The plasma branched-chain amino acid (BCAA)/aromatic amino acid (AAA) molar ratio was examined in relation to cognitive dysfunction and alcohol withdrawal symptoms in 40 alcoholics. Plasma amino acids were examined with a programmed Hitachi 835-50 Amino Acid Analyzer. Cognitive functions were examined using the number connection test and performance tests (digit symbol test, block design test) of the Wechsler adult intelligence scale (WAIS). Plasma amino acids and cognitive function test were performed after alcohol withdrawal state. The BCAA/AAA molar ratio in alcoholics was significantly lower than that in controls (normal volunteers). The BCAA/AAA molar ratio in patients with transient hallucinations or delirium tremens was significantly lower than that in patients without these symptoms. The BCAA/AAA molar ratio had correlations with the values of liver function tests. The BCAA/AAA molar ratio had positive correlations with the scores of the performance tests of WAIS in patients with delirium tremens. These results indicate that abnormalities of amino acid metabolism caused by liver damage may have an important role in the cognitive dysfunction of alcohol dependence.

EXPRESSION OF GABAA RECEPTOR ISOFORMS IN ALCOHOLISM.

EXPRESSION OF GABAA RECEPTOR ISOFORMS IN ALCOHOLISM. I. M. Lewohl*, D. I. Crane and P. R. Dodd. CRC Laboratory, Royal Brisbane Hospital Foundation, Q 4029, and Faculty of Science and Technology, Griffith University, Q 4111, Australia. Chronic and excessive alcohol abuse leads to a selective loss of neurones in the superior frontal cortex and is accompanied alterations in GABAA receptors. These receptors are pentameric protein complexes composed of a number of isoforms designated α₁-6, β₁₋₄, γ₁₋₃, δ and ρ₁₋₂. Combinations of subunits form receptors which differ in their pharmacological properties and regional distribution. Thus, variations in subunit expression may account for the differences in GABA neurotransmission characteristic of long-term alcoholism. The expression of the α isoforms of the GABAA receptor was analysed by competitive RT/PCR using primers designed from the conserved regions of α₁₋₃. Total RNA was extracted from the superior frontal and motor cortices of 6 control (<20g ethanol/day) halcoholic and 4 alcoholic-cirnotic cases (>80g ethanol/day) matched for age and post-mortem delay. No significant differences were found in the expression of α₁, α₂ or α₃ between case group. However, the profile of α expression was shown to be significantly different between the case groups (F_{8,5}=3,37, p=0.0035) with no difference between frontal and motor cortices. The difference in α expression may reflect an alteration in the subnomulation of GABAA receptors in the brains of alcoholics. p=0.0035) with no difference between frontal and intooic collects. In a difference in α expression may reflect an alteration in the subpopulation of GABA_A receptors in the brains of alcoholics irrespective of cirrhosis. The subunit composition and functional characteristics of GABA_A receptors in alcoholic and alcoholic-cirrhotic cases is currently being elucidated.

DEPRESSION, ALCOHOL USE, AND NEUROCHEMICAL LEVELS IN A SAMPLE OF COLLEGE UNDERGRADUATES. J. Walter, M. D. Anderson, V. Chandhoke, & J. M. Flinn*. Department of Psychology & The Shared Instrumentation Facility, George Mason University, Fairfax, Virginia 22030.

Nessarch Instrumentation Facility, George Misson University, Fairrax, Virginia 22030.

This research seeks to examine the relationship between serotonin and dopamine pathways and depression and alcohol use, in a sample of undergraduate male college students from two universities. Subjects were divided into minimal (n=15) and heavy (n=17) drinking groups, based on current alcohol use as evaluated using the Substance Abuse Subtle Screening Inventory (SASSI), Alcohol Use Disorders Identification Test (AUDIT), and self-report of drinking patterns. Some students were drawn from an alcohol education program, others volunteered to meet a research requirement. Of the volunteer group, over 30% were determined to be at high risk for alcohol abuse. Depression was assessed using Beck's Depression Inventory (BDI). Tryptophan and tyrosine pathways were evaluated using HPLC measures of urine.

Significant correlations were observed between alcohol consumption and depression as measured by AUDIT and BDI respectively (r = .377, p < .025). Analyses of neurochemical levels to date show that depression correlated significantly with urinary levels of dopamine (r = .336, p < .05), HIAA

Analyses of neurocnemical levels to date show that depression correlated significantly with urinary levels of dopamine (r = -336, p < .05), HIAA (r = -310, p < .05), and there was a trend for HVA (r = .258, p < .10). However, no significant correlations were observed between AUDIT scores and these neurochemicals.

DRUGS OF ABUSE: AMPHETAMINES III

REVERSE DIALYSIS APPLICATION OF AMPHETAMINE PRODUCES A DELAYED, SUSTAINED INCREASE IN EXTRACELLULAR GLUTAMATE LEVELS IN RAT VENTRAL TEGMENTAL AREA. M.E. Wolf* and C.J. Xue. Department of Neuroscience, Finch Univ. of Health Sciences/The Chicago Medical School, North Chicago, IL 60064.

Considerable evidence supports the idea that excitatory amino acid (EAA)containing projections from the prefrontal cortex (PFC) to the ventral tegmental area (VTA) are important in the development of behavioral sensitization to amphetamine We have shown previously that systemic AMPH produces a delayed, sustained increase in extracellular glutamate levels in the VTA that reaches statistical significance 2-3 hrs after AMPH injection and is prevented by haloperidol (Xue et all, J. Neurochem, in press). We speculated that repeated elevation of VTA glutamate levels upon repeated AMPH injection elicits compensatory changes in EAA receptors in the VTA which contribute to the development of behavioral sensitization. In the present study, reverse dialysis application of AMPH in the VTA (1-100 μ M for 1 hr) was similarly found to elicit a delayed, sustained increase in extracellular glutamate levels which commenced after return to normal perfusion solution. This effect was mimicked by SKF 38393 but not quinpirole, prevented by SCH 23390, and observed in both water- and AMPH-pretreated rats. Both systemic and intra-VTA AMPH elicit sensitization when administered repeatedly, so neurochemical changes associated with both routes of administration, such as the delayed increase in VTA glutamate levels, are good candidates for a role in sensitization. Interestingly, some rats exhibited a decrease in glutamate levels during reverse dialysis application of AMPH in the VTA, an effect not noted after systemic AMPH. Experiments are in progress to further characterize this phenomenon. Supported by USPHS grant DA07735 from NIDA.

EFFECTS OF THE AMPA RECEPTOR ANTAGONIST NBQX ON BASAL AND AMPHETAMINE-INDUCED INCREASES IN LOCOMOTION AND RAT NUCLEUS ACCUMBENS DOPAMINE OVERFLOW. P. Vezina* Department of Psychiatry, The University of Chicago, Chicago, IL 60637

In vivo microdialysis in the freely moving rat was used to assess the effects of the AMPA receptor antagonist NBQX (2,3-dihydroxy-6-nitro-7sulfamoyl-benzo(f)quinoxaline, 30 mg/kg, i.p.) on the nucleus accumbens (NAcc) dopamine (DA) overflow and locomotor activity observed following acute systemic injections of either saline or amphetamine (1.0 mg/kg, i.p.) Measurement of the DA recovered in 20 min dialysate samples was assayed with HPLC-EC. Locomotor activity was estimated by photocell beam interruptions. NBQX produced no effect on extracellular levels of DA in the NAcc nor did it produce locomotor effects of its own. NBQX also did not affect the increase in NAcc DA levels produced by amphetamine when the latter was injected 40 min later. However, NBQX completely blocked the increased locomotion produced by amphetamine. These findings are consistent with the view that NBQX can act at sites postsynaptic to DA neuron terminals in the NAcc to influence acute amphetamine-induced locomotion. In a separate experiment, NBQX repeatedly injected with amphetamine blocked the development of locomotor sensitization normally produced by amphetamine. These results suggest an additional role for AMPA receptors in the production of locomotor sensitization by amphetamine. AMPA receptors may be recruited by the DA that is released by amphetamine in the ventral tegmental area, where it is known to act to produce locomotor sensitization

THE EFFECT OF REPEATED AMPHETAMINE ADMINISTRATION ON THE EXPRESSION OF NMDAR1 mRNA IN RAT VENTRAL TEGMENTAL AREA, NUCLEUS ACCUMBENS AND MEDIAL PREFRONTAL CORTEX. W.X. Lu*, L.M. Monteggia, C.-J. Xue and M.E. Wolf. Department of Neuroscience, Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL

Behavioral sensitization to amphetamine (AMPH) is associated with alterations in glutamate transmission in perikarya (ventral tegmental area, VTA) and terminal regions (nucleus accumbens, NAc) of the mesoaccumbens dopamine system. The medial prefrontal cortex (mPFC) is an origin of glutamate projections that regulate the mesoaccumbens dopamine system. We have recently found changes in mRNAs for AMPA receptor subunits in NAc and mPFC of AMPH sensitized rats (W. Lu et al, J. Neuroscience, submitted). The present study examines the expression of mRNA for the NMDA receptor subunit NR1 in VTA, NAc and mPFC of AMPH mRNA for the NMDA receptor subunit NR1 in V1A, NAC and mPrC of AMPH sensitized rates. Rats are treated for 5 days with 5 mg/kg/day AMPH sulphate or vehicle (control), and perfused 3 or 14 days after last injection. A novel in situ hybridization method (Lu et al, J. Neurosci. Meth. 65:69-76,1996) with two ³⁵S-labeled oligonucleotide probes (complementary to nucleotides 375-420 and 1011-1056; DuPont, PA) was used to examine NR1 mRNAs in NAc and mPFC. NIH Image computer software was used for quantitative analysis of autoradiographs. In NAc, levels of NRI mRNA were decreased in the repeated AMPH group after 14 days withdrawal (74.8±7.7% of control group; P<0.05), but not after 3 days withdrawal. In mPFC, no change in NRI mRNA was found at 3 days withdrawal, but a significant reduction was observed in the repeated AMPH group tested after 14 days withdrawal (76.1±7.1% of control group; P<0.05). Because of relatively low NR1 mRNA levels in VTA, parallel studies are in progress using alternative techniques with greater sensitivity, including nuclease protection assays and in situ hybridization with an NR1 ribonucleotide probe (801 Sty1-1401 Xho1). Our results, along with others reported previously, suggest that adaptations in excitatory amino acid transmission accompany AMPH sensitization. Supported by NIDA grant DA 07735.

EFFECT OF REPEATED AMPHETAMINE TREATMENT ON MRNA LEVELS FOR AMPA GLUTAMATE RECEPTOR SUBUNITS IN VENTRAL MESENCEPHALON.

EFFECT OF REPEATED AWHHETAMINE TREATMENT ON MRNA LEVELS FOR AMPA GLUTAMATE RECEPTOR SUBUNITS IN VENTRAL MESENCEPHALON. M.T. Bardo*, B.A. Mattinqly, P.M. Robinet and J.E. Margulies. Dept. Psychol., Univ. Kentucky, Lexington, KY 40506, Dept. Psychol., Morehead St. Univ., Morehead, KY 40516, Dept. Psychol., Univ. Hawaii, Honolulu, HI 96822. Previous work has shown that repeated amphetamine treatment decreases mRNA levels for the GluR2 AMPA glutamate receptor subunit in the nucleus accumbens. The present study examined the effect of amphetamine on GluR2 mRNA levels in the ventral mesencephalon containing the A9/A10 dopaminergic cell bodies that innervate the striatum and nucleus accumbens. Rats received amphetamine (1.25 mg/kg, i.p., once daily) for 10 consecutive days and were tested for locomotor activity after each injection. The locomotor stimulant effect of amphetamine was enhanced across repeated injections; on the tenth injection, amphetamine treated rats displayed a 5-fold higher level of activity than saline controls. Following the last locomotor test, rats were killed and the ventral mesencephalon was dissected for analysis of GluR2 mRNA levels using an RNase protection assay in which a riboprobe for GluR2 was transcribed from a 3' fragment of GluR2 mRNA levels in the ventral mesencephalon compared to saline controls. These results suggest that regulatory processes involving AMPA receptor subunits in the ventral mesencephalon, as well as in the nucleus accumbens, may be related to the development of locomotor sensitization produced by repeated amphetamine treatment.

AMPHETAMINE PERFUSION INTO THE NUCLEUS ACCUMBENS INCREASES EXTRACELLULAR GLUTAMATE. A. Dalia, D.M. Weinstein, N.J. Urestky, and L.J. Wallace. College of Pharmacy, The Ohio State University, Columbus, OH 43210.

Psychostimulant drug induced locomotor activity (LMA) and reward appear to require activation of dopaminergic receptors and glutamatergic receptors in the nucleus accumbens (NAC). Consistent with this hypothesis, systemic cocaine or amphetamine increases extracellular glutamate in the NAC as measured by in vivo dialysis. This study determines whether activation of dopaminergic receptors in the NAC increases glutamate levels in this brain area. Amphetamine administration through a dialysis probe stimulated LMA and increased extracellular glutamate. Both responses were blocked by prior systemic injection of the non-specific DA antagonist haloperidol, by the D1 antagonist SCH23390, or by the D2 antagonist eticlopride. Administration of the D1 agonist SKF38393 and the D2 agonist quinpirole together through the dialysis probe stimulated LMA and increased extracellular glutamate. The glutamate uptake inhibitor D1-threo-B-hydroxy-aspartate also increased extracellular glutamate but did not stimulate LMA. Systemic caffeine stimulated LMA without increasing extracellular glutamate in the NAC. These data demonstrate that the combined activation of D1 and D2 dopaminergic receptors in the NAC increases the level of extracellular glutamate in this area and that increased levels of glutamate do not correlate with stimulation of LMA. (NIH grants DA06776 and DA7722)

ELECTROPHYSIOLOGICAL AND CONFOCAL STUDIES ON AMPHETAMINE ELICITED POTENTIAL CHANGES IN SNAIL NEURONS. M.C.Tsai*and Y.H.Chen. Department of Pharmacology, College of Medicine, National Taiwan University, Taipei, Taiwan.

National Taiwan University, Taipei, Taiwan,

The role of the intracellular calcium ions on the bursting firing of action potentials in central neurons elicited by amphetamine was studied in the identified RP4 neuron of the African snail, Achatina fulica Ferussac. Confocal microscopy revealed the localization of the neuron. Bursting activity of the potentials was elicited by amphetamine if amphetamine was applied either extracellularly or intracellularly. The bursting firing of potentials was decreased following either intracellular injection with EGTA or magnesium ions or extracellularly application of lanthanum ions. Intracellular injection of calcium ions elicited bursting activity of potentials in the RP4 neuron, however, intracellular injection of calcium ions did not prolong the duration of the bursting firing of action potentials elicited by amphetamine. It is concluded that the bursting activity of potentials elicited by amphetamine is associated with intracellular calcium ions. (Supported by grants NSC-84-2331-B-002-107 and NSC-85-2331-B-002-289 from National Science Council, Taipei, Taiwan, R.O.C.).

METHYLENEDIOXYMETHAMPHETAMINE-INDUCED INHIBITION OF NEURONAL FIRING IN THE NUCLEUS ACCUMBENS IS MEDIATED BY BOTH SEROTIONIN AND DOPAMINE T. Obradovic*, K. M. Imel and S. R. White. Dept. of Veterinary and Comparative Anatomy, Pharmacology and Physiology and Program in Pharmacology and Toxicology, Washington State University, Pullman, WA 99164.

Methylenedioxymethamphetamine (MDMA) is a mood elevating drug that cause an increase in extracellular concentrations of dopamine (DA) and serotonin (5HT) and depresses glutamate-driven firing of neurons in nucleus accumbens (White et al., Neurosci. 62: 41, 1994). The purpose of this study was to investigate whether the inhibitory effect of MDMA on neuronal activity in the accumbens may be mediated by DA, 5HT or both monoamines. Multibarrel micropipettes were used for extracellular recording combined with microiontophoresis in the core region of the nucleus accumbens of urethane-anesthetized rats. Fluoxetine, which prevents MDMA-induced 5HT release, significantly attenuated MDMA-induced inhibition of glutamate-evoked firing in the accumbens. The 5HT antagonists ketanserin, methysergide and WAY 100135 also significantly attenuated the MDMA-induced inhibition and the inhibition was mimicked by 5HT agonists that are relatively selective for 5HT_{1A}, 5HT_{1B}, 5HT_{2A}, $_{2C}$ and $5\mathrm{HT}_3$ receptor subtypes. These observations suggest that MDMA-induced inhibition in the accumbens is mediated at least in part by $5\mathrm{HT}$ receptors. However, depletion of DA by pretreatment with the neurotoxin 6-hydroxydopamine and the synthesis inhibitor α-methyl-p-tyrosine significantly attenuated the MDMA-induced inhibition without altering 5HT-induced inhibition of cells in accumbens. These data suggest that MDMA depression of neuronal excitability in the nucleus accumbens core is mediated by both 5HT and DA receptors. Furthermore, multiple 5HT receptor subtypes appear to be involved in the inhibitory effect of MDMA. This work was supported by NIH grant DA08116.

CHARACTERIZATION OF SINGLE-UNIT ACTIVITY IN THE SUBSTANTIA NIGRA PARS RETICULATA OF FREELY MOVING RATS. <u>J. M. Gulley* and G. V. Rebec.</u> Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

We have previously shown that the firing rates of motor- and nonmotorrelated neurons in the striatum of ambulant rats increase and decrease,
respectively, after systemic administration of amphetamine and other
psychomotor stimulants (Haracz et al, Neurosci. Biobehav. Rev., 17:1,
1993; White et al., J. Neural Transm., 102:99, 1995). In the present study,
we extended this line of investigation to the substantia nigra pars reticulata
(SNr), which receives both direct and indirect projections from the striatum.
Under conditions of quiet rest, SNr neurons discharged at relatively rapid
rates (20-40 impulses/sec), but showed complex changes (increases,
decreases, or no changes) during periods of movement. Amphetamine (1.0
mg/kg, sc), in contrast, routinely produced increases in firing rates, and
these effects were blocked by subsequent administration of haloperiod (1.0
mg/kg, sc). These preliminary results indicate that no simple relationship
exists between neuronal activity in the SNr and that seen in the striatum.

DOPAMINE BUT NOT GABA INHIBITION IS BLUNTED IN THE NUCLEUS ACCUMBENS CORE FOLLOWING REPEATED ADMINISTRATION OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA). S.R. White*, T. Obradovic and K. M. Imel. Dept. of Veterinary and Comparative Anatomy, Pharmacology and Physiology and Program in Pharmacology and Toxicology, Washington State University, Pullman, WA 99164.

We have previously reported that repeated exposure to the euphoria-inducing drug MDMA (ecstasy) attenuates the inhibitory effects of dopamine (DA) and serotonin (5HT) on glutamate-evoked firing of neurons in the nucleus accumbens (Soc. Neurosci. Abst., 1995, 21:969). The purpose of the present study was to determine whether the MDMA effect is specific for monoamines or whether MDMA-pretreatment also blunts the inhibitory effect of GABA in the accumbens. Adult male Sprague-Dawley rats received subcutaneous injections of MDMA (20 mg/kg) twice per day for 4 successive days. Control rats received equivalent injections of saline. Either 1-4 days or 9-15 days following the last injection, rats were anesthetized with urethane and multibarrel micropipettes were employed for single unit recording combined with microiontophoresis in the core region of the nucleus accumbens. Dose-response curves were generated for the effects of DA, 5HT and GABA on glutamate-evoked firing of the nucleus accumbens cells. At both early and late test periods following the last injection of MDMA, the inhibitory effects of DA and 5HT on glutamate-evoked firing were significantly reduced compared to effects in the saline control group. However, the doses of glutamate required to fire the cells at equivalent baseline firing rates, and the inhibitory effects of GABA on the glutamate-evoked firing did not differ for the MDMA-pretreated and the control rats. These results suggest that MDMA pretreatment specifically alters DA and 5HT neurotransmission in the nucleus accumbens rather than changing the general level of excitability of the accumbens cells. This work was supported by NIH grant DA08116

457.10

AMPHETAMINE (AMPH) INCREASES PHOSPHORYLATION OF NEUROMODULIN (NM) AND SYNAPSIN I (S1) IN STRIATAL SYNAPTOSOMES, S Michelhaugh*, S Iwata, GHK Hewlett, A Czernik#, K Meiri‡ and ME Gnegy, #Rockefeller Univ., New York, NY 10021; +SUNY Health Science Ctr., Syracuse, NY 13210; Univ. of MI Med. Sch., Ann Arbor, MI 48109. AMPH increases dopamine release in striatal neurons increasing locomotion and stereotyped behaviors in animals. We found that acute AMPH increased phosphorylation of the presynaptic protein NM in rat striatum. Phosphorylation of MM as a disconsisting of the Co²⁺ timing.

AMPH increases dopamine release in striatal neurons increasing locomotion and stereotyped behaviors in animals. We found that acute AMPH increased phosphorylation of the presynaptic protein NM in rat striatum. Phosphorylation of NM at ser⁴¹ by protein kinase C (PKC) leads to dissociation of the Ca²⁺-binding protein calmodulin (CaM). In this study we examined the phosphorylation of NM by AMPH, using a state specific antibody for phosphoser⁴¹-NM, and its binding to CaM in Percoll purified rat striatal synaptosomes. Phosphorylation of NM was maximal at 2 min at 37°C using 1 µM AMPH. To test the effect of AMPH on CaM binding to target proteins, CaM was immunoprecipitated from synaptosomes treated with buffer or 1 µM AMPH for 2 min. Immunodetectable CaM increased in the AMPH-reated synaptosomes with no change in total. NM co-immunoprecipitated with CaM but was unchanged by AMPH. There was, however, a decrease in the amount of co-immunoprecipitated MARCKS (myristolated alanine rich C-kinase substrate) after AMPH. Phosphorylation of MARCKS by PKC also leads to CaM dissociation. CaM dependent protein kinase II (CKII) also co-immunoprecipitated with CaM and the amount increased after AMPH. To determine whether AMPH can activate CKII, we measured S1 phosphorylated at site 3, the CKII substrate site, using a state specific antibody. S1 phosphorylation at site 3 responded dose-and time-dependently to AMPH. To determine whether PKC activation and release of CaM led to S1 phosphorylation, synaptosomes were pretreated with 10 µM Ro 31-8220, a specific PKC inhibitor, and then treated with or without AMPH. The PKC inhibitor prevented the AMPH-induced increase in phosphoser ⁴¹-NM and site 3 phospho-S1. These results suggest that AMPH treatment leads to an activation of PKC. Phosphorylation of MARCKS and NM would dissociate CaM, which could bind to and activate CKII, increasing phosphorylation of S1. Funded by NIDA grant DA 05066.

EFFECTS OF (-)EPHEDRINE HYDROCHLORIDE ON EXTRACELLULAR DOPAMINE LEVELS WITHIN RAT NUCLEUS ACCUMBENS. P.J. Wellman*, C.L. Livermore, D.K. Miller, T. Green, and J.R. Nation. Texas A&M University, College Station, TX, 77843-4235.

Systemic injections of the sympathomimetic agent (-)ephedrine hydrochloride [(-)EPH] produce an internal cue in rats resembling that of cocaine HCl (Gauvin, D.V., et al., Psychoparmacology, 110(3), 309-19). The present study examined the effects of systemic (-)EPH injections on extracellular dopamine levels within rat nucleus accumbens (NAC). Adult male Sprague-Dawley rats were surgically prepared with indwelling bilateral guide cannulae through which a 3 mm concentric microdialysis probe was subsequently positioned within the medial aspects of the NAC. After establishing basal levels of dopamine and it's metabolites (DOPAC and HVA) within 20 minute fractions, rats were injected (i.p.) with either 5, 10, or 20 mg/kg (-)EPH, with additional samples collected every 20 minutes for 100 minutes post-injection. Dopamine levels in the NAC were elevated after (-)EPH administration, whereas metabolite levels were reduced relative to basal levels. These data suggest that (-)EPH may produce neurochemical cues similar to that of cocaine HCl. R010A07932-02

EXTRACELLULAR NOREPINEPHRINE, SEROTONIN, AND DOPAMINE RESPONSES TO METHYLPHENIDATE: COMPARISON TO AMPHETAMINE AND COCAINE, R. Kuczenski* and D. S. Segal, Dept. of Psychiatry, University of California, San Diego, La Jolla, CA 92093-0603

Although dopamine (DA) plays a critical role in the behavioral effects of amphetamine-like stimulants, the dissociation between the quantitative effects of the drug on extracellular (EC) DA and behavior (particularly stereotypies) suggests that other transmitters, including serotonin (HT) and norepinephrine (NE), likely contribute to the behavioral response. To further examine the role of HT and NE in the stimulant response, we compared the effects of behaviorally similar doses of amphetamine (AMPH), cocaine (COC) and methylphenidate (MP) on regional biogenic amines using microdialysis. These drugs were chosen because of their different mechanisms of enhancing monoamine function. As we had previously shown for AMPH and COC, MP induced a dose-dependent increase in hippocampal NE. The maximal NE response was ar to comparable doses of COC, but substantially less than comparable doses of AMPH. In contrast to the effects of all three drugs on NE, whereas stereotypy-inducing doses of both AMPH and COC increased EC HT in caudate-putamen, even the highest doses of MP tested failed to affect CP HT. With respect to DA, MP increased both CP and nucleus accumbens (NAC) DA in a dose-dependent manner. At low doses (5 - 10 mg/kg), the magnitude of the response was comparable to COC and consistent wi other DA uptake blockers, i.e., the NAC response was relatively greater than the CP response. However, as the dose of MP was further increased, the DA response become more AMPH-like, both in terms of magnitude and relative regional efficacy. These data support our contention that stimulant-induced behaviors are not strictly dependent on the quantitative features of the CP and NAC EC DA responses, but are likely modulated by other transmitter systems. In addition, the data suggest first, that a stimulant-induced increase in HT is not a prerequisite for the appearance of perseverative behaviors, and, second, that higher doses of MP may release DA in addition to blocking its uptake (Supported by NIDA)

A ROLE FOR D1 AND D2 RECEPTORS IN THE MEDIATION OF LOCAL AMPHETAMINE-INDUCED ACETYLCHOLINE RELEASE IN THE NUCLEUS ACCUMBENS. A. S. Keys* & G. P. Mark, Dept. of Behavioral Neuroscience, Oregon Health Sciences University, Portland, OR 97201.

Nucleus accumbens (NAc) dopamine activity is a putative

Nucleus accumbens (NAc) dopamine activity is a putative mechanism that mediates the rewarding properties of both natural reinforcers and drugs of abuse. Recent studies have demonstrated the modulation of ingestive behavior by acetylcholine (ACh) interneurons of the NAc and suggest that the ACh/dopamine interaction in this area may also be involved in drug reward processes. The present experiment examined the effect of local perfusion of amphetamine on ACh release in the NAc as measured by *in vivo* microdialysis and the possible dopamine D₁ and D₂ modulation of this treatment. A biphasic dose response curve was observed in that a moderate dose of amphetamine (50uM) produced a 140% increase in ACh release that persisted for 15 min following cessation of drug perfusion (F=5.74, p<.0001) while a high dose (1mM) produced trends toward decreased ACh release followed by a significant 135% increase during recovery (F=57.6, p<.0001). Both the increase due to the moderate dose and the rebound from the high dose were blocked by concurrent treatment with the D₁ antagonist, SCH 23390. The high dose-decrease was attenuated by the D₂ antagonist, sulpiride (10uM). Also, a tonic D₁ inhibition of ACh release in the NAc, which was not dose-responsive, was also observed. These data suggest that amphetamine's biphasic effect on NAc ACh release is at least partially mediated via selective D₁ and D₂ mechanisms.

CHARACTERIZATION OF THE EFFECTS OF METHCATHINONE INDUCED DOPAMINE RELEASE. M. P. Gygi* J. W. Gibb. A. E. Fleckenstein and G. R. Hanson. Department of Pharmacology & Toxicology, University of Utah, Salt Lake City, UT 84112.

Methcathinone ("CAT") is an increasingly popular stimulant that was

Metheathinone ("CAT") is an increasingly popular stimulant that was classified a Schedule I drug in 1993. The mechanism by which CAT elicits its stimulating effects is unknown, however, users compare CAT to methamphetamine and cocaine, both of which cause an increase in synaptic dopamine. The rise in extracellular dopamine is necessary for these stimulants to elicit their behavioral and toxic effects. With microdialysis we determined that in awake rats CAT (1.0 and 10 mg/kg, s.c.) induced dopamine release in a dose-dependent manner. Further, we observed that CAT produced increasing locomotor activity in rats using doses of 0.3 - 10 mg/kg, s.c., and that the highest dose also elicited stereotypy. Our laboratory previously demonstrated the neurotoxic potential of CAT in animals receiving higher doses (20 and 30 mg/kg, s.c.). Using neurotensin tissue levels to assess the downstream consequences of CAT-induced dopamine release, the striatal content of neurotensin was analyzed in animals treated with these higher drug doses and sacrificed 18 h later. We found that CAT increased neurotensin tissue levels in a dose-dependent fashion, suggesting that dopamine released by CAT has subsequent functional consequences. AN ESCALATING DOSE "BINGE" MODEL OF AMPHETAMINE PSVCHOSIS: BEHAVIORAL AND NEUROCHEMICAL FEATURES, D.S. Segal* and R. Kuczeński. Psychiatry Department, UC San Diego, La Jolla, CA 92093-0603

Stimulant-induced psychosis most frequently occurs during a high dose, multiple daily ("binge") exposure pattern of stimulant abuse. Thus, an appropriate animal behavior model should include exposure to escalating doses of the stimulant, followed by characterization of the behavioral and neurochemical responses during multiple runs. This approach should provide the greatest potential for understanding the mechanisms and processes most frequently associated with the induction of psychosis To simulate the high dose abuse pattern, rats were exposed to escalating doses of amphetamine (Escalating Dose phase: 1.0 to 8.0 mg/kg) prior to multiple daily injections of relatively high doses of the drug (Run phase: 8.0 mg/kg/2 hrs x 4 injections). The behavioral response was monitored continuously during the course of these treatments as well as to subsequent amphetamine challenges at various times after discontinuation of drug treatment. During this Escalating Dose-Run pattern of amphetamine administration, a unique behavioral profile emerged which was qualitatively and quantitatively different from other treatment regimens. The altered profile exhibits both sensitization and tolerance of some components, including a profound increase in the expression of locomotor activation relative to the time spent engaged in continuous focused stereotypy. In parallel studies, in vivo microdialysis revealed progressively declining regional extracellular dopamine and serotonin responses, both within and between successive runs. In contrast, the norepinephrine response remained relatively unaltered. The possible role of these neurochemical changes in the altered behavioral profile, and the manner in which these effects may be implicated in the induction of amphetamine psychosis will be discussed. [Supported by NIDA]

CHARACTERIZATION OF β-PHENYLETHYLAMINE-INDUCED MONOAMINE RELEASE IN RAT NUCLEUS ACCUMBENS: A MICRODIALYSIS STUDY. D. Nakahara' and M. Nakamura. Department of Psychology, Hamamatsu University School of Medicine, 3600 Handacho, Hamamatsu 431-31, Japan

In vivo microdialysis was used to investigate the effect of β phenylethylamine on extracellular levels of monoamines and their metabolites in the nucleus accumbens of conscious rats. At all doses tested (1, 10 and 100 $\mu\text{M}),$ infusion of $\beta\text{-phenylethylamine}$ through the microdialysis probe significantly increased extracellular levels of dopamine in the nucleus accumbens. These increases were dose-related. The potency of 100 μ M β -phenylethylamine to increase the extracellular level of dopamine was comparable to that of the same dose of methamphetamine. On the other hand, B-phenylethylamine had a much less potent stimulating effect on serotonin than dopamine levels. The only highest dose (100 μ M) caused a statistically significant action to serotonin. Over the dose range tested (1, 10 and 100 $\mu\text{M}),~\beta\text{-phenylethylamine}$ had no effect on extracellular metabolite levels of dopamine and serotonin. suggest that β-phenylethylamine stimulates a release of monoamines, preferentially dopamine, without affecting monoamine metabolism. Supported by a scientific research grant from the Ministry of Education, Science and Culture of Japan.

ROLE OF MESOLIMBIC δ-OPIOID RECEPTORS IN MEDIATING THE AFFECTIVE COMPONENT OF MORPHINE-WITHDRAWAL. M. Funada, A. Pani and T.S. Shippenbergs* Division of Intramural Research, NIDA, NIH, Baltimore, MD 21224 δ-Opioid receptor antagonists produce aversive states in morphine-

δ-Opioid receptor antagonists produce aversive states in morphine-dependent, but not drug-naive, animals. The neural substrates mediating these effects were assessed using place preference conditioning and microdialysis. Male SD rats, with indwelling intracerebral guide cannula, were implanted s.c. with two pellets containing morphine (75 mg) or placebo. Place conditioning produced by the δ-opioid receptor antagonists naltrindole (NLTR) and naltriben was examined 4 days later. Systemic or intracerebroventricular (ICV) infusion of either antagonist produced place aversions in morphine-treated animals. These effects occurred in the absence of physical withdrawal signs. Place aversions were also observed after antagonist infusion into the nucleus accumbens (NAC) and the doses producing this effect were significantly lower than those effective ICV. Neither antagonist produced a conditioned response in placebo-treated animals. Preliminary dialysis studies revealed no effect of NLTR on NAC dopamine (DA) overflow in placebo-pelleted animals. However, in morphine-treated animals ac. 40% decrease in DA was seen. These data indicated an important role of NAC δ-opioid receptors in mediating the aversive stimulus effects of morphine withdrawal. An involvement of mesolimbic DA neurons in mediating the affective component of morphine withdrawal is also suggested.

MEUROPEPTIDE SF (NPSF) PRECIPITATES MORPHINE ABSTINENCE SYNDROME IN THE RAT. J.R. Lake, W.D. Moon, B.P. Corbit, S.L. Webb, J.K. Hall, D. Haynes, H.-Y.T. Yang' and D.H. Malin. Univ. of Houston-Clear Lake, Houston, TX 77058, & NIMH Neurosci. Ctr. at St. Elizabeth's, Washington, D.C. 20032.

Neurosci. Ctr. at St. Elizabeth's, Washington, D.C. 20032.

NPSF, recently discovered in the rat CNS, shares an identical C-terminal sequence with Neuropeptide FF (NPFF). NPFF has antiopiate activity; 2 µg precipitated a morphine abstinence syndrome in dependent rats, while 10 µg induced a quasi-morphine abstinence syndrome (QMAS) in naive rats. This study tested whether NPSF would have similar actions. Thirty-six rats were cannulated in the third ventricle and implanted s.c. with an Alzet osmotic minipump. Eighteen rats were infused for 7 days with 0.27 mg/kg/hr morphine sulfate, and 18 were infused with saline alone. Three groups of 6 morphine dependent rats were injected i.c.v. with 1.64 (equimolar to 2 µg NPFF) or 6.10 µg NPSF or with bestatin:saline vehicle alone. Three groups of 6 opiate naive rats were similarly injected. The high dose precipitated an average of 51.8 signs in 20 min, the low dose 36.3 signs, and vehicle alone 10.5 signs (p<.05 vs. vehicle). Only the high dose induced a significant QMAS in opiate naive rats. ANOVA revealed significant effects of dependence and NPSF dose. Thus NPSF has antiopiate activity and is similar in potency to NPSFF. (NIDA DAO6554, K. Burgess, Texas A&M Univ., P.I.)

REGULATION OF THYROTROPIN-RELEASING HORMONE IN MORPHINE WITHDRAWAL. L.G. Gahn* and K.A. Sevarino. Division of Molecular Psychiatry, Dept. of Psychiatry, Yale U. School of Medicine, New Haven, CT 06508

Thyrotropin-releasing hormone (TRH), administered systemically, ameliorates some of the physical symptoms of opiate withdrawal in rats. In this study we investigated the role of TRH in opiate withdrawal by examining the regulation of ppTRH mRNA, TRH peptide, and TRH receptor binding. Rats were implanted with one morphine pellet (75 mg) daily for 4 days. On day 5, rats were given naltrexone to induce withdrawal and sacrificed at various times. ppTRH mRNA was quantitated by in situ hybridization and RNase protection, receptor binding was measured by receptor autoradiography, and TRH peptide levels were determined by radioimmunoassay. During withdrawal, levels of ppTRH mRNA in the central gray increased to twice control by three hours and to three times control for 6-36 hours, returning to normal 3 days later. Morphine or naltrexone alone did not produce the increase in message levels. At three hours of withdrawal, smaller increases were observed in the amygdala (50%) and medulla (15%). Also at three hours, TRH peptide levels were unchanged in the central gray, but decreased 30% in the amygdala, and TRH receptor binding was unchanged in the central gray but decreased 30% in the amygdala. These data demonstrate that the TRH pathway, at the levels of mRNA expression, peptide levels, and receptor binding, is regulated during morphine withdrawal and suggest a role for TRH in mediating opiate withdrawal symptoms. PRECIPITATED MORPHINE WITHDRAWAL FOLLOWING MICROINJECTION OF METHYLNALTREXONIUM INTO THE PAG. K.L. Jones* and G.A. Barr. Biopsychology Doctoral Program, Dept. of Psychology. Hunter College-CUNY, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th St. NY, NY 10032.

Considerable progress has been made in understanding the anatomical substrates that underlie the opiate withdrawal syndrome in the adult animal. However, at the present time there are no available data regarding the anatomical substrates of the opiate withdrawal syndrome in the infant animal. In this study, we examined the behavioral effects of morphine withdrawal by microinjection of methylnaltrexonium into the ventral region of the periaqueductal gray (PAG). Morphine was injected s.c. (10.0 mg/kg) at the nape of the neck twice daily from the first to the seventh day of life. Controls were saline treated animals. On day 6 all animals were fully anesthetized with Metafane, placed in a stereotaxic device adapted for infant animals, and implanted with a cannula aimed at the PAG. Following surgery pups were kept in a warm, moist incubator until fully recovered, and then returned to the dam. On the afternoon of day 7, a target pup was microinjected with saline or methlynaltrexonium to precipitate withdrawal. Pups were observed in a warm chamber with the remainder of the litter for a total of 20 minutes, and behaviors were recorded every 15 seconds on a checklist. When that observation period ended, the pup was anesthetized and placed back into the litter. A total of 5 pups were injected and tested in this manner. The results show that morphine-exposed rat pups that received microinjections of methylnaltrexonium into the PAG demonstrated alterations in their behavior including increased rolling, walking, head and paw movements as compared to control animals. These alterations in behavior patterns are similar to those observed in infant rats when withdrawal is precipitated peripherally. The PAG is therefore an anatomical substrate involved in the mediation of the opiate withdrawal syndrome in the infant rat. Supported by RO1-DA06600.

A SELECTIVE AMPA ANTAGONIST, LY293558, BLOCKS MORPHINE-WITHDRAWAL-INDUCED ACTIVATION OF LOCUS COERULEUS NEURONS AND BEHAVIORAL SIGNS OF MORPHINE WITHDRAWAL. W.T. Kendrick¹, K. Rasmussen¹, J. H. Kogan², F.P. Bymaster¹ and G. K. Aghajanian³. ¹Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285; Departments of Pharmacology² and Psychiatry³, Yale University School of Medicine, 34 Park St., New Haven, CT 06508.

The glutamate receptor subtype that mediates the morphine-withdrawal-induced activation of locus coeruleus (LC) neurons was examined in this study using *in vitro* and *in vivo* single-unit electrophysiological recordings. For LC neurons recorded *in vitro* in rat brain slices, the selective AMPA antagonist, LY293558, showed a greater than 10-fold selectivity for inhibiting the excitatory effects of AMPA vs. NMDA. LY293558 also greatly reduced the response of LC neurons to glutamate in a concentration dependent manner. In *in vivo* recordings in anesthetized rat, pretreatment with LY293558 (0.1-10 mg/kg, s.c.) dose-dependently suppressed the morphine-withdrawal-induced activation of LC neurons. In unanesthetized, morphine-dependent animals, pretreatment with LY293558 (1.30 mg/kg, s.c.) dose-dependently suppressed naltrexone-precipitated morphine-withdrawal signs. These results indicate: 1) AMPA receptors mediate a large component of the excitatory effects of glutamate on LC neurons; 2) activation of AMPA receptors plays an important role in the morphine-withdrawal-induced activation of LC neurons; 3) AMPA antagonists can suppress many signs of morphine withdrawal in awake animals; and, 4) AMPA antagonists may have therapeutic effects in man for the treatment of opiate withdrawal.

MONOAMINE METABOLISM IN THE RAT LOCUS COERULEUS AND BEHAVIOR DURING MORPHINE WITHDRAWAL: EFFECT OF A NO-SYNTHASE INHIBITOR. N. Javelle, B. Renaud, L. Denoroy* and L. Lambás-Señas, INSERM CJF 95-06, Univ. C. Bernard, 69373 Lyon, France.

Electrophysiological studies have reported an hyperactivity of noradrenergic neurons of the locus coeruleus (LC) during opiate withdrawal. To further examine the changes in the LC during withdrawal, we monitored catecholaminergic and serotonergic metabolisms using microdialysis concomitantly with behavior. Moreover, since behavioral studies have suggested a role for nitric oxide (NO) in the morphine dependence, we have examined the effect of a NO-synthase inhibitor on behavioral and biochemical changes observed during morphine withdrawal. In morphine-treated rats (2 mg/kg/h, s.c., 5 days), naltrexone (100 mg/kg, s.c.) induced a marked increase (+ 280%) in concentrations of 3.4-dihydroxyphenylacetic acid (DOPAC), an index of the functional activity of the LC noradrenergic neurons. The concentrations in the serotonin metabolite 5-hydroxyindoleacetic acid (5-HIAA) were also increased (+ 70%). All morphine-treated rats exhibited classic behavioral symptoms of naltrexone-precipitated opiate withdrawal. These results i) confirm the hypothesis of an activation of LC noradrenergic neurons induced by opiate-withdrawal and ii) document further the involvement of serotonergic input to the LC during morphine withdrawal withdrawal.

serotonergic input to the LC during morphine withdrawal. Pretreatment of morphine-treated rats with an inhibitor of NO-synthase, L-N-nitro arginine p-nitroanilide (L-NAPNA, 100 mg/kg, i.p.), reduced the naltrexone-induced increase in DOPAC (+40% vs + 280%) and attenuated behavioral symptoms of morphine withdrawal. These results suggest that L-NAPNA may attenuate the morphine withdrawal syndrome by decreasing the noradrenergic hyperactivity of LC neurons.

INHIBITION OF CONSTITUTIVE BUT NOT INDUCIBLE NITRIC OXIDE SYNTHASE ATTENUATES SIGNS OF MORPHINE WITHDRAWAL. D.B. Vaupel*, A.S. Kimes and E.D. London, Brain Imaging Section, Intramural Research Program, National Institute on Drug Abuse, P.O. Box 5180, Baltimore, MD 21224

The NMDA-receptor-mediated nitric oxide pathway has been linked to opiate tolerance and dependence. Inhibitors of nitric oxide synthase (NOS), having different degrees of selectivity for constitutive (c) or inducible (j) isoforms of the enzyme, were evaluated for their ability reduce signs of naloxone-precipitated morphine withdrawal and to affect blood pressure in rats. Inhibitors specific for cNOS included 7-nitroindazole (7-NI), 3-bromo-7-nitroindazole (3-Br-7-NI) and S-methyl-L-thiocitrulline (Me-TC). These drugs characteristically produced dose-dependent reductions in weight loss, diarrhea, wet dog shakes, grooming, and mastication; and increased exploratory activity. These drugs3-Br-7-NI selectively inhibits the neuronal isoform of cNOS, whereas 7-NI exhibits no selectivity between the neuronal and endothelial isoforms. Me-TC, which is selective for neuronal cNOS. produced a strong vasopresssor response, but the indazoles did not. By comparison, aminoguanidine, which is a selective inhibitor of iNOS, reduced fewer signs of opioid withdrawal and had a lower relative potency; it also lacked vasopressor activity. These results suggest that iNOS does not have a primary role in nitric oxide-mediated processes that modulate the opioid withdrawal syndrome. If NOS inhibitors are considered for development as treatment medications, 3-Br-7-NI and 7-NI would be preferable because they do not elevate mean arterial pressure. Because 7-NI significantly increased abnormal posturing and escape jumps and 3-Br-7-NI did not, 3-Br-7-NI emerged as the most effective NOS inhibitor in reducing opiate withdrawal signs in the rat

ENHANCEMENT OF TAIL-BITING IN MORPHINE WITHDRAWN RATS FOLLOWING EXPOSURE TO CONTEXTUAL CONDITIONED FEAR STIMULI. B.J. Caldarone, G.C. Abrahamsen, D.L. Mongeluzi, H.S. Stock, P. Balan, & R.A. Rosellini. Department of Psychology, University at Albany: SUNY, Albany, NY, 12222.

Previous studies from our laboratory have shown that exposure to contextual conditioned fear stimuli can enhance naloxone-precipitated withdrawal behaviors in morphine-naive rats. The present study examined the effects of conditioned fear stress on abrupt withdrawal behaviors in rats that were previously dependent on morphine. Male Sprague-Dawley rats were implanted with either two 75 mg morphine pellets or 2 placebo pellets. After 6 days, pellets were removed and abrupt withdrawal behaviors (teeth chattering, mastication, forelimb tremors, wet dog shakes, backward ambulation, and tail-biting) and weight loss were measured. Peak withdrawal effects were observed 2 days following pellet removal. Five days following pellet removal, when withdrawal behaviors returned to control levels, rats were either administered footshock to condition fear to a context, or received no fear conditioning. On the day following fear conditioning, rats were reexposed to the conditioned fear context and withdrawal behaviors were recorded immediately following removal from the context. Morphine withdrawn rats exposed to the conditioned fear context exhibited a higher frequency of tail-biting compared to control groups. No group differences were observed for any other of the measured withdrawal behaviors. These results suggest that exposure to conditioned fear stimuli can reinstate at least one behavioral sign of abrupt withdrawal in rats that were previously withdrawn from morphine. ONTOGENY OF MORPHINE TOLERANCE IN RATS. W. Jin. G. A. Jacob, and C. P. Cramer*. Dept. of Psychology, Dartmouth College, Hanover, NH 03755-3549
Unlike adults, neonatal rats given single daily injections of

morphine do not develop tolerance (Fanselow & Cramer, 1988; Burton & Cramer, 1994). In the studies reported here, we first identified more precisely the age at which tolerance first appears. In the first two experiments, pups where given 0, 2.5, or 5 mg/kg morphine sulfate once daily for 5 days, and then tested for tolerance on the sixth day by measuring shifts in dose-dependent response to morphine-induced analgesia. When injections were begun at Day 10 postpartum, pups tested on Day 15 did not show tolerance. However, when injections were begun at Day 13, pups tested on Day 18 showed a significant shift in the dose-response curve indicative of tolerance. The third experiment explored one possible explanation for this relatively late onset, namely that the pupbehavioral repertoire did not allow expression of tolerance that had nonetheless been acquired. Pups were given the injection regime as in the first experiment, from Days 10-14, but they were instead tested on Day 18, at which age they did in fact manifest tolerance. These results suggest that there is a developmental transition between Day 15 and Day 18, specifically in the ability to express tolerance, which occurs at least several days later than the ability to acquire it.

Microinjections of alpha-flupentixol into the nucleus accumbens block morphine reward in rats that are opiate dependent and in withdrawal, but not in animals that have recovered from dependence. K. Nader*, T.

but not in animals that have recovered from dependence. K. Nader*, T. Luxton and D. van der Kooy, Neurobiology Research Group, Dept. of Anatomy, Univ. of Toronto, Toronto, Ontario, MSS 1A8.

We have previously reported that alpha-flupentixol pretreatment, but not lesions of the tegmental pedunculopontine nucleus (TPP), blocked the acquisition of conditioned place preferences for environments paired with intra-VTA morphine (500 ng/0.5µl/side) in rats that were trained while in a state of heroin dependence and withdrawal. Training animals while in non-withdrawal states (previously drug naive or after having recovered from dependence) produced the opposite pattern of results. These findings suggest that separate dopamine dependent and independent motivational systems exist within the VTA. Furthermore, the dopamine sensitive system is activated only when animals are in motivational states of withdrawal. We tested the effects of microinjections of alpha-flupentixol directly into the nucleus accumbens on systemic morphine reward in animals that are either opiate dependent and in withdrawal or have recovered from dependence. Bilateral microinjections of either 3µg or 30 µg/µl/side of alpha-flupentixol into the nucleus accumbens blocked the acquisition of conditioned place preferences for environments paired with 10 mg/kg (ip) morphine in animals into the nucleus accumbens, blocked the acquisition of conditioned place preferences for environments paired with 10 mg/kg (ip) morphine in animals that were trained while in a state of heroin withdrawal. These animals were given a 2 week period to recover from dependence and were subsequently conditioned using the identical procedure. Pretreatment with intra-accumbens administration of 3 µg/µl/side of alpha-flupentixol had no effect on the acquisition of conditioned place preferences for environments paired with 10 mg/kg (ip) morphine. These data suggest that the mesolimbic dopaminergic pathway is only necessary for mediating morphine's rewarding properties when animals are in states of dependence and withdrawal. INHIBITORY EFFECTS OF NEFIRACETAM DEVELOPMENT OF DEPENDENCE AND TOLERANCE TO MORPHINE. T. Nabeshima* A. Itoh, S. Nakayama, Y. Noda, T. Mamiya, T. Shiotani and T. Hasegawa, Dept. of Neuropsychopharmacol. and Hospital Pharm., Nagoya Univ. Sch. of Med., Nagoya 466, Japan

Morphine (MOR), a most potent opioid analgesic, induces dependence and tolerance, and it hampered the use in clinical. Therefore, it is important to attenuate the development of dependence and tolerance to MOR. It has been reported an involvement of the changes in second messengers such as cAMP and Ca2 action of MOR. In this study, therefore, we investigated the effects of nefiracetam on the development of dependence and tolerance to MOR, since nefiracetam affects the cAMP level and Ca^{2+} influx into the neuronal cells.

When mice were administered MOR (6 or 20 mg/kg, s.c.) twice daily for 5 days and then challenged by naloxone (NAL, 5 mg/kg, i.p.) 2 hr after the last MOR injection on the 6th day, they showed the signs of withdrawal such as jumping, diarrhea and body weight loss. Co-administration of nefiracetam (5 or 10 mg/kg, p.o.) with MOR during the subacute treatment period, significantly reduced these signs precipitated by NAL. However, acute administration of nefiracetam did not affect these symptoms in the MOR-dependent mice. Subacute administration of MOR also induced the tolerance to its analgesic effect. This tolerance was also significantly attenuated by the administration of nefiracetam in combination with MOR. However, acute administration of nefiracetam failed to produce analgesic effect and had no effects on the analgesic effect of MOR in the MOR-naive mice.

These findings suggest that co-administration of nefiracetam with MOR attenuates the development of dependence and tolerance to MOR. Although the mechanisms underlying these phenomena should be further investigated, co-administration of nefiracetam may be useful strategy to attenuate the development of dependence and tolerance of MOR in the clinic. (Patent No. 95147M)

CHRONIC TREATMENT WITH MORPHINE IS ASSOCIATED WITH HETEROLOGOUS TOLERANCE OF GUINEA PIG LOCUS CERULEUS (I.C.)
NEURONS. J. Meng, W.W. Fleming and D.A. Taylor*. Dept. of Pharmacol. and Toxicol., R.C. Byrd Hlth. Sci. Ctr., West Virginia University, Morgantown, WV 26506-9223.

Chronic exposure to morphine leads to the development of a heterologous subsensitivity of guinea pig nTS and myenteric neurons as well as supersensitivity to several different excitatory agonists. In contrast, rat LC neurons develop a highly specific reduction in the responsiveness confined to opioids following exposure to morphine. The current studies were conducted to characterize the nature of the change in responsiveness induced by chronic exposure to morphine in guinea pig LC neurons. Morphine treatment was accomplished by pellet implantation (75 mg/pellet) 7 days prior to the experiment. Extracellular electrophysiological recordings were obtained from LC neurons in pontine slices from control and morphine-treated guinea pigs. Agonists were added to the physiological saline and administered by superfusion as either single concentrations or in a concentration-response curve of cumulatively increasing concentrations. The results indicate that LC neurons from guinea pigs treated with morphine exhibit a nearly 10-fold rightward shift of the concentration response curve to morphine with no change in maximum. The heterologous nature of the change in responsiveness was demonstrated by the similar reduction in magnitude of responses to muscimol following chronic treatment. Responses of LC neurons uscimol (1.0 μ M) were reduced from 93 ± 4 % inhibition in control neurons to 21 ± 15% inhibition in neurons from animals chronically exposed to morphine. These data are qualitatively and quantitatively similar to previous studies from both the guinea pig brainstem nTS and myenteric plexus/longitudinal muscle which indicate that chronic exposure of guinea pigs to morphine leads to a change in responsiveness which is exhibited as subsensitivity to a variety of inhibitory substances. The data provide the first demonstration of nonspecific reductions in sensitivity of guinea pig LC neurons following morphine treatment and suggest that the cellular mechanisms underlying the development of tolerance to morphine in the guinea pig LC may be similar to those previously described in either neurons of the guinea pig myenteric plexus or nTS. Supported in part by NIH Grant DA 03773.

Tolerance to Morphine is Mediated by Nutritive and Non-Nutritive Dietary Variables. KRISTEN E. D'ANCI*, ROBIN B. KANAREK, AND ROBIN MARKS-KAUFMAN, Dept. of Psychology, Tufts Univ., Medford, MA 02155.

Recent research showed that following repeated administration of morphine

Recent research showed that following repeated administration of morphine morphine-induced analgesia (MA) decreased in rats drinking a saccharin solution in comparison to rats drinking a sucrose solution. This difference in MIA may be due to a difference in the development of tolerance to morphine's analgesic effects. The present experiment evaluates the differing effects between a palatable, nutritive sucrose solution and a palatable, non-nutritive saccharin solution on the development of tolerance to MIA.

Forty-five adult male Long-Evans VAF rats were used. All rats had ad lib access to chow and water. Additionally, 15 rats were given a 0.15% wV saccharin solution and 14 rats were given a 32% wIv sucrose solution to drink for three weeks. MIA was assessed via the radiant heat tail-flick method. To induce tolerance, half of the rats in each dietary condition were given a priming injection of 7.5 mg/kg morphine sulfate. The remaining rats received saline injections. All rats were given a tail-flick test 30 minutes post-injection. One week after the priming session, tolerance was measured according to a cumulative dose paradigm. Rats received injections of 2.5 mg/kg of morphine sulfate every 30 min. until a final dose of 12.5 mg/kg was achieved. MIA was measured immediately prior to and 30 min. following each injection.

Rats drinking the sucrose solution had significantly higher analgesic responses than rats drinking saccharin or water alone, regardless of priming condition. MIA was suppressed in rats drinking either saccharin or water one week following a priming dose of morphine but was not suppressed in rats drinking sucrose. The results suggest that intake of palatable, nutritive fluids curbs tolerance to MIA. The present study supports previous results demonstrating differences between saccharin and sucrose intake on MIA. Funded by NIDA Grant No. DA04132 to R.B.K and R.M.K.

SPINAL AMINO ACID RELEASE AND MORPHINE TOLERANCE IN RATS CHRONICALLY INFUSED WITH SPINAL MORPHINE AND THE EFFECT OF REPETITIVE NALOXONE ANTAGONISM.

T. Ibuki*, M. Marsala, T. L. Yaksh, Anesthesiology Res. Lab., Univ. of California, San Diego, CA 92003-0818

The Beffect of Repetitive NALOXONE ANTAGONISM.

Thukik', M. Marsala, T. L. Yaksh, Anesthesiology Res. Lab., Univ. of California, San Diego, CA 92093-0818.

Recent studies in our laboratory showed that chronic spinal infusion of morphine had no significant effect on the resting release of spinal amino acids, but naloxone injection in these morphine tolerant animals evoked an immediate increase in the release of glutamate and taurine [1]. In the present study we examined the effect of daily transient naloxone antagonism on the development of tolerance and the spinal release of several amino acids (glutamate, taurine, serine, glycine). Rats, implanted with spinal loop dialysis catheter and lumbar intrathecal catheter were continuously (3 days) infused with morphine (20 nmol/µlhr) or saline (1µl/hr) and received daily saline (s.c.) or naloxone injections (0.6mg/kg). The degree of tolerance was evaluated daily by measuring hot plate escape latency prior to s.c. injection and withdrawal signs immediately after. In the same animals microdialysate samples were collected before and after naloxone or saline injection. Rats infused with chronic spinal morphine and transiently antagonized with naloxone developed the highest degree of tolerance. These animals also showed a significant and progressive increase in the concentration of glutamate, aspartate and taurine after repetitive naloxone injections. In control animals chronic infusion of morphine combined with saline (i.p.) injection had no effect on resting spinal amino acid release. Our results indicate that periodic antagonism yields a progressive enhancement in spinal glutamate release and an exacerbated degree of tolerance. We hypothesize that these events are causally related. (Supported by NS16541-TLY; NS32794-M.M.)

EFFECTS OF PROTEIN KINASE INHIBITOR H-7 ON THE ANTINOCICEPTIVE ACTIONS OF MORPHINE IN RATS. P. Sacchetti*, D.C. Jewett, R.R. Witte II and A.M. Young. Department of Psychology, Wayne State University, Detroit MI 48202

It has been suggested that tolerance to functional effects of μ opioids may result from agonist-induced constitutive activation of μ opioid receptors via a phosphorylation mechanism (Wang et al. Life Sci. 54:PL339-350, 1994). The present study examined the ability of the general protein kinase inhibitor H-7 (1-(5-Isoquinolinylsulfonyl)-2-methylpiperazine) to reverse and/or prevent tolerance produced by cumulative or chronic exposure to morphine (MS) in rats. Male Sprague-Dawley rats were tested in a warm-water tail withdrawal assay, and ED50 values for MS were determined by cumulative dosing procedures. Acute pretreatment with H-7 (50-150 nmol, i.c.v.), 30 min prior to MS, did not change control latencies or the ED50 for the antinociceptive effects of MS. Furthermore, H-7 (50-150 nmol) did not alter the normal time course of MS (10 mg/kg) effects. Tolerance was established by administering doses of 17.8 mg/kg MS, b.i.d., for 2 days, followed by 32 mg/kg MS, b.i.d., for 4 days. The magnitude of tolerance was assessed by re-determination of the MS dose-response curve. pretreatment with H-7 (150-1500 nmol) did not reverse MS tolerance, but did produce short-term increases in locomotor activity and vocalization. In a second experiment, doses of H-7 (50-150 nmol) were administered 30 min before each MS injection during chronic MS treatment. Co-administration of H-7 did not prevent the development of MS tolerance. These data suggest that i.c.v. injections of H-7 may not prevent or reverse the tolerance produced by chronic MS treatment in rats. [Supported by DA03796 and K02 DA00132]

ETORPHINE TOLERANCE STUDIES DIFFERENTIATE μ OPIOIDS IN AN ANALGESIC ASSAY <u>M.J.Tiano, E.A. Walker, L.A. Dykstra*</u> Department of Psychology, University of North Carolina at Chapel Hill. Chapel Hill. NC 27599

Opioids are differentially sensitive to receptor alteration by repeated agonist treatment. The hypothesis that these differences are related to efficacy was tested using higher efficacy agonists etorphine and /-methadone, high efficacy agonist morphine, and lower efficacy agonists buprenorphine and dezocine in an analgesic assay. Rats were placed in restrainers and the latencies for tail withdrawal from 55°C water were measured. Repeated treatment of 0.0064 mg/kg per day etorphine for 7 days increased the doses required. for 100% maximum possible effect for morphine, buprenorphine, and dezocine. The ED₅₀ values for morphine, buprenorphine and dezocine were increased by 3, 6. and 9-fold, respectively. Additionally, after repeated etorphine treatment. no dose of dezocine produced 100% maximum possible effect. Repeated treatment with 0.0064 mg/kg per day etorphine failed to alter the etorphine or /-methadone dose-response curves. The present finding that the greatest degree of tolerance was observed for buprenorphine and dezocine and the least amount of tolerance was observed for etorphine and I-methadone support the hypothesis that the magnitude of tolerance is inversely related to the relative efficacy of the agonist tested. BETA-FUNALTREXAMINE ANTAGONISM OF THE DISCRIMINATIVE STIMULUS AND ANTINOCICETIVE EFFECTS OF MORPHINE AND ETONITAZENE. J.A. Moretti* and A.M. Young. Department of Psychology, Wayne State University., Detroit, MI 48202.

The present experiments investigated effects of the selective, irreversible µ opiate antagonist beta-funaltrexamine (β-FNA) on discriminative stimulus, rate-altering, and antinociceptive effects of morphine sulfate (MS), and antinociceptive effects of etonitazene HCL (ETZ). In all experiments, agonist potencies were determined using cumulative dosing procedures. In discriminative stimulus experiments, male Sprague-Dawley rats were trained to discriminate 3.2 mg/kg MS and saline under FR15 schedules of food reinforcement. Rats were then administered various doses of β-FNA (5-40 μg i.c.v.), and tested with MS 24 h later. B-FNA dose-dependently reduced the potency of morphine's discriminative stimulus and rate-altering effects. Higher doses of β-FNA (20 & 40 μg) suppressed the maximal discriminative stimulus effects of MS. β-FNA was also used to antagonize the antinociceptive effects of MS and ETZ in a warm-water tail withdrawal assay. B-FNA was more potent in antagonizing morphine's antinociceptive effects than its discriminative effects, suggesting that fewer receptors are needed to produce a full effect in a drug discrimination assay. Furthermore, doses of β-FNA (10 & 20 µg) that prevented MS from producing a maximal effect in the antinoniception assay merely shifted the ETZ dose-effect curve to the right. Indeed, doses of β -FNA up to 40 μg did not prevent ETZ from producing maximal antinociceptive effects, suggesting that ETZ is a higher efficacy agonist than MS.(Supported by R01 DA03796 and F31 DA05701)

Effect of morphine-3-glucuronide (M3G) on the analgesic actions of $\delta_1\text{-}$ and $\delta_2\text{-}$ and $\kappa\text{-}$ opioid receptor agonists in mice. <u>Jing-Tan Bian, Peter T. Thomas*and Hemendra N. Bhargava</u>, Dept. Pharmaceutics/Pharmacodynamics, Univ. Ill., Chicago, IL 60612

M3G is a major metabolite of morphine. It has been shown to be a physiological antagonists of morphine as well as its metabolite, morphine-6-glucuronide. Binding studies have yielded contradictory results for the interaction of M3G with multiple opioid receptors. The present studies examined the $\underline{\text{in vivo}}$ interactions between M3G and $\delta\text{-}$ and κ -opioid receptor subtypes. The effects of M3G administered i.c.v (0.01, 0.1 or 1.0 μg per mouse) or i.p. (3 to 100 mg/kg) on the analgesia induced by i.c.v. injections of [D-Pen2, D-Pen3] enkephalin (DPDPE), a δ₁- opioid receptor agonists or [D-Ala², Glu ⁴] deltorphin II (deltorphin II), a δ_2 -opioid receptor agonist, were determined in male Swiss Webster mice. DPDPE or deltorphin II (15 µg per mouse) produced robust analgesic effect 15 min after the drug administration. The analgesic action of DPDPE or deltorphin II was not modified by either i.c.v. or i.p. injections of M3G. U-50,488H, a k-opioid receptor agonist at a dose (25 mg/kg, i.p.) produced analgesia. The analgesic response to U-50,488H was also not altered by M3G (10, 20 or 40 mg/kg, i.p.). It is concluded that in vivo, M3G does not interact with δ_1 - δ_2 - or κ -opioid receptors (Supported by grant DA-08867 and a Research Scientist Development Award, K02-DA-00130 from the National Institute on Drug Abuse).

COMPARISON OF TESTS USED TO EVALUATE THE BEHAVIOR OF AGED ANIMALS. R.N.McLay, R.E. Harlan, S.M.Freeman, A.J. Kastin, J.E. Zadina* Neuroscience Training Program and Depts. of Anatomy, Pathology and Medicine, Tulane Univ. Sch. of Med., and VA Med. Ctr. New Orleans, LA 70112

Young (2 mo.) and aged (24 mo.) healthy Fisher344xBrown Norway rats were evaluated in the eight arm radial maze, Barns circular platform maze, and Morris Water Maze, all of which have been used previously to demonstrate learning and memory deficits in aged animals. Rats also were tested for motor performance on a rotorod and by measurement of locomotor activity. As expected, aged animals showed significantly impaired performance (p<.05) in the Barns, Morris, and eight-arm radial mazes. Important differences were noted, however, among the results in the three mazes. Ten out of 10 aged animals were designated cognitively impaired (those outside the 95% confidence interval for young animals) in the eight-arm radial maze. Eight animals of 10 in the Morris maze, and only 6 of 10 in the Barns maze were designated as impaired. Evaluation of performance of aged rats in the eight-arm radial maze was judged to be problematic since aged rats had a significantly (p < 0.01) higher percentage of errors of omission than young animals. For aged animals, a significant (p<0.05) correlation also was found between motor performance on the rotorod and performance in the Morris maze, indicating that physical or motor functions could contribute to performance in this maze. No such correlation was seen in young animals or in glucocorticoid-induced models of accelerated hippocampal senescence. No significant correlations were found among motor tests and senescence. No significant correlations were found among motor tests and measures of learning and memory in the Barns maze. The lower percentage of animals judged to be cognitively impaired by assessment in the Barns maze may therefore reflect a smaller bias against aged animals with motor impairments.

459.3

DIMINISHED HIPPOCAMPAL CELLULAR RESPONSIVITY DURING CLASSIC AL CONDITIONING IN AGED RABBITS. <u>S.D. Bern*, MA Seager & R.L. Borgnis</u>. Center for Neuroscience and Department of Psychology. Miami Univ. Oxford. OH 45056.

Aged rabbits as well as those with hippocampal lesions show behavioral learning deficits in a trace NM paradigm. It is also widely known that the hippocampus is adversely affected early in the aging process.

Taken together, these findings suggest that the behavioral deficits observed in old animals may be the result of a malfunctioning hippocampus. Studies done in vitro have demonstrated that hippocampal neurons taken from old animals after trace conditioning show reduced responsively to stimulation. However, only one study to date has recorded from the hippocampus while old animals were performing in a trace conditioning task.

The present study involved training old $(40-49~{\rm mos.})$ and young $(3-7~{\rm mos.})$ rabbits in a trace jaw movement paradigm with a 300 ms tone CS, 450 ms trace period, and a 200 ms water US. Animals were trained to a criterion of 8 CRs on any 9 consecutive trials on two consecutive days. Animals were then transferred to a delay paradigm where the CS and US overlapped.

Results indicate that old animals took significantly more trials to reach criterion than young animals. This learning deficit in the old group was accompanied by less responsive CA1 neurons. Both groups showed significant increases in hippocampal activity, but the young animals' increase was much greater. This was true on the first three days of training as well as on criterion day. Time series analyses are being performed to correlate unit firing with the rhythmic behavioral responses elicited in this paradigm. Preliminary results indicate that, in this trace paradigm, the cells' activity may be more closely related to the periodicity of the slow waves than to the behavior.

SHORT-TERM BUT NOT LONG-TERM ESTRADIOL REPLACEMENT IMPROVES RADIAL-ARM MAZE PERFORMANCE OF YOUNG AND AGING RATS. C.L. Williams* Dept. of Psychology: Experimental, Duke University, Durham, NC 27708.

Circulating steroid hormones have been shown to influence hippocampal physiology and morphology. Because the hippocampal formation is known to be involved in learning and memory, the current study investigated whether short- or long-term estradiol replacement to ovariectomized rats would influence performance on a radial arm maze task.

on a radial arm maze task.

In Experiment 1, female Sprague Dawley CD strain rats were ovariectomized at 2 months of age and were implanted with silastic capsules containing no estradiol or one of 2 doses of estradiol. Serum levels of estradiol in these groups were monitored and females were divided into 3 treatment conditions: No Estradiol (serum levels < 20 pg/ml), Low Estradiol (mean serum level = 400 pg/ml), and High Estradiol (mean serum level = 200 pg/ml). Silastic capsules were replaced regularly to maintain serum estradiol within these ranges. Rats were trained daily on a 12-arm radial maze task with 8 baited and 4 unbaited arms immediately after estradiol replacement, and retrained at 14 months of age after 12 months of chronic estradiol replacement. Estradiol at both High and Low doses improved working memory performance of rats after short-term estradiol replacement, but not after long-term replacement.

To determine if rats' responsiveness to estradiol decreases with age, or whether chronic replacement is an ineffective treatment, a second group of Sprague Dawley rats was ovariectomized at 15 months of age and given estradiol replacement via silastic capsules as described above. Rats were trained daily on a 12-arm radial maze task. Results revealed that after short-term estradiol replacement, 16 month old rats showed more accurate overall choice performance than rats with no estradiol.

These data suggest that estrogen improves spatial memory in young and aging rats if treatment is short-term. However, chronic estrogen administration may not be effective as a cognitive enhancer. (Supported by AG09525)

FACILITATION OF COGNITIVE FUNCTIONS IN AGED RATS BY PAST EXPERIENCE DEPENDS ON THE TYPE OF INFORMATION PROCESSING INVOLVED. A COMBINED CROSS-SECTIONAL AND LONGITUDINAL STUDY
F, Dellu, W. Mayo, M. Vallée, M. Le Moal and H. Simon*. Lab. de Psychobiologie

F. Dellu, W. Mayo, M. Vallée, M. Le Moal and H. Simon*. Lab. de Psychobiologie de Comportements Adaptatifs, INSERM U.259, Domaine de Carreire, rue Camille Saint-Saëns. 33077 Bordeaux Cedex, France.

The origin of the impact of individual history on behavior across the life-span, which is commonly observed clinically, has not been studied. This is why the role of previous training in a cognitive behavioral task in subsequent memory performances was studied in a combined longitudinal (animals repeatedly tested when young, at 2-3 months, middle-aged at 12-14 months, and old at 23-26 months) and cross-sectional (animals tested once at those agesy) study, in male Sprague-Dawley rats. Different types of memory (reference and working memory) and/or information processing (route or place learning) were assessed in three different tasks (T-maze, Morris water-maze and 8 arm radial-maze). Our results indicate that experience prevents age-related impairments in the learning phase of the T-maze and the Morris water-maze, in both middle-aged and old rats. Non-experienced animals of the same age were found to present age-related memory deficits. However, previous experience did not have any effect on the learning of the radial-maze or on the transfer performance. It is suggested that controlled processes (intentional and attentional) are impaired by aging and cannot be improved by training, whereas automated processes appear to benefit from it. These data underline the heterogeneity of cognitive aging and indicate that aging is not inevitably accompanied by a decline in performance.

that a meetine interregionary of cognitive aging an indicate that aging is not inevitably accompanied by a decline in performance.

AGE-RELATED NONNEURAL TISSUE PATHOLOGIES IN MALE RATS: LACK OF CORRELATION WITH MNEMONIC AND MOTORIC ABILITIES. M.V. Wagster 1.5.9, I.K. Berzins*, J.A. Kotzuk*, K.M. Frick*, M.E. Barra*, M.E. Mooney*, A.L. Markowska*, D.L. Price 1.3.5, Dept. of Pathol.*, Neurol.*, Neurosci.*, Compar. Med.*, and Neuropathol. Lab.*, Johns Hopkins Univ. Sch. of Med. & Dept. of Psychol.*, Johns Hopkins Univ., Balt., MD 21205.

Aged primates and rodents can display varied behavioral performance on a number of tasks, particularly those in cognitive and motor domains. We determined the extent to which nonneural tissue pathologies influence capabilities on tasks designed to assess these behaviors. Thirty Fisher 344 male rats aged 23 months and twelve animals divided equally among the age groups, 4, 11, and 17 months, were tested for reference memory and working memory in the Morris Water Maze and on several sensorimotor tasks. After final testing, the animals were sacrificed and organs were removed including heart, lung, liver, kidneys, pancreas, thyroid, and eyes. The paraffinembedded tissues were stained with hematoxylin & cosin, and rated on a 0-5 scale by one of the investigators who was blind to the animals' age and behavioral status. Numerous pathologies, particularly in heart, liver, testis, kidney, and hemic system were found in the oldest animals. Moderate to severe pathology existed in the oldest animals as follows: heart, 20%; liver, 13%; kidney, 63%; and testis, 100%. Despite these findings, there was no consistent relationship determined between memory or motor abilities and extent of pathology. In summary, we conclude that age-related degenerative changes in multiple organ systems do not account for the variability seen in memory and motoric ability with age.

ACUTE BUT NOT CHRONIC ADMINISTRATION OF ESTRADIOL INCREASES SPINE DENSITY OF DENTATE GRANULE CELLS IN THE AGED RAT. P. Henderson 1, C.L. Williams 2, and G. Einstein 1*. Dept. of Neurobiology 1 & Dept. of Psychology: Experimental 2, Duke University, Durham, NC 27710.

Estrogens have been shown to have widespread effects on many brain regions in developing and young animals. Little, however, is known about the effects of estrogens on the aging brain and associated changes in cognition. For this reason, we looked at changes in the morphology of neurons in the hippocampus, a brain region involved in learning and memory, in both aging and young rats. Female Sprague Dawley CD strain rats were ovariectomized at 2 months of age and were treated with no estradiol, chronic estradiol for over one year (either low or high dose), acute estradiol (at 24 and 48 hours prior to sacrifice), or chronic and acute estradiol As a control for any changes due to aging alone, young adult rats (4-5 months old) were ovariectomized and treated with either no estradiol or acute estradiol. In brain slices from these animals, dentate granule cells were intracellularly filled with Lucifer Yellow, filled neurons were traced using a drawing tube, and dendritic spine density was calculated.

using a drawing tube, and dendritic spine density was calculated. By doing this, we found: (1) aged rats have a significantly lower dendritic spine density than young adults; (2) chronic estradiol does not ameliorate the loss of spines with normal aging; (3) in contrast, acute estradiol does ameliorate the loss of spines with normal aging, increasing spine density to the level seen in young adults. These results suggest that the aging female hippocampus is still responsive to estrogens and that their action on this brain region depends on the temporal pattern of their administration.

AGE-RELATED DECLINE IN MEMORY-RELATED BEHAVIOR IN FEMALE FISCHER 344 X BROWN NORWAY F1 RATS. G. Rajakumar* N. C. de Fiebre. G. Simpkins and J.W. Simpkins. Department of Pharmacodynamics & Center for Neurobiology of Aging. College of Pharmacy, University of Florida, Gainesville, Florida 31610.

To determine the effects of aging on memory-related behavior in female rats, we monitored estrous cycles through vaginal lavages for one month in F344 X BN F1 rats of ages of 6 mo (young), 12-14 mo (middle -aged) and 24-28 mo (aged), then evaluated behavior in a spatial task using the Morris Water maze. Young and middle-aged animals show normal 4-5 day estrous cycles, while aged rats exhibited extended periods of diestrus, evidence of repeated pseudopregnancy. Rats were trained for three days (12 trials /day) in a paradigm using a submerged platform. Acquisition of the behavior was not different among the three age groups. Following a 24 h delay, rats were given a single learning trial with the submerged platform, then were immediately tested for behavior with the platform removed. Memory-related performance for specific age groups showed the following: Young rats spent more time in the target quadrant than the remaining three quadrants (P<0.05). Middle aged rats crossed the target quadrant than the remaining three quadrants (P<0.05). Middle aged rats crossed the target quadrant more often the regret quadrant to the target quadrant to the adultive training latencies. Only, of the ability to non-spatially learn the task as measured by training latencies. This deficit is associated with the age-related occurrences of repeated pseudopregnancy. (Supported by NIA 10485).

IMPAIRED SPATIAL LEARNING AND MEMORY IN MATURE AND OLD SPRAGUE DAWLEY RATS.

J.M. Wyss*, J.A. Franklin, X.H. Feng, and Th. van Groen. Dept. of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294.

Studies in our laboratory indicate that in old Sprague Dawley (SD) rats there is a selective breakdown in the limbic cortex, this reorganization should disrupt the transfer of information between the hippocampal formation and many areas of neocortex. Our previous studies demonstrated that lesions of this circuit lead to impaired spatial learning and memory. In the present study we employed a water maze task to test that learning and memory are disturbed in these old rats. At the end of the five day training period, young (i.e., three month old SD) displayed the best performance and had the shortest escape latency, i.e., 15 ± 3 sec, 12 month old SD were somewhat slower to learn, i.e., 17 ± 5 sec, 18 month old SD were slower to learn, i.e., 53 ± 15 sec, and most 24 month old SD did not learn, i.e., an escape latency of 65±58 sec. Also, only young SD displayed a clear preference for the correct quadrant in the probe trial, whereas the other groups of older rats did not spent most of their time searching in the correct quadrant. However, both the 12 month old and the 18 month old SD did display a spatial bias in their learning curves. Furthermore, it should be noted that the young animals were very similar in their learning capability, but the older rats displayed a large variability in their performance, i.e., some were good learners and others did not learn at all. These data demonstrate that in old rats, the breakdown of the connections between the retrosplenial cortices and the hippocampal formation lead to an impairment of spatial learning and memory. NIH: R01 AG 11958

A DEFICIT IN THE REDISTRIBUTION OF PROTEIN KINASE C (PKC)-Y IN AGED F344 RATS IS RELATED TO AN IMPAIRMENT IN SPATIAL WORKING MEMORY.

F. Morrell*, M.A. Rossi, L. deToledo-Morrell, Dept. of Neurological Sciences, Rush Medical College, Chicago, II, 60612

F. Morrell*, M.A. Rossi, L. deToledo-Morrell, Dept. of Neurological Sciences, Rush Medical College, Chicago, IL 60612.

A significant association between spatial working memory and the hippocampal distribution of PKC-γ was identified in aged male F344 rats using the eight-arm radial maze task. Twelve aged (27 mos. old) rats were behaviorally separated into 6 memory-intact and 6 memory-impaired animals. As controls, we used 7 young (5 mos. old), memory-intact rats. All animals were sacrificed and brains rapidly dissected and frozen at -80 °C following the last day of behavioral testing. Ten micron thick coronal tissue sections were taken beginning 1mm caudal to the septal pole of the dorsal hippocampal formation. The tissue was immediately transferred onto nitrocellulose (NC) film-coated microscope slides (Grace Bio-Oncology, Ml). Avidin-biotin peroxidase immunchistochemistry was then carried out using affinity purified anti-PKC-γ (GIBCO-BRL) specific for the hinge region of this PKC isoform. Purified PKC-γ protein calibration standard ladders were prepared and processed on NC coated slides along with the tissue. All PKC immunostaining on NC film-coated microscope slides was then quantified using image analysis software. In both dentate gyrus (DG) and CA1 subfields of the hippocampal formation, the data demonstrate a significant inverse correlation between choice accuracy and the ratio of soma to proximal dendrite immunostaining. The extent of spatial memory impairment correlates with a higher cell body to dendrite ratio for DG (r=0.814, p<0.001) and CA1 (r=0.825, p<0.001) immunostaining. Absolute hippocampal levels of PKC-γ did not vary with chronological age (young vs. old). Consequently, there appears to be a deficit in a hippocampal soma-to-dendrite redistribution of PKC-γ in aged rats with poor spatial working memory. AGE ASSOCIATED BEHAVIORAL DEFICITS IN F344/BN RATS. <u>I.P. Kesslak*</u>, T. J. Zomorodian, J. Chia, C.W. Cotman, Institute for Brain Aging, Dept Neurology, Univ. Calif., Irvine, CA 92697. In the normal population there is an increase in behavioral

In the normal population there is an increase in behavioral impairment associated with age. Rats of the F344/BN strain are long lived, with a mean life expectancy of 36 months. A battery of behavioral tests was used to characterize functional ability for F344/BN rats 3, 22, 32 and 36 months of age. Animals were tested on the 8-arm radial maze, water maze, spontaneous alternation and open-field. Repeated measures analysis of variance (ANOVA) indicated that after 21 days of testing on the 8 arm maze there was a significant difference between the young, 3 month old rats, and the older groups, which did not statistically differ from each other. Older rats made fewer choices and had longer latency to complete the task, however, they also made fewer errors than the young group. The water maze was more sensitive than the 8-arm maze for the detection of age related deficits, with the youngest group having the best performance and the oldest group the longest latency to locate a submerged platform after 10 days of testing. Hypoactivity and reduced spontaneous alternations was also observed with increased age. In the very aged group there was frequent physical limitations, such as reduced mobility, tumors and a high mortality rate. Results indicating a behavioral deficit for the aged rats may be due in part to performance deficits, rather than cognitive deficits. Supported by the MacArthur Foundation and NiA.

SPATIAL MEMORY-IMPAIRED AGED F344 RATS SHOW A REGION SPECIFIC DEFICIT IN G-PROTEIN COUPLING OF THE M1 MUSCARINIC CHOLINERGIC RECEPTOR. M.A. Rossi' L. deToledo-Morrell, D.C. Mash', F. Morrell, Dept. Neurological Sciences, Rush Med. College, Chgo, IL 60612, 'Dept. Pharmacology & Neurology, U. of Miami School of Medicine, Miami, FL.

The ability of acetylcholine and other full agenists to stimulate postsynaptic M1 muscarinic receptor-mediated second messenger signalling is important for memory function. However, in Alzheimer's disease, as well as aged rodents, the

The ability of acetylcholine and other full agonists to stimulate postsynaptic M1 muscarinic receptor-mediated second messenger signaling is important for memory function. However, in Alzheimer's disease, as well as aged rodents, the density of this receptor subtype appears to remain unchanged relative to controls. Physiologically, in mammals, including humans, G-protein coupled high agonist affinity (K_,) and G-protein uncoupled low agonist affinity (K_,) M1 receptor states concurrently exist. The K_/K__ ratio for agonist, an index of G-protein coupling, has been shown to directly correlate with agonist efficacy of M1 muscarinic cholinergic receptors. In the present study, we demonstrate a relationship between age-dependent spatial memory impairment and alterations in K_/K_, Following testing in the eight-arm radial maze task, the high and low agonist affinity states of the M1 muscarinic receptor were measured using in situr receptor binding autoradiography in the HF of 5 young (6 mos. old) and 12 old (27 mos. old) F344 rats. A competition binding study was performed using the M1 muscarinic cholinergic receptor antagonist [Hpliprienzepine (2.5 nM), with increasing concentrations of carbachol (1x10 ** -1x10 ** M), the competing agonist. Two major findings were observed. First, a significant age effect (young vs. old) of the K_/K_, ratio was seen only in CA3 (F=22.4, p<0.001). Secondly, when young (n=5), old memory-intact (n=6) and old memory-impaired (n=6) animals were compared using a two-way ANOVA followed by multiple comparison tests, K_/K_, was found to be significantly decreased (p<0.05) in old-impaired rats compared to the old-intact and young animals in dentate gyrus, CA3 and CA1. Moreover, no such memory-related effect was seen in neocortex, the internal control. There was no significant difference in the density (B_{ns}) or affinity (K_g_) of [Hpiprienzepine binding between the groups. The presence of a memory-dependent effect in the HF and lack of a similar change in neocortex suggests that th

THE SUBCELLULAR DISTRIBUTION OF HIPPOCAMPAL PKC-γ IS RELATED TO SPATIAL LEARNING IN INDIVIDUAL AGED RATS. P.J. Colombo*¹, W.C. Wetsel², & M. Gallagher¹ ¹Department of Psychology. University of North Carolina, Chapel Hill, NC 27599, and ²Lab. of Cell. and Mol. Pharm., NIEHS, Research Triangle Park, NC 27709.

The protein kinase C (PKC) isoforms comprise a family of enzymes

Ine protein kinase C (PKC) isotorms comprise a family of enzymes important for signal transduction and implicated in activity-dependent neural plasticity and memory formation. In the current study, long- and short-term training protocols were used to determine whether age-related spatial memory impairment is associated with age-related alterations in hippocampal PKC-γ immunoreactivity. Six- and 24-month-old male Long-Evans rats were trained using our standard spatial learning protocol in a water maze (3 trials/day for 8 days). Two weeks later, all rats were given 6 trials in a new spatial environment to acquire a new escape location. Rats were decapitated immediately after behavioral testing, the hippocampi were homogenized, and soluble and particulate fractions were prepared from individual subjects. Proteins were separated by 10% SDS-PAGE, transferred electrophoretically to PVDF membranes, and immunostained for PKC-γ. ANOVA revealed a significant increase in PKC-γ immunoreactivity in the soluble fraction of aged-impaired rats (N=15) in comparisons with aged-unimpaired (N=12) and young rats (N=13). The concentration of PKC-γ in the soluble fraction was correlated significantly with place-learning. These results indicate that the subcellular concentrations of PKC-γ in the hippocampus of aged rats may be related to spatial memory formation.

EFFECTS OF AGE AND OPEN FIELD EXPOSURE ON PHORBOL ESTER BINDING IN THE RAT HIPPOCAMPUS AND CORTEX. A.H. Nagahara, I.A. Dowd, and R.I. Handa*. Department of Cell Biology, Neurobiology, and Anatomy. Loyola Medical Center, Maywood, IL 60153.

Previous findings in our laboratory showed age-related changes in the induction of c-fos m-RNA in the prefrontal cortex and caudate of aged rats following exposure to an open field. The present study examined age-related changes in phorbol ester binding, a measure of membrane-associated protein kinase C. Three age groups (5, 14, & 21 mo) of male Fischer 344 rats were used in the present experiment. Animals were exposed to a novel square open field for 20 min or remained in their home cages. Animals were sacrificed immediately after exposure to the open field or directly from their home cage. The level of phorbol ester binding was measured by quantitative autoradiography using [3H]phorbol 12, 13-dibutyrate. As previously reported, no significant age-related difference was observed in the number of box entries or rearing in these animals. Age-related increases in phorbol ester binding were observed in the CA1, CA3, and dentate gyrus of hippocampus, the caudate, and the anterior ingulate in the 21-mo rats (vs. 5-, 14-mo); however, no age-related changes were observed in retrosplenial and somatosensory cortex. In addition, exposure to the open field resulted in a decrease in phorbol ester binding in the hippocampus, caudate, and several cortical areas across age groups. No significant Age x Open Field interaction effects were observed. These findings suggest age-related alteration in the levels of membrane-bound protein kinase C in certain brain regions of aged rats. Supported by USPHS AA098696 (RH) and K21-AA00192 (AHN).

DIFFERENTIAL GENE EXPRESSION IN AGING MICE RELATED TO SPATIAL LEARNING PERFORMANCE. L.L. Bellush*, J.P. Walker, A.M. Wright, and R.A. Colvin. Program in Neurobiology, College of Osteopathic Medicine, and Dept. of Psychology, Ohio Univ., Athens, OH 45701. We are exploring the hypothesis that decline in spatial learning ability in

aging rodents is related to changes in gene expression. Using a hidden platform version of the Morris water maze, we have consistently found about 30% of 24 mo. old mice to have no learning impairment (unimpaired), while another 30 to 40% show significant impairment relative to young controls (impaired). Motor and sensory impairments were experimentally ruled out. Poly-A+ mRNA was isolated from the cholinergic forebrain nuclei of the impaired and unimpaired mice and bound to Biomag beads. Using AMV reverse transcriptase, a single stranded cDNA library was synthesized on Biomag beads using the Poly-A* mRNA as a template. Biomag-cDNA from unimpaired mice was used to synthesize a complimentary or sense strand cDNA. Subtraction hybridization was performed by adding the unimpaired sense strand to the impaired Biomag-cDNA beads. All complimentary sequences were hybridized leaving only differentially expressed sense strand cDNA (subtracted cDNA) in solution. The resulting subtracted cDNA library was amplified by PCR. Southern blot analysis revealed 3 distinct bands of 282, 331, and 532 base pairs. These results, indicate the differential expression of 3 possible genes in the unimpaired cholinergic forebrain nuclei. Subcloning and sequencing of the subtracted cDNA may reveal genes whose protein products are vital for the proper function and support of the cholinergic system. Supported by the Ohio University College of Osteopathic

DEVELOPMENTAL DISORDERS III

460.1

Examining MCI Mechanisms Using Fractionated Reaction Time C.A. Lewis, P.R. Surburg & R.D.Devoe*. Indiana University, Bloomington, IN 47405. One method of assessing neural development is to look at the acquisition of motor milestones. One milestone that appears at the age of eight is cross lateral integration inability to attain this milestone is called midline crossing inhibition (MCI). Individuals with mental retardation (MR) manifest developmental delays and MCI persists. Eason and Surburg (1993) developed a new method to assess MCI which is predicated upon an information processing model. Crossing the midline is considered a more complex task and requires more processing time than ipsilateral movements as evidenced by slower reaction times (RT). The purpose of this study was to investigate the processing that occurs during midline crossing of individuals with MR by measuring premotor and motor times. By fractionating RT into premotor and motor time, a determination can be made whether MeI is the result of information processing by the central nervous system or peripheral processing by the peripheral nervous system. Seven adults with MR were tested with the same midline crossing apparatus and protocol (Eason and Surburg, 1993) implementing a choice RT and movement time task of the lower limb. Subjects performed nine ipsilateral, nine contralateral and nine midline motions completely randomized on four different days. Surface EMG recorded muscle activity of the tibialis anterior in order to measure premotor and motor times. All data was collected online using a sample rate of 1KHz. Results of a 3 x 4 (direction by day) repeated measures ANOVA for premotor time were a significant main effect for direction and an interaction effect of day by direction. Post hoc analysis determined the premotor time in the contralateral movements were significantly slower than premotor time in the midline and ipsilateral directions. There were no significant differences for motor or movement times but total reaction time (premotor + motor) results demonstrated a significant MCI effect. In conclusion, MCI was present in these individuals with MR and longer premotor times in the contralateral direction implies that this difficulty in crossing the midline is due to information processing in the central nervous system.

7B2 AND PC₂ ARE ABSENT IN SOME PRADER-WILLI PATIENTS THAT ARE ALSO UNABLE TO PROCESS THE VASOPRESSIN PRECURSOR CORRECTLY. B.A.Th.F. Gabreëls, D.F. Swaab and F.W. van Leeuwen*. Neth. Inst. Brain Res., 1105 AZ. Amsterdam. The Netherlands.

1105 AZ Amsterdam, The Netherlands.

Prader-(Labhart-)Willi syndrome (PWS), with an incidence of 0.5 (per 10⁴ births), is characterized by infantile hypotonia, early childhood obesity, mental deficiency, short stature, small hands and feet and hypogonadism. This syndrome is associated with a defect at chromosome 15q11-q13, close to the location of the 7B2 gene (15q13-q14). In 70% of the cases small or large deletions are present. The remaining PWS patients display maternal uniparental disomy (22%) or other abnormalities of chromosome 15. 7B2 is considered to be a neuroendocrine chaperone of the processing enzyme PC₂. Since 7B2 gene products are expressed in neuroendocrine cells that are probably affected in PWS (e.g. by a pleiotrophic influence of the neighboring deletion), the presence of 7B2 and PC₂ was studied immunocytochemically in the supraoptic and paraventricular nucleus of the hypothalamus of six subjects clinically diagnosed as PWS patients. Molecular genetical diagnosis of this fixed PWS material was only partially possible.

Four of the six PWS patients studied showed no reaction to the 7B2 antibody MON-102, whereas all 30 control patients did. However, two of the four MON-102 non-reacting PWS patients reacted to other 7B2 antibodies. Surprisingly, the two 7B2 immunonegative PWS patients did not react with various vasopressin antibodies either, whereas they did react normally with five antibodies recognizing the vasopressin precursor. In these two patients no PC2 immunoreactivity was found. Thus, it is possible that the symptoms of diabetes in these two patients are not merely attributable to poorly regulated diabetes mellitus. In the other patients 7B2 and PC2 were expressed. In conclusion, the vanishing of 7B2 gene products is not obligatory for PWS, possibly due to the variable genetic background of PWS patients. The absence of 7B2 in two patients may result in a premature processing of proPC2 and in the subsequent inability to process the vasopressin precursor accurately. Brain material was obtained via the Netherlands Brain Bank (coordinator Dr. R. Ravid).

QUANTITATIVE ANALYSIS OF GRAY MATTER VOLUMES IN CHILDHOOD-ONSET SCHIZOPHRENIA AND ATTENTION DEFICIT/HYPERACTIVITY DISORDER.

J.N. Giedd, F.X. Castellanos*, J.C. Rajapakse, L.K. Jacobsen, J.A. Frazier, S.D. Hamburger, J.L. Rapoport. Child Psychiatry Branch, National Institute of Mental Health, Bethesda, MD 20892-1600.

We have previously found decreases in total brain volume in children with childhood-onset schizophrenia (COS) (Frazier et al., 1996) and in boys with attention deficit/hyperactivity disorder (ADHD) (Castellanos et al., 1996). We now report gray matter volumes for 28 COS subjects and 52 age-, sex-, height-, weight-, and handedness-matched controls and 59 ADHD boys and their 64 matched controls. Gray matter volumes were obtained using an innovative automated segmentation algorithm based on probabilistic modelling of gray and white matter distributions. Subjects with COS had a 10% smaller total cerebral volume with a 15% reduction in gray matter and 6% reduction in white matter. The decrease in gray matter in COS (but not white matter) remained significant (p=.005) after covariance for total brain volume. In contrast, subjects with ADHD had a 4% decrease in total brain volume with a 4% decrease in gray matter and a 5% decrease in white matter. Neither decrease remained significant after covariance for total brain volume. For controls and the two patient groups gray matter decreased and white matter increased significantly with age, but none of the slopes differed between groups. These data indicate different developmental processes specific to these two disorders.

GABAA RECEPTOR EXPRESSION IS REDUCED IN ANGELMAN SYNDROME BRAIN. T. M. DeLorey, B. Minassian, A. Datt, A. V. Delgado-Escueta*, R. W. Olsen. Depts. of Pharmacology and Neurology, UCLA, and West Los Angeles VA Medical Ctr., Los Angeles, CA 90095

GABA_A receptor expression appears to be reduced in postmortem brain of a patient with Angelman syndrome, measured by autoradiography and mRNA levels. Angelman syndrome is a severe form of mental retardation with epileptic episodes being present in ~90% of the probands. This syndrome has a prevalence rate of 1 in 10,000 births. Approximately 70% of Angelman syndrome probands have a large (~4 Mb)deletion in chromosome 15q11-13. Within this deletion region is found a cluster of three GABA_A receptor subunit genes (GABRBB3, GABRA5, and GABRG3). The postmortem brain of a 3-year old female Angelman syndrome proband with epilepsy was studied for altered GABA_A receptor expression as compared to an age and gender matched normal brain. Radioligand binding using the benzodiazepine antagonist flumazenil revealed a reduction of approximately 50% in the temporal cortex of Angelman syndrome brain as compared to control temporal cortex. In addition, mRNA levels as determined by RT-PCR using primer sets for the GABA_A receptor subunits β_3 , were found to be reduced. Other mRNAs, including β -actin and GABA_A receptor subunits β_2 and α_5 were present in AS in normal amounts. Supported by NS22071 and NS 21908.

INHIBITION OF BEHAVIOR IN A MOUSE MODEL OF DOWN SYNDROME. M.E. Coussons-Read and L.S. Crnic*, Dept. of Psychology, Univ. Colorado Denver, Denver, CO 80217 and Depts. Pediatrics and Psychiatry, Univ. Colorado School of Medicine, Denver, CO 80262.

The Ts(1716)65Dn (Ts65Dn) mouse carries a translocation chromosome containing most of the human Down syndrome (DS) homologous region of mouse chromosome 16 and has shown promise as a model for understanding the mechanisms behind the neural, behavioral and immune phenotype of human DS. Hyperactivity, poor Morris maze learning and lack of avoidance of the open arms of the plus maze have been demonstrated. Mice were tested for spontaneous alternation and laterality in a T maze, shock motivated spatial learning and reversal in a Y maze, shock sensitivity, and auditory startle and shock potentiated startle habituation. Trisomic (TS) mice alternated significantly more than non-trisomic littermate controls (44 vs 23%, p .01), but showed no difference in laterality or shock sensitivity Simple left-right spatial learning was not impaired, however the TS mice required significantly more trials to reach criterion in reversal triaining (42 vs 17 trials, p < .002). Habituation of startle was retarded in the TS mice, with no habituation evident in the first 50 trials, in contrast to the normal habituation in controls (p < .025 for the interaction between genotype and trial block). This trend was not significant for the shock potentiated startle, where neither group habituated. Together with preliminary data indicating delayed reversal in a non-spatial black-white discrimination task, these data support the interpretation that inhibition of behavior is impaired in these mice. Supported by HD04024, HD17449, MH11090 and MH17449.

PELIZAEUS-MERZBACHER DISEASE (PMD) - CLINICAL, RADIOLOGICAL AND MOLECULAR BIOLOGICAL STUDY, INCLUDING A SYMPTOMATIC CAREER K Murayama, +S Murayama*, #H Kosaka, H Watanabe, M Kodama, +l Kanazawa & K Kodama Dpt. Pediatrics, National Rehabilitation Center for Disabled Children, Tokyo, Japan, +Dpt. Neurology, the University of Tokyo & #Dpt. Pharmacology, the University of California, San Diego

PMD is a sex-linked-recessive progressive neurological disorder characterized by developmental disturbance in the formation of myelin in the central nervous system. The abnormality in the gene for proteolipid protein (PLP) was reported in about 10-30% of PMD. In the middle-sized urban center for handicapped children (200 beds in the ward), ten male patients matched the clinical diagnosis of PMD. The age ranged from one year to 32 years. All cases showed psychomotor retardation associated with 1) the reversal of signal intensity in T2-weighted images (T2WI) of the gray and white matter of the brain MRI; and 2) the lack of response after the first wave in auditory brain stem response. The analysis of PLP gene proved that four out of ten cases (two out of three cases with positive family history) had a point mutation of the gene. One case with a point mutation had a concomitant heterodupulication of the gene. Clinical picture of the cases with abnormal PLP gene was relatively homogeneous and usually severer than the case with normal PLP gene. The mother of one case (32 years of age) with heterozygote of a point mutation (Exon 2, 134A-G, Leu45Arg) first presented with slowly progressive spastic paraparesis in the kindergarten. Cerebellar scanning speech was noticed in the junior high school, and intention tremor at the age of 22 years. She was now in almost wheel-chair-bound state with prominent nystagmus, dysmetria and dysarthria. Her brain MRI was typical in the reversal intensity in T2WI of the gray and white matter, but was different from male PMD in relatively normal Flair images. Since symptomatic career of PMD was very rare, the study of this case may provide new insights into the biology of PLP.

Subcellular Localization Supports a Role for the Fragile X Mental Retardation Protein in Transporting mRNAs from the Nucleus to Somatodendritic Ribosomes SM Hersch*. C-A Gutekunst*, Y. Feng, ST. Warren. Departments of Neurology* and Biochemistry, Emory Univ. School of Medicine, Atlanta, GA 30322

Accumulating evidence points to a role for the fragile X mental retardation protein (FMRP) in transporting specific mRNAs from the cell nucleus to cytoplasmic ribosomes; however, FMRP has not yet been visualized in the cellular compartments that this model would predict. We have used specific monoclonal antibodies and immuno-electron microscopy (EM), with DAB and immunogold as labels, to study the subcellular localization of FMRP in rat brain. Immunoreactive study the succentual localization of FMRF in fat obtain. Infiniteleactive neurons occurred throughout the brain, containing label primarily in the perikaryon and proximal dendrites. EM revealed FMRP immunoreactivity in somata, large and small dendrites, dendritic spines and some axon terminals. Unlabeled dendrites and spines suggest that FMRP localization may be selective in particular dendrites and spines. EM, using immunogold, allowed exquisite resolution of FMRP location. Immunogold particles were found in neuronal, but not glial, nuclei. Some were visualized within nuclear pores. In neuronal cytoplasm, immunogold particles were primarily found in association with free ribosomes. Occasional immunogold particles were found on the cytoplasmic surface of rough endoplasmic reticulum. In dendrites and dendritic spines, immunogold particles were cytoplasmic and were found in the submembranous regions in which ribosomes commonly occur. These findings are consistent with the hypothesized role for FMRP as a translocating RNA binding protein. Supported by the Howard Hughes Medical Institute (SW) and NS01624 (SH).

CNS NORADRENERGIC TRANSMISSION AND AGE-RELATED BEHAVIORAL CHANGES IN TS65-DN MICE, A PUTATIVE DOWN SYNDROME MODEL. J. Flórez*, R.M. Escoribuela*, I.F. Vallina, M. Megías*, C. Baamonde, C. Martínez-Cue¹, M. A. Lumbreras¹, A. Fernández-Terue¹, F. Mayor¹, D. Crespo³, A. Tobeña³, M. Dierssen¹, Dept. ¹Physiology & Pharmacology and ³Anatomy & Cel. Biology, Univ. Cantabria, Santander; "Unit Med. Psychology, Univ. Auton. Barcelona; *Dept. Molec. Biology, Univ. Auton. Madrid, Spain.

Further characterization of Ts65Dn mice has included: a) the biochemical analysis of β -adrenergic transmission in hippocampus (HC), cerebral cortex (CX) analysis of β-adrenergic transmission in hippocampus (HC), cerebral cortex (CX) and b) the study of age-related behavioral and cognitive changes. In 4-month-old male Ts65Dn mice, binding studies performed with β-HJCGP-12177 showed no change in β-adrenoceptor densities and slightly reduced affinity in CX, and reduced density in HC, compared to control (non-trisonic litter mates). Adenylate cyclase activity, measured by cAMP accumulation, was also depressed in HP and CX, but not in CB of Ts65Dn mice in basal conditions and after stimulation with both isoprenaline and forskolin, β-ARK immunoreactivity, a regulatory protein of β-adrenoceptors, was not modified in the CB of Ts65Dn mice. Ts65Dn males (9-month-old) were tested in the plus mage for the evaluation of memory (latency to move from the open to the enclosed arm), in the open field to study their habituation pattern, and in the the enclosed arm), in the open field to study their habituation pattern, and in the Morris water maze for measuring spatial working memory (by using the repeated acquisition paradigm). In all experiments three groups were included: Ts65Dn, control (non-trisomic litter-mates) and swiss mice. Ts65Dn showed alterations in the plus maze and in the open field, as well as impaired learning performance. The results showed that: a) young adult Ts65Dn males have impaired β -adrenergic transmission in specific brain areas; and b) in 9-month-old Ts65Dn, behavioral and cognitive parameters remain disturbed as previously found in 4-month-old. THE RELATIONSHIP BETWEEN MUTATION SIZE AND COGNITIVE AND VISUAL PROCESSING SKILLS IN FEMALE FRAGILE X CARRIERS. W. Pizzi*1, S. Block², R. Brusca-Vega¹, E. Berry-Kravis³, D. Maino². Northeastern IL. Univ.¹, Illinois Coll. Optometry², Rush Medical Coll.³.

Chicago, IL.

The Fragile X gene contains a trinucleotide (CGG) repeat which is unstable and expands as it is passed from carrier to the affected offspring. There are two mutated forms of the gene in female carriers; the premutation, with 43-200 CGG repeats, and the full mutation with >200 repeats. This gene is thought to produce a protein necessary for normal brain development which is reduced in the mutated state. In this study, fragile X the mutated state. In this study, fragile X premutation and full mutation female carriers were compared on three tasks of visual processing and cognitive skills. In each of there were significant differences between In each case. premutation and full mutation carriers on Regression analyses showed a significant negative correlation between the number of trinucleotide repeats and scores on these tests. These data suggest that as the number of CGG repeats increases there is a corresponding decrease in cognitive ability.

MULTIPLANE MORPHOMETRY OF CINGULATE GYRUS IS CORRELATED WITH NEUROPSYCHOLOGICAL AND ERP

CORRELATED WITH NEUROPSYCHOLOGICAL AND ERP MEASURES OF DIVIDED ATTENTION IN AUTISM. P. G. Lesnik, K. T. Ciesielski*, A. Caswell, J. E. Knight, E. G. Benzel, B.E. Hart, and K. Yaksich. Clinical Neuroscience Laboratory, Department of Psychology, University of New Mexico, Albuquerque, NM 87131.

Since recent PET studies showed the significant role of the anterior cingulate gyrus (CG) and consistent frontal dorsolateral coactivation in divided attention tasks in healthy humans (Corbetta, et al.,1993; Devinsky, et al.,1995), and since ERP and neuropsychological observations revealed a specific inhibitory deficit in divided attention in autism (Ciesielski, et al.,1995) we suggest that morphological abnormalities in CG may underlie deficits in divided divided attention in autism (Clesseiski, et al., 1995) we suggest that morphological abnormalities in CG may underlie deficits in divided attention and frontal brain dysfunctions reported in autism. High-functioning subjects with autism and (age, gender) matched controls were submitted to 1.5 Tesla brain MRI and to frontal lobe assessment using The Wisconsin Card Sorting Test and the Stroop Test. A new protocol for multi-plane quantitative MRI analysis of CG was developed. Results in autism in contrast to controls, revealed significantly reduced morphometric measures of natorice CG (co. 05). significantly reduced morphometric measures of anterior CG (p<.05). These findings were correlated with poorer performance on frontal lobe tests (p<.001) and with decreased amplitude of negative waves to targets recorded during an ERP divided attention task (p<.05) and increased enhanced negative waves to task irrelevant stimuli (p< .05). The above converging evidence is discussed in the context of mesialfrontal and anterior limbic involvement in autism.

PLATELET SEROTONIN IN AUTISM, ASPERGERS SYNDROME, AND PDD-NOS: GROUP COMPARISONS AND THE EFFECTS OF FAMILIAL LOADING.

G. M. Anderson*, P. Szatmari, C. J. McDougle, P. A. McBride, L. M. Hall, L. A. Hoult, and D.J. Cohen. Yale Child Study Center, New Haven, CT 06510, and the Depts. of Psychiatry, McMaster University, Hamilton, Ontario L8N 3Z5 and Cornell University Medical College, New York, NY 10021.

Studies of platelet serotonin (5-hydroxytryptamine,5HT) in autism have found substantial group mean elevations in autistic individuals compared to normal controls. Recently, we have reported that the elevation is not associated with the lower intelligence often seen in autism. In order to further examine the specificity of the increased platelet 5HT, we have studied relatively large groups of Autistic, Aspergers Syndrome, and Pervasive Developmental Disorder-Not Otherwise Specified (PDD-NOS) patients. In addition, we have compared patients with and without an affected sibling in an attempt to replicate the report that autistic patients with higher familial loading have even higher platelet 5HT. Such studies, in large well-characterized patient groups, should lead to a better understanding of the behavioral correlates and genetic determinants of elevated platelet 5HT. INDICES OF AMINO ACID TRANSMISSION IN HUMAN INFANTS VULNERABLE TO HYPOXIA <u>D. L. Andersen and P. R. Dodd*</u> Clinical Research Laboratory, Royal Brisbane Hospital Research Foundation, Brisbane, Q 4029, AUSTRALIA.

Selective neurotoxicity may underlie vulnerability to asphyxia at birth, as well as SIDS. Term (39 weeks' gestation) control cases have more GLU-R_{NMDA} sites (labelled with [³H]MK801) in frontal cortex than do preterm (~28 weeks') control cases, but vulnerable cases fail to show this increase. Cerebral cortex samples were obtained at autopsy and slow-frozen for storage at $-80^{\circ}\mathrm{C}$. Homogenate binding assays were carried out on rapidly thawed tissue pieces; data were processed with the EBDA and LIGAND programs. There were no significant differences in GLU-R_{NMDA} binding-site affinity ($\mathrm{K_D}$) or density ($\mathrm{B_{MAX}}$) between SIDS cases and controls. However, these sites continued to accumulate postnatally, as evidenced by a rise in $\mathrm{B_{MAX}}$. There were no differences between SIDS cases and controls in the maximal glutamate enhancement of [³H]MK801 binding, although this parameter had still not reached adult levels, suggesting that GLU-R_{NMDA} sites continue to undergo structural reorganization postnatally. GABAA_A receptor sites were invariant in $\mathrm{K_D}$ and $\mathrm{B_{MAX}}$ for [³H]diazepam or [³H]flunitrazepam across all regions during infant development, but values differed from those found in adults. [³H]Diazepam $\mathrm{B_{MAX}}$ was significantly higher in infant than in adult controls, particularly in temporal and occipital cortices, whereas the $\mathrm{B_{MAX}}$ for [³H]flunitrazepam was lower. GABA enhancement of [³H]diazepam binding in temporal cortex differed significantly in infants and adults. Taken together, these data suggest that the amounts and the structures of the human GABAA receptor site differ markedly in infants and adults.

EXCITATORY AND INHIBITORY NEUROTRANSMITTER RECEPTOR EXPRESSION IS ALTERED IN RETT SYNDROME AND IN A MOUSE MODEL FOR RETT SYNDROME. M.E. Blue*, C.F. Hohmann, S. A. Wallace, S. Naidu and M.Y. Johnston. Kennedy Krieger Res. Institute, Johns Hopkins Univ. Sch. of Med. and Morgan State Univ. Baltimore, MD 21205

The role of glutamate receptors in Rett Syndrome (RS), a neurological disorder almost exclusively found in females, which is characterized by profound impairments in motor and cognitive function, was examined by receptor autoradiography for NMDA, AMPA, kainate (KA) and metabotropic (mGluR) receptors in the basal ganglia of 8 cases (ages 2-30 years) and in 8 normal cases (ages 4-20 years). The distribution of EAA receptors also was studied in a mouse model for RS, in which neonatal basal forebrain (nBM) lesions lead to altered maturation of cerebral cortical neurons and connections and cognitive impairments. Mice were studied at postnatal day 10 (P10), P14 and P30. In human RS cases, the densities of AMPA (p<0.05) and GABA (p<0.0001) receptors were reduced in the putamen compared with controls, but the caudate was less affected. NMDA, KA and mGluR receptors were not significantly reduced in the caudate or putamen. The globus pallidus exhibited visible densities of mGluR and GABA sites, but neither site was significantly affected in RS. The density of AMPA, KA and NMDA receptors in the basal ganglia decreased with age in both groups. NMDA receptors were decreased significantly in all layers except layer VI of parietal cortex on the nBM lesioned side versus both sides of control mice. AMPA and KA receptors were not significantly affected. mGluR receptors were increased significantly in layers I-III on the nBM lesioned side at P10; but not at P14 and P30. The findings suggest that both excitatory and inhibitory transmitter function is profoundly but selectively altered in the basal ganglia of RS patients. The preferential decline of binding in the putamen, which serves a primary motor function, is consistent with the prominent motor deficits observed in RS. Preservation of the mGluR, NMDA and KA sites suggests that specific neurotransmitter systems are affected in RS. The selective changes in glutamate receptors observed in the nBM lesioned mice, with some similarities to those observed for RS, support in the nBM

DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID—ACCUMULATION AND AGGREGATION

461.1

PERMEABILITY AND RESIDUAL PLASMA VOLUME OF HUMAN, DUTCH VARIANT, AND RAT AMYLOID \(\beta\)-PROTEIN 1-40 AT THE BBB \(\frac{\text{Geoffry L. Curran*, Jill J. Haggard, Dennis J. Selkoe, and Joseph F. Poduslo Mayo Clinic/Foundation and Harvard Medical School

Amyloid β -protein (A β) has been identified as a primary component of both parenchymal and vascular amyloid deposits in Alzheimer's disease (AD). While A β is produced continuously by cells in the nervous system as well as in peripheral tissues, the extent to which A β in brain parenchyma of AD is derived from peripheral locations is not known. The ability of A β to cross the BBB may lead to localized toxic effects in specific neuronal populations with subsequent increased production of parenchymal A β . To begin to address this issue, the permeability of normal human, the Dutch variant, and rat A β 1-40 at the BBB was determined in the normal adult rat. The permeability coefficient-surface area (PS) product was quantified for each protein after correction for the residual plasma volume (V $_p$) occupied by the protein in the capillary bed of different brain regions using the i.v. bolus injection technique with the same protein radioiodinated with a second isotope of iodine to determine separately PS and V $_p$ values. The PS for normal and Dutch A β ranged from 13-22 x 10-6 ml/g/s in different brain regions, which is 130 to 220 times greater than albumin. These high PS values compare to that of insulin, whose uptake is decidedly by a receptor-mediated transport process, and suggest a similar mechanism for A β . Remarkably, the PS for rat A β was 4 times higher and ranged from 54-82 x 10-6 ml/g/s for different brain regions, suggesting a distinctive species specificity. While the V $_p$ values of human and rat A β were comparable, the Dutch variant was 2 to 3 times higher, indicating adherence to the capillary walls in different brain regions, consistent with the pathology that has been described in brain capillaries with this variant. SDS-PAGE of ¹²⁵I-human A β after 60 min uptake revealed intact protein in plasma and in different brain regions. The high PS values observed for A β at the BBB suggest sources outside the nervous system may contribute, at least in part, to the cerebral A β deposits s

ACTIVATED ALZHEIMER'S DISEASE PLATELETS RETAIN MORE MEMBRANE-BOUND AMYLOID PRECURSOR PROTEIN. <u>Davies TA</u>, Long HJ, Sgro K, Seetoo KF, Tibbles H, Billingslea AM, Fine RE, Levesque CA, Smith SJ, Berkowitz, EM*, Wells JM, Simons ER. Boston U. Sch. of Med. and Boston City Hospital, Boston, MA and V.A. Hosp, Bedford, MA

Activated platelet α -granules' soluble contents are secreted and membrane-bound contents translocated to the plasma membrane. Membrane-bound proteins include the β -amyloid precursor protein (APP) from which the β -amyloid (A β) deposits found in the cerebrovasculature of patients with Alzheimer's Disease (AD) may originate. We found that activated platelets from AD patients exhibit less APP processing, retaining more of the protein on their surface and secreting less as soluble fragments, than do controls. Surface labeling demonstrated that there is little APP or p-selectin on the surface of resting platelets. Upon activation, control platelets exhibited both proteins on their surface while advanced AD patients exhibited similar amounts of p-selectin as controls, but retained significantly more surface APP. AD platelets secreted similar amounts of most soluble α -granule contents as controls, but less APP fragments. Platelets from non-demented age-matched donors, Pick Disease or Down Syndrome patients, or patients in early to mid-stage AD, resembled controls. Together these results suggest an APP processing defect specific to platelets from patients with advanced AD. Since activated platelets adhere to the endothelium, the excess APP carried on the membrane of activated AD platelets may account for greater deposition of A β -containing products in the cerebral vasculature of these patients. Supported by NIH AG11526, AG10684, HL07501 and VA Merit grant.

INTERFERON- γ INDUCES ACCUMULATION OF THE AMYLOID β PRECURSOR PROTEIN IN MULTIVESICULAR BODY-LIKE ORGANELLES IN HUMAN BRAIN PERICYTES AND SMOOTH MUSCLECLLS. M.M. Verbeek¹, I.Otte-Höller¹, D.J. Ruiter¹, R.M.W. de Waal¹, A.R. Cools²*. Depts. of ¹Pathology and ²PsychoNeuroPharmacology, University Hospital, Nijmegen, The Netherlands.

Accumulation of the amyloid B protein (AB) in leptomeningeal and cortical vessels is one of the pathological characteristics of the brains from patients with Alzheimer's disease (AD). Previously it was suggested that excessive Aß production in AD brains is related to abnormal intracellular trafficking of the amyloid β precursor protein (APP). We studied the intracellular localization and secretion of APP in cultured smooth muscle cells from human leptomeningeal vessels as well as human brain pericytes from cerebrocortical capillaries. Both these cell types are candidate for producing vascular Aß in AD brains. Microvascular endothelial cells were studied as a control celltype. By using immunofluorescence and immunoelectron microscopy we demonstrated that APP is found in both lysosomal and non-lysosomal organelles in these cells, but in the ER and Golgi compartments of endothelial cells. Treatment with the cytokine interferon (IFN)-γ or with chloroquine caused an accumulation of APP in multivesicular body (MVB)-like organelles, accompanied by a reduction of APPsecretion. FITC-labeled dextran or 6 nm-gold particles coupled to BSA, allowed to be ingested by these cells, accumulated in these MVB-like organelles, confirming their endosomal nature. Our studies show that inflammatory mediators, such as IFN- γ , may contribute to the process of aberrant APP routing by concentrating APP in a MVB-like compartment, possibly by enhancing the rate of endocytosis of cell surface molecules, such as APP. Supported by the Netherlands Organization for Scientific Research (NWO).

461.5

FOCAL UPTAKE OF ALZHEIMER AMYLOID BETA PEPTIDE BY MECHANICALLY INJURED LEPTOMENINGEAL VESSEL WALLS R. Prior*, G.E. Wihl, D. D'Urso, R. Frank, I. Prikulis and G. Pavlakovic, Department of Neurology, University of Düsseldorf, 40225 Düsseldorf, Germany.

The abnormal deposition of amyloid beta peptide (AB) is a major neuropathological feature of Alzheimer's disease (AD) and of cerebral amyloid angiopathy (CAA). In CAA, AB is deposited within the wall of small cortical and leptomeningeal vessels. CAA is associated to AD but may occur also without dementia. CAA is an important cause of intracerebral hemorrhage in the elderly. We have previously established organ cultures of canine leptomeninges as a model to study the pathogenesis of CAA (Prior et al., J Neurosci Meth., in press). Focal AB deposits were observed in living canine leptomeningeal vessels when leptomeninges of old dogs with CAA were incubated in culture medium containing nanomolar concentrations of AB (Prior et al., Neuroreport 6: 1747-51, 1995). This experimental setup resembles the situation in vivo, where leptomeningeal vessels are surrounded by cerebrospinal fluid (CSF) containing soluble AB. Leptomeningeal vessels without CAA or vessels of young dogs did not show any AB deposits.

Here we report that deposition of soluble AB can be observed in normal vessels of

Here we report that deposition of soluble Aß can be observed in normal vessels of young dogs after mechanical damage to the vessel wall. Mechanically injured or cut living vessels were incubated in culture medium containing 100 nM to 10 μ M of fluorescein-coniugated Aß(1-40) or Aß(1-42). After two days, cryosections were analyzed by fluorescence microscopy. Sections were immunostained for different vessel wall antigens (smooth muscle actin, desmin, collagen III, fibronectin) and confocal microscopy analysis showed that Aß1-40 and Aß1-42 deposits were localized within the tunica media of small arterioles as usually observed in CAA Our results suggest that CAA may be experimentally induced in normal vessels and that soluble Aß derived from the CSF may bind to an extracellular matrix component of the vessel wall in vivo, Extracellular matrix binding and progressive accumulation of CSF-derived Aß may be an important pathogenetic mechanism during the development of CAA. Supported by DFG (Mu630/5-3 to R.P.).

PHARMACOLOGICAL MODULATION OF ALZHEIMER'S β -AMYLOID PRECURSOR PROTEIN LEVELS IN THE CSF OF RATS WITH FOREBRAIN CHOLINERGIC SYSTEM LESIONS. <u>V. Haroutunian*, N. Greig, X-F. Pei, T. Utsuki, L. D. Acevedo, R. Gluck, K.L. Davis and W.C. Wallace</u> Dep. Psychiatry. The Mount Sinai Sch. of Med., New York, NY. and Lab. Cell. and Mol. Biol., Gerontology Res. Cent., NIA, Baltimore, MD.

Abnormal deposition and accumulation of Alzheimer's amyloid β -protein (A β) and degeneration of forebrain cholinergic neurons are principal features of Alzheimer's disease. In rat model systems, lesion-induced forebrain cholinergic deficits (nbM) are accompanied by significant induction of cortical β-amyloid precursor protein (β-APP) mRNAs and increased levels of secreted β-APP in the CSF. We studied whether β-APP secretion from cholinergic targets could be altered pharmacologically. Scopolamine, a muscarinic receptor antagonist, was administered to determine whether APP could be induced by direct disruption of muscarinic receptor function. One week of scopolamine administration (0.5mg/kg/hr, N=7) led to a significant (p<0.01) increase in the CSF levels of secreted β-APP in sham lesioned rats indicating that antagonism of muscarinic receptors is sufficient for induction and secretion of β-APP. However, scopolamine did not upregulate further β-APP secretion in nbM lesioned rats. Opposite results were seen when cholinergic function was augmented by cholinesterase inhibition. One week of treatment with phenserine (2.5mg/kg/bid, N=7), a novel, reversible acetyl-selective cholinesterase inhibitor, significantly decreased the levels of secreted β -APP in the CSF of forebrain cholinergic system-lesioned (nbM) rats (p<0.01), whereas DFP, a relatively nonspecific cholinesterase inhibitor, failed to affect CSF levels of secreted β-APP. These results suggest that the secretion of β-APP into the CSF can be pharmacologically modulated, but that this modulation is dependent upon the status of the forebrain cholinergic system and the pharmacological properties of the drugs used to influence it. REMOVAL OF ALZHEIMER AMYLOID BETA PEPTIDE BY LEPTOMENINGEAL MEMBRANES. G. E. Wihl, G. Pavlakovic, D. D'Urso, R. Frank, I. Prikulis, H. Koeller* and R. Prior. Department of Neurology, University of Disseldorf, 40225 Disseldorf, Germany.

University of Düsseldorf, 40225 Düsseldorf, Germany. Soluble amyloid beta peptide (AB) is produced by cortical neurons and released to the cortical extracellular space and the cerebrospinal fluid, where AB species of different length are detected in nanomolar amounts. Progressive precipitation of soluble AB into senile plaques and the amyloid deposits of cerebral amyloid angiopathy (CAA) is a central event during the pathogenesis of Alzheimer's disease. The precipitation of soluble AB is dependent on the concentration of the hydrophobic AB peptide. An efficient removal of AB from the cortical interstitial fluid may therefore be important to prevent excessive AB-amyloidogenesis. Cultured rat microglial cells have been shown to remove AB added to the cell

Cultured rat microglial cells have been shown to remove AB added to the cell culture medium (Shaffer et al., Neurobiol Aging 16: 737, 1995). We have established organ cultures of canine leptomeninges as a model to study the pathogenesis of CAA (Prior et al., Neuroreport 6: 1747, 1995). Leptomeninges cover the surface of the cerebral cortex and are interposed between the cortical extracellular space and the cerebrospinal fluid. Therefore, we investigated whether leptomeningeal membranes have an AB-removing capability. Organ cultures of canine leptomeninges were incubated with 1 µM of biotinylated AB1-40 in the culture medium. ELISA-analysis of culture supernatants was performed at 6, 24, 48 and 72 h and revealed a progressive decline of AB to 200 nM at 72 h. Control experiments with dead leptomeninges or with medium in the absence of leptomeninges showed only minor decreases of AB concentrations. Preliminary immunofluorescence data suggest that the uptake of AB is accomplished by macrophages or other phagocytosing cells present in the leptomenings. Our results demonstrate the ability of leptomeningeal membranes to remove soluble AB from cerebral fluids indicating their potential function in the prevention of Alzheimer's disease neuropathology. DISTRIBUTION OF AMYLOID β_{42} SPECIES AND INTRACEREBRAL HEMORRHAGE IN ALZHEIMER'S DISEASE R.N. Kalaria*, H. Mori, D. L. Cohen and D.R.D. Premkumar. Departments of Neurology and Pathology, and the UH Alzheimer Center, Case Western Reserve University, Cleveland, Ohio 44106, USA; Tokyo Institute of Psychiatry, Setagaya-ku, Tokyo 154, Japan.

Recent advances have demonstrated that amyloid B (AB) protein exhibits carboxyl- and amino-terminal heterogeneity in cortical and cerebrovascular amyloid deposits of Alzheimer's disease (AD). Using carboxyl end-terminal specific antibodies to AB peptides, both AB40 and the longer more pathogenic $A\beta_{42}$ species have been localized in cerebral vessels of AD subjects. Here, we assessed the distribution of AB species in cerebral vessel fractions from AD subjects with and without cerebral amyloid angiopathy related intracerebral hemorrhage. Using quantitative immunochemical and ELISA methods, we found that the ratios of $A\beta_{42}/A\beta_{40}$ were greater in samples derived from AD subjects with hemorrhages compared to those without. While it is not definitively known whether vascular cells also produce the AB₄₂ form, further immunocytochemical assessment of the vascular abnormalities and amyloid infiltrated cerebral vessels indicated that the longer AB42 appears associated with the degenerative process, particularly in subjects with intracerebral hemorrhage. Our studies suggest that the AB42 species is also involved in cerebrovascular degeneration leading to intracerebral hemorrhage that is found in a population of AD subjects. Supported by grants from WHO-NINDS, NIA (NIH) and ADRDA.

CEREBROSPINAL FLUID TAU AND BETA-AMYLOID 1-40/42 IN ALZHEIMER'S DISEASE M. Kanai*, E. Matsubara, Y. Igeta, Y. Tomidokoro, K. Ishiguro, T. Kawarabayashi, M. Watanabe, M. Shizuka, T. Nakamura, K. Okamoto, S. Hirai and M. Shoji, Department of Neurology, Gunma University School of Medicine, 3-39-15 Showa, Maebashi, Gunma 371, Japan. Tokyo Metropolitan Neurological Hospital, 2-6-1 Fuchu, Tokyo 183, Japan.

The 4-kd amyloid beta protein (A β) deposited as amyloid in Alzheimer's disease (AD) is produced and released by normal proteolytic processing of the amyloid beta protein precursor (β APP) and is readily detected in cerebrospinal fluid (CSF). Here, we present the levels of A β in CSF from a total of 77 subjects, including 45 patients with AD, 16 with early-onset AD and 29 with late-onset AD, 24 normal control subjects, and 8 patients with other neurological diseases. The CSF level of a novel form of the β -amyloid peptide (A β) extending to position 42 (A β 1-42) was determined in patients with AD as well as controls. In addition to measurement of CSF A β 1-42 levels, A β 1-40 peptides, microtubles-associated protein tau, and were also assessed. The CSF tau levels were 219 \pm 89pg/ml in early onset AD, 377 \pm 220pg/ml in late onset AD, 124 \pm 96pg/ml in control, and 105 \pm 69pg/ml in other neurological diseases. The CSF A β 1-40 were 1448 \pm 734fmol/ml in early onset AD, 1479 \pm 582fmol/ml in late onset AD, 1434 \pm 726fmol/ml in control and 1416 \pm 391fmol/ml in other neurological diseases. The CSF A β 1-42 were 115 \pm 50fmol/ml in early onset AD, 113 \pm 45fmol/ml in late onset AD, 212 \pm 125fmol/ml in control and 159 \pm 91fmol/ml in other neurological diseases. The CSF A β 1-42 levels were found to be significantly lower in AD patients as compared with that in patients with other diseases and control subjects. And it is interesting that CSF A β 1-42 levels were found to be significantly lower in AD patients relative to controls, whereas deposit in the brain tissue of patients with AD, suggesting that diminished in clearance may account for its reduction in CSF. Tau levels were increased in AD patients Taken together, our results suggest that the enzyme-linked immunosovrent assay of cerebrospinal fluid tau and A β 1-42 may prove to be a reliable and early diagnostic test for AD.

AMYLOID β PROTEIN SPECIES IN CEREBROSPINAL FLUID OF PATIENTS WITH ALZHEIMER'S DISEASE. A.Tamaoka*(1), N.Sawamura(1), S.Shoji(1), M.Shoji(2), S.Hirai(2), Y.Furiya(3) and H.Mori(3), Department of Neurology, University of Tsukuba, Tsukuba, Ibaraki 305(1); Department of Neurology, Gunma University, Maebashi, Gunma 371(2); Department of Molecular Biology, Tokyo Institute for Psychiatry, Setagaya, Tokyo 156, Japan(3).

To search for a diagnostic laboratory test for Alzheimer's disease (AD), cerebrospinal fluid (CSF) levels of amyloid β protein (A β) species (CSF-A β) with different carboxy termini, i.e., A β X-40 and A β X-42(43) as well as A β 1-40 and A β 1-42(43), were measured in patients with AD and age-matched controls without

dementia (CTR) using sandwich enzyme-linked immunosorbent assays (ELISAs). The present study revealed that both CSF-A β X-42(43) and A β 1-42(43) levels were significantly lower in the AD patients (p<0.005) than in the CTR group, whereas neither CSF-A\(\beta\)X-40 nor CSF-A\(\beta\)1-40 levels showed any differences between the two groups. In addition, although there was no difference between the ratios of AβX-40 to A β 1-40 in the AD and CTR groups, the ratios of A β X-42(43) to A β 1-42(43) were increased in the AD group compared with those in the CTR group (p<0.05). Recently, Aβ42(43) with carboxy termini ending at residue 42(43), the amino terminal of which is often truncated and/or modified, has been shown to play an important role in the formation of amyloid fibrils, and to preferentially deposit as diffuse plaques, the earliest neuropathological changes in AD brains. Taking these facts into consideration, increased adsorption of AB42(43) to AB deposition in AD brains, decreased secretion of AB42(43) to CSF and/or increased clearance of Aβ42(43) from CSF might explain the diminished levels of Aβ42(43) in the CSF of AD patients. Moreover, CSF-Aβ42(43) could reflect increased amino terminal truncations and/or modifications of AB42(43) in AD brains.

ANALYSIS OF PLASMA AB CONCENTRATION IN NON-DEMENTED SUBJECTS OF ALL AGES.

C.B. Eckman , D. Yager, N. Graff-Rafford, and S.G. Younkin*
Mayo Clinic Jacksonville, Jacksonville, FL. 32224

Mayo Clinic Jacksonville, Jacksonville, FL. 32224

Using sandwich ELISAs that specifically detect AB1-40 and AB1-42(43), we have recently found that the various FAD-linked PS1 mutations, one FAD-linked PS2 mutation, and the FAD-linked mutations at both sites in the ßAPP gene significantly increase the concentration of AB1-42(43) in human plasma. During the course of this experimentation an apparent correlation was observed between age and Aß concentration in a small group of young controls. To pursue these observations further we utilized sandwich ELISAs specific for AB1-40 (BAN-50/BC-05), and Aß42(43) (BNT77/BC-05) to analyze approximately 170 non-demented subjects ranging in age from 21-97 years old. Our analysis of plasma samples from these subjects (i) confirms that AB1-40 is the major Aß peptide in plasma, (ii) shows that in a small percentage of individuals Aß42(43) is elevated into the range associated with FAD, and (iii) indicates that the concentration of plasma Aß1-40 and Aß42(43) increases with age. Collectively these results suggest that AD may develop in some patients as a consequence of elevated extracellular Aß42(43) that is demonstrable in plasma long before disease develops. Additional results from our ongoing as well as prospective studies are clearly needed, however, before drawing any conclusion about the risk for AD that is conferred by elevation of plasma Aß42(43).

ALZHEIMER'S SOLUBLE AMYLOID β IS A NORMAL COMPONENT OF URINE. E. Matsubara', S. Governale, M. Calero, T. Wisniewski, B. Frangione and J. Ghiso'. Dept of Pathology, New York University, New York, NY 10016 and 'Dept of Neurology, Gunma University, Gunma, Japan.

Amyloid beta $(A\beta)$ is a constituent of the fibrils deposited into senile plaques and cerebral blood vessels of patients with AD, Down's syndrome and HCHWA-Dutch type. Although originally thought to be an aberrant degradation product of its precursor βPP , it has been found as a soluble component $(sA\beta)$ in plasma and CSF where it is normally present at a very low concentration (1-5 ng/m), $sA\beta$ circulates in both biological fluids associated to high density lipoprotein (HDL) particles. The biochemical basis for this relationship is not fully understood; however, several studies indicate that applipoprotein J, present in a subset of HDL particles plays a role as a carrier molecule for $sA\beta$ in biological fluids and in the transport of $sA\beta$ across the blood-brain barrier.

In order to understand the factors involved in the regulation of the plasmatic levels of sA β , we investigated whether the peptide was present in urine and how alterations in the glomerular filtration and/or tubular resorption may affect the urinary levels of sA β . Immunoprecipitation experiments were carried out with anti-A β antibodies and detection of sA β was achieved via immunoblot analysis. Soluble A β (4.4 kDa) immunoreactivity was present in normal urine, and was more evident when specimens from glomerular and/or mixed proteinuria were examined. The identity of sA β was corroborated by N-terminal sequence. Edman degradation of the 4.4 kDa band obtained from immunoprecipitation of 20 mg of urinary lyophilized protein from 2 cases exhibiting mixed proteinuria yielded the sequences DAEFRxDxGXEV and DAEFRhDsGYEV respectively corresponding to the intact N-terminus of the A β peptide. The data indicate that sA β is a normal component of the urine, and entities affecting the glomerular filtration and/or tubular resorption will reflect the amount of sA β present in the urine. Quantification of Alzheimer's β-amyloid peptide levels in the plasma, CSF and brain tissue from guinea pig following administration of classical proteases inhibitors. D.M. Tummolo. S.C. Sun. O. Xiang, H. Zhou, J.S. Jacobsen, and J. Sonnenberg-Reines* Central Nervous System Disorders, Wyeth-Ayerst Research, CN-8000, Princeton, New Jersey 08543.

Alzheimer's disease is characterized by the progressive formation of insoluble amyloid plaques in the brain which consist of the 4 kDa β -amyloid. peptide (βAP) βAP is derived by proteolysis from the amyloid precursor protein, βAPP . Using a highly sensitive and selective sandwich ELISA, developed to analyze βAP levels in transfected cells, we have found inhibitors which alter the levels of βAP in the conditioned media. To further assess these inhibitors in vivo, we have modified a guinea pig model first reported by C. Eckman and S. Younkin in 1995 (Neurosci. Abstract, # 208.5). Similar to their initial reports, we find the plasma levels of βAP in increase 2 to 4 fold in animals treated with phosphoramidon, a metalloprotease inhibitor. Levels of βAP in the cerebrospinal fluid are similarly elevated in these animals. This phenomenon is dose dependent and transient with peak values observed at 2 to 4 h and return to basal values by 24 h post treatment. Analysis of brain extracts indicate that βAP levels in these animals are not altered by this treatment. One interpetation of the data is that phosphoramidon is inhibiting a catalytic protease that is responsible for the turnover and degradation of βAP . The effect of pepstatin, an aspartyl protease inhibitor, reported to inhibit βAP in tissue culture cells was also tested in this paradigm and will be discussed. Since βAP formation leads to amyloid deposition, the guinea pig model may be useful in developing therapeutic stratagies to inhibit βAP associated with Alzheimer's disease.

BIOCHEMICAL ANALYSIS OF AMYLOID β PROTEIN WITH AMINOTERMINAL PYROGLUTAMATE 3 IN ALZHEIMER'S DISEASE BRAINS. Y. Harigaya*¹, C. B. Eckman¹, C-M. Prada¹, T. C. Saido² and S. G. Younkin¹. ¹Mayo Clinic Jacksonville, Jacksonville, FL 32224, ²Department of Molecular Biology, Tokyo Metropolitan Institute of Medical Science, Tokyo 113, Japan

The amyloid deposited in senile plaques of the Alzheimer's disease (AD) brain is composed of a 39-43 amino acid protein referred to as the amyloid β protein (A β). In previous work, we employed specific sandwich ELISAs to analyze the total $A\beta$ in ADcerebral cortex after direct extraction into formic acid, and showed that most of the $A\beta$ in AD brain is amino-terminally truncated or modified (Gravina et al. JBC 270:7013,1995). Recent immunocytochemical studies have shown that Aβ species with amino-terminal pyroglutamate3(3pE) are deposited in senile plaques (Saido et al. Neuron 14: 457,1995). To quantitate these Aβ species beginning at 3pE biochemically, we developed specific sandwich ELISAs to detect $A\beta3pE-40$ (BA-27/anti-N3pE) and $A\beta3pE-42$ (BC-05/anti-N3pE). Using these ELISAs, we have analyzed direct formic acid extracts of temporal cortex from AD patients and normal controls. Using specific sandwich ELISAs employed in our previous work, the A\(\beta\)1-42(BAN-50/BC-05), Aβ1-40(BAN-50/BA-27), AβX-42(BC-05/4G8) and AβX-40(BA-27/4G8) in these extracts was analyzed in parallel. Cryostat sections cut from blocks adjacent to the regions analyzed biochemically were immunostained with 4G8 antibody. Both Aβ3pE-42 and Aβ3pE-40 were invariably detected in AD brains, although the amounts varied from case to case. In all AD cases, a substantial fraction of the total A β ending at A β 42 was A β 3pE-42 and a substantial fraction of the total A β ending at A β 40 was A β 3pE-40. Thus the results of our biochemical analysis suggest that species beginning at A β 3pE constitute a substantial fraction of the A β deposited in the AD brain. This suggests that AB species beginning at 3pE may play an important role in amyloidogenesis and plaque formation Supported by Uehara Memorial Foundation, Japan (Y.H.)

STRUCTURE ACTIVITY ANALYSIS OF A\$ DEPOSITION WP Esler, ER Stimson, JR Ghilardi, AM Felix, Y-A Lu, BP Tseng, N Casey, HV Vinters, ML Kamovsky*, JP Lee, PW Mantyh and JE Maggio

BCMP Dept., Harvard Med. Sch., Boston, MA 02115; Molec. Neurobiol. Lab (151), VA Med. Ctr., Mpls, MN 55417; Peptide Research, Hoffmann-La Roche, Nutley NJ 07110; Chem. Dept., Boston Univ., Boston, MA 02215; Dept. Pathol. & Lab. Med., UCLA Med. Ctr. LA, CA 90024.

Deposition of the $\beta\text{-amyloid}$ peptide (A β) in the form of amyloid plaques in the cerebral cortex of patients is widely considered to play a causative role in the development of Alzheimer's disease (AD). The process of $A\beta$ deposition in AD can be modeled in vitro by measuring the deposition of physiological concentrations of radiolabeled $A\beta$ peptides onto pre-existing plaques in preparations of unfixed AD human cerebral cortex. While in vitro deposition of AB peptides onto amyloid in AD cortex is very favorable under physiological conditions, essentially no binding is observed with age-matched non-AD tissue. To elucidate conformational features in the A β peptide important to plaque growth, A β congeners with a series of sequence alterations within the central hydrophobic cluster (residues 13 to 23) were synthesized and examined in deposition assays. Minor sequence alterations (point mutations) in this region of $A\beta$ were found to have significant effects on the ability of the peptide to deposit. While some point mutations abolished activity, others accelerated in vitro deposition. Using biophysical methods, effects of sequence alterations on activity were found to correlate with particular changes in Aß analog conformation in water (which is neither α -helix nor β -sheet). Together, these results suggest that certain primary, secondary and tertiary structural features in $\ensuremath{\mathsf{A}\beta}$ are important for amyloid deposition and may serve as targets for therapeutic intervention. Supported by NIH (AG11852, AG12853, AG10123, AG12435), VA (Merit Review), and the American Health Assistance Foundation (AD94071)

TEMPLATE SPECIFIC DEPOSITION OF AB1-40 ONTO CEREBRO-VASCULAR AMYLOID AND AB1-42 ONTO PARENCHYMAL AMYLOID IN THE HUMAN ALZHEIMER DISEASE BRAIN J.R. Ghillardi, M.P. Finke, S.D. Rogers, E.R. Stimson, W.P. Esler, J. E. Maggio,

Cntr., Mpls., MN 55417; BCMP Dept., Harvard Medical School, Boston, MA 02115; UCLA Med. Cntr., LA, CA 90024; Dept. of Psychiatry, Univ. of Minnesota, Mpls., MN 55455

Although cerebral deposition of the ß-amyloid peptide (Aß) is an invariant

Although cerebral deposition of the β -amyloid peptide (Aß) is an invariant teature of Alzheimer disease (AD), there are marked differences in the forms of Aß that comprise parenchymal and cerebrovascular amyloid (CVA) deposits. Whereas parenchymal amyloid is primarily composed of $A\beta^{1.42}$. CVA is primarily composed of $A\beta^{1.42}$. Or determine it template specificity plays a role in the differential composition of CVA and parenchymal amyloid deposits, we examined the localization and kinetics of physiological concentrations of 125 1- $A\beta^{1.40}$ and 125 1- $A\beta^{1.42}$ deposited onto aggregates of $A\beta^{1.40}$ or $A\beta^{1.42}$ and onto sections of human AD brain. In aggregates composed of either $A\beta^{1.40}$ or $A\beta^{1.42}$ deposits preferentially deposits onto aggregates of $A\beta^{1.40}$. Whereas 125 1- $A\beta^{1.42}$ deposits more avidly onto CVA than 125 1- $A\beta^{1.42}$ deposits more avidly onto parenchymal plaques than 125 1- $A\beta^{1.40}$. Additionally, 125 1- $A\beta^{1.42}$ appears to deposit onto a greater number of parenchymal plaques in sections of human AD brain than does 125 1- $A\beta^{1.40}$. These data suggest that different forms of $A\beta$ ($A\beta^{1.40}$ 0 or $A\beta^{1.42}$ 1) have an intrinsic template specificity in that they preferentially deposit onto self vs. non-self aggregates. This intrinsic template specificity of different forms of $A\beta$ may contribute to the differential localization, composition and toxicity of CVA and parenchymal amyloid deposits. Blockade of $A\beta$ deposition onto CVA or plaques may therefore require distinct therapeutic agents. Supported by NIH AG11852, AG12853 and a VA Merit Review.

CONGO RED BLOCKS THE INHIBITORY EFFECT OF ALZHEIMER'S Aß PEPTIDE ON Na*/Ca*- EXCHANGE. R.A. Colvin*, C.A. Derrico and A. Wu. Program in Neurobiology, Ohio University College of Osteopathic Medicine, Athens, OH 45701.

The inhibition of Na⁺/Ca²⁺ exchange by synthetic Alzheimer's amyloid-β peptides (AB) was studied using plasma membrane vesicles isolated from whole rat brain. Only pre-aggregated $A\beta_{1:40}$ and $A\beta_{2:5:35}$ peptides were shown to reduce vesicular Ca content. Both peptides produced a maximal reduction in Ca content of approximately 50%. The peptides reduced Ca content with similar potency and half maximal effects were seen at less than 10 µM for Aβ₂₅₋₃₅. Calcium loaded vesicles mediate a rapid Ca²⁺/Ca²⁺ exchange, which also was inhibited by aggregated $A\beta_{25-35}$. Aggregated $A\beta_{25-35}$ did not affect the passive Ca permeability of the vesicles. Aggregated A $\beta_{3:35}$ reduced Ca content in plasma membrane vesicles isolated from normal and AD frontal cortex with less potency but the same efficacy as seen in rat brain Aggregated Aβ_{25.35} did not produce nonspecific effects on vesicle morphology such as clumping or loss of intact vesicles. When placed in the buffer used to measure Ca content, Congo red at molar ratios of less than one blocked the inhibitory effect of preaggregated A\(\beta_{25-35}\). When added in equimolar concentrations to freshly dissolved and unaggregated AB25-35, Congo red also was effective at blocking the inhibitory effect on Ca content. Vitamin E (antioxidant) and N-tert-butyl-α-phenylnitrone (spin trapping agent) failed to block the inhibitory action of $A\beta_{25;35}$. These data are consistent with a proposed mechanism where aggregated $A\beta$ peptides interact with the exchanger protein and inhibit Ca^{2+} transport. Supported by a grant from the Alzheimer's Association.

ELECTROSPRAY IONIZATION MASS SPECTROMETRY STUDY OF β-AMYLOID FEPTIDE: CONFORMATIONAL DEPENDENT AGGREGATION Y.G. Chen, S. K. Brining, V. Nguyen, -²O.P. Rabin* A. Yergey* - ¹Section on Metabolism and Mass Spectrometry, The National Institute of Child Health and Development, - The National Institute of Aging, NIH, Bethesda, MD 20892-1580.

Electrospray ionization mass spectrometry (ESI-MS) was used to study the conformation and aggregation of the synthetic β-amyloid peptide, residue 1-40 (βA4) as a function of concentration (250, 125, 57 and 6 μM) and sample aging, All mass spectra showed a major envelope of peaks at my (6104, 72, 8, 866, 8, 1083, 3.

Electrospray ionization mass spectrometry (ESI-MS) was used to study the conformation and aggregation of the synthetic β-amyloid peptide, residue 1-40 (βA4) as a function of concentration (250, 125, 57 and 6 μM) and sample aging. All mass spectra showed a major envelope of peaks at m/z 619.4, 722.8, 866.8, 1083.3, and 1444.2 corresponding to charge states of 7-3 respectively of a monomeric form of βA4. We found that the average charge state of the envelope associated with the monomeric form decreased by ca. 0.35 as samples were aged. In the 250μM samples, additional, weaker envelopes of peaks corresponding to charge states of βA4 dimeric, trimeric and tetrameric βA4 species were also seen. We found that these aggregates became weaker and ultimately were absent in both the more dilute solutions and in aged aliquots of the concentrated sample. It is known that βA4 solutions exhibit a random coil <-Σ 9-sheet equilibrium which shifts toward the β-sheet form with solution aging. We interpret our mass spectra in a manner that is consistent with these models of β-amyloid behavior. First, the decreasing charge state of the ESI-MS envelope of βA4 is taken to show that the relatively open form of the peptide associated with a random coil form is capable of supporting a higher charge state than the more compact β-sheet form. The higher charge state than the more compact β-sheet form. The higher charge state than the more compact β-sheet form to be a consequence of the presumed very compact nature of this form which is likely to be present in a charge state that would place it at a m/z beyond the range of our instrument. We have shown that ESI-MS can be used to monitor conformational changes and aggregations of β-amyloid proteins simultaneously, an ability that is a novel tool for the study of these molecules.

A MODEL FOR STRUCTURE DEPENDENT BINDING OF CONGO RED TO ALZHEIMER B-AMYLOID FIBRILS. <u>D.B.Carter* and K.C.Chou.</u> CNS Research, Pharmacia & Upjohn, Inc., Kalamazoo, MI 49001.

The cytotoxic β -amyloid fibril is a logical candidate for the entity causing the initiating damage to neurons in AD and Down's syndrome. We have derived a model of binding for the dye molecule, Congo Red (CR), to a gb-sheet structure of β -amyloid (1-42). This model is based on the crystal coordinates of CR binding to porcine insulin fibrils from Turnell and Finch (JMB 227:1205-1223, 1992). The stretch of 9 amino acids (ERGFFYTPK) of the pseudo β -sheet in the insulin dimer has a pattern of residue types common to other congophilic amyloidogenic peptides such as Alzheimer β -amyloid (15-24) (QKLVFFAED), transthyretin (PLMVKVLDA), and Islet amyloid peptide (NNFGAILSS). The common pattern of residue types suggests the possibility that the amyloid-like fibers of amyloidogenic peptides are congophilic because the corresponding cross segments can also form an anti-parallel β -sheet similar to the one in the insulin dimer. The CR molecule has been aligned along the homologous stretch of amino acids in Alzheimer β peptide (2 molecules in anti-parallel distorted or pseudo β -sheet conformation) using the crystal coordinates from the Turnell-Finch paper to arrive at a putative structure for CR binding to Alzheimer's amyloid fibrils. Funded by Pharmacia and Upjohn Inc.

Aβ AGGREGATION IN CELL CULTURE: SIMILAR AGGREGATION OF ¹²⁵I-Aβ AND ENDOGENOUS Aβ AND INHIBITION BY CONGO RED. M.B. Podlisny*, P. Amarante, D. Walsh, E. Stimson,

CONGO RED. M.B. Podlisny*. P. Amarante. D. Walsh, E. Stimson, J. Maggio. D. Teplow & D. Selkoe. Harvard Med. School, Boston, MA Aggregation of soluble 4 kD Aβ monomers into HMW insoluble fibrils is a critical process in the development of AD. We previously described a cell culture model of aggregation of secreted Aβ under physiological concentrations and conditions. Immunoprecipitation (IP) of conditioned media (CM) of metabolically labeled APP-transfected CHO cells revealed SDS-stable oligomers of Aβ of 6, 8, 12 and 16 kD, in addition to Aβ and p3. Oligomer:monomer ratios were increased when media were conditioned without serum. Congo red (CR) prevented this enhanced oligomer formation. To study these low MW oligomers without IP, we have performed experiments using ¹²⁵I-Aβ₁₋₄₀ (IAβ₄₀) as a tracer in the CM and analyzed the results by SDS-PAGE and size exclusion chromatography (SEC). Whereas IAβ₄₀ incubated at 37° in serum-free unconditioned medium (DMEM) migrated at 4 kD. IAβ₄₀ incubated in serum-free medium of APP-CHO cells migrated at ~4, 6, 8, 16 and 25 kD. IAβ₄₀ incubated with these cells in the presence of 10 μM CR migrated only at 4 kD. Addition of 10% serum to the cultures decreased the rate of IAβ₄₀ aggregation. Incubation of IAβ₄₀ with APP-CHO CM alone (without cells) produced similar aggregation of the peptide. Consistent with our gel analyses, SEC showed an extra peak of IAβ₄₀ in samples incubated with cells vs in DMEM alone. We conclude that both endogenous and synthetic Aβ spontaneously undergo aggregation into SDS-stable oligomers in CHO cultures, and the process is inhibited by CR. This system can be used to examine initial events in physiologic Aβ aggregation and to screen anti-aggregation compounds. Supp:AG 06173.

THE TOXICITY OF THE ALZHEIMER'S β -AMYLOID PEPTIDE CORRELATES WITH A DISTINCT FIBRE MORPHOLOGY.

B. Seilheimer*, B. Bohrmann, D. Stüber, F. Müller, and H. Döbeli Hoffmann-La Roche Ltd, CH-4002 Basel, Switzerland.

In an attempt to understand better the relationship between physical properties, morphology and cellular toxicity we have prepared several β-amyloid (Aβ) peptides according to a highly standardized biotechnical method. Peptides generated were either mutated inside the membrane anchor segment around amino acid position 35 or their carboxyl terminus was shortened from 42 to 41, 40 or 39 amino acids. The time-dependent self assembly of monomeric Aβ into fibres was simultaneously monitored by electron microscopy, circular dichroism spectroscopy, analytical ultracentrifugation, and Aβ-mediated cellular toxicity was quantified in PC12 cells using inhibition of MTT reduction. The transition of Aβ monomers into fibres was analyzed by more than 600 electron micrographs. It revealed morphological changes from seed-like structures to premature and mature fibres. Seeds were of spherical appearance, premature fibres presented as elongated structures with a rough surface and with varying thickness depending on the Aβ's sequence. Mature fibres were characterized by a periodic variation of their thickness along the length axis. The proportion of these different structures and the total amount of aggregated Aβ was amino acid sequence-depended. We could demonstrate that wild-type Aβ1-42, and its oxidized version carrying a methionine sulfoxide residue at position 35 have the highest fibre formation rate observed and exert toxic activity in the MTT-assay at very low nanomolar concentrations. The carboxyl-terminus tended to aggregate at a much slower rate, and are non-toxic at naturally occurring concentrations. Thus, correlations can be drawn between physical properties, fibre morphology and cellular toxicity.

PERLECAN BINDING TO ALZHEIMER'S DISEASE BETA-AMYLOID PROTEIN (A8) 1-40 REGARDLESS OF THE EXTENT OF FIBRILLOGENESIS G.C. Castillo. C.Ngo, and A.D. Snow* Dept. of Pathology, Neuropathology Labs, Box 356480, University of Washington, Seattle, WA 98195

Perlecan is a specific heparan sulfate proteoglycan implicated in Alzheimer's disease (AD) amyloidosis. In the present study, we assessed perlecan's postulated effects on beta-amyloid protein (AB) fibrillogenesis and determined the binding interactions of perlecan with Aß during increasing stages of amyloid fibril formation. The effects of perlecan on Aß fibrillogenesis were first evaluated using a Thioflavin T fluorometry assay. Aß 1-40 or 1-42 at 25 µM in TBS (pH 7.0) was incubated at 37°C for 2 weeks either alone or in the presence of 0.1 µM perlecan. Aliquots were taken for analysis at 1 hr, 3 days, 1 week and 2 weeks. Perlecan was found to be a potent and early accelerator of AB 1-40 fibrillogenesis, causing a significant 4.8-fold increase at 1 hour, and a 2.4-fold increase at 3 days By 1 and 2 weeks, perlecan had no further effect on AB 1-40 fibrillogenesis. Perlecan also enhanced AB 1-42 fibrillogenesis, with a significant 1.8-fold increase observed at 3 days, and a significant 2.0-fold increase maintained at both 1 and 2 weeks. In a second study, using a solid phase binding immunoassay, we determined whether AB 1-46 binds perlecan regardless of the extent of AB fibrillogenesis. AB-perlecan interactions were evaluated following incubation of AB at 37°C for 1 day (minimal AB fibril formation), 3 days and 1 week (maximal Aß fibril formation). The extent of Aß fibril formation was assessed by Thioflavin T fluorometry and found to increase 2.7-fold from 1 day (97 fluorescent units) to 1 week (262 fluorescent units). AB 1-40 bound perlecan at all time points with both high affinity and low affinity binding sites observed at 1 day (Kd = 1.5 X 10 ⁻¹³ M and $K_d = 8.8 \times 10^{-9} M$), 3 days ($K_d = ~5.0 \times 10^{-13} M$ and $K_d = 2.4$ X 10 ⁻⁸ M) and 1 week (K $_d$ = $^{\sim}$ 4.5 X 10⁻¹³ M and K $_d$ = 1.1 X 10⁻⁷ M). These results demonstrate that Aß interacts with perlecan regardless of the extent of Aß fibrillogenesis and further implicates an important role for perlecan even in early stages of AB amyloidosis Partially supported by NIH AG12953-02 and AG05136.

BUTYRYLCHOLINESTERASE (BCHE) ALTERS THE AGGREGATION STATE OF AB AMYLOID K.L. Barber¹, M.M. Mesulam^{3*}, G.A. Krafft³ and W.L. Klein¹ Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208; ²Neurology & ³Mol. Pharmacology, Northwestern Univ. Sch. of Med., Chicago, IL 60611

Amyloid B peptide (AB) is the principal component of senile plaques in Alzheimer's disease (AD). Recent observations suggest that the putative neurotoxicity of Aß may be influenced by the supramolecular state of the Aß aggregates. The state of AB aggregation may be determined by numerous factors, including the effects of additional proteins that are also present within senile plaques. One of these proteins, BChE, is found in significantly higher quantities in AD plaques than in plaques of age-matched non-demented brains. The current study was designed to explore the effect of BChE on the *in vitro* aggregation of Aß. The AB aggregates, formed with or without the addition of BChE, were adsorbed to formvar coated gold grids and processed for examination by whole moun transmission electron microscopy (WMTEM). Aggregates of AB comprised structurally heterogeneous forms, including flocculant, amorphous and fibrillar species. Co-incubation of AB 1-42 with low doses of BChE for 24 hours blocked the formation of fibrils and resulted in the aggregation mostly of amorphous precipitates. At 72 hours, numerous fibrillar structures were detected. Co-incubation with higher concentrations of BChE for 24 hours inhibited even amorphous aggregates and yielded clouds of tiny speckles. At these higher concentrations of BChE, no fibrillar deposits were seen even after 72 hours. These preliminary observations indicate that BChE promotes a more amorphous, flocculent, and less fibrillar state of Aß aggregation. The mechanisms underlying this effect and its potential influence on Aß-induced neurotoxicity remain to be determined. Supported by grants to WLK from NIH & Alzheimer's Association

DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID-NEUROPATHOLOGY

462.1

TOWARDS AN ANIMAL MODEL FOR ALZHEIMER'S DISEASE C Czech, S Dreisler, N Touchet, N Clavel, B Schombert, G Ret, F Revah*, L Pradier, and GL Tremp Rhône-Poulenc Rorer S.A., GENE & MEDICINE Department, Centre de Recherche Vitry-Alfortville, 94403 Vitry sur Seine, France
The causative factors in Alzheimers disease (AD) aetiology im-

The causative factors in Alzheimers disease (AD) aetiology implicate both genetic and environmental factors. A small percentage of early-onset familial AD cases are due to mutations in the APP gene. The large majority of these cases is linked to mutations in two genes, named presentilin 1 and 2 (PS 1, 2). The mechanism(s) by which the mutations lead to neurodegeneration remains to be elucidated. The modified proteins might interfere with the normal production and clearance of beta-APP. In order to get insight into this process and to create a rodent model for Driver designed to approach the process and to create a rodent model for the process and to create a rodent of the process and to create a rodent of the process and to create a rodent of the process and to create a rodent of the process and the process are processed to the process and the process and the process and the process and the process and the process and the process are processed to the process and the process are processed to the process and the process are processed to the process and the process are processed to the process and the process are processed to the process and the process are processed to the process are processed to the process and the process are processed to the process are processed to the process are processed to the process are processed to the process are processed to the process are processed to the process are processed to the process are processed to the process are processed to the processed to the process are processed to the processed to the processed to the processed to the process are processed to the processed to the processed to the processed to the processed to the processed to the processed to the pr

In order to get insight into this process and to create a rodent model for AD, we decided to express human wildtype and mutated PS1 in transgenic mice and rats. The transgenes consist of an housekeeping gene promoter and the corresponding human PS1 cDNA. We obtained several independent transgenic mouse and rat lines harbouring 2-20 copies of the hybridgene. A robust overexpression of transgene-specific RNA was observed in the brains of mice from several independent lines. To study the interaction between PS 1 and APP *in vivo*, we created mice expressing both, mutated human APP and human PS 1. Since AD is amultigenic disease, we intend to combine several AD linked genes and risk factors in the same animal. A better understanding of the genetic and extra-genetic events; their interaction and timing, leading to AD is crucial for the development of an innovative therapeutic approach.

Gene-Targeted Mice For APP and Cu-Zn SOD-1 for Studying AB Metabolism and Amyloid-Related Neuropathologies

D. Howland, A. Reaume, M. Savage*, D. Flood, S. Trusko, Y.G. Lin, L. Pinsker, D. Lang, B. Greenberg, R. Siman, and R. Scott Cephalon, 145 Brandywine Pkwy., West Chester, PA. USA, 19380.

We have used gene-targeting to introduce the Swedish familial AD (FAD) mutations and convert mouse AB to the human sequence in mouse. Swedish mutant "humanized" APP is expressed at normal levels in brain and cleavage at the mutant B-secretase site is both accurate and enhanced resulting in elevated AB production. In brains from mice homozygous for the mutant APP allele, human AB levels are approximately one order of magnitude greater than those measured in normal human brain. Correct developmental and spatial mutant APP expression in conjunction with high levels of human AB production in the absence of APP overexpression make this animal model ideal to screen for pharmacological modulators of AB production. We are currently administering compounds, predicted to affect AB metabolism, in these animals to measure effects on AB (by ELISA) and associated APP processing fragments. In addition, the neuropathological consequences of chronic high level AB production in brain is being analyzed in a longitudinal study. To complement these experiments we have generated mice double homozygous for the mutant APP allele and a cytoplasmic Cu-Zn SOD-1 knockout allele (see D.G. Flood et al. Soc. Neurosci. Abstr., 1996) to analyze the combined effects of AB overproduction and increased oxidative stress on brain neuropathology.

The deposition of amyloid β protein $(A\beta)$ is an important early event in the development of Alzheimer's disease. To produce animal model which overexpresses $A\beta$, we generated three sets of mice expressing the transgene of carboxyl-terminal fragments (CTF) of amyloid β protein precursor (βAPP) ($\beta ANOR\beta$: signal peptide and 99 amino acid residues of CTF, $\beta AANOR\beta$: methionine and 103 amino acid residues of CTF, and $\beta A\Delta NL\beta$: methionine and 103 amino acid residues of CTF, with substitution of KM-NL type mutation) under control of the cytomegalovirus enhancer / chicken β -actin promoter. The transgenic mRNA was detected by RT-PCR. The transgenic protein was detected as 11.4 kD CTF in $\beta A\Delta NOR\beta$, and as 11.8 kD CTF in $\beta A\Delta NOR\beta$ and $\beta AANL\beta$. The transgenic CTF was detected from many organs, but the amount of mRNA, CTF, and $A\beta$ did not correlate well. In $\beta ANOR\beta$, β deposition was detected in pancreas with severe degeneration of acinar cells and infiltration of macrophages. In $\beta A\Delta NOR\beta$ and $\beta A\Delta NL\beta$, β deposition was not obvious in brancreas, in spite of much expression of the transgenic CTF in pancreas. In brain, $A\beta$ deposition was detected only in $\beta A\Delta NL\beta$. In the brain of $\beta A\Delta NL\beta$, there was intracellular deposition of dense substances that were stained by anti-A β antibodies in the neurons of cerebral cortex and hippocampus. Our findings indicate that tissue-specific posttranslational processing may play a pivotal role in $A\beta$ production, and that the KM-NL type mutation may accelerate intracellular Aβ deposition in neurons in vivo.

PREDICTORS OF β-AMYLOID DEPOSITION IN THE CANINE.

M. J. Russell*, Y. Hou, M. Bobik, J. S. Marks, and R. G. White.

Comparative Aging Lab., Dept. of Anesthesiology, University of California, Davis, CA 95616.

Canines spontaneously develop β-amyloid (Aβ) plaques in their The deposition of diffuse AB is viewed as an early stage of plaque development and is the most common form of plaque in dogs. We have examined a number of factors as predictors of AB deposition and found a positive relationship between several. Our findings suggest that four indicators are strong positive predictors. These are: 1) The cerebral spinal fluid (CSF) levels of soluble amyloid precursor proteins (sAPP). There is a high correlation of diffuse amyloid plaques with sAPP CSF levels. 2) The existence of littermates with plaques in their brains. Animals who have littermates with amyloid plaque deposition also show plaques in their 3) The breed of dog. Breeds differ in the onset and distribution of amyloid plaques. 4) The age of the animal. In a colony of dogs raised under controlled environmental conditions age of onset within the colony is very specific. These data indicate that Aβ deposition can be predicted with accuracy in the canine by a combination of factors. In environmentally restricted dogs a regression of age and sAPP levels provides R value of 0.92 with amyloid deposition in brain. Supported by NIA grant RO1AG 11350.

DISTRIBUTION OF β-AMYLOID IN THE CANINE BRAIN. Y. Hou, M. Bobik, R. G. White, J. S. Marks, and M. J. Russell. Canine Aging Lab., Dept. Anesthesiology, Univ. California, Davis.,

The distribution of amyloid plaque deposition in the canine brain was studied by employing β-amyloid (Aβ) immunohistochemistry (10D5 antibody from Athena), in the brains of ten randomly selected aged dogs. Formalin fixed tissues were embedded in paraffin and serial sectioned Aß plaques were counted in eight sections from each dog, analyzed by brain region and combined by quantitative image analysis to form an average distribution in the canine brain. Positive plaques were widely distributed. The highest densities were found, in descending order of concentration in the: 1) dentate gyrus of the hippocampus, 2) medial and posterior ectosylvius gyrus, 3) medial and posterior sylvius gyrus, and 4) proreus gyral cortex in the frontal lobe.

There are significant differences between dog and human AB distribution. Plaques were found in the olfactory bulb in only one dog, and the entorhinal cortex was one of cortical areas least affected. No amyloid deposits were detected in the brain stem or cerebellum. This study reveals a general distribution of \(\beta \)-Amyloid in canine brain and better defines the canine Alzheimer's disease-like Aß deposition in this AD animal model

Supported by NIA grant RO1 AG 11350.

DEVELOPMENT OF Aß IMMUNOREACTIVE PLAQUE-LIKE DEPOSITS IN HIPPOCAMPAL SLICE CULTURES Harris*, J.J. Sigel and S.A. Frautschy UCLA Depts. Medicine and Neurology, Los Angeles, CA 90095 and GRECC, Sepulveda VAMC, Sepulveda, CA 91343

Hippocampal slice cultures provide an excellent in vitro model to study the development of AB deposits and the resulting multicellular changes associated with Aß plaque development. Using monoclonal antibodies anti-β(42) [2G9] and anti-β(40) [10G4], Aβ immunoreactive plaque-like deposits were observed in slices following treatment with AB (1-40) + (1-42). These deposits are 31-42 um in diameter and are characterized as diffuse. Addition of transforming growth factor beta, which orchestrates the brain's response to injury, results in deposits that are larger (36-54 um) and stain more intensely with 2G9. These deposits are more compact and contain numerous glial processes running throughout the deposits. Using imaging techniques, we can study the time course of plaque development in these slices. These slices also provide a model to rapidly screen therapeutics designed to reduce Aß deposition and plaque formation. This work is supported by grants NS30195 and AG10685.

462.9

ENTORHINAL CORTEX PATHOLOGY AND COGNITIVE PERFORMANCE IN AGING AND ALZHEIMER'S DISEASE: FINDINGS FROM THE NUN STUDY Tina I. Tektirian.* D.A. Snowdon, D. Racke, K.P. Riley, D.G. Davis, I.W. Ashford, N.S. Soultanian, W.R. Markesbery, I.W. Geddes, Sanders-Brown Alzheimer's Disease Research Center & Department of Anatomy & Neurobiology, Lexingfon, Kentucky.

Whether B-amyloid (AB) plaques, neurofibrillary (NF) pathology, or a combination of these neuropathological hallmarks are associated with cognitive and memory dysfunction in Alzheimer's disease (AD) or normal aging has been debated. Our studies specifically focus upon these issues and the entorhinal cortex, as this area is critical for learning and memory. Neuropathological data was correlated with neuropsychological data from the Nun Study, a longitudinal study of aging and Alzheimer's disease in 678 Catholic Sisters; the Sisters are annually examined using the CERAD cognitive test battery. AB load (% of entorthinal cortex occupied by AB), was measured in 47 cases. NF pathology (59 subjects) was assessed with Gallyas and PHF-1 immunostaining and further characterized by Braak staging (Acta Neuropathol. 82: 239, 1991). Participants were evaluated as a total group and were also subdivided into cognitively impaired and unimpaired groups. Regression analyses indicate that AB load is associated with lower scores on the Mini-Mental State Examination (MMSE) in both the total and impaired groups known and the cognitive tests (i.e. Boston Naming, Verbal Fluency, Delayed Word Recall, and Constructional Praxis). Additionally, each 1% increase of AB load (range: 0-14%) was associated with a 1.7 point decrement on the MMSE. With regard to NF pathology, the shift from the Braak transentorhinal/entorhinal stages (I & II) to the limbic stages (III & IV) was associated with poorer performance on all cognitive tests (i.e. Delayed Word Recall) but no clear difference in performance on other cognitive tests. Transition from the limbic to isocortical stages (W & VI) was significan

AMYLOID B PROTEIN DEPOSITION IN BRAINS OF NON-DEMENTED EAST AFRICANS

J.A. O'gengo, D. L. Cohen, J.G. Sayi, W.B. Matuja, J. N. Kitinya, J.K. Kimani, R.P. Friedland and R.N. Kalaria. (SPON: Society of Neuroscientists of Africa) Departments of Neurology and Pathology, Case Western Reserve University, Cleveland, Ohio 44106, USA; Department of Human Anatomy, University of Nairobi, Kenya; Neurology Unit and Pathology Institute, Muhimbili Medical Centre, Dar es Salaam, Tanzania.

Environmental and genetic factors have been invariably implicated in the etiopathogenesis of Alzheimer's disease (AD). The investigation of prevalence rates of AD in different populations could provide clues to the identification of these factors. Previous studies have suggested that AD and Aß deposition is uncommon in Nigerian Africans. We assessed the deposition of amyloid B (AB) protein and other lesions associated with typical AD in brains of aging East Africans. Brain tissue was obtained from routine or coroner cases that came to autopsy at two academic institutions in East Africa. Here, we found that 17% of the (5/30) brains from subjects with an age range 50 to 83 years exhibited parenchymal as well as vascular amyloid ß deposits. Plaques were predominantly positive for the longer more pathogenic AB₄₂ form. Our observations suggest the occurrence of AB deposits in brains of nondemented East Africans seems similar to age-matched normal controls from our institutions in Cleveland.

PROGRESSION OF REGIONAL NEUROPATHOLOGY IN ALZHEIMER'S DISEASE (AD) AND NORMAL ELDERLY: FINDINGS FROM THE NUN STUDY. DS Wolf, M Gearing, DA Snowdon, H Mori, WR Markesbery. SS Mirra*. Dept of Pathology & Lab Medicine, VA Medical Center & Emory Univ School of Medicine, Atlanta, GA; Sanders-Brown Center on Aging, Univ of Kentucky, Lexington, KY; & Tokyo Inst of Psychiatry, Tokyo, Japan. While diffuse plaques in the neocortex may represent an early stage in the

While diffuse plaques in the neocortex may represent an early stage in the evolution of neuritic plaques, plaques in striatum and cerebellum retain their predominantly diffuse nature in AD, regardless of disease duration. Exploring these regional differences may provide clues to factors influencing the progression of AD neuropathology. We had the opportunity to study autopsy brain tissue derived from 15 cognitively normal and 5 AD subjects. All participants were enrolled in The Nun Study, a longitudinal study on aging and AD (Snowdon et al, JAMA 1996;275:528-532); subjects were elderly Catholic sisters in whom the CERAD neuropsychology battery had been performed within one year of death. Diffuse and neuritic plaques, neurofibrillary tangles (NFT), and distribution of beta-amyloid (AB) and apolipoprotein E (ApoE) were assessed in temporal cortex, striatum, and cerebellum without knowledge of clinical status. Examination revealed diffuse plaques in striatum in 6 (40%) and in cerebellum in 4 (27%) of the 15 non-demented sisters and in all 5 AD cases. These subcortical plaques labelled with antibody to AB42 but not AB40. In the 20 cases overall, the frequency of striatal and cerebellar plaques generally paralleled the frequency of striatal and cerebellar plaques generally paralleled the frequency of striatal and cerebellar plaques generally paralleled the frequency of neuritic plaques and NFT and correlated with decline in some neuropsychological measures, e.g. delayed word recall, word recognition, and MMSE. Our findings suggest that subcortical diffuse plaques occur relatively early in the progression of AD pathology and coincide with neocortical pathology and cognitive changes. Thus, it is unlikely that temporal factors alone account for regional differences in progression of AD neuropathology. Supported by R01AG09862, AG05144, and AG10130.

462.10

AMYLOID PLAQUE DISTRIBUTION ALONG THE LONGITUDINAL AXIS OF THE HIPPOCAMPUS IN ALZHEIMER'S DISEASE AND PARKINSON'S DISEASE. F.-L.F. Chang*, X. Figueroa and A. Wagner UCSF-Fresno Dept. of Neurology, and Alzheimer's Dis. Ctr., and VA Med. Ctr., Fresno, CA 93703
Both Alzheimer's disease (AD) and Parkinson's disease (PD) are neurodegenerative disorder. While the pathophysiology and clinical presentation of the two diseases are quite different, cognitive impairment frequently develops as PD progresses. Questions were raised regarding the neural substrates of the dementia sociated with PD.

We studied the distribution of amyloid plaques within the hippocampus along its entire longitudinal axis in AD or PD patients using Bielschowsky silver and thioflavin-S stains. We found a significant positive linear correlation between the extent of cognitive impairment (estimated from scores on Mini-Mental State Exam within one year of death) and the density of amyloid plaques in the CA1 subfield of the hippocampus for AD. We found a similar correlation in our PD cases using regression analysis. There was a trend of higher plaque density in the rostral, head segment (pes hippocampus) along the longitudinal axis in both AD and PD. A gradient of increased amyloid plaque density was also noted from the subfield CA2, through CA1, to the subiculum in both AD and PD.

Our findings suggest comparable distribution of pathology within the hippocampus as dementia progresses in both AD and PD. Studies are needed to document more comprehensively the distribution of pathology for PD patients developing dementia in later years. The results can benefit diagnostic classification and staging, and provide a basis for researches into treatment

(Supported by the State of California Department of Health Services, the Fresno VA Medical Center, and the UCSF Fresno Foundation.)

BOTH β-AMYLOID 1-40 AND 1-42/43 ARE DEPOSITED IN THE EARLIEST FORMED PLAQUES DURING AGING AND EARLY DEMENTIA. J.L. Price* C.D. Myers and D.W. Wavek, Dept. of Anatomy & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110

Previous work in other labs has shown that \(\beta\)-amyloid (A\(\beta\)) occurs in a shorter, 40 amino acid form and a longer, 42-43 amino acid form. Aβ42/43 is more insoluble, and in early Down syndrome cases is preferentially deposited in the earliest formed plaques, suggesting that it is responsible for initial plaques formation. Down syndrome is advantageous for the study of early plaque formation, because all cases show substantial plaques in their early 20's, but the cellular processes that produce excess $A\beta$ in Down

plaques in their early 20's, but the cellular processes that produce excess A β in Down syndrome are different from those in aging or sporadic Alzheimer's Disease (AD). In this study, early plaque formation was studied in 9 non-demented aging cases (CDR=0) and 7 very mildly demented subjects (CDR=0.5). The subjects were assessed in the ADRC of Washington University, either before death, or by a retrospective dementia interview. Sections through the orbital, insular and temporal cortex were stained with the 10D5 antibody (against both forms of A β), or with the end-specific antibodies BA27 (against A β 40) or BC05 (against A β 42/43). All of the CDR=0.5 cases met standard criteria for AD, and had more plaques than the CDR=0 cases, which were selected to ensure the presence of at least a few plaques. Plaques were mapped with the aid of a computerized microscope digitizer, and areas of maximum plaque deposition were selected for determination of the density of plaques stained with each antibody. In all of the brains, plaques were found that were positive for both $A\beta40$ and $A\beta42/43$

Although precise quantitative comparisons between immunohistochemical stains with different antibodies are limited, in half of the brains more AB40 positive plaques were found than $A\beta42/43$ positive plaques, while in the other brains there were more $A\beta42/43$ than $A\beta40$ plaques. The ratio of $A\beta40$ to $A\beta42/43$ plaques showed no relation to age, dementia rating, or to total plaques stained with the 10D5 antibody. It appears, therefore, that there may be no preference for either form of $A\beta$ in aging and early sporadic AD. (Supported by NIH grant AG-03991).

LOCALIZATION OF RNA WITHIN NEUROFIBRILLARY TANGLES AND SENILE PLAQUES IN ALZHEIMER'S DISEASE. S.D. Ginsberg*¹, P.B. Crino², V.M-Y. Lee¹, J.H. Eberwine², and J.O. Trojanowski¹. Depts. of ¹Pathology and ²Pharmacology, Univ. Pennsylvania Sch. of Med., Philadelphia, PA 19104.

The distribution and composition of neurofibrillary tangles (NFTs) and senile plaques (SPs) have been characterized within the Alzheimer's disease (AD) brain, although little data exists on their non-proteinaceous components. We tested the hypothesis that NFTs, neuropil threads (NTs), and SPs contain cytoplasmic RNA species. Acridine orange (AO) histofluorescence was employed, by itself or in combination with thioflavine-S (TS) staining and immunohistochemistry for astroglial and microglial epitopes, to identify immunohistochemistry for astroglial and microglial epitopes, to identify RNA in paraffin-embedded tissue sections of the hippocampal formation and entorhinal cortex from 33 postmortem cases of AD, Down's syndrome (DS), and age-matched normal controls. AO stained the cytoplasm of hippocampal and entorhinal neurons in normal controls, and labeled NFTs, NTs, and SPs within the brains of AD and DS patients. AO histofluorescence was abolished with RNase, but not DNase or proteinase K, indicating the relative specificity for RNA contribution and six department of approximately 80% of the contribution and six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the six department of the protein and the protein an species. Quantitative analysis demonstrated approximately 80% of NFTs identified with TS colocalized AO, whereas approximately 55% of TS-stained SPs contained AO labeling. AO-stained SP's colocalized with microglial cells, and were apposed to, but not colocalized with astrocytes. The characterization of the RNAs in NFTs and SPs may lead to the identification of gene transcripts that contribute to their deposition. Supported by grants from the NIH.

NEOCORTICAL NEURITIC PLAQUES ARE LESS REACTIVE WITH ANTI-PHF ANTIBODY IN LEWY BODY DEMENTIA THAN IN ALZHEIMER DISEASE. W. Samuel*, R. Crowder, L. Hansen. Dept. of Neurosciences: Univ. of Calif., San Diego, La Jolla, CA 92093. BACKGROUND: Besides having neocortical plaques and entorhinal neurofibrillary tangles (NFT) with paired helical filaments (PHF), the brains of about 25% of patients meeting criteria for Alzheimer disease (AD), also have cortical and subcortical Lewy bodies (LB). Designated the Lewy body variant (LBV), they differ from pure AD cases in having a predominance of diffuse and neuritic plaques (NP) and very few neocortical NFT. Using different techniques, we sought to replicate a recent Western blot analysis of brain homogenates which found that the neocortex of LBV patients reacted positively with anti-PHF antibody only in the relatively few cases in which neocortical NFT were seen. METHODS: Routine histopathological examination classified cases as AD (n=14) or LBV (n=12) and quantified midfrontal neocortical NP per microscopic field using a 10X objective and NFT using a 40X objective. Midfrontal 10um paraffin sections were processed by the immunoperoxidase method for reactivity with a monoclonal antibody which binds phosphorylated PHF. After washing, the sections were counterstained with thioflavin-S. NP were counted in five randomly-selected 10X fields, following which we switched from fluorescent to light microscopy so as to assess each plaque for anti-PHF reactivity. RESULTS: The LBV and AD did not differ significantly in age (79.5-81.2 yrs), male/female ratio, or terminal neuropsychological test scores. On routine histopathology, the LBV (39.7) and AD (42.1) did not appreciably differ in numbers of NP per 10X field, but the LBV (0.33) had significantly (p<.05) fewer NFT per 40X field than did the AD (1.29). Among subjects observed to have midfrontal NFT, which comprised most of the AD cases but only a third of the LBV, 81-84% of NP reacted positively with the anti-PHF antibody. Among subjects without NFT, 52% of the NP of AD cases but only 12% of the NP of LBV cases were anti-PHF positive (p<.05). CONCLUSION: LBV differs from AD in that its plaque neurites do not, for the most part, contain PHF. SUPPORT: National Institute on Aging; Veteran's Administration Central Office.

Novel 100kD protein associated with amyloid plaques in AD brains. M.L.Schmidt*, M. Forman, V. M.-Y. Lee, and J.O. Trojanowski. Path. and Lab. Med., U.of Penn. Sch. of Med., Philadelphia, Pa 19104-4283.

Monoclonal antibodies (MAB) were raised to a PHFtau enriched preparation obtained from pooled brains of 2 Alzheimer's disease (AD)patients and 1 Downs Syndrome (DS) patient with AD. 59 MABs recognized the PHFtau preparation by ELISA and 55 of these MABs immunostained neurofibrillary lesions in AD brain sections. The other 4 MABs (i.e. AMY 117, 135,144,155), however, immunostained plaques in AD tissue and immunoblotted a protein of about 100 kD. Double immunolabeling with an AMY MAB and a polyclonal antibody to AD amyloid β protein (Aβ) showed that AMY immunoreactivity was frequently located at the periphery or adjacent to the Aβ positive plaques. AMY positive plaques were found in the frontal cortices of the majority of AD patients and all DS/AD patients. No AMY positive plaques were observed in cerebella of AD and DS/AD patients that had Aβ deposits. AMY positive plaques were extremely rare or not detectable in elderly normal and schizophrenic patients as well as in patients with other neurodegenerative diseases. These results indicate that a hitherto unrecognized 100 kD protein is closely associated with a large majority of senile plaques in AD and DS/AD. Further studies are necessary to clarify whether this protein contributes to the toxicity of amyloid deposits or the formation of dystrophic neurites and close of neurons and synapses in AD.

NEURONAL ENERGY METABOLISM IS NOT REDUCED BY SENILE PLAQUES IN ALZHEIMER'S DISEASE.

K. Hatanpää*, D.R. Brady, K. Chandrasekaran and S.I. Rapoport. Lab. of Neurosciences, NIA, Bethesda, MD 20892.

A decrease in cerebral energy metabolism precedes clinical dementia in patients with Alzheimer disease (AD). In the post mortem AD brain, mRNAs for subunits of cytochrome oxidase (COX) are decreased. Because COX expression is regulated by functional needs for energy, these decreases likely reflect synaptic degeneration, which leads to reduced synaptic firing and downregulation of oxidative phosphorylation enzymes, including COX. Our recent results indicate that a decrease in COX mRNA precedes formation of neurofibrillary tangles (NFTs) in AD pyramidal neurons in midtemporal cortex, and that COX mRNA further decreases as NF formation progresses [Hatanpää et al. 1996, Ann. Neurol., in press]. In this totrination progresses (nataripae et al. 1996, Am. Neurol., in press). If an study, we focused on senile plaques, that with NFTs are the major pathologic features in AD. Frozen sections from midtemporal cortices of 4 AD cases were subjected to in situ hybridization for COX subunit III mRNA (COX mRNA), followed by immunohistochemistry with PHF-1 antibody to detect neuritic plagues. Additional sections were used for COX histochemistry to detect COX enzyme activity, followed by Thioflavin S staining to detect plaques. There was no statistically significant decrease in COX mRNA in tangle-free neurons within 15 µm from a plaque, compared with tangle-free neurons that were not close to any plaque. Plaques also were not associated with decreased COX activity, with the exception of plaque cores, that were devoid of COX activity. Therefore, plaques likely do not contribute to decreased energy metabolism in AD and may not be a causal factor in neurodegeneration

BUTYRYLCHOLINESTERASE (BCHE) IN THE LIFE CYCLE OF ALZHEIMER'S DISEASE (AD) PLAQUES. A.L. Guillozet^{1*}, J.F. Smiley¹, D.J. Selkoe², D.C. Mash³, M.-M. Mesulam¹. ¹Northwestern University, Chicago, IL 60611. ²Harvard

Mash', M.-M. Mesulam'. 'Northwestern University, Chicago, IL 00011. 'Harvard University, Boston, MA 02115. 'Juniversity of Miami, Miami, FL 33136.

The normal human cerebral cortex contains very little BChE, expressed mostly by neurons of deep layers and subcortical neuroglia. In AD, the core, halo and neurites of senile plaques express intense BChE enzyme activity. Whether BChE expression is an early or late event in the process of AB plaque maturation is unknown. Our assumption concerning the lifecycle of plaques is that the AB peptide is initially deposited in a diffuse (thioflavin S-negative) form which subsequently undergoes transformation first into a compact (thioflavin S-positive) but non-neuritic form, and then into a compact-neuritic form. This transformation may take many years and only the final neuritic form is significantly correlated with clinical dementia. In 8 brains from control (non-demented) and AD subjects, dementia. In 8 brains from control (non-demented) and AD subjects, matching sections were processed for the demonstration of AB, thioflavin-S, and BChE. In 2 control specimens where all AB plaque deposits were thioflavin-S negative (i.e., diffuse), the plaques were also BChE-negative. In the other 3 control specimens, regions and layers that contained only diffuse plaques had no plaque-bound BChE whereas regions and layers with compact plaques contained plaque-bound BChE. In 3 AD specimens where AB deposits were almost invariably of the compact or neuritic type, plaques were almost always associated with intense BChE activity. We had previously shown that plaque-bound BChE is likely to originate from neuroglia and that its enzymatic activity is selectively inhibited by protease inhibitors (Wright, Geula, Mesulam, PNAS, 93). The present observations indicate that BChE activity appears at the intermediate stage of plaque formation and that it may therefore constitute one of the factors involved in the transformation of an initially benign AB deposit into a compact and neuritic form associated with neural degeneration and dementia.

LOCALIZATION OF PRESENILIN-2 RNA IN RAT BRAIN BY IN SITU HYBRIDIZATION. S.A. Benkovic*, D.G. Morgan, and M.N. Gordon. Department of Pharmacology and Therapeutics,

We have generated templates for in situ hybridization probes by RT-PCR using rat brain RNA. The nucleotide sequence for PS-2 was obtained from Genbank (accession sequence for PS-L was obtained from ceneank (accession number L44577) and primers were selected from the region of least homology between PS-1 and PS-2 (hydrophilic loop VI-VII). Probe templates were sequenced and confirmed to be PS-2. Densitometric analysis of in situ hybridization revealed that PS-2 is expressed in the rat hypridization revealed that Ps-2 is expressed in the rat-brain in virtually all brain regions examined. Levels of PS-2 in superficial cortex were higher than deeper cortex. Levels in the caudate nucleus and superior colliculus were moderate and similar to deep cortical expression. The strongest signal for PS-2 was seen in the neuronal layers of the dentate gyrus and hippocampal the neuronal layers of the dentate gyrus and hippocampal CA fields. Expression of PS-2 in the cerebellar granule cell layer was high, while levels in the molecular layer and pons were low. Liver and spleen displayed strong hybridization signals, while the level in kidney was lower. Emulsion dipped slides indicated a purely neuronal localization of PS-2 mRNA. The molecular layers of cortex and hippocampus were devoid of signal. White matter regions had grain densities similar to sense strand control signals. These data indicate a distribution of PS-2 RNA with a strong, if not exclusive localization to neurons. Supported by Alzheimer's Association IIRG 93-083 and Pfizer Inc.

PRESENCE OF INSULIN-LIKE GROWTH FACTOR II/ MANNOSE-6-PHOSPHATE RECEPTORS IN THE NEURITIC PLAQUES OF ALZHEIMER, S. DISEASE BRAIN, S. Kar*, U. Beffert, S. Dore, S. Gentleman, Y. Robitaille, J.H. Grubb, J.W.S. Sly, D. Dea, J. Poirrer and R. Quirion, Douglas Hosp, Res. Center, Dept. Psychiat, McGill Univ., Montreal, Canada, 1 Dept. of Anat., Charing Cross and Westminster Med. PEdward A. Doisy Dept. Biochem. Mol. Biol., Saint Louis Univ., St. Louis, USA.

The insulin-like growth factor-II/Mannose-6-phosphate (IGF-II/Man-6-P) receptor is a multifunctional protein which binds different classes of ligands including IGF-II and Man-6-P bearing lysosomal enzymes. This receptor, besides participating in transmembrane signal transduction and endocytosis also functions in the targeting of newly synthesized lysosomal enzymes. In Alzheimer's disease (AD) brain, the marked over expression of certain lysosomal enzymes in vulnerable neuronal populations and their association to B-amyloid containing neuritic plaques have been correlated to altered metabolic functions. These data when analysed with reference to functions of IGF-II/Man-6-P receptors in sorting of lysosomal enzymes may suggest a role for these receptors in the pathogenesis of AD. In the present study, to investigate the possible involvement of IGF-II/Man-6-P receptors in AD, we studied the anatomical distribution and measured the levels of these receptors in selected regions of AD (n=6) and age-matched normal (n=6) postmortem brains. Our immuno-histochemical results showed that IGF II/Man-6-P receptors are widely but selectively distributed in pyramidal neurones and B-amyloid containing neuritic plaques of frontal and hippocampal regions of AD brains. Western blot analysis also revealed a parallel increase in the level of these receptors in the frontal cortex and hippocampal regions of Certain AD brains. These results together with the altered levels of lysosomal enzymes provide an anatomical basis to suggest a role for IGF-II/Man-6-P receptors in the pathogenesis of AD. RAT SOLEUS MUSCLE IN CHLOROQUINE-INDUCED MYOPATHY SHARES IMMUNOHISTOCHEMICAL CHARACTERISTICS WITH ALZHEIMER'S DISEASE. K. Tsuzuki^{1)*}, R. Fukatsu², Y. Takamaru³, T. Yoshida², Y. Hayashi², N. Sasaki², H. Yamaguchi⁴, N. Fujii¹⁾ and N. Takahata² Depts of ¹⁾Microbiology and ²⁾Neuropsychiatry, Sapporo Med. Univ., South 1, West 17, Sapporo 060, Japan. ³⁾Sapporo City General Hospital, ⁴⁾College of Medical Care and Technology, Gunma Univ., Gunma 371, Japan

Alzheimer's disease (AD) affected brain is characterized by the deposition of amyloid β protein (A β). A β is proteolytic cleavage product of amyloid precursor protein (APP) that vary slightly at the carboxy-terminus, yielding species of 40, and 42(43) amino acids. These species have been reported to play different role in AD pathogenesis.

Chloroquine-induces myopathy in rats similar to rimmed vacuole (RV) myopathy in humans. We demonstrated immunohistochemically that AB, APP N-, C-terminal regions and cathepsin D accumulate in RVs in chloroquine-induced myopathy in rats. Moreover, Aβ immunoreactivity co-localizes with apolipoprotein E, SP-40,40, α₁antichymotrypsin, and ubiquitin, so-called amyloid-associated proteins

The purpose of this study, is to elucidate whether AB is cleaved from APP, or APP fragments containing A β accumulate in the RVs, which species of A β is present in the RVs. Two end-specific for the C- terminus of A β , BC40 and BC42, and A β 90/12, a monoclonal antibody were used, which reacts with the N-terminus of AB, reacting both with APP containing Aβ and cleaved Aβ. Immunohistochemical studies were carried out with denervated soleus muscle 14 days after the initial injection of chloroquine. Transverse paraffin sections were stained according to the streptavidin-biotin peroxidase technique. Muscle fibers suffering from chloroquine-induced myopathy contained both cleaved Aβ40 and Aβ42. Aβ42 appeared to predominate over Aβ40.

In conclusion, our results provide further evidence that chloroquine-induced hyopathy in rats is a useful model for understanding APP processing into $A\beta$ in terms of the pathogenesis of AD.

A PS1 MUTATION LEADS TO AD PATHOLOGY AND INCREASED ABO

A PS1 MUTATION LEADS TO AD PATHOLOGY AND INCREASED A&22 BURDEN IN BRAIN BY MIDDLE AGE IN 4 FAD PATIENTS. C.A. Lemer*, F. Lopera, K.S. Kosik, J. Cssa, T.C. Saido, H. Yamaguchi, D.J. Selkoe, J.C. Arango, V. Brigharmand Women's Hospital, Harvard Medical School, Boston, MA 02115.

Overproduction of AB42 appears to play a role in FAD due to certain missense mutations (e.g., BAPP). Here, we examined C- and N-terminal AB immunoreactivity (IR) and other markers of AD pathology in the brains of 4 Colombian FAD patients (47-62 yrs) bearing the E280A PS1 mutation. All 4 cases contained massive amounts of AB22 in plaques in cortex himpocampus, midbrain and cerebellum; and in blood vessels. cortex, hippocampus, midbrain and cerebellum, and in blood vessels. Less A $_{40}$ IR was seen. FAD patients had a significantly greater A $_{42}$ plaque burden in 4 brain regions compared with those of 12 sporadic AD cases. In addition to A $_{40}$ vascular staining, many blood vessels also contained AB₄₂ IR. N-terminal AB staining revealed a subset of plaques (mostly cored) and blood vessels throughout the brain. Many tau- and ubiquitin-positive NFTs were observed in cortex and hippocampus. Neurofilament-positive neurites were seen in a subset of plaques, many of which were tau-negative. The cerebellum contained abundant AB₄₂ plaques, a subset of which contained ubiquitin-positive, tau-negative neurites. Severe gliosis in the cerebellum and cerebral cortex was observed. PS1 IR was seen in a minority of neuritic plaques. Our results are consistent with earlier findings of increased AB₄₂ production in fibroblasts and plasma from patients with PS1 mutations. The increased levels of AB₄₂ in brain provide insight into the mechanism by which mutant PS1 leads to amyloidogenesis in AD. We are now examining these tissues for Aβ-associated proteins. Supported by NIH grants to KSK and DJS. Neurofilament-positive neurites were seen in a subset of plaques, many

ARE INSULIN-LIKE GROWTH FACTOR II/ MANNOSE-6-PHOSPHATE RECEPTORS INVOLVED IN THE UPTAKE OF B AMYLOID PEPTIDE INTO RAT PRIMARY HIPPOCAMPAL CULTURED NEURONS? D.S. Auld*, U. Beffert, S. Kar, N. Aumont, S. Doré, J. Poirier and R. Quirion, Douglas Hospital Research Centre, Depts, of Psychiatry, Neurol. & Neurosurg., McGill Univ., Montreal, Quebec, Canada H4H 1R3.

Neurosarg., McGill Univ., Montreal, Quebec, Canada H4H 1R3.

Excessive extracellular deposition of B-amyloid (AB), a polypeptide of 39-43 amino acids, in brain parenchyma and cerebral blood vessels is a pathological hallmark of Alzheimer's disease (AD). It is further suggested that AB accumulation may initiate and/or contribute to the process of neurodegeneration in AD. However, at present, it is not clear how the effects of AB peptides are mediated in either physiological or pathological conditions. In this context, the recent localization of insulin-like growth factor II/ Mannose-6-phosphate (IGF Il/Man-6-P) receptor in the AB-containing neuritie plaques of the AD brain (S. Kar et al., this meeting) raises the possibility that these receptors may be involved in mediating the effects of AB peptides. Indeed, evidence accumulated over the last decade indicates that IGF II/Man-6-P receptor is a multifunctional protein which is distributed widely but selectively throughout the brain and brids different classes of ligands including IGF II, Man-6-P bearing lysosomal enzymes, proliferin, transforming growth factor B and thyroglobulin. In the present study, to evaluate the functional interrelationship, if any, between AB peptides and IGF II/Man-6-P receptors, we have used Western blot analysis to measure the effects of IGF II on the cellular uptake of AB peptides in rat primary hippocampal cultured neurones. Our results indicate that IGF II (10nM - 1µM) significantly decreases cellular uptake of AB1-40 into cultured hippocampal neurones. Furthermore, apolipoprotein E-induced cellular uptake of AB1-40 is also decreased by IGF II (10nM - 1µM). These results indicate that IGF II/Man-6-P receptors may modulate the cellular uptake of AB peptides and therefore may have implications for AD pathology. (Supported by MRCC, FRSQ and Alzheimer Soc. Canada)

EFFECTS OF GENETIC RISKS ON CEREBRAL GLUCOSE METABOLISM IN

ALZHEIMER'S DISEASE.

Department of Geriatric Medicine, Tohoku University School of Medicine, Sendai 980, JAPAN, ²⁾Cyclotron and Radioisotope Center, Tohoku University School of Medicine, Sendai 980, JAPAN, ³⁾Department of Psychiatry, National Institute on Alcoholism, Kurihama National Hospital, Kanagawa 239, JAPAN

Studies with positron emission tomography (PET) and ¹⁸F-2-fluoro-2-deoxy-Dglucose (FDG) for patients with Alzheimer's disease (AD) have indicated a typical metabolic pattern with reductions in the temporo-parietal junction and considerable heterogeneity in the metabolic alterations. On the other hand, polymorphisms of several heterogeneity in the metabolic alterations. On the other hand, polymorphisms of several genes and increased levels of certain molecules have been associated with the onset or the clinical progression of AD, while the biological mechanisms underlying these changes remain unsettled. In the present study, FDG-PET scans were performed on patients with AD following determination of the apolipoprotein E (APOE), alartichymotrypsin (ACT), and presentilin-1 (PS-1) genotypes and levels of cerebrospinal fluid tau (CSF-tau). We sought to investigate the effects of these indices as well as the Mini-Mental State Examination (MMSE) scores and the age of onset, on cerebral glucose metabolism. Significant and positive relationships between the regional metabolic rate of glucose (rCMRglc) and gene dose of APOE*4 was observed particularly in the frontal areas, and gene dose of ACT*A was greatly and negatively associated with rCMRglc in multiple regions, especially in the temporal and parietal areas by simple correlational and multiple regression analyses. The levels of CSF-tau were negatively related to rCMRglc in the medial frontal areas for mildly-demented patients, suggesting that patients with high levels of CSF-tau show reduced frontal metabolism from the earliest stage of AD. The effects of gene dose of PS-1*1 on rCMRglc were relatively weak in all the cerebral regions. Finally, these relationships were confirmed using statistical parametric mapping (SPM) analysis on a pixel-by-term of the carries of the parametric mapping (SPM) analysis on a pixel-by-term of the carriest stage. were confirmed using statistical parametric mapping (SPM) analysis on a pixel-by-pixel basis.

EVALUATION OF STEREOTACTIC NORMALIZATION OF PET IMAGES IN ALZHEIMER'S DISEASE (AD) USING NONLINEAR KERNEL ANALYSIS H.I. Litt. 1.2, B. Horwitz*2, ¹Department of Biophysics, SUNY at Buffalo School of Medicine, Buffalo, NY 14214, ²Laboratory for Neurosciences, NIA, NIH, Bethesda, MD, 20892.

Transformation of images into a standard stereotactic space is often used in intersubject PET studies. The normalization process may be less successful if the image being normalized is significantly different from the stereotactic template, e.g. as a result of atrophy or functional change in AD. We have developed a method that allow quantitative evaluation of a stereotactic normalization using the Volterra model of nonlinear systems. This model considers the output at a point to be dependent upon interactions among points in a region of the input known as the system memory. We calculated Volterra kernels for the transformation between a PET template in stereotactic space and FDG-PET images from 6 AD patients (Mini-Mental Status (MMS) score 0-26) and 9 matched controls. A 7*7 pixel system memory modelled the transformation for controls better than AD patients, as assessed by the difference between the model's predicted output and the template image. There was also a significant correlation between the model error and disease severity as measured by MMS score. Areas of greater error in the model fit included parietal, temporal, and dorsal occipital cortex, as well as parts of the cingulate gyrus, regions significantly affected in AD. These results demonstrate that spatial normalization algorithms may not perform as well in patients with AD, especially for those with severe disease. FUNCTIONAL RESPONSE TO AUDIOVISUAL STIMULATION IN ALZHEIMER PATIENTS: POTENTIAL FOR THERAPEUTIC INTERVENTIONS. P. Pietrini*, M.L. Furey, A. Dani, U. Freo, M.J. Mentis, G.E. Alexander, S.I. Rapoport, and M.B. Schapiro. Lab. Neurosci., Natl. Institute on Aging, NIH, Bethesda MD 20892, USA

Positron emission tomography (PET) studies in patients with Alzheimer disease (AD) at rest (eyes/ears covered) have shown reductions in regional cerebral metabolic An less (eye-bases covered) have sinown reductions in legional cerebral microacomic rates for glucose (rCMRglc) in neocortical association areas that worsen with increasing dementia severity. This study assessed the ability of AD patients of different dementia severity to respond to stimulation. High-resolution PET and the double FDG injection procedure were used to measure rCMRglc at rest and during a passive audiovisual stimulation (AS) paradigm (watching a movie) in 15 patients with probable AD (9M/6F; mean age 70±10 yr, Mattis dementia rating scale score 91±33, range 23-128) and in 14 matched healthy controls (6M/8F; mean age 71±8). W Mattis core 141±30. and in 14 matched healthy controls (6M/8F; mean age 71±8 yr; Mattis score 141±3). As compared to controls, at rest AD patients showed decreased rCMRglc in most cortical areas with a sparing of the subcortical regions. During AS, controls showed significant rCMRglc increases in auditory temporal and in occipital and parietal visual cortical regions (up to 28% in calcarine cortex). Despite the metabolic reductions at rest, during AS the AD patients also showed significant rCMRglc increases in the same areas (up to 21% in occipital-parietal visual cortex), although to a lesser extent than controls in some parietal and occipital visual areas. The magnitude of rCMRglc responses in primary and association visual cortex in AD patients was directly correlated with the Mattis score (L calcarine r=.79; p=.0005; L occipital association r=.74; p=.002). The 6 mildly demented AD patients (Mattis score 120±9) had rCMRglc responses in visual regions similar to controls atthough the decipies found in the controls atthough the decipies found in the controls at the option of the controls atthough the decipies found in the controls at the option of the controls atthough the decipies found in the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of the controls at the option of th responses in visual regions similar to controls, although they had significantly lower rCMRglc in parietal areas in both experimental conditions. In contrast, the 3 severely demented AD patients (Mattis 36±11) showed minimal or no response to stimulation in visual areas. These results indicate that the brain of mild AD patients retains an almost normal capability to be stimulated in at least some cortical regions and suggest that neuronal function in areas affected by the pathological AD process in mildly/moderately demented patients may benefit from timely therapeutic intervention once appropriate agents become available. REDUCED CYTOCHROME OXIDASE ACTIVITY IN CA1 NEURONS AND POSTERIOR PARIETAL CORTEX AFTER CHRONIC BRAIN ISCHEMIA J.C. de la Torre*, A. Cada, N. Nelson, G. Adams, R.J. Sutherland, F. Gonzalez-Lima. Departments of Neurosurgery and Psychology, Univ. of New Mexico, Albuquerque, NM 87131 and Univ. Texas, Austin, TX 78712.

We have reported that chronic 2-vessel occlusion (bilateral carotid artery

ligation) induces a mild cerebral ischemic insult that mimics Alzheimer's dementia in rats.¹ Chronic 2-VO in 10 month old rats, results in selective damage to CA1 neurons accompanied by hippocampal reactive astrocytosis and visuo-spatial memory deficits. In the present study, male Sprague-Dawley rats age 19 months were subjected to 2-VO and tested in the Morris water maze (MWM) weekly for 4 weeks after surgery. Following MWM testing, rats were decapitated and brains were flash-frozen for cytochrome oxidase (CO) activity. Immunoreaction for GFAP and MAP-2 and for Palmgren silver stains were done a separate group of similarly treated rats.

Results show a significant effect by 2-VO on visuo-spatial memory impairment as compared to controls. CO analysis revealed that only the posterior parietal cortex and posterior CA1 neurons had a marked reduction of activity. Other regions of the brain showed no CO reductions after 2-VO with respect to controls. Increased GFAP density and reduced MAP-2 activity were noted in 2-VO rats but no CA1 neuronal damage or loss was apparent

These findings suggest that reduced mitochondrial oxidative phosphorylation in posterior parietal cortex and CA1 neurons may impair visuo-spatial memory function. Ischemia-induced metabolic decline of the cell's energy supply may be a key element in triggering the structural neuronal damage that eventually develops in this model.

463.4

REGIONAL CEREBRAL GLUCOSE METABOLISM DURING STIMULATION PREDICTS DEMENTIA SEVERITY IN ALZHEIMER DISEASE PATIENTS. A. Dani*, P. Pietrini, M.L. Furey, U. Freo, M.J. Mentis, G.E. Alexander, S.I. Rapoport, and M.B. Schapiro Lab. Neurosci., Natl. Inst. Aging, NIH, Bethesda MD

In patients with Alzheimer disease (AD), rCMRglc at rest (eves/ears covered) is In patients with Alzheimer disease (AD), rt.MRgic at rest (eyes/ears covered) is abnormally reduced in most necortical areas and reductions become more severe with worsening of dementia. To test the hypothesis that brain metabolism during functional stimulation would be a better predictor of dementia severity than metabolism at rest, due to a progressive loss in the ability of the AD neurons to fully respond to stimulation, we studied 15 patients with probable AD and different themselved from the control of the degrees of dementia (9M/6F; mean age 70±10 yr, Mattis dementia rating scale score 91±33, range 23-128) at rest and during a passive, broad audiovisual stimulation (AS) paradigm (watching a movie). By using PET and the double FDG injection procedure (Brooks, 1987), rCMRgic was measured at rest and during AS. The two experimental conditions were counterbalanced. As compared to rest, absolute experimental continuous were connected and configurations. Compared to Test, absolute in CMRglc (mg/100 g/min) during AS was significantly higher in regions primarily involved in the task, including temporal auditory and in parietal and occipital visual cortical areas (up to 21% over rest). Global gray matter CMRglc significantly predicted dementia severity (as measured by the Mattis DRS) during AS (r=.69; p=.004) but not at rest (r=.47; ns). Similarly, rCMRglc in primary and association visual cortical areas was significantly correlated with dementia severity during AS. (e.g., Left occipital association and L calcarine r=.61, p=.016; L auditory r=.52, p=.047) but not at rest (r=.32, .25, and .47 respectively, ns). These results demonstrate that rCMRglc measures of neuronal function during activation of visual cortical regions closely reflect dementia severity whereas the same regions at rest do not. At rest, functional reserve mechanisms may minimize differences, whereas stimulation may function as a stressor that maximizes severity related differences in neuronal activity. This research was supported by the NIA intramural program.

OLFACTORY EVOKED REGIONAL CEREBRAL BLOOD FLOW IN HEALTHY AGING AND ALZHEIMER DISEASE. <u>D.A. Kareken, G. D. Hutchins, R.L. Doty*, P.J. Moberg, K. Caldemeyer, & M.R. Farlow</u>. Indiana Alzheimer's Disease

P.J. MODERS, N. Catelmeyer, & M.R. Farlow. Indiana Alzheimer's Disease Chtr/Indiana Univ. Schl. of Med. & VA Med. Chtr., Indianapolis, IN 46202. Olfaction deteriorates in normal aging, but in Alzheimer Disease (AD) the deterioration is greater, and begins early in the disease. As a prelude to study of the regional cerebral physiology of olfaction in AD, healthy elderly subjects were studied with positron emission tomography (PET) while inhaling a set of odorants. The sample consisted of 5 right handed, elderly subjects without history of cerebral disease or dementia (4 female, 1 male; mean age=72.2±7.35; all non-smokers). All scored normally on olfactory tests (identification, threshold). Subjects were imaged in a Siemens 951/31R PET scanner after injecting 50 mCi of H₂O¹⁵ into a venous catheter in the subject's dominant arm for each of four scans. Two scans were acquired while subjects sniffed 16 consecutive odors (scans 1 & 3), and two while subjects sniffed odor blanks (scans 2 & 4). Image subtractions were (A) 1-2, and a replication set (B) 3-4. In subtraction A, a significant increase (8.40%) in regional cerebral blood flow (rCBF) occurred near the right frontotemporal junction, corresponding to piriform (olfactory) cortex. In the replication (B), an rCBF increase (7.29%) at near identical coordinates fell just below the significance threshold. Areas of increased rCBF that missed statistical significance, but were replicated across both sets of scans, included the left piriform area, and left and right orbitofrontal areas. The results agree with prior studies showing similar regional activation during olfactory stimulation. Contrasted with other studies, there is greater right than left activity in the piriform area. This may be due to gender or aging effects. The findings demonstrate the potential of PET for characterizing olfactory related changes in the regional cerebral physiology of aging. Future comparable studies are planned in patients with AD. Supported by: Physiologic Imaging Research Center & the Alzheimer Disease Center (P30 AG10133), Indiana University; VA Medical Center, Indianapolis; Smell and Taste Center, University of Pennsylvania

INSULIN-INDUCED ENHANCEMENT OF MEMORY IN ALZHEIMER'S DISEASE IS INDEPENDENT OF GLUCOSE S. Craft, S. Asthana, J. Newcomer, I. Tic-Matos, E. Hunter, C. Lofgreen, M. Raskind*, C. W. Wilkinson, R. Veith, S. Plymate, K. Brodkin, L. Gibson, S. Latendresse, GRECC, VA Puget Sound Health Care System and University of Washington, Box 358280 (182B), Seattle, 98195

WA, 98195.

Alzheimer's disease (AD) is accompanied by disruption in glucose metabolism that may contribute to its characteristic memory impairment. Increasing glucose availability by raising plasma glucose improves memory in patients with AD (Craft et al. 1992, 1994; Manning et al., 1993). Such memory improvement is associated with glucose-stimulated elevation in endogenous insulin levels, raising the question of whether improvement is due to changes in insulin, independent of hyperglycemia. To address this question, 12 patients with AD and 10 control subjects participated in four metabolic conditions on separate days: 1) Elevated insulin (3p. μ/ml/ml) asseline glucose (95 mg/dl); 2) Elevated glucose (225 mg/dl)/baseline insulin (8 μ/l/ml; 3) Elevated insulin/glucose; and 4) Baseline insulin/glucose. Intravenous infusions of insulin, dextrose, saline, and somatostatin were used to achieve steady metabolic states, during which memory (prose recall) and selective attention (Stroop interference test) were measured. Patients with AD showed improved delayed memory [F(1,11)=5.15, p<0.4] and reduced selective attention errors [F(1,11)=5.16, p<0.4] in the elevated insulin/baseline glucose condition relative to the baseline insulin/glucose condition. No changes were noted in the elevated glucose/baseline insulin condition. These results suggest that glucose-improved memory in AD is secondary to elevations in endogenous insulin response to hyperglycemia. These results also suggest that insulin activates mechanisms affecting the medial temporal memory system. Documented insulin receptors in the hippocampus, insulin-mediated increases in glucose utilization in entorhinal cortex, and insulin modulation of cholinergic and noradrenergic systems are potential mechanisms for such effects. Finally, our findings suggest that meuroendocrine factors play an important role in the pathophysiology of AD.

This study was supported by RO1-AG-10880 from the National Institute on Aging. Alzheimer's disease (AD) is accompanied by disruption in glucose metabolism

NEURONAL DEATH IN THE RAT (SHRSP) CEREBRAL CORTEX FOLLOWING PERMANENT FOCAL ISCHEMIA. T. Nitatori *, Y. Karasawa², H. Komiyama², H. Araki², E. Kominami³ and Y. Uchiyama⁴. Dept. of Cell Biol. & Neuroanat. J. Sch. of Med. Iwate Med. Univ., Morioka 020, Japan, Pharmacol. Lab.², Taisho Pharmaceutical Co. Ltd., Ohmiya 330, Japan, Dept. of Biochem.³, Juntendo Univ., Sch. of Med., Tokyo 113, Japan, and Dept. of Anat.⁴, Osaka Univ. Med. Sch., Osaka 565, Japan.

The cortical neurons are known to be vulnerable to anoxic insults, which result in neuropathological changes within the infarcted area. The present study examined the early histopathological changes in the cortical neurons after focal cerebral ischemia, induced by permanent unilateral

which result in neuropathological changes within the infarcted area. The present study examined the early histopathological changes in the cortical neurons after focal cerebral ischemia, induced by permanent unilateral occlusion of the middle cerebral artery (MCA). Cortical neurons within the focal ischemic area at the territory of MCA rapidly underwent cell death, whereas within ischemic penumbra, neuronal death required a certain time period after ischemic onset. It remains, however, undefined whether death of these neurons are necrosis or apoptosis. We therefore analyzed the degenerating process of the cortical neurons within the focal area and ischemic penumbra of the cerebral cortex after focal ischemic onset. At 2 hrs after ischemic onset neurons within the focal area were already swollen, while their plasma membrane were broken into pieces and fragments of disintegrated organelles scattered within the cytoplasm. Expanded Nuclei of these neurons showed positive staining of TUNEL. On the other hand, neurons with typical necrotic swelling and those with a high electron density were detected within the ischemic penumbra 6 hrs after the onset of ischemia. The latter neurons exhibited cell shrinkage accompanied with an increase in immunoreactivity for lysosomal cysteine proteinases. Nuclei of these neurons showed positive staining of TUNEL from 1 to 3 days after ischemic onset. Degenerated neurons were heterophagocytosed by microglial cells invaded into the area. These results suggest that acute death of the cortical neurons within the focal area after the onset of ischemia by MCA occlusion is necrotic, whereas neuronal death within the ischemic penumbra consisted of necrosis and apoptosis.

Delayed Neuronal Death Following Transient Forebrain Ischemia in Rat Hippocampus: A Comprehensive Temporal Analysis
M. Guglielmo*, P. Chan, C. Doberstein, D. Demers, M. Primiano, D. Palm, N.

Knuckey, C. Johanson and M. Epstein: Dept. of Clin. Neurosci., Program in Neurosurg., Brown Univ. & RI Hospital, Providence, RI 02903

The pyramidal cells of the hippocampal CA1 region are particularly susceptible to delayed neuronal death (DND) following transient forebrain ischemia (TFI). Although detayed neuronal cearn (DND) following transfert foreorant schemia (1FI). Anthorgin necrotic cell death does occur after ischemia, evidence for a gene-regulated active process in DND has been demonstrated in rodent models of global ischemia (Kirino, et al. 1984, Heron, et al. 1993), as well as in focal ischemia (Li, et al 1995). To investigate the mechanisms of DND in CA1 following TFI, we comprehensively examined the temporal distribution of TUNEL immunostaining, neuronal ultrastructure, and DNA fragmentation.

unuas/incture, and DNA fragmentation.

TFI was induced in normothermic adult rats by bilateral carotid artery occlusion with hypotension. Animals were perfused with 10% neutral buffered formaldehyde 6, 12, 18, 24, 48, 72 hours and 7, 14, and 28 days following the induction of TFI (n=4, each time point). Paraffin 8µm sections were stained using a TUNEL staining kit (Oncor) and DAB chromagen. Similar recovery animals were used for CA1 electron microscopy and for DNA gel laddering.

microscopy and for DNA gel laddering.

Cresyl violet stains of rat hippocampus demonstrated early ischemic changes in the CA1 region by 24 h and clear evidence of cell death by 48h. Later time points confirmed extensive but selective cell loss throughout CA1 alone. Faint TUNEL staining was detected within the nuclei of CA-1 neurons as early as 12 hours following TFI. Dense staining at 48 and 72h post ischemia corresponded with the appearance of characteristic 200bp DNA fragments detected by electrophoresis at the same time points. Ultrastructural findings at these time points demonstrated chromatin condensation and nuclear indentation with relative preservation of cellular condensation and nuclear indentation with relative preservation of cellular condensation. organelles. These results suggest that ischemia-induced hippocampal neuronal death is

an active process resembling apoptosis.

APOPTOSIS AND NECROSIS FOLLOWING SPINAL CORD ISCHEMIA IN THE RAT. H. Kato^{*}, G. Kanellopoulos², M. Mackey², Y. J. Wu¹, C. Y. Hsu¹, N. T. Kouchoukos² and D. W. Choi¹, Depts. of Neurology¹ and Surgery², and Center for the Study of Nervous System Injury. Washington University School of Medicine. St. Louis, MO 63110.

We examined the nature of neuronal death induced by ischemia in the rat spinal cord. Transient (15-20 min) spinal cord ischemia was induced in male adult Long-Evans rats using a 2F Fogarty catheter, passed through the left carotid artery to occlude the aortic arch, combined with blood volume reduction. Histopathological changes were assessed between 6 hr and 7 d later.

Changes were most marked in the lumbar cord. Two major types of neuronal death were observed. The first type, prominent in intermediate grey matter, was characterized by typical acute "ischemic cell change" by 6 hr: in H&E sections, neurons became darker with pyknotic nuclei. Between 1-7 days, these cells gradually underwent acidophillic degeneration and lost nuclear staining ("ghost cells"). Diffuse nuclear TUNEL-positivity developed after 1 day. The other type of neuronal death was seen only between 1-2 days in small neurons in the dorsal horn. These neurons exhibited nuclear condensation, apoptotic bodies, and intense nuclear TUNEL staining. DNA extracted from whole lumbar cord showed a ladder pattern on gel electrophoresis. Injection of the NMDA antagonist, dextrorphan (30 mg/kg) i.p. 15 min before a 15 min period of spinal cord ischemia attenuated both types of neuronal death and resulted in improved functional outcome at 1-2 days after ischemia

Study was supported by NIH NINDS grant NS 32636 (DWC) and APA (DWC and CYH)

DELAYED NEURONAL DEATH OF THE CA1 PYRAMIDAL CELL OF THE RAT HIPPOCAMPUS FOLLOWING TRNSIENT FOREBRAIN ISCHEMIA IS APOPTOTIC. C. S. Bae, J. K. Kim¹, M. S. Suh, Y. Y. Chung, K. H. Lee and B. Y. Kim². Dept. of Anatomy and 'Pharmacology, Chonnam University Medical School, Kwangju 501-190, Korea

The CA1 pyramidal cells in the hippocampus are selectively vulnerable and undergo cell death several days after brief forebrain ischemia. It is controversial whether this delayed neuronal death is necrotic or apoptotic. To delineate the morphological characteristics of the delayed neuronal death, the structural changes of the CA1 pyramidal neurons were examined using in situ nick-end labeling and electron microscopy. Ischemia was induced for 20 min using four vessel occlusion in Sprague-Dawley rat. Nuclei of the CA1 neurons were nickend labeled by biotinylated dUTP mediated by terminal deoxytransferase 3 and 4 days after ischemic insult, but not in 1 and 2 days and not in CA2-4 sectors. Strong reaction was noted along the margin of nucleus. In electron microscopy two types of degenerating neurons in CA1 pyramidal layer were observed 2 days after ischemic insult; one type, the majority of degenerating neurons, showed increased cellular electron density, the other lost most cytoplasm. Many degenerating pyramidal neurons with dense cytoplasm showed irregular in shape and were shrunken, and contained well-developed cytoplasmic organelles such as Golgi complex and endoplasmic reticulum. Some dense cells contained dense bodies, vacuoles and fragmentary membranous organelles. Chromatin condensation was often noted along the nuclear membrane. A microglialike cell fused with various degenerating neurons. These data suggest that delayed death of the CA1 pyramidal neurons showing increased cellular density after brief ischemia is mainly apoptotic.

REVELATION OF AN APOPTOTIC COMPONENT OF NEURONAL CELL DEATH AFTER OXYGEN DEPRIVATION USING ANTINECROTIC AGENTS. J.-C. Copin, Y. Li, L.F. Reola, and P.H. Chap*. Departments of Neurosurgery and

Neurology. University of California. San Francisco CA 94143.

We have previously shown that 3-day-old mouse cortical neurons in primary culture subjected to 9 h of oxygen deprivation died by necrosis but showed some signs of apoptosis (DNA laddering and decreased of DNA degradation by cycloheximide treatment) which may indicate that necrosis masks apoptosis under these experimental conditions (Copin et al., J. Neurotrauma, in press). In order to further study this phenomenon we have treated neurons in primary culture with different pharmacological agents known to interfere with the necrotic pathway elicited by the sequence of oxygen

deprivation and reoxygenation.

In the non-treated group, 50% of the cells died 24 h after 9 h of oxygen deprivation. Inhibitors of nitric oxide synthase (L-NAME and 7-nitroindazole) and a hydroxyl radical scavenger (alpha-pheny-tert-but/nitrone, PBN) were totally ineffective to prevent this cell death; verapamil and nimodipine (L-type calcium channel blockers), alpha-tocopherol (an antioxidant involved in membrane protection) and MK-801 were partially effective; trolox (a water-soluble analog of alpha-tocopherol) and DNQX (a kainate/quisqualate-receptor antagonist) were totally effective. These two latter agents were also able to reduced free radical generation detected in the non-treated group by flow cytometry in the presence of 6-carboxy-2',7'-dichlorodihydrofluorescein diacetate. However, TUNEL staining as well as Hoechst staining revealed much more apoptotic cells in DNQX treated cells as compared to the non-treated hypoxic group. Apoptotic cells were also detected in the trolox-treated group. These results were confirmed by TUNEL staining coupled with flow cytometry. Furthermore, two days after oxygen

deprivation, 30 % of the trolox-treated neurons degenerated, though inhibition of protein synthesis dramatically prevented this post-hypoxic degeneration.

Our data indicate that DNQX and trolox treatment can prevent cell necrosis induced by oxygen deprivation and reoxygenation, and that apoptotic process can be unmask after hypoxia using neuronal protective agents. (supported by NIH grants NS14543, NS25372, AG08938)

FUNCTIONAL RELATIONSHIP OF CHANGES IN MICROTUBULE ASSOCIATED FUNCTIONAL RELATIONSHIP OF CHANGES IN MICRO I UBULE ASSOCIATED PROTEIN 2 (MAP-2) WITHIN DEDNRITES AND EXPRESSION OF PROTO-ONCOGENES BCL-2 AND BAX IN GERBIL HIPPOCAMPAL NEURONS AFTER ISCHEMIA. R.C.S. Lin*. Dept. of Neurobiology and Anatomy, Medical College of Penn. and Hahnemann Univ. Philadelphia, PA 19102

We previously reported that dendritic beading and subsequent loss of MAP-2

immunoreactivity in CA1 hippocampal pyramidal cells occurs after a 5-min ischemic insult, assessed with immunocytochemical and immunoblotting methods. In particular, a beaded MAP-2 immunostaining pattern in the apical dendrites of CA1 pyramidal neurons was noted within 1 day after ischemic insult. To further assess the cellular mechanisms and potential significance of functional changes assess the central mechanisms and potential significance or incidental critical and sometimes and somata of CA1 neurons, we compared a 5-min. ischemic insult which results in hippocampal neuronal death vs. a 2-min. insult which is sublethal to hippocampal neurons, to examine possible differences in dendritic morphology to hippocampal neurons, to examine possible differences in definition morphology using immunocytochemical techniques. We found that a 2-min, sublethal ischemic insult also induced dendritic beading of MAP-2 immunoreactivity in the apical dendrites of CA1 hippocampal pyramidal cells. However, in contrast to the 5-min insult, there was no obvious loss of MAP-2 immunoreactivity or cell loss in the hippocampus up to 7 days post-ischemia. Dendritic beading of MAP-2 was particularly obvious in CA1 pyramidal cells 3-4 days post-ischemia. Dendritic beading of MAP-2 appeared less obvious after longer survival (up to 7 days), suggesting reversibility of MAP-2 changes in dendrites after a 2-min. injury. Upregulation of bcl-2, a presumed neuronal survival marker and oncoprotein, was found in the hippocampal CA1 sector after a 2-min. ischemic insult. In addition, increased immunoreactivity of bax, a presumed programmed cell death marker and oncoprotein, was also noted in the hippocampal CA1 sector. Co-expression of beaded MAP-2 immunoreactivity in dendrites with proto-oncogenes bcl-2 and/or bax at the single cellular level in hippocampal neurons is being investigated Supported by Alzheimer Foundation to RCSL.

BAX GENE KNOCKOUT DELAYS CEREBRAL INFARCTION IN MICE SUBJECTED TO PERMANENT FOCAL ISCHEMIA. C. Du^{1*}, C.M. Knudson², R. Hu¹, X.Z. Liu¹, S. J. Korsmeyer², C.Y. Hsu¹ and Center for the Study of Nervous System Injury and Dept. of D.W. Choil. ¹Center for the Study of Nervous System Injury and Dept. of Neurology, ²Howard Hughes Medical Institute, Washington Univ. School of Medicine, St. Louis, MO 63110.

Growing evidence suggests that ischemic brain injury may in part reflect the occurrence of programmed cell death. Since programmed cell death in many systems is reduced by elimination of the bax gene, we tested the hypothesis that mice deficient for the bax gene would sustain reduced cerebral infarction after a focal ischemia

Wild type and bax-null littermates (back-crossed extensively into a C57/B6 background) were subjected to bilateral common carotid occlusion for 90 min. combined with permanent ligation of the right middle cerebral artery. After 1 day, increased Bax immunostaining was present in neurons in the ischemic cortex. Gross infarct volume at 1 day assessed by TTC staining was dramatically decreased in bax knockout animals, histological examination showed less neuronal degeneration and TUNEL staining. However, by 3 days, infarct volume in bax knockout animals was not significantly less that control

These results suggest that the bax gene system importantly influences brain cell death occurring over the first day after a permanent focal ischemic insult, but that other factors can compensate for bax gene absence in the ultimate pathogenesis of brain infarction after such insults

NUCLEAR CONDENSATION AND FRAGMENTATION FOLLOWING CEREBRAL HYPOXIA-ISCHEMIA OCCURS MORE FREQUENTLY IN IMMATURE THAN OLDER RATS. U.I. Tuor*, R. Sidhu and M.R. Del Bigio. Inst. for Biodiagnostics, NRC, R3B 1Y6 and Univ. of Manitoba, Winnipeg, Manitoba. One feature of apoptotic cell death is condensation and fragmentation of the nuclear chromatin into apoptotic bodies. Nuclei with punctate chromatin, indistinguishable light microscopically from those observed during apoptosis, were observed frequently following cerebral hypoxia-ischemia in 1 week old rats whereas they appeared less common in older animals. In the present study we investigate quantitatively the age dependence of this type of cell death

whereas they appeared less common in older animals. In the present study we investigate quantitatively the age dependence of this type of cell death.

Cerebral hypoxia-ischemia was produced in 18 rats by occluding the carotid artery under anesthesia and then exposing the animal to 8% oxygen for 2, 1 or 0.5 hr in 1,2 and 4 wk old animals, respectively. The animals were perfusion fixed with 10% buffered formalin 1-2 days after hypoxia-ischemia. Paraffin embedded sections were stained with hematoxylin and eosin and the number of pyknotic nuclei or nuclei with fragmented chromatin within damaged areas of the cerebral cortex were counted with the aid of image analysis.

There was a pronounced difference between the incidence of pyknosis or fragmented chromatin in 1 week old animals. In 1 week old animals the majority of injured neurons in the cortex had nuclei

fragmented chromatin in 1 week old compared to 2 and 4 week old animals. In 1 week old animals the majority of injured neurons in the cortex had nuclei consisting of punctate condensed chromatin whereas relatively few (18.0±2.2%) were pyknotic (663±97 vs.139±24 cells/mm², respectively; ±SEM). In the 2 and 4 week old animals the majority (73±9% and 92.9±1.8%, respectively) of the injured cells were pyknotic (p<0.002, compared to 1 week). A few scattered cells with punctate chromatin were observed in the contralateral cerebral cortex. Similar morphological differences in the appearance of the nucleus of hypoxic-ischemic cells have also been observed in human infants compared to adults. Because DNA laddering studies support an apoptotic type of cell death in 1 week old rats, we suggest that the immature brain retains a part of the cell death "program" that is reactivated following a hypoxic-ischemic insult. EFFECTS OF BCL-2 ON MITOCHONDRIAL Ca2+ UPTAKE AND PROTEOLYTIC ACTIVITY. A.N. Murphy', Vamsi Moothai, D.E. Bredesen2, and G. Fiskum. Dept. of Biochem., Geo. Washington Univ. Med. Ctr, Wash., D.C. 20037, HHMI-NIH Research Scholar, Lab. of Cardiac Energetics, NHLBI, NIH, Bethesda, MD 20892, and ²Burnham Institute, La Jolla, CA 92037

bcl-2 overexpression 1) significantly potentiates the maximal Ca2+ uptake capacity of mitochondria oxidizing NAD+linked substrates by 1.7 fold using digitonin-permeabilized GT1-7 neural cells and 3.9 fold using isolated mitochondria, and 2) inhibits Ca²⁺-induced mitochondrial respiratory inhibition. Measurements of pyridine nucleotide redox state during uptake of sequential Ca2+ pulses indicate that Bcl-2 enhances the rate of recovery of NAD(P)H following Ca2+-induced oxidation, and inhibits the persistent net oxidation associated with high Ca2+ loads in control mitochondria. In correlation, TPP + electrode-based measurement of mitochondrial membrane potential ($\Delta\Psi$) and simultaneous measurement of Ca2+ uptake indicate that a persistent complete loss of ΔΨ is associated with lower Ca2+ loads in control vs. bcl-2 overexpressors. In addition, the presence of 3 mM ATP or 20 µM cyclosporin A (an inhibitor of the mitochondrial membrane permeability transition) significantly enhances uptake and decreases, although does not eliminate, the difference (1.3 fold) in maximal uptake between control and bcl-2-expressing digitonin-permeabilized cells. Preliminary evidence also indicates that proteolytic ICE-like activity (measured using the fluorogenic substrate Z-D-E-V-D-AFC) is 2 fold higher in digitoninpermeabilized control than bcl-expressing cells, and is detectable in the mitochondrial fraction of control cells. These data implicate a role for Bcl-2enhanced resistance to loss in $\Delta\Psi$ and protease activation in protection from apoptotic death. (ONR #N00014-96-0284, NS34152)

BOTH BCL-2 AND BCL-X, PROTECT PRIMARY ASTROCYTE CULTURES FROM H₂O₂ AND SUBSTRATE DEPRIVATION INJURY, BUT NOT COMBINED OXYGEN-SUBSTRATE DEPRIVATION. R.G. Giffard, I.L. Koumenis, X. Sun, L. Xu and M.C. Papadopoulos. Dept. of Anesthesia, Stanford University, Stanford,

Retroviral vectors were used to overexpress bcl-2, bcl- $x_{\rm L}$, or β -galactosidase in primary astrocyte cultures. More than 95% of the cells in the cultures expressed the gene of interest, as determined by immunocytochemistry. Cells were subjected to injury by exposure to hydrogen peroxide, substrate deprivation or combined oxygen substrate deprivation (OSD). Injury was assessed morphologically and quantitated by release of lactate dehydrogenase. Both bcl-2 and bcl-x_L reduced 200-400 µM hydrogen peroxide injury by 40-50%, and 24 h substrate deprivation injury 40-50%. Neither was able to provide significant protection from OSD. In an attempt to define why these genes are protective in oxidative stress injuries, we measured antioxidant enzymes. Both bcl-2 and bcl- $\chi_{\rm L}$ led to higher superoxide dismutase activity, bcl-2 increased glutathione peroxidase 40% compared to uninfected controls, while catalase was unchanged with either. Glutathione levels were increased 35% over β-gal controls by bcl-2. The level of lipid peroxidation measured with cis-parinaric acid was less in bcl-2 overexpressing cells subjected to substrate deprivation than control cells. Bcl-2 overexpression appears to increase antioxidant defenses and protects against hydrogen peroxide and substrate deprivation but not combined oxygen substrate deprivation.

NEUROPROTECTION OFFERED BY OVEREXPRESSION OF BCL-2 IS DEPENDENT ON THE DURATION OF REPERFUSION. N.Panahian* M.Halterman¹ 2, H.Gelbard³, H.J.James³, D.Howard¹ 2, H.Federoff¹ 2, Division of Molecular Medicine&Gene Therapy, Dept. of Neurology¹, Dept. of Microbiology and Immunology³, and Pediatric Neurology³ Univ. of Rochester School of Medicine, Rochester. NY 14642.

In the ischemic cascade leading to programmed cell death, protooncogene bcl-2 blocks apoptosis at its distal step. This study examines the role of postischemic reperfusion and its duration on the outcome of neuroprotection offered by cortical bcl-2 overexpression. Five hr prior to induction of ischemia, 2 µl of viral suspension containing 105 infectious particles of either HSVlac or HSVbcl2 was stereotaxically injected into the border zone distribution of the ischemic penumbra. Focal ischemia was induced for 1 hr under halothane anesthesia (filament model) followed by either 23 or 30 hrs of reperfusion. Consecutive sections were stained with H&E, internucleosomal DNA fragmentation (ONCOR) and for presense of antigen expression (PGP polyclonal AB against bel-2; Krajewski et al.). HSVbcl2 treated rats sacrificed at 24 hr showed less ischemic changes (p<.01) as well as reduced cerebral edema (p<0.05) in the cortex compared to HSVbcl2 treated rats sacrificed at 31 hr [(26.7+/-14% (n=6) vs 65.3+/-7% (n=4)]. No significant neuroprotection was observed in both HSVlac treated groups sacrificed at the same time intervals. HSVlac and HSVbcl2 treated groups failed to show any statistical difference in the cumulative behavioral score and stroke volume. It was not possible to salvage the neurons of the caudate (ischemic core) in any of the treated animals. Ongoing studies are needed for evaluation of extent of TUNEL labeling of HSVbcl2 and HSVLac injected animals to determine whether regional neuroprotection was achieved. TRANSGENIC MICE DEFICIENT IN THE p53 PROTEIN ARE RESISTANT TO TRANSIENT RETINAL ISCHEMIA. <u>D. R. Rosenbaum*</u>, <u>P. S. Rosenbaum, A. Aggarwal and J. A. Kessler</u>. Albert Einstein College of Medicine, Bronx, NY 10461.

There is mounting evidence that apoptosis plays an important role in the delayed cell death that occurs following transient ischemia. Furthermore, the p53 protein is an important factor that leads to cell death in circumstances where apoptotic cell death occurs. The purpose of this study was to determine if transgenic mice that have attenuated expression of p53 are resistant to transient retinal ischemia. We have previously demonstrated that cell death in this model is in part secondary to apoptosis. Wild type and two groups of transgenic mice, one homozygous and the other heterozygous for a p53 null gene were subjected to transient retinal ischemia by raising IOP to greater than systemic pressure for 60 minutes. Seven days later the eyes were examined histologically. In addition, electrophysiologic (ERG) studies were performed at baseline and at 7 days post reperfusion. There was preservation of the retinal histoarchitecture as determined histopathologically in both groups of transgenic mice as compared to wild type controls. There was also preservation of the ERG b-wave in the transgenic groups as well. These data further support the hypothesis that the delayed cell death that occurs following transient retinal ischemia is in part apoptotic and that p53 plays a significant role in this process.

OCCURRENCE OF NEURONAL NECROSIS AND APOPTOSIS FOLLOWING THE RETINAL ISCHEMIA: INDUCTION OF p53 AND bel-2 mRNA C.K. Joo'* K.-Y. Park', M.S. Park', B.J. Gwag', and M.H. Choun', 'Depts. of Opthalmology and Anatomy, Catholic Univ. School of Medicine, Seoul 137-040, Korea: 'Dept. of Pharmacology, Ajou Univ. School of Medicine, Suwon 44 I-749, Korea.

School of Medicine, Suwon 441-749, Korea.

We investigated patterns and molecular events of neuronal degeneration following ischemic injury in retina. Elevation of intraocular pressure(IOP) to 160-180 mmHg for 90 minutes produced a widespread neuronal degeneration over 1 - 5d. Interneurons in the inner nuclear layer appeared to undergo the initial degeneration over 1 - 3d. Retinal ganglion cells slowly degenerated over 5d following the ischemia. The electron microscopy study revealed concurrent induction of neuronal necrosis (characterized by dispersed chromatin condensation and mitochondria swelling) and apoptosis (characterized by chromatin aggregation and condensation).

aggregation and condensation).

To study whether cell death or survival genes are involved in the process of neuronal degeneration (e.g. apoptosis), expression pattern of p53, interleukin-1 beta converting enzyme(ICE), or bcl-2 mRNA was analyzed using a reverse transcriptase-polymerase chain reaction(RT-PCR). Levels of p53 mRNA were not changed 4 hrs after initial injury, and gradually elevated during 24-72 hrs. The mRNA expression of ICE remained constant through 3 d following the ischemia. Expression of bcl-2 mRNA was increased in 24 hrs and returned to the control level in 72 hrs. Levels of actin mRNA were not changed through the degeneration process. The present study suggests that retinal ischemia induces neuronal necrosis and apoptosis through mechanisms involving upregulation of p53 and Bcl-2 mRNA. Supported by Biotech.

ISCHEMIC CA₁ HIPPOCAMPAL NEURONS EXPRESS bax AND CAN BE RESCUED BY bcl-2 INDUCTION WITH A HERPES SIMPLEX VIRUS (HSV) AMPLICON. F.J. Antonawich*, H.J. Federoff*, S. Krajewski², J.C. Reed² and J.N. Davis. SUNY at Stony Brook, Stony Brook, NY 11794, ¹University of Rochester, Rochester, NY 14627, ²LaJolla Cancer Research Center, LaJolla, CA 92037.

5 min. of bilateral common carotid artery occlusion in the Mongolian gerbil results in a selective, delayed death of CA_1 pyramidal neurons. bcl-2 appears to protect a variety of cells from cell death in vitro. We used Western blots to estimate levels of bcl-2, bax, and bcl-x at 6 and 72 hr after carotid occlusion. Bcl-2 and bcl-x remained the same following transient ischemia, however, bax levels dramatically increased at 6 hr of ischemia compared to sham operated animals. At 72 hr bax levels were still elevated but were less than at 6 hr.

500 nl of an HSV amplicon encoding human bcl-2 was injected into the CA₁ region 24 hr before carotid occlusion and the animals sacrificed 72 hr after occlusion. Immunohistochemistry demonstrated both glial and neuronal bcl-2 expression around the injection site with apparent rescue of neurons demonstrating bcl-2 immunoreactivity. By contrast, silver degeneration stains demonstrated ischemic cell death in areas remote from the site. Neurons in the inunediate center of the injection site also showed cell death. This cytopathic effect may be due to either cell debris or helper virus in the amplicon preparations. These experiments suggest that 1) bax overexpression may be important in ischemic cell death and 2) bcl-2 overexpression can prevent ischemic cell death $in\ vivo$. (Supported by NS 30559 from the NIH and the VA)

464.14

DELAYED NEURONAL DEATH IN POST-ISCHEMIC RAT HIPPOCAMPUS IS NOT ASSOCIATED WITH TRANSCRIPTION OR TRANSLATION OF THE APOPTOTIC GENES p53 AND INTERLEUKIN CONVERTING ENZYME-I(ICE) LTorres-Munoz ', B.Roberts', C.Wood', T.S.Nowak,Jr. ', W.A. Pulsinelli ', C.K. Petito '*, 'Dept. of Path., Univ. of Miami Sch. of Med., Miami, FL, 33101 and 'Dept. Of Neurology, Univ. of Tennessee College of Medicine, Memphis, TN 38163.

