultures did not affect iron uptake by the cells in the culture. However, the absence of Tf in the medium. More iron remained in cells from both Hp and normal mice if Tf was removed from the medium. The efflux of iron in the absence of Tf in the medium was greater in the wild type mouse cultures than in the Hp mouse cultures. These results demonstrate that Tf is not required for iron uptake into mixed glial cell cultures, indeed its absence resulted in an increase in i

OLIGODENDROCYTES DERIVED FROM MOUSE BRAIN TRANSIENTLY EXPRESS A FERRITIN RECEPTOR IN VITRO. S. Hulet. S. Powers, and J.Connor. George M. Leader Family Laboratory for Alzheimer's Disease Research. Pennsylvania State University. The Milton S. Hesrshey Medical Center. Hershey, PA.

Traditionally ferritin has been thought of as the intracellular iron storage protein because of it's abitity to store ferric iron in it's hollow core. Iron in ferritin is considered unavailable for toxic radical producing reactions. Recently, we have identified a ferritin receptor in the brains of adult C57 B1/6 mice. This novel protein binds ferritin in a saturable and competitive manner characteristic of receptor-ligand interactions. Autoradiographic analysis reveals the ferritin receptor is predominantly located in white matter tracts in the adult mouse. This distribution is in direct contrast to the distribution of transferrin receptor which is found heavily throughout cortex and shows very low distribution throught white matter tracts. The goal of this study is to identify the specific cell types in vitro that hind ferritin.

that bind ferritin.

We used 2-4 day old C57 B1/6 mice to generate mixed glial cell cultures. The mixed glial cell cultures were incubated for 1 hour with fluorescein labeled ferritin. Cultures were labeled concomitantly with antibodies to different cell specific markers. Fluorescent microscopy revealed that two populations of cells were taking up the ferritin. 1) Small, round, non-process bearing cells sitting on the top of the astrocyte bed layer which were O4 and 01 positive. However, process bearing cells which were LDL+ which is a microglial marker. The GFAP + bed layer of astrocytes were ferritin uptake negative. This evidence strongly suggests that oligodendrocytes transiently express a ferritin receptor. The significance of this research lies in the ability of each ferritin molecule to carry up to 4,500 iron atoms, while the traditional iron transport protein transferrin can deliver only 2 atoms of iron to the cell. Thus ferritin may be the iron transport protein of choice for oligodendrocytes. Supported by NS22671 (NIH)

LOW EXTRACELLULAR Na* CONCENTRATION PROMOTES STIMULATION OF GLUCOSE UTILIZATION BY K* IN CULTURED ASTROGLIA. <u>J.Gotoh.</u> <u>M.J.Law and L.Sokoloff*</u>. Laboratory of Cerebral Metabolism, National Institute of Mental Health, Bethesda, MD 20892.

Previous studies (Takahashi et al., PNAS, 92:4616-4620;1995) demonstrated stimulation of glucose metabolism in cultured astroglia by agents, e.g., veratridine or monensin, that promote Na* entry into the cells. Membrane depolarization by elevated extracellular K* concentrations ([K*1],) in the 2.7-56 mM range, however, had no consistent effects on glucose utilization under standard incubation conditions with bicarbonate buffer and extracellular Na* concentration ([Na*1],) in the 105-155 mM range. To investigate the possibility of a relationship between [K*1], and [Na*1], on astroglial energy metabolism, we have compared the effects of increased [K*1], on glucose utilization in cultured astroglia incubated in normal and in nominally Na*-free media. Astroglia were prepared from newborn rat cortex and studied after 20-24 days in culture. Cells were incubated in Dulbecco's bicarbonate-buffered saline (DBS) containing 2 mM glucose, tracer amounts of 2-deoxy-D-[1*C]glucose ([1*C]DG), and 2.7, 5.4, 28, or 56 mM [K*1], for 15 min followed by a 5 min incubation in [1*C]DG-free buffer for efflux of unmetabolized [1*C]DG. Na*-free conditions were obtained by substitution of choline for Na*. In experiments carried out with 10 different cultures no significant changes in [1*C]DG phosphorylation were observed with increasing [K*1], during incubations in medium containing normal [Na*1], but unmasked stimulations of [1*C]DG phosphorylation by elevated [K*1], above 2.7 mM that appeared to be concentration-dependent (4.2%, ps.0) 1.3 t.5 mM. 5.8 m.Sc.0 (1.3 t.2 m.M. 5.75 m.Sc.0) 1.3 t.5 m.M.

p<0.05, at 5.4 mM; 38%, p<0.01, at 28 mM; 57%, p<0.01, at 56 mM). These results suggest that K' effects on astroglial energy metabolism are normally obscured by the energy metabolism associated with Na'-dependent processes but become apparent when these processes are limited by low [Na'].

INTRACELLULAR ACIDIFICATION IN MOUSE CEREBRAL ASTROCYTES CAUSED BY RAPID INFLUX OF AMMONIUM IONS T. N. Nagaraja and N. Brookes. Dept. of Pharmacol. & Exptl. Therap., Univ. of Maryland Sch. of Med., Baltimore, MD 21201.

Exposure of most cell types to 20 mM NH₄Cl produces a rapid intracellular alkalinization as free NH₃ diffuses inward and is protonated in the cytoplasm. Typically, the alkalinization declines slowly, over a time course of several minutes, in the continued presence of NH₄Cl (Boron & De Weer, *J. gen. Physiol.*, 67:91, 1976). We report here an unconventional response to NH₄Cl in primary cultures of mouse cerebral astrocytes, observed using the pH indicator BCECF to measure intracellular pH (pH₁) fluorometrically. After a brief alkalinization, which peaked in 2-4 sec, the astrocytes exhibited a rapid and intense acidification in the continued presence of 20 mM NH₄Cl. Intracellular pH declined with a half-time of 5-7 sec to reach a sustained level 0.44±0.004 pH units (±SE, n=3) below the initial resting pH₁ in the nominal absence of HCO₃. This sustained acid shift reached 0.36±0.02 pH units (n=6) in response to 1 mM NH₄Cl, and saturated at 5 mM NH₄Cl. However, the initial rate of acidification did not show saturation. The initial rate of acidification produced by 1 mM NH₄Cl, and saturated at 5 mM NH₄Cl. However, the initial rate of acidification did not show saturation. The initial rate of acidification and by 24% in the presence of 55 mM ouabain. The combination of Ba²⁺ plus bumetanide prevented net acidification. Our results suggest that both active and passive influx of NH₄+ acidifies the astrocytes by sustaining an outward diffusion gradient of NH₃ (compare NH₄+ transport in the thick ascending limb of Henle's loop; Good, *Annu. Rev. Physiol.*, 56:623, 1994). The primary route of entry for NH₄+ was via inwardly-rectifying K+ channels. This influx is driven by the inside-negative membrane potential. A second uptake route was via the Na+K+.2Cl⁻ cotransporter. (Supported by NIEHS grant ES03928).

TRANSFER AND EXPRESSION OF GALACTOSYLCERAMIDASE MEDIATED BY ADENO-ASSOCIATED VIRUS. <u>H.Chen¹</u>, <u>D. M. McCarty²</u>, <u>S. Gowen²</u>, <u>D. Wenger⁵</u>, <u>K. Suzuki¹.⁴</u>, <u>K. Suzuki¹.⁴</u>, <u>UNC</u> Neuroscience Center¹, Gene Therapy Center², Dept. of Pathology & Laboratory Medicine³, Neurology & Psychiatry⁴, University of North Carolina, Chapel Hill, NC 27599, and Division of Medical Genetics, Thomas Jefferson University, Philadelphia, PA 19107⁵.

We have explored the possibility and strategies of gene therapy for neurodegenerative diseases using the twitcher mouse as an animal model. Twitcher is an authentic murine model of globoid cell leukodystrophy (GLD, Krabbe disease) in humans caused by a deficiency of the lysosomal enzyme, galactosylceramidase. Lack of this enzyme activity results in degeneration of oligodendrocytes due to an accumulation of the toxic metabolite, psychosine, followed by demyelination, with infiltration of macrophages (globoid cells). Thus, we targeted transfer of the galactosylceramidase gene into oligodendrocytes. A recombinant adeno-associated virus (rAAV) vector containing 2.1 kb of human galactosylceramidase cDNA (rAAV galc) was constructed under the control of the murine myelin basic protein (MBP) promoter/enhancer. Infection of primary normal mouse glia cells and a transformed oligodendocyte cell line with rAAV galc indicated that the trans-galactosylceramidase gene was expressed. In vivo, doses of approximately 2 x 104 infectious units of rAAV galc in 2 µl of saline were injected into the right cerebral hemisphere of normal mice. At several time points after the injection, the mice were killed, total RNA extracted and mRNA purified. By RT-PCR analysis, expression of the specific transgalactosylceramidase gene was found at least up to 2 months. Further investigation to evaluate the duration and distribution of galactosylceramidase expression is now underway. (Supported by research grants, NS24453, NS24289, T32-HD07201 and a Mental Retardation Research Center grant, HD03110 from USPHS).

POTASSIUM ACCUMULATION IN REACTIVE GLIAL CELLS IN SITU. W. Walz*, I.A. Paterson and W.A. Wuttke. Dept. Physiology, Univ. Saskatchewan, Saskatoon, SK S7N 5E5, Canada.

Adult rats, previously treated with kainic acid, exhibited loss of neurones and gliosis in the CA1 layer of the hippocampus within 3d. We impaled cells of hippocampal slices (400 μ m) with two channel microelectrodes and these cells had a membrane potential of -74 mV $\,$ (3.5 mM [K⁺]_°). Lucifer yellow injections combined with immunostaining showed that most of the cells were GFAP positive and coupled to up to 29 other cells. Of these coupled cells 75% were GFAP positive. Quite unexpectedly we found GFAP negative cells coupled to these GFAP positive cells. In another set of experiments one electrode channel contained a K+-sensitive resin. $[K^+]_i$ was 78 mM (E_K = -79 mV). Increase of external $[K^+]$ to 10 mM led to an increase of the internal [K+] by 24 mM. Bumetanide had no effect on the accumulation, whereas barium doubled the time course to reach a plateau value. Ouabain exposure decreased the internal [K+], but did not affect the K+ uptake. We conclude that these glial cells from gliotic tissue retain their K+ clearance properties and that K+ accumulation is based on Na+, K+-ATPase and Donnan-mediated KCl influx. In addition these cells are well coupled, however their role as spatial buffers is questionable since our data suggest the existence of a significant Cl conductance. Supported by the MRC of Canada.

H*-ATPASES AND GLIAL PH-REGULATION. Ch. Volk, T. Albert, O. Kempski*, Inst. Neurosurg. Pathophysiol., Univ. Mainz, 55101 Mainz/Germany

Glial cells play a major role in cerebral ion homeostasis and in the control of cerebral tissue pH. Several pH-regulating mechanisms, such as Na⁷H⁻ and CI/HCO₃-antiport or Na⁷/HCO₃-cotransport are present in astrocytes. Here we studied the contribution of proton-translocating ATPases (H⁻ATPases), so far best described in various epithelial cell types. Intracellular pH (pH) of C6 glioma cells and rat astrocytes was measured in vitro using the pH-sensitive dye BCECF under strict control of extracellular parameters. To clarify the role of H⁺-ATPases, inhibitors of several subtypes of H⁻-ATPases were applied in HEPES-buffered media: 1 mM N-ethylmaleimide (NEM, blocks several types of H⁺-ATPases), NBD-CI (50 µM, more specific for the vacuolar subtype), ortho-vanadate (100 µM, inhibitor of E,E₂-type ATPases), and oligomycin (10 µM, specific for the F₆F, mitochondrial H⁻-ATPase). After application of NEM a pH-decrease was observed in C6 glioma and astrocytes. The pH, in C6 cells fell within 15 min from 7.04 ± 0.03 to 6.70 ± 0.03 (p<0.001 compared to controls without NEM). After 15 min a slow partial pH, recovery was seen and after 60 min pH, was 6.87 ± 0.04. Exposure to NEM in Na⁺-free media to prevent Na⁺/H⁺-exchange caused a more pronounced pH, reduction: after 20 min pH, had decreased from 7.07 ± 0.03 to 6.44 ± 0.04, while Na⁺-free media alone had only a minor effect. Application of NBD-CI caused a pH-decrease of 0.40 ± 0.07, comparable to that caused by NEM. In rat astrocytes pH, decreased from 7.04 ± 0.03 to 6.61 ± 0.08 with NBD-CI. Suggesting activation of Na⁺/H⁺-exchange and swelling below a threshold of approx. pH=6.7. The data demonstrate that H⁺-ATPases of the vacuolar type contribute significantly to pH-control in glial cells at physiological extracellular pH. (Supported by DFG Ke 338/3-2)

EVIDENCE FOR OUTWARDLY RECTIFYING AND CFTR-LIKE CHLORIDE CHANNEL EXPRESSION IN CULTURED MAMMALIAN ASTROCYTES. C.D. Lascola* and R.P. Kraig. The Committee on Neurobiology and Department of Neurology, University of Chicago, (Licago, IL. 60637.

Astroglial anion channels are likely to play important roles in K+ homeostasis, pH regulation, and volume control. Resting astrocytes in culture normally have a negligeable chloride conductance. Following changes in cell morphology and cytoskeletal actin, however, astroglial whole-cell Cl conductance increases (Lascola and Kraig, J Neurosci, 1996). We have recently identified two candidate Cl' channels that may contribute to morphology-dependent whole-cell Cl currents. In excised, inside-out patches, we observed an outwardly rectifying Cl channel activated by prolonged depolarization (n=17), high ionic strength (600 mM NaCl; n=5), or exposure to 0.025% trypsin (n=3). The slope conductance in symmetrical solutions of 150 mM NaCl (10 TES; 1 MgCl₂) was 71pS at positive potentials (60 to 80 mV) and 36 pS at negative potentials (-60 to -80mV). Application of 200 µM DIDS produced flicker block; 1 mM Zn²⁺ produced complete block. In excised patches with symmetrical 150 NMDG-Cl solutions and 180 nM PKA (catalytic subunit), we also observed small, ohmic single Cl channels with a conductance of ~10 pS (n=5), suggesting the presence of CFTR-like Cl channels. In whole-cell experiments, inclusion of CTP-AMP (n=5) or the PKA subunit (n=3), both with 5 mM Mg-ATP, also induced a Cl current ~200 pA at 100 mV. This conductance was blocked by 1 mM DPC, but not 200 µM DIDS. Incubation overnight in serum-free Ringer, followed by application of 5 μM cytochalasin D, appeared to sequentially activate both CFTR-like and outwardly rectifying channels in cell-attached patches. Together, these results suggest astrocytes, which maintain aspects of epithelial organization in brain, also express Cl' channels previously characterized in airway and gastrointestinal epithelia. These channels appear to be modulated by changes in the actin cytoskeleton, and may therefore contribute to Cl' conductances accompanying changes in astroglial morphology. (Supported by NS-19108)

ION AND AMINO ACID CONTENTS OF ASTROCYTES GROWN IN HYPOOSMOTIC MEDIUM. J.E. Olson* Depts of Emergency Medicine and Physiology & Biophysics, Wright State Univ Sch Med, Dayton, Ohio 45401.

Osmolyte contents of cultured astrocytes were measured during 24 hr in hypoosmotic medium to examine mechanisms of brain adaptation to prolonged hypoosmotic hyponatremia. Medium osmolality was reduced from 310 mOsm (isoosmotic) to 220 mOsm by altering the NaCl concentration of serumsupplemented growth medium (Olson et al., Neurochem Res, 6:1337-1343, 1981). After 1, 12, or 24 hr, cells were incubated for 5 min in osmotically matched saline containing [3H]-3-O-methylglucose plus [14C]-sucrose as markers of intracellular and extracellular spaces, respectively. Radioactivity, potassium, amino acid, and protein contents were determined by liquid scintillation counting, atomic absorption spectroscopy, HPLC, and the Folin reaction, respectively. Cell volume in isoosmotic medium was 5.3±0.2 µl/mg protein (mean±SEM, N=15). After 1 hr in hypoosmotic medium the volume was elevated by 30% (p<0.05) but returned to normal at 12 and 24 hr. Taurine content fell by 88% in the first hour from an initial value of 137±9 nmol/mg protein and remained at 11-26 nmol/mg protein for the remainder of the exposure period (p<0.05). Aspartate decreased by 54% from its initial value of 37±5 nmol/mg protein after 1 hr in hypoosmotic medium and was unchanged thereafter (p<0.05). Cell contents of potassium, glutamate, glutamine, asparagine, tyrosine, and alanine were not altered at any time. The data support the importance of taurine as an osmolyte for astrocyte volume regulation and suggest potassium lost from brains of hypoosmotic hyponatremic animals does not come from astroglial cells. Electrophysiological characterization of astrocytes and astrocytoma cells in slices from human biopsies and experimental intractanial brain tumors.

