*12,537 volunteer abstracts, 18 symposia abstracts, 24 history of neuroscience abstracts, and 58 teaching of neuroscience abstracts.

1996 PROGRAM COMMITTEE

Clifford B. Saper, M.D., Ph.D.

Chairperson

Harvard Medical School, Beth Israel Hospital

Arthur P. Arnold, Ph.D.
University of California, Los Angeles

Jocelyne Bachevalier, Ph.D.
University of Texas Health Science Center, Houston

Jeffery L. Barker, M.D.
National Institutes of Health/NINDS

M. Catherine Bushnell, Ph.D. McGill University

Catherine E. Carr, Ph.D. University of Maryland

Raymond J. Dingledine, Ph.D. Emory University School of Medicine

Stephen S. Easter, Jr., Ph.D. University of Michigan

David A. Greenberg, M.D., Ph.D. University of Pittsburgh School of Medicine

Steven E. Hyman, M.D.
National Institute of Mental Health, NIH

Leonard K. Kaczmarek, Ph.D.
Yale University School of Medicine

Ned H. Kalin, M.D. University of Wisconsin Medical School

David M. Katz, Ph.D.

Case Western Reserve University School of Medicine

Pat Levitt, Ph.D.
UMDNJ–Robert Wood Johnson Medical School

Arthur D. Loewy, Ph.D.
Washington University School of Medicine

Paul J. Lombroso, M.D. Yale University

Marla B. Luskin, Ph.D.
Emory University School of Medicine

Amy B. MacDermott, Ph.D.
Columbia University, College of Physicians and Surgeons

Rodney K. Murphey, Ph.D. University of Massachusetts

Karen L. O'Malley, Ph.D.
Washington University School of Medicine

Marcus E. Raichle, M.D. Washington University School of Medicine

Bryan L. Roth, M.D., Ph.D.

Case Western Reserve University School of Medicine

Mark A. Segraves, Ph.D. Northwestern University

Barry E. Stein, Ph.D.

Bowman Gray School of Medicine, Wake Forest
University

Peter L. Strick, Ph.D.
Syracuse VA Medical Center, SUNY-HSC at Syracuse

W. Thomas Thach, Jr., M.D., *Incoming Chairperson* Washington University School of Medicine

Bruce S. McEwen, Ph.D., *ex officio* The Rockefeller University

Michael J. Zigmond, Ph.D., ex officio University of Pittsburgh

SOCIETY FOR NEUROSCIENCE POLICIES ON THE USE OF ANIMALS AND HUMANS IN NEUROSCIENCE RESEARCH

POLICY ON THE USE OF ANIMALS IN NEUROSCIENCE RESEARCH

The Policy on the Use of Animals in Neuroscience Research affects a number of the Society's functions that involve making decisions about animal research conducted by individual members. These include the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in *The Journal of Neuroscience*, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. The responsibility for implementing the policy in each of these areas will rest with the relevant administrative body (Program Committee, Publications Committee, Editorial Board, and Committee on Animals in Research, respectively), in consultation with Council.

INTRODUCTION

The Society for Neuroscience, as a professional society for basic and clinical researchers in neuroscience, endorses and supports the appropriate and responsible use of animals as experimental subjects. Knowledge generated by neuroscience research on animals has led to important advances in the understanding of diseases and disorders that affect the nervous system and in the development of better treatments that reduce suffering in humans and animals. This knowledge also makes a critical contribution to our understanding of ourselves, the complexities of our brains, and what makes us human. Continued progress in understanding how the brain works and further advances in treating and curing disorders of the nervous system require investigation of complex functions at all levels in the living nervous system. Because no adequate alternatives exist, much of this research must be done on animal subjects. The Society takes the position that neuroscientists have an obligation to contribute to this progress through responsible and humane research on animals.

Several functions of the Society are related to the use of animals in research. A number of these involve decisions about research conducted by individual members of the Society, including the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in The Journal of Neuroscience, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. Each of these functions, by establishing explicit support of the Society for the research of individual members, defines a relationship between the Society and its members. The purpose of this document is to outline the policy that guides that relationship. Compliance with the following policy will be an important factor in determining the suitability of research for presentation at the Annual Meeting or for publication in The Journal of Neuroscience, and in situations where the Society is asked to provide public and active support for a member whose use of animals in research has been questioned.

GENERAL POLICY

Neuroscience research uses complicated, often invasive methods, each of which is associated with different problems, risks, and specific technical considerations. An experimental method that would be deemed

inappropriate for one kind of research may be the method of choice for another kind of research. It is therefore impossible for the Society to define specific policies and procedures for the care and use of all research animals and for the design and conduct of every neuroscience experiment.

The U.S. Public Health Service Policy on Humane Care and Use of Laboratory Animals (PHS Policy) and the Guide for the Care and Use of Laboratory Animals (the Guide) describe a set of general policies and procedures designed to ensure the humane and appropriate use of live vertebrate animals in all forms of biomedical research. The Society finds the policies and procedures set forth in the PHS Policy and the Guide to be both necessary and sufficient to ensure a high standard of animal care and use and adopts them as its official "Policy on the Use of Animals in Neuroscience Research" (Society Policy). All Society members are expected to conduct their animal research in compliance with the Society Policy and are required to verify that they have done so when submitting abstracts for presentation at the Annual Meeting or manuscripts for publication in The Journal of Neuroscience. Adherence to the Society Policy is also an important step toward receiving help from the Society in responding to questions about a member's use of animals in research. A complete description of the Society's policy and procedures for defending members whose research comes under attack is given in the Society's Handbook for the Use of Animals in Neuroscience Research.

LOCAL COMMITTEE REVIEW

An important element of the Society Policy is the establishment of a local committee that is charged with reviewing and approving all proposed animal care and use procedures. In addition to scientists experienced in research involving animals and a veterinarian, the membership of this local committee should include an individual who is not affiliated with the member's institution in any other way. In reviewing a proposed use of animals, the committee should evaluate the adequacy of institutional policies, animal husbandry, veterinary care, and the physical plant. Specific attention should be paid to proposed procedures for animal procurement, quarantine and stabilization, separation by species, disease diagnosis and treatment, anesthesia and analgesia, surgery and postsurgical care, and euthanasia. The review committee also should ensure that procedures involving live vertebrate animals are designed and performed with due consideration of their relevance to human or animal health, the advancement of knowledge, or the good of society. This review and approval of a member's use of live vertebrate animals in research by a local committee is an essential component of the Society Policy. Assistance in developing appropriate animal care and use procedures and establishing a local review committee can be obtained from the documents listed below and from the Society.

OTHER LAWS, REGULATIONS, AND POLICIES

In addition to complying with the policy described above, Regular Members (i.e., North American residents) of the Society must also adhere to all relevant national, state, or local laws and/or regulations that govern their use of animals in neuroscience research. Thus, U.S. members must observe the U.S. Animal Welfare Act (as amended in 1985) and its implementing regulations from the U.S. Department of

Agriculture. Canadian members must abide by the *Guide to the Care and Use of Experimental Animals*, and members in Mexico must comply with the *Reglamento de la Ley General de Salud en Materia de Investigacion para la Salud of the Secretaria de Salud* (published on Jan. 6, 1987). Similarly, in addition to complying with the laws and regulations of their home countries, Foreign Members of the Society should adhere to the official Society Policy outlined here.

The following principles, based largely on the PHS *Policy on Humane Care and Use of Laboratory Animals*, can be a useful guide in the design and implementation of experimental procedures involving laboratory animals

Animals selected for a procedure should be of an appropriate species and quality and the minimum number required to obtain valid results.

Proper use of animals, including the avoidance or minimization of discomfort, distress, and pain, when consistent with sound scientific practices, is imperative.

Procedures with animals that may cause more than momentary or slight pain or distress should be performed with appropriate sedation, analgesia, or anesthesia. Surgical or other painful procedures should not be performed on unanesthetized animals paralyzed by chemical agents.

Postoperative care of animals shall be such as to minimize discomfort and pain and, in any case, shall be equivalent to accepted practices in schools of veterinary medicine.

Animals that would otherwise suffer severe or chronic pain or distress that cannot be relieved should be painlessly killed at the end of the procedure or, if appropriate, during the procedure. If the study requires the death of the animal, the animal must be killed in a humane manner.

Living conditions should be appropriate for the species and contribute to the animals' health and comfort. Normally, the housing, feeding, and care of all animals used for biomedical purposes must be directed by a veterinarian or other scientist trained and experienced in the proper care, handling, and use of the species being maintained or studied. In any case, appropriate veterinary care shall be provided.

Exceptions to these principles require careful consideration and should only be made by an appropriate review group such as an institutional animal care and use committee.

POLICY ON THE USE OF HUMAN SUBJECTS IN NEUROSCIENCE RESEARCH

Experimental procedures involving human subjects must have been conducted in conformance with the policies and principles contained in the Federal Policy for the Protection of Human Subjects (United States Office of Science and Technology Policy) and in the Declaration of Helsinki. When publishing a paper in *The Journal of Neuroscience* or submitting an abstract for presentation at the Annual Meeting, authors must sign a statement of compliance with this policy.

POLICY ON ETHICS

It is expected that authors submitting papers or abstracts will have conducted their work in strict accordance with the following statement on ethics approved by the Society for Neuroscience in November 1989 and amended in November 1993.

The Society for Neuroscience believes that progress in understanding the nervous system materially benefits human welfare. It recognizes that such progress depends on the honest pursuit of scientific research and the truthful representation of findings. While recognizing that both scientific error and differences of interpretation are a natural part of the creative process, the Society affirms that misconduct, in the form of fabrication, falsification, or plagiarism, jeopardizes the success of the entire scientific endeavor. Members of the Society assume an obligation to maintain the highest level of integrity in all scientific activities.

The primary responsibility for considering and resolving allegations of scientific misconduct lies within the individual academic communities and institutions where scientific work is carried out. The Society for Neuroscience therefore supports the principle that academic institutions should develop and have in place procedures to deal with allegations of scientific misconduct. However, the Society has a special responsibility and interest surrounding those scientific activities for which it is directly responsible, e.g., publication of *The Journal of Neuroscience* and the presentations at the Annual Meeting.

Every author of articles or abstracts submitted for publication in *The Journal of Neuroscience* or the neuroscience *Abstracts* agrees to assume full responsibility, within the limits of his or her professional competence, for the accuracy of the report. In the case of multiple-authored papers, each author should have made a significant intellectual or practical contribution to the scientific work; "honorary authorship," i.e., the granting of authorship to persons who have made no substantive contribution to a scientific report, is not appropriate.

Scientists must have access to their original research results. The retention of accurately recorded and retrievable results is essential for the progress of scientific inquiry. Moreover, errors may be mistaken for misconduct when primary results are unavailable. Primary data should remain in the laboratory and should be preserved as long as there may be a reasonable need to refer to them.

Authors submitting articles or abstracts do so with the understanding that reports have not been submitted elsewhere. An abstract is a proper forum for rapid communication of work that will subsequently appear as a full-length article. However, submission of abstracts reporting already published work or publication of multiple similar manuscripts or abstracts, i.e., duplicate publication, is improper. When previously published data are presented as part of a new manuscript or abstract, as in a gradually developing longitudinal data set, or if a subject group or condition is included again for comparison purposes, citations to the previously published work should appear explicitly in the new report.

Scientific publication is an important part of the process by which priority is established for experimental work and ideas. Duplicating without citation of text previously published by others or expropriating the experimental findings of others without attribution, i.e., plagiarism, is unethical. When authors of articles or abstracts have prepublication access to related work of others, as in a review process, care must be taken to avoid the appearance that priority is being claimed for work already done by others.

It is the responsibility of the authors, therefore, and not of the Society or the Editorial Board of *The Journal of Neuroscience*, to ensure that relevant prior discoveries are appropriately acknowledged in manuscripts that are submitted to the *Journal* for publication.

Questions raised about the conduct of experiments or their presentation will be evaluated preliminarily by the Editor of *The Journal of Neuroscience* (in the case of an article in the *Journal*) or by the Chair of the Program Committee (in the case of an abstract), in consultation with the Chair of the Publications Committee and the Secretary of the Society. If possible, the matter may be resolved informally at this level. However, if deemed appropriate, the matter will be referred to the institution where the scientific work in question was done. There, it would be expected that the matter would be reviewed in accordance with institutional procedures for handling allegations of misconduct. At all stages, every effort should be made to ensure that the process is fair and just, both for those who are accused of misconduct and for those who have raised the issue of scientific misconduct.

Based on their own findings or those of the institution, the *Journal* Editor or the Chair of the Program Committee, in consultation with the Chair of the Publications Committee and the Secretary of the Society, may recommend action to the Publications Committee. The Publications Committee will then decide on appropriate action, including, for example, retracting a published report. The Council of the Society and the relevant institution will be informed of any action that is taken. Council retains the right to consider additional action. In accordance with the Bylaws, this action could include, for example, expulsion from the Society. If it is found that allegations were not made in good faith, or were maliciously motivated, action may be recommended for those responsible.

In the event that a published article or abstract is to be retracted, a statement of retraction will be published in *The Journal of Neuroscience* or in the *Abstracts* for the next Annual Meeting.

	Special Lecture—11:15 a.m.	413.	Excitatory amino acid receptors: structure, function,	
375.	Why Do Brain Cells Die So Readily After		and expression—metabotropic glutamate receptor	03
	Hypoxic-Ischemia Insults?	414.	Regional localization of receptors and transmitters II 1	040
	D.W. CHOI	415.	Receptor modulation: up- and down-regulation II	043
		416.	Cardiovascular regulation: peripheral autonomic control1	04:
	Slide Sessions—8:00 a.m.	417.	Gastrointestinal regulation: peripheral mechanism1	049
376.	Visual cortex: striate V	418.	Urogenital regulation: sexual organs	05
377.	Cardiovascular regulation: ventral medulla II	419.	Somatosensory cortex and thalamocortical	
378.	Gene structure and function II		relationships V	054
379.	Hypothalamic-pituitary-gonadal regulation II	420.	Somatosensory cortex and thalamocortical	
	Opioid receptors III		relationships VI	05°
	Developmental genetics III961	421.	Visual cortex: extrastriate—mapping	
	Oculomotor system: pursuit, 3-D stimuli,		Visual cortex: extrastriate—functional organization II 1	
	head movements		Auditory, vestibular, and lateral line: hair cell properties19	
383.	Pain pathways		Auditory systems: central physiology—forebrain	
	Cognition: memory I		Auditory systems: central anatomy—forebrain	
	Serotonin receptors		Olfactory systems: olfactory bulb anatomy	
	Axon guidance mechanisms and pathways I		Olfactory systems: invertebrates	
	Postsynaptic mechanisms: electrical excitability and		Motor systems and sensorimotor integration:	,
307.	Ca ²⁺ signalling	120.	invertebrate sensory and motor systems II	071
200	Alzheimer's disease: tau and ApoE	120	Motor systems and sensorimotor integration:	,,,
	Long-term potentiation: physiology II	429.	invertebrate sensory and motor systems III	በደሰ
309.	Long-term potentiation, physiology if	420	Cortex: connectivity	
	Destay Cassians 9:00 a m		Basal ganglia: function III	
200	Poster Sessions—8:00 a.m.			
	Genesis of neurons and glia: adult		Basal ganglia: dopamine	
	Genesis of neurons and glia: regulation		Cerebellum: physiology, models	
	Cell lineage and determination IV		Vestibular system: behavioral studies	
	Cell differentiation and migration VI		Reflex function: animal studies	
	Cell differentiation and migration VII		Muscle	
	Morphogenesis		Brain metabolism and blood flow IV	
396.	Neurotrophic factors: biologic effects—		Brain metabolism and blood flow V	
-	BDNF and NT-4 I		Cognition: frontal/prefrontal	
397.	Neurotrophic factors: biologic effects—		Cognition: language II	
	BDNF and NT-4 II		Cognition: memory II	
	Neurotrophic factors: biologic effects—NT-3		Learning and memory: systems and functions $V \hdots 1$	
399.	Neurotrophic factors: receptors and cellular		Learning and memory: systems and functions VI1	
	mechanisms III		Learning and memory: systems and functions VII1	
400.	Neurotrophic factors: receptors and cellular		Learning and memory: systems and functions VIII	
	mechanisms IV	446.	Learning and memory: pharmacology VI	126
401.	Neurotrophic factors: receptors and cellular		Learning and memory: pharmacology VII1	
	mechanisms V		Neural plasticity II	
402.	Neurotrophic factors: receptors and cellular	449.	Motivation and emotion: drugs	135
	mechanisms VI	450.	Motivation and emotion: other	138
403.	Cerebral cortex and limbic system	451.	Biological rhythms and sleep:	
404.	Development of visual cortex I		circadian rhythms II1	139
405.	Regeneration: altered gene expression—CNS	452.	Neuroethology: invertebrates	142
	Transplantation: mostly spinal cord	453.	Stress II	146
	Neuroglia and myelin III	454.	Hormonal control of reproductive behavior IV	149
	Other ion channels I		Neuropeptides and behavior II	
	Other ion channels II		Drugs of abuse: ethanol, barbiturates, and	
	Acetylcholine: structure/function I		benzodiazepines III	155
	Acetylcholine receptors: nicotinic—regulation of	457.	Drugs of abuse: amphetamines III	
	gene expression		Drugs of abuse: opioids IV	
412	Excitatory amino acids: pharmacology—		Aging: memory	
	metabotropic receptors 1035		Developmental disorders III	

	sion nber & Title Page		sion nber & Title Page
461.	Degenerative disease: Alzheimer's-beta-amyloid—	491.	Aging processes: hippocampus
	accumulation and aggregation		Aging processes
462.	Degenerative disease: Alzheimer's-beta-amyloid—		Staining, tracing, and imaging techniques III
	neuropathology1172		Presynaptic mechanisms: calcium and release1239
463.	Degenerative disease: Alzheimer's—cognitive	495.	Calcium channel structure, function, and
	function II		expression II
	Ischemia: apoptosis		Potassium channels: structure and function
	Trauma III		Potassium channels: modulation I
	Trauma IV		Potassium channels: modulation II
	Neuropsychiatric disorders: schizophrenia I		Acetylcholine: structure/function II
	Neuropsychiatric disorders: imaging II	500.	Acetylcholine receptors: muscarinic—
	History of neuroscience	501	structure/function I

DEVELOPMENTAL EXPRESSION OF THE MU, KAPPA AND DELTA OPIOID RECEPTORS IN THE MOUSE Y. Zhu*, M. Hsu, J. E. Pintar. Dept. Neurosci. & Cell Biol., UMDNJ Robert Wood Johnson Med. Sch., Piscataway, NJ 08854 Previously we have reported the distribution of the μ . κ and δ opioid receptor

Previously we have reported the distribution of the μ. κ and δ opioid receptor mRNAs during late gestational and neonatal mouse development. The present study extends previous results to earlier embryonic stages and additional peripheral structures. Significant levels of κ mRNA were detected in the gut epithelium as early as e9.5 and by e11.5. κ receptor mRNA is expressed in not only the epithelium but also some scattered cells, presumably migrating neural crest cells, surrounding the gut wall. At the same stage, μ receptor mRNA begins to be expressed in the ventral spinal cord and the vagal ganglion, in addition to the facial(VII) and vestibulocochlear(VIII) ganglia described before. At e13.5, positive hybridization signals of μ receptor are readily detected in the mantle layer of the hindbrain, tectum and tegmentum of the midbrain and pons, as well as in the thalamus and hypothalamus, while κ receptor mRNA is also observed in the dorsal thalamus and tegmentum, which are comparable to the μ expression sites. Cells expressing κ receptor mRNA are also located in peripheral tissues including rostral pial progenitors and mesenchyme just beneath the dorsal limb ectoderm (both sites of δ receptor mRNA are also detected in the heart at this age, though in the ventricle instead of the atrium. We have also begun to examine the expression pattern of opioid receptor mRNAs in the placenta and uterus. At e7.5, the earliest stage that has been examined so far, striking expression of δ receptor mRNA is observed in the trophoblast giant cells, which remains until at least e18. Cells expressing both μ and κ receptor mRNAs are located in the peripheral uterus, while κ mRNA expression is also detected in the decidual basalis, which remains a major site of expression throughout post-implantation stages. These results described above suggest that early developmental events in neural and non-neural tissues may be mediated by opioid receptors and provide the first cellutar localization of opioid receptor gene expression in the plac

CATECHOLAMINE RECEPTORS: LOCALIZATION AND STRUCTURE

329.1

RECONSTITUTION OF FUNCTIONAL DOPAMINE RECEPTORS
BY COEXPRESSION OF N- AND C-TERMINAL RECEPTOR
DOMAINS P. Barbier, R. Maggio*, A. Colelli, F. Vaglini, F. Fornai and G.U.
Corsini Institute of Pharmacology, School of Medicine, University of Pisa (Italy)

An N-terminal D2 dopamine receptor clone was constructed and coexpressed in cell cultures possessing a separate gene fragment encoding the C-terminal sequence of the D2 receptor. The truncated receptor (referred to as D2-trunc) contained transmembrane domains (TMD) I-V and the N-terminal portion of the third cytoplasmic loop (i3). whereas the C-terminal receptor fragment (referred to as D2-tail) possessed TMD VI and VII and the adjacent intra- and extracellular sequences. Expression in COS-7 cells of any of these two polypeptides alone did not result in any detectable [3H]spiperone binding activity. However, specific [3H]spiperone binding could be observed after coexpression of the D2-trunc and D2-tail gene constructs. Initial pharmacological characterization indicated that the reconstituted receptor behaved in a similar manner to the wild type D2 receptor. This data raises the intriguing possibility that dopaminergic receptors can behave in a fashion analogous to multiple subunit receptors. It appears that the i3 loop can function as a linker between the two functional domains. Our findings confirm and extend analogous data for muscarinic and adrenergic receptors indicating that this phenomenon could be of general importance for the entire superfamily of G protein-coupled receptors.

329.3

CHARACTERIZATION OF ANTIBODIES TO DOPAMINE D4 RECEPTORS IN RAT BRAIN. R. E. Harlan*, M. M. Garcia and R. J. Webber Tulane Medical School, New Orleans, LA (REH, MMG) and Research & Diagnostic Antibodies, Berkeley, CA (RJW).

Antibodies were generated in rabbits against synthetic peptides corresponding to amino acids 16-30 or 176-185 of the cloned human dopamine D4 receptor. Sera were screened with ELISA against the cognate peptide and related peptides. Sera demonstrating specific binding were used in western blots against whole rat brain homogenates. These blots revealed single bands at an apparent molecular weight of 51 kDa. Immunocytochemistry was performed in rat brain sections fixed with either 3% neutral-buffered paraformaldehyde or PLP. Essentially identical results were obtained with both fixatives and with antibodies directed against either peptide. In the olfactory bulb, glomeruli were well labeled with diffuse and punctate immunoreactivity, while numerous fine dots were observed in the external plexiform layer, sometimes arranged along apical dendrites, and on the surface of cells in the mitral and internal granular layers. A prominent band of immunoreactivity was observed in layer 4 of cerebral cortex, especially in sensory areas. Immunoreactivity consisted of a meshwork of fine dots in layer 4, with a somewhat decreased intensity in layers 1-3. Organization into barrels was evident, but not striking. In layer 5, small intense puncta were observed along apical dendrites of many neurons. In the caudate-putamen, scattered labeled neurons were observed amidst a moderately-intense neuropil consisting of a multitude of fine dots. In the hippocampal formation, diffuse immunoreactivity was observed in the molecular layer of the dentate gyrus, with fine dots associated with many neurons in the granule cell layer. Supported by LEQSF RDA-29 to MMG

329.2

DOPAMINE D1, D2 , β_2 -ADRENERGIC AND 5-HT_{1B} SEROTONIN RECEPTORS EXIST AS DIMERS. <u>G.Y.K. Ng., S.P. Lee, G. Varghese, Z. Xie, L. Grupp*, M.R. Brann, B. O'Dowd, and S.R. George.</u> Depts. of Pharmacology and Medicine, Univ. of Toronto, Toronto, ON, MSS 1A8, the Addiction Research Foundation, M5S 2S1, Toronto, ON, Canada, and the Depts. of Psychiatry and Pharmacology, Univ. of Vermont School of Medicine, Burlington, VT, 05405

We provide direct physicochemical evidence that dopamine D2 and D1, β2adrenergic and 5-HT1B serotonin receptors exist as dimers in crude membranes from cultured cells, and following solubilization and immunoprecipitation of these receptors. Intriguingly, immunoblots of crude membranes from human caudate nucleus revealed that the D2 dimer was the predominant species. The G-protein coupled receptor (GPCR) dimers were stable in SDS and under reducing conditions indicating that dimerization was not attributed to covalent disulphide bonds. Incubation of the GPCR dimers with receptor-specific peptides, under high temperatures, or low pH resulted in the dissociation of dimers to monomers. Exposure of living D2 expressing cells (D2/cells) to glutaraldehyde resulted in a conversion of receptor monomers to dimers due to the irreversible cross-linking of receptor monomers. Using the D2 receptor as the model for other GPCRs, we investigated the function of dimers. D2 dimers and monomers were labeled by benzamide antagonists whereas only monomers were labeled by butyrophenone antagonists, which explains the discrepancy in receptor densities estimated by these ligands in PET studies. Further, dopamine exposure of D2/cells mediated an increase in cell surface D2 monomers and dimers involving the translocation of intracellular receptors. We conclude that D2 and other G protein-coupled receptors exist as receptor dimers and that dimers play a functional role in the response to agonist exposure. This work was supported by the Medical Research Council of Canada, National Institute of Drug Abuse, and the Ontario Ministry of Health.

MONOCLONAL ANTIBODIES AGAINST HUMAN α_2 -ADRENOCEPTOR SUBTYPE C2: CHARACTERIZATION AND PRODUCTION. <u>S. Liitti, M.-T. Matikainen, H. Närvä, M. Koulu* and M. Jalkanen</u>. *Dept. of Pharmacology and Clinical Pharmacology and Centre for Biotechnology, Univ. of Turku P.O.B 123, FIN-20521, Turku, Finland

We have raised and characterized monoclonal antibodies (Mabs) against the human α_2 -adrenergic receptor subtype C2 (α_2 C2) in mice. The Mabs were raised against a bacterially expressed fusion protein which consisted of sequence from the putative third intracellular loop (amino acids 213-343) of human α_2 C2 and GST.

Production of Mabs was first detected with Western blotting. Membranes prepared from α_2C2 -transfected mammalian Shionogi 115 (S115) and Saccharomyces cerevisiae yeast cells were used as antigens. Membranes from S115 cell lines expressing the α_2 -adrenergic subtypes C4 and C10 and wild type Saccharomyces cerevisiae yeast cells were used as negative controls. The α_2C2 receptor antibody production of the hybridomas was also screened with TR-IFMA (Time Resolved ImmunoFluoroMetric Assay). Ten out of forty-four positive clones were recloned and retested. Three α_2C2 specific monoclonal cell lines were expanded to in vitro production in hollow fiber systems. The specificity of the Mabs was further determined by immunoprecipitation of receptors solubilized from S115 cells expressing only one cloned α_2 -adrenergic receptor gene product.

Scatchard analysis of Europium-labelled antigen (amino acids 213-343 of α_2 C2) revealed binding affinity constants of 0.4, 0.7 and 1.6 nM⁻¹ for the three Mabs and K_ds of 2.6, 1.4 and 0.6 nM, respectively.

This study was funded by grants from the Technology Development Centre of Finland.

α2-ADRENOCEPTORS IN GUINEA-PIG AND HUMAN CORTEX: α2D VERSUS α_{2A}. S.C. Cheetham*, E. O'Brien, R.W. Horton & D.J. Heal. Knoll Pharmaceuticals Research and Development, Nottingham, NG2 3AA, UK and Department of Pharmacology, St. George's Hospital Medical School, London, SW17 ORE, UK. Based on molecular biological and radioligand binding studies, four subtypes of α_2 -adrenoceptors have been identified; α_{2A} , α_{2B} , α_{2C} and α_{2D} (Bylund et al., 1994, Pharmacol. Rev., 46, 121-136). We have determined the subtype of α₂-adrenoceptors in guinea-pig cortex and human temporal cortex (Brodmann area 38) using radioligand binding techniques. Inhibition constants for a range of agonists and antagonists which distinguish between the known α2-adrenoceptor subtypes were obtained by displacement of [3H]RX 821002 binding from cortical membranes. There was a highly significant correlation between the pK_i values of the ligands for α₂-adrenoceptors in guinea-pig cortex and the α_{2A} (r=0.864; P< 0.001) and the α_{2D} (r=0.945; P<0.001) subtypes, with much weaker correlations with the α_{2B} (r=0.614; P<0.01) and the α_{2C} (r=0.667; P<0.05) subtypes, indicating that the α_2 -adrenoceptors are of the α_{2A} or α_{2D} subtypes. Similar results were obtained for human temporal cortex; α_{2A} (r=0.919; P<0.001), α_{2D} (r=0.864; P<0.001), α_{2B} (r=0.130; P=0.686) and α_{2C} (r=0.698; P=0.054). Although the α_{2A} and α_{2D} subtypes exhibit similar affinities for several structural classes of compound, there are ligands which can distinguish between these α_2 -adrenoceptor sub-populations, including rauwolscine, yohimbine, WB4101, fluparoxan and prazosin (Renouard et al., 1994, J. Pharmacol. Exp. Ther., 3, 946-957). These compounds gave K_i values for α₂-adrenoceptors in guinea-pig cortex comparable to those for the α_{2D} , but not the α_{2A} subtype. The converse was true for α_{2} -adrenoceptors in human temporal cortex. These data argue strongly that α_2 -adrenoceptors in guinea-pig cortex are predominately of the α_{2D} subtype, whilst those in human temporal cortex are of the α_{2A} subtype.

Financial support provided by Knoll Pharmaceuticals Research and Development.

DIFFERENTIAL ROLE OF GLYCOSYLATION IN D1 AND D5 DOPAMINE

DIFFERENTIAL ROLE OF GLYCOSYLATION IN D1 AND D5 DOPAMINE RECEPTOR LOCALIZATION AND FUNCTION. C. Bergson* (1), R. Levenson (1), and M. Lidow (2) (1) Pennsylvania State College of Medicine, Hershey, PA 17033; (2) Yale School of Medicine, New Haven, CT 06510. Previous studies revealed that D1 and D5 receptors are co-expressed in many cortical projection neurons, but suggested that they may be carrying out specialized functions by virtue of their different subcellular localization within dendritic spines and shafts (Bergson et al., (1995) J. Neurosci. 15, 7821-7836). N-linked glycosylation is a prominent post-translational modification of bttp D1 and D5 receptors expressed in brain and transferde cells. We have both D1 and D5 receptors expressed in brain and transfected cells. We have investigated the possibility that *N*-linked sugars play a role in regulating the normal localization and/or function of either the D1 or D5 subtypes. Initial studies of receptors expressed in African Green monkey fibroblast (CV-1) cells have revealed that N-linked glycosylation is essential for proper D5 receptor localization in the plasma membrane as well as for its ability to bind D1-like receptor ligands. For example, specific binding of the D1 antagonist SCH23390 is abrogated when receptors are expressed in the presence of 0.5 µg/ml tunicamycin, an inhibitor of protein glycosylation. Further, confocal immunofluorescence reveals that unglycosylated D5 receptors do not reach the plasma membrane, but accumulate in a perinuclear compartment. In contrast, similar studies of D1 receptors suggest that its subcellular localization is not regulated by glycosylation. This information could provide critical insight into the differential regulation of D1 and D5 receptor folding, transport, and function in vivo, as well as help explain the physiological requirements for multiple D1-like subtypes. Supported by NARSAD Young Investigator Award (C.B.) and NIMH grant MH44866-05.

SLA).

D1 AND D2 DOPAMINE RECEPTOR PRUNING IN THE ADOLESCENT FEMALE RAT. S.L. Andersen*, M. Rutstein, J. Benzo, J.H. Hostetter, and M.H. Teicher.

Dept. of Psychiatry, Harvard Medical School, Laboratory for Developmental Psychopharmacology, McLean Hospital, Belmont,

We have previously shown that D1 and D2 dopamine receptors are overproduced and eliminated by a minimum of 35% in the striatum, but not in the nucleus accumbens of male rats during the periadolescent period (Teicher et al 1995). In this study we determined whether this same dramatic pattern was followed in the striatum and nucleus accumbens of female rats the ages of 40, 60, 80, 100, and 120 days. All tissue was harvested on the second day of diestrous to control for hormonal cycling. The density of D1 and D2 receptors was based on quantitative autoradiography v Scatchard analysis of 7 concentrations (0.01-4 nM) of 3H-SCH-23390 and 3H-YM-09151-2, respectively. Data were then analyzed with LIGAND. In contrast to marked receptor pruning observed in male rats across the adolescent period, D1 and D2 receptor decline only slightly in the striatum. Between 40 and 120 days of age, D1 density dropped 20%, while D2 receptor density was attenuated by 10%. Slight pruning was also observed in the nucleus accumbens, with both receptor subtypes declining by 10-20% between 40 and 120 days. We hypothesize that this difference between male and females may reflect differences in the amount of overproduction, rather than elimination of these receptor subtypes and studies are underway to determine if this is the case. These findings may help explain why Tourette's Syndrome and ADHD are much more prevalent in males than females and wane in severity during adolescence.

AGONIST-INDUCED MORPHOLOGICAL CHANGES IN D1A DA RECEPTOR DISTRIBUTION PATTERNS. D.R. Sibley*, C.E. Sortwell¹, K.A. Altemus², M.S. Levine², and M.A. Ariano¹. Molecular Neuropharmacology, ETB, NINDS, Bethesda, MD 20892; 'Neuroscience, FUHS/CMS, North Chicago, IL 60064; ²MRRC, UCLA, Los Angeles, CA 90024.

The distribution of the D_{1A} DA receptor was assessed using subtype specific anti-receptor antisera after acute DA exposure. The immunofluorescent staining of the D_{1A} receptor was examined in: 1) stably transfected Chinese Hamster Ovary (CHO) cells, 2) primary striatal cultures, and 3) rat striatal brain slices. Following agonist exposure as brief as 2-min and as long as 60-min, profound loss of cellular D_{1A} receptor staining occurred in each paradigm. In the slice, immunofluorescent neuropil staining for the D_{1A} receptor also was attenuated. The altered staining patterns were blocked by the DA antagonist (+)-butaclamol or the D₃-selective antagonist, SCH 23390. Receptor expression patterns reverted back to the control pattern 15-min after removing the agonist from the bath. Immunofluorescence for cyclic AMP increased at all DA exposure times in the experimental paradigms, was blocked by receptor antagonists, and decreased to basal staining levels after brief recovery periods. These results demonstrated the functional integrity of the D_{1A} receptor in target cells. Pretreatment with concanavalin A blocked the immunofluorescent decrease in receptor staining, but not the elevation of cyclic AMP, indicating a morphological separation of these two events, parallel to other biochemical reports. The data suggest that the anatomical basis of acute homologous D_{1A} receptor desensitization may be transposition of membrane-surface receptors to a transiently unavailable, intracellular compartment in transfected CHO cells and neurons from rat striatal cultures and brain slices. Supported by USPHS grant NS 32277 (MAA) and NS 33538 (MSL).

DIFFERENTIAL EXPRESSION OF D-2 RECEPTOR SUBTYPES IN RAT CHROMAFFIN CELLS AND SYMPATHETIC NEURONS. S. Sigala*, M. Monselice, V. Pasotti, C. Missale, P.F. Spano. Div. of Pharmacology, Dept. of Biomed. Sci. and Biotec., Brescia University Medical School, Via Valsabbina 19, 25123 Brescia, Italy

Dopamine (DA) is involved in the inhibition of secretion from both neurons and endocrine cells. In chromaffin cells as well as in sympathetic nerve endings, DA receptors belonging to the D-2 family inhibit catecholamine secretion. Chromaffin cells and sympathetic neurons arise from a common bipotential progenitor under the influence of different factors such as Nerve Growth Factor (NGF), that promotes the differentiation into the neuronal phenotype. On this basis, we established primary cultures of newborn rat chromaffin cells, differentiating them into sympathetic neurons with NGF. Using RT-PCR followed by Southern blot, we studied D-2-like receptors expression in adult chromaffin cells and in sympathetic neurons. Our results show that, while D-3 receptor messenger RNA (mRNA) is not present in any cell type examined, adult chromaffin cells express D-4 and both isoforms of the D-2 receptor. Interestingly, the mRNA encoding the shorter D-2 receptor form (D-2s) was expressed at approximately 4-fold higher levels than the mRNA for the longer form (D-21). PCR amplification of mRNA obtained from sympathetic neurons shows that this phenotype selectively express the mRNA encoding for the D-2s isoform. No signal for D-21, D-3 or D-4 receptors was found

Taking together, these data suggest that 1): NGF and glucocorticoid hormones play a role in regulating D-2 family receptor expression. 2) NGF seems to be involved in the regulation of splicing mechanism, since NGF-directed differentiation of newborn chromaffin cells inhibits the expression of the D-21 mRNA. 3) Sympathetic neurons selectively express the D-2s receptor; thus suggesting a specific and different role of the D-2s and D-21 isoforms in the control of catecholamine release. QUANTITATIVE ANALYSIS OF DOPAMINE RECEPTOR TRANSCRIPTS IN D2 AND D4 RECEPTOR-DEFICIENT MICE

G. Zhang*, J.R. Bunzow, J.L. Larson, M.A. Kelly, M.J. Low and D.K. Grandy. Vollum Institute, OHSU, Portland, OR 97201.

Brain dopamine receptors play an important role in movement initiation, congnition, affect and neuroendocrine function. To better understand the contributions that each of the various dopamine receptor subtypes make to behavior and physiology we generated transgenic mice that lack either the D_2 or D_4 receptor. In the present study transcripts from the mutated D₂ and D₄ receptor genes were quantitated. For this analysis a sensitive ribonuclease protection assay (RPA) was designed for D_2 and D_4 dopamine receptor subtypes and cyclophilin (the internal standard). This assay was used to survey a number of different mouse tissues. By RPA mouse retina survey a number of different mouse tissues. By RPA mouse retina was found to be a rich source of D_4 receptor mRNA. Interestingly, receptor-deficient animals expressed $\sim 10\%$ of wild type (+/+) levels of D_4 mRNA, even though the gene's promoter had not been mutated. A similar reduction in D_2 receptor transcripts was also observed in the D_2 knockout mice (-/-): mutant D_{21} and D_{25} transcripts were expressed at $\sim 30\%$ and $\sim 44\%$ of wild type levels (p < 0.05), respectively. Currently mouse D_1 , D_{1b} and D_3 receptor mRNAs are being evaluated by RPA to determine whether any compensatory changes may have occurred in response to the absence of functional changes may have occurred in response to the absence of functional D_2 or D_4 receptors during development. This work was supported by NIDA grant DA0962 (DKG).

CEREBROCORTICAL EXPRESSION OF THE D₁ DOPAMINE RECEPTOR AND DARPP-32 IN RAT BRAIN. <u>K.C. Langley*</u>, <u>C. Bergson*</u> and <u>C.C. Ouimet.</u> Program in Neuroscience, Florida State University, Tallahassee, FL 32306, *Department of Pharmacology, Pennsylvania State College of Medicine, Hershey, PA 17033

The D_1 dopamine receptor is known to regulate DARPP-32 phosphorylation in the caudate-putamen, a region in which almost all neurons contain DARPP-32. In the cerebral cortex, however, the distribution of DARPP-32-containing neurons is restricted to specific laminae. The extent of D_1 receptor overlap with this distribution is not known. This light microscopic study localizes the laminar distribution of the D_1 study localizes the laminar distribution of the D₁ receptor and DARPP-32 in cerebral cortex via double-label immunocytochemistry. The D₁ receptor was localized primarily to dendritic processes and fine puncta, whereas DARPP-32 was localized to both neuronal somata and dendrites. Dendrites expressing both the D₁ receptor and DARPP-32 were observed. Within most cortical areas, occasional cell bodies were outlined with D₁ reaction product and these cells investible. with D_1 reaction product and these cells invariably with D_1 reaction product and these cells invariably contained DARPP-32. Throughout the cortical areas examined, layer VI contained the heaviest dendritic labelling for the D_1 receptor and the strongest neuronal/dendritic labelling for DARPP-32. The colocalization of the D_1 receptor and DARPP-32 in dendrites and certain somata indicates that cortical $\mathrm{D}_1/\mathrm{DARPP}$ -32 mechanisms may mirror those of the basal cardia. ganglia.

DIFFERENTIAL EXPRESSION OF MULTIPLE \$1-ADRENERGIC RECEPTOR TRANSCRIPTIONAL START SITE CLUSTERS IN THE CENTRAL AND PERIPHERAL NERVOUS SYSTEM. Y.-F. Yang', H. Nichols', and C. A. Machida'^{2*}. 'Div. of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006 and ²Graduate Program in Neuroscience, Oregon Health Sciences University, Portland, OR 97201.

In a previous report [Machida, C. A. <u>et al.</u> (1995). Soc. Neurosci. Abs. 21:90], we determined that the rat β 1-adrenergic receptor (β 1-AR) mRNA transcript has multiple start sites, occurring primarily in two major clusters centered at bases -280 and -250, relative to the start site of translation. RNase protection analyses indicated that the two major β 1-AR transcriptional start site clusters were preferentially utilized within the peripheral nervous system (PNS), and that extreme 5' start sites, upstream from the two major clusters, were preferentially selected in the central nervous system (CNS). To more precisely identify the upstream $\beta 1$ -AR transcriptional start sites, we synthesized a series of oligonucleotides, representing \$1-AR sequences spanning positions -495 to -2264. These oligonucleotides served as primers for reverse transcription from mRNA templates obtained from tissues/cell lines, which were either abundant or deficient in β 1-ARs. Interestingly, one primer (representing β 1-AR sequence -1743 to -1764) produced a series of extension products whose 5' ends were delimited within the region -2163 to -1911. These extension products were highly prevalent in cortex, a CNS tissue abundant in β1-ARs, and were almost nonexistent in heart, a PNS tissue containing β 1-ARs. In addition, the extension products were faintly detectable in C6 glioma cells, a cell line originating from a brain tumor and abundant in β 1-ARs, and absent in L6 cells and liver, sources devoid of β 1-ARs. The differential expression of β 1-AR transcripts in the CNS will help define the β 1-AR gene and identify potential CNS-selective β 1-AR promoter elements and enhancers. (CAM is supported by NIH grants RR00163 and HL 42358, and by an American Heart Association Established Investigatorship).

SUBCELLULAR DISTRIBUTION AND PHARMACOLOGY OF [3H]QUINPIROLE AND [3H]SPIPERONE BINDING SITES IN RAT STRIATUM. B. Levant* and G.N. Bancroft. Department of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66160-7417

RS 66160-7417
[PH]Quimpirole is an ergoline dopamine agonist with high affinity for the D₂ and D₃ receptor subtypes. Surprisingly, MAO inhibitors inhibit the binding of [3 H]quimpirole, but not [3 H]spiperone or [3 H](-)NPA, in rat striatal membranes by a competitive mechanism that does not appear to involve the enzymatic activity of MAO (Levant et al., EJP, 246:171, 1993). To further characterize this observation, the density and pharmacology of [3 H]quimpirole and [3 H]spiperone binding sites were compared in subcellular fractions of rat striatum. Total binding activity of both ligands was enriched in the synaptosomal fraction (P₂B); however, there was significantly less [3 H]quimpirole than [3 H]spiperone binding in the P₃ and P₄ fractions. [3 H]Quimpirole binding was inhibited by the MAO inhibitor-displaceable [3 H]quimpirole binding in each fraction were not significantly different from those inhibited by spiperone. In contrast, [3 H]spiperone binding was not inhibited by R0 41-1049 in any fraction. Quimpirole had significantly lower affinity for [3 H]spiperone-labeled sites in the P₃ and P₄ fractions than the affinity of [3 H]quimpirole in these fractions. These data demonstrate that [3 H]quimpirole labels a membrane-associated site and suggest that [3 H]quimpirole labels a membrane-associated site and suggest that [3 H]quimpirole and [3 H]spiperone may interact with distinct binding sites in certain subcellular fractions. [3H]Quinpirole is an ergoline dopamine agonist with high affinity

TRANSIENT D1 SYNTHESIS MODULATING AUTORECEPTOR IN THE PREFRONTAL CORTEX

AND STRIATUM. N.L. Dumont, S.L. Andersen, S.K. Yeghiayan*, and M.H. Teicher. Dept. of Psychiatry, Harvard Medical School, Laboratory of Developmental Psychopharmacology, McLean Hospital, Belmont, MA 02178

Previous research (Teicher et al, 1990) has provided evidence for a D1 Previous research (Teicher et al, 1990) has provided evidence for a D1 transient synthesis-modulating autoreceptor in rat prefrontal cortex and striatum utilizing the in vivo GBL model. This autoreceptor like effect was apparent at postnatal (P) day 15, waned by P22 and was absent by P60. In order to clarify whether the effect was due to an autoreceptor or a heteroreceptor, we utilized an in vitro slice model. 250µM sections of the prefrontal cortex and striatum were incubated at 37°C in Kreb's-Ringers buffer with the D1 agonist SKF-38393(.01µm-10.0µm); after 20 minutes, the decarboxylase inhibitor NSD-1015 was added and the reaction was terminated 20 minutes later. In a dose-dependent manner, SKF-38393 inhibited L-DOPA accumulation at P15 (see Figure).

This effect persisted in the striatum until P40, but L-DOPA was

until P40, but L-DOPA was uneffected by SKF-38393 in the prefrontal cortex at this age. Research is underway to examine the effect of a D1 antagonist and TTX to determine if this is mediated by a heteroreceptor. Supported by NIMH RO1-43743 to

RECEPTOR-DEFICIENT TRANSGENIC MICE REVEAL D1B (D5) RECEPTORS IN HIPPOCAMPUS. D.M. Montague, J.S. Overcash, C.D. Striplin J. Drago R.B. Mailman and C.P. Lawler. Neuroscience Center, Univ. of North Carolina, Chapel Hill, NC 27599-7250 and ¹Neuroscience Unit, Monash University, Clayton 3168 Australia

The dopamine D_{1A} receptor is the predominant "D₁-like" subtype expressed in the mammalian brain. The targeting of the D1A dopamine receptor gene in mice with a mixed C57BL/6 and 129/Sv genetic background resulted in mice that exhibited essentially normal locomotor responses (PNAS 91:12564). This unexpected finding suggested that some mechanism might be compensating for the loss of the D_{1A} receptor. The D_{1A} knockout model was used in the present study to: i) observe possible density changes in specific receptor populations that may be associated with a compensation for D_{1A} deficiency; and, ii) confirm the presence and location of the rare D_{1B} (D_{3}) receptor subtype, which is normally masked by much higher D_{1A} densities. Quantitative receptor autoradiography studies were performed to determine the densities of D_{1} -like receptors (1 H]-SCH23390) and D_{2} -like (123 I]sulpiride; [3H]N-n-propylnorapomorphine) receptors in various brain regions of wildtype, heterozygote, and homozygous transgenic mice. As expected, the data indicated a near-complete absence of D₁-like receptors in homozygous (-/-) mice and a drastic loss in heterozygotes. Surprisingly, D2 receptor densities were similar among the three genotypes. This evidence suggests that alterations in D2 receptor density are not a factor involved in D1A receptor compensation. Finally, our studies have also provided the first localization and quantification of the less prevalent "D₁like" subtype, the D_{IB}. Autoradiographic data, supported by homogenate binding studies, demonstrated the presence of D_{1B} receptors throughout the hippocampal complex of homozygous mice. Low densities of [3H]-SCH23390-labeled sites were also detected in the parafesicular nucleus of the thalamus in these mice. These findings are consistent with earlier data localizing the mRNA for this receptor to these regions. (MH42705, MH40537, HD03110, MH33127, and GM07040)

SIMULTANEOUS COMPARISON OF D2/D3 RECEPTOR AFFINITY OF NOVEL D3-SELECTIVE DRUGS IN RAT BRAIN. R.J. Flietstra*, B. Levant. Department of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66160.

Several dopaminergic drugs have recently been shown to exhibit higher affinity for D_3 receptors than for D_2 receptors in transfected cell lines. This study used quantitative autoradiography to simultaneously evaluate the D2/D3 selectivities of novel D₃-selective compounds in rat brain. Slide-mounted sagittal sections were incubated with [3H]quinpirole and various concentrations of competing drug. The ability of each drug to inhibit [3H]quinpirole binding in cerebellar lobule X, associated with D₃ mRNA, was used as a measure of D₃ affinity; inhibition of [3H]quinpirole binding in the caudate/putamen, primarily associated with D2 mRNA, estimated D₂ affinity. PD 128907, a dopamine agonist, was more potent in cerebellum than in caudate/putamen, indicating selectivity for the D₃ receptor. In contrast risperidone and domperidone were more potent in the caudate/putamen, indicating a greater affinity for the D2 The D_2/D_3 selectivities of other compounds, including dopamine and UH 232, were also evaluated Supported by NIMH MH52839

MULTIPLE 3H-NEMONAPRIDE BINDING SITES IN HUMAN AND COW BRAIN. D.M. Helmeste*, H. Fang, M. Li and S.W. Tang, Depts. Psychiatry and Pharmacology, University of California, Irvine, Irvine, CA

Tritiated nemonapride has been used to label dopamine D₄ receptors. We reported that a substantial proportion of ³H-nemonapride binding in striatum, frontal cortex and cerebellum in both human and bovine brains represents sigma sites. Using haloperidol (DA and sigma ligand) to define specific 3H-nemonapride binding yielded biphasic Scatchard plots in human striatum (Kds: 0.03 and 7.2 nM). In human frontal cortex and cerebellum, haloperidol (1 µM) also defined more than one 3H-nemonapride site by Scatchard analysis. The dopamine and sigma components of 3Hnemonapride binding can be differentially shown by (+) and (-) butaclamol displacement in striatum, frontal and cerebellar cortex. The sigma site labeled by ³H-nemonapride had a sigma-1 profile [IC50s (nM): haloperidol=5.9, PPAP=45, (±) pentazocine=84, progesterone=400, (-) butaclamol=99, (+)butaclamol=515]. When dopaminergic and sigma sites were blocked with sulpiride and pentazocine, respectively, haloperidol revealed a third component of 3H-nemonapride binding. Spiperone, (+) butaclamol, loxapine and thioridazine but not clozapine, mianserin, (-) butaclamol, sertraline, DOI, (-) PPP, atropine, diphenhydramine or econazole compete for this third component. This suggests an additional dopamine site labeled by ³H-nemonapride, not previously described. (Human tissue from NNRSB, VAMC, LA). (Non-commercial/non-grant funding sources)

INTERACTION OF HUMAN D3 DOPAMINE RECEPTORS EXPRESSED IN Sf-9 CELLS WITH ENDOGENOUS G-PROTEINS AS DETECTED WITH GTP-γ-S BINDING. J.F.Pregenzer, G.L. Alberts and W.B.Im*. CNS Diseases

Research, Pharmacia & Upjohn, Inc. Kalamazoo, MI 49001.
The human D3 dopamine receptor was expressed in Sf-9 cells, using the recombinant baculovirus carrying the receptor cDNA. With cell harvesting at various post infection times, we obtained membranes with different receptor densities of 0.73, 9.2, 26 and 52 pmol/mg protein, as measured with [3H]spiperone binding. The dissociation constant for the ligand was 0.5 nM. The effect of GTP-γ-S on [3H]dopamine binding was variable, depending on the receptor density. The nucleotide at a concentration of 10 μM reduced [³H]dopamine binding by 52%, 13% and 2% with receptor densities of 0.73, 9.2, and 26 pmol/mg protein, respectively. This suggests that the fraction of the D3 receptor coupled to endogenous G-proteins in Sf-9 cells progressively decreased as the receptor density increased. On the other hand, Na* (200 mM), an allosteric modulator, reduced [3H]dopamine binding by 20% to 30 %, regardless of receptor density. Agonist-induced enhancement of GTP- γ -[35S] binding was also observed in membranes of low and high receptor density. A number of agonists for the D2-like receptors enhanced GTP-γ-[³⁵S] binding, whereas antagonists did not. It appears that GTP-y-[35S] binding is useful for characterizing ligand functionality in recombinant human D3 dopamine receptors in Sf-9 cells.