Mechanisms of neuronal death following cerebral ischemia are controversial since morphology studies, and recent TUNEL studies in our laboratory, indicate that these cells die by necrosis yet gel electrophoresis of extracted DNA shows the characteristic ladders of the oligonucleosomes of apoptosis. To more fully evaluate cell death following ischemia, we looked at two apoptotic modulators, p53 and ICE. The p53 transcription factor encodes a protein that has been implicated in programmed cell death or apoptosis (Selter H and Montenarh M, Int J Biochem 1994; 26:154). ICE encodes a putative cysteine protease and induces apoptosis when overexpressed in cultured cells (Kumar et al., Gene Dev 1994; 8:1613). Adult Wistar rats were subjected to 10 min of global ischemia and sacrificed after 1,2,3,5,7, and 14 days. Paraffin embedded sections were examined by in situ endlabeling by the TUNEL procedure; wt p53 and ICE proteins and mRNA by immunohistochemistry, in situ hybridization and northern blot. Results showed necrosis of CA1 neurons between 2 and 3 d. after ischemia with TUNEL-positive cells appearing with, but not preceding, necrosis. Neither p53 nor ICE protein and message were present in the CA1 neurons. Apoptotic bodies, that were TUNEL positive and ICE immunoreactive, were rare and co-localized with oligodendrocyte or microglial-specific markers as previously described (Petito et al., J Neuropath Exp Neurol, in press). These results show that post-ischemic death in CA1 hippocampal neurons is not regulated by p53 or ICE. Rather, they support those studies that indicate that neuronal cell death after global ischemia is mediated by non-apoptotic mechanisms. Supported in part by RO1-NS27416-08, CKP.

INVOLVEMENT OF INTERLEUKIN CONVERTING ENZYME AND ITS FAMILY PROTEASE IN THE CELL DEATH FOLLOWING TRANSIENT GLOBAL ISCHEMIA. T. Himi*, Y. Ishizaki, H. Wakisaka, M. Ikeda and S. Murota. Department of Physiological Chemistry, Graduate School, Tokyo Medical and Dental University, 15-45 Yushima, Bunkyo-ku, Tokyo 113, JAPAN. Recent evidence suggest that interleukin converting enzyme (ICE) and its family protease have a key role for apoptosis to occur in wide variety of cell types. In order to know the molecular mechanism of delayed neuronal death following transient global ischemia, we have investigated the involvement of ICE family protease.

Nine-week-old gerbils were subjected to 10 min of bilateral common carotid artery occlusion followed by reperfusion. Western blot analysis showed cleaved fragment (85 kDa) of poly(ADP-ribose) polymerase in hippocampus in post-ischemic day 4, but not in day 8. Immediate post-ischemic administration of ICE inhibitor, benzyloxycarbonyl-Asp-fluoromethylketone (zD, 25 nmol i.c.v.; 3 times at intervals of 12 hr), significantly ameliorated the number of TUNEL-stained neurons (90 %, day 4) and decrease in the number of CA1 pyramidal cells (80 %, day 8). Ultrastructural study showed these protected neurons sustained normal morphology (day 8). This neuroprotective effect of zD was, however, not observed when administration was started 24 hr after the ischemic insult. In both cases, the number of hypertrophic astrocytes expressing glial fibrillary acidic protein markedly increased in the hippocampal CA1 region (day 8). These findings indicate that ICE family protease plays important roles in early stage of delayed neuronal death following transient global ischemia and that delayed neuronal death can be suppressed by blocking ICE family protease. (Work supported by Research Grant for Young Scientists from the Ministry of Education, Science and Culture of Japan and by Japan Foundation for Health Sciences)

APOPTOSIS AFTER ISCHEMIA AND REPERFUSION IN RAT BRAIN: ROLE OF INTERLEUKIN 1-BETA CLEAVAGE ENZYME (ICE). L. Denner* C. Munsch, C. Kagan, L. Sturgis and R. Tilton. Dept. of Cell Biology, Texas Biotechnology Corporation, Houston, TX 77030

Reversible occlusion of the middle cerebral artery in the rat brain is an established model of stroke in man. Following transient ischemia in the rat, subsequent reperfusion results in the development of an infarct containing cells that eventually die by necrosis and/or apoptosis. One feature of apoptotic death is fragmentation of DNA which can be detected by TUNEL. Using the rat model we showed by TTC staining that 1 hr of ischemia and 4 hr of reperfusion induced a substantial infarct along the rostral-caudal axis that was also positive for TUNEL. Since the ICE family of proteases plays an important, potentially requisite, role in apoptotic death, RT-PCR was used to investigate ICE family member gene expression in apoptosis induced by ischemia/reperfusion. With primers to the known rat sequence, rat ICE mRNA was detected in control neocortex and in neocortex exposed to 1 hr of ischemia followed by reperfusion for 2 hr, 4 hr, 1 day, 2 days or 3 days. Under these same conditions, degenerate primers to the conserved pentapeptide sequence (QACRG) in the ICE family were used with specific primers to the known human sequences. In normal and stroke brains, rat mRNA was detected for Mch2a and Ich1-L but not apopain, TX or Ich1-S. Western blotting indicated that ICE protein was expressed in control brains as well as brains from the various times of reperfusion. ICE catalytic activity was demonstrated by cleavage of the natural substrate, the 33 kDa proIL1-beta precursor, to the 17 kDa mature, active IL1-beta. Catalytic activity was also shown in a fluorogenic assay using a peptide containing the cleavage site in proIL1-beta. These results suggest that ischemia and reperfusion lead to rapid and extensive development of apoptosis which may be mediated by ICE.

DOWNSTREAM TARGETS OF NF-kB ARE INDUCED FOLLOWING TRANSIENT GLOBAL FOREBRAIN ISCHEMIA. E. P. Dixon, D. Stephenson, J. Clemens*, S. P. Little. CNS/Molecular Biology Division, Eli Lilly and

Company, Indianapolis, IN 46285 Ischemic injury initiates a vast array of events including the generation of

Ischemic injury initiates a vast array of events including the generation of free radicals. We have previously reported in a rat model of transient forebrain global occlusion that activation of NF-kB occurs in areas of ischemic damage. Events following NF-kB activation ultimately determine whether cells will undergo necrosis or programmed cell death (apoptosis).

We report the induction of Cu/Zn superoxide dismutase (SOD) protein following 20 minutes of 4-vessel global occlusion in brain regions where ischemic damage and activated NF-kB is apparent. SOD was induced in a time-dependent fashion, with maximal induction occurring at 72 hours post inchamic SOD levels then returned back to base levels at 120 hours post ischemia. SOD levels then returned back to basal levels at 120 hours post ischemia. This increase in SOD may act as an elaborate defense system in neuronal cells to detoxify and protect O₂ or free radical formation during anoxia and reperfusion damage.

We previously reported that typical DNA fragmentation during apoptosis occurs in conjunction with activation of NF-kB in ischemic damaged cells from the CA1 hippocampal region. Sinced apoptosis is tightly regulated by several redox-sensitive transcription factors, we looked at the expression of Bc1-X. Bc1-X has two splice variants and is known for its regulation of apoptosis. In damaged CA1 regions of our ischemic rat model, dramatic increases in Bc1- X_S protein expression occurred at 72 hours post ischemia. The observed increase in Bc1-X_S supports the idea that neurons in the CA1 hippocampal subsector die by the process of apoptosis

In conclusion, since both the pro-apoptotic gene Bc1-X_S and the neuroprotective gene SOD contain elements in their promotors that are responsive to active NF-kB, it is difficult to clearly define the role of NF-kB in ischemic neuronal damage at this time.

RECOVERY OF FUNCTION AFTER TRAUMATIC BRAIN INJURY (TBI): IS ULTIMATE RECOVERY DEPENDENT UPON TESTING FREQUENCY? J.S. Soblosky*, L.L. Colgin, D.A. Chorney, June F. Davidson, and M.E. Carey., Neurotrauma Res. Lab., Dept. Neurosurgery, LSU Medical Cntr., New Orleans, LA 70112
We have developed an animal model of TBI in which the hind- and forelimb sensorimotor cortices are injured

unilaterally in anesthetized rats by a piston impact depressing the dura 1mm @ 5 m/sec. A battery of tests previously indicated that motor recovery occurs in 28-35 days. Two important questions are: 1) whether the recovery rate is dependent on testing frequency and 2) whether the recovery is test specific. To help answer these questions we injured 2 groups of rats. The first group was tested using our usual tests and testing over 35 days. The second group was left undisturbed for 35 days prior to the start of testing. The results of 3 motor tests (narrow flat beam, pegged beam and paw preference) indicated that rats which were not tested until 35 days after TBI showed the same amount of recovery at the beginning of testing that the first group of rats showed at the end of 35 days of frequent testing. These results suggest that the ultimate motor recovery or behavioral adaptation is not dependent upon the frequency of testing and that a general neuronal plasticity occurred over 35 days which did not require test-specific experience. Supported by U.S. Army contract DAMD17-93-C-3008

ADENOVIRUS-MEDIATED NAIP OVEREXPRESSION CONFERS PROTECTION AGAINST GLOBAL ISCHEMIA. S.J. Crocker, D.G. Xu, A.M. Hakim, J.-E. Ikeda, N. Roy, R.G. Korneluk, A. MacKenzie, and G.S. Robertson. Department of Pharmacology, Neuroscience Research Institute, University of Ottawa, Ottawa, Canada K1H 8M5, The Institute of Medical Science³, Tokai University, Kanagawa 259-11, Japan, Molecular Genetics Laboratory⁴, Children's Hospital of Eastern Ontario, Ottawa, Canada K1H 8L1.

We have demonstrated that motor neuron death in spinal muscular atrophy is associated with deletions of a gene which encodes the neuronal apoptosis inhibitory protein (NAIP). More recently we have shown that transient global ischemia selectively increases NAIP levels in neuronal populations which are resistant to the damaging effects of this treatment (Robertson et al. abstract). This observation suggests that resistance to ischemic injury may be conferred by elevated NAIP expression. Consequently, we investigated whether NAIP overexpression would protect CAI hippocampal neurons from delayed neuronal death following transient global ischemia. Recombinant adenoviral constructs (Ad5d1xDNA-TPC) containing either myc-tagged NAIP (3 μ1; 1 X 106 particles μ l⁻¹) or *lacZ* (3 μ l; 1 X 10⁶ particles μ l⁻¹) were stereotaxically injected into the right and left dorsal hippocampus, respectively. Seven days later, all animals were subjected to 10 min of four-vessel occlusion (4-VO). Animals were perfused with 4% paraformaldehyde 5 days following recirculation. Tissue sections from the hippocampus were processed for immunohistochemical detection of NAIP-, Myc-, β -gal- and the neuron specific marker, NeuN. Cell counts of NeuN immunoreactivity revealed that the NAIP construct significantly attenuated the loss of hippocampal CA1 neuron after 4-VO. These results suggest that manipulations which elevate NAIP expression may be useful in the treatment of stoke

SCOPOLAMINE BLUNTS BRAIN LACTATE ACCUMULATION AND THE ACTIVATION OF THE PIP₂ SIGNAL TRANSDUCTION PATHWAY AFTER TRAUMATIC BRAIN INJURY. Q-Z. Gong* B.G. Lyeth, H.S. Dhillon and M.R. Prasad. Divisions of Neurosurgery, Medical College of Virginia, Richmond, VA

and University of Kentucky, Lexington, KY.
Hippocampal levels of lactate, free fatty acids (FFA), and fatty acids (FA) extracted from phosphatidylinositol 4,5-bisphosphate (PIP_2) were measured after central fluid percussion traumatic brain injury (TBI) in rats. Anesthetized rats were frozen in situ with liquid nitrogen at 5 or 20 min after injury. Hippocampi decreased in PIP₂ (by 11% & 19% respectively) while these same acids were dissected and fatty acids extracted and separated from PIP₂ and FFA. Lactate in the suspension was measured with a spectrophotometer. At 5 min after injury, levels of steanc and arachidonic acid fractions were significantly increased in the FFA fraction by 180% & 143% respectively. These alterations were blunted (not significantly different from control) by pre-injury administration of the muscarinic antagonist, scopolamine (1.0 mg/kg i.p.). No significant changes were observed in FA at the 20 min time point in saline-treated TBI rats. Lactate was increased by 232% at 5 min and 165% at 20 min in saline treated rats. In scopolamine-treated rats, lactate increased by only 86% at 5 min and 74% at 20 min. These results suggest that the PIP₂ signal transduction pathway is rapidly activated in the hippocampus after TBI and that the enhanced phospholipase C-catalyzed phosphodiestric breakdown of PIP₂ is a mechanism of liberation of FFA after TBI. The blunting of PIP₂ and FFA afterations in animals treated with scopolamine suggests that activation of muscarinic receptors significantly contributes to the phospholipase C signal transduction pathophysiology in TBI. The reduction in lactate by scopolamine suggests that muscarinic activation also contributes to increased glycolytic metabolism and/or ionic imbalances. EXPRESSION OF CHEMOKINES AND NITRIC OXIDE SYNTHASE-2 FOLLOWING CEREBRAL TRAUMA.

D. Grzybicki*, A. Loihl, Moore, A.R. Glabinski, R.M. Ransohoff and S. Murphy. Depts. Pathology and Pharmacology, Univ. of Iowa College of Medicine, Iowa City, IA 52242, and Dept. Neuroscience, Cleveland Clinic Foundation, Cleveland, OH 44195.

Traumatic injury to the brain initiates multiple interrelated processes (angiogenesis and reactive gliosis) involving resident parenchymal and vascular cells and also infiltrating inflammatory cells. Nitric oxide (NO) and chemokines have been implicated as regulators of the CNS injury response. Following a cryogenic lesion of the cerebral cortex in mice, mRNA for regulators of the cerebral cortex in mice, mRNA for NO synthase (NOS)-2 was detected by RT-PCR ipsilaterally 12 h after injury and persisted for two weeks. While mRNA was also detected contralaterally the time course was shorter (one week). By immunocytochemistry, NOS-2 was seen ipsilaterally in infiltrating macrophages and in glial cells in both hemispheres at 72 h. The expression of monocyte chemoattractant protein (MCP-1) preceded NOS-2. On the lesion side MCP-1 peaked at 6h, was sustained to 24h and had declined by 48h. On the unlesioned side MCP-1 was expressed to a lesser extent (50%) and declined by 24h. MCP-1 has been shown to block the inudction of NOS-2. The expression of NOS-2 in glia could be initiated either by signals from infiltrating cells or by declining MCP-1 levels.

DESCENDING SPINAL CORD EVOKED POTENTIALS EVOKED BY STIMU-LATION AT ACUPOINT. Qing-Yin Zheng, Zhen-Feng Cheng, Lu Guo-Wei, S.S. Haghighi*. Capital University of Medicine, Beijing P.R. China, Dept. of Neurology, & MCPHU, Dept. of Neurosurg. Phila., PA.

Segmental cord potential (Y-sSCEP) evoked by stimulation at the Y acupoint (the center of posterior paw) of Sprague-Dawley rats vanished gradually when the recording electrode was placed more rostrally, for example at C6, another positive slow potential Y-dSCEP could be recorded. Y-dSCEP disappeared completely when the spinal cord had been sectioned at a higher cervical level. Electrolytic lesions of ventral periaqueductal gray (PAG) could also decrease remarkably the amplitude of Y-dSCEP induced by stimulation at the Y acupoint. Similarly, another descending SCEP, NdSCEP could be induced from L3 by stimulation at the N acupoint (2/3 down the anterior limb). It also proved to originate from supraspinal structures. Acupoint stimulation induced dSCEPs had properties of spatial and temporal summation. Local administration of picrotoxin (specific antagonist of presynaptic inhibition) could significantly attenuate the P wave of the dSCEP. These results suggest that the P wave of the dSCEP. These results suggest that the P wave of the dSCEP is the reflection of the primary afferents by activating brainstem strucures.

KDN--A NEW DRUG FOR TRAUMA AND VASCULAR DISEASE OF NERVOUS SYSTEM. Lu Shoulong, Liu Xin, Wang Jianlong and Ying qi Department of Neurosurgery No. 411 Naval Hospital. Shanghai, 200081. China

The authors developed a new drug (KDN) which was prepared from medicinal herbs. It's main indications are: (1) convalescence of various kinds of brain trauma; (2) recovry of cerebrovascular diseases; and (3) encephalatrophy. Animal experiments (with Mongolian rats) showed that KDN could increase the toleratace for hypoxia and ischemia (p<0.01). It has been applied clinically in 5,000 patients with a total effective rate of 96% . The $\mbox{ drug }$ was $\mbox{ taken}$ twice daily, with 10ml each time. One course of treatment was 30 days. Usually, 1 to 2 courses were needed.CT, TCD and r-CBF examinations were made in part of the patients before and after taking the medicine and the results were compared. No toxicity and side effect of this drug were found.

Immunocytochemistry of tumor necrosis factor in spinal cord following a weight-drop injury in rat. CX Wang* and JR Wrathall. Department of Cell Biology, Georgetown University, Washington DC 20007, USA

Previously, we have demonstrated that tumor necrosis factor alpha (TNF) is produced in spinal cord following a static load injury (Wang et al., Eur. Cyt. Net. 5:208, 1994). In the current study, we investigated the presence of TNF in the spinal cord after a standardized weight-drop (10g X 2.5cm) injury at T8 (Wrathall et al., Exp. Neurol. 88:108-122, 1985). The spinal cord at the lesion site was removed for immunocytochemistry at 1, 8, 24 and 72 h after the injury and was also collected from uninjured controls (n=3 per group). TNF staining was absent in the spinal cord from the controls, but was present in all samples of the injured spinal cords. The number of TNF positive cells appeared to increase between 1 and 8 h, and remained at this level through 72 h after the injury. Most of the TNF staining was in the lesion site and in the gray matter adjacent to it. Moreover, the number of TNF positive cells appeared greater at the border of the lesion than in the center. Many neurons in the preserved gray matter adjacent to the lesion site developed cytoplasmic staining for TNF after the injury. In addition, TNF staining was also observed in swollen axon terminals at the edge of the lesion site. Double labeling studies showed macrophages and endothelial cells were not TNF positive. In summary, TNF is present in the spinal cord by 1 h after the injury, and cells stained positively for TNF meet the morphological criteria of neurons. These data indicate TNF production is an acute reaction and may play a role in the death of neurons and degeneration of axons in the injured spinal cord. (Supported by PVA No:1451-01)

LEFT BUT NOT RIGHT DORSAL NORADRENERGIC BUNDLE (DNB) LESIONS IMPAIR MOTOR RECOVERY AFTER RIGHT SENSORIMOTOR CORTEX (SMCTX) INJURY IN THE RAT. L.B.Goldstein*, S. Bullman. Durham V.A. & Duke Univ., Durham, NC 27705

The ability of rats to traverse a narr : w elevated beam has been used to quantitate recovery of hindlimb motor ft. nction after unilateral SMCTX injury. A left but not right locus coeruleus(LC) lesion 2 weeks prior to a right SMCTX lesion impairs beam-walking (BW) recovery (Goldstein et al., 1993). We now compared the effects of left and right DNB lesions. Rats underwent either left (LDNB), right (RDNB) or sham (SDNB) 6-OHDA lesions and one week later were trained at the BW task. Two weeks after DNB surgery, rats underwent right SMCTX suction-ablation (CORLES) or sham cortex surgery. BW was measured over the next 12days. Rats were sacrificed and the extent of the cortex lesion, norepinephrine (NE) levels in cerebral and cerebellar hemispheres, and LC cell counts were measured. DNB lesions did not affect BW training or BW after sham SMCTX lesions. CORLES rats with prior LDNB lesions (n=7) had impaired BW recoveries compared to CORLES rats with prior SDNB lesions (n=8) (ANOVA F 3,16 = 11.6, p<0.003; Fisher LSD, p<0.02). In contrast, the recoveries of CORLES rats with prior RDNB lesions (n=7) did not differ from CORLES rats with prior SDNB lesions (n=7) (Fisher LSD, p=0.81). There were no differences between the groups in the extents of cortex lesions or in LC cell counts. DNB lesions resulted in significant decreases in NE levels in the ipsilateral cerebral cortex, but not in the contralateral cerebral cortex or either cerebellar hemisphere. These data show that NE mediates motor recovery after SMCTX lesions, at least in part, through effects in the contralateral, but not ipsilateral cerebral cortex

HYPOXIA DELAYS RECOVERY OF FOOD INTAKE AND WHEEL RUNNING AFTER FLUID PERCUSSION INJURY R. Bauman*, J. Widholm, J. Dave, and J. Long. Div. of Neurosci., Walter Reed Army Inst. of Research, Washington, D.C. 20307

The purpose of the present study was twofold: (1) to characterize behavioral deficits resulting from lateral fluid percussion injury (FPI) using measures of activity and ingestion, and (2) to evaluate whether these functional deficits would be intensified by post-traumatic hypoxia (PTH). All rats were exposed to a 12 hour light: dark cycle and were housed in individual feeding cages that were attached to standard running wheels. The wheel was freely available and within each feeding cage, the only available food was delivered for leverpressing; 5 leverpresses were required for the delivery of a single 45 mg food pellet. After food intake and wheel running stabilized, rats were surgically prepared. Five days later, in the early hours of the light period, they were anesthetized with halothane and subjected to either parasagittal FPI (4.5±0.1 atm, 20 msec duration) or sham injury (SI). For 30 min after injury, a gas mixture containing 13% O2 and halothane was used to induce hypoxia in half the FPI and SI rats; in normoxic rats, halothane anesthesia was maintained with a 100% O2 source. Recovery of wheel running and food intake was monitored during light and dark periods for one week after FPI or SI. On the day of injury, mean food intakes in the dark, but not the light, for both hypoxic and normoxic FPI groups were reduced below both SI group means, which were themselves not significantly different. Neither mean intakes nor wheel turns of the hypoxic or normoxic FPI rats differed significantly in the dark on the day of injury. However, on the second and third recovery days, mean intakes and mean wheel turns in the dark were significantly less for the FPI hypoxic rats than for the SI normoxic rats. Neither intake nor turns were significantly reduced by either FPI or hypoxia alone on these recovery days. Therefore, hypoxia delayed recovery from FPI. These results indicate that PTH is an important pathophysiological factor influencing recovery from

CEREBRAL EFFLUX OF INTERLEUKIN-18 IN CHILDREN WITH TRAUMATIC AND ANOXIC BRAIN INJURY, AA Pinto, JW Kuluz, CL Schleien*, Pediatric Crit Care Med, Univ of Miami Sch of Med, Miami, FL 33101

Introduction: IL-1B is produced in the brain in response to ischemia, trauma and infection and has been shown to worsen ischemic brain damage. Several studies have shown that the brain concentration of IL-1B increases after these insults, however, the net flux of IL-1B across the blood brain barrier (BBB) has not been documented. In this study, we measure the flux of IL-1B accross the brain in children with severe traumatic and anoxic brain injury.

Methods: Global CBF was measured (N₂O, Kety - Schmidt) in children with severe traumatic (n=4) and anoxic (n=4) brain injury within 24 hr of admission and again daily. Jugular (JV) and arterial (Art) blood samples were drawn within the first 24 hr of admission and then daily. Blood samples were centrifuged, plasma stored at -20°C and Il-1 β measured by ELISA (Genzyme). Cerebral efflux of Il-1 β was calculated by CBF x JV-Art [IL-1 β]. Values are mean \pm SEM.

Results: IL- 1β JV was greater than Art in 12 of 14 time points in the first 48 hours and in only 5 of 12 time points after 48 hr. Over the first day, efflux tended to be greater in the trauma group, with decreasing levels between 24-48 hr in that group. IL- 1β efflux approached zero after 48 hr in both groups.

	0-24h	24-48h	>48h
Trauma	621 <u>+</u> 444	403 <u>+</u> 391	63 <u>+</u> 180
Anoxia	359 + 253	483 + 256	47 + 99

Conclusion: Il-1B efflux from brain to blood occurs in children during the first 48 h after severe brain injury. Possible explanations for this efflux include transport of IL-1 across a disrupted BBa swell as increased intraluminal production of IL-1 by endothelium or leukocytes. The peak efflux occurs sooner after trauma then after anoxia which may be due to the usual delay in BBB disruption after anoxia.

MECHANISM AND PREVENTION OF LETHAL COLD STRESS TO SPINAL CORD (SC) NEURONS. <u>G. Craenen*, S. Jeftinija[@], I. Grants, and J.H. Lucas</u>. Dept. of Physiol.. The Ohio State Univ., Columbus. OH 43210; [@]Dept. of Veterinary Anat., Iowa State Univ., Ames. IA 50011.

Hypothermia has been found to be beneficial in CNS trauma. The parameters for treatment by cooling are still being defined. We previously reported that posttraumatic cooling to 17°C for 2h increased survival of mouse SC neurons subjected to physical (dendrite transection) injury, but that cooling below 17°C caused a lethal NMDA receptor-linked stress to both lesioned and uninjured neurons (J. Neurotrauma 11: 35, 1994).

The present study tested whether cooling below 17°C increases extracellular levels of excitatory amino acids. SC cultures were placed at 10°C or 37°C . HPLC showed that Glu and Asp levels were much higher in the medium of the cooled cultures after 0.5 h $(23 \pm 4 \text{ nM/µg vs } 4 \pm 1 \text{ nM/µg vs } 1 \pm 0 \text{ nM/µg respectively})$. The concentration of each amino acid then declined and reached a plateau at 1-4h that was still several fold higher than control levels (3 cultures/group; p<.0001, two-factor ANOVA). Other amino acids (Gly, Asn, Ser, Gln) showed an opposite pattern with higher levels in the 37°C group.

Both NMDA and non-NMDA antagonists prevented lethal cold injury. Death (tested by erythrosin B) of SC neurons cooled at 10°C for 2h and rewarmed for 22h was 32 ± 10% in the control group, 6 ± 5% with a non-NMDA receptor blocker (50 μM CNQX), 3 ± 5% with a NMDA receptor blocker (100 μM D-APV), and 1 ± 2% with CNQX + D-APV (each group = >120 neurons in 5 cultures; p < .0006, one-factor ANOVA). These results show that death of SC neurons by cooling below 17°C is caused by elevated extracellular Glu and Asp and requires activation of both NMDA and non-NMDA receptors. MODE OF SPINAL MOTONEURON DEATH FOLLOWING INJURY IN ADULT MICE: AN EM STUDY L. Li⁺, L.J. Houenou⁺, W. Wu⁺, M. Lei⁺, D.M. Prevette[†] and R.W. Oppenheim[†] Neurobiology & Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC 27157, ²Neurosurgery, Eastern Virginia Medical School, Norfolk, VA 23501.

Experimental lesions have been widely used to induce neuronal degeneration and to test the ability of trophic molecules to prevent lesion-induced alterations. However, the morphological mechanisms of spinal motoneuron death (i.e., apoptosis or necrosis) following different lesion modes is not clear at the present time. At the light microscopic level, we have found that spinal motoneurons are atrophied following sciatic nerve axotomy in neonatal mouse. By contrast, motoneurons in adult mouse increase in size following spinal root avulsion. The objective of this study is to characterize injury-induced cell death using electron microscopy (EM).

Our results show that one day following spinal root avulsion, motoneuron size and morphology on the lesion side was similar to that of control, untreated animals except for some apparent cytoplasmic condensation. From 3 days to 2 weeks after the root avulsion, the motoneurons on the lesion side increased in size and the cytoplasm became hyperchromatic, the nuclear envelope was indistinct, and the nucleoli and nuclei were condensed and irregular. The cytoplasm contained fragmented organelles and numerous small granular profiles. Mitochondria were absent, and the cell membrane was disrupted indicating, that the injured neurons were not viable. In addition, the motoneurons on the lesion side appear to have lost contact with adjacent glial cells and neurons. Collectively, these observations indicate that adult mouse motoneurons die by necrosis following injury by root avulsion. We are also examining the mode of cell death in the neonatal mouse following axotomy as contact will be made for the two lesion modes (i.e., distal axonal axotomy so root avulsion) in mice. In addition, studies are in progress to examine whether DNA fragmentation detected by the TUNEL method occurs in these injury models. Supported by MDA and NIH.

INHIBITION OF NEURAL NETWORK ACTIVITY WITH GAMMA-AMINOBUTYRIC ACID (GABA) DOES NOT INCREASE SURVIVAL OF SPINAL CORD (SC) NEURONS SUBJECTED TO PHYSICAL (MEMBRANE DISRUPTION) INJURY. J.H. Lucas* and G.W. Gross. *Dept. of Physiology, Ohio State Univ., Columbus OH 43210 and Center for Network Neuroscience, Univ. of North Texas, Denton TX 76203.

Previous investigations showed that posttraumatic cooling (2h at 17°C followed by rewarming) or barbiturates (thiopental or pentobarbital) increase survival of mouse SC neurons subjected to a defined, physical injury (UV laser microbeam transection of a primary dendrite; J. Neurotrauma 11: 35, 1994). A possible protective mechanism for both treatments is reduction of activity-dependent metabolism.

Barbiturates decrease activity by potentiating GABA-induced inhibitory postsynaptic potentials. We investigated the effect of GABA on neuronal survival after dendrotomy. In mouse SC cultures (21-28 DIV) neurons were selected for surgery or to be unlesioned controls. In the experimental group 30 μM GABA was added to the medium just after cell surgery. This concentration stops spontaneous burst activity of mouse SC cultures grown on multimicroelectrode plates. A primary dendrite was transected from each neuron selected for surgery (distance from soma = 100 μm). Survival was tested at 24h by erythrosin B. In the experimental group survival was 42% ± 8 compared to 45% ± 12 in the untreated control group (5 cultures/50 lesioned neurons per group). Survival of the 50 unlesioned control neurons in each group was 100%. These data indicate that reduction of activity-dependent metabolism is probably not the mechanism of protection by hypothermia and barbiturates, and agree with earlier studies showing lack of protection by other inhibitors of synaptic and/or spike activity (10-12 mM Mg⁺² and 2 μM tetrodotoxin). Supported by NINDS 29683 to JHL.

CHARACTERIZATION OF A MODIFIED NERVE INJURY MODEL OF NEUROPATHIC PAIN IN RATS. J.Remillard., R. Quirion., A. Dray, P. Birch, C. Wahlestedt, D.P. Ménard. Astra Pain Research Unit, 275 Armand-Frappier, Laval, Québec, CANADA, H7V 4A7, Douglas Hospital Res. Ctr., Dept. Pharmacol. and Therap., McGill University, 6875 Lasalle, Verdun, Québec, CANADA, H3H 1R3

A standardized constriction nerve injury model was recently proposed by Mosconi and Kruger (Pain 64: 37-57, 1996). The application of fixed-diameter polyethylene cuffs to the rat sciatic nerve produces behavioral responses rather similar to those observed in human peripheral neuropathies. The aim of this study was to quantify the nociceptive behavior of these animals. Surgeries were performed on male Sprague-Dawley rats under ketamine/xylazine anesthesia. An incision of 1 cm was made at the mid-thigh level and the left sciatic nerve was exposed. A 2 mm long cuff of PE-60 polyethylene tubing (ID 0.03") was cut longitudinally and applied to encapsulate the nerve. Animals showed pain-related behaviors such as abnormal gait and limb position. Paw-flick latencies and paw-pressure thresholds were recorded to assess thermal and mechanical hyperalgesia. To test for mechanical allodynia, a series of 10 von Frey hairs of incremental stiffness (0.4 - 20.9g) was presented 6 times to each paw 10 days following surgery and the percent response was calculated. Paw-flick latencies (ipsilateral paws: 5.5±0.5s, contralateral paws: 8.5±0.4s, control rats: 7.7±0.4s) and paw-pressure thresholds (ipsilateral paws: 138±17g, contralateral paws: 174 ±18g, control rats: 228±49g) ipsilateral to the cuffed nerve were decreased compared to control and contralateral paw values 6 days post-surgery. The injured paws showed mechanical allodynia i.e. 53±10% compared to 5±2% for controls in response to the 0.98g hair. However, the contralateral paws of operated animals displayed a decreased response (23±13% compared to 92±5% for controls using the 12.5 g hair). These animals hence display mechanical and thermal hyperalgesia along with mechanical allodynia providing a good model to study analgesics and chronic pain mechanisms. Supported in part by MRC to R.Q.

INVOLVEMENT OF TUMOR NECROSIS FACTOR-ALPHA IN THE PATHOPHYSIOLOGY OF EXPERIMENTAL BRAIN INJURY. <u>L. Fan* S.M. Knoblach. A.G. Yakovlev and A.I. Faden.</u> Georgetown Institute for Cognitive and Computational Sciences. Georgetown Linix Medical Center. Washington PC 20007.

Computational Sciences, Georgetown Univ. Medical Center, Washington DC 20007. Tumor necrosis factor-alpha (TNF- α) is a pleiotropic cytokine implicated in the immune and inflammatory cascades initiated by a variety of CNS insults, including brain trauma. To examine the role of TNF- α in the pathophysiology of brain trauma, we studied the modulation of this cytokine in a widely used, clinically relevant model of traumatic brain injury (TBI).

Anesthetized, male Sprague-Dawley rats were subjected to craniotomy followed by sham (0 atm) or moderately-severe levels (2.5-2.8 atm) of lateral fluid percussion injury. The level of TNF-α mRNA in the ipsilateral hippocampus was determined via semi-quantitative RT-PCR in samples taken from 0.5 h to 3 wks after TBI. Postraumatic increases in TNF-α mRNA peaked 0.5 h after injury, and remained significantly elevated at 24 h. In addition, at 4 and 8 h after TBI, TNF-α was present in CNS cells visualized with double-label immunostaining.

significantly elevated at 24 h. in addition, at 4 and 8 h after 1B1, 1NF-α was present in CNS cells visualized with double-label immunostaining.

To examine the effect of injury-induced elevations in TNF-α, chimeric soluble TNF receptors (sTNFR;Fc) were used to specifically antagonize TNF-α in separate studies that evaluated behavioral and histological outcome measures. Animals treated with intracerebroventricular (37.5 μg/10 μl) injections of sTNFR;Fc 15 min. before and 1 h after TBI performed significantly better in a series of standardized motor tasks than did IgG-treated, injured controls. In addition, histological analysis of the hippocampus ipsilateral to the injury revealed that sTNFR;Fc treatment significantly preserved CA1 cells of the pyramidal layer, compared to injured controls. However, when administered intravenously (0.2-5 mg/kg) after trauma, sTNFR;Fc did not improve behavioral outcome.

These results indicate that enhanced posttraumatic expression of TNF- α within the CNS contributes to the behavioral deficits and histological changes associated with TBI. The effects of treatment with sTNFR:Fc appear to depend upon route of administration and/or timing. (Supported by CDC CCR306634 and NCMRR T32HD07459).

UPREGULATION OF RETINOIC ACID (RA) SYNTHESIS FOLLOWING SPINAL CORD INJURY. D.J. Morassutti*, P. Zhang, U.C. Drager and P. McCaffery. Dept of Neurological Surgery, U. of Louisville, Louisville, KY 40292 and E.K. Shriver Center for Mental Retardation, Waltham, Mass 02254.

Endogenously synthesized RA in the embryonic mouse spinal cord may serve to rescue motoneurons from morphogenetic cell death, and also stimulate neurite outgrowth into developing limbs. This proposal is supported by *in vitro* reports which demonstrated that RA substantially improved spinal motor neuron explant survival and enhanced axonal growth. By postnatal day 13, RA falls to very low and evenly distributed levels throughout the adult SC. These data, and the concept that regenerative efforts likely involve the recapitulation of developmental events, prompted us to examine the expression of retinaldehyde dehydrogenase (RalD), a RA synthetic enzyme, in adult SC injury.

Control Sprague-Dawley rats had a laminectomy but no SC injury; the experimental group received a mild contusive injury(12.5cm; NYU impactor). There were 30 rats per group, and animals were sacrificed begining on the day of surgery, and then every 2d until day 10. The SC's were removed in 3mm long sections at the surgery/injury site, and immediately rostral and distal to it. RalD activity was analysed, and the results revealed a 3-4 fold increase in activity over the first 4 days, in all groups; with a return to normal levels by D-8 to10 in all except the lesion site. This significant upregulation of RalD activity suggests that RA may be playing a role in SC injury. This work was supported by NIH grants HD05515 and EY01938.

INFLUENCE OF C4/C5 CHRONIC SPINAL CONTUSION ON EXPIRATORY MOTOR DRIVE DURING THE EXPIRATION REFLEX IN ANESTHETIZED RATS. D.C. Bolser', G.W. Schrimsher', B. O'Steer', J. McKenzie', and P.J. Reier''. Dept. Of Physiological Sciences', and Depts of Neuroscience and Neurosurgery', University of Florida, Gainesville, Fl, 32610. Patients with cervical spinal injuries have impaired pulmonary

Patients with cervical spinal injuries have impaired pulmonary defensive reflexes due to loss of descending motor drive to spinal motoneurons. We speculated that rats with chronic cervical spinal contusions would have reduced motor drive to rectus abdominis (RA) and pectoralis (P) muscle motoneurons during an expiratory defensive reflex, the expiration reflex (ER). Wistar rats were subjected to spinal contusion at the C4/C5 spinal level. Two months later, lesioned animals (n=7) and age-matched controls (n=8) were anesthetized and EMGs were recorded from the left rectus abdominis and right pectoralis muscles. Expiration reflexes were evoked by mechanical stimulation of the larynx. RA and P EMGs during expiration reflexes were normalized to the largest burst in each EMG observed during asphyxia (asphyxic maximum), performed at the end of the experiment. In intact animals, ER bursts for the RA and P were 18±3% and 47±7% of the asphyxic maximum, respectively. In animals with cervical contusions, ER bursts for the RA were 28±5% (p<0.05) and P were 37±5% (p<0.2) of the asphyxic maximum. In intact animals, there was no significant relationship between RA and P burst amplitudes during the ER (r=0.7, p<0.001). These results suggest that cervical spinal contusions produce highly specific and sometimes subtle effects on motor drive to cervical and thoracolumbar spinal motoneurons during pulmonary defensive reflexes. (Supported by the State of Florida BSCIRTF and the M.F. Overstreet Chair for SCI Research).

INCREASED NITRIC OXIDE SYNTHASE (NOS) ACTIVITY IN SENSORY AND MOTOR PATHWAYS DURING LOCOMOTOR RECOVERY AFTER SPINAL CORD INJURY: A POSSIBLE ROLE FOR NITRIC OXIDE (NO) IN NEURAL PLASTICITY, Z. Zhang* and L. Guth Dept. Biology, College of William and Mary, Williamsburg, VA 23187.

Spinal hemisection in rats produces immediate ipsilateral hemiplegia; this is followed by restoration of locomotor function during the ensuing 7-10 d. Nitric oxide (NO) may play a role in this phenomenon, since injection of the i-NOS inhibitor, aminoguanidine, transiently restores hindlimb move ments in paraplegic mice, and since n-NOS is upregulated after injury (Wu, 1993). The present report describes increased n-NOS in sensory and motor pathways concomitant with restoration of locomotor function. Spinal hemicrush at T10. was performed on adult rats. At intervals of 3 d to 4 wks postoperatively, cryostat sections were incubated for NOS activity by the NADPH-diaphorase reaction. In normal rat, NOS was expressed in discrete sensory and autonomic neuronal populations of the gray matter, but not in white matter. After injury: (a) Sensory system. Many ascending tracts became lightly-stained rostral to the lesion at 2 wks. This reaction was initially ipsilateral and subsequently bilateral. No change occurred caudal to the lesion. (b) Motor system. by 2-4 wks, axons of many descending tracts caudal to the lesion became intensely stained ipsilaterally. In the ventral horns caudal to the lesion, the motor neurons stained bilaterally with increasing intensity from one to four wks post-operatively. This staining was especially pronounced in the lumbar cord; it did not occur rostral to the lesion. Conclusion: The correlation between locomotor recovery and enhanced expression of neuronal NOS prior to nerve regeneration, suggests possible physiological role for NO in this aspect of neuronal plasticity (Supported by NIH grant NS-21460).

465.16

INFLUENCE OF C4/C5 CHRONIC SPINAL CONTUSION ON INSPIRATORY MOTOR DRIVE DURING AUGMENTED BREATHS IN ANESTHETIZED RATS. G.W. Schrimsher², D.C. Bolser¹, B. O'Steen², J. McKenzie¹, and P.J. Reier². Dept. of Physiological Sciences³, and Depts of Neuroscience and Neurosurgery², University of Florida, Gainesville, Fl, 32610.

Patients with cervical spinal injuries have impaired pulmonary defensive reflexes due to loss of descending motor drive to spinal motoneurons. We speculated that rats with chronic cervical spinal contusions would have reduced motor drive to diaphragm (DIA) and pectoralis (P) muscle motoneurons during an inspiratory defensive reflex, the augmented breath (sigh). Wistar rats were subjected to spinal contusion at the C4/C5 spinal level. Two months later, lesioned animals (n=7) and age-matched controls (n=10) were anesthetized and EMGs were recorded from the right hemidiaphragm and right pectoralis major muscles. Augmented breaths (AB) occurred spontaneously or were evoked by mechanical stimulation of the intrathoracic trachea. DIA and P EMGs during augmented breaths were normalized to the largest burst beautised in the algorithm of the experiment. In intact animals, both DIA and P EMGs during ABs were 58±3% of the asphyxic maximum. In animals with cervical contusions, DIA ABs were 103±21% (p<0.02) and P ABs were 29±2% (p<0.001) of the asphyxic maximum. There also was a positive linear relationship between DIA and P burst amplitudes during ABs in intact animals (r=0.44, p<0.01), that was not present in animals with cervical contusions (r=0.02, p<0.9). We conclude that C4/C5 spinal confusion eliminates phrenic motoneurons that provide inspiratory reserve and reduces excitatory inspiratory motor drive during ABs to cervical spinal motoneurons caudal to the lesion. GENDER SPECIFIC ALTERATION IN NITRIC OXIDE SYNTHASE ISOFORMS AND ACTIVITY FOLLOWING TRAUMATIC BRAIN INJURY IN THE RAT. L.K. Gorman*, M.J. Williams, P.D. Hurn and R.J. Traystman. Department of Anesthesiology and Critical Care Medicine, The Johns Hopkins Medical Institutions, Baltimore, MD 21287.

Nitric oxide (NO) has been implicated as a neurotoxin in numerous animal models of focal and global cerebral ischemia although its role in traumatic brain injury (TBI) has not been well-studied. Many isoforms of nitric oxide synthase (NOS), the enzyme that synthesizes NO, exist. Some may be deleterious to the brain (e.g., neuronal NOS - nNOS) following TBI and some may be beneficial (e.g., endothelial NOS - eNOS). We determined if the activity and the levels of NOS were altered in a gender specific manner following a midline fluid percussion injury. Three month old male, female, and female ovariectomized Sprague Dawley rats were subjected to a moderate (2.8 atm) fluid percussion injury. Rats were decapitated, and their brains were rapidly removed and dissected into various cortical areas, medial septal area (MSA), dorsal and ventral hippocampus, and cerebellum. NOS activity was measured by assessing the conversion of ¹⁴C-arginine to ¹⁴C-citrulline. Both nNOS and eNOS levels were measured using a human brain and endothelial synthase ELIZA. Immediately following TBI, overall NOS activity was decreased in the male rats (30-66%), increased in the female rats (33-97%), and showed no change in ovariectomized rats. However, nNOS levels for all of the groups revealed increases in the cortical regions (20-45%) and in the MSA (57-59%). One hour following TBI, eNOS levels were increased in the MSA of male and ovariectomized rat, and decreased in female rats. These results demonstrate that while NOS is altered following TBI, specific isoforms of the enzyme may be affected in a time dependent and gender specific manner. (Supported by NS20020)

AMPHETAMINE TREATMENT DOES NOT ALTER EDEMA FORMATION AFTER CORTICAL CONTUSION IN THE RAT. R.L. Sutton*, Department of Surgery, Hennepin County Medical Center and Department of Neurosurgery, University of Minnesota, Minneapolis, MN 55415

Delayed treatment with D-amphetamine (D-AMPH) has been previously reported to improve sensorimotor recovery after traumatic brain injury (TBI). To determine if these behavioral effects are related to actions of D-AMPH on edema formation, rats with sham injury (N=12) or TBI (N=12; 2 mm compression of right sensorimotor cortex at 3.3 m/s velocity) were treated (IP) with saline or D-AMPH (2 mg/kg) at 18 h postsurgery. The percent water content (Mean \pm SEM) in frontal (FCx), parietal (PCx) and visual cortex (VCx) and hippocampus (Hp) was determined at 24 h postsurgery using the wet-dry weight method [$\% H_{2}O = (\text{(wet tissue weight-dry tissue weight)/wet tissue weight)} X 100].$

Saline-treated rats with TBI had significant (p's <0.05 vs sham) increases in percent water content in the right PCx (84.38 ± 0.74 vs 78.00 ± 0.48), VCx (81.39 ± 0.83 vs 78.81 ± 0.30) and Hp (80.59 ± 0.47 vs 78.48 ± 0.55). D-AMPH treatment did not alter the extent of edema formation in PCx (83.69 ± 1.35), VCx (80.77 ± 0.63) or Hp (80.61 ± 0.18) ipsilateral to TBI. No significant edema was found in the right FCx or in any regions contralateral to TBI. Support: Minneapolis Medical Research Foundation.

RAPID ASTROGLIAL ACTIVATION FOLLOWING C2 SPINAL CORD HEMISECTION

Scott D. Hadley, Robert P. Skoff*, and Harry G. Goshgarian. Department of Anatomy and Cell Biology, Wayne State Univ., Sch. of Med., Detroit, MI 48201

The retraction of astroglial processes in the phrenic nucleus within two hours following C2 spinal cord hemisection in the rat has been suggested to be related to the unmasking of the latent crossed phrenic pathway which mediates recovery of the ipsilateral hemidiaphragm (Exp. Neurol. 120:233-44). In the present LM study, left C2 spinal hemisection causes a very rapid (within 1h) ipsilateral increase in glial fibrillary acidic protein (GFAP) immunoreactivity (IR) 1-2 spinal cord segments rostral and caudal to the C2 lesion. GFAP-IR is significantly enhanced in the ventral horn of spinal cord segments C3-4 ipsilateral to the lesion as compared to the contralateral ventral horn. Astrocytes in this region are characterized by thickened, highly branched immunoreactive processes. The dorsal horn and white matter ipsilateral to the lesion also demonstrate increased GFAP-IR when compared to the contralateral side. The early time course of these observations suggest that the increased GFAP-IR may not be due to an increase in GFAP biosynthesis as has been observed with fiber tract degeneration. Rather, early detection of enhanced GFAP-IR is evidence for rapid astroglial activation in response to spinal cord injury and may represent a depolymerization and redistribution of GFAP from astroglial processes to soma. Depolymerization and redistribution of GFAP may be necessary prerequisites to astrocytic process retraction during neuronal-glial plasticity in the phrenic nucleus and may be induced by extracellular ionic changes, alterations in neurotransmitter signals, or by some other diffusible factor released upon injury.

EFFECTS OF INFANTILE HYDROCEPHALUS ON ASTROCYTOSIS AND AXONAL OR SYNAPTIC GROWTH. J.P. McAllister, II*,R.W. Connelly, W.E. Bingaman, N. Boonswang, M.B. Slivka, and M.G. Luciano. Department of Neurosurgery, The Cleveland Clinic Foundation, Cleveland, OH 44195.

Although hydrocephalus occurs frequently, relatively little is known about both the onset of neuronal damage and the potential for recovery in this disorder. To investigate the temporal changes in astrogliosis and axonal or synaptic growth that occur during the progression of hydrocephalus, GFAP and GAP-43 levels were analyzed in a feline model of kaolin-induced infantile hydrocephalus. Hydrocephalus was induced by intracisternal injection of kaolin in 10 day old kittens. Animals were subsequently prepared as acute untreated, shunt treated, and chronic hydrocephalic groups, and compared to saline injected age-matched control animals. Progression and severity of ventriculomegaly was monitored by ultrasonography at various times before and after shunting and at the time of sacrifice. RNA and total protein were isolated from primary visual cortex (area 17) and analyzed by Northern and Western blotting techniques. Acute untreated hydrocephalic animals exhibited GFAP RNA and protein levels that were 100% and 159% higher than controls, respectively. GFAP levels returned to normal in the shunt treated animals, except when shunt malfunction occurred. Chronic hydrocephalic animals exhibited GFAP RNA and protein levels that were 209% and 764% higher than controls, respectively. In contrast, GAP-43 RNA and protein levels remained unchanged in all experimental groups compared to controls. These results suggest that an astrocytic response occurs during the progression of hydrocephalus, this response can be reversed by successful shunt treatment, and untreated chronic hydrocephalus continues to produce an even more pronounced astrocytic response. The fact that GAP-43 levels do not decline may indicate either that axonal and synaptic growth is not impaired, or that plasticity and regeneration occur as hydrocephalus becomes more severe

The effects of isoprostanes and $\text{PGF}_{2\alpha}$ on rat cerebral ARTERIOLAR DIAMETER. S. W. Hoffman and E. F. Ellis. Dept. Pharmacol/Tox, Medical College of Virginia, Richmond, VA 23298-0613.

Isoprostanes are prostaglandins generated by cyclooxygenase-independent, free radical attack of membrane arachidonate. Others have reported that isoprostanes are potent vasoconstrictors of the peripheral vasculature, however their effect on cerebral blood flow (CBF) is unknown. Previous research has shown that traumatic brain injury (TBI) causes brain lipid peroxidation (LP) and CBF reduction. Although free radical scavengers have been shown to be therapeutically effective at ameliorating these pathological processes, no causal link has been made between LP and vasoconstriction. Therefore, the investigation of isoprostanes may be relevant in understanding ischemia that follows TBI. We investigated the activity of $10^9 \cdot 10^5$ M E₂- and F₂-isoprostanes (8-epi-PGE₂ and 8-epi-PGF_{2a}) and PGF_{2a} on pial arteriolar diameter in anesthetized rats using the closed cranial window technique and *in vivo* microscopy. All three prostanoids produced significant vasoconstriction. Of these prostanoids, 8-epi-PGF₂ α produced the greatest vasoconstriction (34%±2), followed by 8-epi-PGE₂ produced the greatest vasconstriction ($94\%\pm2$), followed by 8-epi-PGE₂ ($20\%\pm2$). After six washouts over a 30 min. period, both 8-epi-PGF_{2 α} and 8-epi-PGE₂ treated vessels remained slightly constricted, whereas the PGF_{2 α} treated vessels regained normal vasomotor tone. The co-infusion of a thromboxane A_2/PGH_2 receptor antagonist (SQ29548) completely blocked the vasoconstriction by 8-epi-PGF $_{2\alpha}$ and 8-epi-PGE2, indicating that these prostanoids mediate their effects through activation of this receptor. These results show that by-products of LP can affect the cerebral vasculature and may play an important role in secondary events after TBI. Supported by NS27214.

POLYAMINE METABOLISM FOLLOWING TRAUMATIC BRAIN INJURY. C. Henley. C. Mills. K. Wey. D. Himes. J. Goodman* C. Robertson.

Otorhinolaryngology and Communicative Sciences and Neurosurgery
College of Medicine, Houston, TX 77030, USA.

The inital step in polyamine synthesis, the decarboxylation of ornithine to form

putrescine, is catalyzed by ornithine decarboxylase (ODC). Putrescine accumulation, resulting from increased ODC activity following injury, has been accumulation, resulting from increased ODC activity following injury, has been hypothesized to mediate blood brain barrier breakdown, vasogenic edema, and neuronal death. The purpose of this study was to quantify changes in ODC and polyamines after traumatic brain injury (TBI). Adult, male anesthetized rats underwent a right parietal craniectomy and were subjected to pneumatic impact injury (2.5mm deformation; 5m/sec). Tissue samples were obtained 48,12,24,72 hr after TBI from 4 bilateral areas: superomedial "A", lateral "B", and inferomedial "C" parietal cortex and the hippocampus. Controls received SHAM surgery. ODC activity was determined by measuring decarboxylation of ["C]-omithine and polyamines were quantified by high performance liquid chromatography-fluorometic detection. ODC increased after TBI in the ipsilateral cortex and hippocampus in a bior tri-phasic fashion: the first peak 8 hr (up to 40-fold), the second 24 hr in "B" and "C" and 72 hr in "A", "B", and hippocampus. A biphasic increase in putrescine was also observed. In the ipsilateral cortex, putrescine increased up to 10-fold 4 hr post TBI, followed by a decrease at 8 and 12 hr. A secondary increase occured 24 or 72 hr post TBI. ODC activity and putrescine levels followed the same temporal pattern in post TBI. ODC activity and putrescine levels followed the same temporal pattern in the contralateral cortex. In general, the magnitude of increase did not exceed that in the ipsilateral cortex. We have shown that ODC and putrescine increase significantly in the traumatized brain. Biochemical and molecular studies of the ODC/polyamine system after TBI should help identify the role of polyamines in CNS injury-recovery and provide rationale for pharmacological studies to identify neuroprotective agents useful in management of head injury. DEVELOPMENT OF A LARGE ANIMAL MODEL OF ADULT ACQUIRED OBSTRUCTIVE HYDROCEPHALUS M.J. Johnson*, M.G. Luciano, I. Ayzman, A.S. Wood, J.P. McAllister, II. Dept. of Neurological Surgery, The Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44195

Hydrocephalus is a condition characterized by cerebral ventricular enlargement and neurological deficit. While neuropathological charges due to hydrocephalus have been assessed in patient populations, these studies lack stringent control of variables such as the location of the obstruction which produces hydrocephalus or the time course of the disease. Most of the animal models currently used in hydrocephalus research are too small to enable implementation of clinical hardware or to provide optimal resolution with diagnostic imaging. Thus, we have developed a large canine model of acquired obstructive hydrocephalus in which both the duration and cause of hydrocephalus are controlled. This model will allow us to study the anatomical and physiological progression of the disease with high resolution imaging techniques such as MRI, PET, and SPECT, and to correlate these images with histological and immunohistochemical changes. The size of this model also facilitates the measurement of the reversibility of functional changes by surgical intervention. Acute procedures on 13 animals allowed examination of the location and size of the obstruction immediately after surgery. In 14 chronic animals, hydrocephalus was induced and the progression of ventriculomegaly was monitored using MRI for 5-6 weeks. During model development, several materials were tested. Focal obstruction of the fourth ventricle could be produced using either a cotton pledget or cyanoacrylic glue in combination with a balloon catheter Immunohistochemical analysis of hydrocephalic tissue compared to controls has revealed increases in GFAP as a function of the severity of hydrocephalus. Thus, GFAP appears to be a useful marker of damage in the hydrocephalic brain. In summary, this large animal model of obstructive hydrocephalus will allow examination of the normal progression of this disease and the efficacy of clinical intervention. HO-1 ACTIVATION IN BRAIN FOLLOWING SUBARACHNOID INJECTIONS OF HEMOGLOBIN, HEME AND HEME ANALOGS.

INJECTIONS OF HEMOGLOBIN, HEME AND HEME ANALOGS. Christopher P. Turner* Frank R. Sharp & S. Scott Panter., Dept. Neurology 127, VA Medical Center, 4150 Clement St., San Francisco, CA 94121, USA. In the brain, the pro-oxidant heme is metabolized into biliverdin, iron and carbon monoxide (CO) by the enzyme hemeoxygenase (HO). The potentially toxic free iron is bound by ferritin, and CO may be a critical player in a number of important neuronal processes. Expression of HO is controlled by two separate genes, HO-1, found mainly in glia, and HO-2 found mostly in neurons. Using immunohistochemical techniques, we have previously shown that injection of a purified oxy-hemoglobin (oxy-Hb) solution into the subarachnoid space of adult female rats leads to a global induction of the stress gene protein, HO-1, throughout the brain. This induction was observed principally in microglia. We have recently observed a similar induction in microglia following subarachnoid throughout the brain. This induction was observed principally in microglia. We have recently observed a similar induction in microglia following subarachnoid injection of methemoglobin. We hypothesized that the heme component in Hb is responsible for the HO-1 induction, and subarachnoid injection of heme promoted an increase in microglial expression of HO-1. The same result was observed following injection of heme analogs such as Zn- or Sn-protoporphyrin. These observations support the hypothesis that the protoporphyrin-IX metal complex of Hb is the principal agent in promoting HO-1 induction. Heme analogs are known to be inhibitors of HO activity but were still able to induce HO-1 expression. It is likely that these compounds act directly through the heme/metal binding site of likely that these compounds act directly through the heme/metal binding site of the HO-1 gene, or that they promote heme accumulation which acts through the same regulatory site. Since HO-1 is expressed in very small amounts in glia, activation of this gene would be necessary to promote de novo expression of HO-1 protein and, thus, control potentially toxic elevations of intracellular heme. Direct activation of the HO-1 gene by heme would be one way of promoting rapid induction. Such a mechanism would suggest a protective role for the HO-1 stress gene. REGIONAL PATTERN OF 72 kD HEAT SHOCK PROTEIN (HSP72) AND IN SITU DNA FRAGMENTATION IN NEURONS AFTER SEVERE CONTUSIVE BRAIN INJURY IN RATS. M. Chen*, R.S.B. Clark, P.M. Kochanek, J. Chen, R.A. Stetler, K. Basta, D.W. Marion, S.T. DeKosky, R.P. Simon, and S.H. Graham. Depts. of Anesthesiology/Critical Care Medicine, Neurology, and Neurosurgery, and the Safar Center for Resuscitation Research, University of Pittsburgh, PA 15213.

Hsp72 is induced in neurons after ischemic and traumatic brain inury (TBI), is a sensitive marker of cellular stress, and may serve a neuroprotective role. We examined the regional and cellular pattern of hsp72 mRNA and protein expression and compared it to the pattern of *in situ* DNA fragmentation after severe TBI in rats.

Anesthetized adult rats were subjected to severe controlled cortical impact injury to the left parietal cortex immediately followed by 30 min of hypoxia (PaO₂=35-45 torr). Rats (n=27) were killed at 6, 8, 24, 72, or 168 h after trauma. Naive rats were used as controls. Brains were removed and in situ hybridization, immunocytochemistry, and Western analysis for hsp72, or terminal deoxynucleotidyl transferase-mediated biotin-dUTP nick-end labeling (TUNEL) was performed. Hsp72 mRNA was expressed in neurons in the ipsilateral cortex, CaA hippocampus, hibus, and dentate at 6 h. Hsp72 mRNA was expressed primarily in ipsilateral cortical neurons at 24 h and by 72 h hsp72 mRNA expression returned to basal levels. Hsp72 protein was seen in ipsilateral cortical neurons, and few hilar and CA3 neurons at 24 and 72 h. Hsp72 protein was also detected in endothelium and glia. Western analysis detected an increase in hsp72 protein in ipsilateral cortex at 8 and 24 h. Induction of hsp72 mRNA or protein was not detected in the contralateral hemisphere or controls. TUNEL-positive neurons were seen in ipsilateral cortex and dentate at 6 h, and in ipsilateral cortex, dentate, hilus, and CA3 at 24 and 72 h, but not in the contralateral hemisphere or in controls.

The regional pattern of hsp72 mRNA and protein expression in neurons is similar to the pattern of *in situ* DNA fragmentation after severe TBI in rats. Further study is required to determine if this represents a neuroprotective response, or is merely a marker of cellular injury. Supported by NIH/NINDS 2P50 NS30318-04A1.

EVIDENCE FOR APOPTOSIS OF OLIGODENDROGLIA IN LONG TRACTS UNDERGOING WALLERIAN DEGENERATION AFTER SPINAL CORD INJURY (SCI) IN MONKEYS. <u>I.C. Bresnahan*, S.L. Shuman, M.S. Beattie, Dept. of Cell Biol.</u>, Neurobiol., and Anat., and Neuroscience Program, The Ohio State University, Columbus, OH 43210.

We have recently shown that cells in the white matter exhibit several features of apoptosis over a considerable period following spinal cord contusion lesions in the rat (Crowe et al. 1995; Shuman et al., 1996, this meeting). We found that nuclear condensation typical of apoptosis was detectable using either nuclear stains (e.g. Hoechst 33342), TUNEL staining, toluidine blue staining of semi-thin plastic sections, or standard Nissl stains. We therefore examined material from a series of monkey (macaca mulatta) spinal cord contusion cases (Bresnahan et al, 1976, J. Neurol. Sci., 28:521) to determine whether apoptotic nuclei were present in this material. Alternate sections were stained using cresyl echt violet and for degenerating fibers, using the Fink-Heimer silver stain. This allowed for a comparison between the locations of apoptotic cells and degenerating fiber tracts. Four contusion lesions (200-500 g-cm) and one spinal hemisection (7-10 da post-SCI) were studied, with apoptotic profiles and fiber degeneration plotted independently.

In tracts both rostral and caudal to lesions in every case, there was precise correspondence between the presence of apoptotic profiles and degenerating fibers. Electron microscopy showed that some of the apoptotic cells were oligodendrocytes. It is suggested that demyelination of long tracts after SCI is due at least in part to apoptotic death of oligodendrocytes associated with dying axons. (Supported by NS-10165).

EFFECT OF CYCLOHEXIMIDE ON DNA BREAKDOWN, TISSUE LOSS, AND BEHAVIORAL OUTCOME AFTER SPINAL CORD IMPACT INJURY. X. Z. Liu¹*, X. M. Xu², R. Hu¹, C. Du¹, G. S. Fan¹, C. Y. Hsu¹, D. W. Choi¹, ¹Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110; ¹Dept Anat. & Neurobiol, St. Louis Univ Sch Med, St. Louis, MO 63104.

In the preceding companion abstracts, we show morphological and biochemical evidence suggestive of apoptosis cell death in the rat spinal cord after mild impact injury. To test this idea further, we subjected the rat spinal cord to moderate (12.5 g-cm) impact using the NYU device, and treated the rats with cycloheximide (1 mg/kg immediately post injury followed by 1 mg/kg q 3d for 4 wks), or saline.

Cycloheximide treatment reduced the amount of DNA breakdown in injured tissue (ELISA assay) by 50% at 24 hr post injury. Weekly behavioral assessment using the Basso-Beattie-Bresnaha (BBB) OSU open field grading system showed that this cycloheximide treatment produced an improvement in hindlimb function detectable as early as 2 wks post injury and persisting up to 4 wks post injury (median BBB score: cycloheximide, 16; saline, 12, n=12, P<0.05 by Mann-Whiney 2-sample test). Morphological assessment of tissue loss showed that the cycloheximide treatment reduced tissue loss in the epicenter (cycloheximide, 0.932; saline, 0.446 mm², n=12, P<0.05 by Student's 1-test) as well the adjacent rostral and caudal segments. These findings corroborate the accompanying morphological and biochemical studies suggesting that apoptosis contributes importantly to cell death and loss of function after submaximal impact injury, and support the possibility that acute pharmacological blockade of apoptosis may achieve therapeutic benefits.

SUCROSE GAP RECORDING OF MEMBRANE RESEALING IN CUT MAMMALIAN SPINAL CORD AXONS R. Shi*, T. Asano and A.R. Blight, Div.Neurosurg., Univ. NC, Chapel Hill, NC 27599. Membrane sealing is an important part of the neuronal response to

Membrane sealing is an important part of the neuronal response to injury. Sealing of axons was studied in isolated adult guinea pig spinal cord, using sucrose gap recording to monitor membrane potential changes, and uptake of horseradish peroxidase (HRP) to examine permeability to large molecules. A 35 mm strip of white matter was placed in a recording chamber, the central 12.5 mm superfused with Krebs' solution and the ends carried through sucrose gaps to compartments filled with isotonic KCl. The negative gap potential stabilized over 30-60 min., and the evoked compound potential similarly increased in amplitude to a stable plateau. When the strip was cut at the face of the sucrose gap, the gap potential decreased immediately towards 0 mV, then began to repolarize. Recovery of 90% of the initial potential occurred in c.40 min. at 37°C, with a single exponential time course. At 25°C, the rate of recovery was slowed by a factor of 2. HRP histochemistry showed an equivalent rate of sealing of the severed axons. At 37°C, almost all axons were stained when transferred to 0.015% HRP solution at 1 and 15 minutes after transection, less than half were stained when transferred at 30 minutes, and few were stained at 1 hr. At 25°C, approximately 50% of axons stained when transferred at 1 hr post injury. The correlation between gap potential and HRP exclusion indicates the potential can be used as a continuous indicator of membrane integrity. Removal of Ca²⁺ from the medium arrested resealing of axons within the duration of the experiment. Supported by the Canadian Spinal Research Organization and grant NS-33687 from NIH-NINDS.

MORPHOLOGICAL EVIDENCE OF GLIAL INVOLVEMENT IN APOPTOTIC CELL DEATH FOLLOWING SPINAL CORD CONTUSION. <u>S.L. Shuman*, J.C. Bresnahan, and M.S. Beattie</u>. Neuroscience Program, Dept. of Cell Biology, Neurobiology & Anatomy, The Ohio State University, Columbus OH 43210

Apoptosis is a form of active cell death characterized by morphological features such as condensed chromatin, reduced cytoplasmic volume and membrane blebbing. Apoptotic cell death has recently been observed following contusion injury to the rat spinal cord (Crowe, et al.) and is present up to three weeks post-injury, particularly in white matter tracts. We used immunocytochemical techniques in an effort to identify the cell types involved in this model of apoptotic cell death. Seven rats received a 25g-cm contusion injury at T10 using the NYU weight drop device. Animals were sacrificed at 24 hours (n=2), 8 days (n=3) or 3 weeks (n=2) post-injury. Sham injuries were performed on two additional animals which survived for 24 hours or 8 days. Spinal cord tissue was sampled up to 17mm rostral and caudal to the lesion center. Tissue sections were stained with the monoclonal antibody OX-42 to identify microglia and counterstained with cresyl violet. Cresyl violet staining revealed clusters of condensed material that were identical in morphology to apoptotic cells stained with the nuclear dye Hoechst 33342 (HO342). The spatial and temporal distribution of apoptotic profiles observed with cresyl violet was also similar to previous studies using HO342. A wave of apoptosis began at the contusion site, and over a period of three weeks spread both rostrally and caudally in the white matter. OX-42 (+) profiles ranged from ramified resting microglia to round, darkly stained cells containing one or more clumps of condensed Nissl material. Some apoptotic profiles were not immunoreactive for OX-42; many of these appeared to be contacted by microglia, especially at greater distances from the lesion center (70.0% at 7mm; 83.3% at 13mm). Only a small fraction (11.2%) of normal cells in the white matter exhibited such close apposition, suggesting a role for microglial activity in apoptotic cell death following spinal cord injury. COMBINATION TREATMENTS OF CHRONIC SPINAL CORD INJURIES WITH SCAR DISRUPTER, NEUROTROPHIC FACTOR-COATED BEADS AND FETAL CELLS, MATRIX OR MYELIN ANTIBODY. J.D. Peduzzi* and F.R. Fischer. Dept. Physiol Optics, University of Alabama at Birmingham, Birmingham, AL 35294.

Modification of the spinal cord structure after chronic injury was attempted using combination treatments. Adult Sprague-Dawley rats received a contusive spinal cord injury (10 g wt. dropped 2.5 cm) at T8 vertebral level. Treatment was given at 2 months post injury to animals exhibiting similar behavioral deficits using the combined behavioral score (Gale, Kerasidis & Wrathall, 1985). The 3 treatment groups received scar disrupter (EDTA) then NT-3 coupled to red fluorescent beads and BDNF coupled to green fluorescent beads. These microspheres label cells binding the neurotrophic factors and permit longer availability of the factors (Riddle, Lo & Katz, 1995). In addition, group 1 received laminin-collagen matrix, group 2 - E14 fetal spinal cord cells and group 3 - Gal-C antibody. The control group received buffer and plain fluorescent beads only. Four days after treatment, animals were sacrificed and the brains and spinal cords were examined. Numerous double-labeled cells were present in spinal cord-projecting regions of the brain. Transplants had regions of good integration with spinal cord. With the Gal-C antibody or matrix treatment, cavity boundaries became irregular

OMENTAL TRANSPOSITION IN CHRONICALLY SPINAL CORD INJURED RATS. H. Q. Yan*, G. L. Clifton, S. J. Liu, K. Yang, C. E. Dixon and R. L. Hayes. Dept. of Neurosurgery, Universityt of Texas Medical School at Houston, Houston, Texas 77225

The omentum has been used over the years for a variety of clinical problems Recently it has been shown that placing the omentum on the brain and spinal cord can lead to an extensive development of vascular connections at omental/CNS interface. These findings had led to increasing interest in placing the omentum on to the human spinal cord. The conflicted resent reports of clinical trials are throughout the world (United States, Europa, Asia). We investigated the effect of omental transposition (OT) on chronically spinal cord injured rats and wanted to explain the clinical findings. Four groups (spinal cord injury (SCI) with OT, SCI with sham OT, Sham SCI with OT and sham SCI with sham OT) of animals were used for the study. SCI was made by an electronically controlled apparatus. The severity of the injury was measured by open field walking (Tarlov), inclined plane severity of the highly was measured by open field washing (failov), inclined planted (angle test) and grid walk. One month after the injury or the sham injury, the rats were undergone OT or sham OT. After another one month, the animals were sacrificed for histopathological studies. The injured segment of spinal cord becomes thinner than the control (sham SCI) and most of them (4 out of 5) have a big cavity in the center of the cord. OT produces the pressure on the spinal cord in both injured and control rats. However, in SCI with OT group, the cavity in the center of the cord is markedly reduced or disappeared in 3 out of 4 animals. Our experiment also confirms other reports that there are new vascular connections between the omentum and spinal cord. Our data suggest that the effect of OT in humans might be due to the revasolization and/or reduce the size of the cavity in the center of the spinal cord resulted from SCI.

EARLY EFFECTS OF TRAUMATIC BRAIN INJURY STUDIED "IN VITRO" D. O. Maris, R. D'Ambrosio, S.M. Grady, H.R. Winn and D. Janigro. Univ. of Washington. Dept. of Neurosurgery Seattle, WA 98104

In vivo studies have demonstrated that hippocampal long-term potentiation is

impaired or abolished following cortical fluid percussion injury (FPI), an animal model of traumatic brain injury (TBI). Furthermore, FPI has been shown to decrease CAI post-synaptic excitability measured *in vivo*. We tested the hypothesis that the effects of TBI induced in juvenile rats *in vivo* persist and can be investigated in isolated hippocampal slices maintained in vitro. TBI was induced by medial FPI. After 24 to 48 hours both hippocampi were extracted and slices were obtained with standard methods. Recordings of field excitatory postsynaptic potentials (fEPSPs) and population spikes (p.s.) were performed from CA1 strata radiatum and pyramidale. fEPSPs threshold differed in control ν_8 . post-FPI slices (59±3 and 82±6 μ A respectively, n=9, p<0.02). Higher stimulus intensities were required to elicit a population spike in post-FPI animals (80±7 vs 185±27 μA, p<0.01). While half maximal activation of CA1 pyramidal cells from FPI rats was achieved with current intensities of 242 ±7. μ A, 130 ±5 μ A were required to elicit the same response in slices from control rats. Thus, in agreement with results from in vivo experiments, post-FPI responses recorded in vitro were characterized by a marked neuronal hypo-excitability. The opposite form of LTP, long-lasting depression of synaptic activity (LTD), could be elicited in both FPI and control slices (21±3% and 26±8% depression respectively as measured 30 minutes after LTD induction). We conclude that FPI deficits persist and can be studied in vitro. At least at early stages, FPI does not affect the synaptic mechanisms involved in LTD induction and maintenance. PROGESTERONE, BUT NOT METHYLPREDNISOLONE, REDUCES EDEMA IN FEMALE RATS AFTER CORTICAL CONTUSION.

M.E. Fritts**, E.A. Castro.*, D.G. Steinf, and R.L. Roof.*. *Dept of Psychology and Neuroscience Prog. Texas Christian Univ., Ft. Worth, TX 76132. *fDept of Neurology, Emory Univ., Atlanta, GA 30322.

Progesterone (P) has been shown to reduce brain edema, lipid peroxidation, secondary neuronal death, BBB damage and cognitive deficits after cortical contusion. Methylprednisolone (M) may also improve recovery after brain injury but is associated with negative side effects and has a limited window of opportunity. P is effective in relatively small doses (4 mg/kg compared to 30 mg/kg) and reduces edema when given up to 24h after injury! We have recently found P to be more effective at reducing edema after contusion in male rats².

To compare the effectiveness of the two steroids in reducing edema in females, brain water content was measured 72h after mediofrontal cortical contusion in female rats treated with P, M, or the vehicle (propylene glycol). Females were given contusions (while in proestrus) using a pneumatic piston impactor. P was injected lh(ip), 6, 24, & 48h (se) after injury (4 mg/kg per inj.). a regimen previously shown to be effective. M was given lh (60Mg/kg, ip), 2h and 6h (30 mg/kg, ip), the regimen shown to be most effective in the males².

As was seen in male rats, P was significantly more effective at reducing edema compared to vehicle (r(13)=4.05, p<0.01) and Mtreated females (r(14)=3.07, p<0.01). M did not significantly reduce edema compared to the vehicle. Female data will be presented alone and in comparison to that of males. Our results support continued investigation of progesterone and demonstrate its potential as a treatment for brain injury. Exp. Neur. 138:246-251 (1996). *Poster at SFN 1996 meeting. SEX DIFFERENCES IN RECOVERY AFTER CORTICAL TRAUMA IN RAT DEPEND ON ESTROUS STAGE. <u>D.L. Stibick* & D.M. Feeney</u> Depts. of Psychology & Physiology, University of New Mexico, Albuquerque, NM

Female sex hormones reportedly lessen severity of brain injury and promote behavioral recovery; however, these studies utilized males and/or ovariectomized female rats administered hormones at very high dosages. We propose that normal levels of the multiple circulating hormones in female rats produce differences in recovery from cortical injury. To test this hypothesis, male and female rats received unilateral impact injury to the hypothesis, male and female rats received unilateral impact injury to the sensorimotor cortex (Weisend & Feeney, 1994). Female rats were contused during one of four estrous stages determined by vaginal smears taken the day of surgery. Functional recovery was determined using a beam walk task and rating scale described in the above reference by observers blind to condition. Testing was conducted hourly for 5 hrs. beginning 24 hrs. after injury or sham surgery, then every other day for 15 days beginning 48 hrs. post-surgery. At 25 hrs. post-injury, females recovered significantly faster than males and this depended upon their estrous stage. Female rats in proestrous, when sex hormones are most similar to males, are not significantly different from males. Only rats contused during the other 3 estrous stages with higher levels of sex hormones showed significantly facilitated beam walk recovery compared to males. This excludes other sex differences that could account for these data. Analysis of histology is underway. The results of this study indicate that estrous cycle phase at time of cortical trauma modifies functional outcome. Normal levels of female sex hormones enhance recovery and this could be exploited for therapeutic intervention. [Supported by UNM RAC grant].

ENRICHED HOUSING IMPROVES WATER MAZE PERFORMANCE IN MEDIOFRONTAL CORTEX CONTUSED AND SHAM MALE RATS. E.A. Castro*, M.E. Fritts, & R.L. Roof, Dept. of Psychology and Neuroscience Program. Texas Christian University, Ft. Worth, TX 76132. Enriched housing conditions (EC) result in thicker cortices and increased dendritic branching in brain intact rats. EC rats also perform better on maze tasks than rats kept in impoverished housing conditions (IC). EC after brain injury may encourage new neuronal connections, thus replacing some of those lost, as well as encourage behavioral flexibility and use of multiple strategies to solve tasks. EC's effects after brain injury have been examined but primarily after damage to specific brain injury have been examined but primarily after damage to specific sensory and motor areas and with lesion models that do not mimic injury normally sustained by humans.

We tested EC/IC effects after injury to the mediofrontal cortex, an area

We tested EC/IC effects after injury to the mediofrontal cortex, an area important for attention and spatial orientation and also a brain area commonly damaged in humans. Male rats were given cortical contusions or sham surgery followed by 38 days in either EC (large group cage, with ladders, tunnels, toys, etc) or IC housing (small, individual cages, no objects). On the last 8 days, rats were tested in the Morris water maze (2 trials/day). The release position was changed between trials. The platform remained in the same position for the duration of testing.

A strong, overall, beneficial effect of EC on water maze performance was seen. In addition, EC lesion rats performed better than IC lesion rats and closer to sham levels. The brains of these rats are being examined for anatomical changes. It is not yet known whether the housing influenced physiological recovery, but benefits of EC partially counteracted the water maze deficit associated with this lesion. These data suggest EC after brain injury may improve recovery of function.

PROGESTERONE IS MORE EFFECTIVE THAN METHYLPREDNISO-

PROGESTERONE IS MORE EFFECTIVE THAN METHYLPREDNISOLONE AT REDUCING EDEMA AFTER CORTICAL CONTUSION IN MALE RATS. R.L. Roof,** M.E. Fritts,* E.A. Castro,* R.A. Powell,* & D.G. Stein,* Dept. of Psychology and Neuroscience Prog., Texas Christian Univ., Ft. Worth, TX 76132. Dept. of Neurology, Emory Univ., Atlanta, GA 30322. We previously reported that Progesterone (P) reduces edema after cortical contusion in rats. P also reduces lipid peroxidation, secondary neuronal death, BBB damage and cognitive deficits in this injury model. Methylprednisolone (M) is currently used to treat spinal cord injury and has been shown to improve recovery after brain injury. However, its efficacy is limited by negative side effects associated with the large doses needed and by its limited window of opportunity. P is effective in relatively small doses (4 mg/kg compared to 30 mg/kg) and reduces edema when treatment is delayed 24h after injury.

To compare their effectiveness in reducing edema, brain water content was measured 72h after mediofrontal cortical contusion in male rats given P, M, or the vehicle. P was injected lh(ip), 6, 24, & 48h(sc) after injury (4 mg/kg per inj.), a regimen previously shown to be effective. M

given P, M, or the vehicle. P was injected 1h(ip), 6, 24, & 48h(sc) after injury (4 mg/kg per inj.), a regimen previously shown to be effective. M was given in one of three regimens (all ip) (A: 60 mg/kg at 1h, 30 mg/kg at 2 & 6h; B: 60 mg/kg at 1h, 30 mg/kg at 6, 24, & 48h; C: 90 mg/kg at 1h, 45 mg/kg at 2 & 6h). 60-90 mg/kg M given ip has been shown to be equivalent to 30 mg/kg given iv.

There were no significant differences among the M regimens, but a trend (p=0.07) suggested A was most beneficial. In no case did M significantly reduce edema compared to vehicle controls. P-treated rats had less edema than the vehicle group and all of the M-treated groups. These findings support continued investigation of progesterone and demonstrate its potential as a treatment for brain injury.

MICROGLIAL CELL ACTIVATION IN THE BRAIN OF THE ADULT RAT FOLLOWING EXPOSURE TO AIR BLAST J.K.E. Persson*1-3. A. Sāliō²²-1 and A. Suneson*1 Department of Neuroscience. Karolinska Institutet, Anatomy building, S. 171-77 Stockholm. Sweden. ²Department of Surgery, University of Göteborg, S-4f.3 45 Göteborg, Sweden. ³Department of Human Studies (FOA 54), National Defence Research Establishment, S-172-90. Stockholm, Sweden.

It has been controversial whether the exposure to moderate air blasts at levels not inducing any macroscopical signs of damage to the brain or skull results in structural CNS changes. The aim of this study was to elucidate the microglial cell reaction in the CNS after exposure to a moderate air blast injury.

Anaesthetized rats were exposed to a pressure characterized air blast generated by either of two different charge weights of pentaerythrittetranitrate at a distance of 1 m in an open detonation chamber. Four-six hours, 18 hours, 48 hours and one week, respectively, following blast exposure the rats were reanaesthetized, perfused and the brain removed followed by immunohistochemical processing for detection of the complement receptor CR3 which is localized at the membranes of microglial cells.

Compared to sham-exposed rats, there was an increased anti-CR3 immunoreactivity in all investigated parts of the brain following exposure to either charge at 18 hours, 48 hours and one week, but not at four-six hours post-blast. Light microscopic examination of cresy violet stained sections from representative parts of the brain following exposure to either charge at 18 hours, 48 hours and one week, but not at four-six hours post-blast. Light microscopic examination of cresy violet stained sections from representative parts of the brain did not reveal any histological differences between the experimental and the sham groups immediately after the blast exposure and during the following survival period there were no behavioural differences between the experimental and the sham rats, indicating any bl

THE EFFECTS OF PROTRIPTYLINE ON FUNCTIONAL RECOVERY FOLLOWING TRAUMATIC BRAIN INJURY. X. Ma*, R.G. Griffith, P. RODELOWING TRAUMATIC BRAIN INJURY. X. Ma*, R.G. Griffith, P. Robichaud, B. Wolfson, G. Stolz, D. Marion, and C.E. Dixon, Brain Trauma Research Center, Department of Neurosurgery, University of Pittsburgh, PA 15260.

Protriptyline, a tricyclic antidepressant with activating properties, has been reported in a series of case studies to improve function in brain injured patients [Wroblewski, et al., Brain Injury, 7(4), 353-362, 1993]. However, there are currently no published laboratory reports on the use of protriptyline to enhance functional recovery following experimental TBI. We examined the effects of daily protriptyline treatment on functional recovery (motor and spatial memory performance) in twenty rats following controlled cortical impact injury (4 m/sec, 3.0 mm tissue deformation). Sham animals (n=5) were surgically prepared, but not injured. Beginning one day after injury, animals were injected daily with either protriptyline (5 mg/kg, i.p., n=10) or saline (n=10). Rats were trained prior to injury and retested on days 1-5 for motor (beam balance and beam walking) performance. On days 14-18, animals were trained on the Morris water maze task. Results indicate that a 5 mg/kg dose of protriptyline does not attenuate motor or spatial memory deficits after TBI. However, during the water maze swim, injured rats made significantly more right turns (101.4 \pm 9.4) than left turns (72.1 \pm 3.9) (p < 0.01). This pattern of turning after protriptyline administration may be analogous to circling behavior that has been reported to unmask chronically lowered striatal dopaminergic activity on the injured side of the brain. Supported by CDC R49CCR-312296 and NIH P50NS30318.

NEUROPSYCHIATRIC DISORDERS: SCHIZOPHRENIA I

467.1

THE NOVEL, ATYPICAL ANTIPSYCHOTIC, S 16924, ENHANCES DOPAMINE (DA) AND NORADRENALINE (NAD) RELEASE, AND DECREASES SEROTONIN (5-HT) RELEASE, IN FRONTAL CORTEX OF FREELY-MOVING RATS, J.-M. Rivet*, A. Gobert, L. Cistarelli, S. Girardon, O. Muller, G. Lavielle and M.J. Millan, I.D.R.S., 125 Chemin de Ronde, 78290 Croissy, France

((-)-l-(benzodioxane-5yl-3-[3-(4-fluorophenacyl)pyrrolidine]-l-oxa-S 16924 propane) has high affinity at cloned 5-HT_{1A} (K_1 = 1.9 nM, D_4 (6.2) and 5-HT_{2A} (2.4) vs D_2 (2.8.8) receptors. Here, we examined its influence upon monoaminergic transmission in rats implanted with a cannula in frontal cortex (FCX), or both accumbens and striatum. Samples were taken every 20 min and analysed by HPLC/coulometric detection. After 3 basal values, drugs (mg/kg, base) were injected s.c. and analysed over 60 min. WAY 100,635 (N-{2-[4-(2-methoxy-phenyl)-1piperazinyl]ethyl}-N-(2-pyridinyl) cyclo-hexanecarboxamide) (WAY) was given 20 min prior to S 16924. Changes (Mean ± S.E.M. in %) are relative to basal (= 100 %).

	Frontal Cortex		Accumbens		Striatum	
Drug	DA	NAD	5-HT	DA	5-HT	DA
	(1.4)	(1.8)	(1.0)	(4.9)	(0.8)	(9.2)
VEH / VEH	92±3	105±5	99±7	100±2	88±4	97±2
VEH / S 16924 (2.5)	163±5	200±10	53±4	112±8	54±5	115±2
WAY / VEH	88±3	103±10	103±10	91±2	99±8	101±4
WAY (0.16) / S16924 (2.5)	123±6*	158±11*	105±9*	N.T.	N.T.	N.T.
VEH	98±3	107±6	90±6	99±2	85±4	96±2
Clozapine (2.5)	163±8	238±15	101±5	109±6	89±6	94±3
Haloperidol (0.63)	131±5	174±11	75±6	130±6	89±6	129±2

Both S 16924 and clozapine selectively increased DA release in FCX. S 16924 also decreased 5-HT release and the 5-HT_{1A} antagonist, WAY, reduced its actions. Thi pattern of release may contribute to the distinctive antipsychotic profile of S 16924. This study was supported by Servier Pharmaceuticals

467.3

INTRINSIC ACTIVITY OF THE POTENTIAL ANTIPSYCHOTIC CI-1007 AT D2, D3 AND D4 DOPAMINE RECEPTORS.

L.M. Georgic*, D.H. VanLeeuwen, R.G. MacKenzie, T.A. Pugsley, Y.H. Shih, L.D. Wise, J. Wright and T.G. Heffner. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

Whereas current antipsychotics are antagonists at dopamine (DA) D₂ receptors, CI-1007 is a partial DA agonist with moderate intrinsic activity at DA D2 receptors in neurochemical, electrophysiological and behavioral tests. We compared the affinity and intrinsic activity of CI-1007 at cloned human DA D2, D3 and D4 receptors. Receptor binding affinity determined in CHO cell membranes with [3H]-spiroperidol revealed K_i values of 25.5 nM at D_2 , 16.6 nM at D_3 and 90.9 nM at D_4 receptors. CI-1007 showed agonist-like stimulation of [3H]-thymidine uptake in CHOp-5 cells transfected with D2 or D3 receptors with maximal stimulation of 66% and 84%, respectively, and EC₅₀ values of 1.3 nM and 4.5 nM, respectively. CI-1007 caused only 10% maximal stimulation of [3H]-thymidine uptake in D4-transfected cells and blocked the stimulation of [3H]-thymidine uptake caused by the DA agonist quinpirole with an IC_{50} of 40 nM. These results demonstrate that CI-1007 is a partial agonist with moderate intrinsic activity at DA D2 receptors, high intrinsic agonist activity at D3 receptors and low, antagonist-like intrinsic activity at D₄ receptors. This spectrum of activity may contribute to an improved antipsychotic profile for CI-1007. (Supported by Warner-Lambert.)

NEURODEVELOPMENTAL PATHOGENESIS OF SCHIZOPHRENIA. N. Rajakumar*, P.C. Williamson, J.A. Stoessl and B.A. Flumerfelt, Departments of Psychiatry, Clinical Neurol. Sci. and Anatomy and Cell Biology, Univ. of Western Ontario, London, Ontario, Canada N6A 5C1.

Neuroimaging and postmortem evidence implicates two candidate neural circuits in the manifestation of schizophrenic symptomatology, namely, the prefrontocortical-temporal lobe circuit and the prefrontocortical-subcortical circuit. Based on these findings, Weinberger and associates have proposed an animal model of schizophrenia employing neonatal lesions of the ventral hippocampus (Neuropsychopharmacology '93; 9: 67-75). The present study suggests an alternative model in which neonatal excitotoxic lesions of the mediodorsal thalamic nuclei result in adult manifestations indicating enhanced activity of the mesolimbic dopaminergic system similar to that seen in schizophrenia. Sprague Dawley rat pups (postnatal day 4) were injected bilaterally with quinolinic acid (120 nM/µl) or saline into the mediodorsal thalamic nuclei using a stereotaxic approach. Both lesioned and sham animals were tested for behavioral manifestations following saline, d-amphetamine (2.5 mg/kg.i.p.), or apomorphine (300 μg/kg, s.c.) injection in a well habituated environment at 10 weeks. The duration of locomotion, rearing, sniffing, mouth movements and grooming were recorded in 3 min blocks of time for a period of one hour using a microcomputer with custom-designed software. The animals were sacrificed and the extent of the lesions was verified using Nissl stain. The results indicated markedly enhanced locomotion and exploratory activity in response to novel environment or external stimuli in lesioned animals 7-10 weeks postnatally. Moreover, the lesioned animals showed increased locomotion and rearing following d-amphetamine or apomorphine treatment at 10 weeks, in contrast to sham rats in which these responses were suppressed, suggesting enhanced mesolimbic dopamine activity. [Supported by MRC Canada].

467.4

BEHAVIORAL PROFILE OF THE D2 / D3 / 5-HT1A PARTIAL AGONIST, PD 158771: A POTENTIAL ANTIPSYCHOTIC F. W. Ninteman*, A. E. Corbin, D. J. Johnston, J. N. Wiley,

L. Christoffersen, L. T. Meltzer and T. G. Heffner. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI, 48105.

PD 158771, a partial agonist at brain dopamine (DA) D₂ and D₃ as well as serotonin (5-HT)_{1A} receptors, produced antipsychotic-like behavioral effects in preclinical rodent and primate tests. PD 158771 inhibited spontaneous locomotion and blocked amphetamine- and apomorphinestimulated locomotion in mice and rats, effects consistent with its D₂ partial agonist activity. PD 158771 did not cause catalepsy in rats at a dose 20-fold higher than the ED₅₀ dose for locomotor inhibition. PD 158771 also produced anxiolytic-like effects in a Vogel conflict test in rats, effects consistent with its 5-HT_{1A} partial agonist activity, but did not show antidepressant-like effects in a behavioral despair test in rats. Like known antipsychotics, PD 158771 caused long-lasting and potent inhibition of conditioned avoidance responding (CAR) in squirrel monkeys but had a lower liability than haloperidol and SDZ 208-912 for inducing EPS in haloperidol sensitized squirrel and Cebus monkeys. EPS signs were absent at the CAR ED_{50} dose and were of lesser intensity than typical antipsychotics at multiples of the CAR ED₅₀ dose. These results suggest that PD 158771 may provide an improved antipsychotic profile. (Supported by Warner-Lambert.)

EFFECTS OF THE D₂/D₃/5-HT_{1A} PARTIAL AGONIST PD 158771, A POTENTIAL ANTIPSYCHOTIC ON MONOAMINE SYNTHESIS AND RELEASE IN RATS. H. C. Akunne*, S. Z. Whetzel, M. D. Davis, L. W. Cooke, L. T. Meltzer, T. G. Heffner, T. A. Pugsley. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

PD 158771 (PD) is a novel dopamine (DA) D₂-like and serotonin (5-HT_{IA}) partial agonist with minimal extrapyramidal side effects being developed as a potential antipsychotic (see Ninteman et al., and Zoski et al., at this meeting). As expected from the in vitro studies indicating partial DA agonist (PDA) actions, PD (3-30 mg/kg, i.p. or p.o.) antagonized the gamma-butryolactone (GBL)-induced accumulation of DOPA in striatum and mesolimbic regions of rat brain, causing a maximal 61 % reversal in striatum. PD (2.5 mg/kg, i.p.) inhibited the relatively slow neuronal firing of substantia nigra zona compacta DA neurons in chloral hydrate anesthetized rats, an effect reversed by haloperidol. Intravenous dosing of PD indicated that it produced partial inhibition of more rapidly firing DA neurons consistent with a PDA action. In absence of GBL, PD (0.3-30 mg/kg, i.p.) decreased DA synthesis in striatum and mesolimbic region, but not in frontal cortex probably reflecting a lack of DA autoreceptors controlling DA synthesis in this region. In intracerebral microdialysis studies, PD (10 mg/kg, i.p) decreased DA overflow from both striatum and nucleus accumbens of anesthetized rats, with the effect being greater in the nucleus accumbens than in the striatum. PD (0.3-30 mg/kg, i.p) decreased 5-HT synthesis and release in various brain regions probably reflecting an agonist action at 5-HT_{IA} autoreceptors on the dorsal raphe nucleus based upon its high affinity (K₂ = 3.5 nM) for 5-HT_{1/k} autoreceptors on the dorsal raphe indexes used upon to sign affinity (K₂ = 3.5 nM) for 5-HT_{1/k} receptors . PD (3-30 mg/kg, i.p.) did not effect DOPA accumulation in the NE-enriched brainstem arguing against potent alpha-adrenergic activity in rat brain. These findings indicate that PD exhibited agonist actions at DA autoreceptors and 5-HT_{1A} receptors in vivo, effects that may provide an improved antipsychotic profile. (Supported by Warner-Lambert.)

FANANSERIN (RP 62203), A POTENT D4/5-HT2A RECEPTORS ANTAGONIST IN PRECLINICAL STUDIES

FANANSERIN (RP 62203). A POTENT D_u/5-HT_{2A} RECEPTORS ANTAGONIST IN PRECLINICAL STUDIES
Piot O, Doble* A, Heuillet E, Pelitet F, Reibaud M, Betschart J, Pauchet C,
Obinu M-C, Malleron J-L, Mignani S and Imperato A.
Rhône-Poulenc Rorer, CRVA, Psychopharmacology, Vitry sur Seine, France
Fananserin (RP 62203), a naphtosultam derivative, exhibited higher affinity
for human dopamine D₄ receptors (Ki = 5.8 nM) than for D₂ receptors (Ki = 0.12 nM). Functionally, RP 62203 was an antagonist which
blocked the inhibition of forskolin-stimulated adenylate cyclase activity by
the dopamine agonist quinpirone and blocked the interaction of ³H-GTP_YS
with the activated D4 receptor/G protein complex. RP 62203 idi not
increase the extracellular concentrations of either dopamine itself or its
metabolites DOPAC and HVA in the frontal cortex in rats. RP 62203 had
also no effect on the metabolism or utilization of 5-HT. RP 62203 had
also no effect on the metabolism or utilization of 5-HT. RP 62203 dosedependently reduced acetylcholine release and the enhancement of
acetylcholine release induced by amphetamine in the prefrontal cortex in
rats. RP 62203 was able to block apomorphine-induced climbing and to
reduce some behaviours induced by relatively low doses of amphetamine
Moreover, RP 62203 has been shown to inhibit head-twitches produced by
different 5-HT agonists. Interestingly, RP 62203 reduced some effects
in humans. Unlike D₂ receptor antagonists, RP 62203 did not block the
conditioned avoidance responses in rats. RP 62203 did not block the
conditioned avoidance responses in rats. RP 62203 to induce extrapyramidal sideeffects in man. Certain atypical antipsychotics, in particular clozapine has
higher affinity for dopamine D₂ receptors and serotonin 5-HT₂, receptors
than for D₂ receptors. This preferential binding may be the basis of the
unique clinical profile of such compounds. The preclinical profile of
fananserin indicates that it may have promise as an antipsychotic agent.

CHRONIC LOW-DOSE HALOPERIDOL EFFECTS ON D3 INDUCED HYPOMOTILITY. M.R.Lynch* and J.Loucks Ormsby. V.A. Medical Center and S.U.N.Y. Health Science Center., Syracuse, NY 13210

Mesolimbic dopamine (ML DA) D3 receptors have been implicated in pathophysiologic substrates for schizophrenia. D3 agonism suppresses behavioral activity and decreases ML DA metabolism. Thus, D3 sites may participate in generating negative symptoms of schizophrenia (anergia and amotivation). We attempted to determine if 21 days of 0.1 mg/kg haloperidol (H) would induce an alteration in this receptor population, detected by behavioral assessment. We previously reported that similar treatments induce subsensitivity to low-dose apomorphine hypomotility, possibly via alteration in this D3 substrate. Matched groups of male, Sprague-Dawley rats (500-550g, n=16/group) received daily H or lactic acid (LA) and were retested on day 21 for photocell activity. Both groups then received acute 7-OHDPAT (7-OH, selective D3 agonist) or saline (S) 48 h after the last H or LA injection and were tested for 10 min in the activity chamber at 5 min post s.c. agonist or S. Acute 7-OH significantly suppressed behavioral activity, but rats 48 h withdrawn from H showed similar hypomotility. D3 agonism decreased both ML and striatal DA turnover, but these effects were also no different for chronic H versus LA. Funded by the Department of Veterans Affairs Medical Research Program.

RECEPTOR BINDING AND FUNCTIONAL CHARACTERIZATION OF THE D₂/D₃/5-HT_{1A} PARTIAL AGONIST PD 158771, A POTENTIAL ANTIPSYCHOTIC. K.T. Zoski, H.C. Akunne, L.M. Georgic, R. M. MacKenzie, T.A. Pugsley, Y.H. Shih, L.D. Wise, D.L. Wustrow, T.G. Heffner*, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI

Partial D₂ agonists (PDA) that have a preferential affinity for dopamine (DA) autoreceptors combined with serotonin (5-HT_{1A}) agonist action reduce DA as well as 5-HT synthesis and release, and could exert antipsychotic-like effects. PD 158771 (PD, {4-[2-(4-phenyl-piperazin-l-yl)-ethyl]-cyclohexyl}-pyrimidin-2-ylamine trans) exhibits antipsychotic/anxiolytic effects in certain rodent and monkey models (see Ninteman et al., this meeting). In vitro PD was shown to have potent affinity for human D21, D3 and D42 receptors expressed in CHO K1 cells with Ki values of 5, 14 and 35 nM, respectively. PD is a PDA with about 60 % and 23 %intrinsic activity at human D_{2L} and D_{3} receptor (inducing [3 H]thymidine uptake in CHO p-5 cells), respectively, as compared to quinpirole that exhibits 100 % intrinsic activity; at human D_{4,2} receptors the compound was antagonist-like. PD had high affinity for rat hippocampal ($K_i = 3.5 \text{ nM}$) and human ($K_i = 2.6 \text{ nM}$) 5-HT_{1A} receptors. Similar to the 5-HT_{1A} agonist 8-OH-DPAT, its affinity for 5-HT_{1A} receptors was reduced in the presence of the guanyl nucleotide Gpp(NH)p and the receptor density was increased with Mg²⁺, findings consistent with an agonist action at 5-HT_{1A} receptors. In addition, PD exhibited moderate affinity (K. < 100 nM) for 5-HT2, alpha, histamine H1 and sigma receptors and weak or no affinity for DA D₁, muscarinic, and a variety of other receptors. In conclusion, PD exhibited potent affinity and partial agonist actions at DA D₂₁, D₃ and 5-HT_{1A} receptors, results that could provide an improved antipsychotic profile. (Supported by Warner-Lambert.)

467.8

Effect of fananserin, a D4/5HT2 antagonist, on DA and ACh release in the prefrontal cortex of rats. Interaction with amphetamine.Mr. Obinu., J.M. Miquet and A. Imperato* Rhone-Poulenc Rorer, Centre de Recherche de Vitry-Alfortiville, 13 Quai Julies Guesde, Vitry sur Seine, France, 94403. Classical neuroleptics are known to induce acute and long-term extrapyramidal symptoms in up to 75% of patients. In contrast, clozapine has

been defined as an *atypical neuroleptic" because does not induce any significant extrapyramidal symptom and because, differently from classical neuroleptics, is active not only on positive but also on negative symptoms of

Clozapine has been found to be the only antipsychotic with higher affinity for D4 than for D2 dopamine receptors. Classical neuroleptics have similar

D4 than for D2 dopamine receptors. Classical neuroleptics have similar degree of affinity for both receptors. Hence, it seems that the preferentiality of clozapine for D4 compared to D2 receptors may be an important mechanism contributing to its "atypical" clinical profile. Fananserin, a naftosultam derivate, has recently been found to be selective for D4 receptors (Ki = 5.8 nM) compared to D2 receptors (Ki > 1000 nM). We studied its effect on DA and ACh release in the prefrontal cortex of rats, where studied its effect on DA and ALh release in the pretronal cortex of rats, where there is the highest density of D4 receptors, and we have observed that this compound at the doses of 3 and 15 mg/Kg s.c. does not modify DA release and metabolism. In contrast, haloperidol (0.25 mg/Kg s.c.) as well as clozapine (10 mg/Kg s.c.) increases DA release and metabolism. Moreover, fananserin (3, 5 and 15 mg/Kg s.c.) like haloperidol (0.25 mg/Kg s.c.) decreases ACh release and reduces the amphetamine-induced increase in

ACh release.
Since, fananserin has also a high affinity for 5HT2 receptors, we have Since, latitatiseriii rias also a riigii atimitiy for 5/1/2 receptors, we rave compared the effects of fananserin to those of ritanserin. We have observed that ritanserin (6 and 10 mg/Kg s.c.) does not modify DA release and metabolism but differently from fananserin does also not modify ACh release. The lack of increase in DA release could suggest that fananserin, better than haloperidol and clozapine, can reduce DA transmission and, consequently, be more effective as antipsychotic.

INCREASE IN DOPAMINERGIC INNERVATION OF THE CINCULATE CORTEX INDUCED BY CHRONIC, BUT NOT ACUTE, NEUROLEPTIC ADMINISTRATION IN THE RAT. A. J. Langa*1. Manklow, C.*, de Cabo, C.*, Vaccarino*, F.J. and Arifuzzaman*. A.I. Depts. 'Pharmacology and 'Posychology, University of Toronto, Toronto, ON, Canada Pharmacological studies of antipsychotic drugs (i.e., neuroleptics) reveal a consistent correlation between their climical efficacy and their affinity for dopamine (DA) receptors. While classical neuroleptics preferentially bind to the DA D₂ receptor, atypical neuroleptics, such as clozapine, have a higher affinity for the D₄ receptor. Previous studies have shown that in the precent rate further acute memorateric administration increases DA While classical neuroleptics preferentially bind to the DA D, receptor, atypical neuroleptics, such as clozapine, have a higher affinity for the D₄ receptor. Previous studies have shown that, in the mesostriatal system, acute neuroleptic administration increases DA release and turnover, as well as the affinity of tyrosine hydroxylase (TH) for its ptendine cofactor. In the mesostriatal system, tolerance to these neuroleptic-induced effects develop after chronic administration. Interestingly, in the mesocortical system tolerance to these effects does not occur. However, the neuroanatomical and cellular basis of these processes remains unclear. The aim of the present study was to assess the effects of acute and chronic administration of different DA antagonists on the regionally specific pattern of DAergic innervation of the cingulate cortex, using immunocytochemistry with antibodies against TH (the rate-limiting enzyme of DA synthesis). Male rats were assigned to two different treatment groups, and received daily i.p. injections for either 3 days (acute treatment) or 30 days (chronic treatment). In each group the animals were assigned to different drug-treated sub-groups, and received either the classical neuroleptic haloperidol (HAL, 2mg/kg), the splecial received either the classical neuroleptic haloperidol (RACLO, Img/kg), the splecial received either the classical neuroleptic haloperidol (RACLO, Jmg/kg), the selective D₁ antagonist SCH23390 (0.1mg/kg), or vehicle controls. The results obtained revealed that acute (3 days) administration of the different DA antagonists, as well as vehicles, did not alter the distribution pattern of TH-immunoreactive fibers in the different regions of the DAergic system. However, after chronic (30 days) treatment a dramatic increase in The DAergic innervation was observed in the cingulate area showing the highest increase in TH-immunoreactive (TH-IR) fibers was Cg3. In the HAL-treated animals, a strong increase in number and intensity of the TH-IR fibers was equally seen in

SCHIZOPHRENIA-LIKE LIMBIC-CORTICAL NEUROPATHOLOGY IN RATS: LOCOMOTOR RESPONSES TO ANTIPSYCHOTIC DRUGS. J. G. Csernansky*, P. S. Jacobs, J. L. Jackson, & M. E. Bardgett Department of Psychiatry, Box 8134, Washington Univ. Sch. Med., St. Louis, MO 63110.

Spontaneous and amphetamine-elicited locomotor activity in rats has been used as a reliable preclinical indicator of antipsychotic drug action. We have recently demonstrated that rats with limbic-cortical neuropathology exhibit a heightened level of novelty- and amphetamine-induced locomotor activity relative to controls. The purpose of the present study was to determine if the suppressive effects of antipsychotics on novelty and amphetamine-elicited behavior were altered in rats with limbic-cortical neuropathology. Young adult male rats (60 days of age) received ventricular infusions of kainic acid (KA) (4.5 nmol per side) or saline. Every rat which received KA exhibited hippocampal pyramidal cell loss and, in a minority of the lesioned rats, cell loss in the amygdala, piriform cortex, and laterodorsal thalamus was observed as well. Thirty days after surgery, lesioned and control rats were injected with either haloperidol (.15 mg/kg, s.c.) or clozapine (6.3 mg/kg, s.c.), at doses which bind approximately 50% of dopamine D₂ receptors in the nucleus accumbens. In response to both antipsychotics, lesioned rats demonstrated less suppression of novelty-and amphetamine-elicited locomotor behavior. These data indicate that limbic-cortical neuropathology can disrupt normative behavioral responses to antipsychotics, thus raising the possibility that limbic-cortical neuropathology may undermine the clinical efficacy of antipsychotic drugs. Schizophrenia-Like Limbic-Cortical Neuropathology in Rats: Delayed Effect of a Developmental Lesion. <u>E-M. E. Montgomery*</u>, <u>M. E. Bardgett, & J. G. Csernansky</u>. Department of Psychiatry, Box 8134, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Kainic acid (5nmol or 10 nmol/microliter concentration) or

Kainic acid (5nmol or 10 nmol/microliter concentration) or artificial CSF was delivered to post-natal 7 (P7) rats through a bilateral intracerebroventricular injection. Cell body counts were conducted at P8, P14, P45, and P75. Nissl stained coronal sections at the level of the dorsal and ventral hippocampus, striatum, and nucleus accumbens were examined.

Although the injection of kainic acid was delivered at P7, significant reductions in cell body populations were not observed until P45 and P75. In addition, kainic acid had a dose-dependent effect, with the greatest cell loss at P45 observed in the K10 group. At P75, significant cell loss was observed in both the K5 and K10 groups. Furthermore, significant cell loss was observed in the dorsal but not ventral hippocampus. In addition, the effects of kainic acid administration on Glur2/3 and GluR1 subunit expression were examined in the same areas and at the same ages.

examined in the same areas and at the same ages.

Since the neuropathology associated with schizophrenia may stem from developmental disruption of hippocampal efferents and abnormal mesolimbic glutamate-dopamine interactions, these results shed light on the pathogenesis of schizophrenia. THE DISCRIMINATIVE STIMULUS EFFECTS OF CLOZAPINE IN SQUIRREL MONKEYS. <u>I.Bagley, G.Carey and J.Bergman*</u> Harvard Medical School, NERPRC, Southborough, MA 01772-9102.

Drug discrimination procedures were used to study the involvement of serotonergic (5HT₂) and muscarinic (MUSC) actions in the interoceptivestimulus effects of clozapine (CLZ). Squirrel monkeys were trained to respond under a 10-response fixed-ratio schedule on one lever after injections of CLZ (1.0mg/kg,i.m.) and on a second lever after injection of vehicle. Cumulative dosing procedures were used to determine the effects of the 5HT-/MUSC antagonists cyproheptadine (CPR;0.01-3.0mg/kg) and promethazine (PRM;0.3-10.0mg/kg), the MUSC antagonists atropine (ATR;0.03-1.0mg/kg) and scopolamine (SCP;0.01-0.3mg/kg), and the 5HT₂ antagonists ritanserin (RTN;0.1-10.0mg/kg), ketanserin (KTN;0.1-17.8mg/kg) and cinanserin (CNN;0.1-17.8mg/kg). SCP, ATR, PRM and CPR produced dose-related increases in responding on the CLZ associated lever and, at one or more doses, fully substituted in all monkeys. KTN, RTN and CNN produced responding on the CLZ-associated lever (avg < 40%) but did not fully reproduce the effects of CLZ in any monkey. However, combinations of moderate doses of SCP (0.01-0.03mg/kg) and KTN (0.1-0.3mg/kg) or CNN (10.0mg/kg), but not RTN, fully mimicked the effects of CLZ in all monkeys. These results suggest that the discriminative stimulus effects of clozapine in squirrel monkeys involve its actions at both 5HT2 and MUSC receptors. (supported by USPHS DA003774 and MH07658)

SCHIZOPHRENIA-LIKE LIMBIC-CORTICAL NEUROPATHOLOGY IN RATS: FOS RESPONSE TO ANTIPSYCHOTICS. D. L. Roe, M. E. Bardgett, C. A. Csemansky*, & J. G. Csemansky Department of Psychiatry, Box 8134, Washington Univ. Sch. of Med., St. Louis, MO 63110

Fos, the protein product of the immediate early gene, *c-fos*, is proving useful in the preclinical assessment of antipsychotic drugs (APDs), since it has been found that typical and atypical APDs produce distinctive patterns of Fos induction. While both induce Fos in the nucleus accumbens shell, typical APDs also induce Fos throughout the striatum. Previous work in this lab has shown that increases in dopamine turnover following acute haloperidol are diminished in the accumbens shell in rats that have received intracerebroventricular (ICV) infusions of kainic acid (KA). ICV infusion of KA also produces graded neuronal loss in several limbic-cortical brain areas that show signs of pathology in schizophrenia. Thus, we hypothesized that similar differences should be seen in Fos induction in KA lesioned and non-lesioned animals. In the present study, rats received ICV infusions of either KA (4.5 mmol) or vehicle. At 25-28 days post-lesion, rats received either 17.8 mg/kg clozapine, 1.5 mg/kg haloperidol, or saline, and were sacrificed three hours later. These drug doses were chosen to produce a maximal Fos response. Fos production was assessed in several regions, including the nucleus accumbens core and shell, and the striatum. Though the differential patterns of Fos induction produced by clozapine and haloperidol were in agreement with previous studies, no significant differences were found between lesioned and non-lesioned animals. We are now gathering data at additional lower doses of clozapine and haloperidol. Supported by MH01109 to MB.

CLOZAPINE AS A DOPAMINE D₁ RECEPTOR AGONIST.
<u>P. Salmi</u>^{1,2} and S. <u>Ahlenius</u>^{2*}, Division of Biological Psychology¹,
Department of Psychology, Stockholm University, Stockholm, Sweden
and Department of Behavioral and Biochemical Pharmacology², Astra
Arcus AB, Södertälje, Sweden.

Clozapine is generally considered to be an antagonist at dopamine D_1 receptors. Thus, clozapine not only blocks adenylyl cyclase-activity coupled to dopamine D_1 receptors but also various dopamine D_1 receptor agonist-induced behaviors in the rat.

In the present study we have examined rat body temperature after administration of clozapine and its two major metabolites. Clozapine (0.625-10.0 mg kg⁻¹, s.c.) produced a robust hypothermia in the rat. This effect was not observed after administration of the two major clozapine metabolites, N-desmethylclozapine (0.625-10.0 mg kg⁻¹, s.c.), or clozapine-N-oxide (0.625-10.0 mg kg⁻¹, s.c.), suggesting that the two metabolites do not contribute to the hypothermia produced by clozapine administration. Furthermore, the clozapine-induced hypothermia was fully blocked by pre-treatment with the selective dopamine D₁ receptor antagonist NNC 687 (4.0 mg kg⁻¹, s.c.), providing evidence for dopamine D₁ receptor agonist properties of clozapine. Thus, the present study demonstrates the efficacy of clozapine as an agonist at dopamine D₁ receptors involved in temperature regulation in the rat. We suggest that the intrinsic efficacy of clozapine at dopamine D₁ receptors may importantly contribute to its atypical profile as an antipsychotic.

467.16

SOME BEHAVIORAL EFFECTS OF CLOZAPINE AND NOVEL ANTIPSYCHOTICS IN MONKEYS. J. Tidey*, G. Carey and J. Bergman. Harvard Medical School, NERPRC, Southborough, MA 01772.

The atypical antipsychotic drug, clozapine, has several therapeutic benefits which have prompted the search for compounds with similar behavioral actions. The present experiments were conducted to compare the behavioral effects of clozapine (CLZ), haloperidol (HAL), and the novel drugs olanzapine (OLAN), seroquel (SER), risperidone (RIS) and remoxipride (REM) in squirrel monkeys using three procedures. In a procedure related to conditioned avoidance, which may predict the potential antipsychotic activity of drugs, CLZ and OLAN were found to decrease response rates without greatly increasing the delivery of multiple shocks; the other drugs both decreased response rate and, at doses at least-2- to 3-fold higher, increased the delivery of multiple shocks. In an observational procedure, all drugs except CLZ and SER produced catalepsy-associated behavior (static, rigid and/or abnormal postures and movements) in all monkeys. In a drug discrimination procedure, in which monkeys were trained to discriminate injections of CLZ from those of saline, CLZ, SER, and OLAN dose-dependently increased responding on the CLZ-associated lever. SER fully reproduced the discriminative stimulus effects of clozapine; OLAN partially substituted for CLZ at doses up to 0.3 mg/kg but higher doses eliminated responding. These results suggest that SER and OLAN have behavioral effects similar to those of CLZ and may have promising therapeutic advantages. (supported by DA03774, MH07658, and RR00168).

A MARMOSET MODEL FOR TARDIVE DYSKINESIA

Per E. Andrén* and Lars M. Gunne. Dept. of Pharmaceutical Biosciences and Dept. of Psychiatry, Ulleråker, Uppsala University, PO Box 591, S-75124

Tardive dyskinesia (TD), a potentially irreversible syndrome of involuntary movements following long-term neuroleptic administration, is characterized by orofacial dyskinesias and/or choreoathetoid movements in limbs and trunc. TD-symptoms similar to those seen in humans have been observed in experiments on monkeys (Cebus apella, Macaca speciosa, Macaca mulatta) following long-term treatment with neuroleptic drugs.

In the present study we have investigated the possibility of using marmosets (Callitrix jacchus) as a model for TD. Six marmosets were administered haloperidol-decanoate (Haldol Depot 5-15 mg/kg i.m.) once a month. After 21 months of treatment three animals showed occasional perioral twitchings and grimacing as well as tongue protrusions. Two of these animals had a frequency of masticatory movements which was less than 6 times/min whereas one animal had masticatory movements of 6-20 times/min and also showed dyskinetic movements in the right leg and arm. All neuroleptic-treated monkeys showed somewhat rigid movements, decreased rapidity of coordinated movements, head checking and vocalizing. Our investigations demonstrate that marmoset monkeys treated for months or years with haloperidol-decanoate will develop symptoms resembling TD.
This study was supported by the Swedish MRC grant #11565.

ALTERATIONS IN NMDA RECEPTOR DENSITY IN A RAT MODEL OF TARDIVE DYSKINESIA. <u>M. F. Egan*, E. Hamid, S. Baca, T. M. Hyde</u>. NIMH Neuroscience Research Center at St. Elizabeths, Washington, D.C. 20032

Long-term neuroleptic treatment in rodents induces a syndrome of vacuous chewing movements in some (+VCM group) but has little effect in others (-VCM group). The VCM syndrome, a behavioral analogue of tardive dyskinesia (TD) in humans, has been used to investigate the neurochemistry of TD. To assess the role of alterations in cortical regulation of the striatum we measured NMDA receptor density using quantitative Rats were treated for 36 weeks with haloperidol autoradiography. decanoate or vehicle and then withdrawn for an additional 28 weeks. VCM ratings were performed every 3 to 4 weeks. A +VCM group, a -VCM group and vehicle-treated controls were selected for post mortem studies (N=10 to 12 per group). Tritiated MK801 was used to label NMDA receptors in sections through the mid striatum and nucleus accumbens. An overall group effect was found (F=18.0, p=.0001). This effect was most pronounced in the ventromedial striatum and the core region of the nucleus accumbens. Post hoc comparisons demonstrated that -VCM rats had lower levels than +VCM and vehicle-treated controls. +VCM rats were intermediate between -VCM and control groups. These findings parallel changes reported previously in CCK gene expression in the medial prefrontal cortex, where -VCM rats had reduced levels compared to +VCM and vehicle groups. The data suggest that -VCM rats have greater alterations in glutamatergic corticostriatal activity compared to +VCM rats. The VCM model may be useful in elucidating the role of altered prefrontal regulation of subcortical structures in TD. Funding for this research was provided by NIMH.

Norway. ²GRECC Unit, Bedford VA Medical Center, Bedford MA, ³Massachusetts
General Hosp. and Harvard Medical School, Boston, MA.

The pathophysiologic basis of tardive dyskinesia (TD) remains unclear. It has been proposed that TD may be a result of excitotoxic neurodegeneration in the striatum caused by a neuroleptic-induced increase in striatal glutamate release striatum caused by a neuroleptic-induced increase in striatal glutamate release and impaired energy metabolism. To investigate this hypothesis, haloperidol decanoate (HAL; 38 mg/kg every 4 weeks IM) and the succinate dehydrogenase inhibitor 3-nitropropionic acid (3-NP; 8 mg/kg/day via osmotic minipumps), were administered alone or together (HAL/3NP) for 16 weeks to 4 months old female Sprague-Dawley rats (n=15-18/group). Control rats received sesame oil IM and had empty plastic tubes SC. Vacuous chewing movements (VCM), a putative analogue to human TD, were recorded during and after drug treatment. 3-NP, HAL, and HAL/3NP treatments resulted in increased VCM. VCM. Nowever, was more pronounced and appeared earlier in the HAL/3NP rats. however, was more pronounced and appeared earlier in the HAL/3NP rats. After drug-withdrawal, increases in VCM persisted for 20 weeks in the HAL After drug-windrawar, increases in Ver M persisted for 20 weeks in the FAM and HAL/3NP rats. Brains from each group were analyzed for histopathological alterations. Bilateral striatal lesions were present only in rats with high levels of VCM in the HAL/3NP treated rats. Nerve cell depletion and astrogliosis were prominent histopathologic features. There was selective neuronal sparing of both large- and medium-sized aspiny striatal neurons. These results suggest that mild mitochondrial impairment in combination with neuroleptics results in stratal excitotoxic neurodegeneration which may underlie the development of persistent VCM in rats and possibly irreversible TD in humans.

MU OPIOID RECEPTORS AND TARDIVE DYSKINESIA: A STUDY ON A RAT MODEL OF TD. E. H. Hamid*, T. M. Hyde, S. M. Baca, and M. F. Egan. National Institute of Mental Health, Neuroscience

and M. F. Egan. National Institute of Mental Health, Neuroscience Center at St. Elizabeths Hospital, Washington, DC 20032.

Chronic neuroleptic therapy induces tardive dyskinesia (TD) in a sub group of patients on this class of medications. Similarly, in a rat model of TD, chronic haloperidol treatment induces vacuous chewing movements (VCMs) only in a sub group of treated animals. Examining the neurochemical differences between rats with (+VCM) and without (-VCM) neuroleptic-induced dyskinesia may shed light on the pathophysiology of TD. Previous studies on the TD rat model has shown an induction in enkephalin mRNA in rat striatum after chronic treatment with haloperidol, suggesting rat striatum after chronic treatment with haloperidol, suggesting the involvement of mu-opioid system in the development of VCMs. To test this hypothesis, rats were treated with haloperidol decanoate or vehicle for 36 weeks and withdrawn for 28 weeks. VCM, VCM groups as well as vehicle controls were selected for post mortem receptor autoradiography studies that was performed using ³H-DAMGO as a specific ligand for mu-opioid receptors. Our data show a significant reduction in mu-receptor density in dorsolateral, dorsomedial, and ventromedial striatum in both the +VCM and -VCM groups compared to vehicle treated rats. No significant differences were seen between +VCM and -VCM groups. The results indicate that chronic haloperidol treatment produces a very long term down-regulation of mu-opioid receptors. These results also suggest that endogenous mu-opioid receptors are not directly involved in the expression of VCMs, yet it does not exclude their role in eliciting motoric side effects after long term

IN VIVO $^{31}\mathrm{P}$ NMR SPECTROSCOPY SHOWED AN INCREASE IN THE GLYCEROLPHOSPHORYLCHOLINE CONCENTRATION IN THE PRE-FRONTAL CORTEX OF SCHIZOPHRENIC PATIENTS. Y. Shirayama*, T.

Yano, K. Takahashi and T. Ogino. Dept. Psychiatry, Kanto Teishin Hospital, Div. Biochem. Cellular Biology, National Institute of Neuroscience, NCNP and Dept. Psychiatry, National Center Hospital, NCNP, Tokyo, Japan. Phospholipid metabolism of cell membranes and high energy phosphate metabolism in the prefrontal cortex of patients with schizophrenia (12 males) receiving neuroleptic medication were studied non-invasively with in vivo 31P NMR localized (ISIS) spectroscopy operating at 2 Teals and compared to prome control care matched 16 males). non-invasively with in VIVO "IP NMH localized (ISIS) spectroscopy operating at 2 Tesla, and compared to normal controls (age matched 16 males). Phosphodiesters (PDE) are breakdown products of phospholipids while phosphomonoesters (PME) are precursors of membrane phospholipids. The peak intensities of PDE's components, glycerolphosphorylethanolamine (GPE) and glycerolphosphorylcholine (GPC), and PME's components, phosphorylethanolamine (PE) and phosphorylcholine (PC). in the ³TP MMR spectra were analyzed using a non-linear least squares method combined with prior knowledge of the chemical shifts. Absolute metabolite concentrations were quantified using a spectrum that was acquired using the same ISIS sequence from a phantom containing a phosphate solution of known concentrations. T₁ of each component was measured by a localized (cereberum) inversion recovery method to compensate saturation effects. This strategy provided a high accurate method for the concentration estimates. (mean error : less than 5 %). The schizophrenic patients showed an increased concentration in GPC but not other phospholipid metabolites such as GPE, PE and PC. No differences in high energy phosphate metabolism including phosphocreatine, inorganic phosphate and adenosine triphosphate were observed between controls and patients. The alteration in the GPC concentration may contribute to pathophysiology of schizophrenia with mild negative syndrome.

A MEDIAL PREFRONTAL 1H MRS STUDY OF NEVER-TREATED A MEDIAL FRONTAL MAD SOLD OF WEEK HAZED SCHIZOPHRENICS AND NORMALS. P.C. Williamson, R. Bartha, D.J. Drost, A. Malla, N. Rajakumar and J.P. Girvin, University of Western Ontario, London, Canada N6A 5A5.
The objective of this study was to quantify medial prefrontal levels of N-

acetyl aspartate (NAA), glutamate (Glu), glutamine (Gln), y-aminobutyrio acid (GABA), choline (Cho) and phosphocreatine and creatine (PCr) with ¹ magnetic resonance spectroscopy (MRS) in never-treated schizophrenic patients (n = 9) compared to normals (n = 9) matched for age, sex, and parental education. Single volume MR spectra (4.5cc) were acquired on a Siemens SP4000 Helicon whole body imager operating at 1.5 Tesla with a STEAM sequence (TR=1500ms, TE=20ms, TM=30ms, 550 averages, 4096 points, 250 μ s dwell time, total time=14 minutes). All data were analyzed in the time domain using an automated fitting algorithm incorporating *in vitro* prior knowledge of metabolite peak characteristics. Metabolite levels were normalized to the water signal from the region of interest. No significant differences were found in levels of NAA, Glu or Cho between the groups in this region which included anterior cingulate cortex However, schizophrenic patients had higher levels of Gln (p < 0.010) and PCr (p < 0.090) and lower levels of GABA (p < 0.025) compared to normals (t-test, one tailed). As Gln is a precursor of Glu, decreased glutamatergic activity was suggested in schizophrenic patients. Decreased GABA levels may reflect a loss of interneurons which has been reported on post-mortem examination. Findings are consistent with the involvement of basal ganglia thalamocortical pathways in schizophrenia.

DOSE-DEPENDENT EFFECTS OF METHYLPHENIDATE ON ACTIVITY, ATTENTION, AND MAGNETIC RESONANCE MEASURES IN CHILDREN WITH ADHD. M.H. Teicher*, A. Polcari, C.D. English, C.M. Anderson, S.L. Andersen, C.A. Glod, P. Renshaw, Dept Psychiatry, Harvard Med. School, McLean Hospital, Belmont MA 02178.

Twelve prepubertal children with ADHD completed a four week triple-blind placebo controlled trial of methylphenidate (MPH: 0.5, 0.8 and 1.5 mg/kg in divided dose). Activity was assessed using an infrared motion analysis system that tracked the position of 4 reflective markers 50 times per sec. to a resolution of 0.04 mm while they completed a repetitious continuous performance attention task (Teicher et al 1996). MR data were obtained at each dose using a 1.5T GE Signa scanner with an Advanced NMR Systems whole-body echo planar coil. T2* relaxation times were calculated from a 32 echo planer spin echo series using incremental increases in TE.

MPH exerted strong effects on composite measures of activity and attention. Activity measures were 61.1% worse on placebo than in normal controls. Subjects were 33%, 5.6%, and 2.4% overactive on low, intermediate, and high dose, respectively ($F_{3,33} = 3.3$, p = 0.03). Patients were 19.8%, 10.1% and 2.1% less attentive than normal controls on placebo, low and intermediate dose, and were 1.5% more attentive on high dose ($F_{3,33} = 9.49$, p = 0.001).

There were striking associations between blind MRI and quantitive behavioral measures. In 7 males with completed vol. measures there was a 0.892 correlation between right caudate vol. and number of movements (microevents) on placebo (p = 0.01). Similarly, in 8 subjects with complete and analyzed T2* measures, there was a 0.810 correlation between right caudate T2* and number of microevents (p = .015). The optimal dose of MPH for each subject exerted significant effects on frontal and caudate T2* (p = 0.013), which varied by hemispere (p = 0.008), affecting right hemisphere much more than left. MPH decreased caudate and increased frontal T2*. (Supported by NIMH RO1 48343 (MHT) & John Alden Trust (PR)).

MRI MEASUREMENTS OF THE AMYGDALA-HIPPOCAMPUS COMPLEX AND THE PARAHIPPOCAMPAL GYRUS IN SCHIZOPHRENIA. K. Vladar*, R.W. Buchanan, W.T. Carpenter. Maryland Psychiatric Research Center, UMAB, Md, 21228.

Measurements of the amygdala-hippocampus (AH), parahippocampal gyrus (PHG) are presented in a large group of patients with schizophrenia, and age, race, gender, handedness, and SES matched controls (Sch Male: 37, Healthy Male: 20, Sch Female: 22, Healthy Female: 16). Three mm contiguous coronal MR-images of the brain were used to measure the whole extent of the structures. PHG was divided into anterior and posterior part, the anterior part containing mostly the entorhinal cortex. The presence and extent of the uncal notch was also assessed on a scale of 0-2. A series of ANCOVA procedures were used to analyze the results of volume estimations, side (R or L) used as repeated measures, total cranial volume and age as covariates. Notch assessment was analyzed by Chi-square statistics. Mean volumes (adjusted for total cranial volume) were smaller for every measurements in the schizophrenia group. There was a significant main effect for the volume of AH and the total PHG by diagnostic groups (P < 0.004, p < 0.04, respectively), but no significant diagnostic groups (1 < 0.04, p < 0.04, respectively), our significant effect by gender or side. The group difference in PHG was accounted for by the anterior part (Tukey test p < 0.04), with no significant contribution from the posterior part. Volume measurements for both AH and PHG were strongly correlated in the schizophrenia group (p values < 0.000), while a modest correlation was found in the healthy control group(p < 0.03 and p<0.06). There was no significant difference by diagnostic group in the presence and extent of the uncal notch.

MRI-ASSISTED MEASUREMENTS OF EEG ASYMMETRIES IN SCHIZOPHRENIC PATIENTS F. Yang, R. Coppola, M. Myslobodsky, and D.R. Weinberger CBDB, NIMH Neuroscience Center at St. Elisabeths, Washington, DC 20032

This exploratory study aims to investigate whether the corrections of electrode placements based on individual MRI data alter interhemispheric EEG asymmetry values. EEG was derived from 32 channel recordings in 6 pairs of MZ twins discordant for schizophrenia (relaxed wakefulness, eyes closed). An interactive algorithm was developed for projecting surface electrode locations to the 3D brain rendering based on 3D MR images acquired in the sagittal plane, 124 slices at 1.5 mm spacing. Given that no α difference between the twins was obtained α values were pooled. Spearman r was computed between total α (8.5 - 12.5 Hz) and lateral brain asymmetry values assessed at the top 20% of the dorso-ventral length (DVL) in the plane passing through P3-P4 and slanted at 32-39° to the AC-PC plane. Full range α values were found to correlate at statistically significant level (r = .51, p < 0.05) with lateral brain asymmetry. The significance was contributed by slow alpha (α_1) (8.5 - 10.5 Hz) (\mathbf{r} = .56, \mathbf{p} < 0.05). Fast alpha (α_2) (10.5 - 12.5 HZ) showed modest and statistically nonsignificant correlations with brain asymmetry index. The magnitude of r values for α and α_1 was reduced when electrodes were repositioned so as to maximize the anatomical homotopy of locations. The difference between the twins emerged when θ (6.0 - 8.5 Hz) and δ (0.5-6 Hz) bands were compared. Both correlated significantly with frontal asymmetry at F3 and F4. These data indicate that imbalanced EEG potentials depend to a significant extent upon anatomical brain asymmetry. It is thus imperative to use individual MRI data to provide corrections of bilateral electrode placements.

GRAY MATTER VOLUME DEFICITS IN WEIGHT-RECOVERED ANOREXICS. E. K. Lambe, D. K. Katzman, D. J. Mikulis, and R. B. Zipursky*. Clarke Institute of Psychiatry, Toronto, Ontario, Canada.

Structural changes have been observed in the brains of low-weight anorexics, including increased cerebrospinal fluid (CSF) and decreased gray matter. We hypothesized that recovered anorexics would show reduced gray matter and elevated CSF volumes compared to controls.

matter and elevated CSF volumes compared to controls.

We used magnetic resonance imaging (MRI) to compare the brains of 12 weight-recovered anorexics (mean age ± standard deviation: 19±7 years; time recovered: 5±6 years, range 1-23 years) with 18 healthy controls (mean age: 20±7 years) and 13 acutely ill anorexic adolescents (mean age: 15±1 years). Axial, dual-echo scans of the whole brain were segmented into gray matter, white matter, and CSF compartments using Brain Image software developed in 1949 by Reiss. Brain measures were corrected for the significant effects of intracranial volume and age, based on regression analysis of 30 healthy female controls.

T-tests showed that the weight-recovered group had significantly smaller gray matter volumes (p<.01) and greater CSF volumes (p<.01) than normal controls. By contrast, the recovered anorexics had significantly smaller CSF volumes (p<.01) and greater gray (p<.05) and white matter volumes (p<.05) than low-weight anorexics. Neither the gray matter deficits nor CSF elevations in the recovered group were correlated with the length of time since recovery.

The persistent gray matter volume deficits in recovered anorexics suggest that there may be an irreversible component to the brain changes associated with anorexia nervosa. The neuropathological features of this irreversible component have yet to be explained.

RELIABILITY AND VALIDITY OF A PROCEDURE FOR MEASURING SPECIFIC REGIONS OF THE PREFRONTAL CORTEX: A MAGNETIC RESONANCE IMAGING STUDY. R.W. Buchanan, K. Vladar, W.T. Carpenter, P. Barta, and G. Pearlson*. Md. Psych. Res. Ctr., Univ. of Md., Baltimore, Md, 21228.

Altered prefrontal cortical function has been implicated repeatedly in the pathophysiology of schizophrenia. Attempts to examine if this altered function reflects structural changes in the prefrontal cortex have been hampered by the failure to examine more functionally and structurally homogeneous subregions. We have developed reliable neuroanatomical landmarks for dividing the prefrontal cortex into superior, middle, inferior, and orbital regions. These landmarks are "drawn" on a 3-dimensional MRI representation of the brain. The four regions are then "painted" with different colors, with the colors depicted on MRI slices displayed in the coronal, sagittal, and transaxial views. The total gray matter volume of each region is estimated by the Cavalieri method, using the "paint" and the three views to guide the measurements. The validity of the procedure was examined in 19 normal controls (NC) (14 males and 5 females) and 18 schizophrenic patients (SP) (12 males and 6 females). The only regions that significantly differentiated SP from NC were the right and left inferior prefrontal cortex (which include Broca's Area) (mean±SD) (right: SP: 7.7±1.5; NC: 9.1±2.1; t=2.26, p=.03; left: SP: 8.0±1.5; NC: 9.0±1.6; t=2.39, p=.02). The relationship of these prefrontal region volumes and symptom and neuropsychological test performance data will be presented.

SEX DIFFERENCES IN REGIONAL PREFRONTAL ANATOMY IN PATIENTS WITH SCHIZOPHRENIA P.E. Cowell*, R.A. Adler, M.X.-H. Yan, R.I. Grossman# and R.E. Gur, Depts. of Neuropsychiatry & Neuroradiology#, University of Pennsylvania Philadelphia PA 19104.

University of Pennsylvania, Philadelphia, PA 19104.

A prior study from our lab showed sex differences in correlations between symptom severity and frontal lobe size in patients with schizophrenia. The present study examined subfields of the prefrontal cortex to further probe differences in cortical anatomy between men and women with schizophrenia, and compare them to normative sex differences. Subjects were 27 controls (12 men; 15 women) and 22 patients with schizophrenia (14 men; 8 women). Spoiled GRASS MRIs with Imm slice thickness were obtained from a 1.5 Tesla scanner at UPENN. MRIs were segmented for gray matter, white matter and CSF, then aligned to a standard sagittal plane on which prefrontal regions were drawn. Prefrontal cortex was divided into 4 subfields within each hemisphere: dorsolateral; dorsomedial; orbitolateral; orbitomedial. Interrater reliability for 10 cases yielded ICCs of. 81-.99. Analysis of covariance with repeated measures was used to investigate regional effects of schizophrenia and their interactions with sex. Diagnosis and Sex were classifying variables: Dorsal vs. Orbital (DO), Medial vs. Lateral (ML), Hemisphere (RL), and Tissue Type (GW) were repeated measures; Cranial Volume and Age were covariates. Examination of the DO x GW x Diagnosis effect (p<.05) revealed that, overall, dorsal gray subfields were smaller in patients than controls. Post-hoc analyses of the DO x ML x GW x Diagnosis x Sex effect (p<.01) indicated that sex differences in patients were localized to the dorsolateral prefrontal white matter - women had smaller volumes than men (p<.01). Sex differences in controls were nonsignificant and similar in magnitude across all subfields. These findings suggest that the neurodevelopmental processes distinguishing patients from controls may be semi-independent of those underlying sex differences within schizophrenia . Funded by MH42191 & MH43880.

EVENT-RELATED POTENTIAL AND NEUROANATOMICAL CORRELATES OF LANGUAGE COMPREHENSION DEFICITS IN SCHIZOPHRENIA. P. B. Ward*, C. Levitan, C. Loneragan, B. Liebert, J. Redenbach, E. Ganser, S. Chaturvedi, S. V. Catts, P. T. Michie, S. Andrews, N. McConaghy, School of Psychiatry, University of New South Wales, Sydney, 2052 Australia.

This study examined the relationship between ERP indices of compatible processing. (MAO) and deviations of the processing (MAO) and deviations of the processing (MAO).

This study examined the relationship between ERP indices of semantic processing (N400) and auditory sensory memory (mismatch negativity: MMN), MRI-derived volumetric measures, and measures of language comprehension in schizophrenic patients. N400 was elicited by visual presentation of sentences with congruous and incongruous endings. MMN was elicited by infrequent deviant longer duration tones (100ms) presented among shorter (50ms) standards while patients undertook a simple visual distraction task. 3D volumetric MRI scans were obtained, and cortical areas visualized and measured using the BRAINS package developed at the University of lowa (NC Andreasen et al). Language comprehension was assessed using the Relational Concepts scale of the Luria-Nebraska Neuropsychological Battery, WAIS Vocabulary and Comprehension scales and the Peabody Picture Vocabulary Test. Twenty five patients, all of whom meet DSM-III-R criteria for schizophrenia and are completely right-handed, were tested. Language comprehension deficits were associated with reduced left hemisphere N400 amplitudes, and were not correlated with MMN amplitudes. Such deficits were also correlated with reduced left superior temporal gyrus volumes, but not with measures of prefrontal cortical volume. These results are consistent with lateralised temporal cortical dysfunction as the neural basis of language comprehension deficits in schizophrenia. PREFRONTAL CORTEX ACTIVATION IN SCHIZOPHRENIA IS RELATED TO RESPONSE ACCURACY ON A WORKING MEMORY TASK AS MEASURED BY FMRI D. S. Manoach, D.C. Goff, G. Schlaug, C. Saper, D. G. Darby*, A. Benfield, R. R. Edelman, and S. Warach. Dept. of Neurology, Beth Israel Hosp.. Harvard Med. Sch., Boston. MA 02215.

Previous studies have shown altered activity in prefrontal cortex in schizophrenia ("hypofrontality"). We investigated whether a non-spatial working memory task would lead to task-related signal changes in prefrontal cortex and whether activation would be associated with performance. Task-related signal change was examined using the Sternberg Item Recognition Paradigm (SIRP) and fMRI. The SIRP is a continuous performance, choice reaction time test that requires working memory. Eight male schizophrenic subjects were visually presented with 5 target digits to remember. Following presentation of the targets, subjects responded to single digits that appeared on a screen by pressing triggers to indicate whether or not the digit was a target. In the control condition, which did not involve working memory, subjects responded to the visual display of arrows pointing right or left by pressing the corresponding trigger. Reaction time and trigger press were recorded for both conditions. Eight contiguous axial slices were acquired using a gradient-echo echoplanar imaging sequence and a 1.5T Siemens Vision scanner to detect changes in cerebral blood oxygenation (BOLD technique) related to task condition. Regions of activation were determined by cross-correlation analyses using a boxear reference function to compare the working memory condition to the control condition. Suprathreshold prefrontal cortical activation was observed in 5 of the 8 subjects. The 3 subjects who did not show activation in this region made significantly more errors in the working memory condition. These findings suggest that prefrontal activation on working memory tasks in schizophrenics may depend on ability to perform

CEREBRAL GLUCOSE METABOLISM IN CHILDHOOD ONSET SCHIZOPHRENIA

L.K. Jacobsen, 'A.J. Zametkin, 'A.C. King,' S.D. Hamburger,' J.D. Van Hom,' K. F.
Berman, 'J.A. Frazier, 'K. McKenna, 'C.T. Gordon, 'J.L. Rapoport*

Child Psychiatry Branch, ²Clinical Brain Disorders Branch, NIMH, NIH, MD, 20892 Decreased frontal cortical glucose metabolism has been frequently replicated in adult schizophrenics both at rest and while engaging in tasks normally associated with increased metabolism in this brain region, such as the Continuous Performance Test (CPT). This relative "hypofrontality" may reflect abnormal development of neural circuitry subserving the frontal cortex. Cerebral glucose metabolism was examined in 16 adolescents (mean age 14.2±1.7) with onset of schizophrenia by age 12 (mean age at onset 9.9±1.8) and 26 healthy adolescents matched for age, sex, and handedness. Subjects were injected with 33.7 to 50.3 Mbq of ¹⁸F-fluorodeoxyglucose shortly after beginning a 30 minute auditory CPT task with eyes patched.

Schizophrenics made fewer correct identifications (hits, t=3.11, p<01) and more incorrect identifications (false alarms; t=4.67, p<.001) during the CPT. Region of interest analysis revealed no significant group differences in global cerebral glucose metabolism, but increased metabolism in parietal (F=6.74, p<.05) and posterior frontal regions (F=7.09, p<05) and decreased metabolism in anterior frontal (F=6.72, p<.05) and posterior medial frontal (t=2.04, p<.05) regions in schizophrenics. After controlling for performance for the subset of 13 schizophrenics and 20 healthy subjects for which performance data were available, schizophrenics continued to show increased parietal metabolism (F=5.27, p<05). Negative symptoms were significantly negatively correlated with anterior frontal (r=.68, p<.01) and anterior temporal (r=.52, p<.05) regions and positively correlated with posterior frontal regions (r=.52, p<.05).

These findings support neurobiologic continuity between childhood and adult onset schizophrenia and suggest that events leading to emergence of schizophrenic symptoms in association with abnormal neurodevelopment can occur in early adolescence. NIMH

VERBAL MEMORY AND REGIONAL BRAIN VOLUME IN SCHIZOPHRENIA JM Goodman*, LJ Seidman, JM Goldstein, EA Hoge, DN Kennedy, N Makris, VS Caviness, MT Tsuang, Dept. of Psychiatry, Harvard Medical School and Center for Morphometric Analysis, MGH. Charlestown, MA 02129
Although memory impairment in schizophrenia is well documented, the nature

Although memory impairment in schizophrenia is well documented, the nature and cause of the dysfunction remains unclear. Methods: We used the California Verbal Learning Test, a 16 item multiple trial list learning task, to assess auditory verbal episodic memory acquisition, storage and retrieval in 28 schizophrenic patients and 24 matched controls. Subjects also underwent whole brain MR imaging for calculation of regional brain volumes. We hypothesized that schizophrenics would demonstrate impaired encoding and retrieval, and would have regional brain volume deficits in areas thought to contribute to episodic memory processes. Based on neuroimaging and lesion studies, we hypothesized that encoding would correlate with left prefrontal volumes, storage with medial temporal lobe and thalamic volumes, and retrieval with prefrontal, cingulate and precuneal volumes. Results: Schizophrenics performed significantly more poorly than controls on total number of words learned and were less likely than controls to use semantic information to aid encoding. Patients also benefited disproportionately from a recognition vs a free recall test format, indicating a retrieval strategy deficit. Patients did not, however, show accelerated rates of forgetting. Significant differences in regional brain volumes were detected in the thalamus, hippocampus-amygdala complex, anterior cingulate gyrus, and the left middle frontal gyrus. Significant correlations between regional brain volumes and memory measures which were present in normals were absent in schizophrenic patients. Conclusion: Schizophrenic patients have structural abnormalities in a widely distributed system for episodic memory which contribute to disruption of memory functions.

TEMPORAL CORTICAL VOLUME CORRELATES WITH ILLNESS DURATION IN FIRST EPISODE SCHIZOPHRENIA G.L. Haas', M.S. Keshavan, J.A. Sweeney, N.R. Schooler, W.W. Bagwell, and J.W. Pettegrew. Center for Neuroscience of Mental Disorders (CNMD), Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15213 Cumulative evidence indicates volume reductions in temporal cortex in schizophrenia, particularly on the left side. Observations of an association between illness duration and temporal lobe volume reductions have also been found in schizophrenia. These findings have been taken to support a progressive neuropathological process in schizophrenia. In this study, we examined the association between indices of illness duration (time from onset of prodrome to first psychotic symptom, and time from onset of first psychotic symptom to assessment) and the volume of brain structures implicated in the pathogenesis of schizophrenia, i.e. the superior temporal cortex, the amygdala-hippocampal complex, prefrontal cortex, caudate, and lateral ventricles in a series of 18 neuroleptic-naive, first-episode DSM-III-R schizophrenic patients. All scans were conducted using a 3-D SPGR pulse-sequence and morphometric measurements were carried out by a rater blind to clinical information Duration of illness was inversely correlated with left superior temporal cortical volume (p<.01) and left amygdala-hippocampal complex volume (p<.04), controlling for age and cranial size. Caudate volume did not vary with duration of psychotic symptoms; instead, caudate volume was inversely correlated with duration of prodrome (p<.01) and age of first prodromal behavior change (p<.05). Each of these findings was more prominent in males. No such relationships were seen in prefrontal cortical or lateral profition in flash. No such relationships were seen in periodic conteal or lateral ventricular volumes. These findings suggest that there may be progressive changes in temporal lobe independent of treatment. In contrast, caudate abnormalities appear to be related to the age at onset of the earlier behavioral changes. Other brain regions implicated in schizophrenia, such as PFC, may not manifest evidence of progression during the early phase of illness. KETAMINE-INDUCED EFFECTS ON BEHAVIOR AND rCBF IS ENHANCED IN SCHIZOPHRENIC COMPARED TO NORMAL NDIVIDUALS A.C. Lahti*, H.H. Holcomb, M.A. Weiler, P.K. Corey, M. Zhao, D. Medoff, C.A. Tamminga, MPRC, University of Maryland School of Medicine, Baltimore, MD 21228

We have previously shown in schizophrenia that the non-competitive NMDA antagonist ketamine in subanesthetic doses produced a dose-dependent short-lived exacerbation of psychotic symptoms (Lahti 1995) and that regional cerebral blood flow (rCBF) measured using H₂¹⁵O and PET increased in anterior cingulate, and diminished in hippocampal and primary visual cortex (Lahti, 1995). We have now compared this response in schizophrenics with that in normal volunteers. individuals (n=10) show a dose-related increase in psychotic features with Multidudas (II-10) show a dose-related inclease in psychiatric states included illusions and perceptual distortions, unusual thought content and suspiciousness. These were milder than symptoms in schizophrenic patients who experienced hallucinations, delusions and thought disorganization. The effect of ketamine lasted longer in patients than in normals (26.6 (±5.2) minutes for patients, 16.6 (±8.2) minutes for normals). The effect of ketamine on rCBF changes was evaluated by contrasting the first three post ketamine injection scans (6,16 and 26 minutes after ketamine) with the three baseline scans. Both normals and schizophrenics showed an increase in anterior cingulate rCBF, but the activation was significantly greater (P<0.05) in schizophrenics. Differences in the course of rCBF changes over 65 minutes in the two groups will be presented. These data suggest that already-psychotic persons are more sensitive to the effect of ketamine and implicate a dysfunctional glutamatergic system in schizophrenia.

REGIONAL BRAIN ACTIVITY ASSOCIATED WITH PURSUIT GAIN IN FIRST DEGREE RELATIVE OS SCHIZOPHRENIC PATIENTS. G.A. ODriscoll*, C. Benkelfat, R. Joober, S. Lal, S. Mattysse, P. Holzman, P. Florencio, S. Evans, McGill University, Department of Psychology, Montreal, Canada, H3A 1B1.

Compared with normal controls, schizophrenic patients and their first-degree relatives have elevated rates of abnormal eye tracking. This familial pattern is not found in non-schizophrenic psychotic disorders. These data suggest that eye tracking deficits are a manifestation of a genetically-mediated brain pathology in schizophrenia. We used positron emission tomography (PET) and the ¹⁵O water bolus subtraction method to characterize patterns of brain activation associated with pursuit eye tracking deficits in first-degree relatives and matched controls. Subjects performed smooth pursuit and fixation in the PET scanner. Eye movements were monitored with high-speed infrared oculography.

We predicted that relatives and controls would differ in activation of frontal eye fields (FEF), a hypothesis supported by correlations between pursuit quality and performance on frontal neuropsychological tasks in schizophrenic patients and relatives (Katsanis and Iacono, 1991; Park and Holzman, 1994). Preliminary results (10 first degree relatives, 7 controls) support this prediction. Activity in right FEF was significantly correlated with a measure of pursuit quality, gain (r=.58). Activity of motion area MT/MST, an area sensitive to target movement on the retina, was negatively correlated with FEF activity (r=-.69), and with pursuit quality (r=-.44). These results suggest that alterations in frontal function may underlie eye tracking deficits in first degree relatives. However, data collection is ongoing, and a larger sample size is warranted.

468.17

THE METHODOLOGICAL TEST-RETEST EFFECTS OF REPEATED [15]O PET BLOOD FLOW IMAGES IN SCHIZOPHRENIC AND NORMAL VOLUNTEERS AT REST AND DURING TASK PERFORMANCE. D.R. Medoff*, H.H. Holcomb, A.C. Lahti, Z. Zhao, L. Chen, C.A. Tamminga, Maryland Psychiatric Research Center, University of Maryland School of Medicine, P.O. Box 21247, Baltimore, MD 21228

Blood flow studies allow up to 15 or more scans to be completed in the same person in the same imaging session. Therefore this technique is suitable to explore the effects of a variety of behavioral and/or pharmacologic probes in a repeated measures type design. However, time in the scanner itself may have a significant effect on metabolic activity, which may vary across subject populations or activity state. We have looked at the time effect and the variability across scans of the same condition in normal controls and schizophrenic patients during rest, a sensory motor control task, and a demanding attentional task in which subjects were fully trained. Comparisons between the four rest scans showed that both normals and schizophrenics had significantly greater blood flow in the frontal and temporal areas in the first scan compared to the following three scans. Over time, regardless of condition, there was a trend for the posterior cingulate to have decreased blood flow in normal controls. These findings are an important consideration in the design and interpretation of blood flow data. In particular it highlights the importance of having more than one scan per experimental condition and to be sure the order of the scans is counterbalanced.

468.16

RESPONSE TIME (RT) VERSUS rCBF CORRELATIONS IN SCHIZOPHRENIC PATIENTS (SZ) AND NORMAL VOLUNTEERS (NV) DURING TONE RECOGNITION H. H. Holcomb. A. C. Lahti, D. R. Medoff, P. J. Caudill, P. Corey, D. Warfel, Z. Zhao, L. W. Chen, and C. A. Tamminga. Maryland Psychiatric Research Center, University of Maryland School of Medicine, Baltimore, MD 21228.

Healthy observers take longer to make recognition decisions about stimuli that are similar than about stimuli that are different. As the observer's accuracy falls the RT normally increases. In this PET study of tone recognition we have determined how healthy NV differ from unmedicated SZ, in rCBF vs. RT correlation patterns. Fourteen unmedicated schizophrenic patients and twelve healthy volunteers were scanned using the bolus water, H₂¹⁵O PET methodology. During each study subjects made 60 forced choice decisions, each during a fixed 2 second intertrial interval, regarding the frequency identity of the stimuli, high or low. Accuracy and RT were digitally recorded for each trial. The average RT for accurate trials was correlated with rCBF using SPM95 statistical methods. Whereas the NV group exhibited a positive correlation between RT and rCBF in the right frontal cortex, the SZ group's significant positive correlations were restricted to bilateral middle temporal gyri. Significant negative correlations for NV were found in the cerebellum and right primary auditory cortex; SZ subjects exhibited a significant negative correlation in the left primary motor cortex. The patient group's correlation pattern differed significantly from the NV group's. These observations are consistent with the SZ group's inability to assign greater neural activity to the sensory-motor system during fast accurate decisions, and to the frontal lobe during slow recognition choices. SYMPOSIUM. NEUROBIOLOGY OF OB PROTEIN (LEPTIN): A PERIPHERAL SIGNAL ACTING ON CENTRAL NEURAL NETWORKS TO REGULATE BODY ENERGY BALANCE. L.A. Campfield, Hoffmann-La Roche (Chairperson); J. Flier, Harvard Univ.; S.C. Chua, Rockefeller Univ.; S.C. Woods, Univ. Washington.

OB protein is secreted from adipose tissue, circulates in plasma and acts on central neural networks controlling body fat through coordinated regulation of feeding, metabolism and the autonomic nervous system. Following demonstration of biological activity, OB protein binding to choroid plexus led to the cloning of a central OB-R receptor. L. A. Campfield will present an overview of OB protein neurobiology including the effects following central administration, localization of central OB-R receptors, and patterns of neuronal activation following peripheral and central administration of $C\!B$ protein. J. Flier will discuss the role of OB protein in the modulation of neuroendocrine responses to fasting and obesity. S.C. Chua will review the role of mutations of the OB-R receptor in the development of the phenotypes of the obese diabetes (db/db) mouse and obese fatty (fa/fa) rat. S. C. Woods will review studies on the interaction of centrally administered OB protein with insulin and other neuropeptides on central neuronal networks and the resulting coordination of behavioral and metabolic effects. A discussion period involving the audience and the speakers will end the symposium.

.

SYMPOSIA

SYMPOSIUM: GLUTAMATERGIC NEUROTRANSMISSION: A VIEW FROM THE DENDRITE. R. Weinberg, UNC, and F. Conti, Univ. Ancona (co-chairs); L. Trussell, Univ. Wisconsin; H. Monyer, Univ. Heidelberg; R. Huganir, Johns Hopkins; F. Edwards, University College (London).

Glutamate plays a central role in neurotransmission. By integrating recent data from multiple disciplines, we will provide a functionallyoriented overview of current research into glutamate, from the point of view of the postsynaptic dendrite. Trussell will review electrophysiological data and modeling studies showing how glutamate diffusion and uptake interact with different ionotropic receptors to shape the EPSC. Monyer will review data from molecular biology, biophysics, and immunocytochemistry showing the influence of subunit composition on channel conductances. Calcium entry (via NMDA receptors or calciumpermeable AMPA receptors) may activate kinases and other second messengers. Huganir will discuss how phosphorylation may influence glutamate receptors, and present recent data on proteins that may be involved in anchoring receptors at the synaptic membrane. Edwards will review the structure of simple and perforated excitatory synapses in the hippocampus, explaining how synaptic heterogeneity may account for the observed distribution of synaptic events, and raising the possibility that changes in synaptic structure may underlie long-term plasticity.

LOCALIZATION OF Ca²⁺-BINDING DOMAINS IN HUMAN (hslo) Ca²⁺-ACTIVATED K* CHANNELS. J.D. Krause* C.D. Foster & P.H. Reinhart, Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710, and Dept. of Pharmacology GlaxoWellcome Research Institute, RTP, NC 27709.

We have used a combination of site-directed mutagenesis and inside-out patch clamp analysis to localize Ca^{2^+} -binding domains in Ca^{2^+} -activated K^+ channel α -subunits analysis to location and the state of the s channel. In order to determine whether amino acid substitutions at these sites alter the apparent Ca^{2+} sensitivity by disrupting a Ca^{2+} binding domain or by perturbing protein rearrangements subsequent to Ca^{2+} -binding, we have measured the selectivity for channel activation by calcium versus other divalent cations. This measure is expressed as the ratio of the concentration of each divalent ion required to half maximally activate the channel at zero membrane potential, normalized to the concentration of calcium required to activate the channel. For the wild-type channel the normalized ratio for $[Ca^{2^+}]:[Sr^{2^+}]:[Mn^{2^+}]$ is approximately 1:120:2000. Thus, Ca^{2^+} is three orders of magnitude more potent than Mn^{2^+} and two orders of magnitude more potent than Sr^{2^+} in activating the channel. For mutations which act downstream of Ca^{2^+} -binding it is assumed that this ratio should remain largely unaffected, whereas, mutations which act by disrupting the Ca²⁺-binding site are likely to perturb this ratio. Mutating asparagine 222 to serine (N222S) reduces the apparent sensitivity to these three ions approximately 100-fold, without significantly changing the potency ratio. In contrast to this effect, neutralization of aspartate residues in two separate C-terminal domains causes a large shift in the potency ratio. Mutating aspartate 358 to asparagine (D358N) gives rise to a potency ratio of 1:200:15 while mutations at a second site (D886N) give rise to a potency ratio of 1:100:10. These observations indicate that at least two distinct C-terminal domains contribute to the formation of Ca²⁺-binding sites, and regions of the protein more proximal to the pore participate in the structural rearrangements leading to channel activation. A "CALCIUMSTAT" CONTROLS BK CHANNEL GATING. M. Schreiber and L. Salkoff* Department of Anatomy and Neurobiology, Washington University School of Medicine. Saint Louis. MO 63110.

Washington University School of Medicine, Saint Louis, MO 63110.

The high conductance Ca²⁺-activated K* channel (mSlo) plays a key role in regulating calcium entry in a variety of cell types. Our previous analysis of the functional architecture of this channel indicates that it has two distinct parts: a "core" resembling a voltage-dependent K+ channel, and an appended "tail" that provides the calcium-sensing function (Wei et al., 1994). To reveal the function of the tail in gating, we created two mutants which differ in sensitivity to calcium by a factor of 10⁴. We then coexpressed them to create mosaic channels. Single channel analysis detected five forms, corresponding to five stoichiometries. Each exhibited a unique calcium dependence. were similar, however, with regard to voltage sensitivity and activation kinetics. Several lines of evidence suggest that all four tails are needed for channel activation and may form a single structure, a "calciumstat," which senses free calcium. Calcium, however, binds independently to at least one site on each tail. Binding of calcium to the calciumstat regulates the conformational free energy difference between the closed and open states of the channel, and sets the position of its g/V curve on the voltage axis. The substitution of a hypersensitive mutant tail for a hyposensitive mutant tail contributes an incremental amount of conformational free energy equivalent to a shift of -45 mV. The apparently simple opening kinetics of all mosaic forms suggests a single voltage-dependent step leading to channel opening. This could be explained by the calciumstat cross-linking the four voltagedependent subunits, in effect creating a single voltage sensor out of four Supported by the NIH and the Muscular Dystrophy Association (L.S.)

DEVELOPMENT OF A COMPETITIVE RT-PCR METHOD FOR QUANTIFICATION OF Slo AND PNMT mRNA IN ADRENAL TISSUE. J. Xie. P. Lappas, W. Yao, E. Carpenter-Hyland, and D.P. McCobb*. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Stress-related stimuli to the adrenal medulla dramatically alter mRNA levels of catecholamine synthetic enzymes such as phenylethanolamine N-methyl transferase (PNMT) in adrenal chromaffin cells. To determine whether transcripts for specific ion channels which control catecholamine secretion in these cells are similarly regulated by stress factors, we have developed competitive RT-PCR methodology for quantification of Slo (BK-type calcium-activated potassium channel) as well as PNMT expression. Specific competitor templates to be added in known quantity to samples of adrenal mRNA containing unknown quantities of native templates were constructed for Slo and PNMT using a simple PCR-based strategy. 20bps were inserted into the wildtype sequence before transcribing in vitro to make competitor RNA. Estimates of native template are made by measuring relative intensities of gel bands of native and competitor RT-PCR products from a series of reactions containing different amounts of competitor. The point at which products would be equal is determined by fitting a line to the log function of product ratios for the series Corrections for differences in amplification efficiencies and product length are made first. Experiments in which rSlo transcript amounts were measured gave surprisingly consistent results, supporting the quantitative accuracy of the method. RSIo mRNA in six rat adrenal glands was measured twice, and the mean ratio of first to second trials was 1.07 \pm 0.15 (SD). The ratio for left and right glands from the 3 animals was 0.94 ± 0.19. Our best estimates of Slo copy number in 25ng of total RNA, obtained by averaging data from left and right glands, were 16,000, 16,100, and 20,200 for the 3 animals. This method will allow us to measure changes in expression accompanying alterations in neural and hormonal inputs to the gland. Supported by Cornell University.

COUPLING OF CHARGE MOVEMENT AND PORE OPENING IN A HUMAN MAXI K CHANNEL (*HSLO*): NUMBER OF CHARGES PER CHANNEL. <u>E. Stefani* and L. Toro.</u> Dept. of Anesthesiology, UCLA, Los Angeles, CA 90095-1778.

We studied the coupling between gating and ionic currents of a Maxi K channel (hslo) and determined the number of effective charges per channel. We used Cs[†] to measure ionic currents, and tetraethylammonium to isolate gating currents (B). A shows G-V and Q-V curves of hslo expressed in oocytes. At negative voltages, a small amount of charge moves prior to pore opening indicating the presence of closed states prior to the open states. These initial closed states agree with the "Cole-Moore" shift in the ionic current. With further depolarization, in contrast to other voltage gated ion channels, the G-V curve crosses the Q-V curve and charge movement follows pore opening. Raising

internal Ca^{2+} shifts both curves. These results indicate that the channel transits through closed states before opening and that open transitions also carry charge. We normalized both the number of channels and the amount of charge per membrane capacity measured in 3-6 giant patches of the same cell; we obtained 4.4 ± 0.8 charges/channel (\pm SD, 3 cells). This number is consistent with less charged residues in the S4 region of *hslo* as compared to other voltage gated ion channels of the S4 superfamily. Supported by NIH. L. Toro is an EI of the AHA.

STABLE EXPRESSION OF THE HUMAN CA²⁺ ACTIVATED K+ CHANNEL α-AND β-SUBUNITS IN HEK293 CELLS. Philip K. Ahring. Dorte Strøbæk, Palle Christophersen. Søren-Peter Olesen and Teit E. Johansen+, NeuroSearch A/S, Smedeland 26, DK-2600 Glostrup, Denmark.

The high-conductance Ca²⁺ activated K⁺ channel (BK channel) is composed of an αsubunit and a β -subunit, of which the α -subunit gives rise to functional channels when expressed alone. We have stably expressed the BK α-subunit and co-expressed the α -subunit along with the β -subunit in HEK 293 cells. For co-expression we constructed a plasmid with two expression cassettes, the \alpha-subunit was expressed under the control of the CMV promoter and the β-subunit was expressed under the control of the SV40 promoter. Cell lines expressing the α-subunit have proved stable for more than 40 passages, and cell lines co-expressing the α + β -subunits for more than 20 passages. Studies of the modulation of the BK channel gating by changes in $[Ca^{2*}]_i$, presence of β -subunit, NS1608 and paxilline were carried out using I/O patches. The cells expressed 200-800 BK channels per patch giving rise to macro currents. The BK channel α-subunit was sensitive to changes in [Ca2+], in the physiological range 300-1000 nM with 50% channel activity at 18±6 mV (n=6) at 1000 nM [Ca²⁺]_i, as determined by tail current analysis. Presence of the β-subunit increased the voltage sensitivity as seen by a leftward shift of the activation curve by -30 mV (n=9) at $1000 \text{ nM} [\text{Ca}^{2+}]_i$. The β -subunit had no influence on the time constant for activation which was 1.38ms (α) and 1.33ms ($\alpha+\beta$). The time constant for deactivation, however, was increased from 2.53ms (α) to 13.78ms (α+β). 10μM NS1608 shifted the activation curves for the α + β -subunit towards negative membrane potentials by -47.7mV. This is similar to the NS1608-induced shift observed for the α -subunit alone, suggesting that the effects of the β -subunit and NS1608 are mediated by separate mechanisms. The effects of the BK channel blocker paxilline was independent of the presence of the β -subunit.

DISCRETE STEPS IN THE BIOGENESIS OF THE SHAKER K* CHANNEL REVEALED BY A MUTATION IN THE S3 TRANSMEMBRANE DOMAIN. C.T. Schulteis*, N. Nagaya, and D.M. Papazian. IDP Neuroscience and Department of Physiology, UCLA School of Medicine, Los Angeles, CA 90095-1751.

Department of Physiology, UCLA School of Medicine, Los Angeles, CA 9095-1751.

The biogenesis of voltage-dependent K* channels includes folding and assembly steps that establish tertiary and quaternary interactions. In Shaker K* channels, two potential quaternary interactions have been identified: (1) a homotypic N-terminal interaction critical for channel assembly and (2) an interaction between adjacent N- and C-termini detected in native channels by the oxidation of disulfide bonds between cysteine residues C96 and C505 (Schulteis et al., 1995, Biophys. J. 68: A266). The mutation D316K in transmembrane segment S3 of Shaker disrupts an intrasubunit interaction with K374 in the S4 segment, resulting in protein that fails to mature (Tiwari-Woodruff et al., 1996, Faseb J. 10: A145). To test whether the homotypic N-terminal interaction can be established in the presence of this folding mutation, we determined whether D316K subunits have a dominant negative effect on the expression of Shaker-IR subunits. D316K subunits exerted a strong dominant negative effect. This effect was mediated by amino acids 97-196 in the N-terminal as deletion of this domain eliminated the dominant negative effect. We also tested the proximity of the N- and C-termini in D316K by oxidation of protein in intact cells. C96 and C505 failed to form disulfide bonds between D316K subunits. Rescue of the folding defect in the double mutant D316K+K374E restored the C96/C505 interaction. These data indicate that the folding defect introduced by D316K prevents the C96/C505 interaction, but does not preclude the homotypic N-terminal interaction mediated by amino acids 97-196. Our results suggest that biogenesis of Shaker channels involves an initial step mediated by N-terminal interaction mediated by anino acids 97-196. Our results suggest that biogenesis of Shaker channels involves an initial step mediated by N-terminal interaction mediated by anino acids 97-196. Our results suggest that biogenesis of Shaker channels involves an initial step mediate

REGULATION OF INACTIVATION IN SHAKER POTASSIUM CHANNELS BY OXIDATION. <u>T. Hoshi* and S. H. Heinemann.</u> Physiology and Biophysics, Univ. of Iowa, Iowa City, USA and Max-Planck Society, Res. Unit "Mol. & Cell. Biophysics", Jena, Germany.

Inactivation time course of one variant of the Shaker potassium channel, ShC/B, exhibits considerable variability when expressed in Xenopus oocytes. At the single channel level, this variability is observed as the modal gating involving the fast inactivation and slow inactivation modes (Aldrich et al., Cold Spring Harbor Symp. 55, 19-27, 1990). We investigated the mechanism responsible for the variability in the inactivation time course of the ShC/B channels in Xenopus oocytes.

The whole-cell ShC/B currents recorded with a two-electrode voltageclamp amplifier show a complex inactivation time course. Frequently, the inactivation time course could not be readily described by a sum of exponential components. We hypothesized that oxidation may be involved in regulation of the inactivation process and examined the effects of chloramine-T (Ch-T) using the inside-out configuration of the patch clamp. Ch-T (200 µM) dramatically slowed the inactivation kinetics of the ShC/B. We also examined the effects of Ch-T on the ShB channel. The ShB and ShC/B channels differ only in the amino-terminus segment and share all the cysteine residues. However, Ch-T did not alter the ShB inactivation kinetics.

The differential effects of Ch-T on the two Shaker channels which

share the cysteine residues suggest that other amino acid residues may be oxidized or that the cysteine residues are differentially protected from oxidation. (Supported by HFSP).

THE SCALING OF PARAMETER MANIFOLDS IN COMPARTMENTAL MODELS OF HIPPOCAMPAL NEURONS. R. M. Eichler West* and G. L. Wilcox. Graduate Program in

THE SCALING OF PARAMETER MANIFOLDS IN COMPARTMENTAL MODELS OF HIPPOCAMPAL NEURONS, R. M. Eichler West* and G. L. Wilcox, Graduate Program in Neuroscience. Department of Pharmacology, and Minnesota Supercomputer Institute, University of Minnesota. Minneapolis. MN 55455.

We previously demonstrated the use of Genetic Algorithms (GAs) for selecting conductance parameters in compartmental models of hippocampal neurons (Eichler West and Wilcox, SNn abstract 21:788.7. 1995). Successful parameter choices demonstrated a high correspondence between simulated and experimentally-obtained behaviors for the fitness criteria chosen. Our previous GA application selected parameter manifolds for the 114 total conductance values (representing six channel types in each of 19 compartments) in the Traub model (J. Neurophysiol. 1991). In this present study, we extend this GA approach to select the conductance parameters in a morphometrically realistic compartmental model (51500 compartments).

Four results are presented. 1) The channel distributions selected for the full morphometric model are compared to those selected for the 19 compartment equivalent cylinder model. This comparison addresses the suitability of reduced complexity models for network simulations. 2) The GA also searched the morphometric model for calcium buffering terms defined with respect to volume and these results are reported. There was previously no one-to-one correspondence between the calcium terms and the physical dimensions of the model because Traub selected his parameters arbitrarily. 3) A function parameterization was developed for the GA search to reduce the complexity and dimensionality of the representation. This reduced the number of model evaluations needed to obtain a high fitness solution. 4) The contribution of local voltage-gated dimensionality of the representation. This reduced the number of model evaluations needed to obtain a high fitness solution. 3) The contribution of local voltage-gated and/or calcium-dependent channel conductances to t

GENETIC MAPPING OF QUANTITATIVE TRAIT LOCI ASSOCIATED WITH STRESS REACTIVITY IN THE WISTAR-KYOTO HYPERACTIVE RAT, P. Mormède*, H. Courvoisier and M.P. Moisan. Génétique du Stress, INSERM - INRA - Université de Bordeaux II France

In order to better understand the molecular mechanisms of interindividual variability of stress responses and associated pathology we have undertaken a genetic linkage analysis on a F2 intercross between 2 rat strains (Wistar-Kyoto Hyperactive and Wistar-Kyoto) that differ markedly in their stress reactivity. The phenotyping consisted of 3 behavioral tests (activity cages, openfield and elevated-plus maze) and several neuroendocrine measures (corticosterone, prolactin, renin activity) in blood plasma collected after novel environment stress. A multifactorial analysis was performed in order to synthesize these data and to classify each F2 rat according to its degree of reactivity along each independent factor. Each of these 196 F2 rats was also genotyped using 67 rat microsatellite genetic markers that were polymorphic for the parental strains. A major QTL related to the locomotor activity / reactivity was detected on chromosome 8, with a LOD score of 9.5, explaining 29% of the difference between the strains.

STRESS ELICITED ACTIVATION OF TYROSINE HYDROXYLASE AND DOPAMINE-β-HYDROXYLASE GENE EXPRESSION IN C-FOS KNOCKOUT MICE: TISSUE AND SEX SPECIFIC DIFFERENCES. <u>E. Sabhan¹</u>, <u>L. Serova¹*</u>, <u>E. Saez²</u>, <u>B. Spiegelman²</u> Dept. of Biochem. and Mol. Biol., New York Med. Coll., Valhalla, NY 10595. ² Dana-Farber Cancer Inst., Boston, MA, 02115.

Increased c-fos expression has been reported in many tissues to numerous types of stress. Increased binding of c-fos and c-jun to the AP-1 site of the TH promotor may be one of the regulatory mechanisms involved in mediating the response to stress. To test this hypothesis the effect of repeated immobilization stress (IMO) on tyrosine hydroxylase (TH) and dopamine-β-hydroxylase (DBH) gene expression was examined in c-fos knockout mice. Basal levels of TH mRNA in adrenals was similar in wild-type (+/+), heterozygous (+/-) and c-fos null (-/-) mice of both sexes. There was a large induction (6-10) fold in adrenal TH mRNA after 3 daily IMO in all genotypes, suggesting that either c-fos is not essential or another gene product can replace its effect. In contrast, basal levels of DBH mRNA in adrenals appeared to be reduced in the cfos deficient mice but were increased even more in -/- than in +/+ mice after IMO. In brain stem, DBH induction by stress was reduced in heterozygotes and fos deficient male mice or prevented in female mice. These results indicate that the c-fos gene has tissue specific influences on the regulation of DBH gene expression by IMO. (Supported by NIH grants NS32166 and DK31405).

CIRCULATING ANGIOTENSIN ILIS NOT INVOLVED IN REGULATION OF ADRENAL TYROSINE HYDROXYLASE GENE EXPRESSION INDUCED BY IMMOBILIZATION STRESS. R.Kvetnansky*, M.Rusnak, B.B.Nankova¹, S.Zorad, P.Blazicek, J.Jelokova, O.Krizanova and E.L.Sabban¹. Inst. Exp. Endocrin., Bratislava, Slovakia; ¹Dept. Biochem. & Mol.Biol., New York Med. Coll., Valhalla, N.Y. 10595

Immobilization (IMO) stress increases tyrosine hydroxylase (TH) gene expression in rat adrenal medulla (AM). The aim of this study was to examine the mechanism(s) of this change. Our previous results have shown that acetylcholine (ACH) and splanchnic innervation do not play a significant role in the elevation of TH mRNA levels induced by IMO. The rise in TH mRNA occurred even in denervated AM of hypophysectomized rats. These data suggest that messengers other than ACH or ACTH are involved in regulation of TH gene transcription. Angiotensin II (AII) was shown to induce TH gene expression in cell cultures. We evaluated a possible involvement of AII in IMO-induced TH gene expression. Repeated administration of AI (8 ng/kg, i.v.) did not affect levels of TH mRNA in AM. Saralasine, an AII receptors antagonist, did not affect control or IMO-elevated TH mRNA levels. Nephrectomy (N) caused more than a 95% decrease in levels of plasma renin which plays a major role in AII formation. After N no decrease but a significant rise in TH mRNA levels in unstressed rats was found and IMO-induced increase was not reduced. Thus, during IMO stress the adrenal medullary TH gene expression is activated by a nonneuronal and nonpituitary-mediated pathway without involvement of renin-angiotensin system. Supported by NIH Grant NS 32166; Slovak Grant Agency for Science (95/5305/043; 95/5305/272), LV-9301 Stress, and US-Slovak Project 93 024.

BEHAVIORAL EFFECTS OF PREPRO-TRH178-199 IN THE RAT FOLLOWING ICV ADMINISTRATION. R.F. McGivern¹, E. Redei² San Diego State Univ.¹, San Diego, CA 929120, Univ Pensylvania.², Phila., PA 19104

We have recently demonstrated an inhibitory influence of prepro-TRH₁₇₈₋₁₉₉ on ACTH secretion in vivo and in vitro, suggesting that it may function physiologically as a corticotropin release inhibiting factor (CRIF). Processing of the TRH prohormone yields several non-TRH hormones including prepro-TRH₁₇₈₋₁₉₉, a 22 amino acid peptide that is detectable by RIA in several brain regions activated by stress such as amygdala, septum, hypothalamus and periaqueductal gray. Behavioral studies of prepro-TRH₁₇₈₋₁₉₉ were conducted in adult male Sprague-Dawley rats following intracerebroventricular (icv) injection. Animals were tested in a 15" diameter open field for 30 minutes or in a light/dark box for 15 minutes. Each animal was removed from the home cage and injected with CRIF (0.6 ug/kg or 6.0 ug/kg in 3ul volume) or the vehicle 5 minutes prior to testing (N=6-17 animals/dose). Videotape analysis of the behaviors revealed that the 6.0 ug/kg dose of prepro-TRH₁₇₈₋₁₉₉ significantly increased several behaviors in the open field compared to vehicle treatment. These included grooming (p<0.0001), locomotor activity (p<0.01), rearing (p<0.05), and active sniffing (p<0.001). The 0.6 ug/kg dose of prepro-TRH₁₇₈. 199 significantly reduced rearing behavior throughout the testing period (p<0.05) and activity during the initial 5 minutes (p<0.05). In the light/dark box, the 6.0 ug/kg dose of the peptide significantly increased the number of entries into the light compartment (p<0.01) as well as the total time spent in that compartment (p<0.01). Overall, these results indicate that prepro-TRH₁₇₈₋₁₉₉ is behaviorally active and suggest that its effects include some fear-reducing and arousal properties. THE BRAIN POLYAMINE-STRESS-RESPONSE; PROGRESSIVE DEPLETION OF POLYAMINES. G.M. Gilad, J.M. Rabey' and V.H. Gilad. Lab. of Neuroscience, Dept. of Neurology, Tel Aviv-Sourasky Medical Center, and 'Dept. of Neurology, Assaf Harofeh Medical Center, Tel-Aviv 64239, Israel.

A transient increase in polyamine (PA) metabolism is a

A transient increase in polyamine (PA) metabolism is a common response to acute stressful stimuli. In the brain, repetitive stressor applications result in a recurrent increase in the activity of ornithine decarboxylase (ODC), the enzyme catalyzing the first limiting step in PA synthesis. We now sought to examine the effects of chronic intermittent stress (restraint, 3 h per day for 14 days) on PA concentrations (measured by reversed-phase HPLC method) in the hippocampus and on open field behavior of adult male C57BL/6 mice, and to study their modulation by treatment (intraperitoneal injections twice daily) with the ODC inhibitor α -difluoromethylornithine (DFMO, 200 mg/kg). The findings demonstrate that inescapable chronic intermittent stressors result in a recurring transient increase in putrescine, but lead to a progressive depletion of spermidine and spermine. DFMO treatment reduced the stressinduced putrescine increases, but did not prevent the reductions in PAs. Behaviorally, DFMO treatment led to a reduction in stress-induced open field activity. The study further implicates the PA-stress-response as an adaptive mechanism in the brain reaction to stressful stimuli. Supported in part by the German-Israeli Foundation for Scientific Research and Development.

CHRONIC RESTRAINT STRESS CAUSES ULTRASTRUCTURAL CHANGES IN RAT MOSSY FIBER TERMINALS A. M. Magariños*, J.M. Garcia Verdugo* and B.S. McEwen. Laboratory of Neuro-endocrinology, The Rockefeller University, New York, NY 10021; "University of Valencia, 46100, Burdassot, Spain.

Chronic repeated stress induces hippocampal atrophy in the apical dendrites of CA3c pyramidal neurons based on light microscopic Golgi impregnation analysis. This morphological change is correlated with deficits in spatial memory tasks and requires excitatory amino acid mediation since daily administration -before each restraint session- of an NMDA receptor blocker or the antiepileptic, phenytoin, prevents the stress-induced hippocampal atrophy. Since the major excitatory input to CA3 pyramidal neurons is the mossy fiber projection from the granule neurons in the dentate gyrus, we studied the ultrastructure of mossy fiber terminals in the stratum lucidum of restraint-stressed (6h/d/21d) male rats compared to controls. Fixed sections were dehydrated and flat embedded in Durcupan. Ultrathin sections were examined and photographed for ulterior morphometry. Undisturbed control rats showed mossy fibers terminals packed with synaptic vesicles evenly distributed. After 21d of daily restraint stress, animals showed terminals containing compact vesicle clusters that were restricted to 30% of the mossy fiber boutons area. No differences were found in the mean bouton area or mean invaginated dendritic spine area. However, the mean mitochondria area was larger in the mossy fiber terminals of restraint-stressed rats compared to controls. We suggest that repeated stress causes a presynaptic ultrastructural rearrangement that is associated with enhanced glutamate release. This is consistent with data showing by in vivo microdialysis that stress enhances glutamate release. (Supported by MH 41256, the Health Foundation and Servier, France).

DIFFERENTIAL EXPRESSION OF c-fos mRNA IN THE MALE SYRIAN HAMSTER BRAIN FOLLOWING SOCIAL DEFEAT OR RESTRAINT. S. Kollack-Walker*, H. Akil and S.J. Watson Mental Health Research Institute. University of Michigan. Ann Arbor. MI 48109-0720.

Social defeat in the male Syrian hamster is characterized by an increase in the levels of plasma cortisol and corticosterone and by the activation of specific subpopulations of neurons within the central nervous system [Kollack-Walker et al., Soc. Neurosci, Abstr., 21: 501]. To determine if the pattern of neuronal activation observed following defeat is present in other stressful situations, c-fos mRNA expression was analyzed in males who were stressed by social defeat or restraint. Beginning one week prior to testing, male hamsters were habituated to handling and to the novelty of exposure to another male's cage. On the day of the experiment, animals were either handled as controls or stressed by placing the animal in a restraint tube or allowing the animal to be defeated by a dominant male. Following 30 min of testing, all animals were killed by decapitation, their brains removed for c-fos in situ hybridization, and trunk blood collected for analysis of plasma cortisol and corticosterone levels. Results demonstrated increased c-fos mRNA expression within the prefrontal cortex, rostral septum, paraventricular nucleus of the hypothalamus and locus coeruleus of males exposed to either stressor, although the intensity of labeling appeared stronger in defeated males than in restraint males. In addition, c-fos mRNA increased selectively within the caudal septum, anterior, ventromedial and ventral premammillary nuclei of the hypothalamus, medial amygdala and dorsal periaqueductal gray in defeated males, and within the lateral hypothalamus and zona incerta in restraint males. These results suggest the presence of a neural circuit that responds to stressors in general, as well as circuits that reflect the unique physical and psychological qualities associated with social defeat and restraint. PIG NEOCORTEX MORPHOLOGY, BEHAVIOR AND IMMUNITY

J.M. McGlone^{1*}, J.L. Morrow-Tesch², M. K. Jarvinen³, S.D. Fullwood, T.

L. Powley³, ¹Texas Tech U., Lubbock, TX 79409-2141; ²USDA-ARS; ³Purdue U., W. Lafayette, IN 47907.

The domestic pig ($Sus\ scrofa$) is used for agricultural production and as a biomedical model. Aims were to determine age effects and diverse environments on development of the neocortex, behavior and immunity. Littermates (6 sets, half-sib, female) were randomly assigned to one of 3 treatments: euthanized at birth, or raised crossfostered and in an indoor, simple environment (fan ventilation & concrete floors) an outdoor, complex environment (straw on earth). After 8 weeks, behaviors were observed, blood was collected for immune measures, and pigs euthanized for brain tissue samples The primary auditory, somatosensory and visual neocortex were sectioned (Golgi-Cox staining). Non-truncated, layer IV neurons (n = 493) were digitized (Eutectics Neuron Tracing System). increased 15% (P < .01) in all 3 neocortex regions from birth to 8 weeks. Auditory cells decreased in length, membrane surface area and had fewer segments (all P < .001) at 8 weeks compared with birth. Visual cortex cells increased in length and membrane surface area (P < .05) at 8 weeks compared with birth. Pigs reared in more complex outdoor environments had more auditory dendritic segments than pigs reared indoors (4.86 vs. 4.24 ± 0.22 , P < .01). Outdoor pigs were more active and showed greater rooting (P < .05) than indoor pigs. Outdoor pigs had more white blood cells (P < .05) than indoor pigs, but lymphocyte proliferation, neutrophil chemotaxis and NK activity were similar for each. Diverse environments did not lead to neuroanatomical signs of deprivation. USDA-ARS, NIH DK27627 and NIMH01023.

EXPOSURE TO PREDATOR ODOR SUPPRESSES CELL PROLIFERATION IN THE DENTATE GYRUS OF ADULT RATS VIA A CHOLINERGIC MECHANISM. <u>L.A.M. Galea*, P. Tanapat, and E. Gould.</u> Lab. of Neuroendocrinology, The Rockefeller University, New York, NY 10021

The production of granule neurons in the dentate gyrus of the adult rat has been shown to be suppressed by adrenal steroids and excitatory input, factors that are both elevated in response to stress (Gould and Cameron, in press) These experiments were designed to examine the influence of a naturally aversive experience, exposure to predator odor, on the proliferation of cells in the dentate gyrus of adult rats. Using ³H-thymidine autoradiography, the production of cells in the dentate gyrus was examined following exposure to trimethyl thiazoline, a component of fox feces. Exposure to fox odor resulted in a rapid decrease in the number of ³H-thymidine labeled cells in the dentate gyrus. This suppression of cell proliferation was not the result of a stressinduced rise in adrenal steroids because the effect persisted in rats exposed to fox odor following adrenalectomy with low level corticosterone replacement. This effect was, however, prevented by pretreatment with the cholinergic muscarinic receptor antagonist scopolamine. These results indicate that exposure to fox odor inhibits cell proliferation in the adult dentate gyrus through a cholinergic, but not adrenal steroid, mechanism. These findings raise the possibility that suppression of cell proliferation plays a role in the integration of information regarding a potentially threatening experience

PROLONGED EXPOSURE TO STRESS REDUCES THE DOPAMINERGIC RESPONSE IN THE VENTRAL MEDIAL PREFRONTAL CORTEX TO A SUBSEQUENT STRESS EXPOSURE.

Brian A, Horger*, Bret A, Morrow, John D, Elsworth, and Robert H, Roth.
Departments of Psychiatry and Pharmacology, Yale University, School of Medicine,
333 Cedar Street, New Haven, CT 06520.

Stress-associated increases in dopaminergic (DAergic) activity in the ventral aspects of the medial prefrontal cortex (mPFC) have been postulated to have a role in the initiation of a coping response to the stressor. Prolonged exposure to restraint stress results in an initial increase in DA metabolism in the mPFC, peaking 20 min after stress onset, followed by a subsequent decline in DA metabolism, returning to baseline levels after 90 min of stress exposure (Roth et al., 1988, Ann NY Acad Sci, 537,138). Preexposure to a variety of short term (20-30 min) stressors has been shown to augment the DAergic response in the mPFC to a subsequent stressor. The present study examined the effects of prolonged exposure to uncontrollable stress on the DAergic response to a subsequent stress exposure in subregions of the mPFC. Male Sprague-Dawley rats were restrained for 120 min. Controls were unhandled. Twenty-four hours later, all subjects were restrained for 20 min before decapitation. HPLC analysis of tissue concentrations of DOPAC and DA revealed decreased stressinduced DA utilization (DOPAC/DA) in the ventral, but not dorsal, aspects of the mPFC in subjects that had received prolonged stress preexposure relative to controls Prolonged exposure to uncontrollable stress has been shown to induce a learned helplessness phenomenon where, during subsequent exposures to stress, subjects are less likely to engage in escape avoidance behaviors. Given the postulated role of the ventral mPFC in the initiation of coping behaviors, the present data may provide a relevant neurochemical correlate of learned helplessness. Supported in part by US PHS (MH 14092).

PREDATOR EXPOSURE STRESS INDUCES CHANGES IN EXPRESSION OF ZIF/268 MRNA IN THE RAT BRAIN JN. Nikulina* R.P. Hammer, Jr. E. Cooke, D.C. Blanchard, and R.J. Blanchard, Dept. of Psychology. University of Hawaii, Honolulu, HI 96822 and New England Medical Center, Boston, MA 02111.

In a painless model of psychological stress male rats were exposed to an innate threat stimulus, a predator. Rats were moved in their home cages to a test room and placed under an empty cat chamber with a mesh bottom. Five minutes later, a cat was introduced into the chamber for a one hour period. Controls were exposed to a toy cat. Rats were exposed to a predator for one or five daily sessions. Extremely high (80-90%) levels of crouching and freezing were observed during exposure to the cat, but not to the control stimulus. No evidence of behavioral habituation was found over five sessions. The rats were sacrificed two hours after the last predatory exposure and the brains prepared for in situ hybridization of zif/268 mRNA. Zif/268 is an immediate early gene that serves as a transcription regulatory factor that is rapidly induced in brain neurons by synaptic transmission. We used a [23S]-labeled oligonucleotide probe for in situ hybridization of zif/268 mRNA.

Ziff268 mRNA expression two hours after the single cat exposure was most prominent in basolateral armygdala. As ziff268 mRNA is usually markedly reduced at 120 min poinduction, such prolonged expression may be indicative of secondary neuronal activation. After five days of cat exposure ziff268 mRNA expression in basolateral armygdala was not reliably enhanced, suggesting habituation or reduced duration of the response seen after a single exposure. Behavioral habituation did not occur over the same regimen, suggesting either that there is not a one-to-one relationship between ziff268 mRNA expression in basolateral armygdala and behavioral response to the cat, or, that the ziff268 response became more restricted to the actual period of cat exposure over repeated sessions.

NEUROBIOLOGICAL CORRELATES OF POST-TRAUMATIC STRESS DISORDER_ID_Lewine*_I_Canive. WW Orrison Jr._IT Davis. JC Edgar_SL_Provencal_B Roberts. R Escalona. and D Graeber. The New Mexico Institute of Neuroimaging, The New Mexico Regional Federal Medical Center, 2100 Ridgecrest Dr, SE, Albuquerque, NM, 87111

Post-traumatic stress disorder (PTSD) is a condition precipitated by an unusually threatening event such as combat, torture, or rape. PTSD is unique among psychiatric disorders because the percipitating event can be clearly identified. The core features of PTSD include: (1) re-experiencing the traumatic event, (2) persistent avoidance of trauma-related stimuli or a general numbing of responsiveness, and (3) chronic and persistent symptoms of increased physiological arousal. PTSD is typically conceptualized as a psychogenic condition, but recent data suggest identifiable neurobiological correlates, and perhaps substrates of the condition. In the present study, brain structure and function were evaluated in 42 combat veterans with a diagnosis of PTSD and no history of head trauma or other neurological conditions Twenty control subjects without PTSD were also evaluated. Eleven PTSD patients showed abnormal cortical atrophy or white matter lesions on magnetic resonance (MRI) examination, whereas none of the control subjects had abnormalities. Electroencephalography and magnetoencephalography were used to examine the relationship between sound intensity and the magnitude of the 200 millisecond component of the auditory evoked response. For control subjects, 19 of 20 showed augmentation of the brain response as a function of sound intensity. The other control subject showed a reducing pattern with response amplitude to the loudest sound being less than that found for intermediate intensity sounds. Only 14 of the 42 PTSD patients showed the normal augmentation pattern. Eight PTSD patients had poor responses at all sound intensities, and twenty subjects were reducers. These data indicate that many PTSD patients have specific neurobiological abnormalities. Supported in part by grants from NARSAD and Picker International.

VISUAL CORTEX: EXTRASTRIATE-ATTENTION

TASK-RELATED MODULATION OF NEURONAL RESPONSES IN VISUAL CORTEX OF THE MACAQUE. A.E. Ipata. G. di Pellegrino. G. Gervasoni and L. Chelazzi.* Department of Neurological and Visual Sciences, Section of Physiology, University of Verona and Department of Psychology, University of Bologna, Italy.

Dominant views maintain that visual attention either selects input from a restricted region of space (space-based theories) or individual objects in the scene (object-based theories). The present single-unit recording study tested the hypothesis that visual attention can also lead to selective processing of individual features presented within a single spot of the visual field and belonging to the same object. A single colored, oriented bar (whose pair of features resulted from all possible combinations of 4 colors and 4 orientations) was presented inside the receptive field (RF) of neurons at the V1/V2 border and in area V4 of one macaque, while the animal had to discriminate either feature of the stimulus in different trials. 18 out of 45 cells at the V1/V2 border and 37 out of 63 cells in area V4, selective for color or orientation, or for both, responded differently to the same stimulus according to which feature the animal was required to discriminate. This effect was often specific to one of the colors and/or orientations that drove the neurons. Also, 17 out of 45 cells at the V1/V2 border and 20 out of 63 cells in area V4 varied their baseline firing rate depending on the task. In some neurons we also measured visual responses in a control condition where the animal had to detect a luminance change of the fixation point. 29 out of 38 cells at the V1/V2 border and 28 out of 31 cells in area V4 showed variation of the response to the RF stimuli in the control task relative to either or both peripheral discrimination tasks. These results support either a hierarchical model of selective attention whereby attention can in turn be directed to a certain region of space, then to an individual object within this region and finally to one of its constituent features, or a dynamic model whereby selective processing can be devoted to any kind of representation (spatial regions, integrated objects or individual features) according to current behavioral goals. ATTENTION INCREASES CONTRAST SENSITIVITY OF CELLS IN MACAQUE AREA V4. J.Reynolds*. T.Pasternak, and R.Desimone. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892 and Center for Visual Science, University of Rochester.

When two or more stimuli compete within a cell's receptive field, responses are determined by the attended stimulus. Such effects may be the result of an increase in sensitivity to the attended stimulus, which biases the competition between stimuli in its favor. To test for an increase in sensitivity, we placed a single patch of grating within the receptive fields (RF) of V4 neurons and measured responses to sequences of gratings over a range of contrasts. The monkey's task was to indicate when a target grating, which differed from non-target gratings in shape and orientation, appeared in the sequence. One sequence of gratings appeared within the RF, and a second, simultaneous, sequence of gratings appeared at a distant location outside the RF. The monkey's attention was manipulated by cueing it to perform the task at one location or the other.

With attention directed away from the RF, responses of cells increased with stimulus contrast, reaching saturation at higher contrasts (>20-40%). When the monkey attended to the RF, responses to low contrast gratings were typically stronger (17% increase). There was an increase in cells' contrast sensitivity with attention, which was on the order of 30% and was observed in over 70% of recorded neurons. The effects of attention diminished as contrast was increased, with, on average, no effect at the highest contrast. At all contrast levels, the spontaneous firing rate of the cells was higher when attention was directed to the RF. We interpret the boost in sensitivity and the increased baseline activity as evidence of a bias given to cells processing attended stimuli.

ATTENTION ENHANCES NEURONAL RESPONSES WITHOUT ALTERING ORIENTATION SELECTIVITY IN MACAQUE AREA V4.
C.J. McAdams* and J.H.R. Maunsell Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

We recorded from individual neurons in area V4 of a macaque monkey while he performed a delayed-match-to-sample task designed to reveal the effects of attention on orientation selectivity and response variability. Two stimuli were presented on each trial, one inside the receptive field and one outside. In the "attend" mode, the animal was required to signal changes in the orientation of the receptive field stimulus. In the "no-attend" mode the animal signalled changes in the color of the other stimulus. By recording responses elicited by sample stimuli of different orientations presented in the receptive field, we obtained two orientation tuning functions for each neuron under conditions of identical visual stimulation: one from the attend mode and the other from the no-attend mode. Most neurons (135/185) had orientation tuning curves for both conditions that were well fit by Gaussian functions. For 73% of these cells, the amplitude of the attend tuning function was greater than that of the no-attend tuning function (median +20.8%, n=135). In contrast, attention did not sharpen the tuning (median 0.6% narrower). Attention did not significantly alter the function relating the mean rate of firing to its variance (t-test, p>0.25). Because noise does not increase proportionally with the firing rate of cortical neurons, attention, merely by amplifying the responses to oriented stimuli, improved the theoretical discriminability of those stimuli (median change in d' -2.7%).

those stimuli (median change in d' -2.7°).

Thus, attention enhances responses without altering the underlying orientation selectivity or the inherent variability of neurons in area V4.

ATTENTIONAL MODULATION MAY UNDERLY SHIFT-INVARIANT VISUAL RESPONSES. E. Salinas*, and L.F. Abbott. Volen Center, Brandeis University, Waltham, MA 02254.

Recent neurophysiological results (Connor et al., J. Neurophysiol. 75:1306, 1996) indicate that some neurons in area V4 possess attention fields that are spatially localized but do not necessarily overlap with their classical receptive fields. Because attention modulates the amplitude of the visual responses, the firing rates of these neurons can be modeled as a product of two functions: one that depends on the location and type of visual stimulus, and another that depends on the distance between the current location of the attentional focus and the preferred attentional location for the cell, which is at the center of its attention field. Using theoretical calculations and computer simulations, we show that an array of neurons including different combinations of receptive field and attention field centers can serve as a basis set from which selective responses that are invariant with respect to shifts in the stimulus location can be constructed.

We model an array of neurons with filters similar to those of simple cells, but whose responses are also modulated in a multiplicative way by attention. These cells respond to presented images, and their activity drives an output neuron through synaptic connections. When the synaptic connections satisfy a simple mathematical condition, the output unit responds maximally to a preferred image appearing at the same position as the focus of attention. If the attentional focus is shifted, the location at which the preferred image elicits a maximum response shifts as well, to the current locus of attention. This mechanism does not interfere with the selectivity of the output neuron; its preferred image can be arbitrarily complex.

Thus, cells modulated by attention can drive downstream neurons with translation-invariant responses that can be highly selective for complex visual patterns, e.g., faces (Hasselmo et al., Exp. Brain Res. 75:417, 1989). Supported by NSF-DMS9503261 (L. F. A.) and the Conacyt-Fulbright-IIE program (E.S.).

MODULATION OF REAFFERENT VISUAL RESPONSES IN MONKEY LATERAL INTRA-PARIETAL AREA (LIP) J. Gottlieb*and M. E. Goldberg. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

In natural environments multiple stable visual stimuli are brought in and out of view by saccades. We designed a "stable array task" to mimic such an environment, and used it to study visual LIP neurons that had delay-period responses on standard delayed-saccade tasks (Kusunoki and Goldberg, Soc. Neurosci. Abstr. '95).

In the stable array task a circular 8-element array appeared once and remained on the screen for long blocks of trials (> 10 min). A peripheral fixation target appeared on each trial, from which the monkey made visually-guided saccades to the center of the screen, bringing at least one array element (a "RF stimulus") into the neurons' receptive field (RF). Neurons had no reafferent responses in this condition, regardless of initial fixation position. To examine whether this finding was due to the permanence of the array elements we removed one RF stimulus from the initial array, and turned it on at the onset, and off after the end of each trial. Stimulus onset was 0.5-3 s before the saccade, always outside the RF. Neurons had strong reafferent responses to these newly-appeared, though familiar, stimuli. Responses occurred whether or not the monkey made unrewarded saccades to the stimuli

We next tested whether stable RF stimuli preselected as saccade targets elicited reafferent responses. We used the 8-element stable array and briefly flashed a cue on each trial during peripheral fixation (outside of the RF). After the initial centripetal saccade the monkey made a second saccade to the array element matching the cue. LIP neurons responded only when the second saccade was directed to a RF stimulus. Responses usually preceded the first saccade (always out of the RF) and lasted through the second (into the RF). We interpret them as predictive visual responses occurring only when a target for a subsequent saccade was brought into the RF. Reafferent visual responses in LIP are thus strongly gated by the behavioral significance and salience of stimuli. Supported by the National Eye Institute.

NEURONAL RESPONSES IN AREA 7a TO STIMULI THAT ATTRACT ATTENTION. C. Constantinidis* and M.A. Steinmetz Krieger Mind/Brain Institute

and Department of Neuroscience, Johns Hopkins Univ., Baltimore, MD 21218.

Neuronal responses were recorded from posterior parietal area 7a of monkeys performing a spatial version of a delayed match-to-sample task. The monkeys were required to maintain fixation while a series of stimuli were presented and to release a behavioral bar when a match stimulus appeared at the same location as the initial stimulus of the series (cue). The cue was either a single square stimulus or a salient stimulus in a 3x3 grid of squares (distractors) centered 25° apart. Salient stimuli differed in color from the identical distractors. The monkeys were trained to remember the location of the cue and to release the bar when a subsequent stimulus appeared at the cued location. The mean firing rate in 74% (153/207) of the neurons recorded was

significantly different depending on whether an element of a cue array presented inside the receptive field was salient. A transient response to a distractor was observed in neurons with short response latencies but was completely absent from neurons with longer latencies. The population response to a salient stimulus, as judged by the average PST histogram, became significantly larger than the response to a distractor 120 ms after the onset of the cue array (t-test, p<0.05). Presentation of arrays consisting of 9 identical elements and lacking a salient stimulus to attract attention evoked weak or no responses

Our previous studies have shown that responses to a match stimulus are suppressed relative to a nonmatch stimulus presented at the same location. We have now observed that the magnitude of this suppression was similar following single and array cues. Responses to a nonmatch stimulus were not suppressed when it followed a cue array even though the nonmatch stimulus appeared at the same location as a distractor element in the array. Our results suggest that area 7a neurons encode the locations of salient stimuli in complex visual scenes, possibly for redirecting visual attention. Supported by NIH EY09129.

DISTINGUISHING CORTICAL AREAS INVOLVED IN VISUAL PROCESSING VERSUS TASK CONTROL USING FMRI E.A. DeYoe*, P. Schmit, J. Kummer & J. Neitz, Dept. Cell. Biology, Medical Col. Wisconsin, 8701 Watertown Plank Rd., Milwaukee, WI 53226 (deyoe@post.its.mcw.edu)

Performance of a visual discrimination task involves not only the analysis of the stimulus and selection of a response but also control of attention and other factors that direct the execution of the task. We used functional MRI (FMRI) to distinguish cortical areas having correspondingly different functions. During echo-planar FMRI, each of 4 subjects observed a central fixation point while detecting 3 groups of targets superimposed on a surrounding checkered annulus. During each individual trial, the targets appeared for only 0.5 s. thereby forcing the subject to maintain fixation to perform correctly. Subjects indicated if all 3 groups contained the same or a different number of targets. Within each scan series, the discrimination trials were presented at four different rates: 0, 0.21, 0.75, and 1.21 presentations per second. In occipital visual areas, the FMRI response amplitude increased as the trial presentation rate increased. However, the slope of the response function varied from voxel to voxel. In contrast to occipital cortex, responses in superior parietal and dorsolateral frontal cortex remained relatively constant in amplitude as the trial presentation rate increased. These areas were also poorly activated during passive viewing of the display. Together our results suggest that at least some areas of superior parietal and frontal cortex are largely unaffected by the visual processing "load" (trials per block). Since they are nevertheless strongly activated during task performance, their function may be related to setting up and controlling task execution rather than performing visual computations per se. This would be consistent with proposals that superior parietal and dorsal frontal cortex are involved in the control of spatial attention. This approach may provide a novel criterion for identifying areas performing so called "executive" functions. Supported by NIH EY10244.

CODING THE INTENTION FOR AN EYE OR ARM MOVEMENT IN POSTERIOR PARIETAL CORTEX OF MONKEY.

L.H. Snyder*, A. Batista, R.A. Andersen, Division of Biology, Caltech, Pasadena, CA

Visual targets elicit responses in the lateral intraparietal area (LIP) and 7a of posterior parietal cortex. This activity may persist after target removal, especially if the animal plans an eye movement to the location of the extinguished target. This may reflect attention to that point in space, or an intention to move toward that location. Because we often look at or reach towards what interests us, neural correlates of spatial attention and movement intention can be difficult to distinguish. We trained animals to make either eye or arm movements to the same spatial location, reasoning that intention but not attention would depend on movement type

Peripheral red or green targets were flashed (150 ms) while animals fixated and pointed at a central target. The peripheral cue instructed the type (red=saccade, green=reach) and direction of the upcoming movement. The movement itself was delayed until after fixation light offset, which occurred 1-1.6 s later. Neuronal activity depended on intended movement in 62% of 314 cells active during and immediately following cue presentation (100-300 ms after cue onset). In these cells, significant responses were obtained only prior to one of the two types of movement. Delay activity depended on movement intention to an even greater extent (83% of 276 cells active 150-600 ms after cue offset). In LIP, most cells preferred intended saccades, while in a region medial and posterior to LIP, most cells preferred intended reaches. These results show that, in a delayed movement task, the activity of many parietal neurons reflects movement intention.

PET AND ERP STUDIES OF COMPLEX FORM ANALYSIS AND LUMINANCE DETECTION DURING SPATIAL SELECTIVE ATTENTION G.R. Mangun*1,2 J.B. Hopfinger^{1,2} C. Kussmaul^{1,3} E. Fletcher^{1,3} H.J. Heinze⁴. Center for Neuroscience¹ & Depts. of Psychology² & Computer Sci.³, University of California, Davis CA 95616; Department of Clinical Neurophysiology, Otto-v-Guericke University, D-39120 Magdeburg, FRG⁴.

Previously, we combined positron emmision tomography (PET) and event-related potentials (ERPs) to demonstrate that selective attention to a location in the visual field produced activations in human extrastriate cortex (fusiform gyrus) contralateral to the attended hemifield at a latency of 80 msec (Heinze et al., 1994). Here, using the 150-water PET method and 3-D acquisition, we replicate and extend these findings by showing that attentional activations at the border of the fusiform and lingual gyri are primarily dependent on spatial selective attention. There was, however, a slight nonsignificant tendency for the fusiform activity and the Pl component of the ERP to be greater in magnitude during form discrimination (symbol matching) as compared to luminance detection (illuminated pixel present or absent) -- we believe that the more demanding perceptual requirements in the form discrimination task induced the subjects to allocate more attention. In addition, in the present data, there was also activation in the middle occipital gyrus contralateral to the attended location. Ninety-channel ERP recordings showed that the contralateral P1 attention effect showed similar (minor) amplitude changes as did the PET activity, as a function of task (form versus luminance). The present findings significantly strengthen our hypothesis of close associations between early ERP attention effects and neural activity in the human extrastriate cortex. Specifically, they identify an early, spatiallydefined selection process that acts to modulate signals from attended regions of the visual scene. [This work was supported by NSF, NIMH, NINDS, the James S. McDonnell Foundation, and a UC Faculty Research Grant].

FMRI OF HUMAN PARIETAL AND OCCIPITAL AREAS FOR PROCESSING

FMRI OF HUMAN PARIETAL AND OCCIPITAL AREAS FOR PROCESSING VISUAL MOTION AND THEIR GRADED MODULATION BY SPATILAL AND FEATURAL ATTENTION M. S. Beauchamp* and E. A. DeYoe Graduate Program in Neuroscience, University of California. San Diego(mbeauchamp@ucsd.edu) and Dept. Cell Biology. Medical College of Wisconsin, Milwaukee, WI 53226

Subjects responded to visual stimuli under different attentional conditions while whole brain FMRI was used to record the response of parietal and occipital motion-processing areas. In the baseline condition, subjects' spatial and featural attention was directed away from a motion-containing stimulus. Shifting spatial attention to the motion stimulus without featural attention produced a larger response, while a combination of spatial attention and attention to motion resulted in the largest response.

In the first experiment, the visual task consisted of luminance discriminations made at the center of the display, focusing the subjects' spatial attention on the fixation point and their featural attention on luminance. The visual stimulus consisted of a fixation point with luminance increments/decrements and an annulus consisting of coherently moving points on a background of incoherently moving points, previously demonstrated to activate motion areas. Visual areas located in lateral occipital cortex, the location of human area MT and associated visual areas (hMT+) responded with an average signal change of 2.52 MR intensity units, with an average volume of 394 mm³ activated cortex. Parietal visual areas totaling 2220 mm³ responded with a signal than activated cortex. Partetal visual areas totaling 2220 thit responded with a signal change of 2.46 MR units. In the second experiment, subjects fixated at the center of the display but attended to the color of points in an annulus defined by motion and color. hMT+ response increased 35% over experiment 1 to 3.41 MR units, with volume increasing 64% to 647 mm³. The response of parietal areas increased 122% to 5.46 units with volume increase of 23% to 2730 mm³. In the third experiment 5.46 units with volume increase of 23% to 2730 mm². In the third experiment subjects performed speed discriminations, focusing both their spatial and featural attention on the motion stimulus. hMT+ response increased 105% over baseline to 5.16 units, with volume increasing 393% to 1940 mm² while partical intensity increased 202% to 7.44 units with a volume increase of 109% to 4640 mm². Supported by an HHMI Fellowship to MSB and NIH RO1-EY10244 to EAD.

AN IMPAIRMENT OF THE TEMPORAL DYNAMICS OF ATTENTION IN VISUOSPATIAL NEGLECT. M. HUSAIN*, K. SHAPIRO, J. MARTIN and C. KENNARD, Dept. of Clinical Neuroscience, Charing Cross Hospital, University of London, U.K. and School of Psychology, University of Wales, Bangor, U.K. Identification of a briefly-presented visual stimulus is associated with an impairment in the ability of normal subjects to detect a second stimulus if it appears within 500 ms of the first. This phenomenon has been termed the attentional blink owell time. We examined the temporal dynamics of visual attention in a group of seven patients (mean age = 66) with right hemisphere lesions and left-sided visual neglect. In these experiments all stimuli were presented at the same spatial location.

Subjects were asked to view a rapid serial visual presentation (RSVP) in which a stream of letters was displayed successively at fixation. Each letter was presented for 131 ms with an interstimulus interval of 49 ms, yielding a presentation rate of 5.5 item/sec. In each RSVP stream all the letters were black except one which was white (target 1 or T1). T1 occurred 8-16 items after the onset of the stream. On half the trials, a black X (target 2 or T2) was presented at some point, varying randomly from trial to trial, in the ten-item letter stream that followed T1. On the other half of trials, there was no T2.

All subjects were tested under two conditions in which they were given different

instructions, in the territeria letter steam that forthcat 11. On the other hand trials, there was no T2.

All subjects were tested under two conditions in which they were given different instructions. In the single-target task, they were asked to say whether thay had detected a T2. In the dual-target task, they were asked to identify the T1 and also say whether they had detected a T2. On the single-target task, neglect patients detected T2 on 80-90% of occasions it was presented, irrespective of where it was in the RSVP stream. On the dual target-task, the probability of identifying T1 was 0.71. However, when patients correctly identified T1, their ability to detect a subsequent T2 was significantly impaired (42-67% detection) for >1600 ms afterwards. Agenaticed control subjects showed a normal attentional blink which was significantly less protracted and less profound than patients with neglect.

This investigation demonstrates there is an impairment of temporal as well as spatial components of attention in visual neglect. The implications for models of visual attention and neglect will be discussed.

NEURONAL ACTIVITY IN MACAQUE SUPPLEMENTARY EYE FIELD IS ENHANCED UNDER CONDITIONS OF STIMULUS-RESPONSE INCOMPATIBILITY. S.N. Gettner* and C.R. Olson. Dental School, University of Maryland, Baltimore, MD 21201.

Human imaging and lesion studies have suggested that frontal cortex is selectively involved in stimulus-response tasks in which stimulus and response are incompatible, as when a cue is presented at a and response are incompatible, as when a cue is presented at a different location from the response target. To characterize neural activity under such conditions, we recorded from the supplementary eye field (SEF) while monkeys performed a task in which the color of a cue (red, green, blue or magenta) indicated which of four targets (right, up, left or down) should be selected for an eye movement. A cue of any color could be presented in superimposition on any of the targets. Conditions could either be 'congruent' - cue location identical to target location - or 'incongruent' - cue location different from target location. We found that neurons were direction selective, and that location. We found that neurons were direction selective, and that during the delay period there was a smooth transition from activity reflecting the location of the cue to activity reflecting the direction of the response. In around half of the sampled neuronal population, the mean firing rate during the delay period depended significantly on the type of trial (congruent vs. incongruent). A large majority of neurons exhibiting dependence on trial-type fired more strongly during incongruent trials than during congruent trials. We conclude that the SEF is particularly involved in generating eye movements under

conditions of stimulus-response incompatibility. NIH (RO1 NS27287); NIH (NRSA 1 F32 NS09452)

475.12

MACAQUE SUPPLEMENTARY EYE FIELD: ENHANCED ACTIVITY DURING EYE MOVEMENTS SELECTED ON THE BASIS OF AN ARBITRARY ASSOCIATION VS. A NATURAL SPATIAL RULE. <u>C.R. Olson</u>* and <u>S.N. Gettner</u>. Dental School, University of Maryland, Baltimore, MD 21201.

Frontal cortex may be selectively involved in generating movements under conditions when the pairing between stimuli and responses is learned rather than hardwired. To test this idea, we recorded from 315 neurons in the supplementary eye field (SEF) of monkeys performing an oculomotor task in which, on interleaved trials, targets were selected either on the basis of a natural spatial rule (go to the target on which the cue flashed) or on the basis of an arbitrary learned association (go to the target associated with the pattern of the foveally presented cue). SEF neurons fired robustly during the delay between presented cue). SEF neurons fired robustly during the delay between the cue and the signal to respond and were selective for the direction of the impending eye movement. Around half of task-related neurons fired differentially as a function of the rule guiding response selection, with a majority favoring the 'pattern' condition. Even in a variant of the task where 'pattern' and 'spatial' cues were presented at identical eccentric retinal locations, a majority of differentially active neurons favored the 'pattern' condition. We conclude (1) that partially non-overlapping populations of SEF neurons mediate the selection of eye movements according to 'spatial' and 'pattern' rules and (2) that movements according to 'spatial' and 'pattern' rules and (2) that activity in the SEF is greater overall when targets are selected on the basis of arbitrary learned associations than when they are selected on the basis of a natural spatial rule.

MODULATION OF OSCILLATION IN INFERIOR OLIVARY NEURONS BY A HYPERPOLARIZATION-ACTIVATED CATION CURRENT (I_h). <u>T. Bal* and D.A. McCormick</u> Section of Neurobiology, Yale Univ. Sch. Med., New Haven, CT 06510

Intracellular recordings of guinea pig or ferret inferior olivary neurons (IO) in vitro revealed that these neurons could generate sustained (up to 20s) endogenous 4-8 Hz oscillations at hyperpolarized membrane potentials following the injection of a brief hyperpolarizing current pulse (figure).

Cesium, a specific blocker of ${\bf l}_{\bf h}$ when applied extracellularly, had several effects that were indicative of a role for ${\bf l}_{\bf h}$ in the generation of oscillation in IO neurons. We propose that ${\bf l}_{\bf h}$ contributes to the determination of the resting membrane potential such that reduction of I_h results in hyperpolarization and an increased propensity of oscillation through removal of inactivation of the low threshold Ca²⁺ current (I_T). In this manner extracellular application of Cs+ resulted in marked "ensemble oscillations" in the inferior olive. In single cell oscillations, I_h contributes to the generation of the afterhyperpolarization through its *de-activation* during the Ca²⁺ spike and its *activation* during the afterhyperpolarization (generated by an apamin-sensitive $I_{K,Ca}$). Thus, I_h contributes to the "pacemaker potential" that times the occurrence of Ca²⁺ spikes in IO cells. Supported by N.I.H..

WHAT IS THE ROLE OF THE INFERIOR OLIVE IN OCULOMOTOR FUNCTION? E. Marsh* and R. Baker. Department of Physiology and Neuroscience, New York University Medical Center, New York, NY 10016

Climbing fiber activity was analyzed in the goldfish vestibulocerebellum in order to establish a role for the inferior olive (IO) during optokinetic (OKR) and vestibular (VOR) performance and adaptive plasticity. Two prevailing viewpoints, largely based on the presence of error signals and rhythmicity, argue that the IO acts as either a "teacher" or "clock" by directly adapting or commanding Purkinje cell output; however our data do not support either hypothesis. Recording of complex spike activity revealed spontaneous IO discharge to be random and modulation during OKR and VOR to be directionally selective, associated with retinal slip, and independent of Purkinje cell type as determined by simple spike eye movement sensitivity. These IO characteristics remained unchanged throughout either OKR or VOR adaptation. IO sensitivity therefore appears to be independent of any gain state and/or operation in the oculomotor system. After selective IO lesions, as later confirmed with biocytin labeling, OKR and VOR performance and adaptive plasticity were still intact; however, eye position records exhibited a distinct tremor independent of any oculomotor task in either the light or dark. Power spectrum analysis revealed a frequency range from 2-6Hz with eye velocivity peaks clustered around 2-4%. Lesions that included the mossy fiber projection from Area II to the cerebellum also removed velocity storage and most of the adaptive velocity peaks clustered around 2-4°/s. Lesions that included the mossy fiber projection from Area II to the cerebellum also removed velocity storage and most of the adaptive plasticity. These findings demonstrate that mossy fiber pathways alone, through the cerebellum, are sufficient to produce robust oculomotor plasticity thereby discounting a teaching role for the IO. The lack of complex spike rhythmicity also does not support the IO acting as a "clock" that directly gates cerebellar Purkinje cell output. On the other hand, the eye movement tremor observed after IO lesion may be in agreement with some role in timing. Collectively, these results suggest an alternative hypothesis arguing that IO properties are best designed to regulate intrinsic cerebellar cortical operations by influencing both the mossy-parallel fiber and the inhibitory interneuronal loops that affect the level of activity or 'set point' of Purkinje cell output. Therefore, by acting not only directly on Purkinje cells, but also on the intracerebellar gain loops, the IO controls the dynamics of various mossy fiber loops and hence only indirectly commands oculomotor system function. (NIH NS13742)

THE ROLE OF THE INTERPOSITUS NUCLEUS IN SACCADES IS DIFFERENT FROM THE ROLE OF THE FASTIGIAL NUCLEUS, F.R. Robinson*1, A. F. Fuchs*1, A. Straube², and S. Watanabe³. ¹Dept. Physiol. and Biophys. Univ. of Washington, Seattle, WA 98195, ²Abteilung Neurologie, Klinikum Grosshadern, Marchioninistrasse 15, 81377 Munich, Germany, and ³St. Marianna Univ. Sch. of Medicine, Kawasaki, Japan
The ventrolateral posterior interpositus nucleus (VPIN) of the monkey

cerebellum contains a "distinct group" of neurons that discharge bursts of action potentials for saccades (Van Kan et al., '93). VPIN is anatomically separate from the saccade-related region in the caudal fastigial nucleus (CFN) Is its role in saccades also distinct?

Recordings show that, like CFN neurons, most VPIN cells (n=14) burst for nearly every saccade. However, unlike CFN bursts which often lead contralateral and lag ipsilateral saccades, VPIN bursts vary their latencies to lead upward (n=4) or downward (n=3) saccades depending on the neuron. Also unlike CFN neurons, some VPIN neurons show a reduction in firing rate late in saccades with a downward component. Finally, some VPIN neurons (n=5) show a burst late in the saccade that is non-directional and outlasts the end of the saccade.

end of the saccade.

Inactivating VPIN neurons unilaterally with muscimol makes upward saccades slightly too large but does not bend them toward the side of the injection like CFN inactivation does. Bilateral VPIN inactivation makes upward saccades more hypermetric (gain-1.5), downward saccades slightly hypometric (gain -0.85) and makes horizontal saccades angle upward slightly. Because saccade-related activity in the VPIN is different from that in the CFN and the consequences of VPIN inactivation are also different we conclude that VPIN function is different from that of the CFN.

A COMPUTER SIMULATION OF CALCIUM-INDUCED CALCIUM RELEASE IN A CEREBELLAR PURKINJE CELL E. De Schutter* Born Bunge Foundation, Univ. of Antwerp, Belgium

Cerebellar Purkinje cells are known to contain extensive calcium stores covered with ryanodine receptors. The physiological role of these stores remains, however, unclear. Application of caffeine, causing activation of the ryanodine receptor, has been shown to result in distinct but rather unspecific changes in the firing pattern of cultured Purkinje cells (Brorson et al. J. Neurosci. 11: 4024, 1991)

We incorporated calcium stores in a standard compartmental model of the Purkinje cell (De Schutter and Bower J. Neurophysiol. 71: 375, 1994) which has been expanded to include detailed calcium dynamics. Calcium uptake and calcium-induced release were simulated with the steady-state equations of Goldbeter et al. (PNAS 87: 1461, 1990) and 100 mM of the buffer protein calsequestrin was included in the stores. This model could replicate the results of Brorson et al. (1991). At low maximum rates CICR caused a transient interruption of bursting followed by slower period bursting. At higher rates simple spike firing was interrupted. These changes showed complex temporal dynamics and were due to the activation of dendritic K+ channels.

This model of CICR is, however, not very robust because it depends on depletion of the stores to end release, a condition which can only be achieved if the release of bound calcium from calsequestrin is assumed to be very slow. Therefore we will introduce a gating model with inactivation of the ryanodine receptor channel into the Purkinje cell model. Supported by NIMH MH52903 and NFWO (Belgium).

THE ROLE OF GLUTAMATE IN D1 AGONIST INDUCED INCREASES OF SUBTHALAMIC NUCLEUS NEURONAL FIRING RATE: NORMAL VS. 6-OHDA LESIONED RATS. K.A. Allers¹* D.S. Kreiss², M.J. Tweny², J.L. Juncos¹, and J.R. Walters², Dept. of Neurology, Emory University School of Medicine, Atlanta, GA 30322, and ²Experimental Therapeutics Branch, NINDS/NIH, Bethesda, MD 20892.

Current models of the basal ganglia predict dopamine (DA) agonists decrease subthalamic nucleus (STN) firing via action in the striatum to disinhibit GP neurons allowing greater GABAergic inhibition of the STN. However, we have found that the D1 agonist SKF 38393 and the D1/D2 agonist apomorphine increase firing rate in the STN in normal rats. It has been suggested that local STN presynaptic D1 receptors on cortical glutamatergic afferents may contribute to these excitatory DA agonist effects. A role for glutamate was investigated using in vivo extracellular single unit recording in locally anesthetized rats. Naive and 6-OHDA lesioned animals were pretreated with the NMDA antagonist MK-801 (0.1mg/kg, i.v.) or the AMPA antagonist NBQX (3.7mg/kg, i.v.) followed by SKF 38393 (20mg/kg in naive, 10mg/kg in lesioned, i.v.). SKF 38393 administered alone increased STN firing by 224 \pm 36% of basal rates (n=10) in naive rats and 245 \pm 63% (n=8) in lesioned rats. Neither MK-801 or NBQX alone had a significant effect on the firing rate of STN neurons. The SKF 38393 induced increase was not attenuated by MK-801 pretreatment ($264 \pm 35\%$, n=6) in naive rats, but the increase was completely blocked by MK-801 in lesioned rats (90 \pm 11%, n=10). In contrast, NBQX pretreatment significantly attenuated the SKF 38393 induced increase in firing rate in naive rats (149 \pm 16%, n=11) but not in lesioned animals (151 \pm 59%, n=6). These results suggest that 1) glutamate plays a role in mediating D1 agonist induced increases in STN firing rates; and 2) glutamatergic mechanisms/pathways mediating this effect are dramatically altered by lesion of DA neurons with NMDA receptors playing a more significant role in the lesioned rats. These results have implications for glutamate antagonist pharmacotherapy of Parkinson's disease

METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION IN CEREBELLAR PURKINJE CELLS AS SUBSTRATE FOR ADAPTIVE TIMING IN EYE BLINK CONDITIONING. D. Bullock*, J.C. Fiala and S. Grossberg. CNS Dept., Boston University, Boston, MA 02215.

To understand how the cerebellum adaptively times the classically conditioned nictitating membrane response (NMR), a mathematical model of the metabotropic glutamate receptor (mGluR) second messenger system in cerebellar Purkinje cells was constructed and simulated. In the model, a spectrum of slov responses, generated postsynaptically by mGluR-mediated phosphoinositide hydrolysis and calcium release from intracellular stores, bridges the interstimulus interval (ISI) between the onset of parallel fiber activity associated with the conditioned stimulus (CS) and climbing fiber activity associated with the unconditioned stimulus (US) onset. Temporal correlation of metabotropic responses and climbing fiber signals produces persistent phosphorylation of both AMPA receptors and Ca²⁺-dependent K⁺ channels. The former mediates longterm depression (LTD) of AMPA receptors; the latter enables CS-induced metabotropic activation to cause a timed reduction in membrane potentials and in the Purkinje population firing rate during the CS-US interval. The Purkinje cell firing decreases disinihibit cerebellar nuclear cells, whose excitatory response constitutes a learned movement command. Purkinje cell learning times this response, while nuclear cell learning can calibrate it. The model reproduces key features of the rabbit's conditioned eye blink response, the NMR: Purkinje cell population response is properly timed; delay conditioning occurs for ISIs of up to four seconds whereas trace conditioning occurs only at shorter ISIs; mixed training at two different ISIs produces a double-peaked response; and ISIs of 200-400ms produce maximal responding.

CEREBELLAR GRANULE CELL ACTIVITY CORRELATES WITH THE ACTIVITY IN PRIMARY SOMATOSENSORY CORTEX IN THE AWAKE, FREELY-MOVING RAT. M.J. Hartmann* and J.M. Bower, Division of Biology. Caltech, Pasadena, CA, 91125

Our previous work in awake rats has shown that the cerebellar granule cell layer (GCL) of crus IIa responds to light tactile stimulation of perioral structures. We have recorded simultaneously from primary somatosensory cortex (S1, left hemisphere) and from the GCL of crus IIa (right hemisphere) in awake, freely-moving rats. During initial electrode implantation, we determined the perioral receptive field at each recording site, and later confirmed these fields in the awake rat. Behaviors were videotaped and synchronized with the neural signals

We compared spatio-temporal patterns of activity in S1 and crus IIa during eating, grooming, drinking, and exploratory behaviors. We will present a video of synchronized neural and behavioral data, showing that cerebellar activity at each electrode site was largest when the rat's behavior resulted in tactile stimulation of the appropriate receptive field. In contrast, activity remained close to background levels during any movements that did not directly stimulate the receptive field (e.g. chewing) When receptive fields in S1 and the cerebellar GCL overlapped, multiunit responses in the GCL were temporally correlated with the multiunit responses in S1.

We carefully examined the GCL activity associated with rat drinking sequences

Each lick elicited highly correlated bursts of activity between S1 and cerebellum at the times when the tongue protnided and retracted past the respective perioral receptive fields. Our results demonstrate that GCL and S1 responses are temporally correlated in the awake animal, and that responses in the GCL of crus IIa are most directly related to tactile stimulation of perioral surfaces, not to motor activity in itself

ALTERATIONS IN GAD-65 mRNA LEVELS IN THE BASAL GANGLIA AFTER CHRONIC DOPAMINE AGONISTS IN 6-OHDA-LESIONED RATS. K.M.Merchant, L.M.Needham*, N.F.Nichols, D.L.Feldpausch. CNS Diseases Res., Pharmacia & Upjohn, Inc., Kalamazoo, MI 49001.

The present study investigated alterations in the GABA synthetic enzyme GAD-65, to examine the possibility that chronic intermittent treatment with D1-like and D2-like agonists produce differential neuroadaptive responses in the caudatoputamen (CP), globus pallidus (GP), and substantia nigra pars reticulata (SN-r). Compared to the sham-treated side, GAD-65 mRNA was increased significantly in the ipsilateral CP and SN-r, but was decreased in the ipsilateral GP. These data indicate that increases in striatopallidal GABA activity may contribute to the enhanced GABA output of the nigrothalamic neurons. Chronic treatment with the D1-like agonist (+)SKF 38393, D2-like agonist (-)quinpirole, D2-selective agonist U-95666A, as well as the indirect dopamine agonist L-dopa (plus benserazide) further increased GAD-65 mRNA levels in the lesioned CP compared to the unlesioned side. However, in the GP and the SN-r, the D2 agonists differed significantly from the other agents. Thus, both quinpirole and U-95666A reversed the asymmetry in GAD-65 mRNA levels in the GP and SN-r, SKF 38393 did not reverse the lesion-induced imbalance in either the GP or SN-r, and L-dopa reversed the asymmetry only in the SN-r. Interestingly, behavioral studies also distinguished the effects of the D2 agonists from the others. Thus, quinpirole and U-95666A produced sensitization in the turning rate, SKF 38393 induced tolerance, and L-dopa did not produce timedependent change in turning. These data indicate that the rate of turning produced by chronic dopamine agonists may be related to their ability to alter the activity of selective GABA projections.

ULTRASTRUCTURAL LOCALIZATION OF GLUR1 GLUTAMATE RECEPTOR SUBUNIT IN STRIATAL PROJECTION NEURONS. C.L. Veenman Medina, Q. Chen, and A. Reiner.* Anat. & Neurobiol., UT-Memphis, TN 38163; Behav. Biol., Fed. Inst. Technol., Zurich, CH 8603*

LM immunohistochemical studies have revealed that GluR1 glutamate receptors subunits are sparse on the perikarya of striatal projection neurons in rats and pigeons, but abundant in neuropil. To determine if neuropil labeling for GluR1 reflects dendritic and/or spinous labeling of striatal projection neurons, we carried out LM and EM immunohistochemical studies. In LM studies in pigeon, we found that colchicine treatment led to abundant perikaryal labeling for GluR1 in striatal neurons with a medium spiny morphology. In EM immunohistochemical studies of GluR1 localization in pigeon and rat striatum, we found that GluR1 was abundant and common in the spines of striatal neurons, and also present in scattered dendrites. We quantified the relative abundance of GluR1 labeled structures in pigeon striatum. For comparison, we also quantified GluR2/3 subunit abundance, which appears to be found in the perikarya and dendrites of nearly all striatal projection neurons. At the EM level, we found that spines were labeled as frequently for GluR1 as for GluR2/3, but dendrites were only labeled 33% as commonly for GluR1. Thus, our study indicates that GluR1 and GluR2/3 glutamate receptor subunits commonly localize to the spines of striatal medium spiny neurons, but in contrast to GluR2/3, the GluR1 subunit seems to be much less common on dendrites and perikarya of these neurons. AGE-RELATED DECLINE IN DOPAMINE TRANSPORTERS WITH [I-123]B-CIT SPECT: ANALYSIS OF GENDER, STRIATAL SUBREGION, AND NEUROPSYCHOLOGICAL CORRELATES. C. H. van Dyck* J. P. Seibyl, M. Laruelle, K. Sheff, K. L. Marck, S. S. Zoghbi, Y. Zea-Ponce, R. M. Baldwin, D. S. Charney, R. B. Innis, Yale University School of Medicine, New Haven, CT, 06520.

We have previously reported age-related decline in dopamine transporter (DAT) binding in human striatum with [123]28-carbomethoxy-38-(4-iodophenyl)tropane ([123]]B-CIT) single photon emission computed tomography (SPECT) (J Nucl Med 1995;36:1175). We extended this analysis in a larger sample to examine effects of 1995;36:11/5). We extended this analysis in a larger sample to examine effects of gender and striatal subregion and to investigate neuropsychological correlates in the oldest subjects. [123]B-CIT binding in striatum was studied in 72 healthy human subjects (40 M, 32 F) who ranged in age from 18 to 85 y. Following injection with [123]B-CIT (mean \pm SD = 6.2 \pm 1.2 mCi), subjects were scanned with the brain dedicated Picker 3000 or 3000XP SPECT cameras. A reconstructed transaxial slice at the level of the striatum was used to determine tracer uptake in striatal and occipital the level of the striatum was used to declimine tracer uptake in surfax and occupied regions of interest. We estimated the specific-to-nondisplaceable equilibrium partition coefficient, V_3 ", as (striatal - occipital)/occipital uptake approximately 18 to 24 h post injection. V_3 " showed a significant inverse correlation with age (r = -0.78, p < post injection. V_3 ° showed a significant inverse correlation with age (r = -0.7.8, p < 0.0001), declining by 61% over the age range studied or approximately 9% per decade. There were no differences in the rates of decline for males (64%) vs. females (59%) or caudate (65%) vs. putamen (59%). The laterality index was unaffected by age. In the oldest age group (69 to 85 y) V_3 ° was significantly correlated with simple reaction time (r = -0.46, p < 0.01) but not with finger tapping speed. These results confirm previous reports of DAT loss with aging and suggest that humans fail to show the gender differences predicted by animal studies. They further demonstrate that show the gender differences predicted by admind studies. They further technolistate that aging, unlike Parkinson's disease is associated with a relatively symmetric loss of DATs in caudate and putamen and in both hemispheres. Finally, they provide the first evidence for a relationship between nigrostriatal dopaminergic function and neuropsychological performance in normal aging. (Supported by AFAR.)

EVIDENCE FOR SPECIFIC RETINOIC ACID-MEDIATED GENE REGULATION IN THE DEVELOPING AND ADULT BASAL GANGLIA: PRESENCE OF LIGAND, BINDING PROTEINS AND TRANSCRIPTION FACTORS. R.H. Zetterström*, L. Solomin, T. Perlmann, U. Eriksson, L. Olson. Dept. of Neuroscience, Karolinska Institute; and Ludwig Institute for Cancer Research, Stockholm Branch, S-171 77 Stockholm, Sweden.

science, Karolinska Institute; and Ludwig Institute for Cancer Research, Stockholm Branch, S-171 77 Stockholm, Sweden.

Retinoic acid (RA) is the main active form of vitamin A. We have used a RA bioassay, in situ hybridization and immunohistochemistry to delineate the possible role of RA in the basal ganglia. RA levels are higher in striatum than several other areas of the developing and adult brain. The cellular retinol-binding protein CRBPII is expressed in patches in the developing striatum and at low levels in the adult: CRBPII is not expressed. The cellular RA-binding protein CRABPI is strongly expressed in many medium spiny neurons of both the developing and adult striatum, while CRABPII expression is confined to large, presumably cholinergic, neurons in striatum. The RA receptor transcription factor RARα is weakly expressed in the development but not in the adult, while RARβ is very strongly expressed in the development but not in the adult, while RARβ is very strongly expressed in the developing striatum, with lower levels found in small neurons of the adult. RARγ is negative in the CNS. The RXR transcription factor RXRα is not clearly seen, while RXRβ has a general weak CNS expression. RXRγ is strongly expressed specifically in striatum and with a mediolateral gradient during development, while patchy in the adult. The transcription factor NGF1-B, member of a subgroup of the steroid hormone receptor superfamily which also includes NOR-1 and NURR-1, can compete with RAR as a heterodimerization patter for RXR, allowing RXR to be responsive to 9-cis-RA. NGF1-B, is expressed in patches in neonatal striatum and in scattered cells in the adult. NOR-1 does not heterodimerize with RXR, but is strongly and distinctly expressed in the classical patch and marginal zone pattern during striatal development and in scattered cells of the adult. NURR-1 can also dulthood. Our results demonstrate specific expression is key components of the retinoid system including binding proteins and transcription factors as well as

NITRIC OXIDE INCREASES GAP JUNCTION PERMEABILITY BETWEEN STRIATAL NEURONS. P. O'Donnell* and A.A. Grace. Depts. Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Several studies have established a role for nitric oxide (NO) in a diversity of

brain functions. Among possible targets of NO are gap junctions, which have a distribution similar to that of NO synthase (NOS). The role of NO in regulating striatal neuronal gap junction permeability was assessed in a brain slice preparation by taking advantage of the ability of the fluorescent dye Lucifer yellow to cross gap junctions, resulting in the labeling of additional cells beyond the one injected (Figure). In control conditions, intracellular injection of Lucifer did not reveal any case of coupling in the dorsal striatum or accumbens core (0/11). Injections in the presence of the NO donor sodium nitroprusside (100 µM) resulted in a significantly higher incidence of dye coupling (6/10, 60%, p=0.004; Fisher exact test). Similarly, stimulation of cortical afferents by means of trains of constant current pulses delivered to corticostriatal fibers resulted in dye coupling in 56% of the cases tested (9/16; p=0.002). The role of NO in the cortical afferentdependent increase was confirmed by repeating the cortical afferent stimulation experiments in the presence of the NOS inhibitor L-NAME (10-20 µM or 1 mM), which prevented the increase in coupling (0%, 0/13; p=0.001 compared to cortical afferent stimulation in physiological saline). Furthermore, the inactive enantiomer D-NAME failed to block the cortical afferent stimulation-mediated increase in coupling (43%; 6/14). These results suggest that activation of NO, either by exogenous administration or endogenously by activating cortical afferents, results in an increase in gap junction permeability between striatal medium spiny neurons. This action may result in control of afferent-regulated synchronization of striatal neuronal activity via NO-mediated activation of gap junctional conductance. Supported by MH45156, 01055 (AAG), Tourette's Syndrome Association, and a NARSAD Young Investigator Award (P.O'D.).

VISUAL SYSTEM: DEVELOPMENT II

PRENATAL DEVELOPMENT OF LAYER-SPECIFIC LOCAL CIRCUITS IN MACAQUE PRIMARY VISUAL CORTEX. E.M. Callaway*, A. Sawatari and A.K. Wiser, Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, La Jolla, CA 92037.

We have studied the specificity of development of layer-specific local circuits in macaque primary visual cortex (V1). Several-hundred neurons were intracellularly labeled in living brain slices prepared from the primary visual cortex of 7 macaque monkeys aged 95 days post-conception (E95) to 2 days postnatal (P2). Axomal and dendritic arbors of labeled neurons were reconstructed to assess their relationships to the cortical layers. We were particularly interested in the development of specificity for "sublayers' dominated by input from magno- (M) or parvocellular (P) streams.

Previous studies have implicated activity independent mechanisms in the development of axonal arbors specific for the 4 main cortical layers - 2/3, 4, 5 and 6. In macaque V1, layer 2/3 is subdivided into layers 2/3A, 3B, 4A, and 4B; while layer 4 is subdivided into 4Cα and 4Cβ. We refer to these laminar divisions as "sublayers". Individual neurons in mature animals have axons that are highly specific of these sublayers. Most notably, layer 4Cβ spiny stellate neurons have dense axonal arbors in layers 4A and 3B, but their axons pass unbranched through layer 4B. And layer 6 pyramidal neurons that target layer 4C do not form "incorrect" branches in layer 4C.

We find that spiny neurons in layers 2-4B or layer 5 specifically target superficial and deep layers without forming "incorrect" branches in layer 4C. Similarly, layer 6 pyramidal neurons that target layer 4C do not form "incorrect" branches in layer 5 deported by the substance of sublayer-specific projections with the substance of sublayer-specific projections in valve 4C spiny stellates branch in layer 6 have axonal branches in 4Cα as well as 4Cβ, whereas these projections are specific for 4Cβ in more mature animals. There is similar exuberance in axonal a

Anisotropic growth of Macaque striate cortex during the first months OF LIFE. <u>G. Blasde</u>, D. Campbell. Department of Neurobiology, Harvard Medical School, Boston, MA 02115 and <u>L. Kiorpes</u>. Center of Neural Science, New York University, New York, NY 10003

The results of previous optical imaging experiments (Blasdel et al., 1995) suggested that striate cortex grows anisotropically, perpendicular to the ocular dominance columns of old world primates during the first weeks of life. Since these results were obtained from different animals, however, one could not rule out the possibility they resulted in part from individual variation. We have now overcome this uncertainty by recording from the same cortical regions sequentially during the first 2.5 months of life. In one animal, recorded at 15 and 75 days of age, the asymmetry of cortical growth was evident from vascular patterns, which expanded 12% and 3% parallel and perpendicular to the border between V1 and V2. Direct measurements of cortical magnification (Campbell and Blasdel, 1995) revealed corresponding changes of 11.2% and 3%, which caused magnification anisotropy to increase from 46% to 55% during the same period of time. One unexpected observation concerned the minimum spacing of visual stimuli that were effective at producing cortical maps of visual location. While this could be as small as 0.6° in 75 day old animals, it needed to be at least 1.5° earlier on, at 15 days of age, which suggests that the representation of adjacent spatial locations in separate cortical regions may undergo refinement during the first months of life. Supported by EY06586 and EY10862.