A. Bordey, N. Ullrich and H. Sontheimer*, Neurobiology Research Center and Dept. of Physiology & Biophysics, Univ. of Alabama at Birmingham.

We studied astrocytoma cells in acute slices from patient biopsies and in slices from tumors experimentally induced in SCID mice by injection of D54MG cells and compared their properties to normal astrocytes in rat hippocampal slices. Recordings were obtained by the whole-cell patch-clamp technique with Lucifer Yellow in the pipette to mark cells for subsequent identification with antibodies to GFAP and for visualization of cell-cell coupling by means of dye spread. Astrocytoma cells were extensively dye coupled. On average, dye spread to more than 20 neighboring cells. Normal astrocytes rarely coupled to more than 3 neighboring cells. Resting membrane potential of astrocytoma cells was -47mV and -20mV in slices from human biopsies and in SCID mice as compared to -65mV in astrocytes from adult rats (P30-P34). Like cultured astrocytoma cells, astrocytoma cells in tumor slices expressed large outwardly rectifying chloride currents in response to depolarizing voltage steps. Currents activated at potentials >45mV, did not inactivate during voltage steps and showed outward transients upon termination of voltage steps. Tail current analysis showed current reversal close to the predicted equilibrium potential for Cl ions (+3mV). Cl currents were not observed in normal astrocytes which, however, consistently expressed voltage-activated Na+ and K currents. Indeed, TTX-sensitive Na+ channels were observed in most astrocytes (90%) and, unlike previously suggested, were still present in adulthood. While in cultured astrocytoma cells and in experimental tumors CI currents were the predominant current type expressed, 92% of astrocytoma cells in slices from acute biopsies additionally expressed voltage-activated TTX-sensitive Na^+ currents (mean peak amplitude of -210pA) like those observed in normal adult astrocytes (-490pA). As such, astrocytomas from patient biopsies express mixed features typical of normal astrocytes and those of astrocytoma cell lines. (R01-NS-31234)

OSMOLALITY DEPENDENCE OF ANION AND POTASSIUM CONDUCTANCES IN CULTURED ASTROCYTES G. Li* and J.E. Olson Departments of Emergency Medicine and Physiology & Biophysics, Wright State University School of Medicine, Dayton, Ohio 45401.

Astrocytes are thought to modulate neuronal excitability in the CNS by controlling local ion and amino acid concentrations. Volume-sensitive anion channels mediating amino acid efflux have been described in C6 glioma and MDCK cells. We studied the electrophysiology of cultured astrocytes to identify osmolalitydependent channels which might contribute to volume regulation. In the whole cell patch configuration with 140 mM KCl in the electrode, slope conductance was determined with voltage steps between -90 mV and -50 mV from a holding potential of -70 mV. Astrocyte conductance increased by 775±332% (mean±SEM) and cell capacitance was unaltered when the cells were transferred from isoosmotic (290 mOsm) to hypoosmotic (200 mOsm) medium (N=6). Niflumic acid (250 μ M) completely reversed the conductance increase while 5 mM BaCl₂ had no effect. No conductance change occurred in 200 mOsm me dium when the patch solution contained 140 mM K-gluconate rather than KCl. However, a hypoosmotically induced, niflumic acid-sensitive conductance increase was measured when 200 mM taurine (pH=8.2) replaced chloride salts in the patch electrode and bathing solutions. In 140 mOsm medium, astrocyte membrane conductance increased 1326±408% relative to that in isoosmotic medium (N=9). Niflumic acid (250 μ M) and BaCl₂ (5 mM) inhibited 60.1±11.4% (N=9) and 82.4±15.0% (N=5) of this increase, respectively. We conclude activation of anion channels in 200 mOsm medium can lead to chloride and taurine loss from astrocytes. Potassium channels are activated with greater cellular swelling. Characterization of volume regulated chloride currents in human astrocytoma cells.

N. Ullrich and H. Sontheimer. Neurobiology Research Center and Dept. of Physiology and Biophysics, University of Alabama at Birmingham, Birmingham AL, 35294 and Interdepartmental Neuroscience Program, Yale Univ. School of Medicine, New Haven CT 06510.

Unlike neurons, glial cells can divide postnatally and, under neoplastic conditions, can divide rapidly to form astrocytomas. We have recently described a chloride current that characterizes both primary cultures and established cell lines of human astrocytomas and glioblastomas. These currents are outwardly rectifying, are mediated by a =100pS channel, and are sensitive to chlorotoxin, a 36aa scorpion venom toxin that also blocks epithelial chloride channels. Because rapidly proliferating astrocytomas in humans are clinically associated with peritumoral edema, we were interested to learn whether these chloride currents can be modulated by changes in osmolality typically associated with edema. Using the whole-cell and cell attached patch clamp technique we recorded from astrocytoma cells and observed chloride currents in all cells. Astrocytoma cells responded to a hypotonic challenge (66% osmolarity) with cell swelling as well as with an increase in Cl current amplitude by ~50% of control. Chronic exposure to osmotic challenges altered proliferation as determined using ³H-thymidine incorporation. Control and sister cultures were grown for 24 hours in media with the osmolality adjusted to (in mOsm): 145, 205, 265, 325, 375, or 410. Proliferation was maximal ~325 mOsm and decreased in either hypo- or hyperosmolar solutions. Addition of chloride channel blocker chlorotoxin (590nM) to the hyposmotic solutions partially overcame the osmotically-induced changes in proliferation. These results suggest that astrocytoma chloride currents associated with the swelling response may be involved in regulation of cell volume. We are presently investigating the adaptive role of chloride channels for cell survival during osmotic challenges.

DOWN-REGULATION OF MOUSE ALDOSE REDUCTASE mRNA IN THE SCHWANN CELLS BUT NOT IN THE ENDOTHELIAL CELLS OF SCIATIC NERVE BY HYPERGLYCEMIA. D. T. W. Fu, A. Y. W. Lee, C. X. F Lin, S. S. M. Chung and S. K., Chung*. Institute of Molecular Biology. The University of Hong Kong.

Previously, it has been reported that reduction of blood flow and conduction velocity deficit in the nerve occurs within 1 wk of hyperglycemic induction. It has been suggested that the activation of the first enzyme, aldose reductase, of the polyol pathway, in the endothelial cells causing the hypoxic-ischemic related damage in the nerve might contribute to these functional deficit. However, our previous finding showed that AR mRNA is not expressed by the endothelial cells that is strongly expressed by the Schwann cells. Here, we report the regulation of AR and its related proteins, mouse vas deferens proteins (MVDP) and fibroblast growth factor-regulated factor-1 (FR-1) and sorbitol dehydrogenase (SD) mRNA in the Schwann cells by short-term hyperglycemia. Groups of 6-8wk old female and male mice were treated with streptozotocin (STZ, 200mg/kg body wt), 50% galactose or vehicle only. After 1, 2, and 3 wks of treatment, the sciatic nerves from the matching group were dissected after cervical dislocation. In-situ hybridization was performed on 7 micron frozen sections using 35S-labelled gene-specific probes. To our surprise, the AR mRNA in the Schwann cells of female mice was dramatically reduced after 1 and 2 wks of hyperglycemia. However, the male mice show less dramatic but gradual decline in the level of AR mRNA in the Schwann cells. Only small changes in AR mRNA expression was observed in galactose-fed mice. No significant induction of AR, MVDP, FR-1 and SD mRNA expression in the endothelial cells with hyperglycemia. These findings should help us to further understand the function of these proteins and their potential role in diabetes-related neuropathy. (HKU 35994M)

MODULATION OF RAT MICROGLIA O2 GENERATION BY THE MARINE 14KDA PHOSPHOLIPASE A₂ INHIBITOR MANOALIDE. <u>A.M.S. Mayer, E. Presto and W.C. Prozialeck</u> Pharmacology Dept. Chicago College of Osteopathic Medicine, Midwestern University, Downers Grove, IL 60515.

As of October 1, 1995 we have initiated a project whose long-term objective is to characterize marine natural products with potential for the treatment of neuroinflammatory disorders. For this purpose we have begun by establishing an in vitro paradigm, i.e. harvested rat primary microglial cells, since these cells have been shown to release neurotoxic superoxide anion (O_2) upon immune stimulation. The specific aims of these experiments were the following: a) to establish a well-defined protocol for the isolation and histochemical characterization of rat brain microglia; b) to characterize agonists that would stimulate rat microglia O_2^- generation and c) to determine the effect of marine 14kDa phospholipase A_2 inhibitors on O_2^- generation. O_2^- release was assessed by the SOD-inhibitable reduction of ferricytochrome C. Our results were the following: a) a well-defined ex vivo protocol for the isolation of rat brain microglia was successfully established; b) positive identification of in vitro rat brain microglia cultures was performed by established histochemical techniques (OX-42 and LDL); c) phorbol 12-myristate 13-acetate (PMA) was determined to be a convenient agonist to stimulate rat microglia O2 generation in a dose- and time-dependent manner and d) the potent 14kDa phospholipase A_2 inhibitor, the marine natural product manoalide inhibited Q_2^2 generation in a dose- and timedependent manner. Studies are presently underway to a) characterize other agonists that will stimulate and/or prime microglial O2 generation, b) determine additional marine natural products that might modulate microglial O_2^- generation and c) initiate mechanism of action studies on active compounds.

MICROGLIAL AND IMMUNE CELL RESPONSE TO INTRACRANIAL GLIOMA MODIFICATION BY IL-10 AND IL-2. M. A. Wilson*, P. Johnston, A. M. Fulton, and J. Laterra. Kennedy Krieger Research Institute; Depts. of Neurology, Oncology, & Neuroscience, The Johns Hopkins Univ. School of Medicine; Cancer Center and Dept. of Pathology, Univ. of Maryland, Baltimore, MD 21205.

Genetically modified cells that secrete cytokine gene products offer a promising approach to treatment of primary brain neoplasms, which are often fatal. Immortalized rat brain endothelial cells (RBEZ-Hygro) were engineered to express interleukin-2 (RBEZ-IL2); 9L rat gliosarcoma cells (9L-Neo), syngeneic to Fisher 344 rats, were engineered to express interleukin-10 (9L-IL10). Adult Fisher 344 rats (5/group) received intrastriatal injections of 2 x 10⁶ RBEZ cells (Hygro or IL2) and 10⁵ 9L cells (Neo or IL10) as follows: 1) RBEZ-Hygro + 9L-Neo; 2) RBEZ-IL2 + 9L-Neo 3) RBEZ-Hygro + 9L-IL10; 4) RBEZ-IL2 + 9L-IL10. Rats were sacrificed 15 days later. Tumor growth was assessed in H & E-stained sections. Microglial and immune cell responses were assessed using immunocytochemical detection of the microglia/ macrophage antigens CR3 (OX-42), MHC-I (OX-18), MHC-II (OX-6), the T-cell antigens CD4 (W3/25, also on microglia), CD8 (OX-8, also expressed on NK cells in rats), a pan-T-cell antigen (OX-52), and the NK-cell antigen NKR-P1 (3.2.3). cross sectional areas were reduced to 66% of control (group 1) in the RBEZ-Hygro/9L-IL10 group (p<0.01). At the cellular ratios used, IL-2 alone (group 2) had no effect on tumor size. However, IL2 combined with IL-10 (group 4) dramatically reduced tumor size to 18% of control (p<0.001). A number of differences were noted between groups in the morphology, density and immunoreactivity of microglia. For example, in the absence of IL-10, CD8 was expressed in small round cells (presumed cytotoxic Tcells/NK cells). However, in both groups expressing IL-10, CD8 was remarkably elevated in a second population of cells with the morphologic features of microglia/ macrophages. This suggests a role for CD8+ microglia/macrophages in the observed antitumor effect of IL-10, which is enhanced in the presence of IL-2. Support: NIH NS-01329, Robert Leet & Clara Guthrie Patterson Trust.

AUTOLOGOUS ASTROCYTE CULTURES FROM ADULTS: LONG TERM CHARACTERIZATION AND THERAPEUTIC POTENTIAL. S.A. Withiam-Leitch*, R.C. Chou, R.J. Plunkett and T.J. Langan. Depts. of Neurol. and Neurosurg., School of Medicine, SUNY, Buffalo, N.Y., 14222. Our laboratories described previously the recovery of adult astrocytes

from gelatin implanted into injured rat striata and demonstrated their secretion of neurotrophic substances. Eventual therapeutic use of these astrocytes requires their expansion and long-term characterization.

Adult astrocytes survived in culture >10 mos. and were dramatically expanded through repeated passage. The type 1 astrocytic phenotype persisted after ≥6 passages as demonstrated by staining for the astrocyte markers GFAP, 7B11, and RAN2. The proliferative kinetics, however, differed markedly between early and late passage cultures. Primary cultures become confluent in 10-14 d, while passage ≥ 5 times caused confluence and proliferation arrest in only 1-2 d. Both early and late passage cultures secreted neurotrophic agents, as demonstrated by addition of astrocyte conditioned media to a dorsal root ganglion bioassay. Neurite outgrowth occurred after 8 passages. Immunocytochemistry identified further the components of this neurotrophic potential. Late and early passage cells expressed the extracellular matrix molecule laminin, which facilitates neurite extension, and tenascin, which is known to guide neuronal processes. Both early and late passage astrocytes contained Glial Derived Neurotrophic Factor (GDNF), which promotes recovery in animal Parkinsonism

In summary, astrocytes from injured adult rat brain survive in culture for many months, can be expanded dramatically, and even after repeated passage produce molecules with potential roles in brain regeneration. (Supported by N.I.H. grant NS-30718 to T.J.L.)

NF1-deficient mouse Schwann cells are angiogenic, invasive and can be induced to hyperproliferate: reversion of some phenotypes by an inhibitor of farnesyl protein transferase. <u>Haesun A. Kim</u> and <u>Nancy Ratner*</u>. Department of Cell biology, Neurobiology and Anatomy, College of Medicine University of Cincinnati, Clincinnati, OH, 45267

Neurofibromatosis type 1 (NF1) is one of the most common inherited human autosomal diseases. Formation of neurofibromas is one of the major defining features of NF1. Schwann cells may be the primary pathogenic cells in neurofibromas since majority of cells in the tumors are Schwann cells and Schwann cells, but not fibroblasts, from neurofibromas show angiogenic and invasive properties and are found without association to neurons within tumors.

The NF1 gene product, neurofibromin, functions as a Ras-GAP, suggesting that loss of NF1 might lead to tumor formation due to inadequate regulation of Ras Increased Ras-GTP has been demonstrated in Schwann cells isolated from NF1-deficient mice. However, elevated Ras activity in these cells is correlated with decreased cell proliferation suggesting that additional genetic and/or epigenetic alterations might be required for Schwann cell hyperplaisia.

Here we show that Schwann cell derived from NFI-deficient mice are invasive and induce angiogenic responses in vitro. Furthermore, colonies of hyperproliferating NFI null mutant Schwann cells develop in the absence of serum that show growth factor independent proliferation, lose contact with axons in vitro, and decrease expression of the Po but fail to grow in soft agar; hyperproliferating cells develop after a week lag in Schwann cells heterozygous at WF1. An anti-Ras drug, the farnesyl protein transferase inhibitor, L-739,749, is able to inhibit mutant Schwann cell hyperplasia, but not invasion, suggesting a requirement for Ras activation in NF1 deficient Schwann cells for acquisition of some tumor phenotypes. Supported by NIH NS-28840 DAMD J3030

A COMMON MORPHOLOGICAL RESPONSE OF ASTROCYTES TO DIFFERENT BRAIN INJURIES: THE "DARK" ASTROCYTES.