BINDING CHARACTERISTICS OF IODINATED LIGANDS FOR DOPAMINE D4 RECEPTORS. H. F. Kung*, M.-P. Kung, D. A. Stevenson, Z.-P. Zhuang, J. M.

D4-RE-EF 1083. A. S. Chumpradit, X.-M. Sun. Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Binding characteristics of two iodinated compounds, trans-5-hydroxy-2-(N-n-propyl-N-3-jodo-2-propenyl)aminotertalin ((S)-5-OH-PIPAT), and 3-[4-(4-iodophenyl)piperazin-1-yl]methyl-1H-pyrrolo(2,3-b)pyridine (IPMPP). were todopheny)pipera. D4 (D4.2 variant) receptors expressed in CHO cells. Saturation analysis revealed high-affinity-site binding for both [125 I](S)-5-OH-PIPAT (K_d = 0.36 ± 0.08 nM) and [125 I](PMPP (K_d = 0.39 ± 0.18 nM). The number of D4 receptor sites labeled with [125 I](PMPP at 25 °C was four times higher than that labeled with [125 I](S)-5-OH-PIPAT (572 fmol/mg protein vs. 124 cells). higher than that labeled with [123](S)-5-OH-PIPAT (572 fmol/mg protein). A significant decrease of the number of binding sites was observed with [125](S)-5-OH-PIPAT when assays were carried out at 37 °C. In contrast to [125](S)-5-OH-PIPAT, [125][IPMPP] labeled more D4 sites at 37 °C. The magnesium ion stimulated the binding of [126](S)-5-OH-PIPAT, but it showed no effect on [125][IPMPP] binding. Gpp(NH)p significantly inhibited specific binding of [125][IPMPP] binding was not affected. These data strongly suggest that [125](S)-5-OH-PIPAT is an agonist radioligand and [125][IPMPP] is an antagonist radioligand for labeling dopamine D4 receptors expressed in CHO cells. In addition, results of measuring D4 receptor-stimulated [125]GPTy8 binding in CHO cells lend support to the agonist and antagonist activity for (S)-5-OH-PIPAT and IPMPP, respectively. Unfortunately, neither radioligand is adequate for visualizing D4 receptors in rat brain sections due to the lack of dopamine subtype selectivity of receptors in rat brain sections due to the lack of dopamine subtype selectivity of [1251](5)-5-OH-PIPAT and the high non-specific binding of [1251][PMPP. A more desirable radioiodinated ligand with better subtype selectivity and lower non-specific binding should be developed in the future for the characterization of D4 receptor binding. (Supported by NS-24538)

EXCITOTOXIC LESIONS OF THE MEDIAL PREFRONTAL REDUCE DOPAMINE D1-LIKE BINDING SITES IN THE VENTRAL TEGMENTAL AREA. K. Dewar ', P.-P. Rompré', J. Stewart' and R.A Warren's 'Psychiatry Department, University of Montreal and 'Psychology Department, Concordia University, Montreal (Québec),

Repeated exposure to amphetamine (AMPT) results in a progressive increase in its locomotor activating effect, a phenomenon known as sensitization. Although the exact mechanism(s) involved in the development of AMPT sensitization remain(s) unclear, several studies suggest that activation of dopamine D1-like receptors in, or near, the ventral tegmental area (VTA) is important. The localization of tegmental D1 receptors on afferent terminals is suggested by the absence of D1 mRNA in the VTA. Since the mPFC neurons not only project to the VTA but also contain a significant amount of D1 mRNA, D1 receptors may be localized on these mPFC terminals. In this study, we investigated whether excitotoxic lesions of the mPFC reduced D1-like binding sites in the VTA. Male Wistar rats were anesthetized with pentobarbital and ibotenic acid (2 μ g/ μ l or 10 μ g/ μ l) or its vehicle was microinjected at three anterior-posterior placements the left mPFC (between 3.2 and 4.5 mm from bregma, 1 μ per placement). Ten days after surgery, animals were sacrificed, their brains removed, and divided into midbrain and forebrain blocks. The forebrain region was sectioned and stained with formal-thionin to verify the nature and the extent of the lesion, while the midbrain block was used for autoradiographic quantification of D1-like receptors using the selective D1 receptor antagonist [129]SCH23938. Small excitotoxic lesions (low dose) of the mPFC resulted in a significant loss in D1-like binding sites in the ipsi- (42%) and contralateral (15%) VTA compared with vehicle control. The larger, non-specific lesions (high dose) resulted in a similar ipsilateral (43%) but a larger contralateral loss (38%) in D1-like binding sites. These findings demonstrate that a significant amount of D1-like receptors are located on mPFC efferent to the VTA

330.4

GTP SENSITIVITY OF DOPAMINE D3 RECEPTORS IN THE RAT BRAIN. J. M. Vessotskie*, M.-P. Kung, S. Chumpradit and H. F. Kung. Departments of Pharmacology and Radiology, University of Pennsylvania, Philadelphia, PA

Dopamine D3 receptors are members of the D2-like dopamine receptor family. It is well documented that agonist binding to dopamine D2 receptors in rat brain is GTP and pertussis toxin sensitive (Olianas et al., J Neurochem 48:1443, 1987). is GTP and pertussis toxin sensitive (Olianas et al., J Neurochem 48:1443, 1987). The results of experiments to examine the GTP sensitivity of agonist binding to D3 receptors in native state are ambiguous because appropriate tools are not available. Recently, a radioiodinated ligand, S(-)-5-OH-PIPAT (5-hydroxy-2-(N-n-propyl-N-3'-iodo-2'-propenyl)aminotetralin), was shown to bind with high affinity ($K_1 = 0.1$ nM) to dopamine D3 receptors in molecular layers 9 and 10 of rat cerebellum using autoradiographic techniques (Vessotskie, Abs Neurosci 341.2, 1995). This brain region contains high densities of D3 receptors with minimal contamination of D2 or D4 receptors (based on mRNA expression, Bouthenet et al., Brain Res 564:203, 1991; Van Tol et al., Nature 350:610, 1991). A series of autoradiographic experiments was completed to examine the effect of GTP on D3 receptors. Increasing concentrations of GTP but not ATP, decreased $(\frac{123}{18})S(-5)$ receptors. Increasing concentrations of GTP, but not ATP, decreased [123]S(-)-5-OH-PIPAT (putative agonist) binding to D3 receptors in the cerebellum by 60%, but did not influence [123]INCQ298 (putative antagonist) binding. Analysis of competition experiments of S(-)5-OH-PIPAT for [125]]NCQ298 binding revealed that a two site model best fit the data. Additional competition experiments were performed, using dopamine, the endogenous neurotransmitter, and [125]NCQ298, performed, using dopamine, the endogenous neurotransmitter, and [1°T]NCQ298, to insure that the effect was not a ligand characteristic. The presence of 100 µM Gpp(NH)p caused a rightward shift of the dopamine inhibition curve. Autoradiography experiments of D3 receptors in the Major Island of Calleja showed the presence of 300 µM GTP decreased [125T]S(-)-5-OH-PIPAT binding by 27% without influencing [125T]NCQ298 binding. These experiments suggest that D3 receptors in the rat brain are GTP sensitive. The pertussis toxin sensitivity of D3 receptors is currently under investigation. (Supported by MH-51880)

LOCALIZATION OF THE IMIDAZOLINE / GUANIDINIUM BINDING DOMAIN ON MONOAMINE OXIDASE B. R. Raddatz* and S.M. Lanier Dept. of Pharmacology, Medical University of South Carolina, Charleston, SC 29425. Two members of the family of imidazolina hinding materials. imidazoline binding proteins were recently identified as monoamine oxidase A and B (MAO-A and B). Although some imidazoline/guanidinium derivatives inhibit enzyme activity, the imidazoline guantinium derivatives infinit enzyme activity, the imidazoline binding domain on MAO appears to be distinct from the enzyme active site suggesting an additional motif for regulating enzyme function. To identify the imidazoline binding domain on MAO-B, a radiolabeled photolabile imidazoline derivative was used to covalently label the protein. The photolabeled MAO-B was isolated covalently label the protein. The photolabeled MAO-B was isolated by SDS-PAGE, the gel slice containing radioactivity was excised and the protein was digested to completion with CNBr (70% formic acid, 24 hours at 37° C). The resulting peptide fragments were separated on a 15.5% acrylamide gel using a Tricine buffer system and radiolabeled peptides detected by autoradiography. Radiolabeled peptides of M, -13,000 for rat MAO-B and M, -8,000 for human MAO-B were identified. Based on the species differences in the primary sequence of rat and human MAO-B and the M, of labeled peptides following CNBr digestion, the site of photoincorporation of the imidazoline ligand is apparently localized to a 73 amino acid fragment (residues 149 - 222) of MAO-B in these two species. In contrast to the site of action of various mechanism-based MAO inhibitors that interact with the FAD cofactor at Cys-397, the imidazoline binding domain represents a potentially novel site for enzyme regulation. (Supported by NS 24821/CTR 2235, RR was supported by 5-T32-HL07260-18) enzyme regulation. (Supp supported by 5-T32-HL07260-18)

FACTORS INFLUENCING SELECTIVITY FOR D_{IA} VS. D_{IB} (D₃)

Wyrick and RB Mailman. Univ. of North Carolina, Chapel Hill, NC 27599, &
Purdue University, W. Lafayette IN 47907

We have tested the hypothesis that the ligand binding domain of the $D_{1\rm A}$ and $D_{1\rm B}$ receptors are similar except for subtle differences in the accessory hydrophobic region, and in the orientation of the amine binding region. We have used and/or synthesized several chemical classes, including hexahydrobenzophenanthridine, phenyltetrahydrobenzazepine, tetrahydroisoquinoline (THIQ) and aminodihydroxytetrahydronapthalene (ADTN) derivatives. Drugs were tested 10-HO cells transfected with either of the human isoforms. None of this wide range of compounds showed even as much as a ten-fold selectivity for either isoform. For example, 7-chloro-8-hydroxy-N-methyl-1-phenyl-1,2,3,4-THIQ and analogs with phenyl ring substituents (R= Cl or CH₃) displayed similar affinity for $D_{1\rm A}$ and $D_{1\rm B}$ While o-substitution (regardless of the electronic character of the substituent) doubled the preference of THIQs for $D_{1\rm B}$ receptors, this was still a rather subtle change. This area was probed further by the synthesis of a series of phenyl-substituted compounds. Whereas the o-, o-dimethyl substituted THIQ analog had a 2.7-fold preference for the $D_{1\rm B}$ receptor, an o-isopropyl substitution decreased ligand affinity for $D_{1\rm A}$ neceptors, without changing the affinity for $D_{1\rm A}$ receptors. These data suggest that $D_{1\rm A}$ and $D_{1\rm B}$ receptors as we somewhat similar steric pockets. In the absence of predictive molecular models of the $D_{1\rm A}$ and $D_{1\rm B}$ receptors, we believe that development of a selective ligand should utilize a pharmacophore that incorporated into a novel structural backbone. RESIDUES IN THE FIFTH MEMBRANE-SPANNING SEGMENT OF THE β₂ ADRENERGIC RECEPTOR ACCESSIBLE IN THE BINDING-SITE CREVICE D. Fu*, and J. A. Javitch. Center for Molecular Recognition & Dept. of Psychiatry, Columbia University: NYS Psychiatric Institute, NY, NY 10032.

Using the substituted-cysteine accessibility method, we previously mapped the residues in the fifth membrane-spanning segment (M5) that are accessibl binding-site crevice of the dopamine D2 receptor (Javitch et al., Biochem. 34:16433, 1995). We mutated twenty-four consecutive residues in and flanking M5 to cysteine and expressed the mutant receptors in HEK 293 cells. Thirteen of these mutants reacted with charged polar sulfhydryl-specific derivatives of methanethiosulfonate (MTS) added extracellularly, and were protected from reaction by a reversible dopamine antagonist. Of the thirteen accessible residues, ten were consecutive, from Phe189 to Phe198. This pattern of accessibility is inconsistent with the expectation that M5, like M3, forms a fixed α-helix, one side of which is accessible in the binding-site crevice. Six of the ten consecutive accessible residues are identical to the aligned residues in the β_2 adrenergic receptor. We have now mutated to cysteine twelve consecutive residues in M5 of the β_2 receptor. MTSethylammonium (MTSEA) did not inhibit antagonist binding to wild type β_2 receptor but did inhibit binding to seven of the twelve β_2 cysteine mutants. Binding to three cysteine mutants, the aligned residues of which were accessible to MTSEA in the D2 receptor, was unaffected by MTSEA at 2.5 mM. Furthermore, MTSEA did not change the IC50 for isoproterenol competition with the antagonist [3H]CGP-12177 in these mutants. It appears, therefore, that these three residues in the β_2 receptor are not accessible to reaction with MTSEA. This may reflect a difference in the structures and/or packing of membrane-spanning segments in the two receptors. Alternatively, the conformational changes involved in receptor activation may differ The pattern of accessibility is consistent with M5 in β_2 receptor being an α -helix, one side of which is accessible in the binding-site crevice. Supported by NS07258.

DOPAMINE D₃ RECEPTORS IN BASAL GANGLIA/MESOLIMBIC AREAS DETECTED BY ³HI-PRAMIPEXOLE RECEPTOR BINDING STUDIES. M.Camacho-Ochoa*, E.L.Walker, D.L.Feldpausch, and M.F.Piercey. Pharmacia & Upjohn Inc., Kalamazoo, MI, USA 49001.

Although there are 5 dopamine (DA) receptor subtypes, little knowledge exists concerning their distribution. mRNA distributions suggest D $_3$ receptors located mostly in mesolimbic regions, but D $_3$ receptor antibody binding sites (Brain Res 649:95, 1994) and some D $_3$ mRNA have also been found in caudate (Brain Res 564:203, 1991). We have now used 8 concentrations of 3 [H]-pramipexole (PPx), a D $_3$ preferring DA agonist useful in Parkinson's Disease (PD) to extimate K_s 5 by saturation analsis in various brain regions of coronal sections of rat brain. In clonal cell lines expressing rat receptors, 3 [H]-PPx has a D $_3$ K, of 0.37 nM and a D $_2$ K, of 7.2 nM at high affinity binding sites relevant for agonist activity (Eur J Pharmacol 290:29, 1995). In anterior brain slices, $[^3$ H]-PPX bound with affinities comparable to D $_3$ high affinity sites (0.2 - 0.4 nM) in Islets of Calleja (ICj), n accumbens olfactory tubercle and caudate and with lower affinities (1.5-10 nM) in L septum, M septum (MS), and diagonal band (DBB). Binding in more caudal segments had higher K_a 5, suggesting possible mixed D_a/D_3 receptor populations for both caudate and nucleus accumbens shell and core, and D $_2$ receptors for n basalis. However, ICj K_a 5 were still in the D $_3$ high affinity range. It is concluded that D $_3$ receptor distribution is broader than suggested by mRNA studies and that PPx's efficacy in treating PD could, in part, be due to stimulation of basal ganglia D $_3$ receptors. DA receptor populations suggested for MS, DBB, and n basalis are consistent with known DA neuron projections into forebrain cholinergic areas (Prog. Brain Res 98:31, 1993).

RESIDUES IN THE SEVENTH MEMBRANE-SPANNING SEGMENT OF THE DOPAMINE D2 RECEPTOR ACCESSIBLE IN THE BINDING-SITE CREVICE. J. A. Javitch*, D. Fu, J.A. Ballesteros, and J. Chen. Center for Molecular Recognition & Psychiatry, Columbia University; NYS psychiatric Institute, NY, NY 10032; Physiology & Biophysics, Mt. Sinai School of Medicine, NY, NY 10029. The binding site of the dopamine D2 receptor, like that of other homologous G

protein-coupled receptors, is contained within a water-accessible crevice formed among its seven membrane-spanning segments. Using the substituted-cysteine accessibility method, we are mapping all the residues exposed in this binding-site crevice. We mutate individual residues in the membrane-spanning segments to cysteine, express the cysteine-substitution mutants in HEK 293 cells, and examine antagonist binding to mutant receptor in intact cells. If mutant receptors are nearnormal in their binding, we determine whether the substituted cysteine is at the water-accessible surface of the binding site by testing its accessibility to small, charged hydrophilic, lipophobic sulfhydryl-specific derivatives of methanethiosulfonate (MTS). These reagents react covalently with cysteine, and if the engineered cysteine faces into the binding-site crevice, the reaction will block antagonist binding irreversibly and will be retarded in the presence of ligand. We previously mapped the residues that form the surface of the binding-site crevice in the third and fifth membrane-spanning segments. We have now mutated to cysteine, one at a time, twenty-six consecutive residues in and flanking the seventh membrane-spanning segment (M7). Nine of these mutants reacted with the MTS reagents added extracellularly and were protected from reaction by a reversible dopamine antagonist, sulpiride. Thus, we infer that the side chains of these nine residues are in the water-accessible surface of the binding-site crevice. The pattern of accessibility of the cysteine substitution mutants is consistent with M7 being a kinked α-helix but not an ideal α-helix. Supported by MH01030, MH54137, NS07258, NARSAD, the Scottish Rite, the Mathers Charitable Trust and DA09083.

IN VIVO BINDING OF [PH]SCH 23390: EVALUATION OF THE IMPORTANCE OF REBINDING TO RECEPTORS IN SLOWING THE APPROACH TO EQUILIBRIUM. A.N. Gifford', S.J. Gatley and N.D. Volkow. Medical Dept., Brookhaven Natl. Lab., Upton, NY 11973. The importance of rebinding to receptors in influencing the kinetics of the *in vivo* binding of a high affinity radioligand was examined by comparing the time

for striatal [3H]SCH 23390 binding to reach equilibrium in tissue homogenates with that in brain slices and in vivo. In homogenates [3H]SCH 23390 binding reached equilibrium in approximately 60 min. By contrast, in rat striatal slices incubated in [3H]SCH 23390 the radioactivity levels in the slice continuously increased over a 4 h period, with no indication of an approach to equilibrium at the time of termination of the experiment. However, radioactivity in the slice reached a steady state in less than an hour when D₁ receptors were blocked by inclusion of a high concentration of the selective D₁ antagonist, SCH 39166, in the incubation medium. In the in vivo experiments [3H]SCH 23390 was given to mice both as a bolus injection and as a constant intravenous infusion over a 4 h time period. Following the bolus injection striatal and cerebellar radioactivity levels reached a peak only 15 min after the injection. However, following a constant infusion striatal levels of radioactivity continued to increase in an almost linear fashion throughout the 4 h infusion period whereas increase in an amost linear rasinon intrognous the 4 in intraston period wincestee cerebellar levels of radioactivity and serum levels of [FH]SCH 23390 reached a steady state within 15 min. Calculations based on the slice experiments suggested that a primary factor accounting for failure of [3H]SCH 23390 levels to reach equilibrium in vivo is its hindered diffusion through receptor rich tissue as a result of repeated rebinding to receptors. These observations have important implications for the widely used compartmental models for the *in* vivo binding of PET and SPECT ligands. Supported by NIDA grant DA 06891

DESTRUCTION OF SEROTONERGIC NEURONS DOES NOT ALTER BINDING OF THE D3 LIGAND [125I]-7-OH-PIPAT IN THE MEDIAN AND PARAMEDIAN RAPHE NUCLEI OF THE RAT. G.D. Stanwood'. R.P. Artynsynyn. M.P. Kung. R.K. Raghupathi, A. Singh, I. Lucki, and P. McGonigle. Institute of Neurological Sciences and Department of Phamacology, University of Pennsylvania, Philadelphia, PA 19104.

Recent morphological and microdialysis studies suggest that the ascending serotonergic projections from the raphe nuclei to the forebrain are regulated by dopamine D2-like (D2, D3, D4) receptors. The expression of dopamine D2 and D3 receptors was therefore examined at the level of the raphe nuclei in the rat brain using quantitative autoradiography. The D2/D3 ligand [125]]-MCQ 298 labeled a moderate density of sites in the dorsal, median and paramedian raphe nuclei and the anterior, ventral and dorsal tegmental nuclei. [125]]-7-OH-PIPAT (D.2 M), which has been shown to be D3-selective in the presence of GTP (300 μM) and DTG (1 μM), labeled a low density of sites in the median and paramedian raphe nuclei as well as in the tegmental nuclei. No labeling was detected in the dorsal raphe nucleus. Binding of [125]]-7-OH-PIPAT was unaltered by the addition of the 5-HT_{1,A}-selective antagonist MPPF (100 nM) to the assay buffer indicating that it does not label 5-HT_{1,A} receptors under these conditions. A second D3 ligand, [125]-5-OH-PIPAT (0.25 nM), produced an identical pattern of labeling. Animals were lesioned with the neurotoxin 5,7 DHT to determine whether the receptors labeled by [125]-7-OH-PIPAT are located on serotonin containing cells in the raphe nuclei. Extensive lesion of serotonergic neurons did not alter [125]-7-OH-PIPAT binding, suggesting that D3 receptors in the median and paramedian raphe are not located on serotonin-containing neurons. D3 receptor expression in the nucleus accumbens and substantia nigra was also unchanged following 5,7 DHT lesion. (Supported by NS-18591, MH-48125, and MH-51880.)

FUNGAL TRIPRENYL PHENOLS SHOW AFFINITY TO THE BRAIN DOPAMINE D, RECEPTOR IN VITRO. K. Dekermendjian', M.R. Witt', Q. Sterner' and M. Nielsen'*. Research Institute of Biological Psychiatry, St. Hans Hospital, Dk-4000 Roskilde, Denmark.

From extracts of the mushroom Albatrellus ovinus we isolated the four known triprenyl phenols scutigeral, ilicicolin B, neogrifolin and grifolin as well as the two new triprenyl phenols metabolites which we named ovinal and ovinol. All six triprenyl phenols competitively inhibited the in vitro binding of $^3\text{H-SCH}$ 23390 (R-(+)-7 chloro-8 hydroxy-3-methyl-1-phenyl-2,3,4,5-tetrahydrol-1H-3-benzazepin-7-ol) to the dopamine D₁ receptor subfamily in rat striatab brain membranes. The 1Cs0 values were in the range of 2.6 - > 50 μM . Grifolin additionally inhibits the specific binding of $^3\text{H-spiperone}$ (ICs0 20.2 μM) to the dopamine D₂ receptor subfamily and is therefore not subfamily specific. Ovinal, ovinol, scutigeral, neogrifolin and illicicolin B had no effect on $^3\text{H-spiperone}$ binding suggesting that these compounds selectively interact with the dopamine D, receptor subfamily. The structure of the compounds was determined by NMR spectroscopy.

HIGH AFFINITY 3 [H]-MK-912 BINDING TO α_{2B} -ADRENOCEPTORS IN NEONATAL RAT LUNG . M.A. LEWIS*.A.L.KIRIFIDES and E. E. CODD. Drug Discovery Research, The R.W. Johnson Pharmaceutical Research Institute, Welsh and McKean Roads, Spring House, PA 19477-0776.

We used the potent and highly selective α_2 -adrenoceptor antagonist 3 [H]-MK-912 to characterize high affinity binding to the α_{2B} -adrenoceptor subtype in neonatal rat lung. Many previously published radioligand binding assays used conditions that prevent the formation of the agonist high affinity state of the receptor. The present study was performed using 50 mM Tris buffer in the presence of 5 mM MgCl₂ to promote formation of the agonist high affinity state of the receptor. Saturation experiments using 3 [H]-MK-912 under these conditions fit a single-site model with a K_d value of 0.97 nM. Agonist competition curves better fit a two-site model with approximately 30% of labeled sites in the high affinity state. Agonist competition experiments conducted in the presence of GTPyS and/or NaCl shifted curves to the right and fit a single-site model indicating the uncoupled or low affinity state of the receptor. Antagonist competition curves yielded a high affinity component comprising approximately 90% of the sites with the remaining 10% yielding a tissue unspecific low affinity (>µM) component. These results indicate that this assay, under conditions promoting the agonist high affinity state, may be able to differentiate agonist from antagonist binding to the α_{2B} adrenoceptor.

EFFECTS OF MEDIAL PREFRONTAL CORTICAL, NIGRAL, AND STRIATAL LESIONS ON STRIATOLIMBIC D₂ AND D₄ DOPAMINE RECEPTORS. F.I. Tarazi*, S.K. Yeghiayan, A. Campbell, and R.J. Baldessarini. Psychiatry & Neuroscience Depts, Harvard Medical School; Mailman Research Center, Belmont, MA 02178.

We examined changes in striatolimbic D₂ and D₄ dopamine (DA)

We examined changes in striatolimbic D₂ and D₄ dopamine (DA) receptor binding following: [1] unilateral surgical ablation of anterior medial prefrontal cortex (MPC) to remove descending glutamatergic projections mainly to the nucleus accumbens (ACC), [2] unilateral injections of 6-hydroxydopamine into substantia nigra (SN) to destroy ascending DA projections, [3] intrastriatal (STR) injections of kainic acid to degenerate intrinsic neurons locally. Rats were sacrificed one week after lesioning; contralateral striata served as controls. D₂ receptors (D₂/R₃) were quantified autoradiographically with the D₂-like (D₂/D₃/D₄) ligand ³H-emonapride, while D₄Rs were quantified with ³H-nemonapride plus 300 nM S(-)-raclopride to occlude D₂/D₃ receptors, as well as 100 nM pindolol and 500 nM 1,3-ditolylguanidine (DTG) to mask 5HT_{1A} and sigma sites. Nigral lesions was verified by the loss of DA transporters (×85%) measured by *in vitro* autoradiography with ³H-GBR-12953. Ablation of MPC and neurotoxin lesioning of SN did not change D₂R or D₄R binding in STR. However, D₄R, but not D₂R binding was significantly decreased (-27%) in ACC after MPC ablation. Kainate injection in STR produced large losses of D₂R (-50%) and D₄R (-22%). These results suggest that the majority of D₂Rs and a portion D₄Rs in STR are on intrinsic neurons postsynaptic to DA afferents, and that some D₄Rs, at least in ACC, may be located presynaptically on glutamatergic afferents.

HIGH AFFINITY AGONIST BINDING TO THE α_{2C} - ADRENOCEPTOR IN THE OPOSSUM KIDNEY CELL LINE. <u>A. L. KIRIFIDES*, M.A. LEWIS and E. E. CODD.</u> Drug Discovery, The R.W. Johnson Pharmaceutical Research Institute, Spring House, PA 19477.

Human α_{2A} -, α_{2B} - and α_{2C} -adrenoceptors (AR) belong to the family of membrane bound G-protein coupled receptors regulated by mono and divalent cations and guanine nucleotides. Whereas many previously published radioligand binding assays used conditions conducive to formation of the agonist low affinity state of the receptor, the present study was performed using 50 mM Tris buffer in the presence of 5 mM MgCl₂ to promote formation of the agonist high affinity state. We previously studied human cloned receptors under these conditions and were able to differentiate agonists from antagonists by their binding characteristics. The present study used an OK cell line derived from an opossum kidney which expresses the α_{2C}-AR. Saturation studies using the α₂-antagonist [3H]-MK-912 fit a single site model with a K_d value of 0.044 nM. Similarly, competition curves by several antagonists were best fit by a one site model. In contrast, competition curves by several agonists were best fit by a two site model. Agonist inhibition curves conducted in the presence of GTP yS (G-protein uncoupling agent) were best fit by a single site model with affinities similar to the low affinity site found in the presence of MgCl2 (high affinity binding conditions). Comparison of these results with those obtained from the human cloned $\alpha_{\text{2C}}\text{-AR}$ produced similar results. In both studies, antagonist inhibition curves were best fit by a single site model whereas agonist data were best fit by a two site model. These and related data suggest that the present assay conditions can be used to distinguish agonist from antagonist binding to α_{2C} -AR in the OK cell line.

ZINC ALLOSTERICALLY MODULATES ANTAGONIST BINDING TO CLONED D1 A DOPAMINE RECEPTORS EXPRESSED IN CHO CELLS. John A. Schetz* and David R. Sibley. Molecular Neuropharmacology Section, ETB/NINDS/NIH, 9000 Rockville Pike, Bethesda, MD 20892.

Zinc ions were found to inhibit antagonist binding to the cloned rat D_{1A} dopamine receptor expressed in Chinese Hamster Ovary (CHO) cells. The nature of zinc's action was characterized by measuring the radioligand binding properties of [3H]-SCH23390 in the presence or absence of zinc ions. Zinc exerts a low affinity (micromolar Ki value), dose-dependent inhibition of the binding of [3H]-SCH23390 primarily by decreasing the ligand's affinity for the ${\sf D}_{\sf 1A}$ receptor. Zinc inhibition is completely reversed by addition of the divalent cation chelator EDTA and not mimicked by an equal concentration of manganese (a cation of similar size and equal charge). This effect is specific for zinc ions as various zinc salts produce identical effects. The mechanism of zinc inhibition appears to be allosteric modulation of the dopamine receptor protein since zinc increases the KD of ligand binding and Schild plots of zinc inhibition reach a plateau. Moreover, zinc accelerates the dissociation of [3H]-SCH23390 from its receptor. Here we report the inhibition of antagonist binding by zinc, and demonstrate that the mechanism of zinc inhibition is a dosedependent, reversible and allosteric modulation of the D1A dopamine receptor protein. (Supported by NINDS/NIH).

AFFINITY AND INTRINSIC ACTIVITY OF DOPAMINE AGONISTS AND PARTIAL AGONISTS AT THE CLONED hD₂₀, hD_{4,7}, hD_{4,7} RECEPTORS. C.A. Tamminga^{**}, A. Mutin^{*}, E.V. Cochrane^{**}, and R.A. Lahti^{**}, *Maryland Psychiatric Research Center, Univ. of Maryland School of Medicine, Baltimore, MD, USA.

The dopamine D_2 -family of receptors is made up of the D_2 , D_3 and D_4 receptors (Civelli et al., 1991). Dopamine agonists and partial agonists have been evaluated in the treatment of schizophrenia (Tamminga et al., 1978, 1986, 1992). In this study using receptor state (high- and low-affinity agonist states) binding affinities (Lahti et al, 1992) and h D_{2n} , h $D_{4,n}$ membranes (cells courtesy M. Caron and H.VanTol) the affinity and intrinsic activity of dopamine agonists and partial agonists were determined. For the hD_{2n} receptor affinities at the low-affinity agonist state ermined using [3H]-raclopride + GTP and at the high-affinity agonist state [3H]- 3 - 3 -BPP has high intrinsic activity at both the hD_{4n} and hD_{4n} receptors (+)-3-PPP has high intrinsic activity at both the h 3 - 3 -graph appears to have higher intrinsic activity at the h 3 - 3 - 3 -graph and has a the h 3 - 3 -graph and has a the hold of

HIGH RESOLUTION SCATCHARD ANALYSIS OF THE D, RECEPTOR PYRAMIDAL (PN) AND NONPYRAMIDAL (NP) NEURONS IN THE RAT MEDIAL PREFRONTAL CORTEX (mPFCx). S.A. Davidoff, H.-M. Chu^{*} and F.M. Benes. Laboratory for Structural Neuroscience, McLean Hospital, Belmont, MA; Department of Psychiatry and Program in Neuroscience, Harvard Medical School, Boston, MA.

The results of a recent colocalization study employing fluorescently

The results of a recent colocalization study employing fluorescently labelled ligands suggested that D, receptors may be preferentially localized on NPs in rat mPFCx. To explore whether the binding affinity ($K_{\rm o}$) and/or maximal receptor density ($B_{\rm max}$) of D, receptors may differ with respect to PNs, NPs or in neuropil of rat mPFCx, a Scatchard analytic technique has been adapted to high resolution autoradiography to determine the specific $K_{\rm d}$ and $B_{\rm max}$ values. Frozen sections of mPFCx were incubated for 45 min at $20^{\circ}{\rm C}$ in five concentrations of tritiated SCH23390 (1-12nM) in the presence or absence of the competitive inhibitor SKF38393 (100nM). The D, antagonist was found to bind with a similar affinity to PNs ($K_{\rm d}$ =1.7nM) and NPs ($K_{\rm d}$ =2.7nM), as well as in neuropil ($K_{\rm d}$ =2.2nM) in layer VI of the rat mPFCx. The $K_{\rm d}$ values obtained were similar to those reported by other groups. It is noteworthy that the $B_{\rm max}$ values for PNs (4.8 grains/100 μ m 2) and NPs (5.7 grains/100 μ m 2) were also quite similar. These results are consistent with the idea that D, receptors may be broadly distributed in several neuronal compartments of rat mPFCx. Accordingly, Scatchard analyses will provide a useful approach to determining whether various neurotransmitter receptors differ with respect to $K_{\rm d}$ or $B_{\rm max}$ on PNs, NPs and/or NPL in patients with schizophrenia and other neuropsychiatric disorders. CONSTITUTIVE ACTIVITY OF A CHIMERIC DOPAMINE RECEPTOR L.B.Kozell* and K.A.Neve. Dept of Physiology & Pharmacology, Oregon Health Sciences University & VAMC, Portland OR., 97201.

Chimeric D1/D2 dopamine receptors facilitate the identification of structural determinants of ligand binding and effector coupling. Our previous work has led us to several hypotheses. First, transmembrane region VII (TMVII) is important in the selective potency of several D1-selective ligands. Second, determinants of drug efficacy are dissociable from those for drug affinity at D2 receptors, with TMVII important in selective binding of some agonists, and TMVI important for efficacy Third, incompatibilities between TMI and TMII from D2, and TMVII from D1 receptors result in non-functional chimeras. To expand upon and test these hypotheses further, we constructed chimeric D1/D2 receptors with D2 receptor sequence at the amino and carboxy terminal ends, and expressed them in HEK293 cells. One of these chimeras, CH6*, with D1 receptor sequence only from TMV through TMVI, had higher affinity for non-selective and most D2-selective agonists, than either D1 or D2 wildtype receptors. The affinity of CH6* for most antagonists and D1-selective agonists fell between D1 and D2 receptor affinities. CH6* coupled to Gs, as was indicated by stimulation of adenylate cyclase by most dopaminergic agonists, although the ability of CH6* to activate adenylate cyclase was reduced when compared to D1 receptors. Thus, the region around and including the 3rd intracellular loop of the D1 receptor was sufficient for coupling to this effector. Several observations suggested that CH6* was a constitutively active receptor. CH6* had increased affinity for most dopamine agonists. In the absence of agonist stimulation, cells expressing CH6* had elevated basal levels of cAMP, which could be inhibited by several dopamine antagonists, including spiperone and clozapine. The D1-selective antagonist, SCH23390, was able to stimulate adenylate cyclase slightly, suggesting that SCH23390 has intrinsic activity at CH6*. [MH45372 and VA Merit Review Program]

CATECHOLAMINES: DOPAMINE II

331.1

DENSITY OF DA NERVE TERMINALS AS ESTIMATED FROM CONCENTRATION-RESPONSE CURVES E. Agneter, M.R. Emmerling*, W. Sauermann, E.A. Singer, T.J. Feuerstein. Neuroplarmacology Units, Univ. of Vienna (A-1090, Austria), Parke-Davis (MI 48105Ann Arbor, USA), and Freiburg (D-79106, Germany)

ent study tries to establish a link between functional data on presynaptic autoinhibition of [3H]-DA release and the density of DA nerve terminals in slices of rabbit prefrontal cortex (PFC) and striatum (STR), respectively. Superfusion experiments have shown previously that the behavior of mesocortical and striatal DA terminals during single and repetitive electrical stimulation is different (Agneter et al. 1994, JPET 269:470). The disinhibition of [³H]-DA release by blockade of D₂-autoreceptors with sulpiride allowed to estimate the biophase concentration of endogenous DA. Estimation was based on the finding of direct proportionality between occupancy of D2-autoreceptors and resulting inhibition of [3H]-DA release in both tissues. Congruent concentration-inhibition curves and their identical antagonist-induced shifts to the right proved the identity of release-modulating $D_{2^{\circ}}$ autoreceptors in PFR and STR. The disinhibition of $[^{3}H]$ -DA release over the frequency range used for electrical stimulation (0.05-100 Hz) was paralleled by the estimated increase in the endogenous DA concentration, being highest at 1 - 10 Hz. The highest DA biophase concentration induced by electrical stimulation was about 7 times higher in the STR than in the PFC. A space parameter λ was defined reflecting the mean distance of all the autoreceptors from all the release sites within the tissue to assess a mutual inhibition of DA terminals by released DA, assuming an exponential decay of the DA biophase concentration with time and distance. The estimate of λ in PFC was about 4 times larger than that in STR

Autoreceptors on a single STR terminal are not only activated by DA released from this very same terminal, but are also activated by DA released from neibourghing terminals. Therefore, autoinhibition of DA release is more pronounced in the STR than in the PFC were, due to the lower density of DA terminals, such an intense mutual inhibition of DA terminals does not exist.

The study was supported by grants from the Ministry of Sience to E.A, and T.J.F.

INTRINSIC ACTIVITY DETERMINATIONS FOR VARIOUS DOPAMINERGIC AGENTS AT HUMAN D₂₈, D₂₁, D₃, AND D₄₂ RECEPTORS USING [³⁵S]GTPγS BINDING. <u>T. P. Wasik, M. I. Cockett, R. Ochalski and T. H. Andree*</u>. Wyeth-Ayerst Research Inc., CN 8000, Princeton, N.J. 08543.

Agonist-induced stimulation of [35 S]GTP γ S binding is becoming increasingly valuable as a tool for assessing intrinsic activity at a wide variety of receptors. The present study examined the effects of various dopamine (D_2 family) agonists, partial agonists and antagonists to stimulate or block [35 S]GTP γ S binding at D_{28} , D_{21} , D_3 and D_{42} , cloned human receptors. In addition, the relative affinity of these compounds for the high affinity (3 H-quinpirole) vs the low affinity (3 H-spiperone + GppNH) state of the D_3 receptor in rat striatal tissue was determined. Maximal responses obtained with [35 S]GTP γ S binding in CHO cells with human D_{28} and D_{21} , respectively) in rat striatal tissue. These results support and extend the results obtained by Tamminga et al. (Soc. Neurosc. 21: #252.9, 1995) and Lahti et al. (Mol. Pharmacol. A2:432, 1992) in characterizing intrinsic activity levels of agonists at the D_{21} and D_{44} receptors. The present results demonstrate the value of [35 S]GTP γ S binding in determining the intrinsic activity of agents for a variety of dopaminergic receptors and should be of value in discovering new dopaminergic agents for treatment of dopamine-related disorders such as schizophrenia and Parkinson's disease.

BLOCKADE OF 5-HT₃ RECEPTORS INCREASES DOPAMINE RELEASE IN NEOSTRIATUM. AN IN VIVO MICRODIALYSIS STUDY IN CONSCIOUS RATS. X.-M. Li*, K. W. Perry, D. Wong and R. W. Fuller, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana

The in vivo modulation of dopamine (DA) release in rat neostriatum by one of serotonin (5-HT) receptor subtypes 5-HT3 receptor, has been studied by means of a microdialysis analysis performed in conscious rats. The results indicate a possible inhibitory regulation of DA release by 5-HT3 receptors in the neostriatum according to the following findings: (1). A 5-HT3 antagonist, zatosetron (LY277359), perfused into neostriatum significantly increased extracellular DA level in the neostriatum in a dose-dependent way with a peak increase found at 50 μM ; (2). While LY306801, an inactive isoform of zatosetron, at same dose (50 μM) did not change the DA level; (3). Consistently another 5-HT3 antagonist, LY278584 which has an affinity for 5-HT3 receptors about 1/3 of that of zatosetron, at 150 μM also caused a significant increase in the DA level; (4). In the presence of 50 μM , but not 5 μM zatosetron a further increase in the DA level was achieved when the extracellular 5-HT level was risen by systemic co-administration of a 5-HT uptake inhibitor, fluoxetine, and the 5-HT precursor, 5-HTP.

The present studies demonstrating a specific and selective pharmacological action of zatosetron at 50 µM on DA release, indicate that 5-HT₃ receptors probably mediate the negative regulation of DA release in neostriatum.

SPATIAL MAPPING OF EVOKED DOPAMINE RELEASE IN STRIATUM WITH MICROELECTRODE ARRAYS, S.F. Dressman, A.C. Michael*, Department of Chemistry, University of Pittsburgh, PA

Electrical stimulation of the medial forebrain bundle in rats causes dopamine release in striatum that can be monitored by cyclic voltammetry at microelectrodes constructed from 7-µm diameter carbon fibers. Stimulation responses recorded with cylindrical electrodes, 200-400 µm long, depend very little on the exact placement of the electrode in striatum, which implies that cylindrical electrodes measure a spatially averaged response. The responses recorded at disk electrodes, prepared so that only the cross section of the fiber serves as the active region of the electrode, are highly sensitive to the location of the electrode: movements of the electrode over distances as small as 40 µm can cause dramatic changes in the stimulation response. This implies that stimulated dopamine release is heterogeneous on a micrometer scale. When disk electrodes are used, the change in the stimulation response induced by nomifensine administration (20 mg/kg i.p.) is also highly dependent on the specific features of the recording site.

Mapping the spatial distribution of dopamine release in striatum on a micrometer

scale is important because local dopamine concentrations measured at disk electrodes are not linearly related to each other, nor to spatially averaged values measured at cylinder electrodes. Arrays of microelectrodes are being developed for this purpose These arrays consist of four individually-addressable, 1-µm diameter, disk electrodes separated in space by 10-20 µm

EFFECTS ON IN VIVO DOPAMINE RELEASE IN THE STRIATUM AND IN THE SUBSTANTIA NIGRA BY VOLTAGE-SENSITIVE CALCIUM CHANNEL BLOCKERS. F. Bergquist*, J. Donason and H. Nissbrandt, Department of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg,

Dopamine (DA) is released not only from the terminals of the nigro-striatal neurons but also from their dendrites. The importance of voltage-sensitive calcium channels (VSCC) for terminal DA release in the striatum has hitherto mostly been characterised by in vitro studies and overall very few studies on their importance for nigral dendritic DA release has been published.

charactensed by in vitro studies and overall very few studies on their importance for nigral dendritic DA release has been published.

The aim of the present study was therefore to comprehensively investigate in vivo the relative physiological importance of L-, N- and P/Q/R-type VSCC in the striatum and in the substantia nigra pars reticulata (SNr). The effects of local perfusion of Ca^{2+} -free buffer and specific VSCC blocking drugs on DA release were determined by microdialysis in awake rats.

Perfusion with Ca^{2+} -free buffer decreased DA release by 90% and 70%, respectively, in the striatum and in the SNr. In both brain parts the L-type VSCC blocker, nimodipine (100 μ M), decreased DA release modestly (by 10% to 15%) whereas neomycin (0.5 mM), an unselective P/Q/R-type VSCC blocker, decreased the release by 75% to 85%. The N-type VSCC blocker ω -Conotoxin GVIA (1.0 μ M) and the P-type VSCC blocker ω -Agatoxin IVA (1.0 μ M) inhibited DA release in the striatum by 55% and 80%, respectively, but unexpectedly induced an increase of DA release by 30% and 45%, respectively, in the SNr.

Our observations support a functional coexistence of different VSCC-types on striatal DA terminals with a dominance of the P-type of VSCC. The clear-cut effect of neomycin in the SNr suggests a role for P/Q/R-type VSCC. However, the stimulatory effects of the selective N- and P- type VSCC blockers are obscure. Tentatively, the effects of these drugs may be explained by indirect effects due to decreased release of various transmitters localized in nigral afferents. EFFECTS OF HALOPERIDOL AND NOMIFENSINE ON EVOKED DOPAMINE EFFLUX IN AMBULANT RATS. J.R.C. Christensen*1, P.A. Garris², R.M. Wightman³, and G.V. Rebec¹. ¹Program in Neural Science and Dept. Psychology, Indiana University, Bloomington, IN 47405; ²Dept. Biological Sciences, Illinois State University, Normal, IL 61790; 3Dept. Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

We used fast-scan cyclic voltammetry at carbon-fiber microelectrodes to assess the effects of haloperidol, a dopamine (DA) receptor antagonist, and nomifensine, a DA reuptake blocker, on extracellular DA in the striatum of freely moving rats. DA-containing neurons in the substantia nigra compacta were electrically stimulated over a frequency range of 10 - 60 Hz. Haloperidol (0.5 mg/kg, sc) produced an increase in maximal efflux inversely proportional to stimulation frequency with a maximum response cf 300% at 10 Hz, but no change at 60 Hz. Nomifensine (5.0 mg/kg, sc), in contrast, produced a constant increase of approximately 200% at each stimulation frequency. Taken together, these results suggest that in awake, unrestrained rats inhibitory autoreceptors modulate DA release only at low stimulation frequencies, while blockade of reuptake continues to be a major factor in the clearance of synaptic DA efflux even at high frequencies.

EFFECT OF HANDLING STRESS ON AMYGDALA DOPAMINE RELEASE: COMPARISON WITH OTHER DOPAMINERGIC REGIONS F. M. Inglis* and B. Moghaddam. Department of Psychiatry, Yale University School of Medicine, VA Medical Center 116A/2, West Haven, CT 06511

Several studies have demonstrated a role for catecholamines in the amygdalar complex in stress, arousal and conditioned behaviours. Using in vivo cerebral microdialysis, TTX-sensitive and calcium-dependent dopamine efflux was assessed in the basolateral nucleus of the amygdala in the rat. The effects of twenty minutes of handling on dopamine release in the basolateral amygdala was examined, and the response compared with three other dopamine-containing regions, the medial prefrontal cortex, the nucleus accumbens, and the caudate nucleus. In agreement with previous reports, dopamine release increased during stress in the prefrontal cortex. Dopamine efflux also increased in the nucleus accumbens, but was unaltered in the caudate nucleus. In the nucleus accumbens and prefrontal cortex, a two-fold increase in dopamine occurred in response to stress: this increase was largest in the twenty minute sample period after the cessation of stress. During this period, rats showed significant behavioural arousal, such as exploratory behaviors and grooming. Dopamine efflux from the basolateral amygdala also increased two-fold during handling stress; in contrast with other areas, this response was maximal during the application of the stress, and returned to baseline more rapidly than in other structures examined. These results provide evidence for differential regulation of dopamine release in these brain regions in response to handling stress

IN SITU DETERMINATION OF DOPAMINE RELEASE AND UPTAKE IN FREELY MOVING RATS P. A. Garris*, J. R. C. Christensen, G. V. Rebec and R. M. Wightman. Department of Biological Sciences, Illinois State University, Normal, IL 61790; Department of Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599; Department of Psychology and Program in Neural Science, Indiana University, Bloomington, IN 47405

A technique was established to monitor dopamine in real time in brain extracellular fluid of freely behaving rats. Parameters describing in situ dopamine release and uptake processes were determined from these measurements. Fast-scan cyclic voltammetry at carbon-fiber microelectrodes was employed to monitor dopamine elicited by electrical stimulation of the substantia nigra. Extracellular dopamine in the striatum was frequency and current dependent. When low frequencies and currents were applied, detectable levels of dopamine could be elicited without a perceptible behavioral response An exciting finding was that evoked concentrations of dopamine were significantly higher in freely moving compared to anesthetized rats. Our findings indicate that this difference is the result of an inhibitory effect of anesthesia on dopamine release. In contrast, dopamine uptake is unaffected. Conclusions: (1) fast-scan cyclic voltammetry at carbon-fiber microelectrodes is a viable technique for the measurement of dopamine in brain extracellular fluid of freely behaving rats and (2) transient changes in striatal concentrations of extracellular dopamine elicited by electrical stimulation are affected by anesthesia. This research supported by NSF (IBN 9222349).

DOPAMINE RELEASE AND INTRACRANIAL SELF-STIMULATION. R. M. Wightman* and P. A. Garris. Department of Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599-3290; Department of Biological Sciences, Illinois State University, Normal, IL 61790-4120

Animals with stimulating electrodes implanted in select regions of the brain repeatedly press a lever to receive a train of electrical pulses. Considerable evidence suggests that dopamine plays a role in this behavior termed intracranial self-stimulation (ICSS)¹. In this study, fastscan cyclic voltammetry was employed to investigate relationships between extracellular dopamine and ICSS with high temporal resolution. Under anesthesia, a stimulating electrode was permanently implanted in the ventral tegmental area at a site that elicits dopamine release in the nucleus accumbens as measured by a carbon-fiber microelectrode. ICSS was observed in all animals tested following recovery from surgery. The stimulus trains (24 pulses at 60 Hz, 1ms pulse widths, 40-60 μ A amplitude) that supported ICSS also evoked dopamine release when applied by the experimenter to freely moving rats. However, in only one out of three animals was dopamine clearly observed during ICSS. The preliminary conclusion is that dopamine release can occur during ICSS but is not necessary. This research supported by NSF (IBN 9222349). ¹Phillips, A.G., Fibiger, H.C., Neuroanatomical bases of intracranial selfstimulation: untangling the Gordian knot, in <u>The Neuropharmacological Basis of Reward</u>, J.M. THE EFFECTS OF CHOLECYSTOKININ FRAGMENT 26-33, SULFATED (CCK-8S), ON DOPAMINE (DA) RELEASE FROM OLFACTORY TUBERCLE AND STRIATAL SLICES IN VITRO. Mark D. Barsamian, Cheryl Aretha, and Matthew P. Galloway. Cellular & Clinical Neurobiology Program, Dept. of Psychiatry & Behävioral Neurosciences, Wayne State University Sch of Med, Detroit, MI 48202.