OPTICAL RECORDING OF FUNCTIONAL CONNECTIVITIES IN ORGANOTYPIC CULTURES OF RAT VISUAL CORTEX AND THALAMUS CONTAINING COMPETING AFFERENTS. Christian M. Müller*, Max-Planck-Institute for Developmental Biology, 72076 Tübingen, Germany

One feature of the visual system in mammals with frontal vision is a segregation of information processing of either eye at multiple levels along the visual pathway. This segregation occurs in an activity-dependent manner during development, largely due segregation occurs at an arthyrocycloned manner until generopinent, largery due to spontaneous activity. In the present study we prepared organotypic cultures from embryonic thalamus and postnatal rat cortex grown at an air-medium interface. Either two thalamic explants or two cortical explants ('source cultures') were co-cultured with one visual cortical sitiec ('target culture'). Responses in the target cortex to electrical stimulation in the source-structures were visualized after 3 to 6 weeks in vitro using the voltage sensitive dye Di-4-ANNEPS and a 464 photodiode array. In cortico-cortical cultures responses were most prominent in layers 2/3 of the target cortex. Response amplitudes decayed from close to the apposition site with the stimulated cortex but often propagated over the entire extent of the target cortex. There was no clear evidence for a segregation of functional domains preferentially activated by either of the two competing afferents. In thalamo-cortical cocultures the initial response was localized in layers 6 and 4 followed by a prominent, polysynaptic response in layers 2/3. These responses often revealed a patchy pattern along the extent of the target cortex. In cases where functional interactions between the sourcethalami were weak, the two afferents could activate discrete, alternating patches in layers 2/3 of the target cortex. In contrast, when strong functional connectivities were found between the source-thalami, activity-patches were either absent or overlapping. The data suggest that spontaneous activity is not sufficient to drive a significant segregation of domains activated by competing afferents in cortico-cortical cocultures, but may do so in thalamo-cortical cocultures when the source-explants reveal only weak interconnectivities.

ENGULFMENT OF IgG CONTAINING NEURONS BY MACROPHAGES IN

THE DEVELOPING BRAIN, M.B. Upender, P.E. Leckman, and J.R. Naegele. Wesleyan University, Biology Dept., Middletown, CT 06459.

Microglia, or brain macrophages have long been recognized as an important cell type during brain development and during responses of the nervous system to injury. Macrophages are targeted to sites of naturally occurring cell death, retracting axons and degenerating glial scaffolds throughout normal brain development. The molecular signals that enable microglia to distinguish dying from living neurons and axons have not been identified, but it is likely that both cell surface and long-trace circulture molecules. and axons have not been identified, but it is likely that both cell surface and long-range signaling molecules will be involved. One candidate molecule is immunoglobulin or an IgG-like molecule, since IgG receptors facilitate removal of senescent cells by macrophages elsewhere in the body. Ig-immunoreactivity has been found within neuronal subpopulations in the ventricular, intermediate and subplate zones of the cerebral cortex, the ganglion cell layer of the retina and the deep nuclei of the cerebral untring development. This immunoreactivity declines during the second postnatal week and is undetectable in the adult (Upender and Naegele, Neurosci. Abst. 20, 689; Upender et. al., submitted). Each of the regions undergoes developmental cell death concurrent with the period when intraneuronal Ig-immunoreactivity is present. Recent evidence shows that this Ig-like immunoreactivity is due to uptake or synthesis of IgG in developing brain (Dunn et al., this years abstracts). The present study investigated the role of intraneuronal IgG in mediating microglial phagocytosis in several areas of the developing CNS in rodents. At early postnatal times, activated microglia were identified with the in rodents. At early postnatal times, activated microglia were identified with the mAb ED-1 or GS-1 isolectin B4 and found closely apposed to Ig-immunoreactive neurons. At later times, Ig immunoreactivity was lost and resting microglia were distributed more uniformly throughout the brain. These observations suggest that macrophages engulf Ig-containing neurons leading to their disappreance. Intraneuronal IgG may serve to recruit and/or activate macrophages in regions of naturally-occurring neuronal death. Supported by NIH EY09749.

THE DEVELOPMENT OF VISION IN THE ZEBRAFISH. S. S. Easter, Jr.* and G. N. Nicola, Dept. Biology, U. Michigan, Ann Arbor, MI 48109

We determined behaviorally when zebrafish (Danio rerio) begin to see, and correlated these observations with the development of the retinofugal projection, the retinal image, and the extraocular muscles.

Behaviors: Individual embryos and larvae, 48-96 h post fertilization (hpf), were videotaped, 10-20 naïve animals at each age. Visual startle response (VSR: body twitch) was evoked by a sudden decrease in light intensity, and indicated that the fish sensed light. The optokinetic response (OKR: tracking eye movements) was evoked by rotation of a striped drum, and indicated that the fish extracted and integrated information from the retinal image of the stripes. VSR developed over 68 - 79 hpf, many hours after the the onset of a touch-evoked startle response. Eyeless fish did not make a VSR, ruling out a role for a non-retinal light sense. OKR developed over 73 - 80 hpf, and was always in the direction of drum rotation, which suggests that the coding of the direction of image movement was hard-wired (i. e not determined experientially). Retinal Image: The formation of the retinal image was studied in live melanin-deficient fish (reared in dilute phenylthiocarbamide), in which the absence of a pigmented retinal epithelium allowed direct visual access the image formed by the lens. The image appeared early on the third day, but behind the plane of the photoreceptor outer segments; the eye was initially far-sighted. Gradually the focal length shortened and the best image was at the level of the photoreceptor outer segments by 96 hpf. Extraocular Muscles: They were examined immunocytochemically with light- and electron microscopy. They were absent at 66 hpf, evident but immature at 72 hpf, larger and more mature by 96 hpf.

Earlier work showed that retinal photosensitivity and most of the retinofugal projection were present prior to the onset of VSR. The later onset of the OKR is attributable to the delayed maturation of the extraocular muscles and the retinal image. (NIH grant EY-00168.)

IMMUNOGLOBULINS IN THE DEVELOPING CEREBRAL CORTEX

<u>I.A. Dum", E. M. Lukacsi and J.R. Naegele</u> Department of Biology, Wesleyan University, Middletown, CT 06457-0170

Wesleyan University, Middletown, CT 06457-0170
Homotypic antisera against IgG have previously been reported to label the subplate zone in developing kitten, rat and mouse visual cortex (Dunn et al., 1995, Cerebral Cortex 5:494; Fairen et al., 1992, NeuroReport 10:881). The labeling is most intense perinatally then is lost with maturation. Biochemical analyses of perinatal rat cortex have attributed this staining to two polypeptides of MW 53 and 27 kDa (Upender and Neural 1004 Sea Nurs Metr. 20(69)). Herell peny the identities of those Naegele 1994, Soc. Neur. Abstr. 20:689). Until now, the identities of these cortical antigens were unknown. The 53 kDa polypeptide has now been purified from PND 2 rat cortical cytosol using a combination of differential centrifugation, DEAE affinity and immunoaffinity chromatography. Internal amino acid sequence analyses from multiple chromatography. Internal amino acid sequence analyses from multiple polypeptides generated by tryptic digests of the 53 kDa antigen identify it as IgG heavy chain. The largest sequenced polypeptide has 100% homology to residues 226-233 of the rat Ig Gamma 2a chain C region. The

source of this IgG in the developing cortex is unresolved.

The pattern of IgG staining in mouse cortex is similar, but not identical, to IgG staining in rat and kitten cortex. IgG immunoreactive peptides have been identified in mouse cortical cytosol. SCID (Severe Combined Immune Deficiency) is a mouse mutation resulting in deficient IgG assembly. Although SCID serum contains IgG heavy chains, immunocytochemical and biochemical analyses show that SCID cortex does not. These data suggest neuronal uptake of IgG via a mechanism requiring intact molecules. Current studies are investigating the source of cortical IgG and comparing laminar and volumetric differences between normal and SCID mice. Supported by EY09749.

DEVELOPMENTAL PATTERNS OF ON/OFF RETINAL GANGLION CELL ACTIVITY LEAD TO SEGREGATION OF THEIR AFFERENTS UNDER A HEBBIAN SYNAPTIC RULE. C.W. Lee* and R.O.L Wong. Dept. of Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

During the development of the ferret visual system, activity dependent synapse elimination leads to laminar segregation of ON and OFF-type retinal ganglion cell (RGC) afferents in the dorsal lateral geniculate nucleus (dLGN). Using calcium imaging and intracellular dye-filling techniques, we previously demonstrated that the ensemble firing patterns of morphologically identified ON and OFF RGCs undergo developmental changes during the segregation period. OFF RGCs exhibit higher burst frequencies than ON RGCs and the correlation between the bursts of ON and OFF RGCs is reduced during the segregation period. In an analysis of these patterns under a variety of linear Hebbian synaptic rules we show that the changes in the bursting patterns lead to ON/OFF segregation in the dLGN. We verify this analysis with computer simulations of synaptic development of RGC inputs to the dLGN using the experimentally recorded bursting patterns, and examine which parameters [e.g., the degree of competition among synapses] lead to segregation. Significantly, we show that the recorded bursting patterns do not support segregation under all Hebbian plasticity rules. For example, we demonstrate that the BCM model of synaptic plasticity does not lead to ON/OFF segregation in the dLGN (though it is important to note that the BCM was designed to model cortical, not LCN, plasticity). These results suggest that the bursting patterns of ON and OFF RGCs during the segregation period can provide the appropriate cues for refinement of their connections in the dLGN. Combining multi-neuronal recordings and computational modeling can thus reveal important insights into the processes of synaptic competition during development, which are not evident with each method alone. GENETIC BACKGROUND AFFECTS THE OCULAR RETARDATION PHENOTYPE. M.H. Hankin*A, C. Bone-LarsonA, S. Basut, J.D. Radelt, D. Greent and M. Burmeistert. ^Medical College of Ohio, Toledo, OH 43614 †Univ. Michigan, Ann Arbor, MI 48109, and ‡Univ. Kansas, Kansas City, KS

Ocular retardation (or), a recessive murine mutation caused by a null allele of the Chx10 homeobox gene (Burmeister et al., 1996), is characterized by severe microphthalmia, a thin poorly laminated hypocellular retina lacking differentiated bipolar cells, optic nerve aplasia and blindness. In addition to or /+ mice with normal eyes, the F1 progeny of 129/Sv-or /l or / x Mus musculus castaneous (CASA/Rk) backcrossed to 129/Sv-or /l or / had eyes ranging in castaneous (CASA/HK) backcrossed to 12/3/3/-0/7/0/7 had eyes tanging in size from small to nearly normal, in addition. After selecting for large eye size for 4-6 generations, some of these or/lor/ mice exhibited functional responses (ERG and pupillary constriction). This suggested that CASA/Rk genes were "modifying" the or/ phenotype. We show that a significant portion of the normal phenotype is recovered in these modified or/ mice, including: increased eye size, retinal thickness and lamination compared to or/ mice, and increased eye size, retinal thickness and lamination compared to or' mice, and the presence of an optic nerve with centrally connecting ganglion cell axons. Immunohistochemical staining indicates the presence of poorly differentiated bipolar cells. Although the modified or' retina is larger than seen in the original mutant strain (i.e., 129/5v-or'/or'), the rate of retinal progenitor cell proliferation is not increased above the depressed levels seen in 129/5v-or'/or' mice. These observations indicate that the CHX10 transcription factor acts on genes which regulate cell proliferation in the early developing retina. We hypothesize, therefore, that the persistence of retinal ganglion cells which are able to form connections with the brain provides trophic support which permits bipolar cell survival in the modified or' retina. The incomplete differentiation of these bipolar cells, however, may indicate that the expression of CHX10 is essential for attaining and/or maintaining the mature bipolar cell of CHX10 is essential for attaining and/or maintaining the mature bipolar cell phenotype. Supported by NIH and the Ohio Lions Eye Research Foundation.

DENDRITIC DEVELOPMENT OF PUTATIVE BLUE GANGLION CELLS IN THE RHESUS MACAQUE. M.D. Snyder and M.A. Kirby*. Departments of Pediatrics and Natural Science, Loma Linda University, Loma Linda, CA 92350. We previously reported that the arbors of parasol cells that ramify in the middle

layers of the inner plexiform layer (IPL) are transiently bistratified, becoming unistratified during late fetal periods. In this study we examined cells that ramify in the extreme inner and outer layers of the IPL (i.e., receiving S or blue wavelengths) and compared their dendritic growth to cells ramifying in the middle IPL layers

Timed dated fetal monkeys were delivered by C-section, euthanized, and their retinas rapidly removed and placed into oxygenated media (Eagles, 37° C). Crystals of HRP were inserted into the retinas at various locations and allowed to incubate for 3 hrs. The retinas were then fixed with 2% gluteraldehyde in phosphate buffer (pH 7.4) and processed for HRP histochemistry using diaminobenzidine. Dendritic arbors were measured in wholemounts with quantification of the depth of each portion of the arbor in the IPL

During mid-gestation ganglion cells with all or part of their arbor in the extreme inner or outer IPL (putative blue ganglion cells) formed <u>four</u> classes. The majority (58%) of putative blue cells were unistratified with their arbors ramifying either in the inner- or outer-most IPL. The second class (26%) corresponded to the adult small-bistratifed cells. These cells had bistratified arbors with one portion in the innermost IPL and the other ramifying in the middle IPL (cells of this class were also observed with portions of the arbor in the outer extreme IPL and the rest in the middle). The third class (13%) were bistratifed with one part of the arbor in the inner most layer of the IPL and the other in the outer most layer of the IPL. Lastly, 3% of putative blue cells were observed to have tri-stratified arbors. These cells had the majority of their dendritic arbor in the middle IPL layers with small portions ramifying the extreme inner and/or outer IPL. In conclusion, putative blue ganglion cells undergo similar development and precision of dendritic growth as other ganglion cells, with the exception of the rarely encountered tri-stratified cells.

BIOMECHANICAL SIMULATION OF FOVEAL DEVELOPMENT. <u>SPRINGER</u>* Department of Cell Biology and Anatomy, New York Medical College, Valhalla, NY 10595.

The mechanisms that lead to the development of the human fovea are unknown Retinal histogenesis is complete by the beginning of the third trimester. However, a fovea is not apparent at that time. A fovea appears gradually, and it is fully developed by five years of age. Over this time the eye enlarges considerably. Eye growth, in the absence of cell addition to the retina, probably causes the retina to be stretched very slowly over time. The role of considerable eye growth, and its effect on retinal stretching, are difficult to examine experimentally. However, the effect of retinal stretching on foveal development can be simulated mathematically using finite element analysis.

A model having a notch was used to simulate a foveal depression in the ganglion cell (GCL) and inner nuclear layers (INL). As the material was stretched in the X-plane, the notch lifted toward the vitreal surface. The effect of stretching the notched material on a simulated underlying cone photoreceptor cell layer (CCL) was then examined. Elastic trusses, that simulated cone cell axons, were used to link the overlying GCL+INL to the underlying CCL. Stretching both the overlying notched material and the underlying CCL caused the CCL to flow toward the center of the overlying notch in the GCL+INL.

Besides the movement of retinal ganglion cells and inner nuclear layer cells away from the foveal center and the movement of cone photoreceptor cells toward the foveal center, several other aspects of foveal development were simulated in the model. Without adding additional variables, the model was able also to simulate the elongation of foveolar cone photoreceptor cells and the axons of Henle. The simulations suggest that two variables play a significant role in development of the fovea. Eye enlargement generates a small, but sufficient, force that stretches the retina slowly over time. A perturbation in the homogeneous geometry of the GCL+lNL, namely the foveal notch, determines the movement of the cone photoreceptor cells toward the foveola, and cone photoreceptor cell morphology

GLUTAMATE RECEPTOR ANTIBODIES DESTROY CORTICAL NEURONS BY

A COMPLEMENT-DEPENDENT MECHANISM. M. Patel. X.-P. He, S. Janumpalli, K. Whitney and J. O. McNamara. Depts. of Medicine (Neurology), Neurobiology, and Pharmacology, Duke University Medical Center, Durham, NC 27710.

Rasmussen's encephalitis (RE) is a rare disease of childhood characterized by progressive destruction of one cerebral hemisphere, severe epileptic seizures, hemiparesis, and ultimately dementia. We recently demonstrated that RE is an auto-immune disease and and unmalely demenda. We recently definionated and R.F. is all auto-immune disease and one of the autoantigens is glutamate receptor GluR3 (Rogers et al., Science 265-648-651, 1994). We postulated that the interaction of serum GluR antibodies (Abs) with GluRs in the CNS triggered seizures and death of neurons. To begin to test this idea, we engineered a glutathion-S-transferase GluR3 fusion protein (GSTGR3) that contains amino acid residues 246-455 of the N-terminal extracellular domain of rat GluR3. A subset of rabbits residues 246-455 of the N-terminal extracellular domain of rat Gluc3. A subset of rabotis immunized with GSTGR3 but not GST developed epileptic seizures and a neurologic syndrome similar to that observed previously. We sought to determine whether GluR Abs destroyed neurons and if so, by what mechanism. Cell death was quantitated by measuring release of LDH from cortical neurons isolated from E18 rats and maintained in primary culture. Glutamate and other low MW substances were removed from plasma by filtration over a molecular sieve. Filtered plasma from GSTGR3-immunized rabbits (n=5) killed over a indicedual sever. Intercupant of Gold Continuing and Control and Contro of complement to the IgG destroyed neurons. Passage of plasma over a GSTGR3 affinity column selectively removed GluR Abs and eliminated the cell death-inducing effects of the GSTGR3 plasma, whereas passage over a GST affinity column failed to remove GluR Abs or climinate the cell death. We conclude that circulating GluR Abs can destroy cortical neurons by a complement-dependent mechanism. We suggest that one way by which circulating GluR Abs in patients with RE may contribute to neural injury and seizures is by destroying cortical neurons through a complement-dependent mechanism Supported by NS 17771 from NINDS

478.3

MECHANISMS OF NEURONAL DEATH DURING EXCITOTOXICITY EFFECTS OF TEMPERATURE. L. Kiedrowski. The Psychiatric Institute. University of Illinois, Chicago, IL 60612.

The hypothesis tested was that excessive Ca2+-buffering by mitochondria collapses mitochondrial membrane potential ($\Delta \psi$) and plays an important role in excitotoxicity. To this end, effects of glutamate (GLU) on $[Ca^{2\nu}]_i$ and $\Delta\psi$ were studied simultaneously in primary cultures of cerebellar granule cells loaded with fura-2 and tetramethylrhodamine (TMR), respectively. Neurons were exposed for 15 min to 50 µM GLU and 10 µM glycine applied in a Mg2+-free Locke's buffer at 22 °C and 37 °C. Following GLU removal, conditioned culture medium was reapplied, and dishes were placed in an incubator. After 24 h, the same microscopic field in which $[Ca^{2-}]_i$ and $\Delta \psi$ were earlier monitored was recovered, and the integrity of the plasma membrane was tested using propidium iodide (PI). Nuclei of the same neurons were examined for the presence of chromatin condensation. An increase in temperature from 22 °C to 37 °C during the GLU challenge strongly improved Ca²⁺ buffering and neuronal survival: as many as 65% of neurons failed to buffer Ca²⁺ at 22 °C, while only 15% failed to do so at 37 °C; 60% of neurons died at 22 °C, but only 25% at 37 °C. The failure to buffer Ca2+ was well correlated with a collapse of $\Delta \psi$, since neurons that failed to decrease [Ca²⁺]_i, also failed to reaccumulate TMR in mitochondria; at 22 °C, 85% of these neurons stained with PI after 24 h. Unexpectedly, at 37 °C, 57% of neurons that died, upon GLU removal, maintained Δψ and showed a prompt decrease in [Ca2+]i. In these neurons, an evident chromatin condensation was observed after 24 h, but the plasma membrane was still impermeable to PI. It is concluded that there may be at least two mechanisms operative in GLU-excitotoxicity: 1) one that involves a collapse of Δy and destabilization of Ca^{2^+} homeostasis, and 2) one in which neither Ca^{2^+} homeostasis nor $\Delta \psi$ are immediately destabilized

FORMATION AND COMPOSITION OF IBOTENIC ACID INDUCED CALCIFI-CATIONS IN RAT SUBSTANTIA NIGRA. C. Nitsch*, G. Herrmann and A. L. Scotti. Inst. of Anatomy of the University Basel, 4056 Basel, Switzerland.

The neurotoxic glutamate agonist ibotenic acid (IBO) is frequently used to place locally restricted axon-sparing brain lesions. In certain vulnerable areas as the substantia nigra (SN) e. g., neuronal degeneration is accompanied by the local formation of calcium deposits. Formation of the calcium deposits and their possible association with cartilage-, bone- and brain-specific glycoproteins and components of the extracellular matrix was investigated in the present series of experiments. Male rats received an intranigral injection of 7 μg IBO in 0.7 μl buffered H₂O. One week after IBO application, calcium deposits were detectable in the vicinity of the lesion in the Alizarin stain. Ultrastructural analysis revealed that the deposits probably originate from the calcium accumulated in the degenerating dendrites and perikarya of the GABAergic SN pars reticulata neurons which contain the calcium-binding protein parvalbumin. Astrocytes separating the degenerating neurons from their intact presynaptic boutons express the bone-specific glycoprotein osteocalcin. Laminin and collagen III-positive blood vessels proliferate into the lesion focus. Between degenerating calcium-filled neurons and astrocytes as well as microglia a fibrillar matrix is formed which is positive for heparan sulfate normally absent from brain tissue. During the following weeks this matrix enlarges stepwise and is infiltrated with anorganic calcium salts, thus giving a picture resembling the annual growth rings of trees. The evolving bodies incorporated smaller calcium deposits resulting in large concretions. It is suggested that the different outfit of neurons with calcium-binding proteins together with the response repertoire of glial cells towards modulation of the compounds of the extracellular matrix following excitotoxic cell death, provide the permissive substrate for the calcification process Supported by funds of the University Basel.

DISRUPTION OF NEURONAL CA²⁺ HOMEOSTASIS BY NITRIC OXIDE INVOLVES ATP DEPLETION. J.R. Brorson*, R.A. Sulit, and H. Zhang. Depts. of Neurology and Neurosurgery, The University of Chicago, Chicago, IL 60637

Nitric oxide (NO) has in recent years been recognized as an important mediator of excitotoxicity. We previously reported that NO exposure disrupts $\mathrm{Ca^{2+}}$ homeostasis in cultured hippocampal neurons. Using patch clamp and $[\mathrm{Ca^{2+}}]_i$ microfluorimetric methods, we have studied the mechanism of this effect.

The NO releasing agent S-nitrosocysteine (SNOC, 300μM) over 20 minute The NO releasing agent S-introsocysteine (SNOC, 500µm) over 20° infinite exposures gradually produced a delayed rise in $[Ca^{2+}]_t$ accompanied by a slowing of recovery from 50mM K⁺ depolarization-induced $[Ca^{2+}]_t$ transients. These effects of SNOC were not mimicked by inactivated SNOC, nor by the components of SNOC. L-cysteine and NaNO2, but they were blocked by the NO scavenger oxyhemoglobin, confirming NO as the responsible agent. They were not mimicked by 8-bromocyclicGMP, and they were blocked by superoxide dismutase, suggesting that they involved peroxynitrite formation. The poly-(ADPribose) synthetase (PARS) involved peroxynitrite formation. The poly-(ADTribose) symuteate (FAS) antagonist benzamide did not prevent the effects of SNOC on slowing of $[Ca^{2+}]_i$ recovery; however, the effects of SNOC could be mimicked by the mitochondrial ATP synthase inhibitor oligomycin. Similar effects on $[Ca^{2+}]_i$ homeostasis were seen in combined perforated patch- $[Ca^{2+}]_i$ fluorimetry experiments, in which the $[Ca^{2+}]_i$ transients were induced by direct depolarization, but not in combined whole cell patch clamp- $[Ca^{2+}]_i$ fluorimetry experiments in which an ATP-regenerating system was supplied via the patch pipette.

We conclude that prolonged exposures to NO disrupt $[Ca^{2+}]_i$ homeostasis in hippocampal neurons by impairing Ca^{2+} extrusion from the cytoplasm, apparently as a result of inhibition of mitochondrial metabolism leading to depletion of ATP. The disruption of [Ca2+], homeostasis may potentially contribute to the delayed neurotoxicity of NO. Supported by NIH grant NS01630, the Schweppe Foundation, and the Brain Research Foundation.

CULTURED MURINE OLIGODENDROCYTES ARE HIGHLY VULNERABLE TO AMPA/KAINATE RECEPTOR - INDUCED DEATH. J.W. McDonald*, S.P. Althomsons, D.W. Choi and M.P. Goldberg. Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

CNS demyelination and oligodendrocyte death may be important functionlimiting sequelae in many neurological disorders including stroke, spinal cord and brain trauma, multiple sclerosis, and white matter encephalopathies. We established an in vitro co-culture system of well differentiated oligodendrocytes on an astroglial monolayer, a system that supports oligodendrocyte survival and differentiation DIV 14-28 oligodendrocytes were selectively Gal-C immunoreactive, expressed high levels of AMPA receptor protein (GluR B/C) subunit by immunohistochemistry, and were highly susceptible to exposures of AMPA for 24 hrs. Little astrocyte death was present under these conditions. The EC_{50} for AMPA-induced oligodendrocyte death was approximately 10 $\mu\text{M},$ comparable to that of cortical neurons. This death was associated with early cytoplasmic swelling and was sensitive to co-application of the AMPA receptor antagonist, NBQX observations consistent with excitotoxic form of death. The NMDA antagonist MK-801 or the growth factors CNTF or IGF-1 did not reduce death. Inhibition of AMPA receptor desensitization by cyclothiazide enhanced AMPA-induced death. Although exposure to glutamate was not very toxic, blockade of glutamate uptake with t-PDC, markedly augmented death. As we have previously demonstrated for neurons, AMPA-induced death of oligodendrocytes was markedly enhanced by reduction of extracellular pH to 6.6. These data suggest that high vulnerability to death induced by low concentrations of excitotoxins is not unique to neurons, and raise the specific possibility that excitotoxic oligodendrocyte death may play an important role in the pathogenesis of certain neurological disorders Supported by NIH NINDS grants NS 32140 (MPG) and 36636 (MPG and DWC)

478.7

Ca2+ changes driven by electrical activity are depressed, not increased, in post-ischemic hippocampal CA1 neurons destined for death. J. A. Connor*, J.J. Petrozzino, S. Razani, R. Cormier & R.C.S. Lin ^. The Lovelace Institutes, Albuquerque NM 87108 ^Med. College of. PA. &

Lovelace Institutes, Albuquerque Nav 87105 *Ned. Conege of PA. & Hahnemann University, Philadelphia, PA 19102.

CAI neurons subjected to a 5-10 min global ischemia initially survive the insult but, for undetermined reasons, up to 90% die over the next few days. It is widely agreed that large Ca²⁺ increases, during the ischemic period, initiate death dealing processes, and it has been speculated that delayed increases in Ca²⁺ loading during electrical activity or the loss of Ca²⁺ regulation are proximal causes of death. We have measured Ca²⁺ homeostasis of CA1 neurons in brain slices from adult gerbils following 5 min, *in vitro*, ischemia. Brain slices were prepared 1, 2, &3 days after the insult and examined by microelectrode recording and fluorescence imaging of fura-2. At 1 day after the insult (P-i 1), neurons were indistinguishable from controls with respect to maximum Ca²⁺ changes evoked by current injection, time course of Ca²⁺ recovery, and resting Ca²⁺ levels. Over the next two days however, the maximum changes during firing were suppressed, by ≈ 65% on average at P-i 3. Resting Ca²⁺ trended to lower levels. Recovery time course following spike induced loading was unchanged, indicating that buffering and uptake mechanisms were functional. Dendrite beading, an anatomical correlate of CA1 neuron degeneration was confirmed for a sub population of the experimental neurons by co-injection of biocytin with fura-2 and later examination. The results point to Ca2+ 'starvation' not delayed overload as a factor in the CA1 death program.
Support from Alzheimer Foundation to RCSL

ENHANCED RECOVERY FROM OXYGEN/GLUCOSE DEPRIVATION OF HIPPOCAMPAL CAI EPSPS IN CALBINDIN KNOCKOUT MICE, G.J. Klapstein**, P. Gray, I. Mody, M.S. Airaksinen, M. Meyer, and H. Thoenen, Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA, and Dept. of Neurochemistry, Max-Planck Institute for Psychiatry, Martinsried, F.R. Germany

Neurochemistry, Max-Planck Institute for Psychiatry, Martinsried, F.R. Germany' Calcium binding proteins are thought to act as intracellular calcium buffers, thereby shielding against Ca^{2*} mediated pathology. It has been speculated that the selective vulnerability of certain neurons to Ca^{2*} dependent injury may stem from a lack of calbindin (CB) content. We tested this hypothesis by examining in vitro the effects of transient oxygen/glucose deprivation (OGD) on synaptic responses of CA1 pyramidal cells, one of the most vulnerable neurons to ischemia in the mammalian brain. We compared the effect of OGD in 5 CB nullmutant mice (CB-/-) with their heterozygote littermates (CB+/-, n=5) and wild-type controls (CB+/+, n=5).

heterozygote littermates (CB+'-, n=5) and wild-type controls (CB+'+, n=5).

Coronal brain slices (350µm thick) were incubated, submerged at 35°C in a recording chamber and perfused constantly with ACSF in an atmosphere of warm, moist carbogen (95% O₂, 5% CO₂). Extracellular field EPSPs were recorded from stratum radiatum of area CA1. All experiments and analyses of EPSP slopes were conducted blindly with respect to the genotype of the animals. Following a control period of at least 10 minutes, OGD conditions were imposed for either 6 or 8 minutes by substituting sucrose for glucose (equimolar) in the perfusion solution, and 95% N₂, 5% CO₂ for carbogen, resulting in a rapid and dramatic reduction (91-100%) in EPSP slope for all genotypes. All genotypes recovered well following 6 minute OGD (n = 8-15), with little difference in either recovery rate (time constant of recovery; t. min: slope for all genotypes. All genotypes recovered well following 6 minute OGD (n = 8-15), with little difference in either recovery rate (time constant of recovery; τ, min: CB-/- 4.45; CB+/- 6.08; CB+/+ 9.26) or degree of recovery (normalized % recovery ± sem, measured at 30 min post-OGD: CB-/- 85 ± 13; CB+/- 65 ± 12; CB+/+ 93 ± 11) following return to control conditions. Following 8 minute OGD (n = 11-16), however, EPSPs in CB-/- and CB+/- recovered faster (τ=6.17 min and 5.71 min) than wild type (τ=29.6 min) but CB-/- recovered to a significantly greater degree (72 ± 10%) than either of the other two genotypes (CB+/- 26 ± 9%; CB+/+ 21±19%). Our data are inconsistent with a purely neuroprotective role of calbindin. Supported by grant NS-27528. GJK holds an AHFMR postdoctoral fellowship.

ZINC TOGETHER WITH LOW pH POTENTIATE KAINATE-INDUCED DEATH OF ASTROCYTES. S.L Sensi*, L.M.T. Canzoniero, J.Y. Koh, and D.W. Choi. Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Although astrocytes express AMPA and kainate receptors (Holzwarth et al.,

J.Neurosci.,14:1879, 1994), they are highly resistant to death induced by excitotoxins when tested by themselves at normal pH. However, during ischemia in vivo, extracellular pH decreases. Further, it is likely that zinc, normally present in the presynaptic vesicles of central glutamatergic neurons, is released. We examined the effect of adding zinc and lowering pH, on the vulnerability of cortical astrocytes to kainate exposure

Murine cortical astrocytes (DIV 15-21) exposed to 1 mM kainate for 1 hr at normal (7.4) or acidic (6.2) pH did not exhibit degeneration assayed 24 hr later. While astrocytes are vulnerable to injury induced by high concentrations of zinc (300 μM)(Yokoyama et al., Neurosci .Lett. 71:351, 1986), 1 hr exposure to 50 μM zinc at either pH 7.4 or 6.2 was also non-toxic.

However, 1 hr exposure to 1 mM kainate in the presence of 50 µM zinc and lowered pH to 6.2, produced extensive glial injury.

Further studies will be necessary to understand the mechanisms underlying this

toxic potentiation, but present data raise the possibility that AMPA/kainate receptor activation on astrocytes can be lethal under ischemic conditions, or other conditions where extracellular zinc and protons are increased. Supported by NIH NINDS grant NS 32636 (DWC)

CREATINE REDUCES GLUTAMATE-MEDIATED APOPTOTIC CELL DEATH IN A NEURONAL CELL LINE. Zun Lee and Mario D. Saltarelli. Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322

Excitotoxicity, defective cellular energy metabolism, and oxidative stress have been implicated as interrelated pathological mechanisms underlying various neurological disorders. Neuroblastoma hybrid cells (N18-RE-105) undergo apoptotic cell death via a slow oxidative mechanism involving glutathione depletion when they are exposed continuously to glutamate *in vitro*. To investigate the role of the phosphocreatine/ creatine kinase (PK/CK) system in neuronal death, we determined the effect of creatine supplementation on glutamate-mediated N18 cell death in vitro. As previously reported (Br. Res. 444:325), glutamate-mediated cell death (as determined by fractional LDH release) increased in a time- and concentration-dependent manner. However, when either creatine (5 mM) or the creatine analog β guanidinopropionate (β-GPA; 1mM) was added to the incubation medium, cell death significantly decreased (40% ± 3% reduction; X ± S.E.M.; N 12; p < 0.001). Similar protection by both creatine and β -GPA was also observed when cell death was determined by direct cell counting. L-Buthionine-sulfoximine (100 $\mu M),$ an irreversible inhibitor of γ glutamylcysteine synthetase, completely reversed the protective effects of creatine and β-GPA, suggesting potentiation of intracellular glutathione as the underlying protective mechanism. We hypothesize that creatine administration inhibits neuronal apoptosis through the enhancement of intracellular energy and antioxidant reserves. Supported by NINDS CIDA NS01651 (MDS).

LACTATING RATS ARE PROTECTED AGAINST THE EXCITOTOXICITY OF KAINATE D.A. Cruz, K. A. Berghorn, and G.E. Hoffman*. Department of

Neurobiology, Univ. Pittsburgh, Pittsburgh, PA, 15261.

Use of kainic acid (KA) serves as a model for temporal lobe epilepsy. KA produces seizures in the limbic system, and when severe, the seizures lead to exitotoxic cell death. Areas most vulnerable to damage are the CA1 and CA3 regions of the hippocampus. KA acting on non-NMDA receptors promotes the initial depolarization; actions involving NMDA receptors later lead to cell death. We determined earlier that lactating rats were resistent to behavioral and transcriptional effects of an NMDA agonist, raising the question of whether seizures and the excitotoxicity of KA could also be attenuated in the lactating animal. Lactating rats (day 9 post-partum) and cycling rats selected on diestrus I (DI) were given a single i.p. injection of 9 or 12 mg/kg KA. Three days after KA injection, the rats were anesthetized, perfused and examined for neuronal morphology. Seizure activity was evident in all rats. All lactating rats (n=6) survived treatment. The lactating animals that received 9 mg/kg resumed nursing within 24 of treatment. None of the DI rats (n=3) survived 12 mg/kg KA; 1 of 3 DI rats receiving 9 mg/kg of KA died within 12 hrs after injection. Seizures persisted intermittently for 48 h in surviving DI rats; in lactating rats seizures subsided within 24 h. Examination of the hippocampus using neutral red and acid fuchsin revealed damage to CA1 and CA3 in the surviving DI rats that exceeded that in the lactating rat, irrespective of the KA dose. Lactating rats receiving 9 gm/kg KA had little evidence of excitotoxic cell injury or cell death. These experiments show that lactation provides protection against KA induced neuronal excitotoxicity. HIGH-POTASSIUM-INDUCED NEURONAL DAMAGE IN VIVO: EFFECTS OF GLUMATATE-RECEPTOR AND SODIUM-CHANNEL BLOCKADE.

GLOBATATE B. Sohn and A.F. Alcaraz. Exp. Neurol. Lab., VA Med. Ctr., Sepulveda, CA and Dept. of Neurology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA. Microdialysis probe delivery of an isotonic high-K* solution to the rat amygdala for 60 min produces neuronal necrosis, edema and increases in extracellular glutamate (GLU_o) (3-4-fold) and aspartate (ASP_o) (2-fold) (Fujikawa et al., Neuroscience, 1996). The competitive NMDA-receptor antagonist CGP 40116 dialysed unilaterally in rats with high-K* perfusion of both amygdalae is neuroprotective but does not affect the severe edema. In this study we determined the effect of CGP 40116 on extracellular amino acid concentrations during high-K⁺ perfusion and the effect of reduced NaCl perfusion and Na⁺-channel blockade, with and without combined NMDA- and AMPAreceptor blockade. Bilateral CMA/11 guide cannulae were placed in the basolateral amygdaloid nuclei of adult Wistar rats. The next day CMA/11 microdilays probes were inserted and perfused with KRB solution for 2 h in freely-moving rats. The solution was then switched bilaterally for 60 min to 100 mM KCl in modified KRB (of which 12% was extracted by tissue). In the CGP 40116 experiments, one side contained either $36 \mu M$ (n=6) or $360 \mu M$ (n=7) CGP 40116 during baseline and high-K⁺ perfusion; 42% of the 36 μ M and 48% of the 360 μ M CGP 40116 were extracted by tissue. In the reduced NaCl + TTX experiments, one side contained 15 mM NaCl + 3.3 mM TTX (42% was taken up by tissue) during high-K* perfusion, with (n=6) or without (n=7) bilateral 360 μ M CGP 40116 + 500 μ M NBQX during baseline and high-K* perfusion. bilateral 300 µm Cu7 40116 - 300 µm NoQX during baseline and ingli-K periusion.
36 µM CGP 40116 alone had no effect on high-K-induced increases in GLU, and ASP, whereas the neuroprotective 360 µM concentration prevented the high-K-induced elevation of GLU $_{\circ}$ (290 ± 41% on the control side vs. 149 ± 15% on the CGP 40116 side; p < 0.001). Reduced NaCl + TTX alone decreased tissue edema slightly but did not protect neurons, and it did not add to the protective effect of CGP 40116 + NBQX. The reduction in GLU_o by CGP 40116 may play a role in its neuroprotective effect. Na*/Cl influx may not contribute to high-K*-induced neuronal death in vivo. (VA-supported.)

CELL DIFFERENTIATION AND MIGRATION VIII

479.1

INVOLVEMENT OF THE DROSOPHILA LIM HOMEOBOX GENE *islet* IN NEURONAL DIFFERENTIATION. S. Thor and I.B. Thomas*, Molecular Neurobiology Laboratory, The Salk Institute, 10010 N. Torrey Pines Rd. La Jolla, CA 92037.

The LIM homeobox genes encode a distinct family of transcriptional regulators. One distinguishing feature of these genes is that they appear to be expressed in discrete subsets of differentiating neurons. To elucidate the possible subsets of differentiating neurons. To elucidate the possible role of these genes in controlling neuronal differentiation we have cloned the Drosophila homolog of the vertebrate islet genes. From a series of promoter fusions to an axontargeting tau-myc reporter, we have found that islet is expressed in a subset of differentiating motorant interneurons. In islet mutants a subset of the islet expressing neurons show pathfinding defects. In addition, some of the islet expressing interneurons are dopaminergic and can be visualized by the expression of tyrosine hydroxylase (TH). The expression of islet precedes the onset of TH expression and in islet mutant embryos we observe an apparent loss of TH expression, suggesting that islet may be involved in the direct transcriptional regulation of TH.

STRENGTH OF INTERCELLULAR COMMUNICATION HAS A PRONOUNCED INFLUENCE ON NEURONAL DIFFERENTIATION. R. Rozental, M. Urban, A. Andrade-Rozental, G.I. Fishman, E.M. Eves, M.R. Rosner and D.C. Spray. Depts. Neurosci. & Med., A. Einstein Coll. Med., Bronx, NY 10461; Inst. Biophysics "Carlos Chagas Filho", Fed. Univ. Rio de Janeiro, Brazil; Ben May Inst., Chicago, IL 60637.

We have shown that electrotonic coupling (g_i) via Cx43 is quite strong among immature neuroblasts and that Cx43 mRNA progressively decreases during neuronal differentiation. To examine the possible coordinate regulation between gap junction down-regulation and acquisition of neuronal phenotype, we have used an SV40 immortalized rat hippocampal neuronal cell line that is highly coupled by a single connexin-type (Cx43) and that can be induced to differentiate with retinoic acid (0.3 μ M) as evidenced by immunocytochemical and functional criteria; these were compared with cells further transfected with Cx43 by electroporation, to cells treated with heptanol (2-3 mM) or 18-α-glycyrrhetinic acid (10-40 μ M), inhibitors of gap junctional coupling, and to cells treated with hexanol (2-3 mM) or glycyrrhizic acid (10-100 μ M), respective controls. We show that constitutive over expression of Cx43 in transfectants antagonizes neuronal differentiation; in contrast, uncoupling treatments lead to more rapid neuronal maturation. Thus, decreased intercellular coupling appears to be permissive for early steps in neuronal differentiation.

MAMMALIAN NEURAL CREST CELLS EXPRESS FUNCTIONAL GAP JUNCTIONS - EVIDENCE THAT GAP JUNCTIONS MODULATE THE SURVIVAL OF NEURAL CREST CELLS, P.G. Bannerman.* T.M. Oliver, Z. Xu. and D.E. Pleasure . Neurology Research, Children's Hospital of Philadelphia, Philadelphia, PA 19104.

Connexons are the functional units which comprise supramolecular Connexons are the functional units which complexes suprainforeural complexes termed gap junctions. Gap junctions are widely held to perform pivotal role(s) in mediating intercellular communication during the development of eukaryotic organisms. We show for the first time that mammalian neural crest cells (NCC), the progenitor cells of the peripheral nervous system (PNS), assemble demonstrable gap junctions as assayed by dye (lucifer yellow) transfer experiments. Immunohistochemical techniques demonstrated that NCC express the connexon processing as (CAS) both in vivo and in vitro.

Immunohistochemical techniques demonstrated that NCC express the connexon protein, connexin 43 (Cx43) both in vivo and in vitro.

We hypothesized that Cx 43⁺ connexons participate in the regulation of intracellular communication during the early development of the mammalian PNS. We tested this hypothesis by perturbing the function of NCC gap junctions in a neural tube explant culture paradigm A) using the uncoupling agent octanol and B) inhibiting the synthesis of Cx 43 connexons by antisense methodology. Our data shows that octanol(1mM) but not hexanol(1mM) (which does not uncouple gap junctions), markedly decreases the survival of a subset of NCC. Studies with phosphothiolated antisense/sense oligomers (22mer,150uM) which overlap the initiation and termination sites of the rat sequence for Cx43 (Genebank Accession phosphothoridate antisense/serise brigoniers (22)fiet, journy with overlap initiation and termination sites of the rat sequence for Cx43 (Genebank Accession #M19317), provide strong evidence that perturbation of Cx43 synthesis also decreases the survival of a subpopulation of NCC. These results clearly demonstrate a role for gap junctions in the development of NCC.

SEROTONIN MODULATES IN VITRO NEURONAL MIGRATION IN RODENT CEREBRAL CORTEX. J.-P. Hornung* and J. Durig. Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

We tested the influence of serotonin on the migration of layers II/III neurons, which leave the cell cycle late (E16/17 in mouse, E19 in rat) and reach their final laminar distribution 3 to 5 days later. Both in rats and mice neurons destined to the upper layers were labelled by systemic BrdU injection to the dam on the day of their final division. One to three days later, embryos were harvested and slices of the cerebral cortex were maintained in organotypic cultures for 7 days. Culture medium contained various concentrations of serotonin (0,1,5, or 10 μ M) or 5 μ M of agonist or antagonist of the 5-HT1a (8-OHDPAT/NAN-190), or of the 5-HT2 (alphamethyl-5-HT/ritanserin) receptors. After one week in culture, slices were fixed and immunostained for BrdU. Brains of embryos of the same litters were fixed, cut, and stained in parallel to verify that labeled neuroblasts had not migrated prior to the culture period. Compared to the situation *in vivo*, many neuroblasts did not complete their migration to their expected final laminar position in layer II (with the present conditions of labeling). However, the proportion of labeled neuroblasts which succeeded in reaching layer II was directly proportional to the concentration of serotonin in the medium. This proportion was also high after 5-HT1a agonist treatment but was low in the presence of the 5-HT1a antagonist (combined with 5 μM 5-HT) or the 5-HT2 agonist. Neuronal migration in cultures treated with medium supplemented with dopamine or noradrenaline (10 μ M) was comparable to that of controls (with 0 μ M 5-HT). These data suggest that serotonin has a selective promoting function (5-HT1a-mediated) on neuronal migration in the cerebral wall which could ultimately affect laminar cortical organization in cases of monoamine metabolism disturbances. DOPAMINE ALTERS THE EXPRESSION OF PARVALBUMIN DURING CORTICAL DEVELOPMENT IN VITRO. L.L.Porter*, J.-P.Hornung. Inst. Anat., Univ. of Lausanne, 1005 Lausanne, Switzerland.

We examined the effects of dopanine (Da) on the morphological and temporal patterns of parvalbumin (Pv) expression during neocortical development. Organotypic slice cultures of the cerebral cortex were prepared from neonatal rats (PN 2/3) and maintained for 6 to 35 days.in-vitro (DiV) in serum-enriched medium. Slices were fixed and immunostained for Pv immunoreactive (IR) neurons. Under control conditions, Pv IR cell bodies are first noted in cingulate ar neurons. Under control conductors, FV IX cert bodies are trist noted in congulate and perirhinal cortex at 6 DiV and are restricted to these regions. In Da (10 µM) enriched medium, Pv IR somata are detected not only in cingulate and perirhinal cortices, but also throughout frontal and parietal cortices at 6 DiV. The labeled somata are distributed throughout the deep cortical laminae. This pattern of Pv IR in Da enriched cultures at 6 DiV is similar to that in control cultures at 14 DiV. Da enriched cultures at DiV 14 exhibit an increased density of labeled somata in the enriched cultures at DiV 14 exhibit an increased density of labeled somata in the deep laminae, as well as, labeled neurons throughout all cortical laminae. Also, dendritic labeling is more extensive and a dense network of axons is evident in the deep laminae. This pattern emerges in control cultures by DiV 21. The differential development of Pv expression is apparent at all time intervals examined. Lower doses of Da (1 µM) appear to be less effective in altering Pv expression at earlier times. To determine if these effects are mediated by specific dopamine receptor subtypes, the cultures were maintained in SKF 38393 or quinpriole (D1, D2 agonists), or in Da with SCH 23390 or eticlopride (D1, D2 antagonists). These treatments indicate that the Da induced alteration of Pv expression is not mediated by D1 receptors. However, the D2 antagonist appears to block the effects of Da and the D2 agonist minings Da. Thus. a D2 receptor-mediated effect may be the the D2 agonist mimics Da. Thus, a D2 receptor-mediated effect may be the mechanism by which Da alters the pattern of Pv expression during cortical development. The relationship between the onset of Pv expression and functional activity in the cortex raises the notion that activation of the D2 receptor system may stimulate cortical activity, which in turn leads to enhanced Pv expression. DEVELOPMENTAL CHANGES OF PROTEIN KINASE C ISOFORMS IN CEREBELLAR GRANULE CELLS: IMPLICATION FOR NEURONAL DIFFERENTIATION AND SURVIVAL. W.W. Lin*, C.W. Wang and D.-M. Chuang. Department of Pharmacology, National Taiwan University, Taipei. Taiwan and Section on Molecular Neurobiology, NIMH, NIH, Betheda, Maryland 20892-1272

The primary cultures of cerebellar granule cells (CGC) grown in high K+ (25 mM) medium progressively differentiate in vitro by the appearance of neuronal aggregation and neurite outgrowth. These differentiation features occur after 3- to 4-day in vitro (DIV) and reach a mature stage after 8 DIV. Longer cultivation of CGC (≥13 DIV) triggers the processes of spontaneous cell death. To address the role of protein kinase C (PKC) in the development of CGC, we measured the kinase activity as well as the protein level of kinase isoforms. As the CGC culture proceeded, we found that the PKC activity time-dependently increased by 3.2 fold. reaching a steady state at 8 DIV. Western blot analysis using PKC isoformspecific antibodies revealed an increase in PKC $\alpha, \gamma, \mu, \lambda$ and ι from 2 to 8 DIV. A slight change was observed for PKC ϵ , while the isoforms of δ,θ and ζ were not detected. Compared to the 8 DIV cultures, the immunoactivity of PKC1, ϵ and λ was decreased and that of PKCα or γ was unchanged at 13 DIV, while that of PKCµ was still increased. In cultures grown in 25 mM KCl containing MK801, a NMDA receptor antagonist, CGC survived more than 20 DIV and all six PKC isoforms except PKCa, were increased more robustly and persistently up to 13 DIV. On the contrary, when CGC grown in 3 mM KCl medium, the immunoactivity of each PKC isoform at 2-4DIV was similar to that observed in K25 cells, although no remarkable differentiation features were observed Coordinated with the appearance of cell death at 8 DIV in low K⁺ cultures, PKCa. μ,λ and $\iota,$ but not $\gamma,\,\epsilon,$ were markedly decreased. Taken together, induction and accumulation of PKC isoforms may play a more important role in the maintenance of neuronal survival than initiation of neurite outgrowth.

A MODEL FOR THE DIFFERENTIATION AND MAINTENANCE OF THE EMBRYONIC RADIAL GLIAL SCAFFOLD IN MAMMALIAN FOREBRAIN K.E. Hunter* and M.E. Hatten, Laboratory of Developmental Neurobiology, The Rockefeller University, 1230 York Avenue, New York, New York 10021.
The radial glial scaffold is a transient structure in the mammalian forebrain, first appearing at the onset of cortical plate formation, being maintained

throughout embryogenesis, and disappearing perinatally, at which time the radial glia transform into mature astrocytes. The scaffold plays a key role in corticogenesis, since the glial fibers provide the primary substrate and template for neuronal migration. We have previously reported the existence of a soluble protein whose effects and in vivo expression suggest that it may function as a radial glial maintenance factor (Proc. Natl. Acad. Sci. USA, **92**:2061-2065). The molecular identity of the protein is being elucidated but the intriguing question of how it might function *in vivo* remains. In addressing this question of with lings in tendent. Who remains in addressing this question we have utilised the *reeler* mouse, in which there is a disturbance of glial guided neuronal migration during corticogenesis. Using immunohistochemical analysis we have found that the radial glial scaffold in *reeler* cortex is disorganised and poorly differentiated, that it disappears prematurely, and that astrocytes appear in *reeler* cortex earlier than normal. Together with our previous observation that *reeler* astrocytes cannot respond to our differentiation factor in vitro although the activity is present in reeler cortex (Soc. Neurosci. Abs. 315.6), these findings suggest that radial glia themselves may be a direct site of reeler gene action. Transplanting astrocytes into embryonic forebrain has revealed differences in the capacity of normal astrocytes to incorporate into either a normal or reeler cortical environment, and has suggested there may be a defect in the way in which the differentiation factor is presented in *reeler* cortex. These findings begin to illuminate the question of how the radial glial cell scaffold is initially established and maintained, and subsequently transforms, in the mammalian forebrain. INTRA-UTERINE TRANSPLANTATION OF NEURAL PRECURSORS ALLOWS THE STUDY OF NEUROLOGICAL AND TARGETED MOUSE MUTANTS IN A WILD-TYPE BACKGROUND. <u>U Maskos*, O Brüstle, and</u> RDG McKay, LMB/NINDS/NIH, Bethesda MD 20892-4092.

RDG McKay, LMB/NINDS/NIH, Bethesda MD 20892-4092.

Neural precursors derived from E14 wild-type and transgenic mouse embryos were transplanted into the ventricular system of E16 to E18 rat embryos using intra-uterine transplantation (O Brüstle, U Maskos & RDG McKay, Neuron 15, 1275-1285, 1995], thus distributing them over the entire neuroepithelium. The transplanted cells were followed using genetic marking methods, i.e. the expression of a lacZ reporter gene, in situ hybridisation to mouse DNA, and mouse-specific neural antigens. The precursors were able to leave the ventricle and migrate into the parenchyma where they differentiated into neurons in a region-specific manner. This method was used to analyse NMDA receptor R1 mutant mice. The NMDA receptor is one of the most intensely studied proteins in the brain because of its involvement in neurotransmission, synaptic plasticity and neurodegeneration. Homozygous mutant animals die on the day of birth,

neurodegeneration. Homozygous mutant animals die on the day of birth, which precludes their analysis at the most interesting later stages of development and maturity.

Embryos from matings of heterozygous animals were dissected and genotyped by PCR. Single cell suspensions from homozygous null embryos were injected into E18 rat embryos. Analysis of young and adult transplanted animals showed that the mutant cells survive, migrate and differentiate in the wild-type background.

This new method now allows to study the phenotype of fully differentiated cells that would otherwise not be accessible because of embryonic or neonatal death of the animal, and, as a transplantation technique, allows the heterochronic and heterotopic placement of cells into a large number of brain areas

DIFFERENTIATION OF OLIGODENDROCYES FROM MULTIPOTENT SUBVENTRICULAR ZONE PROGENITOR CELLS IN VITRO IS REGULATED BY CNTF/IL6 gp130 CYTOKINES AND INTRINSIC CELLULAR SIGNALS R. Marmur*, M. F. Mehler, P. Mabie and J. A. Kessler, Dept. of Neurology and Neuroscience, Albert Einstein Col. Of Medicine, Bronx NY, 10461

Little is known about epigenetic signals that regulate the differentiation of early oligodendrocyte progenitors at the pre-OLP stage (A2B5-/O4-). Embryonic day 17 multipotent subventricular zone (SVZ) progenitor cells were processed for A2B5 immunoselection and the A2B5- SVZ progenitors were utilized for our experimental paradigms. Compared to moderate density cultures, high density rise to a higher proportion of post-mitotic OLs (galactocerebroside, GC+; 5±3% vs. 15±6% of the total cells) and accelerated the generation of GC+ OLs (10 vs. 6 DIV). Application of CNTF but not 1L6 enhanced the relative proportion of OLs (30±7% of total cells) and further shortened the temporal interval for oligodendrocyte differentiation (4 DIV). In the absence of added factors, no proliferating OLPs (O4+/BrdU+) were detected at 4 DIV. Application of bFGF (Ing/ml) resulted in the generation of proliferating OLPs (9-11% of the total O4+ cells), while combined application of bFGF/IL6 enhanced these proportions (16-19% of total O4+ cells), whereas bFGF/CNTF cotreatment significantly decreased these proportions (1-2% of the total O4+ cells). Subsequent factor withdrawal (4 DIV) and propagation in defined SFM for 5additional days demonstrated that bFGF/IL6 pre-treatment further enhanced, while bFGF/CNTF pre-treatment restricted the number of GC+ OLs compared to bFGF alone. We conclude that intrinsic factors within the SVZ culture system as well as specific cytokine subgroups regulate the mitogenic capacity of nascent OLPs as well as the temporal development of OLs. A REGIONALLY DISTRIBUTED RADIAL GLIAL ANTIGEN: A CANDIDATE FOR SIGNALING AN END TO NEURONAL MIGRATION. <u>E. S. Anton*, W. D.</u> Matthew^, and P. Rakico. ° Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06514 . ^Dept. of Neurobiology, Duke University School of Medicine, Durham, NC 27710.

During the development of cerebral cortex, neurons generated in the ventricular zone sequentially migrate to the interface between cortical plate and marginal zone (layer 1), where they stop, detach from the radial glial fibers, and become part of the laminar architecture of the cerebral cortex. To elucidate mechanisms that signal neurons to end their migration, a panel of antibodies previously known to recognize embryonic CNS antigens was screened in developing rat cerebral wall. One of the antibodies, PC2A1 recognizes an antigen (a doublet of ~ 330 kDa) that is primarily localized to the developing cortical plate. During corticogenesis, the superficial strata of the cortical plate appear to label more intensely than the lower strata of the cortical plate. Interestingly, the marginal zone is devoid of labeling. In vivo and in vitro, double labeling studies using various glial markers and PC2A1 mAbs, indicate that PC2A1 recognizes a radial glial cell surface antigen. The prominent spatial and temporal distribution of PC2A1 antigen in the region of radial glia spanning the developing cortical plate suggests that it may function as a positional indicator for cessation of neuronal migration. Preliminary results from in vivo studies using BrdU-labeled migrating neurons support this hypothesis, since exposure to PC2A1 mAbs disturbs the settling of neurons at the interface between the cortical plate and marginal zone. [Supported by NS22807 (PR) and a Public Health Service Fellowship (EA)].

THE FORSE-1/Lex CARBOHYDRATE EPITOPE IS INVOLVED IN MIGRATION OF DEVELOPING CORTICAL NEURONS. K.L. Allendoerfer.*
B.S. Kim, and P.H. Patterson. Division of Biology, Caltech, Pasadena, CA 91125.

During cortical development, newly-generated neurons migrate away from the ventricular zone through diverse extracellular environments to their final positions in the cortical plate, which will become the adult cortex. Cell-surface carbohydrate moieties, which mediate adhesion and recognition events in the immune and hematopoictic systems, could provide a high degree of complexity to the environment through which the young neurons move. We have recently shown that the FORSE-1 monoclonal antibody (mAb), which labels the proliferative neuroepithelium of the telencephalon, specifically binds to the LewisX (LeX) carbohydrate epitope. We find the FORSE-I/LeX carbohydrate epitope on two types of molecules in embryonic rat brain: neutral glycolipds in the early types of molecules in embryonic rat brain: neutral glycolipds in the early embryo, and the chondroitin sulfate proteoglycan, phosphacan, at late embryonic and early postnatal stages. In order to study the function of the FORSE-1/LeX carbohydrate in the brain, we injected FORSE-1 mAb, control mAbs, and oligosaccharide agonists and antagonists into the ventricles of the E15.5 embryonic rat brain. FORSE-1 mAb-producing hybridoma cells survive well after injection, and they secrete mAbs that penetrate throughout the developing cortex. Effects of FORSE-1 mAb treatment on neuroblast migration are assayed in situ by labeling a cohort of neuroblast hitparable may the moules. in situ by labeling a cohort of neuroblasts through BrdU injection into the mother and measuring the distance this cohort of cells has migrated in treated and control and measuring the distance this cohort of cells has migrated in treated and control embryos by E21.5 (after 6 days of mAb exposure). Our inititial experiments indicate that in the presence of FORSE-1, neurons generated on E16.5 have migrated a much shorter distance from the ventricular zone by E21.5 than those in control brains (uninjected, mock-injected, and those injected with a control mAb, HNK-1). These results suggest that the FORSE-1/LeX carbohydrate epitope is important for neuroblast migration in the developing cerebral cortex. Supported by the Helen Hay Whitney Foundation (KLA), the NIH (PHP), and Caltech SURF (BSK).

NEURONAL CHANGES IN GRAY MATTER OVERLYING WHITE MATTER LESIONS IN DEVELOPING HUMAN NEOCORTEX. M. Marín-Padilla*. Dept Pathology. Dartmouth Medical. School, Hanover, NH 03755.

Perinatal brain damage in prematurely born infants who suffered perinatal asphyxia requiring prolonged hospitalization has been associated with the late occurrence of neurological sequelae (cerebral palsy, epilepsy, mental retardation). Rapid Golgi study of the neocortex of 22 infants who survived clinically documented white matter damage (necrosis) -for hours, days, months, and years-has demonstrated secondary neuronal alterations in the overlying and still developing gray matter (acquired neocortical dysplasia). The main consequence of white matter damage (infarction) is the local destruction of the axis-cylinders (axons) of corticipetal, corticofugal, and association fibers affected by the lesion. Consequently, the overlying and still developing gray matter is deprived of some afferent fibers needed for its 'normal' maturation and the severed axons of its projective neurons will failed to reach their targets. The following observations have been made in this secondarily affected gray matter. Its developing neurons are able to survive this type of injury (deprivation) and to continue their structural and functional 'albeit abnormal' maturation. Affected gray matter neurons undergo progressive differentiation (transformation) of their dendritic and axonic arborizations; some of them become large hypertrophic meganeurons. The axons and collaterals of affected projective neurons are exclusively distributed intracortically. These neurons are subsequently transformed into local-circuit interneurons. Accordingly, the intracortical neuropil of the affected gray matter region increases significantly. The direct vascularization of the gray matter by leptomeningeal perforating vessels remains unaffected. The evolution of these acquired cytoarchitectural alterations in the overlying gray matter will be illustrate by exploring simultaneously acute, subacute (healing), and chronic (repaired) underlying white matter lesions. The study proposes that acquired gray matter alterations could cause local cortical dysfunction which could play a role in the pathogenesis of neurological disorders.

DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID-PATHOGENESIS

480.1

ENHANCED PATHOLOGIC PROPERTIES OF DUTCH-TYPE MUTANT AMYLOID 6-PROTEIN. W.E. Van Nostrand* and J. Davis. Dept. of Medicine, Health Sciences Center, State University of New York, Stony Brook, NY 11794-8153.

Cerebrovascular amyloid B-protein (AB) deposition is a pathological feature of several related disorders including Alzheimer's disease and hereditary cerebral hemorrhage with amyloidosis Dutch-type (HCHWA-D). This latter disease is caused by a point mutation in the gene that encodes the amyloid β-protein precursor (ABPP) and results in a Glu -> Gln substitution at position 22 of AB. In comparison to Alzheimer's disease, the cerebrovascular Aß deposition in HCHWA-D is generally more severe, often resulting in intracerebral hemorrhage when patients reach fifty years of age. We recently reported that ${\rm AB}_{1-42}$, but not the shorter AB₁₋₄₀, induces pathologic responses in cultured human cerebrovascular smooth muscle (HCSM) cells including cellular degeneration that is accompanied by a marked increase in the levels of cellular ABPP and soluble AB peptide. In the present study, we show that the HCHWA-D mutation converts the normally nonpathologic A81-40 into a highly pathologic form of the peptide for cultured HCSM cells resulting in enhanced cell death and higher levels of cellular ABPP compared to wild type AB1-42. findings suggest that these altered functional properties of HCHWA-D mutated AB may contribute to the early and often severe cerebrovascular pathology that is the hallmark of this disorder.

HYDROGEN PEROXIDE INDUCES AB ACCUMULATION IN NEURONS Y. Ohyagi* and S. G. Younkin. Mayo Clinic Jacksonville, Jacksonville, FL 3222-

Amyloid β (A β) protein is a soluble 4 kD protein, which is normally secreted but characteristically deposited in the Alzheimer's disease (AD) brain. We reported at the last Neuroscience Meeting (Ohyagi et al. '95) that fetal guinea-pig primary mixed brain cell cultures vigorously secrete AB. We now present studies of AB metabolism in those cells using Aβ-end-specific monoclonals.

The mixed primary cultures were prepared from fetal brain and maintained in medium containing 5% calf serum. Sandwich ELISAs revealed that 90% of Aβ in the medium was $A\beta_{1-40}$ while 10% was $A\beta_{1-42(43)}$, and that $A\beta$ was detectable even in the cells, but by contrast, 60% of A β was A $\beta_{1-42(43)}$. This finding is of considerable interest because $A\beta_{1:42(43)}$ is the major $A\beta$ that is deposited in AD brain. We then treated these cultures with H₂O₂ at various concentrations. After H₂O₂ treatment, secreted Aβ levels were substantially decreased, but the cellular Aβ content was gradually increased, and the increase in cellular $A\beta_{1.42(43)}$ was larger than that in cellular Aβ₁₋₄₀. These effects of H₂O₂ were significantly prevented by antioxidants α-tocopherol or N-tert-butyl-2-sulpho-phenylnitrone Immunocytochemically, $A\beta_{42(43)}$ was clearly deposited in the damaged cells, and most of those cells seemed to be neurons. Combined analysis with Perls' stain for Fe³⁺ and appropriate immunocytochemical markers revealed that Fe³⁺ appeared in the damaged neurons. These results may indicate that an iron-related radical generation caused by H_2O_2 such as the Fenton reaction $(H_2O_2+Fe^{2\star}\rightarrow Fe^{3\star}+OH^{\star}\bullet OH)$ occurs in the neurons, and that hydroxyl radical ($\bullet OH$) formation may contribute to AB accumulation. In AD brain, Fe^{3*} and A $\beta_{42(43)}$ were found in some neurons as well as senile plaques. This suggests that our in vitro finding of intraneuronal AB accumulation caused by H2O2 may be related to AD pathology (Supported by French Foundation for Alzheimer Research)

AMYLOID β CYTOTOXICITY IS ASSOCIATED WITH DEFICIENT ACTIVATION OF AN OXIDATIVE STRESS REGULATORY PATHWAY IN NEURAL CELLS. A. Kopp* Stanton. Dep't of Med., Deaconess Hosp., Boston, MA 02215

Amyloid β (Aβ) stimulates H2O2 production. Aβ cytotoxicity is caused, at least in part, by H2O2. Aß circulates, yet the main pathologic changes occur only in neural cells. We studied whether there was a difference in how a neural cell line (B12) regulates oxidative stress versus non-neural cells (Hep G2, a liver cell line). After 24 hrs. of Aβ(25-35) exposure, 55% of the HepG2 cells were viable; only 11.1% of B12 cells were viable. A β stimulated H2O2 production in both cell lines: (B12 - 3 x control; HepG2 - 2 x control). Activity of the hexose monophosphate (HMP) shunt, source of the main intracellular reductant, NADPH, was measured. AB caused a 67% increase in the HMP shunt in HepG2 cells. In B12 cells Aβ caused no increase in HMP shunt activity; yet exogenous H2O2 increased HMP shunt activity in B12 cells. Catalase decreased HMP shunt activity in both cell lines. Conclusion: Aß cytotoxicity of B12 cells is mediated, at least in part, by lack of activation of a critical oxidative stress defense mechanism.

β-AMYLOID-ASSOCIATED FREE RADICAL OXIDATIVE STRESS: RELEVANCE TO ALZHEIMER'S DISEASE. D. A. Butterfield*, R. Subramaniam, K. Hensley, M. Aksenova, M. Aksenov, M. Harris, K. Allen and J. Carney. Dept. of Chemistry and Pharmacology and Center of Membrane Sciences, University of Kentucky, Lexington, KY 40506.

 β -amyloid peptide (A β) is the central constituent in senile plaques (SP) in Alzheimer's disease (AD) brain. Our group first demonstrated A β -associated, oxygendependent free radicals using electron paramagnetic resonance (EPR) spin trapping methods, a result recently confirmed by others. A free radical-based model of Aβinduced neurotoxicity in AD was developed to account for and unify into one theoretical framework the numerous reports of multiple membrane protein and lipid alterations in brain membranes in AD. Explicit tests of the model, which states that Aβ-derived free radicals react with key components of neuronal and glial cell membranes leading to their dysfunction and subsequent cell death, have been conducted. EPR spin trapping and spin labeling, histofluorescence, measurements of enzyme activity and protein carbonyl levels, etc. were used. We found that Aβassociated free radicals in brain membranes cause: lipid peroxidation (consistent with the findings of others that $A\beta(25-35)$ inserts into the lipid bilayer domain of brain membranes); protein oxidation; inhibition of multiple transmembrane transport systems; increased reactive oxygen species; large accumulations of intraneuronal Ca2+; and brain cell death. All these $\ensuremath{\mathsf{A}\beta}\xspace$ inhibitable by free radical scavengers, consistent with a free radical basis for these findings. Our model predicts, and we found, that in AD brain the hippocampal and inferior parietal regions, rich in SP, exhibit significant protein oxidation, while the cerebellum, poor in SP, does not, relative to age-matched controls in rapid autopsy material. An important role of $A\beta$ methionine in these processes is emerging, and our data to support this role will be presented. Our findings are consistent with Aβ-associated free radical oxidative stress being a fundamental process in AD. Supported by NIH grants AG-10836; AG-05119.

MITOCHONDRIAL FAILURE INDUCES ABNORMAL CEREBRAL ZINC HOMEOSTASIS: A PRELUDE TO AMYLOID FORMATION? C.S.Atwood1, X.Huang1, R.Matthewsf, R.D.Moir, M.F.Bealf, R.E.Tanzi, A.I.Bush*. Genetics & Aging Unit, &Theurology Res., Mass. Gen. Hosp., Boston, MA. flirist-authors Aß, the main component of plaque amyloid in Alzheimer's disease (AD), specifically binds zinc, when, at physiological concentrations, it increases the peptide's resistance to proteolysis and rapidly induces amyloid formation (Bush et al., Science, 265, 1464; 1994). Rat Aß is not as sensitive to the effects of zinc. We have confirmed our initial findings using various techniques including turbidometry as well as sedimentation analysis of tritium-labeled peptide, and concluded that aggregation of a 10 µM solution of AB1-40 by 10 µM AU(II) at pH7.4 is a robust test of the patency of the synthetic peptide, but is contingent upon (a) the presence of isotonic NaCl. (b) the freshness of the peptide stock, since aged peptide (eg frozen and thawed) has attenuated interaction with zinc, (c) the conformation of the peptide, since -n-belical promoting solvents enhance zinc-induced precipitation and its reversibility.

These in vitro data are important since they describe pathophysiological conditions that could be emulated. The brain compartmentalizes high concentrations of zinc in glutamatergic boutons by an energy dependent mechanism, so we studied the effect of 3-nitroproprionic acid, a mitochonodrial (succinate dehydrogenase) inhibitor, upon cerebral zinc homeostasis in rats. Zinc in frontal cortical tissue samples fell 70% within 9 hours, but copper levels in the frontal cortex were unaffected. This change probably reflects the loss of reuptake of zinc into synaptic boutons following neurotransmission. Similar changes in zinc levels in AD-affected neocortex have been reported. Failure of reuptake of zinc following neurotransmission may cause an elevation in extracellular zinc levels in the vicinity of the synapse (which cannot be appreciated by this assay), p

PYROGLUTAMATE-MODIFIED AMYLOID β-PEPTIDE IN ALZHEIMER'S PYROGLUTAMATE-MODIFIED ANTI-OTO PTET THE BURNEY OF SYNDROME C. Russo, L. M. DeBusk, T. C. Saido*, X. M. Xu, M. Tabaton, P. Gambetti and J. K. Teller Institute of Pathology, Case Western Reserve University, Cleveland, OH 44106, U.S.A. and Metropolitan Institute of Medical Science, Tokyo 113, Japan

We have recently demonstrated that soluble amyloid β -peptides (sA β), ending at residue 42 precede amyloid plaque formation in Down's syndrome (DS). The same pathogenic mechanism seems to operate in Alzheimer's disease (AD). The soluble peptides can be resolved into at least three forms, one being modified by cyclization of the N-terminal glutamate at the third residue (pyrA β). We have characterized this form by electrophoresis, immunoblotting with a pvrAB-specific antibody. HPLC and enzyme analysis in sporadic and familial AD and DS brains. In DS pyrAß was already present in the youngest brain under study (four days old). It increased, relatively to the full length $sA\beta$, with age becoming the dominant peptide in plaquerich DS brains. In all AD brains, both sporadic and familial, carrying various mutations in the AB precursor protein, the peptide was consistently the most abundant form. This result was confirmed by immunocytochemical analysis. The identity of the peptide and its modification was confirmed by chromatographic analysis followed by ELISA and by abolishing its immunogenicity after an enzymatic removal of the N-terminal residue. The pyroglutamate-modified $sA\beta$ could not be detected in the cerebro-spinal fluid, blood serum or cultured cells overexpressing AB precursor protein indicating that the peptide is uniquely specific for the brain parenchyma. The facts that the peptide appears in DS long before $\ensuremath{A\beta}$ deposits are detectable, is dominant in all AD brains, is more hydrophobic than $A\beta(1-42)$, and is stably N-terminally blocked point to its crucial role in both plaque formation and pathogenesis of AD

MOLECULAR FACTORS CONTROLLING Aβ FIBRIL NUCLEATION AND ELONGATION.
D.B. Teplow *Ć, A. LomakinĆ#, G.B. Benedek*, and
D.M. WalshĆ. ΔDepartment of Neurology, Brigham and Women's Hospital; †Department of Neurology (Neuroscience), Harvard Medical School, Boston, MA 02115; *Department of Physics, and Center for Metarial Science and Engineering Messachusett Institute of Material Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA, 02139.

One strategy for treating Alzheimer's disease is to inhibit amyloid fiber formation. Successful implementation of this strategy requires an understanding of the key molecular factors controlling the kinetics of fibril nucleation and elongation. We have developed a model system in which the kinetics of fibrillogenesis is reproducible and experimentally manipulable. This has allowed us to use quasielastic light scattering spectroscopy to continuously monitor fibril nucleation and growth. Analysis of the temporal change in fibril length in the context of a simple, powerful mathematical model of fibrillogenesis produces quantitative information on the equilibrium, kinetic, and geometric parameters describing the process, including nucleation and elongation rates. We report here our initial findings on the relative roles of $A\beta$ primary structure, solvent conditions, and exogenous molecules (chaperones) in controlling the kinetics of fibrillogenesis. This information contributes to the knowledge base necessary for the rational design of the rapeutic agents targeted to critical steps in the process of $\ensuremath{\mathsf{A}}\xspace\beta$ fiber formation.

65ZINC BIODISTRIBUTION IN RAT AND BINDING TO HUMAN ALZHEIMER'S DISEASE CORTICAL LESIONS. <u>A.W. Lyckman*1, K.L. Moya*2, L. Di Giamberardino</u>3, and <u>B. Tavitian*1,3</u>. CEA-SHFJ(1), CNRS URA2210 (2) & INSERM U334 (3), 4 place du Général Leclerc, 91401 Orsay, France,

To date there is no in vivo diagnostic technique for Alzheimer's disease (AD). Zn^{2+} is a ubiquitous protein cofactor with important links to CNS function, notably as a neuromodulator in hippocampus and cortex. Among the potential Zn^{2-} -binding sites is soluble amyloid peptide $\beta A4$. To begin evaluating Zn^{2+} as a tracer for brain function and pathology by positron emission tomography (PET), we examined the biodistribution of $^{65}\text{Zn}^{2+}$ by γ -counting in adult rat, and the specificity of metal cation binding to postmortem cortex from AD patients using Timms staining and storage phosphor autoradiography.

Systemic injection of a trace dose of ⁶⁵Zn²⁺ (20 μCi; 600 μCi/mg; 0.1 μmol) in rat

revealed at 15 min a relatively high uptake (%-injected dose/kg) in peripheral organs, e.g., liver (38.6), blood (6.2) and plasma (10.5), which decreased 32-86% over a four hour survival time. Uptake was lower at 15 min in frontal cortex (0.6), posterior cortex (0.7), striatum (0.5) and hippocampus (0.7) but increased 31-51% over the same period. Preincubation of AD cortex with Zn²+ (but not Cu²+, Ni²+, or Pb²+) at concentrations ≥

100μM, resulted in specific argentophilic colabeling of thioflavin S deposits in parenchyma and vessels, as well as specific staining of white matter. Highly selective $^{65}\text{Zn}^{2+}$ -binding to white matter in AD cortex, which was competed by exogenous cold

 Zn^{2+} , was revealed by storage phosphor autoratiography. Our data demonstrate selective Zn^{2+} uptake in CNS in vivo and high selectivity for cortical amyloid deposits and cortical white matter in AD brain in situ. 63 Zn, a potent β^{+} emitter with 38 min half-life, may be useful as a brain PET tracer, with particular implications for white matter pathology, hippocampal dysfunction and AD.

We thank Dr. André Delacourte for kindly providing AD brain tissue; M. Clavier, I. Doignon and R. Hässig for technical assistance. Supported by CEA, CNRS & INSERM.

Amyloid B Peptides in Cerebellar Preamyloid and Cortical Neuritic Plaques of Down's Syndrome Patients M.Lalowski¹. A. Golabek². C.A. Lemere³. D.J. Selkoe³. E. Kolodny²*. B. Frangione³. T. Wisniewski². Dept Pathol ¹ and Neurol.². NYU Medical Center. NY 10016: Harvard Med. Sch.³. Boston. MA 02115

Alzheimer's disease (AD) and Down's Syndrome (DS) are both associated with the deposition of amyloid β (A β) in senile plaques. An early stage in the development of senile plaques is thought to be "preamyloid" or diffuse plaques. This is based, in part, on studies in DS individuals where diffuse plaques occur at a very early age. After the age of 40 most DS patients develop the neuropathological features of AD in the cerebral cortex. in addition, many DS patients also have extensive preamyloid deposits in the cerebellum. These cerebellar preamyloid lesions do not progress to neuritic plaques. We have studied biochemically and immunohistochemically (using epitope specific anti- $\Delta\beta$ antibodies) the composition of DS cerebellar preamyloid in 5 patients ranging in age from 46 to 65. In two of these DS patients aged 57 and 62 we also identified the composition of neuritic plaque Aβ. The major preamyloid Aβ peptide in the cerebellum was Aβ17-42 (70-95% of total AB), which correlated with our immunohistochemical studies. Other minor preamyloid AB peptides included Aβ1-42, 8-42, 11-42 and 1-40. Aβ17-42 was also found as a minor component of cortical neuritic plaque amyloid (3-4%); however, the $\Delta \beta$ 17-42 from neuritic plaques was partially oxidized by mass spectroscopic analysis, while cerebellar $\Delta \beta$ 17-42 was not. In vitro, we show that $\Delta \beta$ 17-42 peptides are less fibrillogenic then Aβ1-42 by Thioflavin T assay and electron microscopy, with oxidation increasing the fibrillogenic potential. These studies, our previous biochemical extractions in aged dogs and other work all suggest that the initially deposited $A\beta$ peptide in preamyloid is $A\beta17$ -42. Since Aβ17-42 was the major peptide in DS cerebellar preamyloid, where progression to neuritic plaques does not occur, our data also indicate that the presence of $A\beta$ peptides extending to residue 42 does not itself lead to the development of neuritic plaques and other factors are also likely to be importan

AGGREGATION OF Αβ IS GLYCEROPHOSPHOCHOLINE, A METABOLITE GREATLY INCREASED IN ALZHEIMER'S DISEASE BRAIN. WE Klunk,

CJ Xu, RJ McClure, & JW Pettegrew. Laboratory of Neurophysics, Dept. of Psychiatry, WPIC, Univ. of Pittsburgh, Pittsburgh, PA 15261 There is increasing evidence that deposition of the $A\beta$ peptide in

There is increasing evidence that deposition of the $A\beta$ peptide in Alzheimer's disease (AD) brain plays an important role in the pathophysiology of this dementia. There is evidence that, at least in cell culture, $A\beta$ is toxic to neurons. This toxicity is totally dependent on the state of aggregation of the peptide. Monomers have little or no toxicity while beta-sheet fibrillar aggregates are toxic. Alzheimer's disease could be viewed as an abnormality in the kinetics of aggregation of $A\beta$. Anything which accelerates aggregation beyond a certain threshold could produce the disease phenotype. A third copy of the APP gene (Down syndrome) or the disease phenotype. A third copy of the APP gene (Down syndrome) or the presence of the "Swedish mutation" may accelerate the kinetics by increasing production of A β . The codon 717 mutations may accelerate the kinetics by increasing the percentage of the more rapidly aggregating Aβ(1-42/43). Other endogenous factors such as zinc can accelerate aggregation. In this study, we examined several metabolites whose levels are altered in metabolites, post-mortem AD brain. Several including glycerophosphoethanolamine, glycerophosphocholine, glycerophosphate, accelerated the rate of aggregation of $A\beta(1-40)$ as measured by light diffraction. The acceleration was concentrationdependent and occurred at metabolite concentrations found in AD brain. This finding may explain the progressive deposition of $A\beta$ with normal aging and the exaggerated deposition in AD since PDE levels increase with normal aging and to a much greater extent in AD.

PRO-INFLAMMATORY RESPONSE MOLECULES ARE DIFFERENTIALLY ASSOCIATED WITH APOPTOSIS AND CEREBRAL INFLAMMATION IN AN EXPERIMENTAL MODEL OF ALZHEIMER'S DISEASE. S.A.L. Bennett*1.2, J. Lakins², T. Fortin¹, M.P.R. Tenniswood², J. de la Torre¹, and B. Pappas¹. Neuroscience, Carleton University, Ottawa, Ont, K1S5B6 ²W.Alton Jones Cell Science Center, Lake Placid, NY, 12946.

Complement proteins are upregulated in and around senile plaques during Alzheimer's' Disease indicating that pro-inflammatory molecules may contribute to progressive neurodegeneration. This upregulation is also associated with hypoperfusion of cerebral tissue or chronic vascular insufficiency (CVI). To further explore this relationship, we induced CVI in rats by permanent bilateral ligation of the common carotid arteries (2-VO). Behavioural, immunohistochemical, Western, and Northern data demonstrates that 2-VO results in progressive behavioural dysfunction, increased neuronal apoptosis, accumulation of carbohydrate-containing lesions, and upregulation of both the pro-inflammatory response molecule, platelet activating factor receptor (PAFR), and the complement regulatory protein, clusterin. These pathologies are time-dependent. Between 2-27 weeks of 2-VO, increases in PAFR and clusterin expression are localized to brain regions apparently undergoing apoptosis as assessed by morphological examination and TUNEL. By 27-40 weeks of 2-VO, enhanced PAFR and clusterin expression are associated with brain regions exhibiting infiltration of peripheral inflammatory cells, reactive gliosis, and senile plaque formation. These data suggest that pro-inflammatory response and complement regulatory molecules are differentially associated with both apoptosis and inflammation during progressive neurodegeneration. [Supported by grants from HFSPO, Ontario Heart and Stroke, and Alzheimer Society of Canada.]

DENDRITIC LOCALIZATION OF PRESENILIN-1 IN RAT BRAIN: COMPARISON WITH PRESENILIN-2 BY IMMUNOCYTOCHEMISTRY. M.N. Gordon*, L.M. Refolo, Y. Harigaya, C. Eckman, M. Prada, S. Younkin and D.G. Morgan. Dept. of Pharmacology & Therapeutics, Univ. of South Florida College of Medicine, Tampa, FL 33612-4799 and The Mayo Clinic, Jacksonville, FL 32224.

Polyclonal antisera were generated against synthetic amino acid sequences of presenilin-1 (PS-1) and presenilin-2 (PS-2) deduced from published gene sequences. Four independent antisera, recognizing 2 distinct epitopes (amino acids 1-14 and 57-70) of PS-1 stained (1) a 52kDa protein on western blots of rat brain homogenate and (2) dendritic profiles of large pyramidal neurons in the cerebral cortex and hippocampal CA fields. Specific staining was abolished by preabsorption of the antisera with the relevant peptide. In addition, antisera purified by affinity for the antigenic peptide retained the dendritic localization of immunostaining and selectively immunoprecipitated a 52 kDa protein from rat brain homogenates. This dendritic staining with PS-1 was strikingly similar to that observed for microtubule-associated protein-2 (MAP2). The large number of PS-1 mutations capable of causing familial AD coupled with the shift toward more amyloidogenic forms of Ag in carriers of these mutations will focus attention on the dendritic compartment as sites where PS-1 mutations modify APP metabolism. PS-2-like immunoreactivity was localized to neuronal somata in initial studies using antisera directed against amino acids 17-33 of PS-2. Most neurons were labeled, with strongest immunoreactivity in hippocampal pyramidal and granule cells and in entorhinal cortex. No positive staining was observed in the molecular layer of the cerebral cortex or white matter. Thus, PS-2 immunoreactivity appears most intense in those brain regions most affected in AD. THE ALZHEIMER'S A\$1-42 PEPTIDE INDUCES CA1-SPECIFIC A\$ IMMUNO-STAINING AND SYNAPTIC DECAY IN HIPPOCAMPAL SLICE CULTURES. B.A. Bahr', K.B. Hoffman', P.W. Vanderklish', B.T. Kawasaki', A.J. Yang', U.S. Hess', K. Guthrie*, C.M. Gall', C.G. Glabe' & G. Lynch! 'Crr. for Neurobiol. of Learning & Memory, 'Dept. Molec Biol & Biochem, 'Dept. Anatomy & Neurobiol, Univ of Calif, Irvine, CA 92717.

Buildup of the amyloid β-peptide (Aβ), deterioration of synaptic contacts, and the loss of neurons are well known characteristics of Alzheimer's disease and are especially pronounced in the hippocampal CA1 region (see Honer et al., Neurobiol. Aging 13:375, 1992; West et al., Lancer 344:769, 1994). Previous studies have indicated that internalized Aβ is sequestered into lysosomes and induces the production of potentially amyloidogenic fragments (Knauer et al., P.N.A.S. USA 89:7473, 1992; Yang et al., J.B.C. 270:14786, 1995), and that similar amyloidogenic accumulations are linked to the decay of hippocampal synapses (Bahr et al., Exp. Neurol. 129:81, 1994). The present study tested whether Aβ1-42 targets specific cells and affects synaptic function in long-term hippocampal slices, a culture system that possesses stable, adult-like synapses for months. Aβ1-42 (30 μM) pre-incubated in serum-free media was applied daily to 68 cultured slices for 8-10 h and then overnight at 17 μM with 20% heat-treated serum. Over one to nine days of treatment, selective labeling with anti-Aβ antibodies increased gradually in dense bodies in the somata and apical dendrites of CA1 pyramidals and in numerous puncta in the stratum lacunosum-moleculare, 12- to 18-day treatments produced less than expected CA1 effects and trace stratum granulosum labeling. Control slices treated 6-18 days with random1-42 or Aβ1-28 peptides exhibited no anti-Aβ the latter band being produced over 6-12 days). In addition, autoradiography showed region-specific buildup of β-C]Aβ1-42 increasing over 1-3 days. EPSPs recorded from CA1a, which exhibits robust Aβ effects, were 25% smaller in Aβ slices than in the same area of control slices (p-C0.01), t-test, t-8t, no difference was seen when recording from CA1a, which exhibits robust Aβ effects, were 25% smaller in Aβ slices than in the same area of control slices (p-C0.01), t-test, t-8t, no difference was seen when recording from CA1a where the immunostaining

28 MONTH OLD RATS WITH A 16 MONTH HISTORY OF UNILATERAL NIGROSTRIATAL LESION: DRUG-INDUCED BEHAVIOR AND RESPONSE TO GRAFTED DOPAMINE NEURONS AND SCHWANN CELLS. T.J. Collier* and K. Steece-Collier. *Dept. Neurological Sci., Rush Presbyterian Med. Ctr., Chicago, IL 60612; and Dept. Neuroscience, The Chicago Medical School, North Chicago, IL 60064.

The parameters of old age and protracted history of neural deficits are seldom included in animal models of neurodegenerative disease. In order to address the influence of these factors in the response to cell grafting therapies for Parkinson's disease, we are studying male F344 rats that received large unilateral lesions of the nigrostriatal dopamine (DA) pathway at 12 months of age, and reached the age of 26 months prior to testing the efficacy of cell implants for DA replacement. Over the 14 months following lesion and prior to grafting, rats were tested for rotational behavior in response to amphetamine at 1 month intervals, and rotation to apomorphine at 2 month intervals. Animals exhibited high rates of rotation to amphetamine over the first 7 months after lesion. From 8 months post-lesion onward, rotation to amphetamine declined coincident with the development and progressive increase in behaviors we have tentatively classified as dyskinesias. Following intrastriatal implantation of a single DA neuron-rich cell suspension or a co-graft of DA cells + Schwann cells (SC), rats receiving co-grafts exhibited a reduction in rotation that was more consistent and greater in magnitude than rats receiving a DA graft alone. Neither type of implant affected 'dyskinetic' behavior. Our evidence suggests that the variables of advanced age and prolonged lesion duration significantly affect the response of rats to neural grafting in the DA system. The better success of the DA-SC co-graft supports the utility of SC as sources of DA neurotrophic activity, and suggests that replenishment of the trophic environment of grafts in aged individuals with a long history of neural deficits may be required for optimal therapeutic outcome. SUCCESSFUL GRAFTS OF CRYOPRESERVED MESENCEPHALIC, DOPAMINERGIC NEURONS IN PRIMATES. <u>I.R. Sladek Jr.</u> ^{1*}, <u>B.C. Blanchard¹, J.D. Elsworth²</u>, <u>T.J. Collier³, J.R. Taylor²</u>, <u>R.H. Roth²</u>, and D.E. Redmond Jr. ² Dept. of Neuroscience, Chicago Medical School, North Chicago, <u>IL 60064</u>; ² Depts of Psych, & Pharm, Yale University School of Medicine, New Haven, CT 06510; ³Dept. of Neurol. Sci., Rush Medical School, Chicago, <u>IL 600612</u>

The ability to store embryonic neural tissue is important for the application of grafted tissue in the treatment of Parkinson's disease. Transplants of fresh and cryopreserved dopamine (DA) neurons were made into six, male, MPTP-treated African green monkeys. Each received E44 tissue from one donor; half was implanted as fresh, solid grafts; the other half was cryopreserved, stored briefly at -80°C, thawed and grafted into the contralateral side. Thus, three fresh grafts were placed into the right caudate nucleus, while three equal-sized, cryopreserved grafts from the same donor were implanted into the left caudate nucleus within 3-4 hours of placement of the fresh grafts. Grafts were allowed to grow for 3 months. Brains were analyzed for tyrosine hydroxylase cell and fiber patterns. Three animals received manually frozen cells and there previously cells that were reconserved with an automated annature.

cells and three received cells that were cryopreserved with an automated apparatus. All six animals had grafts of cryopreserved DA neurons. Some were comparable to fresh grafts, and two grafts in one animal each contained over 1000 DA neurons. Fiber outgrowth was comparable to fresh grafts. Some grafts were found deep in the caudate and were indistinguishable from fresh grafts. A second animal had a graft with over 1000 DA neurons. Our prior studies with fresh tissue indicate that 1000 DA neurons/graft is adequate for functional improvement following MPTP. In one animal, 42% of the total DA neurons in grafts were derived from the cryopreserved tissue. On average, cryopreserved grafts had fewer total DA neurons.

tissue. On average, cryopreserve grants had rewer load DA heurons. It is possible to cryopreserve primate neural tissue and to obtain substantial DA neuron survival after transplantation. The findings also reveal a variability that suggests that further studies are needed to develop an effective cryopreservation procedure for primate dopamine neuroblasts in order to maintain maximal viability and function after transplantation. Supported by NS24032 and RSA MH00643 (DER).

EIGHT YEARS EXPERIENCE WITH FETAL NEUROTRANSPLANTATION IN PATIENTS WITH ADVANCED PARKINSONS DISEASE. CR Freed, * RE Breeze, MA Leehey, 'SA Schneck,' CF O'Brien,' LL Thompson,' LO Ramig,' CA McRee, 'JC Mazziotta,' RS Miletich,' and D Eidelberg. 1. University of Colorado School of Medicine, Denver, CO 80262; 2. UCLA Medical Center, Los Angeles 90024; 3. National Institutes of Health Bethesda, MD 20892: 4. North Shore University Hospital Manhasset, NY 11030.

Since November 1988, we have performed embryonic mesencephalic transplants in 25 patients, 17 males and 8 females, with a mean age of 58 and duration of Parkinson's disease of 14 years. Most patients have received putamenal implants (23/25) with simultaneous bilateral placement of strands of tissue from one to six embryos 7 to 8 weeks post conception which had been in tissue culture prior to transplant. The current surgical approach uses needle passes through the forehead, with a superior and inferior pass into each putamen bilaterally. Activities for Daily Living scores provided the best clinical measure of patient outcome. At one year after transplant, this value fell 30% in the "off" state and 40% in the "on" state. Drug doses were reduced an average of 40% and one patient discontinued all medication by 18 months after surgery. Hoehn and Yahr scores improved about 1.1 unit from 3.5 to 2.4. Pre and postoperative ¹⁸fluorodopa PET scans have been obtained in 10 patients with 8/10 showing improved putamenal uptake bilaterally. Complications included one death from brain hemorrhage. There have been no complications from the frontal approach (n=8). After improving progressively for 3 to 4 years after a unilateral implant in caudate and putamen, our first patient has deteriorated during years 6 to 8 as shown by clinical exam, PET scans, and increased L-dopa requirements. Retransplant on the unoperated side is planned. Unilateral pallidotomy is being considered for patients with persistent drug induced dyskinesias. We conclude that embryonic neurotransplants provide substantial and sustained benefit to patients with advanced Parkinson's Disease. Supported by grants from Robert E. Stanton, NIH, and the National Parkinson Foundation

481.5

SIX TO NINE YEAR FOLLOW-UP OF PARKINSON'S DISEASE PATIENTS AFTER UNILATERAL AUTOLOGOUS ADRENAL MEDULLARY AND HUMAN FETAL VENTRAL MESENCEPHALIC BRAIN GRAFTING. I. Madrazo, R.E. Franco-Bourland*, H. Castrejón, C. Cuevas, F. Ostrosky-Solís, E. Magallón, C. Zamorano, I. Grijalva, G. Guízar-Sahagún. IMSS, INNSZ, UNAM México, D.F., México

This year marks the tenth anniversary of the first two successful cases of Parkinson's disease (PD) treated with autologous adrenal medullary (AM) brain transplants (New Engl J Med 316 (1987) 831-834). The purpose of human brain grafting is to deliver sufficient endocrine or neural tissue to neurodegenerate areas of the brain, in order to supply adequate amounts of the missing neurotransmitters, as well as other neuroprotective and neurotrophic factors for functional recovery. In an attempt to restore the dopaminergic deficiency of PD, we have tested the clinical potential of the unilateral striatal implantation to PD patients of dopamine-rich autologous AM and human fetal ventral mesencephalic (VM) grafts. Using open microsurgery for the implantation of tissues to the ventricular wall of the caudate nucleus (CN), the strategies for grafting one gram of autologous AM tissue included placement: to one cavitated site, to multiple sites without precavitation, and cografting with peripheral nerve tissue (intercostal nerve) to one site, after precavitation; in the case of homotransplantations, the total VM tissue from one fetus was embedded to one site in the CN. Using the Unified Parkinsonism Rating Scale, the Hoehn and Yahr, and the Schwab and England evaluation scales, transplanted PD patients from all groups have been followed by us now for over 6-9 years. All transplantation groups compared, those patients cografted with AM/peripheral nerve tissue, and those with fetal VM grafts appear to have benefitted the most from surgery. This work was funded by the Interinstitutional Research Foundation for the Regeneration of the Central Nervous System, México.

ASTROCYTES ENGULF IMPLANTED DOPAMINE MICROSPHER-ASTROCT TES ENGOLF IMPLANTED DOPAMINE MICROSPHER-ES: MECHANISMS FOR FIBER GROWTH? A. McRae*1, E.A. Ling?, S. Hjorth³, A. Dahlstrom¹, D. Mason⁴, T. Tice⁴, Inst. of Anatomy & Cell Biology¹ and Pharmacology³, Univ. of Göteborg, Medicinaregatan 3-7, S-41390 Göteborg, Sweden; National Univ. of Singapore², Singa-pore 119260; Southern Res. Institute⁴, Birmingham, AL 35255, USA.

Controlled-release dopamine (DA) loaded microspheres (MS) made with the biocompatible biodegradable polyester excipient poly (DL-lactide-co-glycolide) (PLG) induce dopamine (DA) fiber growth in the 6-OHDA denervated rat striatum. Functional recovery appears related to the degree of fiber growth. Unexpectedly electron microscopic (EM) investigations revealed that astrocytes engulf MS implanted in the host striatum. Scanning EM and confocal laser microscopy confirmed that cultured striatal astrocytes take up DA loaded MS and have a preference for small diameter MS. Unilateral 6-OHDA denervated rats displaying 400 or more contralateral rotations to apomorphine were implanted with DA loaded MS contralateral rotations to apomorphine were implanted with DA loaded MS having diameters less than 45 µm or greater than 45 µm. Small diameter MS induced significant reductions both in the number of apomorphine rotations and DA fiber growth. In contrast, rats bearing larger diameter MS displayed only slight reductions in apomorphine induced rotational behavior and had rare fiber growth. These results suggest that astrocytes may play a role in the ability of implanted DA MS to promote fiber growth and assure functional recovery. In view of the numerous trophic factors associated with astrocytes these mechanisms could be of therapeutic importance in Parkingson's disease or other neurodegenerative disorders. importance in Parkinson's disease or other neurodegenerative disorders.

REASONS FOR LIMITED CLINICAL BENEFIT FOLLOWING FETAL NIGRAL TRANSPLANTATION IN THE TREATMENT OF PARKINSON'S DISEASE. T.B. Freeman, J.H. Kordower, R.A. Hauser, B.J. Snow, P.R. Sanberg, C.W. Olanow. University of South Florida, Div. of Neurosurgery, Tampa, Florida.

Over 200 patients have received fetal nigral transplants for the treatment of

Parkinson's disease (PD) in 17 centers worldwide. Preliminary evidence of clinical efficacy has been demonstrated. In our patients, significant improvement from baseline to latest evaluation (mean of 18 months) was noted in UPDRS motor (mean baseline to latest evaluation (mean of 18 months) was noted in UPDRS motor (mean of 28.E. = 50.8.£ 7.2 vs 35.7 ± 5.5, p = 0.28) and UPDRS ADL scores (32.1 ± 2.9 vs 21.2 ± 3.1, p = 0.28) while "off". Also percent time "off" significantly decreased from 34.8 ± 5.1% to 16.5 ± 4.9% (p = .046). This correlates with reliable increased fluorodopa uptake on PET scan (Ki = 0.0069 ± 0.0005 vs 0.0111 ± 0.0007, p = .003) and autopsy-proven graft survival with organotypic host reinnervation. However, it is not appropriate at this time to offer fetal nigral transplantation as

a definitive therapy for PD. Only three centers have demonstrated reproducible preliminary improvement in both clinical outcome and FD-PET. Although supranormal DA neuronal survival has been demonstrated at autopsy, only 53% of the limited target area has been reinnervated. The survival rate of transplanted DA neurons is only 5%, limiting the practicality of widespread use of the technique. Many symptoms of PD have not been improved and many symptoms improved significantly but not completely. This most likely correlates to the limited regions of reinnervation, multisystem degeneration in PD and possible inability of DA grafts to influence "non DA" symptoms. These and other issues remain to be studied further in the laboratory and with well-designed clinical trials. Although preliminary results are encouraging, neural transplantation remains an experimental therapy. SUPPORTED BY NIH GRANT #1 RO1 NS32842-01

CORTICAL INTERNEURONS UPREGULATE NEUROTROPHIN EXPRESSION IN RESPONSE TO TARGETED APOPTOTIC DEGENERATION OF NEIGHBORING PYRAMIDAL NEURONS *IN VIVO*. <u>Y. Z. Wang*</u>, <u>V. L. Sheen</u> and

IN RESPONSE TO TARGETED APOPTOTIC DEGENERATION OF REIGHBORING PYRAMIDAL NEURONS IN VIVO. Y. Z. Wang*, V. L. Sheen and J. D. Macklis. Department of Neurology and Program in Neuroscience, Harvard Medical School, and Division of Neuroscience, Mental Retardation Research Center, Children's Hospital, Boston, MA, 02115

Embryonic neocortical neurons and multipotent neural precursors transplanted into regions of adult mouse neocortex undergoing photolytically induced, synchronous apoptotic degeneration of callosal pyramidal neurons can respond to reexpressed developmental signal molecules, selectively migrate into these regions, differentiate into pyramidal neurons, accept afferent synaptic input, and re-form distant projections with specificity. The signal molecules include spatially and temporally specific upregulation of the neurotrophins BDNF, NT4/5, and NT-3, and the TrkB receptor, uniquely during the 3 week period of ongoing apoptosis and directed differentiation within the experimental regions. In the current experiments, we have begun to examine the specific cellular localization of these upregulated messages following induction of targeted apoptosis, using in situ hybridization. Pyramidal neurons in C57B/6J mice (n=10) were retrogradely targeted with photoactive nanospheres and noninvasively activated at 4 weeks of age to initiate apoptotic degeneration in lamina II/III of neocortex. We performed in situ hybridization with ³⁵ sadiolabeled oligoprobes and riboprobes 3 and 6 days after induction. BDNF mRNA expression was specifically increased in local interneurons surrounding degenerating pyramidal neurons, uniquely within the regions from intact (n=6) and experimental mice showed no mRNA upregulation. These findings suggest that the induction of BDNF mRNA (and potentially the other upregulated neurotrophins) is a specific effect of targeted apoptosis that my result from intercellular signaling between degenerating pyramidal neurons and surrounding interneurons. These results, and analysis of the cellular lo

VERSATILE EXPRESSION OF LONG-TERM CULTURED EGF RESPONSIVE PROGENITAL CELLS FROM FETAL BRAIN. F. C. Zhou* and Y. H. Chiang, Depts. Anatomy and Neurobiology Program, Indiana Univ. Sch. Med., Indianapolis,

Epidermal Growth Factor (EGF) responsive progenital cells from fetal mesencephalon cells can be isolated and cultured in the form of neurospheres (Reynold and Weiss, 1992). We previously isolated the EGF-responsive neurospheres from embryonic 12-16 days old fetal brain, and characterized the differentiation of astroglial cells (Chiang, Silani and Zhou, 1996). In this study, we report the longevity and versatility of neuronal /glial expression of the non-passage neurospheres. Non-passaged neurospheres can be maintained in 10 ng/ml EGF supplemented DMEM / F12 culture medium for more than a year. When plated on poly-D-lysine and laminin substrate in neurobasal medium with 2% fetal calf serum, the neurospheres grow and differentiate into glia and neurons with similar expression (described below) regardless of age (3, 6, and 9 months old). Many progenitor cells still remain undifferentiated (Nectin-positive), capable of dividing (PCNA-positive), and maintain immature features (\$100-positive radial fibers). Glial marker (glial information in maker (galactic and the protein) and the protein of Immunocytochemical staining against 5-HT, 5-HT transporter (5-HTT), and 5-HT1A, indicate that many 5-HT-. 5-HTT-, and 5-HT1A immunoreactive (IR) cells exist in the long-term cultured mesencephalic neurospheres. In addition, a smaller population of 5-HT-, 5-HTT-, and 5-HT1A positive cells were also found in the population of 3-H1-, 3-H11-, and 3-H11A positive cells were also found in the striatal and cortical neurospheres, but not in our primary culture. In contrast, tyrosine hydroxylase was expressed in small size neurons in a small proportion of the mesencephalic neurospheres. This indicates that the progenitor cells we isolated are versatile in their expression in a number of phenotypes. On the other hand, the low expression of TH was also noticed. The use of differentiation factors to increase TH expression is currently in progress in our laboratory. (PIRC 22-821-01)

SCHWANN CELL MICROIMPLANTATION INTO THE ADULT CENTRAL NERVOUS SYSTEM: IMMUNOLOGICAL RESPONSES. C.C. Stichel*, G. Wunderlich, S. Hermanns, C. Rosenbaum, C.O. Hanemann, H.W. Müller Molecular Neurobiology Lab., Dept. of Neurology, Univ. of Düsseldorf, D-

40225 Düsseldorf, Germany.

Over the past decade experimental studies have suggested that regeneration of lesioned CNS axonal pathways through Schwann cell (SC) implantation might be developed into a useful therapeutic approach in human neurodegenerative disorders. Although it is known that inflammatory reactions may be a significant impediment to the survival integration and effect of implanted SC a detailed analysis of SC induced immune response in the host tissue is still missing. Moreover, with respect to the clinical perspective, it seems also important to address the nature of immune responses to a delayed or xenogeneic SC implantation.

The present study was designed to examine the immune response to different SC transplantation paradigms. As a lesion and implantation model we used the stereotactically transected postcommissural fornix of the adult Wistar rat (Wr). One group of animals received immediately after transection either an injection of (1)allogeneic(Wr)-neonatal; transection either an injection of (1)allogeneic(Wr)-neonatal; (2)allogeneic(Wr)-adult or (3)xenogeneic(human)-adult SC. A second group received an (4) allogeneic(Wr)-neonatal SC implant 2 days to 4 weeks after transection and (5)control animals were lesioned only. Animals were allowed to survive up to 2 months before immunocytochemical analysis of T-cell infiltration and MHC-expression was performed.

Mechanical transection induced (i) a rapid expression of MHC antigens and (ii) an infiltration of few T-cells, that were all of the helper/inducer subset. While no change in MHC- and T-cell responses were found after immediate or delayed allogeneic SC-implantation, xenogeneic human SC induced a prominent host-defense response. Supported by the DFG.

A HELPER VIRUS-FREE HSV-1 PLASMID VECTOR SYSTEM; IMPROVED TITERS AND LONG-TERM EXPRESSION. A. Geller*, Y. Wang, L. Yu, E. Gussoni 1, L. Kunkel 1, and C. Fraefel, Div. Endocrinology and 1Genetics, Children's Hosp., Boston, MA 02115.

Vectors based on Herpes Simplex Virus Type 1 (HSV-1) have potential for gene transfer into the brain to perform gene therapy of neurological disorders and to study neuronal physiology. However, a number of unresolved problems with HSV-1 plasmid vectors, especially cytopathic effects and immune responses, have limited plasmid vectors, especially cytopathic effects and immune responses, have limited their potential utility. The majority of these problems appear to be caused by the helper virus, so we developed a helper virus-free packaging system for these vectors (reported last year). Following transfection into cultured fibroblast cells, a HSV-1 cosmid set deleted in the DNA cleavage/packaging signals can provide all the required functions for replicating and packaging cotransfected vector DNA. The resulting vector stocks lack detectable helper virus, and therefore gene transfer into the rat brain is more efficient and is associated with markedly reduced cytopathic effects and immune responses compared to vector stocks that are prepared using a helper virus.

We now report data from 3 recent experiments that were designed to further improve and characterize this helper virus-free vector system: (i) By optimizing the transfection protocol we obtained vector titers of >106 infectious vector particles (IVP)/ml from the packaging procedure, and after concentration the titer was ~10⁸ IVP/ml. This represents ~10-fold improvement. (ii) We examined a number of promoters for both the efficiency of gene transfer and the stability of long-term expression in the brain. The promoters which were studied included the neurofilament heavy gene promoter, the tyrosine hydroxylase (TH) promoter, and the cytomegalovirus immediate-early (CMV IE) promoter. Both the TH promoter and the CMV IE promoter supported surprisingly high efficiencies of long-term gene expression. (iii) We developed a method to colocalize vector DNA and a reporter gene product in cells in the brain. Vector DNA was detected by fluorescent in situ hybridization and the reporter gene product was detected by immunohistochemistry.

Grafts of Cells Genetically Modified to Produce NT-3 Promote Corticospinal Axon Sprouting After Spinal Cord Injury. R Grill^{1,*}, K. Murai¹, A Blesch¹, FH Gage², MH Tuszynski^{1,3}. Dept Neurosci., Univ Calif-San Diego, La Jolla, CA; ²Salk Institute, La Jolla, CA; ³VA Med Ctr, San Diego, CA.

Little spontaneous recovery of adult corticospinal motor projections occurs after spinal cord injury in mammals. To assess neurotrophin responsiveness in this projection, primary Fischer 344 rat fibroblasts were genetically modified with MLV retroviral vectors to produce and secrete human NT-3. Transduced cells produced hNT-3 mRNA and biologically active protein in vitro. These cells were embedded into collagen matrices and grafted to spinal cord dorsal hemisection lesion sites in 18 adult Fischer rats. 10 control rats received identical grafts lacking the NT-3 transgene. Animals survived from 1-7 mo, then received WGA-HRP cortical injections to label corticospinal projections. From 1-7 mo later, NT-3 graft recipients showed significantly

elevated corticospinal axon sprouting in the ventral grey matter at the spinal cord lesion site (assessed by densitometry of HRP-TMB reaction product on NIH Image software, corrected for variability in labeling intensity between subjects); NT-3: 3.01±0.79 pixels vs. 1.71±0.23 pixels in controls, p=0.05. Significant differences were also present at the mid-point and distal to the lesion site (p<0.05 in both cases). Lesion extent was verified in all subjects.

These findings indicate that lesioned adult corticospinal axons show

long-term responsiveness to hNT-3 delivered by gene therapy.

IMPROVED SURVIVAL OF NEURONAL PRECURSORS TRANSPLANTED AS MIXED NEURONAL-GLIAL AGGREGATES EA Bonaroti, G Wang, J Hook, M White, S Meriney*, C Achim. Div. of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA, 15213.

Neuronal precursors and stem cells may be a useful alternative to primary fetal tissue for CNS grafting. Others have shown poor survival when pure populations of precursors are transplanted. We hypothesized that neuro-glial interactions, and neurotrophic factors supplied by microglia would improve the survival of precursors transplanted as mixed reaggregates. We have previously described a subset of cells present in reaggregate mixed cultures derived from second trimester human fetal tissue which have the characteristics of precursor cells. These cells are morphologically undifferentiated, mitotically active, and give rise to morphologically undifferentiated, finitotically active, and give lise to differentiated neurons and glia in vitro. A pure population of EGF responsive cells from the subventricular zone of second trimester tissue was generated, labeled with BrdU, and transplanted into the striatum of 12 outbred male SCID mice. An identical volume (10 ul) of mixed aggregate culture was injected into the contralateral hemisphere. Animals were sacrificed at 2, 4, and 6 weeks. Comparison of overall graft volume, and cell counts of BrdU labeled cells using anti-BrdU antibodies and using mixed aggregate cultures. To investigate the role of microglia in the support of precursor cell survival, mixed aggregate cultures were enriched with microglia and graft survival after transplantation assessed. Graft volume measurements and BrdU positive cell counts are currently underway. Glia appear to perform an important role in supporting survival of transplanted CNS tissue. (Supported by CMRF, Univ. of Pittsburgh)

REGULATABLE TRANSGENE EXPRESSION IN BRAIN USING A HERPES SIMPLEX VIRUS VECTOR CONTAINING A STEROID RESPONSIVE INDUCIBLE PROMOTER. P.L. Poliani, T. Oligino, Y. Wang, S.Y. Tsai, B.W. O'Malley, J.C. Glorioso and D.J. Fink*. Departments of Molecular Genetics and Biochemistry and Neurology, U. Pittsburgh, and VA Medical Center, Pittsburgh, PA 15261 and Baylor College of Medicine, Houston TX 77030.

We have previously demonstrated that recombinant HSV-based vectors can be used to transfer and express transgenes in neurons in brain. In order to regulate the expression of the transgene, we constructed an HSV-based vector containing a drug inducible transactivator. A cassette coding for a tripartite transactivator consisting of the yeast GAL4 DNA binding domain, the HSV VP16 acidic transactivation domain. and a mutated hormone binding domain of the progesterone receptor responsive to the drug RU486 (PNAS 91:8180, 1994) under the transcriptional regulation of the human cytomegalovirus immediate early promoter was inserted into the gC locus of an ICP4deleted replication-incompetent HSV genomic vector. A <u>lac</u>Z reporter gene under the transcriptional control of a minimal TATA box-containing promoter downstream of 5 GAL4 binding sites was placed in the TK locus of the same vector.

Vero cells transfected with the vector showed a 30-fold induction in expression measured by ONPG asssay following 24 hrs exposure to 10-7 M RU486. To assess expression in vivo 5 μ l containing 2x10⁶ pfu of virus was injected stereotactically into the hippocampus of 200-250 gm Sprague Dawley rats. At the time of injection and 24 hrs later the animals were treated with either RU486 (15 mg/kg IP) or vehicle alone. At 48 hrs the animals were sacrificed and for β-gal expression determined by X-gal staining. Drug-treated but not control animals showed expression of β -gal in neurons of the injected hippocampus.

This is the first demonstration of drug-inducible transgene expression in brain following vector-mediated gene transfer

Supported by grants from the NIH, Department of Veterans Affairs, and GenVec

MEMBERS OF THE JAK-STAT PATHWAY ARE EXPRESSED IN VIVO IN THE DEVELOPING CNS AND BECOME RECRUITED IN ST14A CNS PROGENITOR CELLS BY ACTIVATED SURFACE RECEPTORS CELLS BY ACTIVATED SURFACE RECEPTORS L. Cattance* L. Conti, S. Govoni* and C. De Fraja Inst. of Pharmacol. Sciences, Via Balzaretti 9, 20133 Milano; *Inst. of Pharmacol., Univ. of Pavia, Pavia-Italy

Via Balzaretti 9, 20133 Milano; "Inst. of Pharmacol., Univ.of Pavia, Pavia-Italy
The presence and activation of members of the JAK-STAT families of
proteins in response to specific cytokines is being deeply investigated in the
hematopoietic system. Although some evidences suggested that cytokines could
play an important role in the brain, very limited informations are available on their
presence and possible involvement in CNS functions. We found that among the
JAK, Jak2 is present at high levels in the different brain regions analyzed, its
expression being more aboundant at early stages of fetal life. Furthermore
Str11,Sta3, Stat5 and Stat6 were also present in vivo in CNS tissues. We were
interested in whether members of the JAK-STAT families can become activated in
CNS progenitor cells in response to specific stimuli. For this purpose different
exogenous cytokine receptors were expressed in the striatal-derived ST14A CNS
progenitor cells. Clonal populations of IL3 receptor or GMCSF receptor (of murine
or human origin) bearing ST14A cells were isolated. Western Blot analyses and
binding assay with iodinated ligands revealed that stable transfectants expressed
high alfinity receptors. Transfected cells exposed to the appropriate cytokine in high affinity receptors. Transfected cells exposed to the appropriate cytokine in the absence of serum, were capable of extensive proliferation. Immunoprecipitation the absence of serum, were capable of extensive proliferation. Immunoprecipitation studies showed that 10 min. after addition of a specific ligand (IL3 or GMCSF), phosphotyrosine containing proteins of different m.w. could be detected. When the same immunoprecipitated material was immunoblotted with anti-JAK2 antibody a tyrosine phosphorylated band of 130KDa corresponding to JAK2 could be detected in Iysates from stimulated cells. Furthermore also Stafs, one of the effectors of JAK2 in hematopoietic cells, was found phosphorylated in the stimulated cytokine receptor-bearing ST14A CNS progenitors. These results indicate that members of the JAK-STAT families are expressed in vivo in the CNS and may be activated in CNS progenitor cells (partially funded by the Hereditary Disease Foundation,USA).

INSULIN-LIKE GROWTH FACTOR-I SIGNALING PATHWAYS IN NEURITE OUTGROWTH. B. Kim*, and E.L. Feldman, Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48109

MI 48109
We have previously shown that insulin-like growth factor-I (IGF-I) can enhance neurite outgrowth and are now investigating its role in lamellipodia formation and neurite initiation. As part of these studies, we are characterizing the signaling pathway that mediates IGF-I's effects on neurite elongation. In our studies, we employ a cell culture model of neuronal growth, the SH-SY5Y human neuroblastoma cells. When SH-SY5Y cells were treated with IGF-I, there was a dose-dependent increase in the tyrosine phosphorylation of the type I IGF receptor (IGF-IR), and 2 MAP kinases: ERK1 and ERK2. While IGF-IR phosphorylation was immediate, maximal phosphorylation of ERK1 and ERK was not reached for 30 min and maintained for up to 4 hr. IGF-IR, ERK1 and ERK2 phosphorylation were inhibited by the type I IGF receptor blocking antibody, ca-IR3, while ERK1 and ERK2 phosphorylation were inhibited by a compound which specifically blocks MEK activity (PD98059). In parallel, PD98059 blocked neurite outgrowth. Inhibition of neurite outgrowth by PD98059 was present only if neurons were cultured for a sufficient period of time to allow for extracellular matrix deposition. Collectively these studies show that IGF-I 1) induces a metric deposition. Collectively these studies show that IGF-1 1) induces a unique pattern of MAP kinase phosphorylation in neurons which results in neurite outgrowth, and 2) may play a role in the organization of extracellular matrix.

482.5

REK, A NOVEL RECEPTOR TYROSINE KINASE IN THE AXL/TYRO3 FAMILY, James J. Fiordalisi, Stephen Crews* and Patricia F. Maness. Dept. Biochemistry, University of North Carolina Sch. of Med., Chapel Hill, NC 27599.

Rek (retina-expressed kinase) is a receptor tyrosine kinase identified by reverse-transcriptase polymerase chain reaction in cultured chick retinal Müller glia. The Rek extracellular region contains two Ig domains and two fibronectin (FN) domains placing it in a family of receptor tyrosine kinases, which includes axl, tyro3, c-mer, and c-eyk. The intracellular domain of Rek contains consensus SH2 binding motifs for PI-3-K (YDLM) and for Grb2 (YVNI) suggesting that Rek triggers several signal transduction pathways. Rek transcripts are restricted primarily to developing brain and retina where Rek may play a role in the differentiation of retinal neurons and glia. Overexpression of rek cDNA in mouse NIH3T3 fibroblasts resulted in ligand-independent activation of the 140kD Rek kinase and induction of morphologically transformed foci demonstrating that Rek has oncogenic potential. Rek-transformed mouse NIH3T3 fibroblasts were found to aggregate as a result of cell-cell

interactions via the Rek extracellular region, suggesting that Ig and FN domains may mediate cell contact signaling in developing neural cells.

These findings indicate that the normal function of Rek is likely to be in mediating cell-cell recognition events governing the differentiation or proliferation of neural cells. It's ability to induce transformation in NIH3T3 cells upon everytyres that previous the terminal central cells. NIH3T3 cells upon overexpression suggests that mutations in rek causing overexpression or kinase activation may contribute to the development of malignant nervous system tumors

This work was supported by NIH grant NS52269.

PROLACTIN ACTIVATES C-JUN AND STIMULATES PROLIFERATION IN PC12 CELLS. Y. Cheng. R.L. Perlman* and D. Mangoura. Department. of Pediatrics, The University of Chicago, School of Medicine, Chicago, IL 60637.

The anterior pituitary hormone prolactin not only participates in

osmoregulation and reproduction but also has important actions in the osnioregulation and reproduction but also has important actions in the nervous system. The prolactin receptor belongs to the super-family of cytokine/growth hormone/prolactin receptors. Prolactin caused a significant increase in c-jun phosphorylation in undifferentiated PC12 rat pheochromocytoma cells. The increase in c-jun phosphorylation was evident within 15 min of incubation with prolactin and was accompanied by an increase in c-jun levels, which peaked at about 2 hr and lasted for several hours. The activation of c-jun was specific, in that prolactin did not stimulate the phosphorylation of c-fos in these that prolactin did not stimulate the phosphorylation of c-fos in these cells. In addition, prolactin caused little or no increase in Erk2 activity. Therefore, prolactin probably activated c-jun in PC12 cells through the JNK signaling pathway. This pathway is activated after NGF withdrawal in PC12 cells, but the importance of its activation by physiological stimuli is unknown. In the long term, prolactin was mitogenic for PC12 cells as measured by direct cell counts. The growth rate of PC12 cells after two days of prolactin treatment (100 nM) is 1.80:1= prolactin treated cells $(5.45 \times 10^5 \pm 0.63)$; control cells $(3.02 \times 10^5 \pm 0.15)$ and 1.75:1 after 72 hr stimulation. Prolactin thus appears to regulate the proliferation and growth of PC12 cells. Prolactin may participate in the regulation of adrenal medullary function in pregnancy and lactation. (HD 09402 and BRF).

MOLECULAR CLONING OF CDGF, A NEUREGULIN-LIKE GENE ENCODING NOVEL LIGANDS FOR ERBB-GENE ENCODING NOVEL LIGANDS FOR ERBB-RECEPTORS. H. Chang, W. Gilbert** and U. J. McMahan. Dept. of Neurobiology, Stanford Univ. Sch. of Med., Stanford, CA 94305 and 'Bio. Labs, Harvard Univ., Cambridge, MA 02138. Neuregulins (also called ARIA, GGF, Heregulin, and NDF) are a

group of polypeptide factors that arise from alternative RNA splicing of a single gene. Through interaction with the erbB-receptors (erbB2, erbB3, and erbB4), neuregulins are thought to play important roles in the regulation of cell growth and differentiation in many tissues including the nervous system. Here we report the cloning of a second neuregulin-like gene, which we named CDGF. Sequence analysis of CDGF cDNA clones shows that they have a motif structure similar to that of neuregulins. Northern blot analysis of adult rat tissues indicates that CDGF transcripts are detected mostly in neural tissues. An alternative splicing site in the EGF-like domain gives rise to two isoforms of CDGF (α and β).

Recombinant CDGFα protein induces the tyrosine phosphorylation of erbB2, erbB3 and erbB4 in cell lines expressing mixtures of these erbBs, indicating that it is a functional ligand for erbB-receptors. A detailed comparison of CDGFs and neuregulins, such as the temporal and spatial regulation of their expression, and their interactions with erbB-receptors, will be crucial for understanding the biological functions of this multi-ligand/multi-receptor signaling pathway. (supported by NIH grant NS14506 to UJM).

CERAMIDE: A NEGATIVE REGULATOR OF NEURITE GROWTH IN RAT SYMPATHETIC NEURONS. M. Bussière*, E.I. Posse de Chaves, J.E. Vance, R.B. Campenot and D.E. Vance, University of Alberta, Edmonton, Alberta, Canada, T6G

Recent studies suggest that the agonist-induced generation of the lipid second messenger ceramide is an anti-mitogenic signal leading to the inhibition of cellular proliferation, cell differentiation and apoptosis. We are investigating the role of ceramide in neurite growth using compartmented cultures of rat sympathetic neurons. We have previously shown that a local increase in the intracellular level of ceramide within the distal neurites of sympathetic neurons, induced by threo-PPMP CPL-threo-1-phenyl-2-hexadecyl-3-morpholino-1-propanol) treatment, results in the inhibition of neurite growth. In agreement with these results, treatment of distal neurites, but not cell bodies/proximal neurites, with 10 mM exogenous cell-permeable C₆-ceramide inhibited neurite growth by 60%. A similar concentration of the closely-related molecule, C6-dihydroceramide, had no effect on neurite growth. The effect of ceramide on neurite growth was not reversible by the concomitant treatment of neurons with ceramide and a molar excess of either ${\rm diC}_8$ -glycerol (a cellpermeable diacylglycerol) or ceramide-1-phosphate, which have been previously shown to reverse certain effects of ceramide on cells. To determine if a metabolite of ceramide might be responsible for the inhibition of neurite growth observed upon ceramide-treatment, the metabolism of a fluorescent analog of ceramide, C₆-NBDceramide, was examined. Greater than 90.2% of the C6-NBD-ceramide taken up was ceramide, was examined. Greater than 90.2% of the C₆-NBD-ceramide taken up was recovered as ceramide-1-phosphate and 2% as sphingomyelin. Less than 3% of the fluorescence was recovered as free NBD, representative of the product of the hydrolysis of ceramide, sphingosine. These results suggest that ceramide plays a key role as a negative regulator of neurite growth and underscores the finding that neurite growth is regulated by local mechanisms within growing neurites. The mechanism of ceramide-mediated inhibition of neurite growth and its relationship to the promotion of neurite growth by NGF will be examined. (Supported by the Rick Hansen Foundation, AHFMR, MRC)

DOES NEURONAL MODULATION OF P21RAS ACTIVITY INDUCE NEUROTROPHIC EFFECTS? R. Heumann*, F. Narz¹, Y. Algür¹, D. Bartsch¹, E. Wagner, H. Berns¹, K. Obst²-and P. Wahle², Ruhr-Univ.Bochum Molekulare, Neurobiochemie¹ or Neurobiologie²,44780 Bochum, Germany

We have previously shown that p21ras activity mediates nerve growth factor induced survival in peripheral sensory neurons of the chick. Here we have produced transgenic mice expressing permanently activated Val12-Ha-ras (rasoncogene) under the control of the neuronal promoter for the synapsin-1 gene During development the transgene protein product was detected perinatally in total brain extracts reaching high levels at P40. In the adult animals high levels of Val12-Ha-ras protein were found in the cortex, hippocampus, septum and lower levels in the olfactory bulb and mesencephalon. The regional and cellular transgene expression pattern correlated with that of the endogenous synapsin protein. Macroscopic inspection of brain sections revealed a 20% enlargement of the cerebral hemispheres displacing the tectum and cerebellum further posterior. Consistently, the cell somata of layer V pyramidal neurons showed an increased diameter. Furthermore, in the cortex there was an increase in neuropeptide Y (NPY) mRNA levels, while the mRNAs coding for glutamate decarboxylase or parvalbumin remained unaltered. In the septum of adult transgenic mice we find elevated choline acetyltransferase activities indicating that neuronal p21ras may regulate this behaviourally relevant enzyme. We tested if transgenic activation of p21ras may lead to a protection of neurons against (excito)toxic damage in dissociated cultures: Embryonic mesencephalic cells were kept in culture for 9 days and identified dopaminergic neurons were partially resistant to the toxic effectes of 6-OHDA, thereby mimicking the effect of neurotrophin-4/5. In cultures of postnatal hippocampal activated p21ras expressing neurons a partial protection against long-term treatment with glutamate (1mM) was established. We conclude that p21ras activation mimics important functions of neurotrophins.

IN VIVO IMAGING OF TrkA WITH SMALL MOLECULE ANALOGS OF NERVE GROWTH FACTOR. L. LeSauteur, R. Lisbona, N-K. Cheung, A. Ribeiro-da-Silva* and H. U. Saragovi. Dept. of Pharm.& Therap, McGill Univ., Mtl, QC, CANADA.

The Nerve Growth Factor (NGF) receptor TrkA, is a 140kDa cell surface protein encoded by the trk proto-oncogene. NGF binding to the extracellular domain of TrkA leads to neuronal survival and differentiation, but can also play a role in neuronal and non-neuronal neoplastic disease including neuroblastoma, small cell lung carcinoma and melanoma.

Scintigraphy using mAbs has proven useful as a non-invasive method to detect neoplasias associated with elevated receptor expression. However, the use of small designed molecules would be more desirable because of increased tissue penetration, reduced immunogenicity and lack of pleitropic effects. The in vivo targeting efficacy (kinetics, tissue penetration, and distribution) of small molecule analogs of NGF (LeSauteur et al., JBC 270:6564,1995) that bind TrkA was evaluated; and compared with an anti-TrkA monoclonal antibody (mAb 5C3) (LeSauteur et al., J. Neurosci. 16:1308, 1996). Nuclear imaging studies were done after injection of 99m-Tc labeled compounds in mice bearing tumors. mAb 5C3 and small mimics of NGF were bioavailable and targeted human TrkA-expressing tumors but not other tumors demonstrating the TrkA specificity of NGF mimics in vivo.

Receptor specific small molecule analogs designed from large polypeptides may be as useful as antibodies, and may be effective agents for the detection, diagnosis and possible treatment of tumors overexpressing TrkA.(Supported by MRC of Canada).

THE LOCALIZATION OF THE p75LNTR IN THE RETINA OF THE ADULT SPRAGUE-DAWLEY RAT. B. Hu, H. K. Yip. and K. -F. So. Developmental Neurobiology & Neuroregeneration Lab., Anatomy Dept., Univ. of HongKong, HongKong. The low affinity neurotrophin receptor, p75LNTR or p75 is a 75Kd cell surface glycoprotein that binds all neurotrophins with similar affinity and is thought to help to ensure the specificity of each neurotrophin. Previous studies have found p75 in the retina ganglion cell (RGC) layer as well as on Müller cells. The exact function of p75 in both permal and lesioned ratios was less certain and contraversial. To insection retina ganglion cell (RGC) layer as well as on Müller cells. The exact function of p75 in both normal and lesioned retina was less certain and controversial. To investigate the role of neurotrophins and the p75 in the maintenance for RGC, we have examined the localization of p75 in the adult rat retina by immunocytochemistry at both light and electron microscopy levels.

Retinal wholemounts with RGC retrogradely labeled by a fluorescent dye Fluoro-Gold were prepared for 192-IgG indirect double fluorescent immunocytochemistry. Parasagittal paraffin (4µm) and cryostat (10–15µm) retinal sections were also processed for 192-IgG immunocytochemistry by the enhanced DAB (ABC) method. Paramagital invites can be alterior princescent returns the control of the control of the processor of

Pre-embedded immuno-electron microscopy study was applied in this study.

Previous studies only distinguished the p75 positive cell type in the retina by simple morphological criteria and by their localization in different retinal layers. It is very difficult to distinguish whether the positive stained membranes belong to RGCs very difficult to distinguish whether the positive stained membranes belong to RGCs or to the surrounding Müller cell processes at light microscopy level. The failure to detect p75 in retinal wholemount implied that it might not be expressed on RGCs. The similarity between the staining pattern of p75 with that of the distribution of Müller cell processes suggests that p75 is on the Müller cell processes and not on the RGCs as previously reported. Electron microscopic studies has further supported our observations. The p75 immunopositive staining are localized on Müller cell processes which not only form the inner limit membrane (ILM), but also wrap around the RGC bodies. The immunopositive staining on RGCs that have previously reported might belong to the surrounding Müller cell processes. We proposed that neurotrophic effects on RGCs mediated by p75 might be through a glia-neuronal pathway rather than on neuron directly.

TRKA EXPRESSION ATTENUATES C6-2B GLIOMA CELL GROWTH: IN VITRO AND IN VIVO STUDIES. S.J. Rabin, C. Tornatore, B.Baker-Cairns, S. Keir and I. Mocchetti*. Dept. of Cell Biology, Georgetown Univ. Sch. of Med., Washington DC 20007, and LMMN, NINDS, NIH, Bethesda, MD 20892.

A novel approach to the treatment of glioblastoma multiforme (GMB) would be to induce the tumor into a differentiated, post-mitotic phenotype to attenuate tumor progression followed by treatment with conventional therapies. Nerve growth factor (NGF) characteristically induces a differentiated, post-mitotic state in cells which express the high affinity NGF receptor trkA. C6-2B rat glioma cells express the low affinity NGF receptor p75 but not trkA and thus are unresponsive to NGF. Upon stable transfection with trkA rat cDNA, C6-2B cells (C6trk+) exhibit novel NGFmediated biochemical and morphological responses. Most important, in these cells, NGF accelerates differentiation and decreases the growth rate, suggesting that expression of trkA attenuates C6-2B cell proliferation. We grafted wild type and C6trk+ cells into 20 ACI nude rats. By 7 days post-transplantation, the wild type C6-2B cells had formed a 1x1 mm tumor in the striatum which was MHC class I positive and Thy1.1 negative, with patchy vimentin immunoreactivity. Scattered CD4, CD8 and CD11b cells could be identified within the tumor mass as well. The transplant was positive for the low affinity NGF receptor p75, and negative for trkA, confirming the identity of C6-2B glioma cells. By day 14 the tumor had doubled in size and by day 28 half the striatum was replaced with the gliomatous cells. In contrast, growth of the C6trk+ cells was markedly attenuated. By 7 days and up to 28 days, these cells had formed only a small nidus of approximately 1x1 mm. Not until day 71 posttransplantation had the C6trk+ formed a significant tumor mass which measured 1x3 mm. Transplanted C6trk+ cells were MHC class 1 positive, Thy1.1 negative and, interestingly, these cells remained trkA positive up to 71 days in vivo. encourage the speculation that expression of trkA in GMB *in vivo* will attenuate tumor progression. MECHANISMS OF SIGNAL TRANSDUCTION THROUGH THE P75 NEUROTROPHIN RECEPTOR. Bruce D. Carter* 1, Christian Kaltschmidt 2, Georg Dechant, Elisabeth Casademunt, Moses V. Chao 1, and Yves-Alain Barde. ¹Dept. Cell Biol. and Anatomy, Cornell Univ. Med. College, New York, NY 10021. ² Inst. for Biochem., Freiburg Univ., 79104 Germany. Dept. Neurobiochem., Max-Planck Inst. for Psychiatry, 82152 Germany.

The neurotrophins bind selectively to distinct tyrosine kinase receptors referred to as the trks, however, they all bind with similar affinity to the p75

referred to as the trks, however, they all bind with similar affinity to the p75 receptor. The significance of neurotrophin binding to p75 is not yet fully understood. We show that NGF binding to p75, in the absence of trkA, results in the activation of NFkB in Schwann cells from rat sciatic nerve. NGF activation of NFkB was also seen in L-cells expressing p75. Surprisingly, the effect was selective for NGF, neither BDNF nor NT3 activated NFkB. These results indicate that p75 is able to signal in non-transformed cells and can discriminate among neurotrophins. To understand the mechanisms of p75 signal transduction, the intracellular domain of the receptor was used in the yeast 2-hybrid system (Gyuris et al., Cell 75:791) to look for associating proteins. The p75-intracellular domain-lexA fusion "bait" was tested for interaction with a fetal human brain expression library. Among the clones fished out was a previously unknown zinc finger protein we termed "neurotrophin receptor interacting factor" (NRIF). The interaction in yeast was shown to be specific for p75 when compared with several other "false baits," none of which were able to interact, as determined by growth was shown to be specific for p75 when compared with several other "talse baits," none of which were able to interact, as determined by growth selection. To further demonstrate the interaction between p75 and NRIF, recombinant NRIF coupled to agarose beads was produced and shown to be capable of precipitating full-length p75 receptor from cell lysates. The mouse homolog of NRIF was cloned and shown to encode for a protein of approximately 35kD. The biological function of NRIF-p75 interaction is currently under investigation. (Funded by the Max Planck Society).

p75-BINDING IS NECESSARY AND SUFFICIENT FOR THE ANTI-APOPTOSIS EFFECTS OF NGF ON NEUROBLASTOMA CELLS. N. F. Schor*. Depts. of Pediatrics, Neurology, and Pharmacology, University of Pittsburgh, Pittsburgh, PA 15213. Prevention by nerve growth factor (NGF) of apoptotic death in neural cells has been variously ascribed to binding of NGF to its low-affinity (p75) or high-affinity (trk A) receptor or to a cooperative interaction between the two. We have previously demonstrated that SH-SY5Y human neuroblastoma cells undergo apoptosis when treated with artimitoric agents such as the antineonlastic agent. with antimitotic agents such as the antineoplastic agent, neocarzinostatin (NCS). SH-SY5Y cells express both p75 (1.3x10'/cell) and trk A (2.6x10'/cell), and bind NGF at both of these receptors. We have shown that SH-SY5Y cells are completely protected by NGF from NCS-induced apoptosis. The present studies test the hypothesis that the protective effect of NGF on neuroblastoma cell lines is the result of NGF binding to p75. In contrast to SH-SY5Y cells, NGP cells express p75 (2.7x10' receptors/cell), but not trk A. NGF (40 nM) completely protects NGP cells from the effects of NCS. In addition, continuously treating SH-SY5Y cells with a mutant NGF that binds to p75 with a 100-fold greater affinity than to trk A (4.2 nM) completely protects SH-SY5Y cells from the effects of NCS. Conversely, two NGF mutants that are 100-fold selective for trk A relative to p75 offered no protection to SH-SY5Y cells from NCS-induced apoptosis. Finally, SH-SY5Y cells were treated with NGF and NCS in the presence or absence of Ab 9651, an antibody that blocks binding of NGF to p75. Ab 9651 abrogates the protective activity of NGF in neuroblastoma cells treated with NCS. (Supported by NIH Fellowship #CA67421) neocarzinostatin (NCS). SH-SY5Y cells express both p75

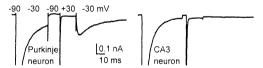

INTEGRATIVE PHYSIOLOGY OF VOLTAGE-GATED CONDUCTANCES ON THE DENDRITES OF CORTICAL PYRAMIDAL CELLS. M. M.

ON THE DENDRITES OF CORTICAL PYRAMIDAL CELLS. M. M. M. Millonas and P. S. Ulinski*. James Franck Institute and Department of Organismal Biology and Anatomy, University of Chicago, Chicago, IL 60637. The dendrites of pyramidal cells typically have potassium and fast sodium voltage-gated conductances, but the role of dendritic conductances in the integrative physiology of pyramidal cells is not understood. In an earlier study using a compartmental model (CNS*96), we suggested that the fast prepotentials or "spikelets" present in pyramidal cells in turtle visual cortex result from fast sodium and delayed rectifier conductances located in spots on dendrites, distant from the soma. These "hotspois" generate dendritic action potentials that propagate into the soma where they are seen as small spikes. This study uses simulated AMPA- mediated conductances constrained by data on geniculocortical EPSPs to investigate the interaction between synaptic inputs and hotspots. Simulated AMPA- mediated conductances constrained by data on genetic described EPSPs to investigate the interaction between synaptic inputs and hotspots. Dendritic synapses can trigger rapidly firing dendritic action potentials which effectively voltage clamp the dendrite, limiting the amplitude of the resultant EPSP at the soma. EPSPs arriving on two different dendrites with hotspots within a time window on the order of 25 msec produce a larger somatic EPSP than if they arrived within the same time window on one active dendrite. All of these results were reproduced by a 4-variable model composed of two coupled Fitzhugh-Nagumo type oscillators, showing that they are robust features of neurons with dendritic hotspots. These results demonstrate the potential importance of interactions between multiple dendritic hotspots and the soma in the integrative physiology of pyramidal cells. SODIUM CURRENTS NEAR THRESHOLD VOLTAGES IN CEREBELLAR PURKINJE NEURONS. Indira M. Raman* and Bruce P. Bean. Vollum Institute, Portland, OR 97201.

The distinctive firing pattern of Purkinje neurons is influenced by persistent sodium current active near threshold voltages (Llinás & Sugimori, J. Physiol. 305:171,1980). We studied TTX-sensitive Na current in freshly dissociated rat Purkinje neurons. A depolarization from -90 mV to -30 mV induced a transient current of \sim 4 nA (50mM [Na $^+$]_o) followed by a steadystate current of ~-40 pA. Unexpectedly, when cells were depolarized to +30 mV and returned to -30 mV, a slow "tail" current developed (rise time 8 ms, decay τ 30 ms). Relative to the peak transient current, the slow tail was $3.5\pm2\%$ and the steady-state current was $1.1\pm0.7\%$. The charge transfer in the first 40 ms of the slow tail was 31±14% of that of the transient current. Hippocampal CA3 neurons had transient and steady-state currents similar to Purkinje neurons but no slow tails. The slow tail current may promote repetitive firing in Purkinje neurons by providing a surge of Na+ current following an action potential. In single channel patches, the channels underlying the slow tail current had a conductance of \sim 20 pS (140mM [Na⁺]_o) and also produced conventional transient currents. NIH (HL35034)

THE T698M-HyperPP Na CHANNEL MUTATION DOES NOT ENHANCE NON-INACTIVATING CURRENTS, BUT CHOLERA TOXIN DOES. T. R. Cummins* and F.I. Sigworth, Interdept. Neurosci. Prog. and Dept. of Cell. & Mol. Physiol., Yale Univ. Sch. of Med., New Haven, CT. 06520.

Mutations in the skeletal muscle sodium channel gene are believed to cause hyperkalemic periodic paralysis (HyperPP). The T704M mutation is the most common HyperPP mutation. We have shown that the corresponding mutation in the rat channel (T698M) alters activation and impairs slow inactivation, and proposed that these changes underlie the pathophysiology of HyperPP. However, it has also been proposed that the T698M mutation disrupts fast inactivation. Therefore we examined fast inactivation of WT and T698M channels stably expressed in HEK293 cells.

Large non-inactivating currents were sometimes observed in WT and T698M cells just after beginning whole-cell recording. At -10 mV, the relative size of the non-inactivating component was 2±2% (mn±SD) of the peak current for both WT (n=47) and T698M (n=59) cells. However, the non-inactivating current rapidly ran down and after 10 min was less than 0.5% of peak in both WT and T698M cells. While we were unable to prevent this rundown, w found that treating the cells overnight with cholera toxin (ChTx) dramatically increased the size of the non-inactivating current. After ChTx treatment the non-inactivating component was about 20% of the peak current. Surprisingly the S1321A mutation, which removes a putative phosphorylation site in the III-IV linker, did not prevent the ChTx effect.

These data indicate that the T698M mutation does not directly affect the size of the non-inactivating component. Interestingly, this component can be modulated, possibly by G-proteins, in cells expressing either WT or T698M channels. (Supported by NIH grant NS21501 to FJS).

RELATIONSHIP BETWEEN Na¹ INFLUX AND INTRACELLULAR [Na¹] IN ISOLATED NERVE ENDINGS.

D. Turner and E.L. Stuenkel¹. Department of Physiology, University of Michigan Medical School. Ann Arbor, MI 48109

A change in [Na¹] has been implicated as a modulatory influence in certain forms of short term synaptic plasticity. However, little quantitative information exists concerning the temporal and spatial characteristics of depolarizing impulse-induced changes in intracellular free [Na¹] at nerve endings. We have, therefore, attempted to quantitate the voltage-dependent properties of Na¹ channel activation and inactivation and determine the relationship between time integrated Na¹ influx and changes in spatially averaged [Na¹] in single rat neurohypophysial nerve endings using whole cell voltage clamp in conjunction with fluorometric monitoring of [Na¹]. Basal [Na¹] in intact nerve endings was found to be ≈ 15 mM. Brief repetitive depolarizing pulses (-90 mV holding, to -10 mV step) of 2 ms duration and frequency similar to that of action potential bursting in vasopressinergic nerve endings (13-40 Hz), evoked inward Na¹ currents (1.47 ± 0.11 nA) that resulted in [Na¹] increases, and were blocked by 0.3 μM TTX. The Δ[Na¹] was shown to be proportional to the applied stimulation-frequency for all periods of stimulation and ranged from 0.35 mM to 2.73 mM. Initially, sodium influx followed a near proportional increase in [Na²] whose rate increased as terminal diameter decreased. However, when sodium influx exceeded ≈ 2.2 mM, regardless of terminal diameter, this relationship became nonlinear suggesting efficient buffering and extrusion of Na². Nerve endings of smaller diameter had greater charge density (pC/μπ²) than those of larger diameter. The data suggest that action potential invasion of small diameter nerve endings can transiently elevate the intracellular [Na²]. (Supported by NiH grant to ELS.)

NA*-DEPENDENT PLATEAU POTENTIALS AND NA*-DEPENDENT K' CONDUCTANCE IN THE NUCLEUS PRINCIPALIS TRIGEMINI NEURONS. V.M. Sandler, E. Puil, D.W.F. Schwarz. Rotary Hearing Center, Dept. of Surgery (ENT) and Dept. of Pharmacology & Therapeutics, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 2B5

Pharmacology & Therapeutics, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 2B5
Little is known about the electrophysiological properties of the nucleus principalis trigemini (PrV) neurons. We have investigated PrV neurons using whole-cell recordings in in vitro brainstem slice preparation. Of three electrophysiologically distinct cell types recorded in the PrV we concentrate on some properties of the spontaneously active bursting neurons. Depolarization by current pulse injection occasionally evoked "plateau potentials" in these neurons. Such plateau potentials were observed consistently during perfusion with Ca²⁺ free media, with or without the Ca²⁺-channel antagonists, Co²⁺ or Cd²⁺ (I mM), and during external TEA (I mM) application. TTX application (e.g., 0.6 nM for 6-10 min.) increased the latency to onset and decreased the duration of the plateau potential without affecting the action potentials shape. TTX also enhanced the negative slope of the plateau potential in a dose-dependent manner. Higher concentrations of TTX (e.g., 60 nM for 10 min.) abolished the plateau potential before completely blocking action potentials. Low [Na²]-perfusion simultaneously reduced the amplitudes of plateau potentials and fast spikes. Both subthreshold and suprathreshold depolarization in Ca²⁺ free ACSF with Co²⁺ (ImM) evoked a long-lasting hyperpolarization at the offset of the depolarizing current pulse. This hyperpolarization was blocked by TTX (more than 5 nM). The magnitude of the hyperpolarization depended on the level of neuronal depolarization. We conclude, therefore, that Na²⁺ entry during a depolarization in necrease a K²⁺ conductance in type I neurons.

SLOW INACTIVATION OF MUTANT SODIUM CHANNELS IN NEUROMUSCULAR DISEASE. <u>L. J. Hayward^{1*}, R. H. Brown, Jr. 1</u>, and <u>S. C. Cannon.</u> Departments of ¹Neurology and ³Neurobiology, Mass. General Hospital and Harvard Medical School, Boston, MA 02114.

Missense mutations of the Na channel α subunit cause a spectrum of neuromuscular disorders with myotonia (SCM), paralysis (HyperPP) or both (PMC, most forms of HyperPP). Defects of rapid inactivation have been identified for most mutants and can account for many of the observed abnormalities in muscle excitability. Ruff (Biophys J. 66:542, 1994) postulated that slow inactivation (SI) must also be impaired to produce sustained paralysis. Cummins and Sigworth (Biophys J. 70, 1996) showed a disruption of SI for a HyperPP mutant (rT698M, homolog of hT704M). We tested whether a defect of Sl is a necessary condition for paralysis. Na currents were recorded from HEK293 cells transfected with $h\beta_1$ and either wildtype rSkM1 or a mutant α subunit: one of three HyperPP (rT698M, rM1585V, rM1353V), one PMC (rT1306M), and one SCM (rG1299E). SI was defined as the fraction of current that failed to recover within 20 ms at -100 mV (where recovery from fast inactivation is >95% complete). Entry to SI was measured after variable-duration conditioning pulses to -10 mV, extent of SI was measured after a 60 sec conditioning pulse, and recovery was measured over 0.1 ms to 10 sec at -100 mV. Impaired SI was defined as: >2-fold slower entry rate. >2-fold increase in residual current that fails to SI at -10 mV, or >3-fold faster recovery rate. The two most prevalent HyperPP mutations (rT698M and rM1585V) both had clear defects of SI. However, two other mutations associated with paralytic phenotypes (PMC: rT1306M; HyperPP: rM1353V) did not have significantly impaired Sl. The SCM mutant (rG1299E), which is not associated with paralysis, also had no defect in SI. We conclude that a disruption of SI probably contributes to the HyperPP henotype but is not necessary for sustained weakness to occur. HHMI (LJH), RO1-AR42703 (SCC), and the Klingenstein Foundation (SCC).

CLUSTERING OF SODIUM CHANNELS ON AXONS IS INDEPENDENT OF MYELINATION IN THE DYSTROPHIC MOUSE 129/ReJ-Lama2^{dy}. T.I. Deerinck¹, V.M. Edelman¹, S.R. Levinson² and M.H. Ellisman¹*. ¹Dept. Neurosciences, UCSD, La Jolla, CA 92093; ²Univ. Colorado Health Sci. Center, Denver. CO 80262.

The processes involved in myelination and the development of nodes of Ranvier have been extensively studied. Despite this, there is no clear consensus as to whether it is the Schwann cell or the axon which defines the sites destined to become nodes of Ranvier in developing and remyelinating nerve. Dystrophic mice of the strain 129/ReJ-Lama2³ have a genetic defect in Schwann cell proliferation and myelinogenesis. In the dorsal and ventral spinal roots of these mice, many axons are either amyelinated or partially myelinated. In previous studies, observations of freeze-fracture replicas have revealed node-like patches of intramembranous particles on axons without nearby Schwann cells, suggesting the possibility of axonal definition of such sites (M. Ellisman, J. Neurocytol. 8:719-735.1979). In addition, the distribution of intramembranous particles at partially myelinated heminodes of Ranvier as revealed by freeze-fracture analysis are similar to that found at normal nodes of Ranvier. In the present study we have identified discrete clusters of sodium channels on axons completely devoid of myelin with a peptide-derived polyclonal antibody against the voltage dependent sodium channel using immunocytochemistry. These clusters appeared as either circumferential rings around bare axons or as asymmetrical patches. In bundles of these amyelinated axons, adjacent regions of neighboring axons could be seen to contain such clusters. Apart from these regions, no significant staining of the axolemma was observed. In addition, partially myelinated axons or heminodes and fully formed nodes of Ranvier also showed discrete positive immunoreactivity for sodium channels. We have determined that axons which develop in an environment deficient in Schwann cells produce focal concentrations of sodium channels. The appearance of these clusters without associated Schwann cells demonstrates that axons define the initial locations of these aggregations and that these sodium channels are not supplied to the axon by transcytosis from Schwan

FIBROBLAST GROWTH FACTORS AND SPATIAL PATTERNING IN THE DEVELOPING NEURAL TUBE. <u>L.Mason*, G.Grasso, R.Mahmood, N.Morton, K.Robertson and H.Sheikh.</u> MRC Brain Development Programme, Dept. Developmental Neurobiology, UMDS Guy's Hospital, London SEI 9RT, UK. Studies by this group and others have implicated fibroblast growth factors (FGFs) in the regulation of early neural tube development. In particular, FGF-3 may function in the organisation of the developing hindbrain and FGF-8 may be part of the activity from isthmus that is responsible for patterning the posterior midbrain.

We have shown that Fgf-3 is expressed in a dynamic spatial and temporal manner in the developing hindbrain which is conserved between chick and mouse embryos (Development [1995] 121: 1399; Anat Embryol [1996] in press). This pattern of RNA distribution is consistent with an early role relating to the development of rhombomeres 4, 5 and 6 and a later function in the development of rhombomere boundaries. We have identified the high affinity receptors for FGF-3 as the IIIb splice variants of FGFRs 1 and 2 (J.Biol.Chem [1995] 270: 6779; 270: 24197; Oncogene [1996] 12: 1503). Examination of the expression of transcripts for these receptors is consistent with the proposed roles for FGF-3 in the hindbrain. We are investigating the functions of FGF-3 in both mouse and chick embryos and data will be presented concerning its role in hindbrain development.

The isthmus (midbrain/hindbrain junction) is an organiser responsible for paterning the posterior midbrain. Fgf-8 is expressed in the isthmus of both chicken and mouse embryos in a spatial and temporal manner which prompted speculation that it might be involved in the organising properties of that tissue (Current Biology [1995] 5: 797). Consistent with this suggestion, we find that ectopic FGF protein can convert diencephalic tissue to a midbrain fate, a property also exhibited by grafted isthmus tissue. Further studies concerning FGF-8 function will be presented. Supported by programme awards from the MRC and International Human Frontier Science Program and projects grants from the MRC and Wellcome Trust.

MULTIPLE WNT GENES EXPRESSED AT THE MEDIAL MARGIN OF EMBRYONIC MOUSE CEREBRAL CORTEX. E.A. Grove*. L. Yip.[†]

S. Tole, and C.W. Ragsdale. Dept. Pharm. Phys. Sci. and Pritzker School Med.[†], Univ. Chicago, Chicago, II. 60637.

Univ. Chicago, Chicago, IL 60637.

To identify developmental control genes for the growth and patterning of cerebral cortex, we employed the PCR procedure of Gavin et al. (1990) to characterize Wnt gene family members expressed in embryonic mouse telencephalon. Five different Wnt fragments were isolated from cDNA derived from embryonic day 12.5 (E12.5) CD-1 mouse cerebral hemispheres: Wnt-3a, -4, -5a, -7a, and a previously unreported mouse Wnt gene. Riboprobes were generated to examine gene expression by in situ hybridization in whole embryos and tissue sections.

CD-1 mouse cerebral hemispheres: *Wnt*-3a, -4, -5a, -7a, and a previously unreported mouse *Wnt* gene. Riboprobes were generated to examine gene expression by *in situ* hybridization in whole embryos and tissue sections.

At E12.5, *Wnt*-3a, -4, -5a, and the novel mouse *Wnt* are expressed along the medial margin of the cerebral cortex, in a band of tissue that extends through the caudal two-thirds of the hemisphere. This band of strong *Wnt* gene expression lies adjacent to the developing choroid plexus (CP), which itself expresses only low or undetectable levels of *Wnt*-3a, -4, -5a, and the novel mouse *Wnt*. Tissue within the band of *Wnt* gene expression appears similar to contiguous pseudostratified neuroepithelium in morphology, but differs in its expression of class III β-tubulin mRNA, a marker of differentiating neurons. At E12.5, a layer of β-tubulin-expressing cells already extends throughout the cerebral hemisphere. This cell layer undergoes a striking transition at the medial margin of the hemisphere, such that at least part of the *Wnt*-positive band contains only scattered cells expressing β-tubulin at markedly reduced levels.

Multiple Wnt genes are expressed at the medial margin of the cerebral hemisphere, between the developing CP on one side and fully typical cortical neuroepithelium on the other. We hypothesize that Wnt genes may be involved in setting up a boundary in the medial telencephalon between developing cerebral cortex and the non-neural CP, and in regulating the subsequent growth of these tissues. Funding provided by the University of Chicago and the Brain Research Foundation.

DIFFERENTIAL EXPRESSION OF BONE MORPHOGENETIC PROTEINS IN THE DEVELOPING VESTIBULAR AND AUDITORY SENSORY ORGANS. <u>Doris K. Wu* and Seung-Ha Oh</u> National Institute on Deafness and Other Communication Disorders, NIH, Rockville, MD 20850.

Our previous study showed that BMP4 (bone morphogenetic protein) is an early marker for all sensory organs of the inner ear (Mol. Biology of Hearing and Deafness Meeting, 95', Abstr2). In this report, we investigated the gene expression of BMP4 during sensory organ differentiation and compared its expression pattern to that of BMP7, since different BMPs may have a co-operative function during development. Among the different BMP genes characterized in the chick inner ear including BMP4, 5 and 7, BMP7 was the earliest one to be activated, starting in the otic placode. By embryonic day 4 (E4), all presumptive sensory organs were within a subset of BMP7 positive areas in the otocyst, except for a portion of the macula utriculus. At this age, BMP7 seemed to be a marker for most of the presumptive sensory and non-sensory portions of the inner ear. Starting at E5, gene expression patterns of BMP4 and 7 showed differences for the vestibular and auditory sensory organs. In the vestibular sensory organs, BMP7 gene expression segregated from the sensory tissues at the onset of differentiation, while BMP4 expression remained in supporting cells, but not hair cells. However, in the cochlea, BMP7 gene expression became restricted to sensory tissue over time, and eventually concentrated in supporting cells while BMP4 gene expression was localized to hair cells.

RETINOID-MEDIATED INDUCTIVE SIGNALING IN THE MOUSE SPINAL CORD FROM EMBRYO TO ADULT. W. W. Rubin* and A.-S. LaMantia. Dept. of Neurobiology, Duke University Med Center, Durham, NIC 27710

We have hypothesized that retinoid-mediated induction is important for early spinal cord development. As early as embryonic day 8.5 (E8.5), proliferative cells throughout the anterior-posterior and dorsal-ventral extent of the cord express a retinoid-sensitive transgene. At E12.5, the expression of the transgene becomes localized to precursors and early post-mitotic cells in cervical and lumbar cord but is excluded from thoracic and sacral cord. We asked whether retinoid-mediated induction contributes to subsequent differentiation and ongoing plasticity in the perinatal and adult spinal cord. At E14.5 through birth, expression is enhanced in the alar plate of the cervical and lumbar cord. In the second postnatal week, however, the transgene is expressed at low levels in a restricted region of the dorsal horn in the thoracic as well as cervical and lumbar regions. As postnatal development progresses, expression of the transgene becomes restricted to a subset of cells in the superficial layers of the dorsal horn. It gradually increases in thoracic cord until adulthood when expression is qualitatively similar to that in the cervical and lumbar regions. Thus, retinoid signals in the spinal cord may play different roles in development and maturity. At early stages, retinoids may play a role in neural differentiation throughout the cord. From midgestation through the first postnatal week, they may be involved in regional differentiation of spinal neurons and circuits, including regionally-specific patterns of afferent innervation. From the second week of life, retinoid-signaling may contribute to plasticity of a subset of dorsal horn neurons in response to changes in the periphery. (Supported by NIH grant HD29178)

A FAILURE OF RETINOID RESPONSIVENESS ACCOMPANIES THE A FAILURE OF RETINOID RESPONSIVENESS ACCOMPANIES IT FEATLURE OF OLFACTORY BULB MORPHOGENESIS IN THE GLI-3 MUTANT MOUSE EXTRA TOES (Xt) A-S. LaMantia,* Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710

Local retinoid signaling in the forebrain and presumptive olfactory placode prefigures the morphogenesis of the olfactory bulb and epithelium. In homozygous extra toes mutant mice (Xt/Xt: a deletion of the Gli-3 transcription factor) the olfactory bulb is absent, while the epithelium can still be recognized. Accordingly, if retinoid signaling is necessary for bulb and epithelium morphogenesis, one would predict that retinoid-mediated gene expression would be absent in the forebrain while persisting in the olfactory pit/placode of Xt/Xt embryos. To assess this issue a retinoid indicator transgene was bred into Xt/+ mice and the pattern of retinoic acid (RA)-mediated gene expression in Xt/Xt mutant/transgenic embryos was evaluated. At embryonic day 10.5 RA-mediated gene expression is absent from the forebrain, but persists in the olfactory pit/placode. When embryos of this age are exposed to exogenous RA via maternal circulation, the forebrain remains unresponsive, even though ectopic or enhanced expression of the indicator transgene can be seen in other regions of *Xt/Xt* embryos including the olfactory pit, as well as throughout the forebrain in littermate +/+ or *Xt/*+ controls. Apparently, a failure of retinoid responsiveness in the forebrain—due Apparently, a failure of retinoid responsiveness in the followant either to the inability of the forebrain to receive or respond to retinoid signals—accompanies the loss of the olfactory bulb in Xt/Xt mice. In contrast, a persistence of retinoid-mediated gene expression accompanies the differentiation of the olfactory epithelium in the absence of its normal target. Supported by NIH-HD 29178.

STABILIZATION OF A HOX GENE PATTERN IN THE LUMBOSACRAL SPINAL CORD OF THE CHICK EMBRYO

C. Lance-Jones' and K. Sharma. Dept. Neurobiology, Univ. Pittsburgh Sch. Med., Pittsburgh, PA 15261.

In the chick embryo, analyses of motor projections after spinal segment reversal indicate that axial differences exist within the lumbosacral (LS) neural reversal indicate that axial differences exist within the lumbosacral (LS) neural tube prior to axon outgrowth. These axial differences appear to be fixed at stage (st) 15 but not at st 13-14. In the cranial neural tube, a unique Hox code identifies individual axial levels. We have asked if the acquisition of axial identity regarding motoneuron projections is temporally correlated with the acquision of a unique Hox identity in the LS spinal cord. To address this question, two types of surgeries were performed at both st 15 and st 13-14. In one set of embryos, 3-4 neural tube segments at the thoracic (T)-LS boundary were reversed. In another, 2-3 segments of T or LS neural tube were exchanged. The expression pattern of Hoxd-10 was assessed by wholemount in situ hybridization with dioxoxienin-labeled probes (cDNA kindly exchanged. The expression pattern or Indu-Tro Was assessed by whole-mount in situ hybridization with digoxigenin-labeled probes (cDNA kindly provided by C. Tabin) at st 25-30. In unoperated embryos, Hoxd-10 is expressed in the LS cord with a peak in midLS regions (LS3-5). No expression is detected in T segments. Following st 15 reversals/exchanges, Hoxd-10 expression is not detected in the original T segments, as in unoperated embryos. The original LS segments express Hoxd-10 at high levels, comparable to that within LS segments in unoperated embryos.
Following st 13-14 reversals/exchanges, Hoxd-10 expression is not detected in the original T segments, as in unoperated and st15 surgery embryos. In contrast, the original LS segments express Hoxd-10 at levels that are much lower then those in unoperated or st 15 surgery embryos. This finding suggests that at st 13-14 environmental factors can alter Hoxd-10 expression within LS segments. The fixation of this Hox pattern appears to occur just before st 15, like the stabilization of axial differences relating to motoneuron target identity. Supported by NIH (HD25676 to CLJ).

SEPARATION OF STRIATAL PATCH AND MATRIX COMPARTMENTS IN VITRO. A. Dori, A. Maric¹, D. Maric¹, L.L. Barker¹, A. Alfahal and W. F. Silverman* Zlotowski Center for neuroscience, Ben-Gurion University of the Negev, Beer Sheva, ISRAEL and ¹, Laboratory for Neurophysiology, National Institute of Neurological Diseases and Stroke, NIH.

The mechanisms governing the establishment of patch/matrix compartments in the striatum and its functional significance are not yet understood. The nature resembles following two separate ways of

The mechanisms governing the establishment of patch/matrix compartments in the striatum and its functional significance are not yet understood. The pattern assembles following two separate waves of neurogenesis in the ventricular area: Cells which produce the patch compartment are generated between embryonic days E12-E16, followed by cells, born from E18 thru the first postnatal week, which form the matrix compartment. We employed a buoyant-density sedimentation protocol using Percoll, to separate proliferating/undifferentiated neural cells from the differentiated neurons of the striatal anlage. The striatum was dissected from E19 fetuses so that the early born - patch compartment cells could be expected to have already differentiated, and would, therefore, accumulate in the high buoyancy band of the gradient. In contrast, we predicted that cells proliferating on E19 would accumulate in the low buoyancy band, and represent - matrix precursor cells. Primary cell cultures were established for the collected fractions, and immunohistochemistry for maturational and compartment-specific markers was carried out to confirm this hypothesis, and to test whether formation of the pattern is dependent upon intrinsic or extrinsic inductive influences. The high buoyancy cells were mostly post-mitotic and expressed markers consistent with their identification as patch cells. The low buoyancy cells, as predicted, were mostly post-mitotic and undifferentiated at the time of dissection, and by 7 days in vitro began to exhibit matrix phenotype markers. These results suggest that the matrix phenotype is specified by an intrinsic program, operating independent of inductive extrinsic factors. Support ed by Israel Acad. Sci

CEREBELLAR DEVELOPMENT REGULATED BY RETINOIC ACID P. McCaffery*, M. Yamamoto and U.C. Dräger E.K. Shriver Center, Waltham, MA 02254 and Harvard Medical School, Boston, MA 02115 Retinoic acid (RA) is a potent activator of gene transcription, and it interacts with other ligands of the nuclear receptor family to guide patterning and differentiation within the developing nervous system. The localization of RA's action is determined by: (1) the distribution of RA receptors, (2) the area of expression of RA binding proteins, and (3) the activity of RA synthesizing and degrading enzymes. The developing cerebellum is a region of the brain where all three modes of regulation act to control developmental natterning. RA synthesis in the developing cerebellum is a region of the brain where all three modes of regulation act to control developmental patterning. RA synthesis in the developing cerebellum is highest in two restricted locations, the associated meninges and the choroid plexus. Changes in the expression of RAR and RXR receptors correlate with discrete events in cerebellar development. With a novel assay for RA binding proteins we find evidence for the expression of a new binding protein in the cerebellar vermis and hemispheres. With a new, sensitive assay for the NADPH-dependent microsomal enzymes that degrade RA, we find spatially and temporally regulated expression of RA-degrading activity. The regionalization of RA synthetic and degradative enzymes will create spatial patterns in RA levels that are likely to have morphogenetic significance for the developing cerebellum. It would be expected that systemic application of RA will distort these patterns. We injected RA into early postnatal mice, during the period of most active cerebellar morphogenesis. Such injections cause a general reduction in cerebellar size, down to 70% of control. Most affected are lobules VIII and XI, where a portion of the granule cells remain undescended in the external granular layer even 6 weeks after birth. These observations support the notion that normal cerebellar development is dependent on support the notion that normal cerebellar development is dependent on temporally and spatially regulated patterns of RA levels within the cerebellar anlage. EXPRESSION PATTERN OF BCL-2, BCL-X AND BAX GENES IN THE DEVELOPING MOUSE NERVOUS SYSTEM. <u>I.K. Mai^T, M.</u>

Krajewska, J.C. Reed and S. Krajewski , Dept. Neuroanatomy, H.-Heine University, Duesseldorf, F.R.G.and the Burnham Institute, La Jolla, CA 92037 The pre- and postnatal development of the expression of several members of the BCL 2 family was studied on a closely spaced ontogenetic series of paraffin embedded specimens. Immunohistochemical localization of Bcl-2, Bcl-x and Bax was performed using polyclonal antibodies against the respective proteins. A first phase of ubiquitous expression involving all members of the Bcl-2 family lasted from the time of the formation of the germinal layers until about E10.5 when the migration of postmitotic neurons is advancing. After E11.5 regional expression patterns, typically confined to settling and differentiation areas of neurons, became manifest. The timing and distribution of the expression of the three members of the BCL-2 family showed substantial overlap in some areas (like the lower motor neuron pool of the spinal cord, the developing motor nuclei of the brain stem, the cerebellum and thalamus) but also numerous locations where a mismatch or reciprocal expression patterns were observed (striatum, cortex, olfactory bulb). Around birth the expression all three members is gradually declining albeit the topographic relation to particular nuclear structures remains evident. The time related expression pattern thus follows a biphasic course: 1. a general expression until the period of neuronal migration and 2. a focussed expression during the late migration period and beginning differentiation of some (selected) neuronal cell groups, which is compatible with the idea of expression of Bcl-2 during the period of the formation and establishment of intermeuronal contacts. The changes in the time related expression patterns and immunohistochemistry with antibodies against HNK-1, CD15 and calbindin on adjacent sections allowed the correlation with defined maturation processes in the CNS, which influence the expression pattern of Bcl2 protein family

EARLY SPECIFICATION OF THE HIPPOCAMPAL CA FIELDS C. Christian and E. A. Grove, University of Chicago, Chicago, IL 60637

When and how the developing cerebral cortex is divided into different areas are questions of great current interest. We address these questions in the mouse hippocampus, asking (1) how early the hippocampus is patterned into the two major fields CA1 and CA3, and (2) whether local cues in the hippocampus are sufficient for normal specification of CA field identity, or if extrinsic signals are

sufficient for normal specification of CA field identity, of if extrinsic signals are required from elsewhere in the brain.

Classical studies in the rodent show clear morphological and connectional differences between fields CA1 and CA3 by the end of the first postmatal week. We find, however, that differences in gene expression arise much earlier. CA1 neurons express the POU-domain gene SCIP from embryonic day (E) 15.5, and CA3 neurons express KA1, a glutamate receptor subunit, from E14.5. Initially, only neurons a each end of the hippocampal plate express SCIP or KA1, while a stretch of neurons in between expresses general neuronal markers but not those specific to CA1 or CA3. SCIP and KA1 expression progresses just bits region so that by kinth (CA3, SCIP and KA1 expression progresses into this region so that by birth (E19.5), CA1 and CA3 type neurons mingle in the narrow transitional field, CA2, other field-specific features mature postnatally, such as the expression of the receptor protein tyrosine kinase Tyro3 in CA1, and the antigen Py1 in CA3. Acquisition of the mature CA1 or CA3 molecular phenotype thus requires at least 3 weeks. To test if extrinsic signals from other brain structures are necessary for the

To test if extrinsic signals from other brain structures are necessary for the development of CA1 and CA3 field identity, we prepared organotypic slice cultures of E17.5 hippocampus. CA1 and CA3 develop normally in these cultures with respect to the progression of SCIP and KA1 expression. Next, we isolated CA1 and CA3 fields in sub dissected explants of E17.5 hippocampus, confirming their identity by expression of SCIP or KA1 respectively. Strikingly, isolated explants, like whole slices, develop new, late-appearing features of CA1 or CA3 in vitro. Thus, our results suggest that by E17.5, the CA1 and CA3 fields can develop their regional identity in the absence of extrinsic signals.

ARCUATE PLAN OF NEUROGENESIS IN AVIAN MIDBRAIN. T.A. Sanders* and C.W. Ragsdale. Committee on Neurobiology, Univ. Chicago, Chicago IL 60637.

The ventral midbrain of chick embryos is transiently patterned into longitudinal zones, called arcs, identified by acetylcholinesterase staining and ventricular surface ridges. The arcs in addition constitute domains for selective expression of developmental control genes, and may be a patterning mechanism by which midbrain neurons are allocated to nuclear fates. The extent to which midbrain arcs form territories controlling cell proliferation and the kinetics of neuronal differentiation remains, however, unexplored.

remains, however, unexplored. We have employed whole-mount in situ hybridization histochemistry to assess whether midbrain neurogenesis also follows an arcuate plan. Antisense riboprobes were prepared to neuronal differentiation markers (class III β-tubulin, middle-molecular weight neurofilament) and candidate vertebrate neurogenic genes (C-Notch-1, C-Delta-1, C-Serrate-1; Myat et al. (1996), Dev. Biol. 174:233).

β-tubulin mRNA expression, an early marker of neuronal differentiation, identified a rostrocaudal maturation gradient in ventral midbrain, which was most advanced at the midbrain-forebrain junction. Superimposed upon this gradient was a series of longitudinal stripes of dense β-tubulin expression. These stripes appeared in a strict, progressive schedule, from HH stage 17 through stage 27, suggesting that neurogenesis in ventral midbrain is controlled at least in part by arc patterning mechanisms. By embryonic day 7 (E7), β-tubulin positive cells were more uniformly distributed, establishing that both arc and interact territories are rich in neurons. Interestingly, even as late as stage 32, neurofilament message expression remained low or undetectable in large expanses of ventral midbrain tissue.

Chick homologues of Drosophila neurogenic control genes were also expressed in arcuate stripes in ventral midbrain at least from E3 through E7. C-Notch-1 was expressed densely but betergoepenously throughout the ventral midbrain with clearly

Chick homologues of *Drosophila* neurogenic control genes were also expressed in arcuate stripes in ventral midbrain at least from E3 through E7. *C-Notch-1* was expressed densely but heterogeneously throughout the ventral midbrain, with clearly discernible arcuate domains. By contrast, the putative *Notch* ligands, *C-Delta-1* and *C-Serrate-1*, were distributed in arcuate stripes that had well-defined borders and were separated from one another by districts almost free of labeled cells.

CELL SURFACE MARKERS OF THE RAT FLOOR PLATE. Z. Kaprielian*. Q. Zhu and D. Kapitula. Departments of Pathology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Region-specific cell surface molecules are thought to play important roles in the morphogenesis of the developing central nervous system (CNS). We previously used the cyclophosphamide immunosuppression method to generate a panel of monoclonal antibodies (mAbs), designated CARO 1-CARO 5(for CAudalROstral), that define anterior-posterior (AP) and dorsoventral (DV) position in the developing rat neural tube. Here we demonstrate that mAbs CARO 2 and CARO 5 preferentially label the floor plate in E12-E18 rat embryos. In contrast to the distribution of other known floor plate markers, the expression of the CARO 2 and CARO 5 epitopes in the developing spinal cord is mediolaterally restricted. mAbs CARO 2 and CARO 5 label the surfaces of the human embryonal carcinoma cell line, NT2/D1, and dissociated embryonic rat spinal cord cells. An immunoblot analysis shows that both mabs recognize a 27 kD protein in detergent soluble membrane fractions derived from NT2/D1 cells and embryonic rat spinal cord. However, mAb CARO 2 immunoprecipitates a 60 kD doublet from NT2/D1 cell extracts, while mAb CARO 5 immunoprecipitates a 20 kD protein from both NT2/D1 and E16 rat spinal cord extracts. Deglycosylation experiments suggest that mAbs CARO 2 and CARO 5 do not recognize carbohydrate epitopes. Immuno-screening of a NT2/D1 cDNA library using mAb CARO 2 has yielded several positive clones that are currently being sequenced. These findings suggest that the CARO 2 and CARO 5 cell surface antigens are novel floor plate markers that may participate in neural tube patterning and/or axon guidance.

LAYER FORMATION IN THE CHICK OPTIC TECTUM: A POSSIBLE ROLE FOR AGGRECAN. N.P. Zilakos, I. Zhizhin, N. Sakellaridis*, N.B. Schwartz and D. Mangoura. Peds, The Univ. of Chicago Sch. of Med, Chicago, IL 60637.

Aggrecan, a large chondroitin sulfate proteoglycan is developmentally regulated in the chick embryo CNS. The time table of

Aggrecan, a large chondroitin sulfate proteoglycan is developmentally regulated in the chick embryo CNS. The time table of this transient, strictly embryonic expression differs among various CNS regions. To better understand how this correlates with morphogenetic events and elucidate the function of aggrecan in brain morphogenesis, we have undertaken topography studies of aggrecan expression in the developing optic tectum, using immunofluorescence with mAb \$103L against the aggrecan core protein. Double staining with nuclear stains allows concomitant identification of the tectum layers. Aggrecan-(\$103L-) immunoreactivity was the strongest at £12 or stage 38, a critical period in the formation and segregation of the outer layers of the tectum. While most neurons were immunopositive, different layers exhibited different features. High immunoreactivity was observed in medium size neurons in layers I and II (tectal ventricle surface). Strong staining was also seen in the lower half of layer VI, and in XII, the future stratum opticum, where retinal axons first ingrow to form synapses. Overall at £12 somata of medium to small size, radially oriented neurons, transversing plexiform or cell-dense layers expressed the highest, and large, horizontally disposed neurons the least immunoreactivity. These data suggest that aggrecan has an important in neuronal positioning and layer formation in the optic tectum. (HD 09402 and BRF).

ACTIVELY PROLIFERATING STEM CELLS IN THE ADULT ZEBRAFISH BRAIN IDENTIFIED BY THE EXPRESSION OF A POU GENE, TAICHI Song Huang and Sheryl Sato*, Genetics and Biochemistry Branch, NIDDK. NIH, Bethesda, MD 20892-1766

Unlike epidermal or hematopoietic cells, neuronal cells constitute a group of stable and long living cells in the adult brain of higher vertebrates. However, some evidence suggests that the neurogenic process is different in lower vertebrates such as teleosts. The number of neurons in the adult fish brain increases constantly throughout adult life. Using zebrafish as a model, we hope to elucidate the cellular and molecular basis of this phenomenon. We have identified a new and important population of actively proliferating neural stem cells in the adult zebrafish brain. These stem cells have several salient features. They are located in the subependymal region throughout the brain, the probable zone of proliferation, and they are capable of incorporating BrdU. In accordance with their undifferentiated morphology, these cells do not express either a neural differentiation marker, acetylated tubulin or a glial-specific marker, GFAP. However, these cells do express a *Brain 1*-related POU gene, *taichi*. The expression of *taichi* in the adult brain is consistent with its expression in proliferating neural cell populations in the developing embryo. Moreover, the neural progenitors within the neural tube of a prim-5 embryo that are *taichi*-positive are in G1 phase. During early zebrafish neurogenesis, we observed that neural precursors follow a unique pattern of migration. The existence of an actively proliferating stem cell population can explain why there is continuous growth of the adult fish brain.

REGULATION OF SYNAPSE STRUCTURE AND FUNCTION BY THE *DROSOPHILA* TUMOR SUPPRESSOR GENE DISCS-LARGE. V. Budnik*, Y.H. Kho, and M. Gorezyca Dept. of Biology, Univ. of Massachusetts, Amherst, MA 01003.

Recent studies show that the mammalian synaptic protein PSD-95/SAP-90 interact directly with NMDA receptors, suggesting its involvement in functional and structural plasticity. In flies a PSD-95/SAP-90 homolog is encoded by discs-large (dlg). Our previous studies show that mutations in dlg lead to abnormal development of glutamatergic postsynaptic structures [Lahey et al. Neuron 13:823 (1994), Current Biol., 1996, in press]. However, DLG protein is expressed at both pre- and postsynaptic membranes. To understand the contribution of pre- or post-synaptic DLG to the establishement of normal synapse structure we used Gal-4 enhancer traps to selectively target dlg expression at motorneurons or muscles. In addition, to determine if dlg is involved in functional aspects of Type I synapses, we used voltage clamp techniques to study synaptic transmission in dlg mutants. We found that by selectively targeting DLG to postsynaptic cells, we were able to substantially rescue the reduced postsynaptic structure in the mutants. In wild type, postsynaptic overexpression of DLG resulted in over development of the postsynaptic specialization. Electrophysiological analysis demonstrated that synaptic currents were 100% larger in amplitude in the mutants. Quantal analysis suggested that this phenotype resulted from a presynaptic defect, which was rescued by presynaptic targeting of DLG. These results suggest that dlg functions in the regulation of neurotransmitter release and post synaptic structure. We propose that dlg may provide a mechanism by which changes in activity regulate synapse structure during development and plasticity.

POSTSYNAPTIC REGULATION OF SILENT-SYNAPSE FORMATION IN COCULTURE OF HETERO-AGED NEURONS. K. Kiyosue*, M. Kasait, T. Taguchi, Dept. of Organic Materials, Osaka Nat¹l. Res. Inst., ABT, Ikeda 563, Japan, †Dept. of Biophys. Eng., Osaka Univ., Toyonaka 560, Japan

Major excitatory synaptic signals in the central nervous system (CNS) are mediated by glutamate at dual component synapses that are composed of N-methyl-D-aspartate receptors (NMDARs) and non-NMDA receptors (non-NMDARs). This type of synapse has a potential to cause the plastic change, such as long-term potentiation (LTP) and the refinement of neural connections. Although the ratio of these receptors are thought to be critical for the plastic change, the mechanism determining the ratio in synaptic sites has not yet been known. To determine whether the ratio of receptors in the sites is controlled by the developmental stage of postsynaptic neurons or not, dual whole cell recording was applied to cocultured neurons prepared from dissociated chick cerebral neurons of different age. Results indicate that the formation of synapse containing the both receptors requires maturing of postsynaptic neurons. In the early developmental stage of postsynaptic neuron, NMDARs were also shown to selectively exist at the synaptic sites prior to non-NMDARs, even though both receptors expressed in functional form in neuronal membranes.

This work was supported by grant from MITI.

MATURATION OF A CENTRAL GLUTAMATERGIC SYNAPSE AND THE ROLE OF CaMKII G-Y Wu, R. Malinow and H. Cline*. Cold Spring Harbor Laboratory, Cold Spring

Whole-cell recording from optic tectal neurons in a whole-brain preparation of Xenopus tadpole were used to study the physiological maturation of a central synapse. excitatory postsynaptic currents in response to single fiber stimulation of optic tract and spontaneous miniature excitatory postsynaptic currents(mEPSCs) in the presence of TTX were recorded from tectal neurons at different development stages along the rostral-caudal axis, corresponding to different timepoints after they receive retinal input. As development rogresses, the amplitude of AMPA component of the evoked EPSC is increased, and the failure rate at hyperpolarized potentials is decreased, however there is no significant change the amplitude of NMDA component of transmission nor the failure rate at depolarized potentials. As a consequence, the NMDA/AMPA ratio and the fraction of pure NMDA responses are decreased. Furthermore, the amplitude and frequency of the mEPSCs at hyperpolarized potentials are increased during development. In some immature cells recorded spontaneous and evoked events are apparent at depolarized potentials but completely absent at hyperpolarized potentials. These results indicate that the initial glutamatergic transmission is mediated only by NMDA type receptors and is silent at hyperpolarized potentials. As synapses mature they acquire a component mediated by

AMPA type receptors that transmit information at hyperpolarized potentials.

In order to investigate the intracellular signal transduction pathways mediating synaptic maturation we have used the Vaccinia virus to deliver the gene for a constitutively active form calcium/calmodulin-protein kinase II(CaMKII) into tectal neurons in vivo. The results show that this synaptic maturational program is mimicked by postsynaptic expression of CaMKII. We propose that initial, randomly formed synapses are postsynaptically silent unless sufficient depolarization is provided by coincident activity. Such activity could activate postsynaptic CaMKII leading to the functional appearance of AMPA responses. Supported by the NSF.

GENE EXPRESSION IN DEVELOPING MOUSE BRAIN IN THE ABSENCE OF

NMDAR1 Roderick A. Corriveau*, Sandra A. Wiese, and Carla J. Shatz, HHMI and Dept. of Molecular and Cell Biology, University of California, Berkeley, 94720 Patterned activity plays a critical role in the development of appropriate synaptic connections in the mammalian CNS, but little is known about the molecular connections in the mammalian CNS, but little is known about the molecular mechanisms underlying activity-dependent synaptic rearrangements. To test the hypothesis that activity of ligand-gated ion channels may contribute to regulation of mRNAs encoding synaptically relevant proteins we have examined mRNA levels in normal and transgenic mice lacking functional NMDAR1 protein because: 1) the NMDA receptor is widely expressed in the CNS, and 2) a number of studies have demonstrated a role for the NMDA receptor in both adult and developmental synaptic plasticity. Levels of mRNAs encoding over 20 different synaptic proteins were compared between P0 mouse brains ± NMDAR1 by northern blot analysis. The largest difference observed to date was a modest (less than two-fold) decrease in the level of SNAP.25 mRNA in NMDAR1 knockout brains. In the majority of cases largest unference observed to date was a modest (tess than two-floot) decrease in the level of SNAP-25 mRNA in NMDAR1 knockout brains. In the majority of cases little if any change was observed (for example: agrin, n-sec1, synaptotagmin (p65, VAMP-2, GluR1, GluR2, KA1, KA2, GluR Delta1, GluR Delta2). The results suggest that, at this particular time in development, the NMDA receptor may not play a large role in regulating global brain levels of synaptic proteins encoded by the mRNAs examined. (The present results do not rule out highly local NMDAR1-

minimum ediated changes in regulation in gene expression.) Alternatively, compensatory mechanisms may substitute for the lack of NMDA receptor function.

We thank S. Tonegawa and Y. Li for the NMDAR1 knockout mice, and S. Heinemann, J. Boulter, R. Scheller, M. Bennett, and P. Worley for providing cDNA clones. Supported by NSF IBN9315390 and NIH MH48018 to CJS.

DISRUPTION OF THE ACTIN CYTOSKELETON LEADS TO A BREAKDOWN OF GIURI LABELED DENDRITIC SPINES D.W. Allison¹, V.I. Gelfand¹, I. Spector² and A.M. Craig¹. ¹ Dept. of Cell and Structural Biology, University of Illinois, Urbana, IL 61801. ²Dept. of Anatomical Sciences, HSC, SUNY, Stony Brook, NY 11794.

Dendritic spines are the predominant sites of excitatory input on mammalian neurons, however their function and structural composition is still largely unknown. We studied the role of the actin cytoskeleton in the organization of GluR1 receptors in dendritic spines of cultured embryonic rat hippocampal neurons. Rhodamine phalloidin staining showed high concentrations of F-actin, which colocalized with synaptic clusters of the excitatory glutamate receptor subunit GluR1 at dendritic spines. Two F-actin perturbing drugs were used in an attempt to disrupt the actin cytoskeleton within the spines. Cytochalasin D, at concentrations of up to 10 µg/ml for 24 hours, could not eliminate the intense rhodamine phalloidin staining that colocalized with spines. Although the remainder of the F-actin throughout the rest of the neuron had been disrupted, the actin at the spines was unaffected, suggesting that the actin meshwork at spines is stabilized and less susceptible to the effects of cytochalasin D. While cytochalain D has multiple activities on actin, latrunculin A, a compound isolated from the Red Sea sponge Negombata (previously known as Latrunculia magnifica), sequesters monomeric actin and depolymerizes actin filaments (Spector, et.al., Cell Motil. Cytoskel. 13,127-144). Exposure of mature neurons to latrunculin A at 5 μ M for 24 hours resulted in nearly a complete reduction of rhodamine phalloidin staining, along with a marked reduction in the number of GluR1 labeled dendritic spines. These observations point to a role for actin microfilaments in the maintenance of dendritic spines and may provide an important tool for the study of the function of spines. Supported by NIH and the Markey Trust.

ACTIVITY DEPENDENT DYNAMIC CHANGES IN TECTAL DENDRITIC ARBOR MORPHOLOGY | ...Rajan* , B. J. Burbach and H. T. Cline. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724

Retinal ganglion cell arbors have dramatic rates of branch additions and retractions within short intervals of time ranging between 30 minutes to 8 hours. Since these axons synapse onto tectal cells we hypothesized that similar activity dynamic changes may occur in the dendritic arbors of the tectal cells. Single cells in the tectum of tadpoles between stages 44-48 were selectively labeled using iontophoresis of Dil. Labeled tectal cells with at least 5 dendritic branches were selected for imaging. These cells receive retinal input and are therefore likely to be influenced by synaptic activity. Individual cells were imaged using time lapse confocal microscopy with a periodicity of either 30 minutes over two hours or 2 hours over an eight hour interval. Three dimensional reconstruction techniques were used to obtain complete information on the rates and positions of branch additions and retractions. We have begun to use pharmacological agents to manipulate the activity dependent events of the arbor dynamics

Tokyo, Tokyo 113, Japan and ⁴Lab. Neuronal Signal Transduction, Frontier Res. Program, RIKEN, Saitama 351-01, Japan. The glutamate receptor ⁵2 subunit (GluR⁵2) is selectively localized in careballar Burkfixia edil (PGC). The null matter transport of GluR⁵2 in GluR⁵2.

cerebellar Purkinje cells (PCs). The null mutant mice deficient in GluR82 have impairment in motor coordination and persistent multiple climbing fiber (CF) innervation of PCs (Kashiwabuchi et al., Cell 81, 245-252, 1995). The present study was undertaken to further examine the nature 1993). The present study was undertaken to further examine the hadre of CF-mediated excitatory postsynaptic currents (CF-EPSCs) of PCs in the GluRδ2 mutant mice. Cerebellar slices (250μm thick) were prepared from mature mice (PN 22-70), and whole-cell recording was made from the PC somata. We found that CF-EPSCs had multiple steps in 69.3% (88/122) of PCs in the mutant mice, whereas only 12.2% (20/164) had multiple steps in the wild type mice. The 10 to 90% rise time of CF-EPSCs in the mutant mice displayed bimodal distribution with mean values of 0.48ms (±0.15ms S.D., n=80) and 1.81ms (±0.59ms S.D., 1320). n=127). In contrast, the rise time in the wild type mice was shorter than 1ms (0.46±0.11ms, mean±S.D., n=106). The passive properties of PC membrane in the mutant mice were similar to those in the wild type mice. These results suggest that, in the GluR82 mutant mice, CFs form ectopic synapses on PC dendrites which are electrotonically distant from the

soma where CFs do not form synapses in the wild type mice.

SAP102 A NOVEL POSTSYNAPTIC PROTEIN THAT INTERACTS WITH THE CYTOPLASMIC TAIL OF THE NMDA RECEPTOR SUBUNIT NR2B. S. Kindler^{1*},B. M. Müller¹, U. Kistner¹, W. J. Chung², S. Kuhlendahl², L.-F. Lau³, R. W. Veh¹, R. L. Huganir³, E. D. Gundelfinger¹, C. C. Garner².

¹ZMNH, Univ. of Hamburg, Germany; ²NRC, Univ. of Alabama at Birmingham, AL 35213-0021; ³Depart. of Neurosci, John Hopkins Univ., Baltimore, MD 21205-2185 Recently, a novel family of synapse-associated proteins (SAPs) has been identified. In the mammalian central nervous system, SAPs are constituents

of the cortical cytoskeleton associated with the pre- and postsynaptic plasmalemma. SAPs are structurally related to DlgA in Drosophila. In the fly, DlgA is essential for the correct assembly of septate junctions and neuromuscular junctions. Here we present a novel SAP comprising at least three isoforms with apparent molecular weights of about 102 kDa, collectively called SAP102. In rat hippocampus, SAP102 is situated in dendritic spines and at PSDs of type 1 asymmetric synapses and is enriched in preparations of synaptic junctions. As with SAP90, SAP97, and DlgA, SAP102 is composed of multiple domains. Amino-terminal are three 90 amino acid repeats, termed PDZ domains. These are followed by an SH3 region and a putative guanylate kinase domain. Interestingly, SAP102 can be coimmuno-precipitated with NMDA receptor complexes solubilized from rat brain synaptosomes. Recombinant proteins containing the COOH-terminal tail of the modulatory NMDA receptor subunit NR2B bind SAP102 from rat brain homogenates. In addition, all three PDZ domains in SAP102 interact with the cytoplasmic tail domain of NR2B in vitro with different relative affinities. Taken together, these data suggest that *in vivo* at excitatory type 1 synapses SAP102 links NMDA receptors in the postsynaptic plasmalemma with the underlying cortical cytoskeleton associated with PSDs. Supported by NIH P50 HD32901 and the German BMBF.

ONTOGENY OF GLUCOCORTICOID RECEPTORS IN THE EMBRYONIC CHICK BRAIN. L. Bordone, L.M.Schrott, and S.B. Sparber*. Dept. Pharmacology, Univ. of MN, Minneapolis, MN 55455. Developmental effects of drugs, including those with abuse liability, have been studied in a chick embryo model. CNS glucocorticoids and

Developmental effects of drugs, including those with abuse liability, have been studied in a chick embryo model. CNS glucocorticoids and their receptors (GR) are important for organizational and functional maturation. Drugs can have direct and indirect action upon the developing neuroendocrine axis, which may lead to long term postnatal dysfunction. We characterized the developmental pattern of GR in two different functional regions which develop at different rates prior to initiating drug studies. The optic tectum (OT), an early developing structure, was compared to the later developing hippocampus (HIPP) on embryonic (E) day 11, 15, 18 and on hatching day (HD). Cytosolic GR were measured using Sephadex LH20 after incubation with 20nM [3H-corticosterone (CORT)], with and without 200-fold excess cold CORT. [GR] showed age-related significant reductions between E15 and E18, with further reductions between E18 and HD. The data are consistent with the idea that a functional neuroendocrine axis, vis-a-vis feedback control of blood [CORT], is established at E14-E15. Embryos maybe more vulnerable to develop-mental insult after this stage. Since [GR] were measured in brains with adrenals intact, current studies will determine if chemical "adrenalectomy" will alter the observed developmental pattern.

NEURONAL RESISTANCE OF A GLUCOCORTICOID-SENSITIVE MURINE STRAIN TO DEXAMETHASONE-INDUCED APOPTOSIS DURING FETAL DEVELOPMENT. B.B. Turner*, S.H. Rapier, R.R. Holson. Dept. of Physiology, College of Medicine, East Tenn. State Univ., Johnson City, TN 37614 and National Center for Toxicology Research, Jefferson, AR, 72079.

Maternal stress or exposure to exogenous glucocorticoids during gestation is associated with neonatal reductions in brain weight. During fetal development, mouse strains differ in sensitivity to glucocorticoids. The A/J strain is glucocorticoid and cleft palate sensitive, whereas, the CD-1 strain is relatively non-sensitive. Using these strains, we have shown that at E13.5 the A/J liver. but none of 8 neural regions, had an increased level of glucocorticoid receptor (GR) mRNA and GRir relative to the CD-1 strain. The A/J strain showed greater dexamethasone (Dex)-induced down-regulation of GR mRNA and protein. Dex injection at E10.5 resulted in greater down-regulation of GR mRNA and GRIr in the sensitive A/J strain for both liver and brain regions. Thus, neural tissue in the A/J strain would appear relatively protected against Dex insult. Here, we asked if Dex-induced reductions in brain weight were due to increased apoptosis. Using the same strain and treatment parameters as previously, apoptotic cells were identified in 8µ sagittal sections by a TUNEL procedure which labeled 3'-OH ends of fragmented DNA. In control sections, only a few, scattered apoptotic cells were seen in the entire brain, other than at sites of developmentally regulated cell death. Dex treatment induced a only a slight increase in the total number of apoptotic cells in brain. No significant strain difference was observed. However, in liver Dex induced a striking increase in the extent of apoptosis in both strains, with the effect being greater in the A/J strain. These results suggest that Dex-induced reductions in brain weight are due primarily to premature terminal differentation rather than to apoptosis. MATERNAL BEHAVIOR ALTERS HYPOTHALAMIC-PITUITARY-ADRENAL RESPONSES TO ACUTE STRESS IN ADULT RATS. D. Liu*, B. Tannenbaum, D. Francis, C. Caldji, A. Freedman, S. Sharma and M.J. Meaney. Developmental Neuroendocrinology Lab, Douglas Hosp. Res. Ctr., Depts. of Psychiatry and Neurology, McGill University, Montréal, Canada H4H 1R3.

Postnatal handling permanently alters endocrine and behavioral responses to stress. However, the critical features for the handling effects are not clearly understood. In several papers Levine (e.g., Levine In "Stress & Society" 1975) has proposed that handling alters the behavior of the mother towards the pups. Handling is known to increase maternal licking and grooming of pups and nursing behavior. The hypothesis is that such changes in mother-pup interactions underlie the effect of handling. In this study we observed the maternal behavior of mothers of unmanipulated pups including time on pups, licking and grooming, nest building, nursing postures, etc. (see Meyers, Dev Psychobiol. 1989). As adults, the offspring of mothers which licked and groomed pups more frequently showed significantly lower plasma ACTH and corticosterone responses to acute stress, an effect that is comparable to that of postnatal handling. The frequency of licking and grooming was significantly correlated with the area under the curve measure for both hormonal responses to stress (r ~-. 60). No other measure of maternal behavior was correlated with HPA responses to stress. These findings support the Levine hypothesis and argue for the importance of maternal licking and grooming in mediating the handling effect. (Supported by MRCC)

ADRENALECTOMY DOES NOT RESULT IN TYPICAL APOPTOSIS IN THE GRANULE CELLS OF THE RAT HIPPOCAMPUS. Z. Hu, H. Ozawa, and M. Kawata*, Dept. of Anat. & Neurobiol., Kyoto Pref. Univ. of Med., Kawaramachi-Hirokoji, Kyoto 602, Japan.

To study the effect of glucocorticoids on the granule cell of the hippocampal dentate gyrus, light and electron microscopy were used to define the detailed morphological change of degenerating granule cells in adrenalectomized rat hippocampus. Electron microscopy revealed that early in the process of cell degeneration the degenerating neurons did exhibit coalescing of chromatin against nuclear membrane and compaction of cytoplasm. However, subsequently, large amounts of lysosomes appeared within the degenerating cells to digest the condensed cytoplasm and nucleus. No obvious apoptotic budding-off of cytoplasm was observed and no typical membrane-bound apoptotic bodies were found within granule cell layer of the dentate gyrus. The remaining degenerating debris were finally circled by glial cells. Under light microscopy, the degenerating debris did not exhibit typical round apoptotic bodies like that in other apoptotic models. These results suggest that loss of glucocorticoids activates a lysosome system to trigger a quickly autolytic procedure resulting in granule cell degeneration. Morphologically, this kind of cell degeneration does not resemble the typical apoptotic cell death.

EFFECTS OF STRESS DURING PREGNANCY ON MATERNAL AND FETAL MEDIAL BASAL HYPOTHALAMIC (MBH) 5a-REDUCTASE AND AROMATASE ACTIVITY. R.W. Rhees*, S.W. Davis, N.A. Jacobson, D.R. Ladle, and E.D. Lephart. Dept. Zoology, Cellular Biology Division, Brigham Young University, Provo, UT, 84602.

The conversion of testosterone to its major metabolites plays an important role in sexual differentiation during development. The presence

The conversion of testosterone to its major metabolites plays an important role in sexual differentiation during development. The presence of the aromatase enzyme in brain is thought to be responsible for the establishment of sexual dimorphic patterns in diencephalic and limbic structures during perinatal development. There is also evidence that brain 5α-reductase (via 5α-reduced metabolites) is important in modulating neuroendocrine function and neural development. The present study was designed to examine the effects of prenatal stress (heat-light-restraint) during the last week of gestation on 5α-reductase and aromatase activity in maternal and fetal MBH. Prenatal stress significantly reduced fetal body weight and fetal anogenital distance. Prenatal stress did not significantly alter MBH 5α-reductase activity (control, 11.9 ± 3.1 vs. stress, 10.1 ± 2.7 pmol/hr/mg protein), whereas, MBH aromatase activity was significantly reduced in stressed (61) vs. control levels (90.1 fmol/hr/mg protein) in maternal animals around the time of birth. In the MBH tissue site, 5α-reductase was not significantly altered by prenatal stress in perinatal animals and there was no significant difference between males vs. females. However, fetal MBH aromatase activity was significantly reduced in prenatally stressed animals compared to controls during the prenatal and perinatal interval, as previously reported. These results indicate that 5α-reductase activity in maternal or fetal brain is not significantly altered by prenatal stress, whereas, aromatase activity is significantly reduced in the maternal and fetal brain sites. THE EFFECT OF 5HT ON HIPPOCAMPAL GLUCOCORTICOID RECEPTOR EXPRESSION: POSSIBLE MEDIATION VIA A 5HT7 RECEPTOR. P. Laplante*, J. Diorio, and M.J. Meaney, Developmental Neuroendocrinology lab, Douglas Hospital Research Center, Depts of Psychiatry and Neurology, McGill University, Montreal, Canada, H4H 1R3

Glucocorticoid receptor (GR) expression in the hippocampus is increased by 5HT, an effect that appears to mediated by a cAMP-dependent cascade (Mitchell et al., J. Neuroscience, 1990; Neuroscience, 1992). In vitro, the 5HT effect on GR is associated with an increase in cAMP levels and is blocked with protein kinase A (PKA) inhibitors. In this study we examined the 5HT receptor subtype underlying these effects on GR expression and activation of cAMP-inducible transcription factors. Primary hippocampal cell cultures were treated with $10\mu M$ 8 bromo-cAMP, 50nM 5-Carboxamidotryptamine (5CT), and 100nM 5HT for two hours and seven days to measure transcription factors and GR levels, respectively. Each of these treatments resulted in an increase in GR expression compared to control. There was also an increase in NGFI-A expression. In each case these effects were not affected by treatment with the 5HT1A receptor antagonist, pindolol. These results suggest that the effects of 5HT on GR expression and cAMP-sensitive transcription factors are mediated by a 5HT7 receptor. (Supported by MRCC)

POSTNATAL HANDLING INDUCES CHANGES IN THE HIPPOCAMPAL EXPRESSION OF CYCLIC NUCLEOTIDE-DEPENDENT RESPONSE ELEMENT BINDING PROTEINS IN THE RAT. J. Diorio*, D. Francis, M. Walker, A. Steverman and M.J. Meaney. Developmental Neuroendocrinology Lab, Douglas Hosp. Res. Ctr., Depts. of Psychiatry and Neurology, McGill University, Montréal, Canada H4H 1R3

Postnatal handling induces long-term alterations in hippocampal glucocorticoid receptor expression, an effect that is mediated by 5-HT induced changes in cAMP levels and protein kinase A activity. In recent studies we examined the effect of handling on the expression of transcription factors that are known to be sensitive to dynamic changes in cAMP. Neonates were handled on each of the first seven days of life and then sacrificed at various times following the last episode of handling. Handling induced a significant increase in cAMP levels and in protein kinase A activity. Brain sections from separate animals were processed for immunocytohistochemistry using CREB, phosphoCREB and CREM antibodies. Handling produced no changes in CREB expression and this was confirmed on Western blots; there were high levels of basal CREB expression in neonates throughout the hippocampus. There was a modest increase in phosphoCREB expression immediately following handling. In contrast, there was a significant decrease in CREM-ir that was apparent at 30 minutes following handling and persisted for at least 240 minutes. At this point it is not evident which of the several CREM isoforms are affected by handling. However, since most CREM-related proteins serve as inhibitors of CREB action on transcription, these data suggest that handling might serve to increase CREB-regulated transcriptional processes via alterations in CREM expression. TIMING OF GROWTH IN EXERCISING HAMSTERS:
EXPRESSION OF IGF-I and GH receptor/BP mRNA.

K.T. Borer*, J.Kennedy, J.Kaplan, K.Stevens,
H.Mehta and M.Drellis. Division of Kinesiology,
University of Michigan, Ann Arbor,MI 48109.

Growth is an episodic process. To determine

Growth is an episodic process. To determine the timing of growth induction and circadian occurrence of growth in exercising mature hamsters, we quantified mRNA for IGF-I and GH receptor/binding protein in total nucleic acids and in RNA extracted from liver and quadriceps muscle, respectively. In the induction experiment, groups of 7 EX (and 6 SED) hamsters were killed after 2, 4, and 8 days of exercise. For the circadian experiment, groups of 6 EX (and 6 SED) hamsters were killed experiment, groups of 6 EX (and 6 SED) hamsters were killed every 4 h over a 24 h period after exposure to 4 weeks of running. As little as two days of exercise was sufficient to induce the expression of IGF-I mRNA in the muscle and liver of exercising hamsters. Expression of IGF-I and GHR/BP mRNA was increased during the first four hours of darkness, the period of increased level of voluntary running. Thus, in mature hamsters, exercise induces expression of growth after two days of running and growth factor gene transcription is highest at the onset of darkness.

LONGITUDINAL SEX STEROID AND MEMORY CHANGES IN HEALTHY ELDERLY MEN AND WOMEN. <u>Linda E. Carlson* and Barbara B. Sherwin</u>. Department of Psychology, McGill University, Montreal, Quebec, Canada. H3A-1B1.

This study investigated the associations, over time, between sex steroids and memory in healthy elderly people. 31 Men (M), 17 female estrogen users (E), and 39 female estrogen non-users (noE), matched for age (x=72.2), were tested on a battery of verbal and visual-spatial memory tests (Time 1 - T1). A blood sample to determine plasma levels of estradiol (E₂) and free testosterone (T) was collected at the time of testing. 1.5 years later (Time 2 - T2), 23 of the M, 23 noE women, and 7 E women were re-tested on the same test battery and another blood sample drawn. The E-users scored higher than the M and noE groups on Delayed Paragraph Recall at T1, coincident with their higher plasma E₂ levels at that time. At T2, E₂ levels had significantly decreased in the M group, and both E-users and M had higher E2 levels than the noE group. At T1 and T2 the M group had higher T levels than the E and noE groups, both of whom performed better than the M group on Category Retrieval at T1, suggesting that higher T levels may hamper performance on this test. Scores on Paired Associates and Category Retrieval decreased over time in the noE group but remained stable in the E group, indicating that E users may be protected from age-related cognitive declines when compared to non-users. T was positively correlated to Visual Paired Associate scores in the men at T2. There were no correlations between $\rm E_2$ and test performance within any of the groups, perhaps due to the limited range of $\rm E_2$ levels in the M and noE groups and/or the small sample size of the E group.

POSTNATAL HANDLING INDUCES CHANGES IN THE HIPPOCAMPAL EXPRESSION OF NGFI-A AND AP-2 TRANSCRIPTION FACTORS IN THE RAT: EFFECTS OF THYROID HORMONES AND SEROTONIN.

RA1: EFFECIS OF IHYROID HORMONES AND SERCITONIN.

<u>D. Francis^{1*}, J. Diorio¹, S. Sharma¹, J.R. Seckl² and M.J. Meaney¹.

¹Developmental Neuroendocrinology Lab, Douglas Hosp. Res. Ctr., Depts. of Psychiatry and Neurology, McGill University, Montréal, Canada H4H 1R3 and ²Molecular Endocrinology Lab, Western Gen. Hosp., University of Edinburgh, Edinburgh</u>

Postnatal handling permanently alters hypothamlamic-pituitary-adrenal responsivity to stress, an effect that is mediated by handling-induced increases in hippocampal glucocorticoid receptor (GR) expression. The effects of handling on GR expression are mediated by thyroid hormones which, in turn, increase 5HT activity at the level of the hippocampus. Previous data from primary hippocampal cell cultures suggest that the effect of 5HT on GR expression is mediated by an increase in cAMP levels. cAMP regulation of gene transcription is mediated by a host of transcription factors, two of which are activator protein-2 (AP-2) and NGFI-A. In the present studies neonates were handled on each of the first seven days of life and then sacrificed following the last episode of handling. We found that 1) handling-induced increases in cAMP are blocked by concurrent treatment with a thyroid hormone synthesis inhibitor, propylthyrouracil (PTU), or with ketanserin; 2) using Western blotting we found that handling produces an increase in the expression of the cAMP-inducible transcription factors NGFI-A and AP-2; 3) these effects were confirmed using immunocytohistochemistry and confirmed that the effect was apparent throughout the hippocampus; 4) the effect of handling on NGFI-A and AP-2 expression is blocked by concurrent treatment with either PTU or ketanserin. The GR gene promoter contains putative binding sites for these proteins suggesting that it is ultimately transcription factor binding to the promoter which may underlie the observed handling effects on GR expression. (MRCC)

IGFBP-6 MRNA EXPRESSION IN THE RAT BRAIN.

A. Grewal and J. Pintar*, Dept. Anat. & Cell Biol., P&S, Columbia Univ., New York, NY 10032 and Dept. Neurosci. & Cell Biol., UMDNJ/RW Johnson Med. Sch., Piscataway, NJ 08854.

The IGFs have previously been implicated in neural development. However, the IGFs, their cell surface receptors and the extracellular IGF binding proteins (IGFBPs) are also present in the adult brain suggesting a larger role in neural function. Here we report the mRNA expression of IGFBP-6 in the adult rat brain using in situ hybridization. The IGFBP-6 mRNA expression pattern is distinct from that of another predominant CNS IGF binding protein, IGFBP-2, which is synthesized largely by the choroid plexus epithelium, as well as IGFBPs -4 and -5 which have previously been characterized in more rostral brain regions.

IGFBP-6 antisense RNA hybridizes most intensely to the brain meninges and major cerebral arteries. In adult rat forebrain, the IGFBP-6 gene is expressed by isolated cells in all six layers of the cerebral cortex and is particularly high in specific brain structures such as the mitral layer of the olfactory bulb, the anterior offactory nuclei and a superficial layer(s) in the anterior cingulate cortex. In the diencephalon, highest mRNA expression is observed in the subthalamic nucleus, the pineal body and the magnocellular portion of the red nucleus. In the hindbrain, IGFBP-6 mRNA is expressed at high levels in the pontine nuclei, the reticulotegmental nucleus, the reticular formation and by cerebellar Purkinje cells. In comparison, regions expressing highest levels of IGFBP-6 at postnatal day 11 (P11) such as the meninges, the mitral layer of the olfactory bulb and the pontine nuclei correspond to a subset of the structures expressing IGFBP-6 mRNA in the adult. Thus discrete high levels of expression are at this early age are more likely related to cell-specific neural function than to developments.egic function

than to development-specific function.

In general, the data suggest that IGFBP-6 produced by the meninges may be secreted into cerebrospinal fluid to modulate IGF bioactivity more globally in the nervous system while high IGFBP-6 production elsewhere within the brain is consistent with more limited paracrine or autocrine functions. (Supported by NIH 21970.)

THYROID HORMONE REGULATED GENES IN THE DEVELOPING RAT BRAIN. <u>A.L.S. Dowling, J. Leonard, and R.T. Zoeller*.</u> Dept Biol., UMass, Amherst, MA 01003, Dept. Med., UMass, Worcester, MA 01655.

Thyroid hormone is an important regulator of vertebrate growth and development, having profound effects on brain development. Despite the wide recognition that thyroid hormone receptors (T₃R₈) are ligand-regulated transcription factors, no thyroid hormone-regulated genes have been identified during mammalian development. We have initiated a study focused on the developing neocortex prior to the onset of fetal thyroid function. Adult female Sprague-Dawley rats were surgically thyroidectomized two weeks prior to mating. Fifteen days after mating, females were given thyroxine (25 µg/kg) or saline in two injections (half-dose each) at 0900h and 1500h. Fetuses were removed from the dam at 0900h on gestational day 16; blood was collected from the dam and T₄ levels were measured by RIA. Fetuses from half of each litter were snap-frozen, while neocortex was dissected from remaining fetuses and total RNA was extracted. RNA from pups obtained from dams exhibiting "high" and "low" serum T₄ were subjected to differential display RT-PCR (ddRT-PCR). Gene fragments appearing either up- of down-regulated by T₄ were extracted from the gel, reamplified, and cloned. *In situ* hybridization of cryo-sectioned littermates was used as an intitial screen for expression in T₃R-containing brain areas. Several gene fragments exhibit neural-specific or neural-plus-liver patterns of expression and have been sequenced. Further characterization of these genes awaits correlation of their expression level and tissue-levels of thyroid hormone during development. Funded in part by UMass Research Council to RTZ.

DISTRIBUTION AND ENDOCRINE REGULATION OF THYROTROPIN-RELEASING HORMONE MRNA IN THE DEVELOPING AMPHIBIAN BRAIN. <u>C. Mitchell-Herpolsheimer* and S.K. Boyd.</u> Dept. of Biological Sciences, Univ. of Notre Dame, IN 46556.

The pituitary-thyroid axis is of key importance in amphibian metamorphosis, but the role of hypothalamic thyrotropin-releasing hormone (TRH) in this system is unclear. We used in situ hybridization histochemistry (ISHH) to examine TRH gene expression in Xenopus laevis during normal and hormone-induced metamorphosis. For distribution studies, tadpoles were raised to representative premetamorphic, prometamorphic and climax stages, brains were cryo-sectioned at 20 μ m, and ISHH was performed using a 48-base probe complementary to the first TRH coding region of Xenopus prepro-TRH (provided by R.T. Zoeller, U. Mass, Amherst). Seven cell populations, including 3 hypothalamic nuclei, were identified which had measurable mRNA levels at all developmental stages tested. Temporal pattern of expression varied with developmental stage for each brain region. To identify potential feedback effects on TRH gene expression, hormone treatments were administered daily to stage-selected prometamorphic tadpoles for 7 days Treatments included TRH, cyclo-(his-pro) (CHP), and prolactin (PRL), all administered intraperitoneally (IP), and thyroxine (TH), administered via absorption from tank water. Controls received amphibian Ringer's solution IP. TH treatment induced premature metamorphosis, and significantly increased hypothalamic TRH mRNA on experimental days 2 and 4, but decreased levels on day 7. PRL induced tadpole growth without differentiation, and reduced TRH mRNA levels by 25%. TRH and CHP mimicked PRL effect on external parameters, and reduced TRH mRNA to an intermediate degree. These data suggest a developmental change in TRH gene regulation. This change may account for the dichotomy in TRH action between amphibian adults and tadpoles, and between amphibians and mammals. Supported by NSF #IBN95-14305 and NIH #HD24653.

HIGH MATERNAL INTAKE OF POLYUNSATURATED FATTY ACIDS DURING PREGNANCY ALTERS BEHAVIOR IN FEMALE OFFSPRING. L. Hilakivi-Clarke*, E. Cho. Z.Gu and M. Raygada. LCC, Georgetown University, Washington, DC 20007.

A dietary deficiency in maternal intake of polyunsaturated fatty acids (PUFA) during pregnancy is linked to permanent functional alterations in the CNS in the offspring. Diet is the only source of essential PUFA, also for the fetus, and the brain is mainly composed of lipids. We wondered whether a high maternal intake of PUFA would alter behavior in the offspring. Pregnant mice were fed with isocaloric diets containing either 43%, 31% or 16% calories derived from fat (corn oil), throughout gestation. Behavior of the female offspring, which were fed with a regular laboratory chow from birth onwards, was studied at the age of 12 months. In utero exposure to a high-fat diet (43% calories from fat) significantly reduced both locomotor activity in an open field (F(2,26)=6.7, p<.005) and time spent immobile in the swim test of depressive behavior (F(2,26)=5.5, p<.01), when compared with in utero exposure to the low-fat diet (16% calories from fat). Aggressive behavior in the resident-intruder test was increased in the high-fat offspring (F(2,24)=4.7, p<.02). No changes in voluntary alcohol intake were noted among the groups. The mothers on the high-fat diet have significantly higher serum estrogen levels than the low-fat mothers. Among the offspring, body weights, serum estrogen levels, estrus cycle, or uterine wet weights are not affected by the *in utero* dietary fat manipulations. Our findings indicate that fetal exposure to high levels of PUFA may permanently reduce depressive-like behaviors and locomotor activity, and increase aggressiveness in female offspring, suggesting masculinization of behavior. We are currently identifying the genes that exhibit an altered expression in the brains of offspring exposed to a high-fat diet through their pregnant mother, using the differential display technique.

486.14

A PIGMENT-DISPERSING FACTOR (PDF) PRECURSOR IN THE LUBBER GRASSHOPPER ROMALEA MICROPTERA. D.C. Davis, J.P. Riehm, R. Keller¹, K.R. Rao*, J.M. Klein. Department of Biology, University of West Florida, 11000 University Parkway, Pensacola, FL 32514, USA. 'Institut für Zoophysiologie, Rheinische Friedrich-Wilhelms-Universität Bonn, Endenicher Allee 11-13, D-53115 Bonn, Germany.

Pigment-dispersing hormones (PDHs) in Crustacea and pigment dispersing factors (PDFs) in insects belong to the same family of amidated octa-decapeptides. Whereas PDHs play a role in the color changes, PDFs seem to be implicated in the circadian pacemaker system.

Screening a Romalea microptera-brain-cDNA library we isolated a clone encoding a prepropeptide which consists of a signal peptide, a PDF-precursor-related peptide (PPRP), and the octadecapeptide PDF which has been sequenced previously (Rao et al., J. Biol. Chem. 262, 2672-2675 (1987)). The sequence of the open reading frame is MTAMAVSGKLLTALVLSTYILGL ALTIQATQYEEDKYQENEVKYGRELASWLAQLAHKNEPAICAHKRNS EIINSLLGLPKLLNDAGRK. Additional clones, possibly encoding other PDF-precursors, are found and are being sequenced. The cDNA sequence reported here represents the first elucidation of an insect PDF-precursor. Except for the similarity in the general organization of the precursor (SP, PPRP, PDF), the SP and PPRP components of the precursor from Romalea show little or no homology to the PDH-precursors of crustaceans. The cDNA sequence from Romalea will serve as a tool to investigate PDF expression in cells of the nervous system of insects.

This work was supported in part by a grant of the Deutsche Forschungsgemeinschaft (Germany) to J.M. Klein (Kl 1001/1-1).

NUTRITIONAL AND PRENATAL FACTORS: MALNUTRITION

487.1

EFFECT OF MALNUTRITION ON THE POSTNATAL DEVELOPMENT OF THE COMPOUND ACTION POTENTIAL IN THE RAT. B. Segura, A. L. Guitérrez, J.C. Guadarrama and I. Jiménez* Dept. of Physiology, Biophysics and Neurosciences, CINVESTAV, IPN and ENEP Iztacala, UNAM, MEXICO.

We have analyzed the effect of malnutrition on the compound action potential (CAP) of cutaneous nerves in developing animals. Malnutrition of puppy rats was evoked by reducing 50% the dairy food intake of mother rats from pregnancy to weaning. Under deep anesthesia (chloral hydrate, 6%), both sural nerves of control and malnutritioned rats at ages of 8, 16, and 30 postnatal days were dissected and placed in a recording chamber with normal Krebs saline at room temperature Suction micropipettes were used for stimulation and recording of the nerves. Relative low intensity stimulation of the control nerves evoked a CAP which is mainly due to activation of group A fibers. This potential varied in electrical threshold, maximal amplitude and conduction velocity depending on the age of the animals. At 8 (n=6), 16 (n=6) and 30 (n=8) days old, the CAP shows a decrease in the electrical threshold (91.0±24 µA, 58±13 µA and 35±10 µA, respectively), an increase in the maximal amplitude (31.9±11.9 μV , 53.6±17.1 μV and 261±103 μV , respectively) and a increase in conduction velocity (6.7±2.1 m/s, 10.4±5.9 m/s and 27.4±10.1 m/s, respectively). The CAP's recorded in nerves of malnutritioned rats shown a similar tendency with age but higher electrical thresholds (280±80 µA n=6, $110\pm56~\mu$ A n=8 and $34\pm5.0~\mu$ A n=8, respectively), lower amplitudes ($7.4\pm2.2~\mu$ V, $38.6\pm15~\mu$ V and $64.5\pm26~\mu$ V, respectively) and slower conduction velocities ($3.35\pm1.1~m$ /s, $8.9\pm2.9~m$ /s and $13.1\pm3.3~m$ /s, respectively) than the control nerves The above results suggests that malnutrition produce a remarkably alteration in the functional properties of the afferent fibers of cutaneous nerves. It is proposed that this effect is associated with changes in the myelination of the axons during development

THE EFFECTS OF OMEGA-3 FATTY ACIDS ON CENTRAL CONDUCTION VELOCITY AND CORTICAL EXCITABILITY IN SUCKLING MALNOURISHED RATS, M.F. Rivera*, F. Sánchez. N.T. Urcuyo. Dept. of Physiology, National Autonomous University of Honduras, Medical School (UNAH), Tegucigalpa, Honduras. Previous work from our laboratory (Quirk et al., 1995) showed that early malnutrition reduces the conduction velocity of corticospinal

Previous work from our laboratory (Quirk et al.,1995) showed that early malnutrition reduces the conduction velocity of corticospinal neurons. To investigate the possible role of fatty acids (a myelin component), malnourishment was produced in rats pups from birth by restricting lactating dams to half of their normal consumption of standard laboratory chow, with or without a fish oil concentrate of omega-3 fatty acid. Reductions of body weight of 65% and 57% at day 21 for malnorished and omega-3 rats, were reduced to 12% by day 70. Total brain weight at day 70 was not reduced. Close to day 75, rats were anesthetized with urethane and the response to surface electrical stimulation of motor cortex was recorded from pyramidal tract at C1. Replicating our previous findings, malnourishment reduced the conduction velocity of the fastest fibers 17% relative to controls (6 controls: 20.79 m/s; 6 malnourished rats: 17.35 m/s). Rats supplemented with omega-3 were not significantly different from controls (18.4 m/s). In addition, the amplitude of responses was reduced throughout a range of stimulus intensities by 34% and 18% in malnourished and omega-3 rats, respectively. Furthermore, at low stimulus intensities, response amplitude in omega-3 rats was normal, suggesting that the number of large corticospinal fibers was normal in this group. (Supported by UNAH).

PRENATAL PROTEIN MALNUTRITION ALTERS VIGILANCE STATE-DEPENDENT PAIRED-PULSE RESPONSE IN ADULT RATS. J.D. BRONZINO*, J.H. BLAJSE, R.J. AUSTIN-LaFRANCE and P.J. MORGANE. Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106.

The effects of prenatal protein malnutrition on hippocampal dentate gyrus field responses to paired-pulse stimulation of the perforant pathway were examined in freely-moving adult rats. Paired-pulse stimulations were applied over a range of interpulse intervals (IPI) during the vigilance states of quiet waking (QW), slow-wave sleep (SWS) and REM sleep in animals of both the control and malnourished diet groups. Differences between the population spike amplitude of first and second evoked response were used to construct a paired-pulse index (PPI) indicative of the modulation of granule cell excitability across vigilance states. Comparison of the PPIs obtained during QW indicated no differences between the diet groups over the three primary phases of granule cell modulation, i.e., early inhibition at IPIs = 20-30 msec., facilitation at IPIs = 50-150 msec., and late inhibition at IPIs = 300-1000 msec. However, both diet groups exhibited behavioral state-dependent changes in PPI measures during SWS and REM sleep, with facilitation being absent during both vigilance states. Prenatally malnourished animals exhibited significantly greater inhibition of the second response during the late inhibitory phase than controls. This higher level of late inhibition during the sleep states suggests that prenatal protein malnutrition affects extra-hippocampal inputs to the dentate gyrus involved in sleep/waking oscillations. These inputs include afferents from the medial septum, medial and dorsal raphé, and the locus coeruleus which synapse on select hippocampal GABA-ergic interneurons. (Supported by NIH/NICHHD Grant # HD22539)

VIGILANCE STATES AND EEG POWER SPECTRAL ANALYSIS BEFORE AND AFTER REM SLEEP DEPRIVATION IN NORMAL AND CHRONIC MALNOURISHED RATS OF 30 DAYS. P. Durán¹¹, I. Medina¹, A. Galván¹, M.A. Guevara², and L. Cintra¹. 'Centro de Neurobiología, and Facultad de Psicología UNAM. A.P. 70228, Mexico, D.F. 04510.

Chronic protein malnutrition (pre and postnatal 6% casein diet) alters structures in the

central nervous system (CNS), during its development, some of them involved in the sleepwake cycle regulation. These alterations may be reflected in the vigilance states and cerebral EEG activity and its temporal pattern of distribution. In this study we analized the EEG of the vigilance states and also we used a power spectral analysis. Using selective REM sleep deprivation and inverted LD cycle ("conflict experiment"), we recorded the occipital cortex and neck muscles activity in chonic malnourished (M) rats of 30 days of age, 24 h before (BD) and 72 h after (RD) REMS deprivation. EEG signal was computed each four seconds and FFT analysis was employed in order to separate EEG by frequency bands as follows: 0.75-4.0 Hz; 4.0-12.0 Hz and 12.0-25.0 Hz from undistinguished rat's vigilance states, and we visually scored the vigilance states. Results revealed decreases in wake and REM sleep and increases in SWS during baseline day. By other hand, spectral analysis showed a significant decrease on 0.75-4.0 Hz band on RD day 2 and 3 and significant increases in 12.0-25.0 Hz band in all RD, however, 4.0-12.0 Hz band showed no significant changes during all experimental days. Temporal pattern of distribution was also disturbed after REM sleep deprivation in M rats, this was found in both, visual and spectral analyses. The increase of 12.0-25.0 Hz band may reflect the hyperactivity in our M animals and probably is a result of an alteration in the inhibitory system. SUPPORTED BY DGAPA-IN-208494

SEROTONIN AND 5-HYDROXI-INDOL ACETIC ACID LEVELS IN DORSAL RAPHE (DRN) AND SUPRACHIASMATIC (SCN) NUCLEI IN NORMAL, CHRONIC MALNOURISHED AND POSTNATAL NUTRITIONAL REHABILITATED MALE RATS BEFORE AND AFTER SLEEP DEPRIVATION. A. Alfaro, L. Cintra, L. Castilla, A. Galván^a and C. Escobar^a. Inst. Nal. Pediatria^a, SS, Centro de Neurobiología^a and Inst. Fisiol. Celular^a, UNAM. México. 04510.

In our previous sleep experiments, we found that chronic malnourished rats had higher slow wave sleep percentages that controls, and also that have increased levels of cerebrai biogenic amines (i.e., 5-HT, NA) throughout the animal' life. Due to the role of 5-HT in the regulatory mechanisms of the vigilance states, in this study we evaluated the 5-HT and 5HIAA concentrations in cerebral tissue in normal, chronic malnourished and postnatal rehabilitated rats before and after sleep deprivation by enforced locomotion. Diet groups vere formed with pups born from dams fed a low (6% casein) or control (25%) diet Malnourished pups were cross-fostered at birth to lactacting dams fed to control diet, so that were designated as 25/25%, 6/25% or 6/6% based on the pre-postnatal diet. Rats of 60 days of age were sacrificed (pre or post-24h of sleep deprivation) and both SCN and DRN were dissected. Samples were analyzed by HPLC technique. Results showed that malnourished rats had increased levels of 5-HT respect to control and rehabilitated animals in both DRN and SCN before and after sleep deprivation. Also, control and rehabilitated rats had very different 5-HIAA levels before sleep deprivation. Sleep deprivation potentiated the increased 5-HT values obtained in malnourished rats. According to our results we can conclude that the synthetic and degradative indices of 5-HT of control rats was very different to indices in malnourished rats. Such finding was not found in rehabilitated rats which may indicate that postnatal nutritional rehabilitation restitutes the appropriate 5-HT enzymatic function. Supported by DGAPA IN-208494 grant.

VIGILANCE STATES AND EEG POWER SPECTRA ANALYSIS BEFORE AND AFTER REM SLEEP DEPRIVATION IN RATS WITH PRENATAL PROTEIN MALNUTRITION AT 30 DAYS OF AGE. L. Cintrat*, P. Durán¹, I. Medina¹, A. Galván¹, and J. R. Galler². ¹Centro de Neurobiología, UNAM. A.P.78228 México. 04510 and 2Boston University School of Medicine, MA,

Prenatal protein malnutrition -PM- (6% casein diet) produces anatomical and physiological alterations in the developing central nervous system (CNS). Sleep-wake cycle has been assessed in the rat in order to understand some of the functional implications of protein malnutrition, as well as the vigilance states. The objective of this study was to evaluate sleepwake cycle and cerebral EEG activity with a power spectral analysis, using a "conflict experiment" and 24 h of REM sleep deprivation. Occipital cortex and neck muscles were recorded in PM rats of 30 days of age, 24 h before (BD) and 72 h after (RD) REMS deprivation. EEG signal was computed each four seconds and FFT analysis was employed in order to separate EEG by frequency bands as follows: 0.75-4.0 Hz, 4.0-12.0 Hz and 12.0-25.0 Hz from undistinguished rat's vigilance states, and we scored visually the vigilance states. Results revealed a significant increase in wake and a significant decrease in SWS at baseline day and also we found increases in wake in RD 2 and 3 during the rest phase Waking and REM sleep showed a circadian phase advance, and SWS had a phase delay in PM rats. Spectral analysis showed significant decreases on 12.0-25.0 Hz band on BD and RD 3. A phase-shift was found in 0.75-4.0 Hz and 4.0-12.0 Hz during the first recovery day. Temporal pattern of distribution was disturbed after REM sleep deprivation in PM rats. PM produces a delay in the maturation of the regulatory mechanisms of vigilance states, and also produces circadian shifts in some components of EEG signal. 24H EEG BANDWIDTHS ANALYSIS IN PRENATALLY MALNOURISHED MALE RATS OF 30 DAYS OLD BEFORE AND AFTER SLEEP DEPRIVATION. A. Galván*, L. Cintra*, P. Durán*, I.

DAYS OLD BEFORE AND AFTER SLEEP DEPRIVATION. A. Galván', L. Cintra, P. Durán', 1. Medina' and J.R. Galler: "Centro de Neurobiología, UNAM. México. 04510 and 'Boston University School of Medicine, MA, USA. It is well known that prenatal protein malnutrition alters several neurophysiological parameters in developing rats (i.e., long-term potentiation, hippocampai kindling, the vigilance states modulation). Nothing is known at this time about how the prenatal malnutrition influences the 24h EEG activity pattern in young rats, and also what happens after sleep deprivation. In this study, we analyzed the 24h EEG pattern in prenatal malnutrition influences the 24h EEG activity pattern in young rats, and also what happens after sleep deprivation. We employed two diet groups that consisted of pups born to dams fed a low (6% casein) or control (25%) diet. Pups were cross-fostered at birth to lactating dams fed the control diet. Depending from the pre-/postnatal diet, pups were denoted as 6/25 (M) or 25/25 (C). Cortical EEG recordings of 30 days old rats were obtained during a basal day-BD and three recovery days-RD (1,2,3) after 24h of total sleep deprivation by enforced locomotion (LD 12-12h). Recorded EEG signals were processed through a power spectral analysis (FFT routine). We analized the EEG bandwidths: 0.75-4.0 Hz; 4.0-7.0 Hz; 7.0-12.0 Hz and 12.0-25.0 Hz from undistinguished rats vigilance states. We found that M rats just had significantly lower and higher relative EEG power values than C animals in the 0.75-4.0 Hz and 4.0-7.0 Hz bands in middle light phase of BD respectively. Whereas in RD, M rats showed lower values in 0.75-4.0 Hz abond and also increased values in the 4.0-7.0 Hz and 7.0-12.0 Hz bands. The 24h EEG response after sleep deprivation was different between C and M groups. Thus, our results showed the impairment in the EEG activities in prenatally malnourished rats which may explain their behavioural deficits, and also highlightened the EEG activity dependence for an appropriate nutritional conditi

EFFECTS OF PRENATAL PROTEIN MALNUTRITION ON POSTNATAL GABAergic AND APOPTOTIC-LIKE CELLS DENSITIES ON FASCIA

DENTATA. Diaz-Cintra, S.*, 3conzález-Maciel A., 3Romero-Velázquez,

R.M. 1Aguilar, A. and 2Morales M.A. 1Centro de Neurobiología, and 2Instituto
de Investigaciones Biomédicas, UNAM, A.P.78228 México. 04510 3UISI-IMP, SS México, D.F

GABAergic (GAD positive cells) and apoptotic-like cells' densities were analyzed on fascia dentata in prenatal malnourished rats. Five weeks prior to mating female rats were fed a 6% casein diet, at birth pups were crossfostered with a normal dam (6/25); meanwhile control group was fed with a 25% casein diet (25/25). From each experimental group six 30 days-old animals were used for morphometric analysis. GAD-positive cells were identified in three sections (rostral, middle and caudal), all cells were counted in a blind manner with respect to the diet. Densities from apoptoticlike cells on fascia dentata were measured in semithin sections across hiliar and granular layer of the fascia dentata. Results showed a significant 30% increase in the number of apoptotic-like cells in prenatal malnourished rats Also, GAD-positive cells were significantly increased in the rostral (112%) and middle (32%) levels in prenatal malnourished animals. Statistically significant decreases (94%) were found between rostral and caudal part only in prenatal malnourished rats. These cellular alterations may affect the functional inhibitory circuit in prenatal malnourished rats, which had also LTP alterations. Supported by DGAPA IN-204093 and IN-209195.

EFFECT OF PROTEIN MALNUTRITION ON THE GENERATION OF NEURONS IN THE LOCUS COERULEUS OF THE RAT. M. Ramzan*, G.J. Blatt, W.A. DeBassio, D.L. Rosene and T.L. Kemper. Department of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118.

Prenatal protein deprivation has been shown to result in high levels of norepinephrine in the brain at birth which persists despite rehabilitation at birth. The present study was undertaken to explore a possible mechanism of this effect by determining the effect of prenatal malnutrition on the time of neurogenesis of the noradrenergic neurons in the locus coeruleus. For 5-weeks prior to mating and during gestation, Sprague-Dawley female rats were given either a 6% casein diet (malnourished group) or a 25% casein diet (control group). Bromodeoxyuridine (BrDU), a thymidine analog that is incorporated into DNA during the synthetic phase of the cell cycle, was injected intraperitoneally into dams on embryonic days E11 and E12 at a dose of 25 μ g/g body weight. Two doses were given 4-hours apart. Prior studies have shown that these neurons are generated on these two days. The pups of malnourished as well as control mothers are cross fostered to other control mothers at birth. On postnatal day 30, male rats were anesthetized and perfused with 4% paraformadehyde and the brains were processed for BrDU immunocytochemistry. The cells which stain positive for BrDU are considered to be born on the specific day. Our positive for BDO are considered to be offin on the specime day. Our preliminary results suggest that there is no significant difference in the number of tagged cells in the two diet groups on E11, however there may be a difference on E12, suggesting that malnutrition may result in a perturbation in the neurogenesis of these neurons. THE FREE FRACTION OF PLASMA L-TRYPTOPHAN AS AN INDICATOR OF BRAIN SEROTONIN SYNTHESIS IN MALNOURISHED NEWBORNS.

G.G. Manjarrez J.L. Contreras, V. M. Magdaleno † G.G. Chagoya, J. Hernández-R. Fena-Velasco A*Laboratory of Neurontogeny. Department of Physiology, Biophysics and Neurosciences, Centro de Investigación y de Estudios Avanzados del IPN *Laboratory of Neurochemistry. Coordinacion de Investigación Biomedica del Centro Medico Nacional and Gynecology-Obstetrics Hospital. No. 4, "Castelazo Ayala" Mexican Institute of Social Security. México, D.F. († In memoriam).

We have reported evidence showing that in rats malnourished during gestation or lactation there is an acceleration in the biosynthesis of brain serotonin, starting in the fetal period coincident with an elevation of both, the concentration of brain L-tryptophan and the activity of tryptophan-5-hydroxylase. These conditions seem to be also present in newborn humans with gestational malnutrition, Indeed, we described an elevation of the free fraction of plasma tryptophan, which suggests an increased transport of this amino acid to the brain with a possible enhancement of serotonin synthesis. Therefore we proposed the hypothesis that in preterm humans with gestational malnutrition, the free fraction of plasma L-tryptophan should be proposed to the proposed the service of the proposed control of the same curves were considered the control group. A prospective longitudinal and proposed the proposed the hypothesis that in preterm humans with gestational engage and the proposed control of the same curves were considered the control group. At 1, 30, 60 and 90 days after birth free fraction and total plasmatic L-Trp were determined, as well as the concentrations blood serotonin and albumin.

In the babies with intrauterine mainutrition the results were as follow: a) the free fraction of plasma L-Trp was significantly lower and 3) Plasma serotonin was significantly lower from day 60, as compared to the same parameters in normally grown-age babbes.

INFILTRATION OF DYE-LABELLED CELLS FROM THE PERIPHERAL CIRCULATION TO SITES OF INJURY $\bar{1}$ N THE CNS. R.J.Allore, Cheng Li, P.M. Richardson. Division of Neurosurgery, McGill University and Montreal General Hospital, Montreal, Quebec, Canada H3G 1A4

After injury in the PNS and CNS macrophages accumulate in diverse sites where they may contribute to the support of neural repair. Our studies have focussed on the question of the timing and the extent of infiltration of peripheral ing and the extent of infiltration of peripheral blood monocytes to sites of injury in the CNS. In these experiments host Lewis rats were injected intracranially with LPS or C.parvum and subsequently, injected I.V. with dye-labelled peripheral blood mononuclear cells from another Lewis rat. One to two days after I.V. injection of labelled monocytes, host rats were sacrificed and cells from the vicinity of the CNS injection site were partially purified and examined by flow cytometry. Preliminary data obtained using this protocol indicate that dye-labelled cells originating in the peripheral circulation can be purified from the lesioned side of the brain and thus that significant numbers of monocytes can be induced to infiltrate injury sites in the CNS. (RJA is supported by the Rick Hansen Foundation)

GENE EXPRESSION IN MAMMALIAN BRAIN CELLS INVOLVED IN THE RESPONSE TO NEURAL INJURY J.K Krady, D. Giulian[‡] and R.J. Milner Penn State Coll. of Med., Hershey, PA 17033 and †Baylor Coll. of Med., Houston, TX 77030

To gain a better understanding of the response of the mammalian CNS to neuronal damage we have employed molecular approaches to analyse gene expression patterns within cell populations that play key roles in the injury response. We have generated cDNA libraries from mRNAs extracted from purified populations of rat microglia, microglia activated with GM-CSF, astroglia and peripheral macrophages. Subtractive hybridization procedures were used to generate additional, subtracted libraries that are enriched in clones of mRNAs specific to one cell type; particular cDNAs from these libraries will be characterized further by sequence analysis. In parallel, we have used differential display techniques to identify and characterize specific gene expression patterns within these cell populations. Initial studies have focused on the expression of the family of genes encoding protein tyrosine kinases (PTKs), which have been impli-cated in signal transduction and cellular differentiation pathways. Degenerate oligonucleotide primers were made to conserved regions within the PTK sequence and used in PCR with DNA from the subtracted or unsubtracted libraries as template. Labeled PCR products were visualized on denaturing gels and fragments of unique size that showed a differential expression pattern from one or more of the cDNA libraries were isolated and subjected to sequence analysis. By this approach, we have identified PCR products encoding sixteen different PTK sequences that are differentially expressed across the cell populations. Three of these sequences appear to represent novel members of the PTK gene family. These experiments demonstrate the power of combining subtractive cloning and differential display approaches and provide the starting material for further analysis of the identified PTKs and their expression in models of neural injury. In addition to providing potential markers for the various cell populations, these studies indicate the diversity of the signaling pathways utilized by these cell populations in their response to injury. Supported by grants from the NIH.