Z. Toth^{1,3}, L. Seress*², C.E. Ribak³ and F. Gallyas¹
Depts. of ¹Neurosurg. & ²Physiol., Univ. Med. Sch., Pecs, Hungary and ³Dept. of Anat. & Neurobiol., Univ. of Calif., Irvine, CA 92717, U.S.A.

Several cell types of various mammalian tissues can be transformed into a special morphological state, the so-called "dark" cell. The goal of this study was to determine whether glial cells have a dark form. Using a special silver method, a considerable number of astrocytes became stainable in rats subjected to compressive or concussive head injuries and following seizures caused by intraperitoneal administration of pentylenetetrazole or kainic acid. Several brain areas displayed argyrophilic "dark" astrocytes in light microscopic preparations. Semithin 2 µm plastic sections stained with toluidine blue showed that these astrocytes were hyperbasophilic. Thin sections for electron microscopy displayed hyperelectron-dense somata and processes of these astrocytes. These processes were identified by their typical shape, inclusion of glial filaments, and their apposition to capillary walls. "Dark" astrocytes with similar features were also observed in postmortem conditions of rat brains that were treated with head injuries. Based on these observations it is concluded that: 1) the nature of the intracellular pathological event in these astrocytes is the same as that of "dark" neurons or "dark" cells of non-neural tissues, and 2) the formation of these astrocytes is governed by biophysical rather than metabolic processes.

CHRONIC IMPLANTATION OF SILICON SUBSTRATE ELECTRODES IN THE GUINEA PIG CORTEX: TISSUE TOLERANCE. P. A. Finger, D. J. Anderson*, J. A. Wiler, J. F. Hetke & R. A. Altschuler. Kresge Hearing Research Inst; Dept. Electrical Engineering & Computer Sci., Univ. Michigan, Ann Arbor, MI 48019.

Multichannel electrode arrays fabricated using integrated circuit processing techniques have been developed for stimulating and/or recording in the central nervous system. These devices can be used in recording in the central nervous system. These devices can be used in their planar form or can be assembled into 3-D structures for volume interaction with the tissue. We have examined the tissue compatibility of these devices after a three month placement in the guinea pig neocortex. Animals were fixed with paraformaldehyde for LM assessment or paraformaldehyde and glutaraldehyde for EM assessment. Brains were carefully removed, blocked, electrodes removed and blocks embedded in plastic and sectioned perpendicular to the electrode tracts. Six micron sections were cut and stained with Paragon stain for LM evaluation and thin sections cut for TEM evaluation. Oval electrode tracts were visible in the sections. They were surrounded by several lamina of glial processes. Neurons between the tracts and in the general region of the tracts had normal numbers and appearance, except for occasional flattening of the most proximal neurons. In several animals, the region at the base of the electrode tracts had increased gliosis and reactive cells, often asymmetric, particularly in animals where the probe platform became embedded in the cranium, rather than remaining free-floating on cortical surface. In conclusion, there is excellent tissue tolerance to a 3 month placement of various configurations of silicon substrate electrodes into guinea pig cortex, with minimal tissue reaction.

SPECIES DIFFERENCES IN THE EFFECTIVENESS OF THE GLIAL-SPECIFIC METABOLIC BLOCKER FLUOROACETATE (FAC). <u>T. C.</u> <u>Pellmar* and D. O. Keyser</u>. Radiation Pathophysiology and Toxicology Department, AFRRI, Bethesda, MD 20889-5603, USA.

We previously reported that the metabolic integrity of glial cells in field CA1 of the guinea pig hippocampal slice is critical to maintenance of synaptic transmission (Keyser & Pellmar Glia 10:237, 1994). We have now tested the sensitivity of two other species, rats and monkeys, to the glial-specific metabolic inhibitor fluoroacetate (FAC). There is a dose-dependant reduction of ATP levels in hippocampal slices in all three species. Guinea pigs are most sensitive (IC₅₀= 31 μ M) followed by monkeys (IC₅₀= 413 μ M) and then rats (IC₅₀= 7.4 mM). Field potentials were recorded in field CA1 of rat and guinea pig hippocampal slices. In the guinea pig, micromolar concentrations of FAC caused a significant decrease in synaptic potentials within 30 min (IC₅₀= 65 μM), while in the rat concentrations of 10-20 mM were required to impair synaptic transmission (IC₅₀= 40 mM). Synaptic potentials in rat slices often showed transient decreases, with recovery occurring during the FAC exposure. These results suggest that species differences exist in glial responses to FAC and that phylogenetic order does not predict the degree of sensitivity. The differences may be due to disparate sensitivities of glial cells to FAC or to dissimilarities in glial-neuronal coupling. These results highlight the need to recognize species differences and to focus more research on the complexities of glial-neuronal communications

SNAP-25 IS DIFFERENTLY REGULATED COMPARING WITH GAP-43 AND SYNAPTOPHYSIN IN DECENTRALIZED SCGS X.-E Hou*, K. Lundmark and A. <u>Dahlström</u> Dept. of Anatomy and Cell Biol., Göteborg University, S-413 90, Sweden During development SNAP25, a 25-kD synaptosome associated protein, is strongly

During development SNAP25, a 25-kD synaptosome associated protein, is strongly induced during late stages of axonal growth and at the onset of synapse formation. In contrast, GAP43, a growth associated protein, is highly expressed during the stage of axonal outgrowth and is decreased upon synaptogenesis. In our previous work it was observed that GAP-43 was up-regulated in the decentralized SCG together with some synaptic vesicle proteins, for instance synaptophysin. In the present work, we have studied changes in SNAP25 in the decentralized SCG and one of the nerve terminal areas (iris) innervated by the adrenergic SCG neurons, using immunofluorescence and immunoblotting methods. The content of immunoreactive SNAP25 showed no obvious changes in the nerve terminal network of irides after decentralization of SCG, by removing 15-20 mm of the cervical preganglionic trunk. On the other hand, in nerve terminals (probably preganglionic) in the SCG, SNAP25 was clearly decreased one day after decentralization, as was GAP-43 and synaptophysin. However, at later post-decentralization intervals (3, 8, 14 and 28 days) many GAP43 and synaptophysin positive varicose nerve terminals and nerve fibers were again observed in the SCG, apparently devoid of SNAP25. These newly appearing terminals are in all likelyhood not regenerated preganglionic terminals, but emanate from other sources, possibly from the principal neurons. Immunoblot of ganglia after decentralization showed an increase in GAP43 and synaptophysin but not in SNAP25. Together with our previous results, the results may indicate that the newly synthesized synaptic vesicles in decentralized principal neurons have a reduced content of SNAP25 in comparison to GAP43 and synaptophysin. Possibly, no increase in SNAP25 synthesis is necessary since a large fraction of this protein is located in the avolemma of the axons and nerve terminals, and it would therefore be possible for newly formed vesicles to recruit SNAP25 from the axolemma in sufficient amounts to match their nee

HETEROGENEOUS PHENOTYPES OF DROSOPHILA MUTANTS IN SYNAPTIC VESICLE RECYCLING. D. Stimson*¹, P. S. Estes², K. S. Krishnan³, and M. Ramaswami^{1,2}. ¹ARL Division of Neurobiology, and ²Department of Molecular and Cellular Biology, University of Arizona, Tucson, AZ, 85721. ³Molecular Biology Unit, TIFR., Homi Bhabha Rd, Bombay, India, 400005.

In Drosophila, synaptic vesicle recycling requires the activity of the shibire (shi) gene product, a small GTPase homologous to mammalian dynamin. At restrictive temperature, shi'' mutants undergo a complete block of synaptic vesicle endocytosis and eventually become paralyzed, following a depletion of synaptic vesicles at the neuromuscular junction (NMJ). Using a Drosophila larval NMJ preparation, we are investigating other mutations which potentially disrupt synaptic vesicle recycling, including stoned (stn), which enhances the paralytic phenotype of shi''. In addition to conducting electrophysiological analyses, we are developing optical methods to assay rates of synaptic vesicle recycling and endocytosis at mutant synapses. Our analyses of wildtype, shi, and stn synapses suggest that mutations which compromise the efficiency of synaptic vesicle recycling need not manifest themselves exclusively as defects in synaptic vesicle endocytosis. Indeed, under certain conditions, such mutations can alter levels of synaptic vesicle exocytosis.

INHIBITION OF CLATHRIN ASSEMBLY BY THE HIGH AFFINITY BINDING OF PHOSPHATIDYLINOSITOL(3,4,5)P₃ TO THE SYNAPSE-SPECIFIC CLATHRIN ASSEMBLY PROTEIN AP-3. W. Hao~, Z. Tan^k, K.K. Reddy*, Q. Du~, J. R. Faick*, S. B. Shears*, and E. M. Lafer*~. ~ Institute of Biotechnology, University of Texas Hith. Sci. Ctr., San Antonio, TX, 78245; ^inositol Lipid Section, Laboratory of Cellular and Molecular Pharmacology, NIEHS, Research Triangle Park, NC, 27709; 'Dept. of Molecular Genetics, University of Texas Southwestern Medical Center, Dallas, TX 75235.

It is now evident that in various cell types many of the proteins involved in vesicle traffic either participate in the metabolism of inositol lipids and inositol phosphates, or they tightly bind these compounds; however, the general significance of these observations remains to be determined. Within the nervous system, it is very important to elucidate these regulatory pathways in order to understand basic mechanisms of synaptic vesicle biogenesis and recycling. It is likely that regulation of these steps of the synaptic vesicle life cycle contribute to the changes in synaptic strength which underlie learning and memory. We have analyzed the interactions of the synapse-specific clathrin assembly protein AP-3 with inositol derivatives. In previously published studies (JBC 270:1564-8,1995) we showed that the amino terminal domain of AP-3 binds with high affinity to highly phosphorylated inositol polyphosphates, and that this binding inhibits AP-3 mediated clathrin assembly. We now report that AP-3 also binds with high affinity to a water soluble analog of PtdIns(3,4,5)P₃ (DiC₈PtdIns(3,4,5)P₃), the consequence of which is potent inhibition of AP-3 mediated clathrin assembly. We have also found that AP-3 is a good substrate for protein kinase A and casein kinase II, and we are characterizing the effects of AP-3 phosphorylation on the binding of AP-3 to inositol lipids and inositol phosphates.

ALTERNATIVE SPLICING GENERATES TWO SYNAPTOJANIN ISOFORMS WITH DISTINCT MEMBRANE BINDING PROPERTIES. A.R. Ramjaun and P. S. McPherson*. Montreal Neurological Inst., Dept. Neurology & Neurosurgery, McGill Univ., Montreal, QC, Canada H3A 2B4

Synaptojanin is a nerve terminal enriched inositol 5-phosphatase of 145 kDa which is thought to function in synaptic vesicle endocytosis. cDNA clones encoding the protein contain two open reading frames (ORFs) separated by an in-frame stop codon. ORF1 encodes the 145 kDa form of the protein which contains a proline-rich domain at its C-terminus with consensus sites for SH3 domain-mediated interactions. A 170 kDa isoform of synaptojanin, with additional SH3 domain-binding consensus sequences appears to be produced by the expression of ORF1 and ORF2. Here, we demonstrate that the two synaptojanin isoforms are generated by the alternative use of a 27 nucleotide exon which encodes the stop codon. Whereas the 145 kDa isoform is highly enriched in adult brain, the 170 kDa isoform is excluded from this tissue and has a widespread distribution in non-neuronal cells. Unlike the 145 kDa isoform, which can be removed from membranes by a low salt wash, the 170 kDa isoform remains membrane associated, even in the presence of 1 M salt. Consistent with this finding, the 170 kDa form, but not the 145 kDa form, can be isolated from membranes as part of a large molecular weight complex suggesting that the additional SH3 domain-binding sites present in the 170 kDa protein mediate a stable interaction with membranes, likely through an SH3 domain-containing protein(s). These properties may allow the 170 kDa isoform of synaptojanin to play a unique, and perhaps more general role in endocytosis, as compared to the 145 kDa isoform Gupported by MRC-Canada and the Alfred P. Sloan Research Foundation).

GENERATION OF MICE LACKING SYNAPTOGYRIN (P29).

R. Janz*, R.E. Hammer and T.C. Südhof. Howard Hughes Medical Institute, UT Southwestern Medical Center, Dallas, TX, 75235-9050

Synaptogyrin (p29) is an integral synaptic vesicle protein with four transmembrane domains (Stenius et al., 1995, JCB). It has a weak but significant homology to synaptophysin (p38), which has a similar overall structure and membrane topology. We have now cloned the mouse gene of synaptogyrin. The exon-intron structure showed conservation between the mouse and a homologous C. elegans gene, indicating a high degree of evolutionary conservation. In order to elucidate the biological function of the protein, we constructed a knockout vector that deletes the second coding exon of the gene and replaces it with the neomycin resistance gene. The vector was used for homologous recombination in embryonic stem cells and several homologous recombined clones where isolated. Heterozygous mice were derived from injection of the cells into mouse blastocysts and breeding of chimaeric offspring. Interbreeding of heterozygous mice then led to the generation of homozygous knockout mice which showed a total lack of the protein, as shown by western blot analysis, whereas the levels of other synaptic vesicle proteins like synaptophysin and synaptobrevin II showed no obvious change. The null mutant is viable, and a homozygous line could be established. These mice will be used for clarifying the biological role of synaptogyrin in an in vivo system and to study genetic interaction with other synaptic proteins by generating double knockout mice using already existing knockout mouse lines, such as synaptophysin (McMahon et al., 1996, PNAS).

UNC-13 EXPRESSION IN WILD-TYPE AND MUTANT C. ELEGANS, R. J. Eustance, J. S. Duerr*, A. L. Duke, and J. B. Rand. Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

We are using a model organism, the nematode Caenorhabditis elegans, to study the processes underlying synaptic neurotransmission. The unc-13 gene is important for normal neuronal function and may be part of a mechanism regulating neurotransmitter release. Mutations in unc-13 result in resistance to aldicarb, an anti-cholinesterase. contains a region homologous to the regulatory region of PKC (Maruyama and Brenner, 1991) with phorbol ester and phospholipid

binding properties, but its function in neurons is currently unknown. We have generated antibodies against UNC-13 using fusion proteins representing amino acids 25-578 (A) or 903-1286 (B) of the 1734 amino acid UNC-13 protein (both fragments exclude the PKC homology region). Anti-UNC-13 sera appear to stain most or all neurons. Antibodies generated against A (anti-A) label synaptic regions; antibodies against B (anti-B) label neuronal processes uniformly. Mutations in unc-104 which cause mislocalization of synaptic vesicles, do not profoundly alter either staining pattern. We have examined twenty unc 13 alleles; most show a severe decrease in staining with anti-A, but none show any change with anti-B. Our current hypothesis is that UNC-13 is located in synaptic regions (but probably not in synaptic vesicles) and is recognized by anti-A. We hypothesize that anti-B recognizes UNC-13 and another possibly related neuronal protein We are interested in identifying this protein and characterizing genes and proteins that interact with unc-13.

SYNAPSIN ISOFORMS ISOLATED FROM LAMPREY REVEAL NOVEL CONSERVED DOMAIN STRUCTURE G. Stefani, H. T. Kao*, O. Shupliakov, L. Brodin, P. Greengard and V.A. Pieribone Lab. of Mol. and Cell. Neurosci.. The Rockefeller University, NY, NY, 10021; Dept. Neurosci. Karolinska Inst.. Stockholm, Sweden.

The synapsins are a family of neuronal phosphoproteins that have been implicated in the regulation of vesicle clustering and neurotransmission. Four mammalian proteins, designated synapsins Ia, Ib, IIa, and IIb, are formed by alternative splicing of two genes (synapsin I and II genes). Comparision of the sequence for each synapsin isoform suggests a domain model for the synapsins: all the synapsin isoforms share homology with each other at the amino part of each protein, while the carboxy ends show divergence.