CCK-8S is colocalized within DA terminals of both the mesolimbic and mesostriatal systems, and where CCK containing 'dense-core' vesicles costore DA, CCK-8S is released from DAergic terminals. Microiontophoretic administration of CCK-8S excites the firing rate of identified midbrain DA neurons and locally perfused CCK-8S augments DA release at a number of DA terminal projection sites. Furthermore, clinical studies have implicated CCK-8S as an anxiogenic compound since administration of CCK-8S fragments (CCK-4 or pentagastrin) induced panic attacks. Therefore, to further characterize DA-CCK interactions, we examined the effects of CCK-8S (0.1-100 nM) on DA release in vitro using either rat striatal (STR) or lacubation with 100 nM CCK-8S did not significantly alter basal DA release in either the STR (25±3 vs. 37±8 nM/mg) or OT (21±4 vs. 15±1 nM/mg). However, incubation with 0.1 nM CCK-8S significantly enhanced K*-stimulated (25 mM) DA release in slices from both regions (STR: 73±4 vs. 150±7 nM/mg, p < 0.001; OT: 70±7 vs. 126±16 nM/mg, p < 0.009). These results are consistant with previous suggestions that CCK-8S may suppress an auto-inhibitory mechanism and that CCK-8S may increase Ca** influx. EVIDENCE THAT EXTRACELLULAR DOPAMINE REGULATES DOPAMINE SYNTHESIS //N V/VO: A MICRODIALYSIS STUDY. Richard S.J. Nassar and Matthew P. Galloway. Cellular & Clinical Neurobiology Program, Psychiatry & Behavioral Neurosciences, Wayne State U Sch Med, Detroit, MI 48202

To assess striatal tyrosine hydroxylase (TH) activity (dopamine (DA) synthesis) in situ, extracellular DOPA levels were monitored after intrastriatal perfusion of the amino acid decarboxylase inhibitor α-difluoromethyl-DOPA (MDL 71,801). Increasing endogenous levels of DA (137 $\pm\,24\%)$ by the intrastriatal perfusion of the DA transporter inhibitor GBR-12909 (10μM) decreased extracellular DOPA levels by 40 ± 8% (p<0.01). Blockade of DA autoreceptors with eticlopride (100μM) prevented the GBR-12909 induced decrease of extracellular DOPA Conversely, the intrastriatal perfusion of either tetrodotoxin (3µM) or Ca++-free artificial cerebral spinal fluid decreased extracellular DA levels (>80% reduction) with a simultaneous increase of extracellular DOPA levels (69 \pm 6% and 126 \pm 22%, respectively). The increase in DOPA levels was ascribed to the loss of dopaminergic tone at DA synthesis modulating autoreceptors since replacement of the tone with quinpirole (100 μM) returned extracellular DOPA levels to basal levels without effecting DA levels. Additionally, intrastriatal perfusion of dibutrylcAMP (to promote phosphorylation of TH) transiently increased extracellular levels of DOPA by 33 \pm 9% (p<0.01). The results suggest that in vivo microdialysis is a useful technique to dynamically monitor both TH activity and DA autoreceptor function. Moreover, the results provide direct evidence that extracellular striatal DA regulates DA synthesis in vivo and support a physiological role for DA autoreceptors. COMPARISON OF THE EFFECTS OF HALOPERIDOL ADMINISTRATION ON AMPHETAMINE-STIMULATED DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX AND DORSAL STRIATUM. E.A. Pehek* and M.A. Schaldach. Dept. Psychiatry, Case Western Reserve University and Cleveland VAMC, Brecksville, OH 44141.

Previous studies have shown that haloperidol administration potentiates the neurochemical effects of dopamine (DA) uptake blockers on nigrostriatal DA neurons. Other work has demonstrated that basal DA release in the mesocortical system is relatively insensitive to the effects of D2 antagonists such as haloperidol. The present study thus examined whether a similar interaction between haloperidol and the DA releaser/uptake blocker d-amphetamine (AMPH) would be observed in the medial prefrontal cortex (mPFC) relative to the dorsal striatum. In vivo microdialysis was employed in male, Sprague-Dawley rats in order to recover extracellular fluid for subsequent determination of DA levels by HPLC/ED. All drugs were administered i.p. Haloperidol (1.0 mg/kg) was given 30 min prior to d-AMPH (5.0 mg/kg). In the striatum, AMPH increased DA levels from 5.42 pg/20 µl to 3.87 pg at 60 min post-administration. Haloperidol pre-treatment potentiated this increase to 212.38 pg, or 41% greater than AMPH alone. In the mPFC. AMPH increased DA levels from 0.51 pg/20 µl to 3.87 pg at 60 min post-injection. Haloperidol potentiated this increase to 8.23 pg, or 113% greater than AMPH alone. Pre-treatment with 20 mg/kg apomorphine blocked the haloperidol potentiation in the striatum (value = 159.68 pg at 60 min post-AMPH) but not in the mPFC (value = 10.52 pg). A dose of 2.0 mg/kg apomorphine did, however, attenuate the potentiation in the cortex (value = 5.16 pg). These results demonstrate that haloperidol augments transporter-dependent DA release in both the mesocortical and nigrostratal systems. This potentiation was greater in the mPFC and was at least partially mediated by antagonism of DA D1/D2 receptors.

ENDOGENOUS NITRIC OXIDE RELEASES STRIATAL DOPAMINE IN VIVO VIA A GLUTAMATE-MEDIATED FACILITATION. "Anthony R. West, Maureen E. Stress, and Matthew P. Galloway CCN Program, Psychiatry and Behavioral Neurosciences, Wayne State University, Detroit, MI 48202.

We have shown previously that intra-striatal infusion of nitric oxide (NO) donors released vesicular stores of dopamine (DA) in a calcium-dependent manner via an N-methyl-D-aspartate (MMDA) receptor-dependent mechanism. As an extension of these studies, we have investigated the influence of the nitric oxide synthase (NOS) substrate, N⁶-hydroxy-L-arginine (HO-ARG) on striatal DA and glutamate (GLU) release *in vivo*. Local infusion of HO-ARG (either 100 M or 1 mM for 120 min) increased DA release to 57± 5% and 122 ± 28% above basal levels respectively. Additionally, perfusion with HO-ARG (1mM) increased extracellular (EC) GLU to 71± 9% over basal concentrations with a time course similar to that observed for DA. Unexpectedly, HO-ARG (2mM) did not increase EC DA when infused under similar conditions. The DA releasing effect of HO-ARG (1mM) was abolished following pretreatment (80 min) with the constitutive NOS inhibitor 7-nitroindazole (7-NIT). Intra-striatal administration of the NMDA receptor antagonist MK-801 (10 M administered 80 minutes prior to and during HO-ARG delivery), significantly attenuated the HO-ARG (1mM)-induced elevation of EC DA levels to approximately 32 % above baseline. Combined with our previous work (U. Neurochem. 66: 1971-80, 1996), these results demonstrate that both endogenous and exogenous NO releases vesicular stores of striatal DA via GLU-mediated NMDA-receptor activation.

EFFECTS OF NEUROPEPTIDE Y AND SIGMA RECEPTOR LIGANDS ON NMDA-STIMULATED [²H]DA RELEASE FROM SLICES OF RAT NUCLEUS ACCUMBENS. D.T. Ault*, J.M. Radeff, and L.L. Werling. Neuroscience Program and Dept. of Pharmacology, The George Washington University Medical Center, Washington, DC 20037.

Although the identity of the endogenous ligands for sigma receptors is unknown, various neuropeptides and steroids have been shown to compete for binding to these receptors. Among endogenous sigma receptor ligand candidates is neuropeptide Y (NPY), which mimics electrophysiological actions of sigma ligands in some preparations. We have previously shown that prototypical sigma agonists such as (+)pentazocine and BD737 inhibit stimulated [³H]DA release in various brain regions. Using a superfusion system, we compared the effect of NPY on stimulated [³H]DA release to the effects of these ligands. In contrast to (+)pentazocine- and BD737-mediated inhibition of release, NPY enhanced release at nM concentrations. However, the same sigma antagonists (BD1008, DUP734, haloperidol and DTG) that reverse (+)pentazocine- or BD737-mediated inhibition, as well as a Y receptor antagonist, PYX₁, all reversed the enhancement. To facilitate determination of the receptor through which NPY-mediated enhancement of release occurs, the effects of ligands selective for Y receptor subtypes were compared to that of NPY. In addition, the effect of PYX₁ on BD737-mediated inhibition of release was investigated. Our findings suggest an overlap in populations of receptors currently designated sigma and Y. These findings may be important because regulation of dopamine release in the nucleus accumbens is critical for both the positive symptoms of schizophrenia and for reinforcement caused by drugs of abuse. (Supported by a NIDA grant to LLW.)

RELATIONSHIP BETWEEN PLASMA AND PLATELET CATECHOLAMINES UNDER BASAL AND ACUTE STRESS CONDITIONS. <u>L_Jerabek*</u>, <u>J.P. Boulenger</u>, <u>F.B. Jolicoeur</u> Psychiatry and Pharmacology Dpt. Sherbrooke University, Quebec, Canada, J.H. 5N4.

One of the major difficulties in assessing the role of catecholamines is related to their short half-life in plasma or urine. Recently, it has been proposed that measuring platelet catecholamine concentrations could alleviate this problem. Platelet catecholamine levels have been shown to reflect the overall sympatho-adrenal activity during the 8-day long life-time of the platelet and to be only modestly affected by acute and short-lived elevations in plasma concentrations following psychological and physical stress. In the present study, we examined the relationship between plasma and platelet concentrations of catecholamines under basal and acute stress conditions. For this latter purpose, we used cholecystokinin tetrapeptide (CCK₁), a neuropeptide known to induce physiological and psychological stress in humans. Sixteen healthy subjects were subjected to CCK₂, challenge (25 µg IV) and their blood samples were taken before and repeatedly after the administration. Plasma and platelet norepinephrine (NE) and epinephrine (EPI) levels were measured using PHLC-ECD. Results indicate that CCK₂ administration increases both plasma and platelet levels of NE and EPI, however, the time course for each blood compartment is markedly different. On the other hand, no correlation patterns were found between plasma and platelet NE or EPI concentrations, under neither basal nor acute CCK₂, induced stress. Nevertheless, significant positive correlations between basal and post-stress. Nevertheless, significant positive correlations between basal and post-stress. Nevertheless, were observed in plasma but not in platelets. For EPI, positive correlations were found between basal and post-stress levels in both blood fractions. In conclusion, our results reveal that both plasma and platelet catecholamine concentrations are affected by acute stress, albeit with different time course. Furthermore, our results indicate a poor co-relationship between plasma and platelets.

EFFECT OF TOLCAPONE, A CATECHOL O-METHYLTRANSFERASE INHIBITOR, ON BRAIN DOPAMINE METABOLISM IN AMPHETAMINE-OR PARGYLINE-TREATED RATS: A MICRODIALYSIS STUDY

M. Törnwall, P. Tuomainen, S. Kaakkola^{1*} and P.T. Männistö². Dept. of Pharmacol. Toxicol., Inst. Biomedicine, and ¹Dept. of Neurology, University of Helsinki, Finland; ²Dept. of Pharmacol., University of Uppsala, Sweden.

Inhibitors of catechol O-methyltransferase (COMT) are novel drugs to be used as adjuncts for L-dopa therapy in Parkinson's disease. One of these substances, tolcapone, inhibits COMT both in peripheral tissues and in the brain. In our previous studies, the new COMT inhibitors were found to increase the availability of L-dopa to the brain by preventing its metabolism to 3-O-methyldopa by COMT in the intestinal wall. This salvage is particularly important when the peripheral dopa decarboxylase is inhibited and L-dopa is not converted to dopamine outside the brain. In the present study, we used in vivo microdialysis to examine the effects of tolcapone (30 mg/kg) on endogenous dopamine metabolism in anaesthetized rats treated either with amphetamine (5 mg/kg) or pargyline (75 mg/kg). Amphetamine- or pargyline-induced decreases in the levels of extracellular 3.4-dihydroxyphenylacetic acid were counteracted by tolcapone. Tolcapone decreased homovanillic acid effluxes below those caused by amphetamine or pargyline, but dopamine effluxes were not further enhanced. These results show that central metabolism of dopamine can be modulated by COMT inhibition even without exogenous L-dopa. However, extracellular dopamine levels are not easily increased. A PARAMETRIC ATLAS OF THE METABOLISM OF [3H]DOPA IN BRAIN OF LIVING RAT P. Deep, H. Kuwabara¹, A. Gjedde², J. Reith*², and P. Cumming. McConnell Brain Imaging Centre, Montreal Neurological Institute, Montreal, Canada H3A 2B4, 'West Virginia, '2Aarhus, Demmark. We have developed a multi-compartmental model describing the uptake and metabolism of [3H]DOPA in living human brain. Non-linear regression analysis of time-activity curves obtained by PET yield estimates of unidirectional bloodbrain clearance (K, ml g³ min²), relative activity of DOPA-decarboxylase (DDC, k₃, min²) and the rate constant for the net elimination of [3H]dopamine formed within brain (k₃n₁ min²). The net blood-brain clearance (K, ml g³ min²) is calculated by linear means. In order to validate this PET method, similar approaches were used to calculate the corresponding kinetic parameters in rat calculated by linear linears. In other to variouse this 12 include, similar approaches were used to calculate the corresponding kinetic parameters in rat brain from a time-series (5-240 min circulation) of autoradiograms obtained from individual rats (n=13) receiving [³H]DOPA (200 μ Ci, i.v.), all scaled to a common arterial input curve.

	K ₁	k_3	k _{out}	K		
caudate	0.047 ± 0.001	0.07 ± 0.01	0.018 ± 0.001	0.009 ± 0.001

INDIRECT EVIDENCE FOR DOPAMINE METABOLISM BY CYTOCHROME P450 2E1 IN THE SUBSTANTIA NIGRA IN VIVO. H. Nissbrandt*, F. Bergquist,

1430 2E1 IN 1HE SUBSTANTIA NIGRA IN VIVO. H. NISBORAGE, F. Bergquist, Jonason. A. Elverfors and G. Engberg, Department of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

The major dopamine (DA) metabolites in the brain are 3,4-dihydroxyphenylacetic acid (DOPAC), homovanillic acid and 3-methoxytyramine. Other alternative pathways for DA must, however, also be taken into consideration, although no data are available on the quantitative importance of alternative catabolic pathways. Such pathways for DA are conjugation of DA with sulphate or glucuronide, formation of 5-S-cysteinylDA or condensation of DA with sulphate or glucuronide, formation of 5-S-cysteinylDA or condensation of DA with sulphate or glucuronide, formation of 5-S-cysteinylDA or condensation of DA with sulphate or glucuronide, formation of S-S-cysteinylDA or condensation of DA with sulphate or GDA synthesis and catabolism in

We have previously presented measurements of DA synthesis and catabolism in the substantia nigra (SN) suggesting that a substantial part of synthesised DA in this brain part is metabolised by unknown non-classical metabolic pathways. In the SN in rat brain relatively high densities of cytochrome P450 2E1 have been

detected. The aim of the present study was therefore to investigate the possibility that this enzyme directly or indirectly is involved in the metabolism of DA in the

Administration of the specific inhibitor of cytochrome P450 2E1, diallyl sulfide (200 mg/kg, an ingredient from garlic) in vivo to rats induced a 30% increase in DOPAC concentrations in the SN but not in the striatum. Diallyl sulphide (200 mg/kg) also increased DA release by around 50% in the SN when measured with microdialysis in awake animals.

These data suggest the possibility that cytochrome P450 2E1 directly or indirectly is involved in the metabolism of DA in the SN. The presence of the enzyme in the SN is especially interesting since the enzyme is known to produce superoxide radicals which can induce cell injury and cell death. EFFECT OF S-ADENOSYL-L-METHIONINE ON DOPAMINE METABOLISM IN THE RAT STRIATUM: AN IN-VIVO MICRODIALYSIS STUDY.

T. Bottiglierr and K. Hyland, Kimberly H. Coutwright and Joseph W. Summers Institute of Metabolic Disease at Baylor University Medical Center, and the Dept of Neurology University of Texas Southwestern Medical School, Dallas, TX, USA

Using in-vivo microdialysis we studied the effect of acute and chronic Sadenosyl-L-methionine (SAMe) administration on dopamine metabolism in the striatum of male Sprague Dawley rats (250-300 g). Microdialysis probes were implanted and animals allowed to recover. The next day probes were perfused with artificial CSF (1µl/min) and samples collected every 20 minutes for analysis of SAMe, dopamine, DOPAC, HVA, & 3-MT. Baseline levels were established over 1 hr then rats were injected with either S-adenosyl-L-methionine butane disulphonate (SAMe-SD4; 200 mg/Kg i.p.) or butane disulphonate (vehicle control) and samples collected for a further 3 hrs. In chronic studies (SAMe-SD4 200 mg/kg/day for 7 days i.p.), dialysis probes were implanted on the 6th day. Rats received the final SAM-SD4 injection the next day and after 30 minutes were perfused with NSD 1015 (100 µM in artificial CSF) and in-vivo tyrosine hydroxylase activity indirectly assessed by the accumulation of L-DOPA.

Dialysate concentrations of SAMe increased after a single i.p. injection of exogenous SAMe-SD4, an effect that was augmented by a repeat injection. Acute injection of SAMe-SD4 had no effect on striatal dialysate concentrations of dopamine or its metabolites. Chronic treatment led to a significantly greater accumulation of L-DOPA in the SAMe-SD4 treated rats as compared to rats receiving vehicle. Our findings indicate that peripherally administered SAMe-SD4 increases brain extracellular levels of SAMe and causes activation of TH. This effect of SAMe on dopamine metabolism may be the mechanism for its antidepressant action.

IN VIVO PHARMACOLOGY OF DIHYDROXYPHENYLACETALDEHYDE (DOPAL). F. Fornai*, M.T. Torracca, L. Bassi, A. Colzi, R. Maggio and G.U. Corsini, Inst. of Pharmacology, Univ. of Pisa, Italy
Using brain dialysis coupled with HPLC with coulometric electrochemical

Using brain dialysis coupled with HPLC with coulometric electrochemical detection we measured dihydroxyphenylacetaldehyde (DOPAL) in the rat trans-striatal dialysate. The peak identified as DOPAL in vivo had the same retention time measured for the enzymatically and chemically synthesized DOPAL which was identified by GLC-mass spectrometry. Based on these findings we carried out a series of experiments to measure, directly in the rat striatal extracellular fluid, DOPAL levels after various pharmacological treatments. MAO-A inhibition suppressed, whereas MAO-B inhibition did not modify DOPAL levels in the dialysate. Administration of non-specific not modify DOPAL levels in the dialysate. Administration of non-specific MAO irreversible inhibitors or the co-administration of specific reversible MAO-A together with MAO-B inhibitors led to the same decrease of extracellular DOPAL obtained after administration of single MAO-A inhibitors. Blockade of aldehyde dehydrogenase (ALDH), or microinfusion of DA through the dialysis probe increased DOPAL extracellular levels. Similarly, administration of a DA vesicular releaser produced a slight increase of DOPAL by contrast, the selective DA uptake inhibitor 6BB 12 909 did not significantly modify striatal extracellular DOPAL concentration. Methamphetamine, at different doses, suppressed striatal DOPAL levels. The assay of DOPAL together with DOPAC represents a reliable tool to measure directly, in freely moving animals, DA oxidative metabolism distinguishing between MAO and ALDH activity. Recent studies (Mattamal, 1995) have shown that microinfusions of exogenous DOPAL cause 1995) have shown that microinfusions of exogenous DOPAL cause neurotoxicity; in line with this, in vivo measurement of DOPAL could shed new lights on the molecular basis of neurodegenerative processes involving monoaminergic neurons.

BOTH MAO A AND MAO B METABOLIZE DOPAMINE SYNTHESIZED FROM L-DOPA IN SQUIRREL MONKEYS. <u>D.A. Di Monte, I. Irwin, L.E. DeLanney, P. Chan, G.M. Petzinger* and J.W. Langston.</u> The Parkinson's Institute, Sunnyvale, CA 94089.

Experimental evidence suggests that, under normal conditions as well as after Ldopa administration, MAO A is primarily responsible for dopamine deamination in rodents. The present study was aimed at determining the effects of MAO inhibitors on the metabolism of dopamine synthesized from exogenous L-dopa in the striatum and substantia nigra of squirrel monkeys. Administration of a single dose of L-dopa (methyl ester, 40 mg/kg, i.p.) caused a significant increase in the levels of dopamine, 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) and in the DOPAC/dopamine ratio in the putamen, caudate and substantia nigra. These changes were more pronounced in the substantia nigra than in the striatum. When L-dopa treatment was preceded by the injection of clorgyline or deprenyl at a concentration (1 mg/kg) which selectively inhibited MAO A or MAO B, respectively, striatal dopamine was increased while striatal DOPAC and HVA levels and DOPAC/dopamine ratio were significantly reduced as compared to the values obtained with L-dopa alone. The two MAO inhibitors also counteracted the increase in DOPAC and HVA levels and DOPAC/dopamine ratio induced by L-dopa in the substantia nigra. The extent of reduction of dopamine catabolism (as assessed by the decrease in DOPAC and HVA levels) in the striatum and substantia nigra was similar with clorgyline and deprenyl. These results indicate that in primates both MAO A and MAO B are involved in the metabolism of dopamine when higher levels of this neurotransmitter are generated from exogenous L-dopa. Furthermore, the substantia nigra may be at a greater risk than the striatum for the potential toxic effects of Ldopa-induced increased dopamine turnover.

D-GLUCOSE -EVOKED INHIBITION OF CRUSTACEAN HYPERGLYCEMIC HORMONE-CONTAINING NEURONS OF THE X-ORGAN OF THE CRAB CANCER BOREALIS. R. Glowik.¹³, J. Golowasch.¹, R. Keller.² & E. Marder.¹¹, Volen Center, Brandeis University, Waltham, MA 02254, USA; ²Institut für Zoophysiologie, Rheinische Friedrich Wilhelms-Universität, D-53115 Bonn, FRG. The X-Organ, located in the evestalks of decapod crustaceans, contains a

The X-Organ, located in the eyestalks of decapod crustaceans, contains a heterogeneous population of neurosecretory cells. These neurons produce several neuropeptides involved in the regulation and homeostasis of physiological processes such as color change and retinal pigmentation, molting, gonad development and carbohydrate metabolism. We studied the process by which glucose concentration in the hemolymph is regulated. We used single electrode voltage and current clamp of cultured X-organ neurons of the crab Cancer borealis.

A subpopulation of the cells responded to D-glucose with a hyperpolarization. These cells all showed immunoreactivity to Crustacean Hyperglycemic Hormone (CHH). Glucose-insensitive cells were not CHH-immunoreactive. Glucosesensitive cells were also inhibited by serotonin and GABA but were not affected by dopamine or Leu-enkephalin. The response was specific for D-glucose, with an EC $_{50}$ of 0.25 mM. No response was seen to either L-glucose, sucrose, galactose, mannose or fructose. The glucose response persisted in the absence of extracellular Na $^{\circ}$ and in low Ca $^{\circ}$ /Mn $^{\circ}$ saline. In voltage clamp, D-glucose evokes a small current with a reversal notential close to that of voltage dependent K° -currents.

with a reversal potential close to that of voltage-dependent K⁺ currents.

We conclude that D-glucose activates a K⁺ current in CHH⁺ cells that, in normal saline induces a hyperpolarization. We propose that this enables glucose to directly regulate the release of CHH into the hemolymph, thus constituting a negative feedback mechanism regulating hemolymph plucose concentration

feedback mechanism regulating hemolymph glucose concentration.

ALTERNATIVE SPLICING AND PERIPHERAL EXPRESSION OF THE L5-67 GENE mRNA OF APLYSIA CALIFORNICA. A. Angers* and L. DesGroseillers. Département de Biochimie, Université de Montréal, Montréal, Québec, Canada, H3T 317.

While screening for the expression of the L5-67 gene in Aplysia tissues, using RT-PCR, we amplified two different fragments in kidney mRNA. The longest fragment corresponds to an amplification from the full-lentgh L5-67 transcript while the shorter band contains a deletion of 148 nucleotides when compared to the cDNA sequence. Isolation of genomic clones showed that these 148 nucleotides are included in a single exon and that the shorter transcript arises by alternative splicing and exon skipping. The first 45 amino acids upstream of the splice site are identical to those of the L5-67 peptide, suggesting that the decapeptide LUQIN may be processed from the short transcript. However, a reading frame shift completely disrupts the C-terminal extremity of the precursor. The shorter L5-67 transcript can only be detected in the kidney, whether northern blotting or PCR is used, whereas the full-lenght transcript is amplified in all tissues. *In situ* hybridization experiments on kidney sections shows an abundant L5-67 specific signal in nerve fibers throughout the dorsal wall of this organ, and in the vicinity of the renal pore. By contrast, no cell body was stained in this tissue. Therefore, the L5-67 mRNA present in the kidney seems to be restricted to the axonal network and most likely originates in the LUQ cells. (Supported by the Medical Research Council of Canada).

GABA AS A PROCTOLIN-COTRANSMITTER IN THE CRAB STOMATO-GASTRIC GANGLION. J. Golowasch'. A. Swensen'. E. Marder', M.J. Coleman² & M.P. Nusbaum². ¹Volen Center, Brandeis University, Waltham, MA 02254; ²Univ Penn, Department of Neuroscience, Philadelphia, PA 19104.

GABA-like immunoreactivity is co-localized with the neuropeptide proctolin in identified projection neurons MCN1 and MPN within the stomatogastric nervous system of the crab Cancer borealis. To verify that the GABA-like immunoreactivity is authentic GABA, HPLC analysis of ganglion extracts was performed. GABA levels were 25 pmoles/stomatogastric ganglion (STG), 50 pmoles/oesophageal ganglion and 1nmole/commissural ganglion.

We also applied GABA focally to STG neurons. All neurons tested showed both depolarizing and hyperpolarizing responses. LP and Int1 responded with a net depolarization that triggers action potentials. All other neurons in the STG showed either a net depolarization that suppressed action potential generation or a net hyperpolarization. The depolarization was mimicked by muscimol and **rans*-aminocrotonic acid (TACA), blocked by the GABA_A antagonist picrotoxin, and appears to be a mixed cation conductance with a reversal potential around **-20mV*. The hyperpolarizing component is primarily an increase in K** conductance, it is mimicked by baclofen and TACA and is not blocked by picrotoxin. Neither response is sensitive to bicucullin and the GABA_c agonist cis-aminocrotonic acid (CACA) has very little effect on either component. We have preliminary evidence that in some but not all STG neurons a third component is present. This response is sensitive to CI injections.

We are currently characterizing in more detail the 3 currents activated by GABA in the different STG neurons and correlating the distribution of these responses with the distribution of proctolin responses on specific target neurons of the STG.

DIFFERENTIAL EFFECTS OF 20-HYDROXYECDYSONE ON THE MORPHOLOGY OF INSECT NEUROSECRETORY CELLS IN VIVO AND IN VITRO. HF McGraw, K. Prier, JC Wiley, and NJ Tublitz*. Inst. of Neurosci., U. Oregon, Eugene OR 97403 USA

The tobacco hawkmoth Manduca sexta contains 4 pairs of lateral neurosecretory cells (LNCs) in each ganglion. Previous work showed that the LNCs undergo a transmitter switch during metamorphosis, changing from producing the Cardioacceleratory Peptides (CAPs) in larvae to expressing bursicon in adults. This transmitter switch is controlled by the two Vth instar pulses of the steroid hormone 20-hydroxyecdysone (20-HE), the commitment peak (CP) and prepupal pulse (PP). The LNCs also undergo a major morphological transformation during metamorphosis. LNCs from day 2 Vth instar larvae (before the CP) and from pharate adults were dye-filled with cobalt. The extent and complexity of the central arbor was much greater in pharate adult LNCs compared to larval LNCs.

To determine the involvement of 20-HE in this morphological change, single LNCs were cultured in either zero, 0.1 (CP), 0.5 or 1.5 (PP) µg/ml of 20-HE for 10 days or a combination of 0.1 and 1.5 µg/ml for 5 days each. The extent 1°, 2°, and 3° branching was measured daily for each cell. Low concentrations of 20-HE preferentially increased 1° processes whereas the higher 20-HE doses caused a significant increase in the extent and number of 2° and 3° branches. These data suggest that the morphological changes exhibited by the LNCs during metamorphosis are differentially regulated by the CP and PP of 20-HE. Supported by NSF grant # 9314537

CLONING OF THE CDNA ENCODING HELLX PEDAL PEPTIDE PRECURSOR.

A.V. Belyavsky, D.A. Poteryaev, I.S. Zakharov and P.M. Balaban*, Engelhardt Inst. of Molec. Biol. Moscow, Russia 117984, and Inst. of Higher Nervous Activity and Neurophysiol., Moscow, Russia 117865

During the searches for the genes preferentially expressed in serotonergic neurons of terrestrial snail CNS, a cDNA encoding multiple copies of a neuropeptide closely related to Aplysia pedal peptide (PeP) was cloned. According to the cDNA sequence, Helix PeP exists in two forms which differ in one amino-acid residue. In situ hybridization studies revealed expression of the PeP gene in all ganglia of the CNS and in the periphery. PeP gene was found to be expressed by (i) some of the identified serotonergic neurons in pedal and cerebral ganglia, (ii) groups of sensory neurons of olfactory analyzer in procerebrum, (iii) some of the peripheral neurons in olfactory bulb, mantle and leg, (iiii) several groups of neurons in pedal ganglia involved presumably in the locomotion control. PeP mRNA is detected in several pioneering neurons early in the course of nervous system formation. The level and pattern of the expression changes during embryogenesis and early post-embryogenesis. The fact that the PeP gene is expressed by functionally different neurons suggests multiple roles for PeP in the nervous system of molluses.

DIRECT NEUROPEPTIDE ASSAY USING MASS SPECTROMETRY OF ISOLATED IDENTIFIED MOLLUSCAN NEURONS AND ITS APPLICATION TO THE VERTEBRATE CNS. R.W. Garden¹, L.L. Moroz², J. Jing², T.P. Moroz¹, E.A. Gallman¹*, M.U. Gillette³, R. Gillette², and J.V. Sweedler¹ ¹Beckman Inst.; ²Dept. Molec. Integr. Physiol. and ³Cell and Struct. Biol., Univ. Illinois, IL, 61801.

Matrix assisted laser desorption ionization (MALDI) in combination with time-offlight mass spectrometry (TOF MS) has been used to determine neuropeptide content in identified neurons from the sea slugs *Pleurobranchaea* and *Aplysia*. Several groups of identified neurons from the CNS of Pleurobranchaea have been assayed: (i) dorsal buccal motoneurons (DBM); (ii) feeding buccal interneurons [efference copy cell (ECC) and ventral white cells (VWC)]; (iii) escape swim central pattern generator (CPG) interneurons (A1) and modulator interneurons for the swimming CPG (A2); (iv) egg laying hormone releasing cells (ELH) and some SCP_Bimmunopositive cells Identified neurons of *Aplysia* with previously characterized peptides were used for comparison to verify this method. The individual neurons were isolated without protease treatment in the presence of the MALDI matrix 2,5dihydroxybenzoic acid (DHB, 1% solution), which acts as a moderate fixative to facilitate the isolation procedure. Consistent neuropeptide mass spectra were obtained in the majority of the cells, suggesting that up to 10-12 individual peptides can be co-localized in individual neurons. Neuropeptides can be reliably detected in smaller peptidergic neurons (30-50 µm). ELH cells of Pleurobranchaea have a major peak (5000-5040) associated with the egg laying hormone. Two similar neuropeptides with MW 607 and 1548 were found both in feeding (VWC) and swimming (A1) interneurons. However, SCPB was not detected in many SCPB-immunoreactive buccal (including ECC) and pedal neurons from Pleurobranchaea, but was detected in Aplysia preparations. The developed protocol has been successfully applied to the rat brain and six peaks suggestive of peptides have been observed in rat retina and six in the SCN. Supported by NS31609 to JVS and NIH RO1NS268338 grant to RG.

NEUROPEPTIDE PROFILES OF SINGLE NEURONS AND CELL CLUSTER RELEASE. Scott A. Shippy, Rebecca W. Garden, Leonid L. Moroz, and Jonathan V. Sweedler*. Beckman Inst/Dept. of Chem., Univ. of Illinois, Urbana, IL. 61801.

In order to understand signal transduction between individual neurons more fully, it is necessary to characterize both the neurochemicals and the dynamics of release. We describe a highly sensitive and selective assay for neuropeptides from individual bag cells from Aplysia californica. Matrix assisted laser desorption ionization (MALDI) in combination with time-of-flight mass spectrometry (TOF MS) is used to profile the neuropeptide content of single cells. The MALDI matrix 2,5-dihydroxybenzoic acid is used in a stepwise fashion to stabilize cell membranes, remove salts, and deactivate endogenous proteolytic enzymes prior to spectrum acquisition. Mass spectra indicate the presence of neuroactive peptides previously characterized by conventional methods. For example, acidic peptide, egg laying hormone, five bag cell peptides and two C-terminally cleaved α-bag cell peptides are detected by MALDI-TOF MS of a single Aplysia bag cell. Furthermore, spectra reveal the possible presence of modified and/or novel peptides. Additionally, we follow the dynamics of neuropeptide release from a bag cell cluster of *Aplysia*. Release is monitored from an electrically stimulated bag cell cluster previously cultured in ³⁵S-methionine containing medium. The inlet of a fused silica capillary (i.d. 50-75 μm) is placed near to a cluster for continuous gravimetric pressure flow. At the outlet end, the sample (100 nL/min.) is absorbed onto a moving membrane strip. Labeled peptides absorbed onto the membrane are detected using a phosphoimaging system. Results demonstrate significant radioactivity only during the afterdischarge. In contrast to stimulated release, data from damaged cell clusters suggests the release of aggregates of neuropeptides. Time and species resolved peptide release is explored by combining the deposition of the sample onto a gel with subsequent separation by electrophoresis. Spatial resolution of release is accomplished by judicious placement of the sampling capillary. The described methods are applicable to neurosecretory cells and clusters in other model systems. Supported by grants NIH NS31609 and NSF CHE925704.

SCPb-INDUCED PHOSPHORYLATION OF A 53 kD PROTEIN IN ISOLATED MYOCARDIAL CELLS OF HELIX ASPERSA, G. Reich, K.E. Doble and M.J. Greenberg*. Whitney Laboratory, of the University of Florida, St. Augustine, FL32086

The myocardial excitation induced by the molluscan neuropeptide SCPb is accompanied by an increase in cAMP. To study the events that follow this increase in cAMP, we digested heart tissue with trypsin to produce dissociated myocardial cells that were spindle shaped, around 400mm long, and that excluded trypan blue. The effects of SCPb on the levels of cAMP in the isolated myocardial fibers was compared in detail with the cAMP levels of whole ventricles. Levels of cAMP levels rise markedly when dissociated cells are treated with SCPb, and the time course of this response is virtually identical to that of the intact tissue. A set of synthetic analogs - FMRMa, FPRMa, FPRFa, and FMRFa previously used to characterize the structural specificity of the SCPb effect on whole hearts, had strikingly similar potencies when tested on the cell preparation. Thus the SCPb receptors seem not to have been damaged by dissociation. Next, isolated cells were incubated with inorganic 32P, then treated with SCPb. After homogenization, electrophoresis, and exposure to x-ray film, SCPb was seen to have induced the phosphorylation of a 53 kD protein. The intensity of the band increased in a dose dependent manner; threshold was 10⁻⁹-10⁻⁸ M SCPb. Forskolin and the cAMP analog 8-CPT-cAMP mimicked the SCPbinduced phosphorylation. NIH HL28440

BIOLOGICAL ACTIVITY OF CEREBRAL PEPTIDE 2 IN THE ABDOMINAL AND BUCCAL GANGLIA OF APLYSIA.

ABDOMINAL AND BUCCAL GANGLIA OF APLISIA.

G. A. Phares* and P. E. Lloyd Committee on Neurobiology, University of Chicago, Chicago, IL. 60637

Cerebral peptide 2 (CP2) is a newly identified 41 amino acid peptide with an amidated carboxyl terminal. This peptide was identified because it was transported from the cerebral ganglion of Aplysia to target ganglia including the abdominal and pedal-pleural ganglia. Immunocytology indicates that CP2 was widely distributed and particularly dense in the neuropil of the buccal and abdominal ganglia. Standard electrophysiological techniques were used to record responses of identified neurons in these ganglia to applications of synthetic CP2. Many neurons in the abdominal ganglion were depolarized by CP2 including some in the respiratory pumping circuit (R20, R25/L25, L7) and some with unknown functions (L5, RG neurons). The and some with unknown functions (L5, RG neurons). The depolarization appeared direct because it persisted in low Ca²⁺, high Mg²⁺ ASW. Many of these neurons also received a compound PSP during the application of CP2. In R20, R25/L25, and the RG neurons the compound PSP was inhibitory, but in L7 it was an E/IPSP. The compound PSP appears to arise from other neuron(s) depolarized by CP2 and was abolished in low Ca²⁺, high Mg²⁺ ASW. Application of CP2 to the buccal capalion avoked rhythmic activity in a purplet of CP2 to the buccal ganglion evoked rhythmic activity in a number of ventral cluster motor neurons. The pattern of activity was similar to ingestive buccal motor programs recorded by others. The only neuron in the ventral cluster that appeared to respond directly to CP2 was the interneuron B41. These results suggest that CP2 is likely to be involved in the generation of several behaviors in *Aplysia*. Supported by NSF Grant IBN 9418815.

EFFECTS OF TACHYKININ-RELATED PEPTIDES AND OTHER PUTATIVE NEUROTRANSMITTERS ON DORSAL UNPAIRED MEDIAN NEURONS OF LOCUST THORACIC GANGLIA, C.T. Lundquist* and D.R. Nässel Dept. Zoology, Stockholm University, S-106 91, Stockholm, Sweden

Four tachykinin-related peptides, Locustatachykinin 1-4 (LomTK 1-4), are known to be distributed in neurons throughout the central nervous system of the locust Locusta migratoria. It has been suggested that these peptides have functions in neural transmission because of their abundant distribution in processes in most neuropils within the CNS of the locust. In search for central actions we have analyzed the physiological response of putative post-synaptic target neurons - the dorsal unpaired median (DUM) neurons of the locust metathoracic ganglion. LomTKs were either bath-applied to an isolated thoracic ganglion or pressure-ejected onto the soma while recording intracellularly the effects on the membrane potential and action potential firing frequency of single DUM neurons. For comparison, the effects of acetylcholine, GABA and glutamic acid were studied. Bath application of LomTK-1 at 0.1µM caused a small and relatively slow, but reversible depolarization (2-5 mV) and a substantial increase in firing frequency of action potentials of the DUM neurons. Bath application of acetylcholine at 0.1mM induced a rapid depolarization and a large increase in firing frequency whereas both GABA and glutamic acid (0.1mM) caused a rapid hyperpolarization, abolishing all spontaneous action potentials. Almost identical results were obtained when LomTK-1 was pressure-ejected (0.1µM, 20-200 msec.) onto the DUM neuron soma. In this case, however, a fast depolarization, followed by a slower and more sustained depolarization was observed. The results indicate a role for LomTK-1 as a transmitter or modulator acting on the thoracic DUM neurons, but the mechanisms remain unknown. We will further investigate the mechanisms that underlie the depolarization and increase in firing frequency by examining which ion channels and/or second messenger systems are involved.

The project is sponsored by the Swedish Natural Science Research Council (NFR).

Friedrich-Schiller-Uni., Jena, D-07743 Germany.

The swimmerets of crayfish make rhythmic movements that propel
the animal forward in the water column. The force, the period, and the
phase of these movements can be altered to the animals' behavioral
requirements. but the neural mechanisms that accomplish these

requirements, but the neural mechanisms that accomplish these alterations are not known. Crustacean Cardioactive Peptide (CCAP) affects visceral and retinal functions in crabs, so we explored its affects

on the swimmeret pattern-generating circuits.

Bath-application of CCAP to isolated crayfish abdominal nerve cords increased the intensity of bursts of impulses in power-stroke motor neurons, but did not alter the period, durations, or phases of these bursts. This modulation was manifest both as an increase in spike frequency in individual motor neurons and as an increase in the number of motor neurons firing during each burst.

In each ganglion that innervates swimmerets, three pairs of interneurons labeled strongly with a CCAP-antiserum. The shapes and locations of the cell-bodies of these interneurons were the same in each ganglion. These interneurons send processes into the Lateral Neuropils, the loci of the swimmeret pattern-generating modules

Thus, these interneurons have properties that suggest to us that they regulate the force produced by the swimmeret system. Supported by NSF grant IBN-9514889 to BM.

LYS-CONOPRESSIN INDUCES TWO SLOWLY-INACTIVATING INWARD CURRENTS IN AN IDENTIFIED NEURON OF LYMNAEA STAGNALIS. P. F. van Soest, R. F. Jansen* and K. S. Kits. Graduate School Neurosciences Amsterdam, Research Institute Neurosciences, Vrije Universiteit, Faculty of Biology. De Boelelaan 1087, 1081 HV Amsterdam, The Netherlands.

The oxytocin-like peptide lys-conopressin is expressed in neurons of the right anterior lobe of the central nervous system of the pond snail Lymnaea stagnalis. Many of these neurons also express a Lymnaea conopressin receptor, suggesting that autotransmission may be important for regulating their activity. Neurons in the anterior lobe are believed to be involved in the regulation of certain aspects of male copulatory behaviour. Both in the co-localisation of peptide and receptor and their putative function, these neurons seem similar to oxytocinergic magnocellular neurons of the vertebrate hypothalamu

The effects of lys-conopressin on an identified neuron, isolated from the anterior lobe of Lymnaea, were studied using whole-cell voltage clamp. When the cell was clamped at its normal resting membrane potential, conopressin induced a slowly-inactivating, inward current. Voltage ramp protocols were employed to study the voltage dependence of the current. Under control conditions, the steady-state current. voltage (I-V) relation shows a region of negative slope resistance. Application of conopressin shifted the entire I-V relation, ranging from -90 to +10 mV, in the inward direction. This effect was dose-dependent. Vasopressin and oxytocin, as well as lower doses of conopressin, could only activate current at voltages above -40 mV. Apparently, the conopressin-activated current is not homogeneous, but consists of two separate currents. Sodium appears to be the main charge carrier for both currents. In neighbouring neurons, only a current corresponding to one of these components could be activated by conopressin. Desensitisation and recovery experiments further support the notion that the conopressin-activated current is comprised of two separate components. Both currents may contribute to the strong excitation that is observed upon conopressin application under current clamp conditions.

SINGLE-CHANNEL ANALYSIS OF A PEPTIDE-INDUCED POTASSIUM CURRENT WHICH MODULATES CONTRACTILITY IN APLYSIA MUSCLE. C. Excleben and V. Brezina*. Dept. of Biology, University of Konstanz, Germany, and Mt. Sinai Medical School, Dept. of Physiology and Biophysics, New York, NY.

Contractions of the ARC muscle of Aphysia are depressed by neuromodulators that activate a K current in the muscle (Brezina et al 1994; J Neurosci 14, 4412).

Large K currents are activated by MMA, a peptide of the myomodulin family, and FMRFamide related peptides (FRFs), and smaller currents by scrotonin (5-HT).

We investigated the molecular basis of the modulation at the level of single K channels in dissociated ARC muscle fibers. The bath solution was normal artificial sea water, while the patch pipette was filled with high K* solution. Under these conditions, the K* equilibrium potential for the patch is shifted more positive than 0 mV, and K channel openings at the resting potential can be seen as inward currents.

While recording from cell-attached patches, application of MMA, FRFc or 5-HT to the rest of the fiber resulted in the slow activation of channels which were inactive in the absence of the modulators. The time course of the response was very similar to that of the macroscopic current recorded under voltage clamp. At the resting potential, the channels carried a mean inward current of -7.8 ± 0.2 pA (SEM, n = 12). The open probability of the channels showed no significant voltage dependence. Under these conditions of high K* concentration on both sides of the membrane, the single-channel current-voltage relationship was linear with a slope conductance of 100 pS. The channels were identified as K channels based on their ion selectivity and the reversal potential (76 mV positive to rest with high K* solution in the pipette near the K* equilibrium potential. Consistent with the pharmacology of the macroscopic current, single-channel gating and amplitude were independent of extracellular Ca* and insensitive to external Ba* (10 mM), b

CHARACTERIZATION OF A POTENTIAL PHEROMONAL ATTRACTANT IN APLYSIA. S.D. Painter, B. Clough, X. Fan, and G.T. Nagle. Marine Biomedical Institute and Department of Anatomy & Neurosciences, University of Texas Medical Branch, Galveston, TX 77555-

Water-borne pheromones play an important role in regulating male and female reproductive behavior in the marine opisthobranch mollusc Aplysia. They attract normally solitary animals into breeding aggregations during the summer reproductive season, and coordinate mating and egg-laying activity in the aggregations. The pheromones elute from recently deposited egg cordons associated with the aggregations, but relatively little else is known about them. None have, as yet, been chemically characterized. A. californica were injected with atrial gland extract to induce egg laying, the cordons collected at 30-min intervals, and eluted in artificial seawater. The eluate was purified on C18 Sep-Pak cartridges, lyophilized and fractionated by C18 reversed-phase HPLC. There were 4 peaks that were attractive in T-maze assay. The fractions were subjected to amino acid and microsequence analyses. Surprisingly, the sequences were identical in all 4 fractions, except for length. All had two potential glycosylation sites, but it is not known whether the sites are utilized. The longest sequence (48 residues) was compared to the BIONET protein sequence database using their Search and Align program. There is no evidence of homology with any sequence currently in the database. Supported by NIH grant HD28500.

CHARACTERIZATION OF cDNAs ENCODING APLYSIA AMIDATION AND CARBOXYPEPTIDASE-RELATED ENZYMES. X. Fan, G.V. Childs, R. Rodriguez, and G.T. Nagle. Marine Biomedical Institute and Department of Anatomy & Neurosciences, University of Texas Medical Branch, Galveston, TX

The bag cells of Aplysia express the egg-laying hormone (ELH), a neuroendocrine peptide that induces ovulation and its associated behaviors. It is encoded by the ELH gene, which also encodes eight other peptide products. Several prohormone converting enzymes (PCs) have been cloned from the bag cells, and are likely to be responsible for the intravesicular cleavage at basic residue sites. The basic residues are then removed by an enzyme(s) belonging to the carboxypeptidase (CP) family. CPs have been well characterized in many systems but had not been studied in Aplysia. We recently cloned a neuronal 561-amino acid preproenzyme that was most closely related to mammalian CPE (Fan & Nagle, DNA Cell Biol., in press). A second neuronal enzyme was detected by RT-PCR. It was most closely related to carboxypeptidase D (Song & Fricker, J. Biol. Chem. 270: 25007-25013, 1995), a novel CPE-like enzyme present in bovine anterior pituitary secretory vesicles. It is known that one of the ELH gene products (ELH) is then amidated. In order to characterize Aplysia peptidylglycine α-amidating monooxygenase (PAM), a CNS cDNA library was screened using a PAM-related RT-PCR product generated from bag cell RNA. The partial clone that was isolated encoded a PAMrelated enzyme that was most closely related to vertebrate PAM sequences. We are currently attempting to determine the remaining sequence of the Aplysia carboxypeptidase D- and PAM-related enzymes by 3'RACE and library screening. Supported by NSF and a UTMB Grant.

NEURONS SURVIVE AND INDUCE FUNCTIONAL TENTACLES WHEN GANGLIA ARE IMPLANTED INTO HOST SNAILS, AS REVEALED BY IMMUNOHISTOCHEMISTRY AND BEHAVIORAL EVALUATION. J.L.Wilson and S.B.Moffett*, Department of Zoology, Washington State University, Pullman WA 99164.

Implanted ganglia become incorporated into the CNS of the pulmonate snail Ovatella myosotis and induce the growth of eyes and tentacles within 1-2 months, these intraspecific implants had a 50% induction rate. A cerebral ganglion from Melampus bidentatus implanted into Ovatella can also be integrated into the CNS to induce supernumerary structures (showing a 10% success rate). The ganglia were inserted into the lateral head region or between the tentacles, with the latter position being more effective in inducing supernumerary structures. Tactile stimulation of the new tentacle evoked both tentacle and whole-body withdrawal. Sacrifice after 1-6 months allowed microscopic and immunohistochemical observations of the implanted ganglia and innervation of the supernumerary structures. The third tentacle may undergo constriction or diminish and disappear after approximately two months; this is associated with the degeneration of the ganglion.

CHARACTERIZATION OF cDNAs ENCODING A POTENTIAL PHEROMONAL ATTRACTANT AND THE NEUROPEPTIDE APGWamide IN APLYSIA. G.T. Nagle, X. Fan, B. Wu, and S.D. Painter. Marine Biomedical Institute and Department of Anatomy & Neurosciences, University of Texas Medical Branch, Galveston, TX 77555-1043.

A partial amino acid sequence has been obtained for a potential water-borne pheromonal attractant in *Aplysia* (Painter et al., <u>Soc. Neurosci. Abstr.</u> 1996). This information was used to synthesize degenerate oligonucleotide primers to produce RT-PCR and 3'RACE probes in order to isolate cDNAs encoding the complete pheromone sequence. A central nervous system cDNA library was initially screened because: 1) the tissue source of the pheromone was not known; 2) cDNA libraries were available for the CNS, but not for reproductive tract organs that could secrete onto the egg cordon (with the exception of the atrial gland); and 3) other peptides involved in regulating reproduction in Aplysia are expressed in both the CNS and the reproductive tract. A CNS 3'RACE product was generated and preliminary sequence analysis established that it encodes multiple copies of the neuropeptide Ala-Pro-Gly-Trp-NH, (APGWamide); this was then used to screen a λ ZAP CNS cDNA library. In addition, an RT-PCR product of the predicted size was generated using atrial gland total RNA, which was consistent with earlier studies showing that extracts of the atrial gland are attractive in T-maze experiments and induce copulatory behavior. This product was used to screen CNS and atrial gland libraries. We are currently characterizing the cDNA clones to determine whether they encode the pheromone. Supported by NSF and a UTMB Small Grant

CIRCULATING LEVELS OF ECDYSIS-TRIGGERING HORMONE DURING PRE-ECDYSIS AND ECDYSIS OF MANDUCA SEXTA.

J. L. Hermesman¹, T. G. Kingan³, W. Gray⁴, D. Zitnan⁵ and M.E. Adams*²

Depts. of ¹Biology and ²Entomology, U. of California, Riverside, CA 92521; ³Dept. of Biological Sciences, U. of Maryland Baltimore County, Baltimore, MD 21228; ⁴Dept. of Biology, U. of Utah, Salt Lake City, UT 84112; ⁵Slovak Academy of Sciences, Institute of Zoology, Dubravska cesta 9, 84206 Bratislava,

Growth and development in insects is punctuated by ecdysis, the shedding of old cuticle at the end of each instar. In the tobacco hornworm, Manduca sexta, ecdysistriggering hormone (ETH) released from epitracheal glands elicits pre-ecdysis followed by ecdysis in all life stages through a direct action on the central nervous system (Zitnan et al., Science 271: 88-91; 1996). Here we report for the first time the detection of ETH in pharate 5th instar hemolymph by quantitative ELISA. An antiserum specific for ETH was produced in rabbits following immunization with a multiple-antigen peptide (MAP) version of ETH. Hemolymph was taken from pharate 5th instar larva just prior to pre-ecdysis, and at time points during the course of the behavioral sequence through ecdysis. Hemolymph samples were heated to of the behavioral sequence through ectoysis. Teninolymph samples were leaded of 90°C, centrifuged, and assyed directly by ELISA. Several blood samples also were fractionated using HPLC and all fractions were assayed. Only the fractions that coeluted with ETH showed immunoreactivity. Detectable levels of ETH appear immediately prior to pre-ecdysis, reaching levels of 50-100 nM at the onset of this behavior. Hemolymph concentrations of ETH remain elevated during pre-ecdysis and ecdysis. Our results confirm the hormonal nature of ETH and indicate that physiological levels of ETH during the performance of natural pre-ecdysis and ecdysis are in the range previously shown to elicit these behaviors in the isolated central nervous system.

ECLOSION HORMONE-EVOKED RELEASE OF ECDYSIS TRIGGERING HORMONE FROM EPITRACHEAL GLANDS, T. G. Kingan*¹, J. L. Hermesman², W. Gray³, D. Zitnan⁴, M. E. Adams⁵, ¹Dept. of Biological Sciences, U. of Maryland Baltimore County, Baltimore, MD 21228; Depts. of ²Biology and ⁵Entomology, U. of California, Riverside, CA 92521; ³Dept. of Biology, U. of Utah, Salt Lake City, UT 84112; ⁴Slovak Academy of Sciences, Institute of California, Providing Parishers (Parishers California) HORMONE Zoology, Dubravska cesta 9, 84206 Bratislava, Slovakia.