GLIAL CELL RESPONSE AND CLUSTERIN UPREGULATION FOLLOWING RUBROSPINAL TRACT LESION. <u>L. Liu¹, M. Svensson*² and H. Aldskogius.¹</u> Dept. of Anatomy, Biomedical Center, Uppsala University, Uppsala¹, and Dept. of Neurosurgery, Karolinska Hospital, Stockholm² Sweden

The rubrospinal tract in adult, anesthetized rats was transected unilaterally at the level of the C3 segment. One day - three months after lesion, the animals were reanesthetized, and sections from the red nucleus, C3 and C8 segments were processed to examine the glial reactions as well as possible expression of complement and clusterin. In the axotomized red nucleus a small increase in immunoreactivity (IR) with antibody OX-42 (microglial marker) was found, but no change in glial fibrillary acidic protein (GFAP) - or transferrin (oligodendrocyte marker) - IR. No profiles IR for the phagocytic marker EDI or for the cell proliferation marker bromodeoxyuridine (BU) were found. No IR for complement C3, C3d and C9 were observed. Some of the neurons showed marked increase in clusterin-IR. In the lateral funiculus of the C8 segment on the operated side, similar findings were made with the exception that EDI- and clusterin-IR were strong, and a few BU-IR profiles were present. In the lesion area at C3 prominent IR for OX-42, EDI and clusterin was observed from two days and throughout the entire postlesion period. There were numerous BU-labelled profiles, which could be labelled with OX-42 as well, indicating that they were all microglia/macrophages. GFAP-IR was increased two and four weeks postlesion. These findings indicate the following: i) the non-neuronal response by intrinsic CNS neurons is much weaker compared to the response in the vicinity of the perikarya of peripherally injured neurons, ii) white matter degeneration is not associated with complement activation, in contrast to Wallerian degeneration in peripheral nerves, iii) clusterin upregulation is a feature of central as well as peripheral axotomy, and also of the response at the site of direct damage of CNS white matter, suggesting the possibility that clusterin may be associated with some aspects of neuronal degeneration. Supported by the Swedish Medical Research Council.

UNILATERAL HYPOTHALAMIC LESION RESULTS IN INCREASED GLIAL IMMUNOREACTIVITY FOR A TYROSINE PHOSPHATASE IN THE POSTERIOR PITUITARY. D. I. Lurie*, D. K.

Kosena, J. A. Watt, and C.M. Paden. Pharm. Sci, U. of Montana, Missoula MT 59813 and Biology, Montana State U., Bozeman, MT, 59717.

Studies of the glial response to injury have historically focused on glial proliferation and hypertrophy. Using such methods, it has been difficult to identify the specific cellular responses to injury. We suggest that a reasonable approach to identifying the different roles that glial cells play following CNS damage is to concentrate on the regulatory signals that may initiate selected molecular acsacades within these cells. The balance between protein phosphorylation and dephosphorylation modulates may. balance between protein phosphorylation and dephosphorylation modulates many cellular functions and tyrosine phosphorylation has been implicated in both glial proliferation and differentiation. We have found a population of cells within the rat posterior pituitary that become immunopositive for the tyrosine phosphatase PTPIC following partial denervation of the neural lobe by a unilateral hypothalamic lesion. PTP1C is an SH2 containing tyrosine phosphatase which is expressed in high levels in hematopoietic cells and is thought to play a role in the signaling cascade triggered by activated receptor protein tyrosine kinases. Rats received a unilateral hypothalamic lesion known to cause axonal degeneration and compensatory collateral sprouting within the neurohypophysis and were allowed to survive for either 5 or 10 days. Brain and pituitary tissue was processed for immunocytochemistry and stained with a polyclonal antibody generated against a PTP1C peptide. By 5 days following the lesion, there was an increase in PTPIC immunoreactivity in cells that resembled microglia. This was correlated with an increase in microglial proliferation and activation associated with phagocytosis of degenerating axons. By 10 days following the lesion, the PTPIC immunoreactivity had largely disappeared indicating that PTPIC is transiently expressed in the posterior pituitary following hypothalamic lesion. These results indicate that a PTPase may be involved in the microglial response to injury in the rat posterior pituitary. Supported in part by NIH NS32507.

TRIMETHYLTIN EXPOSURE UPREGULATES CYTOKINE LEVELS IN MOUSE HIPPOCAMPUS. A. Bruccoleri, H. Brown and G.J. Harry*. Neurotoxicology Group, NIEHS, RTP, NC, 27709.

Trimethyltin (TMT) is a prototypic neurotoxicant that produces severe neuronal necrosis in the hippocampus. In mice, the target neuronal population is neuronal necrosis in the impocampus. In immed, the anger tenuonal population is the dentate granule cells of the hippocampus. In immature male mice, 17 day old CD1 (Charles River, Raleigh, NC), the onset of neuronal necrosis is accompanied by an astrogliotic response. Within 24 hours of TMT administration (2.5 mg/kg body wt, ip), there is induction of neuronal necrosis in the dentate with an accompaning increase in glial fibrillary acidic protein (GFAP) immunoreactive astrocytes and microglia. By 3 days, the neuronal necrosis in the dentate is more pronounced and sparse neuronal necrosis is evident in the CA1 pyramidal cell region. The astrogliotic response is relatively uniform throughout the entire hippocampus while the microglia response is localized to the regions of neuronal impocampus (in the immorphism to spot a technique to the regions of neutronic necrosis. Our lab has previously reported a temporal association between microglia and early expression of pro-inflammatory cytokines in the rat hippocampus following TMT exposure. We now present data on the upregulation of cytokine mRNAs in the mouse hippocampus following TMT. At /various time points from 1 hour to 2 weeks following a single injection of TMT, changes in cytokine mRNA levels were assessed by RT-PCR. Within 12 hours, TNF-α, TNFcytokine mRNA levels were assessed by RT-PCR. Within 12 hours, TNF- α , TNF- β , IL-1 α , and MIP-1 α mRNA levels were significantly elevated. IFN- γ was elevated as early as 1 hour, possibly serving as an early "priming" signal for subsequent inflammatory responses. By 72 hours, TNF α , TNF- β and IL-1 α mRNA levels began to decrease possibly due to the upregulation of an inhibitory factor. While IL-4 and IL-10 mRNA remained undetected at any time point, TGF- β 1 was elevated at 72 hours suggesting its role in downregulation of the proinflammatory cytokines. IL-6, IL-1 β and GM-CSF remained unaltered by TMT exposure. These results suggest a modulatory role for the cytokine cascade in the manifestation of chemical induced neurodegeneration.

Sch. of Med. Seoul, Korea.

**Minorial Physiol. Impulse cells are activated around injured areas and

Sci. of Med. Seoul, Norea.

Microglia, brain's immune cells, are activated around injured areas and aggravate the injury through release of nitric oxide(NO). The activation of microglia correlates well with induction of outward K channels. However, the exact role of K channels during the activation of microglia remains to be delineated.

remains to be delineated.

We prepared microglia from the neonatal rat brains and cultured for two weeks. Lipopolysaccharide(LPS), a bacterial endotoxin, was used to activate microglia. Microglia exposed for 2 days to LPS showed marked expression of K' channels revealed by electrophysiology and immunohistochemistry using a polyclonal antibody to Kv1.5(one of voltage-gated K' channels). The LPS-treated microglia underwent some morphological changes from small and/or ramified cell bodies to large and flat ones, secreted NO, lost mitotic activity, and reduced phagocytosis. To study the function of K' channels in activation of microglia, microglia were treated with LPS in the presence of 4-aminopyridine(4-AP) which blocks up to 90% of the outward K' channels (Narnels(Narnels) and 1994 L. 199 were treated with LPS in the presence of 4-aminopyridine(4-AP) which blocks up to 90% of the outward K' channels(Norenberg et al., 1994, J. Physiol. 475: 15). LPS-induced morphological changes and NO secretion were reduced by 4-AP in a dose-dependent manner, but proliferation and phagocytosis were not influenced. However, tetraethylammonium(TEA) which has less effect on outward K' channels did not block either morphological changes or NO release. These results provide that the LPS-induced expression of outward K' channels are required for microglial activation, particularly morphological changes and NO secretion.

ETHANOL BLOCKS MICROGLIAL MATURATION IN THE RAT CEREBELLUM. N.S. Vettivadan*†, K.E. Light+ and C.J.M. Kane†.

CEREBELLUM. N.S. Vettiyadan*†, K.E. Light* and C.J.M. Kane†. Toept. of Anatomy, College of Medicine, and *College of Pharmacy, University of Arkansas for Medical Sciences, Little Rock, AR 72205. The neuropathology of fetal ethanol exposure includes deficits, malformations and dysfunction in neurons. Direct ethanol damage to astrocytes and oligodendrocytes is also well documented in patients and animal models. However the impact of ethanol on the principal immune cell in the brain, the microglial cell, is unstudied. This study was designed to document quantitatively microglial pathology in a rat model of fetal ethanol exposure. Charles River CD rats were administered ethanol (3 g/kg/dose) or the isocaloric equivalent as dextrose via intragastric intubation at 8 am and 4 pm on postnatal days 2 through 10 inclusive. Each litter of 10 culled pups contained 3 treatment groups: ethanol intubated, dextrose-control intubated and non-intubated suckle controls. Animals were weighed, anesthetised and perfused at 8 am on ethanol intubated, dextrose-control intubated and non-intubated suckle controls. Animals were weighed, anesthetised and perfused at 8 am on postnatal day 11. Microglia in 50 μm mid-sagittal sections of the cerebellar vermis were visualized by *Griffonia simplicifolia* lectin I-B4 binding and the peroxidase reaction. The perimeter of the stained soma and processes of individual microglial cells in the molecular layer of lobule I was measured by computer-aided image analysis. At least a 20% reduction in the cell perimeter was observed in ethanol-treated rats compared to intubated controls (p≤0.05), reflecting impaired process elaboration as a result of ethanol exposure. These results suggest that microglial maturation in the brain is damaged by moderate concentrations of ethanol during the critical period of microglial genesis and maturation. Thus, microglial damage by fetal ethanol exposure may impair the ability of microglia to defend the brain against disease. (UAMS Foundation and UAMS Graduate Student Research Fund).

EXPRESSION OF INTERLEUKIN-15 RECEPTOR α CHAIN IN HUMAN GLIA IN CULTURE. Y.B. Lee* and S.U. Kim. Division of Neurology, Department of Medicine, University of British Columbia. Vancouver, Canada.

Interleukin-15 (IL-15) is a novel cytokine that has recently been cloned and exhibits T cell stimulating activity similar to interleukin-2 (IL-2). IL-15 mRNA is detectable in a wide range of cell types including fibroblasts, epithelial cells, and monocytes, but not in T cells. Recently, we demonstrated that human astrocytes and microglia produce IL-15 constitutively and that IL-15 expression is regulated by proinflammatory cytokines such as interleukin-1 β (IL-1 β), interferon- γ (IFN- γ), and tumor necrosis factor-α (TNF-α) (Lee et al., Soc. Neurosci. Abstr. 21:885, 1995). Recently, a human IL-15 receptor α subunit (IL15Ra) was cloned and showed a high affinity for IL-15. To investigate the biological role of IL-15 in the human central nervous system (CNS), mRNA levels of IL-15Rα in human astrocytes, microglia, and oligodendrocytes were determined by reverse transcription-polymerase chain reaction (RT-PCR). Purified populations of astrocytes and microglia were prepared from fetal brains of 12-20 weeks' gestation, and oligodendrocytes were prepared from adult human brain tissues obtained during epilepsy surgery. IL-15R α mRNA was detected in both astrocytes and microglia but not in oligodendrocytes. In addition, upregulation of IL-15R α in astrocytes was observed after treatment with IL-1 β , IFN- γ , or TNF- α and in microglia by lipopolysaccharide (LPS), IFN-γ, or granulocyte-macrophage colonystimulating factor (GM-CSF). These results suggest that IL-15 produced by astrocytes and microglia has a role in immuno-modulation in the human CNS in a paracrine or autocrine manner. ETHANOL INHIBITS THE PROLIFERATION AND SURVIVAL OF MICROGLIA IN CULTURE. G.J. Brown*, W. Chen, Z.Q. Yang, N.S. Vettiyadan and C.J.M. Kane. Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Fetal ethanol exposure is the leading known cause of mental retardation affecting >1 of 1000 infants a year. The damaging effects of ethanol on the development of neurons and macroglia have been studied. However, the impact of ethanol on the development of the principal immune cell in the CNS, the microglial eetl, is unknown. Microglia were purified from primary cultures of mixed glia established from the cerebral cortex of one-day old Charles River CD rats. Microglia were exposed to ethanol in the culture medium at socially and clinically realistic levels (0.05, 0.1, 0.2, 0.5, 1.0% w/v) with evaporation restricted. The impact of ethanol on microglial survival was determined by MTT assay of cell viability. Ethanol decreased microglial survival significantly in a dose-dependent manner with 35–90% cytotoxicity observed following 4 days of exposure. Proliferation of the surviving cells was quantified by [³H]thymidine or bromodeoxy-uridine incorporation into replicated DNA. Quantitation of [³H]thymidine in cell lysates revealed a significant 10–25% inhibition of proliferation in cultures exposed to ethanol for 4 days. Enumeration of BrdU-labeled microglial by microscopy revealed that ethanol inhibited microglial proliferation 10–25% after 1 day, and 25–40% after 4 days, of ethanol exposure when compared to untreated controls. These results suggest that microglia may be a direct target of ethanol in vivo. A significant decrease in microglial genesis or survival could produce long-term consequences on microglial function in the brain. Since microglial cells directly affect the function and survival of neurons, ethanol damage to the neuronal pathology associated with fetal ethanol exposure. (UAMS Foundation).

GLIAL RESPONSE TO ICV LIPOPOLYSACCHARIDE INJECTIONS IN MICE OF DIFFERENT AGES A.N. Kalchua*. F. Mangiarotti¹, J. Hengemihle, D.L. Speer, D.K. Ingram and M.G. DeSimoni¹ GRC. NIA. NIH. Baltimore. MD 21224. and ¹Mario Negri Institute of Pharmacol. Res. 20157

Chronic inflammation has been implicated in age-related neurodegeneration as Alzheimer's disease (AD). Cytokines, such as IL-6

neurodegeneration as Alzheimer's disease (AD). Cytokines, such as IL-6 and TNFα, have been found in senile plaques associated with activated microglia and hypertrophic astroyctes in AD brains. To develop a model of CNS inflammation, we have conducted ICV injections of the endotoxin, lipopolysaccharide (LPS) to produce glial cell activation in mouse brains. LPS (2.5 μg/μl or 10 μg/μl; 1 μl) was injected into the third ventricles of 6-mo (adult), 19-mo (middle-aged) and 24-mo (aged) male C57bl/6J mice. Beginning 1.5 hours after treatment, mice were perfused with 4% paraformaldehyde buffered with 0.01M PBS, or sacrificed by decapitation for biochemical analysis. Astrocytes were identified using a polyclonal antibody to GFAP, and microglia with the B₄ isolectin from *Griffonia simplicifolia*

simplicifolia. LPS produced localized hippocampal glial activation within the genu of area CA3 at 2.5 $\mu g/\mu l$ in all animals, however, serum and brain levels of TNFa, as well as serum levels of IL-6 were elevated in aged animals compared to adults. In contrast, following 10 $\mu g/\mu l$ LPS, activated glia and macrophages were present throughout the hippocampus, cortex and thalamus of all animals, with strongly elevated serum and brain levels of both IL-6 and TNFa in aged vs. adult animals. Lastly, aged animals were also more susceptible to LPS-induced mortality associated with marked tonic-clonic seizures, than adults.

MICROGLIA AND T-LYMPHOCYTES INTERACT TO PRODUCE TNF-α: REDUCTION BY β-INTERFERON. Chabot S., Stüve O.*, and Yong V.W. Montreal Neurological Institute, Department of Neuroimmunology, McGill University, Montreal, Canada, H3A 2B4.

Clinical trials have demonstrated that \(\beta \)-interferon (\(\beta \)-IFN) is effective in the treatment of relapsing-remitting multiple sclerosis (MS), although the mechanisms of its efficacy remain unclear. In view of the observations that the migration of Tlymphocytes into the CNS is a crucial event in the pathogenesis of MS, and because the cytokine TNF- α can induce apoptotic death to oligodendrocytes, we examined the effect of β -IFN on the level of TNF- α production following the interaction between T-lymphocytes and microglia; microglial cells are known to be a prominent source of TNF-α in the CNS. Cultured adult human microglia were exposed to activated T-lymphocytes for 24h and the culture medium was then collected for ELISA measurements of TNF-α. In co-cultures of microglia and activated Tlymphocytes, the level of TNF-a was greatly enhanced (300-400pg/ml) compared to control (microglia alone), in which no TNF-a was detected. When T-lymphocytes were pretreated with IFN-β (ranging from 0.1U/ml to 1000U/ml), and were then exposed to microglia, the production of TNF-α was reduced in a dose-dependent manner. Pretreatment of microglia with β-IFN had a less marked effect on the subsequent generation of TNF-α in T-lymphocyte/microglia co-cultures. Ongoing experiments are being conducted to assess the mechanism by which β -IFN reduces the production of TNF- α . We suggest that the significant reduction by β -IFN of levels of oligodendrocyte-toxic cytokine, TNF-a, may contribute to the mechanisms of efficacy of β-IFN in MS. INFLAMMATORY AGENTS INDUCE MICROGLIAL NEUROTROPHIN-3 EXPRESSION WHICH ATTENUATE MICROGLIAL TOXICITY ON NEURONS. S. Elkabes* and L.B. Black. Neurosci. and Cell Biol. Robert W. Johnson Med. Sch., UMDNJ, Piscataway, NJ 08854

We previously reported that microglia express neurotrophins *in vitro* and *in vivo*1. These results suggested that microglia, which have been implicated in neurotoxin production in inflammation, also support neurons and glia. To determine whether inflammatory agents regulate microglial trophin expression, we analyzed the effects of lipopoly-saccharide (LPS) and interferon-γ (INF-γ) on the expression of NGF, NT-3 and NT-4 in microglia. Exposure of microglia to LPS and INF-γ for 6 or 24 hours induced a 7-fold increase in NGF, a 2-fold increase in NT-3 and no change in NT-4 mRNAs. These results suggested that microglia support or protect neurons by increasing trophic factor production in response to inflammatory agents. One way of protecting neurons in inflammation is to reduce toxic activities produced by microglia. Since our previous studies indicated that NT-3 regulates microglial proliferation and phagocytosis¹, we assessed whether NT-3 also regulates microglial toxic activities. We studied the effect of microglia conditioned medium on cortical neurons after exposure of microglia to NT-3. Conditioned medium obtained from high density control microglial cultures induced a significant decrease in the number of cortical neurons *in vitro*. Treatment of microglia with NT-3 abolished the toxic effects of microglial conditioned medium on neurons. These results raise the possibility that NT-3 protect neurons by attenuating elaboration of toxins by microglia. (NIH Grant POI HD 23315-06A1 and Trophix Pharma. Inc.) LElkabes et al. 1996, J. Neurosci., 16, 2508.

BASIC FIBROBLAST GROWTH FACTOR INCREASES PHAGOCYTIC ACTIVITY IN A CELL LINE DERIVED FROM PRIMARY MICROGLIAL CULTURES. A.C. Sherwood*, I.B. Black, and S. Elkabes. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Within the central pervous system, microglia respond to neurona.

Within the central nervous system, microglia respond to neuronal damage by altering morphology, proliferating, increasing phagocytic activity, elaborating toxins and trophins, and by increasing expression of markers of antigen presenting cells. Basic fibroblast growth factor (bFGF) is elevated in lesions where microglia are present, following trauma, in experimental acute encephalomyelinitis (EAE), and in Alzheimer's disease. Microglia increase expression of high-affinity bFGF receptors after trauma and in EAE. To further understand the role of bFGF in mediating functions such as phagocytosis, we have used a partially characterized microglial cell line, MK.1, that we have recently developed.

MK.I cells were derived from primary cultures of P2 rat, cortical microglia transfected with the oncogene, p53val 135. MK.I cells express the microglial specific markers, ED-1 and OX-42. Under normal growing conditions these cells are sombrero-like or crescent shaped and 15 %' phagocytize latex beads. They make and respond to neurotrophins. When treated with bFGF (10 ng/ml). MK.1 cells increase proliferation, become elongated and process-bearing, and 50% of the cells phagocytize latex beads. We are employing MK.1 in conjunction with primary microglia to characterize mechanisms through which bFGF contributes to disease pathogenesis. Supported by Trophix Pharmaceuticals.

MICROGLIA IN HUMAN CNS DEVELOPMENT. A. Andjelkovic¹, A. Milosevic², B. Nikolic² and N. Zecevic¹*, ¹University of Connecticut, Farmington, CT 06030 and ²Institute for Biological Research, Belgrade 11000, Yugoslavia.

The development of microglia in the human brain has increasing importance because these cells are a target for fetal HIV infection. To establish the time of their appearance, we examined 9 human embryos and fetuses ranging in age from 4 to 13.5 gestational weeks (g.w.) using antibodies for two specific markers, Ricinus communis agglutinin 1 (RCA-1) and Lycopersicon esculentum (tomato) lectin. At 4 g.w. both markers labeled round, ameboid cells with 1-2 short processes, in the marginal zone of the neuronal tube, in the nearby connective tissue, and aligned on the outer pial surface. Primitive blood vessels were observed only in the caudal region. At 5-6 g.w., in addition to amoeboid cells, poorly ramified microglia were found in the marginal and ventricular zones of the entire CNS. At 7.5 g.w., in the cortical anlage only a few poorly ramified cells were present in the cortical plate, whereas the majority of microglia were found above and below it, following the vascularization pattern. At 13 g.w. adult-like ramified microglia were present in all areas of the CNS and in all developmental zones of the cortex. The appearance of microglia at 4 g.w., when only a few primitive blood vessels were present in caudal regions of the neuronal tube, suggests a possible dual origin for microglia in the CNS. Supported by NIH grant MH53945 (NZ).

DIFFERENTIAL GENE EXPRESSION IN ACTIVATED MICROGLIA. S. Thakker-Varia*, S. Elkabes, A.C. Sherwood and I.B. Black. Dept. of Neuroscience and Cell Biology, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Microglia are immunoreactive cells in the brain that have been

Microglia are immunoreactive cells in the brain that have been implicated in inflammatory defense mechanisms in response to illness and injury. To understand molecular mechanisms leading to microglial activation, we used differential mRNA display, a highly sensitive, rapid differential cloning technique. This method utilizes reverse transcription and PCR to amplify partial cDNA sequences from subsets of mRNA. Display of cDNA from lipopolysaccharide (LPS)-activated microglia and controls revealed that LPS elicited unique patterns of gene expression. Eleven of these LPS-induced bands were isolated from the display, reamplified by PCR and cloned. Partial sequence analysis of one of these bands indicated that the cDNA showed homology to the squamous cell carcinoma antigen gene, a member of the serine protease inhibitor family. Using this approach, the profile of gene regulation in the recently established rat microglial cell line, MK.1, was compared to that of the primary microglia. When the same set of primers were used to display RNA from primary cultures and rat MK.1 cell line, an almost identical cell-specific cDNA pattern was observed. These results confirm that the genes expressed in cell line reflect patterns of genes in primary culture, thus validating the use of rat MK.1 for further investigations. Additional characterization of the differentially expressed genes and their relationship to microglia activation will be explored. (Supported by Trophix Pharmaceuticals Inc.)

THE POSSIBLE ROLE OF EPIDERMAL GROWTH FACTOR IN MICROGLIAL CELL ACTIVATION IN VITRO <u>C. Nolte* and H. Kettenmann</u> Cell. Neurosciences, Max-Delbrück-Center for Molecular Medicine, Robert-Rössle-Str.10, D-13125 Berlin, FRG.

Medicine, Robert-Rossie-Str.10, D-13125 Berlin, FRG.
Epidermal growth factor (EGF) and its receptor (EGF-R) are present in the central nervous system (CNS) and evidence is accumulating that EGF regulates a variety of CNS functions¹. Acute and chronic pathological processes of the CNS are often accompanied by an increase in EGF-R expression¹. Microglial cells which are always activated by insults to the CNS are recruited at the lesion sites by chemotactic movement and proliferation. Since there is evidence for an action of EGF on membrane currents in microglial cells⁶, we asked if EGF might also stimulate microglial chemotaxis and proliferation.

Using primary microglial cells from newborn mouse cortex and a multiwell microchemotaxis assay we demonstrate a dose-dependent effect of EGF (Sigma E-4127; Coll. Biomed. Res. 40010) on microglial chemotaxis. The maximal chemotactic response is achieved by 10µg/ml EGF in the lower compartment. It reaches 300% (± 35%) of the unstimulated control and is about half as high as induced by 10nM C5a, a potent microglial chemoattractant. Checkerboard-analysis shows that the effect of EGF is not purely chemotactic. As demonstrated by BrdU-incorporation and a colorimetric cell-ELISA, EGF (0.01 - 10ng/ml for up to 36h) is not a mitotic signal for microglia.

Our data strongly indicate that microglial cells possess binding sites for

Our data strongly indicate that microglial cells possess binding sites for EGF. EGF specifically activates microglial chemotaxis but not proliferation and thereby might serve to direct microglial cells to the site of brain damage.

DIFFERENTIALLY EXPRESSED GENES POTENTIALLY SERVING TO PROTECT AGAINST NITRIC OXIDE-ASSOCIATED OXIDATIVE STRESS IN ACTIVATED MICROGLIA. K. Sugaya*, M. Chouinard and M. McKinney. Dept. of Neuropharmacology, Mayo Clinic Jacksonville, Jacksonville, FL 32224.

Nitric oxide (NO) generated by NO synthase (NOS) can cause oxidative stress in some cell models. However, NOS-positive cells appear to be resistant to the effects of Alzheimer's disease, a condition in which oxidative stress is known to exist. Since microglia are known to express inducible NOS (i-NOS) and produce copious NO when activated, they appear to have efficient protection mechanism(s) against NO toxicity. In this study, activated microglia were resistant to a concentration of NO which elicited DNA fragmentation in inactivated microglia. This indicates that microglia express protection mechanisms after they are activated. In order to identify those biochemical mechanisms against oxidative stress, we used "mRNA differential display" to clone sequences from genes that are preferentially expressed in activated microglial cells (line BV-2). When checking sequences for homology against the GenBank data base, many genes were found to be differentially expressed in activated BV-2 microglia. The identifiable genes included class II histocompatibility antigens, i-NOS, IL1 and certain cell surface antigens. Among these, we obtained evidence that genes related to lipid transport, antiapoptosis and NO metabolism may play important roles in protecting these cells from oxidative damage. Such findings may in part explain why NOS-positive cells are resistant to oxidative stress imposed from self-generated free radicals.

RELATIONSHIP BETWEEN MICROGLIAL ACTIVATION AND THE ONSET OF WALLERIAN DEGENERATION IN THE DENERVATED NEUROPIL OF THE HIPPOCAMPUS. P.E. Schauwecker* and O. Steward. Dept. of Neuroscience, Univ. of Virginia, Charlottesville, VA 22908

Reactive sprouting following neuronal injury has been suggested to reflect an interplay of cellular signals involving microglia, astrocytes, and neurons. To understand the mechanisms governing neuronal survival and regeneration, it is essential to know more about the time course of cellular responses. This study addresses the temporal relationship between the activation of microglia in denervated neuropil and the onset of terminal degeneration as revealed by selective silver staining in normal mice and in mice carrying a mutation that delays the onset of Wallerian degeneration (Wlds). We used the unilateral entorhinal cortex (EC) lesion as our experimental model to define degeneration and microglial activation within the denervated molecular layer of the dentate gyrus. The onset of degeneration was assessed using the Fink-Heimer method while microglial activation was assessed using immunocytochemistry for Mac-1, an antibody that recognizes the complement component receptor C3_b. C57BL/6 and Wld* mice were killed at 1, 2, 4, 6, 8, 12, 15, and 20 days following an EC lesion. In C57BL/6 mice, microglial induction was present as early as 1 day postlesion with peak activation occurring between 2-6 days postlesion. In contrast, microglial activation was delayed by 6-8 days in Wld mice and the delay in microglial activation temporally coincided with a delay in degeneration. These data suggest that the response of microglia in denervated neuropil zones is triggered by degenerative changes in axons undergoing Wallerian degeneration. Supported by NS29875 P.E.S. was the recipient of NRSA NS09972

CLEARANCE OF APOPTOTIC CELLS IN THE CNS. R. Parnaik, C. Neophytou*, J. Scholes, M. C. Raff, MRC LMCB, University College London, London, England.

It has been known for some time that many neurons and glia die by programmed cell death during neurogenesis, but what phagocytoses and clears these cells from the Central Nervous System (CNS) is much less well

Electron micrographic evidence shows that all pyknotic cells in the cerebellum have already been engulfed by another cell, implying that cells which have not been engulfed by microglia (the resident macrophages and professional phagocytes of the CNS) have been engulfed by another cell

Using a combination of immunohistochemistry and electron microscopy we have shown that several cell types are involved in the scavenging process. In the External Granule Layer (EGL) of the cerebellum a number of neurons die but there are no microglia present in this region. Both Bergmann glia (the radial glia of the cerebellum) and other granule neurons are responsible for the clearance of pyknotic cells in the EGL. In the optic nerve however, where the cells that die are oligodendrocytes, it is apparent that virtually all of the pyknoses are engulfed by microglia. This may mean that certain cell types preferentially elicit phagocytic responses from particular other cell types, - oligodendrocytes and microglia for example. Alternatively, the situation in the optic nerve may represent a more advanced stage of development than the cerebellum at this age and in the CNS the phagocytic role is taken up progressively by the microglia as a

NMDA RECEPTOR 2A/B SUBUNIT EXPRESSION IN TRIGEMINAL MOTONEURONS, INTERNEURONS, AND MESENCEPHALIC TRIGEMINAL NEURONS DURING EARLY POSTNATAL DEVELOPMENT. J.E. Turman, Jr.*, J.Ajdari, B.Cole, and S.H. Chandler. University of Southern California, Dept. of Biokinesiology and Physical Therapy, Los Angeles, CA 90033; and University of California, Los Angeles, Dept. of Physiological Science, Los Angeles, CA 90095.

There are little data at the cellular level that explains the neural mechanisms underlying the transition from suckling to chewing. Trigeminal motoneurons (MotV), mesencephalic trigeminal neurons (MesV), supratrigeminal (SuV), and intertrigeminal (InV) neurons are important constituents of the neural circuitry responsible for these oralmotor behaviors. Insight regarding oral-motor development will be gained by understanding the development of neurotransmitter receptor complexes utilized to modulate the activity of these neurons. This study used receptor immunohistochemistry techniques to describe changes in used receptor immunohistochemistry techniques to describe changes in the expression of NMDA receptor 2A/B subunits in MotV, MesV, SuV, the expression of NMDA receptor 2A/B subunits in MotV, MesV, SuV, and InV neurons during early postnatal development. Neonatal rats at postnatal day (P) 1, 3, 8, 15, and 22 were used. An affinity purified polyclonal antibody against the NMDA 2A/B subunits (Chemicon, Inc.) was used to describe the neuronal and/or neuropilar distribution of these subunits. In MoV neurons, expression was neuronal at P(1) and transitioned to primarily neuropilar labeling by P(22). Neuronal expression in MesV neurons emerged at P(3) and remained neuronal through P(22). Receptor subunit expression in SuV and InV neurons emerged at P(8). Immunoreactivity in these regions became neuropilar between P(15) and P(22). These results demonstrate that the cellular localization and temporal expression patterns of NMDA receptor 2A/B subunits differ among MotV, MesV, SuV, and InV neurons during early postnatal development. AN IN VITRO STUDY OF EARLY BRAINSTEM-SPINAL CORD PROJECTIONS IN THE RAT H.J. ten Donkelaar* and R. de Boer-van Huizen. Dept. Anatomy/Embryology, Univ. of Nijmegen, 6500 HB Nijmegen, Netherlands So far, the early development of brainstem-spinal cord projections in mammals, apart from marsupials, could be studied only by application of Dil to the spinal cord of fixed embryos. In a first series of Dil experiments data by Auclair et al. (1993) were confirmed for rat embryos fixed on embryonic day 13 (E13) or 14 (E14). Cells of origin of interstitiospinal (from the interstitial nucleus of Cajal), reticulospinal and vestibulospinal projections were labeled. The main disadvantages of the Dil technique are the long diffusion time required (at least two months) and difficulties inherent in analyzing fluorescence labeled material. Therefore, an *in vitro* approach was applied. Precisely timed pregnant Wistar rats were used to provide embryos 10-14 gestational days of age. At the proper time, the rats were anesthetized and the embryos taken out by cesarian. The isolated embryos were immersed in an iced Ringer solution that had been oxygenated with carbogen (95% O₂, 5% CO₂). Subsequently, biotinylated dextran amine (3kD BDA, Molecular Probes, D-7135) was applied to the rostral spinal cord. After bbA, Molecular Frobes, Priss) was applied to the deplication the embryos were placed in a perfusion chamber and superfused overnight with freshly oxygenated Ringer solution at room temperature. The next day, the embryos were fixed with 4% paraformaldehyde in phosphate buffer (pH 7.4), embedded in polyacrylamide or in Epon if treated as wholemounts, and cut coronally or sagittally on a vibratome. In the 40 μ m sections, BDA was visualized with an avidin-biotin complex. In E12-embryos, the interstitial nucleus of Cajal, various parts of the reticular formation and the vestibular nucleus complex were labeled. Preliminary data in E10-embryos indicate that already in this stage a few neurons in the interstitial nucleus of Cajal and many neurons in the reticular formation innervate the spinal cord. The present study shows that an isolated brain preparation is well-suited for tracing studies in mammalian embryos.

MOTONEURONE SENSITIVITY TO GLUTAMATE RECEPTOR AGONISTS IS INCREASED DURING THE EARLY POSTNATAL PERIOD. J. Palecek*, G. Abdrachmanova, L. Vyklicky Jr. Institute of Physiology, Czech Academy of Sciences, Videnska 1083, Prague, 142 20 Czech Republic.

Imunohistochemical and in situ hybridization studies have shown that changes in the density and subunit composition of glutamate receptors in motoneurones take place during the early postnatal development of the rat. The aim of our experiments was to find out what is the functional correlate to these changes.

We have used electrophysiological techniques to study wholecell membrane currents induced by selective glutamate receptor agonists NMDA (15 μ M) and kainic acid (KAI 5 μ M) in motoneurones the during early postnatal period of the rat. Recordings were made from 70 visually-identified retrogradely labeled motoneurones in spinal cord slices. The NMDA-evoked current responses normalised to the input resistance of the motoneurones at P2-3 and P4-5 were small. However, a four fold increase was observed between the two age groups P4-5 and P6-7. The mean values ± SEM were: -3.8 ± 0.8 (P2-3), -4.5 \pm 0.8 (P4-5), -18.5 \pm 4.7 (P6-7), -32.1 \pm 11.1 (P8-9), -18.5 \pm 7.5 (P10-11) and -25.6 \pm 9.9 (P12-13) pA/M Ω . In contrast the normalised KAI-evoked currents gradually increased from -5.4 \pm 2.5 pA/M Ω at P2-3 to -22.4 \pm 6.9 pA/M Ω at P12-13.

Our results suggest that the sensitivity of motoneurones to glutamate receptor agonist is developmentally regulated Supported by GACR-305/96/0680, HHMI-75195 and CIPA-930268.

AN ELECTRON MICROSCOPIC STUDY OF DEVELOPING SYNAPSES IN FACIAL AND HYPOGLOSSAL MOTOR NUCLEI OF THE BRAZILIAN OPOSSUM.

T.M. Pepper, J.J. Swanson, M.C. Kuehl-Kovarik, and C.D. Jacobson*, Department of Veterinary Anatomy, Iowa State University, Ames, IA, 50011. Previously, we have shown the apparent development of synapses utilizing immunohistochemistry (IHC) for synapse-associated proteins in the facial and hypoglossal motor nuclei of the Brazilian opossum (J.J. Swanson et al., J. Comp Neurol, in press). This study suggests that synaptogenesis is delayed in the facial motor nucleus (FMN) as compared to the hypoglossal motor nucleus (HMN). In the present study we plan to confirm and extend these findings at the electron microscopic (EM) level. We have examined the ultrastructure of the developing FMN from animals 5 to 25 days of postnatal age (PN). The specific nuclei were identified using methylene blue stained 150µm thick vibratome cut sections (H.D. Dellmann et al., Stain Technology 58:6, 1983). The FMN and HMN were then dissected out for processing, guaranteeing that visualization at the EM level would be confined to areas specific to the nuclei of interest. Initial analysis of the FMN indicates a marked increase of detectable synapses between 5 and 15 PN. These findings are in agreement with our previous studies utilizing synapse markers and IHC. Currently, we are studying the HMN for comparison with the FMN. We expect to see more detectable synapses in the HMN than the FMN at the same ages implying that synaptogenesis in the FMN is delayed in the developing Brazilian opossum. Future studies will investigate facial muscle and facial nerve interactions in regards to this delayed pattern of synaptogenesis in the FMN Sources of support: The Whitehall Foundation and NSF

CATECHOLAMINE CONTENT OF HUMAN FETAL MESENCEPHALON AND STRIATUM. KS Eagle*, E Kogosov, D Jacques and OV Kopyov Neuroscience Institute, Good Samaritan Hospital, 637 S Lucas Ave, Los

The new treatment of Parkinson's disease (PD), and the potential for treatment of Huntington's disease (HD), with neurotransplantation has raised the question of what levels of catecholamines exist within transplanted fetal tissue. Precursors of the substantia nigra are obtained from the fetal mesencephalon for Precursors of the substantia nigra are obtained from the fetal mesencephalon for transplantation in PD patients, while striatal precursors are obtained from fetal lateral ganglionic eminence for HD transplantation. Previous reports have studied catecholamines in the central nervous system of human embryos using immunocytochemical labeling. The present study used a sensitive radioenzymatic assay to visualize catecholamine levels within the striatal precursors of human fetal tissue. Fetal cadavers were obtained with donor consent, in accordance with NIH guidelines. The mesencephalon, lateral ganglionic eminence, and medial ganglionic eminence were isolated and processed for radioenzymatic determination of catecholamines, specifically dopamine, norepinepherine and epinepherine. In mesencephalic tissue, the greatest levels of dopamine were observed at 11 weeks gestational age. Catecholamine contents within the LGE, MGE, and mesencephalon at 10 and 11 weeks gestational age were 8 to 10 times the levels observed in control fetal tissue obtained from medulla and the peduncular area. This study provides further insight into the content of fetal tissue transplants, and aids in the continuing investigation of means to improve the clinical outcome fetal transplantation for neurodegenerative diseases. Future studies will quantify the transplantation for neurodegenerative diseases. Future studies will quantify the levels of gamma-aminobutyric acid and acetycholinesterase in these regions of the fetal central nervous system.

CHARACTERIZATION OF FACIAL AND MOTONEURON PROJECTIONS IN THE DEVELOPING BRAZILIAN

J.J. Swanson*, M.C. Kuehl-Kovarik, and C.D. Jacobson, Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, Iowa 50011

The Brazilian opossum, Monodelphis domestica, is a small marsupial whose young are born in an extremely immature state with a protracted postnatal period of neurogenesis. We have previously shown that facial motoneurons take up peripherally injected cholera toxin subunit B in pups from the day of birth (1 PN) onwards (Swanson et al., Soc. Neurosci. Abs. 21:1039, 1995). These results suggest that the facial motoneuron projections already extend into the region of their target muscles at 1 PN. Facial motoneuron cell bodies were localized near the developing genu at 1 PN and migrated to the facial motor nucleus from 2 to 5 PN. To extend these results we utilized immunohistochemistry for Choline Acetyltransferase-like immunoreactivity

immunohistochemistry for Choline Acetyltransferase-like immunoreactivity (ChAT-IR) to examine developing facial and hypoglossal motoneurons. Facial and hypoglossal motoneurons and nerves were ChAT-IR positive from the day of birth. At IPN, the facial nerve, labeled with ChAT-IR, was observed entering the periphery, extending rostrally toward, and branching in its target muscles. Branches of the hypoglossal nerve, labeled at 1 PN with ChAT-IR, were observed throughout the tongue. We localized presynaptic terminals in muscles innervated by facial or hypoglossal motoneurons using synaptotagmin-like immunoreactivity. These data suggest that facial motoneurons already innervate their target muscles when their cell bodies are still migrating to their final destination in the facial motor nucleus.

SEROTONIN IMMUNOREACTIVITY IN THE VENTRAL HORN OF LUMBAR SPINAL CORD FROM NEONATAL MICE. F. Shaheen, D. Reed and M.H. Droge*. Dept. of Biology, Texas Woman's University, Denton, TX. 76204.

The objectives of this study were to charcterize the serotonin immunoreactivity of the lumbar ventral horn of mice at several stages of postnatal development, and to determine whether the medial ventral horn contains more serotonin than the lateral ventral horn. Balb/C mice aged 1 day, 14 days and adult were perfused with 4% paraformaldehyde, transverse frozen sections (20µM) were cut, and three-step immunocytochemistry was performed using anti-5-HT (provided by J. Lauder) at a 1:7000 dilution. The Vectastain ABC System was used with diaminobenzidine. Both negative and positive controls were included in each experiment. Preabsorption controls were also conducted. The 5-HT immunoreaction was quantified based on optical density obtained via image analysis. The tissue from the 14 day old mice showed the most immuoreactivity, and that labeling included many axon terminals with varacosities. While the optical density data did not reveal a difference between the day old versus adult tissue, more terminals appear to exist in the 1 day old. No difference was found between the medial and the lateral ventral horn

MOTONEURON MATURATION AND PENILE REFLEX ONSET: DEVELOPMENTAL CORRELATES AND ALTERATIONS AFTER SPINAL TRANSECTION. K.A. Burke* and D.R. Sengelaub. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Dendritic and somal development of motoneurons in the spinal

nucleus of the bulbocavernosus (SNB) and the dorsolateral nucleus (DLN) in male rats occurs postnatally and is mature by seven weeks of age. During this period, penile reflexes mediated by these motoneurons emerge (Sachs and Meisel, 1979). Reflex onset may reflect motoneuron maturation or developmental reductions in supraspinal inhibition; in fact, spinal transection accelerates penile reflex onset by ten days, a result that has been attributed to the removal of supraspinal inhibition (Meisel and Sachs, 1980). In this study, we examined the maturation of motoneuron morphology in

relation to penile reflex onset in normal and spinally transected males. Motoneuron morphology was examined in intact males and males who received mid-thoracic spinal transections on postnatal (P) day 25. received mid-thoracic spinal transections on postnatal (P) day 25. SNB motoneurons were retrogradely labeled with cholera toxin-HRP at P28, P35, or P49, and their morphology was assessed in three dimensions (Eutectic NTS). At P35, when only 20-40% of males express penile reflexes, SNB dendritic length and somal size are approaching adult values; by P49 motoneuron morphology and penile reflex expression are fully mature. At P35, all spinally transected males express penile reflexes; SNB dendritic lengths are normal, but SNB and DLN somata are significantly smaller. Thus, maturation of SNB and DLN motoneurons correlates with penile reflex emergence, and changes in spinal motoneuron morphology (and possible alterations and changes in spinal motoneuron morphology (and possible alterations in motoneuron excitability) after transection may be sufficient to account for accelerated reflex onset. POLYNEURAL INNERVATION IN THE HUMAN FETUS AND IN THE RAT A. Gramsbergen, J.IJkema-Paassen, P.G. Nikkels, M.Hadders-Algra

Medical Physiology and Pathology Depts, University of Groningen, Bloemsingel 10, 9712 KZ Groningen, The Netherlands.

It is well known from animal studies that muscle fibres are innervated polyneurally at early stages. During further development, supernumerary nerve endings are retracted (in the rat, e.g. in the 1st 2 weeks of life) and this leads to mononeural innervation. Also in the human, muscle fibres are polyneurally innervated at early stages. Preliminar results indicate that polyneural innervation in the psoas muscle is replaced by mononeural innervation around the 12th week after term age. No data on this muscle are available in the rat. The problem of the present study is how the regression of polyneural innervation in the human relates to that in the rat. These data will enable to compare neuromuscular maturation in both species.

Material of the human psoas muscle was collected from 15 fetuses and babies until 8 months of term age and in 3 adults. In rats we collected material from the 2nd day after birth (P2) until P25. Motor endplates were stained by a AcCholinesterase and silver staining. Polyneural innervation was considered to occur when the axons could be traced back to the main bifurcating point of the nerve. Numbers of axon endings were counted and sizes of endplates were measured.

Polyneural innervation in the human psoas muscle occurs until the end of the 3rd postnatal month but not thereafter. In the rat, this regression is completed between P18 and P22. The regression of polyneural innervation rats's psoas muscle is retarded compared to that e.g. in the soleus muscle by a few days. Considering that the adult type of postural control in the rat develops between P18 and P20, while in the human, adult movement patterns in the leg and the trunk only start to develop after the 1st year of life, it seems that the regression of polyneural innervation is not related to the development of mature movement patterns but rather to increases in muscle activity.

PRENATAL SUPPRESSION OF SEROTONERGIC SYSTEM RESULTS IN MOVEMENT DISORDERS AND HYPOPLASIA OF EXTENSOR MOTONEURONS IN NEWBORN RATS. K. Nakajima, K. Matsuyama and S. Mori*. Lab. of Neurobiology, National Institute for Physiological Sciences, Myodaiji, Okazaki, 444 Japan.

With the use of para-chlorophenylalanine (PCPA), it was possible to make newborn rats in which serotonergic (5-HT) innervations of brainstem and spinal cord were prenatally reduced. To make such model animals, PCPA (300 mg/kg) was intraperitoneally administered to the Sprague-Dawley mother rats beginning on day 8 of gestation followed by a daily administration of 80 mg/kg until the delivery of pups. In the pups born from the PCPA-administered mother, postnatal development of locomotor and swimming movements was delayed in comparison to that in the normal puns born from control mother. Interlimb coordination during swimming movements was disturbed from PND 1 to PND 8. (Nakajima et al., 1995). In this study, postnatal development of fore- and hindlimb extensor motoneurons and 5-HT innervation of the spinal cord was studied. Triceps brachii (TB) and quadriceps femoris (QF) motoneurons (MNs) were retrogradely labeled by intramuscular injections of CTb-HRP (0.4%) solution in the PCPA-treated and control pups at PNDs 1, 6, 14 and 22. 5-HT fibers and terminal varicosities in cervical and lumber enlargements were also assessed by utilizing 5-HT immunohistochemistry. In the PCPA-treated pups at PNDs 1 and 6, the cell body areas of TB- and QF-MNs were smaller than those in the control pups and their dendrites were poorly developed in comparison to those in the control pups. 5-HT immunoreactive fibers and terminal varicosities were poorly distributed in the motoneuron pools in comparison to those in the control pups. These results suggest that 5-HT system contributes to the pre- and postnatal development of motoneurons in the rhythm generating spinal neuronal circuitries.

DEVELOPMENTAL CHANGES IN SEROTONERGIC MODULATION OF EMBRYONIC CHICK MOTONEURONAL EXCITABILITY IN VITRO. T. Hayashi, K.D. Phelan, B. Mendelson, R.D. Skinner* and E. Garcia-Rill. Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205

We previously reported developmental changes in intrinsic membrane properties and effects of serotonin on embryonic chick lumbosacral motoneurons using intracellular recording in a submerged slice preparation (Soc. Neuro. Abstr. 20:46, 21:1791). In the present study, we provide further characterization of the responses to various serotonergic agonists in antidromically identified E12 and E18 motoneurons. Serotonin (5-HT), 5-carboxamido-tryptamine (5-CT, a 5-HT1 agonist) or α -methyl-5HT (a 5-HT2 agonist) were applied at 50 μ M for 60 sec.

Motoneurons from E12 embryos exhibited less prominent inward rectification than E18 neurons. Injection of 1 sec depolarizing current pulses frequently resulted in spike adaptation in E12 neurons, while consistently producing high frequency tonic firing in E18 neurons. The majority of E18 cells also displayed an initial high firing rate prior to reaching steady state. Interestingly, the amplitude of the afterhyperpolarization (AHP), which followed the depolarizing pulses, increased as a function of decreasing time between pulse termination and last spike generation regardless of preceding spike number. This presumably reflects a high calcium buffering capacity in embryonic chick motoneurons. Superfusion of each agonist hyperpolarized all E12 motoneurons (n=7). Restoration of membrane potential to pre-drug levels during the peak hyperpolarization revealed a significant increase (~40%) in firing frequency and a block of spike adaptation. The same agonists produced membrane depolarizations and increased firing frequency in E18 motoneurons (n=16). All three agonists decreased AHP amplitude in E12 and E18 motoneurons. These findings indicate that both 5-HT1 and 5-HT2 receptor subtypes contribute to developmental changes in serotonergic modulation of embryonic chick motoneuron excitability. THE EFFECTS OF AGEING ON CREATINE KINASE SPECIFIC ACTIVITY IN RAT DIAPHRAGM, EXTENSOR DIGITORUM LONGUS AND SOLEUS MUS CLES. O.C. Ramfrez* and E. Jiménez. Dept. of Biochemistry Ctr. Invest. Estud. Avanzados, I.P.N. México, D.F. 07000. Evidences obtained from aged rat diaphragm suggest

that, contrary to fast and slow muscles, the maintenance of choline acetyltransferase (ChAc) activity in the motor nerve terminals is due to continuous activity of this muscle and its motor nerves. It is known that creatine kinase (CK) specific activity (S.A.) is stimulated by muscle contractile activity but depressed by inactivity. Here, it was in tended to demonstrate that in male rat diaphragm, fast-extensor digitorum longus (EDL) and slow-soleus muscles, the CK S.A. could follow a pattern similar to that of ChAc. It was found that, by means of the use of muscle post-mito--chondrial supernatants (27Kxg), and the NADH-coupled reactions technique for CK assay, the CK activity pattern is not similar to that shown by ChAc in EDL, soleus and diaphragm from puberty to senescence. In contrast to ChAc, CK activity from EDL and soleus did not change significantly from adulthood to senescence, whereas rat senescent diaphragm was 86% more CK-dependent than those muscles at the same age. This seems to be due to differences in the metabolic pathways in which these enzymes are involved -- within the same tissues. Worthy of mention is the fact that, regarding the PC/CK shuttle system, male rat diaphragm showed a transition pattern from the aerobic type to the anaerobic one during the studied ages.

REGENERATION: INFLUENCE OF SUBSTRATE

REGENERATION THROUGH LONG ACELLULAR N SEGMENTS DEPENDS ON NEOVASCULARISATION CELLULAR SUPPORT FROM THE ENVIRONMENT.

J.Sørensen, K. Fugleholm.*, H. Schmalbruch., C. Krarup. Dept. of Neurophysiology, Institute of Medical Physiology, University of Copenhagen and Dept. of Clinical Neurophysiology, Rigshospitalet,

Axons ensheathed by an impermeable silicone tube do not regenerate through a 40-mm acellular nerve segment distal to a crush lesion. We have investigated interactions between the near-nerve environment and the accellular nerve segment during axonal regeneration. Nerve de- and regeneration were assessed electrophysiologically by implanted silicone tube electrodes, and by light and electron microscopy. The silicone tubes were made permeable to allow diffusion of solutes (pore size 0.45 µm) or migration of cells (pore size 2.0 mm). In the 0.45-µm experiment, where only oxygen and solutes could enter the nerve from the environment, the central area of the acellular segment contained only dead axons without further degeneration, and no capillaries or macrophages were present. On the contrary, in the 2,0-mm experiment, where macrophage migration and capillary ingrowth from the near-nerve environment was possible, the myelin had been remowed, and regenerating nerve fibers and sprouts traversed the acellular segment in less than 2 months. Axonal growth

traversed the accilular segment in less than 2 months. Axonal growth slowed down in the central part of the segment, but regained speed distally. The study demonstrates that longitudinaly oriented vascular and cellular support from the proximal and distal stumps are not able to secure nerve regeneration in long acellular segments. Nerve repair by long cryotreated nerve grafts requires transversally oriented vascular and cellular support from the near-nerve environment.

INFLAMMATORY CYTOKINES INTERACT TO MODULATE EXTRACELLULAR MATRIX PRODUCTION BY ASTROCYTES. N.A. Di Prospero, S. Meiners, G.M. Krauthamer*, and H.M. Geller.
Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Elevated levels of cytokines are found after traumatic injury and pathological alterations in the central nervous system (CNS) and are believed to contribute to the process of gliosis. Gliotic astrocytes may form a barrier to regenerating axons by either physically obstructing growth or through the generation of a growth inhibitory environment. These studies sought to examine how cytokines present after CNS injury, in particular interferon-gamma (IFN_Y) and basic fibroblast growth factor (bFGF), affect the biochemical nature of the Our laboratory has extracellular matrix (ECM) produced by astrocytes. previously shown that bFGF increases the levels of the ECM molecule tenascin in cortical astrocytes over time. Purified cortical astrocyte cultures from postnatal day 1 rat pups were subcultured into culture wells. Upon reaching confluency, the astrocyte monolayers were exposed to varying concentrations of IFN γ , bFGF, or combinations of both in DMEM + 10% FCS culture media for 8 days. Protein extracts from the cells were examined by Western blotting for laminin, fibronectin, and tenascin. A dose dependent reduction in all three ECM molecules was observed with increasing concentrations of IFNγ. Similarly, IFNy was able to antagonize the effects of bFGF by reducing tenascin levels in cultures treated with both cytokines. These data suggest that the relative types and levels of different cytokines found after injury may dictate the biochemical nature of the glial scar by altering ECM levels. University of Miam.)
We have previously shown that Schwann cells (Sc's) can effect the ability of retinal ganglion cells (RGC's) to recognise their appropriate target regions in Schwann cell/fetal tectal co-grafts when transplanted to the midbrain of newborn rats (Harvey and Plant (1995), Exp Neurol: 134, 179-191). We have now tested these co-grafts transplanted to 20-21 day old rats after lesions to the optic tract. This was carried out to ascertain whether older RGC axons are effected by transplanted Sc's in the same way as developing RGC axons. Control and co-grafts were analysed 19-96 days after transplantation using anterograde tracing (WGA/HRP) and enzyme histochemistry (AChE). In control (pure) tectal grafts retinal axons usually were confined to the graft surface and innervation usually selective for AChE-dense patches in grafts-that represent target sites for retinal axons. Some scatterred retinal axons were seen but few in number and not very far in distance (150 µm). In contrast co-grafted (with Sc's) rats showed dense retinal growth dispersed within the co-graft neuropil away from AChE patches on the graft surfaces and associated with Hoechst 33342 labelled Sc's. RGC axons grew for distances up to 500 µm from the graft surface. However, some rats showed retinal axons confined to AChE patches even though Sc's were in close proximity. It appears, as in earlier work in newborn rats that Sc's can alter the way retinal axons grow into grafted tissue. RGC axons were more scattered and occupied non-target grow into gratter tissue. NOc axons were into exactred and occupied non-raged regions of tectal grafts when transplanted to older rats. Interestingly the Scs appear to have a similar effect whether transplanted to the target (neonatal superior colliculus) or as a bridge between the dorsal lateral geniculate nucleus and superior colliculus. SCHWANN CELL MIGRATION AND ANTIGENIC PROFILE IN AN INJURED PERIPHERAL NERVE IN VIVO; DEPENDENCE ON AXONS M Bresjanac¹*, M. Popović² and J. Sketelj¹ Institute of Pathophysiology¹ and Institute of Pathophysiology², School of Medicine, 1000 Ljubljana, Slovenia.

It is widely believed that peripheral axons require the trophic and guiding influence of Schwann cells (SC) in order to regenerate successfully. Nonetheless, our earlier work, employing a crushed sciatic nerve of a rat, demonstrated a rapid elongation of "naked" axons through acellular nerve segments (1, 2). SC, whose migration probably depends on proliferation, followed the axons rather than leading them. Interestingly, little is known on SC behavior in an injured nerve in the absence of axons, although such information would clearly aid our understanding of their role during nerve regeneration. This study tested the hypothesis that SC rapidly divide and migrate to repopulate an accllular segment of a lesioned nerve even when unaccompanied by axons. Immunohistochemistry to \$100, NGFree, GFAP and NF was employed. Young male Wistar rats were used in accord with NIH Guidelines. In deep anesthesia, sciatic nerve was crushed and a segment distal to the crush was rendered acellular by freeze-thawing (FT). The nerve was cut 3 mm proximal to the crush and at the distal end of the FT segment. The rats were sacrificed 4 and 8 weeks later. At 4 wk, \$100 and NGFrec \oplus cells covered an average 13 mm, i.e., roughly 60% of the average length of the nerve segment. GFAP \oplus cells were not found further than 9 mm distal to the crush, i.e., 41% of the nerve length. At 8 wk, \$100 and NGFrec ⊕ cells were 17 mm distal to the crush. GFAP ⊕ cells were 7 mm behind them, i.e. 68% and 40% of the average nerve length, respectively. In control nerves, where the axons grew ahead of SC, at 4 and 8 wk, S100 and NGFrec ⊕ cells arrived as far as the axons, i.e. to the end of the nerve segment. SC seem to require axonal presence for optimal migration inside an acellular nerve, where they follow the rapidly elongating axons through the old basal lamina tubes.

CHARACTERISTICS OF REGENERATING OPTIC AXONS AND THEIR GLIAL ENVIRONMENT SHORTLY AFTER NEONATAL TRANSECTION IN HAMSTERS. Changying Ling* and Gerald E. Schneider. Dept. of Brain & Cognitive Sciences, M. I. T., Cambridge, MA 02139.

Location and morphological features of regenerating retinofugal axons shortly after transection of the brachium of the superior colliculus (SC) in hamsters on the day after birth (P1) were examined using cholera toxin subunit B (CT-B) as an anterograde tracer. Accompanying changes in their immediate glial environment were found using GFAP immunocytochemistry. In control P1 hamsters, elongating retinal axons were observed through the length of SC, where the majority of their growth cones were oriented caudally and located primarily in the caudal portion. 20h after transection, the CT-B labeled axons were restricted to the region rostral to the cut. Many of them ended with growth cone-like expansions that were aimed caudally; they were located 30-60 microns from the lesion, indicating an initial retraction. At the same time, the density of GFAP positive cells, with an immature morphology, was significantly increased, particularly in regions near the lesion. 48h later, a vigorous regrowth of retinal axons was evident; the majority of them, with large growth cones, had turned ventrally and extended into the deep layers of SC. Only a few axons, if any, were seen directly entering or penetrating the lesion site, a scar-like formation containing dense GFAP+ cells which extended into the region ventral to the lesion with decreasing density. After avoiding the dense part of the scar, axons turned dorsocaudally (within 72h), and regrew into the superficial layers of SC, their original target (within 96h). In their course caudally, the axons also showed some collateralization. Two months later, the superficial SC had been filled by dense retinal axons; the glial scar, defined by an aggregation of GFAP+ cells, remained but it had became much smaller and denser. SCHWANN CELLS CULTURED IN SERUM-FREE (7F) MEDIUM: MYELINATION STUDIES IN VITRO AND IN VIVO.

M. Oudega, C. Fernandez-Valle, P. Wood, A. Gomez, A. Weber, M. Bates,
M. B. Bunge The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL 33136

Autologous rat Schwann cells (SCs) promote axonal growth and myelinate regenerating fibers in the damaged nervous system. A fast procuration of SCs would serve surgical interventions aimed at improving repair of CNS and PNS injury. SC proliferation is increased ≈5-fold by removing serum and adding heregulin (7F) to the standard medium containing 10% serum, forskolin and pituitary extract (D10/M). The differentiative abilities of 7F-SCs, however, have not been determined. SCs grown in 7F or D10/M for 3-4 passages were either co-cultured with sensory neurons in myelination-permissive medium or placed within a polymer guidance channel and implanted into adult rat spinal cord after removal of T8-11 segments. The amount of myelin produced was analyzed by Sudan Black staining, toluidine blue staining, and electron microscopy. Onset of myelination in vitro was delayed by 1 week compared with D10/M-SCs and total myelin was reduced by ≈50% of control levels at four weeks. In vivo, ≈500 myelinated fibers were observed by light microscopy in grafts with D10/M-SCs 4 weeks after implantation, whereas in 7F-SCs grafts fewer than 10 myelinated fibers were observed. Electron microscopic examination of 7F-SC grafts revealed many additional thinly myelinated axons not resolved by light microscopy. Six weeks after implantation, however, the grafts of 7F-SCs had similar numbers of myelinated axons as found in D10/M-SC grafts. The results indicate that although SC proliferation is significantly enhanced by growth in serum-free (7F) medium, differentiation is delayed both in vitro and in vivo. The possibility that long term growth of SCs in 7F medium is associated with loss of differentiative function is being examined. ROLE OF GLIAL DESMOSOMES IN THE REGENERATION OF THE LAMPREY SPINAL CORD D. S. Pijak, G. P. Swain* and M. E. Selzer. Dept. of Neurology and the David

Mahoney Inst. of Neurol. Sce., Univ. of Pa. Med. Ctr., Philadelphia, PA 19104-

A283.

Regenerating axons of the lamprey spinal cord can navigate through a lesion in their correct orientations. Their growth cones are contacted mainly by glial processes, suggesting a role for the glial cells in guiding the regeneration. Lamprey astrocytes contain keratin intermediate filaments and are interconnected by desmosomes. This is characteristic of animals that show CNS regeneration. We have hypothesized that the desmosomes play an important role in regeneration by anchoring glial cells adjacent to the lesion in place, allowing thickened, longitudinally oriented glial processes to enter into the lesion. Regenerating axons can then grow across the lesion along this glial "bridge". To test this hypothesis, transected spinal cords were first bathed in lamprey Ringer with 5mM EGTA added to break the calcium-dependent bonding between hemidesmosomes. In some animals, a mammalian anti-desmosomal antibody (DK80.20, Sigma) was also applied to prevent reannealing. Animals were then allowed to recover for 0 to 60 days. Immunohistochemical methods were used to label the glial processes and regenerating axons. In control animals, glial processes have begun to enter into the lesion by 7 days, with the fastest growing axons entering after 10 days post-transection. Animals treated with EGTA and DK80.20, had a delay in regeneration the tesion and many misoriented glial processes. Regenerating axons had trajectories that were more tortuous than those of controls treated with lamprey Ringer alone or were more fortuous than those of controls treated with lamprey Ringer alone or animals treated with EGTA/Ringer alone or EGTA/Ringer and a nonspecific IgG. Thus desmosomal interconnections among glial cells may contribute to functional regeneration in certain primitive vertebrates. Supported by NIH Grant R01 NS25581 and NSF Grant IBN-9319702.

A TISSUE CULTURE MODEL OF REACTIVE GLIOSIS - THE EFFECTS OF ADULT REACTIVE ASTROCYTES ON AXON REGENERATION. N. Orike¹, L. Kerecuk¹, A. Butt², and J. Cohen¹ SPON Brain Research Association Departments of ¹Developmental Neurobiology and ²Physiology, U.M.D.S., London, SEI 9RT, UK

Reactive astrocytes which arise as a result of injuries to the mammalian central nervous system have been implicated in the failure of axon regeneration. To characterise the phenotype and properties of adult reactive astrocytes, we have modified a tissue culture model system (Trimmer, 1993), in which explants of optic nerve from enucleated adult rats (3-4 weeks post lesion) were cultured on a laminin substratum for periods up to 28 days. After 4 - 5days in vitro, a variety of cell types. identified by immunostaining with neural cell-specific markers, were observed to migrate out of the explants. The major cell types included GFAP+ve astrocytes (\sim 50%), both GD3+ve and -ve, 'reactive' oligodendrocytes (\sim 30%; RIP+ve/galC+ve). macrophages and fibroblasts. Most of the astrocytes from the lesioned optic nerve explants displayed markedly increased GFAP immunoreactivity (characteristic of reactive astrocytes), and the majority (~80%) were also GAP-43 +ve. Additionally, when established optic nerve cultures were cocultured with purified neonatal rat retinal ganglion cells (RGCs), reactive astrocytes from lesioned optic nerve were found to be both poorly adhesive ($\leq 50\%$ of controls) and inhibitory for RGC neurite outgrowth (> 60% shorter neurites) compared with RGCs growing on astrocytes from either neonatal or unlesioned adult optic nerve. This inhibition appeared to be contact mediated, presumably by cell surface molecules associated with the reactive astrocytes, and is likely to contribute significantly to the failure of axon regeneration in the injured adult CNS. (Supported by the Special Trustees of Guy's Hospital and the Wolfson Foundation).

REGENERATION FROM RESPIRATORY AXONAL THROUGH PERIPHERAL NERVE GRAFTS. N. Lammari-Barreault. R. Pallini, L. Lauretti, A. Granato (°), P. Gauthier (ç), E. Fernandez *. of Neurosurgery and Anatomy (°), Catholic University, Rome, Italy; Dept. de Physiologie et Neurophysiologie (ç), Facultè de St Jerome, Marseille, France

In adult rats, central respiratory neurons can regenerate their axons into peripheral nerve (PN) grafts implanted into the medullary respiratory structures (Lammari-Barreault et al, Exp Brain Res 98:238-244,1993). After axonal regeneration into the graft, central respiratory neurons exhibit normal electrophysiological activity and reactivity, and can establish functional connections with phrenic motoneurons or muscolar targets. The long-term preservation of the physiological properties of the respiratory neurons depends on the establishment of functional connections. In the present work, the anatomical distribution of the neurons that projected their regenerating axons into blind-ended PN grafts was investigated by using both single and double retrograde axonal tracers. Horseradish peroxidase (Sigma VI, 8% solution, 0.2-0.5 ul) was injected into the graft. Labeled neurons were distributed throughout the brainstem up to C2 spinal level mainly ipsilaterally to the implanted graft. The highest density of labeled neurons was found in the nucleus ambiguus, nucleus solitarius, area of the lateral reticulae, vestibular spinal nucleus, locus coeruleus. After injection of the fluorescent tracer Fast Blue (Sigma, 2% solution, 0.8 ul) into the graft and Diamidino Yellow (Sigma, 2% solution, 0.2 ul) into the C2 spinal level, only single labeled neurons were seen in the brainstem. This finding indicates that axonal regeneration by respiratory neurons into the graft results from the regrowth of severed axons rather than from the collateral sprouting of respiratory efferent pathways

EFFECTS OF MICROGLIA ON THE REGENERATION OF SENSORY AXONS. C.M.F. Prewitt*, W. Chen, C.J.M. Kane and J.D. Houlé. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Neurotrophic factors bound to nitrocellulose implants can promote regeneration from injured dorsal roots. To investigate the role of non-neuronal cells associated with the implant on regeneration of injured sensory axons, activated microglial cells were seeded onto nitrocellulose membrane prior to implantation into upper quadrant lesions of adult rat spinal cords (L1 level). Fetal spinal cord tissue was transplanted on each side of the membrane and cut dorsal roots were apposed to each side of the nitrocellulose membrane; one side was coated with microglia and the other uncoated side was used as control. Animals with untreated nitrocellulose membranes were a second control. Twenty-one days later, nitrocellulose membranes were a second control. Twenty-one days later, animals were sacrificed and spinal cord sections were processed for immunohistochemical detection of calcitonin gene-related peptide (CGRP) to identify the pattern of growth of regenerated sensory axons. Results showed regeneration of sensory axons into the fetal tissue on both sides of the nitrocellulose membrane implant. However, the number of axons and the extent of axonal growth was greater when associated with microglial cell-coated nitrocellulose than the control side or untreated nitrocellulose implants. Regeneration was mainly directed along the membrane and most axons grew to the ventral edge of the membrane when microglia were present. These results indicate that microglial cells can promote regeneration of sensory axons in the abscence of exogenous trophic factors. Release of cytokines from the implanted microglial cells may be involved in the increased regenerative response. Supported by NIH Grant NS26380.

SCIATIC NERVE TRANSPLANTATION INTO NORMAL AND GLIA-DEPLETED SPINAL CORDS M.B. Durgun¹, S.A. Gilmore² and T.J. Sims*², Depts. of Anatomy, ¹Hacettepe Univ., Faculty of Medicine, Ankara, Turkey, and ²Univ. of Arkansas for Medical Sciences, Little Rock, AR. 72205 Schwann cells exert strong trophic influences on regenerating axons.

Thus, many investigators have used peripheral nerves as bridges to guide regrowing CNS axons. Regenerating spinal cord axons enter and grow robustly within a grafted segment of peripheral nerve, but fail to extend through the host-graft interface in significant numbers when they reach the distal end of the graft. Although efforts have been made to enhance this regrowth into the host, surprisingly little is known about the interface that develops between host spinal cord and transplanted peripheral nerve. This study examines these interfaces in two different host-graft situations. In one situation 3-day-old fresh or frozen sciatic nerves were transplanted into the lumbar spinal cords of 23-day-old normal rats. The second situation was similar except that the glial populations normal rats. The second situation was similar except that the glial populations within the host cords were markedly depleted by exposure to irradiation when 3 days of age (Gillmore S.A. 1963. J. Neuropath. Exp. Neurol. 22:294-301). Following a 20-day postoperative period, the interfaces between host spinal cord and sciatic nerves were examined ultrastructurally and pronounced differences were noted. A distinct astrocyte scar composed of multiple processes completely enveloped the transplanted nerve in non-irradiated host spinal cord and confined Schwann cells and fibroblasts to the area enclosed by the scar. In contrast, a complete astrocytic scar did not form around the transplanted nerve in the irradiated hosts, and Schwann cells migrated from the graft and intermingled with host tissue. Fibroblasts remained in close proximity to the graft. From these observations it seems likely that the formation of a distinct astrocyte barrier in the host must be ameliorated if the transplantation of peripheral nerves is to become a useful strategy in spinal cord repair. Supported by NIH grant NS 04761.

MATURING OLIGODENDROCYTES INHIBIT NEURONAL GROWTH CONE MOTILITY IN DIFFERENT WAYS. S.J. Moorman* and R.M. Gould', Dept. of Anat. and Cell Bio. UNT Health Science Center at Fort Worth, TX 76107; 'NYS Inst. for Basic Res. in Devel. Dis., Staten Island, NY 10314

for Basic Res. in Level. Dis., staten Island, NY 10314
Among the many molecules produced by oligodendrocytes are proteins that might limit regeneration by inhibiting neuronal growth cone motility. Maturing oligodendrocytes can be divided into 5 specific stages from O2A (Stage 1) precursors to mature (Stage 5) myelinating cells based on stage-specific antigen expression and characteristic morphology. Each Stage has a predictable array of surface molecules which, for certain stages, includes inhibitory molecules. We tested whether growth cones respond to contact with each stage of maturing oligodendrocytes the way they respond to contact with the purified oligodendrocyte-specific inhibitory proteins known

respond to contact with the purified oilgodendrocyte-specific infinitiony proteins known to be expressed at specific stages.

Cells from 3-day-old neonatal rats were grown on poly-lysine for 3 to 7 days.

Oligodendrocytes were physically removed from the substratum using a patch-clamp electrode and a micromanipulator. Each 'manipulated' oligodendrocyte was then placed. into contact with a neuronal growth cone for 30 minutes. Growth cone surface area was compared before and after contact with an oligodendrocyte. Surface area decrease of

50% or more = collapse.

As oligodendrocytes matured from Stage 1 to Stage 4, they developed an increasing As oligodendrocytes matured from Stage 1 to Stage 4, they developed an increasing ability to cause neuronal growth cones to collapse, peaking at 95% for Stage 4. This increasing ability to inhibit the neuronal growth cone coincides with the onset of expression of NI35 by Stage 2 oligodendrocytes. Stage 5 oligodendrocytes only induced 15% of neuronal growth cones to collapse on contact. This result is surprising considering NI35 and MAG are both expressed by Stage 5 oligodendrocytes. These results suggest that growth cone response to contact depended on the developmental state of the oligodendrocyte, independent of the presence of inhibitory molecules. Therefore, growth cone response is likely to be dependent on the context in which inhibitory molecules are presented.

EFFECT OF A PRE-DEGENERATED PERIPHERAL NERVE GRAFT AND A CONDITIONING LESION OF OPTIC NERVE ON AXONAL REGENERATION OF RETINAL GANGLION CELLS. S.-W. You¹, K.-F. So^{1.*}, H.K. Yip¹ and K.S. Neuroregeneration Lab. and Developmental Neurobiology Lab., Dept. of Anatomy, The Univ. of Queensland, Australia.

A conditioning lesion performed 1 to 2 weeks before a second lesion has been shown to enhance axonal regeneration in peripheral nerves (PN) but not in optic nerves (ON) in mammals. The lack of a conditioning lesion effect in ON may be due to too long a survival time before the second lesion is inflicted since axons of retinal ganglion cells (RGCs) in rodents degenerate rapidly 7 to 14 days following axotomy. In the present study, we have shortened the survival time (1-8 days) to examine if this has any effect on axonal regeneration of RGCs into a PN graft apposed to the ON transected 1 mm from the optic disc in hamsters. The results showed no beneficial effect since the number of RGCs regenerating their axons into the PN graft 4 weeks after grafting in these animals decreased significantly (Mean=758) when compared to those animals without a conditioning lesion (Mean=1644). Other studies have shown that pre-degenerated PN grafts can enhance axonal regeneration both in the PNS and in the CNS. Thus the effect of pre-degenerated (8 days) PN grafts on axonal regeneration of the RGCs which have had a conditioning lesion (1-8 days) were examined. The number of regenerating RGCs in the groups with a pre-degenerated PN graft (n=24, mean=1290) was significantly more (P<0.01) than that in the groups with a normal PN graft (n=24, mean=758). These data suggest that a conditioning lesion of the optic nerve in adult hamsters resulted in a deteriorative effect on the number of RGCs regenerating axons into a PN graft but this deteriorative effect can be overcome to a certain extent when a pre-degenerated PN graft was used.

REGENERATION OF MOTONEURON AXONS INTO PERIPHERAL NERVE GRAFTS INSERTED INTO THE SPINAL CORD AT VARIOUS TIMES AFTER C5 GRAF IS INSERTED INTO THE SYINAL CORD AT VARIOUS TIMES AFTER CS & C6 ROOT AVULSIONS IN THE ADULT RAT. TJ. Zwimpfer*, C. Tarazi, J.D. Steeves. Depts of Surgery, Zoology & Anatomy, U.B.C., Vancouver, B.C., V6T 1Z4. It has been demonstrated in rats, cats and primates that following spinal nerve root avulsion, injured motoneurons can extend axons into ventral roots or peripheral nerve

(PN) grafts immediately inserted into the cord and result in functional reinnervation of denervated muscles. <u>Delayed</u> reimplantation in human cases of root avulsion has recently been reported. Due to the death of motoneurons following root avulsion, such a delay in reimplantation (ie. weeks to months after root avulsion) could result in less axonal regeneration and recovery but this has not been studied.

Following avulsion of the left C5 & C6 ventral and dorsal roots in adult rats, one end of a 3.5 cm segment of common peroneal nerve was inserted 1 to 2 mm into the ventrolateral aspect of the spinal cord at C5 & C6. Animals were divided into four groups according to the time interval between root avulsion and PN graft insertion: 1) immediate insertion, 2) 1 week, 3) 1 month, 4) 2 months. Two months after insertion, a fluorescent axonal tracer, Rhodamine-Dextran amine (RDA) was applied to the free end of the graft and RDA-labeled neurons in the ipsilateral ventral horn were counted.

Of 39 animals examined, 38 had RDA-labeled neurons. The majority of neurons were in the ipsilateral ventral horn but were also seen in the contralateral ventral horn, and the ipsilateral dorsal horn and Clarke's nucleus. Using the cell counts in the immediate insertion group (n=11animals; mean of 761 cells = 100%) as a reference for comparison, the number of RDA-labeled neurons in the 1 week group was 82% (n=10), 44% at 1 month (n=9) and 38% at 2 months (n=9). This suggests that reimplantation of PN grafts into the spinal cord of patients with root avulsions, should be done within a few weeks of injury. In future studies, the PN graft will be anastomosed to the musculocutaneous nerve to allow electrophysiological and functional studies of biceps muscle reinnervation. Supported by the B.C. Health Research Foundation & the Vancouver Hospital.

PROTEOGLYCAN UPREGULATION FOLLOWING SPINAL CORD INJURY IS CLOSELY ASSOCIATED WITH ACTIVATED MICROGLIA / MACROPHAGES. M.T. Fitch¹, E. Theriault², S. Mortin-Toth², J. Silver¹. ¹Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106

and ²Playfair Neuroscience Unit, University of Toronto, Ontario, Canada. The cellular responses to spinal cord injury include the production of molecules capable of modulating wound healing in the CNS. This study examines the upregulation of chondroitin sulfate proteoglycan (CSPG), a molecule present in the wound healing matrix that may inhibit axon regeneration, in several models of rat spinal injury. It is uncertain why some CNS lesions result in increases in CSPG immunostaining, while other models induce gliotic reactions without observable changes in CSPG levels in the CNS. We have determined that careful dorsal root crush does not lead to detectable increases in CSPG in the dorsal columns, while upregulation of CSPG following spinal cord contusion or penetrating injury occurs within 24 hours and persists for at least 14 days. This increase in CSPG is localized to the tissue within and adjacent to the wound focus. Interestingly, CSPG increases are consistently associated with the influx of macrophages across the blood brain barrier and/or activation of microglia. CSPG localizes with macrophage presence in the lesion cavity, within the tissue adjacent to the wound, and at the interface of cavity and surrounding gliotic astrocytes. The glial dome of the dorsal root entry zone provides an important model in which to examine the role of macrophages in CSPG associated gliosis, as variable macrophage presence in the dome of injured roots correlates precisely with increases in CSPG in this defined area. These observations suggest that macrophages, their products, or other serum components that cross a compromised blood brain barrier may provide a stimulus for changes in proteoglycans after nervous system injury. MOLECULAR ANALYSIS OF DIFFERENTIALLY REACTIVE ASTROCYTES

MOLECULAR ANALYSIS OF DIFFERENTIALLY REACTIVE ASTROCYTES J.R. Bethea*#, D. Canning and J. Silver. The Miami Project#, Univ. of Miami, Miami, FLA and Dept. of Neurosci., CWRU Sch. of Med. Clev., OH Lack of regeneration is due, in part, to an inhibitory environment created by activated astrocytes and/or the infiltration of non-neuronal cells, a process known as gliosis or gliotic scaring. Functionally, astrogliosis can associated with variable biological outcomes. For example, following injury to the CNS complete regenerative failure can result or in some instances there is relatively robust synaptic sprouting. The factors that create these functional differences are poorly understood but are probably mediated in part, by differential one understood but are probably mediated, in part, by differential gene expression in reactive astrocytes. To investigate the molecular events in activated astrocytes that constitute an inhibitory versus a growth supportive environment for neurons, an *in vitro* model of astrogliosis that supportive environment for neurons, an *in vitro* model of astrogliosis that utilizes cortical astroglia on substrate bound 25-35 beta-amyloid (growth inhibitory) in comparison with astrocytes on laminin (growth permissive) was employed. To investigate the genetic differences that distinguish these two models we are utilizing RAP-PCR to identify gene products that are differentially expressed under growth supporting and growth inhibitory conditions. To date, we have identified multiple new gene products that are specifically expressed under growth inhibitory conditions. *In situ* hybridization studies demonstrated that these transcripts are specifically expressed in our in vitro model of inhibitory transcripts are specificary expressed in our *In vitro* model of inhibitory astrogliosis. These studies will allow us to better understand the cellular and molecular events that regulate different forms of reactive astrogliosis and help lead to a better understanding of the mechanisms that cause regenerative failure associated with CNS injury.

Axonal Regeneration into Human Schwann Cell Grafts Placed to Span the Transected Spinal Cord of the Nude Rat. ID Guest. N. Kleitman*. P. Aebischer. MB Bunge. The Miami Project and the Dept Neurol Surgery, Univ Miami School Med, and Centre Hospitalier Universitaire Vaudois, Lausanne.

We are systematically evaluating the ability of human Schwann cell (HSC)/ Matrigel grafts within semipermeable PAN/PVC guidance channels to influence the regeneration of axotomized CNS neurons in the nude rat. In previous studies, distally capped channels were apposed to the rostral transected stump of the spinal cord at 18. Myelimated axons were found within such grafts 30 days after transplantation. Immunopositive serotonergic and noradrenergic fibers were identified in the grafts. Fast Blue (FB) was injected into the cable 5 mm from the rostral interface. Sensory, propriospinal, motor and brainstem neurons of reticular, raphe and vestibular nuclei regenerated into the cables. Using autologous nude rat SCs, the mean numbers of all FB- labeled neurons were similar. In a separate group of experiments, the HSC channel grafts were placed to span thoracic T8-T10 resections. The ability of injured neurons to extend processes into and beyond the grafts was evaluated using anterograde and retrograde tracing following 30 days surviva! PHAL was [iontophoretically] injected 3 mm above the rostral interface (n=5). Labeled propriospinal axons entered grafts; a few processes extended up to 2 mm into the distal host spinal cord. In other animals FB was injected 4 mm caudal, and Fluororuby (FR) 8 mm rostral to the grafts. In each case (n=5), FB-labeled DRG and propriospinal but not brainstem neurons could be identified above the graft. Whereas hundreds of FR positive fibers entered HSC grafts, only a few fibers were seen up to 4mm beyond them. Immunolabeled descending monoaminergic fibers entered grafts in substantial numbers but rarely extended beyond the grafts. The corticospinal tract was anterogradely labeled with FR in 4 animals; fibers did

INTERFERON-GAMMA-INDUCED RECRUITMENT OF MACROPHAGES INTO THE ADULT MOUSE SPINAL CORD. Shalina S. Ousman* and Samuel David. Centre for Research in Neuroscience, MGH Research Institute, and McGill University, 1650 Cedar Ave., Montreal, Quebec, H3G 1A4.

The failure of long distance axon regeneration in the adult mammalian CNS may be due, in part, to the slow removal of myelin and its associated axon growth inhibitory molecules. Slow myelin clearance results from the delayed influx of macrophages and microglial activation. Interferon-gamma (INF- γ) has been shown to promote macrophage recruitment and extravasation into the rat basal ganglia. To determine the effect of IFN-γ on macrophage recruitment and influx into the white matter, we injected IFN- γ (400 units in 1 μ l) into the adult mouse dorsal columns. Mac-1 and F4/80 immunohistochemistry was used to detect peripheral macrophages and microglia at 6h, 12h, 1d, 2d, and 4d after injection of INF- γ . The values given below represent the number of Mac-1 † cells /10mm 2 . In the needle tract, round Mac-1 † cells were present as early as 6h after IFN-y injection, increased at 12h (24.9 \pm 4.7), and were not seen at 4d. In the white matter (0-220 μ m adjacent to the injection site), and we have a sum and the final matter than 2 per final part of the parents are from the first of the first detected at 1d, reached maximal levels at parenchyma of the white matter were first detected at 1d, reached maximal levels at $2d(1.8 \pm 0.3)$ and decreased 2-fold by 4d (0.9 ± 0.3) . Animals injected with vehicle alone showed much lower numbers of Mac-1 $^+$ cells in the needle tract and adjacent white matter. Therefore, in the white matter, round Mac-1 $^+$ cells were seen early (6h and 12h) after IFN- γ injection, and were replaced by process-bearing Mac-1 at later time points (2d and 4d). Similar results were also observed for the grey matter, and F4/80 labelled sections. These results suggest that IFN-y is capable of recruiting peripheral macrophages to the site of injection and the adjacent white matter, as well as, activating microglia. Supported by a grant from the MRC.

CYTES SUPPORT AXONAL REGENERATION IN THE CENTRAL NERVOUS SYSTEM OF ADULT RAT. N. Chauvet, M. Prieto, A. Privat* and G. Alonso. INSERM U336, University Montpellier II, 34000 Montpellier, France.

We have recently shown that tanycytes, a particular type of glial cells of the mediobasal hypothalamus which presents morphological and biochemical similarities with radial glial cells, constitute a preferential support for the regeneration of lesioned neurohypophysial axons. The present study was designed to explore the capacity of tanycytes to support axonal outgrowth of various neurons types

In a first step, the neurotrophic rôle of tanycytes was investigated in vitro. Tanycytes derived from the median eminence or astrocytes derived from the cerebral cortex of 10-day-old rats were cultured for 4 to 7 weeks. Cells obtained from the dissociation of 3-day-old rat mesencephalon, cortex and hypothalamus were cocultured on these glial monolayers, and the number of surviving neurons and their neurite length were quantified after 4 and 8 days. Our data showed that, when ompared with astrocytes, tanycytes greatly improved both survival (6- to 10-fold higher) and neurite outgrowth (2- to 5-fold longer) of cocultured neurons whatever their origin. Conditioning medium experiments showed that diffusible factors from median eminence glial cells slightly increased survival (1.7-fold higher) of cocultured neurons, but had no significant effect on neurite outgrowth. These observations indicate (i) that aged tanycytes have the capacity to support survival and neurite outgrowth for a variety of postnatal neurons and (ii) that this effect is not exerted by secreted molecules. In a second step, the axonal outgrowth-promoting properties of tanycytes were evaluated by transplanting ME tanycytes or cortex astrocytes in extrahypothalamic regions including the mesencephalon and the spinal cord. In both sites, tanycytes transplants were found to be preferentially penetrated by numerous regenerating sprouts of various axons types. All together these data indicate that, in the adult rat CNS, tanyeytes provide a supportive substrate to regenerating outgrowth of lesioned axons. Grafts of tanycytes thus appears as a promising tool for promoting regeneration in the adult CNS. (Supported by IRME and Inversiones Cavdeca, C.A.)

CYTOKINE-MODULATED ASTROCYTES TRANSPLANTED INTO TRANSECTED ADULT RAT OPTIC NERVE FACILITATE RECOVERY OF VISUAL RESPONSE. A. Monsonego | E. Hauben | A.S. Solomon | E. Yoles | * and M. Schwartz | Department of Neurobiology, Weizmann Institute of Science, Rehovot, Israel, and 2Goldschleger Eye Research Institute, Sackler School of Medicine, Tel Aviv University, Sheba Medical Center, Tel Hashomer, Israel.

The inability of the central nervous system of mammals to regenerate after injury has been attributed in part to the failure of astrocytes to acquire essential postinjury characteristics, such as migratory ability, and expression of growth factors, enzymes and cell adhesion molecules. Here we demonstrate recovery of the visual response in transected optic nerve of adult rat following transplantation of mature astrocytes into the injury site, provided that the transplanted cells were premodulated *in vitro* by interleukin- 1β in combination with tumor necrosis factor- α . Of 34 animals with combination with tumor necrosis factor- α . Of 34 animals with completely transected optic nerves and loss of visual evoked potential response, 11 showed recovery starting from 7 weeks after treatment. Recovery was confirmed by unitary action potential and retrograde labeling of retinal ganglion cells by a lipophilic dye applied distally to the lesion. We suggest that poor recruitment of macrophages to the injury site and their inappropriate activation during central nervous system wound repair result in an astrocytic reserver within is not recruitment for avonal growth. This can be reaction, which is not permissive for axonal growth. This can be overcome by astrocytes premodulated by specific inflammationassociated cytokines.

TRANSPLANTATION OF ACTIVATED MACROPHAGES OVERCOMES CENTRAL NERVOUS SYSTEM REGROWTH FAILURE. O. Lazarov-Spiegler¹, A. S. Solomon², A. Ben Zeev-Brann¹, D. L. Hirschberg¹, V. Lavie¹ and M. Schwartz^{1*}. ¹Dept. of Neurobiology, Weizmann Institute of Science, 76100 Rehovot, Israel, and ²Goldschleger Eye Res. Inst., Tel Aviv Univ. Sackler Sch. of Med., Sheba Medical Center, Tel Hashomer, Israel.

The involvement of macrophages, known to play a key role in healing processes, has been a long-standing debate in central nervous system (CNS) regrowth. Here we show that the failure of transected optic nerve (which, like all other CNS nerves in mammals, cannot regenerate) to regrow after injury, can be overcome by transplantation of macrophages preincubated ex vivo. Preincubation with sciatic nerve (spontaneously regenerating nerve). Preincubation with sciatic nerve segments stimulated macrophage activity, using phagocytosis as a marker. In contrast, preincubation with optic nerve segments inhibited the activity. We conclude that a CNS-resident macrophage inhibitory factor may be the basis of what has been known as the CNS immune privilege. This explains the failure of the spontaneously recruited macrophages to support regrowth of transected CNS nerve, circumvented here by the transplantation of sciatic nerve-preactivated macrophages. The transplantation of suitably activated macrophages into injured nerves may globally overcome multiple malfunctioning aspects of response to CNS injury and thus may be developed into a novel, practical and multipotent therapy for CNS lesions.

AGING PROCESSES: HIPPOCAMPUS

491.1

ACUTE TESTOSTERONE AFFECTS AGED MALE RAT HIPPOCAMPAL MORPHOLOGY. <u>L.L. Waldroup</u>¹, <u>C. Isqor</u>², <u>D.R. Sengelaub</u>² and <u>G. Frommer</u>*². ¹Department of Biology, ²Department of Psychology, Indiana University, Bloomington, IN 47405.

We have demonstrated androgen-sensitive sex differences in spatial learning and hippocampal morphology in rats. Androgen levels in male rats normally decline with advancing age, and age-related regressive changes in hippocampal morphology and its behavioral correlates (e.g., spatial learning) have been shown repeatedly. To determine whether age-related declines in androgen are related to regressive changes in the hippocampus, we assessed hippocampal morphology in aged males after acute testosterone (T) treatment.

Hippocampal morphology was assessed in male Fischer 344 rats at 8 and 23 months of age. Aged males were either left intact or castrated and implanted with Silastic capsules containing crystalline T (45 mm, a length which results in plasma T levels typical of young adults) for 6 weeks (n=3 per group). After treatment, brains were extracted, frozen sections taken at 40 μm, and stained with cresylecht violet. Volumes of hippocampal CA1, CA3 fields and the dentate gyrus granule cell layer were measured at 65X; CA1 pyramidal cell soma size and density were examined at 750X. CA1 and CA3 volumes were significantly larger in aged T-treated males and similar to those of young adults. In CA1, this increase in volume was at least partly due to a significant increase in pyramidal cell soma size; no differences in soma density were observed. Because acute T treatment of aged males alters hippocampal morphology, these data suggest spatial behavior may be similarly androgen sensitive. Supported by Indiana University Undergraduate Initiative.

CHANGES IN INTRACELLULAR AND EXTRACELLULAR PH DURING AND AFTER ANOXIA I N HIPPOCAMPAL SLICES FROM YOUNG ADULT AND AGED RATS. E.L. Roberts. Ir. 1.24 and C.-P. Chip. 1 Department of Neurology, University of Miami School of Medicine, Miami, FL 33136, 2 Geriatric Research, Education, and Clinical Center, Miami VA Medical Center, Miami, FL 33125

Decreased intracellular pH (pH_i) may be linked to hypoxic or ischemic brain damage. We examined whether aging increased intracellular and extracellular acidification during anoxia, and slowed recovery of pH, and extracellular pH (pH_a) following anoxia, in hippocampal slices. Hippocampal slices were obtained from Fischer-344 rats aged 6-9 months (young adult) and 25-27 months (aged). pH_i was assessed in hippocampal cells with the fluorescent dye SNARF-1, while pHo was measured with pH-sensitive microelec trodes. Slices were made anoxic by switching the gas mixture bubbled through the bicarbonate-buffered physiological solution surrounding slices from 95% O2, 5% CO2 to 95% N2, 5% CO2. Anoxic episodes were terminated one minute after onset of anoxic depolarization, as seen in a negative shift of the extracellular potential recorded from the reference barrel of the pHsensitive microelectrode. Contrary to our expectations, the magnitude of decreases in pH $_{\rm i}$ and pH $_{\rm o}$ in young adult slices were greater than those in aged slices. Both age groups recovered pH $_{\rm i}$ and pH $_{\rm o}$ 15-20 minutes following cessation of anoxia. The degree of acidification may have been less in aged slices because anoxic depolarization occurred sooner in the aged group. Our results suggest that diminished recovery of extracellular K* homeostasis and synaptic transmission after anoxia in aged hippocampal slices (Roberts et al., Brain Res. 514 (1990) 111-118) cannot be due to increased intra- or extracellular acidification. (Supported by PHS grant AG08710 (NIA), and by a Grant-In-Aid Award from the American Heart Association, Florida Affiliate, Inc.)

AGE-RELATED EFFECT OF ADRENALECTOMY ON RAT CA1 HIPPOCAMPAL Ca²⁺ CURRENTS: . H. Karst^{1,2} T.R. Werkman¹.O.C. Meijer² and M. Joëls¹, ¹Dept. Exp. Zoology, Univ. Amsterdam, Kruislaan 320, 1098 SM Amsterdam and ²Div. of Medical Pharmacol., Univ. Leiden, Wassenaarse-weg 72 2300 RA Leiden, The Netherlands.

Wassenaarse-weg 72 2300 RA Leiden, The Netherlands. Previously it was shown that Ca²⁺ currents of rat hippocampal CA1 neurons change after adrenalectomy (ADX) of young adult rats. Preliminary observations however showed that the effect of ADX dimishes with age. To study this in more detail we recorded Ca²⁺ currents in CA1 neurons of 1, 3 or 6 months old ADX and sham operated rats. Ca²⁺ currents were recorded in hippocampal slices with the patch-clamp technique. It appeared that the low voltage activated (LVA) Ca²⁺ current decreased whereas high voltage activated (HVA) currents increased in amplitude, with age. These data indicate that Ca-currents change with age, not only in early development (<1 month) or in aged animals (Chen et al., Soc. Neurosci. 1996, 236.1), but also in early adulthood. Remarkably, HVA currents of 1 or 3 months old ADX rats were already at the level of the currents observed in 6 months old sham operated controls; currents in 6 months old ADX rats were comparable to the sham controls. The LVA currents in 6 months old ADX rats were comparable to the currents observed in the 1 month old sham group. These results were confirmed using acutely dissociated hippocampal CA1 neurons, where only sustained HVA Ca²⁺ currents are present: Ca currents increased in the 1 but not in the 6 months old rats. The data thus show that ADX of very young animals results in a selective increase of the HVA currents, while ADX of 6 months old rats is only associated with a minor increase of the LVA currents. The expression of Ca²⁺ channel subunits in tissue from the same rats is currently under investigation, with in-situ hybridization. We conclude that the ADX-induced increase of Ca-currents in CA1 hippocampal neurons is age dependent and parallels the age dependent development of these currents in adrenally intact rats. (Grant A110 Dutch Epilepsy Foundation, NEF).

AGE-RELATED CHANGES IN THE RHESUS MONKEY: ON-THE-SLIDE SATURATION BINDING STUDIES OF 7 NEUROTRANSMITTER RECEPTORS. TJ Nicholson. TT Gibbs. R Rizkalla. CC Freeland* & DL Rosene, Dept of Anatomy & Neurobiology, & Dept of Pharmacology, Boston University School of Medicine, Boston MA 02118 and the Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

A number of neurotransmitter receptor systems and the medial temporal lobe have been implicated in normal aging and certain age-related disorders. Receptors from three neurotransmitter receptor systems were investigated: cholinergic [muscarinic type 1 (M1), muscarinic type 2 (M2), & the high affinity choline uptake site (HACU)], excitatory amino acid [kainate (KAI) & N-methyl-D-aspartate (NMDA)], and inhibitory amino acid [gama-amino-butyric acid typeA (GABA,) & benzodiazepine (BZD)]. Saturation binding of the 7 receptors was examined in groups of 3 young (\$\leq 10\$) and 3 aged (\$\leq 20\$) rhesus monkeys using on-the-slide quantitative autoradiography (H²-pirenzipine for M1, H²-oxotremorine for M2, H²-henicholinium for HACU, H²-KAI for KAI, H²-MK-801 for NMDA, H²-muscimol for GABA, & H³-flunitrazepam for BZD). Previous experiments using single concentrations of ligand showed significant decreases in binding with age in all of the receptors except for the BZD receptor which showed a significant increase in binding with age. This led us to perform the current saturation experiments. The M1 receptor shows a significant increase in Kd (decrease in receptor number) and the NMDA receptor shows a significant increase in Kd (decrease in receptor affnity). Preliminary results for the other receptors suggest that in most cases the changes are due to a change in receptor numbers although possible changes in affinity cannot be excluded. These changes were investigated within the hippocampus for all receptors and within the temporal lobe neocortex and amygdala when possible. (Supported by NIH grant PO1-AG00001 & RR-00165)

AGE-RELATED CHANGES IN THE RHESUS MONKEY: ELECTROPHYSIOLOGY AND MORPHOLOGY OF NEURONS IN HIPPOCAMPAL SLICES J.L Luebke and D.L. Rosene* Dept. of Anatomy and Neurobiology and Center for Behavioral Development, Boston Univ. School of Med., 80 E. Concord St., Boston, MA 02118.

Numerous studies in rodents have shown an effect of aging on the synaptic and intrinsic membrane properties of hippocampal neurons (e.g. Barnes, 94). These include decrease in the maximal evoked presynaptic fiber volley and a concurrent greater field EPSP response for a given fiber volley amplitude in aged vs. young rats. Changes in CA1 pyramidal cell resting membrane potential, action potential kinetics and potassium currents associated with aging have also been reported. There have as yet been no published data upon the effect of aging on similar parameters in the non-human primate. However there is substantial anatomical and behavioral data to suggest that age-related alterations in electrophysiological properties of primate neurons are likely. To address this question we have used extracellular recordings of field potential responses and whole cell patch clamp recordings of the intrinsic membrane properties of neurons in hippocampal slices prepared from cognitively tested, Krebs buffer perfused, young and aged rhesus monkeys. All cells from which recordings were obtained were filled with biocytin and subsequently processed for analysis of somatic and dendritic morphology. Preliminary data has been obtained from four young (5) and two aged (29 & 30) monkeys. Initial observations indicate that field synaptic responses are somewhat attenuated in the dentate gyrus of aged as compared to young monkeys. Intrinsic membrane properties (resting membrane potential, input resistance, membrane time constant and amplitude and kinetics of potassium currents) of dentate granule cells were similar in the young and aged monkeys although firing frequency appeared to be decreased in the aged monkey. Morphological examination of filled granule cells suggests a decreased complexity of dendrites in the aged monkey. Further studies ar required to determine if these effects are statistically significant. (Supported by NIH grant P01-AG00001)

THE AGING OF THE NMDA RECEPTOR IN C57BL MICE INVOLVES CHANGES IN AGONIST AFFINITY. K.R. Magnusson* and Ginger Sammonds. Dept. of Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 80523

There is a decrease in binding density of the transmitter glutamate to the N-methyl-D-aspartate (NMDA) subtype of glutamate receptors in the hippocampus and cerebrum during the aging process in C57BI mice, as determined by single concentration assays. The goal of the present study was to determine whether the decreases were due to changes in affinity or total numbers of receptors. Concentration response autoradiography for NMDA-displaceable [³H]glutamate binding was performed on horizontal sections from 3, 10, and 30 month old C57BI mice. Crude synaptic membranes of cerebral cortex were also used for concentration response and glutamate inhibition studies of [³H]CGP39653 binding. In the autoradiographic studies, there was an increase in the Kd for glutamate between 3 and 10 month olds in all regions, which was significant in hippocampus. The Kd in 30 month olds was maintained or further increased in the cortex. In the hippocampus, the Kd for 30 month olds was intermediate between 3 and 10 month olds. There was a significant overall effect of age on Bmax, which decreased across age in the cortex, but increased in the hippocampus of 10 month olds. In cortical membranes, there was a trend for decreasing Kd for CGP39653 and increasing Ki for glutamate with increasing age. These results suggest that some of the problems with the function of the NMDA receptor in aged individuals is due to a change in the receptors that reduces agonist affinity. Supported by NIA/NIH FIRST award AG10607 and RCDA AG00659 to KRM.

AGE-RELATED DECREASE IN RAT HIPPOCAMPAL NON-PYRAMIDAL NEURONS EXPRESSING GLUTAMIC ACID DECARBOXYLASE AND CALCIUM BINDING PROTEINS. A. K. Shetty' and D. A. Turner. Neurosurgery, Neurobiology, Duke Univ. Med. Ctr., VAMC, Durham, NC 27710. We hypothesize that age-related impairments in memory acquisition may partly be

We hypothesize that age-related impairments in memory acquisition may partly be due to loss of hippocampal inhibitory non-pyramidal neurons. We investigated the number of non-pyramidal neurons positive for glutamic acid decarboxylase (GAD) and those expressing calcium binding proteins (calbindin, parvalbumin, and calretinin) in $20~\mu m$ sections from perfused 4 and 24-month male Fischer 344 rats.

Aged rats displayed variable but significant reductions of non-pyramidal neurons throughout the hippocampus. GAD neurons were significantly depleted in CA1 stratum radiatum (SR), and CA3 stratum oriens (SO) and SR (33-54 κ reduction, p <0.05). Calbindin neurons were decreased in the dentate hilus (45 κ , p <0.05), CA1 SO and SR (29-51 κ , p <0.05), and CA3 SO and SR (48-57 κ , p <0.005). Parvalbumin neurons showed significant reductions in CA1 stratum pyramidale (SP, 15 κ , p <0.05), and CA3 SP and SR (30-32 κ , p <0.05). Calretinin neurons were significantly depleted in the dentate hilus (49 κ , p <0.005), and both CA1 and CA3 SO (30-34 κ , p <0.05). However, the ratio of calbindin, parvalbumin, and calretinin neurons to the total GAD neuronal population did not change with aging, and averaged 42 κ in CA1 SR and 70 κ in CA3 SR.

These results demonstrate an age-related decrease in the number of both non-pyramidal neurons positive for GAD, and those expressing different calcium binding proteins in hippocampus. The constant relative ratio of calbindin, parvalbumin and calretinin neurons compared to GAD neurons in all regions of hippocampus with aging suggests actual neuronal loss of cells expressing calcium binding proteins with age rather than merely decreased protein expression. These subgroups of interneurons may represent a majority of all non-pyramidal neurons, suggesting that inhibitory function may be radically altered with aging. Supported by RO1 AG13165, VAMC.

RESTRICTED DISTRIBUTION OF B-AMYLOID SUBTYPES AND COLOCALIZATION WITH APOLIPOPROTEIN E IN THE TEMPORAL CORTEX OF AGED RHESUS MACAQUES. S.G. Kohama* and H.F. Urbanski. Division of Neuroscience, Oregon Regional Primate Research Center, 505 N.W. 185th Avenue, Beaverton, Oregon, 97006.

The number of β -amyloid (β A) plaques is reportedly equivalent to (Poduri et al., Am J Pathol 144:1183) or greater than (Mufson et al., Neurobiol Aging 15:621) the number of apolipoprotein E (ApoE) plaques in the brains of aged rhesus monkeys. Recently, β A (1-40) was found to be more prevalent than β A (1-42) in aged rhesus, unlike humans (Gearing et al., Neurosci. Abstr. Vol 21:109.4). This study examines the prevalence of amyloid plaque subtypes with or without ApoE, in the aged rhesus temporal cortex. Sections of the temporal lobe of adult animals (6-29 yrs) were immunostained with 10D5, an antibody which recognizes β A 1-16, or 21F12, a β A42 specific antibody (Athena Neurosciences). A subpopulation of the oldest animals displayed β A, with the number of plaques varying between animals. In positive cases, the amygdala and temporal cortex had the highest plaque density, with few plaques seen in the hippocampus, and none in the adjacent striatum. In addition, 21F12 labelled plaques only made up a portion of all plaques visualized with the 10D5 antibody. Sections from three animals were further examined by immunofluorescence double-labelling for colocalization of β A (10D5 or 21F12) with ApoE (Chemicon Int.). Smaller, low density plaques were in some cases found to be 10D5 immunopositive/ApoE- or 21F12 immunonegative/ApoE+. However, the vast majority of plaques were double-labelled for amyloid and ApoE, especially when plaque deposits possessed a compact, high density morphology. These results suggest that β A processing in rhesus differs from that observed in humans with Alzheimer's disease and that ApoE is an important component of plaque formation.

491.8

DENDRITIC STABILITY OF DENTATE GRANULE CELLS IN THE RAT HIPPOCAMPUS WITH AGING. <u>G.K. Pyapali and D.A. Turner.</u> Neurosurgery and Neurobiology, Duke Univ. Med. Ctr. and Durham VAMC, Durham, NC, 27710.

Aging results in synaptic reorganization in the CNS. Our hypothesis states that this CNS reorganization involves denervation of neurons due to either cell loss or decreased axonal plasticity, resulting in reactive dendritic growth (Pyapali and Turner, 1994, 1996). We investigated dendritic alterations in healthy DG cells (3, 24 month male F344 rats) using Neurobiotin staining during *in vitro* intracellular recordings and 3D computer-based dendritic reconstructions (Neurolucida).

Total dendritic length of DG cells was not different between aged (3.38±3.29 mm; n=6) and young cells (3.19±2.76 mm; n=7); no neuronal atrophy was observed. Dendritic extent (from the granule cell layer to the fissure) was significantly longer in aged (343±25.8 µm) compared to young animals (290±30.1 µm; p<0.01). Sholl analysis (25 µm spheres) revealed an increase in the number of intersections (p=0.03) and branch lengths (at 300-400 µm from the soma; p=0.02) in the outer molecular layer in aged cells. Branch order analysis did not show any difference in the number of branch orders or length per branch order between the two groups. The trend suggested moderate lengthening of the molecular layer extent with age. The results demonstrate only moderate dendritic alterations of dentate granule

The results demonstrate only moderate dendritic alterations of dentate granule cells with aging, with no evidence of dendritic atrophy. In contrast, CA1 pyramidal neurons show significant increased dendritic branching throughout both apical and basilar trees in 24 month F344 rats (Pyapali and Turner, 1996; Neurobiol Aging, in press). However, DG cells show minimal dendritic sprouting in response to entorhinal cortex lesions whereas CA1 pyramidal cells demonstrate robust sprouting following kainic acid CA3 lesions. Thus, cell populations within hippocampus may show differential dendritic plasticity in response to either denervating lesions or with aging, consistent with our hypothesis that denervation induces dendritic alterations in the aged CNS. Supported by NIA (GKP, DAT) and VAMC (DAT).

DECREASED mRNA OF THE PLASMA MEMBRANE Ca²⁺-ATPase ION TRANSPORTER IN THE HIPPOCAMPUS OF AGING RATS. <u>PG Kaminker, KC Chen*, JP Herman, PW Landfield</u>, Depts. Pharmacology, Anat. and Neurobiol., College of Medicine, Univ. of Kentucky, Lexington, KY 40536.

There is growing interest in the possibility that changes in intracellular Ca²-concentration ([Ca²-]) play a key role in normal brain aging and Alzheimer's Disease. The plasma membrane Ca²-ATPase (PMCA) is an essential protein in [Ca²-], regulation. An aging-related decrease in the V_{max} for PMCA in brain tissue has been found (Michaelis et. al., 1989), which could contribute to a rise in [Ca²-], in aged rat neurons. In these studies we investigated the possibility that reduced gene expression underlies this decline in PMCA activity. Our initial focus has been on the second isoform (PMCA2) previously shown to be expressed predominantly in the brain. A ribonuclease protection assay was employed to measure the steady state PMCA2 mRNA levels in the hippocampal homogenates from three age groups, (3-5 m.o., 12 m.o., and 24 m.o.) of male Fischer 344 rats. The PMCA2 cRNA probe was synthesized from a 282 b.p. cDNA clone obtained from rat hippocampal RNA by RT-PCR, using PMCA2 primers spanning the 3'-end region. A cRNA probe of glyceraldehyde phosphate dehydrogenase was used as an internal control.

Our results show a decrease of about 50% (p<.05) in hippocampal PMCA2 mRNA in mid-aged and aged rats in comparison to young adult rats. This change did not appear to be simply developmental, as the young animals were mature adults, suggesting that alterations in PMCA2 occurred early in the brain aging process. These results are consistent with the possibility that reduced transcription of the PMCA2 gene could account, in part for the previously observed changes in PMCA2 activity and, therefore, could be a significant factor in brain neuronal Ca²-dysregulation. EXPRESSION OF NCAM PSA IN THE HUMAN HIPPOCAMPAL DENTATE GYRUS FROM INFANCY TO OLD AGE. G.B. Fox*. C.M. Ni Dhuill, S.J. Pittock, A.W. O'Connell and C.M. Regan, Department of Pharmacology, University College, Beffeld, Dublin 4, Ireland.

The polysialylated form of the neural cell adhesion molecule (NCAM-PSA) regulates adult neuroplastic events associated with learning and memory. Although perturbations of NCAM function have been related to the severity of the impaired sensory processing associated with autism and schizophrenia, few studies have examined the distribution of NCAM-PSA in neuroplastic regions of the human brain. We now describe the distribution of polysialylated NCAM in the aging human hippocampal dentate gyrus, a region synonymous with processing learning-associated sensory information. Human brain tissue was obtained, with the consent of the senior pathologist, from six major Dublin hospitals within 24 hours post-mortem. The hippocampus was isolated from 16 individuals ranging in age from 5 months to 82 years with at least one sample from each decade. The tissue was dissected from the medial temporal lobe, coated in optimal cutting temperature compound and frozen in liquid nitrogen- or dry ice-cooled n-hexane. Cryosections of the dentate area were prepared and immunostained for NCAM-PSA using a monoclonal antibody specific for the polysialic acid portion of the molecule. Immunoreactivity was localised mainly to neurons in the granule cell layer and their mossy fibre axons of the infant (5-7 months). In early childhood (1-3 years), this immunoreactivity began to decline and was markedly reduced in old age. In contrast, a population of large neurons in the hilar region became immunoreactive only during early childhood and remained in significant numbers into adulthood and old age. These results demonstrate a differential, age-dependent expression of NCAM-PSA in two discrete neuronal populations of the human hippocampal dentate gyrus. DECREASES IN TYPE 1 INSULIN-LIKE GROWTH FACTOR RECEPTORS IN CORTEX AND HIPPOCAMPUS OF AGED RATS. P. Thornton*, S. Bennett, P. Cooney, R. Ingram and W. E. Sonntag, Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

IGF-1 has previously been shown to have an important role in brain function including protein synthesis, neurite outgrowth, release of acetylcholine and cortical development in rodents. In this study, we assessed whether a decline in the type 1 IGF receptor could be a contributing factor in the decrease in brain function that occurs with age. Brain sections from Fisher 344xBrown Norway male rats (10, 19 and 29 months of age) were assessed for ¹²⁵I-IGF-1 and ¹²⁵I-des[1-3]IGF-1 receptor binding by autoradiography. Type 1 IGF receptors were prominent in both layers 2 and 4 of sensorimotor cortex and in hippocampus of all animals. ¹²⁵I-IGF-1 binding tended to increase in layers 2 and 4 from 10 to 19 months of age and decreased significantly from 19 to 29 months in layer 2 (3.65±0.2 vs 2.76±0.2nCi/mg, p<0.05) and layer 4 of cortex.(3.20±0.15 vs 2.42±0.22nCi/mg). In hippocampus, receptor density decreased steadily from 10 to 29 months (3.66±0.22 vs 2.48±0.15nCi/mg, p<0.05). Analysis of adjacent sections with ¹²⁵I-des[1-3]IGF-1 revealed similar decreases with age in layer 2 (35% decrease from 19 to 29 months) of cortex. Binding in hippocampus decreased by 25% from 10 to 29 months) of cortex. Binding in hippocampus decreased by 25% from 10 to 29 months of age. The results of these studies demonstrate an age-related decline in type 1 IGF receptor density and suggest that these decreases may have a role in the decline in brain function with age.

DIFFERENTIAL EXPRESSION OF Na-K ATPase α-1SOFORM mRNAs IN AGING RAT CEREBELLUM. N.B. Chauhan*. G.J. Siegel. Molecular and Cellular Neuroscience Laboratory, Hines VA, Hines IL 60141; Departments of Neurology, Molecular and Cellular Biochemistry, Loyola University Chicago, Maywood IL 60153.

Age-dependent changes in the expression of Na,K-ATPase α1- and α3-mRNAs were analyzed in the rat cerebellum by in situ hybridization. In young rats, α1-mRNA showed prominent labeling in the granular layer (βL), with moderate fine distribution in the molecular layer (ML), Purkinje cell layer (PCL) and white matter (WM) but no clusters over Purkinje cells. In old rats, α1-mRNA remained unchanged in ML and PCL but declined by 43% (p<0.0001) in GL and increased by 624% (p<0.0001) in WM. α3-mRNA in young rats showed large clusters of label on stellate, basket, Golgi and Purkinje cells (PCs) and fine grains diffusely in ML, GL and WM. In old rats, α3-mRNA declined by 87% in ML, 83% in PCL, 84% per PC, and 89% in GL and increased by 111% in WM (all values p<0.0001) relative to young rats. PC numbers were reduced by 30% but the average area of PC profiles did not change significantly. In old rats, the specific cluster-like label related to α3-mRNA on PCs, stellate, basket and Golgi cells was lost. Immunocytochemistry of cerebellum and hippocampus showed no age-related change in the distribution and density of total catalytic polypeptide. Thus, the discordance between changes in the levels of mRNAs in neuronal layers and WM in the face of constant polypeptide levels indicates age-related changes also in polypeptide turnover. Cell- and isoform-specificity of α-isoform mRNAs in aging rat cerebellum may reflect differential regulation underlying age-related impairments in signal transduction and motor learning.

AGING PROCESSES

492.1

AGE-DEPENDENT CHANGES OF THE LEVELS OF FACTORS INVOLVED IN CHOLESTEROGENESIS OF RAT CENTRAL AND PERIPHERAL NERVOUS SYSTEMS. R. Fukuyama*, S. Fushiki* and K. Yanagisawa*. *Dept. Dementia Res., National Inst. Longevity Sci., Obu, Aichi, 474; Dept. Dynamic Pathol., Res. Inst. Neurol. Dis. Geriatrics, Kyoto Prefect. Univ. of Med., Kamigyo, Kyoto, 602 Japan.

A major risk factor for Alzheimer's disease (AD) is gene dose of £4 allele of apolipoprotein E (ApoE), which is assumed to function as a carrier of phospholipids, cholesterol and triacylglycerol. It may be a clue to determine whether de novo biosynthesis or recycling system is dominant for supplying cholesterol in adult brain, in order to understand molecular pathogenesis of AD. We determined the levels of mRNA and protein of hydroxy methylglutaryl CoA-reductase (HMGR), the rate-limiting enzyme in cholesterogenesis, for evaluation of endogenous supply of cholesterol and also determined those of ApoE for evaluation of recycling cholesterol at various ages of rat brain hemisphere and sciatic nerve. Quantity of mRNA of HMGR was estimated by simplified RT-competitive PCR technique. We also measured total cholesterol with enzymatic procedure in order to relate the levels of these molecules to concentration of total cholesterol in each tissue. In all ages examined, levels of mRNA and protein for ApoE and internal control β-actin in both tissues were roughly unchanged. Level of HMGR mRNA in brain showed a peak at 3-4 weeks after birth and slightly decreased thereafter. In contrast, its mRNA level in sciatic nerve showed a dramatic decrease during first 3 weeks. While the level of total cholesterol in this tissue was steeply increased in this period and then reached to plateau level, which was roughly 2.2-fold more than that of corresponding brain. On the other hand total cholesterol in brain showed only a small increase within 3 months after birth. These results indicate that; 1) aged-rat brain utilizes both de novo synthesis and recycling system for supplying cholesterol; 2) aged-sciatic nerve utilizes predominantly recycling system; and 3) that age-dependent change in gene expression of HMGR in central and peripheral nervous systems is likely regulated by the level of total cholesterol in each tissue

492.2

AGE RELATED CHANGES IN GLUTAMATE RECEPTORS IN THE CANINE BRAIN CORRELATE WITH CHANGES IN ANESTHETIC POTENCY C.D. Rinehart, C. Dunlop, A. Wagner and K.R. Magnusson, Depts. of Anatomy & Neurobiology, & Clinical Sciences; Colorado State University, Fort Collins, CO 80523.

With increasing age, animals and humans become more sensitive to the depressant effects of general anesthesia. Antagonists of NMDA and AMPA receptors can also increase the potency of anesthetics. The goal of this study was to determine whether dogs experience a reduction in the functioning of glutamate receptors with age that could thereby impact the anesthetic requirement of the animal. Six young (2-3 years) and 6 middle aged (11 years) beagles were anesthetized with isoflurane to determine the potency (MAC value) for each animal. Following euthanasia, quantitative autoradiography for NMDA and AMPA receptors was performed. The sections were incubated with either 20nM ³H-AMPA or 100nM ³H-glutamate in the presence of 100µM SITS, 1µM kainate and 5µM AMPA or 10nM ³H-MK801 in the presence of 10µM glutamate and glycine. The old dogs showed a significant decrease in binding, with all three ligands, in a majority of the cortical and hippocampal regions. A significant positive correlation was also found between the MAC values for isoflurane and the binding for MK801 sites and NMDA receptors in the cerebral cortex. These results suggest that there is a reduction in the functioning of these receptors with age in dogs and that this change may account for some of the increase in potency of inhalation anesthetics in aged animals. Support: MIKI Society of CSU College of Veterinary Medicine & Biomedical Sciences.

ALTERATIONS IN NMDA RECEPTORS WITH AGE. X. Xu*, S. Bennett, P.Thornton, and W.E.Sonntag Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

N-methyl-D-aspartate (NMDA) receptors have an important role in

synaptic plasticity and neurodegeneration. Two major subtypes of these receptors are present in brain, NMDAR1 and NMDAR2. Heterogeneity of these receptors define specific functional responses of the NMDA receptor. Previous studies indicate that receptors of excitatory amino acids (including NMDA receptors) decline in aged animals and contribute to age-related changes in neuronal function. In this study, we compared NMDAR1 and NMDAR2 levels in cortex of young (4 months of age) and old (29 months of age) male F344xBN rats using RT-PCR with receptor subtype specific primers. Our results indicate the presence of both NMDAR1 and NMDAR2 subtypes in both cortical and hippocampal areas. The NMDAR1 subtypes in both contical and hippocamplar lacks. The NMDAR1 receptor subtype increased 25% in aged animals. However, the NMDAR2 subtype decreased by 31% in old as compared to young animals (relative densities of 31.2±2.0 vs 20.3±1.9, p<0.05). Administration of IGF-1 to aged animals (50ng/hr for 4 weeks) did not appear to alter either NMDAR1 or NMDAR2 mRNA in cortical areas. These data are consistent with decreases in NMDA receptor density previously reported in aged animals and suggest that alterations in receptor subtype heterogeneity may lead to functional changes in neurons in aged animals. Supported by 1 P01 AG11370.

GDNF AUGMENTS BASAL AND STIMULUS-EVOKED RELEASE OF DA IN THE STRIATUM OF AGED F344 RATS. M.A. Hebert*, P.A. Lapchak, and G.A. Gerhardt. Psychiatry. Pharmacology and Neuroscience Training Program, University of Colorado Health Sciences Center, Denver, CO

The objective of this study was to determine if glial cell-line derived neurotrophic factor (GDNF) could produce functional changes in dopamine (DA) nerve endings in the striatum of aged Fischer 344 (F344) rats. Prior studies from our laboratory have shown that DA neurons in aged rats have reduced DA output, and intranigral administration of GDNF enhances stimulusinduced DA overflow in the striatum of young rats. It has not been determined, however, whether aged (24 mo) F344 rats are capable of responding to this factor. Three weeks prior to in vivo microdialysis studies, aged F344 rats received single intranigral injections of 10 µg GDNF (in 10µ1 PBS). The GDNF-treated, 24 mo F344 rats were found to have significant increases in basal DA levels (0.11 \pm 0.00 μ M, n=21, p<0.05) over the vehicle-injected group (0.07 \pm 0.01 μ M, n=21), DOPAC levels (2.45 \pm 0.09 μ M. GDNF-treated. p<0.01) versus (1.99 \pm 0.09 μ M, vehicle-treated) and HVA levels (3.39 \pm 0.11. GDNF-treated, p<0.001) versus (2.21 \pm 0.11 μ M, vehicle-treated). In addition, both potassium- (1.29 \pm 0.16 μ M in GDNF vs. 0.36 \pm 0.04 μ M in vehicle group) and d-amphetamine-induced (0.82 \pm 0.16 μ M in GDNF vs. 0.34 \pm 0.04 μ M in vehicle group) DA overflow, as measured by microdialysis were significantly injection of GDNF is capable of increasing the output of DA from DA nerve endings in aged rat striatum. (Supported by grants from USPHS NS09199, AG06434 and NIH Training Grant HDO7408-02. GDNF provided by Amgen, Inc., Thousand Oaks, CA).

492.7

AGING ASSOCIATED CHANGES IN THE REGULATION OF TRANSCRIPTION FACTOR NF-KB IN RAT BRAIN.

A. Salminen*, P. Wiitanen, M. Helenius. Department of Neurology, University of Kuopio, Kuopio, Finland.

Aging process involves an altered pattern of gene expression and probably changes in transcription factor regulation. Our aim was to study whether aging affects the DNA binding activities (EMSA methods) of NF-κB, CREB, Sp-1, AP-1, and Oct-1 transcription factors in brain samples of rats and mice. We observed a significant upregulation of nuclear NF-κB factor in 30 month old Wistar rats compared to young or 18 month old rats. Similar upregulation also occurred in NMRI mice. Cytoplasmic, inducible NF-κB binding activity was not affected by aging. Supershift assays showed that constitutive NF-kB complexes contained protein components such as p50, p52, and p65. Interestingly, the binding activities of Sp-1 and Oct-1 factors were prominently downregulated during aging e.g. in hippocampus. However, the age-related increase in NF-kB binding activities was considerably less in brain than in other tissues such as liver and heart, suggesting that in rat these tissues are more vulnerable to aging changes than brain.

AGE-RELATED CHANGES IN THE RHESUS MONKEY: NEUROTROPHIN RECEPTOR TRK C-LIKE IMMUNO-REACTIVITY. J.H. Sandell*, L.S. Baker, Jr., T. Davidov and S. Lee. Dept. of Anatomy & Neurobiol., Boston Univ. School of Medicine, Boston, MA 02118.

The receptor tyrosine kinase TrkC is the high affinity receptor for neurotrophin 3 (NT-3). We used a polyclonal antibody against a portion of TrkC (Santa Cruz Biotechnology, used at 1-500 to 1:5000) to detect sites of TrkC-like immunoreactivity in the rhesus monkey brain. We were particularly interested in whether the distribution or density of labeling changed with age. Labeling was abolished in control experiments in which the antibody was preabsorbed with peptide antigen, but was unaffected by preabsorption with heterologous peptide. Frozen sections from 2 monkeys (9 and 26 years old) were used. Selected sections from additional animals were also examined. All

monkeys showed the same distribution of labeling.

TrkC-like immunoreactivity was widespread. Numerous varicose fibers were intensely immunoreactive, with very rare labeling of cell bodies. Sparse populations of positive fibers were observed in the thalamus, hypothalamus, brainstem and cortex. Intense immuno-reactivity was found in the basal forebrain, throughout the raphé complex and in the locus coeruleus. In these latter areas there was a significant reduction in the numerical density of the varicosities in the old animal. We conclude that TrkC-like immunoreactivity in the monkey brain is

greatest in some of the subcortical regions that are most vulnerable in aging, and that our preliminary studies indicate that the density of TrkClike immunoreactive profiles in these regions decreases with age. (Supported by AG-00001.)

492.6

PARTIAL CHOLINERGIC IMMUNOLESIONS AND NGF TREATMENT: COMPARATIVE CHANGES OF CHAT, NGF AND TRANSCRIPTION FACTORS NFkB AND AP-1 IN YOUNG AND AGED RATS.

G. Wörtwein, J. Yu. T.E. Toliver, D. Rassin* and J.R. Perez-Polo. Dept. HBC&G, Univ. of Texas Med. Branch, Galveston, Tx 77555, and Lab. Neuropsychiatry, Univ. Copenhagen and Rigshospitalet-6102, Copenhagen, Denmark

The cholinergic neurons of the basal forebrain (BF) are the major source of cholinergic innervation of the cortex and hippocampus. In Alzheimer's disease there is a severe loss of cholinergic neurones in the nucleus basalis of Meynert, leading to a reduction of cortical cholinergic activity, which correlates with the severity of cognitive deficits. To mimic these cholinergic deficits in experimental animals and study the potential therapeutic effects of nerve growth factor (NGF) we induced a partial lesion of the BF cholinergic neurones by intracerebroventricular (icv.) injection of 1.3µg of the immunotoxin 1921gG-saporin in groups of 3 month and 30 month old rats. The lesion was followed 14 days later by icv. injection of 5.4µg NGF. Basal levels of choline acetlytranserase (ChAT) were reduced in the BF and cortex of aged animals, but not in the hippocampus and olfactory bulb. The lesion resulted in a 40 to 60% reduction of ChAT levels in cortex and hippocampus of both, young and aged rats. NGF treatment restored ChAT to close to normal values in the cortex of aged but not young rats. Basal NFkB binding activity was higher in the hippocampus of aged rats. The lesion had no significant effect on NFkB DNA binding in either age group. However, NGF treatment increased the already higher binding activity in the aged hippocampus even further. There were no basal AP-1 binding activity differences in the hippocampus of young and aged rats and the lesion did not alter this activity in either age group. NGF treatment significantly lowered AP-1 DNA binding activity in the aged hippocampus. There were no differences among the various age and treatment groups with respect to NFxB or AP-1 binding activity in the cortex. This is publication 51A from USPHS P01-A610514 awarded by NIA. AGE-RELATED DIFFERENCES IN PILOCARPINE-INDUCED C-FOS EXPRESSION. D.J. Bucci^{1*}, D.L. Rosen², and M. Gallagher^{1,2}. ¹Curriculum in Neurobiology and ²Department of Psychology, University of North Carolina, Chapel Hill, NC 27599.

Expression of the immediate-early gene c-fos can be induced in specific brain regions of young rats through administration of the cholinergic agonist pilocarpine, an effect that is blocked by the M1 cholinergic antagonist pirenzepine (Hughes & Dragunow, 1993,1994). The topography of activation in forebrain structures coincides with the terminal regions of basal forebrain cholinergic coincides with the terminal regions of basal forebrain cholinergic neurons. In the present study, young (6 mo.) and aged (24-26 mo.) male Long-Evans rats were treated with either saline or pilocarpine (25 mg/kg; IP), and sacrificed 90 minutes after injection. Brains were then processed for *in situ* hybridization histochemistry for c-fos mRNA, using an ³⁵S-labeled antisense riboprobe. In many areas of the forebrain, there was no age difference in the c-fos mRNA response to cholinergic agonist. However, a significant increase in this response was found in retrosplenial cortex, but not in adjacent cortical regions, e.g., parietal cortex in aged animals. Further studies will examine parietal cortex, in aged animals. Further studies will examine levels of Fos protein within this model. (Supported by NIH grants K05-MH01149 & P01-AG09973 to MG.)

NGF IN THE RAT EXTERNAL CAROTID ARTERY IS PRIMARILY ASSOCIATED WITH NERVE FIBERS AND DECLINES WITH AGE. K.A. Crutcher*, J.A. Weingartner, I. Gavazzi* and T. Cowen*, Dept. of Neurosurgery, Univ. of Cincinnati Med Ctr., Cincinnati, OH 45267-0515 and *Dept. of Anatomy and Developmental Biology, Royal Free Hospital School of Medicine, London, UK

The regulation of target innervation is likely to involve neurotrophic factors and there is ample evidence that innervation of target tissues by sympathetic and sensory neurons is regulated by nerve growth factor (NGF). However, the extent to which measurements of NGF in target tissues reflect levels within producer cells or levels within the resident nerve fibers is incompletely known. Recent evidence suggests that within one target tissue, the superior mesenteric artery, the majority of NGF is associated with the nerve fibers (Liu et al., J. Neurochem., in press). This question was examined by measuring levels of NGF in the external carotid artery of both

was examined by measuring levels of NGF in the external carotic artery of both young and aged SD rats with a sensitive 2-site ELISA. The contribution of nerve fibers to the levels of NGF was determined by separating the adventitia and media as well as examining the effect of denervation 3 days prior to procurement.

NGF levels were found to be high in this vessel. The mean value for whole vessel was 33 pg/mg wet weight and 10 pg/mg wet weight for young and aged animals, respectively. When measured separately, 95% of the NGF was found to be associated with the adventitia in the young vessels and 70% in the aged vessels. The age-related loss of NGF was found to occur exclusively within the adventitia (levels in the aged vessels in the aged vessels. The age-related loss of NGF was found to occur exclusively within the adventitia (levels in the aged vessels). adventitia being 15% of the young adventitia). Denervation resulted in a decrease in NGF in the whole ECA of both young (45%) and aged (34%) animals. However, this reduction was due exclusively to declines in the adventitia.

These results suggest that the vast majority of NGF detected in the external carotid

artery in young animals is associated with nerve fibers and that the decline in vascular NGF levels with age, and following denervation, is due to reductions in the levels of NGF within such fibers and/or to a loss of NGF-containing fibers. Supported by the NIH (NS17131) and the British Heart Foundation (PG 93027).

INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) GENE EXPRESSION IN BRAIN VASCULATURE: INFLUENCE OF AGE. J.K.Brunso-Bechtold*, C.D.Lynch, T.M.McShane, P.T.Cooney, M. M.Niblock, P.M.Hutchins, and W.E.Sonntag. Departments of Physiology and Pharmacology, Neurobiology and Anatomy, and Program in Neuroscience, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

IGF-1 has been shown previously to have an important role in brain function. This hormone stimulates acetylcholine release, neurite outgrowth, protein synthesis and the absence of IGF-1 or its receptor impairs brain development. Although IGF-1 is important for brain function, the source of IGF-1 is controversial. Specific brain regions are known to express IGF-1 during critical developmental stages and plasma IGF-1 may also have a role in brain function. There have been several reports that IGF-1 is expressed in peripheral vasculature during wound healing but IGF-1 gene expression in cerebral vasculature during development and/or aging has not been investigated. In this study, we assessed IGF-1 gene expression in cerebral vasculature by in situ hybridization using an antisense RNA probe. Sections from Fisher 344xBrown Norway rats of 3 ages (8-10,20 and 30 months of age) were prepared and IGF-1 gene expression in vasculature from several cortical regions were compared. Results indicate high levels of IGF-1 gene expression in vasculature from each of these areas. IGF-1 mRNA expression was 1.89 to 4.88 fold greater in vessels compared to surrounding tissues and no age-related differences were detected Expression did not appear to be related to vessel size. Our results suggest that vasculature may be an important source of IGF-1 in brain throughout

NEURONAL IGF-I mRNA EXPRESSION DURING DEVELOPMENT AND AGING IN FISCHER344XBROWN-NORWAY RATS M.M. Niblock* C.D. Lynch, P.T. Cooney, T. McShane, J.K. Brunso-Bechtold, and W.E. Sonntag Depts. Neurobio/Anat. & Physio/Pharm., Prog. in Neuroscience, Bowman Gray School of Med., Wake Forest Univ., Winston-Salem, NC 27157 Previous studies have reported significant changes in the expression of insulin-like growth factor I (IGF-I) in specific cell populations of the developing rat brain. Although the expression of IGF-I has been shown to fluctuate in early postnatal life (Bondy, 1991), as of yet no study has assessed whether there are changes in the overall pattern of IGF-I expression that occur as the brain ages. The present study examined IGF-I mRNA expression in the aging Fischer 344 X Brown-Norway rat using a 376 base IGF-I specific RNA probe for *in situ* hybridization. Sagittal brain sections from seven age groups spanning from 2 months to 30 months were processed. Following hybridization. sections were coated with NTB-3 photographic emulsion (Kodak), allowed to expose for 9 days, developed, and counterstained with cresyl violet for light microscopic study. Four brain areas were the focus of computenzed density analyses: the superior olivary complex, the hippocampus, the Purkinje cells of the cerebellum, and layer 2 of sensorimotor cortex. Preliminary results indicate high levels of neuronal IGF-I mRNA expression throughout the brain across the life-span. Although there appears to be a trend of decreasing IGF-I mRNA expression with age, these changes fall short of statistical significance. This finding is particularly interesting in light of the fact that plasma levels of IGF-I have been shown to drop dramatically with age. That IGF-I levels in the brain remain high in spite of the fact that plasma levels of IGF-I in superior or rearross or maintaining dendrites and synaptic connections. Another possibility is that although IGF-I levels remain high as the brain ages, the expression of some other element of the IGF s

EFFECTS OF AGE ON CEREBROVASCULAR VASOMOTION, P.M. Hutchins*, C.D. Lynch, P.T. Cooney, K.A. Curseen, W.E. Sonntag, Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine, of Wake Forest University, Winston-Salem, NC 27157.

Vasomotion is necessary to increase perfusion, reduce the capillary diffusion distances, and thereby maximize transport for a particular vascular geometry. We have developed methodology to analyze the acute spontaneous fluctuations in microvascular dimensions in a chronic cerebrovascular preparation. Intrinsic rhythmic changes in the diameter of cerebral arterioles in sedated young, middle-aged, and old Brown Norway rats were assessed in vivo. All diameter measurements were analyzed using a traditional graphic analysis technique. Graphic analysis of the data revealed that the vasomotion frequency was markedly reduced in the old (24-35 month) Brown Norway rat to less than half that observed in the young (5-9 month) rat, 2.19 ± 0.47 vs. 0.90 ± 0.40 cycles per minute. Furthermore, the young cerebral arterioles exhibited a significantly greater amplitude of vasomotion when compared to the old cerebral arterioles of the same diameter (3.35 \pm 0.58 vs. 1.94 \pm 0.29). Diameter measurements revealed that there was no difference in the size of the arterioles on the cortical surface of any of the three age groups of Brown Norway rats.

These data suggest that a fundamental defect of intrinsic tone develops in the old rat that may contribute to the age-related reduction in microvascular and cardiovascular regulation. We hypothesize that this defect affecting the short-term regulation of the microvascular system, is brought about by long-term structural regulatory alterations. Supported in part by grants 1PO1-NIA-11370, 1RO1-HL-13936 and 1T35-HL-07790.

AGE-RELATED DECREASES IN THE CORTICAL MICROVASCULATURE ARE RELATED TO DECREASES IN GROWTH HORMONE AND INSULIN-LIKE GROWTH FACTOR-1 (IGF-1). C.D.Lynch*, P.M.Hutchins, P.T.Cooney, J.K. Brunso-Bechtold, W.E.Sonntag, Dept. of Physiology/Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

A reduction in cerebral blood flow is a hallmark of advancing age. In the present study, we utilized a chronic cranial window preparation in young (8 months) and old (29 months) Fisher 344xBrown Norway (F344xBN) and BN (5-11 mo. young and 24-35 mo. old) rats to investigate potential mechanisms that contribute to the decreased blood flow with age. Rats were sedated and the microvasculature of the cortical surface was mapped. Young F344/BN rats had an arteriolar endpoint density (where the vessel enters the cortical surface) of 17.7 ± 2.3 arterioles/mm² (n = 15) whereas old F344/BN rats had 12.1 ± 0.7 arterioles/mm² (p<0.05). whereas our F344/bit fats had (2.1 ± 0.7) afteriols/mm¹ (p<0.05). Similarly, young BN rats showed (4.9 ± 1.2) arterioles/mm² and old BN (9.4 ± 0.6) arterioles/mm² (p<0.05). In a second study, we investigated whether daily injection of growth hormone (which decreases substantially in aged animals) would result in an increase in vascular density in F344xBN rats. Our results indicate that 0.25mg growth hormone/day for 32 days increases the arteriolar endpoint density in aged rats by 16%. In addition, arteriolar endpoint density was positively correlated with plasma levels of IGF-1 in BN rats. These data suggest that the age-related reduction in cerebral blood flow may be due to the observed decrease in cerebral arteriolar density, and that these alterations are associated with the age-related reduction in growth hormone and IGF-1. Supported in part by 1 PO1-AG-11370, 1RO1-HL-13936.

492.14

CALORIC RESTRICTION INCREASES CORTICAL MICRO-CALORIC RESTRICTION INCREASES CORTICAL MICRO-VASCULATURE IN AGED ANIMALS. B.Poe*, C.Lynch, P.Cooney, J.K. Brunso-Bechtold, W.E.Sonntag and P.M.Hutchins. Departments of Physiology and Pharmacology, Neurobiology and Anatomy, and Program in Neuroscience, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

With increasing age, there is a decline in cerebral blood flow that is associated with a decline in cortical microvasculature. Recent studies indicate that moderate caloric restriction (60% of ad libitum) decreases both functional and pathological changes with age and increases lifespan. In this study, we assessed whether acute or chronic caloric restriction ameliorates the age-related decline in cortical microvasculature. Male Brown-Norway rats were calorically restricted (n=7) or fed an ad libitum diet (n=13) from 4 months to 35 months of age. Animals were prepared with a chronic cranial window and 1-2 weeks later the cortical surface vasculature was mapped. Results indicate that the number of arteriolar penetrations into the cortical surface were maintained in calorically restricted compared to ad libitum fed animals (15.0±0.9 vs 9.4±0.6 arterioles/mm², p<0.05). To study the acute effects of caloric restriction on cerebral microvasculature, ad libitum fed young (6 months) and old (29 months) animals were prepared with cranial windows and placed on a moderate caloric restricted diet for 35 days. Acute caloric restriction increased arteriolar endpoints by 28.2% in young and 12.2% in old animals. Our results indicate that moderate caloric restriction prevents the loss of cerebral arterioles with age and that acute caloric restriction is capable of increasing vasculature in both young and old animals

INSULIN-LIKE GROWTH FACTOR-1(IGF-1) INCREASES WORKING MEMORY IN AGED ANIMALS. M.Mooney. W.E. Sonntag*, M.Barra, X.Xu, S. Bennett, R. Ingram, B.Poe and A.L. Markowska. Department of Psychotlogy, Johns Hopkins University, Baltimore, MD 21218 and Department of Physiology and Pharmacology and Program in Neuroscience, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157.

The age-related reduction in tissue protein synthesis appears to result, at least in part, from a decline in growth hormone secretion and a subsequent decline in IGF-1. IGF-1 has been implicated in differentiation of cortical neurons and regulation of acetylcholine release in hippocampal neurons. The present study was designed to assess whether behavioral deficits with age may be partially overcome by increasing levels of IGF-1. Fisher 344xBrown Norway male rats (4 months old and 32 months old) were preoperatively trained in behavioral tasks and subsequently implanted with osmotic minipumps to infuse IGF-1 (50ng/hour) or vehicle, icv. Animals were retested at 2 weeks and 4 weeks after surgery. IGF-1 improved performance in the repeated acquisition task. Mild improvements in some measures of the place discrimination task which assesses reference memory were also observed. IGF-1 had no effect on sensorimotor skills but reversed some age-related deficits in emotionality. These data indicate a potentially important role for IGF-1 in the reversal of cognitive impairments that occur in aged rodents.

AGE-RELATED CHANGES IN THE RHESUS MONKEY: RECOGNITION MEMORY IN THE OLDEST OF THE OLD. M.B. Moss*. R.J. Killiany, D.L. Rosene and J. Herndon. Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118 and Yerkes Regional Primate Research Center, Emory University, Atlanta, GA. 30322.

Assessment of recognition memory was performed in a group of five rhesus monkeys 29 to 31 years of age. Based on recently established life span data of rhesus monkeys, this age range represents the "oldest of the old". Their performance was compared to that of five young adult animals (5 to 11 years of age) on two tasks of recognition memory: trial-unique delayed nonmatching to sample (DNMS), and delayed recognition of a novel from a familiar stimulus over a delay. The task was first administered with a 10 second interval between presentation of the sample and the recognition trial. Upon reaching learning criterion, performance was then assessed on two delay conditions with the interval between sample and recognition increased to 120 sec. and then 600 sec. The DRST is a recognition test that requires identification of a novel stimulus added to the increasing array of stimuli. The number of correct responses before committing an error constitutes the recognition span for that stimulus class. Animals were tested on two stimulus conditions, one using spatial position of identical plaques and the other using unique objects. Both a non-repeating and a repeating series of spans were used for each of the two conditions. The oldest of the old group was impaired on all conditions of the two tasks relative the young group. Relative to previous findings in a younger aged group (25-28) of monkeys, the oldest old were more impaired on acquisition of the DNMS task, but were not significantly different from this age range on other performance measures. The results point to a pattern of cognitive dysfunction toward the end of the life span that may be characterized by recognition memory impairment and a disproportionate decline in new learning. EARLY STEPWISE OPERANT TRAINING FACILITATES NOVEL LEARNING IN OLD-AGED RATS: BEHAVIORAL AND NEUROBIOLOGICAL MECHANISMS. K.Pawlik*, M.-L. Nuessgen, G.Sammer and H.-G.Thiele. Dept.s of Psychology and Internal Medicine, Univ.Hamburg, D-20146 Germany.

Earlier research by the first 2 authors showed major facilitation of novel learning in aged rats as function of raising in mo.s 1-3 after weaning. In this exp. behavioral and neurobiological mechanisms of across-age memory facilitation are studied in 150 young (4) and 240 old (15 mo.s at criterion-tests) HAN-Wistar rats raised according to a 3x2 factorial design (early-late-no enrichment; longitudinal training-no training). Criterion tests: 3 new learning tasks (simple vs. delayed-alternation bar-pressing; radial maze); spontaneous activity tests, immunology (blood) assays, EEG recordings, also across age; post-mortem histology (cortex, hippocampus) and HPLC (catechol., 4 brain regions). Results: Facilitation of novel learning due to enrichment is larger in old than in young rats, in old rats more effective if offered late. Facilitation from longitudinal training is more effective than, and additive to, enrichment. Unrelated to general activation, facilitation relates to higher (brainstem) norepinephrine levels, smaller immune assay age-decrements and higher (hippocampal) EEG (theta) power. Results are discussed within contexts of neuronal plasticity theory.

THE EFFECTS OF INCREASING AGE ON ANTISACCADIC EYE MOVEMENTS

A. Olincy*, R.G. Ross, D.A. Young and R. Freedman. Schizophrenia Research Center, Univ. of Colorado Health Sci. Center, Denver, CO 80262.

As the brain ages, a decrease in frontal lobe volume with decreased cortical thickness,

As the brain ages, a decrease in frontal lobe volume with decreased cortical thickness, shrinkage of large neurons, cell loss and decreased density of synapses has been observed. Studies of aging in humans support decreased cerebral blood flow and metabolism in the frontal lobe. The antisaccadic eye movement task is known to be impaired in conditions with frontal lobe pathology. The antisaccadic task activates the frontal eye fields, supplementary motor area, thalamus, putamen and superior parietal lobe. This task measures motor, inhibitory and working memory abilities, functions that may become impaired with aging. Antisaccadic task performance decreases after the age of 60, with increasing numbers of prosaccades and increased latency of the antisaccade. There is no decrease in accuracy of the antisaccade once initiated. By examining the components of the antisaccadic task, impairment in frontal lobe functioning can be clarified. AGE-RELATED CHANGES IN THE RHESUS MONKEY: PATTERNS OF COGNITIVE DECLINE. J. G. Herndon*, M. B. Moss, D. L. Rosene, and R. J. Killiany. Yerkes Regional Primate Res. Ctr., Emory Univ., Atlanta, GA. 30322 and Dept. of Anatomy and Neurobiology, Boston Univ. Sch. of Med., Boston, MA 02118.

We evaluated the performance of young rhesus monkeys (<15 years of age) on six measures of cognitive function to determine the prevalence of impairment among early aged (19-23 years), advanced aged (24-28 years) and oldest old (29-33 years) monkeys. Impairment was defined as performance that fell outside the range for that of young monkeys. For early aged monkeys, prevalence rates were: (1) 25% (95% Confidence Interval - CI: 10-38%) on initial acquisition of Delayed Non-Matching-to-Sample (DNMS), (2) 42% (95% CI: 21-73%) on performance of the DNMS, with 2-min delay, (3) 67% (CI: 43-91%) on the spatial condition of the Delayed Recognition Span Test (DRST), a test of short-term spatial memory, (4) 0% (CI: 0-31%) for memory span in a non-spatial condition of the DRST, (5) 45% (CI: 24-77%) for in Spatial Reversal, a test in which a positional preference must be reversed, and (6) 27% (CI: 11-61%) for Object Reversal. For acquisition of DNMS, DRST - Non Spatial and Spatial Reversal, we detected a significant trend toward increasing prevalence of impairment in increasingly older groups of aged monkeys. Finally we used principal components analysis to derive a Cognitive Performance. The results confirm the multidimensional nature of age-related decline and provide the CPI as a measure representing the global cognitive capacity of the individual. The CPI was negatively correlated with age (r=-78, n=-53, p<0.001). (Supported by NIH grants POI AG00001, R55 AG12610 and RR 00165).

3D-MULTI-IMAGE-STACK-ACQUISITION-SOFTWARE (3D-MISA) FOR

CONFOCAL LASER SCANNING MICROSCOPES

W. Zuschratter*, T.Steffen, K. Braun, B. Michaelis, and H. Scheich, Federal Inst. for Neurobiology, P. O. Box 1860, D-39008 Magdeburg, FRG ²Univ. Magdeburg P. O. Box 4120, 39016 Magdeburg, FRG

Confocal laser scanning microscopy is now widely used to produce image stacks from neuronal tissue with high resolution. However, image acquisition at high magnification is inevitably correlated with a limited overview of sections. To overcome this limitation we designed a software for the automatic acquisition of multiple image stacks in xy-direction (3D-MISA). The system consists of a 4 channel Leica TCS4D confocal laser scanning microscope which was equipped with a xy-motorized stage (Märzhäuser). The 3D-MISA software was linked to the microscope software (Scanware, Leica Lasertechnik). It allows storage and recall of 70 xyz-positions and the automatic 3D-scanning of image arrays between two selected xyzcoordinates. The number of images within one array is limited only by the amount of disk and/or memory available. Currently, our system provides 288 MB RAM which is sufficient to handle 1132 images with 512 x 512 pixels. In practice, 3 fluorescence channels with an array of 5 x 5 x 15 (xyz) images can be acquired during one scan process. Images are than temporally stored on a hard disk and later archived on a CD for further analysis. At the end of the scanning procedure the program provides a gallery of the extended focus images of each channel on a graphic monitor. A gallery of individual focal planes can also be calculated.

In summary, the 3D-multiscan software represents a powerful tool for confocal laser scanning microscopy because it allows image acquisition of coherent regions in combination with high resolution of the single images. Supported by DFG INK15/A1 TP A4

NEUROZOOM - TOPOGRAPHICAL MAPPING AND STEREOLOGICAL COUNTING, DISTRIBUTION OF DATA, AND COLLABORATIVE COMPUTING, W.G. Young*, J.H. Morrison†, P.R. Hof†, E.A. Nimchinsky†, and F.E. Bloom. Dept of Neuropharmacology, The Scripps Research Institute, La Jolla, CA Medicine, NY, NY 10029†. 92037. Neurobiology, Mt. Sinai School of

NeuroZoom is a software application for Macintosh computers, combining topographical mapping functions with stereological counting techniques to collect, in 3D, data on the distribution, density, and number of labelled profiles. The software provides unlimited anatomic structures and layering, and flexible visibility controls and graphical Stereological tools include optical disector, fractionator, rotator, and estimators for structural length, area and volume (see Hof et al, this meeting, for example).

NeuroZoom is being used to create a rat atlas (see Bloom et al, this meeting). Mapping and stereological tools then acquire precise, quantitative data to be displayed in the context of the atlas.

NeuroZoom supports data distribution and sharing in three ways: Peer to peer: data are shared directly with any Internet NeuroZoom user. 2. Peer to server: local labs can install a server database. 3. Server to server: a centralized server acts as a registry for participating local By devising and implementing this easy-to-use software running on any popular and low-cost personal computers, it should be possible to provide the neuroscience community shared common tools for data acquisition, storage, organization, access, distribution, and re-use in community networks. (Supported by the Human Brain Project Consortium grant MH/DA 52154)

THREE-DIMENSIONAL MORPHOLOGY OF ASTROCYTES EXPRESSING GREEN FLUORESCENT PROTEIN. M.D. Andersen¹, R. Bizios¹, W. Shain², J.N. Turner^{1,2}, D.L. Martin^{1,2*}, D.H. Szarowski³, M. Sena-Esteeves⁴, X.O. Breakefield⁴. ¹Rensselaer Polytechnic Institute, Troy, NY 12180, ²Wadsworth Center and School of Public Health, Albany NY 12201-0509, ³Wadsworth Center, Albany NY 12201-0509, ⁴Massachusettes General Hospital, Harvard, Charlestown, MA 02129.

Cellular interactions in tissues are traditionally imaged using selective stains and immunohistochemistry. These methodologies use fixed tissues, precluding visualization of dynamic interactions. To overcome these difficulties astrocytes were transfected with Green Fluorescent Protein (GFP), resulting in cells expressing fluorescent protein allowing visualization of dynamic changes in cell morphology. Both LRM55 cells and astrocytes in primary cell cultures were used. In initial experiments to optimize transfection conditions, LRM55 cells were transfected with wild-type GFP and a redshifted mutation. Expression of GFP was compared using cytomegalovirus (CMV) and phosphoglycerate kinase (PGK) promoters. The PGK promoter resulted in significantly higher expression of GFP with transient transfection. The stable transfection rate was low, <1%. More than 60 clones were screened and several of the most fluorescent lines were maintained for further experimentation. The red-shifted GFP construct was used to optimize visualization because this protein is optimally excited at ~490 nm, matching the excitation wavelength of the argon laser(488 nm). To increase the transfection rate it primary astrocyte cultures, a retroviral construct with the red-shifted GFP and the PGK promoter was used. The three-dimensional morphology of astroglia was observed following injection of varying numbers of cells into cerebellar organotypic cultures Cerebellar cultures were prepared using 400-µm thick tissue slices from 14-day old Wistar rats and cultured for 7-14 days. In order to obtain the highest resolution, injected GFP-expressing cells were imaged using scanning confocal microscopy. Changes in cell morphology are being studied as both a function of time in three-dimensional organotypic culture and following applications of drugs that produce astrocyte stellation in monolayer culture. (This work is partially supported by NIH RR-10957.)

SURFACE GUIDED RECONSTRUCTION OF 3D VOLUME FROM HISTOLOGICAL MATERIAL. <u>D. Kozinska^{1*}, J. Nissanov², Q. Tretiak^{1,2} and C. Ozturk². ¹Dept. Elec. Comp. Eng. ²Biomed. Eng. & Sci. Inst., Drexel Univ., Philadelphia, PA 19104</u>

Reconstruction of brain volume from sectional material can reveal important anatomical information. However, accurate alignment of consecutive sections is typically difficult and consequently reconstruction is not done routinely. We have developed an algorithm which greatly simplifies the task. Using it, registration is guided by prior knowledge of the surface of the tissue. We have previously described a structured light technique which rapidly maps this surface before tissue sectioning (Nissanov et al., 1995, SPIE 2598:334-340) and here we report on the (Nissanov et al., 1995, SPIE 2598:354-340) and nere we report on the algorithm which employs this information to drive alignment. The algorithm consists of three stages. First, sections are aligned to each other using a 2D rigid body distance-based approach. Next, the aligned set is subjected to 3D rigid body matching to the surface (Kozinska et al., 1995, Neurosci. Abst. 21:427.10). In the subsequent step, intersection shear is permitted to better match each section contour with the surface envelope. The last two steps are iterated until a stopping criterion is satisfied. To assess the performance of this algorithm we determined the average residual distance between each section and the surface. We found using 100-section tissue blocks from rat brains, that we obtain an average residual error of less than 4 pixels (160 microns). In addition to its utility in reconstruction of tissue sections, the algorithm, in combination with a reference atlas and 3D alignment, may also prove useful in multimodality fusion of data from different animals. (Supported by NIH P41RR01638).

NEUROZOOM - NEUROANATOMIC ATLASES AND DATABASES FOR ACQUISITION AND DISPLAY OF STEREOLOGICAL DATA, F.E. Bloom*, J.H. Morrison†, E. Battenberg†, and W.G. Young. Dept of Neuropharmacology,

Morrisont, E. Battenbergt, and W.G. Young. Dept of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. Neurobiology, Mt. Sinai School of Medicine, NY, NY 10029t.

NeuroZoom is a software application for Macintosh computers, combining topographical mapping functions with stereological counting techniques (Young et al, this meeting). With it, we have created multiple rat brain atlases with video images of microtome sectioned frozen surfaces, with multiple series of stained sections, and with high resolution MRI image sets. The basic protocol for serially sectioned prepared slides follows. prepared slides follows

Two adult male rat brains (W. Welker, U of WI) were sectioned every 25μ in 2 adjacent series. Each adjacent section was stained either cresyl violet or a fiber stain for a total of 166 horizontal and 500 sagittal sections. Each was imaged with a Zeiss Macroscope and captured with a Leaf digital camera at a resolution of 3400X2800, 24 bits, reduced in density to 72 dpi, and registered with previous sections. The images were opened by NeuroZoom and regions such as pial surface, gray/white matter boundaries, ventricular, and major nuclear groups demarcated, producing a template based, neuroanatomic structural atlas for the rat brain.

The combination of atlas templates, spatially correct precise data, and stereologically accurate counting profiles produce a usable database that supports uniform acquisition of data with NeuroZoom, and the development of probability models of the distribution of cellular profiles through regions of the brain that heretofore have been described only with subjectively acquired boundary information. (Supported by the Human Brain Project Consortium grant MH/DA 52154)

3-D RECONSTRUCTION OF GASTRIC EFFERENT NEURONS AND ASSOCIATED NEUROPEPTIDES AND RECEPTORS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS IN THE RAT. L. A. Ladic and A. M. J. Buchan*. Dept. of Physiology, Univ. of B.C., Vancouver, B.C. V6T 1Z3 Canada

Retrograde tracing, multi-label fluorescence immunohistochemistry, confocal microscopy and 3-D reconstruction techniques were combined to examine the spatial relationship of immunoreactive nerve terminals containing calcitonin gene-related polypeptide (CGRP) and substance P (SP) to identified gastric efferent neurons in the dorsal motor nucleus of the vagus in the brainstem of the rat. The availability of an antibody to the receptor for SP (NK-1r) also permitted observation of the association of peptide and receptor. In 3-D reconstructions of selected retrogradely-labelled gastric efferent neurons, CGRP-immunoreactivity (IR) was visualized in the form of continuous fibres that surrounded the cell body and primary projections of the neurons. Unlike CGRP, SP-IR was observed as punctate labelling of varicosities that surrounded all surfaces of the identified neurons. NK-1r-IR was localized to the cell membrane of the efferents as well as to a subpopulation of the surrounding fibres. SP-IR fibres were observed in close association with the NK-1r-IR on the surface of identified neurons and surrounding fibres. Although no discrete synaptic structures were observed, the close proximity of neuropeptides to the identified gastric efferents and, in the case of SP, to its receptor, would suggest the possibility for neural communication via volume transmission. The combination of techniques described permit detailed visualization and analysis of the 3-D spatial arrangement and location of peptide containing nerve terminals and receptors with respect to all surfaces of identified neurons

NSERC (Canada)

STEREOLOGY AND COUNTING: ESTIMATION OF OBJECT HEIGHT IN SECTIONS; THIS CONVERTS THE LINDERSTRØM-LANG/ABERCROMBIE EQUATION ("ABERCROMBIE CORRECTION") TO THE EMPIRICAL METHOD EQUATION.

J.C. Hedreen*. New England Medical Center, Boston, MA, USA.

Accurate estimation of object height in sections, in the axis normal to the plane of section, is difficult. This estimation is required, for example, in the Linderstrand Long/Abercrophic (LA) proched for

Accurate estimation of object height in sections, in the axis normal to the plane of section, is difficult. This estimation is required, for example, in the Linderstrøm-Lang/Abercrombie (LLA) method for converting counts of profiles to object number. Gaule and Lewin [1896; see Hedreen and Vonsattel historical poster] pioneered a method for this conversion where they first, in a pilot study of 50 serially-sectioned neurons, found the mean number of profiles per cell (k), then obtained a total profile count (n), and finally divided k into n to reach an unbiased estimate for total neuron number (N). Thus, N=n/k. Coggeshall and colleagues [1984, 1990; Pover and Coggeshall, 1991] recently reintroduced and perfected this method under the name 'empirical method'. (Both empirical and LLA methods are now superseded by the disector method.) Consideration of the problem of calculating object height, h, from k shows that mean h=t(k-1), where t=section thickness. Thus preliminary estimation of k in serial sections allows estimation of object height whether h is >t or <t. It is, of course, necessary to estimate t, and also to attempt to correct k for lost caps. One could set out to use the LLA method, calculating h in this way. But substituting this formula for h into the LLA equation converts the latter into the empirical method

equation: $N = n \frac{t}{t+h} = n \frac{t}{t+t(k-1)} = n/k$. Having done the serial section study, one would therefore be better off to forget about LLA and continue with the empirical method. (Supported by NIH-NS29484)

NEW CALIBRATION TECHNIQUE FOR CELL COUNTING METHODS APPLICABLE TO NEUROSCIENCE C. N. R. Henderson* and Qiang Zhang. Palmer Chiropractic University, 741 Brady Street, Davenport Iowa 52803

The ability to make accurate cell counts is essential in neuroscience; providing critical information in studies of the development and normal internal organization of the nervous system, as well as evaluation of the nervous system's response to toxins, hormones, metabolites, and physical trauma. Previous studies have been hampered by cell counting approaches that utilized correction factors to reconcile profile and cell counts (e.g., the methods of Abercrombie and Konigsmark). Unfortunately, the simplifying assumptions underlying these correction factors have been proven incorrect, casting doubt on the conclusions of many seminal neuroscience studies. Sterelogical cell counting methods, such as the physical and optical dissector methods, are unbiased by cell size or orientation and do not rely upon correction factors. Fundamental tenets regarding neurogenesis and branching of dorsal root ganglion cell processes have recently been challenged because of observations made with these new counting techniques. Coggeshall demonstrated that neuroscientists must calibrate their application of cell counting techniques. However, the present calibration method, serial reconstruction, is tedious and requires a great deal of time. In addition, serial reconstructions are not readily applied to calibrate the optical dissector approach. We developed a calibration standard that is inexpensive and easily produced in the laboratory. Moreover, this standard may be used to calibrate all of the new stereological cell counting methods. Our standard, 'Latex Particle Calibration Blocks,' was produced by embedding a known number and size distribution (3 μ m, 6 μ m, and 10 μ m) of red latex beads in JB-4 PLUS resin blocks. Constant sonication maintained the beads in suspension during the early phase of the embedding process. Latex bead populations of known counts were dispersed within 10 resin blocks without clumping, and the blocks were sectioned and counted using physical or optical dissector methods. Bead counts were validated by ser

PRESYNAPTIC MECHANISMS: CALCIUM AND RELEASE

494.1

INTERACTION OF N-TYPE CALCIUM CHANNEL WITH THE SYNAPTIC CORE COMPLEX IS REQUIRED FOR NEUROTRANSMITTER RELEASE. S. Mochida*1, Z.-H. Sheng², C. Baker², H. Kobayashi¹ and W.A. Catterall². ¹Dept. of Physiology Tokyo Med. Coll, Tokyo 160, Japan and ²Dept. of Pharmacology, Univ. Washington, Seattle, Washington 98195, U.S.A.

To examine the functional significance of the interaction of the synaptic core complex (Syntaxin, SNAP25 and VAMP/Synaptobrevin) with N-type Ca²⁺ channels in neurotransmission, we studied the effects of fusion proteins containing the synaptic protein interaction site of the N-type Ca²⁺ channel on synaptic transmission at cholinergic synapses formed between sympathetic neurons in culture. Block of the interaction between presynaptic Ca²⁺ channels and the synaptic core complex by the fusion proteins substantially reduced the efficiency of synaptic transmission. No effect was observed with related control fusion proteins, and no effect on N-type Ca²⁺ channel activity was observed at the site of injection in the cell body, consistent with the conclusion that the synaptic protein interaction site peptides reduce neurotransmitter release without alternation of Ca²⁺ channel function. These results indicate that interaction of presynaptic Ca²⁺ channels with the synaptic core complex plays an important role in neurotransmitter release and is required for efficient synaptic transmission.

KINETIC PROPERTIES OF LARGE CONDUCTANCE K_{Cs} (BK)
CHANNEL ON THE CHICK PRESYNAPTIC NERVE TERMINAL. <u>Sun.</u>
X_P*and Stanley, E.F., Synaptic mechanisms Section, NINDS, NIH,
Bethesda, MD 20802

Several studies have suggested that BK channels in the nerve terminal are involved in the repolarization of the action potential and the cessation of transmitter release. However, these channels are known to be only slowly (>100 ms) activated by the direct elevation of internal calcium (Ca,) and, furthermore, they are not significantly recruited by even strong depolarizations at normal Ca, levels (10.8-10.7). We have explored the function of presynaptic BK channels by *in situ* recording using the calyx nerve terminal of the chick ciliary ganglion.

We first titrated channel open probability with changes in Ca_i and membrane potential. We next confirmed that these channels exhibit a long delay between direct application of Ca_i and channel opening and also that voltage tends to increase the fraction of channels open more than delay the activation time. We then tested whether external calcium (Ca_i: 2-110 mM) could affect the channels. There was no effect on channel activation with pulses beyond E_{Ca} but a prepulse to -20 or 0 mV, enabling Ca influx, reduced the time constants of BK activation by 20-100% in both whole-cell and oncell configurations. This finding suggests that calcium influx can have a long-lasting effect on channel kinetics. Our results suggest that BK channels may be activated by microdomains close to the clustered calcium channels and that their recruitment may require a closely spaces series of action potentials so that the calcium entering during one impulse enables channel opening during the next.

PRESYNAPTIC 5-HT₃ RECEPTORS ARE PERMEANT TO Ca²⁺ UNDER PHYSIOLOGICAL CONDITIONS: DIRECT OBSERVATION USING CONFOCAL MICROSCOPY. P. Rondé and R.A. Nichols* Departments of Pharmacology and Anatomy and Neurobiology, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129

Presynaptic regulation of neurotransmitter release by 5-HT3 serotonin receptors has been inferred in several neuropharmacological studies. To directly observe responses to presynaptic receptor activation, we have recently utilized laser scanning confocal microscopy to measure Ca2+ changes in individual isolated nerve terminals (synaptosomes) from rat corpus striata using the fluorescent Ca2+ indicator Fluo-3. Addition of 5-HT3 receptor agonists was found to induce Ca2+ changes in a subset of individual striatal synaptosomes. Here, we used the same method to investigate the pathway by which Ca2+ enters synaptosomes on stimulation of presynaptic 5-HT₃ receptors. In confirmation of previous results, the inorganic Ca2+-channel blockers Cd2+ plus Co2+ (10 μM each) effectively blocked K*-induced changes in [Ca2+]i. In contrast, Co2+/Cd2+ did not block Ca2+ influx in response to the addition of the 5-HT3 receptor agonist mCPBG (100 nM). Moreover, prior depolarization of the synaptosomes with 20 mM K+ or replacement of external Na+ by the non-permeant ion NMDG did not affect 5-HT3 receptor-induced Ca2+ influx. These results suggest that, in contrast to postsynaptic 5-HT₃ receptors which, on activation, are mainly permeant to Na and K under physiological conditions and consequently induce a large membrane depolarization, presynaptic 5-HT3 receptors are permeant largely to Ca2+, leading to Ca2+ influx into the nerve terminal rivaling that found on K⁺-induced depolarization. (Supported by a grant from the Allegheny-Singer Research Institute).

PRESYNAPTIC FUNCTION AND MODULATION OF INHIBITORY AND EXCITATORY SYNAPSES IN RAT HIPPOCAMPAL CULTURES. Rosenmund, C.*, and Auger, C. MPI biophysical Chemistry, Göttingen, Germany.

The hippocampus has a variety of modulatory inputs that may change both local and global information processing by differentially affecting release and excitability of interneurons and principal cells. We tested presynaptic function in both cells using whole-cell recordings from single autaptic cultured 'microdot' neurons. The external medium was exchanged using a fast-flow system.

whole-cell recordings from single autaptic cultured 'microdot' neurons. The external medium was exchanged using a fast-flow system.

[Ca]o-sensitivity of release was measured by varying [Ca]o from 0.5-10 mM in presence of 4 mM Mg. The Dose-response curves of the postsynaptic currents (PSC's) showed a similar sensitivity (ECso=3.29 vs. 3.31 mM) for EPSC/IPSC's respectively with a slope of 2.28 and 2.14. However, during presynaptic high frequency stimulation (10Hz, 10s, 4 mM Ca) EPSC's showed less depression than IPSC's: 38±25% vs 92±2%(n=18). In 1 mM Ca, EPSC were potentiated by 98±35%, whereas IPSC showed reduction of 52±8% (n=22).

Modulation of release by various neurotransmitter was tested. GABAb agonist baclofen (50 μM) inhibited both synapses (EPSC by 85.3±3%;n=22/IPSC by 81.6±5.1%;n=22), the metabotropic agonists DGGIV (2-5 μM) and (18.38) ACPD (50 μM) inhibited only EPSC's (29.9±6%,n=26). Noradrenergic receptors inhibited a subpopulation of excitatory neurons via α₂ receptors (41.7±6.5%; n=32), whereas inhibitory cells showed an enhancement or inhibition of the IPSC (161-10%). Muscarine (100 μM) showed for both synapses either inhibition or an enhancement of PSC's. Adenosine (50 μM) reversibly inhibited EPSC's (78.1±5.0%;n=21 vs. 7.8±14.2%;n=6). No modulation of vesicle pool size by modulators, as defined by the vesicle release by hyperosmotic solutions, was seen for Baclofen, (15-3R) ACPD, or Noradrenaline (n=10). These results suggest that inhibitory and excitatory synapses have similar Ca sensitivity during low frequency stimulation, but show different dependency on activity. Also, modulation of release is highly diverse between interneurons and principal cells in our preparation. C.R. is a Helmholtz fellow; C.A. is supported by the french government.

ENDOCYTOSIS FOLLOWING SINGLE DEPOLARIZATIONS IN BOVINE ADRENAL CHROMAFFIN CELLS. K.L. Engisch* & M.C. Nowycky. Dept. Neurobiol. & Anat., Med. Coll. Penn., Philadelphia PA

In the perforated patch recording mode, capacitance changes $(\Delta \mathbf{C}_m)$ due to exocytosis (membrane addition) and endocytosis (membrane retrieval) are highly reproducible. Here we examine endocytosis following ΔC_m jumps elicited by calcium entry during single step depolarizations. Under control conditions (5 mM CaCl₂), exocytosis evoked by 40 ms depolarizations was followed by endocytosis that essentially matched the amount of exocytosis in 13/31 cells (compensatory retrieval). In 18/31 cells, exocytosis evoked by a 40 ms depolarization was unaccompanied by endocytosis (no retrieval). In contrast, 320 ms depolarizations initiated endocytosis in 30/31 cells, and in 18/31 cells, the amount of endocytosis greatly exceeded the peak exocytotic increase in ΔC_m (excess retrieval 1,2). The decay in C_m during endocytosis could be fit with a single exponential ($\tau = 4.9 \pm 0.9 \text{ s}$, n = 11), or the sum of two exponentials (τ_1 = 508 ± 95 ms, τ_2 = 5.0 ± 0.5 s; n = 13; or τ_1 = 1.3 ± 0.2 s, $\tau_2 = 32.8 \pm 7.4 \text{ s}$, n = 8). A strong correlation exists between the presence of excess retrieval and a $\tau_1 < 1$ s following a 320 ms depolarization (10/14 cells). The kinetics of endocytosis observed here are remarkably similar to those described in whole cell recordings of melanotrophs 1 and calf adrenal chromaffin cells², suggesting that the underlying mechanisms of endocytosis are highly conserved. CALCIUM CURRENTS IN SYNAPTIC AND NONSYNAPTIC NEURITIC VARICOSITIES OF XENOPUS NERVE-MUSCLE CO-CULTURES. Robert E. Poage* and Stephen D. Meriney, Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Perforated patch clamp recording techniques were used to study Ca²⁺ currents in the varicosities formed by Xenopus laevis motor neuron neurites in culture. Neurites form varicosities (2-8 µm diameter) both at sites of muscle contact (synaptic) and at isolated points along the neurite (nonsynaptic). Whole cell currents recorded in 10 mM Ca²⁺ activated at about -20 mV and reached a peak at about +10 mV in both synaptic and nonsynaptic varicosities (Vhold = -60 or -80). Average Ca2+ current densities were $45\pm19~pA/pF$ at synaptic, and $41\pm12~pA/pF$ at nonsynaptic varicosities. Steady-state inactivation in varicosity recordings was estimated by from H-infinity plots, in which 50% current inactivation was achieved with a holding potential of approximately -30 mV. wConotoxin GVIA (1-2 μ M) blocked 57 \pm 7% of the peak I_{Ca} in synaptic varicosities and 52 \pm 14% in nonsynaptic varicosities. w-Aga-IVA (500 Ca2+ currents in both synaptic and nonsynaptic varicosities were similar and was carried by N-type channels, as well as others that are, as yet, uncharacterized. Since our study of nonsynaptic varicosities was restricted to neurites that made contact with target at another site (to ensure that these were cholinergic), it is possible that target contact by a neuron influences that expression of calcium current at all varicosities along the neurite -- including those that were not in direct contact with target. SIMULTANEOUS FLUOROMETRIC CALCIUM AND pH MEASUREMENTS IN BOVINE CHROMAFFIN CELLS. T.H. Müller Max-Planck-Institute for Biophysical Chemistry, Dept. of Membrane Biophysics, 37077 Göttingen, Germany.

Transient changes in intracellular Ca concentration induced by Ca

influx may also lead to corresponding changes in intracellular pH, since Ca ions are known to displace protons from many binding sites. In order to investigate the relationship between intracellular Ca concentration and pH, these two parameters were measured during voltage-clamp depolarisations causing influx of Ca into bovine chromaffin cells through voltage-gated Ca channels.

The whole-cell configuration of the patch clamp technique was used to load the cells with the fluorescent indicator dyes fura-2 and BCECF, sensitive for Ca ions and protons, respectively. A polychromatic light source was used to excite the dye mixture at different wavelengths and epifluorescence signals were recorded using a CCD camera system. An extension of the classical fluorescence ratio method was developed to separate pH and Ca signals. Both excitation and emission spectra of the individual dyes and the dye mixture were recorded from loaded cells to assess possible dye interactions.

Depolarisations caused a reduction in pH as well as an increase in Ca concentration. The time course of pH changes differed from those of Ca, the latter having a faster rise and decay. These correlated changes may be due to an exchange of Ca ions and protons with cellular compartments other than the cytosol.

THE ROLE OF N- AND P- TYPE CALCIUM CHANNELS IN REGULATING

THE ROLE OF N- AND P- TYPE CALCIUM CHANNELS IN REGULATING TRANSMITTER RELEASE FROM SYMPATHETIC VARICOSITIES OF THE MOUSE! VAS DEFERENS. D. K. Kim and N. A. Laydish Narcotics Research Laboratory. The Institute for Biomedical Research, Department of Physiology, The University of Sydney, N.S.W., Australia, 2006.

Evoked transmitter release from the sympathetic varicosities of the mouse vas deferens is highly dependent on extracellular calcium ([Ca²+]₀). Most spontaneous transmitter release is also dependent on [Ca²+]₀, with about 20% of the spontaneous release persisting in zero [Ca²+]₀. Of the 5 known voltage dependent calcium channels known only N- and P- type calcium channels have been shown to affect transmitter release at the sympathetic varicosities of the guinea-pig vas deferens (Smith & Cunnane, 1996, Neuroscience, 70: 817-824). In this study the effect of various calcium channel blockers on spontaneous and evoked transmitter release has been investigated in order to identify the types of voltage-dependent calcium has been investigated in order to identify the types of voltage-dependent calcium channels found on the presynaptic membrane of the sympathetic varicosities of the

mouse vas deferens.

Sympathetic varicosities were visualised using DiCO₂-fluorescence before Sympathetic varicosities were visualised using DiCO₂-fluorescence before placing an extraceflular electrode over small groups of varicosities to record both evoked (EJCs) and spontaneous excitatory junctional currents (SEJCs). N- type calcium channels were blocked with ω-conotoxin (ω-CTX) GVIA while P- type calcium channels were blocked ω-CTX MVIIA and L- type calcium channels with nifedipine, ω-CTX MVIIA (16nM) decreased evoked average EJC amplitude by 19.6±10.6% (n=5) and in one preparation there was no effect. ω-CTX GVIA (40nM) decreased evoked average EJC amplitude by 79±8% (n=6). Nifedipine (10µM) did not effect evoked EJC amplitude (n=3). SEJC frequency was not affected by any of the calcium channel blockers used.

These results indicate that evoked transmitter release is dependent on calcium

entry predominantly via N -type calcium channels and partly P- type calcium channels. Spontaneous transmitter release, although greatly reduced in [Ca²⁺]₀, is not affected by N-, P- or I- type calcium channel blockers.

PRESYNAPTIC NMDA RECEPTORS CONTROL PRESYNAPTIC CALCIUM Amanda J. Holt*, Neil E. Schwartz and Simon Alford Department. of

Physiology, Northwestern University Medical School, Chicago IL 60611.

The large reticulospinal axons of the lamprey have been shown to receive The large reticulospinal axons of the lamprey have been shown to receive glutamatergic and GABAergic depolarizing synaptic inputs recorded under whole-cell patch clamp. These inputs, whether evoked or spontaneous, are mediated by the activation of NMDA, AMPA and GABAA receptors located on the axons adjacent to their presynaptic elements. Evoked synaptic inward currents were blocked by 2-amino-5-phosphonopentanoate (APS-100µM), 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 10µM) and bicuculline (5µM). The glutamatergic component of this input showed a reversal potential close to zero (0.3±9.1mV; n=3) and the NMDA component was sensitive to the presence of Mg²⁺ in the superfusate. Inward currents were activated in the presence of tetrodotoxin (1µM) by application of AMPA or NMDA. To investigate if the synaptic activation of presynaptic glutamate receptors could alter presynaptic Ca²⁺ concentrations, the 3000 MW dextran-amine-conjugate of Calcium Green¹³⁴⁻¹ (5mM) was applied to the cut end of the spinal cord. Tissue was then maintained in vitro for 12 to 24 hrs to allow retrograde labeling of the extensions. Stimulus induced Ca²⁺ transients were readily observed in the axons with a confocal microscope following microstimulation of the spinal cord (5axons with a confocal microscope following microstimulation of the spinal cord (5-25 shocks at 50 Hz; 5-15µA). Risetimes to individual stimuli were faster than the 23 shocks at 30 H2, 3-13µA, Rischinds on individual stillnith weit aster than the sampling rate (8ms for a single line) and the response decayed to background following 5 shocks in approximately 1.5s. Washout of Mg²⁺ from the superfusate caused a significant increase in the amplitude of the evoked Ca²⁺ transient (increase to 152±7% of control responses; n=6; p<0.05). Addition of AP5 (100µM) to the to 1522/78 of common responses, 11–0, people, 2007. Admin of 172 (1004M) for the 27 people of 27 acting as autoreceptors at the output synapse of the axon. PRESYNAPTIC CALCIUM DYNAMICS AT A PLASTIC GLUTAMATERGIC SYNAPSE Neil E. Schwartz*, Amanda J. Holt and Simon Alford Department of Physiology, Northwestern University Medical School, Chicago IL 60611

Glutamatergic synapses between vestibulospinal and reticulospinal neurons in the lamprey brainstem show long-term potentiation (LTP) following tetanic stimulation of the vestibulospinal pathway. This LTP is prevented by bath application of the mGluR antagonist (R,S)-α-methyl-4-carboxyphenylglycine (MCPG; 500 µM) and requires a postsynaptic Ca²⁺ transient during LTP initiation. Calcium dynamics were investigated at both presynaptic and postsynaptic elements of this synapse. Postsynaptic neurons of the reticulospinal and presynaptic elements of the vestibulospinal systems were loaded with Calcium Green^{TM-1} by retrograde labeling following application of the 3000 MW dextran-amine-conjugate of the dye to the cut end of the spinal cord. During and following tetanic stimulation, a long-lasting Ca²⁺ transient was observed in both pre- and postsynaptic elements with similar decay times. The postsynaptic Ca²⁺ transient was markedly reduced by the application of the AMPA receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 10 µM) and the NMDA receptor antagonist 2-amino-5-phosphonopentanoate (APS; 100µM); the presynaptic Ca^{2+} transient was also depressed but to a lesser extent (to $82\pm6\%$ of control; p<0.05). In the presence of CNQX and AP5, MCPG (500 μ M; a dose sufficient to block LTP induction) caused a significant increase in the amplitude of the presynaptic Ca²⁺ transient (to188±22% of response in CNQX and AP5; p<0.001). However, increasing the dose of MCPG to 1mM reversed this effect. These concentrations of MCPG had no effect on the amplitude of EPSCs recorded in concentrations of MCPG had no effect on the amplitude of EPSCs recorded in reticulospinal neurons following either single shock stimulation of the vestibular tracts or repetitive stimulation. Additionally, in the lamprey spinal cord the mGluR agonists L(+)-2-amino-4-phosphonobutyric acid (L-AP4) and (1S.3R) 1-aminocyclopentane-1.3-dicarboxylic acid (ACPD) had no effect on the amplitude of voltage-gated Ca²⁺ currents. Bath application of quisqualate (5-100µM), in the presence of CNQX (10µM) and tetrodotoxin (1µM), to activate mGluRs caused a dose-dependent increase in presynaptic Ca²⁺. There may be at least two MCPG-sensitive presynaptic mGluRs at this synapse. Supported by NINDS grant # NS32114.

A SIMPLE MODEL OF CALCIUM DYNAMICS AND TRANSMITTER RELEASE FROM NERVE TERMINALS IN THE GUINEA PIG HIPPOCAMPUS.

P. Saggait* I. J. G. Wu and S.R. Sinha Division of Neuroscience, Baylor College of

P. Saggau*, L.-G. Wu and S.R. Sinha. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Most presynaptic terminals in the mammalian CNS are relatively inaccessible to direct investigation. We have overcome this limitation by using presynaptic calcium transients ($\{Ca^{2+}\}_{pre}\}$) optically recorded with either a high-affinity (fura-pt) or a low-affinity (fura-ptra) calcium indicator. A simple model of a mammalian presynaptic terminal was used to constrain several parameters involved with transmitter release and calcium dynamics in the presynaptic terminals of the Schaffer collateral-CA1 synapse in the guinea pig hippocampal slice. The model consists of concentric spherical shells with radial diffusion only. In addition to diffusion, the dynamics of Ca^{2+} binding to intrinsic buffers and to calcium indicators is also included. Transmitter release is modelled as a power function of $\{Ca^{2+}\}_{pre}$ and a saturable process with a finite number of release sites.

Model parameters were adjusted to fit the decay time course of the optically-recorded transients. This procedure indicated that the predominant intrinsic calcium buffer in these terminals is relatively slow (k_{ou} -10⁵/M sec). Both furaptra and fura-2 can be used to accurately measure the degree of nonlinearity between $(\text{Ca}^2)_{\text{pre}}$ and transmitter release. Thus, while fura-2 may be saturated by the local high $[\text{Ca}^{2+}]$ domains responsible for transmitter release, the volume-averaged fura-2 signal still accurately reflects relative changes in these domains. This places a further constrain on the system: the I_{Ca} evoked by a single action potential must be small enough that fura-2 is not saturated and can reflect changes in I_{Ca} . Putting this constrain on the model suggests that I_{Ca} will be on the order of 1 pA, which means that very few calcium channels (<10) are opened.

CORRELATION BETWEEN VESICULAR VOLUMES AND QUANTAL SIZE IN BOVINE CHROMAFFIN CELLS. M.I. Glavinović⁻¹, M.L. Vitale⁶ and J.-M. Trifaro⁶ Departments of Anaesthesia Research¹ and Physiology¹ McGill University, Montreal P.Q. H3G 1Y6 Canada and Department of Pharmacology² University of Ottawa, Ottawa Ont., K1H 8M5 Canada.

Attempts have been made long ago to measure the vesicular diameters from electronmicrographs of thin sections of secretory cells and to estimate the vesicular volumes and the concentration of the substances stored. Since the crossections of the vesicles do not occur exclusively over the largest diameter, but randomly, corrections were suggested to account for it (Coupland, Nature. 217, 384, 1966). In this study we estimated the probability of 'true' vesicular diameters (pdt) from crossectional vesicular diameters determined morphometrically from electron micrographs using Monte Carlo simulation that assumes random and uniform sections. Probability density function (pdf) of the 'true' vesicular diameters is calculated by adding ptds corresponding to each crossectional diameter. Pdfs of crossectional diameters of both adrenaline or noradrenaline secreting cells were skewed, thus not well described by a gaussian function. Basic parameters (means, coefficients of variation and skews) were greater for 'true' than for crossectional vesicular diameters, and for noradrenaline than for adrenaline secreting cells. The relationship between quantal size (determined from the areas underneath the spontaneous current spikes measured electrochemically) and vesicular volume is positive throughout, but becomes less pronounced at higher volumes suggesting that the internal concentrations are lower the greater the vesicular size. Thus vesicular volumes alone do not determine the vesicular contents. Binding capacity of chromogranin and/or ATP - probably plays a major role in determining the amount of catecholamine stored in the vesicle

SOURCES OF SYNAPTIC UNRELIABILITY INVESTIGATED WITH CALCIUM IMAGING IN CULTURED CORTICAL AND HIPPOCAMPAL NEURONS. P.J. Mackenzie* and T.H. Murphy. Kinsmen Lab, Dept. of Psychiatry. University of British Columbia, Vancouver. Canada V6T 1Z3

Changes in reliability at single CNS synapses may mediate various forms of neuronal plasticity. Potential presynaptic sources of variability in synaptic transmission include action potential generation and conduction, Ca^{2+} influx at release sites and vesicle trafficking. To evaluate presynaptic sources of unreliability, we have combined current-clamp recording and Ca^{2+} imaging. Single action potentials (APs) elicited at the soma were reliably conducted (>96% of 994 events) throughout the main axon and collaterals to trigger localized Ca^{2+} influx at all axonal boutons. We confirmed that boutons were functional release sites using FM 1-43, a marker of vesicular turnover. Although conduction was reliable, we observed small fluctuations in the Ca^{2+} transient (<20%) that could impact upon release, given a power relationship between Ca^{2+} transient observed to that expected for successful conduction. Four APs elicited at the soma (25 Hz) were reliably conducted throughout all axonal branches. At higher frequency (4 APs at 100 Hz), conduction was still reliable despite progressive decreases in the amplitude of the action potential during the train (in fact -10% facilitation of the Ca^{2+} transient was observed). Other sources of unreliability were apparent as differences in the magnitude of Ca^{2+} influx between release sites were observed. Preliminary data suggest a positive correlation between Ca^{2+} influx and FM 1-43 loading within a single axon. In conclusion, reliability within a single axon is not likely affected by AP conduction and may be influenced by observed fluctuations in the presynaptic Ca^{2+} transient and differences between boutons in Ca^{2+} influx or vesicle turnover. Supported by MRC of Canada and EHLB Foundation.

ACCOUNTING OF Ca²⁺ & Na⁺ IN PRESYNAPTIC AXON VARICOSITIES J.L. Winslow *1.2, R.L. Cooper², H.L. Atwood ^{1,2}. ¹Biomedical Eng., ²Physiology Dept. U. of Teronto, Toronto, Ont. M5S 1A8.

Toronto, Toronto, Ont. M5S 1A8.

Entry of Ca^{2+} via voltage-activated (Ca_V) channels normally triggers neurotransmitter release. Reconstructed serial electron microscope sections of presynaptic varicosities from crayfish opener muscle neuromuscular junctions show 30-50 synapses which each contain 0-5 active zones (AZs) where Ca_V channels are located.

To investigate the dynamics of ion accumulation during homosynaptic frequency facilitation, we developed a computational model in which concentrations of Ca^{2+} , Na^{+} , and Ca^{2+} buffers can be estimated within a whole presynaptic varicosity. Freeze fracture micrographs of crayfish presynaptic active zones, AZs, show prominent intramembrane particles which are thought to represent Ca_V and Ca^{2+} -activated K^+ channels, and thus provide an estimate of their densities.

estimate of their densities. The effects of numbers of active AZs per synapse and numbers of synapses per variocosity on total $[Ca^{2+}]_i$ and immobile buffer products were investigated. In long pulse trains, we found that $[Ca^{2+}]_i$ was a linear function of action potential frequency for moderate frequencies but non-linear for higher frequencies due to the change in Ca^{2+} equilibrium potential when $[Ca^{2+}]_i$ increases, and interaction of Ca^{2+} pumps. EVIDENCE FOR MULTIQUANTAL RELEASE AT THE HIPPOCAMPAL MOSSY FIBER SYNAPSE <u>D.A. Henze' and G. Barrionuevo</u> Department of Neuroscience and Center for the Neural Basis of Cognition, University of Pittsburgh, Pittsburgh, PA 15260.

We have previously shown that the large mEPSCs (>30 pA) that are observed in whole-cell recordings from CA3 pyramidal cells arise predominantly from the mossy fiber (MF) synapse (Henze et al., submitted). The largest of these mEPSCs can exceed 400 pA. In contrast, recordings from CA1 pyramidal cells reportedly fail to show mEPSCs with amplitudes greater than 30 pA (e.g.: Malgaroli and Tsien, 1992). We hypothesize that the mechanism that gives rise to the largest MF-mediated mEPSCs is the coordinated release of multiple quanta from the multiple release sites in the large MF bouton as seen at the electron microscopic level (Hamlyn, 1962).

Whole cell recordings (V_{met}= -80 mV) were obtained from CA3 pyramidal cells in hippocampal slices submerged in ACSF containing 1μM TTX and 10 μM bicuculline at 33°C. mEPSCs were collected in three minute epochs and analyzed using an algorithm which automated detection and amplitude measurements. Bath application of 1mM α-latrotoxin (LTX), which directly induces vesicular release, caused a 4.26 ±0.89 fold increase in mEPSC frequency while simultaneously shifting the cumulative probability histogram of amplitudes towards smaller amplitudes (n=5: p<0.05 K-5 test). This suggests that LTX's effects occur downstream of the mechanism which leads to the large MF mEPSCs. We then investigated whether release from intracellular Ca²*stores was the mechanism by which multiple vesicles could be synchronously released in a spontaneous manner. Bath application of 1μM thapsigargin (a Ca²*/ATPase inhibitor) caused a shift in the cumulative probability amplitude histogram towards smaller amplitudes (n=2/6). We conclude that multiquantal release occurs in the absence of antipules (n=2/6). We conclude that multiquantal release occurs in the absence of multiple vesicles. PRESYNAPTIC EFFECTS ON AMPLITUDE DISTRIBUTIONS OF RESPONSES TO ASYNCHRONOUS GABA-RELEASE EVOKED FROM A SINGLE PRESYNAPTIC NEURON *IN VITRO*. Jan C. Behrends and Gerrit ten Bruggencate*. Department of Physiology, University of Munich, 80336 München, Germany

The scope of the functional repertoire of single release sites during synaptic transmission is an unresolved matter but it has been proposed that postsynaptic responses at a given site are limited to vary between 0 and 1 quantum by either presynaptic (one vesicle-hypothesis) or postsynaptic (receptor saturation) constraints.

We have recorded inhibitory postsynaptic C1-currents during evoked synaptic transmission between pairs of GABAergic striatal neurons in cell culture under conditions where transmitter release was desynchronized by substituting SrC12 for CaC12 in the extracellular medium. A late ($\Delta t > 50$ ms) phase of the responses consisted of a succession of clearly discernible events with waveforms indistinguishable from ("quantal") miniature postsynaptic currents. Like miniatures, the asynchronous evoked events showed wide, positively skewed amplitude distributions ranging from -5 to >100 pA at -70 mV holding potential. This amplitude distribution was shown to be sensitive to manipulations known to affect the probability of transmitter release, such as variations in Sr²⁺-concentration or addition of the GABAB-receptor agonist baclofen (5-30 μ M): in addition to the expected changes in their frequency, significant (Kolmogorov-Smirnov-test) concurrent shifts in the amplitude distribution of asynchronous events were observed. These results suggests that, at the synapses studied here, the amount of transmitter released simultaneously determines the size of elementary responses underlying evoked synaptic transmission and that this quantity may express presynaptic changes in synaptic efficacy. Supported by the Deutsche Forschungsgemeinschaft (Grants Be-1739 and SFB 220 TP A1).

GIANT, TTX-INSENSITIVE, INHIBITORY POSTSYNAPTIC CURRENTS IN CULTURED NEURONS. C. A. Lewis* and D. S. Faber. Dept. of Neurobiology & Anatomy, Med. Coll. of Penn. & Hahnemann Univ., Philadelphia, PA 19129.

In whole-cell patch clamp studies on cultured rat embryonic spinal cord and medullary neurons, bathed in TTX, APV, and CNQX, large and long-lasting, spontaneous IPSCs (LIPSCs) were occasionally recorded. The amplitudes of these events were an order of magnitude larger than those of mIPSCs. Since these large currents had reduced amplitudes in Ca-free saline and in solutions containing glycinergic or GABAergic antagonists, we conclude that they were probably produced by large and prolonged release of glycine and/or GABA, which subsequently bind to their postsynaptic receptors.

The frequency of mIPSCs increased dramatically during the long, slow decay phase of these LIPSCs. Considering the requirement for extracellular calcium for the occurrence of these large responses, we hypothesize that this increased frequency reflected an increased intracellular [Ca⁺⁺] in the presynaptic terminal. Similar evidence for LIPSCs and prolonged transmitter release was observed in cell-attached patches which also exhibited the smaller, mIPSCs, suggesting that these large events are properties of single synaptic terminals.

Periodic large increases in the frequency of mIPSCs occurred in both cell-attached patches and in the whole-cell mode, and these increases were only sometimes associated with the LIPSCs. The rhythmicity in both recording configurations had similar temporal characteristics, with average interburst intervals of 5 and 12-14 s. Presumably these bursts of mIPSCs reflected periodic oscillations in the [Ca⁺] in presynaptic terminals.

Both the probability and the frequency of occurrence of LIPSCs doubled during the 7 day period of time in culture when experiments were performed, suggesting that these large currents may play a role during development.

RELEASE OF PEPTIDE AND CLASSICAL TRANSMITTERS WITH SINGLE ACTION POTENTIALS. M.D. Whim* and L.K. Kaczmarek. Dept. of Pharmacology, Yale University School of Medicine, New Haven, CT 06520-8066.

Studies in a variety of systems have led to the general formulation that the release of peptide transmitters requires high frequency firing. We have examined this question using <u>Aplysia</u> neuron B2 which synthesizes the small cardioactive peptides A and B (SCPs) and ACh (Lloyd et al, 1985). By culturing single B2 neurons with single pleural sensory neurons (SN) as post-synaptic detector cells, it has been possible to detect the release of the SCPs. In many experiments, a single pre-synaptic action potential was sufficient to induce a slow inward current in the SN. The inward current is likely to involve the release of the SCPs since application of exogenous SCPB to the SN evoked a current with a similar time course, conductance change and reversal potential to the synaptic current. Further, the synaptic current was not markedly affected by a cholinergic antagonist which blocked the effect of ACh on the SN. In contrast, when single B2 neurons were cultured in a soma-soma configuration with buccal neuron B3, single B2 action potentials evoked a rapid outward current in the post-synaptic B3 at a holding potential of -40mV. This outward current was blocked by application of d-tubocurare, reversed around -60mV, and was mimicked by the application of ACh but not the SCPs. The rapid outward current is therefore consistent with the release of ACh from B2. Thus the release of both classical and peptide transmitters from neuron B2 can be evoked with single action potentials. (Supported by NIH).

MOTONEURON NERVE TERMINAL POTASSIUM CURRENT IS PREDOMINATELY CALCIUM-DEPENDENT. John M. Pattillo* and Stephen D. Meriney. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

Calcium-dependent potassium channels have been localized to the active zone of adult frog neuromuscular junctions (Robitaille, et al,: Neuron, 11:645). Release of neurotransmitter following single action potentials has been shown to be potentiated by blockade of these channels with charybdotoxin, presumably due to an increase in calcium influx resulting from a widening of the presynaptic action potential (Robitaille and Charlton, J. Neuroscience, 12:297). To investigate the functional expression of calcium-dependent potassium channels in a nerve terminal, we used perforated patch techniques to measure calcium-dependent potassium current (I_{Kca}) in synaptic varicosities of Xenopus neuron-muscle co-cultures. I_{Kca} comprised a significant majority (60-75%) of the total potassium current in synaptic varicosities (evoked by step to 10mV, Vhold = -80mV). The activation of this current (time to 50% of peak) was approximately 1 ms. In contrast, our preliminary data suggests that IKCa makes up a minority of potassium current in the somas of motoneurons which innervate cocultured muscle cells. These data suggest that I_{Kca} is selectively expressed in nerve terminals. Further, Ikca was activated quickly by depolarization. Taken together, these data are consistent with a role for Ikca in regulating calcium influx and transmitter release following single action potentials. Supported by NIH NS32345

GATING OF RECOMBINANT A-CLASS CALCIUM CHANNELS DURING ACTION POTENTIAL-SHAPED VOLTAGE WAVEFORMS. David L. Brody' #,Terry P, Snutch and David T. Yue#. #Dept. of Biomedical Engineering, Johns Hopkins University, Baltimore, MD, 21205

Little is known about the physiological gating of voltage-gated calcium channels that trigger neurotransmitter release from presynaptic terminals for two reasons. (1) With a few exceptions, presynaptic terminals are not accessible to electrophysiological recording, and (2) unitary currents at physiological concentrations of calcium are too small to resolve clearly. We have approached these challenges by applying action potential-shaped voltage waveforms to recombinant A-Class (P/Q type) calcium channels expressed in HEK 293 cells and recording in 90 mM Ba++. We have carefully corrected for liquid junction potentials, and for the shift in voltage gating due to differential surface

charge screening between solutions containing 2 mM Ca++ and 90 mM Ba++ (+26 mV). Based on whole cell data there do not appear to be significant differences in gating other than this shift. Thus the single channel (middle) and whole cell (bottom) records shown in the figure are likely to accurately represent the gating of these channels to action potentials (top, similar to those recorded by Borst et.al at the Calyx of Held (*J Physiol*, **489**, 825-840.)) under physiological conditions. The inward current is extremely brief even at room temperature, activating and deactivating entirely within the <1 msec repolarizing phase of the action potential. Deactivation is nearly complete before the hyperpolarizing phase. Thus the temporal precision of the action potential seems preserved or even enhanced at the level of calcium influx. INFLUENCE OF DIFFERENT β SUBUNITS ON THE BIOPHYSICAL PROPERTIES OF THE HUMAN $\alpha_{1a,2}$ CONTAINING CALCIUM CHANNELS STABLY EXPRESSED IN HEK293 CELLS. A. Urrutia, M. Hans*, P. Brust. C.C. Lu, E.C. Johnson, M. Harpold and K. Stauderman. SIBIA Neurosciences, Inc., La Jolla, CA 92037.

The biophysical properties of recombinant human calcium (Ca^{**}) channels were studied in HEK293 cells stably transfected with cDNAs encoding full-length human α_{1A-2} and $\alpha_{2x0}\delta$ subunits together with the β_{1b} , β_{2e} , β_{3e} or β_{4e} subunit. Whole-cell recordings revealed that the magnitude of the voltage-activated barium (Ba^{2*}) currents varied with the coexpression of the different β subunit. The peak current amplitude was similar with β_{4e} and β_{2e} (1.5 ± 0.6 nA, n=14 and 1.3 ± 0.6 nA, n=6) and similar with β_{3e} and β_{1b} subunits (0.3 ± 0.1 nA, n=35 and 0.6 ± 0.5 nA, n=7). The voltage-dependence of channel activation was determined from tail-current analysis and could be described by a Boltzmann function with $V_{1/2}$ values varying between 9.4 mV (β_{1b}) and 19 mV (β_{3b}). The rank order for the rate of activation was $\beta_{3e} > \beta_{1b} \approx \beta_{2e} > \beta_{4e}$. The properties of current inactivation kinetics varied substantially with the different β subunits. Cells expressing β_{2e} and β_{3e} displayed bi-exponential inactivation with time constants ($\gamma_{1,7} > 0.6$ 44 ± 13, 30.1 ± 153 ms and 112 ± 37, 1200 ± 750 ms, respectively, while inactivation kinetics with β_{1b} and β_{4e} were mone-exponential with time constants of 347 ± 123 and 415 ± 80 ms. The rank order for the rate of inactivation was $\beta_{3e} > \beta_{1e} > \beta_{4e} > \beta_{2e}$. The noninactivating component with β_{1b} was substantially larger ($36 \pm 11\%$) than with the other β subunits (10-14%). The steady-state inactivation (n_{1e}) was determined using a 20 s test pulse. The $V_{1/2}$ for $v_{1e} > 0.6$ ms, respectively. The findings demonstrate that biophysical properties of calcium channels containing the α_{1A-2} subunit are critically dependent on the specific β subunit. The β subunits may also alter pharmacological characteristics of the channel (see Stauderman et al. this meeting).

A LONG-LASTING FACILITATION OF THE α_{1C} + β_{1b} CALCIUM CHANNEL. J. L. Costantin*¹, J. Zhou², L. Birnbaumer² and E. Stefani² ¹Dept. of Neurology, ²Dept. of Anesthesiology, UCLA School of Medicine, Los Angeles, CA 90024-1769

The α_{10} calcium channel expressed in *Xenopus* oocytes displays prepulse facilitation (Bourinet et al., EMBO J. 1994), that is dependent on the identity of the accessory B subunit that is coexpressed (Costantin et al., Biophysical J. A186, 1996; Cens et al., Pflugers Arch. 1996). We report here that coexpression of the β_{1b} or β_3 subunit causes a long-lasting facilitation that lasts for several seconds. The Figure illustrates currents after coexpression of the α_{1C} + β_{1b} subunit. The current during the second-pulse is elicited by a voltage step to +20 mV, and the prepulse is delivered between the holding potential (-90 mV), and +110 mV, in +50 mV increments. The current during the second-pulse is facilitated by 1.8 fold after an interval of two seconds between the first- and second-pulse. The long-lasting facilitation is not present in the α_{1C} channel when expressed alone, although a shorter-lived potentiation has been reported that decays on the order of milliseconds (Sculptoreanu et al, PNAS.,

ISOLATION, CHROMOSOMAL LOCALIZATION AND CHARACTERIZATION OF THE HUMAN N-TYPE CALCIUM CHANNEL a1B SUBUNIT GENE, D.S. Kim1,

CALCIUM CHANNEL α18 SUBUNIT GENE, D.S. Kim¹, H.H. Jung¹, S. H. Park². A. Thomas¹, and H. Chin.⁴¹¹Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892 and ²Dept. of Anatomy, Korea University College of Medicine, Seoul, Korea. ω-conotoxin-sensitive N-type calcium channels, unlike dihydropyridine-sensitive L-type channels, are exclusively expressed in nervous tissues. To understand the molecular basis for neuron-specific expression of the N-type channel, we have isolated genomic clones encoding human α18 subunit gene, localized to the short arm of chromosome 9 (9q34) by fluorescence in situ hybridization, and characterized its 5' upstream region. The promoter region of the human α18 gene is highly GC-rich, and lacks a typical TATA box but contains several consensus sequences for transcription of the human atB gene is highly GC-rich, and lacks a typical TATA box but contains several consensus sequences for transcription factor binding. Primer extension experiments revealed the presence of a major transcription start site located at -147 and a minor site located at -151. Transfection experiments using luciferase fusion gene constructs demonstrate that: 1) the 4.5-kb fragment of 5' upstream region is able to drive reporter gene expression in neuronal cells but not in nonneuronal cells, consistent with the endogenous α 18 gene expression, and 2) the region between -4500 and -1780 contains a repressor element(s) responsible for the neuron-specific expression of the N-type α 1B subunit gene. Gold particle-mediated transfer of truncated deletion α 1B - Green Fluorescent Protein fusion gene constructs into rat hippocampal slice cultures using a Biolistic apparatus further confirms the presence of important regulatory element(s) in the distal promoter region of the M1B gene

IMPORTANCE OF A B SUBUNIT FOR MEMBRANE ASSOCIATION AND EXPRESSION OF α1A AND α1E CALCIUM CHANNEL SUBUNITS N.L. Brice, G.J. Stephens, N. Berrow and A.C. Dolphin* Dept of Pharmacology, Royal Free Hospital School of Medicine, LONDON NW3 2PF. UK

Native voltage-dependent calcium channels are composed of at least three subunits, a pore-forming $\alpha 1$, a largely extracellular $\alpha 2\text{-}\delta$ and a cytoplasmic β subunit. Little is known about targeting the subunits to the plasma membrane. We have transiently expressed α1A and α1E, α2-δ and β1b either alone or in combination in COS-7 cells, and examined their distribution by confocal immunocytochemistry, in parallel with electrophysiological studies. When alA was expressed alone it showed no preferential localisation to the plasma membrane. In contrast, when $\alpha 1A$ was co-expressed with $\alpha 2-\delta$ and $\beta 1b$ there was clear membrane association, and this could be mimicked by β 1b alone, but not by α 2- δ . Similar results were obtained for expression of other β subunits. Electrophysiological recordings parallel the immunocytochemical results, in that IRa was rarely observed in α 1A or α 1A/ α 2- δ transfected cells, but was observed more frequently (4/22 cells with $\alpha 1A/\beta 1b$, or 44/90 cells with $\alpha 1A/\alpha 2-\delta/\beta 1b$). In contrast, when $\alpha 1E$ was expressed alone, or together with α2-δ or β1b, a similar proportion of cells (8/14, 10/16 and 6/11, respectively) expressed I_{Ba} . When all subunits were expressed a larger proportion of cells (10/12) expressed I_{Ba} . However, the amplitude of $\alpha 1 E$ and $\alpha 1E/\alpha 2$ - δ I_{Ba} was 10-fold smaller than current due to $\alpha 1E/\beta 1b$ or $\alpha 1E/\alpha 2$ δ/β1b. These data suggest that assembly of functional α1A channels in the plasma membrane of COS-7 cells only occurs significantly in the presence of \$1b, and whereas alE channels do assemble functionally in the membrane in the absence of a β subunit, this is significantly enhanced by β subunits.

Cloning of a calcium channel β subunit from the jellyfish Cyanea capillata. Michael C. Jeziorski*, Peter A.V. Anderson, and Robert M. Greenberg. The Whitney Laboratory, University of Florida, St. Augustine, FL

Voltage-gated calcium channels in vertebrates consist of a pore-forming α_1 subunit and several associated subunits $(\beta, \alpha_2 \delta, \text{ and sometimes } \gamma)$. Expression of channel subunits in Xenopus oocytes or other heterologous systems reveals that β subunits have profound effects on the kinetics of α subunits, and highly conserved regions within each subunit are involved in α .- β interaction. Although calcium channel subunits have also been cloned from dipterans, the degree to which calcium channel structure is conserved throughout metazoans is not fully understood. Cnidarians comprise the earliest existing species to possess differentiated tissues, and voltage-gated calcium currents have been identified in neurons of the scyphozoan jellyfish Cvanea capillata and in neural and muscle cells of other cnidarians. We have previously cloned a full-length cDNA from Cyanea encoding a homologue of L-type calcium channel α_1 subunits. Using RT-PCR with degenerate oligonucleotide primers, combined with cloning techniques to extend cDNA sequences, we have now isolated a full-length clone from Cyanea encoding a homologue of a calcium channel β subunit. The cDNA encodes a protein of 457 amino acids that exhibits 47-54% identity to insect and vertebrate β subunits, but is most conserved within the region implicated in interaction with α_1 subunits. (Supported by NRSA grant MH 10625 to MCJ.)

495.6

COMPARISON OF PROPERTIES OF CLONED a1A AND a1E CALCIUM CHANNELS TRANSIENTLY EXPRESSED IN THE COS-7 CELL LINE. G.Stephens, N.Berrow, J.R.Burley, K.Page, I.Tedder, E. Fitzgerald* and A.C.Dolphin Dept of Pharmacology, Royal Free Hospital School of Medicine, LONDON NW3 2PF, UK

The rat calcium channel clones α1A and α1E were expressed in COS-7 cells together with the accessory subunits β1b and α2-δ. Transfected cells were identified by co-expression of cDNA for the reporter Green Fluorescent Protein. Voltage dependent calcium currents were observed between 24 and 72 hours after transfection with the three calcium channel subunits. The current density for the combination $\alpha 1A/\alpha 2-\delta/\beta 1b$ was lower than that for $\alpha 1E/\alpha 2-\delta/\beta 1b$ and the former combination produced a more slowly inactivating current (τ_{inact} 332 \pm 46ms (n=5) at +20mV and 124 ± 13ms (n=5) at -20mV respectively). Tail current deactivation at -80mV was slower for $\alpha1E$ than $\alpha1A$ (τ_{deact} 0.76 \pm 0.06ms (n=4) and 1.28 \pm 0.08ms (n=5) respectively). The voltage-dependence of activation and steady-state inactivation were more depolarised for α1A than for α1E by 25 and 30mV respectively, under the same conditions. Both currents were completely blocked by 100μM Cd2-, whereas only α1A currents were blocked by ω-conotoxin MVIIC (up to 1μM). Dose-response curves for ω-agatoxin IVA revealed K_D values of approximately 11 and 51 nM for α 1A and α 1E currents respectively, but the rate of block of α1E currents was much slower. α1E current was substantially (74 ± 8 %) (n=3) inhibited by the 1,4-dihydropyridine antagonist nicardipine (1μM).

The results suggest that al A expressed in these cells has a greater resemblance to the P type than the Q type component of calcium current in native neurons Although $\alpha 1E$ has some similarities with slowly inactivating central T type currents. the pharmacology and biophysical characteristics of αIE currents do not completely fit any endogenous calcium current component presently identified.

MOLECULAR CHARACTERIZATION OF CALCIUM CHANNELS IN SMALL-CELL LUNG CANCER CELLS. Y.I. Kim, C.E. Davis, J.J. Pancrazio* Departments of Biomedical Engineering, Neurology and and L. Mei. Pharmacology, University of Virginia School of Medicine, Charlottesville, VA

To determine whether the putative P-type calcium channel is expressed in the small-cell lung cancer (SCLC) cells and its level of expression, we have attempted to characterize Ca2+ channel \alpha-subunits from H146 SCLC cells using a molecular biology approach. First strand cDNA was produced from SCLC RNA to be used as a template for a PCR reaction. Primers were chosen in the region of the α -subunit conserved among P-, N-, and L-type Ca²⁺ channels; the sense primer encoding WNI(V)FDF: 5'-CGC GAA TTC TGG AA(C.T) (A,G)T(A,C,G,T) TT(C,T) GA(C,T) TT and the antisense primer encoding VIMDNF: 5'-CGC GGA TTC (A,G)AA (A,G)TT (A,G)TC CAT (A,G,T)AT (A,C,G,T)AC. The size of the PCR products was ~500 bp, as predicted for DNA fragments between the primers of previously characterized calcium channel α-subunits. Furthermore, these products hybridized with the ³²P-end-labeled degenerate oligonucleotide 5'-TGC CA(A,C,G,T) GC(C,T) TC(A,C,G,T) CC(A,C,G,T) GT(A,C,G,T) GC (antisense) encoding ATGEAWQ(H) derived from the amino acid residues between the two primers. Following subcloning of the PCR products, DNA sequencing showed that they encoded a fragment of polypeptide characteristic of α-subunits of calcium channels. Most significantly, all eight clones that had been analyzed by DNA sequencing appeared to encode a single polypeptide which is 91.5% homologous to the Bl-2 (P-type) calcium channel (FEBS, 308: 7-13, 1991). These results suggest that P-type calcium channel may be predominant in SCLC consistent with electrophysiological properties of the calcium channels in SCLC cells (J. Physiol., 488: 303-317, 1995) (Supported by grants from NIH and MDA).

USE OF TRUNCATED AND CHIMAERIC FORMS OF THE $\alpha \mathbf{1}$ AND B SUBUNITS TO STUDY THE VOLTAGE DEPENDENT FACILITATION OF L-TYPE CA CHANNEL. P. Charnet*, T. Cens, A. Valentin, C. Dalle, and J. Nargeot CRBM CNRS UPR 9008 Montpellier France F 34033

L-type Ca currents recorded from Xenopus oocytes injected with the α_{IC} and β_{Ib} subunit cDNAs can be potentiated by strong predepolarisations [1]. We have recently shown that this form of facilitation was not recorded with Ca channels encoded by the α_{1A} , α_{1B} , or α_{1E} subunits. Moreover we have demonstrated that this facilitation required the co-expression of a "permissive" β subunit $(\beta_1, \beta_3 \text{ or } \beta_4)$, since coexpression of the β_2 subunit did not allowed this potentiation [2]. To further identify the molecular determinants of this voltage-dependent facilitation we have constructed N- and C-termini deleted forms of the $\beta_1,~\beta_2$ and α_{1C} subunits and tested their effects on control Ca currents and Ca currents recorded after positive predepolarisations.

Our results suggest that removal of the first 215 amino acid of the β_{1b} subunit and the last 212 amino acids on the β_2 subunit did not change their ability to induce facilitation.

FUNCTIONALLY DISTINCT ISOFORMS OF THE Ca CHANNEL α_{18} SUBUNIT ARE EXPRESSED IN RAT SYMPATHETIC NEURONS. Zhixin Lin, Stephanie Haus, Edward Hawrot' & Diane Lipscombe. Depts. of Neuroscience & Mol. Pharm. & Biotech., Brown Univ., Providence, RI 02912.

We show that multiple isoforms of the Ca channel α_{1B} -subunit, which differ in their activation and inactivation kinetics, are expressed in rat sympathetic neurons. Our cDNA analysis revealed the presence of three potential splice sites characterized by localized sites of sequence deletions or insertions (±A at pos.415, ±SFMG at 1236-, ±ET at 1559-), each of which has been reported in at least one other mammalian α_{1B} clone. In addition, ~10% of α_{1B} clones were characterized by a ~2.5 kb truncation in the 3'UTR. Restriction digest analysis of RT-PCR-derived cDNAs, obtained using several primer pairs and rat sympathetic mRNA, indicated the following composition of the cDNA pool: +A(~50%), -A(~50%); +SFMG (~30%), -SFMG (~70%); +ET (~80%), -ET (~20%). RNase protection analysis confirmed a predominance of α_{1B} sequences lacking SFMG (70%) in sympathetic ganglia and also showed that, in contrast, in brain the $\alpha_{\rm IB}$ isoforms containing the SFMG site predominate. This was true for both adult and new-born brain. Heterologous expression of clones $rscg\alpha_{1B-b}$ (+SFMG/-ET) and $rscg\alpha_{1B-d}$ (-SFMG/+ET) in frog oocytes revealed statistically significant functional differences in the kinetics of channel gating. The activation and inactivation kinetics of $rscg\alpha_{IB-d}$ currents were significantly faster than those of $rscg\alpha_{IB-d}$. The time to peak, following a step to 0 mV, was 22.0 ± 1.0 ms (n=7) for rscg α_{1B-1} currents, compared to 57.8 ± 9.2 ms (n=6) for rscg α_{1B-1} _b. Likewise, the rate of activation of rscg α_{1B-4} currents was 2-fold faster (2.7 ±0.4 ms, n=5) at 0 mV compared to $rscg\alpha_{iB-b}$ (5.0 ± 0.4 ms, n=4). Expression of multiple isoforms of α_{1B} could account, at least in part, for kinetically distinct N-type channel currents seen in recordings from native cells. NIH NS2996.

DIFFERENT SPATIAL PROFILE OF INTRACELLULAR CALCIUM TRANSIENTS AND FLUORESCENT DIHYDROPYRIDINE BINDING IN RELAY CELLS AND LOCAL INTERNEURONS FROM THE RAT DORSAL LATERAL GENICULATE NUCLEJS T. Budde*, T. Munsch, H.-C. Pape. Institut für Physiologie, Otto-vonGuericke Universität, D-39120 Magdeburg, Germany.

The different subtypes of voltage activated calcium (Ca2+) channels (VACC) serve distinct roles in excitation and signaling of thalamic neurons. The subcellular distribution of two types of VACC, the low voltage activated (LVA) and he high voltage activated (HVA) Ca²⁺ current seems to be critical for the electrical properties of thalamic neurons. We used fluorescence imaging of Fura-2 in combination with the whole-cell patch clamp technique to investigate the subcellular distribution of LVA- and HVA-activated Ca²⁺ channels in relay cells and local interneurons of the dorsal lateral geniculate nucleus (dLGN). Cells were visually identified by infrared videomicroscopy. Selective activation of LVA or HVA Ca²⁺ currents by appropriate voltage protocols caused transient changes in the intracellular Ca²⁺ concentration in soma and dendrites of relay cells and local interneurons. However, the amplitudes of these Ca^{2^+} transients were characteristically different in varying regions of the two cell types. In relay cells, LVA Ca^{2^+} transients slightly decreased from soma (100%) to dendrites, whereas HVA transients were strongly reduced (38±19%, n=15). In contrast, the LVA transients in interneurons strongly increased from soma to dendrites (219±124%, n=8) and the HVA transients were only slightly reduced. We also used the fluorescent Ca^{2^+} channel probe STBodipy-DHP (fDHP) to investigate the subcellular distribution of L-type Ca^{2^+} channels. Fluorescence labelling after 1 h incubation with 25 μ M fDHP was highest in the soma and the proximal dendrites. This selective labbeling could be blocked by preincubation with BAYK 8644 (50 μ M). The data suggest that the subcellular distribution of low- and high-voltage activated Ca2+ channels is not homogeneous and different in dLGN relay cells and local interneurons, which may be important for their specific functional role. Supported by the DFG (H.-C.P.) and the Helmholtz program (T.B.).

DENDRITIC T-TYPE CA2+ CHANNELS ON PURKINJE CELLS IN CEREBELLAR SLICE CULTURES.

D. Mouginot, J. L. Bossu and B. H. Gähwiler*. Brain Research Institute,

University of Zurich, CH-8029 Zurich, Switzerland
The presence of low-threshold-activated Ca²⁺ channels was investigated in Purkinje cells (PCs) in rat cerebellar slice cultures, using both the wholecell and the cell-attached recording configurations of the patch-clamp technique, and Ca2+ ions as the charge carrier. A low-threshold fastinactivating Ca^{2+} current could be recorded in isolation either after rundown, or pharmacological block of P/Q-type Ca^{2+} currents. The Ca^{2+} current had a threshold for activation of -60.3 \pm 1.1 mV, and reached a maximal amplitude (-0.69 \pm 0.08 nA) at -33 \pm 1.7 mV. The decay time constant decreased from 25 ms at -60 mV to 15 ms at -30 mV, and both steady-state activation and inactivation were described with Boltzmann equations, with half activation and inactivation of -51 and -86 mV, respectively. The ${\rm Ca}^{2^+}$ current was nifedipine insensitive, but its amplitude was reversibly reduced by NiCl₂ (19 \pm 3%) and amiloride (53 \pm 4%). Cellattached recordings revealed a corresponding ensemble Ca2+ insensitive to P/Q-type Ca²⁺ channel blockers. The ensemble Ca²⁺ current activated at +10 mV relative to the resting potential (RP), and reached a maximal amplitude (-7.9 ± 2.1 pA) at +43 mV relative to RP. Channels giving rise to this channel activity had a conductance of 7 pS and were preferentially located on the dendrites.

N-TYPE Ca CHANNELS MEDIATE THE EGF-INDUCED STIMULATION OF Na CURRENT DENSITY IN PITUITARY GH3 CELLS. E. Monjaraz, A. Navarrete and G. Cota*. Dept. of Physiol., Biophysics, and Neuroscience, Cinvestav, Mexico City, DF 07000.

We previously showed that chronic exposure of GH3 cells to epidermal growth factor (EGF) stimulates high-threshold Ca current density. EGF-treated cells also exhibit an enhanced level of Na current expression. Here, we provide evidence that the latter effect is secondary to the influx of Ca through newly expressed N-type Ca channels. GH3 cells were grown under standard conditions (control cells) or in the presence of 5 nM EGF, 5 μ M nimodipine, 0.2 μ M ω-Aga-IVA, 3 μM ω-CTx-GVIA, or a combination of EGF and a Ca channel blocker. On day 5, EGF and the Ca channel blockers were removed from the culture medium. Subsequently, after a recovery period of 60 min, the cells were subjected to whole-cell patch clamp recording to evaluate peak Na current density at +10 mV (HP -80 mV). Relative to its control value, Na current density increased by a factor of 1.8 in cells exposed to EGF alone, and decreased by half in cells treated only with nimodipine, as reported previously. The stimulatory effect of EGF was unaffected by the continuous presence of ω-Aga-IVA, but was completely blocked by ω-CTx-GVIA. Cells treated with EGF and nimodipine behaved almost as control cells. Finally, neither ω -Aga-IVA nor ω-CTx-GVIA, given alone, were able to induce a significant change in Na current density. Thus, the functional expression of Na channels in GH3 cells is normally sustained by L-type Ca channel activity, but depends on both L-type and N-type Ca channels after EGF treatment. Supported in part by the HHMI.

 $\alpha_{\mbox{\scriptsize 1A}}\mbox{-TYPE}\mbox{ }Ca^{2+}$ Channel mrna and protein are differentially REGULATED BY MELANOTROPE DOPAMINE RECEPTOR STIMULATION P. Sharma J. S.A. Sands J. D.M. Beatty J. K.E. Hagler J. W.Smith J. S.G. Volsen R. R. Sands J. D.M. Beatty J. K.E. Hagler J. W.Smith J. S.G. Volsen Rev. Rev. Lett. 10 (1988) 10 Baker*2. S.J. Morris1 and B.M. Chronwall1. School of Biological Sciences1, University of Missouri-Kansas City, Lilly Research Centre², Windlesham, Surrey, UK.

Melanotopes of the rat pituitary intermediate lobe are tonically inhibited by dopamine axons emanating from hypothalamic neurons. This effect is mediated by dopamine D2 receptors. Chronic stimulation of D2 receptors decreases the rise in intracellular Ca^{2+} on K+ depolarisation in melanotopes (Beatty et al.,1995: Osipenko et al 1994). P-type Ca^{2+} channels, encoded by the α_{1A} gene have been pharmacologically identified in melanotropes (Beatty et al., 1995) of the distribution of the distribution of the distribution of the distribution of the distribution of the distribution pattern and D2 receptor immunoreactivity. Here we report the distribution pattern and D2 receptor regulation of α_{1A} mRNA and protein in the pituitary intermediate lobe in vivo. In situ hybridisation using digoxigenin labelled oligonucleotide probes demonstrate that α_{1A} mRNA was heterogeneously distributed. By densitometry, comparable central sections of individual melanotropes ranged from 0.15-0.90 OD units, with 20-30% of the cells expressing high levels of mRNA. Likewise, immunoreactivity for the protein subunit was distinctly more intense in some melanotropes. Chronic treatment (14d) with the D2 receptor agonist bromocriptine, differentially regulated the $\alpha_{\mbox{\scriptsize 1A}}$ channel mRNA and protein levels. Overall measurements indicated that the protein immunoreactivity decreased whereas the mRNA level increased. Possibly, in vivo down regulation of the α_{IA} channel protein triggers compensatory mechanisms which may lead to reduced degradation or upregulation of the mRNA without affecting protein translation. These results indicate that the P channel is among several melanotope proteins controlled by the D2 receptor.

THE EXPRESSION OF VOLTAGE-DEPENDENT CALCIUM CHANNEL B SUBUNITS IN HUMAN CEREBELLAR PURKINJE CELLS

S.G. Volsen 1, N.C. Day 2, A.L. McCormack 1, R. E. Beattie 1, P.J. Craig 1, P.Ince², P. J. Shaw², I. A Pullar*¹, M. Williams³, M.M Harpold ³ and W. Smith 1. Lilly Research Centre, Windlesham, Surrey UK 1; MRC Neurochemical Pathology Unit, Newcastle Upon Tyne, UK²; SIBIA Neurosciences Inc. La

Purkinje cells are of particular interest in the study of native VDCCs, since the majority of their somatic whole cell calcium current is of P type. Whilst α_{1A} remains the strongest candidate for the pore forming subunit of the P channel, the nature of the associated B protein is not known. To help address this issue, we have prepared both class specific riboprobes and polyclonal antisera to human \$1, \$2, \$3 and \$4 subunits and used them in parallel in situ mRNA hybridisation and immunohistochemical analyses of human cerebellar Purkinje cells. Detailed serial section studies demonstrate that each class of B subunit may be found in single Purkinje cells and their subunit proteins are distributed into specific subcellular domains. For example, \$1, \$2, \$3 and \$4 proteins all produce punctate immunohistochemical staining in the Purkinje cell soma, making the identification of the ß subunit specifically associated with the P channel difficult. However, 83 alone is expressed preferentially in the fine Purkinje cell dendritic arbor where its distribution is identical to α_{IE}

CLONING AND EXPRESSION LOCALIZATION OF CDNA FOR A RAT HOMOLOGUE OF TRP PROTEIN, A POSSIBLE STORE-OPERATED CALCIUM CHANNEL. M. Funayama, K. Goto* & H. Kondo Dept. of Anatomy, Tohoku Univ. Sch. of Med., Sendai, 980 Japan

TRP encoded by a Drosophila trp (transient receptor potential) gene is considered to represent the store-operated Ca²⁺ channel. We cloned 3.2kbp cDNA encoding a potential jegne is considered to represent the storeoperated Ca²⁺ channel. We cloned 3.2kbp cDNA encoding a
possible mammalian candidate for the store-operated Ca²⁺
channel because of high homology to a Drosophila trp
(transient receptor potential) gene from a rat brain cDNA
libraty. The deduced amino acid sequence was 51.8% identical
to TRP and contained ankyrin motifs, a coiled-coil structure
and six transmembrane segments similar to the previously
identified TRP family and named as TRP-R (rat TRP). Northern
blotting detected distinct hybridization signal only in the
brain among various tissues of adult rats. By in situ
hybridization histochemistry on embryonic day 15, no
significant expression signals for TRP-R was detected in a
whole body of rats. On embryonic day 20 and postnatal day 1,
the expression signals were most evident in the septum,
cerebral cortical plate and hippocampal neuronal layers. On
postnatal day 7 and thereafter the expression in the
cerebral cortex and the septum decreased progressively, and
weak expression was remained only in the septum and CA1 and
CA2 neuronal layers of the hippocampus in the brain on
postnatal day 21 and 49. This limited spatiotemporal
expression of this novel molecule suggests that this novel
molecule, TRP-R, is involved in some specific functions
related to the neuronal differentiation.

DOPAMINERGIC REGULATION OF Ca^{2+} CHANNEL α_1 SUBUNIT GENE EXPRESSION IN THE NEUROINTERMEDIATE LOBE OF THE RAT PITUITARY. D. M. Fass*¹, K. Takimoto², & E. S. Levitan.¹². Departments of Neuroscience and Pharmacology², University of Pittchyung. Pittchyung. Ph. 1860. University of Pittsburgh, Pittsburgh, PA 15260.

The dopaminergic input to melanotrophs of the intermediate

lobe of the rat pituitary may inhibit secretion in part by supressing Ca²⁺ channel gene expression. To test this hypothesis, female rats (200-224 g) were treated with dopaminergic agents (the agonist bromocriptine or the antagonist haloperidol--each at 5 mg/kg, IP promocriptine or the antagonist haloperidoi-each at 5 mg/kg, IP injections) to act at D2 receptors for 6 h (one injection) or 30 h (three injections at ~10 h intervals). Total RNA was isolated from neurointermediate lobes and Ca^{2+} channel α_1 subunit mRNA levels, were measured by RNase protection assays. In control animals, we detected α_{1A} and α_{1D} mRNAs. After 6 h, haloperidol increased α_{1D} mRNA levels but had no effect on α_{1A} mRNA levels (n = 2, 6 animals per group). In contrast, bromocriptine decreased α_{1D} mRNA levels (n = 2, 6 animals per group). 30 h treatments produced similar changes in α_{1D} mRNA levels (n = 1, 4 animals per group, α_{1A} mRNA levels were not tested). These data support the hypothesis that α_{1D} mRNA levels are suppressed in vivo in rat melanotrophs by dopamine.

INOSITOL TRISPHOSPHATE AND RYANODINE RECEPTORS IN HUMAN PURKINJE CELLS DURING DEVELOPMENT. N.Zecevic and B.E.Ehrlich*, University of Connecticut, Farmington, CT 06030.

Two receptors regulate release of Ca from internal stores in the cell: inositol trisphosphate (IP3R) and ryanodine (RyR). Changes in intracellular Ca influence cellular development and synaptic plasticity in the CNS. In order to define the timing for the initial expression of these receptors in Purkinje cells of the human cerebellum, we studied 13 human fetuses from 6 to 32 gestational weeks (g.w.) using immunocytochemical methods. Anti-IP3R and anti-RyR antibodies were applied to 14µm frozen sections of fetal brains. A defuse staining was first observed at 11 g.w. for IP3R and at 13 g.w. for RyR in the intermediate zone where Purkinje cells were migrating. At 17-18 g.w. a positive reaction with both markers was found below the molecular layer, in the Purkinje cell layer which was several cells thick. At 27 and 32 g.w. immunoreactivity for both markers was present in Purkinje cells which were now aligned in a single layer with the dendritic tree expanding into the molecular layer. In this study the IP3R was observed earlier than the RyR. In human cerebellum the appearance of these receptors correlates well with cellular maturation and synaptogenesis of Purkinje cells (Zecevic and Rakic, 1976, Yachnis et al., 1993). Supported by NIH grants MH53945 (NZ) and GM51480 (BE).

POTASSIUM CHANNELS: STRUCTURE AND FUNCTION

496.1

IDENTIFICATION OF MYSTERY, A NOVEL PUTATIVE K CHANNEL IN MAMMALIAN BRAIN. W. J. Joiner#+, L. Gan#*, M. D. Tang#!, and L. K. Kaczmarek#. Departments of Cellular and Molecular Physiology and Pharmacology, Yale University School of Medicine, New Haven, CT 06520.

By exploiting the rapidly expanding database of expressed sequence tags and genomic DNA fragments within Genbank we have identified more than 40 novel genes in both prokaryotes and eukaryotes that we believe are members of the K channel superfamily. Here we report the cloning of one of these, which we call the mystery channel, from mammalian brain. Like many other K channels, mystery appears to have 6 potential transmembrane domains and a conserved hydrophobic P-like domain that falls between putative transmembrane domains 5 and 6. However, mystery differs greatly in primary sequence from other 6 transmembrane domain K channels such as the Kv, eag, and slo families. The apparent paucity of charged residues within mystery's presumed S4 domain, which in other 6 transmembrane domain channels is thought to serve as part of a voltage-sensing apparatus, suggests that mystery might serve a role distinct from the rapidly repolarizing currents generated by other K channels displaying a similar predicted topology

IDENTIFICATION OF A NOVEL KVLQT1-LIKE GENE (KL1) M. D. Tang#+ and L. K. Kaczmare! **
Dept. of Cellular and Molecular Physiology and Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT

A combination of traditional and computer-based screening techniques was used to identify a gene from rat brain (KL1). KL1 shares significant sequence similarity (approx. 70%) with the recently partially cloned KvLQT1 gene, implicated in Long-QT Syndrome and highly expressed in heart and kidney. As is the case for cloned Shaker-type K channels, KL1 has 6 putative transmembrane domains and charged amino acid residues in the predicted S4 domain. Unlike KvLQT1, however, KL1 does not possess a long C-terminus.

SEVEN K+ CHANNEL FAMILIES REVEALED BY THE C. ELEGANS GENOME SEQUENCING PROJECT. A. Wei*, T. Jegla and L. Salkoff. Department of Anatomy and Neurobiology, Box 8108, Washington University School of Medicine, Saint Louis, MO 63110.

The wealth of accumulating data from the Caenorhabditis elegans genome sequencing project has rapidly accelerated the discovery of novel potassium channel genes and now places within reach the possibility of describing the total complement of potassium channels used by an individual Using annotated GenBank sequences, BLAST searches of unfinished sequences, and degenerate oligonucleotide PCR screens, we have identified and compiled genes for 31 C. elegans potassium channels and 2 cyclic nucleotide-gated cation channels, representing seven groups of Several novel families of channels were conserved multigene families. revealed, as well as conserved homologues of all known vertebrate families of potassium channels. Present were direct C. elegans homologues of two human potassium channels recently implicated in hereditary long QT arrhythmias. The genes are evenly distributed on all six C. elegans chromosomes, with two instances of gene clustering on the X chromosome. Of particular note is an exceptionally large class of at least 17 genes with a novel subunit structure having two tandem "P" domains; these channels may form dimers in contrast to all other types which form tetramers. Initial reports suggest that these C. elegans potassium channel genes will have mammalian homologues (Lesage, et al., 1996) and may thus represent new conserved potassium channel gene families.

BIOCHEMICAL CHARACTERIZATION OF MOUSE BRAIN GIRK1-GIRK2 PROTEIN COMPLEX. A. Inanobe¹, K. Morishige² and Y. Kurachi¹. ¹Department of Cell Biology and Signaling, Yamagata University School of Medicine. Yamagata, 990-23, Japan, and ²Department of Pharmacology II, Faculty of Medicine. Osaka University, Osaka, 565, Japan.

GIRK1 (Kir3.1) and GIRK2 (Kir3.2) belong to the same subfamily of inwardly rectifying K+ channels. Because the expression pattern of GIRK1 mRNA overlapped with that of GIRK2 in brain, it is speculated that some of the brain G protein-gated muscarinic K+ channels are heteromeric complexes composed of GIRK1 and GIRK2 proteins. No experimental evidence has been, however, provided so far. To examine this possibility with biochemical approach, antibodies against peptides corresponding to sequences of GIRK1 and GIRK2 were developed (anti-GIRK1C1 and anti-GIRK2C5, respectively). Each antibody specifically recognized a single band of membrane proteins of mouse forebrain on SDS-PAGE. The immunoprecipitant of each antibody from membrane proteins extracted with Triton X-100 were composed of several different proteins. In the immunoprecipitant of anti-GIRK2C5, GIRK1 protein was detected by anti-GIRK1C1, and vice versa. In immunohistochemistry, both GIRK1 and GIRK2 immunoreactivities were localized to the similar presynaptic regions in rat VTA. Almost only GIRK1 immunoreactivity was detected in PVN, while GIRK2 immunoreactivity was abundantly observed in the reticulum of SN. These results strongly support the notion that GIRK1 and GIRK2 physiologically form a channel complex in some specific regions of the brain

INTRODUCTION OF NOVEL DISULFIDE BONDS AND HIGH-AFFINITY METAL BINDING SITES INTO A K CHANNEL PORE. H.S. Krovetz, H.M.A. VanDongen, A.M.J. VanDongen.* Department of Pharmacology, Duke University Medical Center, PO Box 3813, Durham, NC 27710.

Voltage-dependent K channels consist of four identical subunits surrounding a central pore. Each subunit contains six putative transmembrane segments, S1-S6. The linker region between the S5 and S6 transmembrane segments forms a hairpin loop that lines the external vestibule and the narrow part of the pore. In order to obtain structural information on the pore region we have introduced novel disulfide bonds and high-affinity metal binding sites by cysteine substitution mutagenesis. Individual replacement of 1379 and Y380 with cysteine resulted in an enhanced block by Cadmium (IC50 = 26 uM and 256 uM , resp). A potassium-selective binding site was detected that affected the apparent Cd^{2+} affinities of the 1379C and Y380C mutants. The double mutant (GYGDIYP => GYGDCCP) resulted in the spontaneous formation of novel disulfide bonds, which obliterated channel function. Breaking these disulfide bonds with dithiothreitol restored function. This reduced channel displayed an extreme sensitivity to cadmium (IC50 = 20 nM). Dimeric constructs were used to demonstrate that the disulfide bond and the high-affinity metal binding site are formed by cysteines at position 379 and 380 in neighboring subunits. Taken together, these data put narrow constraints on several distances in the entry to the narrow part of the pore. The geometry is more consistent with a radial pore model than with either the eight-stranded barrel or the newer

CLONING AND CHARACTERIZATION OF A KIR3.1 (GIRK1) C-TERMIAL TRUNCATED SPLICE VARIANT

C.S. Nelson* and C.N. Allen CROET, Depts. Psychiatry & Physiology

Pharmacology, OHSU Portland, OR 97201.
Southern blot analysis of RT-PCR products from rat heart and hypothalamus revealed multiple products for a C-terminal region of Kir3.1. nypotnatantus reveated multiple products for a C-terminal region of Kirs.1. Sequencing yielded clones for wild type and a putative splice variant with a predicted translation for C-terminal truncation. A second round of RT-PCR yielded identical overlapping products from rat heart, hypothalamus and human heart. Expression in Xenopus oocytes of a full length construct coding for the truncation variant (Kirs.1.0) showed loss of activation by coinjected dopamine D2 receptors as measured using two electrode voltage clamp. When Kir3.1A and Kir3.1 were coinjected no significant difference with respect to high potassium (HiK) and D₂ stitulated current amplitudes, pertussis toxin sensitivity and desensitization was found compared to Kir3.1 channels alone. However, single exponential fits to the agonist stimulated portion of currents showed faster current activation times (Kir3.1=11.2 \pm 0.8 vs. 6.9 \pm 0.6 s=Kir3.1 Δ , p < 0.0047). Overexpression of D2 receptors also revealed an increase in constitutive, HiK activated currents. Kir3.1 Δ as a member of a Kir3.4/3.1\Delta concatemer construct was compared to a Kir3.1/3.4 concatemers during voltage jump relaxations. Kir3.4/3.1\Delta concatemers during voltage jump relaxations. Kir3.4/3.1\Delta concatemers showed no detectable expression except when coinjected with the wild type Kir3.1/3.4 concatemer. Both constructs showed an unresolvable instantaneous current component and a slower component with similar time constants but significantly greater current component amplitude for Kir3.4/3.1\Delta containing channels. Therefore, Kir3.1\Delta is a channel variant with restricted capacity for channel assembly which increases G-protein responsiveness, possibly by alteration of channel gating or relief from magnesium block. MOLECULAR CLONING AND CHARACTERIZATION OF MURINE GIRK2 AND ITS MULTIPLE ISOFORMS M.E. Hodes, Y. Wang, Y. Feng, B. Dupree, B. Ghetti and S.R. Dlouhy. Ind. Univ. Sch. of Medicine, Indianapolis, IN 46202.

A single base change in a G-protein-gated inwardly rectifying K* channel, Girk2, is the primary defect of weaver (wv) mice. The wv channel loses its selectivity for K* and leaks Na*. How expression of mutant Girk2 affects a variety of target neurons and results in death of only some is not known. Although two partial cDNA sequences encoding 414-426 amino acids have been reported for Girk2, northern blot analysis led us to suspect that additional transcripts may exist and may be relevant to the pathology of the wv mouse. We have concomitantly investigated the genomic structure of the locus and isolated a number of different Girk2 cDNA isoforms. Restriction mapping indicates that the gene is probably at least 50 kb. Genomic walking (utilizing primers based upon published cDNA sequence) indicates that the published Girk2 cDNA is comprised of 6 exons. The largest exon (921 bp) contains the majority of the protein coding region of the channel, including the site of the wv mutation. 5' and 3' cDNA RACE from this exon yielded multiple fragments. To date, we have isolated an additional 4 Girk2 cDNA isoforms that include the site of the wv mutation. These include 4 new exons, and we have identified the intron/exon boundaries. One isoform does not appear to be polyadenylated. These isoforms can yield proteins ranging from ca. 300 to over 420 amino acids. Northern blot and in situ hybridization studies indicate that some of these isoforms are differentially distributed in mouse brain and testis. (Supported by P01 NS27613 and R01 NS14426)

496.8

IDENTIFICATION AND EXPRESSION OF POTASSIUM CHANNEL β DENTIFICATION AND EXPRESSION OF POTASSION CHANNEL 5 SUBUNITS IN THE EMBRYONIC AMPHIBIAN NERVOUS SYSTEM. AD Hofmann., MA Lazaroff., K Nakahira., JS Trimmer., AB Ribera. Dept Physiology C-240, UCHSC, Denver, CO 80262, Dept Biochemistry and Cell Biology, SUNY Stony Brook, NY, 11794.