The lamprey is an ancient vertebrate that possesses large pre-synaptic elements which are ideal for studying the physiology of an isolated synapse (Nature 375 which are local for studying the physiology of an Isolated synapse (Nature 3/3 (1995) 493.7). We have used antibodies directed against mammalian synapsins to screen a lamprey cDNA expression library, and have isolated cDNA clones encoding 3 different lamprey synapsins. Preliminary analysis of these clones indicates that they are similar to mammalian synapsin Ia, IIa and IIb. In contrast to the synapsins from mammals (human, bovine and rat) which show high protein sequence homology throughout, lamprey synapsins show high homology to mammalian sequences only over certain regions of the sequence while other domains are highly divergent. These are the first non-mammalian vertebrate synapsins to be isolated and the identification of highly conserved subdomains has revealed new structural and functional information about the synapsins. CLEAVAGE OF SNAP-25 WITH BOTULINUM TOXIN A REDUCES THE CALCIUM SENSITIVITY OF THE RELEASE MACHINERY IN HIPPOCAMPUS. M. Capogna *, McKinney, B. H. Gähwiler and S. M. Thompson. Brain Research Institute, University of Zurich, CH-8029 Zurich Switzerland

The role of SNAP-25 in neurotransmitter release was examined by incubating rat hippocampal slice cultures with botulinum toxin A (BoNT/A, 30-60 ng/ml for 48 hrs). No immunoreactivity for the presynaptic protein SNAP-25 could be detected in treated cultures. The frequency of both spontaneous and mEPSCs, recorded in CA3 cells, was strongly reduced (30- and 12-fold) compared to control cultures. Furthermore, application of phorbol ester or α-latrotoxin did not produce Ca2+-independent increases in mEPSC frequency after BoNT/A treatment. In contrast, spontaneous EPSCs were elicited in BoNT/A treated cultures when $[Ca^{2+}]_0$ was raised from 2.8 to 5 or 10mM (0.09 ± 0.02, 0.8 ± 0.2, 4.5 ± 0.9Hz, respectively). In addition, ionomycin increased the mEPSC frequency in the presence of 10mM Ca2+ (from 0.09 ± 0.02 to 2.6 ± 0.7Hz). Log-log plots of unitary EPSC amplitude vs [Ca2+]0, obtained with pair recording from CA3 cells, were linear, with a slope ~4 in control cultures. In BoNT/A treated cultures this relation also had a slope ~4 but was shifted to the right. Vesicular exocytosis is thus possible from synapses in which SNAP-25 has been cleaved by BoNT/A, although the sensitivity of the release machinery for Ca2+ is decreased, without changes in Ca2+ cooperativity.

A DROSOPHILA NEUREXIN IS REQUIRED FOR SEPTATE JUNCTION FUNCTION IN EMBRYONIC DEVELOPMENT, BLOOD BRAIN BARRIER FORMATION, AND IMAGINAL PATTERNING. J.T. Littleton*, M.A. Bhat, S. Baumgartner, K. Broadie and H.J. Bellen. Howard Hughes Medical Institute. Baylor College of Medicine, Houston, TX 77030.

Intercellular junctions such as adherens and tight/septate junctions mediate cellular adhesion and serve as centers to organize proteins for specific intercellular signaling pathways. Neurexins are a family of transmembrane adhesion like molecules that were first identified as extracellular neuronal receptors for latrotoxin. Based on their structure and protein-protein interactions, it has been proposed that neurexins may function in synapse formation, synaptic vesicle proposed that neurexins may function in synapse formation, synaptic vesticle docking or synapse modification. Interestingly, the role of neurexins may not be confined to the nervous system. Recently, the CASK protein has been identified as an intracellular ligand of neurexins. CASK is expressed in both neuronal annon-neuronal tissues and shares homology with a family of septate junction and synapse associated proteins. We have isolated and characterized a novel member of the neurexin family, Neurexin IV, that is specifically expressed in septate junctions of epithelial and glial cells of Drosophila. nrx IV encodes a transmembrane protein with EGF repeats and laminin G domains with an overall structure describer to the fort and home Naturality. structure similar to that of rat and human Neurexins. In non-neuronal tissues, absence of NRX IV results in mislocalization of the septate junction specific protein CORACLE, a protein 4.1 homolog. Mutant embryos that lack NRX IV activity are paralyzed and have impaired ability to propagate action potentials. activity are paralyzed and larve impaired annity to propagate action potentials, indicating that absence of NRX IV in glia causes a breakdown of the blood nerve barrier. The phenotypes of viable mutants reveal that NRX IV is required for ommatidial polarity in the compound eye and pattern formation in wing development. We propose that NRX IV is a transmembrane protein component of septate junctions that is essential for their function in embryonic development.

blood brain barrier formation, and imaginal patterning.

SNAP-25 BINDING DOMAINS OF SYNTAXIN: AN ANALYSIS OF PRIMARY AND SECONDARY STRUCTURE.

Tam. D. Chung. R.H. Scheller, G.P. Miljanich.

Neurex Corporation, Menlo Cellular Physiology, HHMI, Stanford University Medical Center, Stanford, CA 94305

Interaction between syntaxin 1A and SNAP-25 is a critical step in synaptic vesicle docking and fusion. In the present study, a simple microtiter plate binding assay was developed to study this protein-protein interaction quantitatively. A panel of peptides was prepared to encompass different sequences of syntaxin's H3 domain, periods was prepared to clientings stituted sequences of syntaxin. Affinities of the peptides for SNAP-25 were then determined to evaluate the roles of regions of the H3 domain in this protein-protein interaction. A region of 32 amino acids (amino acids 189-220 of syntaxin) was found to be the minimal binding domain. Peptides spanning the C-terminal region (amino acid 221-266) of the H3 domain failed to bind to SNAP-25 terminal region (amino acid 221-266) of the H3 domain failed to bind to SNAP-25; however, supporting domains that reside within this region are required for optimal binding activity. Thus, extension of the C-terminus of the minimal binding domain greatly enhanced the affinity for SNAP-25. Selected mutations in evolutionarily conserved residues of a putative amphiphilic α-helix within the minimal binding domain greatly reduced affinity for SNAP-25. Circular dichroism (CD) confirmed the presence of amphiphilic α-helicity in the syntaxin H3 domain and the 32-mer minimal binding domain. The CD analysis further suggests that integrity of the 32-mer domain is crucial for maintaining the helical conformation of the entire H3 domain and the C-terminal region is responsible for further stabilizing this conformation. Thermal stability analysis demonstrated that this α-helicity is required for SNAP-25 binding activity and for inhibition by syntaxin peptides of [3H]-norepinephrine release from PC12 cells. Funded by Neurex Corp.

LONG TERM POTENTIATION AND BIOCHEMICAL ALTERATIONS IN THE EXOCYTOTIC APPARATUS. J. E. A. Braun and D. V. Madison* (Department of Molecular and Cellular Physiology, Stanford University Medical Center, Stanford CA 94305)

Upon the pharmacological induction of persistant synaptic potentiation with 4-aminopyridine in rat hippocampal slices, we observed a two-fold increase in an SDS resistant protein complex, composed of the proteins SNAP-25, syntaxin and VAMP. Potentiation was recorded in field EPSP's resulting from Schaffer collateral stimulation in area CA1 of rat hippocampal slices. Hippocampal slices were subsequently solubilized in Triton X-100, isolated by SDS-PAGE and quantitated by densitometry. In addition, larger 7S and 20S complexes, composed of synaptotagmin, α-SNAP and NSF as well as SNAP-25, syntaxin and VAMP were isolated by immunoprecipation or glycerol gradient fractionation and quantitated by densitometry. These protein complexes, or "SNARE complexes", have been proposed to account for synaptic vesicle "docking" to the presynaptic plasma membrane. Each step of the exocytotic pathway is thought to be mediated by a specific protein complex-such that a sequence of protein complex assemblies and dissassemblies underlie the exocytotic cycle. The correlation of an increase in synaptic efficacy with an increase in "docking complexes" implicates more docked vesicles in processes expressing LTP. Supported by Conte Center MH48108.

NT75, THE S-7B8 ANTIGEN, IS A COMPLEX COMPOSED OF SNAP-25 AND SYNAPTOBREVIN/VAMP. T.C. Ritchie*, D. Kluge, S. Zielske and J.D. Coulter. Dept. of Anatomy & Neuroscience Program, University of Iowa, Iowa City, IA 52242.

The S-7B8 antibody recognizes a nerve terminal antigen that is neuron-specific and is both developmentally regulated and differentially regulated in distinct populations of mature neurons. Initially, the S-7B8 antigen was identified as a 75 kDa protein, NT75, on Western Blots of non-reduced proteins. However, purified NT75, when reduced and boiled, resolves into two bands of 29 (p29) and 17 kDa. Tryptic fragments of the major protein, p29, were subjected to microsequencing, and a total of 53 residues of high confidence sequence were obtained from three peptides. A search of protein databases showed the p29 sequence to have 100% identity with the published sequence of SNAP-25. A comparison of Western blot staining with commercial antibodies and antibodies to p29 and NT75 confirmed the identity of p29 as SNAP-25 and showed that the 17 kDa subunit of NT75 is synaptobrevin/VAMP. Immunocytochemical staining patterns of S-7B8 and anti-SNAP-25 are largely similar, as both antibodies yield selective dense labeling in subpopulations of nerve terminals in adult spinal cord and brain. The experiments show that the S-7B8 antigen is SNAP-25. Our previous studies on S-7B8 are consistent with the idea that the function of SNAP-25 is not restricted to synaptic vesicle cycling, but that SNAP-25 is also likely to have roles in the formation, maintenance and plasticity of distinct populations of nerve terminals. Supported by NIH grant NS23783.

TRANSLOCATION OF TETANUS TOXIN H_N-L THROUGH MEMBRANES. <u>T. Lücke, H. Göschel, T. Binscheck, U. Weller¹, and H. Bigalke*</u>, Institute of Toxicology, Hannover Medical School, 30623 Hannover, Germany. ¹Institute of Microbiology, Johannes Gutenberg University, 55101 Mainz, Germany.

Tetanus toxin (TeTx) is composed of two chains. The light chain (L) proteolyses synaptobrevin II and the heavy chain (H) navigates the toxin from the extracellular space into the cytosol via the endosomal compartment. The passage through the endosomal membrane occurs only at low pH. Under conditions corresponding to those prevailing in endosomes, the light chain linked with the N-terminal half of the heavy chain (HN-L) inhibited transmitter release from chromaffin cells and motonerve-endings. This inhibition was not prevented by the ATPase inhibitor, bafilomycin A1, indicating that HN-L bypassed the endosome on its route into the cytosol. At physiological pH HN-L was ineffective. At low pH, but not at neutral pH, H_N-L formed pores in inside-out patches derived from the plasma membrane of chromaffin cells. Whereas the pore formation was also caused by both TeTx and HN, only TeTx, and not HN, blocked exocytosis. The C-terminal half of the heavy chain (HC) and L neither formed pores nor did they inhibit noradrenaline release. We conclude that H_N, at low pH, mediates the passage of TeTx through the endosomal membrane. The passage may be accompanied by pore formation, which is recorded as an increase in membrane conductance. (Supported by the German Research Council, Bi 274/8-1.)

ISOLATING AND IDENTIFYING SYNAPTIC RIBBON ASSOCIATED PROTEINS Tri-Hung Nguyen*and Grant W. Balkema. Biology Department, Boston College, Chestnut Hill, MA 02167.

We have now identified four proteins that cosediment with synaptic vesicles and are labeled by the monoclonal antibody (B16). The B16 mAb has been found to label synaptic ribbons in the retina and recognizes multiple protein bands in a retinal homogenate. One epitope was found on the 88-kDa protein, aconitase, which is found in the synaptosomal fraction. The epitope was mapped to a ten amino acid region (DTYQHPPKDS) containing a double proline "kink". Here, we report the purification and identification of these proteins.

Cow retinas were isolated and washed in iso-osmotic sucrose solution. Retinas were gently homogenized and centrifuged at different speeds (150, 800 and 25,000 x g) to isolate photoreceptor synaptosomes. Relatively pure populations of synaptosomes were hypo-osmotically lysed to release synaptic ribbons and synaptic vesicles. Retinal synaptic vesicles were sedimented by centrifugation after a high speed spin (100,000 x g). Samples from each centrifugation step were analyzed on SDS-polyacrylamide gels and Western blots.

The B16 mAb recognizes four proteins: 66-, 70-, 100- and 110-kDa that cosediment with synaptic vesicles as indicated by anti-synaptophysin antibody. We have isolated sequenced and identified three pentides.

The B16 mAb recognizes four proteins: 66-, 70-, 100- and 110-kDa that cosediment with synaptic vesicles as indicated by anti-synaptophysin antibody. We have isolated, sequenced and identified three peptides resulting from protease digestion of the 100-kDa protein to be the PTB-associating splicing factor, that is rich in proline. These results are consistence with the idea that the B16 mAb recognizes proteins with a shared conformational epitope and bind to synaptic vesicles.

CHOLINE ACETYLTRANSFERASE UNDERGOES COVALENT MODIFICATION BY THE ADDITION OF LONG CHAIN FATTY ACIDS, M. C. Resendes, R. Jane Rylett*, Department of Physiology, University of Western Ontario, London Ont. Canada, N6A 5C3.

The neurotransmitter acetylcholine is synthesized by the enzyme choline acetyltransferase (ChAT) which exists in both hydrophilic (cytosolic) and amphiphilic (membrane-bound) form. Distinct physiological roles have not been ascribed to the different subcellular fractions of ChAT, nor is it clear how the different forms of enzyme are generated or how distribution within the different pools is regulated. The covalent attachment of primarily myristic or palmitic fatty acid to a wide range of cellular proteins is known to dramatically alter both their subcellular distribution and function. Analysis of amino acid sequences deduced from published cDNAs reveals that human, rat, pig and mouse ChAT contains elements of myristoylation and/ or palmitoylation consensus sequences. To examine if ChAT undergoes modification by acylation, cholinergic human neuroblastoma LA-N-2 cells were incubated in the presence of ³H-myristic or ³H-palmitic acids (0.5 and 1 mCi/mL media, 24 h, respectively). Following the labelling period, (O.) and I incline media. 24 It, respectively). Tolowing the faceting period, ChAT was immunoprecipitated and separated by SDS-PAGE. Gels were either immunoblotted for ChAT or lanes were cut a 2mm intervals and digested in 30% H₂O₂ for quantitation of ³H. In both ³H-myristic or ³H-palmitic labelled cells, a 20-30 fold increase in 3H activity was observed in gel slices corresponding to the location of ChAT immunoreactivity from immunoblots. Based upon this data, it would appear that ChAT can exist as an acylprotein in cholinergic cells. Whether acylated ChAT regulates the function or the subcellular localization of the enzyme is currently being investigated.

BASSOON, A NOVEL PRESYNAPTIC PROTEIN FROM RAT BRAIN. E.D. Gundelfinger*, K. Langnäse, L. Sanmartí-Vila, H. Wex, K. Richter, J.T. Fränzer, C.C. Garner#; BL-Institute for Neurobiology, P.O.Box 1860, D.39008 Magdeburg, Germany and #Neurobiol. Res. Center, Univ. of Alabama, S-Birmingham, AL 35213-0021, USA
The knowledge of structure and function of the molecular company of the properties of

The knowledge of structure and function of the molecular components is prerequisite to the functional comprehension of synapses at a molecular level. To get access to novel synaptic proteins we have screened a rat brain expression library with polyclonal antisera against a rat brain synaptic protein preparation. Bassoon is one of the gene products newly identified by this approach. The partial nucleotide sequence of the Bassoon cDNA does not have any correlate in public databases. Northern analysis of various rat tissues identified a brain-specific transcript of 12kb. A wide distribution of Bassoon transcripts in the rat brain has been revealed by *in situ* hybridization. Antibodies against bacterially expressed Bassoon fusion protein recognize multiple bands in the molecular weight range of 150 to >300 kd on Western blots of rat brain protein preparations. The signal is highly enriched in the synaptic junctional protein fraction. Immunohistochemically Bassoon has been detected in synaptic neuropil regions of all parts of the brain. At the ultrastructural level, an exculusive presynaptic localization has been observed, e. g. in excitatory mossy fiber terminals in the hippocampus as well as in parallel fiber terminals in the molecular layer and mossy fiber terminals in the granular layer of the cerebellum. Immunoreactivity appears to be restricted to the active zone. Therefore, we hypothesize that Bassoon could play a role in the presynaptic machinery organizing the presynaptic vytomatrix and/or orchestrating events of the synaptic vesicle cycle. Supported by the German Federal Government (BMBF) and the Land Saxony-Anhalt.