In the tobacco hornworm, Manduca sexta, ecdysis-triggering hormone (ETH) released from epitracheal glands elicits pre-ecdysis followed by ecdysis in all life stages through a direct action on the central nervous system (Zittan et al., Science 271: 88-91; 1996). The neuropeptide eclosion hormone (EH) also evokes ecdysis behavior in vivo, but its in vitro action on the CNS requires the presence of the tracheal system, to which the epitracheal glands are attached. Together, these observations raise the possibility of an endocrine interaction between EH and ETH. We now report that eclosion hormone (EH) evokes release of ETH in vivo, and in We now report that eclosion hormone (EH) evokes release of ETH m vivo, and m viro from individual epitracheal glands. EH prepared by solid-phase chemical synthesis showed chemical and biological identity with the native peptide isolated from extracts of adult corpora cardiaca. Release of ETH was detected by immunohistochemistry and quantitative ELISA. Injection of EH (1-2 pmol) into the hemocoel of pharate larvae and pupae resulted in the loss of immunohistochemical staining in Inka cells of the epitracheal glands and appearance of ETH in the hemolymph. To detect ETH release *in vitro*, epitracheal glands were removed 3-4 hr prior to natural ecdysis ("anterior shrink" in pharate pupae and "air-filled head capsule" in pharate 5th instars). Individual glands were placed in a drop of physiological saline, to which EH was added. Up to 1.7 pmol of ETH appeared in the medium bathing pharate 5th instar glands following exposure to 0.3-1 nM EH. No release was detected after exposure to CCAP or a myotropic Manduca FLRFamide. These findings support the hypothesis that EH initiates the ecdysis sequence through a signaling pathway in the epitracheal glands, resulting in the release of ETH.

TRANSMITTERS IN INVERTEBRATES: NEUROPEPTIDES II

333.1

MECHANISM OF ACTION OF THE CARDIOINHIBITORY PEPTIDE, DROSOPHILA MYOSUPPRESSIN (DMS) Nichols, R. 12*, Dickerson, M.², McCormick, J.² and Paisley, K.²
Depts of BiolChem¹ and Biol², University of Michigan, Ann Arbor,

Myosuppressin peptides, isolated from several organisms, have a high degree of structure identity; only the N-terminal amino acid residue differs. Similar to the myoinhibitory actions of < EDVDHVFLRFamide or leucomyosupressin, LMS (Nachman and Holman) and PDVDHVFLRFamide or SchistoFLRFamide (Robb and Evans), Drosophila myosuppressin, TDVDHVFLRFamide or DMS (Nichols), inhibits heart rate in a dose dependent manner (Dickerson

Amino acid residues critical for the cardioinhibitory action of DMS have been determined by an alanine scan. The alanyl-substituted analogs revealed the following effects on cardioinhibition: T1 (Nterminal threoninyl residue) and D2 accentuate, L8 reduces, and F7 F10, and the C-terminal amide abolish activity. Substitution of R9 has no effect, an observation that is in contrast to the essential arginyl residue of LMS and SchistoFLRFamide inhibitory actions of gut and oviduct motility, respectively. These data suggest that the structural requirements for cardioinhibition are different than those for inhibiting gut and oviduct motility. Supported by NSF and AHA/MI.

GENETIC ANALYSIS OF NEUROPEPTIDE SIGNALING: IDENTIFICATION OF A P ELEMENT INSERTION IN DROSOPHILA PHM. P.H. Taghert*, N. Jiang, M.S. Roberts, Q. Wang, A.S. Kolhekar. Anat. & Neurobiology, Washington University Sch. Med., St. Louis MO 63110, and Neurosci., Johns Hopkins University Sch. Med., Baltimore MD 21205.

Peptide alpha-amidation is widespread and often essential for the synthesis of biologically active peptides. In vertebrates, a single gene (PAM - peptidylglycine-alpha amidating monooxygenase) encodes a large protein with two separable enzymatic domains. The first domain is a monooxygenase (PHM) and the second is a lyase (PAL); together these enzymes convert peptides with C terminal glycines to the alpha amide. To further the genetic analysis of PAM, we have begun to study this

aspect of neuropeptide biosynthesis in *Drosophila*.

Drosophila contains both enzymatic activities. We identified a *Drosophila* gene encoding PHM but lacking PAL. We suspect *PAL* is a separate gene. *dPHM* is expressed in a variety of tissues, including nervous system, endocrine glands and gut. within each tissue, PHM-like immunoreactivity is present in a heterogeneous subset of cells. In embryos, PHM staining first appears around Stage 16 in salivary glands.

APHM is located on the right arm of the second chromosome at 60A12-16. We screened available mutations in this interval and identified a candidate P element

dPHM is located on the right with the screened available mutations in this interval and identified a candidate P element insertion within the PHM transcription unit by PCR methods. We then used blotting, restriction and sequence analysis to confirm the position of the insertion within the signal sequence of the dPHM open reading frame. Two lines of evidence suggest that PHM protein expression may be decreased due to the insertion. Animals heterozygous for the insertion display a weaker band of PHM immunoreactivity on Western blots and produce a lower ratio of PHM to PAL enzyme activity. The stock displays bemogygous lethality that appears to be due to the insertion. Preliminary western blots and produce a lower ratio of PIM to PIM to PIM the insertion. Preliminary analysis of homozygous insertion embryos indicates that some of these animals progress to at least Stage 17 (~75% of embryonic development). Supported by the NIH (#DK-32949 to Betty A. Eipper and #NS-21749 to PHT) and by the McDonnell Center for Cellular and Molecular Neurobiology (PHT)

flp-1 DELETION MUTANTS SUGGEST FMRFAMIDE-LIKE PEPTIDES ARE INVOLVED IN MULTIPLE SENSORY AND MOTOR FUNCTIONS IN CAENORHABDITIS ELEGANS. L. S. Nelson* and C. Li. Department of

CAENORHABDITIS ELEGANS. L. S. Nelson* and C. Li. Department of Biology, Boston University, Boston, MA 02215
FMRFamide-related peptides (FaRPs) have been found throughout the animal kingdom, and have been implicated in many functions, including cardiovascular control and neuromodulation. Recently, mammalian FaRPs have been shown to have anti-opioid activity. In the nematode C. elegans, FMRFamide-like immunoreactivity has been localized to about 10% of the neurons and at least five genes encoding these peptides have been identified. These genes, I/p-1 through I/p-5, appear to be expressed in the animal, and are now being further characterized in our lab.

The I/o-1 gene of C. elegans encodes multiple copies of FLRFamide-

The flp-1 gene of C. elegans encodes multiple copies of FLRFamide-containing peptides. Animals carrying lacZ reporter constructs containing 1.5 kbp of the *flp-1* promoter region have shown that *flp-1* is expressed certain interneurons in the head region of the animal. Further upstream

certain interneurons in the head region of the animal. Further upstream regions have now been isolated and will be used to determine whether additional cells express the flp-1 gene. A flp-7 deletion mutant, or "knockout", has now been isolated from population screens of flp-1::Tcl animals (kindly provided by Ron Plasterk). The deletion was 1.4 kbp, and included almost 4 of the 6 exons as well as the start site of transcription. Multiple phenotypes have been correlated with the flp-1 deletion. These include uncoordinated movement, nose-touch insensitivity, and defects in osmolarity detection. Many of the phenotypes are also seen in mutants missing the α subunit of the neuronal G protein. Rescue of these phenotypes with the wild type copy of the gene is currently underway. Further characterization of phenotypes in f/p-1 deletion animals as well as non-complementation screens for additional f/p-1 alleles are ongoing.

ANALYSIS OF A CNS-PERITRACHEAL NEUROPEPTIDE SYSTEM IN INSECTS. M.A. O'Brien* and P. H. Taghert, Anat. and Neurobiol. Dept., Washington Univ. Med. School, St. Louis, MO 63110.

We have been studying a *Drosophila* "enhancer trap" line that has reporter gene expression co-localized with expression of a myomodulin-like peptide. There is coexpression in prominent neurosecretory cells in the CNS, and in one of two segmental peritracheal cells that have strong reporter gene expression. The myomodulin-positive peritracheal cell is also immunoreactive with an antibody against the *Drosophila* PHM protein, an enzyme in the peptide amidation pathway (see abstract by Taghert et al.). Since many neuropeptides are amidated, this is a good marker for neuropeptide-

expressing certs. This pertiracheal neuropeptide system appears to be widespread in insects. We have found myomodulin-like expression in peritracheal cells in at least two other insect orders. In Mandaca sexta, a peritracheal, myomodulin antibody-positive cell has been identified; this cell is either identical to, or a neighbor to, the inka cell, which produces the ecdysis-triggering hormone (Zitnan et al., 1996). The Drosophila cell may be the homolog to the inka cell, though the cell morphology is quite distinct. In a grasshopper, there is staining in cells with similar morphology to the Drosophila cell, but they are widely distributed along the tracheae. Whether this peritracheal neuropeptide system has a general, endocrine function or a more local function is an important question. Assessing peptide expression in a variety of insects with different physiological demands, as well as monitoring expression throughout development should provide insight into the possible functions of this conserved peritracheal

In order to study this system at a molecular genetic level, we have cloned the region surrounding the transposon in *Drosophila*, with the goal of identifying the gene responsible for the expression pattern and mutating it. We have isolated several cDNAs in the vicinity of the transposon and are in the process of screening them by in situ hybridization to determine if their expression coincides with the reporter gene Supported by NIH Grant NS-21749 (P.H.T)

MODULATION OF THE STOMATOGASTRIC GANGLION OF THE LOBSTER, HOMARUS AMERICANUS. K. S. Richards*, V. Kilman, J. Golowasch and E Marder. VOLEN CENTER, BRANDEIS UNIVERSITY, WALTHAM, MA 02254.

An extensive literature on the modulation of the stomatogastric nervous system (STNS) of several decapod species has been gathered. The STNS of *Homarus* americanus has been relatively neglected, however, partially because it has been less reliable in *in vitro* preparations than some of the other crustacean species. Because of its potential use to study STNS development, we decided to study the presence and action of putative neuromodulatory substances in the H. americanus STNS, and to study the effects of these on motor patterns produced by the stomatogastric ganglion

Anatomical studies of the adult H. americanus showed the presence of immunoreactivity in the STNS after staining with antisera generated to the following transmitter and modulator substances: GABA, glutamate, octopamine, FMRFamide proctolin, buccalin, histamine, red pigment concentrating hormone (RPCH), and cholecystokinin (CCK). In addition, we showed the presence of FMRFamide -like staining in the STG of stage | larvae. We are currently extending these studies to other larval stages

Electrophysiological studies on adults using bath application showed that proctolin. SDRNFLRFamide and crustacean cardioactive peptide (CCAP) enhanced pyloric and/or gastric mill activity. Allatostatin (AST) was inhibitory, as were GABA and histamine. Dopamine evoked rapid tonic firing but not bursting. Surprisingly, the muscarinic agonists pilocarpine and oxotremorine, which strongly activate the STG of other decapod species were not effective.

In summary, as in other crustacean STNS, the *H. americanus* STNS contains and is modulated by a large number of substances.

Supported by NS17813 and the HFSP.

REGULATION OF DROSOPHILA HEART RATE Dickerson, M.1*, McCormick, J.1, Paisley, K.1, and Nichols, R.12 Depts of Biol. & Biol. Chem.2, University of Michigan, Ann Arbor, MI

Although Drosophila melanogaster has served as a versatile experimental organism for developmental neurobiology little is known about the action of neuropeptides due to the lack of structure data, antisera specific to individual neuropeptides, and the development of bioassays. We have isolated peptides, generated sequence-specific antisera, and established Drosophila heart rate assays. By application of neuropeptides, classical transmitters, and pharmacological reagents, and the utilization of mutants, we have begun to analyze the regulation of Drosophila heart rate.

Drosophila FMRFamide peptides, DPKQDFMRFamide, TPAEDFMRFamide, and SDNFMRFamide, increase heart rate; the molluscan cardioexcitatory peptide FMRFamide is inactive. In contrast, Drosophila myosuppressin, TDVDHVFLRFamide, inhibits heart rate. These data indicate that the variant N-terminal sequences of -FXRFamide peptides are important in affecting heart rate.

We have determined that serotonin is cardioexcitatory, while dopamine, GABA, glutamate, proctolin, and octopamine inhibit heart rate. A mixture of serotonin and DMS has an additive effect suggesting that the two substances act through different mechanisms. The action of DMS is suppressed in potassium channels mutants and in the presence of potassium channel blockers, supporting the conclusion that the regulation of heart rate involves potassium channels. Supported by NSF and AHA/MI.

IDENTIFICATION OF LEPIDOSTATIN, AN ALLATOSTATIN-LIKE PEPTIDE, AND MAPPING AND FUNCTIONS OF LEPIDOSTATIN-IMMUNOREACTIVE NEURONS IN MANDUCA SEXTA. N.T. Davis!*, J.A. Veenstra², R. Feyereisen², and J.G. Hildebrand¹². ¹ARL Division of Neurobiology and ²Department of Entomology, University of Arizona, Tucson, AZ 85721.

In the sphinx moth Manduca sexta, we have identified a neuropeptide, Lepidostatin (LS), whose primary structure is AKSYNGLamide. Its C-terminal structure indicates that LS is related to cockroach allatostatins. We used an antiserum that recognizes LS to map LS-immunoreactive (LS-ir) neurons in *M. sexta* larvae. Many interneurons are LS-ir; thus, LS may have neuromodulatory functions. Thoracic motor neurons are LS-ir, but immunoreactivity is lost at metamorphosis. LSimmunoreactivity of these motor neurons may indicate myotrophic or myomodulatory functions. LS and diuretic hormone immunoreactivities are colocalized in neurosecretory cells of the brain and abdominal ganglia; thus LS, released as a neurohormone, may have functions related to diuresis. LS-ir cells of the terminal ganglion innervate the hindgut; bioassays indicate that LS inhibits hindgut contractions. LS does not appear to have an allatostatic function. [Supported in part by NIH grant AI-23253 to JGH.]

DEFINITION OF A CELL TYPE-SPECIFIC ENHANCER OF NEUROPEPTIDE TRANSCRIPTION IN *DROSOPHILA*. R.J. Benveniste* and P.H. Taghert, Dept. of Anat. and Neurobiol., Washington Univ. Sch. of Med., St. Louis, MO 63110

The Drosophila FMRFamide neuropeptide gene is transcribed in about 50 neurons in the CNS, representing at least 17 different cell types. The most prominent are the In the CNS, Jephesenthing at cases 17 different cell types. The most pointeria at all TV neurons, six neuroendocrine cells in the ventral ganglion. Previous work suggested that the FMRFamide promoter is large and mosaic with respect to regulation in different cell types. A 300 bp enhancer dedicated to one of the 17 cell types (OL2) was previously defined. We now define a distinct enhancer specific for

The Tv regulatory region was previously mapped by deletion analysis to a 446 bp sequence between 476 and 922 bp upstream of *FMRFamide*. We tested whether sequences from this region could drive expression by a heterologous promoter (hs43). The 446 bp sequence drove expression of a reporter gene in the Tv neurons of transgenic larvae, as well as in four cells that do not express FMRFamide. While Tv FMRFamide expression continues through adulthood, Tv lacZ expression waned during metamorphosis.

during metamorphosis.

Reduction of the 446-bp sequence defined 169 bp that are necessary for reporter expression in larval Tv neurons. Preliminary results suggest that 59 bp within the 169-bp sequence are necessary for reporter expression in larval Tv neurons. This 59-bp sequence includes a homeodomain consensus-binding site and a CRE-like element, both of which are conserved between the FMRFamide promoters of D. melanogaster and D. virilis. THE EFFECT OF FMRFamide RELATED PEPTIDES (FaRPs) ON THE THE EFFECT OF FMRFamide RELATED PETIDES (FARCS) ON THE PHARYNGEAL AND SOMATIC MUSCULATURE OF THE NEMATODE ROUNDWORM ASCARIS SUUM. David J Brownlee', Lindy Holden-Dye and Robert J Walker. Department of Physiology and Pharmacology, Bassett Crescent East, University of Southampton, Southampton, SO16 7PX, England, UK.

The nervous system of the parasitic nematode, Ascaris suum exhibits widespread immunoreactivity to the FMRFamide-like peptides. More recently a number FMRFamide related peptides, (FaRPs) have been isolated from both free-living and parasitic forms. An in vitro pharmacological approach was used to investigate the functional role of endogenous nematode FaRPs in the control of Ascaris pharyngeal and somatic muscle. Intracellular recordings from Ascaris somatic muscle cells were also performed. The peptides tested on the two muscle preparations were: AF1 (KNEFIRFamide), AF2 (KHEYLRFamide), AF8 (KSAYMRFamide) and PF4 (KPNFIRFamide).

	AF1	AF2	AF8	PF4
Pharyngeal muscle	-	+	/+	0
Somatic muscle	+	+/-	++	

+ excitatory; 0 no effect; - inhibitory $(1nM - 10 \mu M; n=8)$

AF8 inhibited pharyngeal pumping behaviour in a dose-dependent manner (threshold 0.1 nM). The inhibition was characterized by the pharynx remaining in a hyper-contracted state, with no pumping movements. AF8 also caused contraction of the somatic musculature. The peptides tested have potent effects on both the pharyngeal and somatic musculature of Ascaris. However, the peptides cause diverse effects depending on the nematode muscle type under study (see table). This indicates that some, if not all of the FaRPs may have an important functional role in the control of nematode feeding and motility, and the possible coordination of these two behaviours. This work was supported by the Medical Research Council and the BBSRC.

FAMILY OF NEUROPEPTIDES IN *APLYSIA:* RR, BIOCHEMICAL, AND PHYSIOLOGICAL, TIONS. J. Rybak*¹, V. Alexeeva¹, V. Brezina¹, <u>E. C.</u> MOLECULAR, BIOCHEMICAL, AND PHYSIOLOGICAI INVESTIGATIONS. J. Rybak*, V. Alexeeva, V. Brezina, E. C. Cropper', I. Kupfermann', I. Orekhova', D. A. Price', F. S. Vilim', and R. R. Weiss'. Mt. Sinai Med. Schl., NY, NY 10029; "Columbia Univ. NY, NY 10032; "C.V. Whitney Lab, St. Augustine, FL 32086. 7, F. S. Vilim, and Columbia Univ...

NY, NY 10032; 'C.V. Whitney Lab, St. Augustine, FL 32086.

Buccal muscles of *Aplysia* are controlled by primary transmitters and modulatory neuropeptides that interact with each other to shape the characteristics of muscle contractions. Thus, to understand the normal functioning of the buccal mass it is desirable to characterize the full complement of neuropeptides that modulate this organ. Often modulatory neuropeptides exist as members of multi-peptide families. Some peptides were originally characterized using biochemical techniques, others were identified using molecular biology.

Based on cloning studies we now report that three previously identified FRF peptides (a, b, and c; Cropper et al., J. Neurophysiol. 72:2181, 1994) are members of a larger family. The FRF precursor encodes two additional peptides: FRFd and FRFe. Sequential IEX-HPLC and RP-HPLC have shown that all five FRFs are expressed in buccal neurons. Like FRFa-c, FRFd and FRFe are bioactive and depress the size of contractions of the ARC muscle (FRFe is less potent than FRFa-d in this system). Both B15- and B16-elicited contractions are depressed, but the latter more effectively. This differential effect suggests a presynaptic site of action of the FRFs. However, all the FRFs also act directly on the muscle where they activate a voltage-dependent suggests a presynaptic site of action of the FRFs. However, all the FMFs also act directly on the muscle where they activate a voltage-dependent K current, thus depressing contractions. These actions are likely to be physiologically relevant since we find that the FRFs are released in a calcium dependent manner in response to nerve stimulation.

Supported by NIMH, DFG, and the Whitehall Foundation.

CLONING AND SEQUENCE OF A FULL LENGTH FMRFAMIDE CODING cDNA FROM THE BRAIN OF THE CUTTLEFISH Sepia Officinalis, P.K. Loi & N.J. Tublitz. Inst. of Neuroscience, University of Oregon, Eugene OR 97403

officinalis. P.K. Loi. & N.J. Tublitz. Inst. of Neuroscience, University of Oregon, Eugene OR 97403

The overall aim of our work is to determine the neurotransmitters involved in the regulation of chromatophore function in cephalopods. Our previous work (Loi et al., J. of exp. Biol., 1996) showed that FMRFamide Related Peptides (FaRFs) play an important regulatory role in this system, causing contraction of the chromatophore muscles in the cuttlefish Sepia officinalis when applied to an isolated chromatophore bioassay. Immunological and biochemical data in that study also showed that there is likely more than one FaRP involved in chromatophore function. The purpose of this study was to identify the number and structure of FaRPs in Sepia using molecular techniques. As a first step in this process, PCR was performed on a Sepia cDNA brain library (gift of Stratagene Corp.) using primers whose sequences were taken from a FMRFamide coding transcript isolated by Dr. David Price from the squid Loligo opalescens. The PCR generated a 500 base pairs product which was subcloned and sequenced. This partial sequence was used as a template for generating probes to screen the cDNA library for full length transcript of about 1900 bases (b) long. It has about 280 b at the 5' end prior to start codon, 1200 b between the start and the stop codon, and about 400 b from the end codon to the poly. A tail. This transcript encodes for one copy of FIRFamide, one copy of a FaRP decapeptide (ALSGDAFLRFamide), one copy of FIRFamide, and 11 copies of FMRFamide. Each FaRP is, flanked at the 5' end with 10 2 basic residues and an arg at the 3' end. All end with a glycine, which is necessary for the C-terminus amide. In summary, we have demonstrated that the cuttlefish expresses at least four FaRPs, one or more of which may play an important role in regulating chromatophore function. (supported by grants from NSF and medical research foundation of Oregon)

CELLULAR SPECIFIC DISTRIBUTION AND PHYSIOLOGICAL ACTIONS OF MasFLRFamide PEPTIDES. Y.S. Miao*, E.M Waters, K. Heinzen and J.L. Witten. Department of Biological Sciences, U. Wisconsin-Milwaukee, Milwaukee, WI 53201

A family of at least three FLRFamide peptides is present in the nervous and neuroendocrine systems of the tobacco hornworm, Manduca sexta (Kingan et al., 1996). Furthermore, these peptides are developmentally regulated (Witten and Truman, 1996; Kingan et al., 1996). Here we present our preliminary data demonstrating 1) a cellular specific distribution for the peptides in motoneurons (MasF7G) and neurosecretory cells (varying levels of all MasFLRFamides), 2) developmental plasticity in the expression of the peptides in the thoracic neurosecretory cells that parallels previously reported plasticity in the motoneurons (Witten and Truman, 1996) and 3) differential physiological actions of the peptides on skeletal muscle. We analyzed the actions of the MasFLRFamide peptides on the skeletal muscle target of an identified motoneuron that contains MasF7G (abdominal ISMs). As expected, MasF7G was the most potent and significantly enhanced stimulus evoked muscle tension 5 fold. This peptide-specific enhancement of muscle tension is consistent with our hypothesis for different functional roles for the MasFLRF-NH2 peptides: neurotransmitter, local neuromodulator and circulating hormone

MODULATORY EFFECTS OF FMRFamide-like PEPTIDES AND DISTRIBUTION OF FMRFamide-LIKE IMMUNOREACTIVITY IN THE CRAYFISH STOMATOGASTRIC NERVOUS SYSTEM. A.J. Tierney*, J.K. Blanck and A.J. Mercier. Dept. of Psychology, Colgate University, Hamilton, NY 13346 and Dept. Biol. Sci., Brock Univ., St. Catherines, Ontario, Canada

FMRFamide-like peptides have been shown to modulate neural network activity in the stomatogastric ganglion (STG) of marine crustacea We found that several FMRFamide-like peptides also alter network activity in the STG of the crayfish *Procambarus clarkii*. Peptides were bath-applied to isolated, quiescent STGs and activity was recorded via electrodes placed on dvn, lvn and mvn nerves. Relatively high concentrations (5 x 10^{-7} M) of NF1 (NRNFLRFamide), DF2 (DRNFLRFamide), and F1 (TNRNFLRFamide) NF1 (NRNFLRFamide), DF2 (DRNFLRFamide), and F1 (TNRNFLRFamide) elicited robust rhythmic activity in most preparations. We are presently investigating the effects of these and additional FMRFamide-like peptides on bursting activity of individual STG neurons. As in other crustaceans, FMRFamide-like immunoreactivity was detected in somata located in ganglia and nerves anterior to the STG. Commercially-available primary (bovine thyroglobulin conjugated anti-FMRFamide generated in rabbit) and secondary (FITC-labelled goat anti-rabbit IgG) antibodies revealed stained somata in the paired commissural ganglia (12-20 stained somata per ganglion) and the esophageal ganglion (1-3 stained somata per ganglion). An additional pair of stained somata were located in the stomatogastric rerve where the two superior esophageal nerves join this nerve. The stomatogastric ganglion contained no stained somata, but the neuropil was brightly stained. Also, 2-4 stained axons projected laterally in small nerves directly from each STG, possibly indicating direct modulation of directly from each STG, possibly indicating direct modulation of stomatogastric muscles by a FMRFamide-like peptide.

FMRF-AMIDE ACTIVATES AN UNUSUAL RESTING NA CURRENT IN LEECH RETZIUS CELLS. J. A. Strong*, M. D. Hilborn, and C. L. Sahley.
Dept. Biol. Sci., Purdue Univ., West Lafayette IN 47907

The Leech Retzius (R) cell is a large, serotonergic neuron which regulates several behaviors. The cell's usual activity pattern is sporadic or regular firing of single action potentials. FMRF-amide related peptides profoundly alter this activity pattern, causing a small depolarization and increased activity, followed within seconds by induction of endogenous, long-lasting, bursting! We have used single- and two-microelectrode voltage clamp (SEVC and TEVC) in R cells from isolated, desheathed ganglia to examine possible ionic bases for these effects. SEVC experiments showed that Helix FMRF related peptide (FMRF; 20-50 μM) rapidly activated a small inward current (0.5 to 2 nA) and increased conductance at subthreshold potentials near rest (-60 to -50 mV), closely coinciding with the onset of increased activity. The current increased with depolarization over the range studied (-100 to -45 mV). The voltage dependence is very shallow compared to that of the Na currents underlying the action potential, and no time dependence was seen. The current persisted i nominally Ca-free solutions, but required extracellular Na. It bears some similarity to a "persistent" Na current2, and was not blocked by Cs or saxitoxin Modeling of the R cell indicates that the current may mediate the initial depolarization caused by FMRF. A more complete characterization of its voltage dependence is needed to determine whether it could also account for bursting. TEVC experiments showed that FMRF had no effect on the voltage activated Ca current, but did modestly reduce voltage activated K currents (10-25%). This may account for the previously reported FMRF-induced broadening of action potentials.

FUNCTIONAL REDUNDANCY OF DROSOPHILA FMRF-NH₂-RELATED NEUROPEPTIDES AT THE LARVAL NEUROMUSCULAR JUNCTION. R. S. Hewes*, E. Snowdeal III, and P. H. Taghert. Dept. of Anat. and Neurobiol., Wash. U. Med. School, St. Louis, MO 63110. Neuropeptide genes commonly encode large propeptides, from which multiple peptides are derived through enzymatic processing. The functional significance of this organization is not understood. The Drosophila FMRFamide gene encodes at least seven distinct neuropeptides. These peptides share a C-terminal FMRF-NH₂-like consensus sequence, while their N-terminal sequences are divergent. We have examined the effects of six of these pentides on neuromuscular transmission in Drosophila larvae

their N-terminal sequences are divergent. We have examined the effects of six of these peptides on neuromuscular transmission in *Drosophila* larvae at concentrations ranging from 1 pM to 10 µM. Five peptides enhanced abdominal muscle contractions at a threshold of 10 nM; one peptide, SAPQDFVRS-NH₃, had no effect on muscle contraction. At 10 nM the response latencies, the times to peak, and the times to full recovery for each peptide were identical. Thus, at low concentrations, these peptides have equivalent effects on nerve-stimulated muscle contraction.

Three sequence-dependent differences in peptide action were apparent at higher concentrations. At 10 µM, the dose-response curves for 2 peptides had a positive slope. For the other three peptides the dose-response curves peaked or reached a plateau at 0.1-1 µM. At these higher concentrations, the responses to the various peptides also displayed significantly different latencies and times to peak. Thus, (1) these peptides appear to be functionally redundant at low concentrations, and (2) they elicit different responses at higher concentrations. The latter may reflect sequence-dependent differences in kinetics for receptor occupancy and/or the existence of multiple receptor subtypes. We are examining these differences at a cellumultiple receptor subtypes. We are examining these differences at a cellu-

SAR FOR NOVEL CHROMANES: ATYPICAL NEUROLEPTICS WITH 5HT1A AGONISTIC AND D2 ANTAGONISTIC ACTIVITY H. Böttcher¹, G.D. Bartoszyk¹, J.J. Berthelon², M. Brunet², R. Devant³, H.E. Greiner¹, R. Gottschlich³¹, J. März¹, C.A. Seyfried¹, and J.J. Zeiller². ¹Merck KGaA Pharm. Res., CNS-Research, 64271 Darmstadt, Germany, and ²Lipha Centre Recherche Lacassagne, 69003 Lyon, France

Conventional D2 neuroleptics provoke catalepsy corresponding to undesired extrapyramidal side effects in man. Because 5HT1A agonists are known to antagonize haloperidolinduced catalepsy, the combination of D2 antagonistic with 5HT1A agonistic properties may have therapeutic advantages, i.e. may not induce catalepsy. Comparing binding (D2; 5HT1A) and behavioral

data (apo climbing mouse; catalepsy rat; ul-trasonic vocalization rat, USV) it turned out: unsubstituted R1

Bod to loss of DA activity, un- or 8-substituted R2 is essential for both DA and 5HT1A activity, H for R3 required for both DA and 5HT1A. For 5HT1A, X = N and Y = O led to the most active compound 2-[5-(4-fluorphenyl)-3-pyridylmethylaminomethyl]-chromane (IC50 values [nM]: D2 9; 5HT1A 2; ED50 values [mg/kg sc] USV 1.2, climbing 3.4, catalepsy >100).

SPROUTING OF CATECHOLAMINERGIC FIBERS IN THE CORTEX OF RATS WITH NEONATAL LESIONS OF THE RAPHE NUCLEI. JB. Taylor*, M. Cunningham and F.M. Benes. Lab for Structural Neuroscience, McLean Hospital, Belmont, MA; Dept. of Psychiatry, Harvard Medical School, Boston, MA.

To explore whether trophic interactions occur between catecholaminergic and serotonergic projections to rat medial prefrontal cortex (mPFCx), a series of experiments were conducted in which lesions of the raphe nuclei were induced during the neonatal period. On postnatal days 3 and 6, male CD rat pups were given an intraventricular unilateral injection of either vehicle or 5,7-dhydroxytryptamine (10µg/µl) together with an IP injection of nomifensin (25 mg/kg). Lesioned rats showed nearly complete ablation of 5HT-IR staining in the nucleus raphe dorsalis, the nucleus raphe medianis and mPFCx. An immunoperoxidase localization of a monoclonal antibody against tyrosine hydroxylase (TH) revealed a rich plexus of varicose fibers throughout the cortical mantle of both vehicle and lesioned rats, with the greatest density being observed in layers V and VI of both groups. In lesioned rats, there was a two-fold increase in density of TH-IR varicosities on cell bodies (1 = 5,35; p = 0.0007) and in neuropil (1 = 4.08; p = 0.0035) of layer V; a significant increase was also observed in the neuropil of layer VI (t = 2.63; p = 0.03). When the distribution of TH-IR varicosities was compared for different neuronal subtypes in layer V. the density was increased by 100% on pyramidal neurons (p = 0.002), but only 60% on nonpyramidal cells (p = 0.02) in the lesioned group. Overall, these data are consistent with the idea that an early disturbance in the development of cortical 5HT projections may be associated with a preferential sprouting of catecholaminergic systems may occur postnatally. EFFECT OF UPREGULATION OF 5HT2A RECEPTORS ON DOPAMINE-MEDIATED BEHAVIORS, J.G. Hensler*, J.M. Scalzitti and K.A. Truett. Dept. of Pharmacology, Univ. of Texas Health Sci. Center, San Antonio, TX. 78284.

Intracerebroventricular (i.c.v.) infusion of antisense oligodeoxynucleotide (AS oligo), directed against the translation initiation site of the serotonin2A (5HT_{2A}) receptor, for 8 days results in a 50% increase (p \leq 0.05) in the density of cortical 5HT2A receptors as compared to control oligo or vehicle (see Scalzitti et al., Soc. Neurosci, Abst. in press, 1996). We have assessed the effect of these treatments on locomotor behavior and grooming behavior mediated by D2 and D1 dopamine receptors, respectively. On the 7th day of infusion, there was no significant difference in the number of line crossings induced by the D2 receptor agonist quinpirole (0.5 mg/kg, s.c.) in rats receiving AS oligo, control oligo or vehicle infusions. Following 8 days of infusion, grooming behavior (time spent grooming in a 30 min period) induced by the D1 receptor agonist SKF 38393 (2 mg/kg, s.c.) was significantly reduced (Vehicle: 447 \pm 61 sec; Sense oligo: 503 \pm 42 sec; AS oligo: 262 \pm 13 sec, n=5 per group, p≤0.01). This decrease in D1 receptor-mediated grooming behavior in AS oligo infused rats was accompanied by a marked increase in oral dyskinesias (e.g. tongue protrusions) and directed oral stereotopies (e.g. gnawing at the cage bottom). There was no change in the binding of ³H-SCH23390 (0.1 - 8nM) to D1 receptors in striatal homogenates. These data suggest that an upregulation of 5HT2A receptors in brain, as a result of 8-day AS oligo infusion i.c.v., increases the functional sensitivity of D1 receptors. USPHS grant MH52369 and research funds from NARSAD.

334.2

EFFECTS OF APOMORPHINE ON THE SINGLE-UNIT ACTIVITY OF

EFFECTS OF APOMORPHINE ON THE SINGLE-UNIT ACTIVITY OF SEROTONERGIC DORSAL RAPHE NEURONS IN BEHAVING CATS. C.A. Fornal * C.W. Metzler, F.J. Martín and B.L. Jacobs. Program in Neuroscience, Princeton University, Princeton, NJ 08544. Although it is well established that brain serotonin can alter dopaminergic function, relatively little is known about the possible influence of brain dopamine on serotonergic function. Recent neurochemical evidence suggest that increased dopaminergic transmission inhibits the activity of serotonergic neurons in the dorsal raphe nucleus CBRN through increased release of somatogendritic serotonin and (DRN) through increased release of somatodendritic serotonin and subsequent autoreceptor stimulation (Ferré et al., J. Neurosci, 14: 4839-4846, 1994). The present study tested this hypothesis by examining the effects of the dopamine receptor agonist apomorphine on the spontaneous activity of serotonergic DRN neurons in behaving cats. Serotonergic neurons were recorded and identified as described previously (Fornal et al., Serotonergic JPET 270: 1345-1358, 1994). Systemic administration of apomorphine (0.5 mg/kg, i.v.) increased the firing rate of the majority of cells studied, in contrast to its predicted action. The stimulatory action was evident within 30 sec of injection and lasted for approximately 10 to 30 min. The maximal increase in neuronal activity produced by apomorphine ranged from about 10% to 150% above baseline levels. None of the cells tested were inhibited by apomorphine in these trials. In additional experiments, apomorphine (0.5 mg/kg, i.v.) was found to potentiate the increase in serotonergic DRN neuronal activity produced by a maximally-effective dose (0.1 mg/kg, i.v.)of the 5-HT_{1A} autoreceptor antagonist WAY-100635. Overall, these results suggest that increased dopaminergic transmission exerts a stimulatory suggest that increased dopartitiegic transmission exerts a stillulatory, rather than inhibitory, influence on the activity of serotonergic DRN neurons in awake cats. Supported by grants from the AFOSR (F 49620-94-1-0128) and the NIMH (MH 23433).

THE EFFECT OF UNILATERAL LESIONS TO THE SEROTONIN INNERVATION ON THE UPTAKE OF [\$^{1}H]DOPA IN RAT BRAIN. P. Cumming*, V. Ljubic-Thibal, C. Laliberté, and M. Diksic. McConnell Brain Inaging Centre, Montreal Neurological Institute, Montreal, Canada H3A 2B4. To test the contribution of the forebrain serotonin innervation, which contains the enzyme DOPA-decarboxylase (DDC), to the metabolism of [\$^{1}H]DOPA, unilateral lesions were produced by infusion of 5,7-DHT (2 \(\rho_{B}\)) to the MFB of Wistar rats, some pretreated with desmethylimipramine (DMI, 10 mg/kg). One Wistar rats, some prefreated with desmethylimpramme (DMI, 10 mg/kg). One week later, rats were cannulated in the femoral artery and vein, and received $|^3H|DOPA~(200~\mu Ci, i.v.)$, which circulated for 90 minutes. In vivo $|^3H|dopamine$ synthesis in caudate was measured by quantitative autoradiography. Brain sections were incubated with $|^3H|dialopram~(2~nM)$ to label serotonin terminals, or $|^{125}I|RTI~(50~nM)$ to label catecholamine terminals.

		Ipsilateral	Contralateral
sham	[3H]Citalopram	50 ± 25 fmol/mg	$25 \pm 5 \text{ fmol/mg}$
(n=3)	1 ¹²⁵ []RTI	$45 \pm 4 \text{ fmol/mg}$	$46 \pm 5 \text{ fmol/mg}$
	[3H]dopamine	$0.37 \pm 0.02 \text{ nCi/mg}$	$0.45 \pm 0.02 \text{ nCi/mg}$
5,7-DHT	[]H]Citalopram	7 ± 2 fmol/mg	$23 \pm 6 \text{ fmol/mg}$
(n=3)	[125]]RTI	$19 \pm 13 \text{ fmol/mg}$	$40 \pm 5 \text{ fmol/mg}$
, ,	³ H]dopamine	$0.18 \pm 0.05 \text{ nCi/mg}$	$0.49 \pm 0.03 \text{ nCi/mg}$
5.7-DHT	+ DMI[3H]Citalopram	6±3 fmol/mg	24 ± 1 fmol/mg
(n=3)	[¹²⁵][RT]	44 ± 10 fmol/mg	$46 \pm 5 \text{ fmol/mg}$
(/	[3H]dopamine	$0.10 \pm 0.04 \text{ nC/mg}$	$0.26 \pm 0.01 \text{ nCi/mg}$

5,7-DHT infusion extensively damaged serotonin and dopamine innervations, but DMI protected the catecholamine fibres. The decline in striatal [3H]dopamine synthesis in vivo, correlating with reduced [125]RTI binding in vitro, also occurred in the DMI-treated group. This suggests that the forebrain serotonin innervation plays an important role in the synthesis of [3H]dopamine from [3H]DOPA in vivo, but not the storage of [3H]dopamine within the caudate. This research was supported by MRC (Canada) SP-30.

MESOSTRIATAL DOPAMINERGIC ACTIVITY IS POTENTIATED BY STRIATAL 5-HT_{2A} RECEPTORS. <u>V. L. Taylor, G. M. Fadayel and C. J. Schmidt*</u>. Hoechst Marion Roussel, Inc. 2110 E. Galbraith Rd. Cincinnati, OH

Although postmortem investigations have provided evidence of elevated serotonergic activity in the basal ganglia of schizophrenic patients, the consequences of such increased activity remain unknown. Evidence from rodent studies indicates that $5-HT_{2A}$ receptors play a permissive role in some states of dopaminergic activation and that $5-HT_{2A}$ receptor antagonists can attenuate such activation. In the current experiments, the in vivo stimulation of dopamine (DA) synthesis produced by administration of the amphetamine analogue, 3,4-methylenedioxymethamphetamine (MDMA) was potentiated by the mixed 5-HT $_{\rm 2A/C}$ agonist, 3,5-dimethoxy-4-iodophenylisopropylamine (DOI). Similar results were observed in the nucleus accumbens. The prosynthesis effect of DCI was blocked by the selective 5-HT_{2A} receptor antagonist, MDL 100,907. The anatomical site of this interaction between 5-HT_{2A} receptors and the striatal DA system was examined using *in vivo* microdialysis in awake, freely moving rats. Systemic administration of MDMA (10 mg/kg, s.c.) produced a significant elevation of striatal DA efflux which was significantly potentiated by the infusion of DOI (50 uM) into the striatum via the microdialysis probe. DOI infusion alone had no effect on extracellular concentrations of striatal DA. The results suggest that a hyper-responsive dopaminergic system is one potential consequence of increased serotonergic activity in the basal ganglia. Although baseline dopaminergic function would be unaffected under such conditions, any physiological or pharmacological stimuli producing enhanced dopaminergic drive could precipitate the abnormal increases in dopamine release believed to underlie the initiation of a psychotic episode.

PHARMACOLOGICAL CHARACTERIZATION OF THE RECEPTORS PHARMACOLOGICAL CHARACTERIZATION OF THE RECEPTORS INVOLVED IN THE MODULATORY EFFECTS OF SEROTONIN ON [3H]-DOPAMINE RELEASE FROM RAT STRIATAL SLICES. B. J. van Viet, R.R. Terpstra, E. Ronken* & M.A.W. van der Neut. Solvay Duphar BV, Department of Pharmacology, PO Box 900, 1380 DA Weesp, The Netherlands.

Serotonin (5-HT) and dopamine have been proposed as mediators of several suropsychiatric diseases, including depression, schizophrenia and obsessive compulsive disorder. Most research about 5-HT and dopamine has focused on these neurotransmitters individually, with less attention for the pharmacology of central interactions among serotonergic and dopaminergic systems. Therefore, in the present study, we investigated the receptors involved in the modulatory effects of serotonin on [⁵H]-dopamine release from rat striatal slices. 5-HT (0.1-10 µM) caused a dose dependent increase in spontaneous [*H]-dopamine release. The selective 5-HT receptor agonists 8-OH-DPAT, 5-carboxyamido-tryptamine, DOB, DOI and 2-methyl-5-HT tested at the same concentration range did not affect [*H]amine release. Moreover, the selective 5-HT₄ receptor antagonist GR 113808 did not affect the stimulatory effect of 5-HT on dopamine release. Interestingly, we observed that the dopamine-reuptake inhibitors GBR13069 and nomifensine, but not the selective noradrenaline-reuptake inhibitor desmethylimipramine, or the highly selective 5-HT-reuptake inhibitor fluvoxamine, fully inhibited the effect of 5-HT. Taken together, our data indicate that 5-HT-evoked dopamine release is not mediated by either the 5-HT_{1A}, 5-HT_{1D}, 5-HT₂, 5-HT₃ or 5-HT₄ receptor, but rather due to the uptake of serotonin into dopaminergic terminals via "selective" dopamine transporters and subsequent displacement of [3H]-dopamine Solvay Duphar B.V.

334.9

ENHANCEMENT OF ANTIPSYCHOTIC-LIKE PROPERTIES OF RACLOPRIDE IN RATS USING THE 5-HT_{2A} RECEPTOR ANTAGONIST MDL

NACLOPRIDE IN RATS USING THE 5-H12A RECEPTOR ANY ACCOUNTS MID. 100,907. M-LWadenberg*, P. B. Hicks, T. J. Richter and J. L. Browning. Dept. of Psychiatry, Scott & White Clinic, Temple, Texas.

High 5-HT2A receptor affinity in the presence of low DA D2 receptor affinity is implicated in the favorable clinical profile of clozapine. Recently, MDL 100,907, a potent 5-HT2A receptor antagonist with a 300 fold selectivity for the 5-HT2A over the DA D2 receptor site, was proposed as potentially antipsychotic. Using the conditioned avoidance response (CAR) behavior (an animal model traditionally presumed to reflect antipsychotic rather than extrapyramidal side effect, EPS, liability) as a tentative index for antipsychotic efficacy, MDL 100,907 was evaluated as a potential antipsychotic, and also tested as an adjunctive with the specific DA D2 receptor antagonist raclopride. Adult male Sprague-Dawley rats were used. Rats were trained and tested in a computer-assisted traditional shuttlebox paradigm. Behavioral

variables recorded: avoidance, escape, escape failures, and intertrial crosses.

MDL 100,907 (0.1, 0.5 or 1.0 mg kg⁻¹, s.c.) produced a slight suppression of CAR only at 60 minutes after administration. Raclopride (0.14 mg kg⁻¹, s.c.; ED₅₀) alone suppressed CAR only at 30 min after administration. Pretreatment with MDL 100,907 (0.5 - 1.5 mg kg⁻¹, s.c.) enhanced and prolonged the raclopride-induced 100,907 (0.5 - 1.5 mg kg $^{-1}$, s.c.) ennanced and protonged the ractophae-induced suppression of CAR. Raclopride (50 μ g kg $^{-1}$, s.c.) alone had no effect on CAR. Cotreatment with MDL 100,907 (1 mg kg $^{-1}$, s.c.) and raclopride (50 μ g kg $^{-1}$, s.c.), produced a long lasting suppression of CAR both compared to vehicle treated and raclopride treated animals. **Conclusions**: The selective 5-HT2A antagonist alone does not display an antipsychotic profile. However, a selective 5-HT2A receptor antagonist as an adjunctive therapy to a weak DA D2 receptor blocking antipsychotic might be helpful in improving the treatment of schizophrenia, and at the same time

334.11

SEROTONIN-DOPAMINE INTERACTIONS AFTER CHRONIC ANTIDEPRESSANT TREATMENT S. Koch* and M. P. Galloway, CCN program, Dept. of Psychiatry and Behavioral Neurosciences, Wayne State University School of Medicine, Detroit, MI 48202

Repeated administration of antidepressant agents such as the selective serotonin reuptake inhibitor (SSRI) fluvoxamine (FLV) is generally thought to lead to enhanced serotonergic neurotransmission. Since we, and others have shown previously that intracerebral application of serotonin (5HT) facilitates dopamine (DA) release in vivo, we used microdialysis to determine the effect of repeated FLV treatment (10 mg/kg bid x14 d, 1 or 2 day washout) on extracellular (EC) striatal DA levels after a challenge with either FLV, MDMA, or 5HT. In naive rats, acute FLV (10 or 20 mg/kg; ip) increased EC-DA 9-15% whereas in animals pretreated with FLV, EC-DA levels were increased by 33±11% (n=7) and 73±23% (n=12), respectively. Administration of the 5HT-releasing hallucinogen (+)-MDMA (1 mg/kg iv) increased EC-DA 503±101% (n=10) in naive subjects, an effect that was not significantly different in animals treated chronically with FLV (451±103%, n=10). Intrastriatal perfusion of 5HT (10 \(\mu\text{M}\), 20 min) increased EC-DA to 521±56% (n=5) in untreated rats whereas the ability of 5HT to facilitate DA release was significantly attenuated to 305±16% (n=8) in subjects pretreated with chronic FLV. The results support the contention that repeated treatment with an SSRI modifies the interaction between 5HT and DA and suggest that 5HT regulation of DA release may be relevant to the therapeutic action of antidepressants. MODUALTION OF GABA BY SEROTONIN MAY INFLUENCE STRIATAL DOPAMINE RELEASE: MICRODIALYSIS STUDIES IN VIVO. Camille S. Norton* and Matthew P. Galloway. CCN Program, Dept. of Psych and Behav Neurosciences, Wayne State Univ Sch of Med, Detroit, MI 48202.

Recent studies suggest that intrastriatal application of serotonin (5-HT) facilitates dopamine (DA) release and multiple 5-HT receptor subtypes have been implicated in this phenomenon. The neuronal localization of these subtypes may elucidate whether this facilitation is mediated directly on the DA nerve terminal, indirectly through a striatal neuron or a combination of both indirect and direct influences. We and others have suggested previously that the 5-HT4 receptor subtype may regulate striatal DA release *in vivo*. Although 5-HT4 receptors are consistently found in high densities of DA projection fields, evidence suggests that they are on γ aminobutyric acid (GABA) neurons. To investigate further the 5-HT/GABA/DA interactions, we examined the ability of 5-HT to influence extracellular GABA levels *in vivo* and the ability of selective GABA antagonists to influence the 5-HT/DA interaction in the rat striatum. Local perfusion with 5-HT (10 μ) significantly increased both GABA levels (approximately 50% over baseline 24.75 fmol/ul, n=6) and DA levels nearly 7-fold over basal levels (0.96 \pm 0.13 fmol/ul, n=6). presence of the GABA A antagonist, biccuculine (100 uM), the effect of 5-HT on DA levels was significantly attenuated to approximately 3.5-fold above baseline (1.4 \pm 0.19 fmol/ul, n=6). In the presence of the selective GABA B antagonist, 2-hydroxysaclofen (100uM), the 5-HT enhancement of DA levels over baseline (2.26 \pm 0.16 fmol/ul, n = 6) did not differ from controls. These results support a role for GABA (possibly via a striatonigral pathway) in the 5-HT facilitation of striatal DA release. Supported by NIDA 04120 and the Joe Young Sr. Research Fund.

334 10

DIFFERENTIAL EFFECTS OF CHRONIC FLUOXETINE (FLU), CLOMIPRAMINE (CIM) AND IMIPRAMINE (IMP) ON BASAL AND AMPHETAMINE (AMP)-INDUCED DOPAMINE (DA) RELEASE. J. Ichikawa*, T. Kuroki, M.T. Kitchen and H.Y. Meltzer. Dept. Psychiatry, Case Western Reserve Univ. Sch. Med., Cleveland, OH 44106 We reported that the tricyclic antidepressant drugs (ADD) CIM (10 mg/kg) and

IMP (10 mg/kg) increased extracellular DA levels in the striatum (STR) but not the nucleus accumbens (NAC) whereas the selective serotonin reuptake inhibitor FLU (10 mg/kg) decreased extracellular DA levels in both regions (Ichikawa and Meltzer, 1995), suggesting that DA transmission may not be related to the therapeutic action of ADD. However, the antidepressant effects of ADD develop over several days to weeks after starting medication. Therefore, we examined the effect of chronic FLU, CIM, IMP and the vehicle control (VEH) (10 mg/kg/day for 24-28 days in drinking water) on basal and AMP-induced DA release in rat STR and NAC after 3-5 days withdrawal, using in vivo microdialysis (N=6-8). Basal striatal DA levels were not altered by chronic FLU (11.5±1.1 fmol/30 min), CIM (12.7±2.0) and IMP (11.0±2.1), as compared to VEH (13.1±1.1) whereas chronic FLU (6.5±0.6) and CIM (5.1±0.6) decreased, but IMP (12.7±1.5) increased basal DA levels in the NAC (VEH, 9.1±0.7). AMP (0.5 mg/kg, SC)-induced DA release was potentiated by chronic IMP (189±25% of VEH net-AUC: 178±29 release was potentiated by further law (1892.23% of VEH inter-AOC. 1782.25% fmol/180 min) but was attenuated by chronic CIM ($55\pm18\%$) and not significantly altered by FLU ($140\pm21\%$) in the NAC whereas chronic FLU ($54\pm8\%$), CIM (63±11) and IMP (39±4) attenuated AMP-induced DA release in the STR (VEH, 319±35 fmol/180 min). These results suggest that chronic ADD may attenuate AMP-induced activation of striatal DA transmission while sparing basal transmission. Potentiation of basal and AMP-induced DA transmission in the NAC by chronic IMP, but not FLU or CIM, could relate to the potential to produce mania in patients with major depression. Supported by NARSAD.