Differentiation of voltage dependent potassium current in amphibian spinal neurons is delayed with respect to the maturation of calcium current, regulating action potential duration. Maturation of potassium current is pivotal for action potential differentiation, and thus studies have focused on this ion channel. Previous molecular analyses concerned the $K\nu\alpha$ potassium channel subunits. However, auxiliary $K\nu\beta$ subunits also influence function. Thus, the roles of $K\nu\beta$ subunits

in Kv potassium current maturation are being investigated.

Three *Xenopus* Kvβ subunit cDNA clones have been isolated using rat Kvβ1 and Kvβ2 subunit cDNAs as probes. One of these clones contains an entire open reading frame and predicts a protein with 98% amino acid identity to the rat $K\nu\beta2$ subunit. The other 2 clones are partial and most similar to rat $K\nu\beta1$. Whole mount in situ hybridization indicates that Xenopus $K\nu\beta$ genes have a ubiquitous expression pattern in the spinal cord during the period of potassium current maturation. In contrast, $Kv1.1\alpha$ subunit mRNA is restricted to dorsal sensory neurons. Coexpression of *Xenopus* $Kv1.1\alpha$ and $Kv\beta2$ subunits in a heterologous system has not yet provided information regarding the potential functional role of this auxiliary subunit. Given that $Kv \beta$ subunits are thought to interact with $Kv1 \alpha$ subunits, the in sith hybridization results suggest that additional $Kv1 \alpha$ genes are expressed in neurons that reside in non-dorsal regions of the developing spinal cord. Supported by NIH NS34383 (JST) and NS25217 (ABR).

IDENTIFICATION OF PROTEINS ASSOCIATED WITH THE Kv2.1 VOLTAGE-GATED K* CHANNEL. K. Nakahira*, H. Murakoshi, R. Scannevin and J. S. Trimmer, Dept. Biochem. and Cell Biol., SUNY at Stony Brook, Stony Brook, NY 11794.

Recent studies have shown that the highly divergent cytoplasmic domains of voltage-gated K'channel α -subunits from the Shaker(Kv1) subfamily can mediate diverse protein-protein interactions. N-terminal cytoplasmic domains mediate both α/α - and α/β -subunit interaction, while C-terminal cytoplasmic domains interact with PSD-95 family members. Each of these interactions is restricted to members of the Kv1 subfamily, suggesting that members of other subfamilies of K* channel α -subunits may have similar associated proteins. Indeed, previously we have shown that Kv2.1, a member of the Shab (Kv2) subfamily of voltage-gated K' channels, is found in tight association with a 38 kD protein in rat brain (PNAS, 88:10764. 1991). We therefore searched for rat brain proteins that interact with the Kv2.1 polypeptide

We therefore searched for rat brain proteins that interact with the Kv2.1 polypeptide using the yeast two-hybrid system. We screened 3.4 x 10° colonies of a rat brain cDNA library using the N-terminal cytoplasmic domain of Kv2.1 as the bait. We obtained 40 positive colonies, which by sequence analysis were shown to represent 17 independent cDNAs. Some of the cDNAs corresponded to known genes, however, none were similar to known Kv α or Kv β family members. A representative of each cDNA class was then epitope-tagged and co-expressed in COS-1 cells with full length Kv2.1. Some of the expressed polypeptides were found to associate with Kv2.1 in this cell line, as determined by co-immunoprecipitation experiments. Immunofluorescence staining revealed that these same polypeptides also exhibited clear co-localization with Kv2.1. These data indicate that the proteins encoded by the rat brain cDNAs identified in this two hybrid screen can tightly associate with Kv2.1 in mammalian cells, and lead us to further investigate their association with Kv2.1 in mammalian brain and its physiological consequences. Supported by NIH grant NS34383 (to JST).

MOLECULAR CLONING OF VERTEBRATE POTASSIUM CHANNEL cDNA INTERRUPTED BY INSERTION OF TRANSPOSABLE ELEMENT. R. B. Puchalski*, J. Kang and J. H. Teeter. Monell Chemical Senses Center, Philadelphia, PA 19104

We have discovered transposase sequences in a partial length cDNA clone encoding a delayed rectifier K+ channel isolated from channel catfish. The cDNA was cloned by PCR with degenerate oligonucleotide primers corresponding to highly conserved amino acid sequence of different subfamilies of the delayed rectifier K+ channels. The cDNA was synthesized by reverse transcription of total RNA isolated from catfish maxillary barbels and used as a template for PCR. DNA sequence analysis reveals that the clone of 942bp consists a novel sequence of 439bp flanked by a 5' sequence of 360bp similar to transposases and by a 3' sequence of 107bp similar to delayed rectifier K+ channels. The 360bp sequence is 67% similar to a Tc1-like transposon family, which moves in the genome through a DNA intermediate via a cut-and-paste mechanism. The novel sequence might encode the transposon's 3' inverted repeat. Interruption of the coding segment of the putative transposase gene by stop codons in all three reading frames indicates that the transposon is not autonomous and that the 3' sequences of the K+ channel are not translated

POSTSYNAPTIC CLUSTERING OF KV4.2 POTASSIUM CHANNELS IN RAT CENTRAL NEURONES, H. Widmer, G. Alonso and M. Sheng*. URA1197 and INSERM U336, Universite Montpellier II, Montpellier, France.

Ion channels play a key role in determining both neuronal membrane excitability and specificity. Neuronal specificity is achieved by several mecanisms, including influence of afferent network and expression of cell-to-cell specific sets of ion channels. Recently, demonstration of subcellular segregation in central neurons has suggested an additionnal way of modulating neuronal properties. Potassium channels, which form numerous subtypes expressing a wide range of electro-physiological properties when expressed in *Xenopus* oocyte, have been shown to segregate both a the cellular and subcellular level in various brain regions. However, owing to the limitations of light microscopy, the precise localization of the channels on pre- or post-synaptic membrane has not been assessed by now. We used confocal and immunoelectron microscopy to determine in the hypothalamus the localization of Kv4.2 subtype of potassium channel. The Kv4.2 antibody was kindly given by Dr. Sheng (Sheng et al. (1992) Neuron 9, 271). We showed that intense immunostaining was localized to the supraoptic nucleus in which it often formed rings outlining the somata of magnocellular neurones. The even distribution of the staining throughout the nucleus suggests that Kv4.2 channel is present in both vasopressin and oxytocin neurons. Electron microscopy further revealed that staining was essentially associated with the plasma membrane limitating the somata or the dendrites of these neurones and that it was particularly concentrated at the site of synaptic contacts. The specific localisation of the Kv4.2 channel indicate that this channel may play a role in signal integration at the synapse. Any identification of Kv4.2 channels with ion currents described in supraoptic neurons requires further knowledge of the subunit composition of the channel in situ Drs H. Widmer and G. Alonso were supported respectively by CNRS and INSERM grants (FR).

Diversity of voltage-gated potassium channels in a cnidarian. Peter A.V. Anderson*, Alisa E. Shaw, and Michael C. Jeziorski. The Whitney Laboratory, University of Florida, St. Augustine, FL.

The heterogeneity of potassium currents in neurons and other excitable cells is accounted for in part by the Shaker family of voltage-gated potassium channels, which is comprised of four subfamilies (Shaker, Shab, Shaw, and Shal). These subfamilies, fully represented in species ranging from Drosophila to human, are thought to have arisen from an ancestral potassium channel gene. Members of the phylum Cnidaria (jellyfish, anemones, and corals) represent the earliest existing species with differentiated neural and muscle tissues. The recent discovery of homologues of the Shaker subfamily in a hydrozoan jellyfish (Jegla et al., J. Neurosci., 15:7989, 1995) suggests that the four channel subfamilies diverged before the appearance of the first nervous systems. We have used degenerate oligonucleotide primers designed against conserved regions of the voltage-gated potassium channel family to isolate cDNA clones from the sea anemone Aiptasia pallida. RT-PCR, coupled with standard cloning techniques, has led to the identification of three full-length cDNA sequences encoding homologues of the Shaker, Shaw, and Shal subfamilies. Each Aiptasia sequence is more closely related to its counterpart in higher vertebrates (45-67% identity within the core region spanning T1-S6) than to the other two anemone sequences (36-50% identity). Expression of the anemone Shaker homologue in Xenopus oocytes produces a voltage-activated, 4-aminopyridine-sensitive current that exhibits slow inactivation ($\tau=375\pm26$ ms). We plan to use heterologous expression to characterize the remaining channel clones. (Supported by NRSA grant MH 10625 to MCJ and NSF grant IBN-9222803.)

ALPHA-DENDROTOXIN AND DELTA-DENDROTOXIN INTERACT WITH DIFFERENT AMINO ACIDS AT THE PORE REGION OF Kv1.1. R.G. Sorensen' and A. Matlapudi. Dept. Pathology, Anatomy and Cell Biology, Jefferson Medical College, Philadelphia, PA 19107.

The block of the dendrotoxin-sensitive K channel, Kv1.1, by several dendrotoxin homologues purified from green mamba venom was studied. Two homologues, α -dendrotoxin and δ -dendrotoxin, are potent blockers of Kv1.1, with Kd of 6.5 \pm 1.4 and 0.062 \pm 0.038 nM, respectively. The difference in potencies reflects the dissociation rates of the toxins; α -dendrotoxin is readily reversible whereas δ -dendrotoxin has a much slower, largely irreversible, off rate. The dendrotoxin molecules possess a net positive charge.

The dendrotoxin molecules possess a net positive charge. Alanine substitutions of the negatively-charged amino acids found near the ion conduction pathway of Kv1.1, B348A, B350A, B351A, B353A, D361A and D377A, were made to screen for potential electrostatic interactions between these residues and the positively-charged dendrotoxin molecules. The results suggest that $\alpha\text{-dendrotoxin}$ and $\delta\text{-dendrotoxin}$ make electrostatic contact with different amino acids of Kv1.1. For example, the mutation E353A causes a 20-fold decrease in the Kd for block by $\alpha\text{-dendrotoxin}$ while having little effect on the affinity for block by $\delta\text{-dendrotoxin}$, whereas E350A causes a 5-fold decrease in the Kd for δ -dendrotoxin while having little effect on the affinity for block by $\alpha\text{-dendrotoxin}$ while having little effect on the affinity for block by $\alpha\text{-dendrotoxin}$. Additional amino acid substitutions are being made to confirm the electrostatic nature of these dendrotoxin/Kv1.1 interactions. These results will be discussed with respect to the geometry for the binding of the dendrotoxins to Kv1.1. Supported by NIH grant NS31670.

CLONING OF G-PROTEIN-COUPLED, INWARD RECTIFIER K* (GIRK) CHANNELS FROM THE RAT ANTERIOR PITUITARY. K.A. Gregerson* M. Anderson, O. Lauring, P.A. Welling, Depts. of Pediatrics and Physiology, University of Maryland at Baltimore, Baltimore, MD 21201.

Dopamine (DA) is a physiological regulator of prolactin (PRL) secretion, exerting tonic inhibitory control. DA activates an inward-rectifier K⁺ (IRK) channel in rat lactotropes causing membrane hyperpolarization and inhibition of Ca²⁺-dependent action potentials. Both the activation of this effector K* channel and the inhibition of PRL release are mediated by D2 receptor activation and PTx-sensitive G proteins. To study the molecular basis of this channel, a homology-based PCR approach was employed to identify members of the IRK channel family which are expressed in pituitary and may comprise this D₂-activated, G-protein-gated channel.

Non-degenerate primers corresponding to regions specific for IRK channels known to be G-protein-activated were synthesized and used in the polymerase chain reaction with reverse-transcribed female rat anterior pituitary (AP) mRNA as the template. PCR products of predicted sizes for GIRK1, GIRK2, and CIR (GIRK4) were consistently observed by ethidium bromide staining after 18 amplification cycles. No products were observed in reactions using mRNA rather than first strand cDNA as the template, ruling out spurious genomic amplification. Identities of the products were confirmed by subcloning and sequencing. Sequences were identical to the corresponding regions published for GIRK1, GIRK2, and CIR. Expression of each of these gene products in AP was confirmed by Northern blot analysis.

In conclusion, GIRK1, GIRK2, and CIR are excellent candidate subunits for the D_2 -activated, G-protein-gated channel in pituitary lactotropes where they may play a critical role in excitation-secretion coupling.

AMINO-ACID CHANGES IN THE N-TERMINAL SEQUENCE OF KALIOTOXIN RESULT IN PEPTIDES WHICH DISCRIMINATE AMONG KV1 α-SUBUNITS. M. Crest ^V. V. Frémont#, M. Gola^V, I.Y. Barthe*, R. Romi#, H. Rochat#, M.F. Martin-Eauclaire# and I. van Rietschoten#. YLab. de Neurobiologie, UPR CNRS 9024, *Neurobiologie et Mouvements, UPR CNRS 9011, Ch. J. Aiguier 13402 Marseille, France; #Lab. d'Ingéniérie des Proteines, URA CNRS 1455, Faculté de Médecine, 13326, Marseille, France.

Scorpion toxins have been used to reveal the Kv channel structure. However, the reasons of their selectivity among Kv channels remained to be determined. To solve this problem we modified the kaliotoxin (KTX) sequence whithout changing the toxin residues facing the channel pore: i) punctual substitutions in the Glyl to Lys 7 region of KTX increased up to 100-fold the peptide affinity to Kv1.3; ii) the natural KTX isoform, KTX3, which differed from KTX by 5 residues in the N-terminal region had a 50-fold higher affinity to Kv1.3 than KTX; iii) various peptides mutated in the KTX α -helix (Ser11 to Gly22) had affinities up to 200-fold higher than KTX to Kv1.1. Substitution in the N-terminal and a-helix regions of scorpion toxins may provide a suitable approach to construct peptides blocking with a high ratio of selectivity a given Kv1 α-subunit.

SUBUNIT BASIS FOR ION PERMEATION AND GATING SUGGESTED BY SUBCONDUCTANCE LEVELS IN K CHANNELS. M.L. Chapman, D.S. Roane*, H.M.A. VanDongen, A.M.J. VanDongen, Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710 and *Div. of Pharmacology, Northeast La. University, Monroe, LA 71209.

Channel opening and permeation are two essential properties of ion channels, the molecular bases of which are poorly understood. Analysis of single channel behavior of a voltage dependent K channel suggested that intermediate current levels ("sublevels") appeared to be associated with transitions between the open and closed conformations. Since K channels are formed by four identical subunits, it was hypothesized that sublevels corresponded to channel states with heteromeric pore conformations. This subunit-subconductance hypothesis predicts that sublevel behavior should be more abundant when activation is incomplete. Experimental evidence supported this prediction as sublevels were increased tenfold in recordings near the activation threshold. To further test the hypothesis, a mutation was introduced in the amino-terminal region of the voltage sensor of the channel. The resulting channel (drk1-LS) was found to have a slight reduction in the voltage-dependence of open probability but the voltage-dependence of the activation time constant was reduced nearly twenty-fold. Additionally, drk1-LS exhibited sublevel activity over a broadened voltage range. The subunit-subconductance hypothesis predicts just such behavior if the rate of activation is slow, relative to the rate of channel opening. Based on these results a subunit basis is proposed for channel opening and ion permeation

VOLTAGE SENSING IN A JELLYFISH SHAKER POTASSIUM CHANNEL (JSHAK1). N. G. Grigoriev, J. D. Spafford, W. J. Gallin and A. N. Spencer* Dept. of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada, T6G 2E9 and Bamfield Marine Station, Bamfield, B.C., Canada, VOR 1B0.

In all known Shaker K+ channels, except jShak1, the putative voltage sensor (\$4 segment) has seven, conserved, positively charged amino-acids positioned at every third residue. However, in a primitive, Shaker-like potassium channel (jShak1) from the hydrozoan jellyfish, Polyorchis penicillatus there are only six positively charged residues in the S4 segment. When compared with other Shaker currents, jShak1 currents exhibited a strong positive shift (+33mV) in the mid-point of activation. We examined the possibility that 'normal' Shaker electrical properties could be restored by adding a seventh charge 'in phase' with the charged motifs already present. Mutations of the S4 region of iShakl involved insertion of motifs, and rewriting. Electrophysiological analyses showed that none of the constructs expressed currents that had properties similar to other Shakers, despite the seven-charge pattern being restored. Adding charge to the Nterminus of S4 by rewriting does not change substantially any voltagedependent properties. However, mutation by insertion of positively charged motifs in the C-terminal portion of S4 caused significant changes in voltage and kinetic properties. On the basis of this, and other studies, we suggest a synthetic, molecular model of voltage sensing in Shaker channels. Supported by NSERC Canada.

ALTERNATIVELY SPLICED PORE LINING REGIONS IN PANULIRUS SHAKER. M.Kim, D.J.Baro, C.L.Cole, M.Doshi,

H.S.Moskowitz, T.Podleski*, R.M.Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853 Potassium channels play a critical role in the electrophysiological behavior of pyloric neurons in the stomatogastric ganglion (STG) of Panulirus interruptus. By screening cDNA libraries in combination with RACE (rapid amplification of cDNA ends) we have obtained alternatively. amplification of cDNA ends), we have obtained alternatively spliced full-length shaker clones. As in Drosophila, multiple alternative exons occur at the amino and carboxy termini in Panulirus shaker. However unlike Drosophila, alternative splicing was found in the pore-forming region between the S5 and S6 transmembrane spanning domains of Panulirus shaker. Three different pore forming regions were found (0, I, II). Forms I and III are homologous to *Drosophila* and differ in only four amino acids. However, form I has a T residue at the outer mouth of the pore, corresponding to T449 in *Drosophila shaker* while form II has a positively charged R residue at this site. Structure/function studies in Drosophila suggest that this will alter C-type inactivation, drug resistance, and ion permeability. Form 0 lacks a pore forming exon altogether. Expression studies in *Xenopus* oocytes of form II with a short amino terminus exon produced currents with hypothesized rapid C-type inactivation. Expression studies of form 0 produced no functional channel and did not function as a dominant negative. Supported by NIH NS25915.

Kv2.1 SUBUNIT EXPRESSION IN RAT HIPPOCAMPAL INTERNEURONS AND ITS KNOCKOUT BY ANTISENSE OLIGONUCLEOTIDES IN CULTURED HIPPOCAMPAL SLICES, J. Du*, S. Keros & C.J. McBain, Lab. of Cellular & Molecular Neurophysiology, NICHD, NIH, Bethesda MD, 20892.

The potassium channel subunit, Kv2.1, is widely expressed throughout the rat CNS and is thought to have a role in normal physiological function (Maletic-Savatic et al. J. Neurosci. 15, 1995). In the hippocampus, Kv 2.1 is expressed not only in both pyramidal and granule cells, but also in presumed inhibitory interneurons. Experiments were designed to determine whether Kv2.1 was expressed in defined populations of interneurons using double immunostaining with anti-Kv2.1 and markers for identified interneuron subpopulations. Double staining of anti-Kv2.1 and anti-parvalbumin (PV) antibodies show that > 90% of the PV positive basket cells are Kv2.1 positive. Experiments are in progress to determine the distribution of Kv2.1 in other interneuron populations. To determine the functional role of channels formed by Kv2.1 in pyramidal neurons, cultured hippocampal slices were incubated in antisense oligonucleotides directed against Kv2.1 to block subunit expression. Western blot analysis revealed that total Kv2.1 protein content decreased ~30% after a 5-day treatment with antisense (4.5µM) compared with nonsense oligos. Consistent with this reduction, whole-cell delayed rectifier currents from antisense treated CA1 pyramidal neurons were significantly reduced (~26%) when compared to nonsense or control treated cells. Anneal density in outside out patches from antisense treated cells was 52 ± 12 pA/pF compared to 100 ± 25 pA/pF in control or nonsense treated cells. Under conditions of elevated [K¹] o (8.5mM), action potential duration in antisense treated cells was increased 317% of that seen in control or nonsense treated cells. All other action potential parameters were unchanged. Thus functional channels comprising Kv2.1 subunits are expressed in both excitatory and inhibitory cells of the hippocampus and the delayed rectifier currents through these channels selectively contribute to action potential repolarization. This work was supported by the NIH.

CORTICOTROPIN RELEASING HORMONE MODULATION OF A HYPERPOLARIZATION-ACTIVATED CURRENT (I,.), Y. A. Kuryshev', G. V. Childs² and A. K. Ritchie'', Depts. of Physiology & Biophysics¹ and Anatomy & Neurosciences². Univ. Texas Medical Branch, Galveston, TX 77555.

Corticotropin releasing hormone (CRH) increases firing frequency and plays

Corticotropin releasing hormone (CRH) increases firing frequency and plays an important role in stimulation of ACTH secretion from corticotropes. In this work on highly enriched cultured rat corticotropes, we used the amphotericin perforated patch technique to study CRH modulation of a hyperpolarization-activated, sodium-potassium current ($I_{\rm h}$). The compositions of the recording solutions were (in mM): pipette - 60 K₂SQ₄, 30 KCl, 10 NaCl, 1 MgCl₂, 1 EGTA, 10 HEPES, pH 7.2, 300 µg/ml amphotericin B; bath - 50 KCl, 95 NaCl, 10 TEACl, 0.05 CaCl₂, 1 MgCl₂, 5 4-aminopyridine, 10 HEPES, 10 glucose, 03 sucrose, 0.05 LaCl₃, 0.25 BaCl₂, 0.001 TTX, pH 7.4 (36°C). $I_{\rm h}$ activated at potentials negative to -40 mV, was non-inactivating and exhibited slow activation kinetics ($\tau_{\rm ac}$ =507 $_{\pm}$ 82 ms at -100 mV, N=15). The activation curve was well fit by the Boltzmann relation with half-maximal activation at -75.5 mV and a slope factor of 8.0 mV (N=9). In physiological saline the reversal potential of $I_{\rm h}$ obtained by instantaneous current-voltage relations was -46.5 mV (N=4). The reversal potential with changing [Na 1 /[K 1]₀ was described by the Goldman Equation with pNa/pK = 0.161. $I_{\rm h}$ was insensitive to Ba $^{2+}$ (2mM), Cd $^{2+}$ (1 mM) and TEA (25 mM), was slightly attenuated (17%, N=3) with 5 mM 4-aminopyridine, and was blocked in a voltage-dependent manner with external Cs* (Ka=83 μ M at -100 mV, N=3). CRH (20 nM) did not change the amplitude or voltage-dependence of $I_{\rm h}$, but significantly decreased $\tau_{\rm ac}$ by 35% (N=5). These results suggest that $I_{\rm h}$ current could contribute to the resting membrane potential of corticotropes and modulation of $I_{\rm h}$ by CRH could enhance spike frequency by increasing the rate of depolarization during the interspike interval. NONSYNAPTIC MODULATION OF VOLTAGE-ACTIVATED POTASSIUM CHANNELS. S.C. Baraban*, M.C. Bellingham, A.J. Berger and P.A. Schwartzkroin. Depts. of Neurological Surgery & Physiology/Biophysics, University of Washington, Scattle WA 98195.

Nonsynaptic influences, such as the activity-dependent fluctuation in extracellular osmolarity, play key roles in regulation of neuronal excitability. Utilizing whole-cell and single-channel recording techniques in conjunction with infrared differential interference contrast video microscopy, we examined the effect of hypo-osmolar external solutions on voltage-activated K+ channel Hypo-osmolar solutions (osmolarity reduced 10% to 267 mOsm) produced a significant and reversible potentiation of whole-cell K^+ current from lacunosum/moleculare (L/M) interneurons (+43%, n =10). Although cell swelling was induced by this treatment in both interneurons and CA1 pyramidal cells, no potentiation was observed for CA1 neurons (n = 8). Hypo-osmolar solutions did not produce a modulation of hyperpolarization-activated current on either type of neuron. In single-channel outside-out patch recordings from L/M interneurons (n = 7) hypo-osmolar solutions increased the mean open time and the probability of channel opening, no effect was observed on CA1 neurons (n = 3). Ensemble K⁺ current amplitude was increased during application of hypoosmolar solutions only for L/M interneurons. Osmotically-induced modulation of K^+ channel function was not associated with a change in the threshold for activation or the amplitudes of single-channel currents. These data suggest that osmotic stress may play a critical role in regulating neuronal excitation during both normal and pathophysiological conditions. This neuron-specific finding has important implications for understanding nonsynaptic mechanisms which modulate excitability in the central nervous system. ARACHIDONIC ACID BLOCKS THE TRANSIENT POTASSIUM CURRENT IN CAI PYRAMIDAL NEURONS IN ORGANOTYPIC CULTURE. S. Keros, J. Du, and C. J. McBain*. Lab. of Cellular & Molecular Neurophysiology, NICHD, NIH, Bethesda MD. 20892.

Arachidonic acid (AA) strongly modulates both neuronal excitability and synaptic transmission. Recent evidence suggests that AA selectively blocks transient "A-type" outward potassium currents through Kv4.2 homomeric channels in oocytes (Villarroel and Schwarz J. Neurosci. 16, 1996), while currents through homomeric channels formed by members of the Kv1, 2 or 3 subfamilies were largely resistant. Currents through Kv4.2 channels have been proposed to underlie the principal transient curren in the mammalian CNS (Serodio et al. J. Neurophys 72, 1994) consistent with the strong Kv4.2 expression in hippocampal pyramidal neurons (Maletic-Savatic et al. J Neurosci. 15, 1995). To determine whether hippocampal transient currents are through Kv4.2 channels, we have investigated the effects of AA on currents in outside-out patches excised from CA1 pyramidal neurons in organotypic hippocampal cultures prepared from P6-8 rats. AA dose-dependently blocked the transient current in CA1 pyramidal neurons; $IC_{50} = 0.1 \mu M$. At a test potential of +40mV, AA (10 μ M) blocked 70% of the transient current charge transfer. In addition a more rapid time constant of current inactivation was observed in the presence of AA (20ms in control versus 5ms in AA). The effects of AA were mimicked by eicosatetraynoic acid (ETYA), a non-metabolizable AA analog. ETYA (10µM) blocked 75% of the transient current charge transfer and like AA, accelerated the rate of current inactivation. Previously we have shown that the transient current in inhibitory basket cells (but not pyramidal neurons) was selectively inhibited (~40%) when perfused in 0mM [K⁺]₀, consistent with currents through channels predominantly formed by Kv1.4 subunits. Future experiments will determine whether the remaining current fraction in basket cells is sensitive to AA. These data suggest that the transient current in pyramidal neurons is predominantly through channels formed by Kv4.2. This work was supported by the NIH.

MODULATION OF ELECTRICAL DEVELOPMENT OF XENOPUS EMBRYONIC MYOCYTES BY FIBROBLAST GROWTH FACTOR. A.E. Spruce, E. Prabhakar and L.M. Stanford*. Dept. Pharmacology, Univ. of Birmingham, Birmingham. B15 2TT.

The amount of sodium current (IN_B) in *Xenopus* embryonic myocytes is increased by co-culture with dissociated neurons and the absence of synaptic contacts implies an effect of diffusible factors (Prabhakar et al. 1996. Neurosci. Lett. 207:1-3). Fibroblast growth factor (FGF) is known to promote maturation of the neuromuscular junction and here we assess its ability to modulate the developmental expression of voltage-dependent currents in muscle. Myocytes were removed from *Xenopus* embryos at Stages 15-18 and cultured for 18-30 hr in the absence (control) or presence of acidic FGF (aFGF) at 10 ng/ml. Whole-cell patch clamp recordings were made using a pipette solution containing (in mM): 90 K.aspartate, 10 NaCl, 2 MgCl₂, 2 EGTA. 10 HEPES. 2 Na₂ATP, 0.1 cAMP; pH 7.4.

2.4.2 Ap/p. (1.5.4) increased mean I_{Na} density in current-expressing myocytes: 24.8 \pm 5.6 pA/pF (n = 16; control); 57.5 \pm 16.8 pA/pF (n = 16; aFGF); p < 0.04 (t-test). In addition, the proportion of cells containing I_{Na} was increased: 16/25 (control): 16/17 (aFGF); p < 0.05 (Fisher's exact test). In contrast to the effects on I_{Na} , aFGF caused downregulation of the expression of inward rectifier potassium current (I_{IR}). I_{IR} density was 18.8 ± 2.2 pA/pF (n = 13) in control and 4.3 ± 1.1 pA/pF (n = 12) in aFGF (p < 0.0001). Although myocyte capacitance is significantly increased by aFGF (47.5 \pm 2.4 pF; n = 35; control vs. 56.4 \pm 2.3 pF; n = .38; aFGF; p < 0.003, this can not explain the four-fold decrease in I_{IR} density. Mean steady-state outward potassium current was not affected by aFGF, however: 12.2 \pm 2.8 pA/pF (n = 17; control) vs. 14.2 \pm 2.4 pA/pF (n = 17; aFGF). Preliminary results suggest a similar effect of bFGF. Therefore, FGF-induced modulation of current expression is predicted to increase the electrical excitability of emphysionic myocytes.

electrical excitability of embryonic myocytes.

MODULATION OF SINGLE INWARD RECTIFIER POTASSIUM CHANNELS IN XENOPUS EMBRYONIC MYOCYTES. R. Chauhan-Patel and A.E. Spruce*. Dept. of Pharmacology, Univ. of Birmingham, Birmingham, B15 2TT. UK

Current rectification through cloned inward rectifier potassium (IRK) channels is attributed to diffusible blockers (Lopatin et al. 1994. Nature. 372:366). We have investigated whether this mechanism also applies to native embryonic skeletal muscle IRK channels. We have also studied the effect of various potential modulators of channel activity to assess their role in regulating the functional expression of IRK current during development. Myocytes were isolated from Xenopus laevis embryos (Stage 15-20) and cultured for up to 30 hr. The activity of single IRK channels was recorded in cell-attached and excised, inside-out patches (Patel et al. 1995. J.Physiol. 489.P:73P). The pipette and bath solutions contained 120 mM K⁺. Test solutions were applied from an adjacent electrode.

In control solution, IRK channel activity at -60 mV disappears "instantaneously" on application of a voltage step to +60 mV. Perfusion of the excised patch with Mg2+-free (containing 1 mM EDTA) solution did not alter the rectification (n=17). However, when Mg2+-free solution at pH 9.1 (CHES substituted for HEPES) was applied to the patch, channel activity at +60 mV was observed and could be correlated with IRK channel openings at -60 mV (3/4 patches). This result is consistent with the hypothesis that polyamines cause rectification in native IRK channels, since reduction in their state of ionisation at high pH will diminish their binding affinity.

We have also tested the ability of various chemicals to modulate IRK channel activity. Exposure of the cytoplasmic face of excised patches to 1 mM ATP or 10 μM GTP-y8 did not affect the open probability of 1RK channels. However, in cell-attached patch recordings, perfusion of aFGF onto the cell substantially reduces 1RK channel activity within 10 min (3/3).

The financial support of the Wellcome Trust is gratefully acknowledged

MODULATION OF VOLTAGE-DEPENDENT K* CURRENTS VIA cAMP CASCADE IN CULTURED EMBRYONIC NEURONS OF DROSOPHILA: ALTERATIONS IN MEMORY MUTANTS. M.-L. Zhao* and C.-F. Wu. Dept. of Biol. Sci., Univ. of Iowa, Iowa City, IA 52242, USA

Ion channel modulation by the cAMP cascade has been suggested to be an important mechanism underlying neuronal plasticity in the nervous system. In Drosophila, dunce (dnc) and rutabaga (rut) mutants are defective in cAMP metabolism, causing memory deficiencies in adult flies. We have previously observed in subsets of cultured mutant neurons altered frequency coding of firing evoked by step current injection, and aberrant spike activities in response to multiple stimulation paradigms. In order to examine if voltage-dependent K currents are targets of the cAMP cascade, we performed whole-cell voltageclamp recordings on embryonic neurons from dnc and rut mutants. A majority of cells could be divided into two categories based upon different inactivation time constants of the transient K* currents. We found that a variety of properties of voltage-dependent K* currents were affected in neurons of *dnc* and rut, likely due to chronic changes in cAMP levels. Acute application or short-term incubation with membrane-permeable cAMP analogues modified K currents in amplitude, kinetics, and voltage-dependence, which were altered in mutants. Furthermore, we examined, in dnc and rut background, effects of cAMP cascade on heat shock-inducible, identifiable K+ currents mediated by the ShD subunit expressed in transgenic flies. Our results suggest that neuronal voltage-activated K+ currents are potential targets for modulation by the cAMP cascade. Altered modulation in *dnc* and *rut* mutants may contribute to their learning deficiencies. [Supported by NIH grants NS 26528, HD 18577]

CANNABINOIDS ALTER MEMBRANE EXCITABILITY AND SYNAPTIC TRANSMISSION IN CA1 PYRAMIDAL CELLS OF THE HIPPOCAMPUS. M.T.Kirby*, R.E. Hampson, and S.A. Neuroscience Program, and Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC, 27157-1093.

The effects of the cannabinoid agonist WIN 55,212-2 (5µM, RBI) on CA1 pyramidal cells were investigated using the hippocampal slice preparation and sharp electrode intracellular recording. Bath-applied WIN 55,212-2 was found to alter input resistance to both hyperpolarizing and depolarizing current injections (n = 24). WIN 55,212-2 enhanced a hyperpolarization activated inward current (I_0). The increase was effectively blocked by the cannabinoid antagonist SR141716A (300nM, Sanofi) or by intracellular injection of QX-314 (100mM, Astra), yet remained potentiated in 2mM Ba²⁺. WIN 55,212-2 also enhanced a depolarization-activated current that was sensitive to 5mM TEA, such that the combined effect of the drug was to shallow the slope of the overall I-V relationship. Evidence of a presynaptic effect of cannabinoids was supported by a bicuculline-sensitive $(50\mu\text{M})$ hyperpolarization in the presence of WIN 55,212-2 that was attenuated by TTX ($1\mu\text{M}$) or Ca^{2+} -free media.

Constructed input-output curves revealed decreased EPSP amplitudes (via stimulation of the Schaffer collaterals) via WIN 55,212-2. The decrease persisted in bicuculline, and results will be discussed in terms of the above postsynaptic changes in membrane resistance. Collectively, these data illustrate that cannabinoids mediate changes in cellular excitability of hippocampal neurons through at least one presynaptic and two different postsynaptic conductance changes. A-CURRENT DEVELOPMENT IN HIPPOCAMPAL NEURONS: LINKS TO KINASE ACTIVITY AND MEMBRANE INSERTION. Rui-Lin Wu* and <u>Michael E. Barish</u>. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

A-current appears early during development of mouse hippocampal neurons, being present in acutely-dissociated pyramidal neurons as early as embryonic day 15-16. Nevertheless, A-current amplitude in neurons of dissociated cell cultures prepared from E15-E16 hippocampi depends on the extent of contact with co-cultured astroglial cells, an observation suggesting that mRNA(s) related to A-current may be synthesized early, and that regulation of A-current involves other downstream process. In these experiments, we sought to identify processes internal to neurons that limit the appearance of A-current. Neurons were grown in both serum-containing and serum-free media, drugs were added 1-10 hr after cell dissociation and plating, and amplitudes of voltage-gated potassium currents (A-, D- and K-currents) were assayed after 4-7 days. Two main observations have emerged. First, the appearance of A-current, but not D- or K-currents, is linked to neurite outgrowth. Pyramidal neurons grown in serum-containing medium and not in contact with astroglial cells are smaller and have lower A-current amplitudes and densities than neurons with more extensive neurites grown under serum-free conditions that reduce numbers of non-neuronal cells Second, the sensitivity of A-current development to kinase inhibitors is similar to that of membrane transporters regulated by vesicle insertion. Thus development of A-current, but not D- or K-currents, is reduced by continuous exposure to staurosporine (2-20 pM), K252a (1 µM), KT5926 (10 $\mu M)$ and wortmannin (0.1-2 $\mu M)$, but is not sensitive to calphostin C (0.1-0.5 $\mu M),~K252b~(1~\mu M),~KN-62~(10~\mu M)$ or bisindolmaleimide I (1 $\mu M).$ This pattern suggests phosphatidylinositol 3-kinase and/or myosin light chain kinase as possible rate limiting enzyme(s). CANNABINOID AGONISTS MODULATE TWO SUBTYPES OF POTASSIUM A-CURRENT (IA) IN CULTURED RAT HIPPOCAMPAL NEURONS. Shou-Yuan Zhuang*, Jian Mu, Josef T.J. Kittler, Zoe L. Sinclair, M. Todd Kirby, Robert E. Hampson, and Sam A. Deadwyler, Department of Physiology and Pharmacology and Center for the Neurobiological Investigation of Drug Abuse, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

Cannabinoid receptor agonists modulate potassium A-currents (IA) via a cAMP second messenger pathway (Deadwyler et al. 1996, JPET; Hampson et al. 1996, Life Sci.). Investigation of the final link in this cascade from protein kinase to ion channel (see J. Mu, et al., this meeting) revealed differential effects on steady-state and transient inactivation of I_A recorded via whole cell patch clamp in cultured hippocampal neurons. The potent cannabinoid agonist, WIN 55,212-2, enhances I_A via a positive shift in voltage dependence of steady-state inactivation. WIN 55,212-2 also markedly reduced the time constant (tau) of I_A transient inactivation from 50 ms to 25 ms. Inhibitors of cAMP-dependent protein kinase (PKA) also reduced tau. Stimulation of PKA or elevation of cAMP had no effect. Cannabinoid effects on tau were blocked by the cannabinoid receptor antagonist SR141716A (Sanofi).

These effects suggest that I_A actually reflects a combination of potassium channel subtypes. Under control conditions, I_A may consist of currents with 50 ms tau such as those produced by Kv4.2 homomeric channels or Kv1.2/1.4 heteromeric channels. In the presence of cannabinoids acting through cAMP, IA resembles homomeric Kv1.2 currents. RT-PCR and fluorescent antibody labelling have revealed that mRNA and channel proteins for Kv1.2, Kv1.4 and Kv4.2 were present in these cells. ROLE OF PROTEIN PHOSPHORYLATION IN THE CANNABINOID MODULATION OF POTASSIUM A-CURRENT (I_A) IN CULTURED RAT HIPPOCAMPAL NEURONS. Jian Mu*, Shou-Yuan Zhuang, Robert E. Hampson, M. Todd Kirby, and Sam A. Deadwyler, Department of Physiology and Pharmacology and Center for the Neurobiological Investigation of Drug Abuse, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

The potent cannabinoid agonist, WIN 55,212-2, modulates potassium A-current (IA) in rat hippocampal neurons via cAMP-dependent protein kinase (Deadwyler et al. 1995, JPET; Hampson et al. 1995, Life Sciences). The likely mechanism for this modulation is via phosphorylation and dephosphorylation of the I $_{\rm A}$ channel protein. Whole cell currents were recorded from cultured E-18 fetal rat hippocampal neurons, 7-15 days in culture, with TTX 1 μ M, 4-AP 500 μ M and TEA 30mM in the bathing medium to block currents other than I $_{\rm A}$. WIN 55,212-2 (RBI) was applied extracellularly via pressure pipette (2 μ M). IP-20 (10 μ M, Sigma), PKA catalytic subunit (PKAc; 500 units/ml, Sigma), and okadaic acid (2µM, RBI) were administered via the intracellular recording pipette.

The positive shift in steady-state inactivation of I_A and decreased time constant (transient inactivation, tau) produced by WIN 55,212-2 were reversed when PKAc was included in the patch clamp recording pipette. Cannabinoid effects were also blocked by the phosphatase inhibitor, okadaic acid. Addition of the protein kinase inhibitor IP-20 (10µM) with PKAc produced a positive shift in I_A and reduction in *tau* similar to WIN 55,212-2. Together these data suggest that cannabinoid effects on IA are mediated by phosphorylation and dephosphorylation of ion channel

C,-CERAMIDE ATTENUATES POTASSIUM CONDUCTANCES INDIRECTLY VIA RAS IN CULTURED OLIGODENDROCYTES. H. Hida, M. Takeda and B. Soliven*. Dept. of Neurology, The Brain Research Institute, The Univ. of Chicago, Chicago, IL 60637.

Ceramide is generated from sphingomyelin hydrolysis and has

been implicated in TNF- α signaling and stress-induced apoptosis. We have previously shown that TNF- α inhibits K^* currents in cultured oligodendrocytes (OLGs) (Soliven et al., J. Memb. Biol. 124: 127oligodendrocytes (OLGs) (Soliven et al., J. Memb. Biol. 124: 127-137, 1993). To investigate further the signaling mechanisms of TNF- α on OLGs, we studied the effect of C_2 -ceramide (Cer) on inwardly rectifying (I_{Kw}) and outward K^* currents (I_{Ko}) in cultured neonatal OLGs (Gale* cells) and progenitors (O4*Gale* cells) using the whole-cell patch-clamp technique. Cer (10 μ M) decreased the amplitudes of I_{Ko} and I_{Kw} to 64.2 \pm 6.5 % (n=13) and 75.3 \pm 6.9 % (n=13) of the initial current at 5 min after perfusion, respectively. The effect was concentration-dependent and was observed with concentration as low as 1 μ M. The inhibitory action of Cer on K* currents was attenuated by the addition of neutralizing antibody against Ras-n21 in the pipette as 1 μ M. The inhibitory action of Cer on K' currents was attenuated by the addition of neutralizing antibody against Ras-p21 in the pipette solution (92.4 \pm 2.1 % and 103.1 \pm 3.1% of the initial current for I_{Ko} and I_{Kir} , n= 11) or by pretreatment with H-8 (30 μ M) for 1hr (89.1 \pm 2.9 % and 96.4 \pm 4.8 % of the initial current for I_{Ko} and I_{Kir} , n= 7. Pretreatment with quinacrine (10 μ M), inhibitor of phospholipase A, for 1 hr did not block the effect of Cer on K* currents. We conclude that Cer-induced inhibition of K* conductances is due to Ras-mediated channel phosphorylation.

ELECTROPHYSIOLOGICAL STUDIES IN CULTURED HUMAN MICROGLIA J.G. McLamon*, R. Xu, Y.B. Lee1 and S.U. Kim1 Dept. of Pharmacology & Therapeutics, and ¹ Div. of Neurology, Dept. of Medicine, The Univ. of British Columbia, Vancouver, B.C. V6T1Z3

Patch clamp studies have been carried out on microglia isolated from fetal human brains. An inwardly-rectifying K+ current, but no outward K+ current, was expressed within two days of cell adherence. After 5 days of cell attachment to substrate, an outward K+ current was evident in addition to the inward K+ current. The outward K+ current was composed of two components with different kinetic behavior and with different pharmacology. adherent cells (day 1 or 2 after plating) treatments with IFN-y (200 U/ml for 12 h) led to expression of the outward K⁺ current which was not observed in the absence of the cytokine treatment. Two high conductance channels were expressed in inside-out patches including a high conductance BK-type of K(Ca) channel (unitary conductance of 106 pS with physiological levels of K across the patch) and an anion channel (unitary conductance of 280 pS). For K(Ca), with the patch potential held at 0 mV, the open probability was 0.5 with internal Ca2+ at a concentration of 7 μM. Recordings from cell-attached patches also provided evidence for a unitary current which was activated by suction applied to the patch pipette. This channel had a conductance of 30 pS and was non-selective for different cations. The properties and expressions of the different currents in the cultured human microglia may be correlated with functions of these cells in the CNS when activated by a variety of stimuli

ACTIVATION OF INWARD RECTIFYING POTASSIUM CHANNELS BY CANNABINOID CB1 AND CB2 RECEPTORS. Y. Uezono*, Y. Ueda, K. Pleyte, J.T. Eells, F. Izumi and B.Y. Ho, Univ. of Occup. & Environ. Health, School of Medicine, Kitakyushu 807, Japan. and Dept. Pharmacol. Medical College of Wisconsin, Milwaukee, Wi 53226, USA The ability of the cannabinoid receptors to activate G protein-coupled

In ability of the cannabinoid receptors to activate G protein-coupled inward recitifying potassium channels (GIRKs) were studied by expressing the brain (CB1) or peripheral (CB2) cannabinoid receptor with two GIRKs (GIRK1 and CIR) in *Xenopus* oocytes. The cRNAs from various clones were synthesized by in vitro transcription and microinjected into oocytes. Recordings were performed 3-6 days after injection. When the CB1 or CB2 receptor was co-expressed with GIRK1, the cannabinoid receptor agonist CP55940 (1 μ M) elicited 51 \pm 10 and 12 \pm 7 nA current, respectively, at a holding potential of -80mV. When either receptor was co-expressed with both GIRK1 and CIR, the currents elicited by CP55940 were significantly increased to 251 \pm 47.5 (CB1 receptor) and 120 \pm 41 nA (CB2 receptor). Another agonist WIN55212-2 (10 µM) also elicited nA (CB2 receptor). Another agonist WINS5212-2 (10 µM) also clicited 272 ± 69 and 118 ± 32 nA currents, respectively, for the CB1 and CB2 receptors. The EC₃₀ of CP55940 and WINS5212-2 were estimated to be 150 and 440 nM when the CB1 receptor was co-expressed with GIRK1 and CIR. These findings suggest that both the CB1 and CB2 cannabinoid receptors are able to couple to GIRK. Since co-expression of GIRK1 and CIR resulted in much greater currents than expression of GIRK1, GIRKs may be expressed as heteromers. POTASSIUM CHANNELS: MODULATION II

498 1

THE DROSOPHILA ETHER-A-GO-GO (Eag) POTASSIUM CHANNEL SUBUNIT IS A SUBSTRATE FOR CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaMKII)

Z. WANG* and L.C. GRIFFITH Department of Biology and Center for Complex Systems, Brandeis University, Waltham, MA 02254

Behavioral, physiological and biochemical interactions of CaMKII and Eag in Drosophila Melanogaster suggest that an important component of neural plasticity may be mediated through modulation of Eag function by CaMKII (Griffith *et al*, PNAS, 1994). To determine whether Eag was a substrate for CaMKII, partial Eag sequences were expressed in E. coli as glutathione-S-transferase (GST) fusion proteins. Two separate fusions corresponding to Eag N-terminal residues 44-210 and to C-terminal residues 556-802 were examined *in vitro*, as both fragments were presumed to be 506-002 were examined in wirth, as both fragments were presumed to be cytoplasmic. Only the C-terminal fragment was actually phosphorylated by purified CaMKII. In this fragment, one of the CaMKII consensus phosphorylation sites (Thr⁶⁵⁵) falls within the putative Eag cyclic nucleotide-binding domain. Phosphorylation of Thr⁶⁵⁵ by CaMKII could potentially alter binding domain. Prospinory and the ability of cyclic nucleotides to regulate potassium currents. A phosphospecific polyclonal antibody was raised against a phospho-Thr⁶⁵⁵-containing peptide. The purified antibody recognized only the phosphorylated form of the C-terminal fusion protein but not the unphosphorylated form, unambiguously identifying Thr⁶⁵⁵ as an *in vitro* phosphorylation site of CaMKII. However, a corresponding T655A mutant fusion protein was also phosphorylated by CaMKII, indicating the presence of other potential CaMKII phosphorylation site(s). The Thr⁶⁵⁵ phosphospecific antibody did not recognize the phosphorylated form of the mutant fusion protein. Whether ${\rm Thr}^{655}$ is an $in\ vivo\ {\rm target}$ for CaMKII is under investigation. TYROSINE KINASE INHIBITION DECREASES THE LEVEL OF PHOSPHOTYROSINE IN HEK 293 CELLS EXPRESSING Kv3.1 K⁴ CHANNELS. S.D. Critz*, K.P. Wade, and B.A. Wiblea, Rammelkampf Ctr. for Research, Case Western Reserve, Cleveland, OH@ and Dept. of Structural & Cell Biology, Univ. of South Alabama, Mobile, AL. 36688. Although the regulation of K^{\star} channels by serine/threonine kinases is

well known, much less is known about the effects of tyrosine kinase-mediated phosphorylation of these channels. We found previously that tyrosine kinase inhibitors block K+ channels stably expressed in HEK 293 cells (Soc. Neurosci, Abstr. 19:711, 1993).

This effect was examined further biochemically by analyzing the effects of tyrosine kinase inhibition in the cells. Kv3.1 K+ channel transfects were incubated 30 min in depolarizing saline at 10, 30, 100, and 300 μM doses of the tyrosine kinase inhibitor genistein. The cells were lysed and solubilized proteins were processed by SDS-PAGE and Western transfer for immunodetection of phosphorylated tyrosine using mouse anti-phosphotyrosine antibody. We find that the phosphorylation of two proteins (22 kD and 18 kD) are decreased in a dose-dependent manner by tyrosine kinase inhibition. We also determined that the proteins were associated with the particulate fraction. These results suggest that the phosphorylation of tyrosine residues on these proteins may play a role in regulating K+ channel activity. (Alzheimer's Assoc. PRG-90)

MODULATION OF POTASSIUM CHANNEL Kv1.4 BY MUSCARINIC RECEPTOR. T. Rossignol and S.V.P. Jones*. Department Psychiatry, University of Vermont College of Medicine, Burlington, VT 05405.

The effects of muscarinic receptor-induced modulation of a transient potassium channel (hKv1.4) were investigated by co-expression of hKv1.4 with the m1 muscarinic receptor in TSA cells. Using the whole-cell patch clamp technique large outward transient potassium currents were obtained in 80-90% of the cells transfected. Cells were voltage clamped at -60 mV, hyperpolarized to -100 mV for a 1.5 s prepulse, and stepped to a variety of potentials from -110 mV to +50 mV for 500 msec. Current-voltage activation curves were constructed from the peak of the outward current response. To obtain the inactivation curve the cells were held at -60 mV, then stepped to a variety of prepulse potentials, from -110 mV to -50 mV for 1.5 s then depolarized to +50 mV for 500 ms. Current-voltage inactivation curves were constructed from the peak of the outward current at the +50 mV depolarization step. Stimulation of the m1 muscarinic receptor by application of 100 µM acetylcholine, via a pressure ejection pipette, had no significant effect on the peak current amplitude, and produced no shift in the I-V curves. However, preincubation with 100 ng/ml of pertussis toxin (overnight) resulted in a reduction of the peak current amplitude upon application of acetylcholine (n=30). Peak current amplitudes were reduced from 4.15 ± 1.49 nA (n=7) to 3.37 ± 1.24 nA (n=7) in the presence of 100 µM acetylcholine, a decrease of 19%. Current amplitudes returned to control levels of 3.96 ± 1.39 nA (n=7) after washout of the acetylcholine. To investigate the mechanism of action of acetylcholine, a variety of second messengers were applied to the cells. Stimulation of protein kinase C by phorbol esters and activation of cAMP-dependent protein kinase had no effect on Kv1.4, however 5-10 µM arachidonic acid induced a dose-dependent reduction in Kv1.4 current amplitude

ELECTROPHYSIOLOGICAL CO-LOCALIZATION OF ANGIOTENSIN II TYPE 1 (AT,) AND TYPE 2 (AT2) RECEPTORS IN CULTURED NEURONS FROM RAT BRAIN. C.H. Gelband, M. Zhu, R.L. Casto*, P. Posner, and C. Sumners. Dept. of Physiology, Univ. of Florida, Gainesville, FL 32610.

We previously demonstrated that angiotensin II (Ang II) either inhibits or stimulates, via AT1 and AT2 receptors respectively, the delayed rectifier K3 current (lx) in neurons cultured from newborn rat hypothalamus and brainstem (Kang et al., 1993; Sumners et al., 1996). Using standard whole-cell patch clamp techniques, we have investigated whether these responses occur on the same or different populations of neurons. Four distinct electrophysiological responses to Ang II (100 nM) were observed. First, application of Ang II caused a losartan (1 μM) sensitive, AT_1 receptor mediated decrease in I_K (n=10). Second, application of Ang II caused a PD 123319 (1 μM) sensitive, AT₂ receptor mediated increase in I_v (n=10). Third, application of Ang II caused a biphasic effect on I_v. Ang II elicited a losartan sensitive, AT, receptor-mediated decrease in IK followed by a PD 123319 sensitive, AT₂ receptor-mediated increase in I_K (see Figure, n=6). Fourth, the application of Ang II caused a PD 123319 sensitive, AT2 receptor-

mediated increase in Ik followed by a losartan sensitive, AT1 receptor-mediated decrease in I_K (n=3). This indicates the presence of a population of neurons that contain both AT; and AT2 receptors, and other populations that express only a single type of Ang II receptor. (Supported by HL-49130 and an AHA-FL Affiliate II Award).

SIALIDATION MODIFIES THE FUNCTION OF KV1.1 POTASSIUM CHANNELS. W.B. Thornhill and J.F. Margiotta*, Dept. Physiology and Biophysics, Mount Sinai School of Medicine, New York, NY 10029.

Exo- and endo-sialidase sensitivity of brain Kv1.1 potassium (K)

Exo- and endo-sialidase sensitivity of brain Kv1.1 potassium (K) channels suggests that the tetramer contains 150-200 negatively-charged sialic acids, some of which are in an unusual tandem-linked structure. To examine the role of sialidation in K channel function, CHO cells deficient in glycosylation (Lec mutants) were transfected with rat brain Kv1.1 cDNA. Patch-clamping techniques determined that functional Kv1.1 channels were expressed in all cell lines but the voltage dependence of activation (V1/2) was shifted to more positive voltages (up to 23mV) and the activation kimetics were slower in the Lec mutants compared with controls. A similar shift in V1/2 to positive voltages was recorded in control cells expressing Kv1.1 following treatment with sialidase or by raising extracellular calcium. In contrast, these treatments had little or no effect on the Lec mutants, indicating that channel sialic acids appear to be the negative charges sensitive to screening by calcium. The data suggest that sialic acid addition modifies Kv1.1 function, possibly by influencing the local electric field detected by its voltage-sensor, but that these carbohydrates are not required for cell surface expression. Supported by NIH grants to WB Thornhill (NS29633) and JF Margiotta (NS24417).

DIRECT ASSOCIATION OF SRC TYROSINE KINASE WITH HUMAN Kv1.5 POTASSIUM CHANNEL MEDIATED BY AN SH3 DOMAIN INTERACTION. T.C. Holmes*, D.A. Fadool, R. Ren¹ and I. B. Levitan. Department of Biochemistry and Volen Center for Complex Systems, 'Department of Biology and Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, MA 02254.

Tyrosine phosphorylation modulates the properties of potassium channels, but the mechanism(s) that mediate channel/kinase association are unknown. The human isoform of the Kv1.5 potassium channel (hKv1.5) contains proline-rich sequences that are identical to sequences characterized previously as Src homology 3 (SH3) domain binding sites. Additionally, this channel contains potential tyrosine phosphorylation sites. The association of hKv1.5 and Src tyrosine kinase (Src) was examined in HEK 293 cells transfected transiently with cDNA constructs encoding both proteins. hKv1.5 and Src are associated in lysates from these cells, as shown by immunoprecipitation with specific antibodies for hKv1.5 or Src followed by western blot. hHv1.5 also binds to a fusion protein containing the Src SH3 domain, as shown by precipitation and filter binding assay. In contrast, the closely related rat Kv1.5 and Kv1.3 channels, which lack the Src SH3 domain binding site, do not associate strongly with Src kinase. Furthermore, hKv1.5 is tyrosine phosphorylated and functionally modulated by Src kinase. These results provide direct biochemical evidence for a potassium channel-protein kinase signalling complex. Supported by research and training grants from NIH.

498.9

TYROSINE PHOSPHORYLATION OF TWO CLONED CALCIUM-DEPENDENT POTASSIUM CHANNELS. Y. Zhou*, J. Wang and I. B. Levitan. Department of Biochemistry and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

It has been shown recently that tyrosine phosphorylation modulates the properties of voltage-dependent potassium channels. To determine whether calcium-dependent potassium channels are targets for tyrosine kinases, two large-conductance calcium-dependent potassium channels cloned from Drosophila (dSlo) and mouse (mSlo) were expressed in the mammalian cell line tsA201 using calcium phosphate-mediated transfection. The tyrosine phosphorylation of the channels was assessed immunoprecipitation and Western blot analysis, using a phosphotyrosine-specific antibody and antibodies that recognize specifically either dSlo or mSlo. Both dSlo and mSlo channels are tyrosine phosphorylated to a limited extent under basal conditions. The tyrosine phosphorylation of both dSlo and mSlo is increased when channeltransfected cells are treated with the membrane-permeant tyrosine phosphatase inhibitor pervanadate (200 µM, 10-30 min). Co-expression of the constitutively active tyrosine kinase, v-src, with the channel proteins, also causes a large increase in tyrosine phosphorylation of both dSlo and mSlo. Thus cloned calcium-dependent potassium channels are substrates for endogenous and co-expressed tyrosine kinases in cells. Supported by a research grant from NIH.

498.6

THE DROSOPHILA SLOWPOKE (dSlo) CALCIUM-DEPENDENT POTASSIUM CHANNEL IS PHOSPHORYLATED AT SERINE 942. J. Wang* and I. B. Levitan. Department of Biochemistry and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We have shown previously that the cloned calcium-dependent potassium channel, dSlo, can be phosphorylated at Serine 942 (S942) by various protein kinases in vitro (Wang and Levitan, Soc. for Neurosci. Abstr. 21, 1829, 1995). To investigate if S942 is phosphorylated in vivo, we generated two polyclonal antibodies against dSlo. One antibody, against a phosphorylated peptide corresponding to the dSlo sequence flanking \$942 recognizes dSlo on a western blot only when it is phosphorylated at S942. The other antibody, raised against the carboxyterminal 58 amino acids of dSlo, is used for immunoprecipitation as well as western blotting. Immunoprecipitates of dSlo, expressed transiently in the mammalian cell line tsA201, were analyzed on western blots with the phosphorylation-specific antibody. The results indicate that a fraction of dSlo protein is phosphorylated at S942 with basal kinase activity. Treatment of cells with forskolin dramatically increases the phosphorylation, implying that cAMP-dependent protein kinase (PKA) can phosphorylate dSlo at S942 in vivo. Furthermore, dSlo protein immunoprecipitated from Drosophila head lysates is phosphorylated at S942. Thus, the native channel protein is indeed a substrate for protein kinase(s), and S942 is phosphorylated under physiological conditions Supported by a research grant from NIH.

MUTATIONS IN THE S4-S5 LOOP OF THE CALCIUM-DEPENDENT POTASSIUM CHANNEL, mSlo, DECREASE SHAKER BALL PEPTIDE BLOCK AND SHIFT GATING PROPERTIES. M. H. Holmqvist*, D. A. Sullivan and I. B. Levitan. Department of Biochemistry and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

The Shaker inactivating peptide blocks the mouse large conductance calcium-dependent potassium channel, mSlo. In the Shaker channel, the intracellular loop between membrane spanning regions 4 and 5 has been suggested to form part of the receptor for the Shaker peptide (Isacoff et al., Nature 353:86-90, 1991). To test if the peptide also interacts with this loop in mSlo, we mutated three conserved residues in this region to alanines (T229A, S232A, L235A). This triple mutation decreases the number of blocking events by the peptide on reconstituted mSlo channels in artificial bilayers. Furthermore, this mutant is 50 times less calcium sensitive than the wild type channel, as measured with macroscopic currents in inside-out patches from HEK 293 cells transfected with mSlo. At a given calcium concentration, the activation curve of the mutant channel is shifted by 80 mV to more positive potentials. Using constructs with only one amino acid mutated, we found that L235A and T229A mSlo have properties intermediate between wild type and triple mutant channels. Thus the S4-S5 intracellular loop of mSlo plays a role in both Shaker ball peptide binding and the calcium and voltage-dependent gating of these channels. Supported by a research grant from NIH

498.10

SRC TYROSINE KINASE HAS MULTIPLE FUNCTIONAL EFFECTS ON THE CLONED VOLTAGE-GATED K* CHANNEL, Kv1.3. D.A. Fadool*, T.C. Holmes, and I.B. Levitan. Department of Biochemistry and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We are studying the regulation of ion channels by protein tyrosine kinases (TKs) using a cloned voltage-dependent potassium channel, Kv1.3, as a model. Kv1.3 channels are studied by transient overexpression of their cDNAs in human embryonic kidney (HEK 293) cells using lipofectamine transfection. We have demonstrated previously that Kv1.3 tyrosine phosphorylation is increased and current is suppressed, following channel co-expression with the constitutively active cellular TK, v-src. Putative tyrosine phosphorylation sites were changed to phenylalanine (Y to F mutations). These mutagenesis experiments have shown that tyrosine residues 137 and 449 are required for TK induced current suppression, residues 111-113 and 449 are required for increasing the channel deactivation kinetics, and residues 111-113, 137, and 479 are required for decreasing the rate of C-type inactivation of the channel. Thus v-Src can have different effects on Kv1.3 by phosphorylating multiple residues. Whole-cell outward currents in rat olfactory bulb neurons (OBNs), which express Kv1.3 channels, are suppressed following internal application of c-Src^{pp60}. Hence tyrosine phosphorylation of Kv1.3 and related channels may be involved in modulation of the activity of OBNs. Supported by research and training grants from NIH.

SLOB, A NOVEL PROTEIN THAT INTERACTS WITH THE DROSOPHILA SLOWPOKE (dSlo) CALCIUM-DEPENDENT POTASSIUM CHANNEL. W.M. Schopperle, J. Wang and I.B. Levitan*. Department of Biochemistry and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254

Protein-protein interaction is a fundamental mechanism for cellular regulation of protein function. The cloned calcium-dependent potassium channel, dSlo, was used in the yeast two-hybrid system, a genetic tool for studying protein-protein interactions, to identify dSlo-interacting proteins. Putative intracellular portions of the dSlo channel were screened against a *Drosophila* head cDNA library and six clones were identified as potential dSlo-interacting proteins. Four of the clones contained partial sequences of the same cDNA. DNA probes were used to clone the full length cDNA from a cDNA library. The sequence encodes a 483 amino acid protein. Searches for sequence homology with known proteins reveal no specific matches suggesting that the protein, named Slob (Slobinding), is novel. Slob and dSlo interact in vivo, as shown by transiently co-expressing dSlo and HA-epitope-tagged Slob in the mammalian cell line tsA201, immunoprecipitating dSlo, and detecting Slob in the immunoprecipitate by western blotting with anti-HA antibodies. Work is in progess to identify the function of Slob. Supported by research and training grants from NIH.

SUBSTANCE P - INVOKED SENSITIZATION OF (BK-) K+-CHANNELS TO ANESTHETIC INHIBITION IS MEDIATED BY AN INCREASE IN PHOSPHORYLATION. W.H. Stapelfeldt, J.M. Oleszewski. Department of Anesthesiology & CCM, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261, and VA Medical Center, Pittsburgh, PA 15240.

We recently demonstrated that the general anesthetic agents propofol (PRO) and ketamine augment substance P (SP)-evoked inward current responses of guinea-pig inferior mesenteric ganglion (IMG) neurons through synergistic interaction with a SP-invoked signal transduction mechanism, producing selective inhibition of a charybdotoxin-sensitive (BK-) $G_{K(Ca)}$ -conductance which normally restrains SP excitatory responses and which also contributes to the afterspike hyperpolarization (ASH) of these neurons. Aim of the present study was to determine the possible role of a SP-invoked change in phosphorylation in mediating this sensitization. Single-electrode (manual) voltage clamp recordings were obtained from isolated perfused IMGs. Study parameters included baseline ASH amplitudes, SP-evoked inward current responses, and associated changes in ASH amplitudes and peak amplitudes of intermittently (0.5 Hz) evoked electrotonic action potentials (APs) before and during SP responses. Exogenous SP was applied by pressure microejection from nearby micropipets (Picospritzer). Propofol (100 μM) alone had no effect on baseline AP parameters, but caused a significant (44%, p<0.05) increase in the amplitude of SP inward current responses which was related in amplitude (p<0.01) with a decrease in peak ASH amplitudes and selectively occluded by charybdotoxin (CTX, 10 nM). In the presence of the kinase inhibitor staurosporine (100 nM), the SP-invoked effect of PRO, but not the effect of CTX, was abolished. In contrast, in the presence of the phosphatase inhibitor okadaic acid (50 nM), the addition of PRO alone, even in the absence of SP, produced inhibition of ASH amplitudes (p<0.01). These findings suggest that the anesthetic sensitivity of the underlying CTX-sensitive $G_{K(Ca)}$ -conductance to inhibition by propofol is not static but subject to physiologic neuromodulation through a net change in phosphorylation Support: VA MERIT REVIEW, FAER & Syntex Laboratories (Young Investig. Award)

PHOSPHATASE-KINASE BALANCE REGULATING THE HIPPOCAMPAL Ca2+-ACTIVATED K+ CURRENT IAHP IN BASAL CONDITIONS

P. Pedarzani 1*, W. Stühmer 1 and J.F. Storm 2, 1 MPI for Experimental Medicine, Göttingen, Germany, and ²Inst. of Neurophysiology, Univ. of Oslo, Norway.

The slow Ca2+-activated K+ current IAHP underlying spike frequency adaptation in hippocampal pyramidal neurons is regulated by different neurotransmitters (NT) via multiple second-messenger systems and kinases. Previous data (Pedarzani & Storm, Neuron 11, 1023-35, 1993) suggested the presence of a basal phosphorylation-dephosphorylation turnover, affecting the I_AHp in the absence of NT stimulation. By intracellular application of kinase and phosphatase inhibitors, we have found evidence for the structure of protein phosphorylation (PRI) or 24 (PRI) and A (PRI for opposing actions of protein phosphatase I (PPI) or 2A (PP2A), but not of calcineurin (PP2B), and of PKA in this basal modulation of the IAHP.

Whole-cell recordings were obtained from 45 CA1 pyramidal cells in slices from young rats. Inclusion of the PP1-PP2A inhibitors microcystin (5-50 μM; n=6), young ratio. Increasion of the ITTF12 minitorial microsystim ($9-30 \mu M$), $(9-30 \mu M)$, and callyculin A ($5-10 \mu M$); n=3) in the pipette solution invariably caused a substantial run-down in the IAHP amplitude, never seen in controls of comparable durations (n=7). Since these inhibitors block both PP1, PP2A and most likely also PP2B at the concentrations we used, we are currently performing experiments with a specific peptide inhibitor of PP1 to try to define which phosphatase experiments with a specific peptide inhibitor of PPI to try to define which phosphatase is affecting the IAHP in basal conditions. Furthermore, we tested the involvement of PP2B by applying intracellularly the specific PP2B inhibitor FK506 (10-200 µM; n=3; generous gift of Fujisawa). Intracellular application of FK506 had no effect on the IAHP amplitude, suggesting a lack of involvement of PP2B in the basal modulation of this current. Further experiments with a specific PP2B peptide inhibitor will be performed to rule out a possible wash-out of the immunophilin FK-binding protein as a reason for the lack of effect of FK506. Finally, when we co-applied intracellularly microcystin (10 µM) and the PKA inhibitor Rp-CAMPS (500 µM: n=7), we did no longer observe a run-down in the IAHP amplitude, suggesting a role for PKA in counterbalancing the effect of PP1 or PP2A on this current in basal conditions. ATP ACTIVATION OF BK-CHANNELS IN GH3 CELLS INVOLVES PLA, D. D. Denson and D. C. Eaton. Depts of Anesthesiology and Physiology and The Center for Cell and Molecular Signaling, Emory Univ. Sch. of Med., Atlanta, GA

Center for Cell and Molecular Signaling, Emory Univ. Sch. of Med., Atlanta, GA 30322.

BK-channels are activated by both Mg-ATP and ATP-Y-S in excised patches and in lipid bilayers. It has been suggested that this activation is due to a direct PKC mediated phosphorylation of the channel by ATP. Since PLA, production of arachidonic acid is also a potent activator of BK-channels in excised patches and since PLA, can be activated by a PKC mediated phosphorylation it is possible that ATP activation of these channels involves phosphorylation of PLA, and the effects of Mg-ATP and ATP-y-S on BK-channel activation in excised patches. We then examined the effects of Mg-ATP on BK-channel activation in excised patches. We then examined the effects of Mg-ATP on BK-channel recording techniques in excised patches were used for these experiments. Solutions containing 150 mM KCl were used in both the pipette and bath. Ca, in the bath was buffered with 5mM K,EGTA to 0.1 µM for experiments without aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with aristolochic acid and to 1.0µM for experiments with a first part of the property of

MODULATION OF "MAXI" POTASSIUM (K+) CHANNEL FROM NONPIGMENTED CILIARY EPITHELIAL CELLS BY DIBUTYRYL CYCLIC AMP. B. J. Bhattacharyya*, D. Krupin, P. E. Hockberger and T. Krupin. Depts. of Ophthalmology and Physiology, Northwestern University Medical School, Chicago, IL 60611.

Pigmented and nonpigmented epithlelial (NPE) cells in the ciliary body are responsible for secretion of the aqueous humor in mammalian eyes. The ionic conductance of epithelial cell membranes regulates the water and ionic content of the secretion and thereby influence intraocular pressure. As a first step towards understanding ciliary epithlelial secretion, we have examined a calcium-dependent "maxi" K+ channel in NPE cells from enzymatically dissociated (trypsin, 0.5 mg/ml, in Ca/Mg-free, low Cl saline) ciliary bodies from adult rabbits. The channel was detected in 30% of inside-out patches (n = 50) in symmetrical KCl solutions (150 mM) with elevated bath calcium (1.2 mM). The single-channel current displayed a linear I-V relationship with an average slope conductance of approximately 130 pS. The channel open probability was markedly increased by bath application of dibutryrl-cyclic AMP (20 μM), and the conductance was blocked by barium (2 mM) or quinidine (1 mM). These results suggest that a cyclic AMP-dependent mechanism is involved in activation of the "maxi" K+ channel in NPE cells.

LPS RAPIDLY INCREASES BK CHANNEL OPENING IN INSIDE-OUT PATCHES OF RAT CEREBROVASCULAR SMOOTH MUSCLE CELLS M. Hoang, D. M. Mathers* Dept. of Physiology, Univ. of British Columbia, B.C.,

Lipopolysaccharide (LPS) activates the expression of inducible NO synthase (iNOS) in both cerebral and peripheral blood vessels, leading to an overproduction of NO and potentiation of vasorelaxation. This NO-mediated relaxation most likely involves the L-arginine-NO-cGMP pathway. Elevation of cGMP activates the cGMP-dependent protein kinase G (PKG) to phosphorylate large-conductance Ca²⁺-dependent K* channels (BK channels) which hyperpolarize the smooth muscle membrane, resulting in vasorelaxation. We here demonstrate a very rapid increase in the probability of BK channel opening (P_a) in response to acute application of LPS. Using inside-out patches excised from dissociated primary cultures of rat rovascular smooth muscle cells (CVSMCs), BK channel activity was monitored with the cytoplasmic face exposed to saline containing $[Ca^{2+}]_i=1$ μM . application of 100 µg/ml LPS to the culture, P_o rapidly and reversibly increased without changing the amplitude of currents flowing in single channels. This ent of Po was recorded 22.4 ± 3.4 sec after exposure to LPS and averaged a 4.96 fold increase (n = 11). However, following a 4 h period (22°C) pre-incubation of CVSMC cultures with 1 mM of the NOS inhibitor, L-NAME, application of 100 μ g/ml LPS resulted in P_o values not significantly different from values obtained prior to application of the endotoxin. When 0.3 mM cGMP was applied to the cytoplasmic face of the patch, $P_{\rm e}$ also increased by a factor of 3.34±0.88 over control values. These results suggest that the rapid increase in $P_{\rm e}$ on acute application of LPS is apparently mediated by the L-arginin-NO-cGMP-PKG-BK channel pathway.

ACTIVATION OF CALCIUM-DEPENDENT POTASSIUM CHANNELS IN NEURONS BY NEUROTROPHINS. Ninna R. Holm^{1,2}, Palle Christophersen², Søren-P. Olesen², Jørn Hounsgaard^{3*} and Steen Gammeltoft¹. Department of Clinical Biochemistry, Glostrup Hospital; NeuroSearch A/S, Smedeland 26B, 2600 Glostrup; Department of Medical Physiology, University of Copenhagen, Denmark

The neurotrophins are signaling factors essential for survival and differentiation of distinct neuronal populations during development and regeneration of the nervous system. The long-term effects of neurotrophins have been studied in detail, but little is known about their acute effects on neuronal activity. Here we use permeabilized whole-cell patch clamp to demonstrate that neurotrophin-3 (NT-3) and nerve growth factor (NGF) activate calcium-dependent, paxilline-sensitive potassium channels (BK channels) in cortical neurons. Application of NT-3 or NGF produced a rapid and gradual rise in BK current that was sustained for 30-50 min; brain-derived neurotrophic factor and insulin-like growth factor-1 were without significant effect. The response to NT-3 was blocked by inhibitors of Trk tyrosine kinases, phospholipase C and serine/threonine protein phosphatase I and 2a. Omission of Ca^{2^+} from the extracellular medium prevented the NT-3 effect. Activation of protein kinase C decreased the BK current and inhibited the NT-3 response. Our results indicate that NT-3 stimulates BK channel activity in cortical neurons through a signaling pathway that involves protein dephosphorylation. Activation of BK channels may be a major mechanism by which neurotrophins acutely regulate neuronal activity.

Transient absence of an inward rectifier that governs a window of spontaneous activity during muscle cell differentiation is mediated by modulation of a single channel type.

A. K. Davis and W. J. Moody*. Department of Zoology, University of Washington, Seattle, WA 98195.

Coordinate expression of functional ion channels is required for normal cellular differentiation of ascidian muscle (Dallman et al., 1994). We study this organism because it has pigmented muscle cells allowing us to identify muscle precursors at all stages of development. An inwardly rectifying potassium channel ($I_{\rm IR}$) is present at constant density in muscle-lineage cells at all stages of development from the cooyet to mature muscle (36 hours later) except for a brief period of 2-4 hours near neurulation when its functional expression is down-regulated by >80%. $I_{\rm IR}$ is the sole resting conductance of these cells, therefore its absence destabilizes the resting potential. The down-regulation of $I_{\rm IR}$ is temporally coordinated with the first appearance of lineage specific calcium ($I_{\rm CA}$) and slowly activating outward potassium currents ($I_{\rm IR}$) that govern the waveform of the action potential. The coordinate regulation of these ion channels ($I_{\rm IR}$, $I_{\rm IR}$) creates a window of time during which spontaneous activity occurs. Activity (calcium entry) during this window is essential for the normal differentiation of a calcium-dependent potassium current that is expressed in mature muscle and E-C coupling (Dallman et al., 1994).

The transient absence of $I_{\rm IR}$ is a critical factor controlling the expression of

The transient absence of I_R is a critical factor controlling the expression of spontaneous activity in the muscle precursor cells. To address the mechanism of I_R transient down-regulation we examined I_R single channel properties before and after the window of spontaneous activity. I_R has the same single channel conductance before its disappearance (10.35 ± 0.52 pS) as after the window (11.55 ± 1.59 pS) (p=163) suggesting that I_R before and after the window are products of the same gene. We are currently pursuing studies to determine whether I_R reappearance requires mRNA synthesis

PRESERVATION OF SPIKE TIMING AND INCREASED EXCITABILITY UNDER CHOLINERGIC MODULATION IN NEOCORTICAL NEURONS Akaysha C. Tang*, and Terrence J. Sejnowski. The Salk Institute, Computational Neurobiology Lab, La Jolla, CA 92037.

Acetylcholine (ACh) enhances neuronal responsiveness of cortical neurons. Associated with this enhancement is a reduction in spike frequency adaptation: interspike intervals increase with time when a constant depolarizing current is injected. As a result, ACh appears to not only increase the firing rate but also to alter the temporal structure of the spike train. This cholinergic modification of spike timing would lead to a failure in faithful transmission of the input signal if a neural code based on spike timing were used by the brain. We have examined the effects of ACh on spike timing in rat neocortical neurons using the whole cell patch clamp technique (Science 95, Vol268:1503-1506). When physiologically realistic fluctuating inputs are used, ACh preserves the timing of action potentials in the spike train, while at the same time increasing the firing rate by inserting spikes between existing spikes. These two contrasting effects of ACh suggest that under in vivo conditions, cholinergic modulation may be more protean and less limited than we had previously envisaged—permiting the preservation of spike timing information, and at the same time, enhancing the output signal by increasing the firing rate

THE CONTRIBUTION OF AFTERHYPERPOLARIZATION CURRENTS TO CHOLINERGIC ENHANCEMENT OF EXCITABILITY AND PRESERVATION OF SPIKE TIMING IN A NEOCORTICAL NEURON MODEL. A.M. Bartels, M.J. McKeown, A.C. Tang, T.J. Sejnowski*

Computational Neurobiology Lab., Salk Institute for Biological Studies, La Jolla, CA 92037-1099

Recent physiological studies have shown that the effects of cholinergic modulation can be different when physiologically more realistic fluctuating rather than constant depolarizing currents are injected into a neocortical neuron (see companion poster, Tang-Sejnowski, 1996). In a modified version of a 10 compartment neocortical neuron model (Bush-Sejnowski, 93), we show that the effect of cholinergic modulation is a stimulus—dependent simultaneous preservation of spike timing and enhancement of neuronal excitability. We focus on the hypothesis that although playing a dominant role in cholinergic enhancement of excitability under constant depolarizing input I_{AHF} is less important in the modulation of the firing rate under the physiologically more realistic fluctuating inputs. We first constrained the model to reproduce the phenomenon of spike frequency adaptation (SFA) and a reduction in SFA due to cholinergic modulation (modeléd as a decrease in maximum conductance, g_{KCa} .) Next, by varying the fluctuation amplitude and mean intensity of the current injection, we compute a spike count–based index, D, for the contribution of I_{AHF} to enhanced excitability. We found that D can decrease as the amplitude of current fluctuation increases. This suggests that the contribution of I_{AHF} to cholinergic enhancement of neuronal excitability will be more prominent for physiologically unrealistic stimuli than that observed under in vivo conditions.

ROLE OF SEROTONIN₃ RECEPTORS IN ACETYLCHOLINE RELEASE IN THE RAT FRONTAL CORTEX: AN IN VIVO BRAIN MICRODIALYSIS STUDY.

H. Hirano*, M. Hirata, M. Yamada and Y. Matsuda. Department of Neuropsychiatry, Yamaguchi University School of Medicine, Ube, Yamaguchi 755, Japan.

The role of serotomin (5-HT)₃ receptors in the serotonergic

The role of serotomin (5-HT)₃ receptors in the serotonergic regulation of cortically projecting cholinergic neurons was studied using *in vivo* microdialysis to measure extracellular acetylcholine (ACh) concentrations in the frontal cortex of freely moving rats.

(ACh) concentrations in the frontal cortex of freely moving rats. Neither systemically administered selective 5-HT₃ receptor antagonist MDL 72222 (0.02, 0.2 mg/kg, s.c.) nor ondanserron (0.02, 0.6 mg/kg, s.c.) influenced the ACh output in the frontal cortex compared with distilled water. Systemic administration of fenfluramine (10 mg/kg, i.p.) significantly increased cortical ACh release. Pretreatment (60 min) with ondansetron (0.6 mg/kg) did not impact the effect of fenfluramine on ACh release. Local application of the 5-HT₃ agonist 2-methyl-5-HT (1 µM for 60 min) in the frontal cortex via reverse dialysis failed to affect the basal ACh output.

These results suggests that the 5-HT₃ receptors do not play an important role in the serotonergic regulation of ACh release in the frontal cortex.

ENHANCEMENT OF THE EXPRESSION OF CHOLINE ACETYLTRANSFERASE mRNA IN HUMAN T-LYMPHOCYTES BY IMMUNOLOGICAL STIMULATION. T. Fujii, S. Yamada, H. Misawa¹, S. Tajima, K. Fujimoto, T. Kasahara¹ and K. Kawashima³. Depts. of Pharmacology and ¹Biochemistry. Kyoritsu College of Pharmacy, Tokyo 105, Japan and ¹Department of Neurology, Tokyo Metropolitan Institute for Neuroscience, Fuchu City, Tokyo 183, Japan.

Acetylcholine (ACh) a neurotrapemitter in the requirement.

Neurology, Tokyo Metropolitan Institute for Neuroscience, Fuchu City, Tokyo 183. Japan.

Acetylcholine (ACh), a neurotransmitter in the nervous systems, has been suggested to play an important role in the regulation of interaction between the immune and nervous systems. We have previously reported that ACh is present in the blood of various mammals including humans, and that its synthesis is catalyzed by choline acetyltransferase (ChAT), which is known to catalyze ACh synthesis in the nervous system. In the present study, we used detection of ChAT mRNA to examine whether ACh synthesis in T-lymphocytes is stimulated during immune responses. Total RNA was obtained from human peripheral blood mononuclear leukocytes (MNLs) cultured in the presence or absence of T-cell activator, phytohemagglutinin (PHA), and human leukemic cell lines derived from peripheral blood cells. The expression of ChAT mRNA was analyzed by reverse transcription-polymerase chain reaction (RT-PCR) using specific order and reverse primers for human brain ChAT cDNA. A single transcript of RT-PCR product was detected on agarose gel in samples obtained from PHA-stimulated MNLs and T-cell lines (CEM, HSB-2 and MOLT-3), but not in unstimulated MNLs or a B-cell line (Daudi). The position of RT-PCR product obtained from PHA-stimulated MNLs and three T-cell lines was identical with that in the human brain sample used as a positive control. These results suggest that the expression of mRNA for ChAT in T-lymphocytes is enhanced during the immune responses, and indicate that ACh synthesis by ChAT in T-lymphocytes is initiated by immune stimulation.

SPECIFIC CHOLINERGIC IMMUNOTOXINS IN MICE, J. Berger-Sweeney¹, U. V. Berger^{2*}, D. A. Lappi³, C. F Hohmann⁴, A. Ewusi¹, K. M. Frick 1. 1 Wellesley College, Wellesley, MA; 2 Brigham and Women's Hospital, Boston, MA 02115, ³Advanced Targeting Systems, San Diego, CA 92191, and

⁴Morgan State University, Baltimore, MD 21239. We have shown previously that 192 IgG-saporin, a p75 (NGF receptor)-specific antibody linked to the ribosomal inactivator saporin, is an effective lesioning agent for cholinergic basal forebrain neurons in rats (*J. Neurosci.* 14:4507-4519). agent for cholinergic basal forebrain neurons in rats (*J. Neurosci.* 14:4507-4519). The 192 IgG antibody, however, does not crossreact with the mouse NGF receptor, making it unsuitable for studies in mice. The goal of these experiments was to create an effective cholinergic immunotoxin for mice. Monoclonal (gift of D. Anderson) and polyclonal (gift of M. Chao) antibodies to the mouse p75-low affinity NGF receptor were coupled to saporin. The two immunotoxins, uncoupled antibody and saporin, and saline were injected into the medial septal area or the lateral ventricle of mice (n= 4 - 6 per group). Brains were processed for choline acetyltransferase (ChAT) neurochemistry or for immunocytochemistry. ChAT activity levels were reduced by 49% and 30% (relative to controls) in the hippocampi following the monoclonal and polyclonal immunotoxin injection into the ventricle led to 42% and 60% decreases (relative to controls) in cortex and hippocampus respectively; polyclonal immunotoxin injections led to similar but not quite as dramatic reductions. Immunocytochemical analysis using an antibody to parvalbumin (putative GABAergic neurons) revealed no significant reductions in staining of cells in the GABAergic neurons) revealed no significant reductions in staining of cells in the medial septal area after direct monoclonal and polyclonal immunotoxin lesions. These data suggest that we created specific cholinergic immunotoxins in mice. Further experiments will be required to verify specificity and optimal dose ranges. Peripheral Anionic Site Residues Involved in the Interaction of Toxogonin with Carbaryl-Inhibited Acetylcholinesterase. <u>G. Cohen, E. Cohen, F. Adani, Z. Radic*, P. Taylor* and G. Amitai*,</u> IIBR, Israel, "Hebrew University Agricultural Faculty, Israel and *University of California, San Diego, La Jolla, Ca. 92093.

The inhibition rate of acetylcholinesterase (AChE) by 1-naphthyl N-methyl carbamate (carbaryl, CAR) is markedly enhanced by certain quaternary oximes such as toxogonin (TOX). Accordingly, the LD₅₀ of CAR in the presence of TOX decreases by 2-4 fold in mice. We have examined the involvement of peripheral anionic site (PAS) residues of AChE in the interaction of oximes with the carbamylation process. Treatment of mice with the specific PAS ligand propidium (PR) (0.8mg/kg, iv) together with TOX (12.6 mg/kg, im) and CAR (14 mg/kg, iv, 0.7LD₅₀) virtually abolished the TOX-induced increase in CAR toxicity observed without PR (4 out of 5 survivors with PR vs. no survivors without PR). SAD-128, a bisquaternary pyridinium ligand devoid of oxime groups did not alter CAR toxicity in mice (100% survival at 14 mg/kg. iv). These in vivo data indicate the involvement of the PAS of AChE in the toxicity enhancement induced by TOX and that the oxime group is probably required for this effect. Inhibition kinetics of recombinant mouse AChE (mAChE) and its PAS mutants by CAR was measured in the presence and absence of TOX and 1-(2-pyridine aldoxime) 1'-(3-quinuclidinone) dimethylether dichloride (AB-8). Inhibition kinetics of mAChE by CAR (0.1-1 μ M) in the presence of TOX (0.1mM) displayed 10 fold lower value of K_1 and 10 fold larger k_{obs} value than without TOX. Inhibition of the mutant W286R by CAR in the presence of TOX displayed a 2.5 fold lower carbamylation rate constant (k')as compared to the wild type enzyme (k' = 0.088 min⁻¹ vs. 0.22 min⁻¹, respectively, p<0.001). No enhancement by TOX was observed with the triple mutant Y72N/Y124Q W286R. Similar inhibition rate of wt mAChE was obtained in the presence and absence of AB-8. In accordance with these in vitro data, administration of AB-8 did not increase CAR toxicity in mice and survival was observed. Our data indicate that TOX enhancement of inhibition rate of AChE by CAR is influenced by PAS residues of AChE.

BASAL FOREBRAIN CHOLINERGIC SYSTEM: A KNOWLEDGE BASE INSTALLED ON THE WORLD WIDE WEB. L. Zaborszky* and Z. Nadasdy. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

A database is designed for the acquisition, storage and analysis of neuroanatomical, neurophysiological, molecular pharmacological and behavioral data related to the basal forebrain, in particular the basal forebrain cholinergic (BFC) projection system. An important component of this database is a 3-dimensional representation of the basal forebrain relationships and other neurochemical markers. Data acquisition is provided by a commercial neuroscience computer system (Neurolucida, MicroBrightField, Inc.) followed by conversion of data into a WWW (HTTP) based knowledge system. The database is divided into two components, the hypertext pages and the 3-D database. This latter component includes 3-D databases of the reconstructed basal forebrain neurons with different complexities, implemented as virtual reality component includes 3-0 databases of the reconstructor again to reality environments and supported by the VRML protocol. The hypertext pages are edited as standard platform-independent HTML documents. The documents contain either text or images (graphs, diagrams, microscope images, computer graphics). A 3-D reference atlas will ensure relational links among different types of data obtained from different brains at the cellular level. As compared to other neuroanatomy databases the advantages of this database are the following 1) operation system independent, 2) supports links to external databases via the Internet, 3) supports 3-D real time navigations, 4) moves from macro-mapping to cellular and subcellular level of the mapped neural systems.

GABAERGIC MODULATION OF CORTICAL ACETYLCHOLINE RELEASE IN VIVO. M. Giorgetti, L. Bacciotini, M.G. Giovannini & P. Blandina* Dipartimento di Farmacologia Preclinica e Clinica, Universitá di Firenze, 50125 Firenze, Italy.

GABA is the major inhibitory transmitter in the vertebrate CNS, however, there are reports that it facilitated release of ACh from in-vitro preparations of cortex and hippocampus. There are no studies on the effect of GABA on cortical ACh release in vivo. Yet this approach may yield important information about the physiological role of GABA receptors in the modulation of the cortical cholinergic system. We used the microdialysis technique to study the effects of GABAergic agents on cortical ACh release from cortex of freely moving rats. Perfusion flow rate was 3 μl/min. Twenty-four hours after implantation with dialysis fiber, cortex of male Wistar rats (250 g) released spontaneously 2.8±0.1 pmol/10 min ACh (N=25), measured by HPLC with electrochemical detection. Introduction of bicuculline (1-25 μ M), a GABAA antagonist, into the perfusion medium increased spontaneous ACh release. The effect was concentration-dependent, and the maximal increase was about 150%. Spontaneous ACh release returned rapidly to basal values upon perfusion with antagonist free medium. The GABAA agonist muscimol (5-25 µM) alone did not alter spontaneous ACh release. but it (25 μ M) antagonized the effect of bicuculline (10 μ M). Thus, these results suggest that GABA tonically inhibits cortical ACh release through activation of GABAA receptors. Supported by M.U.R.S.T- Universitá di Firenze (Italy)

THE INFLUENCE OF OCCLUSAL AND MASTICATORY FANCTION ON CHOLINERGIC OR CALBINDIN-D28k-IMMUNOREACTIVE NEURONS IN AGING RATS. Hidero TERASAWA¹⁾, Takafumi NINOMIYA²⁾, Toshihiro HIRAII, Yasuhiro IKEDAI, Shin NAKAGAWA*3, Dept. of Removable Prosthodontics, Health Sciences University of Hokkaido, School of Dentistry, Toubetsu, 061-02 Japan¹⁾. Dept. of Anatomy, Sapporo Medical University School of Medicine, Sapporo, 060 Japan2). Dept. of Anatomy, Faculty of Medicine Hokkaido University, Sapporo, 060 Japan3)

The relation between occlusal and masticatory alteration and degeneration of cholinergic or calbindin-D28k immunoreactive neurons in rat brain was investigated using immunohistochemical technique. Eighteen male rats (25 weeks old) were divided into three groups, a control group (fed with a solid diet), a soft diet group (fed with a powder diet containing the same components as the solid one) and a molarless group (all molars were removed at 25th weeks and then fed with a powder diet). After 15 weeks (40 weeks old), their brains were fixed with 4% paraformaldehyde, and cut into $50 \,\mu$ m sections which were processed free-floating. These sections were incubated 2 days with rabbit polyclonal anticholine acetyltransferase (CAT) or mouse monoclonal anti-calbindin-D28k (CB) further processed with the SAB-technique. The number of CAT- in basal forebrain, trigeminal motor nucleus, and CB- in nucleus solitarius positive neurons of the molarless group was the smallest. The number of CAT- and CBpositive neurons in the soft diet group was significantly decreased compaired to the control group. These results define that neuronal degeneration in basal forebrain, trigeminal motor nucleus, and nucleus solitarius likely progress by removal of molars and soft diet

DISTRIBUTION OF NEURONS CONTAINING DIFFERENT TYPE OF CALCIUM BINDING PROTEINS IN THE CHOLINERGIC BASAL FOREBRAIN. S. Poobalasingham. K. Pang* and L. Zaborszky. Rutgers University, Newark, NJ 07102 and Bowling Green State University, OH 43403.

The basal forebrain cholinergic (BFC) projection system has recently attracted considerable clinical interest due its role in arousal, learning, The basal forebrain cholinergic (BPC) projection system has recently attracted considerable clinical interest due its role in arousal, learning, memory and its compromise in neurodegenerative disorders, including Alzheimer's (AD) and Parkinson's diseases. Several recent studies, however, suggest that non-cholinergic, mostly GABA-containing neurons may be important constituents of the basal forebrain (Zaborszky et al., 1986; Gritti et al., 1993). GABAergic neurons represent a heterogeneous class of inhibitory neurons and have been subdivided in other brain areas into different subclasses based upon the presence of different calcium binding proteins. The present study was conducted to quantitatively analyze parvalbumin (PV), calretinin (CR) and Calbindin-D28k (CB) neurons in basal forebrain areas rich in BFC neurons. Alternate basal forebrain sections were immunostained for PV, CR, CB and choline acetyltransferase (ChAT) and immunostained neurons were mapped using a computerized 3-D reconstruction program (Neurolucida). Each cytochemically characterized neuronal population show distinct morphology and distribution pattern. Taken together these non-overlapping population of GABAergic neurons, the ratio of cholinergic/GABAergic neurons is 1:4, however in some basal forebrain areas it is as high as 1:10. It is expected that defining the precise input-output relations of these neurons in combination with their functional characterization will contribute to a better understanding of specific basal forebrain regulatory mechanisms that are compromised in AD and related disorders.

Supported by USPHS Grant NS23945.

BASAL FOREBRAIN CORTICOPETAL SYSTEM: 3-D COMPUTER GRAPHIC RECONSTRUCTION. B. Lynch, D. Orosz* and L. Zaborszky. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

The basal forebrain has recently attracted considerable clinical interest, especially since it has become apparent that some of its cell populations, including the cholinergic cells are severely affected in a number of neurologic and psychiatric disorders. The cholinergic cells, which are widely dispersed in the basal forebrain, provide the major part of the acetylcholine found in the cerebral cortex. Although several studies investigated the efferent projections of this system, there is no consensus which are widely dispersed in the basal forebrain, provide the major part of the acetylcholine found in the cerebral cortex. Although several studies investigated the efferent projections of this system, there is no consensus to the principles which determine this projection (Woolf et al., 1984; Rye et al., 1984; Baskerville et al., 1993). Several recent studies, however, suggest that non-cholinergic, mostly GABA neurons may be important constituents of the basal forebrain. These GABA containing neurons along with cholinergic neurons project to the cortical mantle, may represent interneurons and/or give rise to projections to the thalamic reticular nucleus and the caudal diencephalon. No systematic study addressed the precise distribution and contribution of the non-cholinergic cells to the cortical projection. The retrograde tracer Fluoro-Gold (1.0 ul) was injected into different parts of the somatosensory and auditory cortex of rats. Forebrain sections were stained for the presence of choline acetyltransferase and parvalbumin (PV), a marker for GABAergic cells. Our preliminary studies suggest a surprisingly high proportion (52-65%) of non-cholinergic projection to these cortical areas. Studies are underway to investigate whether other cortical areas receive such a strong non-cholinergic projection and whether PV is colocalized in these neurons. It is expected that using a 3-D reconstruction program, additional clues to the organization of the basal forebrain corticopetal system will emerge.

ACETYLCHOLINE RECEPTORS: MUSCARINIC-STRUCTURE/FUNCTION I

500.1

CYSTEINE **SCANNING** MUTATGENESIS OF TRANSMEMBRANE DOMAIN V OF THE M1 MUSCARINIC RECEPTOR. K. Allman, K.M. Page and E.C. Hulme. SPON: Brain Research Association. MRC National Institute for Medical Research. Mill Hill, London, NW7 1AA, U.K

The aim of this study is to identify amino acids in the m1 muscarinic acetylcholine receptor (mAChR) which contact the acetylcholine sidechain. The pricipal approach was cysteine substitution mutagenesis followed by chemical reaction. Consecutive residues (I188- A196) in transmembrane domain V of the m1 mAChR were mutated to cysteine. and alanine or glycine. Agonist binding studies of these mutants were consistent with a-helicity of this sequence. ACh binding affinity was not affected by mutation of residues predicted to face outwards towards the lipid bilayer, whilst mutation of residues predicted to face inwards towards a ligand binding pocket decreased binding affinity, the largest effects being given by I188C, T192C and A196C. In antagonist binding studies, only the mutation of residue A193 caused an effect The agonist analogue bromoacetylcholine has the potential to alkylate accessible cysteines. Its ability to react with the cysteine mutants was investigated, and it was found to react specifically and irreversibly with T192C. This implies that residue T192 is likely to be a principal component of the binding pocket for the sidechain methyl group of

ISOLATION AND CHARACTERIZATION OF DIFFERENT m1-TOXINS J Carsi-Gabrenas* and LT Potter, Molecular and Cellular Pharmacology, University of Miami School of Medicine, P.O. Box 016189, Miami, FL 33101.

It is now clear that the venom of the green mamba (Dendroaspis angusticeps) contains a number of toxins that are highly selective antagonists of m1 muscarinic receptors. Since the first such toxin was m1-toxin (Max et al, J Neurosci 13, 4293,1993), we call this series: m1-toxin, m1-toxin2, m1-toxin3 etc. These toxins are time-consuming to purify because of their low abundance (~100 μg of each/g dry venom) and similar size (65-66 amino acids), sequence, charge (very weakly cationic) and hydrophobicity. They are also slow to characterize, since their identification requires sequencing, and assays of their specificity require pure cloned m1-m5 receptors. These toxins have been isolated by various combinations of gel filtration on Sephadex G-50 (which separates m1-toxins from toxins of similar size, possibly according to their aromaticity), cation-exchange chromatography and reversed-phase HPLC. The different properties of these toxins are interesting, and some selection of toxins is possible for particular purposes. (1) Their highly conserved amino acid sequences show the structural requirements for anti-m1 and antagonist activity. (2) Their differences from m4-toxin (which is m4-selective) and MT1 (an agonist with m1≈m4 affinity) provide clues as to the residues required for selective anti-m4 and agonist activity. (3) One toxin shows almost perfect selectivity for m1 receptors, and is therefore optimal for physiological studies. (4) Some bind irreversibly at 37°C, facilitating studies of m1 receptors in vivo. (5) Some are very stable to biotinylation, which permits direct anatomical and biochemical assays, and the rapid purification of toxin-receptor complexes by affinity chromatography. (6) Some can be radioiodinated. [Supported by AG-06170].

ASP122 AND TYR124 IN THE M1 MUSCARINIC RECEPTOR ARE CRITICAL FOR RECEPTOR FOLDING BUT NOT FOR SIGNALING. Z. Lu, P.G.Jones, C.A.M. Curtis and E.C. Hulme. SPON: Brain Research Association. MRC National Institute for Medical Research, Mill Hill, London NW7 1AA, U.K

An AspArgTyr triad occurs in a majority of rhodopsin-like G protein-coupled receptors. The fully-conserved Arg is critical for G protein activation, but the function of the flanking residues is not well understood. We have expressed m1 muscarinic receptors mutated at Asp122 and Tyr124 in COS7 cells. Excepting conservative aromatic substitutions of Tyr124, mutations at either position attenuated or abolished expression of binding sites, even though immunocytochemistry using a C-terminally-directed antibody full-length translation. Mutants which bound ligands retained virtually normal abilities to mediate an ACh-induced phosphoinositide response. Expression was substantially rescued by deletion of 129 amino acids from the third intracellular loop. We propose that Asp122 and Tyr124 make inter-domain contacts which are critical for receptor folding, but only exert a secondary effect on signaling. Their role is completely distinct from that of Arg123, whose mutation abolishes signaling, but without diminishing receptor

CLONING AND EXPRESSION OF THE cDNA FOR m1-TOXIN3 JL Krajewski*, IM Dickerson and LT Potter, Pharmacology and Physiology, University of Miami School of Medicine, P.O. Box 016189, Miami, FL 33101.

Mamba venoms contain toxins that are the only specific ligands known for any of the subtypes of muscarinic receptors. The first such toxins to be isolated, MT1 and MT2 (Adem et al. 968, 340, 1988), have nearly equal affinity for m1 and m4 receptors, and MT1 can act as an agonist (Kornisuik et al, Toxicon 33, 11, 1995). In contrast, m1-toxin binds pseudoirreversibly to m1 receptors with m1>>> m4 affinity (Max et al, J Neurosci 13, 4293, 1993), m4-toxin binds reversibly with m4>>m1 affinity, and both are antagonists (Max et al, Neurosci Abstr 19, 462, 1993; Liang et al, Toxicon, in press). We have chosen to express the cDNA for another m1-toxin for four reasons: (1) m1-toxin3 has the highest specificity for m1 receptors of any of the anti-muscarinic toxins; (2) to obtain much larger amounts of an anti-m1 toxin than can be obtained by purification (\sim 100 μ g/g dry venom); (3) to permit studies by site-directed mutagenesis of the amino acid residues that confer high toxin affinity and specificity, and that confer antagonist vs. agonist activity; and (4) to facilitate radiolabeling. Messenger RNA was obtained from the venom glands of a green mamba (Dendroaspis angusticeps). Degenerate primers to regions of the desired protein sequence were made, and RT-PCR was used to prepare cDNA products. RACE techniques were then used to isolate the full length cDNA for m1-toxin3. This cDNA establishes the mature toxin sequence: LTCVKSNSIWFPTSEDCP-DGQNLCFKRWQYISPRMYDFTRGCAATCPKAEYRDVINCCGTDKCNK, which differs from that of m1-toxin only in glutamine-29. This cDNA was used to transfect COS-1 cells, which expressed active toxin. This cDNA is now being used to produce m1-toxin3 in stable cell lines. [Supported by AG-12976]

DISTINGUISHING BETWEEN TWO-STATE ALLOSTERIC AND CONVENTIONAL SINGLE STATE RECEPTOR MODELS. C.-M. Staschen * L.D. Home* and S.T. Ahlers* Naval Medical Institute, Kopperpahler Allee 120, 24119 Kronshagen, Germany. **Legacy Research, Emanuel Hospital, 2801 North Gantenbein Ave, Portland, Oregon 97227, USA; Naval Medical Research Institute, Bethesda, MD 20889-5607, USA.

There are situations with agonist receptor binding that do not fit a conventional single state receptor model. This has renewed interest in the use of a two-state allosteric receptor model that better fits and explains experimental outcomes. The goal of the present study was to determine which experimental design best distinguishes between these models using competitive interactions in radioligand binding studies. Computer simulations were used to generate data from a two-state allosteric model. Then the two-state allosteric model and the conventional single state model were fitted to the computer generated data. Simulated transient data were obtained with Runge-Kutta-Fehlberg solutions of standard kinetic equations. Parameters were selected which allowed simulated data to resemble data from real equilibrium and transient kinetic experiments. A 4% random error was added to the simulated curves. Using these computer generated data, parameters were estimated by weighted least-squares with simultaneous analysis of pooled equilibrium and kinetic data for both the two-state model and the conventional model. Since the conventional model is a special case of the two-state model, the statistical significance of the restricted fit can be evaluated with a partial F-test. Successful statistical discrimination between the two models was obtained with a design consisting of equilibrium, association and dissociation experiments performed with several different radioligand and several different inhibitor concentrations. In contrast, equilibrium experiments alone failed to distinguish between the two different models.

FOOL OF THREONINE AND ASPARAGINE RESIDUES IN AGONIST INTERACTIONS WITH m3 MUSCARINIC RECEPTORS. W.S. Messer. Jr.*, M.A.N. Edgar, J.L. Freed and X.-P. Huang Department of Medicinal & Biological Chemistry, Center for Drug Design & Development, College of Pharmacy, The University of Toledo, Toledo, OH 43606 Conserved amino acids in transmembrane domains V and VI of the rat m3 muscarinic receptor may be important for hydrogen bond interactions with muscarinic ligands (Mess, et al., 1992; Bluml, et al., 1994). Mutant rat m3 receptors, replacing Thr234 or Asn507 with Ala, were stably expressed in CHO cells to test functional activation (PI hydrolysis) by the structurally-related muscarinic agonists CDD-0098 and CDD-0190.

Carbachol, CDD-0198 and CDD-0190 were efficacious agonists for wild-type m3 receptors with Smax levels greater than 400 % above basal, yet carbachol and CDD-0190 were much more potent than CDD-0190. Each ligand exhibited lower potency and efficacy in stimulating PI hydrolysis via Rm3 (TA) receptors. Carbachol and CDD-0198 exhibited modest agonist activity at the Rm3(NA) receptors, yet CDD-0190 was essentially inactive. The data are consistent with a major role for Thr234 in agonist potency, and a lesser (though important) role for Asn507 in agonist activation of m3 receptors.

REGULATION OF m2 MUSCARINIC ACETYLCHOLINE RECEPTOR FUNCTION BY G-PROTEIN COUPLED RECEPTOR KINASE-2 AND ARRESTIN-2. M. L. Schlador* and N. M. Nathanson. Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195.

Seattle, WA 98195.

Muscarinic acetylcholine receptors (mAChRs) couple to intracellular effector molecules through the actions of heterotrimeric G-proteins and are phosphorylated by a number of G-protein coupled receptor kinases (GRKs). In order to test the ability of specific GRKs and arrestins to regulate mAChR function in intact cells, we have chosen to use a transient transfection assay which couples muscarinic receptor activation to changes in expression of a cAMP-responsive reporter

activation to changes in expression of a CAMP-responsive reporter gene.

When overexpressed in JEG-3 choriocarcinoma cells, the m2 mAChR undergoes phosphorylation, sequestration, and a modest functional desensitization upon exposure to agonist. Cotransfection of a cDNA encoding GRK2 with the m2 receptor enhances agonist-induced desensitization as well as receptor phosphorylation. Cotransfection of arrestin2 has little effect on m2 receptor signaling but potentiates the effects of GRK2 on m2 receptor desensitization. The actions of GRK2 and arrestin2 on receptor signaling are blocked by deletion of the third intracellular loop of the m2 receptor (amino acids 217-380), which contains multiple GRK phosphorylation sites. In addition, we have found that cotransfection with either GRK2 or arrestin2 cDNAs enhances both the rate and extent of m2 receptor sequestration. Coexpression of both GRK2 and arrestin2 with the m2 mAChR leads to an enhancement of sequestration that is greater than that seen with either construct alone. These data support the hypothesis that GRK2 and arrestin2 have multiple actions on m2 mAChR function. (Supported by the National Institutes of Health).

MOLECULAR DETERMINANTS INVOLVED IN DIFFERENTIAL EFFICIENCIES OF AND m3 MUSCARINIC COUPLING m 1 RECEPTORS. N.S.M. Geoghagen, R.T. Cline and N.H. Lee*. Department of Molecular and Cellular Biology. The Institute for Genomic Research, Rockville, MD 20850.

The m1 and m3 muscarinic acetylcholine receptors (mAChRs) are members of the G-protein coupled seven transmembrane domain receptor family. Both the m1 and m3 mAChRs elicit dose-dependent increases in the hydrolysis of phosphoinositides in transfected Chinese hamster ovary (CHO) cells. However, the maximal increase in total inositol phosphates elicited with the m1 mAChR is approximately 2-fold greater than in cells expressing similar densities of m3 mAChR. The amino- and carboxylterminal portions of the third intracellular loop (i3-loop) of both receptors are required for efficient signal transduction. With the exception of two amino acids, the terminal portions of the i3-loop are well conserved between the two receptors. In the m1 mAChR, the amino- and carboxyl-terminal portions correspond to the sequences RIYRETENR and SLVKEKKAAR (underlined amino acids are not conserved between the m1 and m3 sequences), respectively. In the m3 mAChR, the amino- and carboxyl-terminal sequences are RIYKETEKR and SLVKEKKAAQ, respectively. We have recently demonstrated that the KKAAR motif in the carboxyl-terminal portion of the m1 mAChR is critical for agonist-mediated signal transduction. To determine whether the two non-conserved amino acids are responsible for potential signaling differences between the m1 and m3 mAChRs, we have mutated these residues and expressed the mutant receptors in CHO cells. (supported by TIGR)

m2-TOXIN, A SELECTIVE LIGAND FOR m2 MUSCARINIC RECEPTORS HH Valentine*, J Carsi-Gabrenas and LT Potter, Department of Molecular and Cellular Pharmacology, University of Miami School of Medicine, P.O. Box 016189. Miami. FL 33101.

The only selective antagonists known for m1 and m4 muscarinic receptors are weakly cationic toxins (Max et al, J Neurosci 13, 4293, 1993; Max et al, Neurosci Abstracts 19, 462, 1993; Liang et al, Toxicon, in press). There are no comparably selective ligands available for m2, m3 or m5 receptors, but they are widely needed as research tools. Since the de-salted venom of the green mamba (Dendroaspis angusticeps) has been shown to inhibit the binding of 3H-Nmethylscopolamine to m2 muscarinic receptors (Liang et al, Toxicon, in press), we have pursued the isolation of a toxin with m2-selective activity. During gel filtration on Sephadex G-50, the NMS-blocking activity of mamba venom on m2 receptors moved with the predominant monomeric toxins of the venom that have molecular masses of about 7000 Daltons. Chromatography of these peptides on Bio-Rex 70 revealed two peaks of NMS-blocking activity, and indicated at least two strongly cationic toxins. Cation-exchange HPLC of the more active of these components yielded one active peak. This "m2-toxin" inhibits the binding of $^3\text{H-}$ NMS to pure m2, but not m1, m3, m4 or m5 receptors in CHO cells. Inhibition curves obtained with m2 receptors from the rat brainstem have a Hill coefficient≈1.0, showing that m2-toxin competes with NMS for m2 receptors, even though it probably binds to an allosteric receptor site, like m1-toxin (Max et al, Mol Pharmacol 44, 1171, 1993). Studies are in progress to finish the purification of m2-toxin, to determine its amino acid sequence, and to establish whether it is an agonist, like MT1 (Jerusalinsky et al, Toxicon 33, 389, 1995), or an antagonist, like m1-toxin and m4-toxin. XANOMELINE, AN M-1 MUSCARINIC AGONIST, SELECTIVELY INHIBITS THE ACTIVITY OF A10 DOPAMINE NEURONS K. Rasmussen* and M. E. Stockton. Lilly Research Laboratories, Eli

Lilly & Co., Indianapolis, IN 46285.

Cholinergic and dopaminergic neurons are known to have complex interactions. Recently, the Ch5 and Ch6 cholinergic cell groups have been hypothesized to play an important role in the etiology of schizophrenia by affecting the activity of dopamine cells. In order to explore the interactions of the cholinergic and dopaminergic systems we examined the effects of xanomeline, an M-1 muscarinic agonist, on the single unit activity of dopamine cells in the substantia nigra (A9) and ventral tegmental area (A10) in chloral hydrate anesthetized male rats. Administration of xanomeline inhibited the activity of A10, but not A9, dopamine cells (ED50=3.0 µg/kg, iv). Xanomeline also reduced the number of spontaneously active A10, but not A9, dopamine cells after both acute (1, 10 mg/kg, sc) and chronic (1, 10 mg/kg/day X 21 days, via osmotic minipump) administration. The effects of xanomeline on the number of spontaneously active dopamine cells was reversed by the administration of the muscarinic antagonist scopolamine. These results support the hypothesis that the cholinergic system has a strong influence on the dopaminergic system and may help to explain some of the effects of xanomeline seen in man. In recent clinical trials with Alzheimer's Disease patients, xanomeline, in addition to enhancing cognition, showed particularly good efficacy in treating certain problematic behaviors including vocal outbursts, suspiciousness, delusions, agitation, and hallucinations. The effects of xanomeline on dopamine neuronal activity described here may play an important role in its reduction of these problematic behaviors in Alzheimer's Disease patients.

L-758,527: A NOVEL M₁-M₂ SELECTIVE MUSCARINIC COMPOUND WITH AGONIST ACTIVITY. R.J. Bendesky, C.M. Harrell, P. Kling, A. Kuo, J. Williams, P. Mallorga, W. Thompson, I. Bell and R. Ransom* Merck Research Labs, West Point, PA 19486

We have identified a novel structural class of compounds that possess significantly higher receptor binding affinity at M₁, M₂ and M₄ vs. M₃ muscarinic receptors. While most of the compounds in the series exhibited antagonist activity, a carbamate, L-758,527, was found to have agonist properties. L-758,527 inhibited [3 H]NMS binding to cloned human M_{1} , M_{2} , M_{3} and M_{4} receptors with K₁ values (nM) of 17, 1, 2014 and 3, respectively. This selectivity profile was also observed in binding assays with endogenously expressed M₁ (cerebral cortex), M₂ (heart) and M₃ (salivary gland) receptors. In rabbit vas deferens, L-758,527 completely inhibited field stimulated contractions with an EC $_{s0}$ of 0.6 μM . The compound similarly inhibited inotropic responses to field stimulation in guinea pig left atria. The effects of L-758,527 in both tissues were atropine sensitive. At M₃ receptors in guinea pig ileum longitudinal muscle, L-758,527 was without agonist activity at high μM concentrations. In a pithed rat preparation, the compound produced a sustained, dose-dependent (ED₅₀ = 0.1 mgKg^{-1}) bradycardia that was reversed by atropine. The compound was also found to be as efficacious as carbachol in functional assays ([35S]GTPγS binding, adenylyl cyclase) with the cloned human M2 receptor but slowed minimal efficacy in PI assays with M1 receptor cells and was an antagonist in assays with M₃ (PI) and M₄([³⁵S|GTPyS) cells.

REGULATION OF THE CHICK M2 PROMOTER BY THE GATA FAMILY OF TRANSCRIPTION FACTORS AND BY CYTOKINES. Marc L. Rosoff*1, John B. E. Burch 2, Neil M. Nathanson I, Dept. Pharmacol., Univ. Washington, Seattle, WA 98195; ² Fox Chase Cancer Inst., Philadelphia, PA 19111.

We have isolated genomic regions containing the putative chick m2 (cm2) promoter and show regulation of cm2 promoter constructs by the cytokines leukemia inhibitory factor (LIF) and ciliary neurotrophic factor (CNTF). The cm2 promoter is also regulated by

the GATA family of transcription factors.

Transfection of constructs containing the cm2 promoter driving the expression of the firefly luciferase gene into a human choriocarcinoma cell line (JEG-3) results in luciferase expression levels similar to those seen with vector alone. Co-transfection of the cm2 firefly reporter constructs with an expression vector containing chick GATA-6 results in a dramatic increase in luciferase activity Currently we are determining the specificity of the GATA factor(s) involved in this regulation. The proximal promoter region of the cm2 gene contains several potential GATA factor binding sites. We are investigating if chick GATA factors will bind these sites in vitro

Using chimeric receptors containing the extracellular region of the GCSF receptor fused to the intracellular region of gp130, the common signaling subunit shared by the LIF and CNTF receptor, we are signaling subunit shared by the LIF and CNTF receptor, we are mapping cytoplasmic regions of gp130 involved with induction of the cm2 promoter by cytokines. We are also defining region(s) of the cm2 promoter necessary for cytokine regulation.

BENZOXAZINE ISOQUINOLINES AS POTENTIAL m4 SELECTIVE MUSCARINIC ANTAGONISTS. C.E. Augelli-Szafran^{1*}, D.W. Moreland¹, C. Nelson², J.R. Penvose-Yi¹, R.D. Schwarz², and J.C. Jaen¹, Departments of Medicinal Chemistry¹ and Pharmacology², Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, Michigan 48105

Selective m4 muscarinic antagonists may be useful in the treatment of Parkinson's Disease. The synthesis of compounds of general structure (1) has led to the identification of several analogs that appear to be m4 selective antagonists. The affinity of these compounds for the five human receptor subtypes (m1-m5) was determined by [3H]-NMS binding using membranes from transfected Chinese Hamster Ovarian (CHO) cells. Functional data (PI hydrolysis and cAMP accumulation) on the most potent compound confirmed its muscarinic antagonist properties. The biological activity and structure-activity relationships (SAR) of these compounds will be discussed

IgG-192 SAPORIN LESIONS PRODUCE UNCOUPLING OF THE M1 MUSCARINIC RECEPTOR P.E.Potter*, C.Gaughan, and Y.Assouline, Departments of Anesthesiology and Neurological Surgery, Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY 10467

Injection of the immunotoxin IgG-192 saporin (SAP) into the medial septum causes a selective lesion of cholinergic neurons projecting from the septum to the hippocampus. To determine the effect of cholinergic lesions on the function of postsynaptic cholinergic receptors, the ability of the M1 muscarinic receptor agonist McN-A-343 to modulate the release of radiolabelled norepinephrine (NE) was studied in hippocampal slices. McN-A-343 did not induce spontaneous release of NE, but enhanced the release evoked by low-frequency electrical stimulation. The effect of McN-A-343 was significantly reduced in hippocampal slices from rats that had been lesioned with SAP. Binding studies using ³H-pirenzepine indicated no changes in either receptor number or affinity after the lesion. Curves for displacement of pirenzepine by oxotremorine-M were constructed in the presence and absence of the non-hydrolyzable GTP analogue GppNHp, to assess the degree of coupling of the M1 receptor to G-proteins. In hippocampal P2 membranes from sham-operated animals, addition of 0.2 mM GppNHp caused a nearly 10-fold shift to the right of the displacement curve. In contrast, the curve was already shifted to the right in hippocampal membranes from SAP-lesioned rats, and addition of GppNHp had little effect. These results suggest that the M1 muscarinic receptor becomes uncoupled from G-proteins after lesion of cholinergic inputs with SAP, and thus less responsive to agonists. Uncoupling of the M1 receptor has also been reported to occur in Alzheimer's disease, and SAP lesions may provide a model in which this phenomenon can be examined. Supported by NIH grant AG11384.

EVIDENCE FROM DIRECT INFUSION MICRODIALYSIS THAT THE SUBTYPE IDENTITY OF THE PRIMARY MUSCARINIC AUTORECEPTOR IS m2 FOR BOTH RAT STRIATUM AND HIPPOCAMPUS. W. Billard, H. Binch III, G. Crosby, and R.D. McQuade* Schering-Plough Research Institute, Kenilworth, NJ 07033

Recently, our laboratory compared the relative binding affinities of several

standard muscarinic antagonists at each of 4 muscarinic receptor subtypes (m1, m2, m3, m4) with their corresponding relative abilities to elevate basal acetylcholine (ACh) levels in vivo in rat striatum following direct infusion through a microdialysis probe (J. Pharmacol. Exp. Ther. 273: 273-279, 1995). The conclusion from this study was that the antagonists' AChelevating effects (a presumed autoreceptor response) were best correlated with their relative binding affinities for the m2 subtype. In the current study the identical correlative approach was used to ascertain muscarinic autoreceptor identity in rat hippocampus. For the 4 antagonists evaluated, i.e. scopolamine, himbacine, AF-DX116, and pirenzepine, potencies for elevating hippocampal ACh (relative to scopolamine) were 1, 3.3, 10 and 33, respectively. Corresponding binding affinities for the same antagonists at the cloned human m2 receptor (0.88, 4.4, 32.4 and 212 nM) provided a much better relative match to the ACh-increasing effects than either m1, m3 or m4 binding data. While the *relative* ACh-elevating potencies of the antagonists were comparable for both brain regions, infusion of a higher concentration of each in hippocampus (3 to 10-fold) was necessary to elevate ACh levels. This likely reflects the much lower cholinergic tone observed in this region, which may require a higher percent occupancy of autoreceptor sites by antagonist before an ACh-releasing response is triggered. In conclusion, these results support an m2 autoreceptor identity for both striatum and hippocampus and reinforce the utility of direct infusion microdialysis as a useful tool in reaching this determination.

PHARMACOLOGICAL CHARACTERIZATION OF PD102807: An m4 SELECTIVE MUSCARINIC ANTAGONIST. C. B. Nelson¹, C.E. Augelli-Szafranl, R.D. Schwarzl*, J.R. Penvosel, J.C. Jaenl, J. Wileyl, K.A. Frey2, 1Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co. 2Neurosciences Laboratory, The University of Michigan, Ann Arbor, MI 48105.

The anti-muscarinic agent Artane (trihexyphenydil) has been used clinically to suppress tremor and relieve rigidity associated with the early stages of Parkinson's disease (PD). However, motor benefits have been accompanied by cognitive decline. In situ hybridization and antibody studies have found that the m4 subtype of muscarinic receptors predominates over m1 in the striatum, while the reverse is true for the hippocampus and cerebral cortex. Thus an antagonist specific for the m4 over m1 subtype could be efficacious against PD motor symptoms without deleterious cognitive side effects.

In the search for selective antagonists, membrane preparations from CHO cell lines transfected with each of the human muscarinic subtypes were utilized in [3H]-NMS competition binding experiments. The compound PD102807 was found to have m4 (IC_{50} =90.7nM) selectivity of 72-fold against m1 (IC_{50} =6569nM), 38-fold against m2 (IC $_{50}$ =3440nM), 10-fold against m3 (IC $_{50}$ =951nM), and 82-fold against m5 (IC50=7412nM). Artane, on the other hand, although found to have considerable m4 affinity, was most potent at the m1 subtype (IC50 values; 1.3nM for m1, 18.6nM for m2, 26.3nM for m3, 6.7nM for m4 and 10.3nM for m5). Measurement of functional activity (PI hydrolysis for m1, m3, and m5 and cAMP accumulation for m2 and m4 receptors) correlated with this profile, as did an autoradiographic study in rat brain where PD102807 bound with highest affinity in the striatum. In a murine in vivo model, PD102807 inhibited spontaneous locomotor activity after i.c.v. administration, however showed little effect following oral dosing. Thus PD102807 may serve as a prototype for the development of an m4-selective antagonist to treat early PD motor symptoms.

LOCALIZATION OF m2-MUSCARINIC RECEPTORS IN ACETYLCHOLINESTERASE-RICH INFRACORTICAL NEURONS OF THE HUMAN AND MONKEY CEREBRAL CORTEX. S.B. Schueler* 1, J.F. Smiley 1, A.I. Levey 2, F. Morrell 3, and M.-M. Mesulam 1. Northwestern University, Chicago, IL, ²Emory University, Atlanta,

GA and ³Rush Presbyterian-S.t. Luke's Medical Center, Chicago, IL Numerous polymorphic AChE-rich neurons are found in Layer VI and the adjacent infracortical white matter of the primate cerebral cortex. These neurons are thought to be cholinoceptive, but this has not been We investigated the expression of the m2-muscarinic receptor subtype in these neurons, using simultaneous immunocytochemistry and AChE histochemistry. These experiments demonstrated a close correspondence between m2-immunoreactive and AChE-rich cells in all cortical areas that were examined. At least 77-90% of AChE-rich infracortical neurons were clearly m2-immunoreactive. Conversely, at least 75-89% of the m2-positive cells were clearly AChE-rich. Comparable results were found in the cerebral cortex of the monkey and in human anterior temporal cortex, which was obtained at surgery. Human infracortical m2-immunoreactive cells were like those of monkey in morphology, density, and AChE reactivity. These findings demonstrate that the vast majority of AChE-rich infracortical neurons in the primate brain express the m2-muscarinic receptors, and support the hypothesis that these neurons are cholinoceptive.

ACETYLCHOLINE AUTOEXCITES RELEASE OF PROOPIO-MELANOCORTIN-DERIVED PEPTIDES FROM MELANOTROPE CELLS OF XENOPUS LAEVIS VIA AN M₁ MUSCARINIC RECEPTOR

F.J.C. van Strien', E.W. Roubos', H. Vaudry', B.G. Jenks'. 'Department of Cellular Animal Physiology, Nijmegen Institute for Neurosciences, University of Nijmegen, Toernooiveld 1, 6525 ED Nijmegen, The Netherlands, 'European Institute for Peptide Research, Laboratory of Cellular and Molecular Neuroendocrinology, INSERM U 413, University of Rouen, 76821 Mt St Aignan, France.

The release of proopiomelanocortin (POMC)-derived peptides from the melanotrope cells in the pituitary pars intermedia of Xenopus laevis is regulated by multiple inhibitory and stimulatory neurochemical messengers. In this study we examined the role of ACh in regulating melanotrope cell activity. *In vitro* biosynthesis experiments demonstrated that dissociated melanotropes can synthesize ACh. Oscillations in [Ca2+], are thought to drive the secretion of POMC-derived peptides from *Xenopus* melanotrope cells. A technique was developed to study simultaneously calcium oscillations and peptide secretion from single melanotropes. Dynamic confocal imaging of [Ca²⁺], revealed that ACh increases both the frequency and the amplitude of calcium oscillations in such cells as well as their release of POMC-derived peptides, in a concentration-dependent way. The actions of ACh on the cells was mimicked by muscarine but not by nicotine, indicating the exclusive presence of a muscarinic cholinergic receptor. Selective muscarinic receptor antagonists showed that ACh acts through an M₁-subtype muscarinic receptor. Immunofluorescence cytochemistry in combination with confocal laserscanning microscopy visualized muscarinic receptors on the surface of melanotrope cells. It is concluded that ACh stimulates the release of POMC-derived peptides from the Xenopus melanotrope in an autocrine way, via a muscarinic M1 receptor, acting on the intracellular free calcium concentration

EFFECT OF GINKGO BILOBA EXTRACT ON MUSCARINIC BINDING SITES IN RAT BRAIN. E. Moyse, N. Ravel*, F. Boilet, C. Lioger, M.T. Droy-Lefnix(i) IPSEN. F-75781 Paris (1): Lab. de Physiologie Neurosensorielle, Univ. Lyonl-CNRS, F-69622 Villeurbanne

The Ginkgo biloba extract (EGb 761, IPSEN, Tanakan) is a well defined drug prepared from green leaves of Ginkgo biloba. Egb761 is mainly indicated for cognitive deficits affecting elderly patients. Experimental behaving data have suggested that some therapeutic effects of EGb761 might be mediated through the central cholinergic system. Thus, chronic treatment of rats by EGb761 prevented scopolamine-induced blockade of odor retention (Ravel et al. 94), suggesting that EGb761 might induce an increase of brain muscarinic receptor density. To test this hypothesis, we assess here effects of the same experimental paradigm in rat upon affinity (Kd) and concentration (Bmax) of muscarime receptors in various brain structures.

Rats chronically administered per os with EGb761 (50 or 100 mg/kg/day) or water were trained in an olfactory delayed matching to sample. At the end of treatment (total duration 6 weeks), rais were sacrificed and their brains frozen and scrially sectioned for saturation assay of 3H-QNB binding by quantitative autoradiography. EGb761 treatment resulted into a significant Bmax increase specific to the glomerular layer of olfactory bulb, significant Bmax decrease in hippocampal CA1 (-69%) and dentate gyrus (-80%), and no change in other olfactory areas (anterior olfactory nucleus, olfactory tubercle and piriform cortex). These effects were more important with a 50 mg/kg dose of EGb761 than with 100 mg/kg, as already reported in behavioral studies.

These data indicate that EGb761 can modulate characteristics of cholmergic

musearmic receptors in specific areas of rat brain. Considering the previously reported interaction between EGb761 and scopolamine on olfactory retention, the hypothesis of a selective decrease of M2 autscarinic autoreceptors in the hippocampus is currently investigated.

TRANSIENT HEAT PRODUCTION ASSOCIATED WITH ACTIVATION OF MUSCARINIC (M1) RECEPTOR EXPRESSED IN CHO CELL, M. Ikeda¹, O. Zoher², D. L. Alkon², H. Nakamura¹, H. Shinagawa¹, H. Inoue¹ and T. Yoshioka¹* Dept of Mol. Neurobiol. Waseda Univ. Tokyo JAPAN, NIH-NINDS, Md, USA.

In order to develop novel technique to know localization of transmitter receptors, we set up thermal imaging system using thermo-sensitive fluorescent dye, EuTTA which has λex = 345 nm and λem = 612 nm, as a probe. CHO and muscarinic receptor expressed CHO (m-CHO) cells cultured in a small dish were incubated in 50 μ M EuTTA solution for 30 min to stain and submitted to measurements. Fluorescence intensity of the dye in living cell membrane was found to be highly temperature sensitive (10⁻¹/°C). Interestingly this dye was also sensitive to pH changes. When 500 µ M Ach (5 µ L) was applied with a glass micropipette for 100 msec, thermal response was observed in m-CHO- but not in CHO cells. Ach responsive cells were identified by Ca imaging. Receptor expression was also confirmed by immunohistochemistry using anti-m1 receptor antibody. Time course of heat production was faster than that of elevation of intracellular Ca. Furthermore atropine, antagonist for ml receptor, also produced transient heat. Therefore it can be concluded that heat is produced when agonist or antagonist binds to its receptor

ACETYLCHOLINE RECEPTORS: NICOTINIC-MOLECULAR BIOLOGY AND KNOCK-OUT

TRYPTOPHAN SUBSTITUTIONS AT THE M4 TRANSMEMBRANE SEGMENT OF THE TORPEDO, AND NEURONAL ACHRS INCREASE OPEN CHANNEL PROBABILITY S. Tamamizu*, J.A. Lasalde, and M. McNamee, Mol. And Cell. Biology, U.C. Davis, Davis, CA 95616

We introduced tryptophan substitutions at different positions of the postulated lipid exposed segment M4 of the *Torpedo* and neuronal α 4 and β 2 subunits in order to examine functional consequences at the single channel level At αG421 both phenylalanine and tryptophan produced a substantial increase in the open time constant for the Topedo receptor. A lack of response from a tyrosine substitution at the $\alpha G421$ suggests that the side chain volume is not the main structural element responsible for the effect of tryptophan on the stabilization of the open state of the channel. Three multiple mutants, α C418WG421A, α C418WG421W, and α C418WGC447W were constructed in order to find a correlation between the number of lipid exposed tryptophans and the channel open time constant. The α C418WG421A double mutant demonstrated that when both previous mutations are combined the open time constant was increased 1.5-fold relative to the α C418W. When the two mutants $(\alpha \text{C418W}$ and $\alpha \text{G421W})$ were combined in a single mutant a functional receptor was expressed and the open time constant of the new double mutant was increased to 33.4 ms.

Estimation of free energy from the rate constants for the opening transition suggests that each tryptophan contributes to the stabilization of the open state of the channel by about 0.8 kcal/mol. This suggests that each subunit contributes in dependently to the energy barrier between the open and closed state. The similar side chain volumes occupied by Tyr, Phe and Trp suggest that the indole group could be a possible candidate to produce a difference between the Phe and Trp free energy barrier. Preliminary data on neuronal subunits $\alpha 4$ and $\beta 2$ suggest that neuronal AchRs also display a similar effect of M4 mutations as *Torpedo* and mouse receptors. DETERMINANTS OF SPECIFICITY FOR α -CONOTOXIN MII ON $\alpha 3\beta 2$ NEURONAL NICOTINIC RECEPTORS. S.C. Harvey*, J.M. α3β2 NEURONAL NICOTINIC RECEPTORS. S.C. Harvey*, J.M. McIntosh^{1,2}, G.E. Cartier¹, F.N. Maddox, C.W. Luetje. Department of Molecular and Cellular Pharmacology, University of Miami, Miami, FL 33101 and Departments of ¹Biology and ²Psychiatry, University of Utah, Salt Lake City, Utah 84112.

 α -conotoxin MII selectively blocks $\alpha 3\beta 2$ neuronal nicotinic receptors (Cartier et al., 1995, JBC 271:7522-7528). We have now identified (Cartief et al., 1993, 1995, 271.7322-7328). We have now identified lysine 185 and isoleucine 188 of α 3, and threonine 59 of β 2, as determinants of sensitivity to this toxin. Important sequence segments were first identified using chimeric subunits. Chimeras of the $\alpha 3$ and $\alpha 4$ subunits, and the $\alpha 3$ and $\alpha 2$ subunits, were expressed in combination with $\beta 2$. Chimeras of the $\beta 2$ and $\beta 4$ subunits were expressed in combination with $\alpha 3$. Toxin sensitivity was determined using a 5 min. incubation with 50 nM toxin, since this blocks $\alpha \beta \beta 2$ receptors (1.8 ± 0.5 % of control) while having no effect on $\alpha 2\beta 2$, $\alpha 4\beta 2$ or $\alpha 3\beta 4$. We identified sequence segment 181-195 of $\alpha 3$ as containing the major α subunit determinant of MII sensitivity. We changed individual residues within this region from what occurs in $\alpha 3$ to what occurs in $\alpha 2$. Only within this region from what occurs in $\alpha 3$ to what occurs in $\alpha 2$. Only the K185Y and I188K mutations had a significant effect on toxin sensitivity (19.3 \pm 3.1% and 42.0 \pm 4.9% of control, respectively). We also identified several sequence segments of $\beta 2$ that contain determinants of toxin sensitivity (1-54, 54-63, 63-80), with segment 54-63 being the most important. When individual residues in this region were changed from what occurs in $\beta2$ to what occurs in $\beta4$, only the T59K mutation had a significant effect on toxin sensitivity (19.4 \pm 10.0 % of control)

PHARMACOLOGY OFα3/β2 RECEPTORS AFTER MUTATION IN M2 CHANNEL LINING DOMAIN. L. M. Colquhoun* and J. W. Patrick

Division of Neuroscience, Baylor College of Medicine, Houston, Tx 77030. Neuronal nicotinic receptors expressed in *Xenopus* oocytes are distinguishable by their pharmacologies. Cytisine is a potent agonist at α3β4 receptors but has primarily antagonist action at α3β2 receptors. The difference in sensitivity between subunits to cytisine has been mapped to differences in their N-terminal amino acid sequences. Mutations in the M2 domain of the α 7 subunit have also been shown to alter pharmacology of that expressed homooligomer. Mutations were made in the M2 region of $\alpha 3$ and $\beta 2$ subunits. The Xenopus oocyte expression system was used to examine the electrophysiology of receptors composed of combinations of wild type and mutated a3 and \(\beta 2 \) subunits.

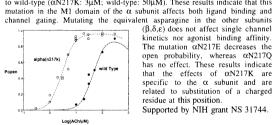

Cytisine blocked α3/β2 receptors but, when β2L251C was substituted for wild type β 2, cytisine potently activated the receptor. The same mutation on α 3 subunit when paired with $\beta 2$ wild type, did not change the cytisine pharmacology. Cytisine was an agonist on receptors containing a mixture of wild type $\beta 2$ and B2L251C. The current elicited by acetylcholine from oocytes injected with $\alpha 3/\beta 2L251C$ desensitized slower than wild type. There was no shift in the doseresponse curve to acetylcholine. D-tubocurarine, dihydro-β-erythroidine and hexamethonium, were tested for agonist activity on α3/β2L251C receptors None of the three elicited a current from oocytes injected with this combination.

Mutation of L251 in β2 subunit alters the pharmacology of a receptor containing this mutated subunit. Mutation of the homologous residue in $\alpha 7$ allows antagonists at this receptor to act as agonists. Unlike $\alpha 7$ where 5 mutated subunits are coexpressed, here 3, or fewer, of the subunits composing the receptor contained the mutation. This was sufficient to allow cytisine, but not other antagonists to gate receptors with this mutation on the $\beta 2$ subunit. (Supported by NIH NS13546)

MUTATION IN THE M1 DOMAIN OF THE ACETYLCHOLINE RECEPTOR α SUBUNIT DECREASES BOTH THE RATE OF AGONIST DISSOCIATION AND RATE CONSTANTS FOR CHANNEL GATING. H.-L. Wang*, N. Bren. A. Auerbach, A. G. Engel, and S. M. Sine Mayo Foundation, Rochester, MN

55905 We previously reported that a point mutation in the M1 domain of the α subunit (α N217K) of the acetylcholine receptor (AChR) caused a slow channel congenital myasthenic syndrome (SCCMS) (Ohno et al. Neurology 46: A214, 1996). When expressed in 293 HEK cells, AChR containing α N217K exhibits prolonged activation episodes strikingly similar to those observed at the SCCMS muscle end plates. Here we use single channel kinetic analysis to show that α N217K markedly decreases the rate of ACh discrepitations usually exchanges will be decreased but the president and SCCMS muscle contents to the content of the dissociation, as well as decreases both the opening and closing rate constants. The kinetic parameters also describe the concentration dependence of the open probability (see Figure), revealing a 20-fold shift in the EC_{sn} compared to wild-type (α N217K: 3 μ M; wild-type: 50 μ M). These results indicate that this

specific to the α subunit and are related to substitution of a charged

residue at this position.

LEVELS OF CHOLINERGIC LIGAND BINDING IN MUTANT MICE LACKING THE β2 SUBUNIT OF THE NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) M. Zoli*, I.-P. Changeux, and M.R. Picciotto Lab of Molecular Neurobiology, Pasteur Institute, Paris, France,

We have generated a line of mice lacking the \(\beta 2 \) subunit of the nAChR using homologous recombination. Regional binding of several nicotinic ligands was evaluated by quantitative receptor autoradiography in mutant and wild type mouse brain. Mutant mice completely tack high affinity nicotine binding in the brain, indicating that nicotine cannot bind with high affinity to nAChRs that do not contain the B2 subunit. Other nicotinic ligands do show residual binding in brain areas expressing the \(\beta \) subunit (such as the habenulo-interpeduncular (MHb/IPN) system), however. Rank order of binding for these ligands in the MHb/IPN of mutant mice was: epibatidine-ytisine>>methylcarbamylcholine-ACh (in the presence of atropine) >nicotine (which was undetectable). We have also used α bungarotoxin binding to determine whether the α7 family of nAChRs is affected by the absence of the β2 subunit of the nAChR. A significant increase (50%) in α -bungarotoxin binding was seen selectively in the CA regions of the hippocampus in β2 mutant mice, indicating that these two families of nicotinic receptor subunits may interact in wild type animals. We also examined the levels of M1 and M2 binding in mutant and wild type mouse brain in order to determine whether other cholinergic markers are perturbed in the absence of the high affinity receptor for nicotine. No significant change in either M1 or M2 receptor binding was observed in any region studied.

Funding for this work was provided by the College de France, the CNRS., the Association Française contre la Myopathie a grant from the Human Frontiers Science Program and a Fogarty/CNRS cooperative Fellowship to M.R.P.

IDENTIFICATION OF RESIDUES THAT DETERMINE CURARE BENTIFICATION OF RESIDUES THAT DETERMINE CURARE SELECTIVITY IN THE ADULT ACETYLCHOLINE RECEPTOR N.D. Bren and S.M. Sine* Department of Physiology and Biophysics, Mayo Foundation, Rochester, MN 55905.

The adult muscle acetylcholine receptor is a pentamer of homologous

subunits with composition $\alpha_2\beta\epsilon\delta$. The two ligand binding sites, formed by αε and αδ subunit pairs, exhibit 100-fold different affinities for the competitive antagonist dimethyl-d-tubocurarine (DMT). We previously showed that Y117 of the γ subunt confers high affinity to the $\alpha\gamma$ site of the fetal AChR, whereas the equivalent residue T118 of the δ subunit confers low affinity to the $\alpha\delta$ site. Here we show that in the adult AChR, the mutation £5117R decreases DMT affinity, but the aromatic mutations, £5117Y and £5117W, show no change in affinity. Thus, although near the site of DMT binding, residue 117 is not the source of high affinity in the ε subunit. To identify residues that confer high affinity in the ϵ subunit, we made ϵ - δ chimeras, coexpressed them with complementary subunits in 293 HEK cells, and measured DMT binding by competition against the initial rate of 125 I- α -bungarotoxin binding. When we introduce ε sequence into the N-terminal 65 positions of the δ subunit, the resulting binding site shows a 10-fold increase in affinity for DMT. Conversely, when we introduce δ sequence between positions 44 and 65 of the ε subunit, the resulting binding site shows a 10-fold decrease in affinity. Thus, DMT selectivity is determined by one or more of the eight residue differences in this segment. We conclude that alternative segments of the ε , δ , and γ subunits confer DMT selectivity to the two binding sites. Supported by NIH grant NS31744.

Generation of mice deficient in the alpha7 neuronal nicotinic receptor gene by targeted recombination

Avi Orr-Urtreger, Finn Goldner, Jim Patrick* and Art Beaudet Department of Molecular and Human Genetics, The Howard Hughes Medical Institute, and the Division of Neuroscience, Baylor College of Medicine, Houston, Texas 77030

The alpha7 neuronal nicotinic acetylcholine receptor subunit forms homo-oligomeric nicotine gated ion channels when expressed in oocytes, has a substantial permeability to calcium, is blocked by the snake toxin α-bungarotoxin and is widely expressed in the brain. To better understand the functional role of this receptor subunit we generated a mouse in which exons eight through ten, which encode transmembrane domains two through four of the alpha7 protein, have been deleted by homologous recombination with a vector in which these sequences were replaced with those encoding a selectable marker. The resulting mouse no longer synthesizes immunoreactive material that can be purified by affinity chromatography on α-cobratoxin columns from detergent extracts of these brains. The brains of these mutant mice appear normal on routine histological examination, show no differences when examined for acetylcholinesterase activity and, at age eight weeks, show normal barrel fields in the somatosensory cortex.

This work was supported by grants from NIDA, NINDS, the HHMI and a fellowship from Fogarty International.

GAMMA-PKC NULL MUTANT MICE HAVE REDUCED SUSCEPTIBILITY TO NICOTINE-INDUCED SEIZURES, E.H. Owen*, J.E. Carter, A. Abeliovich, S. Tonegawa, J.M. Wehner, A.C. Collins. Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309-0447

PKC-γ null mutant mice are differentially sensitive to ethanol but not barbiturates or benzodiazepines. The behavioral effects of each of these drugs result from actions on the GABA receptor. Brain nicotinic receptors contain consensus sites for PKC phosphorylation. Consequently, effects of nicotine on open field activity, body temperature, and seizures were measured in wild type (+/+), heterozygotes (+/-), and null mutant (-/-) mice. Dose-response curves were constructed for each measure. No differences were observed across genotypes for the open field and body temperature tests. However, the (-/-) mice were more sensitive to nicotine-induced seizures than were the (+/+) mice while the (+/-) mice showed intermediate sensitivity. Current evidence argues that nicotine's effects on locomotor activity and temperature are regulated by α4containing nicotinic receptors whereas nicotine-induced seizures are influenced by α 7-containing receptors. The result with null mutants argues that phosphorylation of the α 7-type nicotinic receptor may modulate its activity. Supported by DA-10156, DA-00197, and AA-00141.

CHARACTERIZATION OF THE RAT NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR α7 SUBUNIT GENE. <u>U. Nagavarapu* and R.T. Boyd</u>. Department of Pharmacology, The Ohio State University College of Medicine, Columbus, Ohio, 43210.

nAChRs binding the snake venom toxin, α -bungarotoxin (α Bgt), are expressed in the CNS as well as in autonomic neurons and function as ligand-gated cation channels. Recent evidence supports a role for these α Bgt-AChRs in neurite outgrowth and presynaptic control of neurotransmittelease. Many of these α Bgt-AChRs contain the α 7 subunit. The α 7 gene is also expressed in developing skeletal muscle indicating that nAChRs containing α 7 subunits may play a role in muscle development.

We are interested in isolating and characterizing the rat $\alpha 7$ gene and genetic elements which control cell-specific expression. These elements will probably be complex with distinct elements controlling expression in muscle during development and other sequences controlling expression in specific neuronal populations.

A rat genomic library was screened using a rat $\alpha 7$ cDNA as a probe. Nine genomic clones containing the $\alpha 7$ gene were isolated. The genomic clones were mapped and the exon-intron boundaries localized. The 5' $\alpha 7$ cDNA probe was used to isolate genomic clones containing the 5' flanking region of the $\alpha 7$ nicotinic AChR gene. Restriction fragments from these clones were subcloned and sequenced to identify the promoter region of the gene. Further characterization and expression of these subclones is currently in progress.

TRANSCRIPTIONAL CONTROL OF AN ACETYLCHOLINE RECEPTOR SUBUNIT GENE. Y. He, L.C. Yang, J. G. Ma, S. Houser and T. Schmidt-Glenewinkel*. Department of Biological Sciences, Hunter College and Graduate Center of CUNY, New York, NY 10021

The ard gene encodes a non- α -like subunit of one of the two subtypes of neuronal nicotinic acetylcholine receptors from Drosophila. We have been studying the cis-acting elements required for temporal and spatial expression of the gene encoding this receptor subunit. We have previously shown that a 325 bp fragment of the 5' flanking sequence was sufficient to direct β galactosidase expression in the nervous tissue during development with a pattern very similar to the distribution of transcripts of the corresponding ard gene. DNase I footprinting has been carried out to precisely locate the essential regulatory sequences. Site-specific mutagenesis is performed based on the results of DNase I P-element mediated transformation with the footprinting. mutagenized promoter elements will establish which regulatory sequences are required for temporal and spatial expression of this subunit gene in vivo.

IDENTIFICATION OF CALCIUM BINDING SITES WHICH REGULATE POTENTIATION OF A NEURONAL ACHR. D. Bertrand*, J.L. Galzi, P.J. Corringer, S. Bertrand and J.P. Changeux University of Geneva, 1211 Geneva, Switzerland, Institut Pasteur 75734 Paris Cedex France.

The divalent cation calcium potentiates the physiological response of neuronal nAChRs by enhancing ionic current amplitudes, apparent agonist affinity and cooperativity. The potentiation observed on the a7-5HT3 chimera and its absence on the wild type 5HT₃ receptor indicates that this allosteric modulation depends on the N-terminal domain of the protein. Furthermore, sequence analysis of this protein segment suggests the existence of five putative calcium binding sites. Here, we report that mutations of these putative calcium binding loops alter calcium potentiation of the α 7-5HT $_3$ chimera. Moreover, "grafting" of the most important loop in the 5HT3 receptor results in a serotonin receptor which can be potentiated by extracellular calcium. In addition calcium inhibits terbium binding to a synthetic peptide exhibiting the amino acid sequence of this main loop and mutations within this peptide alter terbium binding

CLONING AN ALPHA-LIKE NICOTINIC ACETYLCHOLINE RECEPTOR (AChR) SUBUNIT FROM THE PARASITIC NEMATODE ASCARIS SUUM. H.L. Brooks ¹, R.C. Foreman ¹, J.F. Burke ², N.C. Sangster ³, L. Holden-Dye ¹ & R.J. Walker **, Department of Physiology and Pharmacology, School of Medical Sciences, University of Southampton, SO16 7PX, ² Department of Biochemistry, University of Sussex, BN1 9QG, ³ Department of Veterinary Pathology, University of Sydney, NSW 2006.

The nicotinic receptor mediating muscle contraction in the parasitic nematode Ascaris suum has been well characterized in terms of its agonist, antagonist and toxin selectivity. This receptor is the target for some commonly used anthelmintics, including levamisole, for which resistant strains are now appearing the parasitic nematodes. In order to facilitate rational anthelmintic design we have set out to establish the structural basis for the pharmacological properties of the Ascaris nicotinic receptor by cloning the nicotinic receptor subunit genes. We have screened an A. suum larval cDNA library at low stringency with PCR fragments, obtained using degenerate probes to the conserved regions of other invertebrate AChR genes (Neurosci. Abst., 334.1:832,1995), and a genomic fragment which encodes the conserved second transmembrane region from the nAChR alpha-like subunit of Trichostrongylus colubriformis. We have cloned the cDNAs of 8 putative nAChR subunits one of these, As38, is an alpha-like subunit and shares 54% amino acid identity with the Drosophila alpha-like subunit and shares 54% amino acid identity to the chick alpha-2 neuronal subunit. Functional characterization of this subunit will be achieved by using the Xenopus oocyte expression system.

FUNCTION OF TRANSGENIC NICOTINIC ACETYLCHOLINE RECEPTORS EXPRESSED IN HUMAN CELLS STABLY TRANSFECTED WITH α7 SUBUNITS. R.J. Lukas*, L. Lucero, C.M. Eisenhour and E. Puchacz. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013 USA.

We have continued studies of stably transfected cells of the SH-SY5Y human neuroblastoma or other clonal lines that express functional nicotinic acetylcholine receptors (nAChR) as homooligomers of transgenic α7 subunits. cDNA inserts containing wild-type or mutant forms of chick \$\alpha 7\$ subunits kindly provided by Jean-Pierre Changeux and Jean-Luc Galzi were subcloned in sense or anti-sense orientations into the pCEP4 expression vector. Following electroporation to introduce transgenes into cells and selection of stable transfectants in hygromycin B, many more cells carrying anti-sense transgenes survived than did cells carrying sense transgenes coding for mutant subunits predicted and shown here to combine to form non-desensitizing, Ca²⁺-permeable nAChR. Inclusion of 100 nM methyllycaconitine (MLA) in culture medium spared sense orientation transfectants from cell death, reflecting MLA's actions as a potent, competitive antagonist of mutant α 7-nAChR function as assessed by isotopic ion flux assays. These assays also show that di-hydro- β -erythroidine (DH β E) is a potent agonist at mutant α 7nAChR and that EC₅₀ values are in the nM range for nicotine activation of mutant α7-nAChR function. Abilities of DHβE, nicotine, and MLA to inhibit specific 125-I-labeled α-bungarotoxin binding to transgenic α7-nAChR do not differ for receptors containing wild-type or mutant subunits. These studies indicate utility of stably transfected cells expressing \$\alpha7\$ subunits as models for elucidating basic principles of ligand-gated ion channel structure and function. NNC 90-0270 - A NOVEL NICOTINE RECEPTOR MODULATOR: IN VITRO CHARACTERISTICS. K. Rimvall, K. Eskesen, M. Sheardown, J. Egebjerg, P.H. Olesen, J.E. Tønder, M.E. Judge, T. Rasmussen and M.D.B. Swedberg. Health Care Discovery, Novo Nordisk, Novo Nordisk Park, DK-2760 Malov, Denmark.

Modulators of nicotinic receptors in the CNS are of potential benefit in a variety of CNS disorders. We have characterized the novel, nicotinic compound NNC 90-0270 in several in vitro tests and compared its effects to those of standard compounds like nicotine, ABT418, lobeline and methylcarbachol (MCC)

NNC 90-0270 inhibits [3H]MCC binding to cortical and hippocampal rat brain membranes and to Sf9 cells expressing the $\alpha4\beta2$ - or the $\alpha3\beta2$ subunit combinations with Ki values between 0.9 and 2.3 nM. It is selective for nicotine receptors, compared to muscarinic receptors, with a MCC/oxotremorine IC $_{50}$ -ratio of 320. NNC 90-0270 induces the release of [$^3\mathrm{H}]$ dopamine from prelabeled rat striatal slices with an EC $_{50}$ of 0.61 nM and with an efficacy, at 1 µM, of 60% relative to 1 µM nicotine. NNC 90-0270 evokes spreading depression in the chick retina (MEC 1 μ M). The values for nicotine and ABT418 were 10 and 23 µM, respectively. NNC 90-0270 acts as an agonist on Xenopus oocytes expressing $\alpha 3\beta 2$ - and $\alpha 4\beta 2$ -subunit combinations with EC₅₀ values of 4.2 and 0.31 μM . At the $\alpha 4\beta 2$ -subunit combination, both MCC and NNC 90-0270 are more efficacious than nicotine giving responses of 230% and 300% at a concentration of 1 μM_{\odot}

Funded by Novo Nordisk.

NNC 90-0270: IN VIVO CHARACTERIZATION OF A NOVEL CENTRALLY ACTING NICOTINIC AGONIST. M. D. B. Swedberg*, T. Rasmussen, M. E. Judge, K. Rimvall, K. Eskesen, J. Egbjerg, M. J. Sheardown, J. B. Hansen and P. H. Olesen. Health Care Discovery, Novo Nordisk, Novo Nordisk Park, DK-2760 Malov, Denmark

NNC 90-0270 is a novel nicotinic agonist with nanomolar affinity for brain nicotinic acetylcholine receptors (nAChR; see Olesen et al., this brain incomine acetylcrionic receptors (in-cont.) see Clesent et al., this meeting). In vitro, NNC 90-0270 was more effective than nicotine at the α 4β2 subunit in the Xenopus Oocytes (see Rimvall et al., this meeting). In a rat nicotine drug discrimination assay (nicotine ED $_{50}$: 0.01 mg/kg), NNC 90-0270 (ED $_{50}$: 0.1 mg/kg), like lobeline (ED $_{50}$: >5.4 mg/kg) and ABT-418 (ED $_{so}$ 0.2 mg/kg), produced partial nicotinic responses, whereas cytisine (ED $_{so}$ 0.7 mg/kg) produced full effect. When comparing oral to s.c. ED $_{so}$'s in the drug discriminaton test, NNC 90-0270 had a ratio of 5 and ABT-418 a ratio of 10. NNC 90-0270, lobeline and ABT-418 all produced dose-dependent response rate decreases, whereas nicotine and cytisine did not reduce rates at the doses tested. Locomotor activity in the mouse was equally reduced by NNC 90-0270 (EDso: 0.4 mg/kg) and nicotine (ED₅₀: 0.3 mg/kg) and less so by ABT-418 (ED₅₀: 10.0 mg/kg). NNC 90-0270 dose-dependently reduced body weights in rats more efficaciously than nicotine at equimolar doses when given via osmotic minipumps for two weeks. NNC 90-0270 and ABT-418 both appear not to cause dosedependent intravenous self-administration in naive mice, whereas nicotine produced a characteristic inverted U-shaped dose-response curve Funded by Novo Nordisk

WALGERIN-1 BLOCKS THE EMBRYONIC MUSCLE-TYPE MACHILLA RECEPTOR (ACHR). J.P. Dilger and J.J. McArdle*. Dept Anesthesiology, SUNY, Stony Brook 11794 and Dept Pharm & Phys, NJ Med School (UMDNJ), Newark, NJ 07103. We previously demonstrated that the lethal effect of Waglerin-1 (WTX) in adult mice is associated with block of the ACHR at the

neuromuscular junction. Conversely, the lack of lethality in neonatal mice is associated with resistance of the immature neuromuscular junction to WTX. To explore the role of the embryonic muscle type ACHR in resistance to WTX, we examined the effect of WTX on the embryonic mouse muscle-type ACHR from BC3H-1 cells. Multichannel currents were activated by rapid perfusion of $100~\mu M$ ACh to outside-out patches. WTX had two effects on the currents. The first was to reduce peak current amplitude (before desensitization); the IC50 was 0.75 μ M WTX. The second effect was to decrease the rate of rise of the current. The effects occurred within 30 sec of WTX perfusion. Recovery from the effects after washout of WTX required tens of minutes and was usually incomplete. The potency and time course of action of WTX at the nicotinic ACHR of the BC3H-1 cell is similar to that described at the mature neuromuscular junction. This would suggest that the ACHR at the end-plate of neonatal mouse skeletal muscle is not particularly resistant to WTX. Similar studies with cells expressing the mature form of the ACHR are in progress. (Supported by NIH grants GM42095 and NS31040).

IDENTIFICATION OF A NOVEL (ISOXAZOLE)METHYLENE-1-AZABICYCLIC COMPOUND WITH HIGH AFFINITY FOR THE CENTRAL NICOTINIC ACh RECEPTOR: NNC 90-0270. P.H Olesen, M.D.B. Swedberg, K. Rimvall, K. Eskesen, M.E. Judge, J.Egebjerg, J.B. Hansen, J.E.Tønder, T. Rasmussen and M.J. Sheardown*, Health Care Discovery, Novo Nordisk, Novo Nordisk Park, DK-2760 Malov, Denmark

New ligands which selectively activate subtypes of the nicotinic acetylcholine receptor (nAchR) may have therapeutic potential for the treatment of central nervous system (CNS) disorders.

Here we report on a novel series of (isoxazole)methylene-1-azabicyclic compounds which possess nanomolar affinity and high selectivity for brain nAChRs. The compounds have different affinity for the various subtype combinations of neuronal nAChRs in transfected cells. The synthesis and structure-activity relationships for in vitro binding assays, in vitro functional assays and *in vivo* functional assays for the leading members of the series are described. Our major lead compound, NNC 90-0270, has a 3.0 nM affinity for rat brain [3H]-MCC binding sites and demonstrates a 400 % efficacy, compared to nicotine, with regards to stimulation of the current response in Xenopus oocyte expressed with the human α4β2 nAChR

Funded by Novo Nordisk

PRELIMINARY CHARACTERIZATION OF ETHYL (3-QUINUCLIDINYL) ACETATE AS A NOVEL ACETYLCHOLINE RECEPTOR LIGAND. D. Canney ², J. Buccafusco ³, R. Aronstam ⁴, M. Gattu ³, M. Zhang ², G. Sterling ^{1*}, P. Doukas ². Temple Univ., Schools of Medicine ¹ and Pharmacy ², 3307 N. Broad St. Phila., PA 19140; Medical College of Georgia ³, Dept. of Pharmacol.and Toxicol., Augusta, GA 30912, Guthrie Research Institute⁴, Sayre, PA, 18840.

Augusta, GA 30912, Guntier Research Institute, Sayte, FA, 18640. Recent studies suggest that neuronal nicotinic acetylcholine receptors (nAChR) may play a role in several CNS disorders including Alzheimer's Disease. Molecular cloning experiments indicate that multiple subtypes of the nAChR exist in brain. Recent work in our laboratories show that 3-substituted quinuclidines exhibit potent CNS activity when administered i.p. to mice. In particular, ethyl (3quinuclidinyl) acetate (EQA) was shown to induce seizures which could be prevented by pretreatment with mecamylamine. The objective of the present study was to evaluate EQA as a potential cholinergic ligand. EQA blocked the vasodilatory response to ACh on blood pressure, and blocked ACh-induced contraction of ileal smooth muscle. Binding studies ([3H]cytisine, [3H]perhydrohistrionicotoxin ([3H]H₁₂-HTX),

scopolamine, pirenzepine, α-bungarotoxin) show that EQA has μM affinity for both muscarinic and nicotinic receptors. Behavioral studies following i.c.v. injections of EQA and methylcarbamylcholine suggest that EQA is a nicotinic antagonist. These data indicate that EQA has varying degrees of affinity/activity for muscarinic and nicotinic receptors in the periphery and in the CNS. Especially interesting is the potential development of EQA-based compounds as neuronal nAChR antagonists. Supported by Med Research Service, Veterans Affairs & Temple Univ.

THE NICOTINIC AGONIST (±)EPIBATIDINE RELEASES [3H]NOREPINEPHRINE BUT NOT ADENOSINE FROM RAT HIPPOCAMPAL SLICES. T.D. White* and K. Semba. Departments of Pharmacology and Anatomy & Neurobiology, Dalhousie University, Halifax, N.S., Canada B3H 4H7.

 (\pm) Epibatidine is a natural toxin from frog skin that exhibits potent analgesic activity unrelated to opioid receptor activation. It has been shown to be an agonist at neuronal nicotinic receptors and to release catecholamines from brain slices. Significantly, epibatidine's analgesic actions in the hot plate test are blocked by adenosine receptor antagonists such as caffeine and theophylline, suggesting that the analgesia may involve extracellular adenosine (Gunther et al., Soc. Neurosci., 21, 247.11, 1995). We determined if epibatidine releases adenosine, which might then act at specific adenosine receptors to produce analgesia. We also compared epibatidine's ability to release adenosine with its analgesia. We also compared epibatidine's ability to release adenosine with its ability to release [H]NE from slices of rat brain and contrasted these effects with the releasing effects of NMDA. In either the presence or absence of extracellular Mg^2 *. (±)epibatidine (0.1 μ M) released [H]NE but not adenosine from hippocampal slices. In contrast, NMDA (300 μ M) released both [H]NE and adenosine from hippocampal slices, incubated in the absence of extracellular Mg^2 * to relieve its block of NMDA receptors. (±)Epibatidine (0.1 μ M) also did not release adenosine from slices of rat parietal cortex, in contrast with NMDA (300 μ M) which, in the absence of extracellular Mg^2 *, readily released adenosine. A very high concentration of (±)epibatidine (40 μ M) failed to release adenosine. These findings indicate that (±)epibatidine does not release adenosine from slices of either rat hippocampus or cortex. However, it is possible, if somewhat unlikely, that epibatidine somehow specifically releases adenosine only from those limbic and spinal regions involved in nociception. Supported by grants from the MRC of Canada to T.D.W. and to K.S., and from the Scottish Rite Foundation to K.S.

EPIBOXIDINE: AN ANALOG OF EPIBATIDINE WITH ALTERED SELECTIVITY AS A NICOTINIC AGONIST, H.M. Garraffo, (Plummer, J.W. Daly and B. Badio*. Laboratory of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20892–0820.

Epibatidine (I), a very potent nicotinic agonist selective for $\alpha_3\beta_{4(5)}$ and α₄β₂-subtypes of nicotinic receptor-channels, is a potent antinociceptive agent (Mol. Pharmacol., 45, 563, 1994). Epiboxidine (II), an analog of epibatidine in which the chloropyridyl moiety is replaced by a methylisoxazolyl moiety, has been synthesized. The methylisoxazolyl moiety has precedent in ABT 418 (III), a nicotine analog in which the pyridyl moiety of nicotine has been replaced by the methylisoxazolyl moiety. Epiboxidine is about ten-fold less potent than epibatidine at central-type $\alpha_4\beta_2$ -nicotinic receptors, and about five-fold less potent than epibatidine at neuromuscular-type $\alpha_1\beta_1\gamma\delta$ nicotinic receptors, while being nearly as potent as epibatidine at ganglionic-type \(\alpha_3\beta_{4(5)}\)-nicotinic receptors.

502.9

ABT-089: DISCRIMINATIVE STIMULUS PROPERTIES AND ELECTROPHYSIOLOGICAL ACTIONS. D.J.B., Kim*, M.S. Brodie, M.W., Decker, S. P., Arneric and J.D., Brioni, Neuroscience Discovery, Abbott Laboratories, Abbott Park, IL. 60064 and University of Illinois, Chicago, IL. 60612-7342.

ABT-089, [2-methyl-3-2(2-(5)-pyrrolidinylmethoxy)pyridine dihydrochloride], is a novel cholinergic channel modulator (ChCM) that has subtype selective efficacy to modulate neuronal nicotinic acceptholine receptor (nAChR) function It displaced [3H]-cytisine binding to the human 4482 subunit combination stably

It displaced [3H]-cytisine binding to the human α4β2 subunit combination stably expressed in the K177 cell line with a 16 nM potency while (-)-nicotine exhibited a Ki=1 nM. In contrast, ABT-089 was 500-fold less potent to displace [125₁]-α-Bgt binding (Ki=10,000 nM) from rat brain membranes (Sullivan, et. al.

This meeting).

A series of experiments was conducted to determine the discriminative stimulus properties of ABT-089 in comparison to (-)-nicotine. Rats were able to discriminate (-)-nicotine 1.9 µmol/kg s.c. from saline in 43 days, but they were discriminate (-)-nicotine 1.9 μmol/kg s.c. from saline in 43 days, but they were not able to discriminate 19 or 62 μmol/kg of ABT-089 from a saline solution after 64 days of training. In rats trained to discriminate 1.9 μmol/kg (-)-nicotine from saline, ABT-089 induced a reduced generalization (6.2-190 μmol/kg, s.c.) and was 100 times less potent than (-)-nicotine to induce the cue. A-94224.3, the enantiomer of ABT-089, induced a saline response at 62 μmol/kg. The effects of (-)-nicotine and ABT-089 were completely blocked by the cholinergic channel blocker, mecamylamine (15 μmol/kg). ABT-089 exhibited comparable effects in (-)-nicotine-trained rats after oral administration. In vitro electrophysiological studies in dopamine-containing neurons in the ventral tegmental area indicated that ABT-089 is a weak partial agonist that can also

teginiental area interaction and AB = 0.087 is a weak partial agoinst that can ask block the excitatory actions of (-)-nicotine.

These data demonstrate that in the present conditions ABT=0.89 could not be discriminated from saline in naive rats in doses up to 62 μ mol/kg, and that ABT=0.89 induced a partial generalization in nicotine-trained rats at doses 100 times higher than (-)-nicotine. (Supported by Abbott Laboratories)

502.11

DIFFERENTIAL EFFECTS OF ABT-089 AND (-)-NICOTINE ON NICOTINIC ACETYLCHOLINE RECEPTOR DENSITY AND FUNCTION FOLLOWING SUBACUTE ADMINISTRATION.

D.J. Anderson*, D. Donnelly-Roberts, J. Campbell, J.R. Pauley 1, P. Magill 1, S.P. Arneric, and J.P. Sullivan, Neuroscience Research (D-47W), Pharmaceutical Products Division, Abbott Laboratories, 100 Abbott Park Rd, IL 60064-3500 and ¹ College of Pharmacy, Univ. Kentucky, Lexington, KY, 40536.

ABT-089 [2-methyl-3-(2-(s)-pyrrolidinylmethoxy)pyridine dihydrochloride] is a

ABT-089 [2-inelly]-5-(2-)-pythology intermediately pythology in the involved in the color is a cholinergic channel modulator with cognitive enhancing properties in rodents and primates; effects that are enhanced following subacute administration (see Decker et al., accompanying poster). The present study evaluated the effects of subacute (14 day) continuous administration of behaviorally effective doses of ABT-089 (1.3 μmol/kg/day) and (-)-nicotine (NIC) (62 μmol/kg/day)) on regional brain densities of the α482 and α7 nAChR subtypes and on nAChR-mediated functional responses. An index of the densities of $\alpha 4\beta 2$ receptors was measured with [3H]cytisine, while $[125I]\alpha$ -bungarotoxin (αBgT) was used for $\alpha 7$ receptors. Autoradiography studies revealed that subacute administration of ABT-089 had no effect on the binding density of either [3H]cytisine or [125I] \alpha BgT in any of the 37 brain regions examined. Similar results were found in radioligand binding studies to washed membranes from 5 brain regions. In contrast, subacute administration of (-)-nicotine significantly (p < 0.05) increased the density of $[^3H]$ cytisine binding sites in all regions examined while regional differences in the ability of this agent to upregulate $[^{125}]\alpha BgT$ binding sites ere observed. Subacute ABT-089 had no effect on efficacy or potency of (-)-nicotine were observed. Studeduc AS1-088 had no effect on efficacy of potency of (3-income to stimulate ⁸⁶Rb⁺ efflux from thalamic synaptasomes in contrast to a 40% decrease in the efficacy of (-)-nicotine observed in rats following subacute (-)-nicotine treatment. Subacute ABT-089 or (-)-nicotine treatment did not alter the ability of (-)-nicotine to stimulate dopamine release from striatal slices. These data indicate that nAChR density and function is differentially modulated following continuous exposure to behaviorally effective doses of ABT-089 and (-)-nicotine. Supported by Abbott Laboratories.

FURTHER CLASSES OF ALKALOIDS ACTIVE AS NONCOMPETITIVE NICOTINIC ANTAGONISTS; SPIROPYRROLIZIDINES, PSEUDOPHRYNAMINES AND IBOGAINE. B. Badio, W. L. Padgett, H.M. Garraffo and J.W. Daly*. Laboratory of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20892–0820.

A variety of alkaloids have proven to be potent and useful noncompetitive blockers of nicotinic receptor-channels. among such alkaloids is histrionicotoxin (I) and various analogs, in which the presence of side chains with varying degrees of unsaturation, markedly affect both potency and selectivity as blockers of different subtypes of nicotinic receptors. Two unique new structural classes of alkaloids acting as blockers are the relatively polar spiropyrrolizidines (Ilabc) and the physostigmine-like pseudophrynaminol (III). The spiropyrrolizidines are selective for ganglionic-type $\alpha_s\beta_{4(6)}$ -nicotinic receptor-channels, while III is very potent and non-selective. In addition to these "amphibian alkaloids", the plant alkaloid ibogaine (IV), now widely studied as an antiaddictive agent, is a very potent and selective blocker of ganglionic-type nicotinic receptors with an IC_{50} in PC12 cells of about 20 nM.

502.10

EFFECTS OF ABT-089, A NOVEL CHOLINERGIC CHANNEL MODULATOR, ON COGNITIVE PERFORMANCE IN RATS AND MONKEYS. M.W. Decker*, A.W. Bannon, P. Curzon, K.L. Gunther, J.D. Brioni, M.W. Holladay, N-II, Lin, Y. Li, J. Daanen, J.J. Buccafusco, M.A. Prendergast, W.J. Jackson, and S.P. Americ' Neuroscience Research, D-47W, AP-9A, Pharmaceutical Products Div., Abbott Labs, Abbott Park, II. 60064 and Dept. of Pharmacology, Medical College of Georgia, Augusta, GA 30912

ABT-089 [2-methyl-3-(2-(S)-pyrrolidinylmethoxy)pyridine dihydrochloride], a

novel ligand at neuronal nicotinic acetylcholine receptors with reduced adverse effects and improved oral bioavailability relative to (-)-nicotine, was tested in a variety of cognitive tests in rats and monkeys. Acutely, ABT-089 only marginally improved the 2-platform spatial discrimination water maze performance of septal-lesioned rats. However, more robust improvement (45% fewer errors on the last training day) was observed when ABT-089 was administered continuously via osmotic pumps (min. observed when AD 1-038 was administed contamously variation pumps are effective dose: 1.3 µmol/kg/day, s.c.). Comparable effects are seen with (-)-nicotine, but at a higher dose (62 µmol/kg/day; Decker et al., 1995, Soc. Neurosci. Abstr. 21:159). In aged rats (20-22 mo.), continuous infusion of ABT-089 enhanced spatial learning in a standard Morris water maze, as indexed by spatial bias exhibited during a probe trial conducted after 4 days of training, but not after 7 days of training or when rats were later trained in a 2-platform spatial discrimination water maze. A small impairment was noted in young rats on the standard water maze, but not on the 2-platform task. ABT-089 did not affect performance of either the aged or young the 2-platform task. ABT-089 did not affect performance of either the aged or young rats during inhibitory (passive) avoidance training. Continuously infused ABT-089 did not affect acoustic startle or prepulse inhibition of acoustic startle in young, aged, or septal-lesioned rats and did not affect locomotor activity in sham- or septal-lesioned rats. Acutely, ABT-089 modestly improved the delayed matching-to-sample performance of mature, adult monkeys (6-12.4 yr.) and significantly improved performance in aged monkeys (22-27.5 yr.). Improved performance in the aged monkeys was restricted to the longest delay intervals and was not accompanied by changes in response latencies. [Supported by Abbott Laboratories]

502.12

ABT-089: A POTENT AND SELECTIVE CHOLINERGIC CHANNEL MODULATOR WITH NEUROPROTECTIVE PROPERTIES J.P. Sullivan, D. J. Anderson, C. A. Briggs, J.E. Campbell, D. Donnelly-Roberts, M. Gopalakrishnan, D. Gunn, Y. He, M.W. Holladay, D. McKenna, N. H. Lin, E. Molinari, M. Piattoni-Kaplan, I, Xue, M. Williams*, and S.P. Arneric. Neuroscience Research (D47W), Abbott Laboratories, Abbott Park IL, 60064

Accumulating preclinical and clinical evidence data suggests that compounds that selectively activate neuronal nicotinic acetylcholine receptor (nAChR) subtypes may have therapeutic utility for the treatment of a number of neurological disorders. In the present study, the *in vitro* pharmacological properties of the novel cholinergic channel modulator ABT-089 [2-methyl-3-(2-(S)-pyrrolidinylmethoxy)pyrriodin-), are described. In radioligand binding studies, ABT-089 was shown to display selectivity towards the high affinity (-)-cytisine binding site present on the $\alpha 4\beta 2$ nAChR subtype (K_i = 16 nM) relative to the [^{125}I] α -BgT site present on the $\alpha4\beta2$ nAChR subtype ($K_i = 16$ nM) relative to the i^{12} -I]0-BgT binding site present on the $\alpha7$ ($K_i = >10,000$ nM) and $\alpha1\beta1\delta\gamma$ ($K_i > 1000$ nM) nAChR subtypes. In cation flux and channel current studies ABT-089 displayed a more complex profile than (-)-nicotine having agonist, partial agonist, and inhibitory activities depending on the nAChR subtype with which it interacts. ABT-089 differentially stimulated neurotransmitter release, the compound displayed a similar potency and efficacy to (-)-nicotine to facilitate ACh release but was markedly less potent and less efficacious than (-)-nicotine to stimulate dopamine release. Additionally, ABT-089 was neuroprotective against the excitotoxic insults elicted by exposure to either glutamate or α 1-42. The potency of ABT-089 to elicit neuroprotection was dramatically increased following subacute (7 day) retartment, a finding that parallels compilier testing in rodents (see Decker et al., this treatment, a finding that parallels cognitive testing in rodents (see Decker et al., this meeting). The differential full agonist / partial agonist profile of ABT-089, as compared to (-)- nicotine and ABT-418, illustrates the complexity of nAChR activation and the potential to dissect responses at subclasses of the neuronal and peripheral receptors. [Supported by Abbott Laboratories]

PHARMACOKINETIC AND SAFETY STUDIES ON ABT-089; AN ORALLY ACTIVE CHOLINERGIC CHANNEL MODULATOR LE. Campbell J.P. Sullivan, W. Arnold, Y. He, M.W. Holladay*, N.H. Lin, J. Daanen, Y. Li, K.C. Marsh, B. Peterson, H. Nellans, J. Trivedi and S.P. Arneric Neuroscience Research (D-47W), Abbott Laboratories, Abbott Park, IL 60064-3500

ABT-089 [3-(2(S)-Pyrrolidinylmethoxy)-2-Methylpyridine] is a cholinergic channel modulator (ChCM) that selectively affects the function of neuronal nicotinic acetylcholine receptor (nAChR) subtypes, enhances cognitive performance and has neuroprotective activity (see accompanying posters). Unlike ABT-418 and (-)-nicotine, ABT-089 exhibits a more complex profile having agonist, partial agonist, and inhibitory activities at discrete nAChR subtypes. This report provides safety and pharmacokinetic information that clearly differentiates ABT-089 from (-)-nicotine and ABT-418. ABT-089 is orally available (33-76% in rat, dog and monkey) and studies indicate that a one-a-day formulation is feasible. In contrast, ABT-418 and (-)-nicotine have poor oral bioavailability in dog and monkey (< 5%) and moderate bioavailability in rat (17 to 29 %). In anesthetized dog, bolus administration of ABT-089 at doses up to 12,500 nmol/kg elicited no significant increases in blood pressure or heart rate. In contrast, significant increases were observed following bolus administration (500 nmol/kg) of either (-)-nicotine or ABT-418. Subacute (14 days) administration of a once a day oral formulation of ABT-089 to conscious dogs followed by infusion of increasing doses of this agent did not elicit any significant changes in diastolic blood pressure or heart rate. Maximal plasma levels in these animals were >300-fold higher than the cognitive enhancing level (i.e. 2-10 ng/ml) in rodents. ABT-089 (0.1 to 100 µM) directly applied to the smooth muscle of guinea pig ileum did not elicit contraction and did not inhibit the ability of ACh, histamine, serotonin or K⁺ to produce normal responses. Thus, ABT-089 may be a safe and effective ChCM for the potential once-a-day oral treatment of neurological disorders. [Support provided by Abbott Laboratories]

EFFECT OF SMOKING HISTORY ON [3H]-NICOTINE BINDING IN HUMAN POSTMORTEM BRAIN. C.R. Breese, C.E. Adams, M.J. Marks, A.C. Collins, S. Leonard. Department of Pharmacology, University of Colorado Health Sciences Center, and Veterans Administration Medical Center, Denver, CO 80262.

It is well established in animals that chronic nicotine administration evokes increases in brain nicotinic receptor numbers. There is also a genetically determined variability in nicotinic receptor numbers in rodents, differences which are thought to affect the sensitivity to nicotine, as well as the development of tolerance. Humans self-administer nicotine principally in the form of cigarettes. We have examined the level of [*H]-nicotine binding in the thalamus and hippocampus of human postmortem brain tissue, from normal non-smoking subjects, and subjects with variable life-long smoking histories. A significant increase in the level of nicotinic receptors was observed in both the hippocampus and thalamus of subjects with life-long smoking histories (hippocampus: F(36, 1)=8.68, p<0.006; thalamus: F(30, 1)=9.633, p<0.005; There was also a modest correlation between the degree of smoking, as measured by the average packs smoked per day, and the number of nicotine binding sites found in the hippocampus and thalamus (hippocampus: r=0.49, p<0.003; thalamus: r=0.44, p<0.02). This data suggests that humans, like rodents, exhibit dose dependent increases in brain nicotinic receptor numbers following chronic nicotine exposure. [This research was supported by USPHS Grants MH44212, DA09457, and VA Medical Research Service]

AUTORADIOGRAPHIC COMPARISON OF [3H]-A 85380, [3H]-EPIBATIDINE AND [3H]-CYTISINE BINDING IN RAT AND MOUSE BRAIN. J.R. Pauly*, D.J. Anderson AND J.P. Sullivan. College of Pharmacy, Univ. of Kentucky, Lexington, KY 40536-0082 and Abbott Labs, Neurosci. Res. D47W Abbott Park II. 60064-3500.

Recent studies have shown that [3H]-epibatidine is a useful ligand for the autoradiographic analysis of brain nicotinic receptors (nAChr's). However, it appears that [3H]-epibatidine may bind to two or more nAChr alpha subunits (α3, α4 and possibly α7). The purpose of the present study was to compare the binding of [3H]-epibatidine and [3H]-cytisine with that of [3H]-A 85380, a newly developed, high-affinity nAChr radioligand (Ki = 50pM). Adjacent sets of cryostat sections were prepared from both rat and mouse brain and autoradiography was performed as described by Perry and Kellar (1995). The binding of three different concentrations of [3H]-epibatidine and [3H]-A 85380 (80pM, 400pM or 800pM) were compared to that produced by 5nM [3H]-cytisine. Qualitatively similar patterns of binding were produced with each ligand. However significant quantitative differences between [3H]-epibatidine and [3H]-cytisine\[3H]-A 85380 binding were identified in both rat and mouse brain. Specifically, the medial habenula, the interpeduncular nucleus and the fasiculus retroflexus bound significantly more [3H]-epibatidine than [3H]-A 85380. The high affinity and subtype selectivity of [3H]-A 85380 suggest that it is an excellent ligand for measuring brain nAChr's. Supported by Abbott Labs and DA-08443.

SMOKER'S LEVEL OF NICOTINE ACTS VIA NICOTINIC RECEPTORS CONTAINING THE α 7 SUBUNIT TO INCREASE GLUTAMATE RELEASE FROM HIPPOCAMPAL NEURONS. <u>K.A.</u> Radcliffe, A. Rajan, M.M. Zarei, M. Yakehiro, J.Y. Hsu and J.A. Dani*. Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The concentration of nicotine achieved by smokers (0.5 μ M nicotine) enhances the frequency but not the amplitude of glutamatergic miniature EPSCs in cultures of hippocampal neurons. Immunocytochemistry and pharmacology indicate that presynaptic nicotinic receptors containing the α 7 subunit mediate the influence of nicotine.

Rat hippocampal neurons were maintained in culture and were typically studied 10 to 30 days after plating. The neurons were whole-cell voltage clamped and mEPSCs were measured before, during, and after direct application of 0.5 μM nicotine. In another protocol, pulses of nicotine (0.5 mM) activated a rapidly desensitizing current indicative of $\alpha 7$ -containing nicotinic receptors. In most (but not all cases), α -BGT (50 nM) or MLA (5 nM) completely inhibited the nicotinic currents, indicating $\alpha 7$ -containing receptors. Both methods of nicotine application increased the release of glutamate as measured by an increase in the frequency (but not the amplitude) of mEPSCs. Nicotine did not have this effect in 0 external Ca. Co-localization with anti- $\alpha 7$ antibody and an antibody against a presynaptic marker (synaptotagmin) further supported the physiology results, suggesting that nicotine accordingly via presynaptic nicotinic receptors containing the $\alpha 7$ subunit. Supported by NIH, NINDS; Smokeless Tobacco Research Council.

502.16

THE EFFECTS OF PRENATAL NICOTINE EXPOSURE ON THE DEVELOPMENT OF BRAIN NICOTINIC RECEPTORS. <u>I.A. Sparks* and J.R. Pauly.</u> PET Division, College of Pharmacy, Univ. of Kentucky, Lexington, KY 40536-0082.

In humans, prenatal exposure to cigarette smoke causes a number of developmental abnormalities. Although the causative agents have not been clearly identified, many studies have focused on nicotine. In the present study female C57Bl/6 mice received as a drinking solution either 2% saccharin or nicotine in 2% saccharin (200 µg/ml) for one month prior to mating and throughout pregnancy. This method of nicotine delivery is non-stressful and produces "smoking relevant" plasma concentrations of cotinine in the dam and the pups. Although there was no difference in maternal weight gain between the two treatment groups, pup weight was slightly reduced by nicotine exposure. [3H]-cytisine and alpha [1251]-bungarotoxin (BTX) receptor autoradiography was performed on maternal and fetal brains obtained on day 19 of gestation (GD19). The pattern of cytisine binding on GD19 is distinct from that observed in the adult CNS with the retina and the pons/medulla having the greatest number of receptors. BTX binding on GD19 more closely resembles the adult pattern as high concentrations of receptors are present in the somatosensory cortex, hippocampus, hypothalamus and dorsal tegmental nucleus. The number of CNS binding sites for each ligand was increased by prenatal nicotine exposure. The functional consequences of increased fetal receptor number remain to be elucidated. Supported by DA-08443.

LOBELINE POTENTLY INHIBITS [¹H]DOPAMINE ([¹H]DA) UPTAKE INTO RAT STRIATAL VESICLES AND SYNAPTOSOMES, AND PROMOTES [³H]DA RELEASE FROM STRIATAL VESICLES AND SLICES. L.H. Teng*, P.A. Crooks, P.K. Sonsalla and L.P. Dwoskin. Graduate Center for Toxicology and College of Pharmacy, University of Kentucky, Lexington, KY 40536 and Dept. Neurology, UMDNJ RW Johnson Medical School, Piscataway, NJ 08854.

Lobeline is currently being developed as a nicotine substitution therapy for tobacco smoking cessation. The present study compared the effects of lobeline and nicotine on [3H]DA uptake and release in rat striatum. In contrast to nicotine, the concentration-dependent increase in [3H]DA release from striatal slices evoked by lobeline was not inhibited by mecamylamine (1-100 μ M), a nicotinic receptor antagonist. Also, in contrast to nicotine, lobeline-evoked [3H]DA release from striatal slices was calcium independent. Thus, the effect of lobeline to evoke [3H]DA release from striatal slices was via a mechanism other than stimulation of nicotinic receptors. In contrast to nicotine, lobeline potently inhibited [3H]DA uptake into striatal synaptic vesicles and synaptosomes with IC50s of 0.88µM and 80µM, respectively. At concentrations < 1 mM, nicotine did not inhibit [³H]DA uptake into vesicles or synaptosomes. Interestingly, lobeline evoked the release of [3H]DA from preloaded synaptic vesicles. The results demonstrate that lobeline acts to release striatal DA, not by stimulation of nicotinic receptors, but by inhibition of DA uptake into presynaptic vesicles and by promotion of DA release from presynaptic vesicles. We suggest that lobeline acts in an amphetamine-like manner, in that lobeline increases cytoplasmic DA concentrations and thereby enhances DA release from the dopaminergic terminal. Supported by the Tobacco and Health Research Institute, Lexington, KY

AMINOGLYCOSIDE ANTIBIOTICS BLOCK ACETYLCHOLINE-INDUCED CURRENTS IN α9-INJECTED XENOPUS LAEVIS OOCYTES. A.B. Elgoyhen, C. Rothlin, M. Verbitsky, D. Vetter and S. Heinemann* Instituto de Investigaciones Farmacológicas (CONICET), Buenos Aires, Argentina and The Salk Institute for Biological Studies, La Jolla, CA.

Ototoxicity is one of the major side effects of aminoglycoside antibiotic treatment. When these drugs are administered in high doses outer hair cells degenerate (Schacht, Otolaryngol. Clin. North Am., 26: 845, 1993). The injection of gentamicin to guinea pigs produces a rapid elimination of the cholinergic olivocochlear efferent system that synapses on outer hair cells. The aim of the present work was to study the effects of aminoglycosides on a9, the nAChR of outer hair cells (Elgoyhen et al, Cell 79: 705, 1994). In vitro transcribed a9 cRNA was injected into Xenopus laevis oocytes. Responses of oocytes to acetylcholine (ACh) were measured under two-electrode voltage-clamp two to seven days after injection. Application of aminoglycosides blocked ACh-evoked currents in a concentration-dependent manner. The order of potency was neomycin > gentamicin > streptomycin > amikacin, with IC50 of 1 μ M, 6 μ M, 14 μ M and $102~\mu M$ respectively, measured at the EC50 (10 μM) for ACh. The antagonistic effect of neomycin and of gentamicin was not overcome by increasing the concentration of ACh, indicative of a non-competitive type of blockade. Our results suggest that at least part of the inner ear side effects of aminoglycosides could be due to the blockade of the cochlear nicotinic cholinergic receptor.

Use-dependent inhibition of neuronal nicotinic ACh receptor by preadrenomeduline precursor protein (PAMP). H. Ishibashi*, Nabekura , O. Murata and N. Akaike. Dept. Physiol., Kyushu Univ. Fac. Med., Fukuoka 812-82, Japan.

PAMP has been recently discovered as a powerful bioactive compound for vasodilation released from adrenal gland. This substance inhibits the release of adrenaline from chromaffin cells stimulated by nicotine, which suggests that PAMP might act as an antagonist on nicotinic acetylcholine (ACh) receptor. Therefore, to elucidate the action of PAMP on the neuronal nicotinic receptor, we employed a conventional whole-cell patch recording on acutely dissociated locus coeruleus (LC) neurons of rats, which receive massive cholinergic projection.

Nicotine as well as ACh elicited a peak followed by a gradual decrease of inward current at a holding potential of -40 mV in almost all LC neurons tested. The peak of nicotine-induced current (Inic) increased in a concentration dependent manner (>10⁻⁵M). Agonists and antagonists studies indicated that the nicotinic receptor in the LC are mainly composed of $\alpha 4$ subunits. PAMP reversibly and noncompetitively inhibited the Inic in a concentration-dependent manner (>10⁻⁹M). In the continuous application of PAMP, this inhibition increased use-dependently. These results indicate that the PAMP exhibits the powerful antagonistic action on neuronal nicotinic ACh receptor-channel complex

INHIBITORY EFFECTS OF STRYCHNINE ON NICOTINIC ACETYL-CHOLINE RESPONSES OF CULTURED RAT HIPPOCAMPAL NEURONS.

CHOLINE RESPONSES OF CULTURED RAT HIPPOCAMPAL NEURONS.

H. Matsubayashi*, M. Alkondon and E.X. Albuquerque, Dept. Pharmacol. Exp.
Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

Strychnine is generally known to act as a specific antagonist of glycine at the glycine-gated channel with an IC₅₀ value of 0.08 µM (Br. J. Pharmacol. 113:165, 1994). However, our study has revealed that this drug is a potent inhibitor of neuronal nicotinic receptors (nAChRs). At least three distinct nicotinic current types, IA, II and III, have been recorded from hippocampal neurons (J. Pharmacol. Fron. Ther. 265:1455, 1993) and these currents are subsequed by n AChRs with p. Ther. 265:1455, 1993), and these currents are subserved by nAChRs with Exp. Ther. 265:1455, 1993), and these currents are subserved by nAChRs with different subunit compositions. In the present study, whole-cell currents of type IA and II were recorded from cultured hippocampal neurons according to the standard patch-clamp technique. The external perfusing solution contained atropine (1 μ M) and tetrodotoxin (200 nM). ATP-regenerating solution was used in the patch pipette to prevent the "rundown" of type IA current. Strychnine inhibited both type IA and type II currents evoked by pulses (0.5-2 s) of ACh (0.3 mM) in a concentration-dependent manner. The IC₅₀s for strychnine in inhibiting type IA and II currents were 1.2 and 37.6 μ M, respectively. Strychnine decreased the peak amplitude of type IA current in a voltage-independent manner without shortenine the decay phase of these currents. The concentration-response decreased the peak amplitude of type IA current in a voltage-independent manner without shortening the decay phase of these currents. The concentration-response curve for ACh (0.05-10 mM) in evoking type IA currents was shifted to the right in the presence of strychnine. These findings suggest that this toxin acts as a competitive antagonist of ACh at the α 7-bearing nAChRs that subserve type IA currents. On the other hand, inhibition by strychnine of type II currents was strongly voltage dependent, and the decay phase of these currents was shortened by this toxin. These results indicate that strychnine inhibits type II nicotinic current by acting as an open-channel blocker of α 4 β 2 nAChRs. In conclusion, strychnine is a potent antagonist of neuronal nAChRs, in addition to being a potent antagonist of glylcine at glycine-gated channels. Support: USPHS grant NS25296.

NEUROSTEROIDS ACT AS ALLOSTERIC ANTAGONISTS ON BRAIN NICOTINIC RECEPTORS A.E. Bullock*, A.L. Clark, S.R. Grady, S.F. Robinson, B.S. Slobe and A.C. Collins Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309

Recent evidence demonstrates that progesterone and it's metabolites are allosteric modulators of GABAergic receptors. Brain nicotinic receptors are members of the same super gene family. With this in mind, we assessed the effects of progesterone and two of it's metabolites (5 α -pregnane-3,20-dione and 5 α pregnane-3α-ol-20-one) on brain nicotinic receptor function using [3H]Dopamine release from striatum and 86Rubidium efflux from thalamus as measures of receptor function. Current evidence indicates that these two assays monitor function of α_3 and $\alpha_4\beta_2$ containing receptors, respectively. Each of the steroids inhibited receptor function although the potency and maximal effect of the steroids varied between the two measures. The inhibition of nicotinic receptor function was noncompetitive in nature and was slow in onset and recovery. One potential explanation for these findings is that the steroids may alter the ratio of ground state to desensitized state of the nicotinic receptor. Thus reducing the number of activatable nicotinic receptors. (Supported by DA05131 and DA00197)

INHIBITORY EFFECTS OF LOCAL ANESTHETICS ON ALPHA-BUNGAROTOXIN-INHIBITORY EFFECTS OF LOCAL ANESTHETICS ON ALPHA-BUNGAROTOXINSENSITIVE NEURONAL NICOTINIC RECEPTORS IN RAT CULTURED
HIPPOCAMPAL NEURONS W.S. Cortes¹²³, H. Matsubayashi, Y.-P. Yu, Y. Aracava¹²,
A.T. Eldefrawi^{1*} and E.X. Albuquerque¹², ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland
Sch. Med., Baltimore, MD 21201, USA; ²Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, RJ 21944, ³Dept. Physiol. Sci., IB, UFRRJ, Rio de Janeiro, RJ 23568, Brazil.

Previous results have shown that bupivacaine and piperocaine can act as open channel blockers at muscle nicotinic acetylcholine receptors (nAChRs) (Mol. Pharmacol. 16:901, 1979; 26:304, 1984) and neuronal nAChRs (Soc. Neurosci. Abs. 19:1535, 1993). In the present study we investigated the effects of bupivacaine and derivatives of piperocaine on the α-bungarotoxin-sensitive (α7 containing) receptor, the predominant neuronal nAChR in the hippocampus (J. Pharmcol. Exp. Ther. 265:1455, 1994). Bupivacaine (1-100 μM) or derivatives of piperocaine (100 nM- 100 µM) were applied via a U-tube as an admixture with 100 µM or 1 mM ACh, and in the bath perfusion. Bupivacaine decreased the peak amplitude of ACh-elicited currents in a concentration-dependent manner with an IC so value of 23.7 µM and Hill coefficient of 0.86. Piperocaine derivatives up to 1 µM had no effect on the ACh- evoked currents, while at 30 μ M piperocaine and its quaternary derivative reduced the peak amplitude of ACh-evoked currents by 42 ± 7.4% (mean ± S.E.M.) and 30 \pm 4.5% respectively, and at 100 μ M piperocaine and its quaternary derivative decreased the peak amplitude of ACh-evoked currents by $75 \pm 9.3\%$ and $83 \pm 3.6\%$. All drugs decreased the peak amplitude of the nicotinic currents in a voltage-dependent fashion. All drugs also shortened the decay phase of the currents; this effect was more clearly observed at low agonist concentration (100 µM ACh) and was not voltage dependent. The potency of either bupivacaine (previous results) or piperocaine derivatives in inhibiting the nicotinic response was much lower when these drugs were applied only via the U-tube as an admixture with the agonist. Thus, these results indicate that bupivacaine and derivatives of piperocaine may interact with the open state of the channel of α -bungarotoxin-sensitive nAChRs, in addition to interacting with a distinct site, which may be located either on the receptor or in the lipid bilayer. METHAMIDOPHOS, BUT NOT ALDICARB, IS A PURE CHOLINESTERASE INHIBITOR N.G. Castro*, M.D. Santos, A.L. Camara, L.E.F. Almeida, M.F.M. Braga, W.M. Cintra, Y. Aracava and E.X. Albuquerque. Lab. Mol. Pharmacol II, IBCCF, UFRJ, Rio de Janeiro, RJ 21944, Brazil & Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA.

Aldicarb (Ald) and methamidophos (Mphos) belong, respectively, to the carbamate and organophophate groups of anticholinesterase (anti-ChE) agents. Here, we analyzed the anti-ChE activity of Mphos in various preparations, and the ability of both Mphos and Ald to interact with muscle nicotinic receptors (nAChRs). In homogenates of sartorius muscles of the frog *Leptodactylus ocellata*, and of diaphragm muscle, brain, and hippocampus of rats, Mphos inhibited the ChE activity with $1C_{50}$ s of 300, 43, 50, and 30 μ M, respectively. Mphos (100-300 μ M) increased the amplitude and prolonged the decay-time constants of nerve-evoked and of spontaneous end-plate potentials recorded from rat diaphragm, and had no effect on end-plate potentials recorded from frog sartorius muscle. or entered on en-plane potentials recorded in on not gastronis muscle. Single-challent currents evoked by ACh (0.2µM) in the presence or in the absence of one of the insecticides were recorded from isolated fibers of interosseal and lumbricoid muscles of the frog Leptodactyllus ocellara, using the cell-attached mode of the patch-clamp technique. Patch micropipettes were filled with ACh (0.2 μ M) either alone or as an admixture with either insecticide. Ald (1-100 μ M) produced a concentration-dependent increase in the number of brief closures and reduction of the duration of the openings (τ_{open}) during burst. The burst duration (τ_{burst}) was not significantly altered. At 300 μ M Ald, although τ_{open} of AChacity and the construction of the Ald-induced channels was further reduced, both the number of openings per burst and the τ_{burst} were reduced. In addition, the mean duration of the Ald-induced channel closures increased with Ald concentration. These alterations indicated a departure from the simple sequential blockade of the channel open state by Ald. In contrast to Ald, Mphos (100 and 300 µM) had no effects on ACh-activated currents recorded from rat myoballs in culture or frog muscle fibers. Our results demonstrate that the anti-ChE Ald can interact directly with muscle nAChRs, whereas Mphos interacts only with ChE, inhibiting more potently the enzyme present in rat preparations than that present in frog preparations.

DIVALENT CATIONS ENHANCE THE RESPONSE OF BRAIN NICOTINIC RECEPTORS TO NICOTINE. T.K. Booker*, A.C. Collins. Institute for Behavioral Genetics, University of Colorado, Boulder. CO 80309.

Recent studies suggest that calcium (Ca) enhances the function of brain nicotinic receptors (nAChRs) expressed in chromaffin cells and Xenopus cocytes. None of these studies assessed potential effects on $\alpha_s B_2$ containing nAChRs. Recently, we have developed an ion (Rb¹) flux assay that monitors the function of brain (especially thalamus) nAChRs. The effects of altering Ca ion concentration on nicotine-stimulated Rb¹ ion flux from thalamus was assessed. Ca ion elicited a concentration-dependent increase in nicotine-evoked Rb¹ ion flux, with an EC $_{\rm 50}$ of 0.42mM Ca. Maximal effects were seen at $^-$ TIMM Ca. The dose-response curves are steep, with a Hill coefficient of 1.64 \pm .45, suggesting a cooperative interaction. Magnesium (Mg) and Barium (Ba) ion also enhanced agonist-stimulated Rb¹ efflux, with maximal effects similar to that of calcium. Coadministration of Ca and Mg resulted in additive enhancement of Rb¹ ion flux, suggesting these two ions produce similar effects via interactions at different sites on the receptor. None of the cations altered the potency of nicotine; only the maximal effect was changed. These effects could arise as a consequence of divalent cation-induced changes in ratio of ground-state to desensitized nAChR. Supported by DA-03194, DA-05197, DA-05681-02.

EFFECTS OF N-(4-ARSENOSOPHENYL)-SUCCINAMIC HYDRAZIDE (ASH)
ON NICOTINIC RECEPTORS R.H.Loring*, R. Moaddell, T. McHugh, X.G. Zhang,
Y.Y. Wu and G.S. Jones, Jr."
Dept. Pharmaceutical Sciences, Northeastern Univ.,
and "Div. Pharmaceutical Sci., Mass. College of Pharmacy, Boston, MA 02115.

Adjacent cysteine residues are part of the agonist binding site of every known type of nicotinic α -subunit. We have previously demonstrated (Loring et al., Mol. Brain Res. 15:113, 1992) that trivalent aromatic arsenicals, which recognize paired but not single thiols, will covalently bond to reduced nicotinic receptors and block the binding of competitive ligands, such as α -bungarotoxin (ABT). The nitrogen of our model compound, p-aminophenylarsonous acid (APA) is not reactive with most amine labeling reagents. Thus, we synthesized the novel compound, ASH, which has a reactive nitrogen. ASH has no effect on native receptors, but potently blocks ¹²⁵I-ABT binding (IC₅₀ ~10 nM) to immunoprecipitated Torpedo α_1 receptors reduced with dithiothreitol (2 mM). Like APA, ASH protects against irreversible alkylation of Torpedo receptors by the affinity agent, bromoacetylcholine, and the antiarsenical, dimercaptopropanesulfonate (DMPS, 1 mM) restores ¹²⁵I-ABT binding to ASH-treated receptors. ASH also blocks ¹²⁵I-ABT binding to reduced chick α_7 and α_8 receptors (IC₅₀'s ~3 µM and 30 nM, respectively). ASH (10 µM) blocks the function of reduced nicotinic receptors in the chick retina, until reversed with DMPS. The amine labeling agent, N-hydroxysuccinimidyl-biotin reacts with ASH to make the biotinylated derivative, biotinyl-(N-(4-arsenosophenyl)-succinamic hydrazide) (Bio-ASH). Bio-ASH is slightly more potent than ASH, and blocks ¹²⁵I-ABT binding (IC₅₀ ~5 nM) to reduced Torpedo α_1 receptors. Bio-ASH also prevents reactivation of functional nicotinic receptors in the chick retina, until reversed by DMPS. We are presently synthesizing and testing an iodinated derivative of ASH (¹²⁵I-Bolton-Hunter-labeled ASH), and other biotinylated ASH derivatives with longer spacer arms. EXPRESSION OF THE \$\beta\$ NICOTINIC RECEPTOR SUBUNIT AND OLFACTORY MARKER PROTEIN mRNAs IN PC12 CELLS. C.J.H. Keiger* M. Bencherif, P.M. Lippiello, G.M. Hellmann and J.C. Walker. UNC Craniofacial Center, School of Dentistry, Chapel Hill, NC 27599 and R. J. Reynolds, Research & Development, Winston-Salem, NC 27102.

Recent studies have described the activation of the $\beta 3$ nAChR subunit promoter as a marker of ganglion cell induction and differentiation during retinal development (Matter, et al., J Neuroscience, 15, 1995). Olfactory marker protein (OMP), expressed in high levels in mature olfactory receptor neurons, is also expressed in some neuroblastoma cell lines (Servenius et al., Cancer Res, 54, 1994). RT-PCR was employed to determine whether the $\beta 3$ nAChR subunit and OMP genes are also expressed in PC12 cells (a model for the study of neuronal differentiation). Cells were tested after treatment with 100 ng NGF for either 2 hours or 7 days. Ion flux studies were also used to determine the function of nAChRs in these cells. Multiple nAChR subunit mRNAs ($\beta 2$, $\beta 4$, $\alpha 3$, $\alpha 5$, $\alpha 7$) were detected in both control and treated cells. $\beta 3$ subunit mRNAs ($\beta 2$, $\beta 4$, $\alpha 3$, $\alpha 5$, $\alpha 7$) were detected in both control and treated cells. $\beta 3$ subunit mRNAs (ever low in control cells and in those treated for only 2 hours, but increased to moderate levels following chronic NGF treatment. Low levels of OMP mRNA were observed in all three groups. As assessed by ion flux studies, functional responses indicated no changes in E_{max} and EC_{50} in response to 10 $\omega 4M$ nicotine.

These findings may suggest a possible role of the \$\beta\$ and AChR subunit and OMP genes in cell proliferation and/or differentiation of sympathetic neurons.

THE NICOTINIC RECEPTOR/IONIC CHANNEL COMPLEX (AChR) IN ANDROGEN-DEPENDENT SKELETAL MUSCLE CULTURES. R.L.M. Rivero.* M. Bielavsky and M.T.R.Lima-Landman. Dept. of Pharmacology, EPM/UNIFESP, São Paulo. Brazil.

The kinetics of the AChR complex is slower in myoballs from androgen dependent skeletal muscles (Perineal - P) primary cultures than in non target (Thigh - T) ones (Lima-Landman et al.; III Int. Symp. Cholinergic Synapse, P3.7, 1994). This finding could be related to the delayed differentiation of the perineal musculature (Cihak et al., J. Anat.; 106: 96, 1970). The present experiments analyzed the influence of cell differentiation and culture age on the AChR complex of these two muscles. Cells from 4 or 6 days old male rats were cultured for 7 and 15 days and used for "patchclamp" studies on "cell-attached" configuration, 22-25° C. The single channel recordings were done in HEPES solution, pH 7.4 with TTX (300 nM) using ACh (400 nM) as agonist. The myoballs presented more than one channel conductance in P as in T cultures. The prevalent one was 34 ± 3 pS in P (n=9) and 35 ± 4 pS in T (n=6) from 4 days old rat cells cultured for 7 days (G 4/7) and 37 ± 2 pS in P (n=5) and 30 \pm 3 pS in T (n=4) for cells cultured for 15 days (G 4/15). The channel conductance in the groups 6/7 and 6/15 was not statistically different from G 4/7 and G 4/15. Hyperpolarization of the cell membrane increased the frequency of channel opening and prolonged the mean channel open time. The mean channel open time (τ), at -165 mV, was 1.21 \pm 0.19 ms and 7.21 \pm 1.29 ms in G 4/7 and 5.51 ms and 6.36 ± 1.14 ms in G 4/15, in T and P respectively. In cells from G 6/7 $\,\tau$ was 5.31 ms and 5.51 ms and in G 6/15. 8.65 ± 2.86 ms and 4.24 ± 1.09 ms in P and T respectively. These results indicate that the slowed differentiation of P muscles could be responsible for the difference in τ. The androgenic influence in the AChR complex, between P and T muscles, will be confirmed by undergoing experiments treating the cultures with an anti-androgenic druchecked growing the cultures in the presence of an anti-androgenic drug. Supported by FAPESP, CNPq. Brazil.

RJR-1647: A NOVEL NICOTINIC AGONIST WITH CNS SELECTIVITY.
P.M. Lippiello*, S. Arrington, K. W. Fowler, M. E. Lovette, L. Reeves, W.S.
Caldwell and M. Bencherif. Research and Development, R.J. Reynolds Tobacco
Company, Winston-Salem, NC 27102.

There is a growing body of evidence from *in vitro* and *in vivo* studies indicating that nicotinic cholinergic ligands with selectivity for CNS nicotinic acetylcholine receptors (nAChR) improve cognitive and attention disorders. The recent characterization of nicotinic agonists with the ability to discriminate between the various nAChR subtypes which are targets of the endogenous neurotransmitter acetylcholine has provided the rationale for the design of compounds with an enhanced "therapeutic window". RJR-1647 exhibits a pharmacological profile suggestive of a strong selectivity for neuronal nicotinic receptors. In several aspects this analog shows a greater selectivity for neuronal nAChR than RJR-2403. The binding affinity to putative $\alpha4\beta2$ receptors is enhanced (Ki = 9 nM vs. 26 ± 3 for RJR-2403). Its efficacy in inducing ion flux from thalamic synaptosomes is comparable to that of RJR-2403, but the potency is 2 and 3-fold greater than those for nicotine and RJR-2403, respectively (EC $_{\infty}$ = 269 ± 55 nM vs. 732 ± 155 nM for RJR-2403). There are also differences in eliciting dopamine release from striatal synaptosomes. RJR-1647 was the most efficacious of the compounds tested (Emax = 124 ± 18% compared to nicotine) with a potency 5 times greater than that for RJR-2403 (EC $_{\infty}$ = 269 ± 55 nM for RJR-1647 vs. 732 ± 155 nM for RJR-2403). Similar to RJR-2403, and unlike nicotine which potently activates human muscle receptors in TE671/RD cells and autonomic ganglionic nAchR's in PC12 cells, no detectable activity was observed at these receptor subtypes with RJR-1647. Another distinguishing feature of RJR-1647 is that apparent *down*-regulation of $\alpha4\beta2$ neuronal nAChR was observed following chronic treatment of M10 cells. The selectivity profile of RJR-1647 may provide important clues for the design of receptor selective ligands.

503.6

RJR-2429: A NICOTINIC AGONIST WITH SELECTIVITY FOR MUSCLE NICOTINIC CHOLINERGIC RECEPTORS. M. Bencherif*, P.A. Crooks', S. Arrington, K. W. Fowler, M.E. Lovette, L. Reeves, W.S. Caldwell, and P.M. Lippiello. Research and Development, R.J. Reynolds Tobacco Company, Winston-Salem, NC 27102, ¹University of Kentucky, Lexington, KY.

The search for nAChR subtype-selective agonists as pharmacological and/or therapeutic tools represents an important milestone to unravel the role of nicotinic acetylcholine (nAchR) receptors in health and disease. We have previously reported the development of a nicotinic agonist having selectivity for neuronal nAChR's (RJR-2403; Bencherif et al., 1995). The present report describes in vitro studies demonstrating that a novel heterocyclic substituted pyridine compound (RJR-2429) is a full agonist and is very potent in activating human muscle nAChR's (EC $_\infty$ = 55 nM; by comparison, epibatidine and nicotine have EC $_\infty$'s of 90 nM and 80,000 nM respectively). In contrast to epibatidine, RJR-2429 exhibits a 100 to 1000-fold selectivity for activation of human muscletype nAChR's compared to CNS subtypes. RJR-2429 binds with high affinity to the $\alpha4\beta2$ receptor subtype (K $_1$ =1.5 nM). However, this binding does not result in any detectable activation, but rather in antagonism of nicotine-stimulated ion flux in thalamic synaptosomes (IC $_\infty$ ca. 80 nM), a preparation containing putative $\alpha4\beta2$ receptors. It is also a weak agonist at nAchR's mediating dopamine release from rat synaptosomal preparations (EC $_\infty$ = 30,300 nM; E $_\infty$ = 29%; epibatidine and nicotine are equipotent at this receptor subtype with EC $_\infty$ ca. 100 nM and E $_\infty$ = 100%). Activation of a putative $\alpha3\beta4$ -containing nAChR in the rat pheochromocytoma clonal cell line (PC12) reveals a potency intermediate between nicotine and epibatidine (EC50's of 30,000 nM for nicotine, 1,000 nM for RJR-2429 and 30 nM for epibatidine). The profile of RJR-2429 may provide important clues for the development of nAChR subtype-selective ligands as probes in the life sciences or as potential therapeutics.

NICOTINE EXCITATION OF DOPAMINE NEURONS IN THE VENTRAL TEGMENTAL AREA IN VITRO - INTERACTION WITH NMDA-RECEPTORS. P. Grillner, L. Arborelius* and T.H. Svensson. Dept of Physiology and Pharmacology, Div. Pharmacology, Karolinska institute, 171 77 Stockholm

The mesolimbocortical dopamine (DA) system originating from the ventral tegmental area (VTA) plays an important role as part of the reward systems in the brain. Several drugs of abuse, including nicotine, stimulate this system. This study aims to: 1) test if the excitatory effect of nicotine on DA neurons in the VTA involves NMDA-receptor activation, and 2) to investigate a putative synaptic input involves (MDA-receptor activation, and 2) to investigate a putative synaptic input to DA neurons mediated by postsynaptic nicotinic receptors. Intracellular recordings were made from DA neurons in VTA in the *in vitro* rat brain slice preparation of the ventral mesencephalon. To study the putative synaptic, cholinergic input, a bipolar stimulation electrode was placed close to VTA, on its caudal side, where cholinergic pathways projecting from the pedunculopontine products to VTA one levels. nucleus to VTA are located. Application of nicotine receptor antagonists. mecamylamine (10 μ M) and dihydro-beta-erythroidine (DHBE) (50 μ M), did not mecanylamine (10 m) and dinydro-beta-erytrodune (DFBE) (30 m). did not significantly alter the firing rate of DA neurons, but blocks completely the excitatory effect of nicotine (10 µM) on DA neurons. Application of 2-amino-5-phosphonopentanoic acid (AP-5) (90 µM) slightly decreased the spontaneous firing activity. The increase in firing frequency induced by nicotine appeared lower in the presence of AP-5 (138.5 %), than in the absence of AP-5 (248 %), suggesting that presence of AF-5 (178.5 %), than in the absence of AF-5 (248 %), suggesting that the excitatory effect of inciotine on DA neurons may partly depend on NMDA-receptor activation. Excitatory postsynaptic potentials evoked by afferent single pulse stimulation were not affected by DHBE at a concentration sufficient to block the excitatory effect of bath application of nicotine. In conclusion, 1) the excitatory effect of nicotine on VTA DA neurons is mediated via nicotinic receptor activation, and 2) the increase in excitability of DA neurons induced by nicotine appears to

require concomitant NMDA-receptor activation.
This study has been supported by The Swedish Medical Research Council (grant no 4747), the Karolinska institute, and The Council for Tobacco Research, USA, Inc.

DEVELOPMENT AND EXPRESSION OF LIGAND-GATED ION CHANNELS IN DEVELOPMENT AND EAPRESSION OF LIGARD-GATED TON CHANNELS IN MEURONS ACUTELY DISSOCIATED NON-ENZYMATICALLY FROM RAT HIPPOCAMPUS. C.T.F. Barbosa^{1,2}, M. Alkondon¹, Y. Aracava², K.L. Swanson^{1,4} and E.X. Albuquerque^{1,2,3} ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201, USA; ²Lab. Mel. Pharmacol., IBCCF, UFRJ, RJ 21944, Brazil. Ligand-gated ion channels are essential elements of neuronal function and have been studied in vitro using cultured neurons, brain slice preparations, and enzymatically disacrated acray. To suite scalible distribute Original Science and Control of the C

dissociated neurons. To avoid possible deleterious effects of enzymes on channel proteins dissociated neurons. To avoid possible deleterious effects of enzymes on channel proteins, we developed a non-enzymatic technique for isolating neurons from the CA1 area of the hippocampus of postnatal rats (2 to 26 days-old), and studied the presence of several ligand-gated ion channels by the whole-cell patch-clamp technique. Hippocampal slices of =500-μm thick were incubated for 3 h in Ca2+-free solution bubbled continuously with a mixture of 95% O₂ and 5% CO₂. Fragments of the slices were sucked into a glass micropipette with a tip diameter of 300-400 μm and transferred to the recording chamber; the passage of the tissue through the micropipette was sufficient to disperse the neurons meanwhile conserving the long processes. Agonists were applied via a U-tube to the neurons in the whole-cell patch-clamp configuration. Application to the neurons of an admixture of NMDA (50 μM) and glycine (10 μM) elicited whole-cell currents, which increased in peak amplitude with neuronal maturation. Currents induced by quisqualic acid increased in peak amplitude with neuronal maturation. Currents induced by quisqualic acid $(20 \,\mu\text{M})$ had the same peak amplitude regardless of age. Glycine $(100 \,\mu\text{M})$ and kainic acid (20 μ M) also evoked whole-cell currents. Whereas the four agonists above induced currents in all the neurons, GABA (20 μ M) only evoked currents in 80% of the neurons. ACh (1 mM) only evoked currents in 60% of the neurons, and these currents were blocked by methyllycaconitine (1 nM) and Pb²⁺ (1-10 µM), indicating the presence of oy inclusive and in a constraint of the party and to the presence of a changardoxin -sensitive nicotinic receptors (nAChRs) in hippocampal neurons developed in vivo. In addition, the amplitude of ACh-evoked currents depended on the length of the dendrites on the neurons such that it was larger in neurons with long dendrites, confirming our earlier results that many nAChRs are located on the dendrites. Thus, the new method of isolating neurons enables studies of ligand-gated channels, particularly those present on dendrites of hippocampal neurons of postnatal rats. CHARACTERIZATION OF NICOTINIC ACETYLCHOLINE RECEPTORS IN CA1 NEURONS OF RAT HIPPOCAMPAL SLICES. M. Alkondon . E.F.R. Pereira 1.2 and E.X. Albuquerque 1.2 Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201, USA; ²Lab. Mol. Pharmacol., IBCCF, UFRJ, RJ 21944, Brazil.

Hippocampal neurons obtained from fetal rats and cultured for 10 to 30 days express at least 3 different subtypes of functional nicotinic acetylcholine receptors (nAChRs), activation of which results in nicotinic currents with distinct kinetics and pharmacology (J. Pharmacol. Exp. Ther. 265: 1455, 1993; 271: 494, 1994). In the present study, we investigated the presence of functional nAChRs in the developing hippocampus of 10- to 17-day-old rats. Hippocampal slices ≈200-µm thick were prepared, and neurons were viewed with the assistance of infrared video microscopy. Matrix covering the neuronal soma and the dendrites were removed by applying a gentle stream of bathing solution via a micropipette. Whole-cell recordings were made from the cell soma, and different agonists were applied using a U-tube positioned on top of the cell. Application of ACh (1 mM), in the presence of 1 μM atropine, induced a whole-cell current that was accompanied by several miniature postsynaptic currents (MPSCs). Application of other agonists such as nicotine, DMPP, (+)anatoxin-a or epibatidine also evoked similar responses. Superfusion of the neurons with d-tubocurarine (10 µM) abolished the agonist responses completely and reversibly. In addition, tetrodotoxin (300 nM) also diminished to a great extent the agonist-elicited responses. The MPSCs evoked by nicotinic agonists appear to be mediated via glutamate and GABAA receptors. The present results indicate that functional nAChRs are expressed in the developing hippocampus and suggest.post- and pre-synaptic roles for the nAChRs. (USPHS Grants NS25296 and ES05730).

SYSTEMIC NICOTINE INDUCED DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS IS DEPENDENT ON NMDA RECEPTOR ACTIVATION IN THE VENTRAL TEGMENTAL AREA B. Schilström, G. G. Nomikos*, P. Hertel, M. Nisell & T. H. Svensson Dep. of Physiology and Pharmacology, Div. of Pharmacology Karolinska Institutet, 171 77 Stockholm

Systemic administration of nicotine (NIC) enhances both firing rate and burst firing of dopamine (DA) neurons in the ventral tegmental area (VTA) as well as DA release in the nucleus accumbens (NAC). Nicotinic receptors in the VTA seem to be of primary importance for these actions of NIC, but recent evidence also suggest that NIC facilitates glutamatergic transmission in brain. Since both burst firing in VTA-DA neurons and DA release are regulated *inter alia* by excitatory amino acid (EAA) inputs to the VTA via NMDA receptors, the present study was undertaken to investigate the putative role of ionotropic glutamate receptors within the VTA for the DA release in putative role of ionotropic glutamate receptors within the VTA for the DA release in the NAC, elicited by systemic NIC administration or local infusion of NIC in the VTA. For this reason the dual microdialysis approach was used, in which one probe was implanted in the VTA and another in the ipsilateral NAC. Both a subcutaneous NIC injection and local infusion of NIC into the VTA (1.0 mM) increased DA output in the NAC significantly. Also infusion of 0.3 mM of NMDA or 0.1 mM AMPA into the VTA increased accumbal DA release. This increased DA outflow was effectively attenuated by the concomitant infusion of the selective antagonists at NMDA receptors. AP-5 (0.3 mM) and non-NMDA receptors, CNQX (0.3 mM), respectively. Infusion of 0.3 or 1.0 mM of AP-5 or CNQX into the VTA did not by itself affect DA levels in the NAC. Simultaneous infusion of CNQX did not affect the DA release induced by systemic NIC. In contrast. infusion of AP-5, starting 40 min before the NIC injection, significantly attenuated the increase in accumbal DA release. Concomitant infusion of AP-5 and NIC completely prevented the increase in DA release in the NAC seen after local infusion of NIC. These results indicate that the stimulatory action of NIC on the mesolimbic DA-system is to a considerable extent dependent upon the concomitant local musion of NIC. These results indicate that the stimulatory action of NIC on the mesolimbic DA-system is to a considerable extent dependent upon the concomitant stimulation of NMDA receptors within the VTA. DIFFERENTIAL DISTRIBUTION OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBTYPES IN RAT HIPPOCAMPAL NEURONS. E.X. Albuquerque^{1,2}, E.F.R. Pereira^{1,2}, C.R. Creveling^{3*} and M. Alkondon¹, Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA; ²Lab. Mol. Pharmacol., IBCCF, UFRJ, RJ 21944, Brazil; ³Technology Devel., NIDDK, NIH, Bethesda, MD 20982, USA

Hippocampal neurons of the rat express at least 3 different subtypes of functional nAChRs, activation of which results in nicotinic currents with distinct kinetics and pharmacology (J. Pharmacol. Exp. Ther. 265: 1455, 1993; 271: 494, 1994). Because the role of each nAChR may depend on its specific location on the neurons, we investigated the distribution of two identified subtypes of nAChRs on rat hippocampal neurons in culture. For this purpose, we used an infrared video microscope to view the neuronal processes, and a nanorobot system of micromanipulators to position the recording and the agonist-delivering micropipettes at the desired locations. Whole-cell patch recording performed at the neuronal soma, and the agonist ACh (in the presence of 1 µM atropine) was applied by pressure to identified regions of the neuron via a micropipette. Nicotinic sensitive to blockade by methyllycaconitine (1 nM) were elicited by application of ACh to the cell body, apical and basal dendrites of pyramidal-shaped neurons and to the cell body and both branches of bipolar-shaped neurons. The peak amplitude of the currents elicited by agonist application to the cell body was larger than that of the currents evoked by agonist application to the dendrites of pyramidal-shaped neurons. In contrast, the peak current amplitude was larger when ACh was applied to the dendrites than when it was applied to the soma of bipolar-shaped neurons. Nicotinic currents sensitive to blockade by dihydro-β-erythroidine (100 nM) were elicited by application of ACh to both cell body and dendrites, however, the amplitude of such responses elicited at the dendrite was larger than that of the responses evoked at the cell soma. The present results indicate that nAChRs are distributed differentially on the neuronal axis, and suggest that they may play a role pertaining to the dendritic compartment of the hippocampal neurons. (USPHS Grants NS25296 and ES05730).

NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS: ANALYSIS OF Pharmacol, Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA; Lab. Mol. Pharmacol, IBCCF, UFRJ, Rio de Janeiro RJ 21944, Brazil.

Intracellular factors that modulate inward rectification of type IA nicotinic currents in cultured hippocampal neurons (Bonfante-Cabarcas et al., JPET 277:432, 1996) were in cultured hippocampal neurons (Bonfante-Cabarcas et al., JPET 277:432, 1996) were investigated using the whole-cell mode of the patch-clamp technique. Internal solutions with malate plus EGTA or EDTA and desired [Ca²¹], and [Mg²¹], were prepared using the program Calc ver. 2.2. Typically in ≈5 neurons under each condition, type IA currents were elicited by application of ACh (2 mM), and peak current amplitudes at positive holding potentials were normalized to amplitudes at -50 mV, giving SE's ≈10%. Using EGTA and 10 µM [Ca²¹], without Mg²¹, the current-voltage relationship showed inward rectification, with normalized values of 0.32, 0.66 and 0.80 at +50, +75 and +100 mV, respectively. Using EDTA and 10 µM [Ca²¹], without Mg²², the inward rectification was eliminated, normalized values being 0.95, 1.97 and 2.88 at +50, +75 and +100 mV, respectively, indicating that natural Mg²² could be removed. Under this condition, the chord conductance increased when the voltage was increased from +40 and ± 100 mV, respectively, indicating that natural Mg^{2^+} could be removed. Under this condition, the chord conductance increased when the voltage was increased from ± 40 to ± 100 mV. Using EDTA with neither (Ca^{2^+}) nor Mg^{2^+} , the peak amplitudes were significantly lower (p<0.05) at ± 50 , ± 75 and ± 100 mV with values being 0.76, 1.16, and 1.44, and the chord conductance was constant from ± 40 to ± 100 mV, suggesting that internal free (Ca^{2^+}) potentiates type IA currents at potentials above ± 40 mV in a voltage-dependent manner. In order to study the effect of $(Mg^{2^+})_1$, internal solutions were prepared using EDTA with $10 \mu M (Ca^{2^+})_1$, and replacing $(Cs^+)_1$ with $(Ca^{2^+})_2$ and $(Cs^+)_3$ multiplication of permeant cations. Surprisingly, $(Cs^+)_3$ multiplication in the normalized values being (0.5) and (1.47) at $(Cs^+)_3$ and $(Cs^+)_4$ multiplication of $(Cs^+$ $[\mathrm{Mg}^2]_1$ (0.1, 1 and 6 mM) decreased normalized peak amplitude at +50 mV with an $IC_{50} = 1$ mM and n_{H} of 0.74. Similar values were obtained at +100 mV. We suggest that Mg^{2+} or TRIS* induce inward rectification by acting by an intracellular mechanism affecting the nAChR. Pathobiochem., Johannes-Gutenberg Univ. Med. Sch., 55099 Mainz, Germany.
Prazole and 4-methylpyrazole (4-MP) act as allosteric agonists at nAChRs by binding to the so-called physostigmine site on the receptors (J. Pharmacol. Exp. Ther., 261;331, 1992, Jab. Neurosci Soc. 20:1137, 1994). We have shown that in enzymatically isolated muscle fibers from the frog L. occelata (method described in J.Pharmacol. Exp. Ther., 252:507, 1990), a high frequency of Ach (0. 4 µM)—evoked single-channel currents (> 10-15 events/min) is always detected. In contrast, only in 20% of the isolated muscle fibers can 4-MP (10 µM) activate single-channel currents, and the frequency of 4-MP induced channel activity is very low (<1 event/min). Here, we describe the optimization of the muscle fibers, and we demonstrate that the region including the physostigmine-binding site can be damaged by proteolytic enzymes. During the dissociation of the muscle fibers, en concentration of epizymes and the time of enzymatic treatment were decreased by 60%, and the external Ca²⁻² concentration was reduced from 1.8 to 0.45 mM. About 1 hour before recording single-channel currents from cell-attached patches, the fibers were transferred to a solution containing 1.8 mM Ca²⁻¹. Under these conditions, in the presence of a-BGT, application of 4-MP to all fibers via the recording ingingle-channel currents from the seconditions, in the presence of a-BGT, application of 4-MP to all fibers via the rec

PHARMACOLOGICAL AND BIOPHYSICAL ANALYSIS OF NICOTINIC CURRENTS IN RAT CULTURED THALAMIC NEURONS, Y. Aracava^{1,2} W.S. Cortes^{1,2,3}, C.T.F. Barbosa^{1,2}, J.N. Hokoe^{2,*} and E.X. Albuquerque^{1,2} Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201,USA; ²Lab. Mol. Pharmacol. JBCCF, Fed. Univ. Rio de Janeiro, RJ 21944; ³Rural Fed. Univ. Rio de Janeiro, RJ 23658, Brazil.

Studies using techniques based on radioligand binding, synaptosomal Rb+ efflux and intracellular recordings have shown that functional nicotinic acetylcholine receptors (nAChRs) are expressed in thalamic neurons (J. Neurostr. 4:2906,1984; J. Neural Transm. 73:77, 1988; J. Pharmacol. Exp. Ther. 264:542, 1993; Prog. Neurobiol. 39:337, 1992). In this study, we characterized some functional properties of nAChRs in cultured thalamic neurons using the whole-cell configuration of the patch-clamp technique. The agonists ACh (0.001-3 mM) and (-)nicotine $(0.001-0.3 \mu\text{M})$ were applied to the neurons via a U-tube in a 0.5-2-sec pulse and the results showed that either ACh (n=8) or (-)nicotine (n=3) could elicit nicotinic currents in these neurons. All neurons tested responded to either ACh (1 or 3 mM) or (-)nicotine (100-300 µM) with currents that exhibited fast rise and decay phases. A rapid "rundown" of these currents was present and it was considerably prevented by using an ATP-regenerating internal solution. Prior exposure of these neurons to methyllycaconitine (1 nM) produced a complete and reversible blockade of these currents. In addition, the 1-V relationship revealed a mild inward rectification of these nicotinic currents (n=4). In a few neurons (n=4), an increase in the frequency of miniatuare postsynaptic currents was noticed during 2-sec pulse applications of 1 mM ACh to the neurons. Thus, these results show that functional nAChRs are present in the thalamic neurons and that their pharmacological and biophysical features resemble those of α-bungarotoxinsensitive nAChRs (α7 or α8 containing) already characterized in other brain regions. FUNCTION OF CENTRAL NEURONAL NICOTINIC RECEPTORS IN CHICK EMBRYOS EXPOSED TO NICOTINE DURING SYNAPTOGENESIS

.A. Chiappinelli*, K.W. Wolf and J.M. Garcia-Ferrer. Dept. Pharmacol. Physiol. Science, Saint Louis Univ. Sch. Med., St. Louis MO 63104

When rat or chick embryos are exposed to nicotine during development, a significant up-regulation of ³H-nicotine receptors in brain occurs (Brain Res. Bull. 23:187, 1989; Soc. Neurosci. Abstr. 21:345, 1995). Our goal in this study was to examine possible functional consequences of this increase in receptor number. We implanted L-nicotine-impregnated pellets onto the yolk sac of chick embryos at 5 days of incubation (d.i.). These sustained-release pellets provided the embryo with a continuous exposure to nicotine between 5-13 d.i., a period during which cholinergic synapses form. A dose-dependent up-regulation of ³H-nicotine receptors was measured in the mesencephalon, with B_{max} increasing to 183-240% of control after exposure to 12 mg nicotine/kg/day. To assess the function of central ³H-nicotine receptors in the mesencephalon, intracellular recording was done in brain slices of 14-19 d.i. chick embryos exposed to nicotine-impregnated or control pellets. The maximum depolarizing response and EC_{50} for carbachol were determined in lateral spiriform neurons (SPL) as described (Mol. Pharm. 46:993, 1994). At the later embryonic stages studied, there were no significant differences between nicotinetreated and control embryos in these functional measures. However, at 14 d.i. after exposure to 12 mg nicotine/kg/day, the apparent affinity for carbachol was reduced almost 3-fold, to $118\pm50~\mu M$. No significant change in the maximum depolarization to carbachol was detected. This affinity change suggests that the structure of nicotinic receptors in the SPL was altered by nicotine. A possible explanation for the affinity change would be an altered subunit composition of the receptors. Since changes were not detected in older embryos examined 4-6 days after release of nicotine from the pellets should have ceased, the effect may be reversible after cessation of nicotine. MODULATION OF NICOTINIC RECEPTOR FUNCTION BY COMPOUNDS THAT ACT THROUGH THE PHYSOSTIGMINE-BINDING SITE. E.F.R. Perciai ^{1,2} A. Schrattenholz ³. A. Maelicke ³ and E.X. Albuquerque ^{1,2} ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA; ²Lab. Mol. Pharmacol., IBCCF, UFRJ, Rio de Janeiro, RJ 21944, Brazil; ³Inst. Physiol. Chem. Pathobiochem., Johannes-Gutenberg Univ. Med. Sch., 55099 Mainz, Germany.

Compounds such as physostigmine, galanthamine, codeine, and benzoquinonium, by binding to a novel site on nAChRs, can activate nicotinic single-channel currents in various preparations. This agonist action, while insensitive to blockade by competitive nicotinic antagonists, can be inabited by the nAChR-specific monoclonal antibody FK1. In fact, this antagonists, can be inhibited by the nAChR-specific monoclonal antibody FK1. In fact, this pharmacological profile identifies a new class of nicotinic agonists (reviewed in *Drug Dev. Today* 1:53, 1996). The efficacy of these agonists is low, so they are unable to evoke sizable whole-cell currents. Recently, however, evidence has been provided that, by acting through this novel nAChR site (the physostigmine site), galanthamine and serotonin can potentiate nicotinic responses evoked by ACh (*Mol. Pharmacol.* 49:1, 1996). Here, applying the whole-cell mode of the patch-clamp technique to rat myoballs in culture, we investigated the ability of decamethonium and d-tubocurarine (d-TC) to interact with the physostigmine and related compounds, that of decamethonium (0.1-10 µM) could be completely inhibited by a-bungarologin (5 µe/ml). In agreement with a previous group (1 Neurosci 15:330 α-bungarotoxin (5 μg/ml). In agreement with a previous report (*J. Neurosci.* 15:230, 1995), we found that at low concentrations (10-40 nM) d-TC potentiates ACh (0.3 μM)evoked whole-cell currents in rat myoballs, whereas at high concentrations (\geq 400 nM) it inhibits the nicotinic currents elicited by application of ACh (0.3 μ M) to the cells. In our experiments, d-TC (40 nM) increased by 57.7 ± 17.8% (n = 4; mean ± S.E.M.), whereas at experiments, d-TC (40 nM) increased by 57.7 \pm 17.8% (n = 4; mean \pm 8.E.M.), whereas at 1 µM it decreased by about 30% the peak amplitude of ACh (0.3 µM)-elicited currents. Also, at higher concentrations of ACh (\geq 1 µM), the potentiating effect of low concentrations of d-TC could not be observed. Initial studies show that following a 30-min perfusion of the cells with FK1-containing external solution, the potentiating effect of d-TC on the ACh-evoked currents could not be detected. Thus, it is possible that the potentiating effect of d-TC on nicotinic currents in rat myoballs is mediated via the physostigmine-binding site. Alternatively, FK1, by binding to the physostigmine site on the nAChRs, could modify allosterically the interaction of d-TC with a different nAChR site. (USPHS Grant NS25296)

DEVELOPMENTAL PATTERN OF $\alpha 7$ NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT IN THE EMBRYONIC CHICK CEREBELLUM. W. M. Kaneko*, L. R. G. Britto, C-C. Wu, J. M. Lindstrom and H. J. Karten. Dept. of Neurosciences, University of California, San Diego, La Jolla, CA 92093.

Previous studies have demonstrated the spatially restricted distribution of neuronal nicotinic acetylcholine receptor (nAChR) subunits in the mammalian and avian adult brain. Little, however, is known about the development of these receptor subunits. The embryonic chick provides an excellent model to study developing subunits because the developmental stages are well defined and much of the biochemistry of nAChR subunits have been conducted in the chick. Furthermore, the cerebellum, due to its well-characterized organization, provides an appropriate substrate for detailed study. The present study demonstrated changes in the pattern of expression of the neuronal nAChR subunit α 7, an α -bungarotoxin sensitive subunit, using immunohistochemical techniques in the developing chick cerebellum. We found that Purkinje cell bodies were immunoreactive for $\alpha 7$ antibodies at embryonic day 12 (E12). This immunoreactivity increased along the dendrites until E16. On E16, the immunoreactivity diminished from the more distal portions of the dendrites and α 7-immunoreactivity was expressed mainly on the cell body in a manner similar to that seen at E12. This particular developmental pattern of α 7 expression is similar to the level of α -bungarotoxin (α Bgt) binding sites seen during the development of the brain. The transient expression of the nAChR α 7 subunit provides evidence for the involvement of this subunit in the development of aBgt-sensitive nAChRs and suggests that E12 to E16 may be a critical period for the developing neuronal cholinergic system. NICOTINIC SINGLE-CHANNELS RECORDED FROM NEURONS IN INTACT CILIARY GANGLIA OF CHICK EMBRYO. W.R. Weaver*, I.-Z. Guo, T.L. Tredway and V.A. Chiappinelli. Dept. Pharmacol. and Physiol. Sci., Saint Louis Univ. Sch. of Med., St. Louis

Weaver*, I.-Z. Guo, T.L. Tredway and V.A. Chiappinelli. Dept. Pharmacol. and Physiol. Sci., Saint Louis Univ. Sch. of Med., St. Louis MO 63104

There is evidence for multiple nicotinic channel conductances in acutely dissociated neurons of chick embryo ciliary ganglia (Margiotta et al., Dev. Bio. 135:326-339, 1989). To avoid altering the receptor proteins during dissociation, we developed an enzyme treatment method that kept the ganglia intact while still allowing formation of tight seals. Ciliary ganglia isolated from 15-16 day old chick embryos were superfused with a mixture of collagenase (200 U/ml) and thermolysin (10 U/ml) at 32 °C for a 30 min period. This process was monitored under Nomarski optics at 400X magnification to avoid over-treatment. Preparations were then superfused with normal chick hepes tyrode at room temperature. Pipettes with or without acetylcholine (ACh) were used to obtain cell-attached single channel recordings. Lucifer yellow (0.5 mM) was used to verify the recording site. Forty seven of 76 recordings with ACh (3-300 μM) showed inward currents at holding potentials of -40 to -120 mV. Current-voltage analysis showed single channel slope conductances from 27.7 to 54.7 pS at ACh concentrations 3 to 30 μM (30 μM, 37.9 ± 3.2 pS (n=5)). While at 100 to 300 μM ACh, the slope conductance range decreased to 15.8 to 24.8 pS (300 μM, 21.3 ± 1.7 pS (n=4)). The conductances of these two groups (30 and 300 μM) were significantly different (p<0.005). All neurons showed similar resting membrane potentials upon switching to whole cell configuration. These results suggest at least two nicotinic channels that show different sensitivities to ACh exist in 15-16 day old chick embryo ciliary ganglia.

DIRECT MEASUREMENT OF FUNCTIONAL NICOTINIC RECEPTORS ON PRESYNAPTIC TERMINALS USING WHOLE-CELL PATCH-CLAMP. I.S. Coggan* and D.K. Berg. Dept. of Biol., UC San Diego, La Jolla, CA 92093.

Nicotinic acetylcholine receptors (AChRs) are widely expressed in the central and peripheral nervous systems but their functions are largely unknown. A popular hypothesis is that the receptors are often presynaptic in location and modulate transmitter release. The large calyces formed on chick ciliary ganglion neurons by preganglionic terminals permit a direct test of the hypothesis in situ.

Whole-cell patch-clamp recordings were made from calyces in embryonic ganglia while perfusing with 20-100 µM nicotine. The agonist induced a small inward current often followed, by a train of action potentials (APs) that

μM nicotine. The agonist induced a small inward current often followed by a train of action potentials (APs) that overrode the voltage clamp (the dimensions of the calyx prevent complete space clamp). Recordings from ganglionic neurons demonstrated that full excitatory postsynaptic currents (epscs) were triggered by the nicotine, presumably in response to presynaptic APs, and that increases in the frequency of spontaneous miniature epscs sometimes occurred as well. Tetrodotoxin (1 μM) blocked the nicotine-induced APs in the calyces but not the inward currents. α-Bungarotoxin at 60 nM completely blocked the presynaptic responses to nicotine. The results demonstrate that AChRs sensitive to α-bungarotoxin can increase the excitability of sensitive to a-bungarotoxin can increase the excitability of the presynaptic terminal and enhance transmitter release. DIVERSITY OF Ca2+ RESPONSES TO NICOTINIC RECEPTOR ACTIVATION IN BOVINE ADRENAL CHROMAFFIN CELLS
S. Donoghue & R. J. Bookman* Dept. of Mol. and Cell. Pharmacology,
University of Miami School of Medicine, Miami, FL, 33101

Neuronal nicotinic receptors (nAChRs) possess an intrinsic Ca²⁺ permeability. In adrenal chromaffin cells, influx of Ca²⁺ (and other permeability. In adrenal chromaffin cells, influx of Ca^{2+} (and other cations) after stimulation of nAChR depolarizes the membrane potential thereby activating voltage-gated Ca^{2+} channels. The resulting increase in $[Ca^{2+}]_i$ may also release Ca^{2+} from internal stores. We have developed a pharmacological approach (i.e., *killer soup* = thapsigargin + agatoxin + conotoxin + DHP) to isolate the contribution of Ca^{2+} influx through nAChR to the overall $[Ca^{2+}]_i$ signal. Changes in $[Ca^{2+}]_i$ were measured by ratio-imaging video microscopy using fura-2. The agonist-stimulated increases in $[Ca^{2+}]_i$ in the absence of *killer soup* can be classified into two types. Type A responses are characterized by an initial peak and a increases in [Ca²⁺]_i in the absence of killer soup can be classified into two types. Type A responses are characterized by an initial peak and a quick recovery to baseline, even in the presence of the agonist, DMPP. The type B responses typically have smaller peak values but show a maintained elevation of Ca²⁺ during a 5 min agonist application, suggesting a lack of desensitization. Surprisingly, the same types of responses were recorded in experiments with killer soup present. The relative peak amplitudes and recovery rates were similar. While we cannot rule out a change in receptor function, these results suggest that the Ca²⁺ influx through nAChRs is the main determinant of the whole cell [Ca²⁺]_i response in adrenal chromaffin cells. If correct, this finding then raises the question of whether the observation of secretion under voltage clamp with capacitance measurements or amperometry will reveal a similar diversity of secretory responses to nAChR activation. IN VITRO ACTIVATION OF ALPHA-4 BETA-2 nAChR BY RJR-2403 IN VIRO ACTIVATION OF ALPHA-4 BETA-2 nACHR BY RJR-2403 SUGGESTS DIFFERENTIAL DESENSITIZATION RELATIVE TO NICOTINE. J. Watterson¹, B. Moulton¹⁴, P. Lippiello², M. Bencherit² and R. L. Papke¹ Department of Pharmacology and Therapeutics, University of Florida, Gainesville, FL 32610 and Research & Development, R. J. Reynolds Tobacco Co., Winston-Schop, NC 32103.