SELECTIVE DEPLETION OF CLEAR SYNAPTIC VESICLES AND ENHANCED QUANTAL TRANSMITTER RELEASE AT FROG MOTOR NERVE ENDINGS PRODUCED BY TRACHYNILYSIN, A TOXIN ISOLATED FROM THE STONEFISH (Synanceia trachynis) VENOM. C. Colasante^{1,2}, F.A. Meunier¹, A.S. Kreger³, J. Molgo¹ and J. Bruner^{1,4}. ¹Lab. Neurobiologie Cellulaire et Moléculaire, C.N.R.S., 91198 Gif sur Yvette Cedex, France; ² Centro de Microscopía Electrónica, Univ. Los Andes, Mérida Venezuela ³Medical Sciences Research Institute, Herdon, Virginia 22070, USA

The protein toxin trachynilysin (TLY) significantly increased spontaneous quantal acetylcholine (ACh) release from motor endings, as detected by recording miniature end plate potentials (MEPPs) in isolated frog cutaneous pectoris neuromuscular preparations. Ultrastructural analysis of nerve endings in which quantal ACh release was stimulated to exhaustion by 3 hrs exposure to TLY revealed swelling of nerve terminals and a marked depletion of small clear synaptic vesicles (SVs). The number of large dense core vesicles (LDCVs) per terminal cross-section remained unaffected. LDCVs contained calcitonin gene-related peptide (CGRP), as revealed by colloidal gold immunostaining, and TLY-treated nerve endings exhibited similar CGRP-like immunofluorescence as untreated endings. TLY-induced ACh release caused permanent incorporation of SV membrane into the axolemma as revealed by synaptophysin immunolabeling. We conclude, that the ability of stonefish (S trachynis) venom to elicit spontaneous quantal ACh release from motor nerve endings is a function of TLY, which selectively stimulates the release of Svs and impairs their recycling but, does not affect the release of LDCVs Supported by Direction des recherches Etudes et Techniques (grant 94/067).

ODQ, A SELECTIVE INHIBITOR OF NO-ACTIVATED GUANYLYL CYCLASE, BLOCKS THE INDUCTION OF LONG-TERM DEPRESSION IN RAT HIPPOCAMPUS.

TERM DEPRESSION IN RAT HIPPOCAMPUS.

A.T. Gage* and P.K. Stanton. Departments of Neuroscience & Neurology,
Albert Einstein College of Medicine, Bronx, NY 10461-1602

The putative retrograde messenger nitric oxide (NO) is controversially suggested to play a role in inducing both long-term potentiation (LTP) and long-term depression (LTD) of synaptic strength. NO activates two separate enzymes, an NO-stimulated guanylyl cyclase (NOGC) and an ADP ribosylase. The putative guanylyl cyclase inhibitor LY83583 has been reported to block induction of LTP. However, this compound is a more potent inhibitor of nitric oxide synthase, leaving the question of the role of cyclic GMP unanswered for either LTP or LTD. We utilized a recently developed selective NOGC inhibitor IH-[1,2,4]oxadiazolo[4,3-a]quinoxalin-1-one (DDQ), to determine whether NOGC activation is necessary for the induction of hippocampal LTD.

We recorded in in vitro hippocampal slices from 13-28 day old male Sprague-Dawley rats in an interface chamber at 34° C. Schaffer collateral axons synapsing on CA1 pyramidal neurons were stimulated each 60 sec, and evoked excitatory postsynaptic potentials (epsps) recorded in stratum radiatum.

axons synapsing on CA1 pyramidal neurons were stimulated each 60 sec, and evoked excitatory postsynaptic potentials (epsps) recorded in stratum radiatum. After a 30 min baseline, 2 μM ODQ was bath applied for 1 hour, after which low-frequency stimuli (LFS; 1 Hz/15 min) were given to induce LTD. ODQ alone had no significant effect on Schaffer collateral-evoked epsp slopes. However, it did block the induction of LTD as assessed 60 min post-LFS. Control LTD in untreated slices = -22.9 ± 3.2% (p<0.05, paired t-test, n=22); ODQ-treated slices = -5.7 ± 4.7% (n=16, no significant LTD). In some slices, after an initial LFS in the presence of ODQ, the drug was washed out for 60 min, after which a second identical LFS now elicited stable LTD. At previously potentiated synapses, ODQ showed less effective blockade of LTD. Thus, we conclude that NOGC activation is a necessary step in the induction of de novo LTD, but, perhaps, only a partial contributor to depotentiation. (Supported by NIMH Grant #45752)

DE-POTENTIATION OF LTP OF SYNAPSES BETWEEN PRIMARY AFFERENTS AND DORSAL HORN NEURONS. J.C. Marvizon* and E.A. Mayer. CURE: Dig. Dis. Res. Cent., Dept. of Medicine, UCLA, Los Angeles, CA

Transversal spinal cord slices with attached dorsal roots and ganglions were prepared from 14-30 days rats as described by Randic et al., J. Neurosci. 13, 5228-5241 (1993). Intracellular recordings from neurons in the substantia gelatinosa were used to study their synaptic responses to electrical stimulation of the dorsal root. The average resting membrane potential and membrane input resistance of 22 neurons was -68 \pm 2 mV and 170 \pm 16 M Ω , respectively. Synaptic plasticity was induced by delivering a tetanus to the dorsal root consisting of three trains of 1 s at 10 s intervals of high frequency (100 Hz) pulses (6-20 V, 0.4 ms). This tetanus produced LTD in two neurons, evidenced by a long lasting (40 min) decrease in EPSP amplitude. LTP was induced in three other neurons by the same tetanus accompanied by a depolarization of the neuron to about -60 mV. The membrane potential was kept constant at -85 mV except during the tetanus. After the presence of LTP was established for 30 min., a second, identical tetanus was delivered while hyperpolarizing the neuron to -100 mV. Except for a short initial increase (post-tetanic potentiation), the evoked EPSPs were significantly lower than after the first tetanus but higher than the baseline, remaining unchanged for the rest of the recording (40 min). A similar de-potentiation of LTP was observed in three neurons. These results indicate that the membrane potential of substantia gelatinosa neurons determines the direction of the synaptic plasticity induced by tetanic stimulation of the dorsal root. Moreover, since changes in the membrane potential restricted to the duration of the tetanus are sufficient to produce this effect, they seem to be involved in induction but not the xpression of synaptic plasticity. Further studies are necessary to determine whether LTD and de-potentiation of LTP are the same or different phenomena in these neurons. (Supported by a Pilot and Feasibility Award, NIH 5P30 DK41301)

INDUCTION OF HIPPOCAMPAL LTD REQUIRES RELEASE OF CA²⁺ FROM SEPARATE PRE- AND POSTSYNAPTIC STORES AND ACTIVATION OF PRESYNAPTIC CAM KINASE II. Magali Reyes, Allyson T Gage and Patric K, Stanton*. Neuroscience, Albert Einstein Coll. Med., Bronx, NY 10461

Postsynaptic increases in [Ca²⁺] and activation of Ca²⁺/calmodulin-dependent protein kinase II (CAMKII) are both necessary to induce long-term potentiation (LTP) of synaptic strength. A smaller rise in postsynaptic [Ca²⁺] also appears to be required to induce long-term depression (LTD). It is not known whether Ca²⁺ for LTD comes from influx and/or intracellular stores, if pre- and/or postsynaptic stores are necessary, or if activation of CAMKII is required to induce LTD.

Bath application of thapsigargin or cyclopiazonic acid, which deplete all intracellular Ca2+ pools, blocked induction, but not maintenance, of LTD by low frequency stimuli (1Hz/15min) at Schaffer collateral-CA1 synapses in hippocampal slices. Injecting thapsigargin into single CA1 pyramidal cells also prevented LTD. Selectively depleting Ca2+-gated stores with bath applied ryanodine also blocked LTD, but postsynaptic injection did not. Thus, LTD requires Ca2+ release from presynaptic ryanodine stores and postsynaptic IP3-gated stores.

Extracellular application of the CAMKII inhibitor KN-62, at a concentration which blocks LTP, also prevented induction of LTD. In contrast, impaling CA1 pyramidal neurons with electrodes containing KN-62 did not impair LTD, although it did block LTP in the same cells. Thus, presynaptic CAMKII is necessary to induce LTD, while postsynaptic CAMKII plays a role in LTP. (NIMH Grant #45752)

LOW FREQUENCY STIMULATION OF AFFERENT AS-FIBERS INDUCES LONG-TERM DEPRESSION OF PRIMARY AFFERENT NEUROTRANSMISSION, J. Sandkühler and M. Randić. Department of Veterinary Physiology and Pharmacology, Iowa State University, Ames, IA, 50011. Fine primary afferent nerve fibers including nociceptors terminate in laminae

I and II of the spinal dorsal horn. It is believed that this region is important for plastic changes in spinal nociception. Here we have identified a robust long-term depression (LTD) of primary afferent neurotransmission in Aδ-fibers which can be induced by repetitive low frequency stimulation (LFS) of dorsal roots (DRs). Intracellular recordings were made from lamina II neurons in transverse slices of young (18-27d) rat spinal cord. Electrical stimulation of L4 or L5 DRs evoked stable mono- or polysynaptic EPSPs in all neurons studied. Conditioning stimulation of DRs consisted of 900 pulses (10V, 0.1ms) given at 1 Hz. As a quantitative parameter of synaptic strength the peak amplitude of A&-fiber-evoked EPSPs was measured. LFS of afferent A&-fibers caused a stable, longlasting decrease in synaptic efficacy (EPSP amplitude decreased to $40.8 \pm 10.3\%$ of control; n≈8). When A- and C-fibers were recruited conditioning stimulation was as effective as A-fiber stimulation alone. This form of LTD required activation of postsynaptic NMDA receptor, since D-APV (50 µM), the NMDA receptor antagonist, reversibly reduced or abolished the generation of LTD (86.1 \pm 13.5%, n=7). LTD is independent of GABA, or glycine receptor activation. In the presence of calyculin A (100nM), an inhibitor of protein phosphatases 1 and 2A, LTD was somewhat more expressed (to $15.0\pm6\%$, n=4). Following LTD synaptic strength could be increased to its original maximal level, indicating that LTD is reversible and not due to deterioration of individual synapses. This LTD of primary afferent neurotransmission may be involved in long-lasting segmental antinociception following afferent stimulation. Supported by the NINDS, the National Science Foundation and Deutsche Forschungsgemeinschaft.

A ROLE FOR MU OPIOID RECEPTORS IN LONG-TERM DEPRESSION IN SUBSTANTIA GELATINOSA OF THE SPINAL CORD, <u>J. Zhong and M. Randić.</u> Dept. of Veterinary Physiology and Pharmacology, Iowa State University, Ames, IA 50011.

Evidence indicates that mu opioid receptor activation attenuates primary afferent neurotransmission, and is also involved in the mediation, or modulation, of activity-dependent synaptic plasticity in the brain. We have reported the existence of long-lasting decrease in synaptic strength in the spinal substantia gelatinosa (SG) neurons resulting from the low frequency stimulation (LFS) of primary afferent A5-fibers (Sandkühler and Randić, this meeting). The underlying mechanism of this phenomenon is not known. To assess the role of opioid receptors in the induction of long-term depression (LTD) of primary afferent neurotransmission we examined whether naloxone, a non-selective opioid receptor antagonist, and CTAP, a selective mu opioid receptor antagonist, could affect the LFS-induced LTD using conventional intracellular recording from the SG neurons in transverse slices of young rat (17-22-d-old) spinal cord. The strength of primary afferent neurotransmission was assayed by measuring the peak amplitude of EPSPs that result from stimulation of primary afferent fibers in L4 or L5 dorsal roots (DRs) with electrical shocks of 3-8V (0.1ms duration) intensity. Conditioning stimulation of DRs, which consisted of 900 pulses given at 1 Hz, produced a long-term depression of EPSP amplitudes (to 40.8 \pm 10.3% of control, n=8) in SG neurons when A δ -fibers were recruited. In the presence of extracellular naloxone (1µM), or CTAP (100nM), the same LFS did not cause LTD (CTAP: 136.1 ± 30.8%, n=6). This finding suggests that the activation of mu opioid receptors is required for LTD of EPSPs at primary afferent synapses with neurons in the SG. Supported by the NINDS and the NSF.

BRAIN-DERIVED NEUROTROPHIC FACTOR BLOCKS LONG-TERM DEPRESSION IN RAT VISUAL CORTEX, Y. Akaneya, T. Tsumoto* and H. Hatanaka†. Dept. of Neurophysiology, Biomed. Res. Ctr., Osaka Univ. Med. Sch., Suita, 565 Japan and †Div. of Prot. Biosynth., Inst. for Prot. Res., Osaka Univ., Suita, 565 Japan

Brain-derived neurotrophic factor (BDNF) is suggested to play a role in formation of ocular dominance columns and input-dependent modification of neuronal function in developing visual cortex. Since long-term depression (LTD) is supposed to be a synaptic basis for such a use-dependent alteration in structure and function of visual cortex, we have studied effects of BDNF on the induction of LTD in visual cortical slices prepared from young rats. Layer II/III field responses evoked by test stimulation of layer IV at 0.1 Hz were not significantly changed by BDNF at the concentration of 20 ng/ml. On the other hand, BDNF at this concentration blocked the induction of LTD of field responses by low-frequency stimulation (1 Hz for 15 min) of layer IV. This action of BDNF was antagonized by K252a, an inhibitor of receptor tyrosine kinases, at the concentration of 200 nM. When K252a alone was applied to slices, LTD of the stronger magnitude than in control slices was induced while responses to test stimulation were not significantly changed, suggesting that endogeneous BDNF may prevent synapses from being depressed to some degree during low-frequency inputs. These results suggest that BDNF may play a role in use-dependent changes in synaptic connectivity in the developing visual cortex. Supported by a Grant-inaid from the Japanese Ministry of Education, Science, and Culture.

CESIUM PREVENTS LTD MAINTENANCE AND CAUSES EPILEPTIFORM ACTIVITY BY AN EFFECT ON BOTH NEURONAL AND GLIAL CELLS. S. Gasparini*, R. D'Ambrosio, D. DiFrancesco and D. Janigro*, Univ. of Milan* and Dept. of Neurosurgery, Univ. of Washington, Seattle, WA

We have investigated the effects of brief and prolonged applications of extracellular

We have investigated the effects of brief and prolonged applications of extracellular cesium (Cs*) on the electrical properties of CA1 pyramidal cells, interneurons and astrocytes by using the *in vitro* hippocampal slice. Field potential recordings revealed that Cs causes synchronous, interictal-like bursting and prevents maintenance of long-term depression (LTD). Whole cell recordings showed that brief (<2 min.) bath exposures to Cs* caused pyramidal cell hyperpolarization associated with decreased membrane conductance due to blockade of an inward h-type current. After prolonged exposures a late depolarizing response was observed; this effect was not associated with changes in membrane conductance and vanished when the rate of slice perfusion was increased. Recordings from interneurons revealed that I_h is expressed in a subpopulation of interneurons and that Cs effects on interneurons expressing I_h are comparable to those observed in pyramidal cells Consistent with this effect, the early component of the IPSP recorded in pyramidal cells was decreased by Cs*. However, evoked population-spikes were depressed by Cs*. The specific neuronal I_h blocker Zeneca ZD-7288 failed to affect LTD and did not cause synchronous bursting. We concluded that Cs* actions on LTD and Cs-induced epileptifiom activity were not due exclusively to its effects on neurons. Recordings from astrocytes revealed that, in contrast to pyramidal cells, glial cells were depolarized by Cs*. Cs* depressed glial depolarizations induced by elevation of [K]_o. Thus, the effects of Cs* on CA1 synchronization and synaptic plasticity appear to be mediated by both glial and neuronal cells. Supported by NIH 51614.