MODULATION OF THE FIRING ACTIVITY OF LOCUS COERULEUS NEURONS IN THE RAT BY THE 5-HT SYSTEM. P. Blier, N. Haddjeri and C. de Montigny* Neurobiological Psychiatry Unit, McGill University, Montréal, Canada, H3A 1A1.

The aim of the present study was to investigate a putative modulation of locus coeruleus (LC) norepinephrine (NE) neurons by the serotonin (5-HT) system using in vivo extracellular unitary recordings and microiontophoresis in anesthetized male Sprague-Dawley rats. To this end, the potent 5-HT $_{1A}$ receptor antagonist WAY 100635 was used. WAY 100635 and 5-HT failed to modify the spontaneous firing activity of LC NE neurons when applied by microiontophoresis. However, the injection of WAY 100635 (100 μ g/kg, i.v.) suppressed the spontaneous firing activity of LC NE neurons. Lesioning 5-HT neurons increased the firing activity of LC NE neurons and abolished the effect of WAY 100635 on these neurons. The selective 5-HT, receptor antagonist BRL 46470A (10 and 100 µg/kg, i.v.), the 5-HT₁₀ receptor antagonist GR 127935 (100 μ g/kg, i.v.) and the 5-HT,_{A/18} receptor antagonist (-)pindolol (15 mg/kg, i. p.) failed to prevent the suppressant effect of WAY 100635 on the firing activity of LC NE neurons. However, it was prevented by the 5-HT,_A receptor antagonist BMY 7378 (1 mg/kg, i. v.), the non-selective 5-HT receptor antagonists spiperone (1 mg/kg, i. v.) and metergoline (1 mg/kg, i. v.), and the 5-HT₂ receptor antagonist ritanserin (0.5 mg/kg, i. v.). In conclusion, these results indicate that 5-HT neurons exert a tonic inhibitory effect on NE neurons which is potentiated by WAY 100635. 5-HT, receptors are not likely involved in this effect of WAY 100635 because it is not prevented by the 5-HT, receptors antagonist (-)pindolol. Given that WAY 100635 has significant 5-HT, affinity and that all drugs that prevented its suppressant effect on NE neurons are endowed with 5-HT₇ affinity (except BMY 7378 which shuts off 5-HT neuron firing activity), it is concluded that the latter effect of WAY 100635 is mediated by presynaptic 5-HT, receptors.

Concentrations of Free Dopamine, Serotonin, Norepinephrine and Their Metabolites in Ventricular CSF of Parkinson's Disease Patients H. Zheng, M.C. Schiess*, H.J. Nauta, J.G. Bonnen Departments of Neurology and Neurosurgery, Univ. of Texas Medical Branch, Galveston, TX 77555-0539.

In order to correlate neurotransmitter concentrations with relative severity of various Parkinsonian symptoms this study determined the concentrations of dopamine (DA), serotonin (5-HT), norepinephrine (NE), and their metabolites in ventricular CSF (V-CSF) of Parkinson's Disease (PD) patients compared to non-PD controls. V-CSF was obtained intra-operatively from eight hyperkinetic PD patients, 4F & 4M ages 43 - 71, undergoing stereotactic posteroventral pallidotomy and four age-matched non-PD controls. CSF which had been immediately stored at -70 °C was analyzed for DA, 5-HT, NE, and their metabolites including DOPAC, HVA, 5-HIAA, and precursor 5-HTP using high performance liquid chromatography with electrochemical detector and quantified by the internal standard method with DHBA and a lower limit of detection of 20 pg/ml. The mean concentration of 5-HT in controls of 0.388 ± 0.036 ng/ml was significantly lower than PD of 3.134 +1.707 ng/ml; 5-HTP, HVA, NE were lower and 5-HIAA higher in controls. Free DA in controls was not detected but had a mean of 8.37 ±2.58 ng/ml in PD. Our preliminary results suggest that free 5-HT is elevated in the V- CSF of hyperkinetic PD patients relative to controls and that free DA concentrations are elevated which may be due to treatment with

PCRH-REB MEDIATES TRANSCRIPTIONAL REGULATION OF POMC GENE UPON CRH TREATMENT OF AtT20 CELLS Q. Han and J. L. Roberts* Fishberg Center for Neurobiology, Box 1065, Mount Sinai Medical School, New York, NY 10029

CRH stimulates POMC transcription through several promoter elements, including PCRH-RE(POMC CRH-responsive element) shown to bind PCRH-REB, which was cloned and shown to be indentical to the largest subunit of Replication Factor C. PCRH-REB is a nuclear protein and has multiple PKA sites. In order to determine the mechanism of PCRH-REB activation of POMC transcription we characterized changes in synthesis or post-translational modification of this transcription factor upon CRH treatment of AtT20 cells. We performed Western blot analyses using a polyclonal antibody raised against recombinant PCRH-REB and a "T7-Tag" monoclonal antibody. against recombinant PCRH-REB and a "T7-Tag" monoclonal antibody. While CRH did not appear to change the levels of PCRH-REB, the factor appeared to undergo proteolytic processing. The full length protein, 140kD, exists only in the initial AtT20 protein extract; whereas the primary immunoreactive proteolytic product, about 70kD, is predominant in the isolated nuclear extract. Interestingly, although there was only a single predominant species of PCRH-REB from nuclear extract upon CRH treatment of AtT20 when analyzed on SDS-PAGE, multiple species came out on a non-denaturing gel. One species was replaced by another one with different mobility characteristic and highest level of expression at 60min when CRH stimulation of POMC transcription reaches maximum, a pattern change that is consistent with the time course of CRH stimulatory effects on POMC transcriptional activity. (supported by NIH-DK27484)

CLONING AND CHARACTERIZATION OF AN OVINE PITUITARY CORTICOTROPIN RELEASING HORMONE (CRH) RECEPTOR COMPLE-MENTARY DEOXYRIBONUCLEIC ACID. D.A. Myers* and T.R. Myers. Dept. Physiology, Univ. of Oklahoma HSC, Okla. City, OK 73190.

In sheep, controversy exists regarding the role of CRH in regulating the hypothalamo-pituitary-adrenal axis (HPA). While numerous reports indicate that AVP is the major "CRH" in sheep, other studies support CRH as the primary ovine corticotropin releasing hormone. To aid in elucidating the role of CRH in activating the ovine HPA we cloned two ovine pituitary CRH receptor (CRHR) cDNAs. Degenerate primers based on pituitary CRHR sequences from human, mouse and rat were used to PCR a 380bp cDNA from ovine anterior pituitary mRNA. The PCR cDNA exhibited >90% nucleic acid homology to rodent and human pituitary CRHR and was used to screen an ovine pituitary cDNA library. We identified two cDNA clones (oCRa and oCRb). The nucleotide sequence of oCRa predicts a truncated CRHR (158 amino acids) exhibiting >90% nucleic and amino acid homology to human, rat and mouse CRHR1 subtype containing the N-terminal extracellular domain and the first transmembrane domain (TM1). oCRa diverges from rat, human, mouse pituitary CRHR and oCRb immediately 3' of the TM1 domain after a putative signal for an exon splice junction (AG/GT), resulting in an in-frame stop codon and thus a premature C-terminus. The sequence of oCRb is identical to oCRa up to the putative splice site in oCRa. The sequence of oCRb encodes a protein with >90% nucleic and amino acid homology to rat, human and mouse pituitary CRHR through TM7. oCRb differs from human, mouse and rat pituitary CRHR in that 132bp have been deleted within the C-terminal intracellular domain. The deletion may result from alternate splicing, or may represent divergence of ovine CRHR from other CRHRs. We are currently expressing oCRa and oCRb in COS-7 cells and examining their binding and signal transduction properties. NIH HD33147

PCRH-REB APPEARS TO PARTICIPATE IN THE BAY K STIMULATION OF POMC TRANSCRIPTION IN AtT20 CELLS. Jacques Jospitre Jr. & James L. Roberts, Fishberg Center for Neurobiology, Box 1065, Mount Sinai Medical School, New York, NY 10029

New York, NY 10029

Previous studies have shown that the L-type calcium channel agonist BayK can stimulate POMC transcription in AtT20 cells similarly to CRH, yet BayK does not induce the large increase in cAMP levels that CRH does. Our group has recently characterized a putative transcription factor, PCRH-REB (POMC Corticotropin Releasing Hormone-Regulatory Element Binding protein) which is induced by CRH, presumably through the activation of the cAMP/PKA system. Since BayK can apparently activate POMC transcription while bypassing the PKA system, we wanted to determine if BayK affected the PCRH-REB system. Cultures of AtT20 cells were treated with BayK (100nM) or CRH (10nM) for 60 min and nuclear extracts were prepared according to the Dignam method. Gel shift analysis was performed with a labeled PCRH-RE (-178/-155 in rat POMC promoter). BayK treated extracts gave a 2-3 fold induced gel shift relative to the control AtT20 cells, that was apparently identical to that observed with CRH. To further characterize the composition of the BayK induced gel shift, an antisera raised against PCRH-REB was used for supershift analysis. A quantitative shift of the BayK induced shift was observed, which was similar to the CRH shift, implying that PCRH-REB was responsible for both shifts. Further, it is known that CRH induced POMC transcription is inhibited by divalent cations, such as cadmium or cobalt, was responsible for both shifts. Further, it is known that CRH induced POMC transcription is inhibited by divalent cations, such as cadmium or cobalt, independent of their effects on calcium channels, and they have been shown to inhibit the CRH induced PCRH-REB gel shift. Current work is focused on determining the dose response of the divalent cation shift inhibitions in both the Bay K treated and the CRH treated cells. Preliminary data suggest that the nuclear extracts from the BayK or CRH treated cells show different sensitivities to the different cations. Thus, although BayK is able to produce an identical shift to CRH, the different sensitivities to the cations and cAMP suggest that they may be acting through different pathways that eventually converge on PCRH-REB or an associated protein.(Supported by NIH-DK27484)

AtT20 CELLS TRANSFECTED WITH THE RAT PREPRO-TRH cDNA EXHIBIT INCREASED SENSITIVITY TO ACTH SUPPRESSION BY DEXAMETHASONE: PROPOSED ROLE OF CORTICOTROPIN RELEASE INHIBITING FACTOR (CRIF). S. Revskoy, F. Aird, P. Whybrow, E. Redei* Lab. of Neuroendocrinology, Dept. of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

The objective of this study was to elucidate a possible link between the effects of the preproTRH intervening peptide (178-199) and glucocorticoids on the inhibition of ACTH secretion from cortiocotrophs. We studied the effect of dexamethasone (DEX) on AtT20 cells transfected with rat preproTRH cDNA containing deletions of either a region of preproTRH cDNA encoding 178-199 (i.e. lacking CRIF) or a fragment located down-stream from the latter region. In addition, the influence of different cell culture conditions, including high and low cell culture density and the effect of steroid-free fetal calf serum, on ACTH suppression by DEX was also investigated in these cell lines. CRIF containing transfected cells demonstrated higher sensitivity to DEX, reaching more than 50% suppression of ACTH secretion at 1-10 nM DEX, while ACTH secretion by both wild type (wt) and transfected cells AtT20 lacking CRIF was suppressed to the same extent by 10-100 nM DEX. Therefore, we suggest that the expression of preproTRH in corticotrophs lowers the concentration of DEX required for inhibition of ACTH compared to those cells lacking CRIF. Significant modifying effect of the cell culture conditions on DEX-induced ACTH suppression was also demonstrated. In particular, unlike high density cultured wt AtT20 cells, CRIF containing transfected cells did not respond to steroid deprivation by increasing ACTH secretion, similarly to wt AtT20 cells cultured at low density. Furthermore, the steroid depleted media did not promote cell proliferation, measured by ³H-TdR incorporation, in CRIF containing transfected cells cultured at high cell density. Hence, CRIF may exert its effect, partially independent of glucocorticoid actions, perhaps through tissue specific growth modifying factors. Supported by Berman Foundation.

IMMUNOTARGETED LESIONS OF PARAVENTRICULAR (PVN) CRF AND AVP NEURONS IN DEVELOPING RATS REVEAL THE PATTERN OF MATURATION OF THESE SYSTEMS AND THEIR FUNCTIONAL IMPORTANCE. C.-D. Walker¹, P. Tankosic², F.J.Tilders and A. Burlet². Douglas Hospital Research Center¹, Dept of Psychiatry, McGill University, Montreal, PQ H4H 1R3, Canada and INSERM U308², University of Nancy, Nancy, France.

During the first weeks of life in rats, the control of ACTH secretion is critical in maintaining low circulating levels of corticosteroids. In neonatal rats, the specific role of both CRF and AVP from the hypothalamic PVN in controlling basal and stimulated ACTH release has not yet been defined. We performed specific PVN lesions of CRF or AVP neurons in 4- and 14 day (d)-old pups by injecting ricin A (Tx) associated with monoclonal antibodies directed towards CRF (CRF/Tx) or AVP (AVP/Tx) or with nonspecific IgGs (IgG/Tx) as controls. Pups received either sham surgery or adrenalectomy (ADX) at the time of lesion and were sacrificed 5 days later for determination of plasma ACTH levels, brain CRF and AVP peptide and mRNA levels. Although the specificity of the lesion was greater in 19d than in 9d-old pups, CRF and AVP lesions did not alter basal ACTH secretion. In 9d pups, CRF mRNA levels were greatly reduced in the CRF/Tx and AVP/Tx groups compared to IgG/Tx group, while in 19d pups, only the CRF/Tx group had reduced CRF mRNA levels. At both ages, AVP mRNA levels were decreased in 19d-, but not 9d-old pups and lesions reduced the ADX-induced increases. Plasma ACTH levels after ADX were not affected significantly by the lesions at both ages. These results indicate that 1) neonatal PVN neurons are still phenotypically immature in the 2nd week of life, 2) the control of ACTH secretion by corticosterone is exerted at different levels as a function of age and 3) lesions of either CRF or AVP neurons are not sufficient to significantly after ACTH secretion during development. (Supported by NSERC Canada).

DEVELOPMENTAL PROFILE OF THE CORTICOTROPIN RELEASING FACTOR RECEPTOR (CRF.) IN THE RAT. M. Eghbal-Ahmadi, C. Hatalski and T.Z. Baram* Pediatrics and Anatomy & Neurobiology. University of California, Irvine, CA 92717.

Rationale: CRF $_2$, the second member of the CRF receptor family, has a distinct distribution in the adult brain, suggesting that it may mediate different functions than those of CRF $_1$. The goal of this study was to determine the age-dependent distribution of CRF $_2$ messenger RNA (CRF $_2$ -mRNA) in the rat. Methods: Pups aged 3, 5, 7, 9 and 12 days (2-3/age point), as well as adults, were

Methods: Pups aged 3, 5, 7, 9 and 12 days (2-3/age point), as well as adults, were sacrificed under stress-free conditions and brains were frozen and sectioned coronally. In situ hybridization histochemistry (ISH) using a riboprobe (courtesy Drs. Lovenberg & Chalmers) was followed by quantitation using the MCID system.

Results: In the adult, maximal optical density (OD) occurred over the ventromedial hypothalamic nucleus (VMH), followed by the hippocampus and the cortical and medial amygdala nuclei (ACO, AM). Lower signal intensity was observed over the lateral septum. Within the hippocampus, OD rank order was CA3> dentate gyrus granule cell layer > CA1. CRF2 was first detectable in the VMH, hippocampus, septum and amygdala complex on postnatal day 3. At that age, OD over the hippocampus was lower than the OD over VMH and the lateral septum. By day 7, CRF2-mRNA levels in the hippocampus equaled those in the VMH. By day 9, CRF3-mRNA was clearly localized in the AM, and VMH levels were significantly higher than hippocampal levels, a pattern maintained to adulthood. By day 12, CRF3-mRNA was evident in the ventral thalamus.

Conclusion: Using ISH, the onset of CRF_2 gene expression is region specific. The rates of increase in CRF_2 -mRNA abundance varies among the regions studied, consistent with differential maturation of the functions mediated by this receptor. Supported by NIH NS 28912 (TZB).

CORTICOSTERONE MODULATES CORTICOTROPIN-RELEASING HORMONE GENE EXPRESSION ASSOCIATED WITH HYPOVOLEMIA IN THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS S. M. Tanimura', G. Sanchez-Watts. & A. G. Watts NIBS program and Dept. of Biological Sciences, USC, Los Angeles, CA 90089

Results from our lab have shown that polyethylene glycol (PEG)-induced iso-osmotic hypovolemia leads to increased levels of corticotropin-releasing hormone (CRH), proenkephalin (pENK), and neurotensin/neuromedin N (NT/N) mRNAs in the dorsal medial subdivision of the paraventricular nucleus of the hypothalamus (PVHmpd). Increases in CRH mRNA levels are seen despite the rising plasma concentrations of corticosterone (CORT). To investigate the potential role of CORT in mediating changes in CRH mRNA in this model, we have used in situ hybridization to determine CRH mRNA levels associated with hypovolemia in the presence of constant plasma concentrations of CORT. Male SD rats were bilaterally (or sham) adrenalectomized (ADX) under halothane anesthesia and implanted with either placebo, 25mg, 50mg, or 10mg CORT replacement pellets (Innovative Research of America). Seven days later, animals were briefly anesthetized and injected subcutaneously with 5mls of 40% PEG (w/v). 5 hours after injection, rats were anesthetized, blood samples drawn and perfusion-fixed. Frozen 15 µm coronal sections were cut through PVH and hybridized using cRNA probes for CRH and pENK. In the intact and all CORT treatment groups, there was a significant increase in the level of CRH mRNA hybridization measured in the PVHmpd of PEG-treated rats as compared to vehicle injected controls. However, in the absence of CORT, the accumulation of CRH mRNA signal was significantly decreased. An increase in pENK mRNA was measured in both intact and placebo-treated ADX'd groups administered PEG, suggesting that the PVHmpd neurons were still able to respond to PEG in the absence of CORT. At least two mechanisms may explain the decreased CRH mRNA levels measured in the PEG-treated placebo group (1) CORT acts (with other factors) to direct transcriptional regulation; in the absence of CORT, CRH gene expression is not activated. (2) In the absence of CORT, mRNA stability is compromised and thus, mRNA degradation occurs more rapidly. Experiments are currently in

LOCALIZATION OF CORTICOTROPIN RELEASING HORMONE RECEPTOR (CRHR) MESSENGER RIBONUCLEIC ACID IN THE FETAL PITU-ITARY DURING DEVELOPMENT. T.R. Myers* and D.A. Myers. Dept. Physiology, Univ. Oklahoma HSC, Oklahoma City, OK 73190.

In sheep, development of the fetal hypothalamo-pituitary-adrenocortical (HPA) stress axis in late gestation results in a preterm rise in fetal plasma cortisol. Fetal cortisol provides the signal for birth in sheep, and matures organs necessary for neonatal survival in most species. In fetal sheep, the paraventricular nucleus is fundamental for HPA maturation. However, little is known about neuroendocrine signals controlling maturation of the anterior pituitary (AP) corticotrope. We have cloned a cDNA for the ovine CRHR; in this study we used double-labelling in situ hybridization to localize mRNA for CRHR in POMC mRNA expressing cells of the pituitary during development. Fetal pituitaries were collected at 105; 118; 128 and 144 days of gestation (DG;term=148DG;n=5/group) and subjected to simultaneous in situ hybridization utilizing a digoxigenin labelled 450 base ovine POMC cRNA probe and a 33 P labelled 380 base ovine CRHR cRNA probe. At all ages, CRHR mRNA co-localized with corticotropes in the anterior pituitary. Of interest, lower POMC expressing corticotropes were typically observed with greater CRHR signals at all ages. We did not observe CRHR hybridization over POMC labelled cells of the neurointermediate lobe melanotropes at any age. CRHR mRNA levels in corticotropes were higher in 105DG fetal AP than at other ages. 144DG fetuses exhibited the lowest hybridization signal; CRHR mRNA in 118 and 128DG groups were intermediate. We have previously shown that CRH expression in the PVN is low at 105DG and peaks at 128DG (Endocrinol.132:2109). Our results indicate that CRHR mRNA levels decline during the period of development that the fetal HPA matures possibly indicating a down regulation of CRHR by CRH or negative feedback regulation by increasing levels of fetal cortisol. HYPOTHALAMIC-PITUITARY-ADRENOCORTICAL (HPA) AXIS CHANGES IN TRANSCENIC MICE WITH IMPAIRED GLUCOCORTICOID RECEPTOR FUNCTION J.M.H.M. Reul*, A.C.E. Linthorst, F.J.H. Tilders¹, I. Dijkstra¹, N. Barden³, F. Holsboer and S. Karanth. Max Planck Inst. of Psychiatry, Clinical Inst., Munich, Germany; 'Research Inst. Neurosciences, Free Univ., Amsterdam, The Netherlands; 'Molecular Psychogenetics Lab, Laval Univ., Quebec, Canada. Recently, a transgenic mouse with impaired glucocorticoid receptor (GR) function

Recently, a transgenic mouse with impaired glucocorticoid receptor (GR) function was created to serve as an animal model for the study of HPA axis changes as occuring in major depression. Adult male transgenic mice showed no changes in baseline plasma ACTH and corticosterone (CORT) levels. Novel environment stress produced an enhanced ACTH response in transgenic mice, whereas CORT responses were not different. In view of this disparity in pituitary and adrenocortical responses, we directed our studies toward the *in vitro* regulation of ACTH secretion in the intact pituitary-hypothalamic complex (PHc) and the pituitary (PI) alone. Basal ACTH release by PHc and PI from normal and transgenic mice was similar, while the release by PI was lower than that by PHc. Stimulation of tissues with either high K* (56 mM) or CRH produced an enhanced ACTH release from both PHc and PI, while the response in PI was larger than that in PHC. The responses to these stimuli were markedly enhanced in tissues from transgenic mice. CORT feedback on basal and CRH-stimulated ACTH release was more effective in PHc than in PI. The feedback capacity of CORT to restrain basal as well as CRH-stimulated ACTH release was more effective in PHc than in PI. The feedback capacity of the pHc than that in the PI of these animals. In conclusion, the *in vitro* data revealed intrahypothalamic mechanisms operating to fine-tune stimulus-evoked ACTH responses and to facilitate feedback action of glucocorticoids. In the transgenic mice we found impaired negative feedback combined with "normal" (i.e., noncompensated) *in vivo* plasma corticosterone responses. Therefore, this transgenic animal may be regarded as a valuable model to study functional glucocorticoid insufficiency at the central nervous system level. *Suppored by Wi-Foundation (I/70 543), Dutch Found Med Health Res (900-564-034) and EC (CII*-CT93-0692)*

Regulation of Corticotropin Releasing Factor (CRF) mRNA in Primary Amygdalar Cultures as Determined by *In Situ* Hybridization. JW Kasckow*1.2, A Regnii¹, PS Gill¹, MK Norman¹, NM Richtand¹.2, SJ Fudala¹, TD Geracioti¹.2, ¹U. Cincinnati College of Med., Dept. Psychiatry, Cincinnati, OH. 45267. ² Cincinnati VAMC, Psychiatry Service, Cincinnati, OH 45220.

The CRF containing amygdalar neurons have been postulated to play a role in the stress response. Little is known as to which stimuli regulate CRF messenger RNA in the amygdala. The effects of dexamethasone (DEX) and the cytokines - interleukin 1 (IL.1) and interleukin 6 (IL.6) on CRF mRNA levels in primary rat amygdalar cultures derived from E19 pups were evaluated. The amygdala was dissected bilaterally and dissociated with 0.25% trypsin. Cells were plated in DMEM:F12, 10% fetal bovine serum, 14 mM glucose, 15 mM NaHCO₃, 5 mM Hepes and pen/strep on Nunc tissue culture slides. At 17 days, triplicate sets of cells were treated 12 hours with either DEX, IL.1 or IL.6 in β-Pit Julip. Following fixation, cells were hybridized with an 35S-labelled rat CRF probe (provided by Dr. A Seasholtz; U Michigan, Ann Arbor, MI). Following this, slides were dipped in NTB-2 emulsion and subsequently developed. Silver grains in cells were counted per treatment and the effects of various treatments were determined based on significance at the P<0.05 level. 100 nM DEX produced very slight but non-significant increases in CRF mRNA relative to control (+18%). Similar non-significant increases in CRF mRNA relative to control. Further characterization of these amygdalar cultures is under way in order to investigate their responsiveness to other potential stimulators and inhibitors of CRF involved in the stress response. These preliminary data suggest that the role of glucocorticoids in regulating amygdalar CRF differs from that in the hypothalamus and that some cytokines do appear to regulate amygdalar CRF. Dr. Kasckow is a Pfizer awardee and a recipient of a NARSAD Young Investigators Award.

Regulation of Corticotropin Releasing Factor (CRF) mRNA in Clonal Cell Lines as Determined by *In Situ* Hybridization. Psychiatry, Cincinnati, OH. 45267.² Cincinnati VAMC, Psychiatry Service, Cincinati, OH 45220.

VAMC. Psychiatry Service. Cincinati, OH 45220.

The NPLC-KC human hepatoma and the BE(2)-M17 human neuroblatoma cell lines have been shown to synthesize and secrete the CRF peptide as well as express CRF messenger RNA. Here, we have analyzed the effects of various second messengers on CRF mRNA utilizing in situ hybridization. Cells were plated in DMEM:F12, 8% fetal bovine serum, 2 mM L-glutamine, non-essential amino acids and 10 U/ml pen/strep on Nunc tissue culture slides. BE(2)-M17 cells had been pretreated with 5 µM retinoia caid for 3 days prior to treatment with various stimuli. Both clonal cell lines were exposed to various crimuli for 13 boars in 8 Bit labe. Estatories Estatories Charles. stimuli for 12 hours in β-Pit Julip. Following fixation, cells were hybridized with an ³⁵S-labelled human CRF probe (provided by Dr. A Seasholtz; U Michigan, Ann Arbor, MJ). Following this, slides were dipped in NTB-2 emulsion and subsequently developed. Silver grains in cells were counted per treatment and the effects of various treatments were determined based on a significance level of P<0.05 level. In the BE(2)-M17 cells, 100 nM dexamethasone produced slight but significant increases in CRF mRNA relative to control (+64%). Significant increases in CRF mRNA in these cells were also noted with 20 nM TPA and 30 µM forskolin (3 fold elevation relative to controls in both). With the NPLC-KC cells. 100 pM interleukin-1. 20 nM TPA and 30 μ M forskolin produced significant elevations relative to control (respectively +45%, +71% and +64%). The above findings make these cells potentially useful models for studying gene expression of CNS CRF neurons. Dr. Kasckow is a Pfizer awardee and a recipient of a NARSAD Young Investigators Award.

CRF AND GR GENE EXPRESSION IN THE PARAVENTRICULAR NUCLEUS OF IMMUNE-CHALLENGED TRANSGENIC MICE EXPRESSING TYPE II GLUCOCORTICOID RECEPTOR ANTISENSE RIBONUCLEIC ACID. N. me, N. Barden* and S.Rivest, Mol. Endocrinol. Lab., CHUL Research Center

and Laval University, Québec, Canada, G1V 402.

The purpose of this study was to investigate the effect of the immune activator lipopolysaccharide (LPS) on the expression of corticotropin releasing factor (CRF) and glucocorticoid receptor (GR) mRNA in the PVN of transgenic mice with impaired GR function caused by endogenous expression of GR antisense RNA. At 3 and 8 weeks of age, control and transgenic mice were sacrificed 4.5 h after a single i.p. and 8 weeks of age, control and transgenic mice were sacrificed 4.5 h after a single i.p. administration of LPS (100 μg/100 g of body weight) or vehicle. Frozen brains were mounted on a microtome and cut in 30 μm sections. mRNAs encoding rat CRF and GR were assayed by in situ hybridization histochemistry using a 3·S-labeled riboprobes and localization of Fos-immunoreactive (Fos-ir) nuclei was determined by immunocytochemistry. Basal expression of CRF mRNA in the PVN, central nucleus of the amygdala (CeA) and geniculate complex was similar in the control and transgenic mice. LPS induced a comparable neuronal activation in the PVN of control and transgenic mice as revealed by the number of Fos-ir neurons. Moreover, the endotoxin caused a significant increase in the CRF mRNA levels within the PVN and CeA, an effect observed in both animal models. The endotoxin did not notably modulate CRF expression in other regions. Although GR mRNA was expressed in and CeA, an etree to observed in both animal models. The endoubt must be modulate CRF expression in other regions. Although GR mRNA was expressed in the PVN of control mice under basal conditions, this transcript was not detected in this hypothalamic structure in LPS-treated and transgenic animals. This indicates that endogenous type II GR mRNA is decreased in the PVN of mice expressing type II GR antisense RNA and that gene is down-regulated by LPS. Hybridization signal for CRF and GR transcripts was not notably altered by the age of mice. These results provide evidence that the basal expression of CRF and the increase of neuroendocrine CRF transcription in response to immunogenic challenges are not significantly affected by impairment of the type II GR function.

INFLUENCE OF INTERLEUKIN-6 ON NEURAL ACTIVITY AND TRANSCRIPTION OF THE GENE ENCODING CORTICOTROPIN-RELEASING FACTOR IN

TION OF THE GENE ENCODING CORTICOTROPIN-RELEASING FACTOR IN THE RAT BRAIN. L. Vallières, S. Lacroix & S. Rivest*. Lab. of Molecular Endocrinology, CHUL Research Center, Ste-Foy, Québec, Canada, GIV 4G2. Interleukin-6 (IL-6) is a pleiotropic cytokine produced by various lymphoid and neural cells. In addition to its classic role during immune and inflammatory responses, IL-6 acts on the central nervous system to elicit changes, such as activation of the hypothalamic-pituitary-adrenal (HPA) axis. This study investigated the effects of systemic and central injection of IL-6 on neural activity and transcription of the corticotropin-releasing factor (CRF) gene in the brain of conscious rats. The animals were sacrificed 1 and 3 h after a single infusion of IL-6 into the right jugular vein (0.83 or 3.0 µg) or the right lateral ventricle (0.2 µg) and their brains cut from the olfactory bulb to the end of the medulla in 30-µm coronal sections. Messenger RNA encoding or 3.0 µg) or the right lateral ventricle (0.2 µg) and their brains cut from the offactory bulb to the end of the medulla in 30-µm coronal sections. Messenger RNA encoding the protein Fos, a marker of neural activity, and the neuropeptide CRF were localized by in situ hybridization histochemistry using *35-labeled riboprobes. The results show that systemic injection of IL-6 induced specific transcription of c-fox gene in most of the sensorial circumventricular organs (CVOs), including the organum vasculosum lamina terminalis, subfornical organ, median eminence and area postrema, as well as in the central nucleus of the amygdala and bed nucleus of the stria terminalis. On the other hand, central injection of IL-6 increased cellular level of c-fox mRNA in the other hand, central injection of 11-6 interescent circular level of C-70s inkiNA in the pependymal layer and the walls of the ventraces meninges, nucleus of the solitary tract and CVOs. These effects seem to be rapid and transient since the signal for c-70s mRNA was detected 1 h after both treatments and vanished 3 h afterwards. Moreover, CRF gene was not activated by either systemic or central administration of IL-6 in the paraventricular nucleus of the hypothalamus. Taken together, these results suggest that paraventricular nucleus of the hypothalamus. Taken togetner, these results suggest utal CVOs may play a crucial role in the effects of systemic IL-6 on neural activity whereas centrally-injected IL-6 can strongly activate cells of the ventricular system and the surrounding structures. Although this differential circuitry may explain distinct origin-dependent functions of IL-6, this cytokine seems to be insufficient by itself to induce transcription of the gene encoding neuroendocrine CRF, the neuropeptide responsible for the posterol of the IDA axis for the control of the HPA axis.

NEUROENDOCRINE DYSFUNCTION IN CORTICOTROPIN-RELEASING FACTOR RECEPTOR 1 (CRFR1)-DEFICIENT MICE K.-F. Lee*, J.-M. Aubry, W.T. Berggren and W.W. Vale. Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037 Signaling pathways dependent on the members of the CRF gerie family, including CRF and urocortin, are involved in a wide-range of neural and endocrine functions. Two CRF receptors, CRFR1 and CRFR2, have been identified. To understand the developmental and physiological roles. and endocrine functions. Two CRF receptors, CRFR1 and CRFR2, have been identified. To understand the developmental and physiological roles of CRF-dependent pathways, mice carrying a CRFR1 mult mutation have been generated. Mice heterozygous for the CRFR1 mutation have no overt phenotype. Homozygote mice derived from intercross of heterozygote mice develop to term and become sexually mature. The levels of circulating corticosterone in both sexes of mutant mice are significantly lower than those of control mice; histological analysis revealed that zona fasiculata of the adrenal gland is substantially diminished. The levels of ACTH were in the normal game although these are considered low given the low levels of the adrenal gland is substantially diminished. The levels of ACTH were in the normal range, although these are considered low given the low levels of corticosterone. Female mutant mice have higher levels of corticosterone compared to male mutant mice, a finding that correlates with higher mortality rate in male mutant mice. Study of the expression of other components of the CRF-signaling pathway has revealed that the expression of CRF in the paraventricular nucleus was up-regulated. The expression of the other potent ACTH secretagog, vasopressin, was unchanged. In contrast to the offspring of heterozygote intercross, the offspring of homozygote fenterozygote fenter intercross, the offspring of homozygote fenterozygote fenter that transplacental corticosterone of heterozygote fendes may be sufficient to promote normal in utero lung development of homozygotes. To test this possibility, corticosterone was added to the drinking water of pregnant homozygous females beginning at E12 for two weeks. The offspring survived to adulthood. Explorations of the endocrine, autonomic and behavioral roles of CRFR1 are in progress. Supported by NIH DK-26741 and the Fdn. for Medical Research, Inc.

FOS mRNA PATTERN AND CRF NEURONAL ACTIVITY THROUGHOUT THE BRAIN OF RATS INJECTED CENTRALLY WITH A PROSTAGLANDIN THE BRAIN OF E2 TYPE. S.Lacroix, L. Vallières, R. Rivest* and S.Rivest, Mol. Endocrinol. Lab., CHUL Research Center and Laval University, Québec, Canada, G1V 4G2.

The present study investigated the effect of central administration of the

prostaglandin of E2 type (PGE₂) on the distribution of the immediate *early* gene (IEG) c-fos mRNA and the transcriptional activity of corticotropin-releasing factor (CRF) and its type 1 receptor in the rat brain. mRNAs encoding the IEG c-fos and CRF₁ and its type I receptor in the rat train. Includes encoung the 12d cybs and exceptor were assayed by in situ hybridization histochemistry using 3S-labeled exonic riboprobes whereas the primary transcript (heteronuclear (hn)RNA) for CRF was detected using intronic probe technology as an index of CRF transcriptional activity. Thirty min after PGE₂ injection into the lateral ventricle, a moderate to strong positive signal for c-fos mRNA was detected in multiple structures of the brain such as the medial preoptic area/organum vasculosum of the lamina terminalis, supraoptic nucleus (SON), paraventricular nucleus (PVN) of the hypothalamus, central nucleus nucleus (SON), paraventricular nucleus (PVN) of the hypothalamus, central nucleus of the amygdala, nucleus of the solitary tract, dorsal motor nucleus of the vagus, area postrema, ambiguus nucleus, and throughout the choroid plexus and leptomeninges. In the parvocellular nucleus of the PVN, c-fos was expressed in CRF-immunoreactive (ir) and oxytocin (OT)-ir neurons, whereas in the magnocellular part of that nucleus and in the SON, this transcript was essentially colocalized in OT-ir neurons. Activation of CRF neuroendocrine cells was also associated with an increase in CRF transcription as revealed by the selective presence of CRF hnRNA in the PVN. Central administration of PGE₂ also induced expression of the CRF type 1 receptor in the parvocellular PVN. Taken together, these results provide clear anatomical evidence that central PGE₂ injection causes specific and selective expression of c-fos in several brain structures recognized to be activated in the brains of acutely immunein several brain structures recognized to be activated in the brains of acutely immune-challenged rats. It is therefore possible that PG of E2 type plays a crucial role within the CNS in the interface between the immune system and brain functions responsible to modulate neuroendocrine circuitry involved to prevent exaggeration of the immunogenic processes.

OBESITY AND FOOD DEPRIVATION REDUCE THE EXPRESSION OF THE CRF TYPE 2α RECEPTOR IN THE VMH OF RATS. E. Timofeeva, D. Richard*, Q. Huang. Department of Physiology, Faculty of Medicine, Laval University, Québec, Canada,

The mechanisms underlying the effects of corticotropin-releasing factor (CRF) and its receptors in the regulation of energy balance have yet to be determined. In this respect, the study was carried out to yet to be determined. In this respect, the study was carried out to investigate the main and interactive effects of food deprivation (48 hours) and obesity on the transcriptional activity of CRF, and CRF type I and 2\alpha receptors. The experiments were performed in lean (Fa/?) and obese (fa/fa) Zucker rats. The mRNA levels of CRF and its receptors were determined using *in situ* hybridization histochemistry. In Fa/? rats, the mRNA levels of CRF in the paraventricular nucleus of the hypothalamus (PVH) were lower in food-deprived rats compared to ad libitum-fed animals. There was no difference between Fa/? and fa/fa in the levels of CRF₁ receptor mRNA, notwithstanding the brain in the teves with the temperature of the three examined. The expression of the $CRF_{2\alpha}$ receptor transcript in the ventromedial nucleus of the hypothalamus (VMH) was lower in the obese rats compared to the lean rats fed ad libitum. In addition, food deprivation caused a significant decrease in the expression of the $CRF_{2\alpha}$ receptor transcript in the VMH of the lean rats. The reduction in the biosynthesis of the $CRF_{2\alpha}$ receptor within the VMH in response to obesity and food deprivation is consistent with a role for CRF in the control of food intake and energy expenditure.

THE EFFECTS OF MULTIPLE SCLEROSIS AND CORTICOSTEROIDS ON HYPOTHALAMIC CRH AND AVP NEURONS. Z. A. Erkut and D. F. Swaab (SPON: European Neuroscience Association), Netherlands Institute for Brain Research, Meibergdreef 33 1105 AZ Amsterdam, The Netherlands.

The hypothalamo-pituitary-adrenal axis (HPAA) is involved in the susceptibility to and recovery from immune-mediated diseases like multiple sclerosis (MS). A

to and recovery room immune-meanated unlessases into multiple sciences (MS). A higher HPAA activity decreases the susceptibility to the disease, and once the disease is established, helps to recover from the symptoms. Increased activity of HPAA at the adrenal, pituitary and hypothalamic level in MS was concluded from increased blood levels of cortisol, urinary free cortisol and blood levels of adrenocorticotropic blood levels of cortisol, urinary free cortisol and blood levels of adrence orticotropic hormone (ACTH). Our group found an increased activity of hypothalamic corticotropin-releasing hormone (CRH) neurons in MS patients, as indicated by increased number of CRH neurons and increased proportion of vasopressin (AVP) colocalization in CRH neurons in the paraventricular nucleus.

However, in MS patients, the increase in endogenous HPAA activity seems

often not to be sufficient to suppress the ongoing immune reaction, and exogenous corticosteroid administration is required to quell the symptoms of the disease. We corticosteroid administration is required to quell the symptoms of the disease. We studied the effects of corticosteroids on human hypothalamic CRH and AVP neurons by a double labelling immunocytochemical method on postmortem brain material of patients who were exposed to corticosteroids before death. The findings show for the first time that both CRH and AVP cell populations express less peptide, during corticosteroid therapy. The number of CRH expressing neurons was only 6 % of the controls (p < 0.003) and the number and staining intensity of AVP cells were quantitatively clearly less than the controls, and hardly detectable in m ost cases. The results also revealed that this suppression alsat at least 2 weeks after the corticosteroid treatment is stopped. Suppression of CRH and AVP neurons may not only cause endocrine effects, but may also be related to the commonly seen cognitive and mood changes of patients under corticosteroid therapy. (Brain material was obtained from Netherlands Brain Bank, and this study was supported by Foundation Friends MS Research, The Netherlands (grant nr. 94-188) and by TUBITAK, Turkey).

ROLE OF THE MINERALOCORTICOID RECEPTOR IN REGULATION OF HIPPOCAMPAL ADRENOCORTICOSTEROID RECEPTOR EXPRESSION.

J.P. Herman*, G.L. Bowers and C.M. Dolgas. Department of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084. Mechanisms underlying regulation of hippocampal adrenocorticosteroid receptors are presently ill-defined. This study evaluated the hypothesis that hippocampal glucocorticoid receptor (GR) and mineralocorticoid receptor (MB) biosynthesis is controlled through the neuronal MR. Experiments examined GR and MR mRNA and GR protein expression following 1) blockade of the neuronal MR by systemic administration of spironolactone (SPIRO) and 2) saturation of MR and GR receptors with high doses of corticosterone (CORT). Male rats received subcutaneous injections of SPIRO (50 mg/kg), CORT (5 mg/kg) or vehicle received subcutaneous injections of SPIRO (30 mg/kg), COR1 (5 mg/kg) or vehicle wice a day for three days. Animals were killed 4 hours following the last injection and tissue processed for in situ hybridization and immunoautoradiography. Plasma corticosterone was markedly elevated in the CORT group (591±159 ng/ml), whereas both OIL and SPIRO groups showed normal AM levels (9.1±1.6, 9.6±1.9 ng/ml, respectively). Corticotropin releasing hormone mRNA expression in the paraventricular nucleus was increased two-fold in SPIRO rats relative to controls. paraventricular nucleus was increased two-fold in SPINO rats relative to controls, consistent with MR-mediated regulation of hypothalamo-pituitary-adrenocortical tone. In hippocampus, GR mRNA was increased by 65% in CA1 and 46% in dentate gyrus of SPIRO treated rats. Parallel increases in GR protein were observed both regions (26% and 19%, respectively). MR mRNA was slightly increased in CA1 (13%) and CA3 (11%). High-dose CORT treatment did not affect GR or MR mRNA expression or GR protein levels in any region analyzed. The results are consistent with previous adrenalectomy studies, and indicate that baseline expression of GR and perhaps MR is maintained by low doses of steroids acting through the neuronal MR. However, high-dose CORT treatment does not appear to down-regulate neuronal GR or MR. The latter data suggest that adrenocorticosteroid receptor down-regulation likely requires neuronal input. REDUCED SENSITIVITY OF MONOSODIUM GLUTAMATE(MSG)-LESIONED RATS TO EXOGENOUS LEPTIN. R. Dawson, Jr.*, W.J. Millard, S.C. Liu, B. Eppler and M.A. Pelleymounter. Dept. of Pharmacodynamics, Univ. of Florida, Gainesville, FL 32610 and Dept. Neurobiology, Amgen, Inc., Thousand Oaks, CA

Leptin (OB protein) is a protein secreted by adipocytes that may act as a feedback signal in the regulation of body composition, appetite and metabolism. The exact target for leptin's feedback signal is unknown but could be the arcuate nucleus of the hypothalamus (ANH) since the ANH plays a pivotal role in neuroendocrine and metabolic regulation. Neonatal administration of MSG to rodents destroys the ANH and produces obesity characterized by extreme metabolic efficiency, hypophagia, hypothermia and growth stunting. Therefore, the current study was designed to test if MSG-induced ANH damage would attenuate the actions of exogenous leptin on food intake and body weight.

Male and female rats received s.c. injections of either MSG (4 mg/g) or saline on postnatal days 2 and 4. Leptin was administered by osmotic minipumps at an approximate dose of 1 mg/kg/day to MSG-treated (n=7) or saline-treated rats (n=6) starting on postnatal day 60 (males) or 61 (females). The control groups were MSGtreated (n=7) or saline-treated rats (n=6) implanted with osmotic minipumps filled with

Leptin significantly (p < 0.05) suppressed night time food intake in saline-treated males on treatment days 2-5 and in saline-treated females on treatment days 3-5. Male and female MSG-treated rats given leptin had modest but nonsignificant reductions in food intake. Male and female saline-treated rats given leptin failed to gain weight, whereas the control groups continued to gain weight. Leptin had no effect on the weight gain in MSG-treated rats of either sex.

The results of the present study suggest that MSG-induced damage to the ANH can blunt the actions of exogenous leptin. Funded by a grant from Amgen, Inc.

INDIVIDUAL DIFFERENCES IN THE NORADRENERGIC REGULATION OF hippocampal corticosteroid receptors. M. Kabbai, PV. Piazza, M. Le Moal and S. Maccari*. INSERM U.259 - Rue C.S Saens, 33077 Bordeaux, France.

Two types of hippocampal corticosteroid receptors (CR) play an important role in regulating the secretion of corticosterone. Type I regulates both basal and stress induced release of corticosterone whereas type II seems to be involved only in the stress response. This study was designed to compare the noradrenergic (NA) regulation of these CR in rats separated, on the basis of their locomotor reactivity in response to novelty in two groups: high responder rats (HR) having a higher locomotor reactivity and low responder rats (LR). NA regulation of CR was assessed in these rats by measuring binding capacity of CR and stress induced corticosterone secretion after chronic treatment with the α l NA antagonist prazosin (0.5 mg/Kg, i.p.). Before the chronic treatment, HR and LR rats were either left with intact adrenal glands or adrenalectomized, their plasma levels of corticosterone being maintained in the physiological range by implanted corticosterone pellets. In this way, direct drug-induced changes in NA transmission, which may be confounded by drug-induced changes in corticosterone secretion occuring in the intact rats were effectively isolated in the adrenalectomized group, allowing the assessment of direct NA regulation of CR. The results demonstrate that in LR rats, the prazosin treatment decreased the number of type I CR in both adrenalectomized and adrenal-intact rats whereas type II CR were reduced only in adrenal-intact rats. In the adrenal-intact LR rats. prazosin induced hypersecretion of corticosterone after stress which may account for the reduction of type II CR noted in this group. No changes were seen in hippocampal CR nor corticosterone secretion in HR rats after prazosin treatment. These results suggest greater NA regulation of type I CR and a greater hormonal control of type II CR. This differential regulation depends on the individual differences, as it occurs only in LR rats.

THE EFFECTS OF CHRONIC INGESTION OF NATURAL OR SYNTHETIC GLUCOCORTICOIDS ON LEARNING AND CHOLINE ACETYLTRANSFERASE ACTIVITY IN YOUNG SPRAGUE-DAWLEY RATS. A.P. Pinney and L.A. Meserve*, Dept. Biological Sciences, Bowling Green State Univ., Bowling Green, OH 43403-0212

Chronic elevation of circulating glucocorticoids has been shown to impair cognitive function, usually by causing neuron death. However, cognitive deficits resulting from glucocorticoid exposure have been demonstrated in the absence of neuron loss. The purpose of the present study was to compare the effects of a synthetic glucocorticoid (prednisone) with a natural one (corticosterone) on learning of the Morris water maze and on Choline Acetyltransferase (ChAT) activity. ChAT is responsible for the production of acetylcholine, a primary neuro responsible for the production of activations, a primary neuro-transmitter for learning pathways in the basal forebrain and the hippocampus. Thirty day old Sprague-Dawley rats were given either prednisone or corticosterone in their drinking water for 30 days. At 60 days of age the animals were administered 10 trials in the water maze (twice a day for 5 days). At 65 days of age, the animals were rapidly decapitated and ChAT activity was analyzed in the hippocampus and basal forebrain. All results were analyzed by ANOVA. The animals given corticosterone spent significantly more time in the water maze than controls on days three, four and five, although ChAT activity was not altered. These animals gained significantly less weight than controls. ChAT activity was significantly depressed in the animals receiving prednisone, but these animals id not demonstrate learning deficits. Thus, this study was unable to correlate between depression of ChAT activity and deficits in cognitive function.

GOLDTHIOGLUCOSE LESIONS PARTIALLY BLOCK LEPTIN'S EFFECTS IN OB/OB MICE. M. Baker, M Cullen, W. Karbon* and M. Pelleymounter. Amgen, Thousand Oaks, CA 91320

Several variants of the leptin receptor have been described, with localization in kidney, testes, white fat, choroid plexus and hypothalamus. The only form that is mutated in the db/db mouse is expressed in the hypothalamus, supporting the theory that leptin regulates energy utilization and intake through a central mechanism. If the receptor that mediates leptin's effects is localized in the hypothalamus, then destruction of areas of the hypothalamus associated hypothalamus, then destruction of areas of the hypothalamus associated with regulation of appetite and energy utilization should reduce or abolish leptin's effects on body weight. Large or small hypothalamic lesions were induced with two doses of goldthioglucose (GTG). The low dose (.3mg/g) destroyed cells forming the ventrolateral border of the ventromedial hypothalamus (VMH). The high dose (1mg/g) caused a more widespread destruction, involving most of the VMH and smaller percentages of the paraventricular and arcuate nuclei. The small GTG lesion did not reduce leptin's efficacy in ob/ob mice, in that leptin's effects on body weight and food intake were essentially the leptin's effects on body weight and food intake were essentially the same in mice with sham or GTG lesions. The larger lesion, however, did reduce leptin's efficacy on body weight and food intake by approximately 60% in comparison to ob/ob mice with sham lesions. These data suggest that the leptin receptor may be primarily localized in the VMH, with extension into the arcuate and paraventricular nuclei. The fact that this fairly extensive lesion of the ventromedial hypothalamus did not completely block leptin's effects suggests either that 1) the receptor is more diffusely localized in the hypothalamus than previously believed, or 2) the peripheral forms of the receptor play a role in leptin's effects on body weight regulation.

PERIPHERAL CYTOKINE INDUCTION OF INTERLEUKIN-1ß GENE EXPRESSION IN SPECIFIC BRAIN SITES. J. R. He⁺, Y. Gao, and L. P. Kapcala. Endocr. Div., Dept. of Med. Univ. of Maryland Sch. of Med., and Baltimore VA Med. Ctr., Baltimore, MD 21201

Although many studies show lipopolysaccharide(LPS) stimulates interleukin(IL)-1 or its mRNA in brain, precise localization of IL-1 production is not clear. Neither is it known whether IL-1 stimulates its own production in brain as in the periphery and to what extent LPS stimulation occurs via generation of IL-1. We compared effects of IL-1β(20μg/kg) and LPS(4,10mg/kg) on IL-1β mRNA(riboprobe in situ hybridization) in various brain sites at 2.5 or 3 hrs after their peripheral(ip) administration to adult male SD rats. Control(saline) rats did not exhibit IL-1ß mRNA in brain. LPS potently induced IL-1ß mRNA in circumventricular organs(CVOs: OVLT,ME,SFO,AP) choroid plexus, meninges, some blood vessels and in some parenchymal sites including hypothalamic paraventricular and arcuate/periarcuate nuclei, and vagal nuclei. IL-1ß weakly induced IL-1ß mRNA(number of positive cells and signal intensity/cell were much less vs LPS) CONCLUSIONS: 1. Peripheral LPS potently induced IL-1ß gene expression in CVOs, choroid plexus, meninges, blood vessels, and in specific parenchymal brain sites. 2. Although the pattern of brain IL-1ß mRNA induced by peripheral IL-1ß and LPS was similar, weak stimulation by IL-1B implicated the importance of other cytokines in the potent stimulation by LPS.