Because of the growing need for therapies for neurodegenerative diseases such as Alzheimer's and Parkinson's, recent endeavors have involved a search for compounds which have distinct activation and desensitization profiles for specific neuronal nicotinic acetylcholine receptor subtypes, particularly the predominant brain $\alpha 4\beta 2$ subtype. Nicotine is well known to be a potent activator of these receptors, but concentrations of nicotine required to produce significant activation also lead to inhibition and/or desensitization. In whole cell voltage clamp studies of Xenopus oocytes co-expressing the α4 and β2 neuronal receptor subunits, the CNS-selective nicotinic agonist RJR-2403, (E)-N-methyl-4-(3-pyridinyl)-3-butene-l-amine (Bencherif et al. 1995; Lippiello et al., 1996), had a concentration-response relationship of comparable potency to nicotine but with greater peak currents relative to nicotine. Based on the measurement of peak currents, the efficacy of RJR-2403 was comparable to acetylcholine and 30% greater than nicotine. The application of 100 μ M RJR-2403 produced a maximal response. Moreover, RJR-2403 did not cause the apparent inactivation which consistently occurs subsequent to activation by nicotine. There was effectively complete recovery of control response amplitude following a 5 min washout of the compound at concentrations up to and including 100 µM. These preliminary findings with RJR-2403 hold promise for future therapeutic development of compounds which are equal or better activators than nicotine, but do not cause the significant inhibition characteristic of nicotine. Further experiments will determine the effects of this new compound on other receptor subtypes, using the oocyte expression

ASSEMBLY AND FATE OF NICOTINIC RECEPTORS CONTAINING THE $\alpha 7$ GENE PRODUCT IN A STABLY TRANSFECTED CELL LINE. P.D. Kassner and D.K. Berg*. Dept. of Biol., UC San Diego, La Jolla, CA 92093. One of the most abundant nicotinic acetylcholine receptors (AChRs) expressed in the central and peripheral nervous systems is a species that binds α -bungarotoxin (α Bgt), fluxes calcium, and contains the $\alpha 7$ gene product. We have stably transfected the quail fibroblast cell line QT6 with wildtype and epitope-tagged chick $\alpha 7$ gene constructs to examine the assembly and fate of $\alpha 7$ -containing AChRs. The stable transfectants express the $\alpha 7$ gene product and

examine the assembly and fate of α /-containing ACnRs. The stable transfectants express the α 7 gene product and are nearly a quarter as efficient as primary neurons at assembling the protein into a species that binds α Bgt. Essentially all of the toxin binding species is found on the cell surface and, when solubilized, sediments at 10S as does the native species from neurons. Moreover, competition binding studies demonstrate that both the wildtype and entirely that the professed species that bind twin and binding studies demonstrate that both the wildtype and epitope-tagged transfected species that bind toxin are indistinguishable pharmacologically from native receptors. The stability of the toxin binding species measured under conditions that blocked appearance of new receptors yields a metabolic half-life of about 10 hours. In contrast, $\alpha 7$ protein incapable of binding αBgt is degraded within minutes. Transfected QT6 cells should permit analysis of mechanisms controlling the assembly and stability of neuronal AChRs destined for the cell surface. (NIH RO1 NS12601 & NS35469, and NIH F32 NS09830)

SUBTYPE-SPECIFIC MODULATION OF NEURONAL nAChRs BY PGE2 C. Du & L. W. Role*. Dept. Anat. & Cell Biol., Columbia Univ., P & S 722 W 168th St., New York, NY 10032.

Our previous studies characterized multiple subtypes of neuronal nAChR channels expressed by individual chick sympathetic neurons. Four of these subtypes are distinguished from one another by biophysical and pharmacological profile (i.e. conductance, kinetics, opening probability (Po), susceptibility to neuronal-bungarotoxin, and rate of desensitization). Each subtype has been seen in isolation without transitions to other states. In view of the differential the levels of expression, clustering and segregation of these nAChR subtypes during development, we have now addressed whether nAChRs might be differentially modulated. We focused initial studies on PGE2 because prior experiments indicate nAChRs are modulated by arachidonic acid (AA; Berg and colleagues: J. Neurosci.15:3679) and specific AA derivatives including prostaglandins (PG)E $_2$ (Tan, Siegelbaum & Role, submitted). Single channel currents gated by ACh (2-20 μ M) were recorded in cell-attached

patches. Baseline records of 5-10 min. were followed by superfusion with PGE2 (10 μ M;) for 2 min.; changes in nAChR channel activity were examined over the next 5-10 min. Under control conditions, activity was relatively stable for up to 30 min. (n=4 patches) and most patches contained 3-5 nAChR subtypes, with γ =15-65 pS. Examination of each channel subtype in the presence of PGE2 reveals that the Po of 15pS nAChRs was reduced by 60%, due to decreases in opening frequency (f) (0.8 Hz vs. 0.6 Hz) and τ_0 (1.0 ms vs. 0.5 ms). In contrast, Po of 25pS nAChRs was increased >3 x, due to increased open duration (from 1.1 ms to 5.7 ms); f was only slightly increased. Larger conductance nAChRs appear to be inhibited by PGE2 although the low f and τ_o , preclude accurate quantitation. These results indicate differential modulation of specific nAChRs by AA derivatives that may permit selectively activation of one nAChR with concurrent suppression of others. (Supported by NS29832.)

THE α5 ACETYLCHOLINE RECEPTOR (ACHR) SUBUNIT ALTERS THE SINGLE CHANNEL PROPERTIES OF HUMAN 03 ACHRS EXPRESSED IN XENOPUS OOCYTES. M.E. Nelson* and J.M. Lindstrom. Department of Neuroscience, University of Pennsylvania Medical School, Philadelphia, PA 19104.

The human neuroblastoma cells IMR-32 and SH-SY5Y express α 3, α 5, α 7, β 2, and β4 AChR subunits with the IMR-32 cells having considerably more functional α3 AChRs than SH-SY5Y. There are at least two AChRs expressed in these "ganglionic-like" cells, one that is αBGT -sensitive ($\alpha 7$ AChRs) and one that is not (α3 AChRs). Several lines of evidence have suggested that a major ganglionic α3 AChR subtype also contains the $\beta4$ and $\alpha5$ subunits. The aim of this work was to characterize cloned human a3 AChRs expressed in Xenopus oocytes at the singlechannel level and to compare their properties to native neuroblastoma AChRs. The chord conductance for IMR-32 ACh-activated channels was 38 pS and the channel open times were 0.6 and 6.3 ms. The channel conductance for heterologously expressed $\alpha3\beta4$ AChRs was 28 pS and the open times were 0.5 and 1.9 ms, while the conductance of $\alpha3\beta2$ AChRs was 25 pS and the open times were 0.7 and 2.6 ms. When the α5 subunit was coexpressed with α3 and β4, the channel conductance was slightly increased (30 pS) and the channel open times became longer. Additionally, the channel bursts were longer when compared to $\alpha 3\beta 4$ or $\alpha 3\beta 2$ AChRs. The channels resulting from coexpressing $\alpha 3$, $\alpha 5$, and $\beta 4$ subunits more closely resembled the channels expressed by IMR-32 cells than did α 3 β 4 or α 3 β 2 AChRs. These results suggest that the α 5 subunit contributes to the functional properties of AChRs expressed by IMR-32 cells.

A PATCH-CLAMP STUDY OF THE HUMAN α4β2 NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR. B. Buisson*, M. Gopalakrishnan, S.P. Arneric, J.P. Sullivan and D. Bertrand. University of Geneva, 1211 Geneva, Switzerland; Abbott Laboratories, Abbott Park, Illinois 60064-3500, USA.

HEK 293 cells stably transfected with human α4 and β2 cDNAs were characterized with patch-clamp and fast drug application techniques. The rank order of potency of four nAChR ligands to activate human α4β2 receptors is: (-)-nicotine > ACh > (-)-cytisine > ABT-418. At saturating concentrations, the efficacy of these ligands is: ABT-418 > (-)-nicotine > ACh >> (-)-cytisine > GTS-21. Coapplication of ACh with dihydro-beta-erythroidine (DHBE) and methyllycaconitine (MLA) reversibly reduces the current with respective IC50's of 80 nM and 1.5 μ M. The current-voltage relationship of human α4β2 displays a strong rectification at positive potentials. Experiments of ionic substitutions demonstrate that human «4β2 nAChRs are permeable to sodium and potassium ions. In the "outside-out" configuration, ACh evokes unitary currents (main conductance 46 pS) characterized by a very fast run-down. In contrast to previously characterized nAChRs the human a4β2 subtype is inhibited by increasing the extracellular [Ca2+] Work supported by the Swiss National Foundation and OFES.

CHARACTERIZATION OF F11 CELLS, A DORSAL ROOT GANGLION CELL LINE: EVIDENCE FOR FUNCTIONAL NEURONAL NICOTINIC RECEPTORS - A. Manelli, D. Donnelly-Roberts, S.P. Arneric*, and P.S. Puttfarcken, Neuroscience Research, D-47W, Abbott Laboratories, 100 Abbott Park, IL 60064-3500
Previous studies have identified nicotinic acetylcholine receptors

Previous studies have identified nicotinic acetylcholine receptors (nAChRs) in nociceptive pathways. (±)-Epibatidine, the potent neuronal nAChR agonist, has been reported to possess more potent analgesic properties (Sullivan et al., JPET:271 1994), relative to morphine. However to date, the potential mechanism underlying the effect of nAChRs on pain transmission remain unclear. To begin to understand the role of nAChRs in the modulation of pain, we investigated the ability of nicotinic agonists to activate nAChR channels in F11 cells. The F11 cell line is a dorsal root ganglion (DRG) hybrid cell line previously reported to possess properties of authentic, peptidergic type-C DRG neurons (Francel et al., J. Neurochem.:48 1987). In support, immunohistochemical studies indicated that the F11 cells possess very similar characteristics to primary cultures of rat DRG cells. Buth models expressed characteristics to primary cultures of rat DRG cells. Both models expressed neuronal markers and a subpopulation of substance P- and calcitioning gene related peptide-containing (CGRP) neurons. (-) Nicotine and (±)-epibatidine evoked a concentration-dependent stimulation of ⁸⁶Rb+ efflux with EC50 of 34.1 µM and 0.32 µM, respectively. These agonists exhibited maximal efficacy of 100% at 100 µM for (-)-nicotine and 102% at 1 µM for (±)- epibatidine. Both events at 100 µM for (-)-incotine and 102% at 1 µM for (±)- epipatidine. Both events can be specifically blocked with mecamylamine. Additionally, preliminary studies indicate that (±)-epibatidine evoked CGRP release from these cells. This is the first evidence of nAChRs present in this cell line and that these receptors regulate the release of CGRP. These results suggests that F11 cells may be a suitable model to investigate the role of nicotinic receptors in nociception. This work was supported by Abbott Laboratories.

ACETYLCHOLINE RECEPTORS: NICOTINIC-BINDING

504.1

ASSOCIATION BETWEEN STRAIN-SPECIFIC a5 AND a7 NICOTINIC RECEPTOR SUBUNIT LOCI AND SENSITIVITY TO THE HIGH DOSE EFFECTS OF NICOTINE: J.A. Stitzel. J.M. Blanchette, and A.C. Collins. Institute for Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309. Previous studies have demonstrated that mice with higher levels of higpocampal a-Bungarotoxin (aBTX) binding sites are more susceptible to the convulsant effects of high doses of nicotine. We have identified strain-specific rflps for the a7 nicotinic receptor subunit gene which codes for the aBTX binding receptor subunit in brain. Strain-specific rflps also have been identified for a nicotonic receptor subunit, a5, that some reports suggest can bind aBTX and/or is a subunit that contributes to a brain aBTX-binding receptor. To determine whether the strain-specific variants of a5 and/or a7 co-segregate with individual differences in sensitivity to the high dose of nicotine, F2 mice derived from a C3H (a strain sensitive to the high dose effects of nicotine) by DBA (a strain resistant to the high dose effects of nicotine) by DBA (a strain resistant to the high dose effects of nicotine) consess were tested for high dose sensitivity to nicotine and genotyped for the a5 and a7 rflps. Animals were scored for overall sensitivity to high doses of nicotine on a scale of one (least affected) to five (death) and for seizure frequency. Animals homozygous for the C3H variant of either a5 or a7 had significantly higher sensitivity scores (3.22 ± 0.18 and 2.8 ± 0.17, respectively) and seized with a higher frequency (43.5% and 32.4%) than those animals homozygous for the DBA variants of a6 and a7 (0.22 ± 0.18 and 2.04 ± 0.2, respectively, for the sensitivity score and 6.9% and 4.0%, for seizure frequency). Results from heterozygotes (a5: score = 2.16 ± 0.15, 9.4% seized) and significantly higher sensitivity score and 6.9% and 4.0%, for seizure frequency). Results from heterozygotes (a5: score = 2.16 ± 0.15, 9.4% seized a7: score = 2.38

ALPHA7 IS THE ONLY SUBUNIT DETECTED BY WESTERN BLOT IN PURIFIED RAT BRAIN MEMBRANE α-BTX BINDING SITES D. N. Chen* and J. W. Patrick. Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030

The rat alpha7 subunit of the neuronal nicotinic receptor forms homooligomeric nicotine gated ion channels which are blocked by α -bungarotoxin (α -BTX) when expressed in *Xenopus* oocytes. However, while alpha7 subunit is found in purified α -BTX binding molecules from rat brain or cultured PC12 cells, other proteins are co-purified with the alpha7 subunit. Purified chick brain α-BTX binding sites are heterogeneous, and the chick alpha7 subunit associates with the chick alpha8 subunit to form hetero-oligomers. In this study, our goal was to understand whether native rat α-BTX binding molecules are homomers of

alpha7 subunits, or heteromers containing other subunits besides alpha7.

We used affinity purified polyclonal antibodies in western blot analysis of affinity purified α-BTX binding sites. We report here that our experimental data strongly suggests that the $\alpha ext{-BTX}$ binding receptor in rat brain membrane is either a homo-oligomer of alpha7 subunits or contains some subunit(s) yet to be cloned that do not cross react with our most panspecific antibodies.

ROLES OF N-LINKED GLYCOSYLATION IN THE FORMATION AND FUNCTION OF α7 NICOTINIC RECEPTOR H. Dang*, D. N. Chen and J. W. Patrick Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030

The α7 subunit of the nicotinic acetylcholine receptor forms homomeric ion channels in Xenopus oocvtes which are blocked by the snake toxin, α-bungarotoxin. The N-terminal extracellular domain of α7 has three consensus sites (NXT/S) for Nglycosylation (N₄₆DS, N₉₀MS, and N₁₃₃AS). In this study, we show that $\alpha 7$ expressed in transfected COS cells and in rat brain membrane are glycoproteins. We also demonstrate by site-directed mutagenesis and COS cell transfection that all three sites are utilized for glycosylation

To elucidate the roles of the glycosylation sites in the formation and function of the α 7 receptor, effects of replacing either the asparagines or serines with alanines on the receptors expressed in oocytes were measured by two-electrode voltage clamp. The number of α -BTX binding sites or the amount of receptor protein on the surface were determined by either the 1251-α-BTX binding assay or an antibody binding assay. Both the N46A and S48A mutants showed increased whole cell currents and surface expression of receptor proteins compared to WT indicating that glycosylation at N46 limits the rate of surface expression of the α 7 receptor. However, both asparagine and serine mutations at the N90 and N133 sites greatly reduced the whole cell currents but not the surface protein expression suggesting that the carbohydrate moieties attached at these sites may be involved in the function of ligand binding domain

COMPARISON OF L-NICOTINE-STIMULATED [3H]DOPAMINE RELEASE FROM FOUR MOUSE BRAIN REGIONS. S.R. GRADY, A.L. CLARK, and A.C. COLLINS. Inst. for Behav. Genetics, U. of Colo., Boulder, CO 80309.

Several brain regions known to release dopamine were compared in order to further characterize the actions of L-nicotine (NIC). Striatum (ST), olfactory tubercle (OT), frontal cortex (FC), and nucleus accumbens (NA) were dissected from C57/6JIBG \$\frac{9}{2}\$ mouse brain slices (1mm thick) made using a mouse brain block. A P2 synaptosome preparation was made from each region and A P2 synaptosome preparation was made from each region and $[^3H]$ dopamine release was assayed as previously described (Grady et al. J. Neurochem. 59:848-856, 1992). Release was stimulated by NIC from all four regions. This release was Ca⁺⁺-dependent and inhibited by mecamylamine and dihydro-ß-erythroidine. Dose response for a 1 min exposure to NIC was determined for each region. EC₅₀ values (μ M), calculated by curve fits assuming $n_1 = 1$, were: ST 0.35 ± 0.04 ; OT 0.15 ± 0.04 ; FC 0.17 ± 0.04 ; NA 0.13 ± 0.03 . Maximum release values (stimulated release/baseline), using the indicated amounts of tissue from one of the control of t o.17±0.04; NA 0.13±0.03. Maximum release values (stimulated release) baseline), using the indicated amounts of tissue from one mouse, were: ST(1/8) 6.45±0.11; OT(1/4) 7.38±0.19; FC(1/4) 2.91±0.06; NA(1/4) 4.28±0.17. In addition, a 10 min exposure to NIC revealed biphasic desensitization as previously shown for striatum (Grady et al. J. Neurochem. 62:1390-1398, 1994). The regions, however, appeared to differ in the ratio of persistent regions, nowever, appeared to differ in the ratio of persistent response to total response with NA having the lowest ratio and ST the highest. ST was significantly different from the other regions (P<0.05).

HETEROGENEITY OF EPIBATIDINE BINDING SITES IN MOUSE BRAIN. M.J. Marks*, B. Coll, K.W. Smith and A.C. Collins. University of Colorado, Boulder, CO.

M.J. Marks*, B. Coll, K.W. Smith and A.C. Collins. University of Colorado, Boulder, CO.

Epibatidine, an alkaloid isolated from the skin of the Ecuadorean poison dart frog, Epipedobates tricolor, is a potent nicotinic agonist in vivo and in vitro. [3H]Epibatidine binds to brain with high affinity and apparently labels several distinct nicotinic receptor subtypes. [3H]Epibatidine binding to mouse brain was measured using regionally dissected tissue and by quantitative autoradiography. The binding of [3H]epibatidine (400 pM) to membranes prepared from olfactory bulbs was inhibited by cytisine, nicotine, acetylcholine, and methylcarbachol. The inhibition profile obtained for each agonist was biphasic with approximately 45% of the binding inhibited at relatively low agonist concentrations. Since the IC of the other agonists, cytisine was used to inhibit binding in ten additional regions. The IC of values for high and low affinity cytisine inhibition did not differ among the regions, but total [3H]epibatidine binding and the percentage inhibited at low cytisine varied among the regions. These results suggest a differential distribution of nicotinic receptors in mouse brain. Quantitative autoradiographic analysis of [3H]epibatidine (350 pM) binding for samples incubated with 0, 5, 50, 150, 500 and 10000 nM cytisine revealed a distinct and restricted pattern for the distribution of sites with low affinity for cytisine: accessory olfactory bulb, medial habenula, interpeduncular nucleus, and fasciculus retroflexus showed high binding, while medial and lateral geniculate nuclei, and inferior and superior colliculi had somewhat less, but still substantial, binding. These sites were virtually undetectable in other brain areas. [3H]Epibatidine binding sites with high affinity for cytisine had identical distribution to those measured with [3H]nicotine. These results confirm that epibatidine binds to at least two nicotinic receptor subtypes, one of which is identical to the high affainty nicotine binding site (presumably \(\

504.7

N-OCTYLNICOTINIUM IODIDE (NONI), A NOVEL NICOTINIC RECEPTOR ANTAGONIST: COMPETITIVE DISPLACEMENT OF [3H]NICOTINE BINDING FROM RAT STRIATAL MEMBRANES AND BRAIN REGION-SPECIFIC DISPLACEMENT OF ['H]CYTISINE BINDING. L.H. Wilkins*, P.A. Crooks, J.R. Pauly and L.P. Dwoskin. College of Pharmacy, University of Kentucky, Lexington, KY

A series of N-substituted nicotine analogues was synthesized and evaluated for inhibition of nicotine-evoked [3H]dopamine release from rat striatal slices and for displacement of [3H]nicotine binding from rat striatal membranes (Crooks et al., Drug Dev. Res. 36:91, 1995). NONI was found to be the most potent (IC50 = 1μ M) and efficacious compound, completely inhibiting nicotine's effect in the release assay. Although NONI completely displaced [3H]nicotine binding, it was the least potent (IC50 = 50 μ M) analogue examined in the binding assay. In the present study, we assessed it NONI was a competitive or noncompetitive antagonist as determined by the pattern of [3H]nicotine displacement from striatal membranes. A parallel rightward shift in the displacement curves was observed with increasing concentration of NONI. Scatchard analysis revealed an increased Kd value (from 1.7 nM at 0 NONI to 30 nM at 22 μ M NONI) with no change in Bmax (68.7 fmol/mg protein) with increasing concentration of NONI, suggesting a competitive interaction of NONI with the [3H]nicotine binding site Similar results were obtained when NONI was used to displace [3H]cytisine (5 nM) binding from rat brain sections. Low concentrations of NONI (0.5 μM) did not significantly displace [3H]cytisine binding, but higher concentrations (10 µM) reduced binding by 20-40%, depending on the brain region analyzed. Thus, NONI is an excellent lead compound for the development of novel, subtype-selective nicotinic antagonists. Supported by the Tobacco and Health Research Institute, Lexington, KY

[1251]IPH, AN EPIBATIDINE ANALOG BINDS WITH HIGH AFFINITY TO NEURONAL NICOTINIC RECEPTORS. M.I. Dávila-García*, J.L. Musachio', D.C. Perry², Y. Xiao, A. Horti³, E.D. London^{1,3}, R.F. Dannals¹ and K.J. Kellar. Department of Pharmacology, Georgetown University School of Medicine, Washington, DC 20007. The Johns Hopkins University Medical Institutions, Baltimore, MD 21287. George Washington University School of Medicine, Washington, DC 20037, 3Division of Intramural Research, National Institute on Drug Abuse, Baltimore, MD 21224.

Prug Abuse, hattimore, MD 21224.

[125]IPH ((±)-exo-2-(2-[125]todo]-5-pyridyl)-7-azabicyclo[2.2.1] heptane), an epibatidine analog was prepared with specific activities from 188 to 1920 Ci/mmol, via a Cu-assisted exchange reaction from bromide to [125]iodide. [125]]IPH has high affinity for neuronal nicotinic acetylcholine receptors in membranes from rat brain, rat adrenal gland and stably transfected cell lines expressing the $\alpha 2/\beta 4$ subunit combination. In all cases, nonspecific binding was low. In adult rat forebrain, this radiolabeled ligand has a similar K_D value iow. In adult rat forebrain, this radiolabeled ligand has a similar K_D value (≈ 50pM) to that of its analog [Hlepibatidine (l'HJEB), and nicotinic drugs compete with a similar rank order of potency for the binding sites labeled by the two radioligands: (±)EB >> cytisine > nicotine > dihydro-B-erythroidine (DHBE) > carbachol > curare. In competition studies, most of the drugs tested show Hill coefficients close to 1 (>0.8), with the exception of DHBE (0.6) and curare (0.7). [123]IPH also labels nicotinic receptors in autoradiographic studies in rat brain. The fact that [1251]IPH labeled to a high specific radioactivity binds with high affinity to neuronal nicotinic acetylcholine receptors makes it a useful compound to study the pharmacology and regulation of these receptors, particularly in tissues with low receptor density.

3H-EPIBATIDINE BINDING: CHARACTERIZATION IN RAT AND HUMAN BRAIN. M.W. Arriola, D.G. Costello, P.W. Sweetnam, and

T.F. Seeger* Pfizer Inc., Central Research Division, Groton, CT 06340.

Epibatidine (EPI), a potent analgesic, appears to mediate its central and peripheral actions through nicotinic receptors. Using [3H]EPI homogenate binding and autoradiographic techniques, we report on the further characterization of EPI binding sites in the rat and human CNS. Competition studies revealed the rank order of potency Competition studies revealed the rank order of potency (EPI>cytisine>nicotine>lobeline>carbachol) at the [3H]EPI site (final conc. 250 pM) was consistent with previous reports. Further studies revealed binding in both species was saturable, reversible, and of high affinity. Two pharmacologically distinct binding sites were discriminated by Scatchard analysis. Apparent affinity was 30 and 350 pM in rat cortex, while in human parietal cortex the corresponding affinities were <10 and 100 pM. In contrast to previous reports, the detection of two sites was dependent on the presence of ions, particularly calcium, in the assay buffer. Analysis of 3H[EPI] autoradiography in the rat brain confirmed it to be reversible, and to consist of more than one binding component, delineated by displacement with nicotine. The majority of [3H]EPI binding areas in rat brain were displaced by nicotine with an apparent IC50 of 25-50 nM. This component was widely distributed throughout the rat brain, with highest densities found in thalamic nuclei. The second component was insensitive to nicotine at up to 1 uM. This site was present in very high density in medial habenula, fasciculus retroflexus, and interpeduncular nucleus. Epibatidine may serve as an important tool for the molecular characterization of nicotinic receptors other than the $\alpha 2\beta 4$ subtype which predominates in the rat CNS. (Funded by Pfizer Inc.)

[3H]-CYTISINE BINDING TO α4β2 NEURONAL NICOTINIC RECEPTORS EXPRESSED IN XENOPUS OOCYTES. M.J. Parker,

RECEPTORS EXPRESSED IN XENOPUS OOCYTES. M.J. Parker. C.W. Luetje* Department of Molecular and Cellular Pharmacology, University of Miami, Miami FL, 33101.

The high affinity cytisine binding site in rat brain (Kd=0.96 nM, Pabreza et al., 1990, Molec. Pharmacol. 39:9-12) is thought to be composed of the α4 and β2 neuronal nAChR subunits (Flores et al., 1991, Molec. Pharmacol. 41:31-37). In order to determine the structural basis for high affinity agonist binding to neuronal nAChRs, we have begun using adjoining a techniques to study neuronal. we have begun using radioligand binding techniques to study neuronal AChRs exogenously expressed in *Xenopus* oocytes. Equilibrium binding assays were performed with [3 H]cytisine in a crude membrane homogenate. To increase receptor expression, the α 4 and β 2 subunits were engineered into the high expression vector, pGEMHE. Expression of α 4 β 2, as measured by two-electrode voltage clamp and α 4 β 3 measured by two-electrode voltage clamp and [3] Hotytisine binding, was increased by approximately 3-fold when the RNA was transcribed from pGEMHE constructs, rather than from pSP64/65 constructs. The Kd for [3] Hotytisine binding to α4β2 expressed in oocytes was 0.88 nM. This is similar to the Kd for expressed in oocytes was 0.88 nM. This is similar to the Kd for [3H]cytisine binding to the rat brain site reported by Pabreza et al., further supporting the conclusion that the high affinity cytisine binding site in rat brain is $\alpha 4\beta 2$. Using this radioligand binding assay, we plan to characterize the affinity of the $\alpha 4\beta 2$ receptor for other agonists and to determine the affinity of other neuronal nAChR subunit combinations for agonists. Ultimately we will use chimeric and mutant subunits to identify amino acid residues responsible for high affinity agonist

CHARACTERISATION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR OF MANDUCA SEXTA: A NICOTINE INSENSITIVE, TOBACCO FEEDING INSECT. H. M. Eastham*, R. J. Lind, A. J. Wolstenholme, S. E. Reynolds & S. Wonnacott. Sch. of Biol. & Biochem., Univ. Bath, Bath, BA2 7AY, U.K.

Nicotine is a potent insecticide, causing a depolarising blockade of the nicotinic acetylcholine receptor (nAChR). However, the larvae of the tobacco hornworm, Manduca sexta. feed on tobacco yet suffer no detrimental effects from the ingestion of nicotine. Trimmer & Weeks (J. exp. Biol. 144:303-337, 1989) postulated that this reduced nicotine sensitivity could reflect in part an altered nAChR, making it a natural, nicotine-insensitive, mutant receptor.

Binding studies on brain membranes from adult Manduca show that [125][qbungarotoxin (α-bgt) labels a specific site with Kd=7.2±2.4nM and Bmax= 186±14.5fmol/mg. Displacement studies show that (-)nicotine (IC₅₀=2.3±1.0μM), (±)epibatidine (1.0±0.23 μ M) and imidacloprid (1.8±0.3 μ M) bind with similar affinities, while ACh (59±14.3μM, with neostigmine) and another tobacco alkaloid, anabasine $(37.9\pm5.8\mu\text{M})$ have lower binding affinities. Honeybee, a nicotine-sensitive insect, gives IC_{50} values for α -bgt, imidaeloprid or nicotine (Tomizawa et al., J. Pesticide Sci. 20:57-64, 1995) comparable to those of Manduca determined here. These results suggest that the nicotine insensitivity of Manduca is not reflected in a lowered nicotine binding affinity at this α-bgt-labelled nAChR

To see if an α-bgt-insensitive nAChR is present in Manduca brain we performed binding assays using [3H]epibatidine. At 1nM and 10nM concentrations no specific [3H]epibatidine binding displaceable by excess nicotine or α-bgt was demonstrated. Using a variety of PCR techniques we have obtained the complete coding sequence of a nicotinic α subunit for *Manduca*. This shows no obvious changes in candidate residues that determine nicotine affinity, consistent with the binding data.

A NEURONAL CELL LINE EXPRESSING A UNIQUE, CNS NICOTINIC ACETYLCHOLINE RECEPTOR SUBTYPE. L. Lucero* and R.J. Lukas. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Our previous work has shown that clonal cell lines of different derivation are excellent models for studies of fundamental properties of diverse, naturallyexpressed nicotinic acetylcholine receptor (nAChR) subtypes. The CATH a cell line (Central, Adrenergic, Tyrosine Hydroxylase-positive cell line "a"), which was isolated by Suri et al. (J. Neurosci. 13:1280, 1993) and a generous gift of Dona Chikaraishi, was derived from a tumor occurring at the ventral aspect of the midbrain/rostral brainstem boundary in a transgenic mouse carrying the SV40 large T antigen oncogene under transcriptional control of rat tyrosine hydroxylase 5'flanking sequences. In support of our reasoning that CATH.a cells might represent a long-sought neuronal cell line that expresses some form of CNS nAChR, we find that they express specific, high-affinity binding sites for [1 H]epibatidine (EBDN; 6 pM $K_{\rm D}$). There are no specific 12 I-labeled α -bungarotoxin binding sites, and EBDN binding sites are found in both intracellular and cell surface pools. Numbers of membrane-bound EBDN binding sites increase ~150% on chronic exposure of CATH.a cells to nicotine. However, EBDN binding competition studies indicate CATH.a cells have lower affinity for agonists such as cytisine and nicotine than do rat or mouse brain α4β2-nAChR, but higher affinity for antagonists such as alcuronium and d-tubocurarine. These relationships are reversed for comparisons of CATH.a cell nAChR and IMR-32 cell $\alpha 3 \beta 4$ -nAChR. Northern analyses indicate expression as mRNA of nAChR &4, \$2, and other subunits. Collectively, these studies suggest that CATH.a cells express a unique nAChR subtype that contains $\alpha 4$, $\beta 2$, plus other nAChR subunits. We hypothesize that the CATH.a cell nAChR subtype is involved in the control of catecholamine release from mesolimbic dopaminergic cells and/or adrenergic cells of the locus coeruleus. NICOTINIC ACETYLCHOLINE RECEPTOR mRNAs DURING DEVELOPMENT OF THE SCN, OTHER BRAIN REGIONS, AND FOLLOWING NICOTINE

OF THE SCN, OTHER BRAIN REGIONS, AND FOLLOWING NICOTINE EXPOSURE *IN VIVO* AND *IN VITRO*. B.F. O'Hara'. V.H. Cao. S.W. Wiler, H.C. Heller, J.D. Miller# and T.S. Kilduff. Ctr. for Sleep & Circadian Neurobiology, Depts. of Psych. and Biological Sciences, Stanford Univ., Stanford, CA 94305. * Dept. of Pharm., Texas Tech Univ. HSC., Lubbock, TX 79430. We have previously found substantial changes in levels of nicotinic acetylcholine receptor (nAChR) subunit mRNAs during development that may underlie the sensitivity of the fetal suprachiasmatic nuclei (SCN) to nicotine (Dev. Brain Res. 84(1995)46-54). Specifically, α7 mRNA increases in the SCN from fetus to adult while α4 mRNA decreases as determined by Northern analysis. β2 levels remain relatively constant. We have now examined several other subunits and find that α2 and α3 follow similar patterns to α4 in the SCN and other brain regions examined. α5, β3 and β4 mRNAs were barely detectable in our brain samples. We have examined both rat and mouse tissue and generally find similar mRNA sizes, however, some mRNAs do vary between the two species and some vary between brain regions and throughout development. More recently we have been examining changes in nAChR gene expression following nicotine exposure in the fetus, adult and throughout development. More recently we have been examining changes in AChR gene expression following nicotine exposure in the fetus, adult and hypothalamic cell cultures. Other groups have found that nicotine exposure can increase nAChR protein levels without any change in mRNA. However, in hypothalamic cell cultures (from E18 rat fetuses) exposed to 100µM nicotine for one hour, we find a several fold increase in α 7 mRNA levels. We find a more modest increase in α 7 mRNA in the hypothalamus and hippocampus following a 1mg/kg s.c. dose of nicotine. In both *in vivo* and *in vitro* conditions, the tissue was frozen after one hour of nicotine exposure. Additional the tissue was noted and chronic nicotine exposure. Adoitional timepoints with both acute and chronic nicotine are now being examined. The in vitro studies utilize cells grown for 3 or 10 days in culture. The 10 day old culture exhibits the highest α 7 mRNA levels suggesting possible glial expression. In contrast, β 2 and other subunit mRNAs are nearly absent in these cultures. (Supported by NIH grants DA00187 and HD29732).

IMAGING NICOTINIC ACETYLCHOLINE RECEPTORS IN BABOON BRAIN BY PET AND SPECT. V.L. Villemagne 1, U. Scheffel*1, A. Horti², J.L. Musachio¹, H.T. Ravert¹, P. Finley¹, M. Stathis¹, E.D. London¹, 2, and R.F. Dannals¹. ¹The Johns Hopkins Medical Institutions.

and ²Intramural Research Program, NIDA, Baltimore, Maryland 21205. Nicotinic acetylcholine receptors (nAChRs) have been implicated in a variety of central processes, such as learning & memory, and modulation of appetite. These receptors also mediate the reinforcing in a variety of central processes, such as learning & memory, and modulation of appetite. These receptors also mediate the reinforcing properties of nicotine in tobacco products and are decreased in the brains of individuals who have died from dementia of the Alzheimer type. In an effort to prepare PET/SPECT radiotracers for in vivo studies of nAchR, we have prepared radiohalogenated [F-18, I-123] analogs of epibatidine, a high affinity potent nAchR agonist. The distribution and kinetics of [F-18]-FPH and [I-123]-IPH were evaluated using PET and SPECT, respectively. After intravenous injection of 5 mCi of high specific activity [F-18]-FPH or [I-123]-IPH into a 20 kg anesthetized baboon (Papio Anubis), sequential tomographic data were acquired over a period of 150 min. Brain activity peaked for both compounds within 60 min post injection, and the binding showed reversible characteristics. Elimination was more rapid from the cerebellum (clearance 11/2 ~ 3 h), and than from the thalamus (11/2 ~ 16 h). Radioactivity concentrations at ~ 100 min post injection were highest in the thalamus; intermediate in the neocortex; and lowest in the cerebellum. Subcutaneous injection of 1 mg/kg cytisine 45 min after injection of [F-18]-FPH reduced brain activity at 130 min by 67, 64, 56, and 52% of control values in the thalamus, hypothalamus, hippocampus, and cerebellum, respectively. High correlation with known densities of nAChR measured in vitro in rat brain was found for [F-18]-FPH (r = 0.90) and [I-123]-IPH (r = 0.87). These results demonstrate the feasibility of imaging nAChR in vivo and suggest that both [F-18]-FPH and [I-123]-IPH can be used to study nAChR in the human brain.

BINDING OF 125I-α-BUNGAROTOXIN AND EXPRESSION OF mRNA FOR THE α7 NICOTINIC, CHOLINERGIC RECEPTOR IN NEURAL CREST-DERIVED TISSUES OF THE RAT. S. Leonard*, C.R. Breese, J. Logel, Y. Rollins and C. E. Adams. Department of Psychiatry, University of Colorado Health Sciences Center., Denver, CO 80262

Cells within the chick cervical ganglia, a derivative of the neural crest, have been reported to express mRNA for the $\alpha 7$ nicotinic, cholinergic receptor. This finding raised the possibility that expression of the a7 nicotinic receptor might be a common characteristic of cells of neural crest origin. The hypothesis was examined in the rat in a variety of organs containing neural crest-derived cells using 125 I-abungarotoxin receptor autoradiography and in situ hybridization for α7 mRNA. Cells within the thymus, adrenal gland, trigeminal ganglia, dorsal root ganglia, superior cervical ganglia, lung, heart and skin were found to both bind 125 I- α -bungarotoxin and express $\alpha7$ mRNA. Other tissues, including the testis, pancreas, ovary, intestine, olfactory bulb and retina, exhibited α-bungarotoxin binding with little to no expression of α 7 mRNA. These results suggest that expression of the neuronal nicotinic receptor α7 is not limited to the CNS but is also present in peripheral tissues of neural crest origin. INDIVIDUAL RAT INTRINSIC CARDIAC NEURONS DISPLAY VARIABLE NICOTINIC PHARMACOLOGIES AND NEURONAL nAChR ß SUBUNIT mRNA EXPRESSION PATTERNS <u>K. Poth*</u>, <u>R.J. Bookman</u>, <u>C.W. Luetje</u>, Department of Molecular and Cellular Pharmacology, University of Miami, Miami FL, 33101. Neurons can assemble nAChRs from a potential pool of at least 11 different subunits. In *Xenopus* oocytes, each functional subunit combination has distinct pharmacological properties. Sensitivity to the agonist cytisine is largely dependent on the identity of the β subunit (Luetje & Patrick, 1991, J. Neurosci. 11: 837-845). Single cell RT-PCR demonstrates that individual neurons cultured from rat intracardiac ganglia express different arrays of nAChR subunit mRNAs (Poth, et.al., 1995, Soc. Neurosci. Abstr. 21: 1335). To determine the effect of differential subunit expression on the pharmacological properties of affreential subunit expression on the pharmacological properties of nAChRs expressed by these neurons, we are assessing agonist pharmacology by measuring changes in [Ca²⁺], with fura-2 fluorescence imaging, and probing subunit mRNA expression with single cell RT-PCR. We find that both whole cell agonist pharmacology and β subunit expression are variable. The ratio of peak Ca²⁺ responses to cytisine and ACh ranged from 0.23 to 1.85. Single cell RT-PCR showed that while some neurons express either $\beta 2$ or $\beta 4$ mRNA, many neurons express both β subunit mRNAs with the ratio of $\beta 2$ to $\beta 4$ mRNA varying from neuron to neuron (in one experiment the β 2:84 ratio ranged from 0.6 to 4.6). This suggests that the pharmacological differences from neuron to neuron are due to differences in the relative expression of neuronal nAChR subunits. We are currently examining this possibility directly by performing pharmacological measurements and RT-PCR in the same neurons. [Support: NIH DA-08102 and AHA-FL]

SEVERAL SUBUNITS OF THE NICOTINIC RECEPTOR GENE FAMILY ARE EXPRESSED IN THE RAT PERIPHERAL VESTI-BULAR SYSTEM. H. Hiel, H.K. Happe*, A.B. Elgoyen, B.J. Morley, Boys Town Nat'l Research Hospital, 555 North 30th Street, Omaha, NE 68131.

A major efferent neurotransmitter in the peripheral vestibular organ is probably acetylcholine (ACh), but the cholinergic receptor(s) have not been identified. Pharmacological data suggest that at least one receptor is a nicotinic cholinergic receptor (nAChR) (Guth et al., Hear. Res. 75, 225-232, 1994). We studied the mRNA expression of the $\alpha 3$ - $\alpha 7$, and $\beta 2$ - $\beta 4$ subunits in the peripheral vestibular system by in situ hybridization with 35S-labeled riboprobes. Alpha 4, α 5, α 6, α 7, β 2 and β 3 nAChR subunits, but not $\alpha 3$ or $\beta 4$ are expressed in the primary afferent vestibular ganglion (Scarpa's ganglion).

The vestibular sensory epithelia were devoid of detectable hybridization signal for the $\alpha 3-\alpha 7$ and $\beta 2-\beta 4$, but vestibular sensory hair cells express the $\alpha 9$ subunit, the subunit recently reported in the cochlear outer hair cell by Elgoyhen et al. (Cell 79, . 705-715, 1994). This observation is consistent with a recent report Guth et al. (Hear. Res. 75, 225-232, 1994) in which the pharmacological profile for the vestibular efferent receptor was reported to be similar to the nAChR on the cochlear outer hair cell. Of Med., Washington, DC 20007 and ³Dept. of Psychiatry, Case Western Reserve University Sch. of Med., Cleveland, OH 44106. To assess the effects of smoking on nicotinic receptors in human brain, we call homeometals highly assess and quantificially repeated and control of the property of the control of the con

To assess the effects of smoking on nicotinic receptors in human brain, we used homogenate binding assays and quantitative receptor autoradiography to compare the density of nicotinic receptors in prefrontal cortex (area 10), anterior temporal cortex (area 38) and hippocampus. Brains were collected from 8 smokers (>20 cigarettes /day) and 8 nonsmokers matched by age (54±4y v. 54±6y) and post mortem interval (21±2h v. 16±3 h). Receptors in homogenates were labeled using [³Hlepibatidine ([³HlEB) or [³Hlcytisine ([³HlEB or 7 nM [³HlCyt). Nonspecific binding was determined with 300 µM nicotine tartrate. In homogenates from prefrontal cortices of smokers, the density of nicotinic receptors labeled by either ligand increased by ~300% nicotine tartrate. In homogenates from prefrontal cortices of smokers, the density of nicotinic receptors labeled by either ligand increased by ~300% compared to nonsmokers (p<0.0001). In anterior temporal cortex from smokers, nicotinic receptor density measured by either ligand increased by ~250% compared to nonsmokers (p<0.0001). For autoradiographic analysis, 20 μm frozen sections were mounted on slides and incubated with 1 nM [³H]EB or 4.5 nM [³H]Cyt and after rinsing and drying apposed to tritium sensitive film for approximately 3 months. Preliminary analysis of autoradiographic images confirms the large increases seen in both cortical regions of smokers. Increases were seen across the laminae, but a particularly dense band of binding was apparent in the deepest layers of the frontal cortex (layer VI), and in two deep bands in temporal cortex (layers IV and VI). Data From hippocampal autoradiography will also be presented. Supported by DA06486 & MH45488.

IDENTIFICATION OF THE SUBUNITS OF THE NICOTINIC CHOLINERGIC RECEPTORS IN THE RAT COCHLEA USING RT-PCR AND IN SITU HYBRIDIZATION. B.J. Modley*, H.-S. Li. H. Hiel, D.G. Drescher, A.B. Elgoyen, Boys Town Nat'l Research Hospital, 555 North 30th Street, Omaha, NE 68131.

There are two neuronal tissues in the mammalian cochlea that are post-synaptic to cholinergic efferent fibers: the outer hair cells (OHCs) and the dendrites of the afferent fibers of the Type I spiral The unusual nicotinic-like pharmacology of ganglion cells. cochlear cholinergic responses and the unique embryonic development of cochlear tissues suggest that the nicotinic cholinergic receptor (nAChR) may be different than those described previously at synapses in the mammalian brain, autonomic ganglia, or skeletal muscle. In this study, we determined the mRNA expression of the α 2-7, α 9, and β 2-4 subunits of the nicotinic acetylcholine receptor (nAChR) family in the rat cochlea. In micro-dissected tissue from the organ of Corti, spiral ganglion, and stria vascularis, we found mRNA expression of the $\alpha 7$ and $\alpha 9$ subunits in the organ of Corti and $\alpha 5$ -7, and $\beta 2$ or the α 7 and α 9 subunits in the organ of Corn and α 5-7, and β 2 and β 3 in the spiral ganglion using RT-PCR. Using in situ hybridization with 35 S-riboprobes, α 9 was localized in hair cells and α 6, α 7 and β 2 were localized in the Type I cells of the spiral ganglion. No evidence of nAChR subunit mRNA expression was found in supporting cells, but $\beta 2$ was expressed in Type II spiral ganglion cells, which are neither cholinergic nor cholinoceptive.

Supported by NIH/NIDCD grant DC002115-12 to BJM.

THE REDUCED EXPRESSION AND FUNCTIONAL LOSS OF CENTRAL NICOTINIC RECEPTORS IN A STRAIN OF GENETICALLY HYPERTENSIVE RATS (SHR) M. Gattu*, A.V.Terry, Jr., JR. Pauly and J.J. Buccafusco. Alzheimer's Research Center, and Dept. Pharmacol. & Tox., Medical College of Georgia, and the VA Med. Ctr., Augusta, GA, 30912 and the School of Pharmacy, University of Georgia, Athens, GA.

Studies from this and other laboratories have shown that the expression of brain nicotinic receptors is dramatically reduced in SHR compared with age-matched normotensive rats. However, it has not yet been determined whether this decrease in expression is reflected in a decrease in nicotinic receptor-mediated function, or whether the hypertensive state causes the decreased expression. We estimated the number of nicotinic receptor binding sites in the brains of 12 week old SHR its normotensive counterpart the WKY strain by using quantitative autoradiographic techniques. Coronal sections were exposed to saturating concentrations of [3H]-cytisine (a4 subunitcontaining sites) and 1^{125} []- α -bungarotoxin (α_7 sites). In general, 1^9 H]-cytisine binding was reduced (by up to 25%) in the brains of SHR vs. WKY. Significant reductions were observed in about 50% of the regions analyzed. SHR exhibited only regional reductions in [125]]-a-bungarotoxin binding sites. These were relegated to the frontal cortex and anterior olfactory nucleus (interstrain differences 29 and 32%). Similarly, the magnitude of nicotine-stimulated *6Rb+ efflux from synaptosomes derived from the frontal cortex and striatum of SHR was significantly lower than that from normotensive rats. Since central nicotinic receptors have also been shown to play are role in learning and memory, we employed a navigational memory task (NMT) and a passive avoidance (PA) task to elucidate any strain differences in memory-related task performance. SHR exhibited significantly impaired performance in learning and re-learning phases of NMT and PA tasks compared to age-matched WKY rats. Thus, the decreased expression of nicotinic receptors in SHR may result in functional impairment both neurochemically and behaviorally, and may be related to the cognitive impairment known to occur in untreated human essential hypertension. Supported by the VA Medical Research Service.

NEUROTOXIC ACTIONS OF N-METHYL-D-ASPARTATE (NMDA)/ GLUTAMATE RECEPTOR ANTAGONISTS IN THE RAT ENTORHINAL CORTEX, G. Wong, J. Väisänen, A-M Lindén, E. Castrén*. A.I. Virtanen Institute,

University of Kuopio, PL 1627, Kuopio, Finland 70211 NMDA/glutamate receptors are formed from a family of ligand-gated ion channels which together mediate many of the neurotoxic effects produced by chemical agents, hypoxia-ischemia, and mechanical injury. As a consequence, antagonists to the channel site have been developed as a strategy to attenuate neuronal injury produced through activation of these receptors. These agents include the channel blockers MK-801, ketamine, and phencyclidine. Nonetheless, these substances have been observed to produce paradoxical neurotoxicity in cingulate, retrosplenial and medial entorhinal cortices as determined by formation of intracellular vacuoles, and induction of mRNAs for immediate early genes, heat shock proteins, and brain-derived neurotrophic factor The aim of the present study was to determine the underlying mechanisms involved in the neurotoxic actions of MK-801 in the rat entorhinal cortex. In these studies, receptor autoradiography using [3H]MK-801 and modulators of the complex (e.g. glutamate, glycine, polyamines) revealed heterogeneity of NMDA receptors in the entorhinal cortex, which was dependent on the layer observed, and is most likely the result of differential NMDAR1 and NMDAR2A,B subunit expression. Furthermore, in situ hybridization studies were used to correlate the specific cortical layers where paradoxical neurotoxic effects were observed (as measured by c-FOS expression) and the expression of various receptor subtypes. Taken together, these results suggests a role for NMDA/glutamate receptor subtypes in mediating neuronal injury

CGS19755 SENSITIVE ELECTRICAL COMPONENT THAT CONTRIBUTES TO SYNAPTICALLY MEDIATED EXCITOTXICITY. J.R. McLeod, M. Shen, S.A. Thayer* Dept. of

Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455. Reducing the extracellular Mg²⁺ concentration ([Mg²⁺]_o) bathing cultured rat hippocampal neurons to 0.1 mM elicited an aberrant pattern of excitatory synaptic activity. 0.1 mM [Mg²⁺]_o elicited repetitive bursts of action potentials associated with large increases in the intracellular Ca²⁺ concentration ([Ca²⁺]; spikes) as indicated by combined-whole-cell current clamp and indo-1-based clamp microfluorimetry. Digital imaging experiments showed that the [Ca²⁺]_i spikes were synchronized, suggesting that these cultures would be suitable for relating synaptic activity to viability. 24 hr exposure to 0.1 mM [Mg²⁺]_o resulted in the death of 18 \pm 4 % of the neurons. The NMDA receptor antagonist CGS19755 (10 µM) protected the network from 0.1 mM $[Mg^{2+}]_o$ - induced cell death (3 \pm 6 % cell death). CGS 19755 blocked the slow depolarization upon which the action potential burst lay, blocked a slow inward current of comparable duration (n=10) and reduced [Ca2+]i spike amplitude by 76 ± 10 % and frequency by 68 ± 13 %. These data suggest that a specific component of the aberrant electrical activity elicited by 0.1 mM [Mg²⁺]₀ preferentially contributes to cell death rather than the integrated somatic response represented by the somatic [Ca2+]; spike.

INTRACEREBRAL NMDA INJECTION STIMULATES PRODUCTION OF INTERLEUKIN-18 (IL-18) IN NEONATAL RAT BRAIN. P. Hagan*, S. Poole, A.F. Bristow, F. Tilders and F.S. Silverstein, Depts. of Pediatrics and Neurology, Univ. Michigan, Ann Arbor, MI, USA, NIBSC, Potters Bar, Herts. UK and Dept. of Pharmacology, Free University of Amsterdam, Netherlands.

Two lines of evidence suggest that IL-1β is a mediator of

excitotoxic injury in the developing brain. Intra-cerebral NMDA injection in 7 day old (P7) rats stimulates IL-1β mRNA expression acutely (Stroke 26:1995); adenovirus-mediated over-expression of IL-1 receptor antagonist (which blocks the biological actions of IL-1β) in the receptor antagonist (which blocks the blological actions of IL-1β) in the brain, confers resistance to NMDA-induced injury (Hagan *et al*, Neuroscience, in press). The goal of this study was to evaluate the duration, magnitude, and distribution of IL-1β production induced by intra-striatal injection of NMDA (10 nmol) in P7 rats. We used a ratspecific IL-1β ELISA to quantify tissue homogenate IL-1β content and immunocytochemistry (ICC) using a monoclonal anti-rat IL-1 β antibody to visualize IL-1 β distribution in the brain. At 2h post-lesioning, IL-1 β increased 3-fold (p<0.001, t-test) over basal levels; concentrations peaked at 6h. Treatment with MK-801(1mg/kg), a non-competitive NMDA antagonist, blocked NMDA-induced IL-1β production. ICC demonstrated that at 6h post-injury IL-1β was concentrated in neurons and ependyma of the lesioned hemisphere. These data provide direct evidence that excitotoxic injury stimulates IL-1β production in vivo

Supported by a grant from the Hearst Foundation (to FSS).

MECLOFENAMATE BLOCKS NMDA RECEPTOR-MEDIATED NEUROTOXICITY IN CORTICAL CELL CULTURES. S.J. Hewett*1, L.L. <u>Dugan²</u>, S.P. Yu², L.M.T Canzoniero², S.L. Sensi² and D.W. Choi² Dept of Pharmacol, Univ. CT Health Center, Farmington, CT 06030; ²Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Previous studies have suggested that free radicals may be important downstream mediators of excitotoxic neuronal death. One plausible source of free radical generation in neurons exposed to excitotoxins is lipid degradation initiated by Ca²⁺ activation of phospholipase A₂, followed by cyclooxygenase and lipoxygenase pathway metabolism. We set out to determine if inhibition of cyclooxygenase/ lipoxygenase pathways would attenuate excitotoxic death in murine cortical cell cultures containing both neurons and astrocytes

We turned to the dual cyclooxygenase/lipoxygenase pathway inhibitor, meclofenamate sodium, used clinically as a non-steroidal anti-inflammatory drug. Neuronal death induced by brief intense exposure to NMDA (200 µM for 5 min) was concentration-dependently decreased by addition of 30-300 μ M meclofenamate. Electrophysiological and 45 Ca 2* flux study indicated that meclofenamate was not an NMDA antagonist. Furthermore, KCl-induced increases in intracellular free Ca2+ were unaffected by meclofenamate (300 µM), arguing that meclofenamate protection was not due to block of voltage-gated calcium channels. Several other inhibitors of cyclooxygenase or lipoxygenase pathways, did not match the strong protective effect of meclofenamate against rapidly-triggered NMDA receptor-mediated neurotoxicity. These results raise the possibility that meclofenamate might be therapeutically useful in neurological diseases associated with excessive NMDA receptor activation

Supported by NIH NINDS grants NS 32636 (LLD) and NS 30337 (DWC).

505.7

EXCITOTOXICITY INDUCED BY EXPRESSION OF NMDA RECEPTORS USING VACCINIA VIRUS IN HUMAN KIDNEY CELLS . J. Renart* M. Díaz-Guerra, M. García-Gallo, C. Moratilla, and M.M. Behrens. Instituto de Investigaciones Biomédicas-CSIC and Departamento de Bioquímica-UAM. 28029-Madrid. Spain.

In order to develop an in vitro excitotoxicity assay the could allow us to generate mutant cell lines resistant to glutamate, we are developing systems to overproduce or express the NMDA receptor subunits R1 and R2A in a

regulated fashion.

By combining transient transfection with constructs containing different NMDA receptor subunits under T7 viral promoters and infection with recombinant vaccinia viruses expressing the T7 RNA polymerase we obtain high levels of expression of the NMDA receptor. In these conditions, NMDAdependent cell death (estimated by cotransfection of a luciferase reporter gene) is only induced if both NR1 and NR2A subunits are cotransfected. Moreover, treatment of the cells with receptor antagonists (APV, MK 801) protects cells from excitotoxicity.

As a complementary approach, we are generating stable cell lines that express NMDA receptor subunits using a tetracycline-dependent system that allows regulation of the amount of protein produced.

EXCITOTOXIC NEURONAL DAMAGE IN ISOLATED RETINAE INVOLVES DE NOI'O NEUROSTEROID SYNTHESIS. P. Guarnen*, C. Casciob, D. Russof, G. De Leod, F. Piccolib and R. Guarnen*, Band SISMEDA, CNR, Inst. Neuropsych. and Inst. of Biology, University of Palermo, Italy.

Isolated retinae have the ability to synthesize pregnenolone (P5) and other neurosteroids. The cytochrome P450scc enzyme responsible of P5 formation is mainly located in retinal ganglion cells where a tonic GABAergic control regulates their steroidogenic activity.

It has been observed that following metabolic stress (ischemia, hypoglycemia, hypoxia), the activation of NMDA receptors leading to retinal degeneration is associated with GABA release from amacrine cells. Moreover, neurosteroids have been shown to modulate NMDA-gated Ca2+ currents. In the present study, we examined whether neurosteroid synthesis may be involved in NMDA-mediated examined whether neurosteroid symmess may be involved in whoth-including neurotoxic events. When isolated retinac were exposed to 1-100 µM NMDA, P5 and P5 sulfate synthesis was increased. The histological evaluation of the retinal damage revealed that the maximum stimulatory effect on neurosteroid synthesis (50 µM NMDA for 30 min) corresponded to an edematous swelling and nuclear pyknosis of neuronal cells in the inner nuclear layer and few cell bodies in the ganglion cell layer. 10 µM MK 801 or 200 µM CPP reverted NMDA effects on the activated neurosteroid synthesis and retinal cytology. Similarly, a reduction of these effects was reported after the addition of a GABAA receptor antagonist, bicuculline (1-100 µM), or 4,4'-diisothiocyano-2,2'-stilbenedisulfonate (400 µM), an anion channel blocker. When isolated retinae were incubated with P5 sulfate (10 µM), cytopathological reactions were observed which closely resemble the excitotoxic damage following NMDA exposure. The results suggest that (i) NMDA receptor stimulation increases neurosteroid synthesis, (ii) this effect is mediated by GABAA receptors, and (iii) neurosteroids newly formed (i.e. P5 sulfate) are implicated in retinal neurotoxicity.

505.6

NITROUS OXIDE, UNLIKE OTHER ANESTHETIC AGENTS, FAILS TO BLOCK MK-801 NEUROTOXICITY V. Jeviovic- Todorovic*, J. Labruyere and J.W. Olney. Depts of Anesthesiology and Psychiatry, Washington Univ Med School, St. Louis, MO.

MK-801 and other antagonists of NMDA glutamate receptors protect neurons against excitotoxic degeneration in conditions such as stroke or head trauma, but against excitotoxic degeneration in conditions such as stoke or lieal training, but these agents also can cause neurotoxic side effects (vacuole formation) in posterior cingulate/retrosplenial (PC/RS) neurons of rat brain. Loss of GABAergic inhibition is a critical feature of the mechanism by which NMDA antagonists cause neurotoxic side effects. Therefore, various agents that facilitate GABA, neurotransmission, including benzodiazepines, barbiturates and anesthetics such as halothane, isoflurane including benzodiazepines, barbiturates and anesthetics such as halothane, isoflurane and propofol, protect against these side effects. While it is desirable to prevent these effects, it is also useful to have anesthetic agents that do not prevent them. For example, in PET or MRI studies investigating the effects of NMDA antagonists on neurons in the brain of non-human primates, it is necessary to anesthetize the subjects with an agent that does not interfere with the GABA_A-linked mechanism of action of the NMDA antagonist. Nitrous oxide, an anesthetic that acts by an unknown mechanism, is not thought to facilitate GABA_A transmission. In the present study we administered nitrous oxide to rats at several concentrations, the highest being 70%, at which concentration the rats were sedated and motionless with reduced response to paw pinch. This level of anesthesia was maintained for 4 hours following administration of MK-801 at a dose (0.5 mg/kg sc) that reliably produces a vacuole reaction in PC/RS neurons. Control rats received this dose of MK-801 without nitrous oxide. Four hours after MK-801 treatment, histological examination of the brains revealed that the control and experimental rats (n = 8 per group) sustained the same degree of injury to PC/RS neurons [217 ± 29 (SD) and 211.6 ± 21 (SD) vacuolated neurons per section in experimentals and controls respectively] Thus, nitrous oxide is an anesthetic that does not interfere with the GABA_A receptorlinked mechanism by which NMDA antagonists injure cerebrocortical neurons Supported by AG 11355, DA 05072 and RSA MH 38894 (JWO).

NMDA-INDUCED EXCITOTOXICITY IN CULTURED HIPPOCAMPAL SLICES. Prabu V. Ayyagari* and Fulton T. Crews. Center for Alcohol Studies and Department of Pharmacology, University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC 27599-

We describe a novel method to investigate NMDA-induced excitotoxicity in the hippocampus. Organotypic hippocampal slices were prepared from 7 day-old rat pups, placed on a membrane at the interface of air and medium and cultured for 7 days. Slices (350 μm) showed intact cytoarchitecture. Hippocampal slices were stained with Trypan Blue, a vital dye that is excluded by living and intact cells. Slices were periodically placed in phosphate buffered saline (PBS) containing 10% Trypan Blue at 37°C for 10 min. Slices were washed 5X in PBS and Trypan Blue staining was quantified using a light box, CCD camera and imaging software. The use of Trypan Blue staining as a measure of cell death was validated by parallel studies that estimated the enzyme Lactate dehydrogenase (LDH) in the medium, and by Hematoxylin Eosin (H&E) staining of the slices. To study excitotoxicity, slices were exposed to $100~\mu M$ NMDA at $37^{\circ}C$ for 30~min followed by a PBS wash and periodic staining and imaging. NMDA induced significant (p < 0.01) cell death in the slices as measured by Trypan Blue staining or LDH release, when compared to control slices exposed to PBS. NMDA-induced cell death was first observed at 4 hours posttreatment and progressed up to 24 hr post-treatment. NMDA-induced excitotoxicity was blocked by a 15 min. pre-treatment with the NMDA antagonist, MK-801. Organotypic brain slices obtained by this simple culture technique, coupled with the use of Trypan Blue staining as a measure of cell death, show great potential in toxicity studies and drug screening protocols. (Supported by NIAAA-AA06069).

TRANSIENT EXPOSURE TO N-METHYL-D-ASPARTATE (NMDA) INDUCES DELAYED NEURONAL DEATH THROUGH APOPTOSIS IN EXPLANT CULTURE OF RAT HIPPOCAMPUS. K. Lee, R. A. Wilson, J. L. Ross, C. Shin¹, Departments of Neurology, Pharmacology and Molecular Neuroscience, Mayo Foundation, Rochester, MN 55905

Excitotoxicity is thought to be a critical mechanism in neuronal injury from a variety of insults including ischemia, trauma and epilepsy. The mode of neuronal death subsequent to the overstimulation of glutamate receptors may take the form of necrosis or a programmed cell death such as apoptosis. We hypothesized that the severity of excitotoxic insult may determine the type of neuronal death, and that delayed neuronal damage is through apoptosis.

Hippocampal explant cultures prepared from 6-10 day old rats were exposed to low (50 μ M) and high (1 mM) NMDA for 30 minutes at 10 DIV. The cultures were then processed at 3, 18, 24, 48 and 72 hours for (1) gel electrophoresis of DNA; (2) TdT dUTP nick end labeling(TUNEL) staining; and (3) acridine orange/ethicium bromide staining.

In cultures exposed to 50 μ M NMDA, DNA fragmentation was evident by TUNEL staining and DNA gel electrophoresis at 24, 48 and 72 hours, but not at 3 or 18 hours. Confocal microscopy with aendine orange/ethidium bromide staining showed nuclear chromatin condensation consistent with apoptosis at the corresponding time points. On the other hand, cultures exposed to 1 mM NMDA showed the pattern of necrosis within hours after the exposure with no evidence of DNA fragmentation.

The results demonstrate that moderate excitotoxic neuronal damage cause delayed neuronal injury through apoptotic process. More severe insult causes immediate necrosis. These findings may eventually lead to a therapeutic window to minimize neuronal damage in acute CNS insults.

NMDA RECEPTOR ANTAGONISTS REVEAL DIFFERENCES IN NMDA- AND GLUTAMATE-INDUCED CALCIUM FLUXES AND NEUROTOXICITY IN VARIOUS BRAIN NEURONS. A. Wägner*, G. Cebers and A. Kalda, Dept of Clinical Neuroscience, Karolinska Institute, Karolinska Hospital, S-17176 Stockholm, Sweden.

Transient periods of ischemia induce excessive release of the excitatory neurotransmitter glutamate followed by neuronal cell death both in in vitro cell cultures and in vivo in the living brain. Accumulated evidence suggests that the release of glutamate triggers a marked inflow of Ca2 into the postsynaptic neurons, an event, which is considered to be involved in glutamate-produced neurotoxicity. In this study we compared the effects of various NMDA receptor antagonists, CGS19755 (Selfotel), CGP39551, and CGP37489 on NMDA/glutamate-induced functional Ca2+ responses (45Ca2+ and [Ca2+]i) and neurotoxicity (LDH activity) in primary cultures of rat cerebellar and cortical brain neurons. Our data indicate that although all the NMDA receptor antagonists were potent inhibitors of NMDA/glutamate-produced Ca2+ responses and neurotoxicity, there were marked differences in their potency between the two types of brain neurons. The observed interneuronal differences in the neuroprotective properties of these agents may be relevant for the observed variations of these drugs in the treatment of ischemia-induced brain lesions in the rat and for the clinical usefulness of these agents in the management of brain damage induced by ischemia in stroke patients.

505.13

GLUTAMATE-INDUCED DEPOLARIZATION OF THE MITOCHONDRIAL MEMBRANE IN CULTURED CENTRAL NEURONS. DEPENDENCE ON Na*. O.V.Vergun, T.P.Storozhevikh, N.P.Vinskaya, V.G.Pinelis and B.L.Khodorov*. Inst. of Gen. Pathology, Moscow 125315, Russia, Inst. of Pediatrics, Moscow 117963, Russia.

Changes in mitochondrial membrane potential were monitored in individual cerebellar granule cells loaded with rhodamine 123 (Rh123); an increase in its fluorescence was considered as a result of mitochondrial depolarization (MD). A prolonged 10-15-min treatment of the culture by 100 μ M glutamate (GLU) (0 Mg²⁺, 10 μ M glycine) induced in most of cells relatively small MD: the Rh 123 fluorescence increased in these cells on the average by about 20% from control.This GLU-induced MD could be greatly (on the average by about 100%) increased by replacement of Na* in the GLU solution by N-methyl-D-glucamine (NMDG). Returning of the cell to the Na*-containing GLU solution led to a partial repolarization of the mitochodrial membrane. Replacement of Na+by Li+ did not enhance the GLU-induced MD. The latter both in Na+- or NMDG- containing solutions was effectively prevented by removal of external Ca²⁺. Control experiments with fura-2-loaded cells showed that a prolonged 100 μM GLU application induced about a 10-fold increase in [Ca²⁺], which did not undergo appreciable changes after replacement of Na* with NMDG. Therefore the observed effects of external Na*removal on the GLU-induced MD were interpreted as a result of [Na+] i lowering which is known to inhibit the mitochondrial Na^*/Ca^{2^*} exchange system. At high $[Ca^{2^*}]$, this inhibition should promote the mitochondrial Ca^* overload culminating in the permeability transition pore opening and mitochondrial depolarization. This process is apparently promoted by an additional cytoplasmic acidification induced by replacement of Na+ with NMDG in the GLU-containing medium (Supported by RFFI and ISF).

HYPOXIA INDUCES TYROSINE DEPHOSPHORYLATION OF NMDA RECEPTOR SUBUNITS AND SUPPRESSION OF SRC-FAMILY KINASE ACTIVITY. Y.T. Wang*, Jodi L. Braunton, Victor Wong and Wei Wang. Dept. Pathol. Hosp. Sick Children, Univ. Toronto, Toronto, Canada M5G 1X8

Pathol., Hosp. Sick Children, Univ. Toronto, Toronto, Canada M5G 1X8.

Overactivation of the N-methyl-D-aspartate (NMDA) type of glutamate receptor has been implicated in brain hypoxia-induced neuronal injury. Because NMDA receptors are phosphorylated and regulated by protein tyrosine kinases (PTKs) and PTK activity can be altered during hypoxia, in the present study we investigated whether the level of tyrosine-specific phosphorylation of NMDA receptor subunits is altered by hypoxic stimulation. Acute hypoxia was simulated in vitro by incubating rat hippocampal slices in glucose-free artificial cerebrospinal fluid saturated with 95% N_2 and 5% CO_2 . Protein tyrosine phosphorylation was analyzed by immunoblotting of slice homogenates. Hypoxic challenge induced a marked decrease in the level of tyrosine phosphorylation of several proteins including a sharp band migrating at 180 kDa. The effect was partially blocked by dephostatin, a membrane-permeable inhibitor of protein tyrosine phosphatases (PTPs), but was not affected by the presence of glutamate receptor antagonists, nor by removing extracellular Ca²⁺. Immunoprecipitation and Western blot confirmed that the 180 kDa tyrosine phosphorylated protein is the 2A/2B subunit(s) of the NMDA receptor, and that upon hypoxic challenge its level of phosphorylation was decreased. Enzyme assays showed that hypoxia resulted in a selective reduction in src-related PTK activity without affecting PTP activity. Thus the present work demonstrates that 2A/2B subunit(s) of NMDA receptors is tyrosine-dephosphorylated as a result of decreased src-family PTK activity under hypoxic conditions and such a change in receptor phosphorylation states may be important for altering NMDA receptor function during brain hypoxic insults. ETHAMBUTOL MEDIATED OPTIC NEUROPATHY IS
MEDIATED THROUGH PERTURBATION OF
MITOCHONDRIAL CALCIUM <u>E. B. Dreyer*</u>, <u>C. Vorwerk, and J. E. Heng</u>, Massachusetts Eye & Ear Infirmary & Harvard Medical
School, Boston, MA, 02114

Ethambutol is a mainstay in the management of tuberculosis and other mycobacterial infections. Although its ability to cause optic neuropathy and visual loss is well known, a mechanism has not heretofore been established. We have established that ethambutol is directly toxic to retinal ganglion cells in vitro, and that this toxicity is mediated through the NMDA receptor. Furthermore, this toxicity appears to involve a perturbation of the mitochondria's ability to buffer cellular calcium levels. Other investigators have demonstrated that the ability of mitochondria to buffer calcium is critical for the cell to resist an excitotoxic challenge. Dissociated neonatal rat retinal ganglion cells, previously labeled with the mitochondrial sensitive dyerhodamine-2, were incubated with ethambutol. Sister cultures were also labeled with the calcium sensitive dye calcium green. Ethambutol caused an approximate doubling in calcium-dependent rhodamine-2 fluorescence over a period of 3-4 minutes. Ethambutol did, however, cause a decrease in calcium green fluorescence, suggesting a decline in cytosolic calcium. Both changes could be blocked with either rotenone or FCCP. These results indicate that ethambutol toxicity is most likely mediated through a perturbation in mitochondrial calcium homeostasis. Supported by the Lions, NIH, Potts & Glaucoma Fnds.

MITOCHONDRIAL REGULATION OF NMDA RECEPTOR-MEDIATED CALCIUM ENTRY AND EXCITOTOXICITY. <u>S.L. Budd* and D.G. Nicholls.</u> Neurosciences Institute, Department of Pharmacology, University of Dundee, Dundee, Scotland, U.K., DD1 98Y.

Neuronal death is caused by Ca²⁺ influx after intense NMDA receptor activation, but the role of Ca²⁺ in the initial intracellular events following an excitotoxic insult remain unclear. This series of experiments sought to clarify the role of mitochondria during NMDA receptor activation in cerebellar granule cells cultured from rats.

Acute exposure of cells to 100µM NMDA in the absence of Mg²⁺ causes calcium loading of mitochondria. Mitochondrially accumulated calcium can then be released following exposure to protonophore. Furthermore, fluorescent monitoring of the mitochondrial membrane potential with rhodamine-123 shows a partial depolarisation of the mitochondria after addition of NMDA.

Exposure of cells to glutamate for 1h results in cytoplasmic Ca²⁺ deregulation and collapse of the cellular ATP/ADP ratio, extensive cell death is seen after just 5h. The mitochondrial respiratory chain inhibitor rotenone (5µM), potentiates Ca²⁺ deregulation by forcing the mitochondrial ATP synthase to reverse in order to support the mitochondrial membrane potential. Cells maintained by glycolytic ATP in the presence of the mitochondrial ATP synthase inhibitor oligomycin also show a cytoplasmic Ca²⁺ deregulation and considerable cell death in response to glutamate indicating that prevention of ATP synthase reversal alone is not neuroprotective. In contrast collapse of the mitochondrial membrane potential and hence mitochondrial Ca²⁺ transport by rotenone plus oligomycin confers complete protection against glutamate excitotoxicity. Thus excitotoxicity is associated with mitochondrial Ca²⁺ accumulation. Cells with depolarised mitochondria maintain a low cytoplasmic free Ca²⁺ concentration in the presence of glutamate and accumulate little "Ca²⁺; this is consistent with a Ca²⁺-mediated feedback inhibition of the NMDA receptor which can be overridden by mitochondrial Ca²⁺ uptake (Sl.B is the recipient of a Medical Research Council studentship.)

PHARMACOLOGY OF THE MITOCHONDRIAL PERMEABILITY TRANSITION PORE (mPTP) IN CULTURED ASTROCYTES AND NON-SYNAPTOSOMAL MITOCHONDRIA. J.M. Dubinsky and B.S. Kristal, Physiology Departments University of Minnesota and University of Texas Health Science Center

The mPTP, associated with hypoxic injury in liver and heart, was studied in 2 preparations. In non-synaptosomal mitochondria isolated from adult rat CNS, decreases in the A450 reflect mitochondrial swelling. In digitonin permeabilized, cultured astrocytes mitochondria were observed microscopically at 530nm with the dye jc-1. Ca-mediated mPTP induction was stimulated by phosphate or phenylarsine oxide but not by tert-butylhydroperoxide. Cyclosporin A (CsA), an inhibitor of liver mPTP, slowed PTP activation in isolated CNS mitochondria. Mitochondrial swelling in astrocytes was only partially prevented by high µM doses of CsA. In both systems, PTP opening slowed substantially in the presence of ADP or ATP. In combination with 1µM CsA, ADP more fully inhibited PTP induction. Ruthenium red (RuR, 10µM), an inhibitor of mitochondrial Ca2+ uptake, prevented Ca2+ induced astrocyte PTP opening. The RuR block was potentiated by addition of 10µM of the Na/Ca exchange inhibitor CGP37157. RuR and CGP37157 were ineffective in 4BrA23187 treated astrocytes where Ca2+ entry was unregulated. Monobromobimane, a thiol crosslinker, prevented mPTP opening in response to oxidants. Supported by the MN Medical Foundation and the MN American Heart Association.

MECHANISMS OF 3-NITROPROPIONIC ACID TOXICITY IN PRIMARY CULTURES OF STRIATAL NEURONS. J.G. Greene*, S-S. Sheu, R.A. Gross, and J.T. Greenamyre University of Rochester Medical Center, Rochester, NY 14642, and Emory University, Atlanta,

We have examined the effects of the succinate dehydrogenase (SDH) inhibitor 3-nitropropionic acid (3NP) on neuronal survival, ATP content, and N-methyl-D-aspartate (NMDA)-induced cytosolic calcium concentration ([Ca²⁺]_c) increases in cultured rat striatal neurons. 3NP caused concentration-dependent ATP depletion and neuronal death following 24 hour incubation. The NMDA antagonist MK-801 prevented the neurotoxicity, but not the ATP depletion, caused by 3NP. Pretreatment of cultures with 3NP (3 mM) for 3 hours did not cause toxicity, but reduced ATP content by 35%. This pretreatment paradigm synergistically enhanced NMDA toxicity, and this enhancement remained pronounced in Mg^{2+} -free solutions. Pretreatment with 3NP did not affect baseline $[Ca^{2+}]_c$ as determined by fura-2 microfluorimetry. NMDA (30 µM) caused a relatively rapid rise in [Ca²⁺]_c, the magnitude of which was not affected by 3NP. However, after a 1 hour treatment, [Ca2+]c was dramatically higher in 3NP-treated neurons. This increased calcium load was washed out slowly and only partially, although calcium in control neurons washed out rapidly and almost completely. These results suggest that in striatal cell culture, the enhancement of NMDA toxicity caused by SDH inhibition may be caused predominantly by disruption of neuronal calcium regulation. THE NEUROPROTECTIVE EFFECTS OF NON-NMDA ANTAGONISTS IN THE SPASTIC HAN WISTAR MUTANT. A.A. Nisim*, M.T. Martin.

M.A. Abdullah and R.W. Cohen. Department of Biology, California State University, Northridge, CA. 91330.

Associated excitotoxicity due to altered glutamate receptor expression has been attributed to neuronal degeneration in many human disorders. The spassic Han Wistar (HW) rat, a possible model of plutamate receptor expression and the control of th of glutamate excitotoxicity, exhibits hyperactivity and fore limb tremor as early as 25 days postnatally. Previous studies with this mutant have shown a progressive loss in Purkinje cells in the cerebellum which is manifested by progressive hind limb paresis and ataxia, culminating in death at approximately 65 days of age. In this study, possible neuroprotection derived from the administration of the AMPA/Kainate receptor antagonist GYKI 52466 hydrochloride (GYKI) in *spastic* HW rats was examined. Starting at 30-32 days of age, the mutants were injected with GYKI (15 mg/Kg) twice a week for three weeks. GYKI-injected mutants (n=6) exhibited increased life span (15%) compared to saline-injected mutants (controls: n=7). GYKI-treated animals showed prolonged weight gain (7% heavier after 45 days of age: 11% heavier after 60 days of age) compared to controls. Motor skill deterioration was monitored by an open-field test which lasted for two minutes. At 50 days, GYKI-treated mutants displayed 24% greater motor skill activity compared to controls. GYKI-treated mutants displayed an improved limb strength as indicated by prolonged periods of hanging on an inverted screen compared to controls at 40 days (23% increase) and 50 days (52% increase). These findings suggest that non-NMDA receptors play a significant role in the observed neurodegeneration in this rat. Supported by a CSUN Research and Sponsored Projects Grant.

ALS-LIKE DEGENERATION OF MOTONEURONS ADMINISTRATION OF L-GLUTAMATE IN THE RAT. SYSTEMIC M. Ishida*, Y. Uyama, T. Saitoh, H. Suzuki and H. Shinozaki. Dept. Pharmacol., The Tokyo Met, Inst. Med. Sci., Tokyo 113, Japan

L-Glutamate has been implicated in the pathogenesis of neuronal damage in the mammalian central nervous system. Systemic administration of high doses of Lglutamate to neonatal rats or mice induces obesity with selective neuron damage in the arcuate nucleus of the hypothalamus and the retina. Recently we found that repeated subcutaneous injection of L-glutamate (4 mg/g/day) in the first 5 - 6 days of life caused irreversible paraplegia in the rat, accompanied by severe muscular atrophy and urinary incontinence. The first signs of parapregia usually begin within 5 days of the first administration of L-glutamate, although, for unknown reason, the incidence of paraplegia was very low (less than 4%) and was not constant. Paraplegic rats did not respond to nociceptive stimuli to lower parts of the body, such as the hindlimbs, the back and the tail. Spinal reflexes, recorded extracellularly from the L3 - L5 ventral roots of 7 day-old paraplegic rats, and induced by electrical stimulation of the dorsal root of the same segment, were considerably decreased, but were still detectable. The cytoarchitecture of the lower spinal cord of the paraplegic rat was much disordered. In the paraplegic rat, ventral roots in lower parts of the spinal cord showed marked atrophy, and the cells of the ventral horn apparently decreased in number. Microscopic observation revealed that the decrease in number of motoneurons first became noticeable about 5 weeks after birth, and developed until 9 - 15 weeks, when most of the motoneurons had disappeared. However, dorsal roots and dorsal ganglion cells in paraplegic rats were intact. The paraplegic rat should provide a useful animal model for elucidating the mechanism underlying certain neurological diseases, in particular, amyotrophic lateral sclerosis (ALS).

THE NEUROPROTECTIVE EFFECTS OF NMDA ANTAGONISTS IN THE SPASTIC HAN WISTAR MUTANT. K.L. Brunson*, A. Khanna, A. Martinez, and R.W. Cohen. Department of Biology, California State University, Northridge, CA. 91330.

We are studying spastic Han-Wistar (HW) mutant rats which develop neurodegeneration in two brain regions (hippocampus and cerebellum). Previous data suggest that the neuronal degeneration is the result of an electronic in distance reconstruction. This work is the first of a

alteration in glutamate receptor expression. This work is the first of a two-part study of the glutamate receptors in the HW mutant. Here, we two-part study of the glutamate receptors in the HW mutant. Here, we analyze the neuroprotective effects of two NMDA antagonists, MK-801 and Ketamine. Mutants were injected (in a two week interval) with either Ketamine (10 mg/Kg) twice a week or MK-801 (1 mg/Kg) once a week starting at 30 days. Both MK-801 injected mutants (n=12) and Ketamine injected mutants (n=6) exhibited longer life spans (27% increase and 10% increase, respectively) compared to saline injected mutants (controls; n=27). Motor skill deterioration was monitored in an open-field test for two minute sessions. After 50 days of age the MK-801 injected mutants displayed 20% greater motor skill activity in the open field test than the controls. Ketamine mutants showed a 39% increase. The neuroprotective effects in the cerebellum were observed with cresyl violet staining of the Purkinje cells. In MK-801 injected mutants there was a 38% increase in Purkinje cells compared to controls. Staining in the hippocampus showed a slight increase in CA3 pyramidal mutants there was a 38% increase in Purkinje cells compared to controls. Staining in the hippocampus showed a slight increase in CA3 pyramidal cells in the MK-801 injected mutants as compared to controls. An increase in spatial learning ability of MK-801 mutants was assessed in a water maze. MK-801 injected mutants (n=3) made 13.3% less errors finding the platform than the controls (n=2), corresponding to the observed pyramidal cell survivorship. The data show that mutants derive protective effects from NMDA antagonists, suggesting a role of glutamate-induced excitotoxicity in neuronal degeneration of our model. This work was supported by CSUN Foundation grants to KLB and RWC.

CHANGES IN PHF- AND GFAP- LIKE IMMUNO-HISTOCHEMISTRY FOLLOWING SYSTEMIC KAINIC ACID INJECTIONS IN RATS. <u>IB Pan *, AL Nikkel, L Bednarz and KE Asin</u>. Neuroscience Discovery, Abbott Laboratories, D-47U, AP9A, Abbott Park, IL

We have examined limbic and cortical pathologic changes in rats systemically injected with kainic acid (KA) by using anti-glial fibrillary acidic protein (GFAP)

injected with Kainic acid (KA) by using anti-gual ribrillary acidic protein (GFAF) and anti-paired helical filament (PHF) antibodies.

Systemic injections of kainic acid (10 mg/kg, se) induced wet dog shakes, tremors and seizures. Rats were sacrificed by perfusion with buffered 4% formaldehyde three, ten, or thirty days post-injection. The brains were sectioned from anterior to posterior at 35 um increments and collected serially. Standard immunocytochemical techniques were used to assess GFAP or PHF expression in cortical and limbic

In rats that survived three days, there was severe tissue damage in the amygdaloid complex. Gross cellular damage that was evident at three days was partly replaced by astroglial cells in the rats sacrificed at ten days. As a consequence of the KA-induced prolonged neuronal depolarization, swelling and neuronal death, resting astrocytes became reactive. Astrocytes within the entorhinal cortex were most obviously involved in these changes. The astrocytes still showed enlarged cell bodies and more thickened processes in rats at ten days post-injection. Interestingly, anti-PHF labeled, degenerating neurites evident in consecutive brain sections from ten-day rats, were no longer evident in sections from thirty-day rats. At thirty days, GFAP+

astrocytes were observed in the neurodepleted area The systemic administration of kainic acid induces not only neuronal damage, as evidenced by increased PHF-like immunoreactivity, but also leads to astrocytic activation. These phenomena may provide a useful animal model for drug discovery efforts in the search for neuroprotective agents

[Supported by Abbott Labs.]

KAINIC ACID INDUCED BEHAVIORAL SYNDROME: CHALLENGE WITH NICOTINIC RECEPTOR LIGANDS. R.D. Shytle*, C.V. Borlongan, and P.R. Sanberg. Div. of Neurological Surgery, Dept. of Surgery, Neurology, Psychiatry and Pharmacology. Univ. of South Flonda Coll. of Med., Tampa, Fl. 33612-4799.

Systemic administration of kainic acid (KA) in rats results in behavioral syndrome characterized by wet dog shakes (WDS), seizures and convulsions. While a number of drugs have been found to either potentiate or prevent this KA-induced syndrome, little is known about the possible influence of cholinergic nicotinic receptor ligands. In the present study, each rat was placed in an open field and pretreated with either saline, nicotine base (0.25-0.5 mg/kg), mecamylamine (0.3-3.0 mg/kg), or lobeline (1.0-10.0 mg/kg) s.c followed 15 min later by 12.0 mg/kg KA s.c. Experimenters blind to the pretreatment conditions counted the number of WDS and scored the occurrence of seizures occurring between 45-180 min. post-KA injection. In contrast to our previous findings under home cage testing conditions, rats pretreated with nicotine exhibited no differences in WDS or seizures relative to rats pretreated with saline. Moreover, mecamylamine, at doses thought to be selective in blocking nicotinic receptors, had no effect on KA-induced WDS or seizures. However, lobeline dose-dependently abolished both KA-induced WDS and seizures. These findings indicate that the testing environment influences the behavioral effects of KA and suggests that lobeline may have neuroprotective properties in animal models of excitotoxicity. (Supported, in part, by grants provided by NINDS, TSA, and the USF President's Council).

DOWNREGULATION OF GIUR2 MRNA IN GERBIL HIPPOCAMPAL CA1 NEURONS IS ASSOCIATED WITH AN INCREASE OF AMPA RECEPTOR

MEDIATED CYTOSOLIC Ca²⁺ AT A LATE POST-ISCHEMIC STAGE.

J. A. Gorter, J. J. Petrozzino", E. Aronica, D. Rosenbaum, M.V.L. Bennett, J. A.

Connor", R.S. Zukin. Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461. "Roche Institute of Molecular Biology, Roche Research Center, 340 Kingsland Street, Nutley, NJ, 07110.

A transient ischemic episode can result in an extensive delayed death of hippocampal pyramidal CA1 neurons. We tested whether Ca2 permeable (GluR2 subunit lacking) AMPA receptors could be a contributing factor to neuronal cell death in the 2-vessel occlusion model of global forebrain ischemia in the gerbil. In situ hybridization revealed that GluR2 mRNA is specifically downregulated in the CA1 region but with a slower time course than previously downregulated in the CA1 region but with a slower time course than previously described after 10 minute four-vessel occlusion in the rat (Pellegrini-Giampetro et al., 1992). Intracellular calcium levels ([Ca²¹]) in individual CA1 pyramidal cells in dorsal hippocampal slices were measured using optical imaging techniques with fura-2 as Ca² indicator. With AP-5 (50 µM), MK-801 (20 µM), TTX (3 µM) and Cd² (100 µM) added in the bathing solution (solution A), a CA1 pyramidal neuron displayed low resting [Ca²¹], in control slices and in 48 and 72 hrs postischemic slices (50-100 nM). Slices were changed to solution A + AMPA (30 µM) and cyclothiazide (10 µM, to prevent desensitization of AMPA receptors). In control and 48 hrs post-ischemic CA1 neurons. AMPA receptor receptors). In control and 48 hrs post-ischemic CA1 neurons, AMPA receptor stimulation did not cause a noticeable Ca²⁺ change. In 72 hrs post-ischemic neurons however, a significant increase was observed. The [Ca²⁺], increased to a mean somatic value of 257±66 nM. These findings suggest that Ca²⁺ permeable AMPA receptors play a role in the mechanisms of delayed neuronal cell death following global ischemia.

GLUTAMATE REGULATES PHOSPHORYLATION OF NEUROFILAMENT HEAVY SUBUNITS BY AMPA/KAINATE RECEPTORS IN RAT SPINAL CORD CULTURES. N. Vartiainen*, K. Kaasinen and J. Koistinaho, A.I. Virtanen Institute, University of Kuopio, P.O.B. 1627, FIN-70211 Kuopio, Finland.

Amyotrophic lateral sclerosis (ALS) is a progressive degenerative disease of motor neurons characterized by a slow loss of upper and lower motor neurons. ALS is largely a sporadic disease, with only 10% of cases being of the familiar form. Increasing evidence suggests that excitotoxicity, autoantibodies to L-type voltage-gated calcium channels (VGCC) and abnormal neurofilament (NF) function contribute to motor neuron loss in the sporadic ALS (sALS). Here we provide immunohistochemical evidence linking the function of kainate (KA) receptors and VGCC to hypophosphorylation of NF heavy subunits in spinal cord (SC) neurons

SC neurons from 14-day old rat embryos were cultured for 10-14 days and processed for immunocytochemistry or Western blotting using monoclonal antibodies recognizing either phosphorylated (pNF-H), nonphosphorylated (nNF-H) or both forms of NF heavy subunits. A 24-h exposure to 2-20 uM KA induced dose-dependent increase in the number of pNF-H neurons; this induction was detectable even following a 3-day exposure to KA. Glutamate (20 uM) dramatically induced NF-H phosphorylation, whereas trans-(1S,3R)-ACPD (20-100 uM) a metabotropic receptor agonist, and NMDA (10 uM) were without clear effects. The KA-induced NF-H dephosphorylation was blocked by CNQX (100 uM), a KA/AMPA-receptor antagonist, and partially prevented by nifedipine, an L-VGCC blocker. The glutamate-induced NF-H phosphorylation was reversed when glutamate (20 uM) was administered in the presence of MK-801 (10 uM), an NMDA-receptor antagonist.

The results indicate that chronic exposure to excitotoxins leads to NF-H dephosphorylation in SD neurons specifically via KA receptors. The alteration in the NF-H phosphorylation involves active L-VGCC. Dephosphorylation enhances the susceptibility of NFs to degradation representing an early change in neuronal injury.

506.4

AMPA INDUCES TWO TYPES OF TOXICITY OF CEREBELLAR PURKINIE CELLS (PCs) IN THE SLICE PREPARATION, Jean C. Strahlendorf and Howard K. Strahlendorf**. Departments of Physiology & Pharmacology*, Texas Tech University Health Sciences Center, Lubbock, TX

PCs are selectively vulnerable to AMPA-induced damage, evincing a type of delayed neurotoxicity referred to as dark cell degeneration (DCD) that morphologically resembles apoptosis. The appearance of DNA laddering produced by nucleosomal breakdown is considered a biochemical hallmark of apoptosis. In cerebellar slices, AMPA (30 µM, 30 min exposure followed by 90 min recovery) induced an early (within 15 min) appearance of DNA laddering as assessed by gel electrophoresis. In addition, aurintricarboxylic acid, which decreases $Ca^{2^{\ast}}$ -dependent endonuclease activity, and cycloheximide, a translational inhibitor, were effective in attenuating AMPAinduced DCD of PCs, further suggesting that DCD may involve a type of programmed cell death. Studies are currently utilizing Hoechst 33258, a fluorescent dye that reveals nuclear condensation/aggregation within apoptotic cells and in situ DNA end nick labeling to detect DNA damage in PC nuclei. AMPA also produces edematous damage (ED) in approximately one third of PCs. Cyclothiazide and diazoxide, two antagonists of AMPA receptor desensitization, reversed DCD and unveiled a fulminating ED. Studies have addressed the ionic nature and pharmacological sensitivity of AMPA-induced ED. These experiments indicate that AMPA can elicit more than one type of degeneration in the same neuronal population and a primary determining factor for the type of toxicity expressed may be AMPA receptor desensitization. Supported by National Ataxia and Whitehall Foundations.

AMPA AND KAINATE RECEPTOR-MEDIATED APOPTOSIS AND NECROSIS IN CULTURED MURINE CORTICAL NEURONS. J. A. Larm, N. S. Cheung and P. M. Beart*. Dept. of Pharmacology, Monash Univ., Clayton, Vic 3168, Australia.

Glutamate receptor-mediated excitotoxicity occurs by over-activation of ionotropic glutamate receptors, particularly those of the NMDA subtype. This study investigated the neurotoxicity of AMPA and kainate (KA) in cultured cortical neurones, and the types of cell death involved. Primary cerebral cortical cultures were prepared from 15d fetal mice in chemically defined, serum-free medium. Immunocytochemistry using neuron-specific enolase and glial fibrillary acidic protein indicated that 95% of cells were neurons. At 6d cultures were exposed to AMPA or KA for 15 min to 24h in antioxidant-free maintenance medium. After a further 1-8h, cellular viability was examined by the MTT procedure, and DNA fragmentation was examined by both the TUNEL technique and agarose gel electrophoresis. AMPA and KA produced concentration-dependent excitotoxicity (EC₅₀ values; 3 & 65 µM) with morphological features of necrosis, including neuronal swelling at 1h, and DNA fragmentation was not observed (8h). LY293558 attenuated the excitotoxicity produced by AMPA, while CNQX attenuated the actions of both agonists. AMPA and KA also produced cell death in cells exposed to fetal calf serum (10%, day zero, 24h) and cycloheximide-sensitive DNA fragmentation, but not neuronal swelling was observed. Excitotoxicity induced by non-NMDA receptors involves necrosis and apoptosis dependent upon experimental milieu. Supported by the NHMRC (Australia).

QUISQUALATE SENSITIZATION IN ANOXIC HIPPOCAMPAL SLICES. L.A. Chase* and J.F. Koemer. Department of Biochemistry, Medical School, University of Minnesota, Minneapolis, MN 55455. Quisqualate sensitization describes a phenomenon in which rat hippocampal CA1 neurons become sensitized to the depolarizing effects of phosphonate analogs of glutamate only after the application of the non-NMDA agonist, quisqualic acid. We found that the potency of L-2-amino-6-phosphonohexanoic acid (L-AP6) for depression of the antidromic population spike is enhanced 6-fold in anoxic quisqualate-sensitized hippocampal slices incubated in the presence of 95% N₂/5% CO₂ (IC₅₀ = 4 μM) in comparison with those which were oxygenated (IC₅₀ = 24 μM). The rate of quisqualate uptake into hippocampal slices, measured by HPLC, does not change in anoxia compared with oxygenated conditions, suggesting that the enhanced potency of L-AP6 observed in anoxia is not a result of increased intracellular quisqualate concentration. Theophylline (200 μM) did not prevent the increase in L-AP6 potency observed in anoxic, quisqualate-sensitized slices suggesting that neither A1 nor A2 adenosine receptor activation caused this effect. Additionally, increasing the extracellular [K¹] had no effect on L-AP6 potency in oxygenated hippocampal slices. In contrast, the IC₅₀ of L-AP6 in quisqualate-sensitized slices does appear to be related to the Nermst potential for Ca² (manipulated by changing the extracellular [Ca²¹] turing anoxia may mediate the observed shift in L-AP6 potency in quisqualate-sensitized slices. Finally, in contrast to oxygenated slices, a 10 min exposure to 2 mM glutamate in anoxic slices partially reverses quisqualate sensitization. We hypothesize that glutamate is a more efficient competitive agonist at quisqualate uptake and release site(s) in anoxia due to the decreased rate of sodium dependent glutamate uptake under these conditions.

DIFFERENTIAL NEURAL VULNERABILITY TO AMPA/KAINATE RECEPTOR-MEDIATED INJURY: ROLES OF Ca* AND FREE RADICAL PRODUCTION. S.G. Carriedo*, H.Z.Yin, and J.H. Weiss. Depts. of Neurology and Psychobiology, U.C. Irvine, Irvine CA 92717.

Neurons possessing Ca²⁺ -permeable AMPA/kainate channels can be identified by a histochemical stain based on kainate stimulated Co²⁺ uptake (Co²⁺(+) cells), and are unusually vulnerable to AMPA/kainate toxicity, probably reflecting rapid Ca2+ entry through these channels. We have previously found GABAergic neurons in cortical cultures (identified by GAD staining; "GAD(+) neurons") and putative motor neurons in spinal cultures (identified by staining with the neurofilament antibody SMI-32; "large SMI-32(+) neurons") to be Co³*(+), and to show greater vulnerability than Co³*(-) cells to AMPA or kainate injury. However, preliminary direct comparison of the vulnerability of these neurons to slow (24 h) AMPA/kainate toxicity suggests that the motor neurons are more vulnerable (10 μM kainate or 2.5 μM AMPA kill about 50% of large SMI-32(+) neurons but < 20% of GAD(+) neurons), supporting the possibility that factors downstream from Ca⁵⁺ entry are contributory. Tyrosine hydroxylase staining labels dopaminergic neurons in midbrain controllory. Tyrosine hydroxylase staining labels object interest controllers. (TH(+) neurons are Co²(-), yet are more vulnerable than most other Co²(-) neurons to slow AMPA/kainate injury, again suggesting a critical role of factors downstream from agonist triggered ion entry.

Toxic effects of free radicals may contribute to degeneration of motor neurons (in ALS)

and dopaminergic neurons (in Parkinson's disease). In preliminary studies using the superoxide sensitive fluorescent dye, hydroethidine, we find kainate to preferentially trigger fluorescence increases in large SMI-32(+) neurons. Ongoing studies aiming to elucidate "downstream" mechanisms that may contribute to the high vulnerability of large SMI-32(+) neurons and TH(+) neurons to AMPA/kainate injury are using fluorescent imaging to see if these cells are relatively deficient their ability to maintain intracellular Ca²⁺ homeostasis, or show unusually high agonist triggered free radical production. CORTICAL CELL CULTURES FROM A TRANSGENIC MOUSE MODEL OF FALS ARE MORE VULNERABLE TO AMPA AND KAINATE TOXICITY

F. Facchinetti", M.E. Gurney*, T.M. Dawson^{1,3} and V.L. Dawson^{1,2,3}.Depts. Of Neurology¹, Physiology² and Neuroscience³. Johns Hopkins School Of Medicine, Baltimore, MD 21287, Upjohn Lab⁴.,

Transgenic mice (line GH1) expressing a human SOD1 containing a gly³³ -ala mutation develop a motoneuron disease similar to familial amyotrophic lateral sclerosis (FALS). To investigate a possible interaction between excitotoxicity and the FALS-SOD1 mutation we compared dose-dependent toxicity of extractive containing and the screen exercise containing and within a device from GHI. glutamate receptor agonists in cortical cell culture derived from GH1 mice vs non-transgenic mice. The human mutated SOD-1 is mice vs non-transgenic mice. The furthal mutated 300-1 is expressed in primary neuronal cultures as assessed by western blot analysis. A more pronounced toxic effect of either kainate (12.5 μ M) and AMPA (5 μ M) is observed in cultures from GH1 mice when compared with controls. Dose-dependent toxicity to either glutamate and NMDA did not significantly differ in GH1 cultures from controls at the 3 concentrations tested (20, 100, 500 μ M). Nitric from controls at the 3 concentrations tested (20, 100, 500 µM). Nitric oxide can react with superoxide to form the highly toxic peroxynitrite. Of the two NO donors, SNP and NOR-3, we observed a small but significant increase of SNP (10, 50 µM) toxicity in cultures from GH1 mice while NOR-3 toxicity is unchanged. Our results suggest a selective vulnerability to non-NMDA agonists of cortical cell cultures expressing a FALS-linked form of human SOD1.

Zn2+ PERMEATION THROUGH Ca2+ PERMEABLE AMPA/KAINATE CHANNELS AND SELECTIVE NEURODEGENERATION. H.Z. Yin*, D.H. Ha and J.H. Weiss. Depts. of

Neurology, and Anatomy and Neurobiology, U.C. Invine, Irvine CA 92717.

Neurons possessing Ca^{3*} -permeable AMPA/kainate channels can be identified by a histochemical stain based on kainate stimulated Co^{3*} uptake (Co^{3*}(+) cells), and are unusually vulnerable to AMPA/kainate receptor-mediated injury. Among neurons which we have found to be highly kainate sensitive and to be Co2+(+) are cortical somatostatin (SS), parvalbumin (PV) and SMI-32 (a neurofilament marker that labels subsets of pyramidal neurons) immunoreactive neurons, and basal forebrain cholinergic neurons (BFCN). The divalent cation, Zn³*, is synaptically released at many excitatory synapses. In prior studies using fluorescent imaging of intracellular Zn³* combined with Co⁵* staining, we found that appears able to permeate Ca2+ permeable AMPA/kainate channels with relative ease.

We have now examined toxic effects of brief kainate and Zn^{**} exposures on cortical SS, PV and SMI-32 neurons, and on BFCNs. Brief (5-15 min) exposures of neuronal cultures to 100 µM concentrations of either kainate or Zn2+ trigger little neuronal injury. However, with Zn* / kainate Co-exposures, relatively little overall injury but substantial damage to cortical SS, PV and SM-32 neurons, and to BFCNs is seen the next day.

Further studies aim to correlate Zn* and Ca* permeation through AMPA/kainate channels

with AMPA/kainate subunit expression in hippocampal neurons. Many large neurons in hippocampal cultures, often with pyramidal morphology, are Co⁵(+), with prominent dendritic Co⁵ staining. Labeling with antibodies to AMPA subunits reveals most of these neurons to lack staining with antibody to GluR2/3, and usually to be GluR4- or GluR1positive. Fluorescent imaging reveals kainate to preferentially trigger Ca* or Zn* accumulation in these neurons. Entry of Ca* or Zn* through Ca* permeable AMPA/kainate channels of some central neurons may serve signalling functions and may contribute to degeneration under certain conditions. Supported by NIH grant NS 30884 and by the Pew scholars program in the biomedical sciences.

CYCLOTHIAZIDE-INDUCED HIPPOCAMPAL INJURY IN IMMATURE RAT BRAIN. W. H. Trescher* Kennedy Krieger Research Institute, Johns Hopkins Medical Institutions, Department of Neurology, Baltimore, MD 21205.

Neurology, Baltimore, MD 21205.

Cyclothiazide, a benzothiadiazide diuretic, selectively inhibits α-amino-3-hydroxy-5-methyl-4-isoxazoleproprionate (AMPA) receptor desensitization. To assess *in vivo* cyclothiazide neurotoxicity, postnatal day (PND) 7 rats received an intrahippocampal injection of one of three doses of cyclothiazide (25 nmol - 250 nmol/0.5 μl). In a second experiment, single doses of chlorothiazide (250 nmol) and hydrochlorothiazide (250 nmol) were injected in the hippocampus. Injury was assessed on PND 14 by comparing regional cross-sectional areas of the dorsal hippocampin on coronal Nissl stained sections. In a areas of the dorsal hippocampi on coronal Nissl stained sections. In a third experiment, in vitro receptor autoradiography was used to evaluate third experiment, in vitro receptor autoradiography was used to evaluate the site of cyclothiazide activity. Cyclothiazide produced dose dependent hippocampal injury with $53.0 \pm 4.3\%$ damage after injection of 250 nmol/0.5 μ l (p < 0.001). Injury produced by chlorothiazide and hydrochlorothiazide was not different than control. With receptor autoradiography, a single concentration of cyclothiazide (100 μ M) reduced [3 H]AMPA binding in the dentate granule cell molecular layer, hilus, and CA3 and CA1 regions by 38% to 48% compared to control (p< 0.001). In contrast, cyclothiazide had no effect on [3H]kainate binding. In summary, cyclothiazide alone produced hippocampal injury in the immature rat brain, likely through selective action at the AMPA receptor. The findings support the hypothesis that receptor desensitization may be a protective mechanism against overactivation of glutamate receptors. Supported by NIH NS01482

MECHANISMS OF KAINATE-INDUCED EXCITOTOXICITY IN

MECHANISMS OF KAINATE-INDUCED EXCITOTOXICITY IN RETINA: UNIQUE ROLE OF CHLORIDE. Q. Chen*, J. Olney, P. Lukasiewicz¹ and C. Romano¹, Dep't. Psychiatry and ¹Dep't. Ophthalmology. Washington Univ. Sch. Med. St. Louis, MO 63110.

Kainate is a powerful excitotoxin in isolated chick embryo retina. We demonstrated last year that this is due to non-desensitizing activation of AMPA-preferring glutamate receptors. Activation of AMPA receptors leads to a Na⁻ or Na⁻√Ca++ influx through cation channels, and the subsequent membrane depolarization may also lead to a Cl⁻ influx through anion channels. In the present study, the role of these ion influxes in excitotoxicity was investigated. Isolated chick retina (embryo 14-15 days) was exposed to kainate for 30 min, and cell damage was assessed 24 hours later by LDH assay. In retina exposed to kainate at 32 μM, Na⁺ omission (Na⁻ replaced by a non-permeable cation, choline) during the kainate exposure provided full protection, whereas Ca⁺+ omission (Ca⁺+ replaced by Mg⁻⁺+, plus 100 μM EGTA) potentiated the neurotoxicity. However, neither Na⁺ omission alone nor the combined Na⁺/Ca⁺+ omission reduced the more severe neurotoxicity by kainate at 320 μM. In contrast, kainate-induced neurotoxicity by kainate at 320 μM. In contrast, kainate-induced neurotoxicity with these findings, whole cell voltage clamp studies in ganglion neurons of salamander retina demonstrated that Cl⁻ constituted a significant component of the whole cell currents induced by kainate, and that replacing extracellular Cl⁻ with methylsulfate modified the currents, presumably by changing the Cl⁻ equilibrium potential. Together, these results suggest that excessive Cl⁻ influx plays a pivotal role in excitotoxicity in the retina. Supported by EY08089, EY08922, EY09370. EY02687.

NR2B SPECIFIC INTERACTIONS BETWEEN HALOPERIDOL AND THE NMDA RECEPTOR Lynch, D.R., Reddy, U., Huang, H., and Gallagher, M.J., Department of Pharmacology and Pediatrics, University of Pennsylvania, Children's Seashore House, Philadelphia, PA 19104-4318 Many compounds which interact with the n-methyl-D-aspartate (NMDA) receptor and modulate its function in a subunit specific manner. The dopaminergic agent haloperidol has been previously shown to exert an 8-10 fold preference for NR2B over NR2A containing NMDA receptors, showing the same subunit dependence observed for the antagonist ifenprodil. We have mapped a determinant of high affinity haloperidol inhibition to the region near amino acid 198 of the NR2B subunit using chimeric NR2A/NR2B receptors. A conserved glutamate residue (E201) in this region was mutated to either asparagine (the residue found in NR2A) or arginine, causing a >10 fold loss in the ability of haloperidol to displace 13-1 MK 801 from these receptors. Mutation to aspartate or alanine caused negligible change in apparent affinity. E201 does not govern the interactions of ifenprodil. Haloperidol interaction is independent from Arg-337, previously shown to cause a 400-fold loss in apparent affinity for ifenprodil. Since haloperidol has been suggested to interact with the strychnine-insensitive glycine site, we also tested the ability of 7-chlorokynurenic acid (glycine site antagonist) to inhibit NMDA-induced currents in oocytes expressing NR1A/E201N mutant receptors, and found no change in the apparent affinity for glycine for these receptors, suggesting that E201 affects haloperidol, but not glycine or ifenprodil interaction with NMDA receptors. (This work was supported by the Grants F32-DA05675, DA07130, and NS01789 from the National Institutes of Health).

PREVENTION OF NMDA-INDUCED BRAIN INJURY IN NEONATAL RATS BY SUBTYPE SELECTIVE NMDA (NR2B) ANTAGONISTS. M.G. Varianian*, P.A. Boxer Neuroscience Therapeutics, Parke-Davis Pharmaceutical Research, Div Warner-Lambert Co., Ann Arbor, MI 48105.

The non-competitive NMDA antagonists, eliprodil and ifenprodil, are selective antagonists of the NR1A/2B subtype of N-methyl-D-aspartate (NMDA) receptors. Haloperidol and trifluperidol are less potent but share this NMDA subtype selectivity, although they are more potent as dopamine D₂ antagonists. Since perinatal rats have a much higher density of NR1A/NR2B (vs NR1A/2A) receptors, we have investigated the effects of ifenprodil, eliprodil, haloperidol, and trifluperidol in a model of NMDA-induced brain injury. In addition, remoxipride, a D2 antagonist with no affinity for NR1A/NR2B receptors was tested to control for non-specific dopaminergic effects. Unilateral striatal microinjections of NMDA (15 nmol/0.5 µl) were performed at postnatal day (PND) 7. Brain injury was calculated on PND 12 by comparing the wet weights of the cerebral hemisphere ipsilateral and contralateral to the injection site. The greatest neuroprotection was seen with haloperidol and eliprodil, which each significantly prevented NMDA-induced injury (67.2 \pm 8.6% and 56.0 \pm 9.5%, respectively; p<0.002) after dosing 3 x 1 mg/kg at hour intervals starting 15 minutes post injection. Ifenprodil and trifluperidol (3 x 1 mg/kg) provided less but still significant protection (35.3 \pm 11.6% and 24.6 \pm 7.3%, respectively; p<0.03, and p<0.002). Remoxipride (2 x 30 mg/kg; dosed 15 min and 2.25 h) was not neuroprotective. These results demonstrate that NR1A/NR2B selective agents are potently neuroprotective in this model of NMDA-mediated brain injury in perinatal rats, although there is not a direct correlation between in vivo potency and affinity at the receptor. INHIBITION OF NMDA-INDUCED BEHAVIORAL RESPONSES BY CP-96,345 IN THE MOUSE. R. A. Velazquez*, K. F. Kitto and A. A. Larson. Dept. of Vet. Pathobiology, University of Minnesota, St. Paul, MN 75108

The non-peptide compound CP-96,345 has been found to inhibit substance P (SP) binding in brain membranes. Several behavioral, physiological and electrophysiological experiments have shown the selectivity of this compound in inhibiting the neurokinin 1 (NK-1) receptor compared to NK-2 and NK-3. Also, CP-96,345 inhibits in a non-stereospecific manner Ca** channels which can account for the non-specific effects seen after the administration of this drug. Intrathecal injections of SP or N-methyl-D-aspartate (NMDA) produce a well characterized caudally-directed biting and scratching (CBS) response that desensitizes following multiple injections. In contrast, repeated injections of kainic acid (KA) increase the number of CBS behaviors. In this study, we examined the effect of 30-min pretreatment with 0.002 to 2.0 mmoles of CP-96,345 on four consecutive intrathecal injections of 22.5 pmoles SP, 25 pmoles KA and 0.3 nmoles NMDA. The number of CBS behaviors were counted over a 2-min interval after each injection. At these dose ranges, CP-96,345 did not inhibit the behaviors elicited by the first injection of SP or KA but it inhibited SP desensitization and KA sensitization to repeated injections in a dose-related fashion. In contrast, at doses as low as 0.02 nmoles, CP-96,345 inhibited NMDA-induced behaviors and blocked NMDA-induced desensitization. The inhibition of NMDA behaviors by CP-96,345 at a dose that failed to inhibit the CBS effect of SP suggest that a non-selective inhibition of Ca** channels may be responsible for these results or that the CBS effect of i.t. injected SP is not mediated by NK-1 sites. [This study was supported by U. S. Public Service Grant DA04090 to AAL.]

PROTECTIVE EFFECTS OF ELIPRODIL IN RETINAL AND NEURONAL CELLS AND TISSUES. I.-H. Pang*, E.M. Wexler, R.J. Walters, M. Reyes, A. Reyes, D.L. Shade, S. Nawy, P.K. Stanton, M.A. Kapin. Alcon Laboratories, Fort Worth, TX 76134 and Departments of Neuroscience, Neurology & Ophthalmology and Visual Sciences, Albert Einstein Coll. Med., Bronx, NY 10461.

Eliprodil, an NMDA-receptor spermine-site antagonist, was tested for its neuroprotective actions in retinal and neuronal cells and tissues. Eliprodil prevented death of cultured rat retinal ganglion cells induced by $100~\mu M$ glutamate with an EC $_{50}$ of 1 nM. At 100 nM of eliprodil, 100% of cells survived the glutamate insult. Eliprodil also protected against glutamate-induced toxicity in differentiated SHSY5Y (human neuroblastoma) cells (CC $_{50}=2$ nM). In both cultured ganglion cells and retinal slices, eliprodil suppressed NMDA (200 μM)-activated currents recorded under patch-clamp.

In rat hippocampal slices in vitro, eliprodil markedly reduced pharmacologically isolated NMDA EPSPs, and protected Schaffer collateral-CA1 synaptic transmission from hypoxia-induced irreversible damage, measured as enhanced recovery of EPSPs following hypoxia (EC $_{50}$ = 500 nM bath applied). In long-term organotypic slice cultures, 5 μ M eliprodil prevented ischemia (hypoxia with hypoglycemia)-induced delayed neuronal death in field CA3, but was much less effective in protecting CA1 pyramidal neurons from cell loss measured with propidium iodide. Thus, eliprodil can be protective against cytotoxic insults by excitatory amino acids or hypoxia in both retinal and neuronal tissues and cells. (Supported by Alcon Laboratories, Inc.)

507.4

PROTECTIVE EFFECTS OF THE POLYAMINE ANTAGONIST, ELIPRODIL HYDROCHLORIDE IN RETINA SUBJECTED TO AN EXCITOTOXIC- OR ISCHEMIC-INSULT. M.A. Kapin*, R. Doshi, L. Chapman, L. Watson, S. Porter, B. Scatton, and M.L. Chandler. Alcon Laboratories, Inc., Fort Worth, TX 76134 & Synthélabo Recherche, Bagneux, France.

Ischemia and excitotoxicity have been implicated in a myriad of retinal and optic nerve head disorders, including glaucoma. In animal models of ocular ischemia or excitotoxicity, N-methyl-D-aspartate (NMDA) antagonists have been shown to ameliorate retinal injury. Presented here is the neuroprotective profile of the polyamine antagonist, eliprodil hydrochloride in retina subjected to ischemia or NMDA administration. Total retinal ischemia, as measured by a cessation of ERG activity, was induced in the anesthetized rabbit by elevating IOP at 140 mmHg for 65 minutes. Following ischemia, restoration of ERG was assessed at 24 and 48 hours in animals (n = 4-6/group) treated i.v. and i.p. with vehicle or eliprodil (1.0-10.0 mg/kg). In vehicle treated animals, A and B waves were suppressed by 60-70% at 24 hours. At 10 mg/kg, eliprodil significantly ameliorated the A and B wave depression throughout the 48 hour experiment. To evaluate retinal excitotoxicity, intravitreal NMDA (5 µl, 20 nmoles) was injected in rats which resulted by 7 days in a dose-related decrease in cells of the ganglion cell layer (GCL) and choline acetyltransferase (ChAT) activity. In animals treated with NMDA but not eliprodil, the loss of cells was 24% and 30%, compared to the non-injected contralateral eyes or vehicle injected eyes in different animals, respectively. At 10 mg/kg, i.p., eliprodil completely prevented the loss of ChAT as well as cells in the GCL. From these results we conclude that eliprodil is neuroprotective of retina subjected to an ischemic or excitotoxic-challenge. (Supported by Alcon Laboratories, Inc.)

SUBTYPE-SELECTIVE ANTAGONISM OF NMDA RECEPTORS BY NYLIDRIN. E. R. Whittemore*, V. I. Ilyin, and R. M. Woodward. CoCensys, Inc., 213 Technology Drive., Irvine, California 92718.

The structurally-related di-substituted piperidines ifenprodil, eliprodil and haloperidol have been shown to exhibit non-competitive subtype-selective antagonism of the NMDA la / 2B receptor combination, as measured in expression systems and in cultured neurons. To further investigate the structural requirements for selective blockade of NR 1a / 2B receptors, we assayed NMDA antagonist activity of the \beta-adrenergic agonist nylidrin, a compound structurally related to ifenprodil in which the piperidine ring has been opened to generate a secondary amine. In Xenopus oocytes expressing cloned NMDA receptors, nylidrin was a potent antagonist of 1a / 2B subunit combinations (IC₅₀ \sim 0.2 μ M) while it was >100-fold weaker at 1a / 2A (IC₅₀ \sim 27 μ M) and 1a / 2C (IC₅₀ \sim 33 μM). Antagonism of 1a / 2B receptors was independent of glycine concentration and associated with a slight increase in apparent affinity for glutamate. Antagonism at the la / 2B subunit was clearly insurmountable with respect to both agonists. Blockade of the 1a / 2B subunit by nylidrin did not exhibit voltage dependence, while blockade of 1a / 2A and 1a / 2C subunits was strongly voltage dependent. Nylidrin also inhibited NMDA responses in primary rat cortical neurons cultured for 7-10 days in vitro, which have been shown to express primarily the 1a / 2B subunit combination. Potency of inhibition in neurons (IC₅₀ - 0.23 μM) was similar to that observed for 1a / 2B receptors expressed in oocytes. Our results suggest that nylidrin is a potent and selective antagonist of the NMDA 1a / 2B subunit combination, and that it may interact with the same allosteric site as previously described for the piperidine compounds mentioned above. Further, nylidrin may be a valuable starting point for directed synthesis in this area (SUPPORTED BY COCENSYS, INC.)

THE EFFECTS OF NEUROACTIVE STEROIDS ON RECOMBINANT NMDA RECEPTORS. N. Yaghoubi*, A. A. Malayev, T. T. Gibbs, and D. H. Farb. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Recent studies have shown that neuroactive steroids can modulate

Recent studies have shown that neuroactive steroids can modulate NMDA receptor responses in cultured neurons. Molecular studies have revealed an important diversity in the NMDA receptor family, which is now known to consist of NR1 and NR2 subunit classes. As a first step towards the characterization of steroid modulation of recombinant NMDA receptors, we have examined the effects of different steroids on NMDA receptors expressed in *Xenopus* oocytes.

Similiar to what has been observed with neuronal NMDA responses, pregnenolone sulfate (PS) was found to potentiate currents through recombinant NR1100:NR2A receptors in oocytes at all NMDA concentrations tested. An EC50 value of $74~\mu M$ was found for PS potentiation of responses induced by 100 μM NMDA. Pregnanolone sulfate ($5\beta3\alpha S$) and epipregnanolone sulfate ($5\beta3\beta S$) were found to decrease the Emax of the NMDA dose-response curve, consistent with a mechanism of non-competitive inhibition. NMDA responses in the presence of 200 μM PS were inhibited by $5\beta3\beta S$ to the same extent as in the absence of PS (EC50 values of 124 μM and 150 μM , respectively), suggesting the existence of independent modulatory sites for inhibitory and potentiating steroids. Preliminary studies have shown that homomeric NR1100 receptors were also modulated by steroids in a manner similiar to modulation of NR1100:NR2A receptors. These results show that expression of recombinant NMDA receptor subunits is sufficient to confer steroid sensitivity. Supported by NIMH MH49469.

(³H)AMPA BINDING AUTORADIOGRAPHY: CYCLOTHIAZIDE BUT NOT BDP-37 HAS LOWER POTENCY IN BRAIN AREAS THAT ARE RICH IN FLOP SUBUNITS. M.S. Mutneja, M. Kessler* and G. Lynch. CNLM, Univ. of California Irvine, CA 92717.

Since AMPA receptors vary across brain regions in regard to subunit composition, drugs that act on these receptors can be expected to have regionally selective effects if they have a preference for certain subunits. The latter question is usually explored using homomeric AMPA receptors expressed in non-neuronal cells. Studies of this kind have indicated in physiological (Partin et al., 1994) and binding experiments (Hennegriff et al. this meeting) that cyclothiazide (CTZ) has about ten times greater affinity for flip isoforms of AMPA receptor subunits. Conversely, BDP-37, a benzoylpiperidine type drug, had a slight preference for flop subunits (Hennegriff et al). The present study examined whether native AMPA receptors in the brain show drug preferences that conform with in situ hybridization results according to which area CA3 and outer cortex appear to have comparatively higher densities of flip isoforms (Sommer et al., 1990). Drug potencies were assessed by measuring the effect on [3H]AMPA binding to rat brain sections. CTZ inhibited binding in hippocampal area CA3 with an EC50 of 24 μ M but had much lower affinity in area CA1 (EC50: 66 μ M). A significant difference was also observed in the cortex with CTZ being more potent in the outer (19 μ M) vs. inner layers (41 μM). BDP-37 exhibited less obvious regional differences but was, if anything, slightly more potent in CA1 and in inner cortical layers. These results show that drug preferences of brain AMPA receptors correspond to those extrapolated from homomeric receptors expressed in non-neuronal cells and demonstrate the usefulness of the latter in investigating drug effects. The data further indicate that benzoyl-piperidine and cyclothiazide type drugs differ in the brain regions they preferentially target; centrally active variants of CTZ might thus produce behavioral effects that differ from those reported for the benzoylpiperidine drugs. (Grant 95-I-0304 from AFOSR and CP-19982 from Cortex Pharmaceuticals)

SUBTYPE-SPECIFIC MODULATION OF STABLY EXPRESSED RECOMBINANT HUMAN N-METHYL-D-ASPARTATE RECEPTORS BY ZINC IONS. S. Grimwood, P.H. Hutson', A.J. Macaulay and T. Priestley. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex CM20 2QR.

Zinc ions (Zn²¹) are known to antagonise native NMDA receptor function in a complex manner which involves both a weak voltage-sensitive component and a voltage-insensitive component. We have investigated the effect of Zn² on cells stably expressing human NR1a/NR2A and NR1a/NR2B receptors using both $^{40}\text{Ca}^{21}$ -influx and whole-cell voltage-clarmp techniques. In the presence of 100 μM L-glutamate and glycine, Zn² inhibited $^{40}\text{Ca}^{21}$ -influx into cells expressing NR1a/NR2B receptors with an ICs0 of 4.66 (4.38, 4.96) μM [geometric mean (-SEM, +SEM) n=4]. Inhibition of $^{40}\text{Ca}^{21}$ -influx into NR1a/NR2A expressing cells by Zn² was concentration-independent over the range 0.3 - 100 μM [54.2 \pm 9.4 % inhibition @ 100 μM (mean \pm SEM, n=4)]. Electrophysiologically, Zn² inhibited both NR1a/NR2A and NR1a/NR2B receptor-mediated currents in a monophasic manner with significantly different ICs0 values of 100 (83.9, 120) μM (n=5) and 6.70 (6.11, 7.35) μM (n=4), respectively (ρ <0.0001, unpaired t test). The electrophysiological results show that Zn² has ~15-fold higher affinity

The electrophysiological results show that Zn² has ~15-fold higher affinity for NR1a/NR2B receptors compared to NR1a/NR2A receptors. However, the manner in which Zn² ions modulate NR1a/NR2A receptor function, as measured by "Ca² influx is not straightforward. The effect of a number of other ligands proposed to inhibit NMDA receptor function through an interaction with the zinc site have also been investigated for subtype-selectivity using the procedures described above.

Distinct Sites for Positive and Negative Modulation of NMDA Receptors by Sulfated Steroids. M. Park-Chung*, F-S. Wu, R.H. Purdy, T.T. Gibbs and D.H. Farb. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston. MA 02118

We have shown previously that the naturally occurring sulfated steroid pregnenolone sulfate (PS) potentiates N-methyl-D-aspartate (NMDA) response at a site distinct from the glycine recognition site. Here we use voltage-clamped chick spinal cord neurons to study further interactions between sulfated steroids and the NMDA receptor. Drug solutions were applied to single neurons by pressure ejection from 7-barrel pipets. Epipregnanolone sulfate (3β-hydroxy-5β-pregnan-20-one sulfate; 5β3βS), which differs from PS only in the presence of a double bond between C-5 and C-6, stereospecifically inhibits the NMDA response. The inhibition of the NMDA response by 5β3βS is a voltage-and agonist-independent, suggesting that 5β3βS does not act as an open channel blocker. Potentiation by PS and inhibition by 5β3βS is also observed in *Xenopus* socytes expressing only NMDAR1 and NMDAR2A subunits. These results argue against the hypothesis that PS and 5β3βS act upon different receptor populations of NMDA receptors. Both PS and 5β3βS act independently of other NMDA receptor modulators such as spermine, arachidonic acid, or redox agents. Surprisingly, 5β3βS and PS is also act independently of each other, suggesting that there are at least two independent steroid modulatory sites that are distinct from previously identified modulatory sites of the NMDA receptor. We suggest that sulfated steroids have the capacity to exert powerful inhibitory and excitatory modulatory effects on nervous system activity through the modulation of NMDA receptors. Supported by NIMH MH49469.

SCN⁻ BLOCK OF AMPA RECEPTORS: INTERACTION WITH THE CYCLOTHIAZIDE BINDING SITE. S.D. Donevan*¹, N.G. Carlson² and M.A. Rogawski³, ¹Dept. of Neurology, ²Dept. of Neurobiology & Anatomy, University of Utah, Salt Lake City, UT 84112 and ³Neuronal Excitability Section, NINDS, NIH, Bethesda, MD 20892.

Previous studies have demonstrated that the chaotropic anion, SCN⁻, non-competitively blocks AMPA-evoked responses (Bowie & Smart, 1993). We sought to evaluate the hypothesis that SCN⁻ blocks AMPA receptors by facilitating desensitization at the site where cyclothiazide reduces desensitization. Whole cell and patch recordings were carried out from cultured hippocampal neurons. Native AMPA receptors in cultured hippocampal neurons were blocked in a concentration-dependent fashion by SCN⁻ (IC₅₀, 1.1 mM). In outside-out patches from these neurons, SCN⁻ enhanced the rate of AMPA receptor desensitization with little effect on the peak AMPA current. Several lines of evidence were consistent with the view that SCN⁻ and cyclothiazide interact at a single binding site. First, cyclothiazide produced a rightward shift of the SCN⁻ concentration-response relationship. Second, SCN⁻ appeared to exhibit a similar subunit selectivity to cyclothiazide as the magnitude of SCN⁻ block was correlated with the degree of cyclothiazide potentiation, which varied over a wide range from cell to cell. Finally, the rate of onset of SCN⁻ block was slowed 100-fold in the presence of cyclothiazide and was similar to the rate of recovery from cyclothiazide potentiation. Taken together, these results support the view that SCN⁻ acts as an inverse agonist at the site where cyclothiazide potentiates AMPA receptors responses and reduces desensitization.

FUNCTIONAL EXPRESSION OF A RAT BRAIN cDNA WHICH ENCODES NAALADase, A GLUTAMATE-GENERATING NEUROPEPTIDASE. R.E. Carter* and J.T. Coyle, Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital and Consolidated Department of Psychiatry, Harvard Medical School, Boston, MA.

There is a growing body of evidence that the N-acetylated alpha-linked acidic dipeptidase (NAALADase) and its neuropeptide substrate N-acetylaspartylglutamate (NAAG) participate in nervous system signaling via glutamate receptors. In order to define the functional relationships of this peptidase and its substrate to glutamatergic communication further, we have undertaken the isolation of NAALADase cDNA clones. We have recently reported the characterization of one NAALADase species, the investigational prostate cancer marker PSM, whose corresponding cDNA was cloned from a prostate cancer cell line (Carter et al. [1996], Proc. Natl. Acad. Sci. U.S.A. 93, 749-753). We have subsequently characterized a NAALADase mRNA expressed in brain by using a combination of immunoscreening and RT-PCR techniques to construct a full-length rat brain cDNA clone. The rat brain clone shows a high degree of sequence similarity to the PSM cDNA, and the two predicted proteins also demonstrate many common structural features. Importantly, transfection of the rat brain cDNA into a NAALADase-negative mammalian cell line (PC3) confers NAAG-hydrolyzing activity which is sensitive to the NAALADase inhibitors quisqualic acid and β -NAAG. Thus, we have extended the molecular characterization of NAALADase species to the nervous system and can now begin to address its expression, and ultimately its function, therein.

RELEASE OF GLUTAMATE FROM PRIMARY SENSORY NEURONS IN CULTURE CAN BE MODULATED BY GROWTH FACTORS M. Rydh-Rinder ^{1,2}, N. Kerekes ², J. Näsström ^{1*} and T. Hökfelt ², ¹ Astra Pain Control AB, Novum Unit 141 57 Huddinge and ² Dept Neuroscience, 171 77 Karolinska Institute, Sweden.

Glutamate (GLU) has been shown to be a sensory neurotransmitter in the spinal cord with a substantial role in nociception. We have studied the effect of different growth factors on potassium (K^+)-, bradykinin (BK)- or capsaicin (CAPS) induced release of GLU from primary sensory neurons in culture. METHOD Dorsal root ganglions (DRG) were dissected from adult male rats, dissociated and plated on 8-chamber slides. The cells received control medium or medium containing either NGF (100ng/ml), BDNF (10ng/ml) or βFGF (10 ng/ml) (3 wells per group), during three days. After a thorough rinse in PBS the cells were equilibrated in ACSF during 5 minutes prior to stimulation and were then subsequently exposed to ACSF containing K^* (60mM), BK (1 μ M) or CAPS (10 μ M). Controls received pure ACSF. Samples were drawn after 15, 30, 60, 120 and 300s. GLU levels were determined using HPLC. Additional experiments were performed using glial cultures derived from peripheral nerve. RESULTS: In cultures treated without growth factors a 6-fold increase was seen after BK stimulation compaired to basal release. All growth factors reduced the BK evoked release, BFGF being the most potent showed almost a total depletion of the response. Capsaicin only induced a minor increase in 0-treated cultures while K+ stimulation only revealed a small increase of GLU levels in the β FGF group. Glial cultures did not exhibit any increased GLU release upon BK stimulation. CONCLUSION: The release of GLU may be regulated by growth factors, whether this is a direct effect or mediated by induction of other regulatory mechanisms remains to be clarified.

EXCITATORY AMINO ACIDS: PHARMACOLOGY-SYNAPTIC RECEPTORS

FUNCTIONAL AND PHARMACOLOGICAL PROPERTIES OF AMPA RECEPTORS IN TYPE I AND TYPE II CULTURED RAT HIPPOCAMPAL NEURONS. M.A. Rogawski* and S.D. Donevan². Neuronal Excitability Section, NINDS, NIH, Bethesda, MD 20892 and ²Dept of Neurology, University of Utah, Salt Lake City, UT 84112.

The majority of cultured rat hippocampal neurons (Type I) show Ca²⁻-impermeable, outwardly rectifying AMPA receptor responses. However, recent studies (Iino et al., 1990) have identified a small population of hippocampal neurons (Type II) that have reduced expression of the GluR2 AMPA receptor subunit and exhibit inwardly rectifying, Ca²⁻-permeable AMPA responses. We have used whole cell and outside-out patch recording techniques to compare the functional and pharmacological properties of AMPA receptors of Type I and Type II neurons. The degree of rectification of kainate-evoked AMPA receptor responses was well correlated with the extent of Ca²⁺ permeability as assessed by reversal potential measurements in a high Ca²⁺/0 Na² extracellular buffer. The time course of desensitization of AMPA responses in outside-out patches from Type II neurons was almost two-fold faster (τ_{des}-5 ms) than in patches from Type II neurons and the extent of desensitization was greater in Type II neurons, suggesting that Type II neurons contain predominately flop subunits. Accordingly, cyclothiazide produced only a two-fold potentiation of kainate currents in Type II compared with the 8-fold potentiation in Type I neurons. The arthropod oxin philanthotoxin produced a potent use- and voltage-dependent block of Ca²⁺-permeable AMPA receptors of Type II neurons. In contrast, the use-dependent blocker pentobarbital and the competitive antagonist NBQX exhibited moderate selectivity for AMPA receptors in Type I neurons. The allosteric antagonist GYKI 52466 was equieffective at AMPA receptors of both cell types These studies demonstrate that native Ca²⁺-permeable AMPA receptors differ functionally and pharmacologically from the more common Ca²⁺-impermeable type. It may be possible to exploit these differences in the development of novel therapeutic agents that selectively target Ca²⁺-permeable AMPA receptors

GLUTAMATE RECEPTOR FUNCTION DETERMINED BY STIMULATION OF RUBIDIUM FROM MOUSE HIPPOCAMPAL SYNAPTOSOMES. <u>Jeanne M. Wehner* and Ying Lu</u>. Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309.

The ability of glutamate receptor agonists to activate ion channels resulting in Na+ and K+ fluxes has been used to develop a functional assay of mouse hippocampal synaptosomes. The efflux of 86Rb+ from synaptosomes was monitored by a B-RAM radioactivity HPLC detector using continuous superfusion methods. Ion flux was evoked in a concentration dependent manner by glutamate receptor agonists, glutamate, kainate, AMPA, and quisqualate upon a 2-sec stimulation. The EC50 values for these agonists were in the range of low uM, similar to those obtained in other functional assays. Pharmacological antagonisms were demonstrated by showing that CNQX shifted the kainate concentration-response curve to the right in a parallel manner. Cyclothiazide, an AMPA receptor modulator, augmented the ion flux mediated by AMPA and quisqualate. Ethanol (25-200 mM) inhibited kainate-mediated 86Rb+ flux from hippocampal synaptosomes. These results indicate that a glutamate-receptor-mediated ion flux can be measured in hippocampal tissues and that the ion flux should serve as a useful assay to examine the effects of ethanol and other drugs on glutamate receptor function in the central nervous system. Supported by AA-03527, AA-00141, and MH-48663.

PDC-STIMULATED STRIATAL GLUTAMATE RELEASE IS ATTENUATED BY REDUCING EXTRACELLULAR CALCIUM AND BLOCKING GLUTAMATE RECEPTORS. S.M. Rawls* and J.F. McGinty. Dept. Anatomy & Cell Biology, East Carolina Univ. School of Medicine, Greenville, NO 27858-4354.

L-trans-pyrrolidine-2,4-dicarboxylic acid (PDC) reverses plasma membrane glutamate transporters and elevates extracellular glutamate levels in vivo. We hypothesized that PDC-stimulated glutamate release is partially mediated by an increase in transynaptic activity. Therefore, the possible involvement of calcium-dependent glutamate release and glutamate receptor stimulation was investigated via reverse dialysis of (1) reduced calcium ACSF, (2) CPP, an NMDA receptor antagonist, or (3) LY293558, a kainate/AMPA antagonist via reverse microdialysis. The reduced calcium did not alter basal glutamate levels; however, a significant attenuation of 1mM PDC-evoked glutamate release was observed. In separate experiments, 100 uM CPP or 100 uM LY293558 administration significantly attenuated PDC-evoked glutamate release without altering basal levels. These data suggest that glutamate transporter reversal by PDC evokes glutamate release, resulting in postsynaptic glutamate receptor stimulation and elevated striatal output. This would indirectly lead to increased thalamostriatal and cortiostriatal activity which would contribute to the PDC-stimulated increase in extracellular glutamate levels. Reduction of extracellular calcium would directly decrease action potential-dependent glutamate release. In addition, glutamate receptor blockade would reduce medium spiny neuronal firing and indirectly attenuate thalamostriatal and corticostriatal activity, resulting in an overall depression of PDC-stimulated glutamate levels. Supported by DA 09256.

NMDA-LIKE GLUTATHIONE-STIMULATED INCREASES IN INTRACELLULAR CALCIUM, ([Ca]i) IN THREE BRAIN REGIONS: INHIBITION BY ETHANOL. W. R. Wilson* and S. W. Leslie. Division of Pharmacology and Toxicology, College of Pharmacy. The University of Texas, Austin, TX 78712.

In the continuing effort to understand ethanol's interaction with NMDA receptors we have examined further the NMDA-like stimulated increases in [Ca]i produced by both reduced (GSH) and oxidized (GSSG) elutathione in cerebellar, cortical and hippocampal

In the continuing effort to understand ethanol's interaction with MMDA receptors we have examined further the NMDA-like stimulated increases in [Ca]i produced by both reduced (GSH) and oxidized (GSSG) glutathione in cerebellar, cortical and hippocampal brain regions. Acutely dissociated rat pup neurons were loaded with fura-2 to monitor GSH/GSSG-stimulated increases in [Ca]i. ethanol inhibition of the response was also examined. Both GSH and GSSG produced concentration dependent, saturable increases in [Ca]i. The response in cerebellum was significantly less than the response in cortex and hippocampus. In addition, GSSG was more efficacious than GSH, producing a maximal response that was almost 2-fold greater than GSH in all brain regions. Furthermore, the GSSG maximal response was comparable to the maximal response produced by NMDA (100µM). Ethanol inhibition of GSH/GSSG-stimulated increases in [Ca]i was more potent in cortex and hippocampus than in cerebellum. The results demonstrate brain region differences in GSH/GSSG-stimulated increases in [Ca]i, that GSSG is more efficacious than GSH and that ethanol is not as effective an inhibitor of GSH/GSSG-stimulated changes in [Ca]i as it is of NMDA-induced changes in [Ca]i.

INTERACTIONS OF HALOTHANE AND CLONIDINE ON THE HIPPOCAMPAL POPULATION SPIKE AND ALTERATIONS BY PICROTOXIN M. D. Sokoll * T. Gerhold and L.R. Davies. Department of Anesthesia Laboratories, University of Iowa College of Medicine, lowa City, IA 52242.

The mechanisms of the mode of action of inhalation

anesthetics remains to be elucidated. Clonidine, an a 2 adrenergic agonist has long been used as an adjunct in veterinary anesthetics and is reported to decrease the minimum alveolar concentration of the anesthetic Dexmedatomidine, a similar acting agent is now being studied in man. We examined the effects of clonidine on the amplitude, latency and slope of onset of the hippocampal slice CA1 population spike (PS). Clonidine was studied at concentrations of 10,30 and 100µM with and without the prior application of 1% halothane. Clonidine was also applied after picrotoxin (30µM).

Clonidine alone produced a dose related decrease in the population spike amplitude. When applied after halothane there was a further decrease in amplitude. The prior application of picrotoxin produced a partial inhibition of the clonidine induced PS amplitude decrease. Clonidine augments the effect of halothane. This may be partially Supported by the Department of Anesthesia Trust Fund and NiH grant RO1 GM38541

STEREOSELECTIVITY OF 2.3-BENZODIAZEPINES ON AMPA RECEPTORS AND SYNAPTIC EVENTS ON NEONATAL RAT SPINAL NEURONES. <u>D. Lodge, N.A. Moore* and M.L. Woolley,</u> Lilly Research Centre, Windlesham, Surrey. GU20 6PH, U.K. Glutamate receptors mediate fast and slow synaptic excitation in the

CNS. The role of AMPA receptors in these two phases of synaptic transmission and the stereoselectivity of 2,3-benzodiazepines were examined by testing the (+) and (-) isomers of LY300168 (GYKI 53655) on dorsal root to ventral root reflexes (DR-VRR) in hemisected spinal cords of 3-6 day old rats.

The fast paucisynaptic and slow polysynaptic phases of the DR-VRR were blocked by (-)-LY300168 with EC50s of approximately 2 and 10 uM respectively. The (+) isomer, up to 20uM, did not reduce either fast or The NMDA antagonist, CPP 100uM, reduced the fast and slow phases by about 5 and 30% respectively.

In nominally magnesium-free medium, (-)-LY300168 10uM and CPP 100uM each reduced the fast phase of the DR-VRR by less than 20%, and each reduced the slow phase by 0 and 65% respectively. The two antagonists applied together, however, produced a near complete abolition of both phases of the DR-VRR.

Responses to exogenous application of AMPA 3uM, but not those of NMDA 30uM, in control medium were reduced by (-)-LY300168 with an IC50 of about 1uM whereas CPP, IC50 versus NMDA of about 0.3uM, had the reverse selectivity and (+)-LY300168 was inactive.

The present results demonstrate the stereoselectivity of 2,3benzodiazepines as AMPA antagonists and the co-activation of AMPA and NMDA receptors in both fast and slow phases of the DR-VRR in neonatal rat spinal cords

NPS 846-HCI, A NOVEL OPEN-CHANNEL BLOCKER OF THE NMDA RECEPTOR: IN VIVO CHARACTERIZATION. A.L. Mueller 1*, L.D. Artman 1, H. Li 2, R.L. Balster 2, D. Taylor 3 and T.N. Parks 3. NPS Pharmaceuticals, Inc. 420 Chipeta Way, Salt Lake City, UT 84108, 2Dept. of Pharmacology and Toxicology. Medical College of Virginia, Richmond, VA 23298, 3Dept. of Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake

City, UT 84132.

NPS 846 HCl, a small synthetic molecule (FW 283), is a novel open-channel of this meeting). NPS 846 HCl blocker of NMDA receptors (L.D. Artman et al., this meeting). NPS 846 HCl possesses neuroprotectant and anticonvulsant activities in the dose range of 1-3 mg/kg i.p. (Y. Chien et al., this meeting). In the present study, no behavioral symptoms were observed when NPS 846·HCl was administered to freely moving rats at doses up to 10 mg/kg i.p. The administration of NPS 846·HCl at doses of 30 mg/kg i.p. and above elicited a characteristic behavioral syndrome consisting of hyperexcitability, increased reactivity to touch, increased muscle tone, and tremors. MK-801-like behaviors (head weaving, backwards shuffling) were rarely observed. NPS 846·HCl, at doses up to 10 mg/kg i.p., did not substitute for PCP in rats trained to discriminate PCP (2 mg/kg) from saline. The 10 mg/kg i.p. dose of NPS 846-HCl produced a marked decrease in overall response rates, indicating that this dose was behaviorally active. MK-801, used as a positive control, fully substituted for PCP at doses of 0.075 and 0.15 mg/kg i.p. The potential for NPS 846-HCl to induce neuronal vacuolization was examined as well. NPS 846-HCl produced no vacuoles in neurons of the retrosplenial and cingulate cortices of rats (0 out of 2 rats treated with 10 mg/kg i.p. and 0 out of 3 rats treated with 30 mg/kg i.p.). MK-801 (5 mg/kg i.p.) produced vacuoles in 6 out of 7 rats. The absence of vacuolization is consistent with the unique behavioral profile of NPS 846 HCl. Taken together, these results demonstrate that NPS 846 HCl, a novel NMDA receptor anta does not elicit the in vivo profile characteristic of most open-channel NMDA

NMDA-ANTAGONISTS MODULATE LOCAL INHIBITORY CIRCUITS IN A DOSE-DEPENDENT MANNER. H.C.R. Grunze^{1,2}, D.G. Rainnie¹, M. Berger², R.W. McCarley¹, Brian F. O'Donnell¹, and R.W. Greene¹. ¹Harvard Medical School & VAMC Brockton, Brockton MA 02401. ²Psychiatrische Universitätsklinik, 79104

e have previously reported the occurrence of an NMDA-dependent modulation of local inhibitory circuits in area CAI of the rat hippocampus (Grunze et al., 1996), whereby NMDA antagonists could suppress evoked IPSP's, as well as their LTP. Here, we further characterize the dose-dependency of the IPSP amplitude suppression in response to bath application of the specific NMDA antagonists APV, PCP, and NAAG. The IPSP amplitude, evoked in response to alvear stimulation, was measured from whole cell patch clamp recordings obtained from CAI pyramidal neurons manually held at - 60 mV. Results are given as the percentage decrease of the baseline IPSP ampli

(± SE) in the presence of increasing concentrations of antagonist.

For APV: 0.4µM- 12±13%; 1µM- 8±16%; 1.5µM- 12±9%; 3µM- 15±3%; 5 µM- 15±4%; 10µM- 36±13%; 25µM- 31±9%; 50µM- 47±9%.

For PCP: 10µM- 24±21%; 25μM- 9±16%; 50μM- 46±6%; 100μM- 48±19%. PCP also has antagonist activity at the sigma opioid receptor, hence, we examined the response to PCP in the presence of the nonspecific opiate antagonist, naloxone. In the presence of naloxone (10µM), 50µM PCP reduced the IPSP amplitude by 40% which is close to that observed in control ACSF. In 4/8 neurons tested, the non-NMDA antagonist, DNQX (5µM), CONITO ACSP. In 4/6 neurons tested, the information among and abolished the IPSP completely, and in the other 4 neurons by 80±22% when compared to baseline values. The endogenous mixed NMDA antagonist NAAG was also capable of reducing the IPSP amplitude by -11±9% at 50µM and -43±15% at 100µM, respectively. Furthermore, in 2/4 neurons tested at 50µM PCP, and in all 4/4 neurons tested at 100µM PCP, a pronounced and reversible increase, up to 50 ms, was observed in the action potential duration evoked in response to depolarizing current injections. Taken together, these results emphasize the role of NMDA receptor activation in generating local inhibitory IPSP's at physiological resting membrane potentials. NPS 846-HCI, A NOVEL OPEN-CHANNEL BLOCKER OF THE NMDA RECEPTOR: IN VITRO CHARACTERIZATION. L.D. Artman¹, B.C. Van Wagenen 1, M.F. Balandrin 1, E.G. DelMar 1, L.G. Hammerland 1* S.D. Donevan 2, M.A. Rogawski 3, K. Williams 4, and A.L. Mueller 1, 1NPS Pharmaceuticals, Inc. 420 Chipeta Way, Salt Lake City, UT 84108, ²Dept. of Neurology, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132, ³Epilepsy Res. Branch, NIH, Bethesda, MD 20892, and ⁴Dept. of Pharmacology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104.

NMDA receptor (NMDAR) antagonist activity was determined in vitro in a fura2-based assay of cytosolic Ca²⁺ in rat cerebellar granule cells (RCGCs) and a NMDA receptor (NMDAx) antagonist activity was determined in thriro in tura2-based assay of cytosolic Ca²⁺ in rat cerebellar granule cells (RCGCs) and a [³H]MK-801 binding assay. 3,3-diphenylpropylamine (DPPA), obtained from a commercial source, possessed modest potency in the RCGC assay (IC₅₀ = 435 nM). Initial medicinal chemistry efforts on this lead compound led to the preparation of NPS 846-HCl (3,3-bis(3-fluorophenyl)-1-propylamine HCl; FW 283) with a 6-fold increase in potency (IC₅₀ = 72 nM). Each compound was less potent in the [³H]MK-801 binding assay (IC₅₀s = 2.1 μM and 285 nM, respectively). MK-801 was equipotent in both assays (IC₅₀s = 5 nM). DPPA and NPS 846-HCl were noncompetitive with respect to either NMDA or glycine in RCGCs. DPPA and NPS 846-HCl blocked Ig in N1E-115 cells and L-type Ca²⁺ channels in RCGCs at concentrations ranging from 3-10 μM. Patch clamp studies in hippocampal pyramidal cells demonstrated that DPPA and NPS 846-HCl were selective for NMDARs over non-NMDARs and that their actions were use- and voltage-dependent, and occluded by Mg²⁺, indicative of open-channel blockade. The NMDAR subtype selectivity of NPS 846-HCl was examined using a Xenopus occyte expression system (NR2A, NR2B, NR2C and NR2D subunits coexpressed with NR1A). NPS 846-HCl (1 μM) inhibited all subtypes equally; MK-801 (30 nM) preferentially inhibited NR2A and NR2B. NPS 846-HCl possesses neuroprotectant and anticonvulsant activities (Y. Chien et al., this meeting) and an in vivo profile distinct from that of most open-channel blockers (A.L. Mueller et in vivo profile distinct from that of most open-channel blockers (A.L. Mueller et al., this meeting)

NEUROPROTECTANT AND ANTICONVULSANT PROPERTIES OF NPS NEUROPROTECTANT AND ANTICONVULSANT PROPERTIES OF NPS 846-HCl. A NOVEL NMDA RECEPTOR ANTAGONIST. Y. Chien! J. L. Raszkiewicz!*, S. Draper!, H.S. White², and A.L. Mueller!. ¹NPS Pharmaceuticals, Inc. 420 Chipeta Way, Salt Lake City, UT 84108 and ²Dept. of Pharmacology, University of Utah School of Medicine, Salt Lake City, UT 84132. NPS 846-HCl. a small synthetic molecule (FW 283), is a novel open-channel blocker of NMDA receptors (L.D. Artman et al., this meeting). To test its potential neuroprotective effects in vivo. NPS 846-HCl was administered (1 mg/kg i.p.) at different times after ischemic insult in male adult Wistar rats subjected to a

2-hr intraluminal occlusion of the middle cerebral artery (the suture model). In all cases, a second dose was administered 5-6 hrs after the first dose. Total, cortical, and striatal infarct volumes were measured by 2,3,5-triphenyltetrazolium staining 48 hrs after suture occlusion. Compared to saline-treated controls, NPS 846-HCl reduced the total infarct volume (corrected for edema) by 71% (p < 0.05), 64% (p < 0.05) and 46% (p < 0.05) when given immediately, 1 hr, or 2 hr after the onset of cerebral and 46% (p < 0.05) when given immediately, 1 hr, or 2 hr after the onset of cerebral ischemia, respectively. The neuroprotective effects of NPS 846-HCl were observed both in cortex and striatum. No apparent behavioral side effects were noted in this study (see also A.L. Mueller et al., this meeting). The anticonvulsant activity of NPS 846-HCl was determined in the Frings audiogenic mouse model of reflex epilepsy. NPS 846-HCl produced a dose-dependent reduction in the seizure score with an ED50 of 2.1 mg/kg i.p. NPS 846-HCl was active in this model following oral administration as well, with an ED50 of 9.7 mg/kg p.o. Motor toxicity was determined by rotorod; TD50 (toxic dose) values were 19.9 mg/kg i.p. and 21.8 mg/kg p.o. These results demonstrate the neuroprotective efficacy of NPS 846-HCl in this rat model of temporary focal ischemia, and suggest that this novel NMDA receptor antagonist possesses a therapeutic window of opportunity of at least 2 hrs. The compound also possesses anticonvulsant activity with a favorable therapeutic index in the Frings audiogenic model of reflex epilepsy. index in the Frings audiogenic model of reflex epilepsy.

KINETICS OF SPONTANEOUS MINIATURE EXCITATORY POSTSYNAPTIC CURRENTS IN PRESENCE AND IN ABSENCE OF CYCLOTHIAZIDE. B. Atassi¹, J.-M. Godfraind*³ and M.I. Glavinovic^{1,2} Departments of Anaesthesia Research¹ and Physiology², McGill University, Montreal, P.Q. H3G 1Y6 Canada, and Departments of Physiology3 and Pharmacology3, Universite Catholique de Louvain, Brussels, Belgium.

It is still controversial whether desensitization of AMPA receptors plays any role in shaping the time course of the fast component of spontaneous excitatory unitary postsynaptic currents (mEPSCs). Similar duration of the time constants of desensitization in outside-out patches and of mEPSCs in whole cell recordings argues for such a role, but implies that transmitter concentration remains high and essentially constant throughout the synaptic cleft (Edmonds et al., Ann. Rev. Physiol. 57, 495, 1995). Prolongation of mEPSCs by compounds that suppress desensitization may be partly due to slower deactivation. We examined in rat hippocampal pyramidal cells (CA1 region; 12 cells) how the relationship between the amplitude and the kinetics of mEPSCs changes as desensitization is suppressed by cyclothiazide (0.1 mM). Both rise (τ_r) and decay (τ_d) times of mEPSCs become much more amplitude dependent in cyclothiazide (slopes increased from 0.12 to 0.67 ms/pA and from 0.40 to 2.09 ms/pA for $\tau_r s$ and $\tau_d s$ respectively; $V_H = -50 \text{ mV}$ 32 °C) with membrane depolarization (from -100 to -50 mV; slopes increased from 0.01 to 0.12 ms/pA and from 0.04 to 0.40 ms/pA for $\tau_r s$ and $\tau_d s$ respectively; T = 32 °C), and with lower temperatures (from 32 to 22 °C; slopes increased from 0.12 to 0.42 ms/pA and from 0.40 to 1.30 ms/pA for τ_s and τ_d s respectively; $V_H =$ -50 mV). No upward shift of the kinetics vs amplitude relationship was observed in cyclothiazide arguing that it does not affect channel deactivation. These observations support the proposition that desensitization plays an important role in shaping the time course of mEPSCs.

DICARBOXYPHENYLGLYCINES AS SELECTIVE ANTAGONISTS OF AMPA-INDUCED DEPOLARIZATIONS IN NEONATAL RAT MOTONEURONES. D. E. Jane, N. K. Thomas, M. Gardener and J.

Watkins* Pharmacology Dept, University of Bristol, Bristol, BS8 1TD, U.K.
Ionotropic glutamate receptors have been categorized in three main groups according to the selective agonists that activate them, the N-methyl-D-aspartate (NMDA), (S)-2-amino-3-(3-hydroxy-5-methylisoxazol-4-yl)propanoic acid (AMPA) and kainate receptors. It is known that both AMPA and kainate induce depolarizations in neonatal rat spinal motoneurones. However selective antagonists capable of discriminating between the effects of these two antagonists are not widely available. Although Pook et. al. (Br. J. Pharmacol. 1993, 108: 179) have reported that 6-nitro-7-sulphamobenzo(f)quinoxaline-2,3-dione (NBQX) has a 12-fold selectivity as an antagonist of AMPA- vs kainate-induced spinal motoneuronal depolarization, additional, and preferably more selective antagonists would be useful particularly in view of the diversity of sub-types of AMPA and kainate receptors now known to exist. As part of a search for such mpounds we report the actions of (RS)-3,4-dicarboxyphenylglycine (3,4-DCPG) and (RS)-3,5-dicarboxyphenylglycine (3,5-DCPG) on AMPA- and kainate-induced motoneuronal depolarizations in the neonatal rat spinal cord preparation. Both 3,4-DCPG and 3,5-DCPG antagonized AMPA-induced depolarizations (apparent $K_D = 137 \pm 20 \mu M (n=3)$ and $167 \pm 13 \mu M (n=5)$ respectively). However, 3,5-DCPG (1 mM) weakly potentiated responses to kainate while 3,4-DCPG (1 mM) displayed very weak antagonism of these responses. It is likely that an increase in potency and AMPA receptor selectivity will be observed once the individual enantiomers have been synthesized and tested. This work is in progress, together with an investigation of the actions of the substances on metabotropic glutamate receptors.

ETHANOL DEPRESSES GLUTAMATE AMPA AND NMDA RECEPTOR-MEDIATED TRANSMISSION IN NEONATAL RAT SPINAL CORD. J. J. Kendig*, E. G. Fong and S. M. E. Wong. Department of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305

Ethanol, an intoxicant, is also a general anesthetic agent, preventing movement in response to a noxious stimulus, a spinal effect. The effects of ethanol were examined in isolated 1-7 day old rat spinal cord on the monosynaptic reflex (MSR) (AMPA+compound action potential); slow ventral root potential (sVRP)(NMDA+metabotropic); dorsal root potential, (DRP)(GABAA via glutamate-excited interneurons); and population EPSP, (pEPSP)(AMPA+NMDA, see abstract by D.L. Tauck and J.J. Kendig). At a general anesthetic concentration (130 mM) ethanol significantly (P<0.05) depressed MSR amplitude (86.0%±6.15 of control, mean ± SE), sVRP area (30% ± 1.51), DRP area (59.0% ± 3.47) and pEPSP area (62.4%±5.15). Effects were selective for NMDA versus metabotropic receptor-mediated sVRP components (P<0.01) and for NMDA versus AMPA-mediated pEPSP components (P<0.05). In the integrated spinal cord ethanol (1) depresses both AMPA and NMDA neurotransmission, NMDA more than AMPA and (2) ethanol depressant effects on glutamate excitatory transmission override GABAA enhancement when the GABAA-mediated DRP is evoked via glutamateactivated interneurons. 508.12

IN VIVO EVALUATION OF AMPA ANTAGONISTS IN THE CAT REGION OF HIPPOCAMPUS IN RATS C. Mathiesen, M. Lauritzen, J. Hounsgaard and L.H. Jensen *. NeuroSearch, Smedeland 26B, DK-2600 Glostrup, Denmark.

Single unit recording have been used to evaluated the in vivo antagonism of neuronal

firing evoked by microiontophoretic ejection of α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA) or the N-methyl-D-aspartate (NMDA) in the CA1 region of the hippocampus in rats. The antagonists were administrated by intravenous injection (i.v.) in the femoral vein. NBQX (30-60 μ mol/kg) inhibited both AMPA and NMDA evoked firing at the highest dose (60 µmol/kg i.v.) whereas 45 µmol/kg given i.v. only inhibited AMPA responses. GYKI 52466 (30 and 61 µmol/kg) selectively inhibited AMPA evoked firing, whereas lower dose (15 µmol/kg i.v.) potentiated NMDA evoked firing in 3 out of 5 experiments. PNQX was tested at doses ranging from 9.0-36 µmol/kg) but were only significantly inhibited AMPA evoked firing at the highest doses uses (36 µmol/kg i.v.) It also have at minor inhibitory effect on NMDA evoked firing. The novel compound NS377 (7-Ethyl-5-phenyl-1,6,7,8-tetrahydro-1,7-diaza-as-indacene-2,3-dione) significantly inhibited AMPA and NMDA evoked firing at doses 2-4 times lower (12-24 µmol/kg i.v.) than the other compounds tested. The antagonists NS377 and NBQX did not only inhibited AMPA but also NMDA evoked firing, which could be related to lack of selectivity at high doses or indirect effect (due to a lack of depolarisation induced relief of Mg2+ block of the NMDA channel when the fast depolarisation is removed by AMPA channel inhibition). The non-competitive antagonist GYKI 52466 selectively block the AMPA evoked activity. PNQX only inhibited the AMPA evoked activity statistically significant which could indicate some degree of in vivo selectivity, but there were only minor differences between the degree of AMPA and NMDA inhibition.

The result indicates, that the AMPA antagonists (like NBOX and NS377) inhibited NMDA responses indirectly which may be advantageous in ischemic therapy. The noncompetitive AMPA antagonist GYKI 52466 shown in vivo selectivity, which could be related to a higher degree of receptor selectivity or some unknown mechanism

NMDA AND AMPA RECEPTORS MEDIATE A POPULATION EPSP IN NEONATAL SPINAL CORD. D. L. Tauck* and J. J. Kendig. Department of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305

Glutamate is the neurotransmitter at the synapse between sensory and motor neurons that drives the monosynaptic reflex in the spinal cord. Stimulating and recording from non-homologous pairs of dorsal and ventral roots, respectively, allows one to record population EPSPs uncontaminated by superimposed population spikes. Using spinal cords isolated from 3 to 7 day old rats, we show that this glutamatergic population EPSP (pEPSP) is mediated by NMDA and AMPA receptors. A competitive glutamate receptor antagonist with high selectivity for the kainate receptor, NS-102 had no effect on the pEPSP. The selective NMDA antagonists AP5 and CPP both reversibly inhibit a slow to develop and long-lasting component of the pEPSP. Both CNQX, an AMPA/kainate antagonist, and NS-257, a selective AMPA antagonist, completely and reversibly blocked that part of the pEPSP not affected by NMDA antagonists. When applied alone, both CNQX and NS-257 depress the fast component of the pEPSP as well as the slower, long-lasting component of the pEPSP leaving a small, slow response that is blocked by NMDA antagonists. Supported by NIH grants GM47818 and NS13108 to JJK.

ANTAGONISM OF NMDA-EVOKED CURRENTS IN RAT CORTICAL CULTURES BY ARL15896AR G.A.R. Mealing, ¹T. Lanthorn*, M.A. Black, N.B. Laferriere, D.L. Small, & P. Morley National Research Council, Ottawa Canada & Astra Arcus USA, Rochester, NY, USA

The low-affinity NMDA antagonist ARL15896 protects primary cultures of rat cortical neurons from NMDA- or glutamate-mediated toxicity and, like memantine, rapidly blocks NMDA-triggered [Ca2+], responses. This whole-cell voltage-clamp study examines the antagonism of NMDA-evoked currents by ARL15896 in this same culture model. ARL15896 caused a rapid and reversible inhibition of NMDA-evoked currents from neurons held at -60 mV, with an IC₅₀ of $8 \pm 1 \mu M$. The EC₅₀ for NMDA was not significantly affected by $10 \mu M$ ARL15896 (p>0.05), consistent with a non-competitive mechanism of block. ARL15896 antagonism is use-dependent, since application of ARL15896 60 s prior to NMDA exposure did not attenuate the initial NMDA-evoked current although the block developed rapidly thereafter. Once bound, ARL15896 remained trapped upon removal of NMDA until subsequent NMDA re-exposure, whereupon currents rapidly recovered. The forward and reverse binding-rate constants were estimated to be 2.406 x 10⁴ M⁻¹ s⁻¹ and 0.722 s⁻¹, respectively. Antagonism was strongly voltage-dependent, as the K_D s at 0 and -60 mV were 60 μM and 11 μM , respectively. Additionally, there was a small component (*25%) of ARL15896 antagonism that was voltage-insensitive. This component of the block does not act at the glutamate site, since it was not influenced by NMDA

In contrast to some uncompetitive NMDA antagonists, such as MK-801, ARL15896 exhibits rapid kinetics. This property could mediate the high margin of safety seen in preclinical studies, while maintaining the efficacy associated with use-dependent NMDA antagonists. ARL 15896 is in clinical trials for stroke This work was supported by the Canada/Astra Fight Stroke Program

SUBUNIT SELECTIVITY OF BENZODIAZEPINE LIGANDS WITH DIFFERENT PHARMACOLOGICAL PROFILES. M.R. Witt*, J. Drejer, S.E. Westh-Hansen and M. Nielsen. Research Institute of Biological Psychiatry, St. Hans Hospital, Roskilde, DK-4000 Roskilde, Denmark

Classical benzodiazepines, which are widely used as anxiolytics, hypnotics and antiepileptics, mediate their activity via an interaction with the GABA, receptor complex. During recent years a series of benzodiazepine ligands which do not exert the full spectrum of classical benzodizepine activity has been identified. Compounds such as NNC13-8199, RP60503 and U78875 have in animal models been characterized as anxiolytics with minor or no sedative activity. In order to elucidate the molecular mechanism of the pharmacological interaction of these compounds with the GABA, recentor complex, a series of experiments were performed on recombinant GABA, receptors. Cloned human GABA, receptor performed on recombinations $\alpha_j \beta_{j,\gamma}$ (x=1,2,3 and 5; y=1,2 and 3) were transiently expressed in Sf9 cells and 3H -Ro15-1788 binding was performed on membrane preparations from the cells in the absence and presence of GABA (100 μM). The classical benzodiazepine diazepam showed as expected positive GABA ratios predictive of agonistic activity on all receptor subunit combinations. On the other hand NNC13-8199 was found to be a weak partial agonist in a few subunit combinations (GABA ratio ~ 1.3) and an antagonist in other combinations (GABA ratio ~ 1). RP60503 appeared to be a pure antagonist at all combi nations tested. U78875 showed partial agonism in some combinations and inverse agonism in others. The data suggest that the lack of sedative activity of the three anxiolytic compounds tested might be explained not only by partial agonism at the benzodiazepine binding sites but also by subunit selectivity.

IDENTIFICATION OF GABA AND DIAZEPAM-RESPONSIVE REGIONS OF THE GABAA RECEPTOR USING γ2/α1 SUBUNIT CHIMERAS. A. J. Boileau, N. V. Cozzi, P. Chen and C. Czajkowski*. Dept. of Neurophysiology. University of Wisconsin, Madison, WI 53706. Although GABAA receptor α subunits are important for binding GABA

Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706. Although GABAA receptor α subunits are important for binding GABA and benzodiazepines (BZDs), the presence of a γ subunit is required for high affinity BZD binding (Pritchet et al., Nature 338, 1989). In order to determine which portions of the γ subunit confer BZD binding, we generated chimeric protein combinations of rat γ 2 and α 1 subunits (Liu, et al., Science 266, 1994) and expressed them with wild type β 2 and/or α 1 subunits. We have generated over two dozen chimeric subunits with crossovers in the 5' extracellular region. Restriction enzyme mapping and DNA sequencing revealed seven distinct γ 2/ α 1 chimeras which encode complete ORF's. Of those expressed with wild type α 1 and β 2 subunits in HEK 293 cells, two exhibited significant levels of [3H]flunitrazepam binding, and when co-expressed with wild type α 1 and β 2 cRNA in Xenopus oocytes displayed diazepam potentiation of GABA-mediated chloride current. By comparing where the cross-over occurred in chimeras that were responsive to BZDs with those that were not, we have identified a 45 amino acid residue region in the 5' extracellular portion of the γ 2 subunit that is necessary for BZD binding and BZD potentiation of the GABA-mediated chloride current. Using the same chimeras we have also identified a 42 amino acid region of α 1 which confers GABA-responsiveness when expressed with β 2 subunits alone. This work was supported in part by funds from U.W.-Madison and a Basil O'Connor Starter Scholar Research Award from the March of Dimes to C.C.

INCREASED SENSITIVITY TO BENZODIAZEPINES IN AGED BASAL FOREBRAIN NEURONS. S.C. Hall* and W.H. Griffith. Dept. Medical Pharmacol. & Toxicol., College of Medicine, Texas A&M University, College Station, TX 77843-1114.

The pharmacology of the γ-aminobutyric acid, benzodiazepine (GABAA/BDZ) receptor complex in young and aged rats was explored using whole-cell patch-clamp recording techniques on acutely dissociated neurons from the medial septum/diagonal band. Previous findings have shown an increase in sensitivity to the GABAA enhancing BDZ drug, midazolam (MD), in aged rats (Griffith and Murchison, J. Neurosci., 15: 2407-2416, 1995). The purpose of this study was to further characterize pharmacologically the increased sensitivity of aged animals to the BDZs. We studied the differences in GABAA receptor pharmacology between young (1-3 months) and aged (24-26 months) Fischer 344 rats by comparing concentration-response curves of GABA (0.3-100 μ M) and MD (0.03-3 μ M). GABA-induced currents were enhanced by MD in both age groups at low GABA concentrations (≤3 µM; young, n=22; aged, n=8). In contrast, during 10 μM GABA, 1 μM MD decreased currents in young (n=12), but continued to increase currents in aged cells (n=4). Flumazenil (1-3 μM) blocked both effects of MD in both age groups (10/12 neurons). Our data suggest MD may change the efficacy and affinity of the GABAA/BDZ receptor in aged rats. (Supported by NIH grant AG07805).

MOLECULAR DETERMINANTS OF BENZODIAZEPINE-MEDIATED POTENTIATION OF THE RAT α1β2γ2 GABAA RECEPTOR. J Amin†, AR Brooks-Kayal*‡, and DS Weiss§ †Dept. of Pharm.&Therap., USF Col. of Med., Tampa, FL 33612; †Depts. of Peds & Neurol., Univ of Penn. & Children's Hosp, Phila., PA 19104; §Neurobiol. Res. Ctr., Univ. of Alabama, Birmingham, AL 35294.

Peds & Neurobiol. Chin' or Penn. & Children's Hosp, Pinla., PA 19104; SNeurobiol. Res. Ctr., Univ. of Alabama, Birmingham, AL 35294. Benzodiazepine (BZD) mediates its actions in the CNS, at least in part, through a potentation of the GABAA receptor, although the molecular components underlying these actions are not fully understood. Two separate, but homologous, domains each comprised of a tyrosine and threonine on the extracellular region of the β subunit, have previously been shown to play an important role in GABA-mediated activation. Here, we examined the role of the corresponding tyrosines of the α and γ subunits on diazepam-mediated potentiation and [3H]Ro 15-1788 binding. Mutant α 1 and γ 2 subunits were coexpressed with their wild type counterparts in Xenopus oocytes or HEK293 cells. Mutation of either of the two conserved tyrosines (to serine) in the α subunit dramatically impaired diazepam-mediated potentiation of GABA-activated chloride currents in oocytes and abolished the binding of [3H]Ro15-1788 to the transfected HEK293 cells. In contrast, the γ subunit mutants had a minimal effect on the EC50 for diazepam (2-fold increase) and did not significantly alter the binding of [3H]Ro15-1788. These data suggest that these two tyrosines of the α subunit may contribute to the BZD binding site. Furthermore, the correspondance of these residues to those in the β subunit critical for GABA-mediated activation suggests that the BZD binding site may have evolved from the GABA binding site. (Supported by NIH AA09212 & NS35291)

[3H]FLUNITRAZEPAM AND [3H]RO15-4513 PHOTOAFFINITY LABEL DIFFERENT DOMAINS OF HUMAN RECOMBINANT GABA, RECEPTORS. M. Davies**, I.L. Martin*, A.N. Bateson*, K.L. Hadingham*, P.J. Whiting* and S.M.J. Dunn** Department of Pharmacology and Division of Neuroscience, Faculty of Medicine, University of Alberta, Edmonton, Alberta, Canada T6G 2H7. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Harlow, Essex, CM20 2OR, U.K.

Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Harlow, Essex, CM20 2QR, U.K.

We have used permanently transfected cell lines that express the human αβ1β1/2. α1β3/2, and α6β3/2 GABA_A receptor subtypes to map the recognition sites for [³H]flunitrazepam and [³H]Ro15-4513. To identify specific areas of the receptor labelled by these compounds, we used a combination of photoaffinity labelling and chemical cleavage by hydroxylamine. Hydroxylamine cleaves at asparagine-glycine amide bonds, which in the receptor subtypes utilized in this study occur only in the α subunits. The photolabelled fragments were then resolved using SDS-PAGE. Using this approach, we determined that α1-containing receptors incorporated [³H]flunitrazepam within residues 1-103, while labelling by [³H]Ro15-4513 occurred between residue 104 and the C-terminal of the α subunit. When membranes prepared from the α6β3/2-expressing cell line were photolabelled with [³H]Ro15-4513, two major protein species were labelled, the sizes of which were consistent with the α6 and γ2 subunits. Cleavage of these photolabelled receptors resulted in a gel profile consistent with incorporation of photolabel into residues lying between 103 and the C-terminal. These results show that the sites photolabelled by the agonist [³H]flunitrazepam and the partial inverse agonist [³H]Ro15-4513 occur within distinct domains of the human GABA_A receptor. Supported in part by MRC Canada.

ANXIOLYTIC PROFILE OF FULL AND PARTIAL AGONIST GABA, RECEPTOR MODULATORS IN SQUIRREL MONKEYS, RATS AND MICE. B. Dubinsky*, A.H. Vaidya, S. DeLuca, C.B. Davis, D.I. Rosenthal, C.T. Cheolsaacs, J.J. Crooke, and R.P. Shank. The R.W. Johnson Pharmaceutical Research Institute, Spring House, PA 19477.

Allosteric modulators of GABA, receptors can induce a wide variety of CNS-related

Allosteric modulators of GABA_A receptors can induce a wide variety of CNS-related effects. An aim of drug discovery researchers who target GABA_A receptors is to identify compounds that selectively induce only the effects that are therapeutically useful, e.g. anxiolytic activity. Hypothetically, the ideal compound may exert a low level of modulatory activity on all of the various types of GABA_A receptors (a partial agonist) or selectively modulate only GABA_A receptors associated with a specific CNS function (a selective agonist or a mixed agonist/antagonist). We examined the validity of these concepts by comparing the in vitro and in vivo activity of some full agonist modulators [alprazolam, chlordiazepoxide, clonazepam, diazepam and lorazepam] to that of partial agonist modulators [abecamil, bretazenil, imidazenil, panadiplon and Ro 19-8022]. Our results in vitro indicate that the so-called full agonists as well as partial agonists have an ability to differentially modulate different types of GABA_A receptors. This differentiation is due to differences in affinities and intrinsic activities. In vivo, the partial agonists usually exhibited lower maximum responses than the full agonists in anxiolytic tests (e.g., Wogel conflict and elevated plus maze in rats and food-reward/tail shock conflict in monkeys) and side-effect tests (e.g., motor impairment, ethanol sleep potentiation, reduced spontaneous motor activity and muscle relaxation). Furthermore, the partial agonists often exhibited a separation between anxiolytic activity and side-effects, but the magnitude of separation differed markedly between the species studied. Also, dose-response curves for partial agonists were often biphasic, i.e. effects observed at low doses disappeared at higher doses. Our results indicate that the simplistic terminology "full agonist", "partial agonist" or even "selective agonist" does not adequately define the activity of most GABA_A receptor modulators acting at the benzodiazepine site.

PAIRED-PULSE DEPRESSION OF SLOW IPSPs SHOWS NO INVOLVEMENT OF GABA_B AUTORECEPTORS IN REDUCTION OF GABA INHIBITION IN THE HIPPOCAMPAL CA1 REGION AFTER CHRONIC FLURAZEPAM TREATMENT. Xu Zeng* and E.J. Tietz. Dept. of Pharmacology, Medical College of Ohio, Toledo, OH 43699

The findings of intracellular recordings in CA1 neurons from I week flurazepam (FZP)-treated rats showed a reduction in monosynaptic GABA_A and GABA_B-mediated IPSP amplitudes. Whole-cell patch clamp recordings from CA1 neurons showed a decreased frequency of spontaneous, but not miniature IPSCs, with this FZP treatment. Thus, in addition to postsynaptic alterations, presynaptic changes may contribute to reduced GABA inhibition in FZP tolerant rats. Since postsynaptic GABA_A, but not GABA_B-mediated responses were reduced by FZP treatment, the role of presynaptic GABA_B autoreceptors in mediating GABA release was assessed by paired-pulse depression of slow IPSPs in *in vitro* hippocampal slices (500 μm) from FZP-tolerant rats (100 mg/kg × 3 days; 150 mg/kg × 4 days in 0.02% saccharin) sacrificed 2 days after treatment. CA1 neurons were recorded with glass micropipettes using intracellular techniques (3M KAc, 60-80 MΩ, I_H = -60 mV). Monosynaptic IPSPs were activated in stratum radiatum/lancanosum < 0.5 mm from the recording electrode in the presence of APV (50 μM) and slow IPSPs of equivalent amplitude (Control: 4.67 ± 0.05 mV, FZP-Treated: 4.53 ± 0.06 mV, p > .05) were activated at interpulse intervals from 250-1250 ms. There were no significant differences (p > .05) in paired-pulse depression between control (n=6) and FZP-treated neurons (n=6). Reduction of interneuron firing rate, rather than of GABA_B autoreceptor function, may be related to decreased presynaptic GABA-mediated inhibition in the hippocampus associated with benzodiazepine anticonvulsant tolerance. Supported by NIDA grant R01-DA04075 and RSDA K02-DA00180 to E.1. T.

Diazepam Increases the Maximal Response to Kojic Amine: Evidence for a Two-State Model of GABAA Receptor Modulation. Y. T. Lee, T. T. Gibbs* and D. H. Farb., Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

The A-type γ -aminobutyric acid receptor (GABA_AR) is a heteropentameric chloride ion channel. The GABAAR is activated by full agonists such as GABA and muscimol, and agonist function is subject to positive and negative modulation by benzodiazepines, barbiturates, neurosteroids, and heavy metal divalent cations. The design of new therapeutic agents would be aided by a general model for GABAAR modulation. As a first step, we have proposed a simple two-state model for GABAAR modulation. This model predicts that, while the efficacy of a full agonist should not be affected by a positive modulator, the efficacy of a partial agonist can be positively modulated. To test this model, we examined the effect of diazepam on the response to kojic amine, which we have shown to be a partial agonist at the $GABA_{A}R$, using whole cell voltageclamp recordings of primary chick spinal cord neurons in culture. In the presence of the positive modulator diazepam, the maximum response to kojic amine was increased while the maximum response to GABA remained the same. The results obtained are consistent with the two-state model for GABAAR modulation. Supported by NIMH MH49469.

A REGIONAL DIFFERENCE IN THE EFFECTS OF MIDAZOLAM ON SYNAPTIC TRANSMISSIONS IN RAT HIPPOCAMPAL NEURONS. Y. Sato, Y. Fujito*, and M. Aoki. Dept. of Physiology, School of Medicine, Sapporo Medical University, Sapporo 060, Japan. Midazolam, an imidazobenzodiazepine derivative, is widely used as

an intravenous anesthetic. Its effects are considered to be mediated mainly through the GABA_A receptor, enhancing the inhibitory action of GABA. In the present study, we compared the effects of midazolam on synaptic transmissions in CA1 pyramidal cells (PCs) and on dentate on symptote distinsishing in CAT pytalindar certific (Cs) and on echaler gyrus granule cells (GCs) in rat hippocampal slices using intracellular recordings. Midazolam (75 μ M) markedly depressed orthodromic evoked spikes in PCs, compared with those in GCs. A GABAA receptor antagonist bicuculline (10 μ M) almost completely antagonized the depressant effects of midazolam on spike generation in PCs, while bicuculline little antagonized midazolam effects in GCs. Midazolam produced depolarizing or hyperpolarizing effects on resting membrane potentials (RMP) with an input resistance decrease in PCs, whereas it produced slight depolarizing effect on RMP without affecting an input resistance in GCs. Midazolam significantly increased the amplitudes of monosynaptic inhibitory postsynaptic potentials in PCs evoked by stimulation near the recording electrode in the presence of glutamate receptor antagonists, but slightly decreased those in GCs. These results clearly demonstrated that midazolam has differential depressant effects on synaptic transmissions in hippocampal neurons. The mechanism of this difference could be due to the different densities and

types of $GABA_A$ /benzodiazepine receptors between PCs and GCs. This work was partly supported by a grant from Foundation of Sapporo Medical University.

DIFFERENTIAL CHANGES IN GABA, RECEPTOR (GABAR) α_1 , β_1 , β_2 AND γ_2 SUBUNIT PROTEINS IN FLURAZEPAM TOLERANT RATS. S. Chen, X. Zeng, W. Sieghart† and E.I. Tietz*, Dept. of Pharmacology, Medical College of Ohio, Toledo, OH 43699 and Dept. Biochemical Psychiatry†, Univ. Clinic of Psychiatry, A-1909 Vienna, Austria.

Prolonged administration of benzodiazepines (BZs) to animals results in the development of functional tolerance in vivo and in vitro. One week flurazepam (FZP) treatment decreased GABAR-mediated early IPSP and spontaneous IPSC amplitude in CAI pyramidal neurons. GABA/BZ receptors were also functionally uncoupled, locally in CAI subregions. Using in situ hybridization methods, decreased α, and β_3 , but not α_3 or γ_2 subunit mRNA were detected in FZP-treated rat brains. We previously demonstrated the sensitivity and reliability of computer-assisted image analysis for quantitation of immunostaining density (Huang et al., 1996). Using this method, we analyzed levels of GABAR α_3 , β_1 , β_3 and γ_3 subunit proteins in rat brain sections (10 μm). Rats were sacrificed immediately after 1 week FZP treatment (100 mg/kg X 3 days; 150 mg/kg X 4 days in 0.02% saccharin water). Control rats received saccharin water for the same time period. Specific GABAR α_2 , β_1 , β_3 and γ_3 subunit antibodies (W. Sieghart) were used as 1° antibodies and biotinylated antirabbit IgG F(ab); fragments as 2° antibodies. Immunostaining was visualized with DAB and staining intensity was measured over images acquired with NIH Image software. As previously found for the α_1 subunit protein β_3 subunit protein significantly decreased in FZP-treated rat brains in parallel with β_3 subunit mRNA in the CA1 s. oriens (-18%) of dentate gyrus; and in CA3 and cortex. Though γ_2 subunit mRNA in the CA1 s. oriens (-18%) of dentate gyrus; and in CA3 and cortex. Though γ_2 subunit mRNA in the CA1 s. oriens (-18%) of dentate molecular layer (-12%), a significant decrease in α_2 my subunit any brain region

ME 3127 is a new benzodiazepine agonist which induces a robust anticonflict effect in rats. In this study we present a characterization of the binding profile of ME 3127. At native receptors in cortex homogenate ME 3127 displaced [3H]flunitrazepam binding competetively with a $K_i = 2.9 \pm 0.5$ nM (n = 11). The affinity of ME 3127 was increased 1.6 fold by addition of 30 µM GABA compared to a 1.5 fold increase for flunitrazepam. Saturation of the benzodiazepine binding site by ME 3127 increased non-equilibrium [15 S]TBPS binding to the same extent as diazepam did, 1.29 \pm 0.03 fold and 1.31 \pm 0.03 fold (n = 4), respectively. This indicates that ME 3127 is a benzodiazepine agonist with full intrinsic activity

The affinity of ME 3127 for recombinant human GABAA/benzodiazepine receptor complexes was studied at $\alpha_x \beta_x \gamma_{2S}$ receptors expressed in baculovirustransfected Sf-9 insect cells. ME 3127 displaced [3H]Ro 15-1788 with some subtype selectivity being approximately 5 times more potent at receptors containing the α_1 or the α_5 subunit compared to receptors containing the α_2 or the α_3 subunit. The ratio between IC50 values for ME 3127 in the absence and presence of GABA (GABA ratio) depended on the subunit combination. At $\alpha_3\beta_2\gamma_2$ and $\alpha_3\beta_3\gamma_2$ receptors the GABA ratios were 2.0 \pm 0.4 and 2.1 \pm 0.3 (n = 3), respectively, whereas ME 3127 had a GABA ratio of 0.9 \pm 0.2 at $\alpha_3\beta_1\gamma_2$ (n =3) indicating that ME 3127 acts as an antagonist at this subunit combination.

The binding [3H]ME 3127 to rat brain homogenate, brain slices and recombinant GABAA receptors is presently being characterized

NALOXONE ANTAGONIZES GABAA/BENZODIAZEPINE RECEPTOR FUNCTION IN RAT CORTICOHIPPOCAMPAL SYNAPTONEUROSOMES. <u>A.I.</u> Svensson*, J.A. Engel and B. Söderpalm, Inst. of Physiol, and Pharmacol., Dept. of Pharmacol., Göteborg Univ., Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Low serotonin (5-HT) neurotransmission has been linked to anticonflict effects and

impulsive/aggressive behaviors in rats, and to impulse control deficiency, aggression, suicide etc. in humans. Impulsive behavior after extensive 5-HT depletion in rats may be reversed with negative modulators of brain GABA_A/benzodiazepine receptors. In an accompanying abstract we report that naloxone reduces 5-HT depletion induced anticonflict and aggressive behaviors, and that amobarbital in turn reverses the naloxone effect in the conflict model used. Also Ro 15-4513, a partial inverse benzodiazepine receptor agonist, reduces 5-HT depletion induced aggression. Naloxone thus produces behavioral effects similar to those produced by negative modulators of GABA_A/benzo-diazepine receptors in 5-HT depleted animals, and GABA_A antagonistic properties of naloxone have been proposed. Hence, weak GABAA/benzodiazepine receptor antagonistic effects of naloxone may explain our behavioral data. Here we have studied the effects of naloxone on rat GABA_A/benzodiazepine receptor function in vitro.

Naloxone (0.1 - 1000 μ M) in a concentration-dependent manner reduced the GABA-induced (10 μ M) 36 Cl -uptake in corticohippocampal synaptoneurosomes, with a 60% induced (10 μ M) = $^{\circ}$ C1 -uptake in correcomposation of naloxone did not by itself affect 3 C1-uptake. Furthermore, the concentration-response curve for GABA-induced 3 C1-uptake (GABA 3, 10, 30, 100 μ M) was shifted to the right by naloxone 1 1000 μ M. The naloxone-induced (1000 μ M) reduction of GABA-mediated (10 μ M) 3 C1-uptake was concentration-dependently reversed by amobarbital (10 - 1000 μ M) but not by

flumazenil (10 - 1000 μ M). These results indicate that naloxone is a weak negative modulator of GABA_A/benzodiazepine receptor function and suggest, together with our behavioral data, that this property may be involved in its anti-impulsive/anti-aggressive effects.

THE EFFECT OF DIAZEPAM UPON THE PHYSIOLOGICAL CHARACTERISTICS OF NEURONES IN THE IMHV OF THE DOMESTIC CHICK P.M.Bradley, B.D.Burns, B.A.Clark and A.C.Webb.(SPON:BRAIN RESEARCH ASSOCIATION) Department of Neurobiology, Medical School, Newcastle upon Tyne, United Kingdom. NE2 4HH.

The avian brain contains an area known as the intermediate and medial

hyperstriatum ventrale (IMHV) which is essential for early learning. Local electrical stimulation of the IMHV in an in vitro brain slice preparation elicits a characteristic extracellular field response. This response is under a considerable degree of inhibition mediated by the GABA_a receptor system. The benzodiazepine receptor is thought to play a role in the modulation of GABAergic inhibition and the IMHV has been shown

to contain a high density of these receptors compared to other forebrain regions.

We therefore examined the effect of the benzodiazepine receptor agonist diazepam (12μ M) upon the electrophysiological properties of the IMHV in slices taken from 3-4 day old birds (N =10). Analysis of the data using the paired t-test showed no significant difference in responses before and after perfusion with the drug. However, comparision of the measurements made under diazepam with those made under the control periods showed that the drug produced a significant (p = 0.0025) increase in the mean peak amplitude $(14\% \pm 2.8)$ of the post-synaptic component of the field response. It has previously been shown that the peak amplitude is dependent upon glutamate receptors of the non-NMDA sensitive subtype. The duration of the response,

which is dependent upon NMDA receptors showed no significant change.

Intracellular recordings from single cells (N = 7) showed that diazepam did not alter the membrane resistance, threshold to internal stimulation, resting membrane potential or duration of response to an external stimulus of the cells. However, 4 of the 7 cells displayed irregularly occuring spontaneous bursts of EPSP's and diazepam appeared to reduce the amplitude, duration and frequency of the bursts in these cells.

PHYSIOLOGICAL, BEHAVIORAL AND SUBJECTIVE EFFECTS OF FLUMAZENIL-PRECIPITATED WITHDRAWAL IN BENZODIAZEPINE-DEPENDENT METHADONE CLIENTS, J. M. Frey*, C. R. Rush and R. R. Griffiths. Johns Hopkins University School of Medicine, Baltimore, MD 21224.

The effects of i.v. administered flumazenil (FLU, Romazicon™; 0-4 mg/70 kg) were studied in six methadone clients with a recent history of chronic benzodiazepine use (at least 450 mg diazepam equiv./mo.). Subjects were converted to p.o. lorazepam administration (5-12 mg/day) during a 7 day stabilization period prior to testing. During the stabilization period, subjects were evaluated for benzodiazepine tolerance development and monitored for sedative intoxication using a variety of psychomotor/behavioral performance, observer and subject-rated measures. All six subjects were determined to be benzodiazepine dependent in a semi-structured clinical interview diagnostic (SCID) for the DSM IIIR. After at least two i.v. practice sessions, FLU was injected (42ml/5 min) in ascending doses in three days of dose run-up testing; dosing run-ups were followed in four subjects by a randomized crossover study up to the highest dose of FLU tolerated during the run-up period. Precipitated withdrawal symptoms reliably occurred within 1-2 min and peaked within 5 min after initiating FLU injections. Composite scores from a 22-item "Subject-rated Withdrawal Symptoms Questionnaire" and the Spielberger Y-1 (State) Anxiety Index indicated that the effects of FLU were both dose and time-dependent from 0.25-4.0 mg/70 kg. Precipitated withdrawal was further characterized by anecdotal self-reports of confusion/difficulty concentrating, anxiety, irritability, dysphoria, dizziness, stomach cramping/pain and numbness in the extremities. This study demonstrates that rapid infusion of FLU in benzodiazepine-dependent volunteers can precipitate symptomology commonly associated with benzodiazepine withdrawal. Supported by NIDA grant DA-03889.

GABA RECEPTORS: ETHANOL

510.1

POSTNATAL ETHANOL EXPOSURE INHIBITS MATURATION OF GABA, RECEPTORS IN DEVELOPING MEDIAL SEPTUM/ DIAGONAL BAND (MS/DB) NEURONS. S.-H. Hsiao1*, J.R. West2, J.C. Mahoney² & G.D. Frye¹. Dept. Med. Pharmacol. & Toxicol. 1, Dept. Med. Anat.2, Texas A&M Univ. Coll. Med., College Station, TX 77843-1114

The GABA, receptor is a ligand-gated Cl channel playing a prominent inhibitory role. Postnatally, expression of GABA, receptor subunits undergoes major changes and may represent a target for ethanol as part of the fetal alcohol syndrome (West et al., Metab. Brain Dis. 9:291, 1994). The present study examined whole cell GABA, currents in MS/DB neurons, acutely dissociated from Sprague-Dawley rats (days PN 12-16). During days PN 4-9, animals were artificially reared (pup-in-the-cup) and exposed twice daily to ethanol (4.5 g/kg/day) or milk alone. GABA (0.3-300 µM) responses were concentration and ethanol treatment dependent. Maximum GABA response for neurons in the ethanol exposed group $(209.08 \pm 15.2 \text{ pA/pF}, \text{n} = 36)$ was smaller than that of cells from artificially reared controls (305.0 \pm 15.18 pA/pF, n=6; p < 0.05). The EC₅₀ values were also smaller after ethanol (4.85 \pm 0.44 μ M vs 7.68 \pm 0.93 μ M; p < 0.05), but Hill coefficients were unchanged. Meanwhile, there were no significant differences between artificially vs normally reared controls, respectively (maximum response: 305.0 ± 47.93 vs 348.75 ± 71.9 pA/pF; p>0.05. EC₅₀: 7.68 \pm 0.93 vs 7.66 \pm 1.50 μ M; p>0.05). These data suggest that the chronic postnatal ethanol exposure significantly changes development of GABA, receptors in MS/DB neurons. 510.3

ETHANOL POTENTIATES AND INHIBITS GABA, CURRENTS IN ADULT HIPPOCAMPAL AND CEREBRAL CORTICAL NEURONS. G.D. Frye* and A.S. Fincher. Dept. of Med. Pharmacol. & Toxicol., Texas A&M Univ., Col. of Med., College Station, TX 77843-1114.

GABA, currents in neurons isolated from medial septum/n. diagonal band of adult rats exhibit a range of sensitivities to ethanol ranging from enhancement to inhibition (Frye et al., Brain Res. 635 283-292, 1994). In this study, acutely isolated adult neurons from Sprague-Dawely rat hippocampus (hippo) or cerebral cortex (cortex) exhibited concentration dependent currents in response to GABA $(0.3-300 \mu M)$ with EC₅₀s of 13.9 and 19.8 μM , respectively. Coapplication of ethanol (10, 30 or 100 mM) and 3 μM GABA did not enhance mean currents. However, many cells showed either potentiation (ie., $\geq 110\%$ of control) or inhibition (ie., $\leq 90\%$ of control) of GABA currents by at least one concentration of ethanol. Ethanol potentiated GABA currents in one subset of neurons (cortex = 3 of 14; hippo = 4 of 14), but inhibited in another subset (cort = 8 of 14; hippo = 6 of 14). Currents in one cortical neuron were both potentiated and inhibited by ethanol. Thus ethanol sensitivity of GABAA receptors on adult hippocampal and cerebral cortical neurons varies widely from cell to cell ranging from enhancement to inhibition. Supported in part by AA06322 (GDF).

CHRONIC ETHANOL DOES NOT UNCOUPLE ALLOSTERIC MODULATION OF GABA, RECEPTORS BY MIDAZOLAM OR LORECLEZOLE IN MEDIAL SEPTUM / DIAGONAL BAND (MS/DB) NEURONS. K.A. Wallace*, A.S. Fincher, G.D. Frye. Dept. of Med Pharmacol. & Toxicol., Texas A&M Univ., College Station, TX 77843-1114.

 $\ensuremath{\mathsf{GABA}}_{\ensuremath{\mathsf{A}}}$ receptor activity is a cutely increased by a wide range of positive allosteric modulators acting at distinct sites on the chloride channel complex. However, chronic treatment with modulators such as ethanol may lead to uncoupling of other allosteric interactions with the GABA receptor. In the present study, Spraque-Dawley rats were made physically dependent on ethanol via a liquid diet. The ability of midazolam (1 µM) or loreclezole (10 µM) to potentiate $GABA_A$ mediated chloride whole cell currents was measured in acutely dissociated MS/DB neurons. In neurons from diet-fed controls, currents activated by 3 µM GABA were significantly potentiated by midazolam and loreclezole (GABA alone: 73.9 ± 7.3 pA/pF, plus midazolam: 119.5, ± 16.7 pA/pF; p < 0.01 - - GABA alone: 79.8 ± 12.4 pA/pF, plus loreclezole: 153.2 ± 28.6 pA/pF; p < 0.01). Chronic ethanol treatment did not change the level of midazolam or loreclezole induced potentiation (GABA alone: 86.7 ± 10.0 pA/pF, plus midazolam: 161.3 ± 34.3 pA/pF; -- GABA alone: 71.3 ± 34.3 pA/pF; 6.3 pA/pF, plus loreclezole: 118.2 ± 12.0 ; p > 0.05 for both drugs relative to control). Near maximum currents GABA (30 µM) were not potentiated by either drug regardless of pretreatment. Thus, loreclezole and midazolam potentiation at the concentrations tested is limited to GABA, responses induced with lower levels of GABA and this enhancement does not show uncoupling after chronic ethanol treatment. Supported in part by AA06232 (GDF).

510.4

ETHANOL ENHANCES GABA IPSC RESPONSES IN ETHANOL SENSITIVE BUT NOT ETHANOL INSENSITIVE MOUSE HIPPOCAMPAL NEURONS. W.R. Proctor* and T.V. Dunwiddie. Dept. of Pharmacology, University of Colorado Health Sciences Center, and Veterans Admin. Medical Res. Service, Denver, CO. The mechanisms of ethanol enhancement of GABAergic neurotransmission are still poorly understood. Although the hippocampus has been reported to be relatively insensitive to accuse ethanol treatment recent observations have shown

acute ethanol treatment, recent observations have shown significant potentiation of selectively activated GABA_A-mediated ignificant potentiation of selectively activated GABA_A-mediated IPSCs in CA1 pyramidal cells by ethanol. In the present study, we compared the ethanol sensitivity of IPSCs in stable, inbred long sleep (ILS) and inbred short sleep (ISS) mice, which are differentially sensitive to the behavioral effects of ethanol. GABA_A-mediated IPSCs, elicited by stimulation in the somal layer instead of in the stratum radiatum, were recorded under voltage clamp conditions with K*-gluconate whole cell electrodes. The IPSCs were pharmacologically isolated by blocking EPSCs with APV (40 µM) and DNQX (10 µM). The resulting IPSCs could be blocked by application of 30 µM bicuculline. Ethanol had no significant effect on IPSCs in ISS mice, but at concentrations of 80 and 160 mM, the IPSCs from ILS neurons were significantly potentiated (128±8.6% of control, n=10). Lower concentrations of ethanol had no effect. These results suggest that the ethanol sensitivity of GABA_A receptors may contribute to the behavioral differences between ILS and ISS mice.

Supported by AA 03527 and the Veterans Administration Medical Research Service.

GABA, RECEPTOR GENE EXPRESSION IN CNS OF RATS "BEHAVIOURALLY DEPENDENT" TO ETHANOL. G. Pinna", M. Eravci, S. Kley, J. Wolffgramm" and A. Baumgartner. Departments of Nuclear Medicine and Neuropsychopharmacology', Klinikum Benjamin Franklin, Free University of Berlin, 12200 Berlin, Germany.

The sensitivity of GABA, receptors to ethanol (ETH) may be related to the GABA, receptor subunit formulation. For this reason, we examined the receptor gene expression of several GABA, receptor subtypes (α₁, α₂, α₃, β₁, β₂, γ₂) in various brain areas of rats chronically exposed to ETH. An animal model was developed to render rats "behaviourally dependent" to ETH. Rats were administered ETH following two different designs: in group A, animals had the free choice between water and two different concentrations of ETH (S and 20% ν/ν), in a three bottle system, during 9 months. The group B received a 5% ETH solution as sole drinking fluid during 9 months. The group B received a 5% ETH solution as sole drinking fluid during 9 months. Tas could choose between water and ethanol for two months (mo. 13-14). In this phase, rats could choose between water and again, two concentrations of ETH. In month 14, all the alcohol solutions were adultereted with 0.1 g/l quinine hydrochloride. Group A, but not group B, full filled the criteria for "behavioural dependence" which was defined as a "loss of control" over drug ingestion, maintained even after 3 months' forced abstinence' and characterised by an unusually high ETH consumption, even when ETH was adulterated with a highly aversive substance such as quinine hydrochloride. This result indicates that the possibility of free choice paradigm for alcohol or water is important for the induction of "behavioural dependence". After the "retest" rats were withdrawn from ETH for one month before sacrification. Quantification of mRNA steady-state levels was performed by Multiple Oligonucleotide Solution Hybridization (MOSH) and densitometric evaluation of the autoradiographs. In cerebral c

AND ETHANOL. H. E. Criswell* T. J. McCown, A. G. S. Oxford, L. Morrow, and George R. Breese. University North Carolina, Chapel Hill, NC 27599. PRESENCE OF mRNA FOR SPECIFIC GABAA RECEPTOR

When ethanol is locally applied to neurons, in vivo, it enhances the action of iontophoretically applied GABA for some neurons but not for others. Responsiveness of a neuron to the type I benzodiazepine agonist zolpidem predicts whether that neuron will respond to ethanol. (J.P.E.T. 273:526-536,1995). Because studies in recombinant systems have shown that the $\alpha 1$ subunit for the GABAA receptor in combination with a β and a γ 2 subunit must be present for low concentrations of zolpidem to enhance the action of GABA, we used whole-cell patch clamp recording followed by RT-PCR of cytoplasm from that cell to relate the presence of mRNA for specific subunits to the action of zolpidem and ethanol. Concentration-response curves for zolpidem showed the presence of a high affinity receptor (10-30 nM), a low affinity receptor (100-300 nM) or both, on individual cells. Those cells that responded to low concentrations of zolpidem universally expressed mRNA for the all subunit, while cells which required the higher concentrations contained the $\alpha 2$ and/or the $\alpha 3$ subunit mRNA. Neurons that showed a response to the low concentration of zolpidem with an increased response to the higher concentrations invariably expressed mRNAs for the $\alpha 1$, as well as the $\alpha 2$ and/or $\alpha 3$ subunits. While fewer neurons showed an enhancement of the effect of GABA by ethanol, the $\alpha 1$ subunit was always present when ethanol was effective. Supported by AA-09122.

FUROSEMIDE AND DMCM ACTIONS ON CEREBELLAR GABAA RECEPTORS OF ALCOHOL-SENSITIVE ANT RATS. R. Mäkelä^{1,2} H. Lüddens and E. R. Korpi^{2,2,3}. Tampere Brain Research Center, University of Tampere Medical School, ²Department of Alcohol Research, KTL, Helsinki, ³Department of Pharmacology and Clinical Pharmacology, University of Turku, Finland and ⁴Department of Psychiatry, University of Mainz, Germany.

We have shown that furosemide, a loop diuretic, specifically reverses the inhibition by GABA of [35S]TBPS binding through a novel binding site in the GABA_A receptors with an $\alpha6\beta2/3\gamma2$ subunit composition, but not in an $\alpha1\beta1\gamma2$ receptor subtype (Korpi *et al.*, Mol. Pharmacol. 47:283-289; 1995). We now present that the ability of furosemide to increase [15 S]TBPS binding and antagonize GABAinduced inhibition of [35S]TBPS binding in cerebellar membranes of alcoholsensitive (ANT) rat line is reduced as compared to those of alcohol-insensitive (AT) rat line. This reduced antagonism ability was not shared by other GABA_A receptor antagonists, e.g., SR 95531. The single amino acid mutation in the benzodiazepine (BZ) binding site of ANT rats (Korpi et al., Nature 361:356-358; 1993) rendering cerebellar BZ-insensitive sites sensitive to BZ agonists did not explain the blunted furosemide antagonism, as confirmed with recombinant receptor studies. DMCM, a β-carboline, acts at low concentrations as an inverse agonist on BZ binding site and at high concentrations, it potentiates GABAA receptor function through a loreclezole at high concentrations, it potentiates $GABA_A$ receptor function through a forectezone binding site in $\beta 2$ and $\beta 3$ subunits (Stevenson *et al.*, Mol. Pharmacol. 48:965-969; 1995). Using quantitative autoradiography with 1^{35} SJTBPS, we demonstrate similar biphasic effect of DMCM on 1^{35} SJTBPS binding in the presence of GABA in cerebellar granule cell layer of AT and ANT rats. These experiments suggest that the cerebellar GABAA receptors of the ANT rats are altered also otherwise than in their BZ-site mutation, either by endogenous compounds, other mutations, or altered subunit composition.

(The study was partly supported by the Finnish Alcohol Research Foundation)

GABA RECEPTORS: ANESTHETICS

511.1

A NOVEL CLASS OF GABA-A RECEPTOR SUBUNIT CONFERS INSENSITIVITY TO ANESTHETIC AGENTS

E.F. Kirkness*, P.A. Davies, M.C. Hanna and T.G. Hales. The Institute for Genomic Research, 932 Clopper Road, Gaithersburg, MD 20878 and Dept. Anesthesiology, UCLA, Los Angeles, CA 90025.

A novel class of GABA-A receptor subunit (epsilon; ε) has been cloned from human and rat tissues. The human ɛl subunit is 506 amino acids in length, and exhibits 20-40% identity with related receptor subunit classes $(\alpha,\,\beta,\,\gamma,\,\delta,\,\rho,\,\pi).$ The human $\epsilon 1$ subunit gene encodes an mRNA of ~3.5 kb that is expressed in discrete brain regions and some peripheral tissues. The human £1 subunit gene has been localized on the X-chromosome

When expressed transiently in HEK293 cells, the £1 subunit does not appear to form homomeric GABA-A receptors. Combinations of α/ϵ , or β/ϵ subunits also fail to express GABA-gated chloride channels. However, combinations of $\alpha,\,\beta$ and ϵ subunits can assemble to form GABA-A receptors that exhibit unique biophysical and pharmacological properties. GABA-evoked currents that are mediated by α/β receptors exhibit outward rectification, whereas activation of $\alpha/\beta/\epsilon$ receptors yields currents that display a relatively linear relationship to voltage Also, in contrast to α/β receptors, which are modulated by low concentrations of anesthetic agents (e.g. pregnanolone, pentobarbital, propofol), the $\alpha/\beta/\epsilon$ combinations are relatively insensitive. However, in common with α/β receptors, the $\alpha/\beta/\epsilon$ combination can be activated directly by high concentrations of these agents. Expression of the $\epsilon 1$ subunit may explain the differential sensitivity of GABA-A receptors to anesthetic agents that has been detected in brain tissues. In addition, the $\epsilon 1$ subunit will be useful for dissecting the dual actions of anesthetic agents at GABA-A receptors Funding sources: Grants from TIGR and NIH.

511.2

ISOFLURANE MODULATION OF ALTERED RHO 1 GABA RECEPTOR SUBUNITS. <u>Eric P. Greenblatt*</u>. Dept. of Anesthesia, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Inhibitory neurotransmitter receptors for GABA and glycine may be important targets in the mechanism of action of volatile anesthetics. The anesthetic isoflurane has been shown to enhance chloride ion currents through these receptors. In contrast, the rho 1 subtype of GABA receptor is insensitive to isoflurane. In an effort to identify a site of isoflurane action on such proteins, mutations were introduced in human rho 1 subunits to induce amino acid substitutions corresponding to residues shared by the structurally related, isoflurane-sensitive GABA α_1 and glycine α_2 receptor subunits. Amino acid residues in two putative transmembrane domains were targeted, given the expectation residues in two putative transmembrane domains were targeted, given the expectation that volatile anesthetics should interact at hydrophobic portions of the protein. Mutants designated rholm1-2 and rholm2-1 were generated, coding for amino acid substitutions M2971 and S325T, respectively. Effects of isoflurane on GABA-gated chloride currents were examined using two electrode voltage clamp in Xenopus oocytes injected with mutant or wild type rho subunit cRNAs. Currents measured in oocytes expressing wild-type rho subunits exhibited characteristic GABA pharmacology and were unaffected by coadministration of isoflurane. In oocytes expressing each mutant, isoflurane inhibited GABA-evoked currents. Although isoflurane-sensitive GABA and glycine receptors typically show enhancement of agonist-gated currents, these results may reflect the possibility that neither single amino acid substitution was sufficient to generate the structural determinant(s) which may define a volatile anesthetic binding site. However, each substitution may have resulted in alterations in protein structure that permitted a functionally significant molecular interaction with isoflurane, and may be relevant to the interaction of isoflurane with its target site on native receptors in the central nervous system.

UPREGULATION OF GABAA RECEPTOR ${\it color}$ and ${\it fig}$ SUBUNIT mRNA LEVELS BY CHRONIC PENTOBARBITAL TREATMENT IN IMMORTALIZED GT1-7 NEURONS. L.-H. Lin* and W.-T. Jang Department of Pharmacology, Chang Gung College of Medicine and Technology, Taiwan.

The present study investigated how GABAA receptor expression was regulated by drugs exerting actions on this receptor complex. Immortalized GT1-7 cell line containing single cell population was chosen as the experimental preparation. The cells were treated for 48 h with various GABA, receptor agonists (i.e. GABA, pentobarbital, $3\alpha\text{-OH-DHP}$, propofol and ethanol), antagonists (i.e. bicuculline, picrotoxin and SR 95531) and inverse agonist (i.e. Ro15-4513). We found that pentobarbital not only increased GABA_A receptor α 3 and β 3 subunit mRNA levels, but also reduced the mRNA level for the house keeping gene GAPDH. The elevated α3 and β3 mRNA levels decremented, within 24-48 h after discontinuation of the drug treatment, to control levels. The other agents showed little effects. To investigate whether pentobarbital modified gene expression via GABA_Areceptor activation or other mechanisms, we treated GT1-7 neurons with picrotoxin for 1 h, followed by a co-treatment of pentobarbital/ picrotoxin for another 48 h. We found that picrotoxin abolished the pentobarbital effects on α 3 and β 3 subunits, but changed little on the pentobarbital effect on GAPDH. It is thus likely that pentobarbital upregulates α3 and β3 subunit mRNA levels by increasing the chloride channel activity via GABA receptor activation. Pentobarbital downregulates GAPDH mRNA level via some biochemical targets other than GABAA receptor. (Supported by grants from Chang Gung Memorial Hospital and National Science Council, Taiwan)

THE GABA, RECEPTOR SUBUNIT GAMMA 2 LONG/SHORT RATIO IS ALTERED BY PENTOBARBITAL USING A MECHANISM DISTINCT FROM RECEPTOR OCCUPATION. R.F. Tyndale*, S.V. Bhave, E. Hoffmann, P.L. Hoffman, B. Tabakoff, A.J. Tobin and R.W. Olsen Addiction Research Foundation and Dept of Pharmacology, Univ of Toronto, Toronto; M5S 1A8; Dept of Pharmacol, Univ. of Colorado, Denver; Depts of Biol and Pharmacol, UCLA, Los Angeles.

Denver; Depts of Biol and Pharmacol, UCLA, Los Angeles. Pentobarbital (PB) treatment of cerebellar granule cells in culture caused a change in the γ-aminobutyric acid (GABA)_A receptor subunit mRNA γ2Long/Short ratio which was dose and time dependant (Society for NSc. abstract, 1995). The γ2L subunit mRNA contains an extra 24 base-pair exon coding for 8 amino acids which contain a protein kinase C phosphorylation consensus site. The 8 amino acid insertion occurs in the cytoplasmic domain between the putative third and fourth transmembrane regions and can be phosphorylated (demonstrated *in vitro*). In the present study, in order to identify whether PB acts directly at the GABA_Λ receptor to cause the shift in the γ2L/γ2S ratio, other GABA agonists and the channel blocker picrotoxin (PX) were tested. Cerebellar granule cells were cultured from postnatal day 7 rats for 4 days before 3 day drug treatments. In a single blind study, RT-PCR was used to detect the GABA_Λ receptor subunit mRNAs, using non-neuronal enclase mRNA as an internal standard. PB decreased the γ2L/γ2S ratio up to 65 percent, while ethanol (100 mM) and 3-α, 5-α dihydroprogesterone (allopregnanolone;1 or 2 μM) did not. Both isomers of hexobarbital (500 μM) caused a small change in the γ2L/γ2S ratio. Picrotoxin (10 μM) for 1 or 3 days had no effect alone on γ2L/γ2S ratio and was unable to block the effect of PB. These data suggest that barbiturates alter the γ2L/γ2S RNA ratio by a mechanism which does not involve direct occupation of the GABA_Λ receptor itself. BARBITURATE ENHANCEMENT OF SINGLE AXON INHIBITORY POSTSYNAPTIC POTENTIALS IN HIPPOCAMPUS. H.M. Pawelzik, J. Deuchars, J. Hahn and Alex M. Thomson. Dept. Physiology, Royal Free Hospital Sch. Med., London NW3 2PF, UK.

To determine the potency with which pentobarbitone facilitates the inhibition elicited by single identified interneurones, dual intracellular recordings with biocytin-filling were performed in 450 µm thick transverse slices of adult rat hippocampus. Presynaptic interneurones were identified by their electrophysiological properties and ability to elicit inhibitory postsynaptic potentials (IPSPs) in a simultaneously recorded pyramid. Single axon IPSPs were 0.5 to 1.6mV in amplitude, had 10-90% rise times of 4.8 to 14.8ms and widths at half amplitude of 35 to 59ms under control conditions (n = 4). These interneurones displayed firing patterns distinguishable from pyramidal cells, but none recorded to date displayed the classical fast spiking pattern often considered typical of inhibitory interneurones. On light microscopic analysis the presynaptic interneurone somata were in or close to stratum pyramidale (SP) in CA1 (n=3) and CA3 (n=1), their dendrites were aspiny and beaded and 3 of these axons ramified in SP. Sodium pentobarbitone at concentrations up to the anaesthetic dose (250 μM) greatly enhanced both the amplitude (by 72 ± 63% SD) and duration of these IPSPs (rise time by $116 \pm 93\%$ and half width by $92 \pm 19\%$). This work was supported by the MRC.

PENTOBARBITAL OPENING OF A HOMOMERIC CHLORIDE ION CHANNEL REQUIRES A SPECIFIC ASPARAGINE RESIDUE, <u>I. N. Cestari* and J. Yang</u> Dept. Anesth. Pain Mgmt and Neurosci. Grad. Prog., UTSW Med. Sch., Dallas, TX. The murine GABA, receptor $\beta 3$ subunit when expressed by itself forms

The murine $GABA_A$ receptor $\beta 3$ subunit when expressed by itself forms homomeric ion channels opened by pentobarbital (PNB). The $\beta 1$ subunit with 82% amino acid identity with the $\beta 3$ subunit does not form channels responsive to PNB. Here we report the results of our chimera and point-mutation studies designed to identify the molecular-structural basis for this profound pharmacological difference between the receptors formed by highly homologous murine $\beta 1$ and $\beta 3$ subunits.

Six chimeras with different portions of the wild-type \$1 sequence replaced by the β3 sequence were constructed and their responsiveness to PNB determined. Only chimeras with a critical segment of the $\beta 3$ subunit amino acids 250 - 341 (numbering based on the mature β3 polypeptide) formed PNB responsive receptors. In this critical region of 92 amino acids, there are 17 amino acid difference between the two parent subunits. Site-directed mutagenesis of one specific Asn residue in the M2 - M3 linker region of the wild-type β3 subunit with a Ser present at the homologous site on the wild-type \$1 subunit abolished the response to PNB. The converse mutation of the serine residue in the wild-type $\beta 1$ to an Asn residue formed PNB-responsive receptors with a dose-response indistinguishable from the wild-type β3 subunit receptor. Substitution of this residue with Gly, Ala, Glu, or Thr gave nonresponsive receptors indicating a critical role of Asn not replaced by other amino acids. The dependence of the peak current response on the ratio of wild-type $\beta 3$ to β 3(N-to-S) mutant cRNA suggests that all five subunits in a pentameric assembly must be wild-type for successful PNB gating of the ion channel. Our results suggest that PNB opening of the ion channel requires a concordant interaction with all five subunits analogous to the neurotransmitter gating mechanism (Supported by R01-GM52325 and CNPq of Brazil)

IN VIVO IMAGING OF VOLATILE ANESTHETIC ACTION IN HUMANS: EVALUATION OF ¹¹C-FLUMAZENIL (FMZ) PET UNDER ANESTHESIA F. Gyulai, M. Mintun*, L. Firestone, J. Price, P. Winter

Depts. Anesthesiology/CCM, Radiology, and PET Facility, U. Pittsburgh, PA 15261
One of the proposed sites of volatile general anesthetic (GA) action, the γ-aminobutyric acid receptor type A (GABA_A-R), can now be studied in vivo by positron emission tomography (PET) using ¹¹C-FMZ. However, GA effects on regional cerebral blood flow (rCBF) could confound anesthetic-related changes in ¹¹C-FMZ binding, by altering ligand delivery. To assess this, following IRB approval (#950389), ¹¹C-FMZ binding and rCBF was measured in 7 healthy volunteers before and during 1.2 vol% isoflurane anesthesia. The effect of a wide range (25-200%) of rCBF values on ¹¹C-FMZ binding was also studied by computer simulation. The distribution volume (DV) of ¹¹C-FMZ, a reflection of both receptor-specific and nonreceptor binding, was estimated using a 2-compartment model (J. Cereb. Blood Flow Metab. 11:735, 1991) to assess how both isoflurane-induced, and simulated rCBF changes affected this parameter. Absolute rCBF was measured using ¹⁵O-water. Regions of interest included areas of high (frontal, occipital cortex), intermediate (thalamus, cerebellum), and low (pons) GABA_A-R density. Comparisons were made by a paired t-test at p < 0.05. Least squares regression was used to correlate GA-related DV changes to rCBF alterations and literature values of GABA_A-R density.

GA increased DV in each examined brain region (p < 0.05), and DV change correlated highly with GABA_A-R density (r = 0.86, p < 0.001). rCBF increased by \sim 30% in 3, and decreased by \sim 30% in 4 subjects. Measured rCBF changes did not correlate with DV alterations (p > 0.05). Finally, large simulated rCBF alterations were associated with trivial (t = 2%) changes in ¹¹C-FMZ DV. These results indicate that GA effects on ¹¹C-FMZ binding, measured by PET, occur independently from rCBF alterations in humans.

DIFFERENTIAL SUBUNIT INFLUENCE FOR THE ACTIONS OF GENERAL ANESTHETICS ALPHAXALONE AND ETOMIDATE ON GABAA RECEPTORS. E. Sanna*, A. Murgia, F. Amato, T. Deserra, M. Usala, P.J. Whiting and G. Biggio. Dept. of Experimental Biology, Univ. of Cagliari, Italy, and Merck, Sharp & Dohme Research Labs, Harlow, Essex, U.K.

Recent studies have suggested that multiple actions of several general anesthetics on GABAA receptors are subunit-dependent. In this study, we have investigated the role of different \beta-subunits in the actions of the anesthetics alphaxalone (AX) and etomidate (ET) on GABAA receptors expressed in Xenopus oocytes. Mixtures of cDNAs encoding human $\alpha1\beta1\gamma2s$, $\alpha1\beta2\gamma2s$ or $\alpha1\beta3\gamma2s$ subunits of the GABAA receptor were injected into oocytes and modulatory effects of GABA (EC20) respon and direct "agonist" action of AX and ET were measured using standard two-electrode voltage-clamp recording. AX $(10^{-7}\text{-}10^4\text{M})$ and ET $(10^{-7}\text{-}10^4\text{M})$ enhanced currents induced by GABA in all three receptors. For AX, higher efficacy (220-280%) was detected with receptors containing \$1 or \$3 compared to those with the \$2 subunit (150%). $\beta2\text{-}$ or $\beta3\text{-}containing receptors showed higher sensitivity (250-300%) to$ potentiation by ET compared to those with the $\beta1$ subunit (140%). When we studied the direct effects of AX and ET, we found that the rank order of receptor sensitivity in relation to the β subunit was $\beta1{>}\beta2{\geq}\beta3$ and $\beta3{\geq}\beta2{>}\beta1$ for AX and ET, respectively. In addition, \$1 homomeric receptors were sensitive to direct activation by ET but, as already shown (Sanna et al., 1995), not by AX. Conversely, α1γ2s receptors were strongly activated by AX but were only poorly sensitive to ET. These results further demonstrate that $\boldsymbol{\beta}$ subunits influence the action of general anesthetics on GABAA receptors, and indicate that the effects of AX and ET differentially vary according to receptor composition. The data support the idea that AX and ET have different sites of action at the level of the GABAA receptor complex.

PROPOFOL INDUCES TYROSINE-PHOSPHORYLATION OF THE GABAA-RECEPTOR β -SUBUNIT. K. Björnström¹,

Å. Schippert², A. Sjölander² and C. Eintrei*¹. Departments of Anaesthesiology¹ and Cell Biology², Linköping University, 581-85 Linköping, Sweden.

Little is known about the action of anaesthetic drugs on the central nervous system. The major theories have involved changes of the cell membrane and its associated proteins. Recently, increasing evidence have been raised that the GABA-receptor-complex might be a target for anaesthetic drugs. The GABA-complex is the major inhibiting system in the brain, and it fits well with the desired action of anaesthetics, i e to reduce nervous excitability. We have previously shown that propofol in neurons induced an immediate intracellular calcium signal.

We used primary cell cultures from new-born rats, cultivated for 10 days in cell culture flasks. The cells were stimulated with 0, 3, 30 μg/ml propofol, by the commercial available solution Diprivan[®], for 0, 60 or 120 sec respectively. We used electrophoresis combined with Western blot technics to detect tyrosine-phosphorylation and the GABAAβ-subunit.

The stimulation by propofol gave an increase in tyrosine-phosphorylation. One of these bands was also detected by an specific antibody against the GABAA β -subunit. The time maximum of tyrosine-phosphorylation was 120 sec.

We conclude that the anaesthetic drug propofol probably cause its anaesthetic effect by changing the GABAA-receptor by tyrosine-phosphorylation.

EFFECTS OF RUN-DOWN AND INTRACELLULAR CALCIUM BUFFERING ON PROPOFOL'S MODULATION OF GABA, RECEPTOR DESENSITIZATION. S. Roder ** J. F. MacDonald and B. A. Orser **. Departments of Physiology & ²Anaesthesia, University of Toronto & Sunnybrook HSC, Toronto, Onlario, Canada, M5S 1A8.

The desensitization of GABA_A receptors observed with saturated GABA concentrations is decreased by anaesthetics such as propofol (PRO). Intracellular Ca²⁺ buffering reduces the time dependent run-down of GABA_A mediated whole cell currents, and may also effect GABA_A receptor desensitization. However, the effects of run-down and intracellular Ca²⁺ buffering on PRO modulation of GABA_A receptor desensitization are not known. Therefore, the whole cell patch clamp recording technique was used to investigate these effects on the modulation by PRO of GABA_A receptor desensitization. Whole cell currents were recorded from cultured embryonic hippocampal neurons using intracellular solutions containing either the low affinity Ca²⁺ chelator, EGTA (11mM), and no added CaCl₂. Using a rapid perfusion system, GABA (600µM) in the absence and presence of PRO (10µM) was applied at 10 min intervals to neurons held at -60 mV. The extent of receptor desensitization was determined from the ratio of steady state to peak current (I₂I₁). In the presence of either EGTA or BAPTA, I₃/I_p of the GABA induced currents decreased over a 30 minute period by 46±7% (n=6) and 26±11% (n=7), respectively. However, PRO increased I₃/I_p by approximately 30% at all time intervals tested and did not depend on either intracellular Ca²⁺ buffer. These data suggest that neither the time dependent run-down of GABA induced whole cell currents nor differences in intracellular Ca²⁺ buffering altered PRO modulation of GABA_A receptor desensitization. GABA PHARMACOLOGY OF CEREBELLAR GRANULE CELLS IN MICE DEVOID OF THE ALPHA 6 SUBUNIT OF THE GABA, RECEPTOR. <u>C.E. Rick*</u>, <u>G.E. Homanics¹</u>, <u>L.L. Firestone¹</u> & N.L. <u>Harrison</u>, Dept. Anesthesia & Critical Care, Univ. Chicago, Chicago, IL 60637; ¹Dept. Anesthesia & Critical Care, Univ. Pittsburgh, Pittsburgh, PA 15261.

The presence of the alpha 6 (α 6) subunit confers benzodiazepine insensitivity on recombinant GABA_A receptors. In the CNS, GABA_A receptors containing the α 6 subunit are found almost exclusively in cerebellar granule neurons. The subunit composition of cerebellar granule neurons is age dependent, early receptors are benzodiazepine-sensitive whereas late ("mature") receptors show the benzodiazepine insensitive pharmacology thought to be associated with the α 6 isoform².

Mice lacking a functional $\alpha 6$ subunit (-/-) were created by embryonic stem cell gene targeting, and their cerebellar granule neurons were compared to wild type mice (+/+). Cells from the cerebellum of 6-7 day old pups were cultured in a high K' medium in order to promote differentiation of cerebellar granule cells. Whole cell patch clamp recordings were made from early (culture day 6-10) and late (culture day 21+) cultures.

All experiments from early cultures, from both +/+ and -/- mice, had GABA EC_{s0} 8-20 μ M; currents in response to submaximal concentrations of GABA were potentiated by the benzodiazepine, midazolam (500nM). Preliminary data suggest that mature cultures from -/- mice maintain their benzodiazepine sensitivity, with no shift in apparent affinity for GABA.

511.10

PROPOFOL MODULATION OF GABA_A RECEPTOR ACTIVATION AND DESENSITIZATION IS MEDIATED BY DISTINCT MECHANISMS. <u>LC McAdam¹², JF MacDonald², BA Orser¹²².</u> ¹Departments of Anaesthesia & ²Physiology, Sunnybrook Health Science Centre & University of Toronto, Ontario, Canada, M5S 1A8

Propofol (PRO, 2,6 di-isopropylphenol) may act at distinct sites on the GABA_A receptor to 1) potentiate GABA-evoked responses, 2) directly activate the receptor in the absence of GABA, and 3) decrease desensitization (Orser et al., J Neurosci 14:7747, 1994). In contrast, the sedative-hypnotic benzodozepine, midazolam (MDZ) does not directly activate the GABA_A receptor but potentiates GABA-evoked responses by binding to a flumazenil-sensitive site. The purpose of this study was to investigate the interactions between PRO and MDZ at the GABA_A receptor.

Whole cell currents were recorded from embryonic cultured hippocampal neurons voltage clamped at -60mV. Currents activated by PRO in the absence of GABA were enhanced by MDZ (0.5 μ M). The EC₃₀'s and Hill coefficients for the currents activated by PRO or PRO + MDZ were 22.3 \pm 4.3 μ M and 15.9 \pm 3.1 μ M, and 1.26 \pm 0.16 and 1.58 \pm 0.29, respectively (mean \pm SEM, n=4). Saturating concentrations of GABA (600 μ M) activated inward currents which peaked (I_0) then declined to an apparent steady-state (I_{av}). The extent of desensitization, estimated from the I_a/I_p ratio, was 0.156 \pm 0.026. In the presence of PRO (10 μ M) or PRO (10 μ M) + MDZ (0.5 μ M), the I_{av}/I_p ratios were 0.198 \pm 0.022 and 0.193 \pm 0.022, respectively (n=7). These data indicate that MDZ increased the apparent affinity of the GABA_A receptor for PRO but did not effect PRO-induced modulation of desensitization. This suggests that there may be distinct mechanisms through which PRO modulates activation and desensitization. 511.12

SUBUNIT-DEPENDENT MODULATION OF RECOMBINANT GABA, RECEPTORS BY GENERAL ANESTHETICS. S.M. O'Shea'*, M.D. Krasowski', C.E. Rick', P.J. Whiting², K.L. Hadingham², C. Czajkowski³, N.L. Harrison¹, ¹U. Chicago, Chicago, IL; ²Merck, Sharpe, & Dohme, U.K; ³U. Wisc, Madison, WI.

We have investigated the role of the \alpha subunit in the modulation of GABA, receptors by the general anesthetics propofol (PRO), methohexital (MTX), and trichloroethanol (TCEt; the active metabolite of chloral hydrate). Fibroblast cell lines which stably express either $\alpha_1\beta_3\gamma_2$ or $\alpha_6\beta_3\gamma_2$ GABA, receptors were studied by both electrophysiological and radioligand assay techniques. Using the whole-cell patch clamp technique, PRO, MTX, and TCEt applied at clinical concentrations significantly potentiated submaximal GABA chloride currents in cells expressing either subunit combination. PRO and TCEt potentiated responses in $\alpha_1\beta_3\gamma_2$ receptors to a far greater degree than those in $\alpha_n \beta_3 \gamma_2$ receptors. This differential effect was reflected in the maximal efficacy of modulation by PRO and TCEt, but not in their apparent affinities. This difference is not related to levels of expression, since MTX potentiation of chloride currents did not vary significantly between $\alpha_1\beta_3\gamma_2$ and $\alpha_6\beta_3\gamma_2$ receptors. Similarly, enhancement of 3H-muscimol binding by PRO was significantly greater in $\alpha_1\beta_3\gamma_2$ than $\alpha_6\beta_3\gamma_2$ receptors; whereas MTX enhances ³H-muscimol binding significantly more in $\alpha_0\beta_3\gamma_2$ than $\alpha_1\beta_3\gamma_2$ receptors. These results taken altogether demonstrate that the difference in efficacy of PRO and TCEt between $\alpha_1\beta_3\gamma_2$ and $\alpha_6\beta_3\gamma_2$ receptors is dependent on the specific anesthetic-receptor interaction and is not a general feature of these two subunit combinations. The relative anesthetic potentcies of PRO and MTX correlate better with modulation of GABA responses in $\alpha_1\beta_3\gamma_2$ than $\alpha_6\beta_3\gamma_2$ receptors, suggesting that the $\alpha_6\beta_3\gamma_2$ receptor subtype may not be a relevant general anesthetic target

PRODUCTION AND CHARACTERIZATION OF MICE DEVOID OF THE BETA 3 SUBTYPE OF THE GABA, RECEPTOR. GE Homanics*. C Ferguson, JJ Quinlan, KD Snyder, ZP Mi¹, and LL Firestone. Dept. Anes/CCM, ¹Dept. Neurobiology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

The beta 3 (β 3) subtype of the GABA_A receptor has been implicated in craniofacial development (PNAS 91:2815, 1994). To test this hypothesis, we used gene targeting in embryonic stem cells to create mice that lack a functional β 3 gene. Beta 3 null mice (-/-) were created by replacing exons 1-3 and ~1.8kb of promoter with a neomycin cassette. Hybridization of neonatal whole brain mRNA with an exon 1-3 specific probe and with an exon 9 specific probe showed that the ~6.0kb β 3 mRNA in wild type (+/+) mice was completely absent in -/- mice, confirming successful creation of a null allele. Approximately 60% of -/- pups are born with cleft palate and die within 24h of birth due to unknown causes; ~5% of -/- mice survive to adulthood. These survivors display a nervous phenotype, but have grossly normal brain histology, normal gait, and no ataxia. The affinity of GABA_A receptors in neonatal whole brain homogenates for 3 H-Ro15-4513 and 3 H-muscimol was similar in +/+ and -/- mice. However, -/- brains reveal a marked reduction in total GABA_A receptor density (from 1.8±0.4 to 0.7±0.1 pmol/mg for Ro15-4513, p=0.003; and from 1.9±0.2 to 1.0±0.2 pmol/mg for muscimol, p<0.002). Both -/- males and females are fertile but females fail to care for offspring. In sum, these results indicate that β 3 is intimately involved in normal palate formation, and production of the normal complement of brain GABA_A receptors.

511 15

PRODUCTION AND CHARACTERIZATION OF MICE DEVOID OF THE ALPHA 6 SUBTYPE OF THE GABA, RECEPTOR. LL Firestone*, J. Quinlan, E Korpi¹, JL Daggett, C Ferguson, ZP Mi², XH Wang³, DR Grayson² GE Homanics. Dept. Anes./CCM, ²Dept. Neurobiol., Univ. of Pittsburgh, Pittsburgh, PA 15261; Biomedical Research Center, Alko Ltd., Helsinki, Finland; ³Med. Col. of Penna, Pittsburgh, PA 15212.

The alpha 6 (\alpha 6) subtype of the GABAA receptor has been implicated in the intoxicating effects of ethanol. To test this hypothesis, we used gene targeting in embryonic stem cells to create mice that lack a functional α6 gene. Alpha 6 null mice (-/-) were created by inserting a neomycin cassette into exon 8. Null mice are viable, fertile, and have grossly normal brain morphology. RT-PCR and Northern blot analyses were used to demonstrate that the targeting event disrupted production of α6 mRNA. Autoradiography of histological sections of adult brains demonstrated that the diazepam-insensitive binding of ³H-Ro15-4513 to the cerebellar granule cell layer of wild type (+/+) mice was completely absent in -/mice. Together, these analyses establish that the gene targeting event results in a nonfunctional α6 allele. Semi-quantitative RT-PCR showed no significant difference in expression of other α subtypes in cortex and cerebella of -/- mice as compared to +/+ mice. Sleep time response (mean±SEM; n=14-15/group) of +/+ and -/- mice to ip injection of ethanol (3.5g/kg BW) following pretreatment with vehicle (V) or Ro15-4513 (Ro; 10mg/kg BW) were: 49.3 ± 5.3 for V,+/+; 41.7 ± 5.9 for V,-/-; 27.8 ± 3.5 for Ro,+/+; and 28.6 ± 4.4 for Ro,-/-. The effect of genotype was nonsignificant; pretreatment with Ro decreased sleep time (p<0.001; ANOVA). Thus, the $\alpha 6$ subtype of the GABAA receptor is not required for normal brain development, normal viability and fertility, nor does it appear to be a critical or unique component of the neuronal pathway mediating the hypnotic effect of ethanol and its antagonism by Ro in mice, as reflected by this sleep time assay Support: NIH grants GM52035, AA10422, and Dept. Anes., Univ. of Pittsburgh.

CONSTRUCTION AND EXPRESSION OF CHIMERIC GABAA/GLYCINE RECEP-TORS. Q. Ye, V.V. Koltchine, S.E. Finn and N.L. Harrison*, Anes and Pharmacology, The University of Chicago, Chicago, IL 60637 GABAA receptors (GABA-R) and glycine receptors (Gly-R) are close relatives in the 'gene superfamily' of ligand-gated ion channels, but they show distinctly different pharmacology. In order to resolve the structural elements involved in various pharmacological modulations, two series of chimeras between the human GABA-R and human Gly-R were constructed and expressed. The first series, the "S" series, was constructed by introducing an XmaI site into a conserved region in the N-termini of the GABA-R ($\alpha 2$ and $\beta 1$ subtractions of the GABA-R ($\alpha 2$ and $\alpha 3$ subtractions of the GABA-R ($\alpha 2$ and $\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R ($\alpha 3$ subtractions of the GABA-R (and Gly-R (α2 subunit) cDNAs, enabling an exchange between the GABA-R and Gly-R cDNA fragments. The resulting S1 and S3 chimeras were mostly GABA-R $\alpha2$ or $\beta1$ with the N-terminal ~30 amino acids replaced by the corresponding region of the Gly-R, while S2 and S4 were mostly Gly-R \(\alpha 2 \) with the same N-terminal region replaced by the GABA-R α 2 or β 1 counterparts. S2 and S4 both formed glycine-gated homomeric channels in HEK 293 cells, with EC50 values of 503 and 16.6 uM (EC50= 50.2 uM in w.t Gly-R \(\alpha\)2). Chimeras S1 and S3 failed to form functional channels by themselves. However, when co-expressed with their complementary GABA-R subunits, S1/GABA \(\alpha \)2 and S3/GABA \$1 both formed GABA-gated heteromeric channels, with EC50 values of 17.2 and 22.5 uM (EC₅₀=8.4 uM in w.t. GABA-R α2/β1). The second series of chimeras, the "X" series, was constructed by introducing an XbaI site into the C-terminal end of the third transmembrane domain (TM3), allowing an exchange of the large cytoplasmic loop (C-loop) and TM4 between the GABA-R and Gly-R. The constructed X1 chimera has the N-terminus and TM1-3 from Gly-R α2 joined by the C-loop and TM4 from GABA-R β1, resulting in a homomeric glycine-gated channel (EC50=364 uM). The chimeras X2 and X4 have the N-termini and TM1-3 from GABA-R α2 or β1 joined by the C-loop and TM4 from Gly-R. X2/GABA-R \(\alpha \) and X4/GABA-R \(\beta \)1 both formed heteromeric GABA-gated channels (EC50=51.8 and 8.2 uM). Further pharmacological analyses of these and other chimeras are presented in the adjoining posters by Koltchine et al. and Mihic et al. Supported by GM45129, GM00623 (NLH) and DA07255 (VVK)

511.19

A SEARCH FOR SITES OF ACTION OF ALCOHOLS ON GABA AND GLYCINE RECEPTORS. M.J. Wick, N.L. Harrison, S.J. Mihic, Q. Ye, S.E. Finn, S. Bhave* and R.A. Harris. Dept. Pharmacology, Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80262 and Dept. Anesthesia, Univ. Chicago, Chicago, IL 60637. Alcohols produce sedation, loss of righting reflex and, at high enough concentrations, anaesthesia. These effects may be produced by their positive modulation of GABA, and glycine receptor function. In contrast, alcohols potently inhibit the function of homomeric GABA p1 receptors (Mihic and Harris, JPET 277:411). Using the chimeric receptor approach discussed in the adjoining posters by Ye et al. and Mihic et al., we are attempting to identify which amino acids are responsible for the positive effects of alcohols on glycine receptors. The X junction site (see Ye et al.) in the C-terminal end of the third transmembrane (TM) domain allowed for the exchange of the TM3 - TM4 intracellular loop plus TM4 between Network of the exchange of the 1M3 - 1M4 intracellular loop plus 1M4 between the receptors. The X-5 chimeric receptor contained glycine $\alpha 2$ sequence from the N-terminal end to the X junction site, and GABA pl sequence from the X junction site to the C-terminal end. The X-6 chimera was the converse of X-5 at the same junction site. X-5 receptors, like glycine α receptors, showed potentiation by ethanol. However, the function of X-6 receptors, like GABA pl receptors, showed marked inhibition by ethanol. These data exclude the TM3 - TM4 intracellular loop as well as TM4 as contributing to the effects of ethanol on these receptors. Thus far, we have not been able to differentiate the sites of action of alcohols and volatile anaesthetics at the glycine receptor. Supported by AA06399, GM47818 (RAH) and GM45129, GM00623 (NLH).

BARBITURATE SENSITIVITY OF THE HUMAN GABAA RECEPTOR: STUDIES USING CHIMERIC GABA/GLYCINE RECEPTORS

V.V. Koltchine*, O. Ye, S.E. Finn and N.L. Harrison. Anesthesia and Pharmacology, The University of Chicago, Chicago IL 60637.
The mammalian GABAA receptor (GABAA-R) can be modulated by a

range of general anesthetics including barbiturates (BARB). Although the native GABA_A-R typically consists of a heteropentameric complex of α , β , and γ subunits, the γ subunit is not required for BARB modulation. The glycine receptor (Gly-R) α subunit forms a functional homomeric receptor which is insensitive to barbiturates. We have used this pharmacological selectivity to investigate the specific domains of the GABAA receptor that confer sensitivity to BARB, by studying the chimeric GABA/Gly-R receptor subunits described in the adjoining poster by Ye et al. Chimeras $X2(\beta_1-gly)$, $X4(\alpha_2/Gly)$, $S1(Gly/\beta_1)$ and S3 (Gly/α_2) did not form functional receptors when expressed alone in 293 cells, but did form functional receptors when co-expressed with the complementary wild-type GABAA-R subunit, as follows: $X2+\alpha 2$, $X4+\beta 1$, $S1+\alpha 2$, $S3+\beta 1$. All of these receptors showed full barbiturate sensitivity, showing both strong potentiation by MTX of the response to GABA and direct gating by MTX. Chimeras X1(Gly- β 1), S2 (β 1-Gly) and S4 (α 2/Gly) formed functional homomeric receptors gated by glycine. Like the wild-type Gly-R α 2 subunit, these three chimeras were completely insensitive to 500 μ M MTX. These results demonstrate that neither the large C-terminal domain 3' from site X (including the cytoplasmic loop and TM4), nor the extreme N-terminal domain 5' to site S, in either $\alpha 2$ or $\beta 1$ subunit, contributes significantly to the modulation of the GABAA-R by MTX. BARB sensitivity must therefore be conferred by the remaining $\sim\!\!300$ amino acid residues of either (or both) the GABA_A-R α or β subunits. Supported by GM 45129, GM 00623 (NLH) and DA 07255 (VVK).