INDUCTION OF NEOCORTICAL DEPOTENTIATION AND LONG-TERM DEPRESSION IN THE ADULT BEHAVING RAT. <u>David J. Froc*. Christopher Trepel, and Ronald J. Racine</u>. Department of Psychology, McMaster University, Hamilton, Ontario, Canada, L8S 4K1.

We have shown that long-term potentiation (LTP) in the chronically prepared rat requires multiple, spaced stimulation sessions. Long-term depression (LTD), in which baseline responses are depressed, and depotentiation, in which previously potentiated responses are depotentiated towards baseline levels, have both been demonstrated in slice preparations. However, there is little evidence of these phenomena in the awake, freely moving rat. Here we report that both neocortical depotentiation and LTD can be readily induced in the adult behaving rat. Animals were implanted with stimulating and recording electrodes located in the corpus callosum and anterior neocortex (parietal area 1), respectively. The depotentiation group received sixty 8-pulse (0.1 msec biphasic; 1259 µA), 24 msec, 300 Hz (train frequency=0.1 Hz) trains per day to induce asymptotic levels of potentiation prior to LF stimulation. I/O measures were also taken on a daily basis, to monitor the effects of this stimulation protocol, and immediately prior to and after LF stimulation. Estimulation consisted of 900, 1259 µA pulses delivered at 1 Hz. Control animals were similarly potentiated to asymptote but did not receive LF stimulation. Following LF stimulation, all experimental animals showed a significant decrease in the late component of the evoked field potential which was still evident 24 hours later. Depotentiation was less pronounced and more transient in contralateral than in ipsilateral recording sites. The LTD animals received the same LF stimulation used to induce depotentiation. Relative to controls a significant reduction in the amplitude of the evoked field potential was observed. We have demonstrated that neocortical synapses are bidirectionally modifiable and that LTD may be induced in naive synapses following one LF stimulation session in the adult behaving rat.

LTD INDUCTION IS NMDAR-INDEPENDENT, AND DEPENDENT ON T-TYPE Ca CHANNELS ACTIVATION AND Ca RELEASE FROM INTRACELLULAR STORES Y. Wang, M.J. Rowan and R. Anwyl Physiology, Trinity College, Dublin 2, Ireland.

Rowan and R. Anwyl Physiology, Trinity College, Dublin 2, Ireland.

Long-term depression (LTD) can be induced by a period of low frequency stimulation (LFS). In the present studies, we have carried out an investigation into the tring of Cachappel responsible for LTD induction.

frequency stimulation (LFS). In the present studies, we have carried out an investigation into the type of Ca channel responsible for LTD induction. LTD of epsps or whole-cell patch-clamped epscs in rat dentate gyrus was induced by prolonged LFS of 900 stimuli at 1Hz, or by an intracellular pairing procedure under voltage clamp conditions. LTD induced by these two procedures measured 40±2%, n=8 and 37±1%, n=7, respectively, at 30 min post-stimulation. The induction of LTD was independent of activation of NMDA receptors. Thus LTD of epscs induced by the pairing procedure in the presence of the NMDA receptor antagonist D-AP5 (100µM) measured 35±1%, n=5, a value not significantly different from control (P<0.001). The induction of LTD of field epsps by 1Hz LFS was inhibited by Ni (50µM), but not by nifedipine (10µM), the LTD measuring 1±1%, n=5, and 36±2%, n=5, in Ni and nifedipine respectively. These experiments suggest that the induction of LTD requires the release of Ca from intracellular stores. Thus the induction of LTD of epses was significantly inhibited by intracellular application of ruthenium red (20 µM), an agent known to bind to, and block the release of Ga from, the intracellular enoplasmic reticulum ryanodine receptor (LTD =1±2%, n=5). LTD of the field epsp was also inhibited by thapsigargin, an agent known to deplete intracellular Ca stores by inhibiting endoplasmic reticulum Ca-ATPase. Thus in 2 µM thapsigargin, LFS of 1Hz induced LTD of 2±1%, n=5, a significant inhibition of LTD.

596.10

LONG-TERM DEPRESSION IN THE CA1 REGION OF THE ADULT RAT HIPPOCAMPUS *IN VITRO*. N. Kemp and Z. I. Bashir*. Department of Anatomy, Medical School, University of Bristol, Bristol, BS8 1TD, UK.

Long-term depression (LTD) can readily be induced in the CA1 region of young (up to 3 weeks old) but not adult rat hippocampal slices by low frequency stimulation (LFS) of the Schaffer collateral-commissural pathway (SCCP). We demonstrate that under certain conditions LFS can induce LTD in slices from adult rats

Hippocampal slices were prepared from female adult rats (170-220g, ~ 8 weeks old). The SCCP was stimulated at 0.033 Hz and standard techniques were used to record field excitatory post-synaptic potentials (EPSPs) from the stratum radiatum. Results are expressed as a change in the slope of the field epsp 30 minutes after the end of LFS (900 pulses, 1 Hz) relative to the pre-LFS baseline.

Two periods of LFS separated by at least 30 minutes resulted in only a small depression of synaptic transmission (5 \pm 1 % and 3 \pm 6 %, respectively; mean \pm sem; n=6). In the presence of the adenosine A1 receptor antagonist, 1,3-dipropyl-scyclopentylxanthine (DPCPX; 100 nM) two periods of LFS resulted in a depression of 8 \pm 3 and 17 \pm 2 %, respectively (n=6). When the experiments were repeated in the additional presence of the NMDA receptor antagonist, D-2-amino-5 phosphonopentanoate (D-APS; 50 μ M) a depression of 4 \pm 3 (n=7) and 13 \pm 3 % (n=5) resulted. In a separate series of experiments, LFS in control conditions followed by LFS in the presence of the GABAA receptor antagonist, picrotoxin (50 μ M) resulted in depression of 2 \pm 7 and 18 \pm 9 %, respectively (n=5).

These results show that LTD can be induced in adult rat hippocampal slices if LFS is given either during adenosine A₁ receptor blockade or during GABA_A antagonism. The LTD obtained in the presence of DPCPX appears to be NMDA receptor independent since it is not blocked by D-AP5. Supported by the Wellcome Trust.

TWO FORMS OF HOMOSYNAPTIC LONG-TERM DEPRESSION COEXIST AT HIPPOCAMPAL CA3-CA1 SYNAPSES Stéphane H.R. Olicit*, Robert C. Malenka and Roger A. Nicoll. Depts. of Cellular & Molecular Pharmacology, Physiology and Psychiatry; University of California, San Francisco CA 94143-0450. In hippocampal CA1 pyramidal neurons of neonatal rats (3-7 days old), activation of L-type calcium channels paired with the activation of metabotropic glutamate receptors induces a long term depression (LTD) of synaptic efficacy at CA3-CA1 synapses [Science 264: 1148-1152, 1994]. This form of LTD appeared to be independent of NMDA receptor (NMDAR) activation and is not associated with changes in quantal size. Interestingly, hippocampal neurons in culture express a form of LTD with similar properties [Neuron 16:103-111, 1996]. This is different from the homosynaptic LTD typically described in older animals (14-30 days) which requires activation of NMDARs [Neuron 9:967-975, 1992] and is accompanied by a decrease in quantal size [Science 271: 1294-1297, 1996]. It was postulated that the differences between these two forms of LTD is related to the ages of the animals. In order to test this hypothesis, we carried out experiments with rats of different ages (6 to 38 days), using standard electrophysiological techniques. Preliminary results indicate that both forms of LTD coexist in neonatal (6-7 days) and older animals (19-38 days). These two forms could be studied in isolation using either APV or MCPG to respectively block the NMDA-dependent and -independent LTD. We are presently carrying out experiments to determine the interaction between both forms of LTD. Supported by the International Human Frontier Science Program and the NIH.

CALCIUM SIGNALS IN SPINES AND DENDRITES UNDERLYING THE INDUCTION OF HIPPOCAMPAL LONG-TERM DEPRESSION. Y. Kovaichuk, Eilers, J. Lisman* and A. Konnerth. Univ. des Saarlandes, 66421 Homburg, Germany.

We combined whole-cell recordings and ratiometric (nonconfocal) Ca²⁺imaging to determine the postsynaptic Ca²⁺ signals underlying the
induction of homosynaptic long-term depression (LTD) in hippocampal CA1 pyramidal cells. We found that subthreshold conditioning trains (5 Hz, 3 min) were sufficient to reliably induce LTD. With this conditioning protocol, the induction of LTD was associated with an elevation in ICa²⁺I. that was restricted to the active spiny dendrite. Interestingly, during the initial period of stimulation, [Ca2+], levels built up gradually and then partially decayed as stimulation continued. Suprathreshold stimulation produced an LTD of a similar extent, even though the associated Ca²⁺ transient had a larger amplitude and occurred within the entire dendritic tree and in the cell body. Applying confocal imaging, we found that subthreshold excitatory postsynaptic potentials were associated with localized Ca²⁺ transients that could be greatly reduced with AP5. These Ca²⁺ transients were large and fast in active spines, and smaller and slower in the adjacent dendrites indicating that they originated in the spines. During the LTD induction, the fluorescence signals reached about the same peak levels (less than 2 µM) in both the active spines and the adjacent dendritic segments. These results provide strong evidence that synaptic NMDA receptor-mediated Ca²⁺ transients, that are restricted to spines and their adjacent dendrites, are sufficient to induce hippocampal

PRESYNAPTIC LONG-TERM DEPRESSION AT THE HIPPOCAMPAL MOSSY FIBER-CA3 SYNAPSE. K. Kobayashi, T. Manabe* and T. Takahashi. Department of Neurophysiology, Institute for Brain Research, Faculty of Medicine, University of Tokyo, Tokyo 113, Japan.

Long-term potentiation (LTP) and depression (LTD) of synaptic efficacy may underlie learning and memory in the brain. The induction of LTP is postsynaptic in the hippocampal CA1 region, whereas presynaptic in the CA3 region. LTD is also well characterized in the CA1 region, but not in the CA3 region. We found that low-frequency stimulation (1 Hz, 15 min) causes LTD of excitatory synaptic transmission between mossy fibers and CA3 pyramidal cells in mouse hippocampal slices. This LTD was input specific and saturable, and could be reversed by highfrequency stimulation. The LTD induction was blocked by an antagonist of metabotropic glutamate receptors (mGluRs). However, activation of mGluRs alone was not sufficient for the LTD induction, indicating the requirement of additional factor(s). The LTD induction was not suppressed by blockade of postsynaptic depolarization, N-methyl-D-aspartate receptors or L-type Ca2+ channels. These results suggest that the mossy fiber LTD is induced presynaptically by pairing of presynaptic activity and activation of presynaptic mGluRs. The long-term bidirectional regulation of synaptic efficacy at the mossy fiber-CA3 synapse may be important for hippocampal information processing.

POSTSYNAPTIC COMPONENT IN THE MAINTENANCE PHASE OF LONG-TERM DEPRESSION OF THE RAT HIPPOCAMPUS. K. Kato⁽¹⁾, T. Inoue⁽²⁾ * and K. Mikoshiba⁽¹⁾⁽²⁾, (1) Lab. of Physiology, CalcioSignal Net Project, ERATO, JRDC, Meguro-ku, Tokyo 153, JAPAN, (2) Dept. of Molecular Neurobiology, Institute of Medical Science, Univ. of Tokyo, Tokyo 108, JAPAN

We have reported that adenosine is involved in the induction of long-term depression (LTD) in the CA1 region of the rat hippocampus after the application of low frequency stimulation (2 Hz. 15 min; LFS) to the Schaffer Collateral. We have investigated components that composed the depression of field EPSPs. One component which recovered rapidly after LFS could be explained as the depletion of transmitter at presynaptic terminals by the sequential stimulations. Another component which recovered slowly after LFS was eliminated by the application of 1 μ M 8-cyclopentyl-1,3dimethylxanthine (8-CPT), suggesting that an increase of adenosine activity occurs. The other component which lasted more than one hour was the maintenance phase established by the unknown mechanism. Quantum analysis using a whole cell clamp configuration in a slice was introduced to test whether the expression of LTD was maintained at pre or postsynaptic site. This result demonstrates that LTD could be expressed mainly at presynaptic site for 10 to 20 min after LFS. However, this presynaptic expression of LTD was gradually reduced in a while and the post synaptic expression became gradually dominant, we concluded that at least partially LTD is expressed at postsynaptic site and the presynatpic expression could be explained partially by the enhancement of adenosine activity.

INDUCTION AND EXPRESSION MECHANISMS FOR STRIATAL LONG-TERM DEPRESSION S. Choi* and D. M. Lovinger Dept. Mol. Physiol. Biophys., Vanderbilt Univ. Sch. Med., Nashville, TN, 37232.

Repetitive activation of cortical afferent inputs to striatal neurons produces long-term depression (LTD) in striatum. We have studied both the induction and expression mechanisms for striatal LTD using a whole-cell voltage-clamp method in acute striatal slices from 10 - 25-day-old rats. LTD was induced by pairing high frequency striatal slices from 10 - 25-day-old rats. LTD was induced by pairing high frequency stimulation (HFS) at 100 Hz, 1 sec duration along with 1 sec depolarization of the postsynaptic neuron to -10 - 0mV, repeated 4 times at 10 sec intervals. EPSC amplitude was reduced to 54.3±5.3% (n=11) of control by the pairing protocol. LTD was blocked by voltage-clamping the postsynaptic neuron at -80 - -90 mV during HFS (EPSC amplitude=99.96±12.6% of control (n=5)), by dialyzing 10 mM EGTA into the postsynaptic neuron (112±5.4% of control (n=5)) or by bath-applying 10 μM nifedipine (93.5±6.7% of control (n=6)), consistent with the previous finding in adult rats that the induction of striatal LTD depends on postsynaptic calcium influx through L-type calcium channels (Calabresi et al., 1994; J. Neurosci. 14.4871). In order to investigate the expression mechanism of striatal LTD, paired pulse facilitation (PFF) and coefficient of varieties (CV) were measured before and after LTD induction. investigate the expression mechanism of striatal LTD, paired pulse facilitation (PPF) and coefficient of variation (CV) were measured before and after LTD induction. LTD expression was accompanied by increases in PPF and CV (PPF=137.7±7.4% of control, CV=186.9±35.2% [n=11]), suggesting a decrease in release probability during LTD expression. Furthermore, the increases in PPF and CV were inhibited by voltage-clamping the postsynaptic neuron at -80 - -90 mV (PPF=108.8±4.5% of control, CV=108.9±19.3% [n=5]), by dialyzing with EGTA (PPF=107.1±6.4% of control, CV=94.0±9.9% [n=6]), suggesting that the increases in PPF and CV were specific for LTD expression. These observations suggest that, although the induction of striatal LTD is dependent on postsynaptic calcium entry, striatal LTD is expressed. of striatal LTD is dependent on postsynaptic calcium entry, striatal LTD is expressed, at least in part, by a decrease in the probability of transmitter release. ACTIVITY- AND NMDA-DEPENDENT INDUCTION OF LTD OF ENTORHINAL CORTICAL INPUT TO GRANULE CELLS OF THE DENTATE GYRUS, in vivo. M.F. Yeckel and T.W. Berger. Div. of Neurosci., Baylor College of Medicine, Houston, TX. 77030, and Dept. of Biomed. Engineering. and Program in Neurosci., U. of Southern California. Los Angeles, CA 90089.

The ability to induce activity-dependent long-term depression (LTD) in hippocampus of adult animals *in vivo* has proven to be problematic. Only recently has this been demonstrated for synaptic input to CA1 pyramidal neurons (Thiels et al., 1994), and has never been observed for perforant path input to the dentate gyrus. In the experiments described here we adapt stimulation parameters designed to provide coincident activation of NMDA receptors and postsynaptic GABAA inhibition, and shown previously to induce LTD of CA1, to demonstrate for the first time the ability to induce activity-dependent LTD of entorhinal cortical input to granule cells of the dentate gyrus.