INTERLEUKIN-1ß AND LIPOPOLYSACCHARIDE REGULATION OF GENE EXPRESSION OF INTERLEUKIN-1ß AND INTERLEUKIN-1 TYPE 1 RECEPTOR IN HYPOTHALAMIC NEURONS AND GLIA. Y. Gao, J.R. He, M.P. Lilly* and L.P. Kapcala. Endocr. Div., Dept. of Med. Univ. of Maryland Sch. of Med. & Baltimore VA Med. Ctr., Baltimore, MD 21201

Different pathological or pharmacological stimuli induce brain IL-1 which can exert various central effects including activation of the hypothalamic-pituitary-adrenal axis. However, little is known about specific factors regulating brain IL-1. We tested the hypothesis that IL-1 and lipopolysaccharide(LPS), a potent generator of IL-1 and other cytokines, stimulates hypothalamic gene expression of IL-1 and its type 1 receptor(IL-1R1). We studied effects(4 hrs) of IL-1B or LPS on IL-1 B and IL-1R1m RNAs(RNase protection assays) in enriched hypothalamic neuronal and glial(predominantly microglia and astrocytes) cultures of day 17 gestation fetal rats. IL-1B(10-11 10-7M) dose-dependently stimulated (~2 fold maximally) IL-1B and IL-1R1 mRNAs in neuronal and glial cultures. Although LPS potently dose-dependently(1-104 ng/ml) stimulated(6-330 fold) IL-1B mRNA in neuronal and glial cultures, it did not increase IL-1R1 mRNA. CONCLUSIONS: 1. IL-1B modestly stimulated gene expression of IL-1ß and IL-1R1 in hypothalamic neuronal and glial cultures suggesting a positive autofeedback regulation. 2. LPS differentially and potently stimulated IL-1B mRNA but not IL-1R1 mRNA in hypothalamic neuronal and glial cultures, presumably because of effects of cytokines induced by LPS in addition to IL-1B.

COMPARATIVE EFFECT OF ACUTE CENTRAL CYTOKINE ADMINISTRATION ON BEHAVIORAL, NEUROCHEMICAL, ENDOCRINE & IMMUNE PARAMETERS IN THE R AT.

C. Song*3, T.J. Connor ¹, H. Anisman ³, A.V. Ravindran ⁴ and Z. Merali ².¹ Dept. of Pharmacol., UCG, Ireland. ²Dept. of Pharmacol. & Psychol., Univ. of Ottawa. ³Dept. of Psychol., Carleton Univ., ⁴Dept. of Psychiat. Royal Ottawa Hospital. Ont. Canada.

In addition to the immune system, cytokines and their receptors have recently been located in many other tissues including the peripheral and central nervous systems (CNS). The pharmacological role and/or physiological function of the various cytokines within the CNS is not fully understood. The present study compared the effects of central (i.c.v.) administration of IL-1β, IL-2, IL-6 (20 ng) and TNF-α (40 ng) on elevated plus maze behavior, monoamine levels in the hypothalamus, plasma corticosterone and catecholamine concentrations and Con A induced spleenic lymphocyte proliferation in the rat, 45 min post administration. IL-1β and TNF-α reduced the number of entries and time spent on the open arms of the elevated plus maze, whereas, IL-2 and IL-6 did not. Cytokine specific alterations in monoamine levels were evident at the hypothalamus. Both IL-1 β and TNF- α increased 3-MT and decreased 5-HIAA and DA concentrations, while IL-2 and IL-6 increased HVA levels. In addition, IL-6 increased 3-MT level. Plasma corticosterone was elevated by IL-1β but not by any of the other cytokines, furthermore IL-1β and IL-6 reduced plasma DA levels. IL-1β reduced and TNF-α increased Con A-induced lymphocyte proliferation. These results demonstrate that in some but not all respects, IL-1B administration may produce stress-like effects on behavior, the HPA axis and immune function, while the other cytokines produce less consistent effects on these parameters.

ALCOHOL STIMULATES INTERLEUKIN-1 ß GENE EXPRESSION IN HYPOTHALAMIC NEURONS AND GLIA. L. P. Kapcalat, Y. Gao, and J.R. He. Endocrine Div., Dept. of Med. Univ. of Maryland Sch. of Med., and Baltimore VA Med. Ctr., Baltimore, MD 21201

IL-1 exerts various potent central effects including activation of the hypothalamic-pituitary-adrenal(HPA) axis. Alcohol(ETOH) is also a potent stimulator of the HPA axis and produces pseudo-Cushing's syndrome in some alcoholics. Consequently, we questioned whether ETOH might activate the HPA axis via induction of brain IL-1. We tested the hypothesis that ETOH stimulates hypothalamic IL-1 gene expression. Effects of prolonged(~52 hrs)ETOH (25 mM=115 mg/dl) exposure on IL-18 mRNA(RNase protection assay) were studied in enriched hypothalamic neuronal and glial(predominantly microglia and astrocytes) cultures of day 17 fetal rats. We also studied ETOH effects on IL-1B and lipopolysaccharide (LPS) stimulation of brain IL-1B mRNA. ETOH exposure stimulated IL-18 mRNA in neuronal(~3 fold) and glial(~4.5 fold) cultures without toxic effects on cell viability. In neuronal and glial cultures ETOH selectively abolished stimulation of IL-18 mRNA by IL-18 but did not after stimulation by LPS. CONCLUSIONS: 1. ETOH stimulated IL-1ß gene expression in hypothalamic neuronal and glial cultures. 2. Presumed induction of hypothalamic IL-1B by ETOH could mediate some central effects of ETOH especially HPA axis activation. 3. ETOH selectively altered stimulation of IL-1B gene expression by specific immune stimuli in neuronal and glial cultures. Supported by VA Merit Review Research Grant

336.4

ADRENOCORTICOSTEROID FEEDBACK IS NOT NECESSARY FOR ADRENO-CORTICOTROPIN STIMULATION BY PERIPHERAL INTERLEUKIN-1B.

M.K. Selmanoff*, L.P. Kapcala, J.R. He, Y. Gao, D.N. Darlington, and
D.E. Carlson. Endocr. Div., Dept. Med., & Res. Div., Dept. Surg., Univ. of
Maryland S.O.M. and Baltimore VA Med. Ctr., Baltimore, MD 21201

The observation that adrenalectomy(ADX) abolishes plasma adrenocorticotropin(ACTH) stimulation by central(icv) interleukin (IL)-1B has been interpreted as evidence supporting the necessity of adrenocorticosteroid feedback for IL-1 stimulation of ACTH secretion. Different mechanisms appear to mediate IL-1 activation of the hypothalamic-pituitary-adrenal axis when IL-1 originates in different body compartments(e.g. different routes of administration). Thus, we tested the hypothesis that loss of adrenocorticosteroid feedback after ADX diminishes plasma ACTH stimulation by peripheral(iv or ip) IL-1B. Adult male SD rats were studied 7 days after ADX or sham ADX for plasma ACTH responses to iv(2µg/kg) and ip(6µg/kg) IL-1B or iv/ip saline(control). Insulin-induced hypoglycemia was a positive control to show ACTH stimulation after ADX. ADX did not diminish ACTH stimulation by iv IL-1B. Stimulation of ACTH secretion by iv IL-1B in ADX rats ranged between normal to exaggerated responses. Neither did ADX diminish ACTH stimulation by ip IL-1B

<u>CONCLUSION</u>: Adrenocorticosteroid feedback is not necessary for facilitating stimulation of ACTH secretion by IL-118 originating in peripheral body compartments(e.g. circulatory-iv, or abdominal-ip). Supported by VA Merit Review Research Grant

EFFECTS OF INTERFERON β-IB AND TRIPTOLIDE ON CONCANAVALIN A-INDUCED PERIPHERAL BLOOD MONONUCLEAR CELL PROLIFERATIVE RESPONSES AND NON-SPECIFIC SUPPRESSOR FUNCTION IN MULTIPLE SCLEROSIS. Zou. M. A. Jensen and B. G. W. Amason*, Dept. of Neurology, University of Chicago, Chicago. IL 60637

Multiple Sclerosis (MS) is an immune mediated demyelinating disease. Non-specific suppressor function, as measured in the Con A suppressor assay, is decreased in MS during active disease. Interferon β-1B (IFNβ-1B) is an approved treatment for relapsing-remitting MS. IFNβ-1B therapy augments non-specific suppressor function in MS patients as measured ex vivo. We investigated potential additive effects of IFNβ-1B and Triptolide on Con A-induced lymphocyte proliferation and non-specific suppressor function of PBMC in vitro. Triptolide is a drug derived from the roots of Triperygium Wifordit f. The results indicate that (1) Both IFNβ-1B and Triptolide inhibit Con A-induced proliferative responses of PBMC in a dose dependent manner. Drug concentrations that yielded 50% inhibition were 53.3 ± 8.3 U/ml (range 37.01 to 72.35) of IFNβ-1B and 1.99 ± 0.13 ng/ml (range 1.73 to 2.30) of Triptolide; (2) Isobologram analysis of dose response curves revealed that IFNβ-1B and Triptolide suppress PBMC proliferative responses in an additive manner; (3) IFNβ-1B augments non-specific suppressor function to 50% of optimum was 97.2 + 7.8 U/ml; (4) Triptolide augments Con A induced non-specific suppressor function (for Con A vs Con A plus Triptolide. Control = 13.8 ± 1% vs 22 ± 3% and for MS 11.6 ± 1% vs 17.5 ± 2%; p < 0.03 for both); (5) IFNβ-1B and Triptolide together fail to synergistically augment non-specific suppressor function. Study supported by PHS-PO-1-NINDS-NS 24575; a gift from the Butz Foundation; a grant from Berlex, Inc. (all to B.G.W.A.).

MOLECULAR REGULATION OF THE IL-1beta SYSTEM IN RAT BRAIN REGIONS IN RESPONSE TO THE CHRONIC ICV MICROINFUSION OF rhIL-1beta AT DOSES THAT YIELD PATHOPHYSIOLOGICAL CONCENTRATIONS IN THE CSF. S.E. Ilyin*, G. Sonti, D. Gayle and C.R. Plata-Salamán. Sch. Life Hlth. Sci., Univ. Delaware, Newark, DE 19716-2590, USA.
RhIL-1beta (RHI-1) was chronically infused (via osmotic minipumps) into the 3rd ventricle of rats, at doses that yield estimated pathophysiological concentrations in the CSF. RHI-1 induced significant anorexia. The nighttime food intake at 60-72 h after initiating the chronic ICV infusion was 21.1±0.8 g (n=7) for heat-inactivated, 15.7±0.6 g (n=8) for 2.0 ng, and 11.5±1.0 g (n=7) for 8.0 ng RHI-1/24 h (p<0.0001). At 72 h, brain regions were isolated from all rats. The IL-1beta system [IL-1 receptor type I (IL-1R1), IL-1 receptor antagonist (IL-1Ra) and IL-1beta] mRNAs levels were determined in brain regions by RNase protection assays. The chronic ICV infusion of RHI-1 increased (p<0.005) the IL-1Ra and IL-1beta mRNA levels in the cerebellum and midbrain, and increased (p<0.03) the IL-1Ra and IL-1beta mRNA level in the cerebellum. The profiles of mRNAs induced were highly intercorrelated within a brain region. Inactive RHI-1 had no effect. The data suggest the operation of a feedback system (IL-1beta/IL-1Ra/II-1RJ). Dysregulation of the CNS IL-1beta feedback system (IL-1beta/IL-1Ra/II-1RJ). Dysregulation of the CNS IL-1beta feedback system (IL-1beta/IL-1Ra ratio) may be reflected in the pathogenicity and severity of neurological diseases associated with increased CSF concentrations of IL-1beta acut has CNS infections.

The present novel integrative approach can be used to study cellular and molecular mechanisms involved in cytokine-induced anorexia (and other neurological manifestations) including cytokine, neurotransmitter, and neuropeptide subsystem (ligands, receptors, transducing molecules, endogenous inhibitors) profiles. Supported by Univ. Del. Res. Grants.

ACTIVATION OF THE ANTERIOR HYPOTHALAMIC SEROTONINERGIC SYSTEM BY INTERLEUKIN-6 AND INTERLEUKIN-1B: IN VIVO

SYSTEM BY INTERLEUKIN-6 AND INTERLEUKIN-18: IN VIVO MICRODIALYSIS STUDIES IN AWAKE F344 RATS. E. Khan Shaghaghi¹, Yue Wu¹, M. Pallardy², H. Lebrec², C. Jacquot^{1*} and A.M. Gardier¹. ¹Lab. Neuropharmacol. JE DRED 92-372, ²Lab. Toxicol. CJF INSERM 9301, Fac. Pharmacie Univ. Paris-Sud, F92296 Chatenay-Malabry, France.

Recently, we demonstrated that a primary immune response to T-cell dependent antigen (sheep red blood cell, SRBC, or keyhole limpet hemocyanin, KLH) decreases hypothalamic and cortical scrotonin ((5-hydroxytryptamine, 5-HT) levels in F344 rats while increasing extracellular 5-HT levels in vivo (Gardier et al., Brain Res., 645 (1994) 150-156). Petreatment with an immunosuppressive drug, cyclosporine A prevented these effects suggesting that a T-lymphocyte product, but not a macrophage one, may be involved in the central scrotoninergic activation induced by one of this antieren. Thus, interleukin-6 (IL-6) might be a good candidate for being a link between antigen. Thus, interleukin-6 (IL-6) might be a good candidate for being a link between the immune system and the central nervous system. To further characterize this hypothesis, we used a microdialysis probe equiped with a microinjection tube as designed by Shintani et al. [J. Neurosci. 13 (1993) 3574-3581] to compare the effects of interleukin-6 (IL-6) and interleukin-1B (IL-1B) administered directly into the anterior hypothalamus, on 5-HT release in the anterior hypothalamus of conscious, freely moving rats. At 10 and 50 ng doses, IL-6 induced rapid and transient increases in extracellular 5-HT levels: the maximal increases were to 157% and 309% of the respective basal values (100 %). Extracellular 5-HT levels were back to baseline values 1 hour after local IL-6 perfusion. Furthermore, 5-hydroxyindolacetic acid (5-HIAA) efflux remained unchanged. However, at a lower dose (1 ng), central IL-6 did not alter extracellular 5-HT and 5-HIAA levels compared to the control group. Central IL-18 (1 ng) induced a dramatic, rapid and transient increase in extracellular 5-HT levels: the maximal increase was to 1127% of the basal value (100%) as well as those of 5HIAA. The present findings provide the first reported *in vivo* evidence that IL-6, although much less effective than IL-1B, is able to directly increase hypothalamic 5-HT release.

THE CENTRAL INJECTION OF INTERLEUKIN-1 β inhibits testosterone SECRETION INDEPENDENTLY OF CHANGES IN PLASMA LUTEINIZING HORMONE LEVELS. <u>C. Rivier* and A.V. Turnbull.</u> Clayton Foundation

Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037
It is well known that central (intracerebroventricular, icv) injection of interleukin-18 (IL-8) significantly lowers plasma luteinizing hormone (LH) concentrations, which in turn reduces testosterone (T) secretion in adult male rats. We have recently observed that in addition, icv IL-18 (30-80 ng) also inhibits the surge in T secretion due to the that in addition, iev IL-1B (30-80 ng) also inhibits the surge in T secretion due to the intravenous (iv) injection of human chorionic gonadotropin (hCG). This diminished testicular responsiveness to gonadotropin appears to be independent of reduced plasma LH concentrations, since blockade of LH alone (using gonadotropin-releasing hormone antagonists) does not acutely impair the T response to hCG. Iev IL-1B increases the plasma concentrations of corticosteroids and IL-6, both of which directly inhibit gonadal steroidogenesis. However, neither adrenalectomy nor CRF antibodies affect the diminished T response to hCG in animals iev injected with IL-1B, indicating that elevated plasma corticosterone is not responsible for the blunted testicular response. Similarly, elevated plasma IL-6 levels do not seem to be the primary cause of iev IL-1B-induced suppression of the T response to hCG. Indeed the peak values of IL-6 over the time course of our experimental paradigm while differing temporally, are quantitatively similar after both iv and iev IL-1B, yet the iev IL-1B far more effectively blunts the T response to hCG. Collectively, these data indicate that IL-1B within the central nervous system can inhibit testicular activity independently of plasma LH or central nervous system can inhibit testicular activity independently of plasma LH or corticosterone levels, and that this phenomenon is probably not directly correlated with elevated plasma IL-6 concentrations. We postulate that neural influences on testicular function, similar to those described for the adrenals and the ovaries, may mediate this action of IL-18 on T secretion. In view of the wide range of pathologies associated with increased brain IL-1 levels, this mechanism may be important during stressinduced inhibition of reproductive function in the male. Supported by NIH HD-13527.

LOCALIZED INFLAMMATION AND THE RELEASE OF BETA-ENDORPHIN

J.C. ALIZED INFLAMMATION AND THE RELEASE OF BETA-ENDORPHIN FROM IMMUNE CELLS. P.J. Cabot* L. Carter, C. Gaiddon* J. P. Loefflef* and C. Stein. Dep. of Anesthesiology and Critical Care Medicine, Johns Hopkins Univ., Baltimore, M.D., 21287-8711, U.SA and * Univ. of Strasbourg, Strasbourg, France.
Recent findings have suggested a significant involvement of the immune system in the control of pain. Immune cells contain opioid peptides which are released within inflamed tissue and act at opioid receptors on peripheral sensory neurons. These immune cells have cell surface receptors for various cytokines and corticotropin-releasing factor (CRF) which, when activated, can evoke the release of opioid peptides. In these studies we sought to characterise the release of the prominent opioid peptide, β-endorphin, in distinct populations of lymphocytes from blood, non-inflamed lymph nodes (LN) and inflamed popliteal LN to assess the role of cell trafficking and the cellular mechanisms of opioid peptide release from immune cells. Male wistar rats were treated with freund's complete adjuvant (150 µl) in the right hind paw which induced an inflammatory response, maximal at four days. The in-vitro release of β-endorphin from immune cells was evoked by interleukin-1β (IL-1β) and CRF and was demonstrated to be dose-dependent from both inflamed and non-inflamed LN. The release of β-endorphin by IL-1β and CRF was reversed by specific receptor antagonsist IL-1ra and alpha-helical-CRF, respectively, and the release was shown to be calcium dependent, indicating the vesicular containment of β-endorphin within the immune cells. Circulating lymphocytes of either treated (1.98 ± 0.08 mg/10° cells) or untreated animals (0.83 ± 0.04 mg/10° cells) contained significantly lower levels of β-endorphin than those within normal (6.88 ± 0.77 mg/10° cells, p<0.05) or non-inflamed LN. (5.54 ± 0.98 mg/10° cells) and were not sensitive to IL-1β or CRF. Similarly, levels of β-endorphin were lower in inflamed EN (3.36 ± 0.21 ng/10° cells) than in non-in

THE INTRACEREBROVENTRICULAR INJECTION OF CORTICOTROPIN-RELEASING FACTOR OR INTERLEUKIN-1 β INCREASES mRNA LEVELS OF CONSTITUTIVE NITRIC OXIDE SYNTHASE IN THE RAT HYPOTHALAMUS. Lee* and C. Rivier. Clayton Foundation Laboratories for Peptide

S. Lee* and C. Rivier. Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037
Nitric oxide (NO) synthase (NOS), the enzyme responsible for NO formation, is found in hypothalamic neurons that are important for the activity of the hypothalamic-pituitary-adrenal (HPA) axis. We reported earlier that systemic (iv) endotoxin injection significantly upregulated mRNA levels of constitutive (c) NO synthase (NOS, the enzyme responsible for NO formation) in the paraventricular nucleus (PVN) of the hypothelayers, while other investigators found that placed at the processing that the control of the process indused the process indused the process indused the process indused the process of the p hypothalamus, while other investigators found that physical stresses induced similar changes. However, the mechanisms leading to increased brain NOS similar changes. However, the mechanisms leading to increased brain NOS values remain unclear. The purpose of the present work was to determine whether neuromodulators known to be increased following stress or endotoxin treatment, were able to stimulate NOS mRNA in the paraventricular nucleus (PVN) of the hypothalamus. Corticotropin-releasing factor (CRF) is the hypothalamic peptide that represents the primary mediator of the activity of the HPA axis; its levels are significantly elevated in the PVN of rats exposed to stress or endotoxin. Interleukin-1B (IL-1B) is a cytokine whose concentrations increase in the brain of rats administrated endotoxin systemically. The intracephoreastricular (rats) (IL-1 β) is a cytokine whose concentrations increase in the brain of rats administered endotoxin systemically. The intracerebroventricular (icv) injection of CRF (1 µg) or IL-1 β (100 ng) was therefore used as pharmacological means to mimic changes in the hypothalamic levels of these secretagogues during exposure to physical stress or endotoxin. Both icv treatments significantly increased hypothalamic cNOS mRNA levels measured 2 h later. These results suggest that CRF and/or IL-1 β may be specifically responsible for increased NO formation in rats exposed to physical stress or injected with endotoxin. Supported by NIMH R01-MH51774.

EVIDENCE FOR THE INVOLVEMENT OF THE CENTRAL NORADRENERGIC SYSTEM IN SYSTEMIC INTERLEUKIN-6 INDUCTION BY PERIPHERALLY ADMINISTERED INTERLEUKIN-18. Q.-H. Huang, A. Takaki, A. Kastin* and A. Arimura, US-Japan Biomed. Res. Labs, Tulane Univ. Hebert Ctr., Belle Chasse, LA 70037, USA, ¹VA Med. Ctr., New Orleans, LA 70146, USA.

The role of the central noradrenergic system in systemic interleukin-6 (IL-6) induction by peripherally administered interleukin-1ß (IL-1ß) was examined in rats. The results demonstrated: (1) intravenous (iv) injection of rhIL-1B (2µg/kg body wt) caused a notable rise in plasma IL-6 levels, and this action was markedly attenuated by intracerebroventricular (icv) pretreatment with either 6-hydroxydopamine (6-OHDA, 100 or 200 µg/rat) or a1-adrenergic receptor antagonist prazoxin (20 µg/rat), suggesting that the central al-noradrenergic system is involved in the iv applied IL-1-induced systemic IL-6 induction; (2) the levels of IL-6 in the brain (hypothalamus, induced systemic IL-6 induction; (2) the levels of IL-6 in the brain (hypothalamus, medulla oblangata, and cortex) did not rise after iv IL-18, suggesting that the brain noradrenergic system probably acts on the peripheral IL-6-producing cells, but not those in the brain, to contribute to the elevation of systemic IL-6; (3) chemical sympathectomy with intraperitoneal (ip) injection of 6-OHDA, but not adrenalectomy, resulted in dramatic reduction of the plasma IL-6 response to iv IL-18, suggesting that the autonomic sympathetic nervous pathway, but not the hypothalamus-pituitary-adrenal (HPA) axis, conveys the neural signals to the periphery to facilitate IL-6 induction; (4) norepinephrine (NE) in vitro at dose range 10-9 10-7 M. (4) production and at dose range 10-9 10-7 M. 10^{-6} - 10^{-4} M was able to stimulate IL-6 production, and at dose range 10^{-9} - 10^{-7} M synergized with IL-1B in inducing IL-6 production from splenocytes. Taken together, the findings support the proposal that the high levels of systemic IL-6 induced by iv IL-18 is partially mediated through the activation of the al-noradrenergic autonomic system in the brain and the consequent increase in the sympathetic outflow to the periphery, and NE released from sympathetic terminals may function as a modulator to interact with IL-1ß in inducing IL-6 production from sympathetic nerve innervated peripheral organs. Sponsored in part by Off. of Naval Res. grant N00014-93-1-0829.

NEURONAL SIGNALING BY INTERLEUKIN-1.

Y. Bai, E. Kouranova, G.M. Jonakait, E. Bonder and R.P. Hart*, Dept. Biol. Sci., Rutgers Univ., Newark NJ 07102.

The effects of cytokines on neuronal function have been largely ascribed to mediation by non-neuronal cells. In order to determine if neurons may be capable of directly responding to inflammatory cytokines, we have examined IL-1 signaling in cultured superior cervical (sympathetic) neurons. Enriched neuronal cultures (<5% non-neuronal cells by visual inspection) contain both Type I IL-1 receptor mRNA and IL-1 receptor accessory protein (IL-1Rap) mRNA. The relative level of these two mRNAs is similar to that found in a Schwann cell line, arguing that these mRNAs are found in neurons in the enriched neuronal cultures and are not due to the presence of contaminating cells. When enriched neuronal cultures are treated with 10 ng/ml hrIL 1β for 2 hr, RNA differential display detects several bands either up- or down-regulated indicating a gene expression response. Some of these bands are different from those regulated in a Schwann cell line in a parallel experiment, indicating that they are specific to neurons. Treatment of enriched neuronal cultures with IL-1 also leads to nuclear localization of the responding transcription factor NF- κB by immunocytochemistry with an anti-p65 antibody. NF- κB translocation is observed in both neurons and Schwann cells in the culture within 1 hr of IL-1 treatment. These results demonstrate that sympathetic neurons likely express IL-1 receptor components, that they respond to IL-1 treatment by activating a transcription factor and that they regulate responding genes. EXPRESSION OF A FUNCTIONAL INTERLEUKIN-15 RECEPTOR COMPLEX BY MICROGLIAL CELLS IN CULTURE. U.-K. Hanisch*, S. Lyons, F. Kirchhoff, C. Nolte, and H. Kettenmann. Department of Cellular Neurosciences, Max Delbrück Center (MDC) for Molecular Medicine Berlin, 13122 Berlin-Buch, Germany.

The study demonstrates the presence of mRNAs for interleukin-15 (IL-15) and all the components of an IL-15 receptor (IL-15R) system in cultured mouse microglia. RT-PCR results, supported by partial sequencing, show that mouse microglia synthesize the novel cytokine, IL-15, and express the cytokine receptor subunits, IL-15Rα, IL-2Rβ and IL-2Rγ, that build up a heterotrimeric high-affinity IL-15R complex. IL-15 supported the growth of microglia *in vitro* at doses of 0.1 to 10 ng/ml, indicating that the microglial IL-15R could transmit signals. The IL-15 effect was demonstrated with complementary experimental protocols estimating cell death and survival (LDH and MTT-3 assays), respectively.

The findings suggest that microglial cells produce IL-15 as an autocrine growth factor. Microglia may serve as an IL-15 source for other neural cell populations throughout the brain. Furthermore, *in vivo* IL-15 could likely be responsible for several CNS effects currently ascribed to the T cell growth factor, IL-2, as IL-15 and IL-2 have overlapping activities. Being related by their immune functions (but not by sequence), IL-15 and IL-2 both share IL-2Rß and IL-2Ry for signaling, while IL-15R α and the homologous, non-signaling IL-2R α may serve as specific binding subunits. Under pathophysiological conditions, microglial IL-15 could act as a chemoattractant and stimulator for invading T cells. In turn, (T cell- or astroglia-derived) IL-2 could affect (activated) microglia. Together the data point to a possible role of the IL-15/IL-15R system in the regulation of microglial physiology and communication. Supported by the BMBF and DFG of Germany.

UP-REGULATION OF THE C-C CHEMOKINE RECEPTOR-LIKE GENE (RBS11) IN THE RAT FACIAL NUCLEUS AFTER MOTONEURON AXOTOMY. Y. Jiang, R.K. McNamara, M.N. Salafranca, N.A. Pennell, W.J. Streit, and J.K. Harrison*. Departments of Pharmacology and Therapeutics, Psychiatry, and Neuroscience, University of Florida, Gainesville, FL 32610-0267.

We have previously reported on the molecular cloning of a novel G-protein coupled receptor whose conceptualized amino acid sequence is most similar to the subfamily of C-C chemoattractant cytokine (chemokine) receptors (Harrison, J.K. et al., Neurosci. Lett., 169:85-89, 1994). This receptor gene (RBS11) is widely expressed in several tissues of the rat with prominent expression in both brain and spinal cord. In order to determine the cellular localization of this receptor in the central nervous system we initially examined for the presence of RBS11 mRNA in extracts of primary cultured neurons, astrocytes, and microglia. Only cultured microglia expressed detectable levels of RBS11 mRNA. The effect of nerve transection on the level of expression of RBS11 mRNA in the rat facial nucleus 4 days after motoneuron axotomy was also assessed using the techniques of northern blot and in situ hybridization analysis. Both methods revealed a significant elevation of RBS11 mRNA in the facial nucleus on the axotomized side 4 days after motoneuron transection. Since microglial proliferation and activation are found in the axotomized facial nucleus, it is our hypothesis that RBS11 is expressed by microglia in vivo. These data implicate chemokine-dependent mechanisms in the cellular response of the facial nucleus to nerve transection. (Supported by grants from the American Heart Association - Florida Affiliate and the National Multiple Sclerosis Society)

INDUCTION OF IL-1b EXPRESSION AND CELL DEATH BY HEXACHLOROBENZENE IN DIFFERENTIATED N1E-115 NEUROBLASTOMA. A.J. Malin. C. F. Ide. A. Arimura* U.S. Japan Biomedical Research Laboratory, and Center for Bioenvironmental Research, Tulane University, New Orleans, LA 70115.

IL-1β has been shown to play a critical role in repair of nervous tissue and has been implicated in both cell death and cell survival. IL-1β is synthesized by both neurons and glial cells. IL-1β protein has been localized to neurons in the suprachiasmatic nucleus, cortex, dentate gyrus, median eminence, lateral hypothalamus, and granular layer of the cerebellum in rat. Hexachlorobenzene (HCB) is a environmental contaminant shown to cause an array of health effects in mammalian nervous, endocrine, and immune systems. In this study, the effects of HCB on IL-1 β expression and cell death were investigated using differentiated murine N1E-115 neuroblastoma cells as a neuronal model. Cell death was measured using the trypanblue exclusion assay after treatment of differentiated N1E-115 cultures with 50 ppb and 150 ppb HCB at 6, 12, 24, 36, 48 and 72 hours. Levels of IL-1 β were measured by ELISA for each dose and time point. IL-1 β -like immunoreactivity was confirmed in the differentiated N1E-115 cells and found to be localized to the nucleus. No nuclear stain was present with pre-absorbed antibody. Results indicate that cell-associated IL-1 β levels and cell death both increase in a time and dose dependent manner. These results suggest that hexachlorobenzene induces a neural immune response which may be regulating cell death in a neuronal model. Supported by Office of Naval Research grant number N00014-3-1-0829.

INTERLEUKIN-15 (IL-15) INDUCES TOXICITY IN MESENCEPHALIC, SEPTAL AND HIPPOCAMPAL NEURONAL CELL CULTURES, F. Mennicken*, S. Bastian-teto and R. Quirion. Douglas Hospital Research Centre, McGill University, Department of Psychiatry, 6875 Blvd. LaSalle, Verdun, Quebec, H4H IR3 Canada

We have previously shown that IL-15 decreased choline acetyltransferase (ChAT) activity in septal cell cultures grown under serum-free medium after 5 days in vitro (DIV) (Soc. Neurosci., San Diego, 1995). The IL-15-induced decrease in ChAT activity (ED $_{50}$ $^{\approx}$ 4 ng/ml) is due to marked neuronal toxicity. We have now investigated if IL-15 is similarly neurotoxic to different types of primary neuronal cultured cells assessing viability by the MTT method (Manthorpe et al., Dev Brain res 25: 191, 1986).

Mesencephalic, septal and hippocampal cultures were prepared from 15, 17 and 19-day old rat embryos respectively. Following enzymatic and mechanical dissociation, cells were allowed to grow in a serum medium for 24 h. This medium was then change to serum-free conditions (N₂ supplement) with IL-15 being added at various concentrations (0.1-50 ng/ml). After 6 DIV, IL-15 induced significant decreases in cell viability (up to 80% at 50 ng/ml) in these 3 types of cultures. IL-15 was highly toxic in septal cell cultures with a significant cell loss at 5 ng/ml whereas 10-30 ng/ml were required for hippocampal and mesencephalic cell cultures. We also observed that IL-15-induced toxicity decreased proportionaly with cell density increments (1.5-7.5 x10⁵ cells/well). The addition of IL-15 after 4 DIV was also found to be neurotoxic. Hence, IL-15 toxicity is not only related to initial phase of in vitro neuronal survival and growth.

Taken together, these results demonstrate the potent neurotoxic effect of IL-15 on neuronal survival. Supported by FRSQ and MRCC.

336.18

IMMOBILIZATION STRESS MODULATES THE EXPRESSION OF INTERFERON-a mRNA IN THE MOUSE. <u>S.Take</u>, <u>Y.Kanemitsu</u>, <u>T.Yasaka</u>, <u>T.Katafuchi</u>, <u>T.Hori and F.Eckenstein</u>, ² Dept. of Physiology, Kyushu Univ. Faculty of Med., Fukuoka 812-82, Japan and ² Dept. of Cell Biology, Oregon Health Science Univ., Portland, OR 97201.

The brain and the immune system communicate with each other using the common ligand-receptor systems. Interferon- α (IFN- α) is one of such ligans that is produced in the brain during neurotropic viral infections, brain injury, etc. and induces a variety of central symptoms including immunomodulation. In the present study, we examined whether or not immobilization stress, one of the "psycological" stress, might modulate the biosynthesis of IFN- α in the mouse.

Male BALB/c mice were immobilized for 15 to 180 min in a prone position by fasting their extremities to a board by adhesive tapes. At the end of immobilization, the mice were decapitated and their organs were rapidly removed to procede to Northern blot analysis of IFN- α mRNA. IFN- α mRNA was constitutively expressed in the brain and immobilization stress for 30 min markedly increased its expression especially in the cerebral cortex. Among the peripheral organs, expression of IFN- α mRNA was markedly enhanced in the liver and spleen by 90 min immobilization stress. Immobilization stress for 90 min also suppressed the cytotoxic activity of splenic natural killer cells measured by a standard chromium release assay using YAC-1 cells as a target.

We have previously reported that intracerebroventricular injection of IFN- α suppressed the cytotoxic activity of natural killer cells which was mediated by the brain opioid-CRF-splenic sympathetic pathway. Taken all things together, we may speculate that immobilization stress-induced IFN- α in the brain might be involved in the brain modulation of the immunity, especially in stress-induced immunosuppression. The further study is going to examin this hypothesis.

DEFICIENT INTRACEREBRAL IFN-γ PRODUCTION IN HSV-2-INFECTED MICE: T CELL RECRUITEMENT, INOS PRODUCTION, AND APOPTOSIS OF HSV-INFECTED NEURONS

Gail Lewandowski*, Dept. of Neuropharmacology, The Scripps Research Inst., La Jolla, CA 92037.

Inst., La Jolla, CA 92037.

In mice infected with virulent herpes simplex virus type 2 (HSV-2), intracerebral IFN-7 production was observed to be significantly less than that in mice
infected with avirulent strains of HSV-1. Consequently, the following questions
were investigated, (i) is the decreased IFN-7 production due to decreased T cell
recruitment in the brains of HSV-2-infected mice? (ii) does the decreased IFN-7
production prevent production of nitric oxide (NO), a putative anti-HSV agent?,
(iii) does the decreased IFN-7 production affect survival of infected neurons, by
either promotion of apoptosis or disruption of synthesis of anti-apoptotic
proteins?

proteins?

Following intravitreal inoculation, numerous CD4⁺ and CD8⁺ T cells were immunohistochemically detected in brain regions positive for HSV-1 antigens. By contrast, very few CD4⁺ and CD8⁺ T cells were detected in the same brain regions in HSV-2-infected mice. Preliminarily, abundant inducible nitric oxide synthase (iNOS) was immunohistochemically detected in HSV-1-positive brain regions. Considerable production of the Bcl-2, an anti-apoptotic protein, was immunohistochemically detected in HSV-positive brain regions in both HSV-1 and HSV-2 infected in HSV-positive brain regions in both HSV-1 and HSV-1 infected brains, as compare to HSV-1-infected brains, was observed using the TUNNEL method.

HSV-2-infected brains, as compare to HSV-1-infected brains, was observed using the TUNNEL method.

Conclusions: (i) insufficient recruitment of CD4+ and CD8+ T cells in the brains of HSV-2 infected mice is the likely basis for decreased IFN-γ production, (ii) decreased IFN-γ production may stem the induction of iNOS, preventing production of NO, (iii) the presence or absence of IFN-γ does not appear to affect apoptosis of HSV-infected neurons.

CYTOKINE RESPONSES TO ADENOVIRUS VECTORS IN THE BRAIN. M.B. Lee*, A.P. Byrnes, J. Lang, H.M. Charlton and M.J.A. Wood. Dept. of Human Anatomy, University of Oxford, Oxford, OXI 3QX, United Kingdom.

Adenovirus vectors can deliver a wide range of genes to post-mitotic cells and are

therefore a valuable research tool and potential therapy for neurological disorders. Although E1-deleted adenovirus vectors are non-replicating, they nonetheless can induce a T cell-mediated immune response in the brain and other organs. In the liver and lung, vector transgene expression is short-lived unless this immune respo suppressed. Although transgene expression in the mouse and rat brain persists for much longer (at least two months), subsequent peripheral exposure to the vector can result in local demyelination and an elimination in marker protein expression. Therefore, adenovirus vectors in the brain can remain as a potential target for the immune system and this limits the therapeutic potential of these vectors. A better understanding of the factors that control the immune response to adenovirus vectors in the brain is needed and an effective immunosuppressive strategy developed if these vectors are to be used in neural gene therapy.

We are currently examining murine cytokine mRNA production in order to characterise the immune response to adenovirus vectors in the brain. Adenovirus vectors were stereotaxically injected into the striatum of C3H mice. RNA from both the brain and cervical lymph nodes were examined. Analysis of IL-4 and IFN-γ message and protein allows different components of T cell immunity (Th1 and Th2 responses) to be differentiated. A semi-quantitative study of cytokine message using the reverse transcriptase polymerase chain reaction (RT-PCR) was used to compare the relative amounts of IL-4 and IFN-y message over a time course. We show here that this is a reliable method to test our hypothesis that the T cell response in the brain is different from the T cell response in the periphery. The results presented here are important for evaluating our efforts to maintain a potentially less deleterious Th2 type response b expressing specific cytokines from the adenovirus vectors. (Supported by the MRC, U.K.).

CARDIOVASCULAR REGULATION: VENTRAL MEDULLA I

337.1

CHOLINERGIC CONTROL OF C1 ADRENERGIC AND OTHER VASOMOTOR NEURONS OF THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) P. G. Guyenet*, A. M. Schreihofer and D. Huangfu. Dept. of Pharmacology, University of Virginia, Charlottesville, VA 22908.

In chloralose-anesthetized rats iontophoresis of carbachol (carb) excited all barosensitive neurons of the RVLM (+8.2 ± 1.2 spikes / s, n=29). The excitation was reduced 85% by iontophoretic methylatropine (n=7) and was blocked by i.v. scopolamine (Img/kg). Nicotine or hexamethonium (iontophoresis) produced no effect. Whole-cell recordings of bulbospinal RVLM neurons (n=54) were made in slices of neonate rat brain (3-10 day-old) using previously described techniques (Li et al., Am. J. Physiol. 269: R1356, 1995). Twenty four of 41 histologically recovered neurons were C1 cells (bulbospinal and immunoreactive for tyrosinehydroxylase). Carb (1-30 µM) depolarized the cells, increased PSP frequency and decreased input resistance. In voltage clamp (approx. -50 mV, 1µM TTX present), both carb and muscarine produced inward current (12.6 \pm 2 pA with 30 μ M carb, n=16; EC₅₀ for carb: $10 \pm 1 \,\mu\text{M}$; $2.6 \pm 0.6 \,\text{pA}$ with 30 μM muscarine). The carbinduced current was reduced 46% by 5 µM methylatropine (n=15) and 84% by 200 μM hexamethonium (n=9). It was linearly related to the holding potential (-120 to -40 mV) and reversed at -22 \pm 2 mV, (n=18; linear extrapolation)

In conclusion, carb exerts pre- and post-synaptic effects on C1 and other vasomotor neurons of RVLM. "In vitro", the postsynaptic effect of carb has a mixed nicotinic and muscarinic pharmacology . "In vivo", the predominant response of these cells to iontophoretically applied carb is muscarinic. The dual cholinergic pharmacology of C1 cells is reminiscent of that of the noradrenergic neurons of the locus coeruleus. (Supported by the NIH: RO1 HL39841 and NIH training grant 5T32HL07284-19).

337.3

PONTINE RETICULAR FORMATION CONTRIBUTES TO THE TONIC CONTROL OF BLOOD PRESSURE. <u>S. Ito and A.F. Sved</u>*. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Neurons in the pontine reticular formation (PRF) appear to contribute to the tonic control of arterial pressure (AP), by providing tonic excitation of bulbospinal neurons in the rostral ventrolateral medulla (RVLM) (Hayes et al. Am. J. Physiol. 266:R237, 1994). However, inhibition of neuronal activity in the PRF elicits only a transient decrease in BP. The present study sought to confirm this observation, and to examine the factors that may contribute to the transient nature of the response. Injection of muscimol (100 pmol in 100 nl CSF) unilaterally into the PRF (1.8 mm lateral from the midline, 8.0 mm below the dura, and 5.0-5.5 mm rostral to the obex with the pipette angled 10° caudally) of chloralose-anesthetized, paralyzed, ventilated male rats decreased AP 22 ± 5 mm Hg and heart rate 22 ± 4 bpm (n=3). These responses were transient, returning to control levels in 37 ± 4 sec. Similar responses were obtained with injections of GABA (10 nmol) or glycine (65 nmol) and responses produced by bilateral injections were not significantly different from those produced by unilateral The size of the depressor response was not altered by either acute or chronic baroreceptor denervation, although responses were slightly prolonged (approx 1 min). In contrast, in rats in which the inhibitory input from the caudal ventrolateral medulla (CVLM) to the RVLM was inhibited by bilateral injection of muscimol into the CVLM, injections of muscimol into the PRF elicited large and sustained decreases in AP. Muscimol injection into the CVLM increased AP from 102 ± 4 mm Hg to 164 ± 4 mm Hg and subsequent injection of muscimol into the PRF decreased AP to 67 ± 5 mm Hg, and this response was maintained for longer than 15 min (n=5). In 3 additional rats, AP fell to below 40 mm Hg and these rats then died. These results suggest that the PRF provides a prominent tonic excitatory input to RVLM vasomotor neurons, and this tonic excitatory input is offset by an inhibitory input from CVLM to RVLM. (Supported by NIH grant HL-38786.)

PROPERTIES OF IRREGULAR FIRING NEURONS IN THE RAT ROSTRAL VENTROLATERAL MEDULLA IN VITRO AND POSSIBLE INVOLVEMENT IN SYMPATHOEXCITATORY FUNCTION. A. Hayar*, P. Piguet and R. Schlichter, Lab. Physiologie Générale, Univ. Louis Pasteur, 21 rue R. Descartes, 67084 Strasbourg, France

The rostral ventrolateral medulla (RVL) is thought to be the major central nervous system site where substances with a2-adrenoceptors agonist properties exert their sympatholytic effects. The purpose of this work was to examine in particular a type of RVL neurons designated as irregularly firing (IF). These neurons were shown to have relatively larger spike duration and amplitude, and were slowly discharging (1- 2 Hz). They were less frequently encountered (25% of the total RVL neurons sampled) and were interspersed between regularly firing pacemaker-like and silent neurons. Using intracellular recordings in rat medullary slices, we looked for properties that could distinguish these neurons (n=50) as a unique group. These neurons were found to have a predominant GABAergic postsynaptic activity that was essentially irregular. This contrasted with the finding that other neurons have a rather glycinergic regular synaptic activity. Noradrenaline (10-100 μ M) hyperpolarized about 80 % of IF neurons. This response was associated with a decrease in membrane input resistance and was mimicked by the α 2-adrenoceptor agonist clonidine (3-10 μ M). Most of these neurons have an inward rectifier current and their input resistance was significantly reduced at hyperpolarized potentials. Preliminary results using intracellular labeling with Lucifer Yellow indicated that neurons of this group appeared to have a distinctive morphology. Taken together, our data indicate that IF neurons recorded in vitro could correspond to a similar group of slowly and irregular firing neurons recorded in vivo and found to be sensitive to a2adrenoceptors agonists, suggesting that they could assume a sympathoexcitatory

Efferents from both the Nucleus of the Solitary Tract and the Caudal Ventrolateral Medulla Synapse on C1 Neurons in the Rostral Ventrolateral Medulla. S.A. Aicher*, I. Jeske, S. Cravo, S. F. Morrison, D. J. Reis and T.A. Milner. Dept. of Neurol. & Neurosci., Cornell Univ. Med. College, NY, NY 10021.

The rostral ventrolateral medulla (RVL) contains reticulospinal adrenergic (C1) neurons that are thought to be sympathoexcitatory and form the medullary efferent limb of the baroreceptor reflex pathway. The RVL receives direct projections from two important autonomic regions, the caudal ventrolateral medulla (CVL) and the nucleus tractus solitarius (NTS). The present study used anterograde tracing from the CVL or NTS combined with immunocytochemical identification of C1 adrenergic neurons in the RVL to compare the morphology of afferent input from these two autonomic regions into RVL. NTS (N=203) and CVL (N=380) efferent terminals had similar morphology and vesicular content, but CVL efferent terminals were slightly larger than NTS efferent terminals. Overall, efferent terminals from either region were equally likely to contact adrenergic neurons in the RVL (21% for NTS; 25% for CVL). While efferents from both regions formed symmetric synapses, NTS efferent terminals were more likely to form asymmetric synapses than CVL efferent terminals. CVL efferent terminals were more likely to contact adrenergic somata than were NTS efferents, which usually contacted dendrites. These findings (1) support the hypothesis that a portion of NTS efferents to the RVL may be involved in sympathoexcitatory, e.g. chemoreceptor, reflexes (via asymmetric synapses) while those from CVL mediate sympathoinhibition (via symmetric synapses) exclusively; and (2) provide an anatomical substrate for differential postsynaptic modulation of C1 neurons by projections from the NTS and CVL. With their more frequent somatic localization, CVL inhibitory inputs may be more influential than excitatory NTS inputs in determining the discharge of RVL neurons. (Support: NIH #HL18974; Amer. Heart Assoc. Grant-in-Aid to SAA).

ADENOSINE INHIBITS RETICULOSPINAL VASOMOTOR NEURONS OF ROSTRAL VENTROLATERAL MEDULLA AND DOES NOT MEDIATE THEIR EXCITATION BY HYPOXIA IN VIVO. M.-K. Sun* & D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York,

Reticulospinal vasomotor neurons of the rostroventrolateral reticular nucleus (RVL) are excited by acute hypoxia even after peripheral chemodenervation (Sun, *Prog. Neurobiol.* **47:** 157-233, 1995). Their membrane response *in vitro* is not abolished by blocking synaptic transmission with tetrodotoxin (Sun & Reis, J. Physiol. Lond. 476: 101-116 1994), suggesting their role as central oxygen-detectors. Synaptic blockade, however, may not affect release of excitatory amino acids (EAAs) and/or adenosine through non-synaptic mechanisms. Blocking EAAergic inputs onto RVL-spinal vasomotor neurons has been shown to have no effect on the hypoxic sympathoexcitatory pressor responses in vivo. Whether adenosine may mediate sympathoexcitatory pressor responses was investigated in chemodenervated rats in vivo. Microiontophoresis of adenosine onto RVLspinal vasomotor neurons inhibited the neurons and microinjection of adenosine into RVL produced a depressor response. Both were abolished by an i.c. injection of adenosine deaminase. The i.c. adenosine deaminase, however, did not attenuate the excitatory responses of RVL-spinal vasomotor and sympathetic neurons and the associated pressor response consistent with our *in vitro* observations. We conclude that (a) excitatory responses of RVL-spinal vasomotor neurons to acute hypoxia are not mediated by adenosine and (b) RVL-spinal vasomotor neurons are central oxygen detectors responsible for the initiation of the excitatory pressor responses of the sympathetic nervous system to acute hypoxia. A5 NEURONS IN NEONATAL RATS: AUTOACTIVITY AND SENSITIVITY TO α2-ADRENERGIC RECEPTOR AGONISTS. D. Huangfu*, and P. G. Guyenet. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

Tyrosine-hydroxylase-immunoreactive (TH-ir) cells of the ventrolateral pons (A5 cells) control autonomic functions and nociception. The electrophysiological properties of spinally-projecting A5 cells were analyzed in brain slices of neonatal rats (age 3-10 days) with whole-cell patch-clamp techniques (electrodes containing Lucifer yellow). Cells were identified in the living slice by the presence of retrogradely transported fluorescent microbeads injected in the thoracic spinal cord 1 or 2 days after birth and their catecholaminergic phenotype was confirmed by immunohistochemistry posthoc (presence of TH-ir and Lucifer yellow). 69% of the spinally-projecting cells recorded (n=36) were TH-ir. 83% of A5 cells were spontaneously active (0.1- 6 spikes/s), their average interspike membrane potential was -63.1±1.6 mV and their input resistance 0.76±0.11 GΩ. Most cells displayed a regular pacemaker-like pattern at rest. Perfusion with a mixture of blockers of ionotropic receptors (kynurenic acid, bicuculline and strychnine) eliminated PSPs but did not reduce the spontaneous activity of the cells significantly (n=5). Slow membrane oscillations were observed when the cells were slightly hyperpolarized. These oscillations persisted when PSPs were eliminated with the mixture of postsynaptic blockers or with 1 µM TTX (n=5). Under voltage clamp (-55 to -60 mV; $1\mu M$ TTX) $1~\mu M$ clonidine, $10~\mu M$ α methylnorepinephrine or 10 μM UK-14304 produced outward current (5-25 pA) in most A5 cells (14/17). Conclusion: A5 neurons have intrinsic pacemaker properties and possess autoinhibitory α2-adrenergic receptors

DIFFERENTIAL INDUCTION OF FOS-IMMUNOREACTIVITY IN HINDBRAIN CATECHOLAMINE (CA) CELL GROUPS BY SYSTEMIC 2-DEOXY-D-GLUCOSE (2DG)-INDUCED GLUCOPRIVATION. T.T. Dinh* and S. Ritter. Department of VCAPP, Washington State University, Pullman, WA 99164.

Decreased intracellular glucose utilization stimulates a number of physiological responses including increased food intake and adrenal medullary secretion. Central CA neurons appear to be involved in these responses: glucoprivation increases turnover of norepinephrine in the hypothalamus; hypothalamic norepinephrine stimulates feeding; hindbrain catecholamine neurons of the A1/C1 and A5 cell groups directly innervate sympathetic preganglionic neurons that project to the adrenal medulla and are activated by glucoprivation. In this experiment, we examined the effect of systemic glucoprivation on Fos-immunoreactivity (-ir) in brainstem CA neurons. The non-metabolizable glucose analogue, 2DG (200 mg/kg), was used to block glucose utilization. Rats were killed 2 hrs after 2DG or saline injection and prepared for immunohistochemistry. Brain sections were double labeled to reveal tyrosine hydroxylase (TH)- and Fos-ir. Neurons in the caudal part of the A1/C1 cell group, some in A6 and a few in C3 along the floor of the 4th ventricle contained both labels. However, rostral C1, A2/C2 A5 and A7 TH-ir neurons did not express Fos in response to 2DG. Saline control injections did not induce c-fos. Results indicate differential involvement of hindbrain CA neurons in responses to glucoprivation. Supported by PHS grant 40498.

IMMUNOLABELLING OF IONOTROPIC AND METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES IN RAT DORSOMEDIAL AND VENTROLATERAL MEDULLA, E.K.A. Corbett, T.F.C. Batten, S. Saha, and P.N. M°William*. Institute for Cardiovascular Research, Leeds University, Leeds LS2 9JT, U.K.