A SEARCH FOR SITES OF ACTION OF VOLATILE ANAESTHETICS ON GABA AND GLYCINE RECEPTORS. S.J. Mihic*, M.J. Wick, N.L. Harrison, Q. Ye, S.E. Finn and R.A. Harris. Dept. Pharmacology, U. Colorado Hlth. Sci. Ctr., Denver, CO 80262 and Dept. Anesthesia, U. Chicago, Chicago, IL 60637. Current evidence suggests that the in vivo effects of volatile anaesthetics result from their interactions with membrane-bound ligand-gated ion channels, such as the GABA and glycine receptors, which are the primary mediators of inhibitory neurotransmission in the CNS. The function of GABA, and glycine receptors is markedly enhanced by pharmacologically-relevant concentrations of volatile anaesthetics. However, GABA receptors formed of p subunits instead show a weak inhibition. Because homomeric glycine \(\alpha\) receptors show significant amino acid sequence homology with homomeric GABA \(\alpha\) receptors, we are attempting to identify the amino acids responsible for the positive effects of volatile anaesthetics on glycine receptors, by creating receptor chimeras. The X junction site (see Ye et al.) in the C-terminal end of the third transmembrane (TM) domain allowed for the exchange of the TM3 - TM4 intracellular loop plus TM4 between the receptors. The X-5 chimeric receptor contained glycine $\alpha 2$ sequence from the N-terminal end to the X junction site, and GABA $\rho 1$ sequence from the X junction site to the C-terminal end. The X-6 chimera was the converse of X-5 at the same junction site. terminal end. The X-o crimera was the converse of X-5 at the same junction site. X-5 was gated by glycine but not GABA and, like glycine α receptors, showed potentiation by enflurane. X-6 was gated by GABA but not glycine and, like GABA ρ1 receptors, showed weak inhibition by enflurane. These data exclude the TM3 - TM4 intracellular loop as well as TM4 as contributing to the effects of contributing to the effects of the contribution of the effects of the contribution of the effects of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effect of the effec volatile anaesthetics on these receptors. GAS CHROMATOGRAPHY-MASS FRAGMENTOGRAPHY WITH NEGATIVE ION CHEMICAL IONIZATION TO MEASURE NEUROSTEROIDS IN BRAIN AND CSF. D.P. <u>Uzunov*</u>, <u>E. Costa and A. Guidotti</u>, The Psychiatric Institute, Department of Psychiatry, University of Illinois at Chicago, Chicago, IL 60612. Neurosteroids [allopregnanolone (ALLO), progesterone (PROG), 5α -dihydroprogesterone (5α -DHP), and dehydroepiandrosterone (DHEA)] are pharmacologically potent modulators of neuronal activity either by regulating transmitter action on ligand-gated channels (GABA_A) or by controlling transcriptional regulation of specific genes. It is not clear, however, whether significant amounts of pharmacologically active neurosteroids are synthesized de novo in brain tissue. We report the development of a specific and sensitive method combining high performance liquid chromatography (HPLC) and gas novo in brain tissue. We report the development of a specific and sensitive method combining high performance liquid chromatography (HPLC) and gas chromatography-mass fragmentography (GC-MF) with negative ion chemical ionization (NIC1) to provide quantification of these neurosteroids in small brain parts (1-10 mg tissue), the CSF (0.1 mL), or plasma (0.01 mL); the procedure allows identification of the chemical structure of the product being measured. We found in normal male human subjects plasma levels of ALLO of 0.59 ± 0.017 pmol/mL and of 5α-DHP 0.65 ± 0.060 pmol/mL; the content of ALLO in the CSF is considerably lower (0.15 ± 0.029 pmol/mL). By administering appropriate blockers of 5α-reductase (SKF-105111) and of 3α-hydroxysteroid oxidoreductase (3α-HSOR) (indomethacin, fluoxetine) to adrenalectomized/castrated (ADX/CX) rats, we have demonstrated that 5α-DHP and ALLO are synthesized in the brain by the demonstrated that $5\alpha\text{-DHP}$ and ALLO are synthesized in the brain by the coordinated action of $5\alpha\text{-reductase}$ and $3\alpha\text{-HSOR}$, with the highest efficacy in the olfactory bulb. The brain concentration of ALLO does not depend on that in peripheral organs because: ω peripheral tissues of ADX/CX rats do not synthesize ALLO and b in ADX/CX rats ALLO is virtually absent in plasma but is only marginally reduced in the brain. Moreover, ALLO is found in significant concentration (approximately 1 nM) in rat brain microdialysates. Taken together these data strongly suggest that the rat brain can synthesize, store, and release ALLO into the extracellular fluid in concentrations that may be sufficient to positively modulate the intensity of GABA-gated CI currents. TOWARD AN ANIMAL MODEL OF OVARIAN HORMONE-RELATED MOOD DISORDERS. Daniel Bitran*, Phyllis Renda, Steven M. Solano, & Sheryl S. Smith¹. Dept. of Psychology, College of the Holy Cross. Worcester MA 01610; & ¹Dept. of Anatomy, Hahnemann Univ., Philadelphia PA, 19102.

Progesterone (P) is thought to Japa a role in the etiology of premenstrual syndrome and postpartum depression. Both disorders are characterized by anxiety and an abrupt decrease in P levels (i.e., P withdrawal). Whereas acute P injection elicits anxiolytic effects via the formation of the GABA_A receptor-active neurosteroid, allopregnanolone (Biran et al., 1993; 1995), P withdrawal has been observed to produce anxiogenic effects (Gallo & Smith, 1993; Costa et al., 1995). observed to produce anxiogenic effects (Gallo & Smith, 1993; Costa et al., 1995). The animal model described herein used pseudopregnancy (PsdP) to test the effect of withdrawal from physiological elevation of P. Prepubertal female rats (21 days of age) were injected with 50 IU pregnant mare serum gonadotropin. Fifty six hours later (day 0 of PsdP), females received 25 IU of human chorionic gonadotropin. Control rats received SC injections of saline vehicle. On days 4, 10, 14, and 18 of PsdP, separate groups of animals (n=6-7 per group) were tested for 5 minutes in a novel open field, followed by a 10 minute test in the elevated plus-maze. Immediately after the behavioral tests, animals were killed, and samples of blood, cortex, hippocampus, cerebellum, diencephalon, uterus, ovary, kidney, and adrenal glands were taken. Blood serum P levels were markedly elevated in PsdP rats on days 4, 10, and 14, with peak levels on day 10. An age-dependent increase in open-field exploration was found in both control and PsdP animals. PsdP produced a delay in adult-like levels of exploratory activity, as animals. PsdP produced a delay in adult-like levels of exploratory activity, as evidenced by a decrease in exploration observed on day 10 of PsdP. Anxiolytic evidenced by a decrease in exploration observed on day 10 of PsdP. Anxiotytic effects were observed in the plus-maze during the the first 5 min test period on day 4 of PsdP. The lack of anxiotytic effect on PsdP days 10-18 could be a result of tolerance to the chronically-elevated levels of P. Current experiments are testing the tolerance hypothesis as well as the effects of P withdrawal using ovariectomy of PsdP animals on day 10, the day of peak P levels. This research was funded by the UPSH Grant MH 50450 to DB.

A REMARKABLY POTENT NEUROACTIVE STEROID GABA, RECEPTOR POTENTIATOR. J.E. Hawkinson*, M. Acosta-Burruel, K.C. Yang, C.S. Konkoy, E.R. Whittemore, R.M. Woodward, R.B. Carter and R.B. Upasani. CoCensys, Inc., 213 Technology Dr., Irvine, CA 92618.

The progesterone metabolite 3α -hydroxy- 5α -pregnane-20-one $(3\alpha, 5\alpha$ -P) potentiates GABAA receptor function acting through a unique site on the receptor complex. Despite extensive synthetic work to optimize several key features of the neurosteroids, increasing their potency has proven to be an elusive goal. Here we report that appropriate substitution in the para position of 3β-phenylethynyl-substituted neuroactive steroids greatly increases potency. In general, hydrogen bond accepting groups are preferred, with p-acetyl conferring optimal potency. 3β -(4'-Acetyl)-phenylethynyl- 3α hydroxy-5 α -pregnane-20-one (Co 5-2791) is ~11-fold more potent than 3α,5α-P as an inhibitor of [35S]TBPS binding in rat brain membranes (IC50 4.7 and 51 nM, resp.). In Xenopus oocytes expressing α1β2γ2L receptors, Co 5-2791 is ~200-fold more potent than 3α,5α-P in potentiating 5 % GABA responses (EC $_{50}$ 0.78 and 160 nM, resp.). In vivo, i.p. Co 5-2791 is 5-fold more potent than $3\alpha,\!5\alpha\text{-P}$ in protecting mice from PTZ-induced seizures (ED₅₀ 0.6 and 2.8 mg/kg, resp.). In contrast to 3α,5α-P, Co 5-2791 apparently has good oral bioavailability (p.o. ED50 0.7 mg/kg). The high potency of Co 5-2791 indicates that the neuroactive steroid binding site contains a large pocket accessible from the 3\beta-position and suggests that hydrogen bond accepting groups on extended 3\beta substituents can interact with residues of the pocket, resulting in a marked increase in potency.

PROGESTERONE WITHDRAWAL PRODUCES BENZODIAZEPINE INSENSITIVITY: A BEHAVIORAL STUDY M.H. Moran, M. Goldberg, S.J. Wieland*, D. Bitran¹ and S. S. Smith. Dept. of Neurobiology and Anatomy, MCP and Hahnemann University, Philadelphia, Pa; 'Dept. of Psychology, College of the Holy Cross, Worcester, MA.

Previous studies from this laboratory have demonstrated that withdrawal (wd) from three cycles of progesterone (P) administration prevents the normally potentiating effect of the benzodiazepine lorazepam (LZM) on GABA-evoked Cl- current (Costa et al. 1995). This effect was shown to be due to the GABA-active metabolite 3 a-OH-5-pregnan-20- one (allopregnanolone). The purpose of the present study was to examine the withdrawal effects of P on the sedative potency of LZM using a variety of hormone administration paradigms as models for PMS/post-partum conditions. Towards this end, rats were treated with P, by i.p. injection (500 µg, 1 or 2xdaily) or via implant (10mm/100 gm body weight). Implants of crystalline P were constructed of silastic tubing (0.132" i.d., 0.183" o.d.) and incubated overnight in 1% gelatin-saline prior to subcutaneous implantation. Three wd cycles of P administration (5 days P, 2 days wd/week) were effective in reducing the sedative potency of LZM (0.50 mg/kg, i.p.) as assessed by position slip during a treadmill locomotion paradigm (i.e., "riding" the treadmill). Position slip frequency was significantly increased following LZM administration to control rats (P<0.05) but was depressed in response to LZM following P wd (7.6 ± 1 vs. 49.6 ± 9.8, P<0.05). A shorter paradigm (2 days P, 1 day wd for three cycles) was effective in depressing position slip frequency in response to LZM using P implants (4.5 ± 1.2 vs. 9.6 ± 1.9, P<0.05), or P implants was ineffective in altering the sedative potency of LZM. These results suggest that wd after ierntermittent exposure to P markedly reduces the sedative potency of the BDZ LZM. This effect may reflect cross-tolerance of the two GABA-active compounds, LZM and allo

PROGESTINS CAN HAVE MEMBRANE-MEDIATED EFFECTS IN RAT MIDBRAIN FOR SEXUAL RECEPTIVITY, C. A. Frye* and S.G. Gardiner. Neuroscience Laboratories, Depts. of Psychology and Zoology, Connecticut College, New London, CT 06320.

Does progesterone (P) have membrane-mediated actions in the rat ventral tegmental area (VTA) to facilitate sexual receptivity? Ovariectomized (ovx) rats (n=10) with cannula over the ventromedial hypothalamus (VMH) and VTA were primed with 2μg, 17β-estradiol (E). After a pre-test (P:BSA), or cholesterol control (CHOL) to the VMH, and were retested. Two hours later, animals were again pre-tested for receptivity, and then P, P:BSA, the P metabolite, 5α-pregnan-3α-ol-20-one (3α,5α-THP), or CHOL implants were applied to the VTA. Subjects were re-tested 0, 30, 90, and 150 minutes later. Animals that received P in the VMH and had P, P:BSA, or $3\alpha,5\alpha$ -THP applied to the VTA, exhibited facilitated receptivity immediately, 30, 90, and 150 minutes post-VTA implantation compared to all other combination implants. Whether P's effects are due to actions at the GABA_A-benzodiazepine receptor complex (GBR) was investigated. Ovx (n=10), E-treated animals received GBR antagonist, bicuculline, or agonist, muscimol, infusions into the VTA and were tested for sexual receptivity. Animals receiving bicuculline to the VTA and 300 µg P showed significant reductions in lordosis 0, 30, and 60 minutes after infusion. Animals receiving muscimol and 0, 50, or 100 µg P showed significant increases in lordosis quotients immediately and 30 minutes after infusion. These data sugges that P can act at neuronal membranes within the VTA to modulate lordosis behavior and that these effects are likely due to actions at GBRs. Subunit-selective actions of 5α-pregnan-3α-ol-20-one and 5α-pregnan-3α,20αdiol on mammalian recombinant GABA, receptors. D. Belelli, *C. Hill-Venning, S. E. Shepherd, J. A. Peters and J. J. Lambert. Neurosciences Institute, Department of Pharmacology, Dundee University. Dundee, DD1 9SY Scotland, U.K.

The activity of the neurosteroids, 5α -pregnan- 3α -ol-20-one ($5\alpha 3\alpha$ -P) and 5α -pregnan- 3α , 20α -diol (5α , 20α -diol), to modulate GABA-evoked currents was investigated in Xenopus laevis oocytes expressing human recombinant GABAA receptors of $\alpha_x \beta_y \gamma_{2L}$ composition (where x=1,2,3,6 and y=1,2) and rat forebrain mRNA. $5\alpha 3\alpha$ -P produced a concentration-dependent potentiation of the inward current evoked by the bath-application of GABA at EC₁₀ at all human receptor subunit combinations tested and at the heterologously expressed rat GABAA receptors. The potency of the steroid varied little across human α_1 -, α_2 -, α_3 - and $\alpha_6\beta_1\gamma_{2L}$, $\alpha_1\beta_2\gamma_{2L}$ and rat GABA_A receptors, By contrast, the magnitude of the steroid maximal effect was approximately doubled (132 \pm 6% of the GABA maximum in the presence of 3 μ M $Sa(3\alpha-P)$ in the $\alpha_6\beta_1\gamma_{2L}$ receptors when compared to the other human or the rat recombinant GABA_A receptors. $Sa(3\alpha-P)$ enhanced the currents evoked by a maximally effective concentration of GABA (i.e. 3mM) to $302\pm43\%$ of control in the $\alpha_6 \beta_1 \gamma_{2L}$ receptor subunit combination whereas it elicited little or no potentiation of the GABA maximal response in the α_1 -, α_2 -, or $\alpha_3\beta_1\gamma_{2L}$ recombinant receptors Notably, $5\alpha 20\alpha$ -diol elicited a reduced potentiation of the GABA-evoked current when compared to $5\alpha 3\alpha$ -P. Furthermore, in contrast to $5\alpha 3\alpha$ -P, the magnitude of the pregnanediol effect did not vary across the α_1 -, α_2 -, α_3 - and $\alpha_6\beta_1\gamma_{2L}$ GABA_A receptor subtypes, while the potency was only marginally affected by the type of α subunit

These findings suggest that the α subtype is an important molecular determinant of the neurosteroid action at the GABA_A receptor. Furthermore, comparison of the α_6 and α_{1-3} amino acid sequences may be instructive for the identification of the molecular locus of the neurosteroid binding site on the receptor protein The work was supported by the MRC.

NEUROSTEROID MODULATION OF GABAA RECEPTOR DEPENDS ON δ SUBUNIT. WJ.Zhu*, JF.Wang, KE.Krueger* and S.Vicini

Depts. of Physiol. & Cell Biol⁺, Georgetown Univ Med Cntr Washington DC 20007 Neurosteroid modulation of GABA_A receptors has been observed with all subunit combinations investigated, however, heterooligomeric GABAA receptors subunit combinations investigated, investigated, interioring of the Containing δ subunits were not previously studied. We describe the effect of δ subunit expression on THDOC (3 α , 21dihydroxy-5 α -pregnan-20-one)-induced potentiation of GABA-gated currents in HEK293 transfected cell and in cerebellar granule cell in vitro. THDOC (10-100 nM) significantly potentiated GABA-gated currents in HEK293 cells transfected with combinations of α1, α6, β3, and γ2 subunit cDNAs while the cotransfection of δ subunit cDNA inhibited this potentiation. In contrast, the direct CI channels activation by THDOC at higher concentration (1-10 μ M) was not significantly dependent on δ subunit cotransfection. These results suggest that the δ subunit expression inhibits GABA_A receptor modulation but not the direct activation by neurosteroids implying the existence of distinct domains on the receptor protein for these actions. The δ subunit is predominantly expressed in the granule neurons of cerebellum and hippocampus in a development-dependent manner. THDOC potentiation of the GABA-gated currents was greater in 4 days than in 14 days in vitro cerebellar granule cells. indicating a development-dependent change in neurosteroid modulation. Single cell RT-PCR analysis of the mRNAs expressed in cultured cerebellar granule cells, shows that an increased number of granule cells at 14 DIV express δ subunit mRNAs as compared to 4 DIV granule cells. The presence of δ subunit mRNAs correlated well with the lack of sensitivity to THDOC. These results suggests that developmental expression of GABA_A receptor δ subunits may play an important role in determining the neurosteroid-induced modification of fast inhibitory synaptic function. CHRONIC NEUROSTEROID TREATMENT DECREASES THE GABA RECEPTOR mRNA LEVELS R. Yu* and M.K. Ticku. Dept of Pharmacology, Univ. of TX Hlth. Sci. Ctr., San Antonio, TX 78284-7764. The GABA, receptors are an important site of action and modulation for

Pharmacology, Univ. of TX Hlth. Sci. Ctr., San Antonio, TX 78284-7764. The GABA_A receptors are an important site of action and modulation for a variety of centrally acting drugs including neurosteroids. We have previously reported that chronic 5α-pregnane-3ol-20-one(5α3α) treatment while not altering the benzodiazepine binding, downe(5α3α) treatment while not altering the benzodiazepine binding, downergulated GABA and TBPS binding, and produced heterologous uncoupling, and decreased efficacy at the GABA_A receptor complex in cortical neurons (Mol. Pharmacol. 45:618, 1994; J. Pharmacol. Exp. Ther. 275:784, 1995). In order to understand the underlying mechanisms of the phenomenon, we investigated the effect of chronic 5α3α (1μΜ, 5 days) treatment on the GABA_A receptor subunit mRNA levels, using RNase protection assay. We found that 5α3α treatment decreased the α and β subunit mRNA levels, while not altering the γ2s subunit mRNA levels may provide an explanation for the heterologous uncoupling phenomenon and decreased efficacy observed in our earlier studies. The decrease in the β2 and β3 subunit mRNA levels may explain the downregulation of GABA and TBPS binding, and decreased GABA-induced Cl-influx. In summary, chronic 5α3α treatment produced downregulation of the GABA_A receptor α and β subunit mRNA levels, and these changes may be associated with the downregulation, heterologous uncoupling, and decreased efficacy of GABA_A receptor complex in the mammalian cortical neurons.

ANTAGONISM OF EPIPREGNANOLONE ON A COMMON NEUROSTEROID MODULATORY SITE OF THE GABA, RECEPTOR COMPLEX IN CNS. S. <u>Fiszer de Plazas* and L. Pignataro</u>. Instituto de Biologia Celular, Facultad de Medicina, Paraguay 2155, 1121, Buenos Aires, Argentina.

The GABA_A receptor complex is modulated by several drugs including

neuroactive steroids. Althoug the 3β hydroxylated isomer of pregnanolone (5βegnan-3β-ol-20-one) , epipregnanolone (EPI), was found inactive in modulating [3H]flunitrazepam ([3H]FNZ) binding, high concentrations of this isomer proved to antagonize competitively the [3H]FNZ binding potentiation induced by neuroactive

The aim of the present work was to study the selective nature of the steroid recognition sites present in the $GABA_A$ receptor complex of chick optic lobe. Accordingly, synaptic membranes were isolated from adult chicks and $1^3H|FNZ$ binding was assayed. Results indicated that 3α-hydroxy-5α-dihydroprogesterone (3α-OH-DHP) as well as alphaxalone (AFX) modulated [3H]FNZ binding in a concentration-dependent manner with half maximal concentrations (EC50) of 1.28 ± 0.32 and $6.56 \pm 0.86~\mu M$ and, maximal enhancements (E $_{max}$) of 97.65 ± 7.29 and 62.98±3.73 %, respectively. The addition of 16 μM EPI to either 3α-OH-DHP or AFX resulted in a decrease in EC50 values to 0.54 \pm 0.09 and 1.04 \pm 0.30 μ M, respectively, with no significant change in E_{max} values. Moreover, when a maximal concentration (16μM) of AFX was added to 3α-OH-DHP concentrations ranging from 16 nM to 16 μ M, additivity was only observed for low concentrations of the latter. When high concentrations were reached, both steroids failed to enhance [3H]FNZ binding above E_{max} for 3α-OH-DHP. These results indicate that both neurosteroids act through a common site and that EPI antagonizes their interaction with this site to a different degree, suggesting marked stereospecificity for such

STEROID MODULATION OF GABAA RECEPTORS IN HYDRA VULGARIS, A.Concas*, P. Pierobon#, M.C. Mostallino, G. Marino#, R, Minei# and G. Biggio, Dept. of Experimental Biology, Chair of Pharmacology, University of Cagliari, 09123 Cagliari, Italy, #Cybernetics Institute C.N.R., 80072 Arco Felice, Naples,

GABAA receptors are present in membrane preparations from Hydra vulgaris, one of the primitive living forms possessing a nervous system (Life Sciences 56:1485, 1995). These receptors are sensitive to muscimol and benzodiazepines and seem to be involved in the regulation of the feeding response. We have investigated the effect of neurosteroids on GABA_A receptors in membrane preparations from Hydra and their role in the living animal. Allopregnanolone (AP) and tetrahydrodeoxycorticosterone (THDOC) increased [3 H]GABA binding with nanomolar potency (EC₅₀ = 142 ± 21 nM AP and 623 \pm 43 nM THDOC) and great efficacy (maximal effect AP: 78 \pm 6.5% at 3 $\mu M;$ and THDOC: 62 \pm 5.2% at 10 $\mu M). The effects of steroids were$ mimicked by other positive allosteric modulators of GABAA receptors. In fact, diazepam (100 $\mu M),$ abecarnil (30 $\mu M),$ pentobarbital (300 $\mu M)$ and alphaxalone (10 μM) enhanced by 20, 23, 78 and 30% [3H]GABA binding to Hydra membranes, respectively. To clarify the functional role of GABAA receptors we studied the modulatory effect elicited by the above drugs on the feeding response. AP and THDOC (1-10 µM) prolonged, in a dose dependent manner, the times of mouth opening induced by 10 μM glutathione; the maximal effect was elicited by 10 μM AP (+32 \pm 2.5%) and 10 μM THDOC (+27 \pm 1.3%). Similarly, alphaxalone (10 $\mu M)$ increased ($\pm 34 \pm 7.5\%$) the action of glutathione, while pentobarbital did not modify significantly this response. The effects elicited by steroids were suppressed by administration of TBPS (1 µM), a specific Cl channel blocker. These results suggest that modulation of GABAA receptors by steroids appeared very early in evolution

THE AMYGDALA MEDIATES THE ANXIOLYTIC-LIKE ACTIVITY OF THE NEUROSTEROID ALLOPREGNANOLONE. K. T. Britton*, Y. Akwa, R. H. Purdy and G. F. Koob. Dept. of Psychiatry, V.A. Medical Center and the UCSD School of Medicine, San Diego, CA 92161 and Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The amygdala is a limbic structure that has long been implicated in the neurobiology of fear and anxiety. Recent studies have shown that amygdaloid nuclei can differentially mediate some of the anxiolytic effects of benzodiazepines in different animal models of "anxiety". We have previously demonstrated that systemic injections of the neurosteroid, allopregnanolone (3α -hydroxy- 5α -pregnan-20-one) can have an "anxiolytic-like" effect in the conflict paradigm, and this effect seems to be independent of the benzodiazepine site of action on CABA/benzodiazepine receptor-chloride ionophore receptors (Soc Neurosci. Abs. n° 207.13, 1995). In the present experiment, allopregnanolone (0-15 μ g) was infused bilaterally into the central amygdaloid nuclei of Wistar male rats which were then tested in a Geller-Seifter conflict test modified for incremental shock. Allopregnanolone produced a substantial increase in punished responding compared to the vehicle-infused controls. At the highest dose (15 µg) the unpunished responding was significantly decreased, indicative of mild sedation. These results suggest that the central nucleus of the amygdala may play a role in the anti-conflict activity of allopregnanolone in the rat. This work was supported by V.A. Merit Review (K.B) and grant AA06420 (G.K).

ALLOSTERIC MODULATION OF GABAA-MEDIATED CURRENTS IN NEURONS OF THE PREOPTIC AREA FROM MALE AND FEMALE RATS. S. T. Smith*1· and L. P. Henderson^{1,2}, Depts. of ¹Physiol. and ²Biochem, Dartmouth

Medical School, Hanover, NH 03755.

The preoptic area (POA) is known to play a key role in neuroendocrine function and the expression of sexual behaviors in rats. Within the POA, transmission mediated by GABAA receptors is known to have significant effects on the expression of sexual behaviors in both males and females. GABAA receptors are hetero-oligomeric proteins for which five different subunit families ($\alpha 1$ -6, $\beta 1$ -4, $\gamma 1$ -3, δ , $\rho 1$ -2) have been identified. Transient expression of GABAA receptor cDNAs in heterologous systems has shown that a γ subunit is required to confer high affinity binding for central benzodiazepine allosteric modulators, and that γ subunit subtypes influence the pharmacology of expressed receptors. High levels of γ 1 subunit mRNA have been shown via in situ hybridization to be restricted to the subunit micha have been shown via it want hybridization to be restricted to the POA, medial amygdaloid nucleus, and the bed nucleus of the stria terminalis (Ymer et al, 1990, Wisden et al, 1992) suggesting that the role of this subunit in determining the biophysical and pharmacological properties of native receptors may be best determined in neurons from the POA. To this end, we have characterized currents elicited by rapid perfusion with GABA of POA neurons acutely isolated from rats of both sexes. Sensitivity of GABAA-mediated currents to allosteric from rats of both sexes. Sensitivity of OABA2-intendate Currients to anostenic modulators, such as zolpidem and the β-carbolines has been assessed. Results obtained from acutely isolated neurons will be compared to analysis of spontaneous synaptic currents in intact slice preparations. Supported by NSF IBN-9319523, NIH NS28668 and an NRSA fellowship (MH11391) to STS.

HORMONE-DEPENDENT AND SEX-SPECIFIC DIFFERENCES IN EXPRESSION OF GABAA RECEPTOR γ SUBUNIT MRNAS IN THE VENTROMEDIAL NUCLEUS AND PREOPTIC AREA OF THE RAT. L. P. Henderson*1.2 P.K. Chang² M. K. Hristova² J.M. Pace³ S. Robinson³ A.S. Clark³ Depts. of ¹Physiol. and ²Biochem., Dartmouth Medical School, Dept. of ³Psychology, Dartmouth College, Hanover, NH 03755.

Gonadal steroids act during a neonatal critical period to induce permanent sexual dimorphisms in the ventromedial nucleus (VMN) and medial preoptic area (POA) of the rat. GABA_A-mediated synaptic transmission within these regions is known to play a key role in the expression of adult sexual behavior, to be sexually dimorphic, and subject to steroid regulation. It is likely that structural differences in receptor subtype contribute to the functional role of GABA_A receptors in mediating sexual behaviors. To test this hypothesis, we have analyzed differential expression of the individual γ subunit mRNAs of the GABA_A receptor in the VMN and the POA of rats of different sexes and ages, and in rats subjected to manipulations in the hormone environment. We find that there is high level of expression of the γ1 subunit mRNA in the POA, consistent with previous reports (Ymer et al, 1990; Wisden et al, 1992, Herbison and Fénelon, 1995) and that sex- and hormone-dependent differences in the levels of γ1 mRNA are evident. In addition, we have examined the expression of the short and long forms of the γ2 subunit mRNA in the VMN since sex-specific differences in the levels of these subunits (which differ in the presence of a PKC target consensus sequence) may contribute to sex-specific differences in current decay kinetics that we have observed previously. SEX DIFFERENCES IN THE ANESTHETIC ACTION OF ALFAXALONE ARE CORRELATED WITH DIFFERENTIAL ELIMINATION M. E. Brewster*, W. R. Anderson, A. Webb and E. Pop, Pharmos Corp., Rehovot, ISRAEL and Alachua, FL, USA and the College of Veterinary Medicine, University of Florida, Gainesville, FL USA

Alfaxalone is a steroid anesthetic chemically related to progesterone. The poor water solubility of this agent prompted us to reformulate the steroid in a 2-hydroxypropyl-β-cyclodextrin vehicle. The anesthetic potency of alfaxalone in male and female Sprague-Dawley rats was assessed using sleeping time as an endpoint. Consistent with earlier reports, a sex difference after i.v. treatment was not observed below 100 µmol/kg (33 mg/kg). On the other hand, significant sex-related potency differences were observed at higher doses such that female animals slept 2.6-times longer at 60 mg/kg and approximately 3-times longer at 72 mg/kg than the respective male group. Sex differences were also observed after i.p. administration. The disposition of alfaxalone in male and female rats after a 50 mg/kg dose of alfaxalone was derivatized (precolumn) using dinitrophenylhydrazine. Results of pharmacokinetic analysis of the plasma data indicated that alfaxalone was more rapidly eliminated from male as compared to female animals. In addition, areas under the concentration curve (AUC) were lower for males than females. For example, plasma AUC's were 906 and 1812 mg*min/L for males and females, respectively. Other tissue compartments manifested similar sex differences. These data are in contrast to those of Fink (Nature 298:270-273 (1982)) who reported that alfaxalone was eliminated with equal efficacy from males and females although the dose used in this study was 12 mg/kg. Since there is a sex difference in activity (after i.v. administration) only above doses of 30 mg/kg, it is possible that pharmacokinetic differences may also only be manifested at higher dose levels.

512.14

THE SEXUAL DIMORPHISM IN GABA, RECEPTOR mRNA DISTRIBUTION AND EFFECTS OF TESTOSTERONE RECEPTOR ANTAGONISTS ON THEIR EXPRESSION IN THE EMBRYONIC RAT CNS. L. Zhang*, W. Ma, A.N. Feldman, G. Xing, F. Lahjouji, J.L. Barker, D.R. Rubinow BPB., NIMH and Lab. Neurophysiology, NINDS, NIH, Bethesda, MD 20892

We used in situ hybridization techniques to study GABA_α receptor subunit (α1, β2, γ2, α2, α3, α5) mRNA expressions in normal controls and rats treated with testosterone receptor antagonists, flutamide (0.5 mg/kg/day) and cyproterone (250 ug/kg/day), from embryonic(E) day 14 to 21. We found that GABA receptor subunit expression was sexually dimorphic in certain brain regions at the transcription level. For example, higher level of $\alpha 5$ transcripts were found at E21 in the male hypothalamus(220% of female), while higher levels of $\alpha 2$ mRNA were discovered in the female thalamus(130% of male). Testosterone antagonists differentially altered the expression of GABA, receptor mRNA in male and female For example, \(\beta 2 \) transcript abundance in cortical and thalamic regions was upregulated by antagonists in males but was unchanged in females. In contrast, female but not male thalamic \(\alpha 2 \) mRNAs were downregulated by the testosterone antagonists. The results indicate that testosterone levels may have detectable if not important effects on the expression of different GABA, subunit mRNAs in different embryonic CNS regions. Such effects on mRNA expression are regional, subunit selective, and age dependent. Although it is unclear how the testosterone receptor antagonists alter GABA_A receptor mRNA expression, effects at both genomic and non-genomic sites may contribute. Testosterone changes in GABA, receptor subunit expression could play an early and possibly critical role in masculinizing the CNS.

EFFECTS OF THE NEUROACTIVE STEROID ALLOPREG-NANALONE ON THE SEXUAL EHAVIOR AND ULTRASONIC VOCALIZATIONS OF MALE RATS. B. Zimmerberg* and E.W. Fish. Williams College, Williamstown, MA 01267

Male sexual behavior is mediated, in part, by GABA-ergic activity. This experiment investigated the effects of i.p. injections of the neuroactive steroid allopregnanalone (AP), a positive modulator of the GABAa receptor, on the sexual motivation and sexual performance of male rats. Sexually experienced adult male rats in control, vehicle (20% beta-cyclodextrin), 1.25 mg/kg, 2.5 mg/kg, and 5.0 mg/kg AP conditions were tested in a T-maze to determine preference for an estrous vs. non-estrous female. The first two AP doses reduced estrous preference. Compared to males in control and 2.5 mg/kg conditions, fewer males in the 1.25 mg/kg, 5.0 mg/kg, and vehicle conditions achieved ejaculation during mating tests with an estrous female. Ultrasonic vocalizations in the presence of estrous bedding, the post-ejaculatory song, and post-ejaculatory activity were not affected by AP. There was a dose dependent reduction of grooming behavior by AP in the T-maze. These results suggest that neuroactive steroids may modulate both sexual motivation and performance in male rats, in addition to an anxiolytic effect as measured by grooming behavior.

POSITIVE COUPLING OF GABA_B RECEPTORS TO ADENYLYL CYCLASE IN RAT OLFACTORY BULB. M.C. Olianas* and P. Onali, Dept. Neurosciences, Univ. Cagliari, Cagliari, Italy.

Activation of GABA_B receptors has been reported to either inhibit or stimulate cyclic AMP formation in the brain. While the inhibitory effect results from a negative coupling to adenylyl cyclase through Gi/Go proteins, the stimulation of cyclic AMP formation has been detected only in intact cell preparations and has been considered to be a secondary event mediated by intracellular messengers. In this study we show that in membranes of rat olfactory bulb, the GABA_B receptor agonist (-) baclofen produced a concentration-dependent increase of adenylyl cyclase activity (EC₅₀ 30 µM). The (-) baclofen stimulation was higher in the granular and external plexiform layers than in the glomerular and olfactory nerve layers. The stimulatory effect of (-) baclofen was mimicked by 3-aminopropylphosphinic acid and GABA, but not by (+) baclofen, and was counteracted by CGP 35348 and CGP 55845A, two selective GABA_B receptor antagonists. The (-) baclofen stimulation did not require Ca²⁺, was abolished by pertussis toxin and inhibited by the addition of the α subunit of transducin, used as a scavenger of Gby. The data demonstrate that in the olfactory bulb GABA_B receptors can directly stimulate adenylyl cyclase activity, likely by promoting the release of $\beta\gamma$ subunits of Gi/Go and the activation of the Ca²⁺-independent forms of the enzyme.

513.2

GAMMA HYDROXYBUTYRIC ACID INHIBITS EXCITABILITY OF DOPAMINE NEURONS THROUGH GABAB RECEPTORS IN THE RAT MIDBRAIN SLICE T.E. Madden and S.W. Johnson* Dept. of Physiol. & Pharmacol., Oregon Health Sciences University, Portland, OR 97201

Gamma hydroxybutyric acid (GHB), a precursor and metabolite of GABA, concentrated in the hypothalamus and basal ganglia has abuse potential. Intracellular electrophysiological recordings were made to characterize the effect of GHB on dopamine neurons in the ventral tegmental area and substantia nigra of the rat midbrain slice. 0.3 mM GHB slowed and 1mM blocked firing of dopamine neurons. Application of GHB (0.1-10 rnM) resulted in concentration-dependent hyperpolarization and reduction in input resistance ($EC_{50} = 0.60 \text{ mM}$) with the maximum mean effects reached at 1.25 mM (56% reduction of input resistance $[74~\text{M}\Omega]$ and 16 mV hyperpolarization). Changes in voltage and resistance were blocked by CGP 54626 (300 uM), but not by bicuculline (30 uM) or strychnine (10 uM). Single electrode voltage clamp recordings demonstrated that increasing concentrations of extracellular K+ significantly shifted the reversal potential to more depolarized potentials. These data support the hypothesis that GHB hyperpolarizes dopamine neurons by GABAB receptor-mediated opening of K+ channels.

EFFECT OF BACLOFEN ON NMDA MEDIATED SYNAPTIC RESPONSES IN RAT MIDBRAIN DOPAMINE NEURON IN VITRO. Y. N. Wu, W. E. Cameron*, and S. W. Johnson. Department of Physiology and Pharmacology, Oregon Health Sciences Univ., Portland, OR 97201.

Effects of baclofen on exitatory postsynaptic potentials (EPSPs) were studied on dopamine neurons in ventral tegmental area and substantia nigra zona compacta of rat brain slices using the patch clamp whole cell recording technique. Baclofen was more potent for reducing the amplitude of the EPSP mediated by NMDA receptors $(EC_{50} = 0.27 \mu M)$ compared with inhibition of the EPSP mediated by AMPA receptors (EC₅₀ = 1.05 μ M). But GABA_A receptor agonist isoguvacine reduced the amplitude of NMDA (51 \pm 3%, n = 7) and AMPA (55 \pm 5%, n = 10) EPSPs to the same extent. The increase in membrane conductance produced by baclofen $(E_{max} = 2.5 \text{ nS})$ was less than that for isoguvacine ($E_{max} = 12nS$). Membrane hyperpolarization was positively related to baclofen inhibition of the NMDA mediated EPSP. The data suggest that $\mbox{GABA}_{\mbox{\scriptsize B}}$ receptor activation may play an important role in regulating NMDA activated channels in dopamine (Supported by PHS grant MH40416.)

MULTIPLE POSTSYNAPTIC GABAB ACTIONS IN RAT HIPPOCAMPUS: EVIDENCE FOR SYNAPTIC AND EXTRA-SYNAPTIC RECEPTORS. T.M. Pham* and J.-C. Lacaille. Center for Research in Neurological Sciences and Department of Physiology, University of Montréal, Montréal. Qc, Canada H3C 3J7.

Postsynaptic GABA_B receptors in the hippocampus are coupled to heterogeneous K⁺ conductances differentially sensitive to Ba2+. Our aim was to determine with intracellular recordings in rat hippocampal slices, if synaptically-released GABA also activated heterogeneous K* conductances via GABA_B receptors. In the presence of GABA_A, NMDA and non-NMDA antagonists, GABA_B IPSPs were induced either by direct electrical stimulation of interneurons or by bath application of 100 µM 4-AP. Monosynaptic IPSPs evoked by stimulation of different layers, oriens (OR; n=13), lacunosum-moleculare (LM; n=13), and radiatum (RAD; n=14), showed no significant differences in amplitude (~-5 mV), peak latency (165ms), recovery time (410ms), or $E_{\rm ex}$ (-92mV). Bath application of the GABA_B antagonist CGP55845A (5μM) suppressed all 3 types of monosynaptic GABA_B IPSPs (amplitude ~5% of control; n=2 OR, 4 LM, 5 RAD). Using recording solution containing GTPγS (25mM), monosynaptic IPSPs were significantly reduced 60 minutes after impalement (amplitude ~4% of control, n=3 OR, 3 LM, 3 RAD). Bath application of 1mM Ba2+ completely suppressed all 3 types of synaptic IPSPs (n=12). Spontaneous IPSPs induced by 4-AP had similar properties (-8.2mV amplitude, 230ms rise time, 1.9s recovery time, and -104mV $E_{\rm ce}$). 4-AP induced IPSPs were totally blocked by bath application of CGP55845A (n=2) and reduced to 6.2±3.4% control (n=5) during recordings with GTPyS-containing solutions. 4-AP induced IPSPs were also completely suppressed by Ba²⁺ (n=10). These results indicate that GABA, released synaptically by stimulation of interneurons or by 4-AP application, may activate, via GABA_B receptors and G-proteins, only Ba2+-sensitive K+ conductances. Other postsynaptic GABA_B actions involving Ba²⁺-insensitive K conductances may thus be activated only via extrasynaptic receptors

IMMUNOCYTOCHEMICAL LOCALIZATION OF GABAC RECEPTORS IN THE MAMMALIAN CNS. R. Enz, J.H. Brandstätter, P. Koulen, H. Wässle* and J. Bormann Max-Planck-Institut für Hirnforschung, D-60528 Frankfurt, Germany

The bicuculline-insensitive GABA_C receptors are thought to be formed by the ρ subunits in the vertebrate retina. RT-PCR and in situ hybridization studies have shown the expression of p1 and p2 subunits in the retina and brain of the rat (Enz et al., 1995, Eur. J. Neurosci. 7: 1495-1501). We have generated polyclonal antibodies against the N-terminus of the rat p1 subunit in order to investigate the distribution of the p subunits in the mammalian CNS. The obtained antiserum recognized p1/2/3 subunits but not the GABAA-receptor subunits $\alpha 1-3$, $\beta 1-3$, $\gamma 2$, δ or the glycine-receptor subunits $\alpha 1$ and β on Western blots or transfected HEK-293 cells. On retina sections immunostaining was present in the outer and more prominently in the inner plexiform layers of different species. Labelling was punctate, indicating synaptic localization. Pre-incubation of the antibodies with the antigen resulted in no staining. Double-labeling experiments with antibodies against the p1 subunit and with antibodies staining either rod and cone bipolar cells or amacrine cells showed expression of ρ subunits at dendrites and axon terminals of rod and cone bipolar cells. Prominent staining of neurons with the p1 antiserum was observed also in rat spinal cord. These findings suggest an important physiological role of GABAC receptors in mediating inhibitory synaptic interaction in the mammalian CNS.

MUSCIMOL & BACLOFEN MICROINJECTED INTO THE ARCUATE NUCLEUS AFFECT VENTILATION DIFFERENTLY IN MALE RATS. E.H. Schlenker* and X-M Lin. Dept. of Physiology and Pharmacology, University of South Dakota School of Medicine, Vermillion, SD 57069

The arcuate nucleus (AN) of the hypothalamus contains high levels of gamma-aminobutyric acid (GABA) which may act on either GABA-A and/or GABA-B receptors to modulate autonomic function. The purpose of the present study was to determine the effects of microinjecting (200nl) muscimol (M), a GABA-A receptor agonist, in doses of 0, 1 and 5 nmol or baclofen (B), a GABA-B receptor agonist in doses of 0, 5 and 10 nmol into the AN of conscious male rats on their ventilation (VE), O2 consumption, and ventilatory responses to hypoxia (HX) and to hypercapnia (HC). M significantly decreased VE (F=11.42, P<0.001) especially at the 5 nmol dose as a result of a decreased tidal volume (Vt). In contrast, B significantly stimulated VE (F=8.69,P<0.001) at the 10 nmol dose due to an increase in Vt. Neither agonist affected O2 consumption, HX, nor HC. Thus, in the arcuate nucleus of male rats GABA may affect VE by acting on both receptor subtypes, and the effect is not associated with changes in O, consumption. NIH Grant # HD30390

513.6

MUTATIONS IN GABA RECEPTOR'S M2 DOMAIN OPEN THE CHANNEL GATE AND PRODUCE DUAL AGONIST EFFECTS. Zhuo-Hua Pan*, Dongxian Zhang, Xishan Zhang, and Stuart A. Lipton. Department of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

The chloride mediated GABA_C (or ρ) receptors belong to the ligand-gated ion channel superfamily. We used rat homomeric GABA ρ 1 receptors, site-directed mutagenesis, and the *Xenopus* oocyte expression system to explore the role of amino acid residues in the M2 domain on the receptor-channel function. Point mutations were made by replacing the threonine at position 314 with an alanine [p1(T314A)] or several other amino acids. Oocytes injected with p1(T314A) mutant cRNA displayed spontaneous inward current when clamped at -70 mV. The current, which reversed at the Cl- reversal potential, was blocked by the channel blocker picrotoxinin but not by the competitive GABA_C receptor antagonist 3-APMPA, indicating that receptor-channels were constitutively open in the absence of agonist. Moreover, low concentrations of GABA (nM) suppressed the spontaneous current (IC₅₀ concentrations of GABA (nM) suppressed the spontaneous current ($IC_{50} = 0.11 \, \mu\text{M}$ and $n_{H} = 0.8$), while higher concentrations (>0.1 μ M) elicited additional inward current. Both of these GABA-evoked effects were blocked by 3-APMPA. Substituting alanine for leucine at position 317 (but not other nearby sites) produced similar effects. Our findings provide electrophysiological evidence that amino acid residues at positions 314 and 317 of the GABA p1 receptor constitute the gate of the channel. The dual but opposing actions of GABA provide direct physiological evidence for multiple conformational transitions during receptor activation possibly reflecting highing of multiple agonist molecules. activation, possibly reflecting binding of multiple agonist molecules. Supported by an AmFAR Award and NIH grant R01 EY05477.

MOLECULAR CHARACTERIZATION OF A NOVEL GABA RECEPTOR TRANSIENTLY EXPRESSED IN THE HIPPOCAMPUS OF NEONATAL RATS. M. Mladinic, E. Cherubini*and A. Bradbury. Biophys. Lab, Int Sch. Adv. Studies (SISSA), 34013 Trieste, Italy.

We have recently described in the hippocampus of neonatal rats a novel GABA response which is bicuculline and baclofen insensitive and is mediated through CI permeable receptor channels. This response which is transiently expressed during development closely resembles that one present in the retina and assumed to be mediated by GABA_C receptors. It is conceivable that this new receptor channel is an heterooligomeric protein assembled from the rho1 or rho2 subunits. In the attempt to clone the novel GABA receptor gene(s) expressed in the neonatal hippocampus during the critical period of postnatal development, two different approaches have been used: RACE (Rapid Amplification of cDNA ends) and screening of a neonatal hippocampus cDNA library. In both approaches we have used the probe previously employed in *in situ* hybridization experiments (rho1+rho2 probe: nucleotide sequence of the rho1 gene 1130-1174 and nucleotide sequence of the rho2 gene 1042-1086) which gave a high signal in neonatal but not in adult rat brain. The RACE protocol generates cDNA by using PCR to amplify copies of the region between a single point in the transcript and 3' and 5' end. The 450bp fragment was obtained as a 3' RACE product using rho1+rho2 and TnTAG primers. The same fragment was obtained by PCR performed on the neonatal hippocampus cDNA library. The fragment was cloned into the Bluescript plasmid and sequenced. The sequence obtained is novel and not present in the database. It is most similar to the expressed sequence tag HFBEL69 from the human fetal brain. We are using this fragment as well as rho1+rho2 oligonucleotide as the probes to screen the neonatal hippocampus cDNA library to obtain the whole length of the gene of interest.

MUTATION OF A CONSERVED LEUCINE IN THE M2 REGION OF HOMOMERIC p1 GABA RECEPTORS. Y. Chang. DS Weiss. Neurobiology Research Center and Department of Physiology and Biophysics, University of Alabama at Birmingham, Birmingham, AL 35294-2001.

 γ -aminobutyric acid (GABA) binds to its receptor and opens an integral, chloride-selective pore. Previous studies demonstrated that mutations of a conserved leucine residue of the putative pore-lining region in the nicotinic receptor alters the channel's gating characteristics. In this study, we assessed the role of the conserved leucine residue in the M2 region of the p1 GABA receptor expressed in Xenopus laevis oocytes. The conserved leucine (L301) was mutated either to another hydrophobic amino acid: glycine (L301G), alanine (L301A), phenylalanine (L301F), isoleucine (L301I), valine (L301V) or to a hydrophilic amino acid: tyrosine (L301Y), serine (L301S), threonine (L301T). All hydrophilic substitutions, as well as L301G and L301A, created spontaneousopening channels, evident as an unusually high inward current in the absence of GABA. The holding current dropped in response to low concentration of GABA (0.01-0.3µM), but at higher GABA concentrations (1-1000µM) the response was biphasic. The results are consistent with the idea that the residue at this position needs both proper hydrophobicity and size for the channel to gate normally. (Grant # NS35291.)

513.11

PROTON SENSITIVITY OF THE RAT ρ_1 GABA RECEPTOR

M. Pasternack^{1*}, C. Rivera¹, K. Wegelius¹, M. Reeben², and K. Kaila¹

Dept. of Biosciences, Div. of Animal Physiology, P.O.Box 17, and ²Institute of

Biotechnology P.O.Box 56, FIN-00014 University of Helsinki, Finland.

Normal and pathophysiological activity induce marked pH changes in nervous tissue. These pH changes have a profound effect on the general excitability of the brain. A sensitivity of $GABA_{\lambda}$ and NMDA receptors to external proton ions has been postulated to underlie the pH-dependence of neuronal activity. We have cloned the ρ_1 GABA receptor CDNA from rat retina and transiently expressed the receptor in a HEK 293 cell line. We studied the sensitivity of this receptor

to external protons using the whole cell patch-clamp technique. We found the ρ receptors to be markedly sensitive to external pH. An increase in external pH (pH $_{\odot}$) from 7.4 to 8.4 increased the GABA-induced conductance by about 70%, whereas a decrease in pH $_{\odot}$ from 7.4 to 6.4 decreased the conductance to about 50% GABA concentration-response experiments revealed that external protons did not affect the EC₅₀ of GABA, but rather that protons inhibited the conductance in a manner independent of the GABA concentration.

We have previously shown that GABA receptors in pyramidal neurons of rat hippocampus are modulated in a dual manner by external protons. At higher GABA concentrations the conductance was upmodulated by protons, whereas at lower GABA concentrations downmodulation was observed. This suggests the presence of more than concentrations downhould and was observed. This suggests the presence of more than one GABA_A receptor population in the hippocampal pyramidal neurons. We have examined the distribution of ρ_1 and ρ_2 transcripts in the rat brain using in situ hybridization and RT-PCR techniques and found that both ρ_1 and ρ_2 are expressed in the rat hippocampus, albeit at a relatively low level. As the ρ_1 receptors studied here have a relatively high affinity for GABA (EC₅₀ = 1.5 μ M) they may well be responsible for the downmodulatory effect of protons seen in the hippocampal neurons at low GABA concentrations

FUNCTIONAL EXPRESSION OF RAT GABA RECEPTOR ρ3 SUBUNIT. Ryuzo Shingai*, Kazuya Yanagi, Teruyuki Fukushima, Kazumi Sakata and Tarou Ogurusu. Department of Information Science, Faculty of Engineering, Iwate University, Morioka 020 Japan

Cloned cDNA encoding GABA p3 subunit was isolated from cDNA library of rat retina. The amino acid sequence of this clone has 63 and 61% homology to human ρ1 and ρ2 subunit respectively. The expression of mRNA for p3 subunit in the retina was shown by Northern analysis. The cRNA made from p3 cDNA was injected into Xenopus oocytes and sensitivity to drugs was investigated under the two electrodes voltage clamp condition. Bicuculline did not block the GABA current, while 10 µM picrotoxin eliminated inward currents induced by 10 µM GABA. This receptor was almost insensitive to diazepam, pentobarbital, and neurosteroids tetrahydrodeoxycorticosterone (THDOC) and 3α -hydroxy, 5α -pregnan-20-one (3α -OH-DHP). Thus ρ3 subunit can form a homo-oligomeric ionotropic receptor, and has pharmacological properties common to the ρ-type GABA receptor subunits, and therefore could participate in functions of GABAc receptor in the retina.

GABA: GAD. GAT AND GABA STUDIES

514.1

Regulation of the mouse glutamate decarboxylase gene expression. Y. Yanagawa*1, T. Kobayashi 1,2, T. Kamei 1, K. Ishii 1, M. Nishijima2, A. Takaku2, H. Asada³, K. Obata³, Y. Sasahara¹, T. Kobayashi¹, and S. Tamura¹

¹ Inst. Development, Aging and Cancer, Tohoku Univ., Sendai, 980, Japan

Mouse glutamate decarboxylase (mGAD65 and mGAD67) is the enzyme responsible for synthesizing GABA. We used P19 cell line to examine the developmentally regulated expression of mGADs, and we cloned the 5' flanking region of mGAD67 gene to investigate the regulatory mechanisms controlling transcription of this gene

(1) P19 mouse embryonal carcinoma cells can be induced to differentiate along the neuroectodermal lineage. Western blot analysis showed that mGAD65 and mGAD67 were not expressed during 4 days after retinoic acd (RA) treatment, but appeared 6 days after RA treatment when neurite outgrowth was observed. The addition of a protein phosphatase (PP) inhibitor, okadaic acid, into the culture medium had an inhibitory effect on the expression of mGAD65 and mGAD67, but that of cyclosporin A did not. These results suggested that GAD expression coincidented with neural differentiation and that PPI or PP2A, but not PP2B, was associated with the

regulation of GAD expression.

(2) 5' -RACE method showed mGAD67 gene transcripts have two different 5' untranslated regions. Analysis of the genomic clones encompassing the 5' -exons revealed that the two transcripts arised from a single gene by alternative splicing using two different donor sites and a common acceptor. The exons were found 1.5 and 0.6 kb upstream of exon 2 RT-PCR method showed that each type was expressed in mouse brain. These results suggested that these transcripts could be regulated under control of independent promoters.

of Education, Science, Sports and Culture of Japan

TARGETED DISRUPTION OF THE MURINE GLUTAMIC ACID DECARBOXYLASE (65 kDa isoform -- GAD65) GENE. Kash, R. Johnson, L. Tecott, D. Lowenstein*, D. Hanahan and S. Baekkeskov

The inhibitory neurotransmitter GABA is synthesized by one of two isoforms of the enzyme glutamic acid decarboxylase (GAD65 and GAD67), each of which is encoded by a separate gene. To address the role of GAD65 in development and central nervous system function, mice lacking GAD65 were generated. Insertion of a neomycin-resistance cassette in exon one created a processor matching and functionally disputed the practice. nonsense mutation and functionally disrupted the protein. Homozygous mutant animals were born at a ratio that did not suggest embryonic lethality. Brains of homozygous mutant animals were shown to lack GAD65 by Western blot analysis and immunocytochemistry. Brain weights revealed the mutation had no effect on overall brain size. Animals were viable but there was a high frequency of spontaneous death (13% to date). Measurement of the threshold to seizure activity showed that mutant animals have a higher sensitivity to the GABAA-receptor antagonist pentamethylenetetrazole (metrazol). Continuous intravenous infusion of the convulsant showed significant differences in both the clonic seizure activity and lethal dose. There is a 30% decrease in the lethal dose, resulting from a 50% decrease in the clonic phase of seizure activity.

INCREASED EXPRESSION OF GLUTAMIC ACID DECARBOXYLASE (GAD) 65KD OR 67KD ISOFORMS LEADS TO INCREASED SYNTHESIS AND RELEASE OF GABA IN CULTURED NEURONS AND ASTROCYTES

K. C. New^{1*}, K. Gale³, R. L. Martuza², S. D. Rabkin^{1,2}. Departments of Microbiology & Immunology¹, Neurosurgery² and Pharmacology³, Georgetown Univ. Med. Ctr., Washington, DC 20007

Defective herpes simplex virus (HSV) vectors were used to express GAD65, GAD67, or β -galactosidase (β -gal) in primary cultures of cerebellar granule cell (CGC) neurons and astrocytes. We evaluated whether the increased expression of GAD leads to regulated release fo GABA. GABA release from neurons occurs through Ca**-dependent vesicular release and Ca**-independent reversal of the Na*/GABA cotransporter. Defective vector Defective vector (dv)GAD infected CGC neurons at 6 days in vitro (div) exhibited only Ca** independent GABA release, induced by glutamate or veratridine. In dvGAD infected CGCs (10 div), Ca**-dependent GABA release was induced by K* depolarization, and Ca**-independent release by veratridine. Similar levels and mechanisms of GABA release were detected in dvGAD65 and dvGAD67 infected neurons. In primary cortical astrocytes, GAD vector infection resulted in isoform specific expression of GAD, and GABA levels were two-fold higher in GAD67 than GAD65 expressing cells. GABA was tonically released from dvGAD infected astrocytes, but no increase in release could be detected after treatment of the cells with $K^{\scriptscriptstyle +}$, veratridine, glutamate or bradykinin. β -gal vector infected or uninfected astrocytes expressed no GAD and contained no detectable GABA. These data demonstrate that GAD expressing defective HSV vectors are able to increase the synthesis and release of GABA in cultures of neurons and astrocytes. Neurologic disorders that result from decreased GABA levels are potential targets for gene therapy using these vectors. Supported by a grant from the NINDS and an ARCS Foundation Scholarship

GABA-ERGIC NEURONS IN CULTURES OF FREEZE-STORED EMBRYONIC RAT NERVOUS TISSUES : A MORPHOMETRIC ANALYSIS USING IMMUNOCYTOCHEMISTRY. M.C.Calvet * and D.Petite. INSERM U 336. Univ. Montpellier II. 34095. Montpellier.

Based on prior work on cryopreservation and subsequent culturing of neural tissue, we have applied the principles of these techniques to embryonic rat cerebral cortex and mesencephalon. Blocks of fresh tissue were dissociated after freezing and storage at -196°C and the cells were cultured for 2-4 weeks before immunocytochemical staining with anti-GABA antibodies. A comparative morphometric analysis of the GABAimmunoreactive (IR) neurons allowed the individualization of two similar populations in both frozen and unfrozen materials: small and large neuritic field neurons. These two types of GABA-IR neurons could be evidenced as well in all the studied cultures with significant quantitative morphological differences linked to their original anatomical structure. Thus, GABA-ergic phenotype is expressed similarly in fresh and frozen cultured neurons with intrinsically programmed morphological features; small and large neuritic field GABA-IR neurons represent respectively local and long range circuits of inhibition indicating that the role of GABA as a major inhibitory transmitter is fundamental to regulate excitatory processes

EFFECTS OF STRESS ON EXTRACELLULAR GABA IN THE MEDIAL PREFRONTAL CORTEX. J.M. Finlay* and Veronica L. Neff, Dept. of Neuroscience, University of Pittsburgh, Pittsburgh, PA, 15260

Previous studies demonstrated that acute stress increases the activity of dopamine- and glutamate-containing projections to the medial prefrontal cortex (mPFC). Because the postsynaptic targets of these projections include the intrinsic γ-aminobutyric acid (GABA) interneurons it is also of interest to determine the impact of stress on these neurons. We have examined the impact of acute tail shock on GABA efflux in the mPFC and begun to characterize the origin of extracellular GABA in this region as determined by in vivo microdialysis. Approximately 18 hr after implantation of a microdialysis probe, basal extracellular GABA in the mPFC of freely moving rats was 59 ± 7 pg/20 μ l (n=5). Thirty min of acute tail shock elicited a biphasic change in extracellular GABA. During application of the tail shock extracellular GABA increased to 85 ± 7 pg/20 ul. Fourty-five min after termination of the stress extracellular GABA had declined to $39 \pm 8 \text{ pg/}20 \,\mu\text{l}$ and subsequently returned to basal levels 90 min following termination of the stress. Local application of tetrodotoxin (1 μM) or 0 Ca** perfusion solution delivered via the microdialysis probe decreased extracellular GABA levels by 66% and 56%, respectively. The present data demonstrate that acute stress alters extracellular GABA in the mPFC. Additional experiments will determine whether dopamine-containing projections modulate the effects of stress on extracellular GABA in the mPFC. GABA TRANSPORTERS IN THE INFERIOR COLLICULUS OF

RATS ARE MAINLY EXPRESSED BY ASTROCYTES.

C.E. Ribak*, W.M.Y. Tong and N.C. Brecha Dept. of Anat. & Neurobiol., Univ. of Calif., Irvine, CA 92717 and CURE, Wadsworth VA Med. Ctr., Los Angeles, CA 90073.

Previous studies that localized GABA transporters (GATs) showed that GAT-1 is found in axon terminals of GABAergic neurons whereas GAT-1 and GAT-3 are present in astrocytic processes. One brain region, the cerebellum, appeared to lack GAT-1 in one of its GABAergic cell types, Purkinje cells. Astrocytic processes compensated for this by isolating their axon terminals in the deep cerebellar nucleus and expressing large amounts of GAT-3. The present study was made to determine the localization of GAT-1 and GAT-3 in the inferior colliculus (IC), a brain region with several types of GABAergic neurons that play important roles in auditory processing. Both GAT-1 and GAT-3 were observed in punctate structures in the central nucleus, dorsal cortex and external nucleus of the IC. Electron microscopic preparations demonstrated that axon terminals forming symmetric synapses, the type previously labeled for GABA, lacked immunoreactivity for GAT-1. Instead, astrocytic processes that enveloped these axon terminals were densely labeled for GAT-1. Also, astrocytic processes as well as their cell bodies displayed GAT-3 immunoreactivity. These data indicate that most axon terminals of GABAergic neurons in the IC lack GATs. In addition, these results suggest that GABAergic neurons in the IC do not possess the ability to release GABA in a calcium-independent, non-vesicular manner, such as when neurons become overstimulated during high activity.

ACUTE RISPERIDONE DECREASES EXTRACELLULAR GABA LEVELS IN THE GLOBUS PALLIDUS AND PRODUCES CATALEPSY. Jeffrey W. Grimm* and Ronald E. See. Der Pullman. WA. 99164-4820 Department of Psychology, Washington State University

Haloperidol, a typical antipsychotic drug which is known to produce extrapyramidal side effects (EPS), has been shown to increase while clozapine, an atypical antipsychotic drug which has a low EPS profile, has been shown to decrease extracellular levels of GABA in the globus pallidus. The present study investigated the effects of risperidone, a putative atypical antipsychotic drug with a low EPS profile, on GABA levels in the globus pallidus. Female, Sprague Dawley rats were surgically implanted with stainless steel guide cannulae through which 2 mm length microdialysis probes were inserted. Probes were perfused with modified Ringer solution and samples were collected at 20 min intervals. Following a 1 hr baseline, rats were injected with risperidone (3 mg/kg sc) and samples were collected for the next 5 hr. Bar and paw test catalepsy measures were made 30 min. 1 hr. 2hr. and 5 hr after drug treatment. Risperidone treatment significantly reduced extracellular GABA levels between 100 min and 220 min following treatment Rats displayed significant bar and paw test catalepsy throughout the measurement period. Front and back paw measures were not significantly different Risperidone-induced catalepsy did not appear qualitatively identical to haloperidolinduced catalepsy in that risperidone-induced catalepsy was not marked with extreme rigidity. Vehicle treated rats did not show altered GABA levels, nor did they show any signs of catalepsy. These results show that risperidone produces decreases in pallidal GABA similar to previously reported effects found after acute clozapine. Differential pallidal GABA modulation may be a marker of the typical or atypical profile of an antipsychotic drug. The effects of alternate doses of risperidone on pallidal GABA levels and catalepsy will be discussed. This research was supported by USPHS Grant DE-09678 (RES) and the state of Washington

STABLE OPA/SULFITE DERIVATIVE OF GABA IN CELLULAR INCUBATION MATRIX, CSF AND TISSUE HOMOGENATES VIA HPLC WITH ELECTROCHEMICAL DETECTION. S. R. Bossi *1. S. A. Morrison and T.J.Maher³. ESA Inc. Chelmsford MA, ² CytoTherapeutics Inc. Providence RI, and ³Massachusetts College of Pharmacy Boston MA.

HPLC with electrochemical (EC) detection has been employed reliably to determine low level concentrations of amines and amino acids from brain tissue Several of these methods employ the use of ophthalaldehyde (OPA) with β-mercapto-ethanol to derivatize the amino functional group of these primary alkylamines to form an unstable alkylisoindole (variable stability observed vs excess OPA) molecular structure which supports EC and fluorescence detection. In this study we used OPA in the presence of sodium sulfite to form a more stable isoindole-sulfonate derivative form of Gamma-aminobutyric acid (GABA). Rat insulinoma (RIN) cells, which are known to secrete GABA (CytoTherapeutics, Inc.) were incubated in Hanks' Balanced Salt Solution buffered with 10 mM Hepes pH 7.4 for 1-3 hrs. Tissue homogenates were prepared from frozen rat brain cortex, cerebellum, striatum and brainstem via sonication with 4°C 0.1M perchloric acid followed by centrifugation and filtering. Human CSF was prepared by filtration with a 0.2 uM filter. All sample matrices were derivatized 1:1 with the OPA/sodium sulfite solution and maintained at 4°C prior to injection. Degradation of derivatized samples (n=6) at 7 and 13 hours was 1.7% and 7.6%. This method allowed for isocratic detection of GABA, via coulometric detection, with elution time of less than 6 minutes. Our linear range was 1-50 ng/mL with the lowest quantitation level of 19.5 pg. Intraday variability was < 3% (n=10). Interday variability was < 5% (n=24). This method provides a stable, sensitive and rapid assay for GABA in a variety of biological matrices

GABA IMMUNOREACTIVE CELLS AND TERMINALS DECREASE IN CEREBRAL AND CEREBELLAR CORTEX OF RATS EXPOSED TO HYPERGRAVITY: PRELIMINARY FINDINGS I. Polyakov*, F. D'Amelio, N. Daunton, R. Fox, M. Corcoran, and L. Wu. Gravitational Research Branch, NASA Ames Research Center, Moffett Field, CA and San Jose State University, San Jose,

Recent behavioral studies have shown that chronic hypergravity exposure produces changes in righting, locomotion, and orientation of centrifuged rats. To correlate those findings with morphological and chemical changes in the CNS we have investigated GABA immunoreactivity in the cerebral cortex and cerebellum of rats exposed to 3G for 14 days. Tissue was obtained from some rats immediately (within 2 hr) following centrifugation and from others after behavioral recovery (44 days after centrifugation). Vibratome sections of perfused brain tissue were processed for staining with anti-GABA serum, and reaction product was visualized by means of the avidin-biotin immunoperoxidase method. In the animals perfused immediately after centrifugation there was a marked decrease in immunoreactive GABAergic cells and terminals in the somatosensory cortex at the level of the hindlimb representation. GABA-IR terminals surrounding somas of large pyramidal cells in Layer V were decreased in the experimental group as compared with controls. In the cerebellum local circuit GABAergic cells ("basket" cells) and terminals in the 3G animals were decreased at the level of the molecular layer. GABA-IR terminals surrounding the Durkinje cells were also decreased. These results indicate that altered gravity can affect the local circuit (BABA neurons that modulate the discharge of "output" neurons (pyramidal and Purkinje cells) of "command centers" (cerebral and cerebellar cortex). We also found that neuroglial cells (astrocytes) of the cerebellar gray (von Bergmann We also found that neurogital cents (astrocytes) of the derebeniar gray (von Berginamicells) and white matter of the 3G animals exhibited hypertrophy, suggesting that astrocytes may participate in the observed phenomena. After behavioral recovery, these alterations were still detectable, suggesting that chronic altered gravity exposure may result in long-term changes in the CNS. SEROTONIN 5-HT2 RECEPTOR-MEDIATED MODULATION OF GABA NEURONS IN THE RAT PREFRONTAL CORTEX. W. M. Abi-Saab, A. C. Grobin, J. F. Cubells*, and A. Y. Deutch. Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06511, and Department of Psychiatry. VAMC, West Haven, CT 06516.

Anatomical studies have shown that serotonin (5-HT) axons synapse with cortical GABA neurons in the rat. In the piriform cortex, in vitro electrophysiological studies indicate that 5-HT depolarizes GABA neurons via a 5-HT_{2a} receptor. In order to investigate in vivo the serotonergic regulation of the GABA neurons in the prefrontal cortex (PFC), we used microdialysis in awake, freely-moving rats. Local administration of 5-HT through the dialysis probe increased extracellular GABA levels in the PFC. Similarly, the 5-HT_{2u/2c} agonist DOI increased in a dose-related manner extracellular GABA levels in the PFC. In order to determine if GABA neurons are targets for DOI, we examined the ability of DOI to induce c-fos expression in cortical interneurons. Preliminary data suggest that DOI induces Fos-like immunoreactivity in parvalbumin-containing interneurons in the PFC. immunoreactivity in parvalbumin-containing interneurons in the PFC, but calbindin-containing interneurons were not affected. Taken together, these data suggest that 5-HT increases extracellular GABA levels through a 5-HT₂ receptor-mediated event, and may selectively target certain parvalbumin-containing GABA neurons in the PFC. PEPTIDE RECEPTOR STRUCTURE AND FUNCTION I

515.1

MOLECULAR CLONING AND THE CHARACTERIZATION OF THE RAT NEUROTENSIN RECEPTOR GENE. H. Maeno¹*K. Tanaka¹, H. Kiyama² and K. Wada¹. 1:Dept. Degen. Neurological Dis. Nat'l. Inst. Neurosci NCNP. Tokyo 187, Japan. 2:Dept. Neuroanatomy, Biochem.. Res. Center Osaka University Medical School., Osaka 565, Japan

. The expression of the neurotensin receptor is spatiotemporally controlled. In order to understand the mechanisms controlling the expression NTR gene, it is important to characterize its promoter. The 5'-terminal region of the rat neurotensin receptor gene was isolated and characterized. Genomic Southern analysis revealed that the NTR gene occurs as a single copy in the rat haploid genome. Primer extension showed that transcription is initiated from -236, -237, -319, and -374 upstream to an adenosine residue on the initiating methionine codon of the rat neurotensin receptor gene. The upstream putative promoter region did not contain canonical TATA or CAAT boxes but has a consensus sequence for the transcription factor Sp1. This promoter is embedded in a large G+C-rich domain with characteristics of a CpG island. Transfection experiments using neurotensin receptor-luciferase fusion genes demonstrated that the 5'-flanking sequence functions as a strong promoter in the NG-108-15 cell. Deletion analysis suggested the presence of a core promoter (-470 to -662) that drives the basal expression of the neurotensin receptor gene.

DIFFERENTIAL MOLECULAR REGULATION OF NEUROTENSIN RECEPTORS BY ENDOGENOUS NEUROTENSIN. W. Rostène, M. Azzi, H. Boudin, D. Gullys, D. Pélaprat* and A. Bérod. INSERM U339, Hôpital Saintain. Antoine, 184 rue du Faubourg St Antoine, 75012 Paris, § Sanofi Recherche, 31036 Toulouse, France

Neurotensin (NT), a 13 amino acid peptide heterogeneously distributed in the central nervous system of the rat brain, has been described to act as a neurotransmitter or neuromodulator.

In the present study, we examined the role of endogenous NT in the regulation of its central receptors following chronic blockade of NTergic transmission with a new its central receptors following chronic blockade of NTergic transmission with a new selective non-peptide NT receptor antagonist, SR 48692. Administration of SR 48692 for 5 or 15 days with 1 mg/kg i.p. enhanced the expression of NT receptor mRNA as shown by quantitative in situ hybridization in the ventral mesencephalon, respectively by 40% and 100%. After a 15-day treatment, the increase of the signal was extended to numerous areas of the brain, such as the anterior cingulate, perirhinal and retrosplenial cortices, the suprachiasmatic nucleus and the posterior cortical nucleus of the amygdaloid complex. Moreover, this treatment revealed the expression of NT receptor mRNA in several nuclei of the diencephalon where it could not be detected in basal conditions. Immunohlot analysis with a specific expression of NT receptor mRNA in several nuclei of the diencephalon where it could not be detected in basal conditions. Immunoblot analysis with a specific antibody directed against the rat cloned NT receptor showed an increase in NT receptor protein in SR 48692-treated rats for 5 or 15 days, correlating well with the increase in NT receptor mRNA levels. However, if a 5-day treatment with SR 48692 enhanced the number of NT binding sites determined on brain membrane homogenates or in vitro autoradiography, the same treatment for 15 days did not alter the number and the affinity constant of the NT binding site.

These results demonstrate that chronic treatment with a specific NT antagonist induces an up-regulation of NT receptors at the level of its mRNA and protein. Furthermore, the lack of changes in the number of NT binding sites after a long blockade of NTerroic treatments with a specific NT entropy of the NT of the NT binding sites after a long of NT of NTerroic treatments with a specific NT antagonist induces an up-regulation of NT receptors at the level of its mRNA and protein.

blockade of NTergic transmission suggests an adaptative regulation of the receptor at the level of its binding sites.

INSERM U339 Hop. St-Antoine 75012 Paris France § INSERM U344, Faculté de Médecine Necker, 75015 Paris, France

Neurotensin (NT) is widely distributed in the central nervous system and peripheral tissues and its actions are mediated by a specific G proteincoupled receptor, the neurotensin receptor (NTR). In this study, we have measured the levels of NTR gene expression by quantitative RT-PCR. In the brain, the highest quantities of NTR mRNA were found in ventral mesencephalon and the hypothalamus, followed by intermediate levels in the prefrontal cortex and striatum, and scant levels in the cerebellum. In peripheral tissues, the highest levels of NTR mRNA were detected in the colon, followed by the liver, and then the duodenum and pancreas

A specific and potent non-peptide NTR antagonist, SR48692, was used to block *in vivo* neurotensin transmission in order to evaluate the effect on NTR gene regulation. Chronic SR48692 administration (1 mg/kg, ip for 15 days) induced an increase of NTR mRNA (50 to 80 %) in the prefrontal cortex, ventral mesencephalon, hypothalamus, and colon, suggesting that endogenous NT exerts a tonic inhibitory control on NTR gene expression. In contrast, substantial reductions of NTR mRNA were observed in the duodenum and pancreas. We suggest that the differential NTR expression is the result of distinct promoters or, alternatively, different NTR subtypes.

PHARMACOLOGICAL ACTIVITIES OF SR 142948A, A NEW POTENT AND SELECTIVE NEUROTENSIN RECEPTOR ANTAGONIST. D. Gully, J. Maruani, B. Labeeuw, F. Donat, A. Bachy, R. Steinberg, J.P. Chambon*, P. Kitabgi, J.P. Maffrand and P. Soubrié. Sanofi Recherche, 195, route d' Espagne, 31036 Toulouse, France

SR142948A 2-{(5-(2,6-dimethoxyphenyl)-1-(4-(N-(3-dimethylaminopropyl)-N-methylcarbamoyl)-2-isopropyl-phenyl)-1H-pyrazole-3-carbonyl)amino}adamantane-2-carboxylic acid, hydrochloride, a new extremely potent and selective neurotensin (NT) receptor antagonist was characterized in comparison to SR 48692. SR 142948A displays subnanomolar affinities for the human NT receptor (IC_{50} =0.3 nM) and equally recognizes the high-and the low-affinity (levocabastine-sensitive) binding sites described in murine species. *In-vitro*, it antagonizes classical NT effects, i.e. NT-stimulated IP1 formation in HT29 cells (IC_{50} = 3.9 nM) or NT-induced [Ca²⁺] imbilization in CHO cells transfected with the receptor cloned from HT29 cells. It dose-dependently (from 0.037 to 640 μ g/kg, p.o.) inhibits circling behaviour induced by unilateral intrastriatal injection of NT in mice with the biphasic profile described for SR 48692. At 100 μ g/kg (i.p.) it completely antagonizes NT-evoked ACh release measured by microdialysis in the rat striatum. In contrast to SR 48692, SR 142948A (p.o.) blocks both hypothermia ($\rm ID_{50}=1.7~mg/kg$ in rat, 3.6 mg/kg in mice) and analgesia (1.4 mg/kg in mice) induced by i.c.v. injection of NT. In summary, the novel and extremely potent NT receptor antagonist SR 142948A retains the properties of the lead compound (no intrinsic agonist activity, oral bioavailability, long duration of action and good brain access), reveals a wider spectrum of activity than SR 48992 likely through inhibition of NT receptor subtypes and thus represent an additional tool for exploring further the therapeutical uses of this new class of compounds.

THE THIRD INTRACELLULAR LOOP OF THE HIGH AFFINITY NEUROTENSIN RECEPTOR IS IMPLICATED IN THE ADDRESSING OF THE RECEPTOR TO THE PLASMA MEMBRANE. Boudin H., Botto J.M., Chabry J., Rostene W., Vincent J.P., Beaudet A.* and Mazella J. Montreal Neurological Institute, Montreal, H3A 2B4, Canada; CNRS, 06560 Valbonne, France; INSERM U339, Hopital St Antoine, 75012 Paris, France.

Most of the physiological effects of neurotensin (NT) in mammalian brain are exerted through interaction with a high affinity receptor which was cloned (Tanaka et al., 1990) and shown to correspond to a seven trans-membrane domain, G-proteincoupled receptor. In order to identify amino acid sequences implicated in the addressing of this receptor to the plasma membrane, COS-7 cells were transfected with cDNA encoding deletion mutants of the receptor. Deletion of a large segment of the third intracellular loop ($\Delta 273-306$) abolished specific binding of ¹²⁵I-NT to transfected whole cells but not to membrane homogenates. In the former, however, confocal immunohistochemical localization of the receptor using an antibody directed against a sequence of the second extracellular loop of the receptor revealed a pile up unoreactivity within intracellular organelles reminiscent of Gogi saccules. COS-7 cells incubated with an antibody directed against a sequence of the third intracellular loop of the receptor were immunonegative, confirming the efficiency of the deletion. Shorter deletions of the third intracellular loop, including deletion of segments Δ 273-282, Δ 287-296, Δ 284-299 variably reduced, but never companies abolished ¹²⁵I-NT binding. We conclude that the third intracellular loop of the NT receptor plays a critical role in the addressing of the receptor from the endoplasmic reticulum/Golgi apparatus to the plasma membrane. The identity of the amino acids implicated in this function and their relationship to those involved in the binding of the receptor to G-protein remains to be established. Supported by CNRS, INSERM, MRC and NATO grants.

CONFOCAL IMAGING SHOWS THAT NEUROTENSIN (NT) INTERNALIZATION IN CAT STELLATE GANGLION IS DENDRITIC AND INFLUENCED BY TARGET-DERIVED AND TRANSYNAPTIC FACTORS.

B. Bachoo, M.P. Faure, C. Polosa* and A. Beaudet. Montreal Neurol. Inst., 3801 University St., Montreal, QC, Canada H3A 2N4.

Preganglionic axons innervating the cat stellate ganglion contain and relea neurotensin. Slices of the cat stellate ganglion, incubated with fluorescent NT (fluo-NT) at 37 °C and examined by confocal microscopy, showed selective fluorescent labeling of a sub-population of TH-positive cells retrogradely labeled by WGA applied to the inferior cardiac nerve. Internalization occurred at concentrations as low as 2 nM fluo-NT, was prevented by an excess of native NT (1 uM), did not occur at 4 °C and was not blocked by levocabastine, indicating that it was mediated through the high affinity NT receptor. For each ganglion cell, internalization was initiated at the level of a single dendrite, within small vesicular organelles. After 10 min, some of the internalized vesicles had moved to the perinuclear region of the perikaryon. The centripetal movement of the labeled vesicles was microtubule dependent since it was blocked by nocodazole. Double labeling with NT-antibodies showed the neurons internalizing NT to be surrounded by a network of NT-IR varicosities. Incubation of ganglion slices in 25 mM K+ known to cause release of NT from preganglionic axon terminals, prevented internalization of fluo-NT, presumably through competition by endogenous NT for the binding sites. Fluo-NT internalization was markedly reduced in ganglion cells which had either been denervated or axotomized 7 days previously. The data suggest that following interaction with its receptor, the NT-receptor complex is rapidly internalized by an endocytic process. The effects of chronic denervation or axotomy suggest that the NT receptor distribution, the uptake process, or both are controlled by a presynaptic and a retrograde, target derived influence. Supported by the MRCC.

515.9

THE LINEAR PEPTIDE BIM 23055 IS AN ANTAGONIST AT SOMATOSTATIN RECEPTOR RAT SST5. G. Liapakis*, A.-M. O' Carroll† and T. Reisine. Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, 36th Str and Hamilton Walk, Philadelphia PA 19104 and † Lab. of Cell Biology, Building 36, National Institute of Mental Health, NIH, Bethesda MD 20892.

Somatostatin (SRIF) induces its multiple physiological actions via five receptor subtypes. While a large number of SRIF agonists are available, there are no antagonists. The linear peptide BIM 23055 binds to the cloned rat sst5 (rsst5) with an affinity of 3.3 nM (Raynor et al.,1993, Mol. Pharmacol. 43, 838 - 844). It has limited ability (15±5% inhibition, n=10) to inhibit forskolin stimulated cAMP accumulation in CHO cells expressing rsst5. In contrast, SRIF and the linear peptide BIM 23052, full agonists at rsst5, inhibit cAMP accumulation by 57±3% (n=7) and 70±2% (n=8), respectively. BIM 23055 competitively blocks the inhibition of cAMP accumulation by BIM 23052, showing it is an antagonist. It does not alter the effects of SRIF, suggesting that SRIF and BIM 23052 may interact differently with rsst5, and BIM 23055 competes for the same site as BIM 23052. The capability of BIM 23055 to block the actions of BIM 23052, a selective rsst5, agonist, indicates that BIM 23055 or its analogs could be useful rsst5, antagonists.

515 6

NEUROTENSIN INTERNALIZES VIA THE LOW AFFINITY, LEVOCABASTINE-SENSITIVE RECEPTOR IN TRANSFECTED COS-7 CELLS, BUT NOT IN GLIAL CELLS. D. Nouel*, J.M. Botto¹, P. Sarret¹, J.P. Vincent¹, J. Mazella¹ and A. Beaudet. Montreal Neurol. Inst., Montreal, Qué., Canada, H3A 2B4, ¹ C.N.R.S., 06560 Valbonne, France.

We previously demonstrated the presence of specific, levocabastine-sensitive neurotensin (NT) binding sites in astrocytes in culture (Nouel et al., '94). The aim of the present study was to determine wether these NT binding sites correspond to the low affinity NT receptor (NTRL) recently cloned by Mazella et al. ('96). RT-PCR made on RNA extracted from astrocytes prepared from cerebral cortex of newborn rats demonstrated the expression of NTRL by these cultured glial cells. To compare the pharmalogical properties of the native glial NTRL with that of NTRL expressed in transfected COS-7 cells, both cell types were labeled for 45 min, at either 4° or 37°C, with 10 nM of a BODIPY conjugate of NT (fluo-NT), in the presence or absence of 1µM levocabastine. After labeling, cells were air-dried and examined by confocal microscopy before or after a hypertonic acid wash to strip off surface-bound ligand. Both astrocytes and COS-7 cells exhibited specific, levocabastine-sensitive fluo-NT labeling. This labeling was displaceable by a hundredfold excess of the NT antagonist SR-48692 in transfected, but not in glial cells. At 4°C, the labeling was exclusively membrane-bound in both types of cells. By contrast, at 37°C, the labeling remained strictly extracellular in glial cells but was mainly intracellular in transfected ones. This intracellular labeling was prevented by co-incubation with the endocytosis inhibitor, phenylarsine oxide and was concentrated within small endosome-like particles, suggestive of receptor-mediated internalization. These results demonstrate that the NTRL is expressed by glial cells and that this native form of the receptor has pharmacological properties distinct from that of the transfected receptor. Supported by the MRC of Canada.

515.8

INTERNALIZATION OF FOUR OF THE FIVE SOMATOSTATIN RECEPTOR SUBTYPES. A. Roth. H.-J. Kreienkamp. R. Nehring. W. Meyerhof. D. Richter Institut für Zellbiochemie und klinische Neurobiologie, Universitäts-

Krankenhaus Eppendorf, Universität Hamburg, Martinistr. 52, 20246 Hamburg The neuropeptide somatostatin exists in two isoforms, SST-14 and SST-28. So far, five different G protein-coupled somatostatin receptor subtypes (SSTR1-5) have been identified in mammals. Although the physiological functions of the five SSTRs have not been resolved yet, the receptor subtypes differ in their pharmacological and functional properties when expressed in mammalian cell lines. Unlike other G protein-coupled receptors, little is known about desensitization and internalization of SSTRs. We investigated internalization of the five rat somatostatin receptor subtypes as well as their recycling in stably transfected HEK cells by biochemical ligand binding assays and confocal microscopy using the labeled ligands, 1251-Tyr11-SST-14 or rho-Ala1-SST-14, and antibodies raised against native or epitope tagged SSTRs, respectively. In contrast to SSTR1-3 which are rapidly internalized in the presence of SST-14 and SST-28, SSTR5 only internalized upon SST-28 stimulation. Phenylarsine oxide and hyperosmolar sucrose blocked internalization. In the case of SSTR4 no receptor endocytosis was observed regardless of the ligand used. In colocalization experiments SSTR3 and transferrin were found in the same intracellular compartment. After removal of agonists receptors reappeared on the cell surface whereas the labeled ligand rho-Ala1-SST-14 remained inside the cell. Reappearance of the receptors was blocked by brefeldin A but not by cycloheximide, indicating that this process was due to receptor recycling and not to de novo synthesis. In this study we showed for the first time that somatostatin receptors internalize and recycle in an agonist-dependent manner. These data may also be of clinical importance as SSTR scintigraphy is used for detecting SSTR positive tumors

prior to radioguided surgery. Supported by Deutsche Forschungsgemeinschaft (SFB 232/B4)

An Interhelical Hydrogen Bond Network In G Protein Coupled Receptors May Stabilize Conformations For Both Intracellular Transport And Multiple Functional Pathways, R.M. Brodbeck, B.S. Sachais, V.V. Karpitskiy, and J.E. Krause*. Washington University School of Medicine, St. Louis MO. 63110

University School of Medicine St. Louis, MO 63110

The substance P (SP) or neurokinin-1 type (NK-1) tachykinin receptor is a member of the G protein coupled receptor superfamily. G protein coupled receptors are predicted to have seven transmembrane helical domains, and are functionally expressed at the cell surface where they bind to multiple ligands and couple to one or more second messenger pathways. Molecular modeling of the rNK-1 receptor longests an interhelical hydrogen bond network in the rNK-1 receptor involving residues located in the putative transmembrane domains, several of which are conserved within the GPCR family. Such a network may play a major role in stabilizing the receptor in multiple functional conformations. Site-directed mutagenesis was utilized to construct point mutants of the rNK-1 receptor which remove the potential for selected putative hydrogen bonds within the predicted network. Binding data from clonally isolated CHO cells stably transfected with the receptor constructs indicate that several of these NK-1 receptor mutants fail to bind ¹²³T-Y⁻¹SP at levels comparable to that of wildtype receptor (E78Q. E78Q-N301D, T124D, Y305A). Further studies examining phospholipid turnover, cAMP production, and arachidonic acid release from CHO cell lines expressing mutant receptors which have both a subnanomolar affinity for SP and a B mas comparable to wildtype, suggest that the configuration of the putative hydrogen bonding network may selectively stabilize receptor conformations which enhance or decrease coupling to specific response pathways. Further analysis of the NK-1 receptor bearing CHO cell lines by immunofluorescence indicates that while the receptor mutants which efficiently bind SP are clearly expressed at the cell surface, variants which are deficient in SP binding appear to be intracellularly localized. These data indicate that the hydrogen bond network predicted for the NK-1 receptor and other GPCRs may have multiple structural roles. Hydrogen bonds may stabilize specific re

STRUCTURALLY ANALOGOUS DOMAINS OF NK1 AND NK2 RECEPTORS ARE FUNCTIONALLY DISTINCT IN INOSITOL PHOSPHATE METABOLISM, ARACHIDONIC ACID RELEASE, AND CAMP PRODUCTION. J.M. Nave Mentzer*, S.K. Schmidt, J.R. de Wet' and J.E. Krause. Dept. of Anatomy and Neurobiology, Washington U. School of Medicine, St. Louis, MO 63110; 1 Dept. Molecular Sciences, Central Res. Division, Pfizer Inc., Groton, CT 06340

Tachykinin receptors have been shown to mediate PI hydrolysis. arachidonic acid release and cAMP production. Activation of the AA cascade may be the mechanism whereby tachykinins mediate inflammatory and nociceptive responses in vivo. The goal of this study was to ascertain if structurally analogous domains of rat NK1 and NK2 receptors are functionally distinct with regard to mechanisms mediating activation of these three effector molecule systems. We used stably transfected CHO cell lines expressing receptors that had either their putative third cytoplasmic loop (C3) or carboxy tail (CT) replaced with the equivalent domain of the other receptor (Blount and Krause, 1993). Agonist binding affinity for truncated and chimeric receptors was similar to that for wildtype receptors. Replacement of the C3 domain of the NK1 receptor with the analogous region of the NK2 receptor (NK1/NK2.C3) resulted in a receptor which possessed a weak IPs response and was unable to produce a cAMP or AA response. By contrast, the complimentary chimera (NK2/NK1.C3) was hyperresponsive (compared to wildtype NK2 receptors) for all three responses tested. The truncated NK1 receptor (NK1∆325) was hyperresponsive for IPs production and AA release, but produced a normal cAMP response. However, the truncated NK2 receptor (NK2 Δ 347) exhibited weak AA, IPs and cAMP responses. These data indicate that structurally analogous domains of NK1 and NK2 receptors are functionally distinct in terms of second messenger generation. Neurokinin-3 receptors in rat dopamine neurons: evidence for somatodendritic and terminal localization and heterogeneity of expression. C.J. Whitty and M.J. Bannon. Depts. of Psychiatry and Behavioral Neurosciences and Pharmacology, Wayne State University, Detroit, MI 48201.

The rat midbrain contains the highest amount of substance P and related neurokinins in the brain and application of neurokinins activates midbrain dopamine (DA) cells. We have previously localized neurokinin-3 (NK3) (but not NK1 nor NK2) recentor mRNA to DA cells of the rat midbrain. In order to better understand the role that neurokinins may play in modulating various DA systems and their targets, NK3 receptor expression in the rat midbrain was examined in greater detail. Significant heterogeneity of NK3 receptor mRNA abundance was seen within and between the DA cell-containing nuclei of the rat midbrain. The ventral tegmental area contained the highest amount of NK3 receptor mRNA, with almost every DA cell NK3 receptor positive. Within the substantia nigra pars compacta, 50% of the DA cells contained little or no NK3 receptor mRNA. The majority of the DA cells in the substantia nigra pars reticulata and pars lateralis were NK3 receptor mRNA negative, although non-DA cells in the most lateral aspect of the pars lateralis were labeled. Since DA neurons of the VTA and dorsal tier of the pars compacta project to the striatal matrix compartment, while DA neurons of the pars reticulata, pars lateralis, and ventral tier of the pars compacta project to the striatal patch compartment, NK3 receptor expression may provide a novel marker for DA cells projecting to striatal patch vs matrix compartments. Neurokinin-3 receptors on DA cell nerve terminals may account for a significant proportion of all striatal NK3 receptors, as evidenced by a significant decrease of striatal NK3 ligand binding after DA cell lesions. Neurokinins may therefore play an important role in basal ganglia function through effects on DA cells at somatodendritic and terminal sites of action. Supported by NS34935.

ADRENOMEDULLIN RECEPTORS ARE PRESENT ON C6 GLIOMA CELLS. T.W. Moody*, M.J. Miller, A. Martinez, E. Unsworth and F. Cuttitta. Biomarkers & Prevention Research Branch, NCI, 9610 Medical Ctr. Dr., Rockville, MD 20850

Adrenomedullin (AM) is a 52 amino acid peptide with structural homology to calcitonin-gene related peptide (cGRP). The receptor for AM is a G-protein coupled receptor with 7 transmembrane domains (Kapas et al., JBC 270:25344 (1995)). Previously, we found the AM is biologically active in MCF-7 breast cancer cells and here the effects of AM on C6 rat glioma cells were investigated. Using a cDNA probe for the AM receptor, a major 1.5 kb band was observed by Northern analysis. Using primers specific for the AM receptor, a 471 bp band was observed by RT-PCR. 125I-AM bound with high affinity (Kd = 3 nM) to a single class of sites (Bmax = 5,000/cell). Specific ¹²⁵I-AM binding was inhibited with high affinity by AM, cGRP, cGRP(8-37) and amylin amide (IC50 values of 3, 10, 30 and 100 nM respectively) but not by proAM N-20 peptide 1(PAMP) or AM(22-52). AM elevated the cAMP and the increase in cAMP caused by AM was reversed by monoclonal antibody (MoAb-G6). These data suggest that AM receptors are biologically active on glioma cells.

CHARACTERIZATION OF THE BINDING AND ACTIVITY OF A HIGH AFFINITY, PSEUDOIRREVERSIBLE MORPHOLINO NEUROKININ-1 RECEPTOR ANTAGONIST S. J. Sadowski*, L.-L. Shiao, E. Ber, S. G. Mills, J.J. Hale, M. MacCoss, T. M. Fong and M. A. Cascieri, Merck Research Laboratories, Rahway, NJ 07065

L-742,694 is a selective morpholino NK-1 antagonist that inhibits the binding of 1251-substance P to the human NK-1 receptor with a $K_d=37$ pM. Increasing concentrations of L-742,694 added to cells 15 minutes prior to agonist progressively increase the apparent EC50 of substance P for inducing the synthesis of inositol phosphate in human NK-1/CHO cells and decrease the maximal level of stimulation observed. In contrast, addition of substance P and L-742,694 to the cells at the same time results in an increase in the EC50 for substance P with no decrease in the maximal level of stimulation. The compound also decreases the apparent number of binding sites for $^{125}\text{I-substance}$ P observed by Scatchard analysis. The observation that altering the order of addition of antagonist and substance P attenuates the effect of the antagonist on the maximal activation suggests that L-742,694 is a competitive antagonist that can behave as a pseudo-irreversible antagonist under some experimental conditions. L-742,694 has reduced affinity for NK-1 receptors in which alanine has been substituted for Gln 165 , His 197 or His 265 in transmembrane helices 4, 5 and 6, respectively. These three residues have previously been shown to be present in the binding site of NK-1 antagonists of several structural classes. In addition, L-742,694 inhibits binding of the quinuclidine antagonist, $[^{125}\text{II}]$ L-703,606 with the same affinity as it inhibits binding of $^{125}\text{I-substance}$ P. These data indicate that L-742,694 binds to the same site within the transmembrane domain of the receptor as previously described competitive antagonists.

Effect of Neurokinin-1 Receptor Antagonists on Stress-induced c-fos Immunoreactivity in the Rat Locus Coeruleus. M.K. Hahn* and M.J. Bannon. Departments of Psychiatry and Behavioral Neuroscience, and Pharmacology, Cellular and Clinical Neurobiology Program Wayne State University Detroit. MI 48201

Clinical Neurobiology Program, Wayne State University, Detroit, MI 48201

The locus coeruleus (LC) noradrenergic cell group of the brain is implicated in animal models of stress and anxiety and in human anxiety disorders. The neurokinin substance P is localized to the rat LC and has excitatory effects on LC neuronal firing rate. The rat LC possesses neurokinin-1 (NK-1) receptor mRNA and binding sites. It is known that various stimuli that increase LC excitability result in expression of the immediate early gene c-fos. We explored whether stress-induced increases in LC c-fos levels could be attenuated by antagonism of NK-1 receptors. Rats received an i.p. injection of the selective NK-1 receptor antagonist RP 67580 (10 mg/kg, Rhône-Poulenc Rorer) or vehicle. Twenty min following the injection some rats were placed in a restraining tube for 1 hr. Rats were anesthetized and perfused 2 hr after cessation of restraint, or 3 hr 20 min after injection for non-restrained animals. Forty μm sections at the level of the LC were processed by free-floating immunocytochemistry using a polyclonal antibody to c-fos and LC cells expressing the brown-black 3,3'-Diaminobenzidine (DAB) reaction product were counted. Control rats that received neither injection nor restraint showed no c-fospositive cells in the LC (0±0, n=3). Restraint resulted in a significant increase in the number of c-fos-positive LC cells compared to control (45±10, n=6, p<0.05). Rats injected with vehicle prior to restraint were not different from restraint alone (66±11, n=3). In contrast, the number of c-fos-positive LC cells compared to restraint talone (91±13, n=6, p<0.05). Injection of RP 67580 alone resulted in a small number of c-fos-positive LC cells (14±4, n=3). In a separate experiment, another selective NK-1 receptor antagonist, SR 140333, (0.3-1.0 mg/kg, Sanofi Recherche) was also unable to block a restraint-induced LC c-fos activation. Thus, NK-1 receptor antagonists do not attenuate stress-induced activation of the LC. These results may have imp

CENTRAL AND PERIPHERAL ACTIONS OF THE NEW BOMBESIN-LIKE PEPTIDES, PHE¹³ BOMBESIN AND SAP-BOMBESIN: EVIDENCE THAT A NOVEL BOMBESIN RECEPTOR SUBTYPE MAY MEDIATE THE HYPOTHERMIC EFFECTS OF BOMBESIN. <u>E.R. Spindel*1, A. Cowana*1, V. Martinez*1, Y. Tache*2</u> and <u>B. Barry*1. Div. Neuroscience, Oregon Rgl. Primate Research Ctr., Beaverton OR 97006; *Dept of Pharmacology, Temple University, Phil., PA 19140 and *Ctr. for Ulcer Research, UCLA, LA, CA 90073.</u>

Recently our laboratory reported that bombesin occurs in multiple forms. For example, the frog *Bombina* orientalis expresses three bombesin-like peptides: Leu¹³ bombesin (prototypic bombesin), Phe¹³ bombesin and SAP bombesin (J. Biol Chem 271:7731,1996). The receptor for Phe¹³ bombesin has been characterized and shown to constitute a distinct subclass of bombesin receptor (BB4). To characterize the biological effects of these peptides, they were administered to rats intravenously and intraventricularly and the effects on temperature regulation, grooming and pentagastrin-induced gastric acid secretion was measured. Phe¹³ bombesin has roughly similar potencies for the GRP and NMB receptors as does Leu¹³ bombesin. Consistent with this, Phe¹³ bombesin had similar effects on grooming and acid secretion as did Leu¹³ bombesin. SAP bombesin which has 10-fold weaker affinities for the GRP and NMB receptors was proportionately less potent. Strikingly, however, despite similar affinities as Leu¹³ bombesin for the known mammalian bombesin receptors, doses of Phe¹³ bombesin ten-fold higher than effective doses of Leu¹³ bombesin had no effect on hypothermia. Therefore the failure of Phe¹³ bombesin to induce hypothermia despite its high affinity for the GRP and NMB receptors suggests that an as yet undescribed bombesin receptor subtype may mediate the effects of bombesin-like peptides on temperature regulation. This research supported by NIH grants CA39237, RR00163 and by Biomeasure Inc.

BIM 26292 IS A POTENT AGONIST FOR THE BOMBESIN BRS-3 RECEPTOR. R. P. Searles*, S. Kim*, J.E. Taylor*, E.R. Spindel*. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton OR 97006 and *Biomeasure Inc., Milford MA 01757.

Four subtypes of bombesin receptors have been characterized to date The BB1 receptor has highest affinity for neuromedin B, the BB2 receptor has highest affinity for GRP and the BB4 receptor has highest affinity for the amphibian peptide Phe¹³ bombesin. To date however no natural or synthetic high affinity ligands for the BRS-3 (BB3) receptor have been described. As part of our ongoing studies to discover the endogenous ligand of the BRS-3 receptor we have established an assay for BRS-3 ligand activity and screened the known natural bombesin-like peptides and a battery of synthetic agonists. To measure BRS-3 activity, Xenopus oocytes were injected with RNA encoding the human BRS-3 receptor (cDNA kindly provided by J. Battey) and then injected with the calcium photoprotein aequorin. 24 hours later oocytes were challenged with ligands. Ligands interacting with the BRS-3 receptor cause an increase in intracellular calcium that can then be measured luminometrically. The most potent natural ligand for the BRS-3 receptor was ranatensin. Of synthetic compounds screened, BIM 26292 (Phe-Gin-Trp-Ala-Val-betaAla-His-Phe-NorLeu amide) was most potent. A response to as little as 5 nM BIM26292 could be detected. Substitution of Leu for the penultimate Phe caused a decrease in potency. The importance of this Phe combined with the potency of ranatensin suggests the natural BRS-3 ligand will also contain a penultimate Phe. The identification of an agonist will now allow tests to determine biological functions of the BRS-3 receptor. This research supported by NIH grants HD 30272, CA39237, RR00163 and by Biomeasure Inc.

CYTOCHEMICAL IDENTIFICATION AND CLONING OF A G-PROTEIN COUPLED GROWTH HORMONE SECRETAGOGUE RECEPTOR. D. Hreniuk, A. Howard, C. Rosenblum, O. Palyha, C. Diaz, D. Cully, P. Paress, K. McKee, M. Dashkevicz, J. Arena, K. Liu, J. Schaeffer, R. Nargund, R. Smith, L.H.T. Van der Ploeg and S. Feighner*. Merck Research Laboratories, Rahway, NJ 07065

Growth hormone (GH) is secreted in a pulsatile manner by somatotroph cells of an anterior pituitary, under the control of growth hormone releasing hormone and somatostatin. A class of small synthetic molecules (i.e., GHRP-6 and non-peptidyl growth hormone secretagogues (GHSs), exemplified by MK-0677) can also mediate GH release. To understand the mode of action of these GHSs, we characterized their receptor by whole-cell binding in rat primary pituitary cell cultures and by cloning of the GHS-receptor (GHS-R). Using biotinylated GHSs and avidin conjugated fluorophores, we were able to show that a subpopulation of GH-containing cells also express the GHS-R. Co-localization of GH and GHS binding sites with dual fluorophore labeling indicated that GHS binding was restricted to a subpopulation of somatotrophs: 33% of rat primary pituitary cells stained positive for GH, while only 50% of these immunocytochemically identified somatotrophs exhibited GHS binding. GHS binding could be displaced by biologically active GHSs, but not with an inactive enantiomer or with gonadotropin releasing hormone.

GHS-R cloning was accomplished using a Xenopus oocyte expression system. We injected Xenopus oocytes with porcine pituitary mRNA. To enhance the sensitivity of the assay, we co-injected acquorin GNA rather than acquorin protein, protein, protein, protein, protein, protein, or the protein of the standard protein, prot

GHS-R cloning was accomplished using a Xenopus oocyte expression system. We injected Xenopus oocytes with porcine pituitary mRNA. To enhance the sensitivity of the assay, we co-injected aequorin cRNA rather than aequorin protein, and G-protein subunit α11 cRNA leading to the reproducible identification of MK-0677 mediated Ca²⁺ release. We now report the cloning of a rare mRNA from human and swine pituitary which encodes the GHS-R. The cDNA has a predicted open reading frame of 366 amino acids, with a transmembrane topology typified by the G-protein coupled receptor family.

p-(4-Hydroxybenzoyl)phenylalanine: An Iodinatable Photoreactive Amino Acid Analog: Application to Substance P Receptor. Carol J. Wilson, S. Shaukat Husain, Evelyn R. Stimson, Lawrence J. Dangott, Keith W. Miller, Frederique Popitz-Bergez*, and John E. Maggio. BCMP Dept.; Dept. of Anesth., MGH; Dept. of Neurobiol.; Dept. of Anesth., BWH; Harvard Med. Sch., Boston, MA 02115.

Benzoylphenylalanine, a photoreactive phenylalanine analog that can be incorporated into a peptide during solid phase synthesis, is a useful probe for investigating the interactions of peptides with their receptors. This probe, however, lacks versatility because it cannot be labeled with radioiodine, requiring radiolabeling of the peptide ligand at a position distal to the photoreactive amino acid. The separation along the primary sequence of the radioisotope and photoaffinity labels limits identification of the photoinsertion site to a peptide fragment rather than a specific amino acid of the receptor protein.

limits identification of the photoinsertion site to a peptide fragment rather than a specific amino acid of the receptor protein.

We have now synthesized p-(4-hydroxybenzoyl)phenylalanine (HBPA) to overcome these disadvantages. HBPA was incorporated at a discrete site into substance P (replacing Phe8) giving an 11-mer peptide that binds with high (nM) affinity and specificity to the substance P receptor. Radioiodination of the substance P analog resulted in the incorporation of ¹²⁵l at the photoreactive amino acid residue yielding a photoreactive probe of high (~2000 Cl/mmol) specific activity. Subsequent photolysis of the radiolabeled peptide in the presence of substance P receptor caused covalent attachment of the peptide to the receptor with high photoinsertion yield (~14%); photolabeling was abolished in the presence of excess unlabeled SP or a specific SPR antagonist CP-96,435. The novel amino acid retains p-barcylphenylalanine's high insertion yield and low reactivity with water, but places the radiolabel and the photoactive moieties within the same residue. HBPA is likely to be useful in the elucidation of the interaction of a variety of bioactive peptides with receptors and other macromolecules.

Non-Radioactive, Pharmacological Binding Studies Using Fluorescent Peptides SK Lau, C Desjardins*, A Gagné, M-P Faure Advanced Bioconcept Inc. 1440 Ste-Catherine Ouest, Suite 424, Montreal, QC H3G 1R8, Canada.

Several fluorescent peptides with a high degree of retention of biological activity have recently been described (e.g. Faure et al., 1994). These fluorescent peptides have been shown to be useful tools in receptor imaging, flow cytometry, as well as in cell sorting. Using distinct fluorescence detection instruments, we have compared binding parameters (Kd and IC₅₀) using fluorescent peptides with those obtained in conventional radioactive binding studies. Fluorescein-labeled neurotensin and Bodipy(504/570)-labeled D-trp¹¹ somatostatin (1-14) have previously been shown to displace corresponding radioactive peptide binding with an IC₅₀ of 0.67 nM and 1.2 nM, respectively. Pooled COS membranes transfected with either the neurotensin or somatostatin receptor (NTR and SSTR2), were used in distinct instruments. First, fluorescent peptide binding was performed in non-equilibrium conditions in 96-well filter plates (Millipore, MA) and relative fluorescence intensity values were derived from scanned images of the filter plate using a FluoroImager (Molecular Dynamics Inc.,CA). In this system, saturation binding of fluo-neurotensinTM to known concentrations of COS-NTR-transfected membranes yielded Kds which were similar to those obtained using radioactive peptides, (0.35 nM fluo-neurotensinTM versus 0.55 nM for radioactive neurotensin assayed in similar conditions). Second, homogeneous fluorescent peptide inding assays were performed using the Beacon Fluorescence Polarization System (PanVera, WI) and the SLM 48000 (Spectronic Instrument, NY). Preliminary studies indicate several limitations to the use of PanVera's instrument for pharmacological characterization of receptors using fluorescent peptides. However, initial results using SLM 48000 indicate significant increases in fluorescence Polarization (4-5 fold over basal values) upon addition of fluo-somatostatinTM to a solution containing 13.2 fmol of transfected receptor membranes. The change in polarization can be reversed by the addition of 500 fold excess

Chem. Ind., Ltd., Tsukuba, Japan.
Pituitary adenylate cyclase activating polypeptide (PACAP) is a new member of the secretin/VIP family of peptides. The specific receptor for PACAP was cloned in rat, human and bovine. PACAP also binds to VIP-1 and VIP-2 receptors, but VIP does not bind to PACAP receptors. Although expression of the transcripts of PACAP receptor gene in tissues was studied using in sin hybridization, distribution of receptor proteins needs to be examined to evaluate functional receptors. Thus, we generated rabbit antisera against a 25 residue synthetic peptide corresponding to the C-terminal intracellular domain of the rat PACAP receptor. Membrane and soluble fractions of CHO cells stably transfected with rat PACAP receptor cDNA were examined in Western blot analysis. Three bands were demonstrated in both membrane and soluble fractions from the transfected CHO cells (57 kDa the most prominent band corresponding to the size of cloned rat PACAP receptor, a larger, less intense band and a weak, smaller than 57 kDa band), but no bands were found in the similar preparations from the non-transfected cells. All these bands disappeared or diminished when the antiserum was preabsorbed with the immunogen peptide, suggesting that all of these bands are related to the PACAP receptor protein. The membranes from the transfected CHO cells bound to ¹²⁵t-PACAP27 and the ligand/protein complex approximated 60 kDa, corresponding to the sum of 57 kDa and molecular size of PACAP27. There were no additional bands. The results indicate that both the larger band, probably the precursor, and the smaller band, degraded product, do not bind the ligand. Unlabeled PACAP27 and PACAP38, but not VIP, displaced the binding, suggesting that the receptors expressed in CHO cells are specific PACAP receptor. Immunohistochemistry with this antiserum showed a distribution of PACAP receptor. Immunohistochemistry with this antiserum showed a distribution of PACAP receptor limunohistochemistry with this antiserum showed a distribution

PHARMACOLOGY OF MELANOCORTIN RECEPTORS: CHARACTERIZATION OF RECEPTOR-LIGAND INTERACTIONS. J. Oosterom, R. A. H. Adan, J. P. H. Burbach, P. R. Bär* and W. H. Gispen, Rudolf Magnus Institute for Neurosciences, Utrecht University, Utrecht, The Netherlands, 3508 TA.

Melanocortins have various physiological roles in the nervous system. The cloning of so far three neural melanocortin (MC) receptor subtypes allows the development of new and selective agonists. The aim of this study is to characterize the molecular interactions between peptide and MC-receptor. We investigated the activity of peptides, analogous to the core sequence of α -MSH, on cloned MC₃, MC₄ and MC₅ receptors as well as on mutated receptors expressed in 293 HEK cells. These data revealed that several residues in the peptide are involved in selective receptor activation. Modifications of the core sequence of α -MSH led to the identification of MC-receptor selective antagonists: [D-Arg*]ACTH-(4-10), [Pro*^{1/9},Gly*]ACTH-(4-10), [Pro*^{1/9},Gly*]ACTH-(4-10). The first three peptides slectively antagonized the MC₄ receptor. In addition, mutation of a histidine residue in transmembrane domain 6 of the MC₄ receptor showed that this residue is important for binding of α -MSH.The *in vitro* analysis of the molecular interaction of MC-receptors and melanocortin peptides will lead to the design of more potent and selective agents. Then, *in vivo* application may lead to a better understanding of the role of MC-receptors in (patho)physiological processes. Source of funding: Netherlands Organisation for Scientific Research (N.W.O.).

INTRACEREBRAL ANTISENSE OLIGONUCLEOTIDE REDUCE MINERALOCORTICOID-INDUCED INGESTIVE BEHAVIORS, R.R. Sakai*. L.Y. Ma. P. Itharat and Fluharry. S.J. Departments of Animal Biology, Pharmacology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104. The physiological, endocrine and behavioral actions of mineralocorticoids are

mediated by specific receptors (MR), located in peripheral tissues and the brain. In an effort to study the regulation and function of these receptors, we have developed short MR antisense s-oligonucleotides sequences that were 15-18 mer in length and given in a dose ranging from 250 ng - 2 µg/day. Three daily interacerebroventricular (ICV) injections of MR antisense significantly attenuated sodium appetite aroused by daily injections of the mineralocorticoid deoxycorticosterone (DOCA) whereas scrambled, sense sequence antisense oligonucleotide or an antisense sequence directed to the glucocorticoid receptor (GR) were ineffective. These antinariorexigenic effects were dose dependent, reversible and specific to DOCA-induced sodium appetite. That is sodium appetite aroused after adrenalectomy which is thought to be generated by marked elevations in angiotensin II activity was unaffected. Radioligand binding analysis of selected brain regions revealed that ICV antisense oligonucleotide treatments produced decreases in the appropriate receptor targeted. Further, the regional distribution and uptake of injected antisense oligonucleotides was further validated by localization of biotinylated probes and immunohistochemistry. The effects of MR and GR antisense oligonucleotide treatment had no effect on the animals daily food intake or body weight. The effects of antisense oligonucleotide treatment on diurnal glucocorticoid secretion and response to a novel stressor was also examined. The results demonstrate that in vivo administration of antisense oligonucleotides attenuate mineralocorticoid receptor expression and function associated with DOCA-induced sodium intake.

Four analogues of dynorphin (Dyn) A-(1-9) incorporating D-Leu in position 8 alone or in combination with the nonhydrolysable psi(CS-NH) thiopeptide bond surrogate between positions 6 and 7 were tested in vitro for their ability to compete with the binding of selective κ , μ and δ opioid ligands using membrane preparations of guinea pig cerebellum (κ) and rat brain (μ and δ), for their ability to block the electrically-induced contractions of the guinea pig ileum (GPI), and for their in vivo antinociceptive (writhing test) and motor (motor dysfunction assay) activities in mice. [D-Leu³]Dyn A-(1-9) displayed an affinity and a selectivity for the κ opioid receptor that were comparable to those of Dyn A-(1-9). The potencies of [D-Leu³]Dyn A-(1-9) in the GPI, writhing and motor dysfunction assays were markedly enhanced (8-12 fold) as compared with those of Dyn A-(1-9). [δ V7(CS-NH), D-Leu³]Dyn A-(1-9), [Lys 6 , δ V7(CS-NH), D-Leu³]Dyn A-(1-9) and [Leu 6 , δ V7(CS-NH), D-Leu³]Dyn A-(1-9) were somewhat less potent than [D-Leu³]Dyn A-(1-9) in all opioid assays. However, the pseudopeptides were more potent analgesic than Dyn A-(1-9) (ED $_{50}$ of 29.5, 23.9 and 15.5 nmol/mouse, respectively, as compared with 90.7 nmol/mouse for Dyn A-(1-9)) and caused no or little motor impairment at analgesic doses. Supported by the MRC (Canada) and INRS (France).

IN VIVO ANTISENSE OLIGONUCLEOTIDES REVEAL THE STRUCTURE/FUNCTION PROPERTIES OF ANGIOTENSIN RECEPTORS CONTROLLING INGESTIVE BEHAVIOR. L.Y. Ma*, S. Chow, R.R. Sakai, J.F. Hines, S. Ho*, P.R. Hartig and S.J. Fluharty. Departments of Animal Biology, Pharmacology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104 and *DuPont-Merck Pharmaceutical, Wilmington DL 19880.

The behavioral actions of angiotensin II (AngII) are mediated by two distinct classes of receptors referred to as the Type I (AT₁) and Type 2 (AT₂) receptors. AngII receptors (AngII-Rs) have been cloned previously and we have used homology-based cloning and AT₂ receptor clones affords the opportunity to investigate the molecular mechanisms underlying the behavioral actions of AngII. Previously, we have demonstrated that antisense oligonucleotides block the expression of AngII-R subtypes in rat brain and significantly attenuate thirst mediated by the renin-angiotensin system. In the present study, we utilized the known structural features of AnglI-Rs to design highly selective antisense oligonucleotides (ASONs) targeted for specific regions of AngII-R mRNAs. Intracerebroventricular administration of ASONs (18 mer) extending from the ATG initiation region and upstream of the amino terminus inhibited the behavioral actions of AngII and significantly reduced the binding of 125I-AngII to brain membranes. In contrast, ASONs targeted for the carboxy terminus also inhibited AngII mediated ingestive responses but did not decrease 1261-AngII binding presumably because ASONs resulted in the expression of truncated receptor unable to couple to Gproteins. Collectively, these results demonstrate the utility of ASONs for investigating the molecular mechanisms of AngII action in the brain.

VASOPRESSIN-INDUCED MOBILIZATION OF INTRACELLULAR CALCIUM IS LINKED TO ELEVATION OF CYCLIC AMP (CAMP)

<u>S.M. Rezazadeh* A. Dibas, M.W. Martin, A.J. Mia and T. Yorio</u> Department of Pharmacology, U. of North Texas Health Science Center at Ft Worth, TX 76107.

Two G-protein-coupled receptors for vasopressin have been characterized. The V₁ subtype stimulates phospholipase C whereas the V₂ subtype activates adenylyl cyclase. In this study, the effects of arg-vasopressin (AVP) on intracellular free calcium ([Ca2+]i) and cAMP was investigated in LLC-PK1 pig kidney epithelial cell line. Using digital imaging fluorescence microscopy of fura-2 loaded cells, we observed that AVP increased $[Ca^{2^{+}}]_{i}$ in a dose and time dependent manner. observed that AVP increased [Ca²], in a dose and time dependent manner. Thapsigargin (10 μ M) abolished this AVP response by depleting Ca_i pools. Addition of dibutyryl cAMP increased [Ca²⁺], and this prevented the subsequent AVP-induced increase in [Ca²⁺], The AVP-induced increases in [Ca²⁺], imay be mediated by cAMP and activation of protein kinase A (PKA), since inclusion of H-7, an inhibitor of PKA, abolished the AVP effect on [Ca2+], We further examined the effect of AVP on cAMP accumulation. Using Dowex-alumina column chromatography, 3H-cAMP accumulation was measured after prelabelling cells with 3H-adenine. Cells loaded with 3H-adenine were incubated with respective drugs for 10 min in the presence of the PDE inhibitor RO20-1724. Forskolin (FSK) or AVP elevated cAMP levels in a concentration dependent manner. Addition of both FSK and AVP resulted in synergistic responses. The AVP-induced accumulation of cAMP was reversed by the V_2 selective antagonist, AVF-induced account and to TANIM was reversed by the V_2 secretic analogous, $[d(CH_2)_5, D\text{-lle}^2, lle^4, Arg]$ -vasopressin (10 μ M). The results suggest that AVP-induced increases in $[Ca^{27}]_5$ in LLC-PK₁ cells are predominantly mediated by cAMP/PKA, and involve the release of Ca, from a thapsigargin-sensitive pool. (Supported by DAMD 17-95-5086 and UNTHSC Grants).

SPATIAL DISTRIBUTION AND TEMPORAL REGULATION OF TYPE I PACAP-SELECTIVE RECEPTOR ISOFORM EXPRESSION IN PRIMARY RAT ASTROCYTE CULTURES. <u>D.M. Jaworski* and K.M. Braas</u>. Dept. of Anatomy and Neurobiology, Univ. of Vermont College of Medicine, Burlington, VT 05405.

The type I pituitary adenylate cyclase activating polypeptide (PACAP)-selective receptor belongs to the family of seven transmembrane-domain G protein coupled receptors. Splice variants of the type I receptor differ in the presence or absence of two 84 bp cassettes, termed HIP and HOP, in the region of the gene encoding the third cytoplasmic loop, a primary site of interaction between the receptor and G proteins. The six splice variants of the type I receptor exhibit different patterns of adenylyl cyclase and phospholipase C stimulation, suggesting a cell specific mechanism for differential intracellular signaling. Rat brain astrocytes exhibit PACAP-selective binding, thus the present studies were undertaken to identify the PACAP receptor isoforms expressed by primary cultures of rat brain astrocytes. To distinguish the specific type I PACAP receptor isoforms expressed by astrocytes, the presence or absence of either one or both of the 84 bp cassettes was examined using reverse transcription PCR with primers adjacent to the cassette insertion site. The predominant molecular form of PACAP receptor mRNA in primary rat cortical, brainstem and cerebellar astrocyte cultures from postnatal day one (P1) animals contained neither insert; low expression of a one cassette variant was also observed. In contrast, astrocyte cultures from the same brain regions from P15 animals exhibited lower receptor mRNA levels and equivalent expression of the short and one cassette isoforms. Southern blot analysis with sequence specific hybridization for the HIP and HOP cassettes will determine the identity of the insert. Combined in situ hybridization histochemistry-immunohistochemistry will be used to determine whether the PACAP receptor isoforms are expressed by distinct astrocyte subtypes. Supported by HD27468.

CHOLECYSTOKININ RECEPTORS IN BOVINE ADRENAL CHROMAFFIN CELLS P.J. Vainio, A.M. Aarnisalo, P.T. Männistö¹, E. Vasar² and R.K. Tuominen*. Dept Pharmacol Toxicol, Inst Biomedicine, Univ Helsinki, FIN-00014, Finland; ¹Dept Pharmacol, Univ Uppsala, Sweden; ²Dept Physiol, Univ Tartu, Estonia

Cholecystokinin (CCK) regulates several functions in gastrointestinal tract, and it is the most abundant neuropeptide in the brain. It participates in the control of feeding, analgesia and anxiety. The two subtypes of CCK receptors, CCKA and CCKB, are both activated by a decapeptide, caerulein. CCKA and CCKB receptors can be blocked by devazepide and L-365.260, respectively. We have used primary cultured bovine adrenal medullary (BAM) cells as a model of nerve cells.

In these cells, caerulein (0,1–100 nM) increased accumulation of inositol phosphates in a concentration dependent manner. The effect of caerulein (100 nM) was antagonized by devazepide (1 μM), but not by L-365.260 (1 μM). CCK-4, a CCKβ receptor agonist, did not induce accumulation of inositol phosphates. Caerulein (30 min, 100 nM) also increased membrane-associated protein kinase C (PKC) activity, as determined by histone phosphorylation assay and immunoblot against PKC α isoenzyme.

In conclusion, primary cultured BAM cells possess CCKA receptors

In conclusion, primary cultured BAM cells possess CCKA receptors linked to phosphoinositidase C signal transduction pathway. The functional significance of CCKA receptors in adrenal medulla remains unknown.

Role of Asp^{2.61}(98) in Agonist Complexing with the Human Gonadotropin-Releasing Hormone Receptor. Vladimir Rodic¹, Colleen Flanagan², Robert Millar², Karel Konvicka³, Harel Weinstein³, Stuart C.Sealfon¹. ¹Fishberg Research Center for Neurobiology and ³ Department of Physiology and Biophysics, Mount Sinai School of Medicine, NY 10029, ²Department of Chemical Pathology, University of Cape Town Medical School, Observatory 7925, South Africa

Cape Town Medical School, Observatory 7925, South Africa.
Previous studies have identified an acidic residue in the third extracellular loop of the GnRH receptor that confers specificity for the Arg8 containing mammalian receptor (J. Biol Chem. 269:22636-41, 1994) and a Lys in helix 3 required for high affinity agonist interactions (J. Biol Chem. 370,1885-18857,1995). In the present study, the role of Asp².61(98) in agonist and antagonist interactions was explored. Mutation of this site to Glu, Ala, Asn and Val eliminated detectable agonist binding. Competition of labeled antagonist by GnRH showed that the affinity of GnRH for the Glu mutant receptor is reduced ~235-fold. All receptor mutants studied were capable of mediating agonist-stimulated phosphoinositol turnover. The EC50 values obtained with most agonists, including GnRH, were increased several orders of magnitude in comparison with the wild-type receptor. Interestingly, the EC50 for Trp² GnRH was equivalent in the wild-type and Glu².61 mutant, whereas the EC50 of GnRH was increased ~70-fold with this mutation. Thus the interaction of Trp²-GnRH with the receptor does not appear to be dependent on the length of this side chain. These results show that high affinity GnRH interaction depends on Asp².61(98), possibly due to a direct interaction with His² in the ligand. Supported by grants NIH DK44943 KO5 DA 00060.

THE EFFECT OF POINT MUTATIONS ON LIGAND BINDING FOR THE ANGIOTENSIN TYPE 2 RECEPTOR.

Rogers, S. Jacobs, and S.J. Fluharty.

Psychology, Pharmacology, and Institute of Neurological Sciences. University of Pennsylvania, Philadelphia, PA 19104.

There are at least two main subtypes of angiotensin II (AngII) receptors, termed Type 1 (AT1) and Type 2 (AT2). Although they share a relatively low level of homology (34%), both subtypes possess nearly identical affinities for AngII. Thus far, mutagenesis studies of this receptor family have focused solely on the AT, receptor subtype. These experiments have identified several amino acid residues that are important in AngII binding [Yamano et al., 1994, JBC 269:14024; Hjorth et al., 1994, JBC 269:30953]. In order to establish the level of similarities in ligand binding that may exist in this receptor family, we have been mutating residues conserved in the AT2 subtype that were identified in the AT1 mutagenesis experiments as important in AngII binding. Analyses of the point mutants lysine 215 to glutamine (K215Q) and aspartate 280 to asparagine (D280N) have been completed. When expressed in COS-1 cells, the K215Q mutant possessed greatly reduced affinity for both ¹²⁵I-AngII and ¹²⁵I-Sar¹,Ile⁸-AngII and was unable to bind the nonpeptide ¹²⁵I-PD122979. In contrast, the D280N mutant bound ligands with wild-type affinities. These data indicate that despite a relatively low homology, some commonalities in the binding mechanism for AngII may exist between the two subtypes. Additional point mutants are being characterized to more fully determine the extent of these similarities. Supported by NS23986 and MH43787.

BASIC AMINO ACIDS AT THE C-TERMINUS OF THE THIRD INTRACELLULAR LOOP ARE REQUIRED FOR THE ACTIVATION OF PHOSPHOLIPASE C BY CCK_B RECEPTORS. H. L. Wang* J. F. Chen and M. K. Sun. Department of Physiology, Chang Gung College of Medicine and Technology, Kwei-San, Tao-Yuan, Taiwan, R.O.C.

Recent studies suggest that charged amino acids of the third intracellular segment are required for the G-protein activation. The third intracellular loop of CCKB receptor also contains three basic amino acids (K333/K334/R335) at the C-terminal end. To test the importance of conserved charged amino acids in the G-protein activation and the stimulation of phospholipase C (PLC), we mutated these amino acid residues and expressed mutant CCKB receptors in COS cells and Xenopus occytes. Subsequently, the ability of mutant receptor to activate PLC was investigated by measuring the formation of inositol phosphates (IP) in COS cells and recording Ca⁺⁺-activated chloride currents from Xenopus occytes.

Site-directed mutagenesis was performed to mutate three basic amino acids, K333/K334/R335, to non-charged amino acids, M333/T334/L335. When the resulting mutant CCK_B receptors were expressed in COS cells and *Xenopus* oocytes, CCK-8 failed to induce IP formation in COS cells and evoke Ca⁺⁺-dependent chloride currents from oocytes. We also mutated each basic amino acid (K333-M333; K334-T334; R335-L335). Each of these mutations resulted in a significant reduction in the activation of PLC by CCK-8. Interestingly, substituting conserved basic amino acids, K333/K334/R335, with another three charged amino acids, R333/R334/K335, did not change the maximal CCK-8-simulated IP formation and the amplitude of CCK-8-evoked Ca⁺⁺-activated chloride currents. These findings propose that basic amino acids at the C-terminus of third cytoplasmic loop are required for the signal transduction by CCK_B receptors. (This work was supported by Chang Gung Medical Research Foundation)

ROLE OF THE AMINO TERMINUS IN LIGAND BINDING FOR THE ANGIOTENSIN RECEPTOR FAMILY. <u>D.K. Yee*, J.N. Heerding, M.Z. Krichavsky, and S.J. Fluharty.</u> Departments of Animal Biology, Psychology, Pharmacology, and Institute of Neurological Sciences. University of Pennsylvania, Philadelphia, PA 19104.

There are at least two main subtypes of angiotensin II (AngII) receptors, termed Type 1 (AT₁) and Type 2 (AT₂). Comparison of their amino acid sequences shows a relatively low level of homology (34%), which is lowest in their extracellular domains. Mutagenesis studies have previously demonstrated that the AT1 amino terminus plays an important role in the binding of AngII; some mutations of this protein domain reduced the affinity for the peptide by more than 5000-fold [Hjorth et al., 1994, JBC 269:30953]. The key residues identified by these AT₁ mutagenesis experiments, however, are not conserved on the AT2 amino terminus. Since the two subtypes bind AngII with identical affinities, we constructed and characterized AT1 and AT2 amino terminal exchange mutants in order to further investigate the role of this protein domain in ligand binding for the AngII receptor family. When expressed in COS-I cells, the affinities of these chimeric receptors for 125I-AngII were essentially identical to that of the wild type receptors. These data suggest that: (i) the AT2 amino terminus is important in the binding of AngII and (ii) despite great differences in their amino acid sequences, the two amino termini can compensate for one another. In addition, pharmacological analyses have demonstrated that the replacement of the AT2 amino terminus with that of the AT₁ did not affect the specificity of AT₂ selective compounds CGP42112A and PD123319. This suggests that specific epitopes that are responsible for the AT2 selective binding of these compounds do not reside in the AT_2 amino terminus. Supported by NS23986 and MH43787.

OVEREXPRESSION OF HUMAN GONADOTROPIN RELEASING HORMONE RECEPTOR PROTEIN IN TRANSFECTED Sf9 CELLS. S.S. Kakar, S. Nath, D.C. Tucker*, N.S. Reddy and L. Jennes. Dept. Physiology and Biophysics, and Dept. Physiological Optics, University of Alabama at Birmingham, Birmingham, AL 35294 and Dept of Anat. & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

Gonadotropin releasing hormone (GnRH) receptors belong to the family of G protein-coupled receptor proteins and have been localized to the anterior pituitary, brain, reproductive organs as well as many steroid-dependent tumor tissues. In order to generate sufficient receptor protein for detailed structural analyses and for the generation of specific antibodies, the full length human GnRH receptor cDNA was subcloned into baculovirus transfer vector pVL 1392 and, after homologous recombination, insect Sf9 cells were transfected with the resulting virus. After several rounds of amplification, the transfected cells exhibited binding for GnRH and its analogs with ligand specificities similar to the pituitary GnRH receptor, however, the affinities were slightly lower. Thus, for example, the GnRH agonist D-Ala⁶-GnRH displaced ¹²⁵I-Buserelin with an EC₅₀ of 3 nM compared to 0.2 nM in pituitary. Metabolic labeling of transfected Sf9 cells with ³⁶S-methionine and ³⁶S-cysteine resulted in the appearance of 56 kDA protein band which is similar to the molecular weight of glycosylated pituitary GnRH receptor proteins. Together, the results suggest that human GnRH receptor protein can be overexpressed in transfected Sf9 cells and that the resulting protein retains its binding specificities. Supported by NIH CA60871 (SSK) and HD 24697 (LJ).

CALORIE RESTRICTION DELAYS THE ALTERATIONS OF GROWTH HORMONE-RELEASING FACTOR RECEPTOR BINDING SITES OBSERVED IN AGING RAT PITUITARY <u>P. Gaudreau*</u>, <u>N. Girard</u>, <u>L. Boulanger and G. Ferland</u>. Neuroendorinology Laboratory, Notre-Dame Hospital Research Center and Departments of Medicine and Nutrition, University of Montreal, Montreal, Canada H2L 4M1.

Growth hormone (GH) secretion is regulated by two hypothalamic peptides, growth hormone-releasing factor (GRF) and somatostatin (SRIF). These peptides exert opposing actions on somatotroph cells by triggering specific G_s- and G_i-protein-coupled receptors. In middle age and old mammals, several changes occur along the hypothalamopituitary GH axis, including alterations of the pituitary GRF receptor binding sites. This leads to a diminution of GH and IGF-1 circulating levels and contributes to aging processes. Because the anti-aging effects of calorie restriction ressemble those of GH, we studied GRF binding in this rat model of successful aging. Interestingly, in 18month-old rats submitted to a moderate calorie restriction from 8 to 18 months of age, high and low affinity GRF binding site parameters remain similar to those of 2-month-old control rats. On the contrary, high affinity GRF binding sites are blunted in 18-month-old ad libidum fed rats. These results suggest that some of the anti-aging effects of calorie restriction are related to the maintenance of pituitary GRF receptor integrity. Functional studies will however be needed to assess the physiological relevance of such nutritional interventions to delay GH somatopause. Supported by MRC (PG) and NSERC (GF)

PEPTIDE RECEPTOR STRUCTURE AND FUNCTION III

EXPRESSION OF CALCITONIN RECEPTORS IN HUMAN NEUROBLASTOMA CELLS. <u>G.Campana</u>, <u>S.Cacciaguerra</u>, <u>M. Canossa</u>, <u>S.Ferri and S.Spampinato*</u>, Department of Pharmacology. University of Bologna, Irnerio 48, 40126, Bologna, Italy.

The 32-amino acid peptide calcitonin (CT) influences calcium homeostasis binding to receptors expressed in osteoclasts and in the kidney. CT also acts on binding sites in the central nervous system, where exogenous CTs modulate appetite, body temperature and pain perception (Spampinato et al., 1984, Neurosci. Lett., 45:135-139). CT receptors have been cloned from peripheral tissues of several mammalians including humans. However, to date CT receptors expressed in the central nervous system have been poorly investigated. We have examined a series of human neuroblastoma cell lines with the aim to detect, by polymerase chain reaction, any mRNA coding for the calcitonin receptor using two primers complementary to an unique sequence of a cDNA (Kuestner et al., 1994, Mol. Pharmacol., 46: 246-255). Electrophoretic analysis of reverse-transcribed total RNA, provided evidence that mRNA coding for this receptor occurs in IMR 32 cells. Receptor binding studies using 1251-salmon CT revealed a high affinity binding site for this peptide (B_{MAX}=4.66 x 10⁻¹⁰ M) and human CT competes with binding at this site (K_i=1.44 x 10⁻¹⁰ M). In cells, loaded with fura-2, human CT (IC₂₅=1.58 x 10-7 M) and salmon CT (IC25=1.62 x 10-7 M) antagonized Ca2+ entry evoked by high extracellular K+ (50 mM). Therefore, IMR 32 cells represent an useful tool to investigate the gene expression and molecular interactions of CT receptors in neuronal cells.

TISSUE DISTRIBUTION OF CLONED CGRP RECEPTORS. A.E. Luebke*, M. Howard, I.M. Dickerson. Department of Physiology and Biophysics, Univ. of Miami Sch. of Med., Miami, FL 33101.

We have recently identified a cDNA from guinea pig cochlea that confers CGRP responsiveness in an oocyte expression assay (Luebke et al. 1996, PNAS, 93:3455-3460). The deduced protein is a small hydrophilic molecule that does not contain an obvious membrane-spanning domain. We hypothesize that this protein is a receptor for CGRP, or is a component of a complex of proteins that together constitute the CGRP receptor. We have mapped the distribution of this CGRP-receptor component protein (CGRP-RCP), and it is colocalized in the cerebellum with neurons that immunostain for CGRP. Two orphan receptors, RDC1 and GPRN1, have recently been implicated as CGRP receptors (Law and Rosenzweig, 1994, BBRC 201:458-465; Kapas and Clark, 1995, BBRC 217:832-838). As a first step in determining the composition of a CGRP receptor, we have begun to map the distribution of CGRP-RCP, RDC1, and GPRN1. Northern analysis and immunohistochemistry have mapped the distribution of CGRP-RCP, and this distribution is being compared to that for RDC1 and GPRN1 in brain, heart and lung determined by in situ hybridization and Northern analysis. This work was supported in part by AHA (FL Affiliate) Grants-In-Aid #9401236 (IMD) and #9501349 (AEL).

CLONING AND EXPRESSION STUDY OF A CGRP RECEPTOR FROM MOUSE UTERUS. M. Howard. G. P. Dahl and I. M. Dickerson*. Dept. of Physiology and Biophysics, Univ. of Miami Sch. of Med., Miami, FL 33136

CGRP-IR neurons have been identified in the uterus and CGRP inhibits spontaneous contractions in the uterus and fallopian tubes, suggesting that CGRP may play an important role in regulation of smooth muscle activity. Using degenerate PCR, we have determined the primary structure of the mouse homologue of the CGRP-receptor component protein (CGRP-RCP) recently isolated from guinea pig cochlea (Luebke et al. 1996, PNAS, 93:3455-3460). The 1.8 kb cDNA of the mouse CGRP-RCP contains a 444 bp open reading frame (ORF) preceded by a Kozak ranslation initiation consensus sequence. An oocyte expression system using the cystic fibrosis transmemberane conductance regulator (CFTR) as a sensor of intracellular cAMP levels was used to monitor CGRP responsiveness of the protein encoded by the ORF. Uterus mRNA was reverse transcribed and PCR amplified using primers that flank the ORF. The resulting RT-PCR product was transcribed in vitro and co-injected into the Xenopus oocytes with CFTR cRNA. Under voltage clamp conditions, oocytes expressing the protein encoded by the ORF produced an inward current when incubated with CGRP. We have carried out northern analysis, western analysis and immunohistochemistry in order to map the expression of CGRP-RCP in the mouse uterus during pregnancy. This work was supported in part by, AHA (FL affiliate) Grant-In-Aid #9401236 (IMD) and NIH #GM48610 (GPD).

CALCITONIN GENE-RELATED PEPTIDE (CGRP) RECEPTOR EXPRESSION IN THE RAT BRAIN. AN IN SITU HYBRIDIZATION STUDY, Y. Tong* 1,2 AJL. Clark 3, S.H. Shen 2 and R. Quirion 1. Douglas Hospital Res. Ctr. Dept. of Psychiatry, McGill Univ., Montreal, Que. H4H 1R3; 2Biotechnology Res. Inst., NRCC, Montreal, Que., 3Dept. of Clin. Endo. The Medical College of St. Bartholomew's Hospital, London, U.K.

The existence of at least two classes of CGRP receptors has been proposed on the basis of the differential potency of CGRP fragments and analogues in *in vitro* bioassays (Dennis *et al.*, J. Pharmacol. Expt. Ther. 251:718, 1989) and behavioral tests (Quirion *et al.*, Ann. N.Y. Acad Sci. 657:88, 1992). The CGRP₁ subtype is particularly sensitive to the antagonistic properties of the fragment CGRP₈₋₃₇ while the CGRP₂ receptor is less affected in addition to being activated by the linear agonist [Cys(ACM)²⁻⁷] hCGRPα. Recently, the cloning of a CGRP₁-tike receptor has been reported (Kapas and Clark, Biochem. Biophys. Res. Comm. 217:832, 1995). It is a seven-transmembrane G-protein coupled receptor highly sensitive to both CGRP and CGRP₈₋₃₇. Additionally, another CGRP binding protein has just been cloned and shown to have a single transmembrane domain (Luebke *et al.*, PNAS, 93:3455, 1996). In the present study, we used a ³⁵S-labelled rat cRNA probe to investigate the discrete expression of the cloned CGRP₁-like receptor in the rat brain. Probes were used at a concentration of 1x10⁷ cpm/ml using a method described in detail elsewhere (Tong *et al.*, Neuropeptides 20:33, 1991). Hybridized sections were exposed for 2 (films) to 6 (emulsion) weeks before development. Specific moderate to strong hybridization signals were observed in the anterior olfactory nuclei, nucleus accumbens, dentate gyrus, and linings of ventricles and choroid plexus. At higher microscopic resolution, many CGRP receptor expressing neurons were diffusely distributed in various hypothalamic, thalamic and brainstem nuclei. Such a localization is reminiscent of that of [¹²⁵I]CGRPα binding sites in the rat brain. Supported by the MRCC.

COMPARATIVE EFFECTS OF [Cys(ACM)^{2,7}]hCGRPα AND [Cys(Et)^{2,7}]hCGRPα IN CGRP, AND CGRP, IN VITRO BIOASSAYS: CHARACTERIZATION, OF A MORE POTENT AND SELECTIVE CGRP-AGONIST. A. Fournier', Y. Dumont', S. St-Pierre' and R. Quirion'. INRS-Santé, Université du Québec, Pointe-Claire, Qc. Canada, H9R 166. Douglas Hospital Research Center and Dept Psychiatry, McGill Université, 6875 LaSalle Blvd, Montréal, Qc. Canada, H4H 1R3.

The existence of CGRP₁ and CGRP₂ receptor subtypes has been proposed on the basis of the differential potency of hCGRP₂, sto antagonize the effect of hCGRPα in the guinea pig atria and in the rat vas deferens (pA₂ of 7.6 and 6.2, respectively: Dennis et al., JPET., 254: 123-128, 1990). Moreover, the linear analogue (Cys(ACM)^{2,3}] hCGRPα, was shown to be more effective to inhibit the rat vas deferens twitch response than to induce a positive inotropic effect in the guinea pig atria (Dennis et al., JPET, 251: 718-725, 1989). Taken together, these results suggested the existence of at least two classes of CGRP receptors, one being more sensitive to the antagonistic properties of CGRP₂, and CGRP₁ while the other is activated by moderate to high nM concentrations of the linear analogue (CGRP₂) However, the rather low potency of (Cys(ACM)^{2,7}]hCGRPα (ED₂0 of 70nM in the rat vas deferens) limits its usefulness. We postulated that modifications of the linear analogue should lead to more potent and selective CGRP₂ agonists. Among them, (Cys(Et)^{2,7})hCGRPα was developed and tested in the guinea pig atria and rat vas deferens, representing prototypical CGRP₁ and CGRP₂ bioassays, respectively. [Cys(Et)^{2,7}]hCGRPα inhibited the rat vas deferens witch response with an ED₂o of 2.6 ± 1.2 nM (30 times more potent than [Cys(ACM)^{2,7}]hCGRPα. while in the guinea pig atria, and is analogue induced only a slight contraction at the high concentration of 1 μM (20 to 30 % of the maximal response induced by hGGRPα. [Tyr⁶, Cys(Et)^{2,7}]hCGRPα and hCGR^{2,7}]hCGRPα also competed with high affinity (low M range) for [

517.7

CHARACTERIZATION OF THE GALANIN RECEPTOR IN THE CHP 212 HUMAN NEUROBLASTOMA CELL LINE, L.-L. Shiao , M. A. Cascieri* and K.A. Sullivan. Molecular Pharmacology and Biochemistry, Merck & Co., Rahway, NJ 07065.

Biological functions of galanin are mediated via membrane bound high-affinity receptors. In order to identify and characterize galanin receptor subtypes, we have detected specific ¹²⁵I-human galanin binding in the CHP 212 human neuroblastoma cell line. galanin binding in the CHP 212 human neuroblastoma cell line. The rank order of potency in the inhibition of 1251-human galanin binding by galanin and the chimeric galanin peptides: [h-Gal = p-Gal = h-Gal(1-19) = M35 >M40 >p-Gal(1-16) = M15>C7 = r-Gal(2-29)], indicates that this cell line displays the same pharmacology as the Bowes melanoma cell line. Scatchard analysis reveals a Kd of 0.07 nM that is in close agreement with the hGALR1 expressed in stable CHO cell line as well as in Bowes melanoma cell line from which hGALR1 expressed in stable CHO cell line as well as in Bowes melanoma cell line from which hGALR1 expressed in stable choice which healed against cloned. Western blot analysis using an antisera raised against HGALR1 crossreacts with a species of approximately 70 kDa in Bowes melanoma membranes which is also observed in a stable CHO cell line expressing hGALR1. Furthermore, Northern blot analysis demonstrated an ~3 kb mRNA in both CHP 212 and Bowes melanoma cells. These data suggest that the human galanin receptors expressed in CHP212 are the same subtype as the cloned GALR1 from the Bowes melanoma cells.

NEUROANATOMICAL DISTRIBUTION OF A NOVEL RAT GALANIN RECEPTOR SUBTYPE. D. O'Donnell*, S. Ahmad, P. Walker, C. Wahlestedt. Astra Pain Research Unit, Montreal, Quebec, Canada H4P 2R2.

Recent molecular cloning studies by our laboratory have identified the existence of a novel rat galanin receptor subtype, GALR2. RT-PCR analysis has revealed that GALR2 mRNA is expressed in various tissues including dorsal root ganglia, spinal cord, brain and certain peripheral tissues. In this study, we further examined the precise neuroanatomical distribution of GALR2 mRNA using in situ hybridization. Frozen rat brain and spinal cord sections with dorsal root ganglia attached were hybridized with ³⁵S-labeled riboprobes. In sagittal brain sections, the highest levels of GALR2 mRNA were detected in the dorsal hippocampus with dentate gyrus granule cells expressing slightly higher levels than pyramidal neurons of Ammon' horn. High levels of labeling were also detected in the mammillary bodies and cerebellum, particularly in some Purkinje cells as well as in numerous cells throughout the molecular layer. Moderate levels of GALR2 were observed in the pontine nucleus and in specific cranial nuclei. Moderate to weak hybridization signal was also present in the superficial layers of the cerebral cortex. Other cephalic areas such as the thalamus and basal ganglia were relatively devoid of labeling. In sections taken at the level of the spinal cord, very high levels of GALR2 mRNA expression were observed in dorsal root ganglia with large, intermediate and small diameter primary sensory neurons being specifically labeled. In contrast, only diffuse labeling was detected throughout the dorsal and ventral

This novel yet distinct pattern of GALR2 distribution within the rat CNS differs considerably from that of the GALR1 and therefore may partially account for the more widespread distribution of galanin binding sites. Moreover, the particularly high levels detected in sensory dorsal root ganglia neurons suggest that GALR2 is likely to play an important role in mediating galanin's antinociceptive actions

CALCITONIN GENE-RELATED PEPTIDE-INDUCED FORMATION OF SECOND MESSENGERS IN CULTURED NEONATAL RAT SPINAL CORD. A.M. Parsons* and V.S. Seybold. Graduate Program in Neuroscience, Univ. of Minnesota, Minneapolis, MN 55455.

Neuroscience, Univ. of Minnesota, Minneapolis, MN 55455.

The signal transduction pathway for calcitonin gene-related peptide (CGRP) receptors in the spinal cord is not known. We investigated the formation of second messengers (cAMP, cGMP and inositol phosphates) formed in response to CGRP in primary cultures prepared from spinal cords of 1-2 day post natal rats. The cultures were maintained for 10-14 days in vitro prior to experiments. Cellular cAMP and cGMP levels were determined by radioimmunoassay. Inositol phosphate formation was determined by recovery of [²H]inositol phosphate. Basal levels of cAMP with the concentration-response curve showing an intermediate plateau at 180 were 50 pmol/mg protein. CGRP increased the level of cAMP with the concentration-response curve showing an intermediate plateau at 180 pmol cAMP/mg protein in response to 0.01 to 0.1 nM CGRP and a maximal plateau of 850 pmol cAMP/mg protein at 300 nM CGRP. This biphasic curve (EC₅₀'s of 0.7 pM and 22 nM) suggests activation of high and low affinity receptors for CGRP. Both neurons and non-neuronal cells contributed to increased cAMP levels in response to CGRP. The CGRP receptor blocker, CGRP₈₋₃₇, antagonized the response. A high concentration of CGRP (1 μ M) moderately increased the formation of cGMP (180% above basal), whereas CGRP had no effect on the formation of inositol phosphates at any of the concentrations tested (0.1 1 μM). In summary, these results suggest that CGRP-induced responses in spinal cord are predominately via the formation of cAMP. The observation that both neurons and non-neuronal cells respond to CGRP indicate that this peptide may have multiple actions in the spinal cord. (This study was funded by NIH NS17702 and NIDA T32DA07234.)

PHARMACOLOGICAL CHARACTERIZATION OF THE RECOMBINANT HUMAN AND RAT GALRI GALANIN RECEPTOR C. Forray*, K. Smith, C. Gerald, P. Vaysse, R. Weinshank, and T. Branchek Synaptic Pharmaceutical Corporation, Paramus N.J. 07652.

We have studied the pharmacological properties of the recombinant GALR1 receptor, in an attempt to understand its role in mediating the effects of galanin receptor, in an attempt to understand its role in mediating the effects of galanin (Gal) in the CNS. LM(tk-) cells stably transfected with either the cDNA of the rat or human GALR1 receptor displayed high affinity binding for [125 I]porcine galanin. Competition binding assays using a series of truncated galanin analogs indicated that both rat and human GALR1 receptors had similar profiles. The rank order of affinities for C-terminal truncated analogs was: $Gal_{(1.29)} > Gal_{(1.16)} > Gal_{(1.12)} > Gal_{(1.29)}$ were inactive ($> 100 \, \mu M$). Human and rat GALR1 also showed similar binding affinities for chimeric Gal antagonists with the following rank order: $M35 \ge M32 > M40 > C7 \approx galantide$.

Functional activity of these receptors was assessed by measuring inhibition of cAMP formation stimulated by forskolin. In LM(tk-) cells expressing the human or rat GALR1 receptors, porcine Gal (1-29) inhibited cAMP formation by 98 and 75% respectively. The galanin "antagonists" C7, M40, M35 and M32 were all found to inhibit cAMP formation to the same extent as porcine Gal (1.29). indicating that in this "in vitro" assay these chimeric peptides are full agonists at the GALR1 receptor subtype. This observation suggests that the GALR1 subtype is not likely to mediate the effects of galanin on nociception or feeding behavior, since these effects have been found to be antagonized by either C7, M40, M35 or M32. These findings remain to be validated using non-peptide galanin antagonists, antisense studies or transgenic animals. (Supported by Synaptic Pharmaceutical Corporation)

PARTIAL SEQUENCE OF A PRODYNORPHIN CDNA CLONED FROM THE BRAIN OF THE MARINE TOAD, BUFO MARINUS. David Walker, Philip Danielson and Robert M. Dores*. University of Denver, Department of Biological Sciences, Denver CO 80208.

In mammals, the precursor, Prodynorphin, contains the sequences of three endogenous opioids, \$\alpha\$-neoendorphin, dynorphin A, and dynorphin B. Although Prodynorphin-related products have been detected in all of the classes of tetrapods, Prodynorphin has not been characterized in any species of non-mammalian vertebrates. In an effort to analyze the evolution of the Prodynorphin gene, we attempted to clone and sequence Prodynorphin cDNA isolated from the brain of the anuran amphibian, Bufo marinus. Using a 3' RACE procedure we were able to sequence a 450 base pair fragment of Bufo Prodynorphin. This region of the cDNA contained the sequences of dynorphin A, dynorphin B, the C-terminal of Bufo Prodynorphin, a stop sequence, and a 300 base pair 3' untranslated region. A comparison of mammalian and amphibian dynorphin sequences will be discussed. This research was supported by NSF grant: 9406967.

PROCESSING SITE BLOCKADE RESULTS IN MORE EFFICIENT CONVERSION OF PROEMKEPHALIN TO ACTIVE OPIOID PEPTIDES. K. Johanning, J.P. Mathis and I. Lindberg*. Dept. of Biochemistry and Molecular Biology, LSUMC, New Orleans, LA 70112.

Prohormones are known to be processed at various clea-

vage sites in a defined temporal order, suggesting the possibility of sequential unfolding of processing sites. investigate whether sequential processing at predefined sites is in fact required for proper processing, site-directed mutagenesis was performed to block known initial cleavage sites within proenkephalin. Pulse-chase/immunoprecipitation experiments were employed to analyze mutant and native proenkephalins in stably transfected AtT-20 cells. While processing did not occur at blockaded sites, surprisingly, overall processing of mutant proen-kephalins proceeded efficiently, and alternative sites were chosen. Processing of mutant proenkephalins occurred more slowly at early stages and more quickly at later stages. Endoglycosidase H experiments indicated that the early slow processing of mutant proenkephalins may be due to delays in intracellular transport. More efficient production of bioactive opioids occurred in all four site blockade mutants examined. We conclude that efficient processing of prohormone precursors does not require a specific temporal order of processing events. Mutant proenkephalins may provide a route for more efficient production of opioid peptides in applications for chronic pain treatment. (DA05084)

IDENTIFICATION OF MULTIPLE FORMS OF ORPHANIN F Q (OFQ) IMMUNOREACTIVITY IN MOUSE HYPOTHALAMIC EXTRACTS. D.I. Ouigley, R.G. Allen*, G. Zhang, J.A. McDougall and D.K. Grandy, Vollum Inst., Oregon Health Sciences Univ., Portland OR 97201.

Recently, a peptide tentatively named Orphanin FQ (OFQ) that binds the opioid-like orphan receptor LC 132 was isolated from porcine hypothalamic extracts. Behavioral studies suggest that OFQ possesses anti-opioid activity. The synthetic peptide was used to produce a polyclonal anti-OFQ antibody in rabbits that does not cross-react with dynorphins, or the multiple forms of β-endorphin contained in mouse pituitary extracts. This antiserum has been used in the development of an OFQ radioimmunoassay (RIA). In initial experiments we determined the levels of OFQ in mouse hypothalamic extracts to be 0.265 pmol/hypothalamus +/- 0.028, S.E.M. (N=4). Additionally, we found very low, to undetectable levels of OFQ immunoreactivity in striatum, spinal cord, hippocampus and the VTA/SNc, with the VTA/SNc extracts containing the highest amount of OFQ outside of the hypothalamus. Since the cDNA clone suggests that OFQ is contained within a larger precursor molecule, we fractionated hypothalamic extracts using reversed phase HPLC. Multiple peaks of immunoreactivity were detected by RIA suggesting that OFQ is contained within a discrete set of biosynthetic intermediates, as are the opioid peptides. This work was supported by NIH grants HD30236 (RGA) and DA08562 (DKG).

FEEDBACK REGULATION OF A POST-TRANSLATIONAL PEPTIDE α:N-ACETYL-TRANSFERASE PARTIALLY PURIFIED FROM BOVINE NEUROINTERMEDIATE PITUITARY. A.B. Manning* and W.R. Millington. Division of Molecular Biology and Biochemistry, University of Missouri-Kansas City, Kansas City, MO 64108.

Post-translational α -N-acetylation of the pro-opiomelanocortin-derived peptides β -endorphin (β-End) and ACTH(1-13)NH2 alters their biological functions, eliminating β-End(1-31)'s analgesic potency, yet potentiating many of ACTH(1-13)NH2's behavioral effects. Previous studies in our laboratory have indicated a single post-translational α -N-acetylating activity modifies both $\beta\text{-End}$ and ACTH(1-13)NH $_2$. Here we report that post-translational peptide $\alpha\text{-N-acetyl-}$ ating activity is inhibited by its reaction end-products. Enzyme activity was partially purified by using DEAE Sepharose and Cibacron Blue 3GA chromatography and measured using 3H-acetyl coenzyme A and ACTH(1-13)NH₂ or β-End as substrates. Kinetic analysis showed K_m values for β -End and ACTH(1-13)NH₂ of 80 μ M and 60 μ M, respectively. Peptide end-product inhibition studies revealed N,O-diacetyl- α -MSH inhibited β -End α -N-acetylation (K_j =213 μ M); N-acetyl- β -End(1-27) also inhibited α -N-acetylation of ACTH(1-13)NH $_2$ (K_i =309 μ M). Inhibition was concentration-dependent and non-competitive and K₁ values were within the estimated range of vesicular peptide concentrations. Coenzyme A, the other reaction end-product, also inhibited ACTH(1-13)NH₂ α-N-acetylation in a concentration-dependent manner (IC₅₀=53 μM) while bromoacetyl coenzyme A (250 μM) inhibited irreversibly. To determine whether inhibition was attributable to the peptides's N-terminal residues, N,O-diacetyl-seryl-tyrosine was tested; the dipeptide inhibited ACTH(1-13)NH2 α -N-acetylation minimally (11 %) and only at high concentrations (600 μ M). Similarly, L-tyrosine-glycine-glycine (600 μ M), β -End's N-terminal tripeptide, inhibited ACTH(1-13)NH $_2$ α -N-acetylation by only 22 %. Cyclo(seryl-tyrosine) (600 μ M), a cyclic derivative of seryl-tyrosine capable of penetrating biological membranes, partially inhibited α -N-acetylating activity (34 %). Thus, α -N-acetylatransferase reaction end-products clearly inhibit enzyme activity although the N-terminal peptide fragments, both des- and α -Nacetylated, have minimal inhibitory effects. (NIDA DA-04598)

CHRONIC EXPOSURE TO CAFFEINE INCREASES OPIOID NEUROPEPTIDE mRNA LEVELS IN THE NEOSTRIATUM AND TYROSINE HYDROXYLASE mRNA IN THE MESENCEPHALON OF THE RAT BRAIN. <u>U. Datta, P.-A. H. Noailles, M. Kraft, Y. Zhang and J. A. Angulo*</u>. Hunter College and the Graduate School of the City University of New York, Department of Biological Sciences, NY NY 10021.

Rats were injected ip with caffeine (20, 40 and 80 mg/kg of body weight) twice daily for nine consecutive days in order to assess the effect of this adenosine receptor antagonist that displays psychomotor stimulant properties, on the expression of preproenkephalin (PPE) and preprodynorphin (PPD) mRNA expression in the neostriatum. We also assessed tyrosine hydroxylase (TH) mRNA levels in the substantia nigra compacta (SNc) and the ventral tegmental area (VTA). Chronic caffeine elevated TH mRNA in the SNc (64% relative to controls) and the VTA (33%). These increases were blocked by concurrent administration of the non-competitive N-Methyl-D-Aspartate receptor antagonist MK-801. In the neostriatum, PPE and PPD mRNA levels were increased (up to two-fold) in all aspects of the caudate-putamen. Concurrent administration of caffeine and MK-801 attenuated the increases observed with caffeine alone. Preliminary observations show that chronic caffeine treatment decreases mu receptor levels in the striatum and accumbens

ALTERATIONS IN THE BLOOD LEVELS OF HEMORPHIN-7 AND β -ENDORPHIN IN PATIENTS SUBJECTED TO OPEN-HEART-SURGERY. E. Nyberg 1 . K. Sanderson 1 . N. Majid 1 . P. Andrén 1 . A. Adem 2 . K. Karlsson 3 . E. Sandström 4 and L.-O.D. Koskinen 5 Department of Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden, 2 Department of Clinical Neuroscience & Family Medicine, Huddinge Hospital, Huddinge, Sweden, 3 Departments of Clinical Chemistry, 4 Thoracic Surgery and 5 Neurosurgery, NUS, Umeå, Sweden. (Spon: SONA)

The hemorphins are opioid active peptides enzymatically released from the β-chain of the blood protein hemoglobin. Previous studies have shown that the level of hemorphin-7 is increased in plasma samples collected from human subjets following long distance running. Furthermore, this increase was parallelled by an elevation of plasma levels of β-endorphin.

In this presentation we describe a study of hemorphin-7 and β -endorphin in patients subjected to open-heart surgery using a heart-lung machine. In the arterial blood flow the level of hemorphin-7 was found to increase with time, whereas β -endorphin remained unaltered. In the blood collected from the jugular venous bulb, however, the level of β -endorphin was increased, whereas no significant changes were found in the hemorphin-7 concentration. It is suggested that hemorphin may produce a release of β -endorphin from the pituitary. It is known that patients undergoing cardiopulmonary bypass generally have a sense of well beeing the first postoperative day. This could be due to the released peptides. However, it could not be excluded that the release of the peptides may be involved in the minor brain injuries often seen in conjunction with open heart surgery.

The study also describes the characterization of the measured hemorphin-7 immunoreactivity using the Pharmacia-SMART system for reversed phase separation. The chromatographic instrument was used to isolate the immunoreactive material for a subsequent analysis by mass-spectrometry, where the identity between the detected activity and the authentic peptide was confirmed.

CHARACTERIZATION OF A NOVEL SOLUBLE PROTEIN FACTOR WITH NON-OPIOID DYNORPHIN A-BINDING AND CORVERTASE ACTIVITIES. T. Yakovleva*, M. Melzig, K. Hjertman, I. Nylander, J. Silberring, G. Bakalkin and L. Terenius. Department of Clinical Neuroscience, Karolinska Institute, S-17176 Stockholm, Sweden.

A novel protein factor with non-opioid dynorphin A-binding

A novel protein factor with non-opioid dynorphin A-binding sites was characterized in human neuroblastoma SK-N-MC cells and in the rat spinal cord. The factor binds dynorphin A-(1-13), A-(1-17), dynorphin A-(2-17) and the proenkephalin fragment peptide E, but not other opioid and nonopioid peptides, morphine, etorphine, naloxone or benzomorphans. The IC50 for dynorphin A-(1-17) and dynorphin A-(2-17) was about 50 and 5 nM respectively. Bound labelled dynorphin A cannot be easily displased by a nonlabelled peptide and seemed to undergo conversion to the shorter fragment Leu-enkephalin which remained bound to the protein. SH groups of the factor were apparently involved in the binding of dynorphin A, since PHMB inhibited this process. The dynorphin A-binding factor has an apparent molecular mass of about 70 kDa and was found in a nuclear extract and in cytosol. These data suggest that the factor functions as a dynorphin A convertase interfering with the activity of this peptide. Supported by grants from the Swedish Medical Research Council (Project 3766) and NIDA (DA-05186-04).

REGULATION OF OPIOID PEPTIDE GENE EXPRESSION IN RAT HIPPOCAMPUS: ROLE OF PROTOONCOGENES. J. S. Won, Y. H. Kim, D. K. Song, and H. W. Suh*. Department of Pharmacology, College of Medicine, Institute of Natural Medicine, HallymUniversity, Chunchon, 200-702. S. Koma

Medicine, Institute of Natural Medicine, HallymUniversity, Chunchon, 200-702, S. Korea.

The effect of cycloheximide (CHX), a protein synthesis inhibitor, on the regulation of proenkephalin (proENK) mRNA level and proto-oncogenes, such as c-fos, 35 kDa-fra, and c-jun mRNA and the levels of their products induced by kainic acid (KA) in rat hippocampus. The proENK mRNA level was markedly increased 1 and 8 hr after administration with KA (10 mg/kg). The proENK mRNA elevation was inhibited by the pretreatment with CHX (15 mg/kg). The intracellular proENK protein levels was not changed by neither KA. The increase of proENK mRNA level was well correlated with c-fos, 35 kDa-Fra, and c-Jun protein levels. C-fos, 35 kDa-Fra, and c-Jun proteins were detected at 1 hr after KA administration, increased gradually, and reached a peak after 8 hr. The increases of c-Fos, 35 kDa-Fra, and c-Jun protein levels elevated by KA were inhibited by the pretreatment with CHX. KA administration increased c-fos and c-jun mRNA levels in 1-2 hr and the levels of these proto-oncoproteins were potentiated by CHX. Furthermore, CHX alone increased the c-jun mRNA level without altering c-fos mRNA level. The AP-1 and ENKCRE-2 DNA binding activities were also increased by KA and were attenuated by CHX. We found that KA-induced AP-1 and ENKCRE-2 DNA binding activities were diminished by the antibodies against c-fos, 35 kDa-Fra, and c-Jun proteins. Furthermore, the cross-competition studies revealed that AP-1 proteins actively participated in ENKCRE-2 DNA domain. In addition, CREB antibody attenuated KA-induced ENKCRE-2 DNA binding activity. The results imply that newly synthesized c-Fos, 35 kDa-Fra, and c-Jun proteins, which bind to AP-1 as well as ENKCRE-2 domain, may play important roles in the regulation of proENK mRNA expression induced by KA in rat hippocampus (supported by grant 95-0403-19-01-3 from KOSEF).

THE SPATIAL RELATIONSHIP BETWEEN PREPRODYNORPHIN IMMUNOREACTIVITY AND KOR1 IMMUNOREACTIVITY IN GUINEA PIG BRAINSTEM <u>S. Shuster¹⁻² M. Riedl², L. Vulchanova¹⁻², J. Wang², and <u>R. Elde*</u>, ¹⁻². ¹Graduate Program in Neuroscience, ²Department of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

A complementary spatial relationship between a receptor and its</u>

A complementary spatial relationship between a receptor and its putative endogenous ligand is one important criterion in conferring a biological interaction in vivo. For the kappa opioid receptor and its putative ligand, dynorphin, this relationship has been inferred, for example, by comparing receptor autoradiography and in situ hybridization with dynorphin immunohistochemistry. In order to elucidate their spatial relationship with greater resolution, antisera were raised to the C-terminus of preprodynorphin (ppDYN) and kappa opioid receptor (KOR1, previously described). The specificity of the preprodynorphin was determined by absorption control with its cognate peptide and by simultaneous two color immunofluorescence microscopy with anti-dynorphin A (1-8). Double labeled sections of guinea pig brainstem, imaged using confocal laser microscopy, revealed both ppDYN immunoreactivity (-ir) and KOR1-ir in many areas including periaqueductal gray, ventral tegmental area, and various on of the trigeminal complex. The degree of overlap of ppDYN- and KOR1-ir was variable within a given region. This relationship also held true at higher magnification. In some instances ppDYN-ir was found in close apposition to KOR-ir elements. In addition, instances in which ppDYN-ir was not immediately adjoined by KOR1-ir were also evident.

ACUTE AND CHRONIC EFFECTS OF INTRAPERITONEAL (IP) MORPHINE SULFATE (MS) ON C-FOS EXPRESSION IN THE NUCLEUS OF THE SOLITARY TRACT (NTS) AND AREA POSTREMA R.D. Hofbauer, E.R. Stevens, A.M. Marshall, D.A. Simone, B.K. Hartman, and P.L. Faris*. Div. of Neuroscience Research in Psychiatry, Univ. of Minnesota, Mpls, MN 55455

The present study was designed to determine if an analgesic dose of MS reported to induce analogs as in the peripheral wagal, and central

The present study was designed to determine if an analgesic dose of MS, reported to induce analgesia via both peripheral vagal and central mechanisms, activates a discrete population of NTS/AP neurons. Rats (n=3) were injected IP with 0 or 10 mg/kg MS. One hour later, animals were sacrificed for subsequent immunohistochemical visualization of the proto-oncogene c-fos using a commercially available antibody (Cambridge). Sections at five levels of the NTS/AP were digitally mapped to numerically quantify and anatomically localize the populations of activated neurons. C-fos positive nuclei were discretely localized to the commissural and medial subdivisions of the NTS. Immunoreactive neurons were also present in AP, but to a lesser extent. The second experiment sought to replicate and extend this finding by determining the effect of morphine tolerance on c-fos activation by IP morphine. Three animals were rendered tolerant to the analgesic effects of morphine (determined by tail-flick latencies) by twice daily injections of 10 mg/kg MS. Three additional animals received nociceptive testing and twice daily saline injections. One hour prior to sacrifice all six animals received a challenge dose of 10 mg/kg IP. The induction of prior morphine tolerance was accompanied by a marked reduction in c-fos compared to the non-tolerant control group. The involvement of these morphine-activated neurons in mediating analgesia is yet to be determined. Supported by NS31223 and MH47189.

NOCICEPTIN CAN MODULATE EVOKED ENKEPHALIN RELEASE FROM THE MYENTERIC PLEXUS. A.R. Gintzler*, I.D. Adapa, L.Toll, V.M. Medina and L. Wang. SUNY Health Sciences Center at Brooklyn, Brooklyn N.Y. 11203 And SRI International, Menlo Park, CA, 94025.

Nociceptin is an endogenous peptide agonist for the ORL1 receptor Initial reports that bears striking homology to opiate receptors. claimed that this peptide had hypoalgesic effects following i.c.v. or i.t. administration. The present study demonstrates that in the absence of opiate receptor blockade, nociceptin can substantially reduce the magnitude of the stimulated release of methionine-enkephalin from the guinea pig myenteric plexus. Nociceptin has low to moderate affinity for opiate receptors ($\mu > k > d$) which, under appropriate conditions, should be sufficient to permit interactions with multiple opiate Indeed, the nociceptin dose response curve for receptor types. inhibition of enkephalin release is substantially altered by naloxone. Following opiate receptor blockade, inhibition of enkephalin release is observed in response to I and 10 nM but a facilitation of release is manifest at higher concentrations of nociceptin. Dose responsiveness for nociceptin modulation of enkephalin release is complicated by the fact that this peptide modulates enkephalin release via naloxoneresistant and naloxone-sensitive receptors, both of which exhibit a concentration-dependent bimodality (albeit in opposite directions). Thus, determination of i.c.v. or i.t. nociceptin dose-responsiveness over several orders of magnitude is suggested before concluding the effect of this peptide on pain thresholds

ORPHANIN FQ/NOCICEPTIN-IMMUNOREACTIVITY IN THE CNS OF ADULT RATS AND ITS RELATIONSHIP TO ENKEPHALIN-AND DYNORPHIN-IMMUNOREACTIVITY. M. Riedl*, S. Shuster, L. Vulchanova, T. Olson, J. Wang, and R. Elde. Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

Recently, two laboratories identified a 17 amino acid peptide that is a likely ligand for an orphan opioid receptor. Termed orphanin FQ or nociceptin, this endogenous peptide is similar in structure to dynorphin A yet lacks the canonical Tyr-Gly-Gly-Phe of other opioid ligands. This study examined some of the distributional similarities between orphanin FQ/nociceptin and two other endogenous opioid ligands, dynorphin and enkephalin, using multicolor immunofluorescent techniques. Antisera raised in both rabbits and guinea pigs revealed prominent orphanin FQ/nociceptin immunoreactivity (-ir) in peptidergic-like fibers in spinal cord dorsal horn, lateral spinal n., dorsal gray commissure, n. of the trigeminal complex, n. of the solitary tract, periaqueductal gray, dorsal raphe n., lateral habenula, paraventricular n. of hypothalamus, various amygdaloid n., lateral septum, bed n. of stria terminalis, and endopyriform n. While tissue from normal animals revealed very little immunoreactivity contained in cell bodies, colchicine treatment resulted in dense staining of vesicle-like structures within cell bodies. As is true for dynorphin- and enkephalin-ir, dorsal rhizotomy did not greatly reduce the staining in spinal cord dorsal horn, suggesting intraspinal or supraspinal synthesis of this peptide. In fact, the distribution of orphanin FQ/nociceptin-ir closely paralleled that of dynorphin- and enkephalin-ir in the spinal cord yet instances of colocalization were rare. In other regions of the CNS, the distribution of these three peptides was more widely disparate. Supported by grants from NIDA.

LONG TERM EFFECTS OF KAINIC ACID-INDUCED SEIZURES ON THE EXPRESSION OF OPIOID PEPTIDES AND AP-1 TRANSCRIPTION FACTORS: I. MORPHOLOGICAL STUDIES. J. Simpson**, G. Bing, Z. Feng, B. Wilson and J. Hong. Neuropharmacology Section, Systems Toxicology Branch, NIEHS/NIH, Research Triangle Park, NC 27709, *Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC.

North Carolina, Chapel Hill, NC.

Although the acute effects of kainic acid (KA) on the expression of various members of the AP-1 transcription factor family and the opioid peptides, dynorphin (DYN) and enkephalin (ENK), have been well characterized, little is known about the long-term effects of KA on these transcription factors and opioid peptides. In hippocampal sections of male Wistar 344 rats at progressive time points following KA administration (7.25 mg/kg), we examined (1) the extent of KA-induced neuronal damage (Nissl stain); (2) the development of KA-induced mossy fiber sprouting using the neo-Timm stain for zinc and immunocytochemistry for DYN and ENK; (3) the level of proenkephalin (PENK) mRNA using in situ hybridization histochemistry; and (4) the expression of KA-induced AP-1 transcription factors using immunocytochemistry for c-Fos, Fos B, FRA, c-Jun, Jun B, and Jun D. KA induced a profound loss of hilar interneurons and CAI/CA3 pyramidal neurons. Sprouting of opioid peptide-containing mossy fibers into the inner molecular layer of the dentate was observed as early as 1-2 w following KA and continued to increase in density and width in the inner molecular layer over time. In addition, the level of mossy fiber ENK-IR was clevated at all time points following KA. The progression of mossy fiber sprouting was accompanied by a second, prolonged induction of FENK mRNA beginning 2-3 w after KA. Whereas KA caused a rapid and transient induction of hippocampal c-Fos, Fos B, c-Jun, and Jun B, a prolonged induction of FRA and Jun D was observed in the dentate granule cells up to 1 year following KA injection. These results indicate that KA causes a prolonged induction of mossy fiber sprouting and/or the prolonged alteration of hippocampal eNK following KA injection may be mediated by the long-term increase in an AP-1 complex containing FRA and Jun D. Supported in part by NS 07166.

EXPRESSION OF Δ FOSB IN THE RAT HIPPOCAMPUS AND STRIATUM AFTER SYSTEMIC ADMINISTRATION OF KAINIC ACID. G. Bing*, W. Wang, Q. Qi, Z. Feng, P. Hudson, L. Jin, and J. Hong. Neuropharmacology Section, Systems Toxicology Branch, NIEHS/NIH, Research Triangle Park, NC 27709.

NIEHS/NIH, Research Triangle Park, NC 27709.

Systemic administration of kainic acid (KA), an analog of glutamic acid, causes limbic seizures and pathophysiological changes in adult rats that are very similar to human temporal lobe epilepsy. One of the earliest changes in gene expression after treatment with KA is the induction of immediate-early genes. The fos and jun families are frequently studied immediate-early genes which are induced by KA. Several groups, including ours, have recently reported that a 35-kDa Fos-related antigen (FRA) is induced for a protracted time by various stimuli. It has been suggested that this FRA is Δ FosB which has a molecular weight around 35-kDa. The present study characterizes the long-term expression of FRA and Δ FosB after systemic treatment with KA. Immunocytochemistry and Western blot analysis using an antibody that cross-reacts with all known FRAs showed that a 35-kDa FRA was induced at high levels in both the hippocampus and striatum for up to 1 month by KA. A semi-quantitative PCR analysis showed that Δ FosB was induced by KA, but its expression lasted for only 6 hours. This result was also verified by Northern blot analysis. These results suggested that the long-term elevated 35-kDa FRA seen with Western blot analysis and immunocytochemistry is a new species of the FRA and not Δ fosB. In addition, this study also indicates that seizure activities induced Δ FosB, and not FosB as reported in earlier studies. The long-term expression of FRA in both the hippocampus and striatum may be associated with the pathophysiological changes after KA administration.

MOLECULAR CLONING AND CHARACTERIZATION OF N23K/N27K (NOCICEPTIN/ORPHANIN FQ GENE) AS DEVELOPMENTALLY REGULATED MOLECULE. Y. Saito*, K. Maruyama * , T.C., Saido, S. Kawashima Dept. Molec. Biol., Tokyo Metropol. Inst. Med. Sci., Bunkyo-ku, Tokyo-113, Japan. *Lab. Neurochem., National Inst. Physiological Sci., Okazaki, Aichi-444, Japan.

We used a subtraction cloning approach to isolate cDNAs of N23K and its splicing form, N27K, whose mRNA and protein are transiently increased during both neuronal differentiation in mouse NS20Y cells and development in mouse brain. Unexpectedly, the amino acids sequence of the N23K/N27K are identical to that of the newly discovered rat nociceptin/orphaninFQ precursor in its C-terminal region, although the rat nociceptin precursor cDNA sequence is incomplete at the 5'-terminus. Using antibodies against each C-terminal peptide of the N23K/N27K proteins, a punctate structure in the perinuclear region and areas near the tip of neurites is visualized in neurally differentiating NS20Y cells. The time of maximal expression correlates with periods of neurite extension, and those expression decrease as the neuritic network develops. This redistribution suggests that the N23K/N27K protein function not only as neuropeptide precursors but also as important components in a process in neurite outgrowth and nervous system development. (Supported by the Ministry of Education, Science and Culture of Japan to Y.S. and by Uehara Memorial Foundation to Y.S.).

LONG-TERM EFFECTS OF KAINIC ACID-INDUCED SEIZURES ON THE EXPRESSION OF OPIOID PEPTIDES AND AP-1 TRANSCRIPTION FACTORS. II. BIOCHEMICAL STUDIES Z. Feng* W. Zhang* G. Bing. J. Simpson* P. P. Hudson, and J. Hong. Neuropharmacology Section, System Toxicology Branch, NIEHS/NIH, Research Triangle Park, NC 27709, *Department of Physiology, DaLian Medical University, DaLian, P.R. China, *Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599,

Studies from our laboratory have shown that kainic acid (KA) injection elicits time-dependent increases in proenkephalin mRNA in the hippocampus. The initial increases in mRNA levels peaked at around 3-6 h and then returned to control levels (short-term increase), and the second phase of increases began at 2-3 weeks after KA injection and lasted for up to at least 5 months (long-term increases). The short-term increase in proenkephalin mRNA levels were closely associated with an increase in AP-1 DNA-binding activity. However, the specific transcription factors regulating the long-term increase in opioid peptide expression are not clear. To determine the possible involvement of AP-1 transcription factors in the regulation of the long-term increases in proenkephalin mRNA levels and in the formation of sprouting, gel-retardation assay, Western blot assays and antisens oligonucleotides were used after systemic injection of KA. The results showed that two AP-1 complexes, AP-1-Upper complex and AP-1-Lower complex occur during the acute stage (0-24 h after KA treatment). However, only the AP-1-Lower complex is seen during the long-term stage (from 3 days to several months after KA treatment). The long-term increase in AP-1 DNA-biding activity is associated with the long-term increases of proenkephalin mRNA and last for at least 5 months. Also, the 35-37-XDa Fra and 28-KDa Jun-D proteins were induced and expressed at high levels. These results suggest that these AP-1 transcription factors play an important role in the regulation of increase in proenkephelin mRNA and the development of mossy fiber sprouting.

519.10

STRESS-INDUCED ALTERATIONS IN THE OPIOIDS CONCENTRATION AND PREPROENKEPHALIN mRNA EXPRESSING CELLS IN THE LAMB BRAIN. K. Pierzchała-Koziec* and M. Dziedzicka-Wasylewska¹. Dept. Anim. Physiol. Agric. Univ. Cracow, Poland. ¹Polish Acad. Sci. Cracow, Poland.

The biosynthesis and release of the enkephalins can be modified with different environmental and experimental procedures. The localization of enkephalins mRNA is prerequisite to investigate their expression and regulation. Therefore, as a part of study dealing with the opioids importance in sheep growth and development, the present experiment was carried out to investigate the effects of stress on the Methershelm (irMET) concentration and the proenkephalin synthesis at the cellular level in the several areas of ram and ewe brains. Animal studies were performed on 3 months old sheep divided into control and stressed by 30 min of isolation group. Brains were removed within 5 min, dissected to obtain the blocks from hypothalamus, hippocampus, striatum, nucleus accumbens, cortex, cerebellum, pons, pituitary, pineal and infundibulum. Small fragments of the areas were taken for radioimmunoassay of immunoreactive Met-enkephalin. The mRNA expression for preproenkephalin was measured by in situ hybridization according to Young et al. (1986). After 28 days of exposure, quantitative analysis of autoradiographic film with an image system show the highest degree of mRNA expressing cells in pituitary followed by nucleus accumbens and pineal. Much lower optical density was noticed in the cortex. The concentration of irMET varies fom 2.4 ± 0.19 in cerebellum to 110.3 ± 11.9 pmol/g in pineal in rams. Of considerable interest, isolation potentiated the synthesis of proenkephalin in all tested areas by 15 - 70% and altered the irMET in several fragments. Unexpectedly, there were clear sex differences in the localization of mRNA, concentration of irMET and stress responses. Thus, the synthesis of preproenkephalin appears to be sex and stress dependent and dissociated from the releasing and processing in some brain areas. Supported by KBN Grant No: 052/PO6/95-08.

Ultrastructural relationship between neurons containing leu-enkephalin and Cambalanting in the ventromedial nucleus of the rat hypothalamus. K.G. Commons⁴, T.A. Milner², and D.W. Pfaff¹ 1Lab. of Neurobiology and Behavior, Rockefeller U., and ²Cornell U.M.C. NY, NY 10021.

The ventromedial nucleus of the hypothalamus (VMN) is thought to regulate a number of neuroendocrine and behavioral functions. The signaling molecules enkephalin and GABA are abundant in parts of VMN, and, in other brain regions, are known to commonly interact with each other. Thus, we sought to determine relationship between leu-enkephalin (enk) and GABA containing neurons in both the ventrolateral (vI) and dorsomedial (dm) subnuclei of VMN in male rats by dual labeling immunohistochemistry and electron microscopy. Enk antisera raised in rabbit localized with the immunoperoxidase method, was used in combination with a GABA antisera raised in rat detected with the immunogold-silver technique. Enk-labeled terminals were abundant and similar between the two subdivisions of VMN 85-90% of the synapses formed by enk-containing terminals were symmetric (inhibitory type) (41/48 in vI; 19/22 in dm), and $\sim 10\%$ of enk containing terminals also contained GABA-labeling (22/173 in vI; 8/69 in dm). Enk-GABA double labeled terminals accounted for one quarter to a third of all GABA terminals (22/66 in vl; 8/32 in dm) . A few dendrites (7) and somata (7) also contained enk labeling; however they were only found in the vl subnucleus of VMN. In single section analysis, enk-labeled dendrites or soma received few synaptic contacts; however many were from GABA-labeled terminals. In both subdivisions of VMN, GABA-labeled dendrites were found, many of which were contacted by enk-containing terminals. These data suggest that there are many possible mechanisms through which neurons containing enk and GABA may interact, and some of these may involve a nested series of inhibitory circuits. CIRCADIAN RHYTHM RELEASE OF IR-OPIOID PEPTIDES AND IR-SYNENKEPHALIN IN THE AMYGDALA OF PENTYLENETETRAZOL-KINDLED

CIRCADIAN RHYTHM RELEASE OF IR-OPIOID PEPTIDES AND IRSYNENKEPHALIN IN THE AMYGDALA OF PENTYLEMETETRAZOL-KINDLED
RATS. M. Asai, G. Matamoros-Trejo, M. Zubieta, G. Linares,
P. Agustin, and F. Antón-Tay*. Instituto Mexicano de
Psiquiatria. *Universidad Autónoma Metropolitana. México
Epileptiform activity has been reported to activate the
Endogenous Opioid System (EOS). Release of opioid peptides
after seizure, has been associated with a protective action
against another seizure. Several studies have shown that
both, the opiate receptors and the enkephalin tissue
content, displayed a circadian rhythm. Their maximal values
are observed during the dark phase, when higher sensitivity
to pain stimulus and epileptiform activity occurs. In the
present study, we analyzed around the clock, the release and
concentration of Immunoreactive (IR)-opioid peptides and of
IR-Synenekaphalin (the non-opioid portion of Proenkephalin)
in the amygdala of pentylenetetrazol (PTZ) kindled rats.
Animals were housed with 12 h-light: 12 h-dark cycles, the
dark period started at 18:00 h. PTZ-kindling was induced in
male Wistar rats (220-260 g) by daily i.p. injection of 35
mg/kg of the convulsant agent. Measurements were conducted
every 4 h. Opioids IR-(Met, Leu, MERF, MERGL, and Syn)
tissue concentration and release were assessed by RIA in
both, amygdala slices of PTZ-kindled rats and sham controls.
The results present herein show that, there were increased
both concentration and release of all opioid peptides,
measured in PTZ-rats from 16:00 h until 04:00 h. IR-Syn was
only detected at 16:00 and 20:00 h. At 16:00 h the opioid
peptides with IR-Syn release and their tissue content
increased. Our results show that besides the circadian
rhythmicity described on both, opiate receptors and
enkephalin tissue content, a daily rhythm in IR-opioid
peptides and synenkephalin release occurs. Thus it is
suggested that EOS is activated before the dark phase.

CHANGES IN THE ANATOMICAL DISTRIBUTION OF OPIOID PEPTIDES, PROLACTIN AND ACTH IN HYPOPHYSIS OF AXOLOTL, Ambystoma mexicanum DURING METAMORPHOSIS. M. León-Olea, M. Sánchez-Alvarez, E. Sánchez-Islas, C. Clapp* and F. Pellicer, Lab. de Histologia, Instituto Mexicano de Psiquiatría. Av. Mex. Xochimileo 101, Mex. D.F. 14370.

The study of opioid peptides is relevant in neurosecretory and hormonal processes related to ontogeny. Therefore, we used the amphibian Ambystoma mexicanum, since its different developmental stages can be manipulated. Metamorphosis was experimentally induced by a unique intraperitoneal injection of T4 (2.5µg/g). Histological and immunohistochemical techniques were carried out to study the anatomical distribution of opioid peptides, prolactine and ACTH in hypophysis of animals at different stages of metamorphosis. Immunoreactivity (IR) to enkephalins (LE and ME) in cells of intermediate and anterior hypophysial lobes presented changes that comprehend its absence in stage I, an important increase in its intensity in stage II, followed by its disappearance in stages III and IV. The IR of other opioid peptides, PRL and ACTH included in this study did not present significant changes during metamorphosis. The existence of IR to opioid peptides in neurons of anterior and intermediate hypophysial lobes, as well as in fibers of median eminence and neural lobe, and the changes in IR intensity of these peptides during metamorphosis suggest a paracrine or endocrine modulatory physiological role of these substances during maturation and developmental processes involved in metamorphosis. Financed by IMP projects 3290 and . 3290a, and CONACyT 1183-N9203.

LOCALIZATION OF α-N-ACETYL-β-ENDORPHIN IMMUNOREACTIVITY AND PRO-OPIOMELANOCORTIN MRNA IN CARDIOVASCULAR NUCLEI OF RAT AND HUMAN BRAIN. D.W. Rosenthal 2, A.B. Manning 2, G.E. Resch 2*, M.J. Manalo 2 and W.R. Millington. 1 ¹ Division of Molecular Biology and Biochemistry and ² Department of Anesthesiology, University of Missouri-Kansas City, Kansas City, MO 64108.

β-Endorphin (β-End), a pro-opiomelanocortin (POMC)-derived opioid peptide, is synthesized by neurons in the hypothalamic arcuate nucleus (ArcN) and the nucleus of the solitary tract (nTS) which project to cardiovascular regulatory sites in the medulla. Chromatographic studies have shown that brainstem β -End is predominantly α -Nacetylated, a modification that abolishes B-End's bradycardic and hypotensive effects. Whether brainstem β-End is α-N-acetylated by POMC neurons in the ArcN, nTS or both nuclei is unknown, however. In the present study, we examined the localization of β-End and α -N-acetyl- β -End immunoreactivity (IR) in rat brain and assessed whether the POMC gene is expressed in the nTS of the human brain, as it is in rat. Consecutive tissue sections were incubated with two antisera: one that recognizes all β-End peptides equally and a second that selectively detects $\alpha\textsc{-N-acetyl-}\beta\textsc{-End}$ derivatives. Consistent with previous studies, B-End IR axons were detected in the ArcN, nTS and throughout the brainstem and subcortical forebrain structures. α -N-Acetyl- β -End IR was largely restricted to the nTS and ventrolateral medulla, although a small number of α-N-acetyl-β-End IR fibers was also detected in the ArcN and nucleus accumbens. β-End, but not α-N-acetyl-β-End, IR axons were present in the midbrain which contains caudal projections from the ArcN, but not nTS POMC neurons indicating brainstem α-N-acetyl-β-End IR is derived from the nTS and not the ArcN. Reverse transcriptase PCR, using specific primers for the rat and human POMC gene, confirmed that POMC mRNA is present in rat nTS and further demonstrated that POMC mRNA is localized in the human nTS although the transcript size was larger than the rat gene product. These data provide evidence that brainstem $\alpha\textsc{-N-acetyl-}\beta\textsc{-End}$ is derived from the nTS, but not ArcN, POMC neurons. (NIDA DA-04598 and St. Luke's Foundation)

RELEASE OF DYNORPHIN A IN THE RAT PERIAQUEDUCTAL GRAY (PAG) AFTER NOXIOUS COLD STIMULATION. L. Xin, E. B. Geller,* M. R. McCaffery, G. H. Sterling and M. W. Adler. Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140

We reported previously that noxious cold stimulation to the rat's tail caused an increased release of substance P (SP) from the PAG and that either noxious cold or PAG microinjection of a high dose of SP increased the release of the endogenous opioid peptide ß-endorphin (ß-E) from the PAG. These findings indicated that endogenous B-E was involved in supraspinal SP antinociception during noxious cold. Since the results from our lab also showed that pretreatment with either $\mu\text{-}$ or k-opioid receptor agonists suppressed the SP release during noxious cold, we investigated whether the endogenous k-opioid peptide dynorphin A (Dyn) could be released after noxious cold. Artificial CSF was microdialyzed into the PAG of freely moving S-D rats. Samples were collected every 30 min for 4 hrs and analyzed for Dyn level by radioimmunoassay. The rat's tail was immersed in a -10 °C water bath 30 sec/min for 5 min. Baseline release of Dyn in the PAG was 0.2-0.6 fmol/fraction. Noxious cold stimulation induced a 60% -130% increase in Dyn release over baseline, occurring mostly in the samples collected 30 and 60 min after cold stimulation. In contrast, warm water (35 °C) stimulation to rat's tail did not cause any Dyn in the PAG may also be involved in supraspinal SP antinocciception during noxious cold. NEUROANATOMICAL DISTRIBUTION AND REGULATION ACROSS PREGNANCY OF THE mRNA FOR THE LONG FORM OF THE PROLACTIN RECEPTOR IN RAT. <u>I.C.</u> Bakowska and <u>I.I. Morrell</u> ^{1*}, IAB, ¹CMBN, Rutgers University, Newark, NJ 07102.

Prolactin by acting on its own receptors in the brain promotes

many behavioral and neuroendocrine changes, including the induction of maternal behavior. Prolactin receptors exist in two forms, a short and a long form. Others have demonstrated the regional distribution in the brain of the mRNA of both forms of the receptor (Chiu&Wise, J.Neuroend, '94). Analysis of brain homogenates reveals that only levels of the long form varies across pregnancy (Sugiyama et al., Endo, '94). As part of our ongoing investigation of the neurochemical basis of maternal behavior, we have examined the neuroanatomical distribution of the mRNA from which the long form of the prolactin receptor (LPRL-R mRNA) is translated, and examined its regulation across pregnancy. A 290-basepair ³³P cRNA probe, complementary to a cytoplasmic domain of the long form of the prolactin receptor mRNA, was synthesized using T3 polymerase. Following in situ hybridization procedures, the slides were coated with Kodak emulsion. Large populations of neurons expressing the LPRL-R mRNA were found in the bed nucleus of the stria terminalis, the medial preoptic area, the supraoptic, paraventricular, the ventromedial, and the arcuate nuclei of the hypothalamus as well as in the medial and central nuclei of amygdala. Overall these nuclei contained more neurons that expressed the prolactin receptor and had higher levels of expression per neuron in brains from females on day 21 of pregnancy than on day 2. For example, relative levels of LPRL-R mRNA in the medial preoptic area were four times higher on day 21 of pregnancy compared to day 2. (Supported by HD 22983 to J.I.M).

REPRODUCTIVE EXPERIENCE DIFFERENTIALLY ALTERS
PROOPIOMELANOCORTIN (POMC) GENE EXPRESSION IN THE MEDIAL BASAL HYPOTHALAMUS (MBH) OF RATS DURING PREGNANCY AND LACTATION, P.E. Mann*, B.S. Rubin, and R.S. Bridges. Dept. Comp. Med., Tufts Univ. Sch. of Vet. Med., N. Grafton, MA 01536 and Dept. Anat. Cell. Biol., Tufts Univ. Sch. Med., Boston, MA 02111

In situ hybridization (ISH) was used to determine if pregnancy (PREG) and lactation (LACT) affect MBH POMC gene expression. In addition, the effects of reproductive experience on POMC mRNA were evaluated. POMC mRNA levels in the MBH were assessed during PREG (days 7, 12, and 21) and LACT (day 12) in rats with and without prior reproductive experience and compared with age-matched, cycling, nulliparous females. ISH was performed using a digoxigenin-labelled riboprobe complementary to 837 base pairs of the POMC gene. The number of cells expressing POMC mRNA in the MBH decreased in primiparous rats on day 12 of LACT when compared with nulliparous rats in diestrus. In addition, POMC cell number in multigravid rats was significantly less than in the nulliparous group on days 7 and 21 of PREG, and day 12 of LACT. Reproductive experience affected the number of POMC mRNA positive cells; there were fewer cells expressing POMC mRNA in the multigravid females on day 7 of PREG and an increase in the number of POMC cells in the multiparous group on day 12 of LACT compared to the primiparous rats. Optical density analysis revealed an increase in reaction product in individual cells on all days of PREG and a decrease on day 12 of LACT in the multiparous group. The results of the present study indicate that POMC gene expression changes across pregnancy and lactation and that repeated reproductive experience has long-term, possibly permanent, effects on the endogenous opioid system. GONADAL STEROIDS REGULATE ENKEPHALIN IN SOCIAL BEHAVIOR CIRCUITRY IN THE MALE SYRIAN HAMSTER A. G. Holt* and S. W. Newman Dept. of Anatomy and Cell Biology and Neuroscience Prog., Univ. of Michigan, Ann

In the male Syrian hamster, enkephalin is distributed throughout neural pathways that control aggression and mating, and both behaviors are dependent upon gonadal steroids in this species. To test the hypothesis that sex steroids regulate enkephalin production, each of twenty male Syrian hamsters was castrated and was immediately implanted subcutaneously with silastic capsules (Dow Corning; 3.18 mm ID, 1.98 mm OD). The capsule contained either 10mm of crystalline testosterone (T) (Sigma; mm (D). The capsule contained either 10mm of crystalline testosterone (1) (Sigma; n=5), arm of crystalline estradiol-17ß (E) (Steraloids Inc.; n=5), or 5mm crystalline dihydrotestosterone (DHT), a non aromatizable androgen, (Sigma; n=5) or nothing, (n=5). An additional five intact animals were implanted with empty silastic capsules. After twelve weeks all animals were injected intracerebroventricularly with 200µg of colchicine in 2µl of .9% saline and 48 hours later were perfused transcardially with 4% paraformaldehyde. The brains were removed and 40µm sections were immunostained paraformaldehyde. The brains were removed and 40µm sections were immunostained using a met enkephalin antibody from Inestar Inc. Enkephalin immunoreactivity (Enkir) was visualized using the avidin biotin technique (Vectastain Elite, Vector Labs).

Analysis of variance indicates that castration, is significantly reduced in the medial septum (MS), anterior dorsal preoptic nucleus (ADPN), horizontal limb of the nucleus of the diagonal band (HLNDB), anterior medial bed nucleus of the stria terminalis(BNSTam), anterior lateral BNST (BNSTal), posterior medial BNST(BNSTpm), posterior medial BNST(BNSTpm), posterior intermediate BNST (BNSTp), medial preoptic nucleus (MPN), anterior nucleus (API), paraventricular nucleus (PVN), and ventromedial (MPN), anterior nucleus (AH), paraventricular nucleus (PVN), and ventromedial nucleus (VMH) of the hypothalamus. Some of these areas maintain enkephalin production after implantation of only T, (BNSTpi, BNSTpm, MPN), or E (AH, PVN), while in others T and E were equally effective (HLNDB, BNSTam, VMH), and in (MS, ADPN, BNSTal), T, E, and DHT were all effective. These results suggest that Enk productions regulated by gonadal steroids within circuitry underlying social behaviors in the male hamster and that this production is differentially regulated by testosterone and its metabolites. OPIOIDS: ANATOMY, PHYSIOLOGY, AND BEHAVIOR-PHYSIOLOGY

520.1

OPIOID SIGNALING: INVOLVMENT OF KINASE CASCADES. HB Gutstein*, EA Rubie, A Mansour, H Akil, JR Woodgett. Dept. Anesth. and MHRI, U. of Michigan, and Ontario Cancer Institute, Toronto, ON Canada

The signal transduction mechanisms that opiates use to mediate cellular adaptive responses are not clear. The MAP kinase cascade is important in transducing proliferative signals. Recently, homologous kinase cascades have been discovered (SAPK and p38/RK) that relay information about events that alter cellular homeostasis. Our aim was to determine whether opioid effects on cellular function could be mediated by these cascades.

C6 glioma cells stably expressing mu, delta and kappa opiate receptors were generated. Cells were stimulated with DAMGO, DPDPE, U50,488, and/or naloxone and lysed. Cascade activation was measured either by kinase assay using c-jun or MBP as substrates, or by western blotting with anti-phospo MAPK or MKK3 (RK pathway). After SDS-PAGE electrophoresis, gels were analyzed using Image Quant software, while blots were developed by ECL. Mu and delta opiates activated MAPK as strongly as the positive control

PMA, while kappa showed moderate activation by western blotting. No significant SAPK or RK cascade activation was observed following opiate agonist treatment in any of the C6 cell lines expressing the 3 opioid receptors. This study provides evidence that mu opiate effects may be mediated in

part by the MAP kinase cascade. These cascades function to link extracellular signals to cellular changes by regulating expression of target genes. The reasons for differential MAPK activation by opiate receptor subtypes in C6 cells are not clear. Further studies are underway to determine how the opiate receptor interacts with the MAPK cascade. Further clarification of the mechanisms and functional significance of these interactions could have important implications for understanding mechanisms underlying analgesis responses and narcotic tolerance and dependence. THE OPIOID MODULATION OF IPSPS INDUCED IN LUMBAR MOTONEURONS BY STIMULATION OF THE NUCLEUS RETICULARIS GIGANTOCELLULARIS DURING CARBACHOL-INDUCED ACTIVE SLEEP. M.-C. Xi⁸, R.-H. Liu, J. Yamuy, F.R. Morels and M.H. Chase. Department of Physiology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The present study was undertaken to test the hypothesis that opioid peptides may modulate the glycinergically-mediated postsynaptic inhibition of motoneurons during active sleep. Opioid peptides have been shown to modulate synaptic transmission in cat spinal motoneurons (Yaksh, Handb. Exp. Pharm., 104/11: 53-90, 1993). In addition, the opioid enkephalin has been reported to selectively increase the spontaneous release of glycine in the rat striatum (Arneric et al., Neurosci. Lett., 66:73-78, 1986). We were therefore interested in determining whether glycinergic IPSPs, which are evoked in lumbar motoneurons by stimulation of the medullary nucleus reticularis gigantocellularis (NRGc) during active sleep or carbachol-induced active sleep, would be affected by opioid peptides. To carry out these studies, intracellular recordings were obtained from lumbar motoneurons in 4 cats anesthetized with a-chloralose, in which active sleep was induced by the microinjection of carbachol into the nucleus pontis oralis (NPO) (López-Rodríguez et al., Brain Res., 699:201-207, 1995). Utilizing this preparation, an opioid peptide receptor agonist and antagonists were juxtacellularly applied to the recorded cells. Electrical stimulation of the NRGc elicited large amplitude, long-latency IPSPs in lumbar motoneurons (amplitude: 1.6 ± 0.3 my (S.E.M.); latency to onset: 29.1 ± 1.4 ms; latency to peak: 53.3 ± 1.4 ms; in = 9). Microiontophoretic applications of morphine, an opinae µ receptor agonist, reversibly increased by 23.1% the mean amplitude of these NRGc-induced IPSPs (n = 5; p < 0.05). In contrast, naloxone, a non-selective opinate receptor antagonist, reversibly increased of decidence of the motoneurons. T

520.3

OPIOID REGULATION OF SEROTONIN RELEASE FROM RAT VENTRAL SPINAL CORD J. Franck 1 **. 1. Nylander 2, and A. Rosén 1 Dept of Physiology and Pharmacology 1, and Clin Neuroscience 2, Karolinska Institute, S-171 77 Stockholm, Sweden.

The effect of met-enkephalin (met-ENK) and opioid receptor antagonists

The effect of met-enkephalin (met-ENK) and opioid receptor antagonists on the electrically evoked release of endogenous serotonin (5-hydroxytryptamine, 5-HT) was studied in superfused slices of the rat ventral lumbar spinal cord. 5-HT was assayed by high performance liquid chromatography, using electrochemical detection. Two electrical stimulation periods (300 pulses, 30 mA, 2 ms, 2 Hz) were given with 40 min interval. Drugs were added to the medium 10 min prior to the second stimulation, and the effect of the drug calculated from the ratio of 5-HT release during each stimulation period (52/S1 ratio). Met-ENK (1x10⁻⁸M--1x10⁻⁶M) reduced the evoked 5-HT release in a concentration dependent fashion. The selective δ agonist, DPDPE, concentration-dependently reduced 5-HT release whereas DAMGO, a selective μ agonist, was ineffective. The selective k receptor agonist, (-)-U-50488 (1x10⁻⁶M) had no, effect on the evoked 5-HT release. The inhibitory effect of met-ENK (5x10⁻⁷M) was completely abolished by the selective δ receptor antagonist IC1-174,864 (1x10⁻⁶M). In contrast, neither a selective μ₁ antagonist (naloxonazine; 1x10⁻⁶M), nor a k antagonist (nor-binaltorphimine; 1x10⁻⁶M) and any effect on the inhibitory action of met-ENK on 5-HT release. The antagonists used had no effect on their own on evoked 5-HT release. To study the possible coexistence of 5-HT and met-ENK in the rat ventral spinal cord, the tissue concentrations of 5-HT, noradrenaline (NA) and met-ENK were measured in rats treated with the selective serotonergic neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT). Two weeks after intracisternal injection of 5,7-DHT, the tissue concentration of 5-HT was reduced by 97%, whereas the concentration of NA was reduced by only 5%. The tissue concentration of met-ENK is present in the rat ventral spinal cord mainly in non-serotonergic nerve terminals and exerts an inhibitory action on 5-HT release. (Supported by the ventral spinal cord mainly in non-serotonergic nerve terminals and exerts an inhibitory action on 5-HT release via δ opioid receptors. (Supported by the Swedish Alcohol Research Fund)

520.4

EFFECT OF OPIOID RECEPTOR AGONISTS ON INTRACELLULAR CALCIUM IN DORSAL HORN NEURONS. <u>S.D. Hocherman*, R.Cerne and M. Randic.</u> Dept. of Veterinary Physiol. and Pharmacol., Iowa State University, Ames, IA 50011.

The synapses between primary afferents and neurons of laminae I-III in spinal cord display a considerable degree of plasticity. Both opioids and calcium have been implicated in this process in central neurons. We examined the effects of mu, delta and kappa opioid receptor agonists on the basal level of calcium ([Ca²⁺]_i) and on NMDA-induced calcium transients in freshly dissociated laminae I-III neurons of the dorsal horn (DH). Fura-2 AM was loaded into the cells and calcium transients were acquired using an intensified CCD camera. A Y-tube system was used for the application of different agents. The presence of calcium transients elicited by NMDA was used as a criterion for accepting a cell for analysis.

Results: a. <u>Basal level of calcium:</u> In the presence of the kappa-receptor agonist U-69,593 (10 μ M), an increase in [Ca²+], was observed in 48% of the cells tested (n=50). The delta-receptor agonist DPDPE (1 μ M) also increased [Ca²+], in 29% of the cells (n=35); with 10 µM DPDPE, the increase in [Ca2+]; was larger and was observed in 42% of the cells (n=19). The mu-receptor agonist DAMGO (10 μM) has produced an increase in 1 out of 6 cells tested.

b. NMDA-induced transients: Changes in NMDA are reported as ratio (r) between the transient produced during or immediately following opioid application and a control transient. In control runs (no opioids applied) $r=1.04\pm18$ (SD, n=11). Both U-69,593 and DAMGO (10 μ M) produced a decrease in NMDA-induced transients ($r=.90\pm.44$, n=47 for U-69,593; $r=.75\pm.25$, n=12 for DAMGO). Following the application of DPDPE (10 µM) some increase in the average response was observed (r=1.23±.57, n=11). These data and the larger SD values associated with the presence of opioids suggest that there is a subpopulation of DH neurons in which opioids modulate the basal level of calcium and calcium transients induced by NMDA in a complex manner. Supported by the NINDS and the NSF.

KAPPA OPIOID MEDIATED INHIBITION OF BRAINSTEM PAIN MODULATING NEURONS IN RATS IN VITRO. Z. Z. Pan* & H. L. Fields, Departments of Neurology & Physiology and the keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

Fields, Departments of Neurology & Physiology and the keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

Neurons in the nucleus raphe magnus (NRM) in the medulla are implicated in pain modulation. In the brainstem slice there are two types of NRM neurons: the primary cell and the secondary cell. Primary cells are indirectly excited by μ opioids through presynaptic inhibition of GABA transmission and functionally correspond to NRM off-cells that inhibit spinal pain transmission. Secondary cells, which correspond to NRM on-cells, are directly hyperpolarized by μ opioids and facilitate spinal nociceptive transmission. In this study using infrared videomicroscopy, whole cell patch clamp recordings were made from NRM neurons in slice preparations. The κ agonist U69593 (100-300nM) produced an outward current (or a hyperpolarization) exclusively in a subpopulation of primary cells which, as shown previously, had no postsynaptic response to the μ/δ agonist met-enkaphalin (10 μM). The secondary cells that were hyperpolarized by enkaphalin were not affected by the κ agonist. The outward current induced by U69593 was selectively blocked by the κ antagonist nor-BNI (100nM) and reversed its polarity near the potassium equilibrium potential. Furthermore, increasing the extracellular potassium concentration shifted the reversal potential to less negative potentials, suggesting that the κ-mediated outward current results from an increase in a potassium conductance. In addition to the hyperpolarization, U69593 also increased a hyperpolarization-activated current (I_h) in these primary cells. The κ-mediated inhibition restricted to primary cells in the NRM indicates that κ opioids in the NRM would have a hyperalgesic effect and/or may counteract the μ opioid-mediated antinociception. Supported by the USPHS grant DA1949 and the National Headache Foundation.

FEDOTOZINE INJECTED INTRAVENOUSLY INHIBITS THE INCREASED ACTIVITY OF LOCUS COERULEUS (LC) NEURONS INDUCED BY COLORECTAL DISTENTION IN RATS. H.Kosoyan* & Y.Taché. UCLA: CURE/Digestive Diseases Research Center., VA Medical Ctr. & Dept. of Medicine & Brain Res. Inst., Los Angeles, CA 90073.

Background: Fedotozine, a newly developed peripherally acting K-opioid agonist, inhibits visceral pain induced by divodenal and colonic distention (Eur. J. Pharmacol., 271; 65 & 245; 1994). Several findings indicate that the pontine noradrenergic nucleus, LC, is activated by visceral simili including bladder and colorectal distention (Br. Res. 375; 117, 1986; Ann. N.Y. Acad. Sci., 697;173, 1994; Soc. Neurosc. 21: 90, 1995). Aim: To assess the influence of systemic fedotozine on repetitive colorectal distention (CRD)-induced activition of LC neuronal discharge rate. Method: Male SD rats (280-320g) were anesthetized with chloral hydrate (400 mg/kg, im) and implanted with an intrajugular catheter for iv (0.3 ml) injection. A catheter ending in a compliant balloon (4 cm) was inserted through the anus-rectum. The distal colon and rectum were distended by delivering into the balloon 3 or 4 ml of air over 1-3 sec for 30 sec. Extracellular single cell activity recording from the LC was performed by glass microppette with 1.0 gm diameter tip (10 MQ), filled with 1 M NaCl in saturated Fast Green Dye. Nerve signals were sent to a window discriminator and counted on a computer. Recording from LC neurons was assessed by established criteria of pattern of firing rate, steady rhythm and shape of the spike. At the end of each experiment recording sites were verified histologically. Maximum 3 min peak changes for CRD and max 5 min peak changes for saline and fedotozine were calculated and expressed as mean ± SEM peak changes from baseline. Results: In 9 rats, iv injections of vehicle and fedotozine (5 mg/kg) 8.1 ± 1.2 min after vehicle had no significant effect on LC neuronal activity (98.4 ± 3.1%, and 111.4 ± 8.3% respectively) and there was

520.9

INCREASED PROBABILITY OF GABA RELEASE LINKS ADENYLYL CYCLASE AND CHRONIC OPIOID TREATMENT. A.Bonci*^{1,2}, G.Bernardi² and J.T.Williams¹, 1:Vollum Institute for Advanced Biomedical Research, Portland OR, USA, 2:Clinica Neurologica, Università di Roma "Tor Vergata" and IRCCS S. Lucia,

The Ventral Tegmental Area (VTA) play a key role in modulating the self-administration of drugs of abuse. The opioid receptors located on the VTA interneurons inhibit GABA-mediated synaptic transmission to disinhibit dopamine projection neurons. In spite of the pivotal role that the VTA plays in the maintenance of drug abuse, little is known about how this GABA synapse is affected after chronic morphine treatment. The present study show that the activation of adenylate cyclase with forskolin and the cAMP dependent protein kinase Sp-cAMPS, produce a larger increase in the GABAA IPSCs after the chronic treatment with morphine compared to controls. Similarly, the frequency of the spontaneous miniature events was increased after the chronic morphine treatment.Conversely, the kinase inhibitor staurosporin and Rp-CPT-cAMPS, decreased the GABAA IPSCs to a greater extent after drug treatment. Our results indicate that chronic morphine treatment increases the probability of GABA release and that this effect is mediated by an upregulation of the cAMP dependent cascade.

ORIGIN OF LOCAL OPIOID-SENSITIVE GABAERGIC AND GLUTAMATERGIC NEURONS PROJECTING TO SEROTONER-GIC NEURONS OF THE RAT DORSAL RAPHE IN VITRO.

GIC NEURONS OF THE RAT DORSAL RAPHE IN VITRO.

T. Jolas* and G.K. Aghajanian. Depts. of Psychiatry & Pharmacology, Yale School of Medicine, New Haven, CT 06508.

We recently reported that opioids suppress spontaneous and NMDA-induced GABAergic IPSCs and glutamatergic EPSCs in serotonergic (5-HT) neurons of the rat dorsal raphe nucleus (DRN) in brain slices. The purpose of the present study was to localize, in the slice, local opioid-sensitive GABAergic and glutamatergic cells projecting to 5-HT neurons, combining voltage-clamping of 5-HT neurons at -90 mV, with RCL (2 M) electrodes and focal introducertic application of NMDA neurons, combining voltage-clamping of 5-HT neurons at -90 mV, with KCl (2 M) electrodes, and focal iontophoretic application of NMDA. After establishing that bath perfusion of NMDA (20 µM) induced PSCs in a 5-HT neuron, focal 30 sec iontophoretic applications of NMDA (10 nA) were given at different positions of the slice until the PSC induction could be reproduced in the 5-HT neuron. The iontophoretic pipette was considered to be at the site of the cell projecting to the 5-HT neuron when PSCs frequency increased within 10 sec. The nature of the projecting neuron was determined by the ability of the AMPA antagonist LY 293558 (3 µM) or the GABA_A antagonist bicuculline (30 µM) to block the NMDA-induced response. Opioid-sensitive glutamatergic cells projecting to 5-HT neurons were found near the border of the DRN and the periaqueductal gray (PAG). Opioid-sensitive GABAergic cells projecting to 5-HT neurons were scattered in the DRN as well as in the PAG. No projecting cells were found beyond the PAG and the DRN.

These results provide evidence that GABAergic and glutamatergic neurons mediating the actions of opioids on local afferents to 5-HT neurons are in the DRN and PAG. Supported by MH17871 & DA08227.

ACTIVATION OF RAT LOCUS COERULEUS NEURONS IN OPIOID WITHDRAWAL IS REDUCED BY INHIBITION OF NITRIC OXIDE SYNTHASE IN VIVO. J. Pineda* and L. Ugedo. Dept. of Pharmacology, Fac. of Medicine, Univ. of the Basque Country, E-48940 Leioa, Vizcaya, Spain.

Biochemical, electrophysiological and behavioral studies have suggested that locus coeruleus (LC) nucleus plays a role in the pathophysiology of opioid withdrawal. The present study examined, using electrophysiological techniques in anesthetized rats, the effect of the nitric oxide synthase (NOS) inhibitor L-NAME (30 mg/kg) on the activation of LC neurons in opioid withdrawal. Opioid withdrawal was precipitated by administration of naloxone (5 mg/kg) in rats that had been pretreated with increasing doses of morphine (10-100 mg/kg/8 h) for five days. In control animals, LC neurons discharged spontaneously at ~2 Hz. In morphine-dependent animals, naloxone precipitated a withdrawal syndrome associated with an increase in LC cell firing rate (~4 Hz). L-NAME, which was administered 1 h before naloxone in morphine-dependent rats, markedly attenuated opioid withdrawal syndrome and reduced the elevation in firing rate of LC neurons (~2.5 Hz). In control animals, L-NAME failed to affect the LC cell firing rate. We conclude that the naloxone-precipitated activation of LC neurons in morphine-dependent rats is reduced by NOS inhibition. This effect might be responsible in part for the effect of NOS inhibitors on opioid withdrawal syndrome. (Supported by SAF96-0071, J.P. is a fellow from the Basque Government.)

OPIOID MODULATION OF THE GABAB IPSP IN DOPAMINE NEURONS OF THE VENTRAL TEGMENTAL AREA. J.M. Delfs* and J.T. Williams. Vollum Institute, Oregon Health Sciences University, Portland, Oregon 97201.

GABAergic afferents from the nucleus accumbens (NA) synapse on dopamine neurons of the ventral tegmental area (VTA). Release of GABA from NA afferents causes a GABA_Bmediated IPSP in these dopamine neurons. Anatomical studies have demonstrated the presence of mu, delta and kappa opioid receptors on the GABAergic afferents to the VTA. The aim of this study was to examine the modulation of the GABAB IPSP in dopamine neurons by the mu agonist DAMGO, the kappa agonist U-69,593, and the delta agonist DPDPE. Evoked GABA synaptic potentials were recorded from dopamine neurons in horizontal slices of guinea pig midbrain using intracellular recording techniques. The ${\sf GABA}_B$ IPSP was inhibited by the opioid agonists DAMGO (1nM-10μM) and U69,593 (1nM-10μM) in a dose-dependent manner by 40-60%. The delta agonist DPDPE ($\ln M$ - $10\mu M$) resulted in a slight inhibition of the GABA $_B$ IPSP (<10%) only at the highest doses. All of the opioid agonist effects were reversible with the non-selective opioid antagonist naloxone (1 $\mu M).$ These results demonstrate that the GABA $_B$ IPSP in dopamine neurons of the VTA is modulated by activation of mu and kappa opioid receptors, but not delta opioid receptors. OPIOID MODULATION OF VENTRAL PALLIDAL RESPONSES TO ACTIVATION OF DOPAMINERGIC PROJECTIONS FROM THE VENTRAL TEGMENTAL AREA. <u>I. Mitrovic* and T.C. Napier.</u> Dept. of Pharmacol. and Neurosci. and Aging Inst. Division for Research on Drugs of Abuse, Loyola Univ. Chicago, Sch. of Med., Maywood, IL 60153.

The ventral tegmental area (VTA) is a major source of dopaminergic innervation to the ventral pallidum (VP). Electrical activation of the VTA elicits early-onset (latency ≤12 ms) inhibitions in the activity of VP neurons that are attenuated by microiontophoresis of dopaminergic antagonists. These results are consistent with a monosynaptic dopaminergic projection from the VTA to the VP. Microiontophoretic application of dopamine or opioid agonists alters spontaneous firing of VP neurons. Using chloral hydrate-anesthetized rats, the present study investigated the ability of iontophoretically applied μ and κ opioid agonists to modulate dopaminergic neurotransmission within the VP elicited by electrical stimulation of the VTA. VTA stimulation (1 Hz, 0.1-1.4mA, 0.1ms) evoked responses in 95% of 21 neurons tested. An early-onset inhibition was encountered in 66% of the neurons responding to VTA stimulation. Fifty-four percent of these neurons were inhibited by the μ opioid agonist DAMGO, and 60% were inhibited by the κ opioid agonist U50488H. One third of the neurons tested with DAMGO and U50488H agonists were sensitive to both. Application of the opioid agonists concomitant with VTA stimulation altered early-onset evoked inhibitions; DAMGO attenuated this response, and U50488H potentiated it. These data suggest that opioids may be able to modulate dopaminergic neurotransmission within the VP, and the mode of this interaction may be opioid receptor subtype-dependent. PROTEIN KINASE INHIBITION REVERSES TOLERANCE ASSOCIATED WITH CHRONIC MORPHINE EXPOSURE IN HYPOTHALAMIC NEURONS OF THE GUINEA PIG, E.J. Wagner* and M.J. Kelly. Dept. of Physiology & Pharmacology, Oregon Health Sciences Univ., Portland, OR 97201.

Tolerance to the effects of morphine with chronic administration has been shown in many different paradigms, and involves an attenuation of the inhibitory effects of morphine in both the peripheral and central nervous systems. In hypothalamic neurons, tolerance is manifested, in part, by a reduction in the potency of the µopioid receptor agonist DAMGO. Recent evidence suggests that the cAMPdependent protein kinase pathway is up-regulated with chronic morphine treatment. The purpose of the present study, therefore, was to determine if the protein kinase inhibitor staurosporine could reverse the tolerance associated with chronic morphine treatment in hypothalamic neurons. To this end, intracellular recordings were made from the arcuate nucleus in hypothalamic slices prepared from ovariectomized female guinea pigs treated for 4 days with either placebo or morphine pellets (4x75mg on day 0; 6x75mg on day 2; implanted s.c.). As expected, chronic morphine treatment elicited a significant reduction in DAMGO potency (EC $_{50}$ =99.0±16.1nM; n=10) compared to placebo-treated controls (EC $_{50}$ =41.7±3.3nM; n=10). A 30 min perfusion of staurosporine (100nM) completely abolished the reduction in DAMGO potency (EC₅₀=38.7±8.1nM; n=3). These results indicate that the tolerance induced by chronic morphine administration in hypothalamic neurons is due, at least in part, to increased protein kinase activity. (This work was supported by Grants DA05158, DA00192 and 5T32 DA07262).

Opioids suppress GABAergic IPSCs in medial septal/diagonal band neurons via μ receptors. M. Alreja* Dept. of Psychiatry, Yale Univ. Sch. of Med., CMHC, New Haven, CT 06508.

The rat medial septal/diagonal band complex (MSDB) contains a high density of µ and δ receptor binding sites and receptor mRNAs. Both inhibitory and excitatory effects of enkephalin have been reported in in vivo and in vitro extracellular studies. Intracellular and pharmacological studies on the effects of opioids on MSDB neurons are lacking. In the present study, the effects of opioids on electrophysiologically characterized cholinergic and GABA-type MSDB neurons were studied in an in vitro rat brain slice preparation using extracellular, intracellular and whole-cell recordings.

In whole-cell voltage-clamp recordings with K gluconate-containing electrodes, bath-applied met-enkephalin (ENK; 3-100 μ M) decreased the frequency of spontaneously occurring bicuculline and TTX-sensitive IPSCs in a subpopulation of GABA-type and cholinergic-type MSDB neurons (n=28). The μ agonist DAMGO (10 nM-1 μ M) mimicked the inhibitory effect of ENK and produced a dose-dependent decrease in the frequency of spontaneously occurring IPSCs (n=8). In contrast, the δ agonist, DPDPE (1 μ M) had little or no effect on GABA-ergic IPSCs (n=3). The inhibitory effect of enkephalin and DAMGO on IPSCs was blocked by prior treatment with the selective μ antagonist CTOP (1 μ M). Consistent with these findings, in intracellular recordings, a subpopulation of GABA-type neurons in the MSDB responded to enkephalin (n=6) and DAMGO (n=4) with a TTX-insensitive outward current, whereas DPDPE had little or no effect (n=3). In conclusion, opioids inhibit a subpopulation of GABA-ergic neurons in the MSDB via the μ receptor and these neurons make local synaptic contacts with both cholinergic and other GABA-type MSDB neurons. Supported by NIH R 29 DA 09797.

EFFECTS OF MORPHINE ON RAT VENTRAL PALLIDAL NEURONS RECORDED IN VITRO. J.X. Liao* and T.C. Napier. Dept. of Pharmacology, Neurosci. and Aging Inst. Div. for Research on Drugs of Abuse, Loyola Univ. Chicago, Stritch Sch. of Med., Maywood, IL 60153.

The ventral pallidum (VP) is a brain region that contains high concentrations of opioid receptors and likely is involved in opioid abuse. The present study was designed to determine the effects of morphine on intracellularly recorded electrophysiological characterisitics of VP neurons from sagittial basal forebrain slices. In the course of these experiments, we found that a lowered osmolar perfusion of artificial cerebrospinal fluid (ACSF) was helpful in obtaining a stable intracellular recording (the concentration of NaCl was decreased from 124 mM to 111 mM). The effects of low NaCl on the electrophysiological characteristics of neurons in VP (n = 43) were determined and compared to those characteristics obtained from recordings conducted in normal NaCl (n = 14). Low NaCl did not alter the resting membrane potential, input resistance, tau, threshold to fire, spike duration and height, or the neuronal response to morphine; therefore, the data obtained with morphine were pooled for low and normal NaCl ACSF. Morphine (10 μM) hyperpolarized 16 of 20 tested VP neurons by 4.1±1.0 mV (mean ± SEM) and inhibited the activity of 6 of 9 spontaneously firing neurons. Morphine generally did not alter neuronal input resistance, tau, spike duration and height, or threshold to fire. However, in 4 of 19 neurons, the input resistance was decreased by more than 35 M Ω . All morphine-induced responses were blocked by the opioid antagonist naloxone (1-10 µM). The results suggest that morphine most consistently alters spontaneous firing in the VP by hyperpolarizing the cell. Work supported by DA05255 to TCN.

A SUBPOPULATION OF THALAMIC RETICULAR NEURONS IS INHIBITED BY OPIOID PEPTIDES. J. Brunton and S. Charpak*, Lab. of Physiology. ESPCI. 10 rue Vauquelin, 75005 Paris France.

Previous work has revealed a widespread opioidergic inhibition of cells located in thalamic relay and intralaminar nuclei (Neurosci. Abstr. 372.1, 1995). In the present work, we investigated if this inhibition extended to the thalamic reticular (RE) nucleus. RE neurons were studied using the whole cell patch-clamp recording technique in brain slices from young rats. Their intrinsic membrane properties were similar to those seen in other preparations, displaying the characteristic accelerating-decelerating low threshold burst pattern with a calcium spike crowned by 5-10 action potentials, followed by a pronounced after-burst hyperpolarization. In several cases, sustained periods of oscillatory behaviour were observed in response to a depolarizing pulse from a hyperpolarized potential, or as a rebound from a hyperpolarizing pulse. Cells were tested with U50488, DPDPE, and DAGO, the respective agonists for the κ -, δ -, and μ -opioid receptor subtypes. 40 % of RE cells were inhibited by DAGO while none responded to either U50 or DPDPE. The effect of DAGO, which persisted in TTX, resulted in a hyperpolarization accompanied by a decrease in membrane input resistance with a reversal potential at about E_K. This opioidergic inhibition has therefore enabled us to distinguish two populations of RE neurons which display similar electrophysiological and anatomical (preliminary results) features Supported by the Swiss National Science Foundation.

NALOXONE INHIBITS CA3 MOSSY FIBER LTP IN RAT HIPPOCAMPAL SLICES W. Jin*, and C. Chavkin Dept. of Pharmacol., Univ. of Wash., Seattle, WA 98195

Mossy fibers constitute the principal source of dynorphin and enkephalin in the hippocampus. It has been shown that endogenous opioid peptides, via activation of Lu opioid receptors, facilitate mossy fiber long term potentiation (LTP) in anesthetized rats (Derrick et al 1994). Presently little is known about how the endogenous opioids mediate the excitatory effect. The goal of this study is to understand the mechanism underlying opioid-mediated facilitation of mossy fiber LTP. Field excitatory postsynaptic potentials (IEPSP) were recorded in CA3 stratum lucidum of rat hippocampal slices, and mossy fibers were stimulated by placing a stimulating electrode in the stratum granulosum of the dentate gyrus. The tetanic stimuli (100Hz for 1s repeated once every 20 sec. for 4 times at \$1/3) elicited a potentiation of the IEPSP amplitude to 217±20% (n=11) of baseline amplitude measured 25 to 30 min after tentanus; this potentiation was maintained for 60 min. Application of the opioid antagonist (-) naloxone (10 µM) prior to and after tetanic stimulation significantly reduced the amplitude of LTP measured at 50 to 60 min (213±24% for control slices, n=11 vs. 136±15%, n=10, P<0.05). To test the hypothesis that endogenous opioids facilitate LTP by depressing GABAA inhibition (disinhibition), bicuculline, a GABAA receptor antagonist, was used. The inhibitory effects of naloxone were still observed in the presence of bicuculline; naloxone significantly suppressed the potentiation immediately following the tetanus under this condition, from 320±50% (control, n=10) to 203±13% (n=9, P<0.05), measured 1 to 5 min after tentanus; the LTP measured at 50 to 60 min was also reduced from 243±30% (control, n=10) to 194±33% (naloxone treated slices, n=9). (+) Naloxone (10 µM), an inactive stereoisomer, had no effect in these experiments. Our results demonstrated that naloxone inhibited the induction of CA3 mossy fiber LTP in rat hippocampal slices, consistent with the previous reports from in vivo studies, and our data support the hypot

DYNORPHIN AUGMENTS THE POTASSIUM M-CURRENT IN CAI HIPPOCAMPAL PYRAMIDAL NEURONS IN VITRO. G.R. Siggins*, S.G. Madamba and P. Schweitzer. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Previous intracellular studies in our laboratory (Moore et al., J. Neurosci.

Previous intracellular studies in our laboratory (Moore et al., J. Neurosci. 14: 809, 1994) showed that opioids have direct postsynaptic actions on rat receptors (KORs) enhanced the voltage-dependent K* conductance I_M, whereas δ agonists reduced I_M. However, several reports have suggested that neither CA1 nor CA3 HPNs show direct postsynaptic opiate effects. Although previous physiological and binding studies suggested that opiate receptors (mostly μ and δ) were located primarily on elements presynaptic to CA1 HPNs, a recent ultrastructural study (Commons and Milner, Proc. INRC, 1996) found profuse postsynaptic DOR localization on dendrites of CA1 HPNs. Therefore, we re-evaluated the role of opioids in CA1 by superfusing a variety of opiates onto rat hippocampal slices while recording CA1 HPNs intracellularly in discontinuous voltage-clamp mode. In contrast to our findings in CA3, 1-8 μM of the δ agonists D-Pen²³-enkephalin, [D-Ala²]-deltorphin-II or DADLE (or the μ agonists D-Pen²³-enkephalin, [D-Ala²]-deltorphin-II or DADLE (or the μ agonist DAMGO) had no significant effect on membrane currents, including I_M, in CA1 HPNs. Surprisingly (because there is little evidence yet for KORs on CA1 HPNs, 0.5 μM dynorphin A significantly increased I_M, to a mean of 131-160% of controls (n = 9); the κ agonist U50,488h also increased I_M, but less consistently. Superfusion of the KOR selective antagonist nor-binaltorphimine (1 μM) or naloxone (1-2 μM) prevented the dynorphin effects (n = 5). These results support our previous CA3 data showing clear postsynaptic (somatic) effects of dynorphin on K⁺ conductances in HPNs, but now in CA1, and suggest that further anatomical studies on KORs in CA1 are warranted. We speculate that the previous inability to observe postsynaptic actions may have resulted from the use of whole-cell clamp or other methodological differences. Supported by NIH grants DA03665 and MH 44346.

PHARMACODYNAMICS OF REMIFENTANIL, A NOVEL ULTRA-SHORT-ACTING OPIOID ANESTHETIC, USING EEG IN MALE SPRAGUE-DAWLEY RATS. SH Haidar JE Moreton*, ZM Liang. JF Hoke², KT Muir² and ND Eddington. Department of Pharmaceutical Sciences, School of Pharmacy, University of Maryland, Baltimore, MD 21201. ²Glaxo-Wellcome, RTP, NC 27709.

Remifentanil (R) is an ultra-short-acting-opioid which binds μ receptors. R is rapidly metabolized by non-specific esterases in the blood and other tissues. We evaluated the pharmacokinetics and the EEG response of R in the rat. Male Sprague-Dawley rats (N=7, Wt.=325±15g) were surgically implanted with stainless steel cerebrocortical EEG electrodes three days before the study. Each rat was infused with R through an external jugular vein cannula (dose=15 μ /min/kg) for 21 minutes. Serial blood samples (N=6) were collected from a femoral artery cannula prior to, during, and after the end of infusion. Blood samples were extracted with acetonitrile and methylene chloride and analyzed by a validated GC-MS assay. EEG was captured and subjected to power spectral analysis (0.1-50 Hz) for edge frequency using a MacIntosh-based software package (Neurodata). EEG was collected continuously from 15 minutes before infusion until return to baseline after infusion. A linked sigmoid Emax model was used to describe the concentration-effect relationship. Mean (±S.D.) parameter estimates are listed below. Edge frequency of 97 was used in this study.

Eo	EC50	Emax	Ke0	t _{1/2} Ke0	Gamma
(Hz)	(ng/mL)	(Hz)	(min ⁻¹)	(min)	
39.9	24.7	19.9	0.41	1.7	11.4
(0.98)	(8.2)	(5.3)	(0.09)	(0.37)	(4.9)

The equilibration half-life (t_{1/2} Ke0) between blood and the effect compartment was comparable to findings of clinical studies evaluating the pharmacodynamics of **R**. (This work is supported by Glaxo-Wellcome.)

OPIOID STIMULATION OF NA,K-ATPASE IN CRUDE SYNAPTOSOMES ISOLATED FROM SELECTED REGIONS OF RAT BRAIN. S.C. Corey Specht* and C. Torres-Silva. Dept. Pharmacology, Institute of Neurobiology, Univ. Puerto Rico, San Juan, PR 009801.

The μ-opioid agonist Methadone (10⁻³M) stimulated the Na,K-ATPase activity in crude synaptosomes isolated from selected regions of rat brain up to a maximum of 20%. Na,K-ATPase was ouabain-inhibited, nitrophenylphosphatase activity. The greatest opioid stimulation was obtained in cortex, superior colliculus, thalamus and subcerebellar medulla. Lesser stimulation was obtained with striatum, hindbrain, and hippocampus. There was no opioid-stimulated activity in cerebellum. Methadone did not stimulate purified Na,K-ATPase, suggesting that intracellular mediators are required. Pertussis toxin blocked the stimulatory effect of methadone, thus confirming the participation of G_i. Forskolin inhibited the basal Kstimulation as well as blocking the effect of methadone, suggesting that cAMP-mediated signalling inhibits the Na,K-ATPase. The potential role of intracellular kinases and phosphatases is under further investigation.

COMPARISON OF THE DISCRIMINATIVE AND ANALGESIC EFFECTS OF MORPHINE AND ITS GLUCURONIDE METABOLITES AFTER CENTRAL AND SYSTEMIC ADMINISTRATION K.W. Easterling* and S.G. Holtzman Emory University, Department of Pharmacology, Atlanta, GA 30322

This study represents an initial characterization of the potential of centrally or systemically delivered morphine-3- β -d-glucuronide (M3G) and morphine-6- β -d-glucuronide (M6G) to substitute for morphine (MOR) in a drug discrimination task. For comparison, the effects of these same drugs were measured in the tail-flick test of analgesia. Rats with a cannula in the lateral cerebral ventricle were trained to discriminate between injections (3 mg/kg SC) of morphine and saline using a discrete-trial avoidance/escape procedure, then were tested twice-weekly with randomized doses of either ICV- or SC-administered SAL, MOR, M3G and M6G. Response latency in the tail-flick test was measured just before the discrimination session began. As previously reported, M6G (\geq 0.3 μ g) given ICV was 10-fold more potent than MOR (ICV) in the tail-flick test whereas M3G (3.0 μ g;ICV) was i Similarly, M6G was 10X more potent than morphine in occasioning MORappropriate responding in the drug discrimination task, whereas M3G was inactive. In contrast, when given SC, MOR (3.0 mg/kg) was 3-fold more potent than M6G (SC) in inducing complete analgesia, and M3G (10 mg/kg) induced partial analgesia (68%). MOR SC also was 3-fold more potent than M6G in the discrimination task, however, M3G (3.0-30 mg/kg, SC) was inactive. In both behavioral assays, as compared to SC administration, M6G s approximately 3,500-fold more potent when delivered ICV, whereas MOR was only 300-fold more potent by this route.

ORPHANIN FQ IS A SUPRASPINAL ANTI-OPIOID PEPTIDE THAT BLOCKS MU, DELTA AND KAPPA ANTINOCICEPTION. <u>J.E. Grisel</u>*, <u>J.S. Mogil, G. Zhang, J.K. Belknap and D.K. Grandy</u>. Dept. of Behavioral Neuroscience, Oregon Health Sciences University, Portland, OR 97201. We have recently shown that orphanin FQ (OFQ), the newly isolated

We have recently shown that orphanin FQ (OFQ), the newly isolated endogenous agonist of the orphan opioid receptor, LC132, does not produce hyperalgesia as originally reported but rather acts as an anti-opioid peptide. Intracerebroventricularly (i.c.v.), OFQ blocks opioid-mediated stress-induced antinociception and systemic morphine antinociception in mice. The present studies were designed to further characterize the anti-opioid activity of OFQ. Nociceptive sensitivity of Swiss-Webster mice was assessed in the 49°C tail-withdrawal (TW) test, before and after drug injection. In the first experiment, cocktails of morphine (0, 1, 10 or 50 $\mu\text{g})$ and either vehicle (artificial CSF) or OFQ (10 nmol) were injected (under light halothane anesthesia) either i.c.v. (into the lateral ventricle) or intrathecally (i.t.; between L4 and L5) in a volume of $2.5~\mu\text{L}$. TW latencies were assessed 15, 30 and 60 min later. Dose-dependent morphine antinociception, but did not affect i.t. morphine antinociception. In the second experiment, cocktails of either vehicle or OFQ (10 nmol) combined with opioid receptor agonists-DAMGO (μ ; 0, 0.02, 0.05, or 1.0 nmol), DPDPE (8; 0, 10, 25, or 50 nmol), or U-50,488H (κ ; 0, 100, 200, or 1000 nmol)—were injected i.c.v. and tested as described. All agonists produced dose-dependent antinociception that was completely blocked by OFQ. In a third experiment, we demonstrated that OFQ does not appreciably bind to μ , δ , or κ receptors expressed in CHO cells. These findings support and extend our contention that OFQ is a supraspinal anti-opioid peptide acting at the LC132 receptor. Supported by grants from NIAAA (JEG), NIDA (DKG) and the VA (JKB).

ORPHANIN FQ IS A FUNCTIONAL ANTI-OPIOID PEPTIDE THAT DOES NOT CAUSE HYPERALGESIA. J.S. Mogil*, J.E. Grisel, M.A. Hunter, R.A. Juarez, J.K. Belknap and D.K. Grandy. Vollum Institute and Dept. of Behavioral Neuroscience. Oregon Health Sciences University, Portland, OR 97201.

The present studies were designed to further investigate the role in nociceptive processing of orphanin FQ (OFQ)/nociceptin, the recently isolated endogenous agonist of the orphan opioid receptor, LC132 (ORL-1, Naïve adult Swiss-Webster mice of both sexes (20-35 g; n=8-11 per were used. Nociceptive sensitivity was assessed in the 46°C tail-withdrawal (TW) test. Following measurement of baseline TW latencies. mice were given subcutaneous (s.c.) injections of saline (10 ml/kg) or naloxone (1 mg/kg), followed by intracerebroventricular (i.c.v.) administration (by direct injection under halothane anesthesia) of vehicle (2.5 µl artificial CSF) or OFQ (1-25 nmol). Post-injection TW latencies were measured 10, 20 and 30 min later. In contrast to previous reports, no hyperalgesia--defined relative to baseline latencies--was observed. We believe that the original conclusion that OFQ produces hyperalgesia was confounded by the existence of stress-induced antinociception (SIA) related to the halothane anesthesia/i c.v. injection protocol, which we observed in vehicle-treated animals. Both OFO and/or naloxone which we observed in vehicle-treated animals. Both OFQ and/or naloxone completely abolished this apparent SIA. Parallel results were obtained using two other nociceptive assays, the hot-plate and writhing tests. propose that OFQ is a novel endogenous anti-opioid peptide, which is further supported by our observation that OFQ dose-dependently reverses systemic morphine antinociception (5 mg/kg, s.c.) in the 49°C TW test (half-maximal antagonism by 7.5 nmol OFQ), and attenuates morphine-induced hypothermia (20 mg/kg, s.c.) and respiratory depression (15 mg/kg, s.c.). Supported by grants from NINDS (JSM), NIAAA (JEG), NIDA (DKG) and the VA (JKB).

521.5

MODULATION OF SPINAL OPIOID ANTINOCICEPTION BY NEUROPEPTIDE FF-LIKE ENDOGENOUS PEPTIDE. <u>K.</u> Jhamandas*, M.Sutak, H.-Y.T. Yang'. Dept. of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada K7L 3N6. 'NIMH Neuroscience Ctr. at St. Elizabeths, Washington, DC. USA 20032.

Neuropeptide FF (FLFQPQRF-NH2), designated as morphine modulatory peptide, enhances spinal opioid antinociception and produces antinociceptive effects. Recently, a NPFF-like peptide SLAAPORF-NHo- has been isolated from the rat brain and spinal cord. To study potential opioid modulatory action of this peptide, its action was evaluated in animals bearing chronic intrathecal catheters. Intrathecal injections of SLAAPQRF-NH₂ (11.2 and 22.4 nmol) produced weak antinociceptive action in the tail flick and paw pressure tests. At sub-effective doses (0.06 - 0.6 nmol) SLAAPQRF-NH2 increased the duration of antinociception produced by intrathecal morphine (6.6 nmol) or [D-Ala2]-deltorphin I (20 nmol) in both tests. At 24 and 48 hours following injections full recovery was observed. SLAAPQRF-NH2 administered alone or in combination with opioids did not affect motor function. The results indicate that SLAAPQRF-NH2, like NPFF, may play a role in modulation of nociceptive signals at the spinal level. [Supported by MRC Canada].