Experiments were performed on adult, male New Zealand white rabbits anesthetized continously with halothane. Stimulating electrodes were placed into the ipsilateral angular bundle and optimized for activation of medial perforant path fibers. Using stimulation parameters identical to those for inducing LTD of CA1, paired pulse stimulation of perforant path fibers (100-400 pairs given at a frequency of 0.5-1.0 Hz; 15-30 ms ISI) did not induce LTD of evoked granule cell responses (pop. spike or pop. EPSP; n=10). In an effort to enhance NMDA receptor-activation, pairs of two-pulse bursts (ISIs of 2.5-5 ms; interpair intervals of 15-25 ms) were given at a low frequency (0.5-2 Hz; 100-400 repetitions) to the perforant path. Results showed that this pattern of burst-pair stimulation is capable of inducing LTD of perforant path-evoked granule cell responses (pop. spike or pop. EPSP; n=12). Induction of dentate LTD was blocked in the presence of the NMDA receptor antagonist d-APV (n=5). Burst-pair stimulation of commissural afferents did not depress CA1 responses. Low-frequency stimulation trains (0.5-2.0 Hz; 900 impulses) did not induce LTD for either perforant path input or Supported by NIH, Human Fron. Org., and NIMH. for commissural input (n=10).

DIFFERENTIAL INFLUENCE OF INCUBATION DURATION ON THE EXPRESSION OF HOMOSYNAPTIC LTD AND LTP IN MATURE HIPPOCAMPUS IN VITRO, X. Xie* and T.W. Berger Dept. of Biomedical Engineering and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA 90089.

The capability of expression of long-term depression (LTD) and long-term potentiation (LTP) at perforant path-dentate granule cell synapse was investigated in hippocampal slices of the adult rabbit. LTP could be reliably induced using high frequency stimulation (100 Hz/40 pulses) in all naive slices incubated between 2 to 12 hours with the similar magnitude of increase. In contrast, the probability of inducing LTD with low frequency stimulation (1Hz/900 pulses) was highly dependent on incubation time: LTD could be induced only in slices incubated for more than 4.5 to 5 hours, but not less. The properties of this LTD are much the same as characterized in young animal by others. First, the LTD is input specific. Second, LTD could be reversed by HFS. Third, induction of LTD was NMDA receptor-dependent. We also observed that LTD could only be induced at zero or low concentration of picrotoxin (15 µM), but not at higher concentration (50 µM). The depressed synapse could still support the expression of LTP. In contrast to the LTD, a similar magnitude of depotentiation of LTP could be induced using LFS throughout the 2 to 12 hour time span of our experiments. Our results suggest that although the synaptic weight seems to remain stable during incubation, the capability to increase or decrease it does undergo unparalleled changes. CEREBELLAR LONG-TERM DEPRESSION (LTD) IN TWO ULTRA-REDUCED POSTSYNAPTIC PREPARATIONS THAT LACK DENDRITIC SPINE COMPARTMENTS. K., Narasimhan* and D.J. Linden. Department of Neuroscience, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205. Cerebellar long-term depression (LTD) is a model system of neuronal information

Cerebellar long-term depression (LTD) is a model system of neuronal information storage in which parallel fiber and climbing fiber inputs to a Purkinje neuron (PN), results in a selective and persistent depression of the parallel fiber-PN synapse. A similar phenomenon may be seen in culture when glutamate pulses and PN depolarization, which replace parallel and climbing fiber stimulation respectively, are co-applied. Here we report that LTD may be induced in two ultra-reduced preparations of the PN, an acutely-disassociated preparation which consists of the soma together with a stump of primary dendrite, and a perforated outside-out macropatch of dendritic (but not somatic) membrane. Using an imaging system of sufficient resolution and dynamic range to detect dendritic spines in cultured PNs, no spines could be seen in either acutely dissociated PNs or PN dendritic macropatches. LTD induced by glutamate/depolarization conjunction in these preparations was similar to that seen in the intact PN, in that it was blocked by postsynaptic BAPTA (20 mM), removal of external Ca, application of the PKC inhibitor chelerythrine (10 uM) or the metabotropic glutamate receptor antagonist (+)-MCPG (250 uM). These preparations also retain the property of associativity, as neither glutamate pulses alone nor depolarization alone induced LTD. These findings suggest that the associative computational property of LTD induction cannot depend upon the presence of separate dendritic spine compartments. Furthermore, LTD induction in the dendritic macropatch suggests that somatic/nuclear processes are not required for this process or the initial stages of LTD expression. Supported by PHS MH51106, NARSAD, and the Klingenstein, McKnight and Develbiss Funds.

LONG-TERM POTENTIATION: PHYSIOLOGY V

Depotentiation of a Facilitated Synaptic Response in the *In Vitro* Amygdaloid Slice. H. Li*, S.R. Weiss, D.-M. Chuang, R.M. Post and M.A. Rogawski. Biological Psychiatry Branch, NIMH and Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Low frequency stimulation (LFS) of the amygdala has been shown to block the development of amygdaloid kindling produced by repeated application of a high frequency stimulus (Weiss et al., 1995). In an attempt to elucidate the underlying mechanism, we studied synaptic plasticity in rat amygdala slices *in vitro* using similar stimulation protocols. Synaptic responses were evoked by stimulation of the external capsule (EC) or stria terminalis (ST) and intracellular recordings were performed in the basal lateral nucleus of the amygdala. High frequency stimulation (HFS, 100 Hz for 1 sec) of EC or ST induced posttetanic potentiation (PTP) lasting 1.4 \pm 0.4 min (n = 3) and short-term potentiation (STP) lasting 8.3 \pm 2.6 min(n = 11). STP but not PTP was blocked by 100 μ M APV, an NMDA receptor antagonist. LFS (1 Hz) of ST or EC alone induced an enhancement (154 \pm 7 %, n=6) in the amplitude of synaptic responses that were maintained for > 30 min following termination of the stimulation. In contrast, when LFS was applied following recovery from the transient potentiating effect of HFS, there was a transient enhancement ($126 \pm 4\%$, n=8) of the synaptic response followed by persistent synaptic depression (76 \pm 7% of baseline response, n=8). This depressed synaptic response could be repotentiated by HFS. These studies demonstrate that LFS in the in vitro amygdaloid slice can depotentiate a facilitated synaptic response. This system may allow analysis of the mechanism by which LFS reverses kindling-induced (Supported by NIMH & NINDS/NIH) synaptic plasticity in vivo.

GABA_B RECEPTOR MEDIATED SUPPRESSION OF INDUCTION OF LONG-TERM POTENTIATION (LTP) IN RAT LATERAL SEPTAL NUCLEUS NEURONS. H. Hasuo*, and T. Akasu. Dept. Physiol., Kurume Univ. Sch. Med., 67 Asahi-machi, Kurume 830 Japan.

Intracellular recordings were made from neurons of rat lateral septal nucleus(LSN) in para-sagittal slice preparations which contain both septum and hippocampus. High frequency stimulations (HFS)(100 Hz, n = 40, 4 trains at 10 s intervals) did not produce a long-term potentiation (LTP) of an EPSP but resulted in a LTP of late hyperpolarizing potential (LHP) in the presence of picrotoxin. The induction of LTP of LHP was blocked by AP5 (100 μ M). The monosynaptic LHP evoked in the presence of CNQX (20 μ M) did not show LTP. A GABA_B receptor antagonist (CGP35348 or CGP55845A) blocked an LHP but did not affect the EPSP after induction of LTP of LHP While, the EPSP recorded with Cs-containing electrode or the EPSP recorded in the presence of CGP55845A showed clear LTP after HFS. These data suggest a functional role of GABAR receptors on the LTP of glutamate receptors in principal neurons of rat LSN. (Supported by Grant-in-Aid (C) 07680904, Japan)

NITRIC OXIDE SYNTHASE INHIBITORS BLOCK LTP IN SYMPATHETIC GANGLIA. G. F. Altememi. Reem S. Alhijailan and K. A. Alkadhi*, Department of Pharmacological and Pharmaceutical Sciences, College of Pharmacy, University of Houston, Houston, TX 77204-5515.

The possible role of nitric oxide (NO) in the induction and maintenance of long term potentiation (LTP) in sympathetic ganglia was studied. Transmission in the isolated superior cervical ganglion of rat was evaluated by measuring the postganglionic compound action potential made submaximal by partial block with hexamethonium (0.4 mM). LTP of the nicotinic pathway was induced by a brief train of supramaximal pulses (tetanus, 20Hz for 20 sec) to the preganglionic nerve. The nitric oxide synthase (NOS) inhibitor L-nitro arginine methyl ester (L-NAME, 10 μ M) completely prevented the induction of LTP when superfused 30 min before tetanus. Similar treatment with the inactive isomer D-NAME had no effect on the induction of LTP. However, LTP was fully expressed when L-NAME was superfused in the presence of the NO donor sodium nitroprusside (100 μ M). The effect of L-NAME on the maintenance phase of LTP was tested by superfusing the drug 60 min after tetanus. The NOS inhibitor completely and reversibly blocked the established LTP. Similar results were obtained using another NOS inhibitor NG-nitro-L-arginine (L-NOARG, 0.5 μ M). Neither L-NAME nor sodium nitroprusside had any significant effect on the basal ganglionic (control level) transmission. These results indicate that both the induction and maintenance of LTP in sympathetic ganglia are dependent on the presence of NO (Supported by an LGIA grant from the University of Houston)

597.4

REVERSAL OF LONG-TERM POTENTIATION IN DEEP LAYERS OF LATERAL ENTORHINAL CORTEX FOLLOWING 1Hz OR 5Hz STIMULATION OF CA1/SUBICULAR BORDER. G.A. Cousens* and T. Otto Dept. of Psychology, Rutgers, the State University of New Jersey, New Brunswick, NJ 08903.

Recent investigation has revealed that deep layers (IV-VI) of lateral entorhinal cortex (LEC) support homosynaptic long-term potentiation induced by theta burst stimulation (TBS) of the ipsilateral CAI/subicular border in urethane anesthetized rats. The present study was conducted to determine whether LTP in this pathway could be reversed by 1Hz or 5Hz stimulation.

Stable monosynaptic field EPSPs (mean maximum amplitude, 37mV; mean peak latency, 6.5ms) were recorded in deep layers of LEC from urethane-anesthetized (3mg/kg) male Sprague-Dawley rats (300-400g) following test pulses delivered to the CA1/subicular border. Potentiation of EPSP amplitude following two bouts of TBS (11 bursts [four pulses at 100Hz] separated by 140 ms) was significantly reduced by either 1Hz (300 pulses; n=3) or 5Hz (300 pulses; n=3) stimulation. Preliminary data indicate that 5Hz stimulation tended to reduce potentiated EPSP amplitude slightly more effectively than 1 Hz stimulation. Histological verification of electrode placement is currently underway.

These data are consistent with the idea that LEC supports synaptic plasticity induced by biologically-relevant stimulation and that this plasticity can be modulated by 1Hz or 5Hz single-pulse stimulation. It is unclear at present whether reversal of LTP in deep layers of LEC reflects the same cellular mechanisms involved in long-term depression. (Supported by Busch Biomedical Research Support Grant #649383)

CHARACTERISTICS OF LONG-TERM POTENTIATION OF THE PERIRHINAL CORTEX FOLLOWING STIMULATION OF THE OLFACTORY BULB IN THE CHRONIC PREPARATION. Robert A. Hodgson* and Ronald J. Racine. Department of Psychology, McMaster University, Hamilton, Ontario, Canada, L8S-4K1.

Olfactory bulb (OB) stimulation is known to produce a long-term potentiation (LTP) effect in the OB and piriform cortex in rats in which the monosynaptic component of the response remains unchanged but the late component is potentiated (Stripling and Patneau, 1988). component change is manifested as an increase in field potential amplitude and is thought to reflect selective potentiation of excitatory synapses terminating on inhibitory interneurons. Here we demonstrate a similar effect in the perirhinal cortex (PRh) following OB stimulation. Stimulating and recording electrodes were chronically implanted in the OB and PRh respectively. Thirty 8-pulse trains (pulse frequency: 300 Hz; pulse intensity: $794~\mu\text{A}$; train frequency: 0.1 Hz) were delivered to the OB every This stimulation produced an amplitude increase in the latecomponent of the evoked potential but had no effect on the monosynaptic component. Experimental animals deviated significantly from controls who received identical implants but no high-frequency stimulation. Only one set of trains was required to produce a significant potentiation effect, and asymptotic levels were reached around the sixth day of stimulation. The response showed no significant decay two weeks following the termination of trains.

LONG TERM SYNAPTIC PLASTICITY MODULATES THE MODE OF SIGNALING BETWEEN PYRAMIDAL NEURONS BY REGULATING THE RATE OF ACTIVITY DEPENDENT SYNAPTIC DEPRESSION. M. Tsodyks and H. Markram of the Dept. Neurobiology, The Weizmann Institute for Science, Rehovot. 76100. Israel.

Synaptic transmission between individual neocortical layer 5 pyramidal neurons was examined using whole-cell patch clamp techniques. We discovered that above a certain frequency of synaptic activation (limiting frequency), the synaptic response is inversely proportional to the frequency. An integrated experimental and computational analysis revealed that synapses which depress rapidly reach this limit at low frequencies and are therefore ineffective in transmitting information about the action potential (AP) rate in presynaptic neurons but are very effective at contributing a phasic signal that emerges when a population of presynaptic neurons changes its activity synchronously. On the other hand, synapses that depress slowly reach this limit only at high frequencies and are therefore more effective at conveying rate information and less effective at conveying temporal information. An examination of how the activity dependent properties of these synapses change following simultaneous activation of pre and postsynaptic neurons (Hebbian pairing protocol) revealed that the form of plasticity observed at these synapses change not an unconditional amplification of the gain of the synapse but an activity dependent temporal redistribution of synaptic efficacy (RSE) during a train of presynaptic APs. RSE modulates the rate of synaptic depression and hence the limiting frequency. RSE thus serves to slide the mode of synaptic transmission along a continuum between rate and temporal signaling. The study was supported by research grants from The Henry S. and Ann S. Reich Research Fund for Mental Health and an ONR grant N00014-96-1-0450.

INDUCTION OF LONG-TERM POTENTIATION IN THE INSULAR CORTEX BY AMYGDALA STIMULATION IN VIVO. M.L. Escobar*, V. Chao and F. Bermúdez-Rattoni. Depto. de Neurociencias, Instituto de Fisiología Celular, UNAM, México, D.F. 04510. México.

Long-term potentiation (LTP) is a form of activity-dependent synaptic plasticity that has been investigated mainly in the hippocampus. It is considered likely that similar mechanisms may also account for aspects of naturally occurring plasticity in the neocortex. The agranular insular cortex (IC), a region of the temporal cortex in the rat, corresponding to Krieg's areas 13 and 14, has been implicated as a neural substrate of Conditioned Taste Aversion and recently, it has been also involved in the acquisition and consolidation of spatial and inhibitory avoidance learning tasks. The IC receives direct projections from the basolateral (Bla) amygdaloid nucleus and it is established that both the amygdaloid complex and the IC contribute to the formation and retention of taste-illness memories. The aim of the present study was to examine whether LTP can be induced in vivo in the adult rat IC stimulating the amygdalocortical projections from basolateral amigdaloid nucleus. Seven adult male Wistar rats weighing 350-400g were used. IC responses were recorded by using a monopolar stainless steel recording electrode placed in the IC stereotaxic coordinates (AP 1.2, ML 5.5, DV 7). Responses were evoked via direct stimulation of the Bla, using a stainless steel monopolar stimulating electrode at coordinates (AP 2.8, ML 5.0, DV 8.5). Low frequency responses were evoked once every 20 sec throughout a 20 min baseline period. The current intensity that elicited a 50% maximal response was determined and used for all subsequent stimulation, including induction of LTP. The IC field EPSP consisted of small (approximately 0.4 mV) potentials elicited with (50-60μA) current intensities. Tetanic stimulation (1 sec trains of 100 Hz) to the Bla induced LTP in the IC, increasing significantly (50%) synaptic responses to low frequency stimulation during a period of at least 1 hr after conditioning training. These results demonstrate that IC LTP can be induced in vivo in adult rats by tetanic stimulation of afferent projections from amygdaloid complex. DGAPA IN 206095

THE EFFECT OF LTP-INDUCTION ON THE RESPONSE TO OLFACTORY CUES IN THE OLFACTORY SYSTEM IN THE RAT. Y. Xu^{1,2}, R.J. Racine², S. Haykin¹, C.A. Chapman² and M. Fahnestock^{4,3}. Communication Research Lab.¹, Dept. Of Psychology², Dept. Of Biomedical Science³, McMaster University, Hamilton, Ontario, Canada, L8S 4K1.