Central cardiovascular regulation at brain stem sites including the nucleus tractus solitarii (NTS), nucleus ambiguus (NA) and ventrolateral medulla (VLM), involves the release of the excitatory amino acid (EAA) glutamate, and its action at both ionotropic and metabotropic EAA receptor subtypes (FJ Gordon, 1995, Clin Exp Hypertens 17: 81). We have investigated the presence of immunoreactivity (IR) for different GluR subtypes or subunits on neurons in the NTS/ dorsal motor vagal (DMVN) complex, the NA, and VLM catecholamine cell areas, using antibodies specific for AMPA subunits (GluR1, 2/3 & 4), kainate subunits (GluR5,6/7 & KA2), NMDA subunits (NMDAR1 & 2A/B), and for the metabotropic subtypes (mGluR1a, 2/3 & 5). Vibratome sections of rat brains perfused with paraformaldehyde/glutaraldehyde mixtures were immunolabelled for receptor subunits using ABC-peroxidase techniques. Sections were dual labelled with antibodies to choline acetyltransferase (ChAT), tyrosine hydroxylase (TH), or nitric oxide synthase (NOS), using alkaline phosphatase conjugated IgGs to label known cell groups with a blue product. Subsets of cell bodies in NTS, NA and VLM labelled strongly for GluRs 1-4, moderately for NMDAR1, but only weakly for NMDAR2A/B. Kainate subunit-IR was markedly stronger in NA and VLM neurons than in NTS neurons. Antibodies to mGluRs also gave characteristic labelling patterns, with the comparative labelling intensity of fibre terminals in NTS and surrounding NA and VLM neurons being mGluR2/3 > mGluR5 > mGluR1 α . Through this study we have begun a mapping of the complex distributions and combinations of GluR molecules on specific neuronal populations in the medulla concerned with cardiovascular and other autonomic control mechanisms.

CARDIOVASCULAR & RESPIRATORY RESPONSES TO ACTIVATION OF A5 PONTINE NEURONS OF THE ANAESTHETIZED RAT. J.P.Lara, M.S. Dawid-Milner, P. López de Miguel, J.A. Aguirre*, K.M. Spyer & S. González-Barón. Dept. of Physiology. School of Medicine. 29080 Málaga (SPAIN).

The role of A5 neurons in cardiovascular regulation is controversial, but very little

is known of its respiratory role. In this study both electrical stimulation (20 $\mu A,\,0.4$ ms pulses, 50 Hz for 5 s) and glutamate microinjections (20 nl, 100 mM, pH 7.4 ± 0.1) were delivered to the A5 region using multibarrel electrodes to characterize its cardiorespiratory function. Experiments were performed in anaesthetized rats (Pentobarbitone, 60 mg kg⁻¹, i.p.). Phrenic nerve activity and blood pressure were recorded. In all cases, electrical stimulation elicited an increase in both blood pressure (p<0.001) and heart rate (p<0.05). The response to glutamate was variable. In 21 animals, glutamate evoked increases of blood pressure (p<0.05) and heart rate (p<0.05). In 6 animals, the response was biphasic with a transient pressor response (p<0.05) followed by a small depressor response (p<0.05). The depressor component of the biphasic response was not elicited by baroreflex activation as the increase in heart rate (p<0.05) was maintained during both phases. In 1 animal, glutamate evoked a depressor response. No topographical organization of these responses was evident. This diversity of cardiovascular responses may reflect the diversity of neurons located within the limits of the A5 region although, a predominant sympatoexcitatory role was demonstrated. These stimuli always produced an expiratory facilitatory response: a decrease in respiratory rate (p<0.01) due to an increase of expiratory time (p<0.01). The respiratory response to electrical and chemical stimulation persisted after blocking the cardiovascular changes with guanethidine (10 mg kg², i.v.). These results add new data regarding the cardiorespiratory role of the A5 pontine region.

IMIDAZOLINE RECEPTORS COUPLE TO PHOSPHATIDYLCHOLINE-SELECTIVE PHOSPHOLIPASE C TO GENERATE DIACYLGLYCERIDE AND TO ELICIT VASODEPRESSION IN ROSTRAL VENTROLATERAL MEDULLA. P. Ernsberger. D Separovic, M Kester & MA Haxhiu. Case Western Reserve Univ, Cleveland OH 44106

Imidazoline receptors of the I₁-subtype (I₁R) selectively bind the agonist moxonidine and the antagonist efaroxan, and are expressed in the rostral ventrolateral medulla (RVLM) where they mediate vasodepression. In pheochromocytoma PC12 cells, I_1R are expressed in the plasma membrane in the absence of α_2 -adrenergic receptors, which also bind moxonidine and efaroxan. Knowing I_1R are not coupled to cAMP, cGMP or inositol(PO4) synthesis, we sought to define I, R's signaling pathway. PC12 cells were treated with moxonidine (1µM) for 15s to 10 min, and diacylglyceride (DAG) was measured in two ways: formation of [³H]DAG from [³H]myristate-labeled phosphatidylcholine (PC), and cellular mass of DAG (DAG kinase method). Phospholipase D (PLD) was assayed as [³H]phosphatidylethanol accumulation. PC-selective phospholipase C (PC-PLC) was assayed by release of [³H]choline-PO₄ Moxonidine increased [³H]DAG by 39±13% at 1min. Total cellular DAG increased 32±10% at 15s. Differentiation with nerve growth factor (50 ng/ml for 36h) potentiated the DAG mass increase at 15s (to 69± 12%) and prolonged it >10min. DAG accumulation was dose-dependent (EC $_{s0}$ =0.27±0.09μM) and efaroxan (1μM) was a competitive antagonist (apparent EC $_{s0}$ =2.4±0.5μM). The α2-antagonist SK&F86466 (10μM) had no effect. The selective PC-PLC inhibitor D609 (100μM) abolished the rise in DAG mass. Moxonidine elicited a 41% rise in l'Hlcholine-PO₄ release, which also was blocked by D609. Moxonidine neither released [3H]choline nor activated PLD. Microinjection moxonidi

of D609 (10 nmol) into the RVLM of SHR rats abolished the vasodepressor response to iv moxonidine (40µg//kg). All data support the model shown, implicating PC-PLC in the cellular and organismic response to 1₁R stimulation. *Support*:R29HL44514

VENTRAL MEDULLARY ADMINISTRATION OF AN OPIOID AGONIST MODULATES THE CARDIOVASCULAR RESPONSES DURING STATIC MUSCLE CONTRACTION, D.C. Caringi, D.J. Mokler, D. Koester, and A. Ally*. Departments of Pharmacology, Biochemistry & Anatomy, University of New England, College of Medicine, Biddeford, ME 04005

Static muscle contraction evokes increases in mean arterial pressure (MAP) and heart rate (HR) in anesthetized animals. It has been reported that activation of opioid receptors in the dorsal horn of the spinal cord attenuates these cardiovascular responses during muscle contraction. The present study determined the effects of administering the μ -opioid agonist [D-Ala2]-methionine enkephalinamide (DAME, 100 μ M) into the ventrolateral medulla (VLM) on the cardiovascular responses elicited during static contraction of the triceps surae muscle using chloral hydrate-anesthetized Sprague Dawley rats. Two microdialysis probes were inserted into the VLM at co-ordinates AP:-2.2; L:+1.9; H: -2.6 with respect to the calamus scriptorius using a stereotaxic guide. Static muscle contraction, evoked by stimulation of the tibial nerve at 3 X motor threshold, 0.1 msec duration, and 40 Hz frequency for 30 sec, increased mean arterial pressure (MAP) and heart rate by 22 ± 1 mmHg and 24 ± 1 bpm, respectively (n=5). The developed tension during the contraction was 384 ± 50 g. Microdialysis of DAME for 40 min attenuated the contraction-evoked increase in MAP and HR (7 ± 3 mmHg and 10 ± 3 bpm). Developed tension did not change during contraction before and after microdialyzing DAME (372 ±58 g). Prior administration of an equimolar concentration of paloxone, an opioid antagonist, blocked the attenuating effects of subsequent microdialysis of DAME. These results suggest that activation of opioid receptors within the VLM appear to play a role in modulating the cardiovascular responses during static muscle contraction.

EXPRESSION OF C-FOS PROTEIN IMMUNOREACTIVITY FOLLOWING PARTIAL BRAIN ISCHEMIA. Sexcius, L.M.*¹, Trouth, C.O.¹, Douglas, R.M.¹, James, S.D.¹, Valladares, E.R.¹, Khansari, P.¹, Peters, J.W.¹ and McKenzie, J.C.². Departments of 1. Physiology and Biophysics and 2. Anatomy, Howard University College of Medicine, Washington, D.C. 20059.

Cerebral ischemia produces a powerful vasomotor response. In this experiment, the expression of c-Fos was examined by immunocytochemistry following permanent occlusion of the right common carotid artery in rats. Histological examination demonstrated the localization of a few c-fos positive cells, along the caudal and rostral VMS, in the A1 and C1 areas, in the NTS, in the locus coeruleus and in the hypothalamus, regions that have been implicated in cardiorespiratory control. These results indicate that centrally induced hypoxia stimulates cells in brainstem cardiorespiratory control sites as well chemosensitive sites at the ventral surface.

FOS EXPRESSION DEFINES NEURAL SUBSTRATES MEDIATING AUTONOMIC RESPONSES TO AIR PUFF STARTLE. A. A. Palmer, M. P. Printz *, Dept. of Pharm., UC, San Diego La Jolla CA 92093-0636

SHR and WKY rats show a differential heart rate and blood pressure response when subjected to air puff startle. Prior studies in our lab indicate that this difference is mediated by the CNS. To determine which brain regions account for the air puff startle response, and the strain differences in the response, we used immunohistochemical labeling for for protein in rat brains in both strains after either startle or chamber restraint, but no startle. A subset of animals from all groups were habituated to the test chamber environment prior to the day of testing Our results show an elevation of fos positive neurons following startle in the following brain regions: RVLM, DCo, VCo, LC, KF, DLL, LDTg, DCG, MGN, PRC, PVA, LH, VMH, DM, PVN, MPA, and LPO (p 0.05). Additionally, we found that there was a strain dependent difference in the fos response in NTS, RVLM, LC, LH, VMH, and DM with SHR showing a greater response than WKY (p < 0.05). Habituation showed an effect only in the RVLM (p \leq 0.05). Interestingly, heart rate, blood pressure, and motor responses were unchanged by habituation. These data identify a diverse group of brain regions activated following the delivery of the air puff startle stimulus, and indicate some brain stem and hypothalamic regions are differentially activated in the two strains. This work supported by NIH HL 35018.

CARDIOVASCULAR EFFECTS OF NITRIC OXIDE AND ADENOSINE IN RAT BRAINSTEM NUCLEI. C. J. Tseng*, W. J. Lo, H. C. Lin and C. S. Tung. Department of Medical Education & Research, Venterans General Hospital-Kaohsiung: Departments. of Pharmacology & Physiology, National Defense Medical Center, Taipei, Taiwan, R.O.C.

Nitric oxide (NO) functions as a second messenger and neurotransmitter in the central and peripheral nervous systems. We reported recently that microinjection of L-arginine (L-Arg) into the Nucleus Tractus Solitarii (NTS) or rostral ventrolateral medulla produced inhibition of blood pressure, heart rate and sympathetic nerve activity. The purpose of the present study was to investigate the possible interaction of NO and adenosine in the NTS. In normotensive Sprague-Dawley rats, intra-NTS microinjection of L-Arg (33 nmol/60 nl) decreased blood pressure and heart rate. These effects were attenuated by prior administration of the specific adenosine receptor antagonist 1,3-dipropyl-8-p-sulfophenyl-xanthine (0.92 nmol). Similarly, prior administration of NO synthase inhibitor NG-methyl-L-arginine or NG-nitro-L-arginine methyl ester significantly attenuated the depressor and bradycardic effect of adenosine (2.3 nmol/60 nl). These results demonstrate a reciprocal attenuation of adenosine receptor antagonist and NO synthase inhibitor on L-Arg and adenosine responses respectively in the brainstem nuclei and suggest that there is an interaction between NO and adenosine in central cardiovascular regulation.

IMAGING OF VENTRAL MEDULLARY SURFACE CHANGES IN THE FREELY BEHAVING CAT. D.M. Rector*, M. Oguri and R.M. Harper. Dept. Neurobiology, UCLA, Los Angeles, CA 90095; Toho University, Tokyo, Japan.

We examined ventral medullary surface (VMS) activity during sleep-waking states and pressor and depressor challenges with imaging procedures. Under sterile surgery, cats were instrumented with electrodes to monitor sleep physiology and with a miniaturized video camera coupled to a coherent fiber probe and a narrow bandwidth illuminator with two wavelengths: red light (700nm), optimized for cell volume changes, and green light (565nm) which is preferentially responsive to perfusion changes. The probe was placed over a 7 mm² intermediate VMS area, and a 96 by 82 pixel image was acquired (12 bits, 100Hz) with alternating wavelengths. Cardiac and respiratory sources could be detected (0.01% peak to peak), as well as pronounced baseline state effects. Large slow oscillations, 0.05% in magnitude, emerged for both red and green light illumination during rapid eye movement sleep (REMS), and not during quiet sleep (QS). Noise-evoked arousal from QS caused a 0.3% drop in reflectance for both wavelengths. A 20µg/kg phenylephrine pressor challenge caused a sustained increase in green light reflectance and a biphasic response in red light reflectance. Depressor challenges with 25µg/kg nitroprusside caused a sustained reflectance decrease in both wavelengths in all states. Light reflectance changes from the VMS during sleep and pressor challenges are both wavelength- and behavioral state-dependent. (Supported by HL-22418 and NIDR DE-07212)

INPUTS FROM THE CAUDAL VENTROLATERAL MEDULLA TO THE LATERAL TEGMENTAL FIELD OF THE CAT: A POSSIBLE BRAINSTEM CIRCUIT FOR VESTIBULOSYMPATHETIC REFLEXES, B.C. Steinbacher

LATERAL TEGMENTAL FIELD OF THE CAT: A POSSIBLE BRAINSTEM CIRCUIT FOR VESTIBULOSYMPATHETIC REFLEXES, B.C. Steinbacher 17**, S.D. Stocker, C.D. Balaban and B.J. Yates. Dept. of Otolaryngology, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA. 15213.

Previous studies have demonstrated that cardioregulatory areas of the brainstem receive input from vestibular afferents. Activation of the otolith organs in the rose-up" direction has been shown to drive an increase in sympathetic nerve activity and a concomitant increase in blood pressure. From electrophysiological studies it has been shown that cells in the caudal ventrolateral medulla (CVLM) respond to activation of vestibular afferents with a short latency response. Neurons in the CVLM have a distinct inhibitory projection to the rostral ventrolateral medulla (RVLM). Since the RVLM projects to sympathetic preganglionic neurons in the thoracic spinal cord, it was initially hypothesized that vestibular information which drives an increase in sympathetic activity is relayed to cells in the RVLM through the same barosensitive cells located in the CVLM. However, two populations of cells exist in an overlapping region in the CVLM: 1) A group of cells which respond to vestibular activation could be antidromically activated from the RVLM. In order to identify what other areas of the brainstem flex collaboration of the projections, the anterograde tracer Phaseolus vulgaris leucoagglutinin and the anterograde/retrograde tracer dextramethylrhodamine were microionophoretically injected into discrete areas of the CVLM. Results of this labeling pattern confirm that there is dense projection to the LTF. Serial sections of tissue were additionally stained with an antibody to tyrosine hydroxylase to determine if PHA-L labeling overlapped central catecholaminergic containing areas of the brainstem corresponding to the A1, A5, A2, C1 regions and the locus ceruleus. These results provide a possible pathway for which cells in the CVLM could relay vestibular interest and the CVLM. As

CHANGES IN GENE EXPRESSION OF NEURONAL NITRIC OXIDE SYNTHASE (nNOS) IN HYPOTHALAMUS AND BRAINSTEM OF ADULT RATS WITH SPONTANEOUS HYPERTENSION. T.L. Krukoff* and D. Plochocka-Zulinska. Dept. of Anatomy & Cell Biology, Faculty of Medicine, Univ. of Alberta, Edmonton, Canada T6G 2H7.

Nitric oxide (NO) has been implicated in a variety of neuronal functions including regulation of sympathetic outflow and cardiovascular activity. We have previously shown that gene expression of nNOS, the synthetic enzyme of NO in neurons, is altered in discrete brain regions of renal hypertensive rats. To determine if the brain NO system is also altered in association with genetic hypertension, we measured levels of nNOS gene expression in discrete areas of the brain from spontaneously hypertensive rats (SHRs) at pre-hypertensive (4 week) and hypertensive (14 week) stages. Levels of nNOS mRNA in hypothalamus (HYP), dorsal pons (DP), dorsal medulla (DM), rostral ventrolateral medulla (RVLM), and caudal ventrolateral (CVLM) were measured with semi-quantitative polymerase chain reaction and compared to levels in control Wistar-Kyoto (WKY) and Sprague-Dawley (SD) rats. In 4 week rats, no significant changes in nNOS gene expression were found in any brain region among the groups. In 14 week rats, significant increases in nNOS mRNA levels were found in the following areas from SHR brains: HYP (56% increase compared to WKY, 104% increase compared to SD), DM (27%, WKY; 45% SD), and CVLM (23%, WKY; 27%, SD). No significant differences were found in the DP or RVLM. In situ hybridization revealed that, in the HYP, increases in nNOS mRNA levels occurred primarily in the paraventricular (parvo- and magnocellular divisions) and supraoptic nuclei. The results suggest that NO production is increased in response to elevated arterial pressure in hypothalamus and brainstem of adult SHRs and support the hypothesis that NO is involved in regulating sympathetic output to the periphery Supported by the MRC and Heart and Stroke Foundation of Canada

Neurons in the fastigial pressor area project fibers to the lower medulla in the common tree shrews. (Tupaia glis). W.Singhaniyom¹, M.Phoglin., P.Kanluan., R.Sudsuang, P.Boonsinsuk and S.Casalotti*; ¹Faculty of Medicine, Srinakharinwirot University, Bangkok and *Neuro-behavioral centre, Mahidol University, Nakornpathom, Thailand.

Previous reports have shown the influence of the fastigial nucleus on arterial blood pressure(ABP) and heart rate(HR) in various animals. However, no information reveals on the precise area of the nucleus responsible for the activities including mechanism underlying the actions. Electrical simulations of of the nucleus in the rostro-caudal direction reveal the highest ABP and HR response in the rostral area (430 umposterior to the rostral pole) while the lesser response was obtained in the middle area (430-640 um) and no response in the caudal area (640-1,200 um). Simultaneous electrical stimulatios and injections of biocytin(30 picolitre) through glass micropipette into the three areas with 12-16 hours survival time. Then, the brainstem were vibratome sectioned (100 um) and processed for biocytin localization. The labelled fibres were found to project bilaterally from the nucleus only after injection into the rostral and middle areas. They are observed just dorsal to the brachium conjunctivum and curved dorso ventrally between the spinal tract of the trigeminal nerve(TSV) and brachium pontis toward the lateral boundary of the superior olivary nucleus(OS). At the caudal level of OS the fibers are splitted into the upper and lower groups. The upper group are observed between the superior vestibular nucleus and the inferior cerebellar peduncle(ICP), and then in ICP caudally . The lower one project caudally occupied the area near the edge of the section between the OS and pyramidal tract. Caudally, the fibres in the ICP move ventrally and along the lateral boundary of the TSV and join the lower group. The joined tract projects caudally toward the medulla and spinal cord. The results suggest the nucleus may exert the cardiovascular effects partly through this tract. (Supported by Srinakharinwirot University)

BRAINSTEM TUMORS IMPAIR CARDIAC SYMPATHOVAGAL BALANCE.
C. Cogliati*, S. Guzzetti, S. Marzorati, R. Magatelli, N. Montano, A. Malliani, Medicina Interna II, Ospedale L.Sacco University of Milan & Div. di Neurianimazione, Ospedale Maggiore, Milano. Italy.
Brainstem represents the major site of integration of neural regulation

of cardiovascular function. To evaluate the contribution of some of its structures to the sympatho-vagal balance, we evaluated heart rate variability (HRV) and its oscillatory components in 13 hospitalized subjects with tumoral brainstem lesions before neurosurgery intervention and in 10 control subjects (C) of similar age. All patients were studied with TC scan or NMR for a precise description of the localization of the lesion. ECG was recorded for 30 min at rest. Patients enrolled in the study were not in therapy with medications interfering with autonomic function. Three patients (Group A) presented a lesion in the ponto-cerebellar region, on the dorsal surface of the brainstem, while the remaining (n = 10; Group B) had a more diffuse localization within the ventral part. Group B displayed a significantly lower RR interval compared to C $(684 \pm 36 \text{ vs. } 990 \pm 28 \text{ significantly lower})$ msec; p<0.05). Moreover both groups A and B had a significant reduction in total HRV (respectively, 598 ± 254 and 450 ± 232 msec²) compared to C $(2399 \pm 423 \text{ msec}^2; p < 0.01)$. A clear difference was found in the ratio between LF (Low Frequency, around 0.1 Hz) and HF (High Frequency, synchronous with respiration) spectral components, considered an index of the sympathovagal balance (Group A: 0.45 ± 0.15 , B: 5.98 ± 1.5 vs. C:1.55 ±0.25 ; p<0.01). In conclusion, while a sympathetic predominance to accompany diffuse ventral brainstem lesions, predominance characterizes patients in whom expansive lesions were likely to involve structures regulating vagal modulation.

AUTORADIOGRAPHIC QUANTIFICATION OF CHOLECYSTOKININ RECEPTORS IN CARDIOMYOPATHIC AND SYRIAN HAMSTER BRAIN. S. Meranit, T.V. Dam?, R.M.Palmour, F.R.Evini and J.Gutkowskaz, 1Depts. Biology and Psychiatry, McGill Unity, McGill Unity, Hashibal Living Hamilton, 1974 1412 Cardiovascular Biochamistry, Hatal Diau Hashibal Hamilton, 1974 1412 Canada

H3A 1A1; ²Cardiovascular Biochemistry, Hotel-Dieu Hospital, H2W 1T8, Montreal, Canada. Quantitative *in vitro* autoradiography was used to examine cholecystokinin (CCK) receptor density in the cardiomyopathic and Syrian hamster brain. The cardiomyopathic hamster, an inbred strain of the Syrian hamster, is a paradigm for the cardiac necrosis that occurs in certain human myocardial diseases. Although the exact neuronal mechanisms in cardiomyopathy are not established, recent findings indicate increased catecholaminergic and serotonergic immunoreactivity in this model. CCK is a gastrointestinal and neuropeptide that has been implicated in both physiological and behavioral processes and is one of the most abundant peptides in the central nervous system. Previous studies indicate that neuronal CCK release is mediated by the 5-HT system. Furthermore, CCK is implicated in the etiology of panic disorder, a psychiatric illness that has been associated with idiopathic cardiomyopathy and which may be accompanied by cardiovascular abnormalities such as reduced heart rate variability, decreased plasma noradrenalin, increased cardiac left ventricular mass and mitral valve prolapse. In the present study, the distribution and density of neuronal CCK receptors in cardiomyopathy were investigated.

125I-CCK-8 binding was examined in coronal and saggital brain sections of age- and sex-matched cardiomyopathic and Syrian hamsters, using unlabelled CCK-4 and CCK-8 as competitors. Binding profiles revealed high density labeling in the cortex and olfactory bulb, while moderate binding was observed in the hypothalamus, thalamus, amygdala, striatum and hippocampus. CCK receptor density was comparable in 30-day old cardiomyopathic and control animals. Increased CCK binding in the frontal cortex was observed in 120-day old cardiomyopathic hamsters as compared to age-matched controls. The results indicate that an altered CCK receptor density is present in the cardiomyopathic hamster brain and that this alteration is concomitant with the time-dependent progression of the disease.

CARDIOVASCULAR REGULATION: BLOOD PRESSURE REGULATION

338.1

Alterations in Stress-Responsiveness in the mRen2(27) Rat. M. Morris*, A.B. Lucion, P. Li, C. Barrett, D. Ganten, C.M. Ferrario and M.F. Callahan. Department of Physiology/Pharmacology and Hypertension Center, Wake Forest Univ., Winston Salem, NC, and Max Delbruck Center, Berlin-Buchs, FRG.

The mRen (27) transgenic model was used to study the influence of the renin angiotensin system on stress responsiveness. The effect of shaker stress on cardiovascular and endocrine parameters was evaluated in male Tg+ and Tg- rats either water replete or salt loaded (2 days of 2% NaCl). The rats were prepared with chronic arterial catheters. After recovery, they were exposed to the stress paradigm, 5 mins of shaking at 150 rpm, with measurement of mean arterial pressure (MAP), heart rate (HR) and plasma oxytocin (OT). The hypertensive Tg+ rats showed an exaggerated cardiovascular response to stress. MAP was increased 26.6±2.3mmHg as compared to 15.8±3.9mmHg (Tg+ vs Tg-). Salt consumption did not alter the magnitude of the pressure response. The tachycardia was also greater in the Tg+ than in the Tg- (74.4±10.3 vs 38.2±9.6 bpm) with a decreased response seen in the Tg+ rats consuming NaCl (48.7±11.1 vs 48.7±10.6 bpm). Stress produced an increase in plasma OT with no difference noted between the groups or with salt loading. The exaggerated MAP and HR stress responses in the Tg+ may be mediated by a greater sympathetic activation previously demonstrated in this model. (Supported by NIH HL51952 and AHA NC93-GS-15)

Blunted Baroreflex Control of Heart Rate in mRen2(27) Rats is Unaffected by NaCl Loading. M.F. Callahan*, D. Ganten, C.M. Ferrario and M. Morris. Department of Physiology and Pharmacology and The Hypertension Center, Wake Forest Univ., Winston Salem, NC, and Max Delbruck Center for Molecular Medicine, Berlin-Buchs, FRG.

The mRen2(27) transgenic rat (Tg+) shows increased arterial pressure and circulating angiotensin. We have shown that salt loading rapidly increases arterial pressure in these rats. We examined the effects of two days of salt loading (2%NaCl in drinking water) on pressor responsiveness and baroreflex function in Tg+ and Hanover Sprague Dawley controls. An aorta catheter was used to measure mean pressure (MAP) and a jugular vein catheter was used to give phenylephrine (0.25-1.25 μ g). The regression of the change in pulse interval on the pressor effect was determined.

At baseline, MAP was significantly elevated in Tg+ rats(130±13 v. 89±3 mmHg). Tg+ rats showed elevated phenylephrine pressor response (62±10 v. 41±9) and blunting of the slope of the reflex curve (0.6±0.2 v. 2.7±0.3). Salt loading increased MAP in the Tg+ rats (147±13 mmHg) but had no effect on pressure in the controls (76±3). Salt loading had no significant effect on the slope of baroreflex curve but tended to diminish the pressor responsiveness. The results indicate that acute salt loading is not associated with a worsening of baroreflex function in mRen2 transgenic rats.(Supported by NIH iNL51952 and AHA NC93-GS-15)

BLOOD PRESSURE OF MREN-2 RATS IS A FUNCTION OF SALT INTAKE. S. Sesoko, D.B. Averill, D. Ganten, D.I. Diz*, and C.M. Ferrario. Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC

Replacement of drinking water with 2% NaCl exacerbates the hypertension of mRen-2 transgenic (TG) rats. The objective of the current study was to determine whether salt restriction of mRen-2 TG rats caused a commensurate change in blood pressure. Adult (12 weeks) male mRen-2 TG rats (n=4) were instrumented for the measurement of blood pressure and heart rate by telemetry Rats were placed in metabolic cages and fed a diet containing 0.13% NaCl (low salt) for twelve days. The diet was then changed to one containing 0.5% NaCl (normal salt) and rats kept on this diet for 6 days. Rats had access to water ad libitum. Blood pressure and heart rate for the last three days of low salt averaged 176 \pm 3 (SEM) mm Hg and 350 \pm 9 beats/min, respectively, whereas by the last three days of normal salt intake blood pressure and heart rate were 193 ± 3 mm Hg and 355 ± 8 beats/min, respectively. This represented a significant (p<0.01) increase in blood pressure. The change to a normal salt diet was also associated with a significant increase in water intake (52 ± 1 ml/day vs 69 ± 1 ml/day, p=0.0001), but body weight was unchanged. The results of this study demonstrate that reduction of salt intake and an associated decrease in water intake ameliorates the hypertension of mRen-2 TG rats. In conclusion, these data demonstrate that mRen-2 TG are salt sensitive on the basis of blood pressure changes commensurate with salt intake. Supported in part by NIH HL51952

EVIDENCE THAT 5-HT $_{\rm ID\alpha}$ and 5-HT $_{\rm IA}$ receptors play a similar role in central cardiovascular regulation in ANAESTHETIZED RATS. M. Gallacher and A.G. Ramage. * Department of Pharmacology, Royal Free Hospital School of Medicine, London, NW3 2PF., U.K.

The regional haemodynamic effects of the 5-HT, receptor agonists DP-5-CT (1A; 3 nmol kg⁻¹) and sumatriptan (1B/1D; 10 nmol kg⁻¹) given i.c.v. (5µl over 20s) were compared in anaesthetized Sprague-Dawley (250-350g) rats. This comparison was carried out in the presence of the following 5-HT₁ receptor antagonists, 100 or 200 nmol kg⁻¹ i.c.v. of WAY-100635 (1A) and/or 600 nmol kg⁻¹ (i.v.) of GR127935 (1B/1D), mianserin or ketanserin (1D α). The rats were anaesthetized with α chloralose (80 mg kg⁻¹) after induction with halothane and artificially ventilated following neuromuscular blockade with decamethonium. BP and HR were measured from the carotid artery. Doppler flow probes were placed on the mesenteric (M) and renal (R) arteries and the abdominal aorta (hindquarters, H,

flow) from which changes (%) in vacular conductance (C) were calculated.

DP-5-CT (n=6) and sumatriptan (n=5) caused immediate and significant (p 0.05; ANOVA) increases in BP of 10±2 and 14±1 mmHg and HR of 124±17 & 56± 24 bpm and decreases in MC of 10 ± 1 & 14 ± 1 %, respectively. GR127935 blocked the effects of sumatriptan but not those of DP-5-CT. In the presence of WAY (100 nmol kg⁻¹) DP-5-CT and sumatriptan caused delayed falls in BP and only the DP-5-CT tachycardia was reduced to 43±4 bpm. The high dose of WAY abolished the effect of DP-5-CT on BP, however the depressor effect of sumatriptan was unaffected. Both drugs still caused a similar tachycardia. The sumatriptan depressor effect could be blocked by the addition of GR127935, mianserin or ketanserin. Only mianserin blocked the sumatriptan induced tachycardia reversing it to bradycardia. These results indicated that activation of central 5-HT $_{1Da}$ receptors has a similar effect on blood pressure as 5-HT $_{1A}$ receptors, in the forebrain causing a rise while in the hindbrain a fall in BP. BRADYCARDIC EFFECT OF IMIDAZOLINE α_2 AGONISTS IS MEDIATED BY PERIPHERAL, PRE-SYNAPTIC α₂-ADRENOCEPTORS

MEDIATED BY PERIPHERAL, PRE-SYNAPTIC α2-ADRENOCEPTORS
IN RATS, I.P. Lillibridge & K.A. Skau*. The Procter & Gamble Co. and U. of Cincinnati College of Pharmacy, Cincinnati, OH.

Using in vitro and in situ models we investigated the brady-cardic effect of several imidazoline drugs. Clonidine, oxymetazoline and UK-14304 had no effect on the rate of isolated, spontaneously beating right atria at concentrations up to 10 μM, indicating that these drugs have no direct effect on cardiac rate. The peripherally selective benzimidazole PGE-6201204, which is a notent α2-α2-α201811 caused bradvezquia in which is a potent α2-agonist, caused bradycardia in pentobarbitol anesthetized rats; this bradycardia was not Thus, cholinergic reduced by acute bilateral vagotomy. Bradycardia by PGE-6201204 was attenuated by treatment with the β -antagonist atenolol and by chemical sympathectomy (iv 6-hydroxydopamine). Idazoxan antagonized the PGE-6201204 bradycardia at doses that inhibit α_2 -adrenoceptors but not at doses that inhibit imidazoline receptors. Likewise, RX-821002 blocked the bradycardia at doses that block α2-adrenoceptors. These results suggest that the bradycardic effect of PGE-6201204 and other imidazolines, is mediated by peripheral α_2 adrenoceptors possibly by reduction in norepinephrine secretion from cardioaccelerator nerves. MREN-2 TRANSGENIC RATS HAVE REDUCED SYMPATHETIC VASCULAR RESPONSE. D.B. Averill*, M. Brady, E. Eyler, D. Ganten, and C.M. Ferrario Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27257

Previous work from this laboratory has shown that enhanced sympathetic outflow may contribute to the hypertension of mRen-2 transgenic (TG) rats. The objective of the current study was to assess the vascular responsiveness of TG rats. Experiments were performed in TG (10-12 weeks old) and age matched Sprague-Dawley (SD) rats. Rats were anesthetized with halothane; catheters were inserted in a femoral artery and vein for measurement of blood pressure (BP) and injection of drugs, respectively. Rats were pithed with a stainless steel rod inserted along the length of the spinal cord. Immediately after pithing, rats were paralyzed, artificially ventilated, and removed from halothane. A second rod was inserted subcutaneously to serve as a ground return for electrical stimulation. A minimum of 1 hour was permitted for BP to stabilize (TG: 61 \pm 13 (SEM) mm Hg and SD: 56 \pm 2 mm Hg). Sympathetic responsiveness was assessed by measuring the BP response to graded electrical stimulation (40 V, 1 msec; 0.25, 0.5, 1, 2 and 4 Hz) of the spinal cord. Both TG and SD exhibited a frequency dependent increase in BP during spinal cord stimulation. However, the increase in BP produced by spinal cord stimulation was approximately 50% (p<0.001) of that obtained in SD. Vascular responsiveness was assessed by measuring the BP response to intravenous injection of phenylephrine (0.1, 0.2, 0.4, and 1.0 µg). In contrast to the diminished blood BP produced by spinal cord stimulation, the pressor response to each dose of phenylephrine was approximately 30% (p<0.001) larger in TG than in SD rats. These data suggest a defect exists in the sympathetic vasoconstrictor neuroeffector pathway that may be compensated by upregulation of $\alpha 1$ adrenergic receptors or nhanced signal transduction downstream from $\alpha 1$ adrenergic activation. in part by NIH HL51952.

338.6

INTRAVENOUS INFUSION OF MIVAZEROL, A NOVEL SELECTIVE ALPHA 2-ADRENOCEPTOR AGONIST, ATTENUATES THE TACHYCARDIC RESPONSE TO INTRATHECAL INJECTON OF NMDA, S.Y. Kim1, K. Raikoff1, E. Wülfert2 and I. Hanin14. Dept. Pharmacol., Loyola University Chicago Stritch School of Medicine, Maywood, IL 60153, and ²UCB Pharmaceutical Sector, Braine-L'Alleud, Belgium.

Our previous studies have shown that intravenous (i.v.) infusion of Mivazerol (MIV) produces a dose-related decrease in heart rate (HR) but not in blood pressure, suggesting that MIV has some specific effects different from those of "classical" hypotensive α_2 -adrenoceptor agonists. The present study was performed to investigate the mechanism of bradycardic action of MIV, focussing on the possibility of a functional interaction between spinal α_2 -adrenoceptors and Nmethyl-D-aspartic acid (NMDA) receptors, in the control of HR. Experiments were carried out in pentobarbital-anesthetized and respiratory assisted male Sprague-Dawley rats in which i.t. cannulae were implanted at the T₂ level 5 days earlier. The i.v. infusion of MIV (15.3 µg/kg/hr), which was maintained from 30 min earlier until the end of experiment, significantly attenuated the tachycardic response to intrathecal (i.t.) injection of NMDA (15 nmol/kg). When an α_2 -adrenoceptor antagonist yohimbine (150 nmol/kg, i.t) was administered 10 min before the i.v. infusion of MIV (15.3 μ g/kg/hr), the tachycardic response to i.t. injection of NMDA (15 nmol/kg) was significantly greater than that observed in the control group. In addition, co-administration of MIV (15.3 µg/kg/hr, i.v.) with the NMDA antagonist 2-amino-5-phosphonovaleric acid (150 nmol/kg, i.t), in doses that gave significant bradycardic responses, had no additive effect on the decrease in HR. These results suggest that: (1) the bradycardic effect due to i.v infusion of MIV is mediated, at least in part, by its inhibition of the postsynaptic response to NMDA in upper thoracic spinal segments; and (2) this effect of MIV is mediated by spinal α_2 -adrenoceptors. 338.8

CENTRAL PRESSOR AND TACHYCARDIC EFFECTS OF γ-MELANOCYTE SIMULATING HORMONE (γ-MSH) ARE MEDIATED BY AN AS YET UNIDENTIFIED MELANOCORTIN RECEPTOR (MC-R). S-J. Li, K. Varga, P. Archer, V.J. Hruby, S.D. Sharma, R.A. Kesterson, R.D. Cone and G. Kunos*. Dept. Pharmacol. & Toxicol., Med. Coll. of VA, Richmond, VA 23298

y-MSH is known to have potent pressor and tachycardic effects when γ -MSH is known to have potent pressor and tachycardic effects when injected intravenously into conscious rats, but the underlying mechanism is unknown (Hypertension 7 (Suppl I): 1145-1149,1985). The present experiments were conducted to identify the nature of the MC-R involved in the cardiovascular effects of γ -MSH. In urethane-anesthetized rats, intracarotid (ic.) injection of γ_2 -MSH elicited dose-dependent (0.1-12.5 mmol) pressor and tachycardic effects. Ic. injections of 1.25-12.5 nmol ACTH(4-10), a γ -MSH analog with minimal affinity for MC3-R or MC4-R, caused similar but smaller effects, whereas ic. injections of similar doses of α -MSH were without effect. The effects of γ_2 -MSH were much more propunged after ic. than after iv, injection, and were much more pronounced after ic. than after iv. injection, and were completely blocked by pretreatment with the ganglionic blocker mecamylamine (2 mg/kg, i.v.). Of the five MC-R cloned to date, MC3-R and MC4-R are expressed in brain, including regions involved in cardiovascular regulation. The novel, selective neural MC-R antagonist SHU9119 inhibits melanotropin effects at the cloned MC-3R and MC-4R at antagonist/agonist dose ratios of ≤1. SHU9119, 1,25-12.5 nmol ic., failed to alter the pressor and tachycardic effects of γ-MSH, 1.25 nmol ic. These findings indicate that γ₂-MSH increases BP and HR by increasing sympathetic outflow at a site(s) in the brain, and that the receptors mediating these effects are distinct from MC3-R or MC4-R.

CENTRAL NERVOUS SYSTEM ACTIONS OF UROCORTIN AND CORTICOTROPIN-RELEASING FACTOR ON CARDIOVASCULAR FUNCTION IN CONSCIOUS RATS. M.K. Borsody and L.A. Fisher*. Dept. of Physiology, The Ohio State Univ. Col. of Med., Columbus, OH 43210

Owing to its central nervous system (CNS) distribution and actions, coticotropin-releasing factor (CRF) is hypothesized to be utilized as a transmitter in neural pathways that mediate the endocrine, autonomic and behavioral responses to stressful stimuli. Urocortin (UCN) is a recently characterized mammalian neuropeptide comprised of 40 amino acids and sharing 45% sequence identity with CRF. While the neural distribution of UCN appears to be more restricted than that of CRF, UCN exhibits greater affinity than CRF for both CRF receptor subtypes in vitro. Therefore, the objective of the present study was to compare the CNS actions of CRF and UCN on autonomic nervous activity and cardiovascular function. All experiments were performed in conscious unrestrained male Sprague-Dawley rats (230-250 g) previously instrumented with intracerebroventricular (icv) cannulas for injection of vehicle (artificial CSF, 10 μ I) and test compounds (45, 150 and 450 pmol CRF or UCN) and with iliac arterial catheters for direct measurement of pulsatile arterial pressure (AP) and heart rate (HR). As expected, icv administration of CRF elicited dose-related elevations of AP and HR as well as behavioral changes consisting of intermittent episodes of grooming, chewing and tunneling under the cage bedding. Surprisingly, at all doses tested, icv administration of UCN produced considerably attenuated cardiovascular and behavioral changes compared to those evoked by CRF injection. In addition, icv administration of the highest dose of UCN (450 pmol) produced delayed reductions of AP, an effect not observed after injection of CRF. Supported by MH53720 and The Roessler Foundation.

BIPHASIC PRESSOR RESPONSE TO CENTRAL BLOCKADE OF NITRIC OXIDE SYNTHASE WITH L-NAME IS INDEPENDENT OF DRINKING BEHAVIOR AND THE ADRENAL GLANDS. H. Liu, M.L. Terrell, J.Y. Summy-Long and M. Kadekaro*. Div. of Neurosurgery, UTMB, Galveston, TX

and [†]Dept. of Pharmacology, Hershey Medical Ctr., Penn. State Univ., Hershey, PA. We have shown that intracerebroventricular (icv) blockade of nitric oxide (NO) synthase with N^d-nitro-L-arginine (L-NAME) attenuates drinking in dehydrated rats and increases arterial blood pressure (BP) in a biphasic mode in water sated and water deprived rats. The objective of this study was to investigate whether the drinking behavior or the absence of the adrenal glands modifies either of the pressor responses after central inhibition of NO production. Two studies were performed 1) In the first (n=35), two groups of rats were dehydrated for 24 h then injected icv with either L-NAME (250 µg/5 µl) or the vehicle, artificial cerebrospinal fluid (aCSF; 5 µl). Water was made available immediately after the icv injections in only half of the animals. 2) In the second (n=13), two groups of acutely adrenalectomized and water sated rats treated with dexamethasone (0.25 mg/kg, i.m.) received an icv injection of either L-NAME or aCSF. BP was recorded before and continuously for 120 min after injection. In dehydrated rats, L-NAME increased BP in a biphasic mode, regardless of whether the animals drank or not. The first peak occurred within 5 min and decayed in 15 min; the second began at 45 min, with a continual rise until the end of the experiment. In dehydrated rats receiving aCSF there was a difference in BP responses associated with drinking. In contrast to the stable levels in animals that did not drink, there was an initial transient rise in BP, as expected in response to drinking, followed by a continuous fall to levels below basal values by the end of the experiment. Adrenalectomy did not modify either pressor response to L-NAME. These results indicate that the biphasic pressor response to icv L-NAME is independent of drinking behavior and release of catecholamines from the adrenal glands. Funded by 2R01-NS23055 (MK).

ACUTE AND SUBACUTE ADRENALECTOMIES ALTER THE PRESSOR EFFECT OF INTRATHECAL VASOPRESSIN IN THE RAT, D.-P. Tan*# and K. Tsou. Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai 200031, China. #present address: Lab. of Biochemical Genetics, NHLBI, NIH, 9000 Rockville Pike, Bethesda, MD 20002, ISA

Biochemical Genetics, NHLBI, NIH, 9000 Rockville Pike, Bethesda, MD 20892, USA.

Previous reports from our group and others have shown that intrathecal injection (IT) of arginine vasopressin (AVP) increase the blood pressure of the rat. This pressor effect is mediated by the spinal V1 receptors and through the sympathetic nervous system. To study the role of the adrenal gland in the pressor effect of IT AVP, we used rats that were sham-operated, 2h or 48h adrenalectomized (ADX) and 48 h ADX with dexamethasone replacement (40 μg/kg/day). Two hour ADX did not change the basal blood pressure (2h ADX 93 ±5 mmHg vs sham-operated 85 ± 5 mmHg; p>0.05). When IT AVP 25 ng was given to 2h ADX rats, the pressor effect was reduced significantly (ΔMBP 27 ± 3 vs 15 ± 1.1 mmHg; p<0.01). This suggests the involvement of adrenal gland in the pressor effect of IT AVP. When IT AVP 25 ng was given to 48 h ADX rats, the pressor effect was not reduced but increased significantly (ΔMBP 27+3 vs 48±6 mmHg; p<0.05). Dexamethasone replacement reduced the increased pressor effect of IT AVP in 48h ADX rats (ΔMBP 28±5 vs 48±6 mmHg; p<0.05). There was no significant difference between the 2h and 48 h ADX rats when the pressor effect of the intravenous injection of nonadrenaline 1.5 μg were compared (ΔMBP 33±5 vs 29±2 mmHg; p>0.05). These data suggest that 1) the reduction of the effect of IT AVP in acute ADX rats is due to the elimination of adrenaline; 2) the increased pressor effect of IT AVP in 48h ADX rats is due to the hypersensitivity induced by the lack of glucocortical hormones; 3) blood vessels do not play a major part in the increased pressor effect of IT AVP in 48 h ADX rats.

Influence of NO synthetase inhibitor on the cardiovascular responses to dopamine and apomorphine in anesthetized rats. Nobufumi Ono*, Yuichi Ono, Hidenori Noguchi, Shuuji Hara, Misa Fukuzawa and Takeshi Kuroda. Medicinal Informatics and Research Units, Faculty of Pharmaceutical Sciences. Fukuoka University, Fukuoka, 814-80, Japan.

We examined the influence of NO synthetase inhibitor on the cardiovascular responses including in the regional blood flow (rBF) to dopamine agonists in urethane-anesthetized rats. The systemic blood pressure was measured from right femoral artery, heart rate from the pressure pulse, and rBF by laser doppler flowmetry under inhalation of O_2 . Non-nitro-L-argininemethylester (L-NAME, 10 mg/kg) administered intravenously increased blood pressure, although decreased heart rate, the rBF of right biceps femoral muscle and right auricle skin. Nitropurusside elicited the depressor effect. Dopamine produced the depressor action at a dose of 5 µg/kg, but the pressor actions at the range of 20-100 µg/kg. The depressor action of dopamine was abolished, and reversed to pressor action by L-NAME. The pressor actions of dopamine at high doses were potentiated by L-NAME. The dose-dependent depressor actions of apomorphine (0.1-1 mg/kg) were markedly inhibited by L-NAME. The duration of pressor response to norepinephrine and epinephrine, moreover, was potentiated by L-NAME, although the maximal response was not altered. These results suggest that L-NAME modifies the cardiovascular response to dopamine and NO may participate in the modulation of sympathetic nerve transmission.

VASOPRESSIN MICROINJECTION INTO THE RAT SUBFORNICAL ORGAN CAUSES DECREASES IN BLOOD PRESSURE. P.M. Smith, K. Sun*, and A.V. Ferguson. Dept. of Physiology, Queen's University, Kingston Ontario, Canada, K7L 3N6

Vasopressin (VP), in addition to its direct vasoconstrictor actions, has been shown to be involved in the central control of blood pressure (BP). This peptide has been implicated in the development of experimental and clinical hypertension as well as increasing the sensitivity of the baroreflex. The subfornical organ (SFO) is one of the seven circumventricular organs and, as is characteristic of these specialized central nervous system (CNS) structures, lacks the normal blood brain barrier, has an extensive vascular supply, and has a dense aggregation of a variety of peptidergic receptors, including VP. It is thus ideally suited to its primary role as a receptor site for blood borne information that would otherwise not have access to the CNS. SFO neurons influence neuroendocrine and cardiovascular systems through extensive efferent neural projections to hypothalamic autonomic nuclei (such as the PVN and SON) which secrete oxytocin and VP.

The present study was conducted to evaluate the cardiovascular effects of VP microinjection directly into the SFO. Urethane anaesthetized (1.4gkg) male Sprague Dawley rats were fitted with femoral arterial catheters for BP measurement. The animals were placed in a stereotaxic frame and a cannula electrode was advanced into the region of SFO. The effect on BP of 5 pmol (in 500nl) of VP microinjected into the region was assessed. The BP response for each animal was calculated as the mean area under the curve (area between the baseline and each BP response) for 165 sec following microinjection. Post mortem histological verification of electrode placement was performed and animals were grouped accordingly. Microinjection of 5 pmol of VP into the SFO resulted in a mean BP decrease of -626.8 \pm 161.4mmHg*sec* (p < .05, Student's t test). VP microinjection into Non-SFO sites or into the ventricle resulted in mean increases in BP of 322.9 \pm 218.1 mmHg*sec and 1417.1 \pm 448.6mmHg*sec* (p < .01, Student's t test), respectively. These results suggest that the SFO may be an essential structure in the feedback control loop through which VP influences hypoythalamic neurosecretory centres.

CENTRAL CARDIOVASCULAR CONTROL THROUGHOUT REPRODUCTION

Y. Takahashi and Q. J. Pittman*. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

In response to altered body water content during pregnancy and the demands of lactation, cardiovascular control mechanisms have to adapt to changing states. In addition, there are alterations in circulating hormone levels and in both the density and in the distribution of central neurotransmitter receptors involved in autonomic control mechanisms. We have measured cardiovascular variables in unanesthetized female rats at various times before and throughout the gestational and lactational periods. Rats were instrumented with chronic indwelling vascular canulae attached to radio telemetry devices permitting chronic telemetric recording of blood pressure in unstressed, freely moving rats. In addition, rats were prepared with indwelling cannulae in the lateral ventricle to permit later administration of arginine vasopressin (AVP), 10 pmol/5 µl ICV. After baseline recordings of blood pressure, cardiovascular and behavioural responses to AVP, (assessed on a 0-6 point scale), rats were bred; (detection of a vaginal plug). At a minimum of one week intervals thereafter, basal blood pressure recordings were taken and cardiovascular and behavioural responses were again assessed after ICV AVP. Virgin female rats displayed mean arterial pressure of 93 \pm 3.84 mm Hg (mean \pm SEM, N=9); blood pressures were statistically unchanged throughout gestation and lactation, except during the last trimester, at which time mean arterial pressure was 80 ± 3.8 mm Hg (P < 0.05). Pressor responses to 10 pmol AVP averaged 16-22 mm Hg throughout the various gestational, lactational and virgin states; no significant difference in pressor or motor behaviour responses were seen over the various times. We conclude that, although basal blood pressure changes throughout gestation, no significant changes are seen in resp central AVP

THE GALANIN ANTAGONIST M40 BLOCKS THE CARDIOVASCULAR EFFECTS ELICITED BY GALANIN N-TERMINAL FRAGMENT (1-15), BUT NOT BY GALANIN (1-29).

J.A. Narváez*, Z. Díaz, P.B. Hedlund\(\frac{1}{2}\), J.A. Aguirre, R. Coveñas\(\frac{1}{2}\) S. González-Barón and K. Fuxe\(\frac{1}{2}\). Dept. de Fisiología. Neuroscience. Karolinska Institute. Stockholm. Sweden. # Dept. de Biologia Celular. Universidad de Salamanca. Spain

Central administration of Galanin N-terminal fragment (1-15) [GAL(1-15)] elicitis hypertension whereas Galanin (1-29) [GAL(1-29)] produces hypotension; both molecules have a tachycardic action. Furthermore, GAL(1-15) decreases baroreceptor sensitivity but GAL(1-29) has no effect, and both molecules modulates differentially the cardiovascular responses of Neuropeptide Y. The aim of this work is to investigate if these molecules could exert their action through different receptor subtypes. Doses of GAL(1-15) (3.0 nmol/rat) and GAL(1-29) (3.0 nmol/rat) were injected intracisternally alone or in presence of subthreshold doses of the Galanin antagonist M40 (0.1 nmol/rat). Mean arterial pressure (MAP) and Heart rate (HR) were recorded during 60 minutes after injections. GAL(1-29) elicited hypotension and tachycardia which remain unchanged in the presence of M40. However, M40 abolished the hypertensive and tachycardic action elicited by GAL(1-15) (p<0.001). In these animals a hypotensive response, similar to that induced by GAL(1-15) alone, was observed. These results demonstrate that M40 blocks the central cardiovascular effects elicited by GAL(1-15) but not by GAL(1-29). Thus, at least regarding the cardiovascular role of Galanin, M40 might distinguish the putative N-terminal recognizing Galanin receptor subtype from the GAL(1-29) receptor. ACTIVATION OF NEURONAL POPULATIONS BY HIGH SODIUM INTAKE IN WKY RATS F. Vahid-Ansari* and Frans H.H. Leenen Hypertension Unit, University of Ottawa Heart Institute, Ottawa, ONT., Canada, KIY 4E9.