PROLACTIN RELEASE, DOPAMINERGIC NEURAL ACTIVITY AND TAIL FLICK LATENCY RESPONSES TO MET-ENKEPHALIN. <u>J. Janik.*</u> J. Tompkins, R. Weise, M. Gardon and P. Callahan. Miami Univ, Center for Neuroscience, Dept of Zoology, Oxford, OH 45056.

Center for Neuroscience, Dept of Zoology, Oxford, OH 45056. The role of met-enkephalin in the suckling-induced PRL increase was studied. Endogenous met-enkephalin was immunoneutralized by injecting anti-rat-met-enkephalin into the right lateral ventricle. The suckling-induced prolactin increase in post-partum, female Sprague Dawley rats was significantly attenuated by the 1.8 μ g dose and totally abolished by the 3.6 μ g dose of antiserum. Antiserum administration did not affect the activity of the tuberoinfundibular dopaminergic (TIDA) neurons. In order to further characterize the antiserum, we tested its effectiveness in reducing latency times in a tail flick test applying low heat stimulus (42°C) to female rats that did not receive any opiate agonist. Anti-met-enkephalin had no effect on baseline latencies. However, opiate antagonists, specifically β -Funaltrexamine (μ antagonist, 5 μ g, ivt), Naltrindole (δ antagonist, 5 μ g, ivt) or nor-Binaltorphimine (κ antagonist, 8 μ g, ivt) significantly attenuated the baseline response to the heat stimulus.

These results indicate that met-enkephalin is necessary for the PRL secretory response to suckling, but that it does not mediate this increase through inhibition of TIDA neurons. Met-enkephalin may not play a role in maintaining tolerance to a mildly noxious stimulus, but the EOP are involved through actions at specific receptor subtypes. Supported by NIH HD 30375-01 to JJ and PC.

MOTIVATIONAL AND MOTORIC EFFECTS OF INTRACEREBROVENTRICULAR ADMINISTRATION OF THE NOVEL NEUROPEPTIDE ORPHANIN FQ. D. P. Devine*, R. Reinscheid, F. Monsma, O. Civelli, O. and H. Akil University of Michigan, Mental Health Research Institute, Ann Arbor, Michigan, 48109-0720 USA and CNS Research, Pharma Division, Hoffman-La Roche AG, CH-4002 Basel, Switzerland.

We used an unbiased Conditioned Place Preference procedure to determine if the newly-identified neuropenide orphanin FO (O-FO)

We used an unbiased Conditioned Place Preference procedure to determine if the newly-identified neuropeptide orphanin FQ (O-FQ) produced motivational effects after intracerebroventricular (i.c.v.) microinjections in rats. O-FQ (0.1-100 nmoles) failed to produce conditioned place preference or aversion, but a pronounced motor impairment was observed during conditioning sessions with the highest doses. Thus, it appears that O-FQ lacks motivational effects when administered at behaviourally active doses. We characterized the locomotor effects of i.c.v. O-FQ using a photocell apparatus, and we characterized O-FQ-induced motor-impairment using a battery of motor skill tests. Acute administration of O-FQ (0.1-10 nmoles) produced hypolocomotion, and repeated administration produced tolerance to this effect. During motor skill tests, rats exhibited a profound O-FQ-induced disruption of balance and motor control. Muscle tone was flaccid, particularly in the hindlimbs, and rats exhibited pronounced gnawing or vacuous oral movements. We are currently assessing which anatomical loci may mediate the observed effects, and we are examining the possibility that O-FQ participates in learning and memory processes. TYR-PRO-LEU-GLY-NH₂ (Tyr-MIF-1) ENHANCES THE ANALGESIA INDUCED BY REPEATED INJECTIONS OF MORPHINE IN RATS. <u>W. L. Nores*</u>, R. L. Bell, A. L. Vaccarino, A. J. <u>Kastin, J. E. Zadina, G. A. Olson, & R. D. Olson.</u> Dept. of Psychology, Univ. of New Orleans & VA Medical Center., New Orleans, LA.

Findings from a pilot study in our laboratory suggested that the endogenous peptide, Tyr-MIF-1, can act synergistically with morphine to produce a more potent analgesic response to thermal pain. Accordingly, we studied the effects of Tyr-MIF-1 on morphine-induced analgesia in rats. Analgesia was measured by subjecting rats (n=10) to a waterimmersion tail-flick test 30 min. after receiving an ip injection of either diluent, morphine (10.00 mg/kg), or morphine+Tyr-MIF-1 (10.00 mg/kg+0.01 mg/kg). The latency of each rat to curl or withdraw its tail (tail-flick) from water maintained at 48°C was recorded. Each rat was tested in this fashion on alternating days for a total of 12 test sessions. A 3 x 12 (Treatment x Session) mixed ANOVA, with session as the repeated measure, yielded a significant Treatment x Session interaction, p<.05. Post hoc analyses revealed that the diminished analgesic response of morphine from session 1 to session 2 was attenuated by Tyr-MIF-1. Furthermore, the analgesic response to morphine was observed until session 5, whereas analgesia induced by morphine+Tyr-MIF-1 remained significant until session 6. The results suggest that Tyr-MIF-1 can enhance the analgesic effectiveness of repeated injections of morphine.

Gi/Go PROTEINS AND SMALL CONDUCTANCE Ca²⁺ ACTIVATED K+ CHANNELS ARE INVOLVED IN SPINAL ANTINOCICEPTION INDUCED BY δ₂-OPIOID RECEPTOR AGONIST [o-Ala²]DELTORPHIN II. <u>H. Mizoquchi*, M. Narita and L. F. Tseng.</u> Department of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226

The effects of the pretreatment with pertussis toxin (PTX) and various K-schannel Medicale College or patient of the protein of the pretry and the prediction of the pretry and the prediction of the pretry and the prediction of the pretry and the prediction of the prediction o

The effects of the pretreatment with pertussis toxin (PTX) and various K+ channel blockers on antinociception induced by δ_2 -opioid receptor agonist [b-Ala²]deltorphin II were studied in male ICR mice. [b-Ala²]deltorphin II was administered intrathecally (i.t.) and the antinociception was measured by the tail-flick test 10 min after the injection. I.t. pretreatment with PTX (0.125-0.5 μ g) for 96 hr dose-dependently attenuated the antinociception induced by i.t.-administered [b-Ala²]deltorphin II. The antinociception induced by i.t.-administered [b-Ala²]deltorphin II was blocked by apamin (5 ng, 10 min), a small conductance Ca²- activated K+ channel blocker, but not by glibenclamide (50 μ g, 10 min), a ATP-sensitive K+ channel blocker. In in vitro [³H]DSLET (b-Ser², Leu⁵]enkephalin-Thr⁴) binding studies using crude synaptic membrane preparation of the mouse spinal cord, co-incubation of GTP γ S (0.1-100 μ M), a non-hydrolyzable GTP analog, inhibited [³H]DSLET bindings. Our results indicates that δ_2 -opioid receptors in mouse spinal cord couples to PTX sensitive Gi/Go proteins, and the antinociception induced by i.t.-administered [b-Ala²]deltorphin II is mediated by small conductance Ca²- activated K+ channels. (Supported by NiH grant DA 03811).

CHARACTERIZATION OF SPINAL ANTINOCICEPTION INDUCED BY 8-1 OPIOID RECEPTOR AGONIST (-)TAN67. L.F. Tseng **, M. Narita! *, H. Mizoguchi! and H. Nagase². *Dept. of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226, *2 Basic Res. Lab., Toray Industries Inc., Kamakura 248, Japan.

The aim of the present study was to characterize 8-1 opioid receptors for

The aim of the present study was to characterize δ-1 opioid receptors for antinociception in the spinal cord of ICR mice using newly synthesized δ-1 agonist (-)TAN67. (-)TAN67 was given intrathecally (i.t.) and the antinociception was measured by the tait-flick test. I.t. administration of (-)TAN67 (5 to 50 μg) produced antinociception in a dose-dependent manner. The antinociception induced by i.t.-challenged (-)TAN67 was dose-dependently blocked by i.t. pretreatment with a highly selective δ-1 antagonist BNTX (0.03 to 0.33 μg), but not by a selective δ-2 antagonist NTB (1 μg), μ antagonist CTOP (50 ng) or κ antagonist nor-BNI (5 μg). In acute antinociceptive tolerance studies, mice tolerant to i.t.-administered (-)TAN67 did not produce cross-tolerance to antinociception induced by i.t.-administered selective δ-2 agonist [D-Ala²]deltorphin II, μ agonist DAMGO or κ agonist U50,488, but it produced cross-tolerance to that produced by δ-1 agonist U50,488, but it produced cross-tolerance to that produced by δ-1 agonist U50,488, but it produced cross-tolerance to that produced by δ-1.t. petretament with pertussis toxin (PTX; 0.125 to 0.5 μg) 96 hr prior to i.t. challenge of (-) TAN67 dose-dependently attenuated i.t.-administered (-)TAN67. Induced antinociception. Furthermore, pretreatment with apamin (2 to 10 ng), a selective Ca²*-activated K*-channel of small conductance (BKc_a) blocker, given i.t. dose-dependently attenuated antinociception induced by i.t.-administered (-)TAN67, whereas i.t. pretreatment with glibenclamide (50 μg), a selective T-S-ensitive K*-channel (K_{XTP}) blocker, did not affect (-) TAN67-induced antinociception. Our results indicate that spinal δ-1 opioid receptors may be linked to PTX-sensitive Gi/Go-proteins and BK_{Ca}, but not K_{ATP}, is involved in spinal δ-1 opioid receptor-mediated antinociception in the mouse (Supported by NIH grant, DA 03811).

INTRACISTERNAL INJECTION OF MORPHINE INDUCES
FACIAL SCRATCHING IN MICE.

Y. Kuraishi. Dept. of Applied Pharmacol., Res. Inst. for Wakan-yaku,
Toyama Med. & Pharm. Univ., Toyama 930-01, Japan.

Epidural and intrathecal administrations of morphine result in pruritus in humans, and the microinjection of opioid μ-agonists into the medullary dorsal horn produces facial scratching in monkeys and rats. The present experiments were conducted to determine whether morphine and μ-agonist, [D-Ala², N-Me-Phe⁴, Gly⁵-ol]enkephalin (DAMGO) induced centrally itch-related behavior, that is, scratching in mice. Male ddY mice (4 -6 weeks old) were used. When intracisternally injected (5 µL), morphine (0.1 - 3 nmol) and DAMGO (0.03, 0.1 nmol) dose-dependently elicited scratching of face, but not ear and body trunk, by the hind paws for about 20 min after injection. The morphine (0.3 nmol)-induced face scratching was inhibited by pretreatment with naloxone (1 mg/kg, s.c., 15 min before). When injected intradermally, morphine (3, 30 nmol, 50 µL) into the rostral back didn't significantly elicit scratching of any areas of the body These results suggest that opioids produce an itch sensation at least in part through opioid μ -receptors in the central nervous system in mice The present experimental model is easy to use and seems to be available to clarify central mechanisms of itch.

DIFFERENTIAL SYMPTOMATIC PRESENTATION IN PREMENSTRUAL SYNDROME (PMS) AS A FUNCTION OF BETA-ENDORPHIN.

Robert H. Loiselle*, A. James Giannini, David Martin and Carlton Turner. Northeastern Ohio Medical College, Boardman, Ohio 44512.

Twenty women, ages 19-28 with PMS-symptoms were studied. All had serum β -endorphin levels on day 1 and day 20 of their menstrual cycle for three consecutive cycles. Symptoms were measured using DSM-III criteria.

Symptom presentation was then compared with 8-endorphin levels using linear regression. Specific symptoms including anxiety, cramping, cravings for food and physical discomfort were found to be associated with significant declines in 8-endorphin levels. As a result, a specific subgroup of PMS-patients with a distinctive tetrad of symptoms associated with 8-endorphin decline was postulated.

DECREASED BLOOD LYMPHOCYTE PROLIFERATIVE RESPONSES MEDIATED BY CENTRAL μ -RECEPTORS. R.D. Mellon* and B.M. Bayer. Dept. Pharmacology, Georgetown Univ., School of Medicine, Washington, D.C. 20007.

Acute administration of morphine to rats decreases whole blood mitogen induced proliferative responses of T-lymphocytes via central opioid receptors (Hernandez et al. 1993). These effects appear to be largely independent of either pituitary or adrenal factors (Flores et al. 1994). Previous studies indicate that opioids decrease natural killer cell cytolytic activity through central µ receptors (Band et al. 1992), however, the specific opioid receptors mediating blood lymphocyte proliferative responses have not been established.

Equimolar doses of morphine, saline, or specific opioid receptor agonists (20 nmol) were administered into the lateral ventricle of freely moving male Sprague-Dawley rats in a volume of $2.0~\mu L$. Analgesia, as measured by tail-flick assay, was measured 30 minutes after injection. Two hours post-injection, whole blood, spleen, and thymus proliferative responses to the T-cell specific mitogen Concanvalin A (ConA) and plasma concentrations of corticosterone were determined.

Results indicate that both morphine and the μ specific agonist DAMGO decreased blood lymphocyte proliferative responses compared to either saline, the κ agonist U50488 or the δ agonist DPDPE. Spleen and thymus proliferation were unaffected by any treatment. Additionally, only morphine and DAMGO increased latency to tail-flick and corticosterone levels. Separate studies with DAMGO show a dose dependent effect on blood lymphocyte proliferation. Further, central administration of CTOP (5 μ g/2.0 μ l), a specific μ -antagonist, blocked the immunomodulatory effects of systemic morphine (6 μ g/kg, sc).

These studies provide evidence that morphine acts through central μ receptors to modulate blood lymphocyte proliferation responses in the periphery.

Foraging Behavior in the Rat Following Manipulation of Reinforcer Palatability, Deprivational State, and Naltrexone and Butorphrenol Administrations

J. Cleary*, E. O'Hare, D.T. Weldon, P.J. Bartz, C.J. Billington and A.S. Levine VA Medical Center and University of Minnesota, Minneapolis, MN 55417

VA Medical Center and University of Minnesota, Minneapolis, MN 55417
Six male Sprague Dawley rats were trained to obtain all of their food nightly
under a seven hour laboratory analog of foraging behavior. Subjects were
trained to respond on one lever, in a two lever operant test chamber, under
randomly assigned search costs of FR-2, FR-5 or FR-10. Completion of the
search requirement resulted in activation of the other lever in the apparatus,
the food-procurement lever. Activation of the food-procurement lever was
preceded by either flashing of the house-light in the chamber, which indicated
a procurement cost of FR-2, or flashing of a bank of colored lights above the
levers, which indicated a procurement cost of FR-10. Completion of the
procurement cost resulted in the delivery of one 45 mg casen-based (sweet)
food pellet. Subjects could decline the procurement opportunity by either
responding on the search lever, or failing to respond on the procurement
lever for more than 15 seconds following procurement lever activation. When
subjects successfully maintained stable body weight under the nightly
foraging paradigm, experimental manipulations of reinforcer palatability (grain
pellets vs sweet pellets), deprivational state (24 hours deprivation), and
effects of naltrexone and butorphrenol administrations (0.3, 1.0 and 3.0
mg/kg) were evaluated. Data were collected at hourly intervals throughout the
nightly feeding sessions and response profiles were compared with control
data under each experimental manipulation. Analysis of the data indicated
dissimilar response profiles for palatability, deprivation state and drug
manipulations. These results suggest that the effects of thesedrugs on
foraging behavior do not mimic environmental manipulations.

PRENATAL EXPOSURE TO NALTREXONE ALTERS SOMATIC AND NEUROBIOLOGICAL DEVELOPMENT IN RAT OFFSPRING. P.J. McLaughlin*, C.M. Lang, S.W. Tobias and I.S. Zagon. Depts. Neuroscience and Anatomy and Comparative Medicine, Penn State University College of Medicine, Hershey, PA 17033.

Little is known about the role of endogenous opioid systems in prenatal development. To examine whether opioids influence development in utero, time-mated nulliparous Sprague-Dawley rats were injected daily from conception to parturition with 50 mg/kg NTX. This drug regimen was found to block opioid receptors all day in the pregnant rat. No differences were noted between control (i.e., sterile water) (CO) and NTX-treated litters in terms of gestation time, litter size, infant mortality, or incidence of congenital malformations. Within 8 hr of birth, all pups were cross-fostered to untreated lactating females. Birthweights of NTX rats were increased 25% from CO levels, and remained 18% to 41% greater than CO values throughout the preweaning period. Crown-rump lengths for NTX-treated neonates were significantly greater than CO values. Wet, dry, and relative weights of selected organs in the NTX group were significantly increased from CO levels at birth, as well as on postnatal days 10 and 21. Brain weights and morphometric measurements of the cerebral cortex and the cerebellum were markedly greater in the NTX group relative to CO values at weaning. These data suggest that an endogenous opioid system functions during prenatal development in the rat, and that a native opioid peptide acts as a tonic negative regulator of growth. Supported by NIH grants HL53557 and NS20500.

TAPE STRIPPING-INDUCED HYPERALGESIA AS A MODEL FOR THE EVALUATION OF ANALGESIC AGENTS. L. Cortes Burgos* and D.L. DeHaven-Hudkins. Adolor Corporation, Malvern, PA 19355.

A model of inflammatory pain was developed which uses tape stripping to produce an abrasion injury by removal of the stratum corneum layer of the epidermis. Male Sprague-Dawley rats are anesthetized with ketaminexylamine, and the right hind paw is treated with a depilatory agent and tape stripped by repeated application and removal of Scotch tape to the dorsal side of the paw. Hyperalgesia in the tape stripped paw is measured by recording the paw pressure thresholds using a Randall-Selitto apparatus. The degree of hyperalgesia observed is maximal after 20 tape strippings. Hyperalgesia is present by 1-2 hr following stripping, is maximal at 4-24 hr and subsides by 72 hr. Peak antinociception occurs at 5 min following intrapaw injection of fentanyl (3 µg), and at 15 min following treatment with morphine (300 µg) or spiradoline (300 μ g), while injection of 300 μ g of the δ agonist SNC-80 fails to produce analgesia. The ED50 values for reference opiate agonists in this model are: morphine, 631 µg, fentanyl, 3.2 µg, and spiradoline, 204 µg. The nonsteroidal antiinflammatory reference agents acetaminophen, acetylsalicylic acid, diclofenac, ibuprofen, indomethacin or naproxen are without significant effect. This model of hyperalgesia detects antinociception produced by μ and κ opiate agonists, and is useful for the assessment of pain resulting from abrasion

CATECHOLAMINE RECEPTORS: SECOND MESSENGER SIGNAL TRANSDUCTION

522 1

EFFECT OF THE STIMULATION OF INSULIN RECEPTOR ON D2 DOPAMINE RECEPTOR ACTIVITY IN FIBROBLAST CELLS. <u>S.</u> Maltais* and P. Falardeau. Centre de Recherche du CHUL and School of Pharmacy, Université Laval, Ste-Foy, Qc, Canada, G1V 4G2

Several observations reveal the importance of the close relationship between insulinergic and dopaminergic systems. Their respective contribution to the regulation of blood glucose level, blood pressure, motor and affective control, and on the regulation of each other activity has been shown. This was further demonstrated in animal studies indicating that diabetic rats are resistant to the locomotor and behavioral effects of the dopamine agonist amphetamine, and largely restored with chronic insulin therapy. Although the relationship between these two systems seems very important, little is known about the direct modulation of the dopamine receptor activity by the activation of the tyrosine kinase signaling pathway through the insulin receptor. In order to verify if the activation of the insulin receptor could modify the activity and the pharmacology of D2 receptor, Ltk-mouse fibroblasts expressing both insulin and human D2 receptors (1000fmol/mg protein) were used. In cells treated with 1 µM insulin for 1 hour, the proportion of receptors in its high affinity state raised from 33% to 50%, without change of the high or low affinity dissociation constants. This is an important evidence that the D2 dopamine receptor could be regulated by important evidence that the D2 dopamine receptor count of regulated with a activation of the insulin receptor. This regulation could involve, as for \(\mathbb{B}\)-adrenergic receptor (EMBO J. 1995 Nov 15; 14(22): 5542-9), a variation in the level of receptor phosphorylation. The variation of the D2 dopamine receptor phosphorylation, and the modulation of the receptor functionality following insulin treatment will be discussed. Supported by a Medical Research Council of Canada grant.

D-1 DOPAMINE RECEPTOR LINKED TO PL HYDROLYSIS MEDIATES TARDIVE DYSKINESIA IN RATS. H. Rosengarten* and A.J. Friedhoff. Departm of Psychiatry, Millhauser Labs, NYU School of Medecine, New York, NY 10016.

Long term neuroleptic therapy and D-1 stimulation by D-1 agonist SKF 38393 induces repetitive jaw movements in rats which are considered to be a rat model of tardive dyskinesia(TD)(1,2). The existence of multiple forms of the dopamine D-1 receptor is supported by behavioral, biochemical, electrophysiological and molecular biological evidence (3.4.5.6.7). More recently a D-1 receptor was identified which is not linked to c-AMP stimulation but to Pl hydrolysis (8). This receptor can be stimulated by dopamine and the D-1 agonst SKF 38393, and inhibited by the D-1 antagonist SCH 23390. RJM can be also induced by SKF 38393 and inhibited by SCH 23390. It has been found in our laboratory that 20-30 % of the D-1 receptors labeled with SCH 23390 are resistant to EEDQ inactivation (9). Reduction of the number of functional D-1 receptors by 70-90% by administering the peptide coupling agent Nethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ), did not affect RJM scores which actually increased following EEDQ inactivation of most of the D-1 receptors. Suspecting that RJM behavior may be induced by a PI system we examined the PI system as a mediator of rat tardive dyskinesia - RJM. As predicted, based on the failure of EEDQ to reduce RJM scores, PI hydrolysis was unaffected by EEDQ, whereas binding analysis of the other caudate from each rat showed an expected 80% decrease of the binding of the D-1 antagonist SCH 23390. This demonstrates that about 20% of D-1 receptors producing RJM (TD) are linked to PI

This study provides evidence that rat TD is elicited by the D-1 receptor pathway linked to second messengers derived from the hydrolysis of phosphoinositides.

FUNCTIONAL ANALYSIS THE DOPAMINE D2 RECEPTOR VARIANTS. Cravchik¹ D.R. Sibley², R.M. Post* and P.V. Gejman¹. ¹National Institute of Mental Health, ²National Institute of Neurological Disorders and Mental Health. Melian Heatin, National Institute of Health, Bethesda, Maryland. The human dopamine D_2 receptor gene (DRD2) has three

polymorphic variants which predict the amino acid substitutions Val→Ala96, Pro→Ser310, and Ser→Cys311 in the receptor protein. We have investigated the receptor binding and signal transduction properties of these D₂ receptor variants by stably expressing them in cultured mammalian cells. The Cys311 and Ser310 variants of the human D2 receptor, which involve substitutions located in the third human D₂ receptor, which involve substitutions located in the third cytoplasmic loop, were markedly less effective in inhibiting cAMP synthesis than the most prevalent form (Pro310, Ser311). Additionally, the variants Cys311 and Ser310 were found to exhibit a higher proportion of high affinity agonist binding than the most prevalent form of the D₂ receptor. The impairment of the Cys311 and Ser310 variants to inhibit cAMP levels thus appears to result from a reduced ability of the receptors to activate the appropriate Gi-like protein. The demonstration of substantial functional differences between PRD2 gene variants found in the human population might between DRD2 gene variants found in the human population might have important pharmacological implications given the widespread use of D2 receptor blocking drugs in the treatment of psychotic disorders.

522.4

THE ROLE OF THE D1 RECEPTOR CARBOXYL TERMINUS IN

DESENSITIZATION AND DOWN-REGULATION. Chun K. Mak' and David R. Sibley. Molecular Neuropharmacology Section, ETB/NINDS/NIH, Bethesda, MD 20892.

The D1 dopamine (DA) receptor has a long carboxyl (C)-terminus containing consensus sequences for phosphorylation by protein kinases. In contrast, the D2 DA receptor has a short C-terminus with no apparent phosphorylation sites. To assess the potential role of the D4 receptor C-terminus in desensitization, we constructed a D4/D2. with the D₁ receptor C-terminus in desensitization, we constructed a D₁/D₂ chimeric receptor in which the D₁ receptor C-terminus was replaced with that of the D₂. The cDNAs of the chimeric D₁/D₂ and wild type (WT) receptors were stably transfected into CHO or C6 cells. Cyclic AMP levels and [³H]SCH-23390 binding assays were used as measures of receptor function and expression, respectively. Both the D₁ WT and D₁/D₂ chimera receptors exhibited similar levels of expression and produced similar cAMP responses in both CHO and C6 expression and produced similar cAMP responses in both CHO and C6 cells. When pre-treated with DA, both the D₁/D₂ chimera and D₁ WT receptors in C6 cells approached complete desensitization within 1 hr, while those in the CHO cells showed moderate desensitization after several hours. In both cell lines, the D₁/D₂ chimera was desensitized to a greater extent than the D₁ WT receptor. In receptor binding experiments, pre-treatment of DA did not lead to significant receptor down-regulation within the first hour for either cell type. A moderate down-regulation was seen in 2 to 7 hours, and 90% down-regulation by 24 hours. There was no difference between the D₁ WT and D//D₂ chimeric receptors in this regard. It is concluded that the C-terminus of the produced the concluded that the C-terminus of the produced the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded that the C-terminus of the concluded the concluded that the C-terminus of the concluded that the C-terminus of the concluded the concluded that the C-terminus of the concluded the chimeric receptors in this regard. It is concluded that the C-terminus of the D₁ receptor does not play a major role in G-protein coupling, desensitization or down-regulation. (Supported by NINDS/NIH).

HYDROXYLAMINE TREATMENT OF THE DOPAMINE D2 RECEPTOR RESULTS IN G-PROTEIN UNCOUPLING S.P. Lee, G.Y.K. Ng, G.A. Cottrell*, M.R. Brann, S.R. George, and B. O'Dowd. Depts. of Pharmacology and Medicine. Univ. of Toronto. Toronto. ON, M5S 1A8, The Addiction Research Foundation, Toronto. ON, M5S 2S1, and the Depts. of Psychiatry and Pharmacology, Univ. of Vermont School of Medicine, Burlington, VT, 05405

Previous studies in our laboratory have shown that both the dopamine D2 receptor (D2R) monomer and dimer are palmitoylated. Palmitoylation may have a role in the desensitization or trafficking of receptors. In our current study, the effects of chemical depalmitoylation of the D2R were examined. D2R-expressing Sf9 cells (D2/cells) were metabolically labeled with [³H]-palmitic acid and immunoprecipitated D2R were shown to be palmitoylated. Incubation of the palmitoylated D2R with 1M hydroxylamine removed the [³H]-palmitate from the receptor indicating that palmitoylation occurs by a thioester bond to cysteine residues. We are currently investigating whether the cysteine in the carboxyl tail is the putative site for palmitoylation in the D2R. Treatment of crude membranes from D2/cells with hydroxylamine resulted in the loss of agonist-detected high affinity sites as detected by agonist competition binding analysis, suggesting that uncoupling from the G-protein occurs as a result of depalmitoylation of the D2R. Saturation binding with the benzamide antagonist [³H]-yM-01951-2 and the butyrophenone antagonist [³H]-spiperone on the hydroxylamine-treated membranes detected a significant decrease in receptor density versus control membranes. Subsequent immunoblot analysis of these tissues showed no significant change in the electrophoretic mobility or intensity of the immunoreactive monomer and dimer species. These data suggest that chemical depalmitoylation lowers receptor affinity for ligand by uncoupling from G-protein but does not change the size or the proportions of D2R dimers and monomers. This work was supported by the Medical Research Council of Canada and the National Institute of Drug Abuse.

522.7

STRUCTURAL DETERMINANTS OF G-PROTEIN COUPLING IN THE DOPAMINE D2 RECEPTOR: CONTRIBUTION OF THE BBXXB MOTIF. B. L. Wiens*, V. J. Watts, and K. A. Neve Oregon Health Sciences University and VA Medical Center, Portland OR, 97201.

Synthetic peptides corresponding to regions in the cytoplasmic domains of G-protein coupled receptors activate G-proteins in vitro. A sequence motif of BBXXB/F or BBXB (B=basic, F=aromatic, X=non-basic residue) at the C-terminal end of these peptides is required for activation of Gi. The dopamine D2 receptor contains two putative G-protein activator sequences with this motif in the third intracellular loop (LRSSR and HHGLH). To test the hypothesis that these sequences are necessary for agonist activation of G-proteins via the D2 receptor we substituted an alanine for the last basic residue of each putative Gi-activator sequence in the rat D2L receptor. These mutants, R230A and H316A, were characterized in HEK293 cells stably expressing similar levels (500-1000 fmol/mg protein) of mutant and wild-type (wt) receptors. The affinities (Kd) of mutant receptors for [3H]spiperone were similar to the wt receptor (approximately 30 pM), as were the apparent affinities (Ki) for the agonists dopamine, 7OH-DPAT, and quinpirole. The ability of H316A to inhibit forskolin-stimulated cAMP accumulation did not differ from the wt receptor, however, the IC50 values of dopamine and 7OH-DPAT inhibition at R230A (IC50=313 and 2 pM) were at least 10-fold lower than at the wt receptor (3500 and 670 pM). In addition, preliminary results indicate that dopamine pretreatment (2 hrs) sensitizes forskolin-stimulated cAMP accumulation via R230A to a greater extent than via H316A or the wt receptor, which exhibit similar levels of sensitization. Although these results do not support the hypothesis that the BBXXB elements in the D2L receptor are required for activation of Gi, the N-terminal region of the third intracellular loop appears to influence G-protein coupling as the mutant R230A exhibits enhanced functional activity. SEQUESTRATION OF DOPAMINE D2 RECEPTORS IS FACILITATED BY G-PROTEIN COUPLED RECEPTOR KINASES 2 AND 5.

K. ITO and T. HAGA*. Dep. of Biochemistry, Inst. for Brain Research, Univ. of Tokyo, Tokyo 113, Japan

We have examined the agonist-dependent sequestration of dopamine D2 receptors in COS-7 cells that had been transiently transfected with expression vectors encoding D2 receptors (the long isoform D2L or the short isoform D2S) and G-protein coupled receptor kinases (GRK2 or Sequestration was assessed by two methods: 1) loss of [3H]sulpiride binding activity from the cell surface, and 2) transfer of [3H]spiperone binding activity from the membrane fraction to a light vesicle fraction, isolated by sucrose density gradient centrifugation. In COS-7 cells expressing D2 receptors alone, almost no sequestration was observed (less than 4%). When GRK2 was co-expressed with D2S, 47% of the receptors were sequestered by treatment with 10-4 M dopamine for 2 hours (EC₅₀ = 2.2×10^{-7} M, $t_{1/2}$ = 25 min). In cells coexpressing GRK5, 25% of the D2S receptors were sequestered following the same treatment. Co-expression of a dominant-negative receptor kinase mutant (DN-GRK2) led to no change in sequestration. These results indicate that GRK facilitates sequestration of dopamine D2 receptors as well as muscarinic m2 and ß2 adrenergic receptors.

DIHYDREXIDINE ACTIVATES D₂ DOPAMINE RECEPTORS COUPLED TO ADENYLYL CYCLASE, BUT NOT TO POTASSIUM ION CHANNELS H.P. Smith¹¹, G.S. Oxford¹, D.E. Nichols², R.B. Mailman¹ and C.P. Lawler¹. Univ. of North Carolina¹, Chapel Hill, NC 27599, and Purdue Univ.², W. Lafayette, IN. 47007

Dihydrexidine (DHX) is a dopamine agonist that has high affinity to both "D₁-like" and "D₂-like" receptors. Functionally, DHX has equally high intrinsic activity at "D₁-like" receptors in rat/primate brain and in molecular systems. Surprisingly, however, there is significant data indicating that DHX has high intrinsic activity at "D₂-like" receptors coupled to inhibition of adenylyl cyclase (AC) activity, but antagonist activity (i.e., low intrinsic activity) at "D₂-like" receptors coupled to potassium channels. The studies using primary cultures of pituitary lactotrophs are consistent with this pattern. DHX (like dopamine) inhibits both forskolin- and VIPmediated stimulation of adenvlyl cyclase activity with a maximal inhibition of 50% and 80%, respectively. The D₂-selective antagonists, (-) sulpiride and (-) eticlopride, attenuate DHX- and dopamine-mediated inhibition of AC, whereas the D₁-selective antagonist, SCH23390, does not. In the same cells, DHX has low intrinsic activity at D₂ receptors coupled to the potassium inward rectifier (GIRK): DHX elicits peak potassium ion currents \leq one-fourth the peak I_K elicited by dopamine, even at concentrations as high as 100 µM. DHX- and dopamine-mediated I_K are blocked by the D_2 -selective antagonists, (-) sulpiride and domperidone, but not the D_1 -selective antagonist, SCH23390. Pituitary lactotrophs express only the D_{2SHORT} and D_{2LONG} molecular isoforms of the receptor, to which DHX binds equally well. In cell lines transfected with either the D28 or D21 receptor, DHX has high intrinsic activity to inhibit D_2 -coupled AC. Thus, the mechanism(s) underlying the effector selectivity of DHX likely involve(s) stoichiometric differences or conformational differences in D_2 receptor coupling to distinct G protein isoforms. This provides further evidence that drugs might have "functional selectivity" in their interactions with the same receptor isoform. (Supported by MH42705, MH40537, and MH33127 grants)

INVESTIGATION OF CAMP-MEDIATED REGULATION OF THE RAT D₁ DOPAMINE RECEPTOR USING SITE-DIRECTED MUTAGENESIS. <u>Dong Jiang* and David R. Sibley.</u> Molecular Neuropharmacology Section, ETB/NINDS/NIH, Bethesda, MD 20892.

Previous investigations of D₁ receptor regulation have suggested a role for the cAMP-dependent protein kinase (PKA) in agonist-induced desensitization and down-regulation. Given the presence of four putative consensus recognition sites for PKA in the D₁ receptor protein, a reasonable hypothesis is that some of these effects are due to direct phosphorylation of the receptor. In order to investigate this possibility, we used site-directed mutagenesis techniques to alter each of the four potential PKA sites to determine the effects on agonist-induced regulation. Using PCR-based methods, we created a mutant D₁ receptor with the following amino acids substitutions: Thr135→Val135, Ser229→Ala229, Thr268→Val268, and Ser380→Ala380. Residue 135 is found within the 2nd intracellular loop of the receptor, residues 229 and 268 are present in the 3rd intracellular loop of the receptor, residues 229 and 268 are present in the 3rd intracellular loop whereas residue 380 is located in the carboxyl terminus of the receptor. Characterization of the wild type (WT) and mutant receptors stably expressed in C6 glioma cells suggests that both receptor expression, antagonist or agonist affinities, or on functional coupling with Gs. Preliminary experiments indicate that dopamine (DA) preincubation of the C6 cells results in desensitization and down-regulation of both WT and mutant receptors. DA treatment induces a maximal 85% receptor down-regulation at 5 hr with a t₁/₂ of −1 hr in an identical fashion for both WT and mutant receptors. In contrast, DA-induced desensitization is attenuated in the mutant receptor. After 1 hr of DA treatment, the WT receptor exhibits -80% desensitization of the C AMP response whereas the mutant receptor is desensitized by only -20%. These results support the hypothesis that direct phosphorylation of the D₁ receptor by PKA is involved in agonist-induced desensitization. (Supported by NINDS/NIH).

DOPAMINE RECEPTORS AND THE REGULATION OF TYROSINE HYDROXYLASE AND AROMATIC L-AMINO ACID DECARBOXYLASE. N.H. Neff*, S. Cho, B. Weiss¹ and M. Hadjiconstantinou. Dept. Pharmacol. and Psychiat., Ohio State Col. Med., Columbus OH, 43210 and ¹Div. Neuropsychopharmacol. Med. Col. Penn. Phila, PA 19129

Acute administered of the dopamine D2 receptor family of agonists to mice decreases the activity of tyrosine hydroxylase (TH) and aromatic L-amino acid decarboxylase (AAAD) in striatum, while D2 antagonists increase these activities. In contrast, D1 receptor agonists or antagonists decrease or increase, respectively, AAAD activity without affecting TH activity. The changes of TH activity after acute treatment with the D2 family of drugs apparently reflect activation/deactivation of the enzyme, while the changes of AAAD appear more complex and include activation/deactivation as well as induction of the enzyme. Chronic treatment with D2 receptor agonists decreased AAAD activity only, while treatment with D2 antagonists increased TH and AAAD in striatum. Similarly, treatment with a D2 receptor antisense oligonucleotide increased TH and AAAD activity in striatum. D1 active drugs had no effect on TH, while D1 antagonists elevated AAAD activity. The increase of TH and AAAD after chronic treatment with D2 or D1 antagonists, and D2 antisense was accompanied by a rise of mRNA for both enzymes, suggesting de novo protein synthesis.

DISSOCIATION OF TYROSINE HYDROXYLASE AND ADENYLATE CYCLASE MODULATION BY D2 DOPAMINE AUTORECEPTORS. C.M. O'Hara, K.L. O'Malley, and R.D. Todd'. Depts. of Psychiatry, Genetics, and Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

D2 dopamine receptors have been shown to inhibit dopamine release and synthesis as well as adenylate cyclase in a number of systems. We have utilized a mouse mesencephalic cell line (MN9D) to show that transfected D2 dopamine receptors are capable of inhibiting dopamine synthesis and release as well as adenylate cyclase activity following agonist stimulation in a pertussis toxin (Ptx)-sensitive manner. Previously we have shown that MN9D cells express the Ptx-sensitive G-protein subunits $G\alpha_{i2}$, $G\alpha_{oA}$, and $G\alpha_{oB}$ but not $G\alpha_{i1}$ or $G\alpha_{i3}$. In the current study, we have determined the specific G-proteins involved in the inhibition tyrosine hydroxylase and adenylate cyclase in this cell line. MN9D cells were cotransfected with the long form of the D2 dopamine receptor and $G\alpha_{l2}$ or $G\alpha_{oA}$ which have been mutated such that they are no longer sensitive to Ptx. In this paradigm, if the specific mutant G-protein couples to the D2 receptor then inhibition should occur in the presence of Ptx. Cotransfected MN9D cells were grown to near confluence, treated overnight in the absence and presence of 100 ng/ml Ptx then assayed for agonist inhibition of forskolin-stimulated cAMP accumulation or dopamine synthesis. For synthesis, the cells were stimulated in the presence of high K+ (60 mM) with the dopamine agonist quinpirole (10 μM); L-dopa accumulation was measured in the presence of the Laromatic amino acid decarboxylase inhibitor, NSD1015(200 μ M) by high performance liquid chromatography/electrochemical detection. Agonist stimulation of D2/Ga; and D2/Gα_{oA} cell lines inhibited dopamine synthesis following Ptx treatment while only the $D2/G\alpha_{i2}$ cell line inhibited cAMP accumulation. In this system, D2-mediated modulation of synthesis is coupled to two G-protein pathways while modulation of cyclase is limited to the $G\alpha_{12}$ pathway. (Supported by MH31302, DA08818)

ACTIVATION OF D5 DOPAMINE RECEPTORS ON CHROMAFFIN CELLS INHIBITS SECRETAGOGUE-STIMULATED Na⁺ UPTAKE BY A cAMP-INDEPENDENT MECHANISM. M.K. Dahmer* and S.E. Senogles. Department of Biochemistry, University of Tennessee College of Medicine. Memphis. TN 38163.

S.E. Senogles. Department of Biochemistry, University of Tennessee College of Medicine, Memphis, TN 38163.

Recent studies have demonstrated that D1-selective and D2-selective dopamine receptor agonists inhibit catecholamine secretion and Ca²+ uptake into bovine adrenal chromaffin cells by receptor subtypes which we have identified as D5, a member of the D1-like dopamine receptor family, and D4, a member of the D2-like dopamine receptor family, and D4, a member of the D2-like dopamine receptor family. The purpose of this study was to determine whether activation of D5 or D4 receptors inhibits influx of Na⁺ which could explain inhibition of secretion and Ca²+ uptake by dopamine agonists. Na⁺ influx was measured by the uptake of ²²Na⁺ into cells. D1-selective agonists preferentially inhibited both dimethylphenylpiperazinium- (DMPP) and veratridine-stimulated ²²Na⁺ influx into cells. The D1-selective agonists, C1-APB (100 μM) and SKF38393 (100 μM) inhibited DMPP-stimulated Na⁺ uptake by 87.5 ± 2.3% and 59.7 ± 4.5%, respectively, while the D2-selective agonist, bromocriptine (100 μM), inhibited Na⁺ uptake by only 22.9 ± 5.0%. Veratridine-stimulated Na⁺ uptake was inhibited 95.1 ± 3.2% and 25.7 ± 4.7% by 100 μM C1-APB or bromocriptine, respectively. The effect of CL-APB was concentration dependent. A similar IC₅₀ (-18 μM) for inhibition of both DMPP- and veratridine-stimulated Na⁺ uptake was obtained. The addition of 8-Br-cAMP (1 mM) had no effect on either DMPP- or veratridine-stimulated Na⁺ uptake suggesting that D1-selective agonists are acting in a cAMP independent manner. PHOSPHOLIPASE C-82 EXPRESSION SWITCHES INHIBITORY DOPAMINE D2 RECEPTOR SIGNALLING TO STIMULATION OF CALCIUM MOBILIZATION. Stephen J. Morris 1, Ronald Kriz², and Paul R. Albert^{1*}. ¹Neuroscience Research Institute, University of Ottawa, Ottawa, Ontario, K1H 8M5. ²Genetics Institute, Cambridge, MA. 02140.

Previously, we had observed that dopamine D2S receptors expressed in GH4 pituitary lactotrophs couple in a pertussis toxin sensitive fashion to inhibition of VIP-stimulated cAMP formation, decreased basal [Ca++]i and to membrane hyperpolarization (Vallar et al. 1991). However, the same receptor when expressed in fibroblast Ltk-cells induced an increase in [Ca++]i which was associated with phosphoinositide turnover. The receptors retained their ability to inhibit cAMP formation and to cause membrane depolarization. All of these effects were sensitive to pertussis toxin suggesting that the receptors mediated their effects through the Gi/Go family of G-proteins. We have created stable cell lines expressing cDNAs for various phospholipase C (PLC) isoforms in the sense and antisense orientation and used them to address the question of how the same receptor expressed in two different cell types can have diametrically opposed effects on [Ca++]i.

GH4 cells stably transfected with D2S receptor and PLC-82

GH4 cells stably transfected with D2S receptor and PLC-82 sense increased [Ca++]i upon agonist addition whereas Ltk- cells expressing D2S and the antisense of PLC-82 have a much reduced calcium flux compared to Ltk- cells expressing D2S alone. Transfection of cells with sense and antisense constructs of PLC-81 and -83 did not cause such effects. The GBy-coupled PLC-82 appears to be obligatory for coupling to increase [Ca++]i. The differential expression of effector molecules (eg. PLC-82) in various cell types can alter the signalling properties of G protein coupled receptors. Supported by NCI, Canada

SPECIFIC COUPLING OF A CLONED HUMAN α2A-ADRENERGIC RECEPTOR TO A PHOSPHOINOSITIDE PATHWAY BY LOW DOSES OF OCTOPAMINE. C.N.Airriess¹*, J.E.Rudling¹, T.R.Cheek¹, J.M.Midgley² and P.D.Evans¹. ¹The Babraham Institute, Lab.Mol. Signalling, Dept. Zoology, Univ. Cambridge, Cambridge, C2B2 3EJ, U.K. and ²Dept.Pharmal.Sci., Univ. Strathclyde, Glasgow, G1 1XW, U.K. Agonist-specific coupling of G-protein coupled receptors to different second

Agonist-specific coupling of G-protein coupled receptors to different second messenger systems has been demonstrated for a number of receptors (see Evans et al., 1995, Prog. Brain Res. 106:259-268). We have shown previously that m- and p-octopamine, which coexist in sympathetic neurons, can couple a cloned human $\alpha 2A$ -adrenergic receptor (α -2AR) to multiple second messenger systems when expressed in a Chinese hamster ovary (CHO) cell line (Evans et al., 1995, Neurosci. Soc. Abstr. 21:1613). Here we report that low doses of (\pm) -m-octopamine specifically will couple the α -2AR (expressed in CHO cells) to a phosphoinositide pathway. The ability of agonists to change intracellular levels of D-m-po-inositid 1,4.5-trisphosphate (IP₃) was assessed using a specific binding assay (Amersham) and their ability to change cytosolic Ca^{2+} levels was assessed using ratio imaging techniques with the dye, fura-2. Very low concentrations (10¹³ to 10¹¹M) of (\pm) -m-octopamine were specifically able to increase IP₃ levels in CHO cells expressing α -2AR when exposed to agonist for 30 min in the presence of 10^3 M LiCl. At higher agonist concentrations this effect was much reduced. Parallel studies indicated that comparable low concentrations of (\pm) -m-octopamine, but not of the catecholamines or (\pm) -p-octopamine, can initiate cytosolic Ca^{2+} signals. Typically, such signals take the form of transient rises, which may or may not be accompanied by oscillatory changes, in intracellular Ca^{3+} levels. These studies provide further evidence for a specific functional role for m-octopamine (co-released with norepinephrine from sympathetic neurons) which may be mediated by phosphoinositide-induced changes in cytosolic Ca^{3+} levels through the activation of an α -adrenergic receptor.

G PROTEIN KNOCKOUT: EFFECTS ON D2 RECEPTOR COUPLING EFFICIENCY FOR DOPAMINE INHIBITION OF PROLACTIN (PRL) SECRETION. E. Meller, K. Bohmaker, P. Albert, P. P. Falardeau² and A. Zaremba. Dept of Psychiatry, NYU Medical Center, New York, NY 10016; Neuroscience Research Institute, Univ. of Ottawa, Ottawa, Canada K1H-8M5; 2Dept. Genetiques Moleculaire, Le Centre Hópital Univ. Laval, Ste-Foy, Quebec. Canada G1V-4G2.

GH₄C₁ cells transfected with pRSVneo express D2S receptors whose expression is under control of a metallothionein promoter. Expression of D2S receptors can easily be up- (by treatment with Zn2+) or down- (by treatment with phenoxybenzamine; PBZ) regulated. Exposure to Zn2+ shifted the doseresponse (DR) curve for dopaminergic inhibition of PRL release to the left, while irreversible receptor inactivation with PBZ shifted the DR curve to the right. Analysis of the DR curves indicated highly efficient receptor coupling (large receptor reserve). GH₄C₁ cells were stably transfected with pcDNA3 vectors containing the cDNA's for Giα3, Goα and Giα2 in antisense orientation. Clones have been isolated in which expression of Gia3 and Goa is selectively attenuated by 75-80%, as determined by Western blot; selection of Giα2 knockout clones is ongoing. Preliminary results show that knockout of Giα3 attenuates dopamine inhibition of PRL secretion and shifts the DR to the right. The effects of altering D2S receptor density, G protein α subunit identity/levels, or both, on DR curves for inhibition of PRL secretion are in progress and are expected to quantify the parameters which specify efficient receptor/effector coupling in this system. Supported by PHS grant NS 23618.

MODULATION AND HETEROLOGOUS SENSITIZATION OF SPECIFIC ISOFORMS OF ADENYLATE CYCLASE BY D2L DOPAMINE RECEPTORS IN HEK 293 CELLS V. J. Watts, 'and K. A. Neve Oregon Health Sciences University and VA Medical Center, Portland OR, 97201

In the present study we have created cells lines expressing the D2L dopamine receptor and type 1 (Ca++-stimulated) adenylate cyclase (AC-I/D2L) or the D2L receptor and type 2 (photbol ester-stimulated) adenylate cyclase (AC-I/D2L). We examined the ability of D2L dopamine receptors to modulate cAMP accumulation acutely as wells the effects of D2 agonist pretreatment on drug-stimulated cAMP accumulation. In AC-I/D2L cells it was found that D2 dopamine receptor agonists inhibited Ca++-stimulated (A23187) cAMP accumulation, although agonist potency was reduced compared to inhibition of forskolin-stimulated cAMP accumulation in D2L-Hek 293 cells. In contrast, dopamine receptor agonists did not inhibit cAMP accumulation in AC-2/D2L cells. Under conditions where Gs was partially activated (100 nM isoproterenol), coincubation with D2 agonists resulted in a potentiation of cAMP accumulation in AC-2/D2L cells. Consistent with the activation of AC-2 via release of βy subunits. We also examined heterologous sensitization of adenylate cyclase by D2L receptors. AC-I/D2L or AC-2/D2L cells were pretreated with dopamine agonists for 2 hours, followed by stimulation of cAMP accumulation under a variety of conditions. The results from these studies demonstrated that D2 agonists sensitized AC-1 mediated cAMP accumulation (A23187-stimulated). The A23187-stimulated cAMP accumulation in dopamine-treated cells was 500 % greater than that in vehicle-treated cells. Similarly, it was found that in AC-2/D2L expressing cells, agonist pretreatment sensitized phorbol ester-stimulated cAMP accumulation approximately two-fold. Pretreatment with D2 agonists under conditions where cAMP accumulation is clevated (AC-2/D2L cells pretreated in the presence of isoproterenol) also resulted in sensitization of phorbol ester-stimulated cAMP accumulation on the complex regulation of specific forms of adenylate cyclase and also provide clues regarding the mechanism for D2 receptor-mediated sensitization of adenylate cyclase activity. Supported by MH45372.

CHARACTERIZATION OF THE 7-HYDROXY-2-AMINOMETHYL CHROMAN WAY-133023 AND ITS ENANTIOMERS IN RODENT BEHAVIORAL TESTS FOR DOPAMINE D2 RECEPTOR ACTIVITY. J.A. Brennan, M.J. Piesla, A.T. Shropshire*, T.P. Wasik, R.A. Scerni, T.H. Andree, R.E. Mewshaw and K.L. Marquis. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

The dopamine D2 partial agonist WAY-133023 [2-(benzylamino-methyl)-chroman-7-ol oxalate] and its enantiomers (Mewshaw et al., ACS, Orlando FL, 1996) were characterized in a battery of in vivo behavioral tests for presynaptic and postsynaptic agonism/antagonism potential at the D2 receptor. In vitro binding studies with WAY-133023 indicate selectivity and high affinity for this receptor (ICSO nM; D2ag=0.4, SHTIA=104, α(1=145) and partial agonist intrinsic activity as indicated by preferential affinity for D2 agonist vs. antagonist binding. Locomotor activity (LMA) effects in non-habituated mice revealed that the in vivo agonist potential of WAY-1330023 lies in the (+)enantiomer [(+)023]. Low doses (0.001-0.003 mg/kg sc) and high doses (0.3-3 mg/kg sc) of (+)023 decrease LMA while intermediate doses (0.01-0.03 mg/kg sc) were less effective. The distomer [(-)023], however, produced only a reduction in LMA (0.1-3 mg/kg sc). WAY-133023 and its enantiomers were also characterized in Ungerstedt's rat rotational behavior model and in antagonism or induction of stereotypic and climbing behaviors in mice. Whereas (+)023 induced stereotypy in mice at doses ≥ 0.3 mg/kg sc when co-administered with a D1 agonist and following reserpine pretreatment, and also induced climbing at 10 and 17 mg/kg sc in reserpinized mice, (-)023 was devoid of activity in these models at doses up to 10 mg/kg sc. Both the (+) and (-) enantiomers antagonized apomorphine-induced stereotypy and climbing in mice (MED= 1 and 10 mg/kg sc, respectively). These in vitrofin vivo results suggest that WAY-133023 represents a new generation of D2 partial agonists which uses the 2-aminomethyl chroman moiety as a completely novel scaffold having access to the D2 agonist pharmacophore.

LEARNING DEFICIT IN DOPAMINE DI RECEPTOR KNOCKOUT MICE. M. El-Ghundi, P. Fletcher, J. Drago, H. Westphal, D. Sibley, P. Seeman*, S.R. George and B. O'Dowd. Add. Res. Fdn, Clarke Inst. Psych., Dept. Pharm., Univ. of Toronto, ONT, Canada, Dept. Anatomy, Monash Univ., Victoria, Australia, NIH-NICHHD, Bethesda, MD, USA

Dopamine D1 receptors (D1) are highly expressed in the hippocampus and prefrontal cortex, suggesting a role in cognitive processes. Mice lacking D1 receptors (D1-/-) were used to investigate the role of D1 receptors in learning. Spatial learning and memory of D1-/- and their wild type (WT) littermates were assessed using the Morris water maze. All mice were given trials in which they were required to locate a submerged platform within 90 s (acquisition) which was then changed to a different location (reversal). The platform was removed from the maze and mice were allowed to swim for 90 s and scored for the % of time spent in the quadrant where the platform was located, and the number of crossings through the previous platform position. The escape latency for both D1-/- and WT during the acquisition phase declined over subsequent trials indicating that they learned the position of the platform. However D1-/- mice learned significantly slower than WT. Probe trials revealed that D1-/- spent less time in the designated quadrant and had reduced numbers of crossings compared to WT. When mice were given trials to escape a visible platform to test their visual acuity and nonspatial learning, no significant difference was observed. The deficits seen in D1-/- were not due to motor impairment since these mice exhibited normal spontaneous locomotor activity, although rearing was reduced, compared to WT in an open field test. These results indicate that D1-/mice are learning impaired, and acquire spatial learning slowly, suggesting that D1 receptors are involved in learning. (Supported by the Medical Research Council of Canada).

BEHAVIORAL CHARACTERIZATION OF DOPAMINE DIA RECEPTOR KNOCKOUT MICE. D.R. Smith C.D. Striplin, R.B. Mailman, J. Drago, C.P. Lawler, and M. Gallagher. Dept. of Psychology and UNC Neuroscience Center, Univ. of North Carolina, Chapel Hill, NC 27599 and Neuroscience Unit, Monash University, Clayton 3168 Australia

Behavioral assessments sensitive to different forebrain systems innervated by dopamine (DA) neurons were conducted on mutant mice in which the D_{IA} dopamine receptor gene was inactivated. The knockout construct was expressed in Sv129 mice from which male chimeras were crossed with C57BL/6 (PNAS 91:12564, 1994). The genotype of each mouse was assessed using Southern analysis. Compared to wild type mice (+/+), homozygote mice (-/-) were impaired severely in a spatial navigation task sensitive to mesocortical DA function. In additional assessments, (-/-) mice were slower to initiate exploration and failed to orient to visual cues, functions associated with the mesolimbic and mesostriatal DA systems. Apart from the initiation of exploration, however, (-/-) mice were as active as, and habituated similarly to (+/+) mice. Finally, (-/-) mice learned to discriminate accurately odor cues, but intermittently failed to initiate performance on trials throughout testing. In contrast to (-/-) mice, heterozygotes (+/-) were not distinguishable from (+/+) mice on any test, with the exception of spatial navigation. In this latter assessment, the accuracy of the spatial bias acquired by the (+/-) mice was lower than that of the (+/+) mice, although (+/-) mice performed normally when learning was guided by a local These results show that (-/-) mice have deficits indicative of a loss of function in multiple forebrain systems innervated by DA, whereas a more circumscribed impairment in mesocortical function is evident in (+/-) mice. (DS holds an APA Predoctoral Fellowship. Supported by MH42705, MH01149, HD03310, and MH33127)

DISRUPTION OF DOPAMINE DI RECEPTOR GENE EXPRESSION ATTENUATES ALCOHOL-SEEKING BEHAVIOUR, S.R. George, M. EL-Ghundi, J. Drago, T. Fan. T. Nguyen, H. Westphal, D. Sibley, P. Fletcher, J. Khanna* and B. O'Dowd. Add. Res. Fdn., Dept. Pharm., Univ. of Toronto, ONT, Canada, Dept. Anatomy, Monash Univ., Victoria, Australia, NIH-NICHHD, Bethesda, MD, USA

Dopamine actions are mediated through the D1-like (D1&D5) and D2-like (D2, D3 & D4) receptors. The contribution of these receptors in mediating brain rewarding properties of ethanol has been difficult to define by pharmacological studies using agonists or antagonists due to lack of selectivity of these drugs. We used dopamine D1 receptor deficient mice (D1-/-) to investigate the role of this receptor in alcohol-seeking behaviors. D1-/- mice reproduce and move normally but are smaller in size than their wild type (WT) and heterozygote (D1+/-) littermates. In a 2-tube free choice limited access paradigm, mice were exposed to water and increasing concentrations of ethanol (3%, 6% & 12% w/v) over 30 consecutive days. Ethanol consumption and preference over water were markedly reduced (85-90%) in D1-/mice compared to WT and D1+/- controls. In support of the hypothesis that dopamine mediates the action of ethanol in the brain, elevation of synaptic dopamine levels by blocking MAOB with selegiline significantly reduced ethanol intake and preference in WT & D1+/- but had no effect on D1-/- mice. The involvement of D1 & D2 dopamine receptor systems in mediating alcohol drinking was further assessed by examining the effects of selective antagonists. Sulpiride caused a 30% reduction in ethanol intake and preference in WT and D1+/- mice, and completely abolished residual ethanol intake in D1-/- mice. SCH23390, was more effective in reducing ethanol intake (75-80%) in WT and D1+/- mice but had no effect in D1-/- mice suggesting that susceptibility to a higher ethanol intake and preference in WT & D1+/mice are mediated by D1 receptors. These findings implicate both dopamine D1 and
D2 receptor mechanisms in alcohol-seeking behaviour in mice, however, D1 receptors play a more important role than D2 receptors in this behavior. (Supported by MRC).

523.4

BIOCHEMICAL AND BEHAVIORAL EFFECTS OF A D₂ DOPAMINE RECEPTOR ANTISENSE RNA VECTOR TRANSFECTED IN MOUSE BRAIN. L.-W. Zhou*, G. Davidkova, S.-P. Zhang, M. Morabito and B. Weiss. Dept. Pharmacol., Med. Coll. PA and Hahnemann Univ., Philadelphia, PA 19129

A D₂ DA antisense plasmid vector (D₂ AS vector) has been shown to inhibit D2 dopaminergic supersensitivity in mice with unilateral 6-OHDA lesions of the corpus striatum. To investigate in greater detail the *in vivo* effects of the D₂ AS vector, we have performed studies in two animal models: normal mice and mice treated with the selective, irreversibly-acting D2 DA receptor antagonist fluphenazine-N-mustard (FNM). In normal mice, bilateral injections into the corpus striatum of D_2 AS vector (25 μg) complexed to DOTAP (10 μg) produced catalepsy within one day, an effect which lasted up to 40 days. This behavior was not observed after similar injections of an "empty" cloning vector, lacking the D_2 antisense sequence. In the FNM model, a single injection of FNM inactivates the total pool of D₂ DA receptors and produces catalepsy within 4 hr of treatment, after which the receptors and behavior return to normal within 8 days. Mice were given a single bilateral intrastriatal injection of the D2 AS vector or the "empty" vector and 5 days later were injected with FNM (20 µmol/kg, i.p.). Catalepsy was scored and the levels of the D₂ DA receptors were measured at various time intervals thereafter. D₂ AS vector treatment significantly reduced the rate of disappearance of the cataleptic behavior induced by FNM. This correlated with an inhibition of the rate of recovery of D_2 receptors. The inhibitory effects of the single injection of the D_2 AS vector on D_2 receptor-mediated behaviors lasted about 50 days. Unilateral intrastriatal injections of the D_2 AS vector also significantly inhibited the recovery of quinpiroleinduced rotations in mice with unilateral intrastriatal injections of FNM. These results suggest that a single injection of a D2 AS vector into mouse brain inhibits the synthesis of D2 DA receptors and induces long-term inhibition of D2 DA receptormediated behaviors.

THE EFFECTS OF RACLOPRIDE ON NON-HORMONAL AND HORMONE-INDUCED SENSITIZATION TO PUPS IN NULLIPAROUS RATS. Y.M. Clarke-Hall*, I. Rosenblatt and Ian Creese. Behavioral and Neural Sciences Graduate Program, Rutgers University, Newark, NJ 07102.

We have previously reported that antagonism of dopamine D2 receptors specifically interferes with several components of maternal behavior. To further explore the role of D2 receptors in maternal behavior in nulliparous rats, we examined the effects of raclopride, a selective D2 receptor antagonist, on both non-hormonal and hormone-induced sensitization to pups. In the first study, raclopride (10 mg/kg/day) or no drug was administered to rats in their drinking water for two days before their initial exposure to 2-day old pups. The rats were maintained for 10 days on raclorpide or normal drinking water and were constantly exposed to pups which were exchanged each day. Animals were considered sensitized to pups when they demonstrated retrieval of 3 pups and crouching/nursing posture when tested with new pups each day. Raclopride completely disrupted non-hormonal sensitization to pups which occurred in all control rats, without significantly affecting their spontaneous activity as measured in photocell cages. In a second study, estradiol (5 mm silastic tube–80 pg/ml serum) and progesterone (2 x 50 mm silastic tubes–80-160 ng/ml serum) were surgically implanted in ovariectomized and hysterectomized rats on day 0 and day 3, respectively. The rats were given an injection (sc) of estrogen benzoate (50 µg/kg on day 16) to activate rapid onset of maternal behavior. Raclopride (10mg/kg/day) was given for different periods of time throughout the study. Preliminary results demonstrated that raclopride, given from 0-16 days, interfered with hormone-induced sensitization to pups when these rats were tested on days 18-28. Together, these results suggest that dopamine and D2 receptors play a crucial role in mediating sensitization to pups. Supported by NIMH.

INCREASED POTENCY OF NEUROPEPTIDE Y TO ANTAGONIZE α_2 -ADRENOCEPTOR FUNCTION IN THE NUCLEUS TRACTUS SOLITARII OF SPONTANEOUSLY HYPERTENSIVE RATS. 5.-N. Yang¹, D.R. Fior¹, A.C. Hansson¹³, P.B. Hedlund¹*, A. Cintra¹, M. Castellano², U. Ganten³, D. Ganten³, L.F. Agnati¹ & K. Fuxe¹. ¹Department of Neuroscience, Karolinska Institutet, 171 77 Stockholm, Sweden; ²Scienze Mediche, Università degli Studi di Brescia, Italy; ³Max-Delbrück-Centrum für Molekulare Medizin, Germany.

The regulation by neuropeptide Y (NPY) of α_2 -adrenoceptors in the nucleus tractus solitarii (NTS) was evaluated in the adult normotensive Wistar Kyoto rat (WKY) and the adult spontaneously hypertensive rat (SHR). The threshold dose (1 pmol/50 nl) of NPY-(1-36) for the vasodepressor response in the NTS of the WKY was five times higher than that (0.2 pmol/50 nl) in the SHR. NPY-(1-36) at 0.2 pmol/50 nl could significantly counteract the vasodepressor response to 1-noradrenaline (800 pmol/50 nl) in the NTS of the SHR, but not in the WKY, in which 1 pmol/50 nl of NPY-(1-36) must be employed to counteract the vasodepressor response to 1-noradrenaline (800 pmol/50 nl). The in situ hybridization and autoradiographical experiments showed that the α_{DA} -adrenoceptor mRNA levels and the B_{max} value of the α_2 -adrenoceptor agonist 3H -p-aminoclonidine binding sites in the NTS of the SHR were substantially lower than those in the WKY. The autoradiographical results showed that in the SHR, NPY-(1-36) at 1 nM led to a significant increase in the K_d value of 3H -p-aminoclonidine binding sites. In the WKY, NPY-(1-36) produced this effect only at 10 nM. The present study provides evidence for an increase of the potency of NPY-(1-36) to antagonistically modulate α_2 -adrenoceptors in the NTS of the SHR, which may contribute to the development of hypertension in the SHR,

REGULATION OF DOPAMINE RELEASE AND SYNTHESIS IN DOPAMINE D₃R RECEPTOR KNOCKOUT MICE. D_.C. Cooper ^{1,*}, T.E. Koeltzow ¹, M. Xu², S. Tonegawa², F.J. White ¹ and M. E. Wolf, ¹ Dept. of Neuroscience FUHS/The Chicago Medical School, North Chicago, IL 60064. ² Dept. of Cell Biology, Cincinnati College of Medicine, Cincinnati, OH 45267. ³Ctr. Memory & Learning, MIT, Cambridge, MA 02139.

The role of dopamine D_3 receptors (D,R) in autoreceptor-mediated regulation of dopamine (DA) synthesis and release was tested in D_3R knockout mice (MUT) and this wild type (WT) littermates. Regulation of DA synthesis by nerve terminal DA autoreceptors was assessed in vivo using the GBL model. Impulse flow in DA cells was eliminated by GBL and decarboxylation of DOPA was inhibited by NSD-1015. We examined the effect of PD128907, a D_3R D_2R agonist, on DOPA accumulation in the ventral and dorsal striatum. There were no differences in basal DOPA accumulation (elicited by GBL and NSD alone) between WT and MUT mice. PD128907 dose-dependently inhibited DOPA accumulation in both regions equally well in MUT and WT mice. The contribution of D_2R s to local regulation of DA release was assessed using in vivo microdialysis in the ventral striatum of freely moving mice. MUT mice had increased basal DA levels compared to WT mice. Reverse dialysis application of PD128907 at PD128907 decreased PD128907 decrea

POSTURAL STRATEGIES DURING REACHING IN UNILATERAL DOPAMINE-DEPLETED RATS: USE OF FORCE PLATFORMS FOR MEASURING GROUND REACTION FORCES. E.J. Miklyaeva*. E.G. Nikiforov, G.J. Tompkins, M.E.Ioffe, N. C. Woodward, I.Q. Whishaw. Dept. of Psychology, Univ. of Lethbridge, AB, Canada, T1K 3M4

In previous experiments it has been shown that rats with unilateral dopamine (DA) depletions (hemiParkinson analogue rats) are impaired in using the contralateral (bad) limbs for skilled movements and for postural adjustments. It was proposed that the bad limbs may be unable to apply force to adjust posture and produce movement. The present study tests this idea by combining videorecording with force analysis. Ground reaction forces applied by each limb were measured with force platforms that were designed specifically for rats. Control rats and rats with unilateral DA-depletion, produced by 6-hydroxydopamine (6-OHDA) injected into the nigrostriatal bundle, reached for food with one limb, while vertical forces applied by each limb were measured. The results confirm that in hemiParkinson analogue rats the affected limbs can mediate relatively normal supporting reactions but cannot mediate normal adjustments in posture. To compensate for this impairment, rats use their good limbs to actively assist weight shifts. The results demonstrate that behavioral compensation can contribute to recovery and suggest that force analysis can assist in measuring DA-depletion-induced deficits.

TRANSFECTION OF D₂ DOPAMINE RECEPTOR ANTISENSE RNA PLASMID VECTOR *IN VITRO* AND *IN VIVO*. G. Davidkova, L.-W. Zhou, S.-P. Zhang*, M. Morabito and B. Weiss. Dept. Pharmacol., Med. Coll. PA & Hahnemann Univ., Philadelphia, PA 19129

To achieve long-term inhibition of the D_2 dopamine (DA) receptors we have developed eucaryotic plasmid vectors (pCEP4- D_2 AS and pCR3- D_2 AS) producing antisense RNA to the D_2 DA receptor. The vectors contain a 322 bp cDNA sequence of the mouse D_2 DA receptor (long isoform) in the antisense orientation relative to a CMV promoter. Vector pCEP4- D_2 AS was stably transfected into human embryonic kidney (HEK) 293_{DL} cells, expressing the mouse D_{2L} receptor isoform, by liposome-mediated transfection. Radioligand binding studies showed that these transfected HEK 293_{DL} cells exhibited markedly reduced levels of D_2 DA receptors. The feasibility of transferring a plasmid vector into mouse brain was determined by injecting mice intrastriatally with a CMV-E. coli LacZ vector complexed with DOTAP (25 μ g DNA/10 μ g DOTAP). Positive histochemical staining for β -galactosidase indicated that the reporter gene was expressed in the injected striatum. Successful transfection of the vector pCR3- D_2 AS into brain was confirmed by PCR amplification of DNA from the injected striata. A behavioral analysis of mice with unilateral 6-hydroxydopamine-induced striatal lesions showed that a single intrastriatal injection of pCR3- D_2 AS significantly inhibited contralateral rotational behavior in response to challenge injections with the D_2/D_3 agonist quinpirole but not to a D_1 or cholinergic agonist. This effect lasted about one month. These studies indicate the feasibility of delivering D_2 DA receptor antisense RNA into the CNS by means of a non-viral plasmid vector, and as a consequence producing long-term specific inhibition of D_2 dopaminergically mediated behaviors.

DOPAMINE SYNTHESIS IS INCREASED IN MICE LACKING DOPAMINE D4 RECEPTORS. T. A. Pugsley* S. Whetzel, A. E. Corbin, D. H. Van Leeuwen, R. G. MacKenzie T. Heffner, M. Rubinstein¹, M. J. Low¹ and D. K. Grandy¹. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105, ¹Vollum Institute for Advanced Biomedical Research, Oregon Health Sciences University L474, Portland, OR 97201.

Dopamine (DA) is a principal neurotransmitter in neuronal systems that project from midbrain nuclei to the striatum, limbic system, frontal cortex and hypothalamus. DA receptors are involved in a number of physiological actions, including movement control, generation of emotion and neuroendocrine functions. Alterations in dopaminergic activity and/or receptors are implicated in the pathogenesis of several CNS disorders including schizophrenia and Parkinson's disease. DA receptors have been subdivided into two families, the D1-like (D1 and D5) and the D2-like (D2, D3 and D4). Similar to D2 receptors, activation of D4 receptors inhibits adenylyl cyclase. However, the in vivo functional role for D4 receptors remains uncertain. Mice lacking functional D4 receptors were generated by gene targeting in embryonic stem cells. Mice with the disrupted D4 gene, both homozygous (-/-) and heterozygous (+/-), developed normally, were fertile and did not display any gross abnormalities. Biochemical studies indicated that basal DA synthesis was increased in mouse striatum but not in hippocampus of (-/-) as compared to (+/+). The Merck D4 receptor antagonist L-745,870 increased DA synthesis in striatum and hippocampus of (+/+), but was inactive in the same brain areas of (-/-) mice. The non-selective DA antagonist haloperidol increased DA synthesis in striatum and hippocampus of both the (+/+) and (-/-) mice. These findings suggest that D4 receptors may play a role in modulating DA synthesis in certain brain regions. (Supported by Warner-Lambert and NIDA Grant DA-09620.)

TRANSGENIC RESCUE OF SNAP-25 RESTORES DOPAMINE-MODULATED SYNAPTIC TRANSMISSION IN THE COLOBOMA MUTANT M.C. Wilson*, S.C. Steffensen, M. Kreifeldt, S.J. Henriksen, Scripps Research Institute, La Jolla, CA 92037

The mouse mutation coloboma (Cm) is a contiguous gene defect which includes the Snap gene encoding SNAP-25, an integral component of the synaptic vesicle docking/fusion core complex required for neurotransmitter release. In support of the involvement of SNAP-25 in the anomalous behavior of Cm/+ mice, expression of a transgene (sp/sp) encoding SNAP-25 ameliorates the hyperactivity, but not the head bobbing or opthalmic deformation attributed to the mutation. We have previously demonstrated that Cm/+ mice have increased recurrent inhibition, reduced theta rhythm by tail pinch and reduced long-term potentiation (LTP) in the hippocampal dentate gyrus compared to normal (+/+) littermates. The involvement of dopamine in these effects was hypothesized based on previous studies demonstrating that amphetamine suppresses the hyperactivity in Cm/+ mice as well as the involvement of mesolimbic dopamine in the induction of theta rhythm and the sensitivity of LTP to dopamine agonists. We sought to identify neurophysiological correlates for the rescued hyperactivity in $sp/sp \cdot Cm/+$ mice. Hippocampal EEG and evoked field potential activity were recorded by staggered microelectrodes oriented in the dentate hilus of halothane-anesthetized mice. In contrast to differences between Cm/+ and +/+ mice, there were no significant differences in the duration or amplitude of theta rhythmic activity (4-6 Hz) induced by tail-pinch (10s), afferent-evoked field EPSPs/population spikes (PSs), paired-pulse pEPSP/PS responses or LTP recorded in the dentate gyrus of $sp/sp \cdot Cm/+$ and $sp/sp \cdot +/+$ mice. Amphetamine (3.0 mg/kg i.p.) produced distinbition of dentate paired-pulse responses in both $sp/sp \cdot Cm/+$ and $sp/sp \cdot +/+$ mice. These findings support the hypothesis that alterations of dopamine synaptic transmission underlie the hyperactivity in Cm/+ mice, and suggest that dopamine neurotransmission is particularly sensitive to alterations in the expression of SNAP-25. CO-ADMINISTRATION OF A PHOSPHODIESTERASE (PDE) INHIBITOR ENHANCES THE INDUCTION OF BDNF mRNA BY ANTI-DEPRESSANT TREATMENTS. S. Morinobul*, M. Takahashi¹, K. Fujimaki¹, N. Okuyama¹, S. Totsuka¹ and R. S. Duman²¹ Dept. of Neuro-Psychiatry, Yamagata Univ. Sch. Med., Yamagata, Japan and

²Dept. of Psychiatry Yale Univ. Sch. Med., New Haven, CT. 06508 We have reported that chronic antidepressant administration increases the expression of BDNF in rat hippocampus. Expression of BDNF is also increased by chronic administration of a PDE inhibitor. Here we examine the regulation of BDNF mRNA by co-administration of a PDE inhibitor (rolipram or Ro 20-1724) with a selective norepinephrine reuptake inhibitor (SNRI) (desipramine or Org 4428) using northern blot hybridization. Acute (1 d) co-administration of a SNRI and a PDE inhibitor did not influence levels of BDNF mRNA. Chronic (21 d) co-administration of a PDE inhibitor with a SNRI resulted in a greater induction of BDNF mRNA in rat hippocampus relative to that observed with either treatment alone. Preliminary studies suggest that co-administration of a PDE inhibitor with desipramine for 11 days also results in a more rapid induction of BDNF mRNA. The results indicate that co-administration of a PDE inhibitor enhances the time course and maximal induction of BDNF mRNA in response to SNRI treatment. BDNF is reported to increase the survival and sprouting of monoamine neurons and to have antidepressant effects in sprouning of monoamine neurons and to nave antidepressant effects in animal models of depression. Moreover, stress is reported to decrease the expression of BDNF and can cause atrophy of vulnerable neurons in hippocampus. Taken together, the results suggest that increased expression of BDNF may play an important role in the therapeutic action of antidepression. action of antidepressants.

BIOCHEMICAL EFFECTS OF BUPROPION IN DEPRESSION Y. Z. Feng, S. Madakasira, N. Goldman, H. Zhu, A. E. Halaris* and J. E. Piletz. Dept. of Psychiatry and Human Behavior, Univ. of Mississippi Medical Center, Jackson, MS 39216

Bupropion is a structurally novel antidepressant whose mechanism of action remains unclear. Bupropion is a weak inhibitor of monoamine reuptake and is not known to block MAO. We investigated the effects of bupropion in 8 depressed patients after 6-8 weeks of treatment. Patients received 300-450 mg/day in divided doses. Last dose was at 18:00 hrs and blood drawing was at 9:00 doses. Last dose was at 19:00 firs and blood drawing was at 9:00 firs on the next day. Plasma concentrations of norepinephrine (NE), dopamine (DA), dihydroxyphenylacetic acid (DOPAC), serotonin (5-HT), 3-methoxy-4-hydroxyphenyl glycol (MHPG) and agmatine were determined by HPLC. Agmatine, decarboxylated arginine, is a novel neurotransmitter candidate. The concentration (mean ± SE) of DA was significantly higher (p<0.05) in post-treatment (241.5 \pm 110.6 pg/ml) than in pre-treatment (46.6 \pm 5.4 pg/ml) depressed patients. The concentration of 5-HT was also significantly higher patients. The concentration of 3-H1 was also significantly higher (p<0.01) in post-treatment (1322.6 \pm 105.3 pg/ml) than in pretreatment (423.3 \pm 117.8 pg/ml) depressed patients and in healthy control subjects (645.7 \pm 142.6 pg/ml). The concentrations of NE, DOPAC, MHPG and agmatine were not significantly different among the pre-treatment, post-treatment and control groups. These results provide evidence that dopamine and serotonin may contribute to bupropion's antidepressant properties. Supported by NIMH grants MH49248 and MH42859.

PHENCYCLIDINE INCREASES MONOAMINE UTILIZATION IN PRIMATE PREFRONTAL CORTEX: BLOCKADE OF EFFECTS WITH S-(-)HA966. RH Roth^{1,2,*}, JD Jentsch³, DE Redmond Jr¹ and JD Elsworth^{1,2}. Depts of ¹Psychiatry,

Pharmacology & Neurobiology, Yale School of Medicine, New Haven, CT 06510.

Recent studies from this lab have demonstrated that phencyclidine (PCP) potently activates monoamine turnover in the rodent brain and that the effect of PCP on dopamine (DA) turnover in the prefrontal cortex (PFC) can be selectively blocked with the γ-hydroxybutyrate-like agent, S-(-)HA966. In order to determine the relevance of these effects to the human brain, the consequences of PCP exposure and S-(-)HA966

Pretreatment on regional monoamine turnover in the primate brain were examined. Young adult male vervet monkeys were treated with PCP (0.3 mg/kg i.m.) or saline. S-(-)HA966 (1-3 mg/kg i.m.) was administered 15 min prior to PCP when given. One hour after PCP, the animals were deeply anesthetized with sodium pentobarbital and were subsequently perfused transcardially with ice-cold heparinized saline. The brain was removed, prepared in 4 mm coronal slices and regionally dissected on an ice-cold platform.

PCP potently activated DA utilization (HVA/DA) in several regions of the frontal

cortex (dorsolateral prefrontal, dorsomedial prefrontal, ventromedial prefrontal and cingulate cortex). Serotonin (5-HT) turnover (5-HIAA/5-HT) was also increased after PCP in all areas studied. S-(-)HA966 pretreatment blocked the effects of PCP on frontal cortical DA turnover.

Frontai cortical DA turnover.

This study demonstrates that PCP alters monoamine transmission in the primate PFC, an area involved in cognition and potentially dysfunctional in schizophrenia. Our lab has recently shown that increased DA turnover in the PFC impairs cognitive ability (Murphy et al., 1996), and as such, the present data suggest that at least some of the acute cognitive dysfunction associated with PCP adminstration may be related to a hyperdopaminergic state of the PFC and that S-(-)HA966 may be useful in preventing these effects.

This study was funded in part by Public Health Service Grants MH-14092 (RHR) and MH-00643 (DER), the Axion Research Foundation and the St Kitts Biomedical

DOPAMINE NIGROSTRIATAL FOLLOWING NEUROPEPTIDE ANTIBODY ADMINISTRATION TO NEONATAL RATS M.L.de Ceballos*1, M.Pernas1 and J.A.Fontenla². ¹Neurodegeneration Group, Cajal Inst., 28002 Madrid; ² Dept.Pharmacology, Univ.Santiago de Compostela, Spain.

Different neuropeptides have a neuromodulatory role on dopamine (DA) nigrostriatal activity. Following neonatal (P2) administration of neuropeptide antibodies (IgGs, 500 µg/rat sc), endogenous levels and release (microdialysis in vivo) of DA and its metabolites were measured in adult animals. Spontaneous locomotor activity and hyperactivity induced by DA agonists (apomorphine 0.5 mg/kg sc and amphetamine 3 mg/kg ip) was assessed as well. Controls were given IgGs from preimmune serum. DA striatal levels were increased by anti-met-enk and anti-SP treatement. DA release was enhanced by anti-met-enk and anti-neurotensin administration, while anti-SP increased HVA and DOPAC release. All treatments enhanced (x2) spontaneous locomotor activity of rats, while DA induced hyperactivity was reduced (50%) compared to control rats. Increased DA levels and release correlates with increased spontaneous activity and may result in subsensitivity of postsynaptic DA receptors which mediate DA agonist behaviour. These results confirm the neuromodulatory role of neuropeptides in basal ganglia. Supported by FIS (94:0403)

EFFECTS OF ALTERATIONS IN PERIPHERAL CORTICOSTERONE ON MESOCORTICAL AND TUBEROINFUNDIBULAR DOPAMINERGIC NEURO-CHEMICAL INDICES. S.E. Lindley*, T.G. Bengoechea, A.F. Schatzberg and D.L.Wong, Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, MSLS P104, Stanford, CA 94305-5485
Disturbances in the learner of the lateral of the l

Disturbances in the hypothalamic-pituitary-adrenal (HPA) axis in psychotic depressed patients have been hypothesized to produce delusions, hallucinations, and other cognitive disturbances through interactions with central dopaminergic (DA) neurons. In investigating this relationship in the male rat, a 7 day elevation in peripheral corticosterone (CORT), achieved through implantation of a sustainedrelease CORT pellet (placebo $4.0\pm1.4\,$ vs. CORT pellet $17.6\pm1.3\,$ ng/ul plasma CORT), resulted in a decrease in medial prefrontal cortex (mPfx) and an increase in median eminence (ME) DA utilization (dihydroxyphenylacetic acid (DOPAC) to DA ratio) and was without effect in any other DA nerve terminal regions examined. This chronic elevation also decreased noradrenergic utilization in the mPfx. Removal of basal levels of corticosterone, achieved through adrenalectomy 7 days prior to sacrifice, resulted in an increase in DA utilization in the mPfx and a decrease in the ME. Taken together, these results suggest plasma corticosterone selectively alters mPfx mesocortical and tuberoinfundibular DA neuronal activity, and is consistent with the hypothesized role of HPA axis-DA interactions in the pathophysiology of psychotic major depression. (Research Supported by NIMH grant MH50604, a NARSAD Young Investigator Award and a DANA Research Fellowship)

DIFFERENTIAL EFFECTS OF ACUTE AND SUBCHRONIC PHENCYCLIDINE ADMINISTRATION ON PREFRONTAL CORTICAL DOPAMINE: RELEVANCE TO SCHIZOPHRENIA. JD Jenisch^{1, 2} and RH Roth^{2, 3}. Depts of ¹Neurobiology, ²Psychiatry & ³Pharmacology, Yale School of Medicine, New Haven, CT 06510. Phencyclidine (PCP) has been used in attempts to model psychosis since PCP can cause psychotomimetic behavior in normal humans. Acutely, PCP induces transient

psychotoform states, while repeated exposure to PCP can lead to more long-term and

psychotoform states, while repeated exposure to PCP can lead to more long-term and robust schizophreniform symptomology. As the neurobiological consequences of PCP administration may have relevance to the pathophysiology of schizophrenia, we have investigated the neurochemical effects of acute and repeated PCP exposure.

Acute PCP treatment (rat: 10 mg/kg; monkey: 0.3 mg/kg) induced marked activation of monoaminergic systems in the rodent and primate brain. In particular, PCP potently increased dopamine (DA) turnover in the prefrontal cortex (PFC) of both species. The effect of PCP on PFC DA was blocked by S-(-)HA966 (3 mg/kg) and clonidine (0.1 mg/kg), drugs which prevent stress-induced increases in PFC DA turnover. The PCP-induced hyperdopaminergic state of the PFC may be the neurochemical substrate for the cognitive effects observed in humans following acute PCP administration as we have recently shown that increased DA turnover in the PFC can lead to comitive impairment (Murphy et al., 1996).

an lead to cognitive impairment (Murphy et al., 1996).

After subchronic PCP treatment (10 mg/kg/day for 14days), basal DA turnover in the rat PFC was significantly depressed, while basal DA turnover in NAc and STR and basal 5-HT and NE turnover were unaltered. In addition, after subchronic PCP administration, the effects on PFC DA turnover of an acute PCP challenge were merely blunted, whereas complete tolerance developed in the NAc. Thus, there is a selective inhibition of basal and stimulated PFC DA turnover after subchronic PCP. The depression of PFC DA activity after repeated PCP may be a more relevant neurochemical model of schizophrenia as a hypoactivity of the dorsolateral PFC esceptiated with degreed DA trenoversheep the beauty between the properties of the properti

associated with decreased DA transmission has been shown in schizophrenics (Weinberger et al., 1986, 1988). Therefore, the inhibition of PFC DA function after repeated PCP may be the most accurate model of schizophrenia yet studied.

These studies were funded by Public Health Service Grant MH-14092 (RHR).

DOPAMINE TERMINALS IN THE MONKEY PREFRONTAL CORTEX SELECTIVELY INNERVATE PARVALBUMIN-CONTAINING LOCAL CIRCUIT NEURONS. DA Lewis, * VA Hawrylak. DS Melchitzky. SR Sesack. Departments of Psychiatry and Neuroscience, University of Pittsburgh, PA 15213.

Complex modulatory actions of dopamine (DA) in the prefrontal cortex (PFC) are likely to involve physiological regulation of both pyramidal cells and local circuit neurons. Our previous work suggests that the latter effect is mediated synaptically by DA terminal inputs to GABA interneurons (J Comp Neurol 363:264). However, this innervation appears not to include the subclass of GABA cells that contain the calcium-binding protein calretinin (Neurosci Lett 200:9). We sought to determine whether DA terminals synaptically innervate the separate subset of GABA local circuit neurons that express parvalbumin (PV). Sections through area 9 of cynomolgus monkeys were labeled with immunogold-silver for PV and immunoperoxidase for tyrosine hydroxylase (TH) to label DA terminals. Electron microscopic examination of fields containing both markers revealed that TH-positive terminals were sometimes directly apposed to PV-labeled dendrites; of these contacts, approximately one third were symmetric synapses. Other THimmunoreactive terminals contacted unlabeled dendrites in the vicinity of PVlabeled processes. Because PV is present in wide arbor and chandelier neurons, which specifically target pyramidal cell soma and axon initial segments, respectively, these findings indicate that DA terminals synaptically innervate one or both of these classes of local circuit neurons. Thus, DA's modulatory actions in the PFC involve selective effects on only certain interneuron populations, some of which mediate potent inhibitory actions on pyramidal cells. Supported by USPHS grants MH50314 and MH43784.

TYROSINE HYDROXYLASE-LIKE IMMUNOREACTIVE ASTROCYTES IN THE RAT BASAL GANGLIA. A.M. Cantuniari, J. Patrickson and C. Moore. Dept. of Anatomy and Biochemistry, Morehouse School of Medicine, Atlanta, GA 30310. Catecholamines are ubiquitous neurochemicals implicated in a variety of neuronal functions including motor and neuroendocrine. Their presence in brain is primarily identified by immunohistochemical localization of tyrosine hydroxylase (TH) one of the enzymes involved in their synthesis, well known for a long time, as a specific marker for dopaminergic neurons. This is a pertinent extension of our previously described distribution of DA receptors subtype D2/3 in astrocytes of the rat SN (A. Cantuniari et al. Abstract 21, 3, 750.15, 1909, 1995, Society for Neuroscience).

A modified immunohistochemical ABC-DAB-α Naphthol method employing a mouse anti-TH antibody (Incstar) and a rabbit anti-GFAP (DACO) was used to identify the presence of Th in astrocytes. Although the TH-like expression within GFAP* astrocytes was heterogenous relative to the regional distribution a general pattern could be observed. TH-immunostaining extended from the cell body to the processes showing different intensity. Our data indicate that TH-like immunoreactivity is present in most (~80%) of the astrocytes in the rat basal ganglia. Among the GFAP* cells certain astrocytes appear more immunoreactive than others. The immunoreactivity of the astrocytes in the basal ganglia appears to be only partially correlated to the size and regional distribution of the cells. This could be an important factor in the rate of DA turnover and synthesis in astrocytes. Taken together with studies of F.G. Seil et al. Brain Res. 1992, Jan. 8, 569; 164-8 in cerebellar cultures our results suggest that TH cannot be considered anymore as a specific marker for dopaminergic neurons in the rat brain. Our data support the view that astrocytes should be considered catecholaminergic as long as they express TH.

LOCALIZATION OF GTP CYCLOHYDROLASE IN MONOAMINERGIC BUT NOT NITRIC OXIDE PRODUCING CELLS. Q. Hwang*, H. Baker, S. Gross and T. H. Joh. Cornell Univ. Med. Coll. at Burke Med. Res. Inst., White Plains N.Y. 10605 and Cornell Univ. Med. Coll., New York, N.Y. 10021

The first and rate-limiting enzyme in tetrahydrobiopterin (BH4) biosynthesis is GTP cyclohydrolase (GTPCH). BH4 serves as the essential cofactor for aromatic L-amino acid hydroxylases, such as tyrosine hydroxylase (TPH) and tryptophan hydroxylases, such as tyrosine hydroxylase (TPH) and tryptophan hydroxylase (TPH), the enzymes responsible for monoamine synthesiz, as well as for nitric oxide synthase (NOS), the nitric oxide synthesizing enzyme. We hypothesized that to provide access to the cofactor a close association exists between BH4 synthesizing and BH4-dependent enzymes. We sought to determine the relationship between GTPCH, neuronal NOS (nNOS) and TH in rat brain and adrenal gland using immunohistochemistry and in situ hybridization. Analyses of adjacent sections revealed specific localization of GTPCH in TH-containing cells in brain including substantia nigra, ventral tegmental area, hypothalamus and locus ceruleus, as well as chromaffin cells of adrenal medulla. GTPCH also was present in TPH-containing cells of the dorsal raphe nucleus and pineal gland. Thus, BH4 can be synthesized in all monoaminergic cells and is readily available for the enzymes requiring it. In contrast, analysis of adjacent sections showed that nNOS was not colocalized with GTPCH. Scattered nNOS positive cells were found in the cortex, striatum, cerebellum and olfactory bulb, all areas that receive monoaminergic innervation. The absence of GTPCH in nNOS cells suggests that the NO-producing cells may either obtain biopterin from monoamine containing processes which terminate in close proximity or take up biopterin released into the blood. POSTSYNAPTIC TARGETS OF TYROSINE HYDROXYLASE-LABELED TERMINALS IN MONKEY ENTORHINAL CORTEX. <u>S.L. Erickson*, S.R. Sesack and D.A. Lewis.</u> Depts. of Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, Pat 15260.

The rostral portions of the entorhinal cortex (ERC) receive a dense donamine (DA) innervation, and this innervation is significantly reduced in schizophrenic subjects. Knowledge of the postsynaptic targets of DA terminals in the ERC will shed light on the functional significance of the abnormal DA innervation of this region in schizophrenia. In other regions of cortex, DA terminals target pyramidal cell dendrites and spines, as well as the dendrites of subpopulations of GABA-containing local circuit neurons. In this study, antibodies against tyrosine hydroxylase (TH) and GABA were used to study the postsynaptic targets of DA terminals in the superficial layers of the rostral subdivision in the adult cynomolgus monkey ERC. TH immunoreactivity was visualized with a peroxidase label and GABA immunoreactivity was visualized with a preembedding gold-silver label. By electron microscopic examination, TH-positive axons were 0.15-0.2 µm in diameter, and were unmyelinated. TH-positive varicosities were as large as 0.7 µm, and most were apposed to unlabeled dendritic shafts or spines. Some TH-labeled varicosities were apposed to dendrites labeled for GABA. These findings suggest that DA may influence directly the activity of both excitatory and inhibitory neurons in the ERC. This work was supported by USPHS grant MH43784.

PRESENCE OF CATECHOLAMINERGIC CALLOSAL NEURONS IN THE VISUAL CORTEX OF THE CAT. B. Jardon*, R. A. Ase, F. Lepore and T. A. Reader. Centre de recherche en sciences neurologiques. Départements de Psychologie et Physiologie, Université de Montréal, Montréal (Québec) H3C 3.17 Canada.

Until now, no data has shown any involvement of chemically-specified neurotransmitters in a possible direct inhibitory function of the corpus callosum (CC); therefore, we began to study the catecholaminergic profile of this large commissure. Initially, the CC of adult cats were dissected in three parts: the genu, the body and the splenium, and the latter division was used to measure its content in CA and some of their major metabolites by high-performance liquid chromatography. In a second series of experiments, callosal neurons were retrogradely labelled by either fluoro-gold or rhodamine-latex-microspheres, injected eleven days before into contralateral visual cortical areas. Brain sections containing the labelled callosal neurons were processed for tyrosine-hydroxylase (TH) and dopamine-β-hydroxylase (DBH) immunocytochemistry. The results show that measurable amounts of dopamine (DA) and noradrenaline (NA) and their main metabolites were present in the splenium of the CC, that the CA levels were significantly lowered following treatment of the animals with the synthesis inhibitor \alpha-methyl-p-tyrosine, indicating the specificity of the method of measurement, and that numerous visual cortical neurons, of which some were identified as callosal neurons and visualized owing to the fluorescent retrograde tracer, showed immunoreactivity for TH, but not for DBH. From these data, TH-immunoreactive callosal neurons can be proposed to be at least partly responsible for the presence of DA in callosal fibers, and they may account for a direct inhibitory function of the CC

MONOAMINE OXIDASE (MAO)- B CONTAINING NEURONAL SYSTEMS IN MAO A DEFICIENT TRANSGENIC MICE, K. Ikemoto^{1*}, K. Kitahama¹, J. L. Valatx¹, M. Jouvet¹, I. Seif², E. De Maeyer². ¹Département de Médecine Expérimentale, INSERM U52, CNRS URA1195, Université Claude Bernard, Lyon, France. ²Institute Curie, CNRS URA1343, Paris, France.

We studied type B momoamine oxidase (MAO B)-containing neuronal systems employing MAO histochemistry in aggressive MAO A deficient transgenic mice, Tg8 line, of which MAO A-activity was not observed in the locus coelureus cells. In contrast, the dorsal raphe and laterodorsal tegmental nuclei contained many MAO B-positive cells. In this mutant line, MAO B-containing cells were distributed in the tuberomammillary, and dorsomedial posterior hypothalamic nuclei. In the thalamus, stained cells were packed in the paraventricular, mediodorsal, central medial, ventrolateral, rhomboid and reuniens thalamic nuclei, as well as the habenular nucleus. In the forebrain, MAO B-containing cells were observed in the preoptic area, striatum, septal nucleus, major island of Calleja, diagonal band, ventral pallidum and amygdaloid nucleus. In this model, we are able to examine exclusively MAO B structures, which has been difficult to be differentiated from MAO A even with pharmacological suppression in normal animals

PHARMACOLOGICAL PROPERTIES OF BURST-FIRING SEROTONERGIC NEURONES IN THE RAT DORSAL RAPHE NUCLEUS

M. Hajós¹, A.E.P. Villa*² and T. Sharp¹, ¹Oxford University Department of Clinical Pharmacology, Radcliffe Infirmary, Oxford, U.K. and ²Department of Physiology, University of Lausanne, Rue du Bugnon 7, Lausanne, Switzerland

We have recently reported a sub-population of presumed 5-HT neurones in the raphe nuclei of anaesthetised rats (Hajós et al. Neuroscience, 69: 189-197, 1995) which display all the electrophysiological features of 5-HT neurones, except that they discharge spike doublets or triplets with a short interspike interval (<10ms). In the present study we analysed some pharmacological properties of these neurones. Extracellular recordings were made in the dorsal raphe of anaesthetised male Sprague-Dawley rats using conventional electrophysiological methods. In some experiments the pharmacological properties of burst-firing 5-HT neurones were compared to single spiking, classical 5-HT neurones were inhibited by i.v. administration of 8-OH-DPAT, a 5-HT₁A receptor agonist or paroxetine, a calestine 5-HT reutrophysion burst.

Both single spiking and bursting 5-HT neurones were inhibited by i.v. administration of 8-OH-DPAT, a 5-HT1_A receptor agonist or paroxetine, selective 5-HT reuptake inhibitor, with equal sensitivity. Interestingly, in burst-firing neurones low doses of 8-OH-DPAT preferentially inhibited higher order spikes, i.e. spikes fired in burst. As with single spiking, classical 5-HT neurones burst-firing neurones were inhibited by prazosin, an α 1-adrenoceptor antagonist. In order to determine whether excitatory amino acid receptors are involved in the generation of bursting activity, MK-801 (0.4 mg/kg, i.v.), and kynurenic acid (0.1-0.5 μ mol, i.c.v.) were administered. Both antagonists failed to alter significantly the bursting activity, although kynurenic acid significantly inhibited the overall firing activity. Microiontophoretic application of glutamate significantly increased the firing rate but did not induce burst activity in single spiking neurones.

Our findings demonstrate that both single spiking and burst-firing 5-HT neurones are modulated by α 1-adrenoceptors and 5-HT_{1A} receptors, and indicate that excitatory amino acid receptors are not involved in the bursting activity. (Supported by the Medical Research Council, U.K.)

525.3

INHIBITION OF DORSAL RAPHE CELL FIRING BY PUTATIVE 5-HT $_{1A}$ ANTAGONISTS: 5-HT $_{1A}$ PARTIAL AGONISM OR α -ADRENERGIC BLOCK-ADE? B.L. Waszczak*, L.P. Martin and D.M. Jackson. Dept. of Pharmaceut. Sci., Northeastern Univ., Boston, MA 02115 and Dept. of Behav. and Biochem. Pharmacol., Astra Arcus AB, Preclinical R & D, S-151 85, Sodertalje, Sweden.

Agonists at 5-HT $_{1A}$ receptors inhibit the firing of serotonergic dorsal raphe (DR) neurons by an action on somatodendritic autoreceptors. Accordingly, 5-HT $_{1A}$ antagonists should shift rightward the dose-response curve for inhibition of firing by highly potent and efficacious agonists such as 8-OH-DPAT while having no effect, or a stimulatory effect, on DR neuronal firing when given alone. Single unit recording studies were undertaken in chloral hydrate-anesthetized rats to assess effects on DR cell firing of several putative 5-HT $_{1A}$ antagonists, including WAY 100635, NDL 249, and p-MPPI. As expected, pretreatment with a 10 μ g/kg i.v. dose of WAY 100635 or NDL 249 caused significant shifts to the right of the dose-response curve for 8-OH-DPAT (ED₅₀ for 8-OH-DPAT, 1.3±0.3 μg/kg; after WAY 100635, 16.9± 2.9 µg/kg; after NDL 249, 6.0±1.2 µg/kg). Surprisingly, however, i.v. administration of both WAY 100635 and NDL 249 alone caused dose-dependent and ultimately complete suppressions of DR cell firing (ED $_{50}$'s 0.6 \pm 0.2 and 0.7 \pm 0.3 μ mol/kg, respectively). It should be noted that the inhibition by these drugs was seen only at high doses (>0.1 µmol/kg), whereas 8-OH-DPAT inhibited firing at 100-fold lower doses. In contrast, a third putative antagonist, p-MPPI, produced no significant changes in DR cell firing even at high (equimolar) doses. To assess the mechanism of the inhibition by high doses of WAY 100635 and NDL 249, we attempted reversal with d-amphetamine (AMPH, 3.2 mg/kg i.v.). The inhibition by both drugs was readily reversed by AMPH, whereas effects of 8-OH-DPAT were not. These results suggest that the inhibitory effects may be due to α -blockade, rather than 5-HT_{1A} agonism, and support the view that these drugs act as "silent" 5-HT_{1A} antagonists. (Supported by Astra Arcus AB)

TERMINAL 5-HT AUTORECEPTOR DESENSITIZATION IN THE ORBITOFRONTAL CORTEX IS PRODUCED EXCLUSIVELY BY DRUGS EFFECTIVE IN OBSESSIVE COMPULSIVE DISORDER (OCD). V. G. Ducharme, C. Bouchard and P. Blier* Neurobiological Psychiatry Unit, McGill University, Montreal, Canada, H3A 1A1.

The only drugs so far demonstrated to be effective in the treatment of OCD are

The only drugs so far demonstrated to be effective in the treatment of OCD are the ones that potently block the 5-HT transporter. These 5-HT reuptake inhibitors (SRI) enhance 5-HT release in the hippocampus and the hypothalamus by desensitizing terminal 5-HT autoreceptors. However, PET scan studies in humans have previously implicated the orbitofrontal cortex (OFC) in the mediation of OCD symptoms. We have shown that, after 8 weeks of treatment with the SRI paroxetine at a high dose (10 mg/kg/day, s.c. using minipumps), the electrically evoked release of [3H]5-HT from guinea pig preloaded brain slices was enhanced and the sensitivity of the terminal 5-HT₁₀ autoreceptor was attenuated, but not after fluoxetine at a low dose (5 mg/kg/day). In order to investigate the efficacy of other antidepressant treatments to alter 5-HT release in OFC, further studies were performed in male Hartley guinea pigs. Superfusion experiments were carried out to assess the evoked release of [3H]5-HT from preloaded brain slices. There was a significant enhancement of [3H]5-HT release in the OFC after 8 weeks of treatment with a high dose of the SRI fluoxetine (10 mg/kg/day) and the sensitivity of the autoreceptor was attenuated. In contrast, the inhibitor of type A monoamine oxidase moclobemide administered for 8 weeks (10 mg/kg/day) did not alter terminal 5-HT₁₀ autoreceptor requires higher doses of SRI, as is often the case clinically in OCD. Electroconvulsive shock treatment and moclobemide, which are effective in OCD. Electroconvulsive shock treatment and moclobemide, which are effective in OCD. Electroconvulsive shock treatment and moclobemide, which are effective in OCD. Electroconvulsive shock treatment and moclobemide, which are effective in OCD. ELECTROPHYSIOLOGICAL EFFECT OF ALNESPIRONE (S-20499) ON RAT LOCUS COERULEUS NEURONS - COMPARISON WITH BUSPIRONE Schmitt P¹: Soulière F¹: Lesourd M²: Renaud B¹: Chouvet G¹ ¹ CJF INSERM 95-06 and Université Claude Bernard Lyon 1, 8 avenue Rockefeller, 69373 Lyon, France ²Institut de Recherches Internationales Servier, 6 place des Pléiades, 92415 Courbevoie Cedex, France

Alnespirone (S-20499), a new chroman derivative, is a selective 5HT_{1A} receptor agonist which displays a slight affinity for α_1 and α_2 receptors (ratio $K_{0.5}$ 5HT_{1A} - α_1/α_2 = 330). Pharmacological studies have shown its anxiolytic and antidepressant activity in several animal models following single or repeated intraperitoneal, scular, subcutaneous and oral administration. Since buspirone, a chemically related $5HT_{1A}$ agonist, is also known to display in vivo α_2 -adrenergic antagonist properties, in spite of its slight affinity for adrenergic receptors (ratio K_{0.5} 5HT_{1.4} $\alpha_1/\alpha_2 = 240$), we have compared the effects of alnespirone and buspirone on the spontaneous activity of locus coeruleus (LC) noradrenergic neurons, before or after administration of the α_2 -agonist clonidine. Extracellular recordings of LC neurons were performed on chloral hydrate-anesthetized rats with glass micropipettes (baseline = 1.9 ± 0.2 spikes/sec, n = 35) and were confirmed by subsequent histological analysis. Clonidine (40 µg/kg i.p.) induced a rapid inhibition of LC activity (100% inhibition in about 7 mn) that was reversed (92% recovery in 15 mn) by subsequent buspirone (10 mg/kg i.p.). In contrast, alnespirone (10 mg/kg i.p.) did not affect the typical and slow recovery to baseline activity after clonidine (17% recovery in 15 mn). On the other hand, clonidine-induced inhibition was prevented by prealable administration of buspirone (20% inhibition in 22 mn) but not alnespirone (100% inhibition in 7 mn, as in control group). These findings indicate that alnespirone, unlike buspirone, is devoid in vivo of significant α_2 -adrenergic properties. As already described, the α_2 -adrenergic antagonist properties of buspirone could be due to its main metabolite (1-PP), and such properties are clearly not shared by alnespirone or one of its metabolites.

525.4

EFFECT OF REPEATED VERSUS SUSTAINED ADMINISTRATION OF THE 5-HT, A AGONIST IPSAPIRONE: ELECTROPHYSIOLOGICAL STUDIES IN THE RAT HIPPOCAMPUS AND DORSAL RAPHE. J. Dong*, C. de Montigny and P. Blier. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada H3A 1A1.

The present study was aimed at examining the adaptation of presynaptic 5-HT_{1A} autoreceptors in the dorsal raphe (DR) and of postsynaptic 5-HT_{1A} receptors in the dorsal hippocampus (DH) during long-term administration of the 5-HT_{1A} agonist ipsapirone given either repeatedly or in a sustained fashion. Concurrent microiontophoretic application of ipsapirone did not attenuate the suppressant effect of 5-HT on 5-HT neurons but markedly decreased it when co-applied on CA_3 pyramidal neurons in the DH. Thus, ipsapirone acted as a full agonist in the DR and as a partial agonist in the DH. Ipsapirone (15 mg/kg/day, s.c. x 2 days) delivered by osmotic minipumps markedly decreased the firing activity of the DR 5-HT neurons. After 14 days of treatment, there was a complete recovery of their firing activity and a desensitization of their somatodendritic 5-HT $_{1A}$ autoreceptors, as assessed using microiontophoretic applications of 5-HT and 8-OH-DPAT onto 5-HT neurons. The same degree of desensitization was obtained when ipsapirone was given repeatedly (7.5 mg/kg b.i.d., s.c. x 14 days). In contrast, the two modalities of ipsapirone administration left unaltered the responsiveness of CA₃ pyramidal neurons to microiontophoretic application of 5-HT and 8-OH-DPAT. In conclusion, longterm administration of ipsapirone most likely increases 5-HT neurotransmission by enhancing the tonic activation of postsynaptic 5-HT_{1A} receptors. In addition, the use of sustained release 5-HT_{1A} agonists should not alter their therapeutic effectiveness in anxiety and affective disorders since the same effects on 5-HT_{1A} receptor functions were produced in this rat model by the sustained and the repeated modes of administration of ipsapirone

525.6

MODULATION OF GUINEA PIG DORSAL RAPHE CELL FIRING BY GR127935, A 5-HT_{1D} AUTORECEPTOR ANTAGONIST. <u>L. Reynolds*</u>. H. Rollema and J. Sprouse. Pfizer Central Research. Groton. CT 06340 USA

GR127935 is a selective antagonist of release-modulating 5-HT_{1D} autoreceptors on serotonergic terminals and as such would be expected to produce increases in extracellular 5-HT. The changes in 5-HT observed in guinea pig cortex are mixed, however (range = -65% to +65% relative to baseline, depending on investigator), possibly due to the presence of somatodendritic 5-HT _{ID} autoreceptors. Blockade of these autoreceptors elevates intra-raphe 5-HT which in turn activates somatodendritic 5-HT_{IA} autoreceptors and slows firing rate. The aim of the present study was to examine this mechanism by directly measuring changes in raphe cell firing following GR127935. In chloral hydrate anesthetized guinea pigs, dorsal raphe cell firing was unaffected by doses of GR127935 ranging from 20 to 20,000 µg/kg iv. 8-OH DPAT, in these and similar neurons, produced the robust dose-dependent inhibitory response expected of a 5-HT $_{1A}$ agonist (ED $_{50}$ = 3.1 µg/kg iv; n = 2-9 cells per dose). Increases in extracellular 5-HT resulting from re-uptake blockade also suppressed unit activity (fluoxetine $ED_{50} = 1.0 \text{ mg/kg i.v.}; n = 3-4 \text{ cells per dose}$). Curiously, lower doses of GR127935 (0.002 - 2 µg/kg iv) yielded highly variable responses with s cells displaying no effect and others a brief excitation followed by a slowly developing inhibition. The most effective dose in this case appeared to be 0.02 μ g/kg which produced an eventual 37 ± 17 % decrease in cell firing (n = 6), although this was not significantly different from baseline. The incomplete nature of this response suggests that (1) a competing receptor mechanism progressively limits the degree of inhibition produced by 5-HT $_{1D}$ autoreceptor blockade, completely overcoming it at higher doses and/or (2) the increase in extracellular 5-HT obtained through blockade of somatodendritic 5-HT_{ID} autoreceptors is insufficient to completely inhibit cell firing.

DIFFERENTIAL EFFECT OF THE 5-HT_{2C/2B} RECEPTOR ANTAGONIST SB 200646 AND THE SELECTIVE 5-HT_{2A} ANTAGONIST MDL 100907 ON MIDBRAIN DOPAMINE (DA) NEURONS IN RATS: AN ELECTROPHYSIOLOGICAL STUDY, 1.C.R. Ashby, Jr. and 2Y. Minabe. PHS Dept., St. John's University, 8000 Utopia Parkway, Jamaica, NY 11439; Ational Institute of Neuroscience, NCNP, Kodaira, Tokyo, 187, Japan.

In this study, we examined the effect of the acute and chronic administration of the 5-HT_{2B/2C} antagonist SB 200646 (SB) and the 5-HT_{2A} antagonist MDL 100907 (MDL) on the number, as well as the firing pattern, of spontaneously active DA neurons in the A9 and A10 areas. This was accomplished using the technique of extracellular single unit recording in anesthetized, male Sprague Dawley rats. Animals received either 1 injection (acute) or 1 injection daily for 21 days (chronic) of SB (10 or 20 mg/kg, i.p.) or MDL (0.01, 0.03 and 0.1 mg/kg, i.p.). Experiments were conducted two hours after the last injection. The acute administration of 0.1 mg/kg of MDL significantly increased the number of spontaneously active A9 and A10 DA cells. The i.v. administration of MDL had no significant effect on the firing rate or pattern of either A9 or A10 DA neurons. In contrast, the acute administration of 20 mg/kg of SB significantly increased the number of spontaneously active A10 DA neurons and i.v. SB significantly increased the firing rate and burst firing of A10 DA neurons. The chronic administration of MDL, at all doses, significantly decreased the number of A9 and A10 DA neurons and this effect was not reversed by 50 μ g/kg, i.v., of (+)apomorphine (APO). The chronic administration of 20 mg/kg of SB selectively decreased the number of spontaneously active A10 DA neurons and this effect was reversed by i.v. APO. These results indicate that the activity of midbrain DA neurons in rats is differentially regulated by the antagonism of 5-HT_{2A} compared to 5-HT_{2B/2C} receptors. Supported by NIMH R2952155-05.

Serotonergic amplification of apically-derived EPSPs in neocortical pyramidal cells via a persistent sodium current. G.J. Marek' and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale School of Medicine. New Haven. CT 06508.

Yaie School of Medicine, New Haven, CT 06508.

Active conductances are required for amplification of excitatory postsynaptic potentials (EPSPs) originating from distal apical dendrites of pyramidal cells. The purpose of the present experiments was to determine the effect of monoamines on amplification of EPSPs from the apical dendrites of pyramidal cells. Serotonin (6-HT) induced an increase in spontaneous PSPs in layer V pyramidals cells in many regions of the rat neocortex (e.g. prefrontal) that was blocked totally by the selective 5-HT_{2A} antagonist MDL 100,907 and the selective AMPA antagonist LY 293558, but not the GABA_A antagonist bicuculline. Under voltage clamp, 5-HT and norepinephrine increased excitatory postsynaptic currents (EPSCs) by 6-fold and 2-fold, respectively while dopamine was ineffective. Focal (microiontophoretic) application of 5-HT enhanced EPSCs from the apical, but not basilar dendrites. The 5-HT-elicited EPSCs were blocked by focal application of the Na* channel blocker tetrodoxtoxin (TTX) to the apical dendrites. The Na* channels required for the 5-HT-mediated increase in EPSCs were intrinsic to the pyramidal cells since intracellular application of the quaternary lidocaine derivative QX-314 resulted in a progressive but delayed block of 5-HT-elicited EPSCs. Finally, slow depolarizing voltage ramps in pyramidal cells showed that 5-HT could enhance amplification of EPSCs by increasing a TTX-sensitive non-inactivating or persistent TTX-sensitive non-inactivating or persistent TTX-sensitive non-inactivating or persistent TTX-sensitive non-inactivating or persistent TTX-sensitive non-inactivating are persistent TTX-sensitive non-inactivating are persistent TTX-sensitive non-inactivating are persistent Tax-activation of 5-HT_{2A} receptors, amplifies EPSPs/EPSCs from the apical dendritic field of neocortical layer V pyramidal cells by increasing a persistent Na* current. Protein kinase C-mediated enhancement of glycine response in rat sacral dorsal commissural neurons by serotonin. N. Akaike*, T. Xu, J. Nabekura. Dept. Physiol., Kyushu Univ. Fac. Med., Fukuoka 812-82, Japan

Modulatory effect of 5-HT on strychnine-sensitive glycine response (IGIv) was investigated in neurons acutely dissociated from rat sacral dorsal commissural nucleus (SDCN) using nystatin perforated patch recording under voltage-clamp. 5-HT potentiated 10-5M Gly-induced Cl⁻ current in a concentration-dependent manner without affecting the affinity of Gly to its receptor. α-Methyl-5-HT mimicked and ketanserine blocked the 5-HT action, indicating that the 5-HT₂ receptor mediated the enhancement. Phorbol and OAG potentiated I_{Gly}. The 5-HT in the presence of these PKC potentiators or chelerythrine failed to potentiate IGIv, suggesting an involvement of PKC in the pathway. This facilitation persisted in the pertussis toxin treatment for 6-8 hr. Neither PKA nor cAMP modulators had any effect on 5-HT potentiation of IGIv. The 5-HT facilitation of I_{Gly} remained even when [Ca²⁺]_i was chelated by BAPTA. In conclusion, the activation of 5-HT₂ receptor coupled to a pertussis toxin-insensitive G-protein increases intracellular DAG formation which increases Ca2+-independent PKC activity, resulting in the potentiation of the Gly response in the SDCN neurons. This potentiation might be one of analgesic mechanisms for nociceptive sensation in the spinal cord level.

5-HT_{1A} RECEPTORS: BINDING

526.1

PURINERGIC RECEPTOR-MEDIATED REGULATION OF 5-HT_{1A} RECEPTOR FUNCTION. K.J. Evans*, K.A. Berg. J.D. Cropper, W.P. Clarke. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284.

Previous work from our laboratory and others has demonstrated that 5-HT_{1A} receptor-mediated inhibition of forskolin-stimulated eAMP accumulation (FScA) in CHO cells is reduced by the phospholipase A₂-(PLA₂) arachidonic acid (AA) signaling cascade and by protein kinase C (PKC). CHO cells express naturally a purinergic receptor that couples to both phospholipase C (PLC) and PLA₂. However, activation of this purinergic receptor with ATP does not alter 5-HT_{1A}-mediated inhibition of FScA. In this study, we have investigated further the lack of effect of activation of the purinergic receptor on 5-HT_{1A} receptor function. In CHO cells expressing =140 fmol/mg of the human 5-HT_{1A} receptor function. In CHO cells expressing =140 fmol/mg of the human 5-HT_{1A} receptor function. In CHO cells expressing =140 fmol/mg of the human 5-HT_{1A} receptor function was evaluated by measuring inhibition of forskolin- (1 µM) stimulated cAMP accumulation after 15 min incubation with the selective 5-HT_{1A} agonist, dp-5-CT (10 nM; =ECS₉). Incubation with ATP (1 mM) did not alter inhibition of FScA by dp-5-CT (27% ± 6% vs 29% ± 5% in the absence and presence of ATP respectively, n=4). However, in calcium-free medium (where ATP-mediated AA release is abolished) incubation with ATP enhanced 5-HT_{1A} function by approx. 50% (from 424% ± 3% to 37% ± 5%, n=3). In calcium-free medium, neither ATP nor hapsigargin altered FScA while, interestingly, in calcium-containing medium ATP did not alter FScA, downregulation of PKC with 24 hr phorbol ester treatment, resulted in an ATP-mediated inhibition of FScA by 50%. These data suggest that the lack of ATP-mediated effect on 5-HT_{1A} receptor function is the result of opposing actions of stimulatory (intracellular calcium) and inhibitory (AA and possibly PKC) factors on the 5-HT_{1A} receptor system. (Supported by USPHS grants HD 26437 and MH 48125).

526.2

CORTICOSTERONE ALTERS 5-HT_{1A} RECEPTOR AND G PROTEIN MEDIATED RESPONSES IN THE HIPPOCAMPUS. <u>D.Y. Okuhara*, N.A. Muma and S.G. Beck</u> Loyola University Medical Center, Maywood IL 60153. Corticosterone (CT) alters the response elicited by the activation of

Corticosterone (CT) alters the response elicited by the activation of several neurotransmitter receptor systems, including receptors which are linked to G proteins. We investigated the effects of CT on the 5-HT concentration response curve for the 5-HT_{1A} receptor, the outward current evoked by the activation of G proteins in subfield CA3 and G protein protein levels in the hippocampus. Four treatment groups were used: ADX, bilateral adrenal-ectomy; ALD, ADX with an aldosterone minipump implant; HCT, ADX with 200 mg CT pellet implant and SHAM. All treatments were for 2 weeks. Discontinuous single electrode voltage clamp data were collected using standard intracellular recording techniques (n=14-16 cells for all treatments).

CT altered the characteristics of the 5-HT concentration response curve for the 5-HT $_{1x}$ receptor. The EC $_{50}$ value obtained from cells from HCT animals (15.1 \pm 5.5 uM, mean \pm SD) was less compared to ADX (10.0 \pm 3.5 uM). The Emax obtained from cells from HCT animals (360 \pm 116 pA) was smaller than cells from ADX (540 \pm 187 pA) animals. The magnitude of the current associated with the activation of G proteins with GTP $_{7}$ S was also modulated by CT. The amount of current required to voltage clamp the cell's membrane potential at -60 mV relative to it's RMP was smaller in cells from HCT animals when compared to ADX, ALD and SHAM, i.e., 46%, 34% and 22% respectively. Furthermore, the current in ADX cells was 30% higher than SHAM. In Western blot experiments, HCT increased the levels of G $_{5}$, G $_{182}$, and G $_{0}$ α -subunit levels when compared to SHAM. Based on these results, we conclude that high levels of CT decreases the maximal current elicited by the activation of the 5-HT $_{1x}$ receptor and this decrease maybe due to a decrease in the function of the G protein linked to the receptor. Supported by PHS NS28512, RSDA MH-00880, and Schmitt Foundation.

PEPTIDE MEDIATED UNCOUPLING OF THE HUMAN 5HT1A RECEPTOR. K.K. Parker*, N. Colson, M.-F. O'Connor, K. Hayataka, and J. Iverson. Dept. of Pharmaceutical Sciences, School of Pharmacy, University of Montana, Missoula, MT 59812-1075.

The human 5HTla receptor is a member of the G proteincoupled, 7-transmembrane segment receptor superfamily. A 15 amino acid peptide (15 MER) derived from the known sequence of the transmembrane segment 5 (TM5)/intracellular loop 3 (i3) region of the receptor has been synthesized by solid state methods. This peptide produces inhibition (non-competitive) of agonist binding in both solubilized and membrane-bound preparations of the receptor, obtained in these experiments from cultured, transfected Chinese Hamster Ovary (CHO) cells (gift of Dr. John Raymond, Duke U.). The IC50 for the inhibitory effect of the 15 MER is about 0.1 uM. The 15 MER is also active against the 5HTla receptor from rabbit brain. The bioactive peptide, bombesin, which has similar length but different sequence from the 15 MER, is inactive in agonist inhibition assays. Peptides from the N-terminal region of the i2 loop and from the C-terminal region of TM7 have also been characterized. These studies have been designed to better understand the biology of the SHTla receptor-G protein inter-face, and will be useful in elucidating the molecular pharmacology of the receptor-signal transduction boundary. Supported by the Montana Science and Technology Alliance, NSF-EPSCoR, and NIH RR10169.

AGONIST AND INVERSE AGONIST EFFICACY AT HUMAN (h) RECOMBINANT SEROTONIN (5-HT)_{1A} RECEPTORS AS A FUNCTION OF RECEPTOR G-PROTEIN STOICHIOMETRY. A. Newman-Tancredi*, C. Conte, C. Chaput, L. Verricte and M.J. Millan, 1.D.R.S., 125 Chemin de Ronde, 78290 Craics, France

Serotonin_{1A} receptor agonists such as buspirone act as partial agonists post-synaptically but as full agonists pre-synaptically. This may be due to differences in receptor reserve. We now report the effect of receptor:G-protein stoichiometry on efficacy. By growing a transfected CHO cell line in suspension or adherent conditions, we generated cultures which express either 1.6 pmol/mg or 5.5 pmol/mg of recombinant h5-HT_{1A} receptor, respectively, as determined by saturation binding with the selective antagonist, [3H]-4-(benzodioxan-5-yl)1-(indan-2-yl)piperazine ([³H]-S 15535¹). However, there was no change in the total number of G-proteins activated by the full agonist 5-HT (1.3 pmol/mg, measured by [35 S]-GTPyS saturation binding) providing preparations in which the receptor:G-protein ratio was \approx 1·1 (RGlow) or \approx 4 : 1 (RGhigh). Agonist efficacy was measured by stimulation of [35 S]-GTPyS binding². The E_{max} value for eltoprazine was 50 % at RGlow receptors but 100 % at RGhigh receptors, relative to 5-HT (=100%). In contrast, the neutral antagonist, WAY 100,635 (N-{2-}[4-(2-methoxyphenyl-)-1-piperazinyl-ghytly-N-(2-pyridinyl))-yclo-hexane-carboxamide), did not significantly alter [35 S]-GTPyS binding from basal levels in either preparation. The inverse agonist, spiperone, decreased basal [35 S]-GTPyS binding by only 12 % in RGlow membranes but by 26 % in RGligh membranes. In conclusion, an increase in receptor:G-protein ratios augments both agonist and inverse agonist efficacy at h5-HT_{1A} receptors.

CHARACTERIZATION OF BRAIN SEROTONIN 5-HT, A RECEPTORS USING A RADIOLABELED ANTAGONIST: COMPARISON WITH AGONIST RADIOLIGAND. M.T. Vilaró¹, J.F. López-Giménez¹, A. Raurich¹, J.M. Palacios², R. Cortés¹¹, and G.Mengod¹. ¹Dept. Neurochemistry, IIBB/CSIC, 08034 Barcelona, Spain.

5-HT_{1A} receptor (5-HT_{1A}R) belongs to the 5-HT₁ receptor family and has potential role as a therapeutic target for affective disorders such as anxiety and depression. The use of radiolabeled agonist compounds such as ³H-8-OH-DPAT for direct labeling of these receptors provides a partial view of the density and localization of these sites because they recognize only the high affinity state of receptors. The recent development of WAY 100635, a 5-HT_{1A}R antagonist, with an equal affinity for G proteincoupled and uncoupled forms of the receptor, provides a new tool to investigate these receptors in the mammalian brain. We have used 3H-WAY 100635 to characterize and visualize (using quantitative autoradiographic techniques) 5-HT_{1A}R in monkey brain. The binding of ³H-WAY 100635 was saturable, with comparable nanomolar affinity and with low non-specific binding in every monkey brain region examined. ³H-WAY 100635 binding was competitively blocked by co-incubation with both unlabeled agonists and antagonists of the 5-HT, AR. When compared with ³H-8-OH-DPAT binding, the density of sites labeled by the radiolabeled antagonist was considerable higher in all the regions examined. Different ratios between antagonist and agonist binding site densities were observed for some brain regions . We have compared the distribution of the binding sites with that of the mRNA coding for 5-HT_{1A} receptor and found a good correlation, confirming its somatodendritic localization.

ALNESPIRONE (S 20499) AND 8-OH-DPAT, TWO 5-HT_{1A} RECEPTOR AGONISTS, MODULATE THE IN VIVO STRIATAL D₁ AND D₂ SPECIFIC BINDING IN MICE - COMPARISON WITH BUSPIRONE P. Protais¹, M. Lesourd², E. Mocaër² and E. Comoy³ Laboratoires de Physiologie (VACOMED) et de Biochimie³, U.F.R. de Médecine-Pharmacie de Rouen, Institut de Recherches Internationales Servier², Courbevoie, France.

Alnespirone (S 20499) has previously been described as a potential anxiolytic drug through its agonist action at 5-HT $_{1A}$ receptors. Some data suggest that S 20499 could also be a weak D2 receptor agonist on the basis of its in vitro D2 affinity, prolactin release inhibition and yawning in rats. In order to test a possible interaction of S 20499 with DA receptors in vivo, we have studied the *in vivo* striatal [³H]-SCH 23390 (D₁ receptor ligand-4 μCi) and [³H]-raclopride (D₂ receptor ligand-4 μCi) binding in mice treated with intraperitoneal doses of S 20499. In the same mice, the levels of DA, 5-HT and their metabolites were measured by HPLC with electrochemistry detection. S 20499 decreased [3H]-SCH 23390 binding at 5,10 and 40 mg/kg, and increased [3H]-raclopride binding at 5 and 20 mg/kg. In these animals, the 5-HIAA/5-HT ratio was decreased at 5 - 40 mg/kg, whereas the HVA/DA ratio was unaffected at all the doses tested of S 20499. Similarly, 8-OH-DPAT decreased [²H]-SCH 23390 binding at 0.25, 1 and 4 mg/kg, and increased [²H]-raclopride binding at 1 and 4 mg/kg. All the tested doses of 8-OH-DPAT decreased the 5-HIAA/5-HT ratio but did not modify the HVA/DA ratio. In the same experimental conditions, buspirone (5 and 20 mg/kg) inhibited completely [³H]-raclopride, but not ³H]-SCH 23390 binding and increased the HVA/DA ratio, but did not modify the 5-HIAA/5-HT ratio. Apomorphine (3 mg/kg) decreased both in vivo striatal [H]-SCH 23390 and [H]-raclopride specific binding as well as striatal HVA/DA and 5 HIAA/5-HT ratios. These results indicate that S 20499 and 8-OH-DPAT do not seem to interact directly with DA receptors. In contrast, buspirone interacts directly with D2, but not D1, receptors.

IDENTIFICATION OF MULTIPLE FORMS OF THE 5-HT_{1A}
RECEPTOR USING STATE-DEPENDENT ANTIPEPTIDE
ANTIBODIES <u>T.E. Anthony and E.C. Azmitia</u> Department of Biology,
New York University, NY, NY 10003

Discrepancies in the immunohistochemical labeling obtained using several different antipeptide antibodies against the 5-HT_{1A} receptor led us to attempt characterization of these antibodies using western blotting to assess their specificity. The results of our characterization efforts have yielded useful insight into the properties of both the 5-HT_{1A} receptor and the antipeptide antibodies themselves.

Two of these polyclonal antibodies generated against peptides derived from the third intracellular loop of the protein (S1A-258 - amino acids 258-274; L_5B_7 - amino acids 243-268 (gift of Dr. Michel Hamon)) have been shown to be highly specific for the receptor when expressed in both HEK 293 cells and COS-1 cells. However, the receptor itself is processed differently in each cell type, being more heterogeneously glycosylated in HEK 293 cells. Furthermore, when expressed in Ltk-mouse fibroblasts (gift of Dr. Paul Albert), the main receptor band of 70 kDa is not recognized by the S1A-258 antibody, but is labeled by the L_8p, which yields a labeling pattern very similar to that seen in HEK 293 cells. Examination of lysates from undifferentiated RN46A immortalized raphe neurons (gift of Dr. Scott Whittemore) has shown additional forms of the receptor not seen in the above mentioned cell types. Interestingly, hippocampal membrane preparations from animals at different stages of development have also shown heterogeneity in the form of the receptor expressed, implying that the modifications observed in culture may play a role *in vivo*. This data may explain the observation that the signal transduction coupling of the receptor varies according to the cell type it is expressed in. (NIA #1 PO1 AG10208)

Identification of Regulatory Elements in the 5' Flanking Region of the Rat 5-HT1A Receptor Gene. John M. Storring. 1* Alain Charest², and Paul R. Albert. 3. Depts of Pharmacology 1 and Biochemistry 2, McGill University, Montreal Quebec H3G 1Y6 and Neuroscience Research Institute, University of Ottawa, Ottawa, Ontario, K1H 8M5 3.

Institute, University of Ottawa, Ottawa, Ontario, K1H 8M5 3.

We have cloned and sequenced 3.4 kb of the 5' flanking sequence of the rat 5-HT1A gene. This intronless region contains a number of DNA elements believed to be important in the regulation of transcription. These elements include two AP-1 sites, two SP-1 sites, and several TATAA and CCAAT motifs. Using RNAase protection and primer extension analysis a major transcription start site was detected in rat tissue at -967 bp from the initial ATG codon. DNAase protection analysis using nuclear extract prepared from 5-HT1A expressing rat RN46A cells demonstrates a 60 bp DNA footprint consistent with the binding of TATAA binding complex located immediately upstream of this start site. To assess promoter activity, a series of 5' flanking region/luciferase constructs has been prepared in the pGL-3 vectors (Promega). Using transient transfection, these constructs have been expressed in a variety of cell types which do (RN46A, SN48) and do not (Ltk-, COS 7, P19) express the 5-HT1A receptor. We have demonstrated that a non-specific promoter, active in all cell types, resides between -1378 bp and -972 bp of the initial ATG codon. A region located between -1378 bp and -1188 bp silences transcription in cell types which do not express the 5-HT1A receptor, but remains permissive for transcription in those cells which do express 5-HT1A. The basal promoter region contains typical TATAA and CCAAT boxes, while the silencer region contains a 52 bp poly GT repeat and an element which expresses 86% homology to the NRSE element known to silence the transcription of a number of neuron-specific genes in non-neural cell types. STRUCTURE-ACTIVITY RELATIONSHIPS OF A SERIES OF 5-HT $_{\rm LA}$ AGONISTS / D2 ANTAGONISTS: POTENTIAL ANTIPSYCHOTICS.

E.K. Moltzen, J. Perregaard, and J. Arnt*, Research Departments, H. Lundbeck A/S, Ottiliavej 9, DK-2500 Copenhagen-Valby, Denmark.

Traditional treatment of schizophrenia mainly involves use of more or less selective dopamine D₂ receptor antagonists. However, all these drugs induce severe extrapyramidal side effects (EPS). Recently it was shown that 5-HT_{1A} agonists are able to antagonize EPS induced by traditional neuroleptics in animal models. Compounds displaying both D₂ antagonism and 5-HT_{1A} agonism might thus have potential as a new type of atvpical neuroleptics.

During our work with a series of aryl piperazines and -piperidines exerting 5-HT $_{1A}$ affinity we discovered that certain structural modifications changed the pharmacological profile from selective 5-HT $_{1A}$ ligands to mixed 5-HT $_{1A}$ /D $_2$ ligands. This series of compounds are exemplified by 3-cyclohexyl-1-[4-(4-(2,2-dimethyldihydro-7-benzofuranyl)-1-piperidinyl)-1-butyl]imidazolidin-2-one (IC $_{50}$ (5-HT $_{1A}$) = 3.5 nM, IC $_{50}$ (D $_2$) = 8.0 nM) and 3-cyclohexyl-1-[4-(4-(2-isopropyloxyphenyl)-1-piperazi-nyl)-1-butyl]imidazolidin-2-one (IC $_{50}$ (5-HT $_{1A}$) = 1.8 nM, IC $_{50}$ (D $_2$) = 6.4 nM). A structuractivity study showed that the branched alkoxy group and a length of the chain connecting the imidazolidinone ring with the piperidine- or piperazine ring of at least four carbon atoms are crucial for affinity for D $_2$ receptors, whereas the 5-HT $_{1A}$

The 5-HT_{1A} efficacy is highly dependent on the 3-substituent in the imidazolidinone ring as well as chain length. Compounds with aromatic substituents and chain length of at least four carbon atoms display most potent 5-HT_{1A} agonistic effect as measured by the 8-OH-DPAT drug discrimination test.

AGONIST-PROMOTED DESENSITIZATION IN TWO NATURALLY-OCCURRING VARIANTS OF THE HUMAN 5-HYDROXYTRYPTAMINE_{1A} RECEPTOR. A. Rotondo, B. Nakhai, D. Goldman and D. A. Nielsen*. Laboratory of Neurogenetics, NIAAA, National Institutes of Health, Rockville, MD 20852.

We recently reported two naturally-occurring polymorphisms of the human 5-hydroxytryptamine] A (5-HT] A) receptor that resulted in substitutions of glycine to serine at amino acid 22 (gly→ser) and isoleucine to valine at amino acid 28 (ile→val) in the extracellular amino-terminal domain of the receptor. To study the pharmacological and functional properties of these variants, the wild type and each variant 5-HT] A receptor was stably expressed in CHO cells. Both the wild type 5-HT1A receptor and the variants gly→ser and ile→val displayed similar saturable high-affinity binding to the selective 5-HT1A agonist [³H]-8-CH-DPAT. Essentially identical pharmacological profiles in competition experiments with 8-OH-DPAT, serotonin and WAY-100478 were observed. Agonist-promoted down-regulation of receptor expression was tested by 24 h exposure to 100 μM 8-OH-DPAT (or 100 μM 5-HT). The wild type and the ile→val variant 5-HT]A receptors underwent a 62±2% and 57±8% reduction in receptor density, while the gly→ser variant underwent a 22±12% reduction. Pre-treatment for 24 h with 100 μM 5-HT diminished 5-HT induced inhibition of CAMP by 28±5% for the wild type and 19±7% for the ile→val variant, but only by 6±1% for the gly→ser variant.

Our results suggest that a mutation at amino acid 22 in the extracellular amino-terminus of the human 5-HT_{1A} receptor decreases agonist-promoted desensitization of receptor expression.

HIGH-AFFINITY SEROTONIN 5-HT_{1A} LIGANDS WITHIN A SERIES OF 6-SUBSTITUTED 1-INDANMETHYLAMINES. <u>I.Perregaard.* J.Arnt. C.Sanchez.</u> Research Departments, H.Lundbeck A/S, Ottiliavej 9, DK-2500 Copenhagen-Valby, Denmark

1-Indanmethylamines with a 6-hydroxy substituent are dopamine D₂ agonists. N,N-Dipropyl-6-hydroxyindanmethylamine binds to dopamine D2 receptors (IC50=11 nM, [3H]-N-0437) and induces contralateral circling behaviour in the Ungerstedt 6-OHDA model in the rat (ED50=0.32 µmol/kg, subcutaneously). Replacement of the phenolic OH group with 6-acylamino substituents eliminates dopaminergic activity. Instead very potent and selective 5-HT1A agonists are obtained. 6-Acetylamino- and 6formylamino-N,N-dipropylindanmethylamine bind with high affinity to 5-HT_{1A} receptors (IC50=0.89 nM and 4.1 nM, respectively, [3H]8-OH-DPAT). In vivo these derivatives are full agonists which induce 5-HT syndrome after low doses. Proper replacements of the propyl substituents reduce 5-HT_{1A} receptor efficacy and eliminate the 5-HT syndrome. 5-HT1A activity is retained in cyclic amine derivatives such as piperidino- and pyrrolidino compounds. Introduction of a 4-fluorophenyl substituent in the 4-position of the piperidine ring in piperidino derivatives results in combined affinities for both 5-HT_{1A} and 5-HT_{2A} receptors. Such compounds even antagonise the 5-HT syndrome induced by the 5-HT1A agonist 5-methoxy-N,Ndimethyltryptamine (5-MeODMT). Anxiolytic properties in isolation induced agression in mice and in footshock-induced ultrasonic vocalization in rats will be presented. Test results for buspirone and 8-OH DPAT will be shown for comparison.

526.12

EFFECTS OF AGONISTS AND ANTAGONISTS OF 5-HT_{1A} RECEPTORS ON BINDING OF [*S*]GTPy8 IN RAT HIPPOCAMPAL MEMBRANES. M.-P. Kung*, D. A. Stevenson, Z.-P. Zhuang and H. F. Kung, Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Kung*, D. A. Stevenson, Z.-P. Zhuang and H. F. Kung, Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Recently, several selective and potent ligands for labeling 5-HT₁, receptors, agonist (R)-8-OH-PIPAT and antagonists p-MPPF and p-MPPI, were reported (IPET 272:429-437, 1995, and Synapse, in press). To characterize further the agonist and antagonist activity of (R)-8-OH-PIPAT, p-MPPF and p-MPPI, the activation of 5-HT₁, receptors by agonists to promote guanine nucleotide exchange, using [¹⁸S]GTPγS binding, was evaluated in rat hippocampal membranes. Agonists, such as 5-HT, (R)-8-OH-DPAT, (R)-8-OH-PIPAT, 5-CT and DP-5-CT all stimulated [¹⁸S]GTPγS binding in a dose-dependent manner resulting a maximum of 65-100% increase over basal level. The potencies of agonist stimulation (pEC₃₀) are in good agreement with the pIC₃₀ binding affinities. Unexpectedly, the iodinated agonist, (R)-8-OH-PIPAT, unlike other agonists evaluated in this study, exhibits a [¹⁸S]GTPγS binding profile consistent with binding to multiple sites. These data suggest that different types of G-protein activation may be involved with different agonists. The stimulation of [¹⁸S]GTPγS binding by (R)-8-OH-DPAT can be antagonized by p-MPPI or p-MPPF (while tested alone did not affect the basal level binding of [¹⁸S] GTPγS). The 5-HT_{1A} agonist-stimulated binding is inhibited by Gpp(NH)p or GTPγS), but not by ATPγS. Homologous displacement by GTPγS of [¹⁸S]GTPγS binding to measure the maximal binding sites, which can be stimulated by (R)-8-OH-DPAT, resulted in a K_d of 2.71 ± 0.68 nM and a B_{max} of 93.7 ± 31.0 fmol/mg protein. Using [¹⁸S]GTPγS binding assay in native tissue preparations provides a useful system to investigate the pharmacology of agonists and antagonists of 5-HT₁, receptors. In addition, relative potency of agonists can be directly measured with this binding assay. (Supported by MH-48125 and NS-35120)

A MOLECULAR ANALYSIS OF THE STRUCTURAL REQUIREMENTS FOR INTERNALIZATION OF THE HUMAN 5-HT1a RECEPTOR N.M. Page., D. McNab and K. Shaw* School of Animal and Microbial Sciences, University of Reading and *Department of Physiology and Pharmacology, University of Southampton, UK

Pharmacology, University of Southampton, UK
The 5-HT1a receptor (5-HT1aR) undergoes desensitization in response to a 10 minute stimulation with its specific agonist, 8-hydroxy DPAT. In part, this response is characterized by a loss of high affinity binding sites, suggesting that the receptor may internalize. Residues within the 2nd and 3rd intracellular loops, carboxy terminal tail and 7th transmembrane domain of some G protein-coupled receptors (GPCRs) have been implicated in the internalization process. We have used a PCR-based strategy to (a) truncate the carboxy terminal tail after D406, (b) create two substitutions, Y399F or Y399A in the NPVIY motif in the 7th transmembrane domain and (c) create substitutions in 4 putative PKC phosphorylation recognition sequences. Moreover, in order to track the fate of internalized receptors by confocal microscopy, we have engineered an epitope tag (PPEPET) into the amino terminal sequence of the 5-HT1aR which may be recognized by the KT3 monoclonal antibody. In all cases, recombinant constructs have been used to stably transfect CHO-K1 cells. Receptor expression was confirmed by saturation binding analysis with [3H] 8-OH-DPAT. Brax values were in the range 250-500 fmol/mg protein. Agonist affinities for the mutant receptors did not significantly differ from the wild type receptor (Kd= approximately 2nM). Following confirmation of functional expression, this system will be used to assess the structural determinants for 5-HT1aR internalization. the Wellcome Trust (UK) is gratefully acknowledged.

CORTICOSTERONE ALTERS FUNCTIONAL AND BIOCHEMICAL PARAMETERS CHARACTERISTIC OF SEROTONERGIC NEURO-TRANSMISSION ASSOCIATED WITH 5-HT, RECEPTORS. A. Czyrak*, M. Bijak, K. Ťokarski, M. Mackowiak, K. Wędzony. Institute of Pharmacology, PAN, Krakow, 12 Smetna street, Poland.

In the present study we investigated the impact of repeated administration of corticosetrone (COR, 10 mg/kg, twice a day, for 7 days) on behavioral, electrophysiological and biochemical parameters characteristic of the 5-HT neurotransmission associated with 5-HT_{LA} receptors. It was found that COR attenuated the 8-OHDPAT evoked disruption of the prepulse-induced inhibition of acoustic startle response and decreased the 8-OHDPAT-induced inhibition of hippocampal CA1 neurons in vitro. Both those effects indicated that chronic COR decreased the functional responsiveness to stimulation of 5-HT_{LA} receptors. On the other hand, we observed that COR increased the number of 5-HT_{the} receptors in the hippocampus, prefrontal cortex and raphe nuclei, as measured by the autoradiographic and saturation binding studies ([°H]8-OHDPAT as a ligand). The hippocampal levels of 5-HT and 5-HIAA were also increased. It is concluded that chronic occupation of glucocorticosteroid receptors by COR attenuates the functional responsiveness to stimulation of 5-HT_{LA} receptors. In contrast to the effects observed in functional studies, the density of 5-HT_{LA} receptors is increased.

THE 5-HT_{1A} ANTAGONIST WAY-100635 INHIBITS 8-OH-DPAT INDUCED INCREASE IN ACTH, CORTICOSTERONE AND OXYTOCIN BUT NOT PROLACTIN A.Vicentic*, O.L.i. F.Garcia, W.Pinto, Y.Li. G.Battaglia and L.D.Van de Kar. Dept.Pharmacol. Loyola Univ.Chicago, Sch.Med., Maywood, II. 60153

The objective of the present study was to examine whether 5-HT_{1A} receptors are involved in the 8-OH-DPAT-induced secretion of ACTH, corticosterone oxytocin and prolactin. Male rats (N=8) received either saline or WAY-100635 (0.1, 1, and 10 mg/kg, sc), 1hr before sacrifice. Rats were challenged with saline or 8-OH-DPAT, (0.5 mg/kg, sc) 15 min before sacrifice. WAY-100635 at the dose of 0.1 mg/kg significantly inhibited the 8-OH-DPAT induced secretion of oxytocin but not corticosterone or ACTH. At the dose of 1 mg/kg WAY-100635 completely blocked the oxytocin response to 8-OH-DPAT and maximaly inhibited the ACTH and corticosterone responses to 8-OH-DPAT. For all three hormones, the 10 mg/kg dose of WAY-100635 produced the same maximum achieved at the 1 mg/kg dose. The lack of inhibition by WAY-100635 (0.1 mg/kg) of 8-OH-DPAT-induced elevation of ACTH and corticosterone suggests a greater receptor reserve for ACTH and corticosterone than for oxytocin. The basal levels of ACTH, corticosterone and oxytocin were not altered by any dose of WAY-100635. In contrast to the other hormones, the increase in prolactin by 8-OH-DPAT was not inhibited by any dose of WAY-100635. Surprisingly the highest dose of WAY-100635 (10 mg/kg) elevated basal prolactin levels. These data indicate that 8-OH-DPAT elevates oxytocin, ACTH and corticosterone levels via activation of 5-HT_{IA} receptors while prolactin secretion may be mediated via non 5-HT_{1A} receptors. (supported by USPHS NS34153 to LVdK).

RELATIVE IMPORTANCE OF 5-HT REUPTAKE INHIBITION AND 5-HT_{1A} AUTORECEPTOR BLOCKADE IN THE CITALOPRAM PLUS WAY100635-INDUCED ELEVATION OF EXTRACELLULAR 5-HT IN THE RAT BRAIN *IN VIVO.* S. Hjorth*, D. Westlin and H.J. Bengtsson. Inst. of Physiology & Pharmacology, Dept. of Pharmacology, Univ. of Göteborg, Medicinareg. 7, S-413 90 Göteborg, SWEDEN.

We, and others, have previously shown that blockade of release-inhibiting 5-HT $_{1A}$ autoreceptors augments the rise in extracellular 5-HT (5-HT $_{ec}$) caused by SSRI, like e.g. citalopram. This study assessed the relative importance of 5-HT reuptake inhibition vs. 5-HT $_{1A}$ autoreceptor blockade in this interaction. Citalopram (CIT; 0.5 or 5.0 mg/kg SC) and the selective 5-HT $_{1A}$ receptor blocker WAY100635 (WAY; 0.01-0.3 mg/kg SC) were given in different combinations, and 5-HT $_{ec}$ in the ventral hippocampus was sampled by in vivo microdialysis. CIT induced a dose-dependent rise in 5-HT $_{ec}$, maximally doubling the initial baseline values within 60 min after injection. Subsequent administration of WAY further augmented, in a dose-dependent manner, the high-dose CIT response (to \approx 4-5 x the pre-CIT baseline); in this regard, the 0.03, 0.1 and 0.3 mg/kg doses were all similarly effective. For comparison, the low-dose CIT response was but mildly, but not significantly, potentiated by WAY (0.3 mg/kg). WAY given alone did not alter 5-HT $_{ec}$. The data agree with previous findings that 5-HT $_{1A}$ autoreceptor blockade reverses the SSRI-induced release suppression, thereby further elevating 5-HT $_{ec}$. In addition, adequate 5-HT reuptake blockade appears to be the primary prerequisite for this interaction to occur. New drugs and/or treatment regimes based on the SSRI/5-HT $_{1A}$ autoreceptor blocker concept should thus emphasize the former property.

TIME-COURSE OF FLUOXETINE AND PAROXETINE DESENSITIZATION OF HYPOTHALAMIC 5-HT_{1A} RECEPTORS: REDUCED NEUROENDOCRINE RESPONSES TO 8-OH-DPAT AND REDUCED LEVELS OF G₁ AND G₂ PROTEINS. O. Li*, N.A. Muma, G. Battaglia and L. D. Van de Kar. Dept. Pharmacol. Sch. Med., Loyola Univ. Chicago, 2160 S. 1st. Ave. Maywood , IL. 60153

The aim of the study was to examine the time-course of desensitization of hypothalamic 5-HT_{1A} receptors induced by 5-HT uptake blockers. Rats were injected daily with the 5-HT uptake blockers fluoxetine (10 mg/kg, ip for 0, 3, 7, 14 or 22 days) or paroxetine (10 mg/kg, ip for 0, 1, 3, 7 or 14 days). Daily injections of either fluoxetine or paroxetine gradually decreased the ACTH, corticosterone and oxytocin responses to 8-OH-DPAT. A partial reduction of the hormone responses to 8-OH-DPAT occurred after 3 days and a maximum inhibition occurred after 14 daily injections of both 5-HT uptake blockers. To determine the mechanism of the desensitization, we examined the effects of the 5-HT uptake blockers on the density of 5-HT_{1A} receptors and their signal transduction system. Autoradiography of ³H-8-OH-DPAT binding revealed that neither fluoxetine nor paroxetine changed the density of 5-HT_{1A} receptors in the hypothalamus or other brain regions at any treatment time. Furthermore, Gpp(NH)pinduced inhibition of ³H-8-OH-DPAT binding was not altered by repeated injections of fluoxetine in any nuclei of the hypothalamus or other brain regions. We further determined the levels of G_i and G_o proteins in the hypothalamus, midbrain and frontal cortex using immunoblots. The hypothalamic levels of G_{i1} and G_{i3} proteins were significantly reduced after 7 and 14 days of fluoxetine injections (the paroxetine data will be shown at the meeting). The time-course of the G protein reduction is similar to the time-course of fluoxetine-induced reduction in hormone responses to 8-OH-DPAT. The levels of Go and Go proteins in the midbrain were significantly decreased after 3 days of fluoxetine injections and remained low until 22 days. Fluoxetine did not change the levels of G_i and G_o proteins in the frontal cortex. In conclusion, repeated injections of 5-HT uptake blockers produce a delayed and gradual desensitization of hypothalamic 5- HT_{1A} receptors, which may in part be due to a decrease in the G_{i1} and G_{i3} protein levels. (Supported by NS34153)

527.4

EFFECT OF ESTROGEN ON SEROTONIN TURNOVER AND THE REDUCTION IN SEROTONIN TURNOVER IN RESPONSE TO 8-OH-DPAT W. P. Clarke & R.J. Thiclen Department of Pharmacol egy University of Texas Health Science Center at San Antonio, San Antonio, Texas 78284.

It was previously reported that estrogen enhances the response of 5-HT $_{1A}$ receptors in hippocampal slices from female rats. A recent report also suggests the reduction in hypothalamic 5-HT turnover in response to 8-OH-DPAT varies with the stage of the estrous cycle. The purpose of the present study was to examine the effect of estrogen on 5-HT turnover in a region containing 5-HT cell bodies and in some areas receiving 5-HT projections. Female rats were ovariectomized and two weeks later sitastic capsules containing cholesterol (CHOL) or 10% estradiol-17 β in cholesterol (EST) were implanted subcutaneously into each rat. Five days later, rats were treated with 0.17 mg/kg, 8-OH-DPAT (DPAT) or saline (SAL) and decapitated 60 min later. The frontal cortex (FCX), anterior striatum (STR), nucleus accumbens (ACB) and a section containing the dorsal raphe (DRN) were majorly dissected on ice and stored at -70 °C. 5-HT and 5-HJAA contents were measured by HPLC with electrochemical detection, and their ratio was used as an index of the turnover of 5-HT. Turnover of 5-HT in rats receiving SAL was significantly increased in EST compared with CHOL treated rats in the DRN (1.12 ± 0.01 , EST; 1.02 ± 0.02 CHOL) and FCX (0.71 ± 0.01 , EST; 0.80 ± 0.03 , CHOL). Similar increases were seen in the ACB and STR, but these did not reach significance. Treatment with DPAT reduced 5-HT turnover in all the brain regions examined; however, the magnitude of the reduction in turnover induced by DPAT was significantly increased in the DRN (3.0.8 \pm 1.7% vs. 20.0 \pm 3.7%) and ACB (43.7 \pm 4.2% vs. 27.8 \pm 3.9%) of EST compared to CHOL treated rats, respectively. No differences were found in the STR or FCX. These data suggest that EST treatment may selectively enhance somatodendritic 5-HT]A autoreceptor responses to DPAT in the DRN.

527.6

IMMUNOCYTOCHEMICAL LOCALIZATION OF THE 5-HT1A RECEPTOR TO SEROTONIN AND NON-SEROTONERGIC NEURONS IN RAT BRAINSTEM RAPHE NUCLEI. T. D. Patel* and F. C. Zhou. Program in Medical Neurobiology and Department of Anatomy. Indiana Univ. Sch. of Med., Indianapolis, IN 46202. Receptor autoradiography studies reveal a high density of 5-HT1A binding sites in the raphe nuclei. Functional studies demonstrate that these 5-HT1A receptors are

the raphe nuclei. Functional studies demonstrate that these 5-HT1A receptors are "somatodendritic" autoreceptors. However, to date, there is no direct visual evidence confirming localization of the 5-HT1A receptor protein to 5-HT neurons. We used double label immunocytochemistry (ICC) to examine the neurotransmitter profile of raphe 5-HT1A-immunopositive cells. For 5-HT1A ICC, polyclonal antisera was generated against a fusion protein containing a portion of the amino acid sequence of the third cytoplasmic loop of the rat 5-HT1A receptor protein. The distribution in rat brain obtained by ICC with this antibody correlates well with the binding site distribution from receptor autoradiography using [3H]-8-OH-DPAT. Specifically, in the hippocampus, the laminar receptor distribution pattern from ICC and receptor autoradiography are superimposable.

In the raphe nuclei, cell body 5-HT1A immunoreactivity (5-HT1A-IR) was

In the raphe nuclei, cell body 5-HT1A immunoreactivity (5-HT1A-IR) was localized at the periphery in a patchy perisomatic fashion with little cytoplasmic staining, and immunoreactive proximal dendritic branches could be visualized extending for some distance. Dense, fiber-like 5-HT1A-IR was also found, especially in the dorsal raphe nucleus. In double labeled sections, we found that most but not all 5-HT and 5-HT1A coregistered. Some 5-HT positive neurons did not exhibit 5-HT1A-IR. It is not clear if these cells were understained for 5-HT1A or whether 5-HT1A was localized on more distal dendritic processes of these 5-HT positive cells. Finally, some scattered 5-HT negative cells exhibited 5-HT1A-IR, suggesting that non-serotonergic raphe neurons might also express functional 5-HT1A receptors. The neurotransmitter profile of these cells is currently under examination.

NEUROCHEMICAL PROFILE OF THE SELECTIVE 5-HT1A RECEPTOR (±)5-ME-8-OH-DPAT AND ITS ISOMERS: AN IN VIVO MICRODIALYSIS STUDY. A-C Trillat 1*. I. Malagié¹. M. Langlois². M. Mathé-Allainmat². B. Brémon². C. Jacquot¹ and A.M. Gardier¹. 1-Lab. Neuropharmacol. JE DRED 92-372. 2-BIOCIS URA CNRS 1843. Fac. Pharmacie, Univ. Paris-Sud, 92296 Châtenay-Malabry. France.

Numerous selective 5-HT₁A receptor ligands have been described as being either full or partial agonists at the 5-HT₁A receptor site in the brain. Few reports described highly selective and silent (compound having no intrinsic activity) 5-HT₁A receptor antagonists making extremely difficult to perform the pharmacological characterization of the 5-HT₁A receptor and its involvement in various pathologies and behavior. A new 8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT, the 5-HT₁A reference agonist) derivative compound, the racemic mixture (±) 5-Me-8-OH-DPAT was synthetized (Langlois et al., BioMed. Chem. Lett. 3 (1993) 2035-2038), then separated in (-) and (+) isomers that all have a high affinity for 5-HT₁A receptors (ki (nM): 6.5; 39.2 and 28.9, respectively). Here, we studied the effects of these compounds at the somatodendritic 5-HT₁A receptors by using in vivo microdialysis in freely-moving rats to measure serotonin (5-hydroxytryptamine, 5-HT) release at nerve terminals located in the ventral hippocampus (vHi) (±) 5-Me-8-OH-DPAT, (-) and (+) isomers (all being subcutaneously administered at a 10 mg/kg dose) had no significant effect on extracellular 5-HT levels in vHi suggesting that they are devoid of 5-HT₁A receptor agonist properties on this test. Conversely, 8-OH-DPAT (0.1 mg/kg s.c.) significantly decreased hippocampal 5-HT. Pretreatment with either (±) 5-Me-8-OH-DPAT or (-) 5-Me-8-OH-DPAT suggesting that these compounds have antagonistic properties at somatodendritic 5-HT₁A autoreceptors. A dose-dependant effect of (·) 5-Me-8-OH-DPAT is a silent and selective receptor antagonist at the somatodendritic 5-HT₁A receptor with activity residing in the (-) enantiomer. (-) 5-Me-8-OH-DPAT is likely to be a useful tool to further investigate the 5-HT₁A receptor function.

CHRONIC ANTIDEPRESSANT ALTERATION OF AGING HIPPOCAMPAL SEROTONIN TRANSPORTER AND RECEPTORS. J.E. Smith*, B.J. Keek, P. Deshmukh, and J.M. Lakoski. Departments of Pharmacology and Anesthesia, Pennsylvania State University College of Medicine, Hershey, PA 17033.

State University College of Medicine, Hershey, PA 17033.

The clinical efficacy of antidepressants is, in part, mediated by ability to bind to the serotonin transporter (5-HTT). While the mechanism of action of antidepressants is presumed to be the same for all ages, the consequences of age-related changes in the 5-HTT are not yet fully understood. Alterations in presynaptic serotonergic transporter (5-HTT) function in the aging hippocampus were studied using electrophysiological techniques to evaluate the sensitivity of pyramidal neurons to serotonin (5-HT) after chronic exposure to antidepressants selective for the 5-HTT. Localization of the hippocampal 5-HTT and 5-HTT_{La} receptors following chronic antidepressant administration was determined using quantitative autoradiographic techniques.

Female Fischer 344 rats ages 3-8, 11-12, 17-22 and >24 mo were injected (10mg/kg/day x 14 days, i.p.) with duloxetine, fluoxetine, desipramine, or vehicle control. After a 24 hr washout, extracellular recordings were performed using an *in vivo* chloral hydrate anesthetized preparation and drug solutions (0.01-0.04 M, pH 5 0-6.0) of 5-HT, fluoxetine, desipramine, and duloxetine were microiontophoretically applied to hippocampal pyramidal neurons in CAI and CA3 subfields. Chronic vehicle treatment did not alter the electrophysiological profile of hippocampal pyramidal neurons. Following chronic duloxetine administration, a decrease in sensitivity (87.7% of IT₅₀ value) of hippocampal neurons to 5-HT was noted in the 17-22 mo group as compared to the age-matched vehicle group. [H]Paroxetine and [H]B-OH-DPAT were used to label 5-HTT and 5-HT_{1x} sites, respectively, and comparisons across age and drug treatment investigated autoradiographic localization of presynaptic and postsynaptic receptors in the hippocampus. Changes in the density of these 5-HT sites may underlie the age-related decrease in sensitivity to 5-HT observed using electrophysiological techniques.

observed using electrophysiological techniques.

EFFECTS OF CHRONIC INTERFERON ADMINISTRATION ON SEROTONERGIC RECEPTORS IN RAT BRAIN S. Abe¹, T. Hori¹*, A. Baba¹, T. Suzuki¹, H. Shiraishi¹ And T. Yamamoto²¹ Dept. of Psychiat., The Univ. of Tsukuba, Ibaraki, 305,Japan ²Lab. of Mol. Recog., Yokohama City Univ.,Kanagawa

Interferon (IFN) has been reported to cause depressive state. Serotonin (5-HT) plays a key role in the pathophysiology of affective disorders, however, the mechanism IFN produces depressive state is not clear. In this study,we investigated effects of chronic IFN (recombinant human IFN- α A/D) administration on 5-HT receptors in rat brain using a radioreceptor assay.IFN was injected for 2 weeks at a dose(100,000 I.U./kg, i.p.,daily) in male Wistar rats.Membrane preparations of individual cortices and hippocampi were prepared.

IFN failed to alter binding of [3 H]ketanserin (5 -HT $_{2A}$ receptor) and [3 H] paroxetine binding (5 -HT transporter). The Scatchard plots of [3 H]8-OH-DPAT binding (5 -HT $_{1A}$ receptor) to rat cortical and hippocampal membranes were curvilinear, which suggested the presence of high- and low-affinity sites. IFN significantly increased both Kd and Bmax values of [3 H]8-OH-DPAT binding to cortical membranes at low-affinity site, but not at the high-affinity site. These results suggest the possibility IFN affects low-affinity site of 5 -HT $_{1A}$. (Supported by a grant from Univ. of Tsukuba Res. Project.)

EVIDENCE FOR FUNCTIONAL PLASTICITY OF MOTONEURON 5-HT_{1A} RECEPTORS AFTER 5,7-DHT LESION, N.M. Kheck^{1*}, P.J. Gannon², B.L. Jacobs³, T.E. Anthony¹ and E.C. Azmitia¹ ¹Dept. of Biology, New York Univ., NY WY 10029; ²Dept. of Otolaryngology, Mt. Sinai Sch. Med., NY, NY 10029; ³Prg. Neuroscience, Princeton University, Princeton, NJ 08544

The "5-HT syndrome" was used to characterize the functional plasticity of putative motoneuron 5-HT_{1A} receptor populations in response to selective serotonergic spinal denervation. We used the 5-HT_{1A} receptor agonist 8-OH-DPAT to induce the 5-HT syndrome, a motor behavioral paradigm which results from serotonergic facilitation of brainstem and spinal motoneuron activity. This model provides a measure of postsynaptic 5-HT_{1A} receptor activation. We have previously reported the localization of 5-HT_{1A} receptors on motoneurons using antipeptide antibodies directed against several epitopes. Rats (n=21) were injected with 8-OH-DPAT (1mg/kg, s.c.), or saline (n=8) and assessed for components of the 5-HT syndrome by three observers. Seven days later, following pretreatment with desimipramine (25 mg/kg, i.p.), rats were lesioned by stereotaxic injection of 5,7-DHT (100 µg of free base in 10 µl vehicle; 0.2% ascorbic saline) into the cisterna magna, at 1 µl/minute. At 11 and 14 days postlesion, rats were again rated (under double-blind condition) for the 5-HT syndrome after injection of 8-OH-DPAT. We observed a marked enhancement of motor parameters, suggesting an upregulation of postsynaptic 5-HT_{1A} receptor activity (denervation supersensitivity). Significant increases were noted in: tremor (84%), hindlimb abduction (73%), Straub tail (45%), reciprocal forepaw treading (27%), and flattened head/body posture (38%). The magnitude of spinal 5-HT lesion was determined by ³H-paroxetine binding (which demonstrated >90% loss of 5-HT terminals). We are currently analyzing the anatomical changes in 5-HT_{1A} receptor-IR in spinal cord sections at 14 days after 5,7 DHT lesion. The behavioral data will be correlated to these postlesion regulatory changes in 5-HT_{1A} receptor expression in spinal motor nuclei. (Research supported by NIA AG 10208)

REGION-DEPENDENT RECOVERY OF SEROTONIN 5-HT_{1A} RECEPTORS FOLLOWING INACTIVATION BY EEDQ. <u>B.J. Keck* and J.M. Lakoski</u>. Depts. Pharmacology & Anesthesia, Penn State Univ. Coll. of Med., Hershey, PA 17033.

The neurotoxin EEDQ (N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline) was used to irreversibly inactivate serotonin 5-HT_{1A} receptors in the hippocampus and frontal cortex to investigate region specific characteristics of receptor turnover. Adult male Sprague-Dawley rats (530-1070 g) were treated with EEDQ (6 mg/kg, s.c.) or vehicle (ETOH/propylene glycol/H₂O, 1:1:2, s.c.) and sacrificed at 1, 2 or 8 days following injection in order to evaluate the time-course of recovery for 5-HT_{1A} receptors. Scatchard analyses using ['H]8-OH-DPAT were conducted and receptor turnover parameters (rate of receptor synthesis, r; degradation rate constant, k; and receptor half-life, T_{l/2}) were detrmined for each brain region.

EEDQ-dependent decreases in 5-HT $_{1A}$ receptor density were observed at day 1 for the hippocampus (88%) and frontal cortex (55%) compared to vehicle-controls; complete recovery (94%) of the receptor density occurred by day 8 in the hippocampus, but not frontal cortex (73% recovery). The rate of 5-HT $_{1A}$ receptor synthesis was greater for hippocampus (r = 36.4 fmol/mg protein/day) than for frontal cortex (r = 4.2 fmol/mg protein/day), and receptor degradation rate constants (k) and half-life values ($T_{1/2}$) were also different for these brain regions (k = 0.38 day $^{-1}$ and k = 0.09 day $^{-1}$, respectively; $T_{1/2}$ = 1.8 days and $T_{1/2}$ = 7.7 days, respectively). Affinity of the 5-HT $_{1A}$ receptor was decreased following EEDQ treatment in the frontal cortex at day 1 (5.5-fold decrease) but returned to the vehicle-control value by day 8. No change was observed in the K_D values for 5-HT $_{1A}$ hippocampal receptors subsequent to EEDQ administration at any time point. Overall, these data revealed region-dependent differences in 5-HT $_{1A}$ receptor turnover properties following EEDQ administration. Studies of regional differences in 5-HT $_{1A}$ receptor turnover as a function of age. Pub No, 55d supported by POI AG 10514 (JML), F32 AG 05728-01 and T32 DA 07277-05 (BJK).

THE (S)-UH-301 INDUCED INHIBITION OF RAT BRAIN SEROTONIN AND DOPAMINE SYNTHESES DO NOT SEEM TO BE MEDIATED BY 5-HT i, RECEPTORS. H. Yu*, B. Backlund Höök, U. Hacksell and T. Lewander, Department of Psychiatry (Ulleråker), S-750 17 and Department of Organic Pharmaceutical Chemistry, Uppsala University, S-751 23 Uppsala, Sweden

Organic Pharmaceutical Chemistry, Uppsala University, S-751 23 Uppsala, Sweden (R)-8-Hydroxy-2-(di-n-propylamino)tetralin mmol/kg, s.c.), a 5-HT_{1A} agonist, induces a decrease in 5-HT (5-hydroxytryptamine) synthesis, measured as a decrease in 5-HT (5-hydroxytryptamine) synthesis, measured as a decrease in the 5-hydroxytryptophan accumulation after inhibition of aromatic amino acid decarboxylase, and 5-HT turnover, measured as the ratio of 5-hydroxytryptophan accumulation after inhibition of aromatic amino acid decarboxylase, and 5-HT turnover, measured as the ratio of 5-HT turnover. (S)-UF-301 (N-UF-301), a 5-HT_{1A} receptor antagonist, dose-dependently (10 - 100 mmol/kg, s.c.) blocked the reduction of 5-HT turnover induced by (R)-8-OH-DPAT (10 mmol/kg, s.c.), However, (S)-UH-301 only partially antagonised the decrease in 5-HT synthesis in the hippocampus after (R)-8-OH-DPAT, indicating that (S)-UH-301 might be a partial 5-HT_{1A} agonist. The decrease in 5-HT synthesis in the hippocampus after (R)-8-OH-DPAT, indicating that (S)-UH-301 might be a partial 5-HT_{1A} agonist. The decrease in 5-HT synthesis after (R)-8-OH-DPAT was completely antagonised in both brain regions by pretreatment with WAY-100635 (D.S mmol/kg, s.c.), a new selective 5-HT_{1A} receptor antagonist. However, WAY-100635 had no effect on the (S)-UH-301 (64 mmol/kg, s.c.) induced decrease in 5-HT synthesis in the hippocampus. In addition, WAY-100635 did not antagonise the previously reported (S)-UH-301 inhibits 5-HT synthesis in the britatum of dopamine synthesis in the striatum by mechanisms that do not seem to be mediated by 5-HT _{IA} receptors. Supported by the Swedish Board for Technical and Industrial development.

AUGMENTATION OF THE ANTIDEPRESSANT ACTION OF SSRIS BY PINDOLOL MAY NOT BE EXPLAINED BY 5-HT1A RECEPTOR ANTAGONISM H.C. Jackson, K.N. Hewitt, L.J. Hutchins, S.C. Cheetham and D.J. Heal (SPON: Brain Research Association) Knoll Pharmaceuticals Research & Development, Nottingham, NG2 3AA, U.K.

Pindolol induces a dramatic and rapid improvement in the antidepressant efficacy of SSRIs - a response which has been explained by selective antagonism of 5-HT1A somatodendritic autoreceptors (Artigas et al., 1994, Arch. Gen. Psych. 51, 248-251; Blier & Bergeron, 1995, J. Clin. Psychopharm. 15, 217-222). This study compares the effects of combinations of pindolol (0.3-6 mg/kg ip) and fluoxetine (1-30 mg/kg ip) in the Porsoit test (PS) - an animal model of depression. The 5-HT1A receptor antagonist WAY100635 (0.03-1 mg/kg sc) was used for comparison. Male CD1 mice (20-30g; n=10-20) were injected with drug and 60 min later placed in water for 6 min. Mobility was measured using a Doppler recording system. Mobility scores of mice given pindolol (1 mg/kg) plus fluoxetine (10 mg/kg) were significantly greater than those of mice given vehicle, fluoxetine or pindolol. However, there was no evidence that WAY100635 potentiated the effects of fluoxetine in the PS. WAY100635 reversed the increase in mobility induced by 8-OH-DPAT confirming its antagonist action at post-synaptic 5-HT1A receptors. Furthermore, WAY100635 significantly increased 5-HTP levels in mouse brain demonstrating antagonism of pre-synaptic 5-HT1A receptors. In contrast, pindolol did not block the 8-OH-DPAT response in the PS and had no effect on 5-HTP levels. These results, highlighting important differences in the pharmacological actions of pindolol and WAY100635, show that 5-HT1A receptor antagonism cannot explain pindolol's potentiation of the effects of fluoxetine in the PS and may not account for its augmentation of the antidepressant actions of SSRIs in man. One alternative explanation is that pindolol is a partial agonist at 5-HT1A receptors. In this context, pindolol (6 mg/kg) increased mobility in the PS in comparison to WAY100635 which was inactive at all doses tested.

LACK OF LONG-TERM EFFECTS OF ALNESPIRONE (\$ 20499) AFTER CHRONIC TREATMENT IN RATS. C. Munoz¹, C. Duyckaerts², M. Lupart¹, M.C. Rettori^{3*}, M. Lesourd³, Biologie Servier, 905 route de Saran, Gidy, France. ²Laboratoire de Neuropathologie, Hopital de la Salpetrière, Paris, France. ³Institut de Recherches Internationales Servier, Courbevoie, France

Alnespirone (S 20499), a new chroman derivative, is a selective pre- and postsynaptic 5HT_{IA} receptor agonist. It displays anxiolytic and antidepressive activities in rats. Since this drug is intended for long-term treatment in humans, we have searched for possible central effects on the serotonergic system. Male Wistar rats were treated by repeated oral dose (100 mg.kg-1.j-1) for 13 weeks, control rats having received the vehicle. The assessment was carried out using a first-tier screen, consisting in a functional observational battery (FOB) and an automated test of motor activity (Figure 8-maze), a measure of glial fibrillary acidic protein (GFAP) in different brain areas and histology for neuronal density (Dirichlet tessellation). No significant difference was observed between the treated and control rats in any of the behavioral tests related to different functional domains of the central and autonomic nervous system and motor activity (horizontal activity and rearings). The treatment did not modify GFAP levels in any tested areas of the brain, particularly in the mesencephalon (dorsal raphe nucleus), hippocampus and cortex, the main pharmacological targets of S 20499. The light microscopic examination of the brain did not reveal any apparent cellular loss and the total number of neurons was not modified in the dorsal raphe nucleus, the major site of action of S 20499. In conclusion, S 20499 did not show any deleterious central effect in rats after chronic

527.17

DIFFERENT RESPONSE TO ANTIDEPRESSANTS ON DRL 72-S IN HOLTZMAN AND HARLAN SPRAGUE-DAWLEY RATS: A NEW APPROACH TO TREATMENT RESISTANT DEPRESSION?

L.S. Seiden*, M. Balcells-Olivero, J. Richards and G. Vosmer. University of Chicago, Department of Pharm/Phys Sci., Chicago, II. 60637

Several antidepressant-like compounds were tested on the Differential-Reinforcement-of-Low-Rate 72-Second (DRL 72-s) schedule, a widely used behavioral screen to determine putative antidepressants. Two outbred stocks of rats, Harlan Sprague Dawley (Hsd:SpragueDawley^R SD^R) and Holtzman (HsdHot: Holtzman SDR) were trained. A dose-response determination for the tricyclic antidepressant imipramine, the 5-HT2 antagonist ketanserin, the β agonist clembuterol and the 5-HT1A agonist 8-OH-DPAT was assessed in both stocks. The two stocks of rats differed in baseline performance on the DRL 72-s schedule. Harlan rats obtained more reinforcements per hour and showed lower response rate than Holtzman rats. In Holtzman rats, imipramine, ketanserin and clembuterol had an antidepressant-like effect on the DRL 72-s schedule (increase number of reinforcements with little change in response rate) confirming previous studies However, in Harlan rats, these drugs did not show an antidepressant-like effect. These compounds disrupted the DRL 72-s performance at low doses and did not increase the number of reinforcements over baseline as seen in Holtzman rats. 8-OH-DPAT had no significant antidepressant effect on Holtzman or Harlan rats Difference in tissue levels of NE, DA and 5HT in different brain regions were also found between both stocks of rats. The present results suggest that behavior response to DRL 72-s as well as response to different antidepressants may be genetically mediated. Since the Harlan rats did not show an antidepressant-like response to any drugs tested, this difference between the stocks may be useful in exploring the genetic bases of treatment resistant depression which does not respond to common antidepressant drugs. SYSTEMIC ADMINISTRATION OF THE 5-HT1A ANTAGONIST p-MPPF ENHANCES THE EFFECT OF FLUOXETINE ON EXTRACELLULAR LEVELS OF 5-HT IN THE RAT STRIATUM. I. M. Chou*, M.-P. Kung, H. F. Kung and I. Lucki. Departments of Psychiatry, Pharmacology and Radiology, Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Previous research suggests that the ability of selective serotonin (5-HT) reuptake inhibitors (SSRIs) to increase extracellular 5-HT may be restrained by the activity of somatodendritic 5-HT_{1A} autoreceptors. Systemic administration of the new, selective 5-HT_{1A} receptor antagonist, p-MPPF (Zhuang, ZP, Kung, MP, and Kung, HF. J. Med. Chem. 1994, 37: 1406-1407), was used to examine the effect of blockade of 5-HT_{1A} receptors in footbination with systemic administration of the 5-HT uptake inhibitor fluoxetine on extracellular levels of 5-HT and its major metabolite, 5-hydroxyindoleacetic acid (5-HIAA), in the striatum. Extracellular levels of 5-HT and 5-HIAA were measured using in vivo microdialysis with electrochemical detection in awake unrestrained rats. On the day of the experiment, dialysate samples were collected for 120 min to establish baseline values. Fluoxetine was injected (20 mg/kg, i.p.) and dialysis samples were collected for 60 min. p-MPPF (30 mg/kg, i.p.) was then injected and dialysis samples collected for an additional 3 hours.

samples collected for an additional 3 hours.

Systemic administration of fluoxetine increased striatal extracellular 5-HT levels to 300% above baseline values. The administration of p-MPPF further increased 5-HT levels, up to a maximum of 700% above baseline. These results indicate that the 5-HT-elevating capacity of SSRIs may be restrained by the inhibitory action of the 5-HT₁A receptor and that 5-HT₁A receptor antagonists may play an important role in the development of future antidepressant drugs. Supported by USPHS grant MH 48125.

8-OH-DPAT ELEVATES EXTRACELLULAR SEROTONIN LEVELS VIA A TRANSPORTER DEPENDENT MECHANISM. D. S. Lorrain, C.J. Smith* & E.M. Hull. State University of New York at Buffalo, Buffalo, NY 14260.

Using in vivo microdialysis, we have shown that application of 8-OH-DPAT into the medial preoptic area (mPOA) dose dependently increased extracellular levels of dopamine and serotonin (5-HT). Although 8-OH-DPAT is a selective 5-HT₁₄ receptor agonist, it also may bind to D₂ receptors, to α_2 receptors and to the 5-HT transporter. The present experiments examined whether 5-HT-_{1A} stimulation or 5-HT transporter inhibition were responsible for 8-OH-DPAT's ability to increase extracellular 5-HT in the mPOA.

In experiment 1, 5-HT-_{1A} receptor stimulated serotonin release was tested using in vivo microdialysis. Adult male rats with probes aimed at the mPOA received either 8-OH-DPAT (500μM) alone in the dialysate or a combination of 8-OH-DPAT plus the specific 5-HT-1A antagonist MPPI (500μM/500μM). Serotonin levels increased significantly following application of 8-OH-DPAT and this effect was not blocked by co-administration of MPPI. In experiment 2, transporter mediated 8-OH-DPAT effects were tested. Adult male rats received either vehicle, the serotonergic neurotoxin 5,7-DHT (6µg) alone, or a combination of 8-OH-DPAT plus 5,7-DHT (8µg/6µg) directly into the mPOA. Five hours following infusion, animals were sacrificed and the brains removed. Dissected mPOA tissue pellets were homogenized and then spun in a centrifuge. The supernatant was injected onto a capillary column for HPLC analysis of 5-HT content. Treatment with 5,7-DHT significantly depleted mPOA 5-HT content when compared to vehicle treated animals. Co-administration of 8-OH-DPAT prevented depletion of 5-HT by 5,7-DHT. Since 5,7-DHT is a transporter-dependent neurotoxin, and since 8-OH-DPAT blocked the neurotoxic effects, these data suggest that increases in extracellular 5-HT after local application of 8-OH-DPAT may be mediated by uptake inhibition. Research supported by NIMH grant MH-40826 to EMH.

THE NEUROTENSIN ANTAGONIST, SR48692, POTENTIATES RAT MEDIAN RAPHE SEROTONERGIC NEURAL ACTIVATION BY STRESS, INTERLEUKIN-1 AND CRF. K. Corley*, T. Phan, W. Daugherty and M.C. Boadle-Biber, Physiol. Dept, VA Commonwealth Univ., Richmond, VA 23298. Acute random, inescapable loud sound activates serotonergic (5-HT) neurons of the median (MRN) but not dorsal raphe nucleus (DRN) (Neurosci. Lett. (1995) 199: 78-80). This response is mimicked by interleukin-1β (IL-1β) and CRF, blocked by neurotensin (NT), and potentiated by the NT antagonist SR48692 (Faseb J. (1996) 10: A131 and A132; Soc. Neurosci. Abstr. (1995) 21: 864). We now report that MRN 5-HT neurons are also activated by swim stress (15 min at 30°C) and tail shock (30 min, 1 mA, 100 msec shocks, VI-1 min). The index of 5-HT neuronal activity was in vivo accumulation of 5-hydroxytryptophan (5-HTP) after NSD 1015 (mhydroxybenzylhydrazine, 100 mg/kg i.p.), an inhibitor of aromatic amino acid decarboxylase, given prior to stress and 30 min before decapitation. MRN but not DRN levels of 5-HTP (determined by HPLC-EC in 2 mm punches) were increased significantly by stress over levels in sham-stressed controls as follows: swim - 16 ± 0.5 versus 9 ± 0.4 and shock - 18 ± 0.4 versus 9 ± 0.1 ng 5-HTP/mg protein \pm SEM (N=4 for each group; P < 0.01). SR48692 (80 $\mu g/kg,\,i.p.\,30$ min prior to stress) further increased MRN 5-HTP levels to 22 \pm 0.4 (swim) and 22 \pm 0.5 (shock) ng 5-HTP/mg protein \pm SEM over stress alone (P < 0.01). SR48692 also potentiated the activation of MRN 5-HT neurons by IL-1 β (10 ng ICV) and CRF (3 ug ICV), increasing 5-HTP levels by 35% over IL-1β and 24% over CRF alone (P < 0.01). SR48692 did not alter basal 5-HTP levels. (Supported by NIH Grant NS14090 to MCBB and a generous gift of SR48692 from Dr. D. Gully, Sanofi Recherche, France)

ENHANCEMENT OF SSRI EFFECTS BY 5-HT_{1A} ANTAGONISTS. REGIONAL SELECTIVITY AND ROLE OF SOMATODENDRITIC AUTORECEPTORS. F. Artigas', L. Romero. Dept. of Neurochemistry, C.S.I.C. Barcelona, Spain

5-HT_{1A} autoreceptor antagonists may accelerate the clinical onset of antidepressants by preventing a negative feedback action of serotonin (5-HT) at somatodendritic level. We have examined the effects of the blockade of 5-HT_{1A} autoreceptors on extracellular 5-HT (5-HT_{ext}) during the treatment with paroxetine, a selective 5-HT reuptake inhibitor (SSRI). Paroxetine (3 mg/kg) elevated 5-HT_{ext} in frontal cortex (FC), dorsal striatum (STR) and dorsal hippocampus (DHPC) by 250-300 %. Ten mg/kg paroxetine did not elevate 5-HT_{ext} further in FC and induced a small additional increment in VHPC. Yet, the concurrent blockade of 5-HT_{1A} autoreceptors with 1 mg/kg WAY-100635 dramatically potentiated the increment of 5-HT_{ext} induced by 3 mg/kg paroxetine in FC and STR (maximal elevation to 1800 % of basal in STR). A moderate potentiation was observed in DHPC. The 5-HT-enhancing effect of WAY-100635 is likely due to its interaction with somatodendritic 5-HT_{1A} receptors, as 1) its application in the DRN also potentiated paroxetine effects, 2) its systemic administration fully reversed the reduction of cortical 5-HT release that followed the activation of 5-HT, autoreceptors by local application of citalogram in the raphe nuclei, and 3) it attenuated the reduction of 5-HT release in FC caused by the systemic administration of paroxetine when the terminal 5-HT transnorter was blocked. These results indicate that 5-HT_{1A} antagonists preferentially potentiate the elevation of 5-HT_{ext} produced by SSRIs in brain areas receiving serotonergic afferents from the DRN. This effect results exclusively from the interaction of WAY-100635 with somatodendritic 5-HT_{1a} autoreceptors. Supported by FIS 95/266.

ATYPICAL AGONISM AT 5-HT_{1A} RECEPTORS BY RS-30199

M. Spedding*, A. Newman-Tancredi, M.J. Millan, C. Dacquet, B. Vickery', D. Tallentire', 'Roche Bioscience, Palo Alto, IdR SERVIER, 125 Chemin de Ronde, 78290 Croissy sur Seine, France.

RS-30199 has been shown to have atypical interactions at 5-HT_{1A} receptors in that it has similar affinity (pKi 7.9) as RS-64459 (pKi 8.1), but RS-30199 is anxiogenic, and devoid of agonist or antagonist effects at the 5-HT_{IA} receptor in guinea-pig ileum, whereas RS-64459 is a partial agonist (Small et al., 1990). The buspirone side chain may modify receptor coupling. At the human 5-HT_{IA} receptor expressed in CHO cells, the two compounds had similar affinities (Kis against [3H]-8-OH-DPAT, 27 and 22 nM respectively), but RS-30199 was almost a full agonist in GTP γ S binding assays, whereas RS-64459 was a partial agonist (Emaxs 90.5%; 49.1%, EC50s 2150 nM; 385 nM), resembling buspirone. Unlike 8-OH-DPAT, RS-30199 (0.1, 1, 10 mg/kg sc) did not induce the 5-HT behavioural syndrome, but was a potent inhibitor of sexual activity in male rats at 0.1, 1 and 10 mg/kg sc, (methods: Tallentire et al., 1996). Unlike 8-OH-DPAT, RS-30199 prolonged intromission latency. RS-30199 (10 mg/kg sc) fully inhibited the facilitation of sexual behaviour caused by the α_{2} adrenoceptor antagonist, delequamine (0.4 mg/kg, po). In conclusion, RS-30199 is an atypical agonist at 5-HT_{1A} receptors.

$5-HT_{1B}$, $5-HT_{1D}$, $5-HT_{1F}$ RECEPTORS

5-HT_{1B} RECEPTORS ARE EXPRESSED IN RAT SENSORY NEURONS IN CULTURE J. J. Chen*, M. R. Vasko, T. P. Staeva, M. Baez and D. L. Nelson, CNS Res., Lilly Res. Labs, Indianapolis, IN 46285; Dept. of

Nelson. CNS Res., Lilly Res. Labs, Indianapolis, IN 46285; Dept. of Pharmacol. & Toxicol., Indiana U., Sch. of Med., Indianapolis, IN 46202 One potential site of 5-HTs actions on nociception at the level of the spinal cord is the terminals of sensory neurons. To determine what subtypes of serotonin receptors mediate the effect of 5-HT on sensory neurons, we examined the subtypes of 5-HT receptors in these neurons using ligand binding and RT-PCR. Dorsal root ganglia cells from £15-£17 rat embryos were dissociated with trypsin and grown in culture. Receptor binding was measured using ³H-5-HT, ³H-Lysergic acid diethylamide (LSD) or ³H-5-carboxamidotryptamine (5-CT) in membranes prepared from neurons cultured for 14 days. The expression of serotonin receptor genes was investigated by RT-PCR analysis of total RNA isolated from the sensory neurons. Equilibrium binding of ³H-5-HT or ³H-LSD revealed highly specific binding sites. 5-CT displaced the ³H-5-HT binding with an IC50 of 2.3 nM, pointing toward the possible expression of 5-HT₁ family, 5 Inginy specims of shiring stees. 3-Ct misplaced the $^{\circ}$ H-3-Thomaing with an IC55 of 2.3 mM, pointing toward the possible expression of 5-HT₁ family, 5-HT₅B or 5-HT₇ receptors in sensory neurons. The low affinity of ritanserin and Way100635 in the binding assays suggested the absence or minimal amount of 5-HT₂ family and 5-HT₁A receptors in these neurons. Further experiments using cyanopindolol displacement of 3 H-5-CT binding revealed two binding sites with IC50's of 1.0 nM and >100 nM, respectively. This two binding sites with IC50's of 1.0 nM and >100 nM, respectively. This demonstrated that at least two subtypes of serotonin receptors are located in sensory neurons. The high affinity of the predominant binding site for cyanopindolol suggested that it could be the 5-HT1B subtype. RT-PCR analysis using primers specific for different subtypes indicated the expression of 5-HT1B mRNA as well as 5-HT1D message. These results demonstrate the expression of multiple subtypes of serotonin receptors in isolated sensory neurons, and the 5-HT1B receptor appears to be the predominant type of serotonin receptor present in these cultures. (Supported by Eli Lilly & Co. and DA07176)

528.3

MODIFIED LIGAND RINDING TO THE NATURALLY OCCURRING PHE-124-CYS VARIANT OF THE HUMAN S-HT₁₈ RECEPTOR M. Bühlen, M. Brüss, H. Bönisch and M. Göthert^{*}, Inst. Pharmacol. Univ. Bonn, Reuterstrasse 2b, 53113 Bonn, Germany

Single strand conformation analysis for DNA sequence variation of the 5-H T_{18} receptor gene from healthy individuals revealed a coding mutation in nucleotide position 371 (T \rightarrow G substitution), leading to an amino acid exchange (Phe \rightarrow Cys) in position 124 of the receptor protein (in the third transmembrane domain close to the junction with the first extracellular loop; Nöthen et al., Biochem. Biophys. Res. Comm. 205, 1194-1200, 1994). Since this substitution may lead to the formation of a disulfide bond with an extracellular Cys, the ligand binding properties of the mutant receptor may be modified. Genomic DNA from an individual, who was heterozygous for the mutation, was used as a template to clone (by PCR) the coding sequence of the wild-type and mutant receptor into the eukaryotic expression vector pSG5. COS-7 cells were transfected with the cDNA of the wild-type or the variant pSG5. COS-7 cells were transfected with the cDNA of the wild-type or the variant S-HT_{IB} receptor, and binding of [³H]5-carboxamidotryptamine ([³H]5-CT) to the plasma membranes from the cultured transfected cells was determined. In competition experiments, the concentration of [³H]5-CT was 1 nM (specific binding, defined by 10 μM 5-HT: ≥ 90%). The full or partial 5-HT receptor agonists, dihydroergotamine, 2-[5-[3-(4-methylsulfonylamino) benzyl-1,2,4-oxadiazol-5-y]]]H-indole-3-y]]ethylamine (L-694,247), 5-CT, 5-HT, sumatriptan, 5-methoxy-3(1,2,3,6-texthaylyro-4-pyridiny)] Hi indole (RU24969) and methysergide inhibited specific [³H]5-CT binding to the mutant and wild-type receptor. The inhibitory potencies at the mutant receptor (pK; 11.0, 9.8, 8.8, 8.4, 7.7, 7.5 and 7.5, respectively) were 0.3-0.5 log units higher than for the wild-type receptor. In conclusion, the naturally occurring Phe-124-Cys substitution in the human 5-HT_{IB} receptor leads to an increase in the affinity of 5-HT_{IB} receptor agonists. In vivo, this may cause pharmacogenetic differences in the action of human 5-HT_{IB} receptor may cause pharmacogenetic differences in the action of human 5-HT_{1B} receptor agonists. (Supported by a grant from the DFG: SFB 400)

AXONAL LOCALIZATION OF THE SEROTONIN 5-HT1B RECEPTOR IN RAT BRAIN. M. Riad* 1, N. Jodoin 1, S. Garcia 1, X. Langlois 2, M. Darmon 2, M. Hamon 2 and L. Descarries 1. 1 Dép. pathologie et CRSN, Univ. Montréal, Montréal, Qc, Canada; ² Neurobiologie Cellulaire et Fonctionnelle, INSERM U288, Paris, France

A pre-embedding protocol was developed for the light and electron microscopic immunocytochemical visualization of 5-HT1B receptor in adult rat brain, using diaminobenzidine (DAB) and gold as markers. Specific polyclonal antibodies raised against a synthetic peptide corresponding to a highly selective portion of the third intracytoplasmic loop of the rat 5-HT1B receptor were used [Langlois et al., J. Neurochem. 65: 2671-2681, 1995]. several fixation procedures tested, perfusion with 4% paraformaldehyde yielded the best results. DAB or gold labeling was mainly observed in the substantia nigra and globus pallidus. This labeling essentially involved fine unmyelinated axons, but spared axon terminals. On the basis of these ultrastructural data, it was concluded that the 5-HT1B receptor of adult rat CNS is mostly located on preterminal unmyelinated axons. Quantitative analysis of the distribution of the gold particles should reveal whether this preferential localization is axolemnal and/or axoplasmic. Lesion and double labeling experiments are planned to determine to what extent it might correspond to an autoreceptor versus heteroreceptor localization (5-HT versus striato-nigral or -pallidal axons). [Supported by the FCAR, FRSQ and MRC grant MT-3544].

GENOMIC CLONING AND HETEROLOGOUS EXPRESSION OF A RECOMBI-NANT GUINEA PIG SEROTONIN 5-HT_{1Dβ}-RECEPTOR. W.H.M.L. Luyten*, Van de Weyer, G. Nobels, A. Parker, P. Van Gompel, M. Ercken, A. Lesage and J.E. Leysen. Dept. Biochem. Pharmacol., Janssen Research Foundat., Beerse, 2340 Belgium.

Significant differences exist between the pharmacological properties of 5-HT_{1D}-Significant differences exist between the pharmacological properties of 5-HT_{1D}receptors (Rs) in various species, rendering extrapolation of e.g. rodent data to humans
hazardous. Human 5-HT_{1Da}- and _{1Dg}-R subtypes are very similar pharmacologically,
but the ligand-binding properties of the latter differ significantly from those of their rat
or mouse homologues, which are therefore called 5-HT_{1B}-Rs. A single amino acid
difference (Thr355Asn) accounts for most of the pharmacological dissimilarity (Nature
360: 161-163 (1992)). Guinea pigs are also used frequently for pharmacological studies
but their 5-HT_{1DB}-R has not yet been cloned or expressed.

PCR-primers, based on regions conserved across human 5-HT_{1DB}-R as well as rat
and mouse 5HT_{1DB}-R sequences, but different from known 5-HT_{1DB}-R sequences were

and mouse 5HT_{1B}-R sequences, but different from known 5-HT_{1Dα}-R sequences were used to amplify from a commercial guinea pig genomic library (Clontech) a ± 770 bp fragment of coding region. This fragment was cloned into pBS SK+, and the sequence showed $\pm 85\%$ identity with that of human 5-HT_{1DB}-R. The purified PCR product was showed 200% feeling with mark of indinal 2-111 [jpg-K. The pullified PCK product was labelled with 32P-dCTP by random-priming and used to screen a ÅEMBL-3 guinea pig genomic library (750,000 plaques; ±3.5 genome equivalents). One positive plaque was identified and purified, and the insert of this \(\lambda \)-clone was sequenced partially by primer-walking (cycle-sequencing followed by resolving reaction products on an ABI 373 automated fluorescent sequencer). The sequence of the open reading frame was 83% identical to that of the published human 5-HT_{1DB}-R sequence. Significantly, a Thr was found at position 355, just as in the human 5-HT_{1DD}-R sequence but different from the Asn found at the homologous position in rat and mouse 5-HT_{1B}-R. The coding region was subsequently PCR-amplified with Pfu (Stratagene), subcloned in the SmaI site of pBluescript (Stratagene) and the sequence verified once more. The insert was subcloned in the pcDNA3 expression vector (Invitrogen) for transient as well as stable expression for pharmacological characterization by radioligand binding and signal transduction. Supported by the Janssen Research Foundation.

DISTRIBUTION OF 5-HT $_{\rm 1Do}$, 5-HT $_{\rm 1D\beta}$ AND 5-HT $_{\rm IF}$ RECEPTORS IN HUMAN BRAIN USING 3 H-SUMATRIPTAN AS A LIGAND M.E. Castro, T. Romón, C. del Arco, J. Pascual, A. Pazos' Dept. Physiol. and Pharmacol., Unit of Pharmacol., University of Cantabria,

The autoradiographic distribution of ³H-sumatriptan binding sites in postmortem brain tissue sections from 11 subjects was analysed. Ten µM 5-HT (to define specific binding), 0.1 µM 5-Carboxamidotryptamine (5-CT) (to examine binding to 5-HT_{1F} receptors) and 0.2 µM ketanserine (to explore labelling to 5-HT_{ine} and 5-HT_{ine}) were added to 3 consecutive sections. Relevant densities of 3 H-sumatriptan binding sites were seen in: visual area = s. nigra> g. pallidus> frontal cortex (internal)> hippocampal subiculum = n. tractus solitarius> n. trigeminalis caudalis = claustrum. The diencephalon and the cerebellum were, in general terms, poor in these binding sites. While 5-HT displaced in all regions more than 90% of 3H-sumatriptan binding, the level of binding insensitive to 5-CT (5-HT_{1F} receptors) was relevant, around 50% of total binding, in several areas such as hippocampus (CA, field), neocortex (internal layers) and n. trigeminalis caudalis, among others. Most 5-HT_{1D} receptors labelled by ³H-sumatriptan belonged to the 5-HT $_{1D}$ class. 5-HT $_{1D}$ receptors represented only 15% of 3 H-sumatriptan binding sites and only over the locus niger.

These results confirm that 3H-sumatriptan binds to 5-HT receptors in several areas of the human brain, though the labelling to 5-HT $_{1DB}$ receptor is still predominant. To our knowledge, this is the first report analysing the autoradiographic distribution of 5-HT_{1F} receptors in the whole human brain Supported by FIS (94/1382) and FAES grants

528.7

CLONING AND CHARACTERIZATION OF RECOMBINANT GUINEA PIG 5-HT_{1DB} AND 5-HT_{1DB} RECEPTORS. J.M. Zgombick*, J.A. Bard, S.A. Kucharewicz, D.A. Urquhart, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652.

The 5-HT_{1D} receptor has been implicated as a molecular target for the treatment of acute migraine based upon the pharmacological actions and clinical efficacy of sumatriptan, a selective 5-HT_{1D} receptor agonist. The guinea pig has served as an animal model of 5-HT_{1D} receptor runction, most recently in evaluating 5-HT_{1D} receptor agonists as potential anti-migraine agents. Since the 5-HT_{1D} receptor subfamily is comprised of two distinct, but Closely-related subtypes, the genes encoding these receptors were cloned from a guinea pig liver genomic DNA library using oligonucleotide probes targeted to nonconserved regions of recombinant human 5-HT_{1DB} receptors are comprised of 378 and 390 amino acids, respectively. Comparison of the deduced amino acid sequences of guinea pig 5-HT_{1DB} receptors subtypes indicate that they display overall and transmembrane (TM) identities of 63% and 77%, respectively. Both clones contain a conserved threonine residue in TM 7, a structural feature imparting 5-HT_{1D} receptor pharmacology. The 5-HT_{1DB} receptor pharmacology with the following rank order of binding affinities: 5-CT > 5-HT > sumatriptan > 8-OH-DPAT > (-)-pindolol. Ketanserin displayed modest (-17-10d) 5-HT_{1DB} receptor subtypes electivity, the pharmacological profiles of recombinant guinea pig 5-HT_{1D} subtypes were nearly indistinguishable. Intraspecies and interspecies comparisons of mammalian 5-HT_{1DB} not properties. High correlations were observed between the binding affinities of compounds for 5-HT_{1D} binding sites and interspecies comparisons of mammalian 5-HT_{1DB} receptors reveal high similarities in amino acid sequences and both recombinant guinea pig 5-HT_{1DB} receptors reveal high similarities in amino acid sequences and both recombinant guin

528.9

CLONING AND CHARACTERIZATION OF A RECOMBINANT GUINEA PIG 5-HT_{JF} RECEPTOR. N. Adham*, J.A. Bard, J.M. Zgombick, M.M. Durkin, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ

The human, mouse and rat serotonin 5-HT_{1F} receptors have been cloned previously by several groups. The antimigraine compound sumatriptan has been shown to have substantial affinity for the cloned human 5-HT $_{\rm IF}$ receptor, suggesting that in addition to 5-HT_{ID} receptor subtypes the 5-HT_{IF} receptor may be a therapeutic target for the treatment of migraine. The guinea pig plasma extravation model has been used to evaluate potential antimigraine drugs. Since species differences in the pharmacology of serotonin receptors are well known, we compared the pharmacological profiles of of serotonin receptors are well known, we compared the pharmacological profiles of the cloned human and guinea pig 5-H $_{T_F}$ receptors in order to evaluate the usefulness of the $in\ vivo$ model in predicting activity of compounds targeted for humans. The guinea pig 5-H $_{T_F}$ receptor was cloned by homology to the human 5-H $_{T_F}$ receptor and transiently transfected into Cos-7 cells to evaluate its binding properties using [3 H]5-HT. High affinity (K₄ \sim 10 nM) [3 H]5-HT binding was detected to membranes obtained from transfected cells. The cloned guinea pig receptor displayed typical 5-HT $_{T_F}$ receptor pharmacology with the following rank order of binding affinities: 5-HT $_{T_F}$ receptor pharmacology with the following rank order of binding affinities: 5-HT $_{T_F}$ sumatriptan > 1-NP> <0-Methyl 5-HT> metergoline>0 methiothepin >5-CT>1. The pharmacological profiles of the cloned guinea pig and human 5-HT_{1F} receptors were almost identical. *In situ* hybridization studies in guinea pig tissue revealed 5-HT_{IF} receptor mRNA expression in the nuclei of the trigeminal ganglion suggesting that the 5-HT_{IF} receptor may play a role in the presynaptic inhibition of neuropeptide release at the level of the intracranial vasculature, thereby blocking the development of neurogenic inflammation. These findings indicate that a selective 5-HT_{JF} agonist

may provide a novel approach to treat migraine.

HIGH AND LOW AFFINITY SEROTONIN 5-HT D RECEPTOR SITES IN BRAIN: CHARACTERIZATION USING A NEW RADIOLABELED ANTAGONIST. G. Mengod', A. Raurich', J.M. Palacios²¹, and R. Cortés¹. ¹Dept. Neurochem., IIBB/CSIC, 08034 Barcelona, Spain.

Serotonin 1D receptor (5-HT_{1D}R), a G-coupled receptor, is one of the most abundant 5-HT receptors in the mammalian brain and the target of anti-migraine drugs. Until now, only radiolabeled agonist compounds were available for direct labeling of these receptors. Agonist ligands, however, recognize only the high affinity state of receptors and provide only a partial view of the density and localization of these sites. The compound GR 125743 is a selective 5-HT $_{10}$ R antagonist. We have used $^3\text{H-GR}$ 125743 to characterize and visualize (using quantitative autoradiographic techniques) 5-HT $_{1D}$ R in the brain of rat, guinea pig, monkey and man. The binding of 3 H-GR 125743 was saturable, with comparable nanomolar affinity and with low non-specific binding in all brain regions examined in the four species. 3H-GR 125743 binding was competitively blocked by coincubation with both unlabeled agonists and antagonists of the 5-HT_{1D}R. When compared with agonists ligands the density of sites labeled by the radiolabeled antagonist was considerable higher in all the regions examined. The ratio between antagonist and agonist binding site densities was not the same in every brain region studied. The results show that $^{9}\text{H-}$ GR 125743 is a new useful tool for the study of 5-HT₁₀ receptors. This ligand appears to label both high and low affinity states of these receptors, and can be used to map these sites differentially and study the alterations after physiological or pharmacological modifications of these

CLONING AND CHARACTERIZATION OF RABBIT AND DOG 5-HT_{1F} RECEPTOR SUBTYPES: A COMPARISON OF THE PHARMACOLOGICAL PROFILE TO THE HUMAN SPECIES HOMOLOGUE. J.A. Bard*. S.A. Kucharewicz, J.M. Zgombick, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

The pharmacology of 5-HT₁-like receptors which mediate vasoconstriction and are implicated in the treatment of migraine has been studied in a variety of tissues from several species, including man, rabbit and dog. Since species differences in the pharmacology of 5-H $_{1D}$ binding sites have long been observed, we further explored this possibility for the 5-H $_{1F}$ receptor subtype. We cloned the rabbit and dog 5-HT_{1F} genes, transiently transfected them into Cos-7 cells and compared their binding profiles in membrane preparations with that of the previously cloned human 5-HT_{1F} receptor. The 5-HT_{1F} genes from rabbit and dog show a high degree of homology to each other and to the previously published human gene, both at the nucleotide and amino acid levels, as predicted for species homologues. The K_d of [³H]-5-HT determined from saturation experiments for the rabbit and dog 5-HT $_{1r}$ receptors was 10 and 13nM, respectively. The B $_{max}$ for rabbit and dog 5-HT $_{1r}$ was determined to be 3.2 \pm 0.3 and 5.1 \pm 0.2 pmol/mg protein, respectively. The rabbit, canine and human 5-HT_{1F} receptors all displayed similar pharmacological profiles. However, sumatriptan exhibited a 10-fold lower affinity at the canine receptor when compared to the human or rabbit 5-HT_{1F} homologues. Finally, we have used reverse transcription-PCR (RT-PCR) to demonstrate the presence of mRNA in both rabbit and dog saphenous veins, which have been used as models for vasoconstriction as related to therapeutics for migraine

Neurogenic inflammation of the dura is thought to be an important component of the pathophysiology of migraine pain. Electrical stimulation (1 mA, 5 Hz, 4 msec) of the guinea pig trigeminal ganglion for 3 min. produced dural extravasation, a component of neurogenic inflammation, which was quantified by an *in situ* fluorescence measurement using Evans Blue. 5-HT_{1DB} and 5-HT_{1D α} receptor activation was originally thought to be associated with the blockade of dural extravasation, in addition to contraction of the rabbit saphenous vein in vitro. We determined the potency of several 5-HT agonists (sumatriptan, DHE, L-69427, LY306258, LY334370, LY302148, and MK-462) 15 minutes after intravenous administration in the dural extravasation model. We correlated the potency in this model with the compounds' binding affinity at the cloned human 5-HT1A, 5-HT1D α , 5-HT1DB, 5-HT1E and 5-HT1F receptors transfected in a mammalian cell line. We also correlated the potency in the extravasation model to each compound's functional activity to inhibit forskolin-stimulated adenylate cyclase in cell lines expressing the same human receptors. The 5-HT1F receptor had the highest correlation coefficient in both analyses ($R^2 = 0.89$ and 0.73 respectively). In contrast, no correlation existed between potency to inhibit dural extravasation and rabbit saphenous vein contraction in vitro for these same compounds. Thus, the beneficial effects of serotonin agonists and partial agonists to inhibit dural extravasation most likely occur via activation of the 5-HT_{1F} receptor without requiring vasoconstriction. Such a mechanism may be relevant to the efficacy of other serotonergic anti-migraine agents that have high 5-HT_{1F} receptor affinity. In addition, a <u>selective</u> 5-HT_{1F} receptor agonist may be beneficial in migraine pain without the liability of coronary vasoconstriction. (Funded by Eli Lilly and Co.)

CHARACTERIZATION OF LY334370, A POTENT AND SELECTIVE 5-HT_{1F} RECEPTOR AGONIST, IN THE NEUROGENIC DURAL INFLAMMATION MODEL OF MIGRAINE PAIN. L.A. Phebus*, K.W. Johnson, J.E. Audia, M.L. Cohen, B.A. Dressman, J.E. Fritz, S.W. Kaldor, J.H. Krushinski, K.W. Schenck, I.M. Zgombick T.A. Branchek, N. Adham, and J.M. Schaus, Eli Lilly & Co., Indianapolis, IN 46285 and Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

Inhibition of trigeminal stimulation-induced neurogenic dural inflammation by serotonergic agents in guinea pigs is best correlated with affinity and agonist activity at the 5-HT_{1F} receptor (see K.W. Johnson et al). LY334370 is a selective, high affinity agonist at 5-HT_{1F} receptors with a K₁ of 1.6 nM. It is devoid of in vitro vasoconstrictor properties at the rabbit saphenous vein in concentrations up to 10-5 M. LY334370 is a potent inhibitor of neurogenic dural inflammation in both the rat and guinea pig models (see table), which may be predictive of efficacy in acute migraine. It was active in this model when administered to animals via the intravenous, subcutaneous, oral or sublingual routes. When guinea pigs were pretreated (p.o.) with LY334370 at 200 pg/kg, a dose which approximates its oral ID₁₀₀, neurogenic dural inflammation was inhibited for at least 16 hours. Inhibition of trigeminal neurotransmitter release through 5-HT_{1F} receptor agonist activity, as demonstrated for LY334370 in the dural inflammation model, may provide a treatment for migraine pain without vasoconstriction and its associated side effects.

Species Route		Pretreatment Time	Estimated ID50	
Rat	i.v.	10 min.	20 pg/kg	
Rat	p.o.	60 min.	30 pg/kg	
Guinea Pig	i.v.	10 min.	30 pg/kg	
Guinea Pig	p.o.	60 min.	45 pg/kg

[³H]LY334370, A SELECTIVE RADIOLIGAND FOR LABELING THE SEROTONIN1F (5-HT1F) RECEPTOR. <u>D.B. Wainscott, J.H. Krushinski, J.M. Schaus*, S.W. Kaldor, B.A. Dressman, J.E. Audia, N. Adham[‡], and <u>D.L. Nelson</u>. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and [‡]Synaptic Pharmaceutical Corporation, Paramus, NJ 07655.</u>

Indianapolis, IN 46285 and *Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

The compound LY334370 fumarate has been identified as a high affinity, selective agonist at the 5-HT1F receptor. Based on these properties the tritiated version of this molecule was examined as a potential radioligand for the study of this receptor subtype. Initial studies focused on characterization at the cloned human 5-HT1F receptor where 18 HILY334370 exhibited a Kd value of 0.451 ± 0.025 nM and a Bmax of 7608 ± 143 fmol/mg protein. Specific binding was > 80 % over a concentration range of 0.031 to 4.56 nM. Examination of possible effects of cations showed that CaCl2 or MgCl2 did not enhance, and in fact concentrations above 1 mM CaCl2 or MgCl2 inhibited 13 HILY334370 binding to the human 5-HT1F receptor. In addition, NaCl and KCl did not enhance 13 HILY334370 binding to the human 5-HT1F receptor. In addition, NaCl and KCl did not enhance 14 HILY334370 binding to the human 5-HT1F receptor, with concentrations above 1 mM NaCl inhibiting the binding. At 37°C association of the ligand-receptor complex was relatively slow, reaching equilibrium only by 120 minutes in the presence of 10 mM MgCl2. In the absence of MgCl2, equilibrium was reached within 60 minutes. Studies investigating the distribution of 13 HILY334370 binding in rat brain homogenates showed highest labeling in cortical areas, corpus striatum, hippocampus and olfactory bulb. In guinea pig, a similar distribution was seen with the exception that more labeling was detected in caudate homogenates and less labeling in homogenates of olfactory bulb. These data demonstrate that [3 HILY334370 can be used as a high affinity, selective radioligand for the study of the 5-HT1F receptor. (Research funded by Eli Lilly and Company).

INVESTIGATION OF THE AGONISTIC ACTION OF ANTI-MIGRAINE COMPOUNDS ON HUMAN 5HT_{1Da}- AND 5HT_{1Da}-RECEPTORS EXPRESSED IN VARIOUS MAMMALIAN CELLS. A.S. Lesage*, R. Wouters*, P. Van Gompel*, W.H.M.L. Luyten*, P. Vanhoenacker*, G. Hagegman* and J.E. Leysen*. *Janssen Research Foundation, Beerse, Belgium; *University of Gent, Belgium.

Alniditan is a novel migraine abortive agent with nM affinity for 5HT_{1D}-receptor subtypes. We investigated the agonistic properties of alniditan, sumatriptan, dihydroergotamine and 5-hydroxytryptamine (5HT) on cloned human 5HT_{1D}-receptors expressed in C6 glioma cells and on cloned human 5HT_{1D}-receptors expressed in HEK293, C6 glioma and L929 cells. Receptor expression levels were 700 to 2000 fmoles/mg protein, after induction of the latter with Na-butyrate and interferon β, respectively. Without induction, receptor expression was only about 50 and 200 fmoles/mg protein. 5HT_{1D}-Receptors are negatively coupled to adenylate cyclase. For measuring cAMP formation cells were grown in MW96 plates. In all the receptor transfected cells, alniditan and the reference compounds produced, similarly as 5HT, a concentration dependent reduction of forskolin stimulated cAMP formation. Hence all compounds were full agonists at both 5HT_{1D}-receptors and for the 5HT_{1DB}-receptors in different cells and at high and low receptor expression levels (but pIC₅₀-values tended to decrease in the latter); preliminary pIC₅₀-values (-log M) are presented in the table.

,,	5HT _{1De}	5HT _{1DB}	-/ P	
	C6 glioma	C6 glioma	HEK293	L929
alniditan	8.9	8.1	8.8	9.0
sumatriptan	8.4	7.3	-	-
dihydroergotamine	8.7	7.9	-	-
5HT	8.6	7.5	8.0	8.3

Stimulation of $5HT_{1DB}$ -receptors, predominantly present in cranial blood vessels and mediating vasoconstriction and stimulation of $5HT_{1Da}$ -receptors, predominantly present in trigeminal nerves and probably causing inhibition of inflammatory peptide release, may have a role in the migraine abortive properties of the compounds.

528 12

LY334370 IS SELECTIVE FOR THE CLONED 5-HT1F RECEPTOR, C.D. Overshiner, N. Adham, J.M. Zgombick, T.A. Branchek, D.O. Calligaro, L.A. Phebus, M.E. Roush, K.W. Johnson, S.K. Hemrick-Luecke, R.W. Fuller, V.L. Lucaites, D.B. Wainscott, D.L. Nelson, M.C. Wolff, M.J. Benvenga*, J.E. Audia, J.M. Schaus, J.H. Krushinski, S.W. Kaldor, B.A. Dressman and J.D. Leander, Eli Lilly & Company, Indianapolis, IN 46285 and Synaptic Pharmaceutical Co., Paramus, NJ 07652. LY334370 fumarate is a high affinity 5-HT1F receptor agonist. LY334370's binding

LY334370 fumarate is a high affinity 5-HT_{1F} receptor agonist. LY334370's binding affinity was determined at other serotonin receptors; 5-HT_{1A}, 5-HT_{1Da}, 5-HT_{1DB}, 5-HT_{1DB}, 5-HT_{2D}, 5-HT_{2B}, 5-HT_{2B}, 5-HT_{2C}, 5-HT₃, and 5-HT₇. The K₁ values were greater than 1 µM at numerous other neurotransmitter receptors, ion channels and uptake sites. Among these binding sites significant cross reactivity was found only at the 5-HT_{1A} receptor. However, in functional assays measuring the inhibition of forskolin-stimulated cAMP production LY334370 acted as a full agonist at both receptors but was 1000-fold more selective for the 5-HT_{1F} receptor than the 5-HT_{1A} receptor. The compound was evaluated in several animal models sensitive to *in vivo* 5-HT_{1A} receptor activity. Rats dosed with LY334370 (10-30 mg/kg, s.c.) did not exhibit serotonin syndrome, hypothermia or antagonize the increased temperature produced by 8-OH-DPAT (0.1 mg/kg, s.c.). The compound (1-10 mg/kg, s.c.) only modestly increased rat plasma corticosterone, and did not block increased corticosterone produced by 8-OH-DPAT (0.3 mg/kg, s.c.). LY334370 (umarate (0.03-10 mg/kg, s.c.) din ot decrease exploratory behavior in rats, although 8-OH-DPAT did at a low dose (0.1 mg/kg, s.c.). The compound (1-10 mg/kg, i.m.) also did not mimic 5-HT_{1A} agonists in the pigeon punished responding test. Pigeons trained to discriminate small doses of 8-OH-DPAT (0.16 mg/kg, i.m.) from distilled water could not discriminate LY334370 fumarate (5-20 mg/kg, i.m.) as 5-HT₁A agonist. LY334370 fumarate (0.1 mg/kg, s.c.) failed to lower brain 5-HIAA levels in rats. LY334370 fumarate (0.1 mg/kg, s.c.) failed to lower brain 5-HIAA levels in rats. LY334370 fumarate (0.1 mg/kg, s.c.) as fully active in the rat dural extravasation model illustrating drug exposure following s.c. (dosing. Thus, LY334370 fumarate is a potent and selective 5-HT_{1F} receptor agonist. (funded by Eli Lilly and Company)

AUTORADIOGRAPHIC LOCALIZATION OF THE SEROTONIN₁F (5-HT₁F) RECEPTOR IN RAT BRAIN USING [³H]LY334370, A SELECTIVE 5-HT₁F RECEPTOR RADIOLIGAND . <u>V.L. Lucaites, J. Krushinski, J.M. Schaus, J.E. Audia, D.R. Gehlert* and D.L. Nelson, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285</u>

LY334370 is a high affinity, selective agonist at the 5-HT1F receptor. On this basis, the tritiated compound was examined for its utility in autoradiography to localize the 5-HT1F receptor in rat brain regions. Maximum specific binding in 12 micron brain sections occurred at 0.5 nM [³H]LY334370 in buffer containing 50 mM tris-HCL, 0.5 mM EDTA and 104 mM NaCl, pH 7.4. The binding reached equilibrium in 3 hours at room temperature. Nonspecific binding was determined in the presence of 1 µM 5-HT. The overall level of binding sites was low. This, coupled with the low specific activity of [³H]LY334370 (31 Ci/mmol), resulted in requiring 12 week film exposure. A band of specific 5-HT1F receptor binding was found in intermediate layers of all cortical regions examined. [³H]LY334370 bound in a stippled pattern in caudate putamen. 5-HT1F receptor binding was seen in cerebellum and very little was present in most brain stem regions. These findings suggest a discrete localization of the 5-HT1F receptor in the rat brain, and confirm the utility of [³H]LY334370 as a potential tool to explore further the localization and possible functions of the 5-HT1F receptor.

DISCRIMINATIVE STIMULUS PROPERTIES OF RU 24969: ANTAGONISM BY THE PUTATIVE 5-HT_{IRAD} RECEPTOR ANTAGONIST GR 127935.

P.M. Callahan, M.G. Bankson and K.A. Cunningham

Dept. of Pharmacology and Toxicology, Univ. of Texas Medical Branch, Galveston, TX 77550-1031.

The neuropharmacological effects of the 5-HT_{1AJB} receptor agonist RU 24969 were investigated in rats (N=16) trained to discriminate RU 24969 (0.5 mg/kg) from saline using a standard two-lever, water-reinforced FR 20 drug discrimination task. In substitution tests, the 5-HT_{1B} agonists CGS 12066B and CP 94,253 (1.25-20 mg/kg) and the 5-HT_{1BZC} agonist TFMPP (0.125-1 mg/kg) substituted completely for the RU 24969 stimulus. The 5-HT_{1A} agonists 8-OH-DPAT and ipsapirone, the 5-HT_{1BZC} agonist mCPP, the 5-HT_{2A} agonist MK 212, the 5-HT_{2A} agonists DOI and LSD and the 5-HT₃ agonist m-chlorophenylbiguanide as well as the 5-HT releaser fenfluramine and the 5-HT reuptake inhibitor fluoxetine engendered ≤50% drug-lever responding. In combination (antagonism) tests, the 5-HT_{1BZD} antagonist GR 127935 (0.125-4 mg/kg) produced a dose-dependent blockade of the RU 24969 (0.5 mg/kg) cue. Likewise, the substitution of CGS 12066B and TFMPP was also completely blocked by GR 127935. Administration of the 5-HT_{1A} antagonist XH 100135, the 5-HT_{2AZC} antagonist ketanserin and the 5-HT₃ antagonist zacopride failed to alter the RU 24969 stimulus. These results suggests that GR 127935 is an efficacious antagonist of RU 24969 and that the discriminative stimulus properties of RU 24969 are mediated primarily by 5-HT_{1BGDD}, receptors.

EFFECTS OF GR 127935 ON TERMINAL 5-HT1D AUTORECEPTORS AND 5-HT SYNTHESIS IN GUINEA PIG BRAIN. C. Moret* and M. Briley. Pierre Fabre Research Center, 17 Av. J. Moulin, 81100 Castres, France.

Guinea pig brain was used to study the effect of the putative 5-HT1D antagonist, GR 127935, on the terminal 5-HT autoreceptor modulating 5-HT release in vitro and in vivo, and on ex vivo 5-HT synthesis. GR 127935 only partially antagonized the inhibitory effect of the non-selective 5-HT agonist, 5carboxamidotryptamine, on electrically evoked release of [3H]5-HT from hypothalamic slices, whereas the non-selective 5-HT antagonist, methiothepin, blocked this effect totally. In vivo the terminal 5-HT1D autoreceptor was studied by measuring the extracellular levels of 5-HT by microdialysis in hypothalamus of freely moving guinea pigs. The 5-HT1D agonist, naratriptan, infused through the microdialysis probe, reduced in a concentration-dependent manner (1-10 µM) the extracellular levels of 5-HT. Naratriptan-induced inhibition (1 µM) was not modified by GR 127935 whereas it was reduced by methiothepin (1 μ M), a concentration which had no effect by itself. Neither local nor systemic administration of GR 127935 (10-100 μ M or 2.5-10 mg/kg ip) modified the in vivo output of 5-HT while methiothepin increased it (10-100 µM and slightly at 10-40 mg/kg ip). The synthesis of 5-HT was determined by measuring the accumulation of 5-HTP after blockade of the decarboxylase. GR 127935 (0.63-10 mg/kg ip) dose-dependently increased 5-HT synthesis by 50-60 % in hypothalamus, hippocampus and substantia nigra. These results suggest that in vitro GR 127935 does not act as a full antagonist at the 5-HT1D autoreceptor in the hypothalamus of guinea pig. In vivo its lack of effect locally or after systemic administration could also be explained by mixed agonist-antagonist properties. The moderate enhancing effect of GR 127935 on 5-HTP formation suggests that tonically activated 5-HT1D receptors modulate directly or indirectly 5-HT synthesis.

TRANSMITTERS IN INVERTEBRATES

AMINO-ACID RECEPTORS FROM THE PARASITIC

INHIBITORY AMINO-ACID RECEIPTORS PROM THE PARASTITE

NEMATODE, HAEMONCHUS CONTORTUS, N.S. Delany*, T.M. Skinner,

Univ. of Bath, Bath BA2 7AY, U.K.

GABA and glutamate act as inhibitory transmitters at nematode neuromuscular junctions. GABA is the major inhibitory transmitter on body and head muscles, whereas glutamate inhibits pharyngeal pumping. The receptors for these transmitters show interesting pharmacological properties and are major targets for existing and future anthelminthics.

We have isolated 5 cDNA clones (designated HG1-5) encoding putative inhibitory amino acid receptor subunits from Haemonchus contortus, a parasitic nematode of sheep and goats. All the clones contain the sequence motifs characteristic of GABAA and related receptors, but show only a low level (-30%) identity to vertebrate GABA and glycine receptor subunits. Expression of HG1, which responds weakly to glycine when expressed as a homomer in *Xenopus* oocytes, has been localised to the nematode nerve cord using an antibody raised against a synthetic peptide corresponding to a unique region of the extracellular domain. It is thus a good candidate for a component of the inhibitory GABA receptor found at the nematode neuromuscular junction. HG2 & 3 are homologues of two putative GABA receptor subunits isolated from C. elegans and are alternatively spliced products of a single gene. They share a common N-terminal extracellular domain, but have different C-terminal channel-forming domains. HG4 and 5 show a high level of sequence identity to the β - and α -subunits, respectively, of the C elegans glutamate-gated chloride channel (the avermectin receptor) and may form part of the analagous receptor in H.

DISTRIBUTION OF GABA IMMUNOREACTIVE NEURONS IN THE LEECH, HIRUDO MEDICINALIS. D.J. Bailey and J.L. Witten* Department of Biological Sciences, U. Wisconsin-Milwaukee, Milwaukee, WI 53201

We have used wholemount immunohistochemical methods to begin mapping the distribution of GABAergic neurons in the central nervous system of the medicinal leech, Hirudo medicinalis. The anti-GABA serum was generously supplied by Dr. Tim Kingan (USDA). Our preliminary results demonstrate a reproducible but sparse distribution of GABA-like immunoreactivity (GLI). Only 1 to 2 pairs of dorsal, anterior neurons per ganglion express GLI. These neurons send processes toward the midline and then travel ventrally towards the Retzius cells. Our findings are in marked contrast to the large number of neurons that exhibit ³H-GABA uptake (Cline, 1983). To clarify this discrepancy and produce a complete map of GABA-like immunoreactive neurons, we are trying to improve penetration of the antisera in the wholemount preparations and are processing sectioned CNS material for GLI. Furthermore, we are trying to localize GLI to terminals on longitudinal body wall muscles that are known to be innervated by inhibitory motoneurons that take up GABA (Cline et al.,

This work was begun in a Neurobiology Laboratory course taught by J.L.W. and has been supported by the College of Letters and Sciences at the U. of Wisconsin-Milwaukee

TWO NOVEL INHIBITORY AMINO ACID RECEPTORS FROM C. ELEGANS FORMED BY ALTERNATIVE SPLICING POSSESS IDENTICAL EXTRACELLULAR DOMAINS. D. L. Laughton, G. G. Lunt and A. J. Wolstenholme *. Department of Biology and Biochemistry, University of Bath, Bath, BA7 2AJ. U.K.

Inhibitory amino-acid receptors, including those for GABA and laterates place as inspectant rate in the functioning of the parameters.

glutamate, play an important role in the functioning of the nematode nervous system, involved in such activities as locomotion and pharyngeal pumping. We have isolated two novel inhibitory receptor cDNAs from the nematode Caenorhabditis elegans which are alternatively spliced products of a single gene. Both receptors are identical within the first 237 amino acids of the N-terminus, but differ in their C-terminal transmembrane domains, which are 83% identical. Northern blot analysis has confirmed the presence of both transcripts in a developmentally mixed population of C. elegans. Analysis of the genomic sequence has also confirmed that the junction between the shared extracellular domain and the alternative transmembrane domains corresponds to exon/intron boundaries within the gene. These results suggest that in nematodes alternative splicing may be employed to create receptor subunits with identical ligand binding domains but different channel forming domains and thus potentially different biophysical channel properties. A similar genomic organisation is found for a related gene, *unc-49*, discovered during the *C. elegans* genome sequencing project. To date, this phenomenon appears to be

unique to nematode ligand-gated ion channel receptors.

GLUTAMATE IMMUNOSTAINING IN THE MUSHROOM BODIES AND CENTRAL BODY OF CRICKETS H. W. Honegger*, B. Lauer and M. Bartos. Institute for Zoology, TU Munich, Germany, and Dept. Biology, Vanderbilt Univ., Nashville, TN 27235

Glutamate is the transmitter at the neuromuscular junction of insects, but it also acts at central synapses. We used an anti-glutamate antiserum from O.P. Otterson (antiserum 607) to double label proctolinergic antennal motoneurons in crickets. In parallel, other central regions of the cricket brain were investigated. The antiserum was routinely preincubated with glutaraldehyde conjugates of aspartate, alanine and to supress the possible detection of amino acids similar to glutamate. In control it was preincubated additionally with glutaraldehyde-glutamate. Immunostaining was done on frozen or paraplast-embedded sections using the avidin-biotin-HRP method.

Most brains showed appreciable background staining, probably due to the function of glutamate in metabolism. However, the mushroom bodies including the calyx, pedunculus, $\alpha\text{-}$ and $\beta\text{-}lobes$, the central body and 50-60 large neurons (20-40 μm diameter) in the median pars intercerebralis showed intense labeling. In some preparations only these regions were stained. In these it became evident that many of smaller glutamatergic neurons in the median pars intercerebralis project into the central body via the protocerebral bridge. Sections of the 4 brains exposed to the antiantiserum, preincubated with glutaraldehyde-glutamate showed no staining indicating that glutamate was specifically detected. Incubation of brains with an anti-GABA antiserum stained only GABAergic input into the calyx and large extrinsic neurons projecting into the α lobes and pedunculi. Our data thus show that glutamate may be the one transmitter in restricted neuropiles of the insect brain which are important for olfactory learning and memory (mushroom body), and act as interface between sensory and motor activity (central body).

A PUTATIVE NICOTINIC ACETYLCHOLINE RECEPTOR ALPHA SUBUNIT MESSENGER RNA IS PRESENT IN BOTH NERVE CELLS AND MUSCLE CELLS IN APLYSIA CALIFORNICA. R.E. McCaman* 1, D. Tamura2, F. Loera2 T. Chang¹, and J. K. Ono², ¹Div. of Neurosciences, Beckman Res. Inst. of the City of Hope, Duarte, CA. 91010, ²Dept. of Biological Science, California State University, Fullerton, CA. 92634.

The accessory retractor muscle (ARC, or the 15 muscle) in Aplysia californica has been extensively studied and shown to be innervated by identified cholinergic motorneurons which release a number of neuropeptides. Electrophysiological recordings from these muscles indicate that they have two types of nicotinic acetylcholine receptors (nAChR), one that mediates an excitatory response blocked by hexamethonium as well as an inhibitory response due to gating of chloride channels and blocked by alpha bungarotoxin (Kozak, J.A., K. R. Weiss, & V. Brezina, 1996, *J. Neurophysiol.*, 75: 660-677). These studies suggested that the excitatory and inhibitory receptors in the ARC had identical characteristics to those found in central neurons. A putative alpha subunit for a nAChR was cloned from the Aplysia central nervous system and neurons known to express the excitatory nicotinic AChR were found to contain mRNA with this cloned sequence (McCaman, R.E. and Ono, J.K., 1993, Soc. Neurosci. Abstracts, 19: 1339). The present study suggests that the ARC muscle and isolated ARC muscle cells contain the same alpha subunit, based on the polymerase chain reaction of cDNA from reverse transcribed mRNA, restriction analysis of the PCR products, hybridization with the cloned sequence, and cloning and sequencing of the amplified sequence from the muscle. In contrast to other systems, it appears that both neuronal and smooth muscle nAChRs may be composed of the same alpha subunit.

529.7

DEVELOPMENTAL AND SPATIAL EXPRESSION OF THE MUSCARINIC ACETYLCHOLINE RECEPTOR IN THE TOBACCO HORNWORM, Manduca . Wang* and B. A Trimmer, Dept. of Biology, Tufts University, Medford, MA 02155

Electrophysiological, pharmacological and biochemical approaches have been used to characterize putative muscarinic acetylcholine receptors (mAChR) in been used to claracterize putative inuscantine acceptational receptors (mACIR) in the central nervous system of Manduca sexta. However, little was known about the molecular properties and the temporal and spatial distribution of mAChRs in Manduca. Using degenerate primers based on the Drosophila mAChR clone in the polymerase chain reaction (PCR), two fragments, MSF 1 and MSF 2, were isolated from genomic DNA and identified as regions of the mAChR gene in Manduca. MSF 1. a 239 nucleotide fragment, corresponds to transmembranes (TM) 3-5 of a mAChR gene while MSF 2, 180 basepairs in length, represents TM domains 6-7. We have used these fragments to characterize the developmental expression and tissue specific distribution in the fifth instar larva by reverse transcriptase (RT)-PCR. Poly A RNA extracted from whole animals at various developmental stages, including the egg, larva, wanderer, pupa, and adult were used with specific primer pairs for MSF 1 and MSF 2. Both fragments were detected in all developmental stages tested with one MSF 2. Both fragients were detected in an developmental stages tested with one exception: MSF 1 was not found to be expressed in the pupal stage. Further tissue specific distribution of MSF 2 was investigated using total RNA isolated from selected tissues of the fifth larval instar in RT-PCR. MSF 2 was identified in the central nervous system and the fat body. However, other tissues such as the salivary glands and intersegmental muscles lacked MSF 2 expression. These studies describe the differential expression of MSF 1 and MSF 2 in the developmental stages and larval tissues evaluated. Furthermore, because MSF 1 and MSF 2 represent different regions of the mAChR gene, the absence of MSF 1 in the pupa introduces the possibility of mAChR heterogeneity in Manduca sexta.

AMINO ACID TRANSMISSION IN HYDRA. A. Pannaccione, P. Pierobon and Kass-Simon.* Dept. Biological Sciences, Univ. of Rhode Island, Kingston, R.I.

Evidence for the existence of classical neurotransmitters in hydra is based on electrophysiological, biochemical and histochemical studies. Évidence exists for ACH, 5-HT, and dopamine (Kass-Simon and Passano, '78, Venturini, '92.) Binding studies have provided evidence for glutamate (kainate and quisqualate) and GABAa receptors (Bellis, et al., '91 and Pierobon, et al., '95.) The present study provides electrophysiological evidence for glutamate and GABA involvement in hydra's pacemaker coordinating systems.

Hydra has 3 main pacemaker systems controlling its behavior: 1) the ectodermal Contraction Burst Pulse (CBP) system controlling longitudinal body contractions; 2) the endodermal Rhythmic Potential (RP) system causing elongation, and the Tentacle Pulse (TP) system producing individual tentacle contractions.

Hydra were recorded from with standard extracellular suction electrodes and

treated with GABA, and GABAa and GABAb agonists & antagonists, glutamate and kainate, AMPA & NMDA receptor agonists & antagonists. Dose response curves were made for all substances and the data analyzed by ANOVA's.

GABA and GABAa agonists significantly reduced CBPs and RPs, but increased

TPs; glutamate and kainate significantly increased RPs and reduce CBPs, and caused the body to elongate.

PURIFICATION OF CHOLINE ACETYLTRANSFERASE FROM THE BRAIN OF THE LOBSTER, HOMARUS AMERICANUS. R. Guo and C. Brandon*. Department of Cell Biology and Anatomy, The Chicago Medical School, North Chicago, IL 60064.

Choline acetyltransferase (ChAT) has not heretofore been purified from crustacean brain. Therefore, as a prelude to immunocytochemical studies in crustacean brain, we have purified ChAT from the brain of the Johster Homarus americanus

Neural tissue (cerebral, sub-esophageal, and thoracic ganglia, plus connectives) was dissected from 140 lobsters, yielding about 75 grams of tissue. Purification of ChAT involved the following steps: 1) Homogenization and centrifugation at 39,000 x g (Specific Activity (SA)=0.0245 Units/mg, Total Activity (TA)=31.319U); 2) 0-60% ammonium sulfate precipitation; 3) gel filtration (SA=0.26U/mg, TA=12.48U); 4) gradient elution from DEAE-cellulose (SA=1.056U/mg, TA=8.96U); 5) gradient elution from Cibachron-F3GA dextran (TA=2.35U); 6) gradient elution from hydroxyapatite (SA=12.73U/mg, TA=0.76U).

The final product had a specific activity of 12.73U/mg, representing a purification of about 520-fold, with a yield of about 2.5%. Lobster ChAT has a molecular weight of 86,000 by SDS-PAGE, and a pH optimum of 7.0. ChAT concentration was highest in the cerebral and thoracio ganglia (0.0245U/mg), intermediate in optic lobe (0.0187U/mg), and lowest in abdominal ganglia and connectives (0.0113U/mg). Supported by FUHS/CMS.

CHARACTERIZATION OF INOSITOL (1,4,5) TRIS-PHOSPHATE-5-PHOSPHATASE IN THE CNS OF Manduca sexta. S. Oazi* and B. A. Trimmer. Dept. of Biology, Tufts University, Medford, MA 02155.

Stimulation of muscarinic receptors in purified CNS membrane preparations of *M. sexta* with oxotremorine-M results in the generation of inositol (1,4,5) trisphosphate (IP₃). We are studying the metabolism of this important signaling molecule by cystolic enzymes (in nerve cord homogenates) and by membrane associated enzymes. The primary products formed in homogenates have been identified by high pressure products formed in nomogenates have been identified by high pressure liquid chromatography analysis to be inositol 1,4 bisphosphate and inositol monophosphate, suggesting the presence of cytosolic IP₃-5-phosphatases. Enzyme rate kinetics of this IP₃ metabolism indicates a low affinity for the substrate (Km 25 - 100µM). However, IP₃ breakdown by purified membranes appears to result from an enzyme with an even lower affinity for IP₃ (Km greater than 100µM) suggesting that IP₃ is metabolized by subtrible prospheteses. In many cortexps, install 1,3,4,5 templicial contents. for I_{γ}^{*} (km greater than 100/LM) suggesting that I_{γ}^{*} is inetatorized by multiple phosphatases. In many systems, inositol 1,3,4,5-tetrakisphosphate (IP_{γ}) is also a substrate for IP_{γ}-5-phosphatase. Measurements of the rate kinetics of [H]-IP_{γ} conversion to inositol trisphosphate in purified membrane preparations ($Km = 1.00 \mu M$) and homogenates (Km = 0.93) membrane preparations ($Km = 1.00 \, \mu\text{M}$) and homogenates ($Km = 0.93 \, \mu\text{M}$) are indistinguishable and reveal the presence of a phosphatase with high affinity for IP₄. This metabolism of [H]-IP₄ (1 μ M) can be completely inhibited by 100 μ M IP₃ suggesting that IP₄ can be used as a high affinity substrate for IP₃-5-phosphatase. Using this method we will compare the inhibitory rate constants (Ki) of IP₃ and other analogs of inositol trisphosphate to identify potent inhibitors of 5-phosphatase for use in single cell studies cell studies

CHARACTERIZATION OF NEMATODE GLUTAMATE RECEPTORS E. Bush, H. Brooks, D.J. Brownlee, L. Holden-Dye*, R.C. Foreman, and R.J. Walker. Dept. of Physiol. & Pharmacol., Univ. Southampton, UK, SO16 7PX.

Two cDNAs isolated from C.elegans, GluClα and GluClβ, expressed in Xenopus oocytes form a glutamate-gated chloride channel which is exquisitely sensitive to the anthelmintic ivermeetin. Here we have undertaken to i) identify blockers of the C.elegans glutamate-gated chloride channel ii) identify responses to glutamate in the parasitic nematode Ascaris and assess the action of ivermectin and chloride channel blockers on this response and iii) isolate cDNAs encoding for glutamate receptors from Ascaris

Celegans GluCla and GluClB cDNAs were expressed in Xenopus oocytes for voltage clamp experiments. Glutamate elicited an inward current (at -80mV; EC50 948µM; maximum current 195 nA). The reversal potential was -20 mV. The response to 1mM glutamate was blocked by $100\mu M$ picrotoxin (55%), 4,4-dinitrostilbene-2,2-disulphonic acid (DNS, 36%) and 5-nitro-2-(3phenylpropylamino)benzoic acid (38%). In Ascaris, glutamate (1mM) had no effect on somatic muscle but inhibited pharyngeal muscle (EC₅₀ 490μM). This inhibition was potentiated by 1pM ivermectin. The response to glutamate was blocked by picrotoxin (500 µM) but not by 100 µM DNS. This suggests the presence of an ivermeetin sensitive glutamate receptor regulating the pharyngeal muscle of Ascaris. We are screening an Ascaris L2 cDNA library with Celegans GluClα and GluClβ to isolate equivalent clones from Ascaris. This will enable a comparison of the pharmacological properties of Ascaris glutamate receptor subunits with the Celegans hetero-oligomer GluCla-GluClβ, and with the native glutamate response in Ascaris pharyngeal muscle.

Thanks to Dr J. Arena and Dr D. Cully (Merck, Sharp and Dohme) for the cDNAs for $GluCl\alpha$ and $GluCl\beta$ and to the BBSRC and MRC for funding.

MELATONIN IN A PRIMITIVE METAZOAN: RHYTHMICITY AND NEURONAL LOCALIZATION. N. Mechawar and M. Anctil*. Dept. Sci. Biol., Univ. de Montréal, Montréal, Québec, Canada H3C 3J7.

Although melatonin has long been considered a vertebrate hormone acting as a photoperiodic messenger, recent findings indicate that it is also present in some invertebrates in which it may be secreted rhythmically. We now report evidence that melatonin is present in neurons of a representative of the lowest invertebrates possessing a nervous system and that melatonin contents exhibit both diel and annual rhythmic patterns. Colonies of the cnidarian Renilla koellikeri were sampled over a 24h period once monthly and extracts were assayed for melatonin by RIA. Melatonin levels were highest in June at the peak of the reproductive season, and lowest in December. There was also a biphasic diel rhythmicity only during the latter part of the reproductive season (June to August). In addition, melatonin and its precursors serotonin '(5-HT) and N-acetyl-5-HT were detected by HPLC. Melatonin-like immunoreactivity was localized in ectodermal neurons resembling previously identified 5-HT-immunoreactive neurons, but also in endodermal neurons associated with the gametes. The results suggest that (1) melatonin is synthesized from 5-HT in Renilla neurons, (2) it is an evolutionarily conserved neurochemical transmitter, and (3) it plays a role in the seasonal reproductive process of this primitive metazoan.