To test the effects of enhanced synaptic connections in the olfactory system on the processing of olfactory signals, we induced long-term potentiation (LTP) at several points in a polysynaptic circuit running from the olfactory bulb to the dentate gyrus of the hippocampus. EEGs were recorded from indwelling electrodes in the olfactory bulb, piriform cortex, entorhinal cortex and dentate gyrus, and analysed using multichannel spectral analysis before and after the induction of LTP. Toluene, a volatile solvent, was used as the olfactory stimulus. After extended baseline recording, LTP was induced by tetanizing, in succession, the entorhinal cortex, piriform cortex and olfactory bulb. Test field potentials were reliably enhanced in the dentate gyrus, entorhinal cortex and piriform cortex, respectively. Prior to LTP induction, exposure to toluene triggered an oscillatory response in all recording sites which lasted about 0.5-2.0 sec. Power spectra revealed a dominant frequency of about 20 Hz. Coherence between all pairs of recording sites was also maximal at 20 Hz during the toluene presentation. Following the induction of LTP, there was little or no change in power or coherence of spontaneous EEG. However, there was a significant reduction in power and coherence in the toluene-induced signal following LTP induction. The dominant frequency of the oscillation also shifted from 20 Hz to about 30 Hz. We are currently investigating the possibility that the decreased power and coherence reflect a context-dependency for the activation patterns that express response potentiation.

A NOVEL ACTION FOR ACETYLCHOLINE (ACh) - MODULATING THE MODE OF SIGNALING BETWEEN PYRAMIDAL NEURONS BY CHANGING THE RATE OF ACTIVITY DEPENDENT SYNAPTIC DEPRESSION. <u>H. Markram</u>* and <u>M. Tsodyks</u> of the Dept. Neurobiology, The Weizmann Institute for Science, Rehovot, 76100, Israel.

We discovered that in synapses between two neocortical pyramidal neurons, the amplitude of the postsynaptic response decreases inversely proportional to the frequency at which the synapse is activated once a certain frequency threshold is crossed (the limiting frequency). We examined the effect of ACh on this unique synaptic property using whole-cell patch clamp techniques. We found that ACh did not merely inhibit synaptic transmission while present, as usually assumed, but rather decreased the rate at which the synaptic response depressed during a train of presynaptic action potentials (APs). The effect of ACh therefore is an activity dependent temporal redistribution of synaptic efficacy. An integrated experimental and computational analysis revealed that synapses which depress rapidly are ineffective in transmitting information about presynaptic AP rates but are very effective at contributing a phasic signal that emerges at the moments when a population of presynaptic neurons changes its activity. On the other hand, synapses that depress slowly are more effective acconveying temporal information. ACh therefore serves to slide the mode of synaptic transmission along a continuum away from temporal signaling towards rate signaling. The effect of ACh is the inverse of the synaptic plasticity observed when the pre and postsynaptic neurons are activated simultaneously. The study was supported by research grants from The Henry S. and Ann S. Reich Research Fund for Mental Health and an ONR grant N00014–96-1-0450.

NMDA-RECEPTOR DEPENDENT LONG-TERM POTENTIATION (LTP) IN THE ADULT RAT VISUAL CORTEX IN VIVO . A.J. Heynen, L.N Cooper*, and M.F. Bear. HHMI/Department of Neuroscience, Brown University, Providence, RI 02912.

Previous studies have demonstrated that LTP of synaptic responses can be induced in the visual cortex *in vitro*. This synaptic enhancement has been shown to be long-lasting, input-specific and dependent on *N*-methyl-D-aspartate (NMDA) receptor activation. In order to determine whether a similar form of synaptic enhancement is present in the intact animal, LTP induction was studied in the adult rat *in vivo*. Male Long-Evans rats (250-400 g) under pentobarbital anesthesia (65 mg/kg i.p.) had a recording electrode positioned in the superficial layers (II/III) of visual cortex and a concentric bipolar stimulating electrode positioned in the ipsilateral lateral geniculate nucleus (LGN). Negative field potentials (FPs) with a latency-to-peak of -13 ms were recorded in response to 0.2 ms stimulus pulses (50-150 µA) delivered to the LGN. FPs were monitored for 60 min. prior to application of theta-burst stimulation (TBS), which previous work has shown to yield robust synaptic potentiation in rat visual cortex *in vitro*. A significant potentiation in the amplitude of synaptic responses was consistently observed following TBS (FP amplitude 60 min. post-TBS = 141.6 ± 8.3 % of baseline; n = 11). TBS-induced LTP was prevented by prior application of the competitive NMDA-receptor antagonist CPP ((±)-3-(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid, 10 mg/kg i.p.; n = 4). In order to determine the duration of LTP, responses were monitored for up to 11 hrs following application of TBS (n = 4). In all cases LTP remained stable for as long as the preparation was viable. Together these results demonstrate that the characteristic properties of LTP observed in slices of visual cortex are also present in the adult visual cortex *in vivo*.

NMDA-INDUCED SYNAPTIC DEPRESSION IN THE CA1 REGION OF THE HIPPOCAMPUS. <u>H.-K. Lee* and M.F. Bear.</u> Dept. of Neuroscience and Howard Hughes Medical Institute, Brown University, Providence, RI 02912. Induction of homosynaptic LTD in CA1 requires activation of NMDA receptors. However, whether NMDA receptor activation is sufficient to induce LTD is not

Induction of homosynaptic LTD in CA1 requires activation of NMDA receptors. However, whether NMDA receptor activation is sufficient to induce LTD is not known. To examine this issue, we studied Schaffer collateral \rightarrow CA1 synaptic transmission in hippocampal slices prepared from young adult rats. Bath application of NMDA (20 μ M, 3 min) produced a reliable long lasting decrease in field EPSPs (81 \pm 2 % of baseline slope, 1 hr post-NMDA application, n = 32 slices). NMDA-induced depression was not stimulation dependent (n = 5), did not require CA3 (n = 6), and occurred in slices maintained both in interface (n = 3) and submersion (n = 6). Occlusion experiments were performed to test if NMDA-induced depression shares similar mechanisms with homosynaptic LTD. Saturation of homosynaptic LTD with several episodes of 1 Hz (900 pulses) stimulation significantly (P < 0.01) reduced the magnitude of NMDA-induced depression (90 \pm 1%, n = 5). However, NMDA-induced depression (17 \pm 2%, n = 5). However, NMDA-induced depression (01 \pm 1M okadiac acid (OKA) did not block NMDA-induced depression of 1 \pm 1M okadiac acid (OKA) did not block NMDA-induced depression of 1 \pm 1M okadiac acid (OKA) did not block NMDA-induced depression of 1 \pm 1M okadiac acid (OKA) did not block NMDA-induced depression of the EPSP was not caused solely by excitotoxic cell loss. Interestingly, however, the decrease in the intracellular EPSP was accompanied by a persistent increase in input resistance. To reduce the possible complication of NMDA toxicity, we tried a lower concentration of NMDA (10 \pm 10 min). Depression was not reliably induced by a single application of NMDA (99 \pm 3%, n = 11 slices), but multiple applications did lead to a measurable depression (83 \pm 3%, measured 20 min post-third NMDA application, n = 4 slices), which showed saturation. Currently, we are testing if 10 \pm 1M of 10 min). Depression was not reliably induced by a HIMI)

LONG-TERM POTENTIATION IN THE NEOCORTEX: EVIDENCE SUGGESTING THAT PERIRHINAL CORTEX MAY PLAY A ROLE IN MEMORY AND PRECONSOLIDATION MEMORY STORAGE, T.L. Ivanco*, M. Michelin, and R.J. Racine. Department Of Psychology. McMaster University. Hamilton, ON, Canada, L8S-4K1.

The hippocampal region, and the entorhinal, perirhinal, and

The hippocampal region, and the entorhinal, perirhinal, and parahippocampal cortices, have been widely cited for their involvement in information storage. There are extensive reciprocal connections between the structures in this system, and between this system and the neocortex. Although LTP has been extensively studied in the *intrinsic* connections of both the hippocampus and neocortex. LTP in the pathways conveying information between these systems have received little attention. Otto and Eichenbaum (1994) previously reported a potentiation effect in the perirhinal cortex following hippocampal stimulation. The current study was designed to investigate LTP in projections from the perirhinal cortex to the frontal cortex in chronically implanted male Long-Evans rats. Multi-session procedures were used to induce LTP as described by Racine et al. (1995). The main finding was a significant long-term potentiation of the polysynaptic components of the response evoked in the neocortex by perirhinal cortex stimulation. Several sessions were required to achieve asymptotic levels of potentiation. We suggest that perirhinal cortex activation may promote enhancement in cortico-cortical pathways secondarily activated by perirhinal inputs.

CONSOLIDATION INTERVAL PLAYS A CRITICAL ROLE IN THE INDUCTION OF NEOCORTICAL LONG-TERM POTENTIATION IN THE ADULT, BEHAVING ANIMAL. Christopher Trepel*, David J. Froc. Robert A. Hodgson and Ronald J. Racine. Department of Psychology, McMaster University, Hamilton, Ontario, Canada, 188-4K1.

The neocortex is widely held to be a primary site for the storage of long-term memory and is believed to store information through many repetitions of similar acts of information processing, producing gradual, incremental changes in the synaptic connections between neurons. Here we demonstrate that the induction of neocortical LTP in the chronically prepared animal follows rules similar to those for the consolidation of memory. Stimulating and recording electrodes were implanted into the corpus callosum and anterior neocortex (parietal area 1), respectively. LTP-inducing stimulation sessions consisted of sixty 8-pulse, 24 ms trains (pulse frequency: 300 Hz; pulse intensity: $1259 \mu A$; train frequency: 0.1 Hz). Three groups of animals received stimulation sessions at varying intervals for 10 days: Once every 6 hours (6h, n=5), once every 12 hours (12h, n=5) and once every 24 hours (24h, n=6). A fourth, control group was implanted but received no trains (n=4). Relative to controls, all stimulated groups showed potentiation of both the early (~10.0 ms to peak) and late (~20.0 ms to peak) components of the evoked response. Population spike enhancement was also clear. After 4 stimulation sessions (or a total of 240 trains), none of the 6h animals showed increases in late component amplitude, while the 12h and 24h groups both showed clear increases. Following 8 stimulation sessions, 3/5 of the 6h animals showed an increase in late component amplitude. Over the 10 day induction period, the 24h group received the fewest number of LTP-inducing trains but showed the largest late component potentiation, followed by the 12h and 6h groups, respectively. There were no differences in early component potentiation between the groups over days. These data demonstrate that the stimulus interval is critical for the induction of neocortical long-term potentiation and offer physiological support for the hypothesis that an incremental consolidation process is essential for information storage in the neocortex

ACTIVITY DEPENDENT SYNAPTIC PLASTICITY - A PROPERTY COMMON TO ALL LAYERS OF ADULT MOTOR CORTEX? M.-S. Riout-Pedotti' and J.P. Poppodius Dept of Neuroscience Prove University Providence B 10/2912

Donoghue. Dept. of Neuroscience, Brown University, Providence, RI 02912.

We have previously shown that LTP and LTD can be induced in motor cortex layer II/III horizontal connections (Hess & Donoghue, 1994). Is the capacity to produce long term synaptic changes common to all layers of motor cortex or is it restricted to certain motor cortical neurons? Here we have investigated plasticity of horizontal pathways that synapse within layer I upon the apical dendrites of layer III and V pyramidal neurons.

Extracellular fieldpotentials to layer I stimulation were recorded in layer I at

Extracellular fieldpotentials to layer 1 stimulation were recorded in layer 1 at distances of .5 mm and 1 mm in parasagittal slices of adult rat motor cortex. Simultaneously, EPSPs were recorded intracellularly from layer III and V pyramidal cells vertically below the field potential recording electrode. High frequency stimulation (HFS) to one or two horizontally displaced sites, routinely did not induce LTP in layer 1 (N=5). However, if the GABAA

High frequency stimulation (HFS) to one or two horizontally displaced sites, routinely did not induce LTP in layer I (N=5). However, if the GABAA antagonist bicuculline was applied focally (1 min., 3.5 mM) at the recording site immediately before HFS, the tetanized pathway was potentiated for at least one hour while an unstimulated control pathway remained unchanged (N=5). LTP could be saturated (N=5) and reversed (N=5) by application of low frequency stimulation (LFS). Layer III (N=10) as well as layer V (N=8) neurons produce EPSPs to layer I stimulation, indicating that intra- as well as extracortical neurons have the potential to produce long term synaptic plasticity in layer I. LFS applied to naive connections in layer I produced horizontal LTD of layer I fields (N=5) and additionally of layer III and V pyramidal cell EPSPs, indicating that plasticity of connections in layer I can influence neurons in superficial and deep layers.

These data indicate that the potential for synaptic plasticity in the rat motor cortex is spread across multiple connection pathways and includes both intracortically projecting and output neurons. Supported by NS22517.

NEOCORTICAL LONG-TERM POTENTIATION IN THE ADULT, BEHAVING RAT: INDUCTION AND COOPERATIVITY EFFECTS FOLLOWING MINIMAL WHITE MATTER STIMULATION.

Ronald J. Racine*, David J. Froc and Christopher Trepel. Department of Psychology, McMaster University, Hamilton, Ontario, Canada, L8S-4K1.

While the neocortex is believed to be a primary site for information storage in behaving animals, it has proven resistant to the induction of long-term potentiation (LTP). We have recently shown that LTP can be reliably induced in the neocortex of awake, freely moving animals if multiple sessions of high-frequency stimulation are applied, and we are currently using these procedures to further investigate the properties of neocortical LTP. Here we report that LTP can be induced in the neocortex following the spaced activation of white matter afferents with tetanizing trains of minimal intensity. We also report that LTP induction requires a threshold level of afferent coactivity (cooperativity). Stimulating and recording electrodes were implanted into the corpus callosum and parietal area 1, respectively. Daily LTP-inducing stimulation consisted of thirty 8-pulse, 24 ms trains (pulse frequency: 300 Hz; train frequency: 0.1 Hz). Four groups of animals received trains of varying pulse intensities: $16~\mu\Lambda$ (single pulses at this intensity evoke early component responses that are 5-10% of maximum amplitude), 32 μ A (single pulses trigger responses 8-14% of maximum), 159 μ A and 501 μ A. A fifth, control group was implanted but received no trains. Relative to controls, all groups showed potentiation of the early (~10.0 ms to peak) component, although the changes were small in the 16 μ A and 32 μ A groups. Population spike enhancement was also clear in the 159 μ A and 501 μ A groups within 1 week of train delivery. All but the 16 μ A group showed a reliable enhancement of the late (-20.0 ms to peak) component. Even in the 16 μ A group 3800cu a female eminatement of the late (-20.0 ms to peak) component. Even in the 16 μ A group, 25% of the animals showed a potentiated late component. Therefore, a threshold for the induction of potentiation appears to exist around the 16 µA mark, indicating a cooperative LTP effect. Moreover, 32 μ A trains reliably induced potentiation effects in both components in the adult, freely moving animal, indicating that white matter stimulation is an effective, low threshold means of inducing LTP in this preparation, as long as the stimulation sessions are spaced and repeated.