High sodium intake affects BP and osmoregulation in part via central effects. In order to localize the central neuronal populations involved, immunohistochemical detection of Fra-like immunoreactivity (Fra-LI) was used to identify those neurons activated by high sodium diet. Groups of WKY rats (4 weeks old) received either high sodium (8% NaCl) or regular sodium (0.5% NaCl) diet for 3, 7 or 14 days. After perfusion, immunohistochemistry was processed on brain sections, 30 μ m thick. Fra-LI expression was quantified within osmosensitive nuclei of lamina terminalis: SFO and MnPo and within BP-regulating areas like PVN, NTS and CG. On regular sodium diet, expression of Fra-LI was low and did not significantly change over the time course in the SFO and MnPo. However, high sodium diet increased Fra-LI in the SFO (> 3 times) after 3 days and maximal expression was observed in the SFO and MnPo after 7 days. In the BP-regulating areas, Fra-LI expressed differently in two divisions of the PVN. After 3-14 days of regular sodium, expression of Fra-LI in the magnocellular and parvocellular portions of the PVN was low and similar. In contrast, high sodium increased Fra-LI in the parvocellular part after 3 days diet (> 2 times) and and the highest expression (> 3 times) after 7 days. Maximal neuronal activation (> 10 times) of the magnocellular part of PVN was observed after 14 days of high sodium diet. High sodium increased Fra-LI in the NTS after 3 days and the highest expression after 7 days (> 2 times). In the CG, high sodium diet increased Fra-LI after 3 days and maximal activation (> 2 times) was observed after 14 days. The present results indicate that immunohistochemical detection of Fra-LI can be used to identify neurons chronically activated by high sodium diet. Since these neuronal populations may differently mediate the BP and osmoregulation by high sodium diet in salt-sensitive hypertension, determining the connectional and neurochemical character of the neurons that display Fra-LI after chronic high sodium diet may yield insight into its neuronal basis. Supported by a grant from MRC.

MOTHER/PUP INTERACTIONS DURING PREWEANLING DEVELOPMENT IN SPONTANEOUSLY HYPERTENSIVE RATS, E. Perdomo, A.K. Johnson, and R.F. Kirby*. Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, Iowa 52242-1407

The expression of hypertension in the spontaneously hypertensive rat (SHR) is dependent on both genetic and environmental factors present in early development (Cierpial, Shasby, & McCarty, 1987). In our first study, we examined the mother/pup interactions of the SHR and their normotensive control strain, the Wistar-Kyoto (WKY). Animals were videotaped across 24 hour periods at 3 ages during preweanling development; postnatal day (PD) 6, PD 12, and PD 18. In both the SHR and WKY, contact varied over the 24 hour light/dark cycle, with greater contact during the light period. Strainrelated differences were also noted on PD 6. During the dark period, SHR displayed much shorter contact bouts than WKY, but at an increased frequency. SHR also had relatively greater amounts of contact during the day than WKY. Early preweanling manipulations, such as cross-fostering, can reduce the elevated blood pressure of adult SHR (Cierpial & McCarty, 1987). Therefore, our second study examined cross-fostering influences on mother/pup interactions. Previous patterns of SHR and WKY differences were maintained. These results suggest that mother/pup interactions during early preweanling development are determined by the mother rather than the pups. Supported by NHLBI HL 14388 and NASA NAGW-4358.

Influence of GABA_A agonist, muscimol, on cardiovascular changes induced by carbachol in conscious rats. F. Onat*, T. Tellioglu, Z. Gören, Ş. Oktay, K. Berkman. Dept. of Pharmacology, Marmara Univ. Sch. of Med., Haydarpaşa, 81326, Istanbul, Turkev.

Previous experimental studies have shown that intracerebroventricular (icv) injection of GABA, agonist, muscimol, resulted in marked decreases in activity. Likewise, it is well recognized that central cholinergic system is also involved in the regulation of central cardiovascular control. In this study, we examined the effect of muscimol on the cardiovascular responses induced by the stimulation of central cholinergic system. All experiments were performed in conscious, Sprague-Dawley rats instrumented with icv guide cannula for drug injection and iliac arterial catheters for direct measurement of mean arterial pressure (MAP) and heart rate (HR). The administration of cholinergic agonist, carbachol (CCh; 0.8 nmol, icv) produced an increase in MAP (22.8 ± 3.1 mm Hg) and a decrease in HR (-97.1 ± 13.1 beats/min). On the other hand, 5 nmol of icv muscimol decreased MAP (-14.7 ± 2.9 mm Hg) and HR (-35.7 ± 17.8 beats/min). All cardiovascular changes in response to both CCh and muscimol 10 min before CCh administration completely abolished maximum MAP and HR changes induced by the icv injection of CCh. Additionally, displacement of (³H)-QNB by muscimol (10³ -10⁴ M) at cerebrocortical and hypothalamic homogenates was investigated. Muscimol failed to displace the muscarnine radioligand from its binding sites suggesting that it does not exert any direct antagonistic activity at muscarinic receptors. All these results suggest that GABAergic system has a inhibitory influence on cholinergic neurons. (Supported by TÜBİTAK, SBAG-AYD-13)

BRAIN NATRIURETIC PEPTIDE MEDIATED CARDIOVASCULAR CHANGES IN DIFFERENT RAT STRAINS . B. R. Dev*, L. Philip and S. J. John. Dept. of Physiology, Faculty of Medicine, Kuwait Univ., P. O. Box 24923, Safat, Kuwait 13110.

Cardiovascular functional changes in response to local administration of brain natriuretic peptide (BNP) into the nucleus tractus solitarius (NTS) were assessed in age-matched, urethane anesthetized spontaneously hypertensive (SHR), Wistar-Kyoto normotensive (WKY) and Sprague-Dawley rats. Catheterization of the femoral artery provided the continuous measure of both blood pressure and heart rate. Microinjection of the vehicle (phosphate buffered saline) alone into the NTS of all the three rat strains did not elicit any significant change in blood pressure or heart rate. A significant reduction in the mean arterial blood pressure and heart rate was observed only in SHRs, whereas in the other two strains, namely, the WKY and Sprague-Dawley rats, there was no appreciable change in their mean arterial blood pressure and heart rate in response to local injection of different doses of BNP into the caudal NTS. These results suggest that the SHRs might be much more susceptible to exogenous BNP than the rats of normotensive strains. Supported by Kuwait University (MY 025).

HEART RATE DYNAMICS IN APNEA OF INFANCY. R.K. Harper*, V.L. Schechtman, M.Y. Lee, J.A. Henslee, G.J. Luna and R.M. Harper. Brain Research Inst. and Dept. of Neurobiology, UCLA School of Med., Los Angeles, CA 90095; and Southwest SIDS Research Inst., Lake Jackson, TX 77566.

Heart rate variability is significantly enhanced in infants with apnea of infancy (AOI); moreover, apneic episodes are associated with marked changes in heart rate. Several conditions associated with altered heart rate variability result in aberrant beat-to-beat dynamics that can provide easy and inexpensive screening tools for the conditions. We studied the dynamics of beat-to-beat heart rate change in infants with persistent apnea and control infants. Polysomnographic recordings were obtained from fifteen 4-7-mo-old infants with persistent AOI. From these recordings and 17 recordings of control infants, R-R intervals (the intervals between successive R waves of the ECG) were determined with 1ms accuracy. For a 6-hr, evening period of each recording, each R-R interval was plotted as a function of the previous interval, and dispersion of subsequent intervals was quantified at slow, fast, and intermediate heart rates. Apneic periods were accompanied by substantial R-R interval patterning changes; however rapid (beat-to-beat) changes occurred only at the onsets of these episodes, and no significant difference in heart rate dynamics emerged between apneic and control infants across the 6-hr periods. We conclude that beat-to-beat dynamics across extended periods cannot be used to screen for AOI, but that the distinctive patterns of heart rate dynamics during apneic events may shed light on the physiology of This research was supported by HD 22695. persistent central apnea.

HEART RATE AND VARIABILITY IN FULL-TERM INFANTS WITH APNEA OF INFANCY. V.L. Schechtman, * J.A. Henslee and R.M. Harper. Brain Research Inst. and Dept. of Neurobiology, UCLA School of Med., Los Angeles, CA 90095; and Southwest SIDS Research Inst., Lake Jackson, TX 77566.

During periods of regular breathing, heart rate is slower and heart rate variability enhanced in selected prematurely-born infants with persistent apnea of prematurity (those with no history of perinatal respiratory distress), relative to full-term infants of comparable postconceptional ages. Evidence suggests that this difference may be linked to the persistent apnea rather than premature birth. Thus, we assessed heart rate and variability in full-term infants with persistent apnea of infancy and control infants. Heart rate and variability (standard deviation of R-R intervals) were compared during periods of regular breathing in 48 infants with persistent apnea and 72 agematched control infants. Heart rates did not differ significantly between the two groups of infants at any age; however, after 3 mo prenatal age, heart rate variability was significantly enhanced in infants with persistent apnea of infancy, relative to control infants. The findings indicate tonic changes in cardiac variation in 4-6-mo-old infants who continue to suffer from apnea of infancy, and demonstrate a physiologic similarity in full-term infants with persistent apnea and prematurely-born infants with persistent apnea but no history of respiratory distress. It is not clear if this autonomic aberration is a consequence of persistent apnea or a pre-existing difference between normal infants and those who continue to show apnea of infancy. This research was supported by HD 22695.

CENTRAL ADMINISTRATION OF CHOLINE INCREASES PLASMA VASOPRESSIN LEVELS IN CONSCIOUS RAT. <u>I. H. Ulus*, V. Savcı, and B. K. Kıran.</u> Uludag Univ. Medical Sch., Department of Pharmacology, 16059, Bursa, Turkey.

In the present study, we examined the effects intracerebroventricularly (i.c.v.) injected choline on both basal and stimulated release of vasopressin (AVP) in conscious rats. Choline (50-150 µg) caused time- and dosedependent increases in plasma AVP levels. The i.c.v. choline-induced increase in plasma AVP was greatly attenuated by the pretreatment of rats with mecamylamine, a nicotinic receptor antagonist. Atropine, a muscarinic receptor antagonist, failed to alter choline's effect. Osmotic stimuli induced by either oral administration of 1ml of hypertonic saline (3 M NaCl) following 20-h deprivation of drinking water of rats, or an i.c.v. injection of hypertonic saline (1M NaCl) increased in plasma AVP several fold. Under these conditions, i.c.v. injection of 50 or 150 µg of choline produced a greater increase in plasma AVP than the increase observed in the basal condition. Choline (50 or 150 µg, i.c.v.) also enhanced the increase in plasma AVP in response to graded blood loss and acute hemorrhage. The effects of choline on plasma AVP levels in normal rats or in the rats subjected to graded blood loos were reduced by the pretreatment with hemicholinium-3, a high affinity choline uptake inhibitor. Stimulation of central nicotinic cholinergic receptors by presynaptic mechanisms is apparently involved in effects of choline on plasma AVP.

CENTRALLY ADMINISTRATED THA RESTORES HYPOTENSION IN HEMORRHAGIC SHOCK IN CONSCIOUS RATS. V. Savci*, I. H. Ulus, S. Gürün, S. Çavun and B. K. Kıran. Uludag University Medical School, Department of Pharmacology, Görükle, 16059, Bursa-Turkey.

Right common carotid artery and left cerebral ventricles of male Wistar rats were cannulated under light ether anaesthesia to monitor blood pressure and drug injections, respectively. Hemorrhagic shock were produced by bleeding 2.1-2.2 ml of blood per 100 g of body weight within 5-10 min Intraventricular (i.c.v.) injection of tetrahydroaminoacridine (THA; 10, 25, 50 µg) increased blood pressure in a dose-and time-dependent manner in both normotensive and hemorrhaged rats. Atropine (10 µg; i.c.v.) greatly attenuated the blood pressure response to i.c.v. THA (25 µg) in both conditions. However, mecamylamine (50 μg; i.c.v.) caused slight blockade in hemorrhaged rats, while it failed to change the response in normotensive conditions. The increase in blood pressure to i.c.v. THA was associated several fold increase in plasma levels of vasopressin and catecholamines but not of renin. Pretreatment of rats with prazosine.an aladrenergic receptor antagonist (0.5 mg kg -1; i.p.) or vasopressin V1 receptor antagonist [β-mercapto-β,β-cyclopenta-methylenepropionyl¹,O-Me-Tyr²-Arg⁸]vasopressin (10 µg kg-1; i.a.). was attenuated the pressor response to THA in both conditions. These data show that THA can restore hypotension in morrhaged rats through the activation of both central muscarinic and nicotinic cholinergic receptors, however the only central muscarinic cholinergic receptors are involved in pressor effect of THA in normotensive animals. Moreover, the increase in plasma vasopressin and catecholamine levels, both, participate the blood pressure effects of THA in both conditions.

SENSORY SYSTEMS: SPINAL CORD I

339.1

PARTICAL SCIATIC NERVE LIGATION LEADS TO A MICROGLIA REACTION WHICH CORRELATES WITH ALLODYNIC BEHAVIOR D.E. Covle* and C. S. Sehlhorst Department. of Anesthesia, University of Cincinnati, Clincinnati, OH 45267-0551

A majority of studies on neuropathic pain have focused on the alterations that occur within neurons following peripheral nerve injury. Since glia have a profound influence on the CNS neural environment and are capable of generating an inflammatory response, this study investigated the response of microglia and astroglia to partial sciatic nerve ligation (PSNL). Forty female Harlan Sprague-Dawley rats were randomized into 10 groups containing 3 PSNL and 1 sham animal per group. Rats were evaluated for withdrawal from touch using Von Frey filaments (evaluator Spinal cords were evaluated for immunoreactivity (IR) to complement receptor iC3b (OX42), major histocompatibility complex II (OX6) and glia fibrillary acidic protein (GFAP) on post-injury days 1, 2, 4, and weeks 1, 2, 4, 6, 8, 10, and 12. The intensity of staining of the ipsilateral verses contralateral gray matter was determined by measuring average pixel intensity. OX42 and GFAP IR was confined to the ipsilateral cord (L3-L5) sections. The main areas of staining were confined to Lamina (Lam) I-III and part of Lam IV of the Dorsal Horn (DH) and Lam IX of the Ventral Horn (VH). A linear correlation was found to exist between gram force (withdrawal) verses percent change in intensity from the contralateral cord yielding a correlation coefficient of 0.8 for OX42 and 0.5 for GFAP. Cells staining for OX6 were rare and occurred in both the DH and VH. This study presents data that support the role of microglia in the development of neuropathic pain. The mechanism by which microglia may potentiate neuropathic pain is unknown but may be mediated through increased hypersensitivity of the DH as well as neural damage due to microglia release of excitatory amino acids, free radicals, and/or cytokines. This study was supported in part by an ASRA Carl Koller Award.

PLASTIC CHANGES IN SYNAPTIC TRANSMISSION OF RAT DORSAL HORN NEURONS FOLLOWING PERIPHERAL NERVE TRANSECTION.

M. Yoshimura*, M. Okamoto ¹, H. Baba ¹, K. Shimoji ¹ and H. Higashi, Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan, ¹Dept. Anesthesiol., Niigata Univ. Sch. Med., Niigata 951, Japan.

Following peripheral nerve injury, pathological state such as allodynia and/or hyperalgesia has been reported to develop in subpopulation of patients. Persistence of the pain after healing of the damaged tissue suggests that plastic changes in CNS, including the spinal cord, may play a important role in processing the pathological pain transmission. To investigate plastic changes in synaptic transmission at the spinal level, whole cell recordings were made from substantia gelatinosa (SG) and laminae IV/V neurons in the spinal cord slice with attached dorsal root from adult rats with or without the sciatic nerve transection (SNT). No significantly changes in passive and active membrane characteristics, including resting membrane potential, input resistance and configuration of action potential and spike after potentials, were detected between normal and SNT rats. In the normal rats, primary afferent stimulation with intensity sufficient to activate Aδ afferents elicited a monosynaptic fast EPSC in the majority of SG neurons. However, in the SNT rats, a polysynaptic EPSC with a long latency was evoked by activation of afferent fibers. The stimulus intensity for eliciting the polysynaptic EPSCs was much lower than that for activation of Aδ afferents, suggesting that AB afferents are likely responsible for generation of the responses. In addition, the conduction velocity and threshold for each afferents were not significantly altered. These observations suggest that synaptic plasticity occurred in a subset of deep dorsal horn neurons tends to transmit tactile sensory information to SG and this plastic change may account for underling mechanism in the pathological pain such as allodynia

LONG-TERM CHANGES IN AFFERENT-EVOKED DORSAL HORN FIELD POTENTIALS ACCOMPANY SCIATIC LIGATION IN RATS. V. Miletic* & G. Miletic. Dept. Comp. Biosci., Univ. Wisconsin, Madison, WI 53706

Following insertion of a glass microelectrode to a depth of about 100 µm, we recorded sciatic-evoked field potentials (FPs) in the spinal dorsal horn of urethaneanesthetized control and ligated rats. The sciatic was stimulated with 0.5 ms long pulses at 0.5 Hz, and the FPs remained essentially invariable for about 30 min of control recordings. We then applied tetanic stimulation to the nerve (a 400 ms train of 0.1 ms pulses at 50 Hz), and recorded the evoked FPs again up to 4 hrs post-tetanus. In control animals, tetanic stimulation produced increases in FPs which peaked at 30 min (175% of pre-tetanus amplitudes), and returned to baseline values at 2 hrs post-retanus. Interestingly, after 2 hrs the evoked FPs began to decrease, and attained only 50% of their pre-tetanus values at 4 hrs. In ligated rats the increase in FPs also peaked at 30 min (175%), but in contrast to control animals, was seen to persist, and at 4 hrs post-tetanus was still 155% of baseline values.

We also recorded sciatic-evoked FPs in another group of control and ligated rats but this time following low-frequency stimulation (a 400 ms train of 0.1 ms pulses at 5 Hz). We again noted different responses in control vs. ligated rats. In controls, a long-term depression in evoked potentials was seen, with the FPs reaching only 40% of their baseline values at 4 hrs. On the other hand, in ligated animals the depression was less pronounced (80%), was maximal at 2 hrs, and by 4 hrs the FPs had essentially returned to baseline.

These data suggest that sciatic ligation modifies afferent-evoked processing in the spinal dorsal horn to invoke plastic changes in excitability that resemble longterm potentiation and long-term depression. These long-lasting plastic changes in neuronal excitability may underlie the development of neuropathic pain in ligated animals. [Supported in part by NIH NS 21278.]

EFFECTS OF CALCIUM CHANNEL BLOCKER ON PROSTAGLANDIN F_{2g}-INDUCED LONG LASTING ALLODYNIA . <u>K.Hara, Y.Saito, Y.Kirihara, N.Imamachi, Y.Yamada, Y.Yamamori* and</u>

Y.Kosaka.

Dept. of Anesthesiol., Shimane Med.Univ., Izumo, Shimane 693 Japan

We have reported that intrathecal (i.t.) prostaglandins (PGs) induce long lasting allodynia (Neurosci, Abst., 1995; Pain, 1996). The present study examined the effect of calcium channel blocker, diltiazem on the $PGF_{2\alpha}$ -induced long lasting allodynia.

Male Sprague-Dawley rats weighing 270-350 g were used The response of the animals to non-noxious mechanical stimulus produced by Semmes-Weinstein monofilaments (SWM) was graded from 0 (=no response) to 3 (=vigorous escape and frequent vocalization). Each SWM response) to 3 (=vtgorous escape and frequent vocalization). Each 3 wm was applied at 3 different sites (neck, flank and hip) on the right and left side of the body. Agitation score (AS) was calculated as sum of the scores in six sites. Following the determination of baseline score, diltiazem 300 - 1000 μ g or normal saline was intrathecally administered 20 min before (pretreatment) or 30 min after (posttreatment) i.t.

injection of 100 ng PGF_{2α}. Measurements were repeated for 7 days. Posttreatment and pretreatment with saline had no effect on the increase of ASs induced by PGF_{2α}. Posttreatment with diltiazem 1000 μ g temporarily reduced ASs by 36% for 10 min and then ASs increased to the same level of posttreatment with saline. From 1 to 7 days after injection, ASs of posttreatment with diltiazem was lower than that of Injection, Associated administration of $PGF_{2\alpha}$ following pretreatment with diltiazem 1000 μg did not produce any increases of ASs for 7 days. These results suggest that L-type calcium channel may participate in the initiation and sustaining of $PGF_{2\alpha}$ -induced allodynia in the spinal cord.

339.7

PLASTICITY IN THE DORSAL HORN FOLLOWING NEUROPATHIC

Neurosurgery, Georgetown University, Washington DC.

There is evidence to suggest that the development of chronic pain is related to plasticity in the central nervous system. We report time-related neural changes in the lumbar spinal cord of the rat in three models of chronic pain and a close constitution with the households. the lumbar spinal cord of the rat in three models of chronic pain and a close correlation with the hyperalgesic behavior quantified in these animals. The neural markers studied were the NK-1 and μ-opioid receptors and constitutional Nitric Oxide Synthase (cNOS) labeled with immunocytochemistry. The Chronic Constriction Injury (CCI) was used as a model of neuropathic pain and a plantar injection of 200 μl of Complete Freund's Adjuvant (CFA) (n=12) was used as a model of inflammatory pain. The animals were divided into four survival times: 4, 7, 14, and 28 days. Behavior was monitored using the thermal withdrawal test for hyperalgesia and von Frey hairs for mechanical allodynia, at 4, 7, 14, and 28 days. Immunolabeling was quantified using NIH "Image" software. The results show that CCI leads to an hyperalgesic hindpaw, which is paralleled by a marked ipsilateral increase in NK1 receptor density, in L1 to L6, that peaks at 4 days and persists at 28 days. A moderate increase in ipsilateral \(\mu\)-opioid receptor density was found in this model at short survival at L4-L5 while a large decrease in ipsilateral cNOS labeled neurons was observed at L4-L5 throughout the 28 day survival. The CFA model also leads to local hyperalgesia which is observed at 4 and 7 days but not at 14 days and beyond. NK1 receptor density increases were most pronounced at 14 days and beyond. NK1 receptor density increases were most pronounced at early survival times. μ-opioid receptor labeling also showed an increase at L4-L5 at early survival times. cNOS reactivity did not change significantly throughout the survival time of the CFA model. We suggest that there is a correlation between the development of chronic pain and neuronal plasticity in the central nervous system. Furthermore, the type of peripheral injury will determine the central changes. While NK1 and μ-opioid receptor density levels increase in both neuropathic and inflammatory pain models, cNOS decreases after nerve injury and is unaffected by peripheral inflammation. NIH RO1 DK47523-01; MRC (Canada).

CALCIUM CHANNEL BLOCKER REVERSES PROSTAGLANDIN $F_{2\alpha}$ -INDUCED INCREASE OF SPINAL DORSAL HORN NEURONAL RESPONSES IN RATS.

Y. Yamamori, Y. Saito, T. Yanagidani*, H. Ishii, M. Shinzawa, Y. Kosaka Dept. of Anesth., Shimane Med. Univ., Izumo, 693 Japan Increase in the response to low intensity stimulation caused by

prostaglandin $F_{2\alpha}(PGF_{2\alpha})$ may contribute to the prostaglandins (PGs) induced long lasting hypersensitive state (Neurosci. Abst., 20, 307 1994). The purpose of this study was to examine the effects of calcium channel blocker, diltiazem on $\text{PGF}_{2\alpha}$ -induced increases of spinal dorsal horn neuronal responses.

Male Sprague-Dawley rats weighing 350-450g were used. Extracellular activity of single spinal dorsal horn neurons were recorded in decerebrated rats. The size of low-threshold RF and responses to brushing were determined. Following determination of neuronal responses after intrathecal(i.t.) administration of PGF_{2α}(100ng/10 μl), evaluation was repeated after i.t. administration of diltiazem ($500 \mu g$) 10 μ). To date eight neurons (7 LT neurons and 1 WDR neuron) have been studied. Four neurons out of five showed increase of RF, and one neuron studied. Four neurons out of five showed increase of RF, and one neuron showed no change after $PGF_{2\alpha}$, while intrathecally administered saline induced no change of RF in three neurons. The mean RF size was increased by 33%, 57% and 66% from the baseline level at 10, 30 and 60 minutes after $PGF_{2\alpha}$, respectively. The responses to brushing was increased in the neurons with the increased RF after $PGF_{2\alpha}$. The $PGF_{2\alpha}$ -induced increase of the RF size was reduced by 91%, 83% and 33% at 10, 20 and 30 minutes after the administration of diltiazem. The responses to brushing were also reduced. These results suggest that calcium channel blocker may reverse PGs induced hypersensitive state by changing spinal transduction of non-noxious information.

INTRATHECAL PROSTAGLANDIN $F_{2\alpha}$ EVOKES FOS EXPRESSION IN THE RAT SPINAL DORSAL HORN

Y. Saito⁸D, Y. KiriharaD, K. HaraD, T. Gonda²D, H. MiyamotoD and Y. KosakaD. 1)Dept. of Anesthesiol., 2)Inst. of Exp. Animals, Shimane Med.Univ., Izumo, Shimane 693 Japan

Intrathecal (i.t.) prostaglandins (PGs) initiate long lasting allodynic state (Neurosci. Abst., 1995; Pain, 1996). To investigate the neuroanatomical aspects of this phenomenon, we examined expression of c-Fos-like immunoreactivity (FLI) in the spinal neuron.

Seven days after implantation of i.t. catheter, male Sprague-Dawley rats were i.t. injected with 100 ng of $PGF_{2\alpha}$ (n=5) or saline (n=4). Agitation scores (ASs) to non-noxious mechanical stimuli evaluated for 3hrs, and then rats were anesthetized and perfused with fixative. Transverse 40 μ m frozen sections of the lumbar spinal cord processed for FLI standard immunohistochemical method.

I.t. administration of $PGF_{2\alpha}$ significantly increased ASs comparing the baseline values, while i.t. saline injection did not produce any increases of ASs. The FLI was significantly elevated after i.t. $PGF_{2\alpha}$ injection, although little expression of FLI was shown after i.t. saline injection. The mean number of FLI expressed neurons following $PGF_{2\alpha}$ and saline were 22.3 ± 9.7 (SD) and 7.4 ± 3.2 in lamina I-II, 10.4 ± 6.5 and 2.6 ± 0.7 in III-IV, and 11.3 ± 4.3 and 3.8 ± 1.9 in V-VI, respectively. The number in lamina VII-X following $PGF_{2\alpha}$ injection did not increase

These results indicate that spinal dorsal horn neuron is capable of expressing FLI following $PGF_{2\alpha}$ treatment, suggesting the alteration of the ability in response to a non-noxious stimulus.

INHIBITORY SYNAPTIC TRANSMISSION IN THE SUBSTANTIA GELATINOSA AND ITS MODULATION BY μ-OPIOID AND GABAB RECEPTOR ACTIVATION. T. J. Grudt* and G. Henderson. Department of Pharmacology, University of Bristol, Bristol BS8 1TD, UK.

The substantia gelatinosa (SG) is the primary site of termination of sensory neurons activated by painful stimuli. Most of the neurons in the SG are interneurons thought to be involved in the processing and modulation of the afferent signal and many contain the inhibitory transmitters GABA or glycine. In order to examine inhibitory transmission in the SG, whole-cell recordings were made from SG neurons in horizontal slices (275 $\mu m)$ of the spinal trigeminal nucleus at 30 $^{\circ} C$. In the presence of the excitatory amino acid receptor antagonists CNQX (10 µM) and D-APV (30 μM) and the GABAA receptor antagonist bicuculline (10 μM), stimulation within the SG evoked IPSCs sensitive to the glycine receptor antagonist strychnine (1 μ M) in 20 of 20 neurons. In CNQX, D-APV and strychnine, IPSCs sensitive to bicuculline were evoked in 30 of 32 neurons. In some neurons, spontaneous glycine or GABA A IPSCs (sIPSCs) were present in TTX (0.5 μ M). The decay of the glycine sIPSCs and some of the GABAA sIPSCs were well-fit by one exponential whereas the decay of other GABAA sIPSCs required two exponentials. Application of the μ -opioid agonist DAMGO (1 μ M) caused a reduction in the amplitude of evoked glycine IPSCs in 8 of 8 neurons to 51±10% of control but reduced the amplitude of evoked GABAA IPSCs in only 4 of 8 neurons, to $55\pm4.8\%$ of control in the neurons affected. By comparison, the GABAB receptor agonist baclofen (30 μ M) reduced the amplitude of the IPSC in all neurons tested, to $5.0\pm1.4\%$ of control for glycine (n=5) and $11\pm2.6\%$ of control for GABAA (n=6). Inhibition of the evoked IPSCs was accompanied by an increase in failures of transmission, indicating that at least part of the inhibition was presynaptic. These results indicate that inhibitory synaptic transmission mediated by glycine and GABA acting at GABA A receptors is present in most if not all SG neurons. This work was supported by NIH grant DA05534-0182.

DIRECT APPOSITION OF SUBSTANCE P AND NK-I RECEPTOR IMMUNOREACTIVITIES IN THE RAT SPINAL DORSAL HORN: AN ULTRASTRUCTURAL DOUBLE-LABELLING STUDY. A.L. McLeod*, V.V. Karpitiskiv*, J.E. Krause* and A. Ribeiro-da-Silva*, Dept. of Pharmacology & Therapeutics, McGill University, Montréal, Québec, Canada H3G 1Y6, and Dept of Pharmacology. Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 633110.

Previous studies showed a conspicuous absence of NK-1 immunoreactivity in lamina II, although this area is known to receive numerous substance P (SP)-containing sensory fibres. The clarification of this apparent mismatch between the distribution of SP and its receptor prompted the present investigation. Adult male Wistar rats were anaesthetized and fixed by vascular perfusion with an aldehyde mixture. Segments C3-C5 of the spinal cord were collected and processed for immunocytochemistry at the light and ultrastructural levels. A polyclonal antibody generated against the rat NK-1 receptor was applied and developed using an ABC protocol. SP immunoreactivity was demonstrated using a bi-specific anti-SP/anti-HRP antibody (for light microscopy), and an anti-SP monoclonal antibody applied to ultrathin sections in a post-embedding immunogold protocol (for electron microscopy). NK-1 receptor immunoreactivity was intense in both lamina I and outer lamina II, and occurred in dendrites and cell bodies. In inner lamina II. NK-1 receptor immunoreactivity was still considerable, although the number of immunoreactive (IR) structures was less. In contrast, SP immunoreactivity was intense in the outer two thirds of lamina II. SP-IR boutons were frequently presynaptic to NK-1-IR dendrites and perikarya. In the middle third of lamina II, NK-1-IR dendrites were frequently post-synaptic to the central boutons of synaptic glomeruli, as well as to SP-IR boutons. In contrast with some other studies, the above results indicate a good correlation between SP-IR boutons and NK-1-IR postsynaptic targets, and give support to the concept that SP acts at a very distance from its release site (Research funded by the Canadian MRC and the NIH)

WDR NEURONAL POPULATION BEHAVIOUR DURING NOXIOUS AND NON-NOXIOUS STIMULI. AN INFORMATION WEIGHING AND NETWORK CODING STUDY WITH MULTIPLE SIMULTANEOUS

NETWORK CODING STUDY WITH MULTIPLE SIMULTANEOUS RECORDINGS. G.E.Biella** P.Gurzi*, F.Gianinetti* and M.L.Sotgiu* stituto di Neuroscienze e Bioimmagini, CNR, Cattedra VI Neurologia, Universita' di Milano; Via Mario Bianco, 9; 20131 Milan, ITALY. Noxious and non-noxious signals are carried by different diameter peripheral fibers and specifically noxious signals are diversely carried to the central structures by distinct spectra of slow conducting fibers. Differences in conduction and laminar arrangement lead to different design of postsynaptic activation in the spinal cord. We investigated if this structural configuration subserves a variable recruitment of cell populations structural configuration subserves a variable recruitment of cell populations depending on the incoming stimuli and induces diverse connectivity properties relying on the stimulus features.

Multiple simultaneous recordings from Wide Dynamic Range (WDR) neurons have been performed in the deep dorsal laminae of the spinal cord of anesthetized and paralysed rats. The responses to mechanical, thermal and electrical noxious and non-noxious stimuli have been selected. The data have been analysed by cross-correlographic techniques and by information starting from Karhunen-Loève tranformations with probability density function estimates (Parzen method). Finally information amount processing by stochastic integration techniques has been performed.

The overall information weighing has shown differences both in the correlographic profiles and in the information estimate in the responses to different stimulations. Noxious stimuli induce a differently timed connectivity among WDR and diverse information weighing. These results demonstrate some discriminative properties of local spinal circuits depending on stimulus modalities. Funds by National Research Council..

PHARMACOLOGY OF METABOTROPIC GLUTAMATE RECEPTOR -MEDIATED MODULATION OF MEMBRANE PROPERTIES IN RAT DEEP DORSAL HORN NEURONS. V. Morisset, J.-C. Gauffre, M. Allard and F.

DORSAL HORN NEURONS. V. Morisset, J.-C. Gauffre, M. Allard and F. Nagy: INSERM U378, Univ. Bordeaux II, 33076 Bordeaux Cedex France. Activation of mGluRs with 1S, 3R - ACPD induces or enhances voltage-dependent plateau potentials in about 26% of lamina V dorsal horn neurons (DHNs), in the cervical region of the rat spinal cord (Morisset and Nagy. Neurosci. Abstr., 21, 377, 1995). This promotes expression of long-lasting after-discharge, bistability, and windup of action potentials when neurons are stimulated by intracellular injections of current. We have investigated the pharmacology of the mGluRs involved in this modulation in a transverse

priamacology of the midiums involved in this modulation in a transverse spinal cord slice preparation (cervical region) of 18- to 22-day old rats. The plateau potential modulated by 15, 38 - ACPD was maintained in the presence of TTX, and blocked by nifedipine-containing medium, indicating that L-type calcium channels were involved. When ionotropic glutamate that L-type calcium channels were involved. When ionotropic glutamate receptors (AMPA, NMDA) were blocked by a mixture of CNQX and AP-5, quisqualate was 5 to 10 times more potent than 1S, 3B - ACPD in promoting plateau properties of lamina V DHNs. The effects of both agonists were reversed by the mGluRs antagonist MCPG. They were not reproduced by L-CCG-1 and L-AP4, the more specific agonists at group II and group III mGluRs, respectively, indicating the implication of the group I receptors mGluR1 or mGluR5. Because these receptors are known to be coupled to phospholipase C, we measured the effect of 1S, 3B - ACPD on phosphoinositide hydrolysis in a crude synaptosome preparation from 20-day-old rat spinal cord. Increasing concentrations of 1S, 3B - ACPD (1 μ M to 1 mM) stimulated IP formation in a dose-dependant manner yielding to an EC5g value of about 300 μ M. This stimulating effect was inhibited by 100 μ M MCPG. Taken altogether, the results suggest the implication of mGluR1 or mGluR5 in the modulation of plateau properties in deep DHNs.

ALTERATION OF FIRING PATTERNS AND ACTIVATION OF SLOW POTENTIALS IN DEEP DORSAL HORN INTERNEURONS BY DIRECT STIMULATION. S.P. Schneider*. Department of Anatomy, Michigan State University, E. Lansing, MI 48824-1316.

To gain insight into dynamics of local integrative function in the deep dorsal horn (laminae III-VI), activity-dependence of neuronal firing patterns was examined using blind whole-cell recordings from hamster spinal slices.

Injection of suprathreshold depolarizing current pulses through the recording pipette (20-30 pulses, 500-700ms, 0.2-0.5Hz) induced changes in spike firing, accompanied by shifts in V_m, that were dependent on stimulus rate and intensity (39/56; 70% of cells). During repeated activation resting V_m hyperpolarized (2-5mV), spike firing decreased and/or frequency adaptation increased (16/39; 41%). These effects reversed within 30-120s after stimulation was terminated. The hyperpolarization and altered spike firing were associated with decreased R_N and were not blocked by application of Cd². Returning V_m to control levels by passing depolarizing current also did not reverse decreased spike firing. In other cells (23/39; 59%) repetitive activation or single 5s injections of suprathreshold current induced depolarizing shifts in V_m (2-6mV), increased R_N, and increased spike firing to depolarizing test pulses. These were prolonged effects, lasting up to 15 min after cessation of stimuli, and were not associated with changes in synaptic activity. Increased firing could be reversed by hyperpolarizing V_m to control levels but was not blocked by application of D-AP5 or CNQX. Intracellular staining revealed that neurons exhibiting firing pattern plasticity had longitudinally oriented axons with dense terminations in laminae III-V.

The findings demonstrate that firing patterns of many laminae III-V interneurons are

capable of considerable plasticity, which may be determined by expression of multiple intrinsic (non-synaptic) mechanisms. Changes in interneuron excitability could alter integrative properties of local networks, contributing to sensory habituation and secondary hyperalgesia. Supported by NINDS grant NS25771.

SENSORY SYSTEMS: SPINAL CORD II

FUNCTIONAL ORGANIZATION OF NEURONAL ENSEMBLES ASSOCIATED WITH SPONTANEOUS CORD DORSUM POTENTIALS IN THE CAT SPINAL CORD. E. Manjarrez, I. Jiménez and P. Rudomin* Dept. of Physiol., Biophys. and Neurosc. CINVESTAV, IPN and IF-BUAP, MEXICO.

We have examined the interaction between the spontaneous cord dorsum potentials (SCDP's) and selected groups of interneurons responding to synaptic inputs from cutaneous and/or muscle afferents. The experiments were performed in 11 pentobarbital anesthetized and unparalyzed cats. SCDP's, dorsal root potentials (DRP's), and spinal extracellular field potentials (EFP's) were recorded by means of conventional methods. Laminar and segmental analysis performed in 6 experiments indicates that the neuronal ensembles involved in the generation of the SCDP's are located in the dorsal regions of the spinal L6-S1 segments, where the cutaneous afferents also terminate (1000 to 1900µm depth). The DRP's as well as the EFP's evoked in the dorsal horn by stimulation of low threshold cutaneous afferents (1.2 to 1.7xT) were facilitated when preceded by the largest SCDP's (selected using a window discriminator). The time course of this facilitation resembled that of the averaged SCDP's and lasted about 50 ms. The DRP's and the EFP's recorded in the intermediate nucleus by stimulation of group Ib fibers (unlike those elicited by group Ia fibers) were also facilitated when conditioned with SCDP's. Single dorsal horn interneurons responding monosinaptically to low threshold cutaneous fibers could be also synchronously activated during the occurrence of SCDP's, suggesting that they contribute, at least in part, to the generation of the SCDP's. Fractal analysis (N=3) of SCDP's has further indicated that the complexity of the organization of the elements associated with the generation of these potentials is increased after spinalization (D=1.5±0.18 to D=2.2±0.16) and is dynamically modulated (but not generated) by descending influences. The experimental paradigm used in this study may provide a novel approach to disclose the functional organization of distributed spinal neuronal ensembles. Supported by NIH 09196, CONACyT 031N9107 and SNI, México.

RATE OF RISE OF CUMULATIVE DEPOLARIZATION REPRESENTS NMDA RECEPTOR INDEPENDENT SUMMATION OF SLOW SYNAPTIC POTENTIALS. G.Baranauskas and A.Nistri, Biophys. Lab, Int Sch Adv Studies (SISSA), 34013 Trieste, Italy.

Action potential windup (an increase in number of spikes after each constant stimulus applied at 0.5-2 Hz frequency) is one of the manifestations of pain induced short term plasticity in the spinal cord. Intracellular recording from neonatal rat spinal neurones in vitro demonstrated that only the rate of rise (RR) of cumulative depolarization (CD) during the train can be correlated with of action potential windup. Several mechanisms for CD were suggested: relief of NMDA channels from Mg block; activation of voltage dependent slow Ca channels; summation of slow tachykinin mediated synaptic potentials. In the present study these issues were examined with intracellular recordings from neonatal rat spinal cord motoneurones in vitro. 19 motoneurones had -71±2 mV E(rest) and RR ranging from 0.1 mV/s to 0.67 mV/s (in 10/19 cells action potential windup could be evoked). RR voltage dependence as well as its amplitude persisted in the presence of NMDA receptor antagonists (25 µM of APV or 20 μ M of CPP) even though the peak of CD was reduced by 37 \pm 5% (n=6). In 3/6 cells the action potential windup still could be observed in the presence of NMDA receptor antagonists. No correlation was found between RR and CD or single EPSP area indicating that intrinsic voltage dependent conductances cannot explain these phenomena. A late component (at 500-1000 ms after the stimulsu) of the slow EPSP in the presence of NMDA receptor antagonists had the same voltage dependence as RR and was linearly related with the size of RR (r**2=0.75, n=11). The tachykinin NK1 receptor antagonist SR140333 reduced RR by a constant fraction at various membrane potentials All this data are consistent with the hypothesis of summation of slow EPSP partly mediated by NK1 receptor s. PROPRIOSPINAL AFFERENT AND EFFERENT CONNECTIONS OF THE LATERAL AND MEDIAL SUBDIVISIONS OF THE DORSAL HORN (LAMINAE I-IV) IN THE RAT LUMBAR SPINAL CORD M. Antal* and M. Petkó. Dept. of Anat., Histol. and Embryol., Univ. Med. School, Debrecen, Hungary, H-4012.

It has been noted by several authors that the medial and lateral subdivisions of the superficial dorsal horn of the spinal cord show many distinct features concerning primary afferent inputs, synaptic and neurochemical properties of interneurons as well as numbers of neurons with axons projecting to supraspinal brain centres. Here we demonstrate that, in addition to these disparities, the medial and lateral subdivisions of laminae I-IV of the spinal dorsal horn appear to be different also on the basis of their propriospinal afferent and efferent connections. After injecting *Phaseolus vulgaris* propriospinal alterent and efferent connections. After injecting *Phaseolus viugans* leucoagglutinin and biotinylated dextran into various areas of the dorsal horn (laminae 1-IV) at the level of the lumbar spinal cord, we found that a number of propriospinal fibres travel one-two segments rostrally or caudally and terminate in areas of the dorsal horn that are identical to that in which their cells of origin are located, forming rostro-caudally oriented cellular laminae in which the neurons are highly interconnected. These cellular laminae both in the medial and lateral subdivisions of the superficial dorsal horn receive strong inputs from laminae V-VI. It has also been revealed that the medial subdivision of laminae I-IV send an abundant projection to the lateral subdivision, but terminals were only occasionally found in the medial dorsal horn after injecting the tracers into the lateral part of laminae I-IV. We have revealed a strong reciprocal commissural projection between the lateral subdivisions of laminae I-IV on the two sides of the spinal cord. The lateral part of laminae I-IV gave rise also to many fibres that terminated in the ventral horn at the segmental level or ascended in the lateral white matter. Injecting the tracers into the medial dorsal horn, however, no commissural fibres were revealed, and terminals in the ventral horn and ascending fibres in the white matter were found only in limited numbers. The findings indicate that the medial and lateral subdivisions of the superficial spinal dorsal horn of rats may play different roles in sensory information processing. INDUCIBLE NITRIC OXIDE SYNTHASE mRNA EXPRESSION IN RAT DORSAL ROOT GANGLIA IS INCREASED BY INTRA-THECAL BUT NOT INTRAPLANTAR INJECTION OF SALINE. Y. Cai*, R. A. Velazquez and A. A. Larson. Dept. of Veterinary PathoBiology, University of Minnesota, St. Paul, MN 55108.

Reverse transcription-polymerase chain reaction (RT-PCR) was used to measure inducible nitric oxide synthase (iNOS) mRNA expression in dorsal root ganglia (DRG) of adult male Sprague-Dawley rats. DRG were sampled separately from thoracic and lumbar regions at 6 or 24 hr after intraperitoneal (i.p.), intraplantar (i.pl.), intrathecal (i.t.) or no injection of saline. iNOS mRNA was not expressed in the DRG of non-injected control rats (n=4), in rats not expressed in the DRG of non-injected control rats (n=4), in rats injected with 50 µl of saline i.pl. (n=4) or sham injected i.pl. (needle prick in one foot only, n=12). However, an i.p. injection (400 µl) of 10 mg/kg of lipopolysaccharide (LPS) greatly increased the expression of iNOS in the DRG, spinal cord, brain, liver, lung and expression of iNOS in the DRG, spinal cord, brain, liver, lung and spleen. When animals were acclimated to the laboratory for only 2 days (n=5), rather than 25.5 \pm 3.5 days for those studies described above (n=20), expression of iNOS was strongly induced in DRG but not spinal tissue even in the absence of LPS. Rats also exhibited strong expression of iNOS mRNA in DRG, but not in spinal tissue, following i.t. injections of 10-20 μ L of saline. No effects were found on expression of constitutive NOS mRNA in DRG or spinal cord following any treatment. Changes in iNOS were identical in thoracic and lumbar DRG. These results indicate that an i.t. injection or insufficient acclimatization is sufficient to induce iNOS mRNA in DRG. These data suggest a possible mechanism by which stress may affect sensory input. [USPHS grant NIDA04090 to A.A.L.]

DEAFFERENTATION-INDUCED ALTERATIONS OF RECEPTOR DENSITY IN THE DORAL HORN C.C. LaMotte 1* K.E. Arsenault 1 M. A. Wolfe ¹. M. E. Helgren ², and S.E. Kapadia ¹. ¹Section of Neurological Surgery, Yale University School of Medicine, New Haven, CT. 06520; ²Dept. of Physical Therapy, Quinnipiac College, Hamden CT. 06518

Past studies in this laboratory have demonstrated the selective destruction of sciatic primary afferents in the dorsal horn following injection of the rat sciatic nerve with pronase enzymes; subsequently, saphenous afferents sprout into the deafferented territory. Accompanying these changes are a decrease of Substance P (SP) and Calcitonin-gene related peptide (CGRP) immunoreactivity in the dorsal horn and a study, we examined changes in density of receptor binding or receptors over a similar time course. SP and CGRP receptor binding was determined with receptor autoradiography and non-NMDA receptor (Glu R1 and Glu R2/3) densities were determined with immunocytochemistry (Chemicon).
Computer image analysis of density in the superficial dorsal horn was compared between the pronase treated side and the contralateral, non-treated side. Ten days following pronase injection, there was an increase in SP, CGRP, and GluR2/3 receptors, and a decrease in GluR1 receptors. By 3 months all receptors were approaching normal. (NIH grants NS10174 and NS13335).

Presynaptic inhibition along the disynaptic reciprocal la inhibitory pathway in the cat. M. Enríquez* J. Nielsen. H. Morita. N. Petersen. and H. Hultborn. Department of Medical Physiology, The Panum Institute. DK-2200, Denmark; and Department of Physiology, Christian-Albrechts-University, Kiel, D-24098, Germany.

Eccles et al (J.Neurophysiol. 26:506. 1963) reported that disynaptic Ia-IPSPs are depressed for about 100 ms following conditioning stimulation of group I afferents from flexor nerves. This long lasting depression was explained as a result of presynaptic inhibitory actions on the terminals of a afferents on the Ia-inhibitory internurones, although the possibility of a presynaptic action onto the terminals of these interneurones was not excluded. Actually, syldence in four of resynaptic inhibitory interneurones. terminals of la afferents on the Ia-inhibitory interneurones, although the possibility of a presynaptic action onto the terminals of these interneurones was not excluded. Actually, evidence in favor of presynaptic inhibitory actions at the terminals of spinal cord interneurones has been presented (Alford et al, Eur.). Neuroscience. 3:107. 1991; Aggelopoulos et al, J.Physiol. 487.P:71P. 1995). The present study was undertaken to investigate this possibility in the well studied la-inhibitory pathway (Jankowska & Roberts, J.Physiol. 222:597. 1972). In five cats deeply anaesthetized with α-chloralose and pentobarbital, we studied the reduction of the monosynaptic Ia-EPSPs during intracellular recording from Ia-inhibitory interneurones. In two units, conditioning stimulation of deep Peroneal, Sartorius or Quadriceps nerves (1.6-2 T) depressed the Ia-EPSP. In support of the notion that this depression was presynaptic in origin, we found that monosynaptic EPSP from descending fibers in the ventral funiculus was not depressed. These data suggest that the tested pathways projecting to these interneurones are subjected to similar patterns of presynaptic inhibition as shown for the terminals projecting to α-motoneurones. We also analyzed the excitability changes of the terminals of individual Ia-inhibitory interneurones following activation of presumed presynaptic inhibitory pathways. Conditioning stimulation of Rexor and extensor nerves (1.3-10 T) increased the excitability of the terminals in 7 out of 8 interneurones, that lasted around 200 ms. Finally conditioning activation of cutaneous nerves (1.6-5 T) induced an increase in excitability in 6 out of 8 units. It shall be noted that this pattern of origin is different to that described for Ia afferent fibers. Because we had not observed long lasting postsynaptic actions during intracellular recordings from Ia-inhibitory interneurones, the observed increase in the excitability of the terminals whose caused by a depolarization in the terminals themselves, rather than by

340.6

ADENOVIRAL TRANSFER OF LacZ TO SPINAL CORD NEURONS. Mannes*, R.M. Caudle, B. O'Connell, D.J. Kim, M.J. Iadarola. NAB/NIDR/NIH

The spinal cord is an attractive and accessible target for gene therapy. The present study examines the ability of replication deficient adenovirus to transfer a test gene containing the cytomegalovirus promoter driving the expression of the LacZ reporter gene (Ad.CMV\(\beta\)gal). Sprague Dawley rats were anesthetized, the spinal cord exposed at C1 and a microinjection of Ad.CMVβgal (5 μl of 1 X1010 pfu/ml infused at 1 µl/min.) was made stereotaxically 0.5 mm lateral to the midline and 3 mm below the pial surface. Rats (3/time point) were sacrificed at 1, 3, 7, and 14 days post- infusion and extracts of spinal cord (divided into 1 cm sections from the injection site), pons-medulla, midbrain, hypothalamus and thalamus were assayed for β -gal activity fluorometrically (4-Methylumbelliferyl β -D-Galactoside). Significant β -gal activity was detected at 1 day (2699 \pm 739) which progressively increased to 7844 \pm 529 by day 7 and remained elevated (6718 \pm 3334) at 14 days. Activity at day 7 was elevated 50 fold over non-injected control tissue (137 \pm 5) The spatial distribution of activity also increased: on day 7, activity was confined to the 1 cm section containing the injection site but by day 14, activity was detected up to 2 cm caudal to this section. No substantial activity was detected in the 4 brain regions rostral to the injection site. The tip of the cannula was located in the anterior horn. Histochemical staining with x-gal revealed reaction product in the motor neurons and neurons in lamina 6 and 7 bilaterally; no staining was seen in the control tissue. Parallel results were obtained using β -gal immunocytochemistry.

This study demonstrates Ad.CMVBgal injected into the ventral spinal cord results in localized, high levels of \(\beta\)-gal activity which reached a plateau by 7 days and was sustained at 14 days. We are currently investigating microinjections into the spinal cord dorsal horn to target sensory neurons. Funded by: IRP/NIDR/NIH

EFFECTS OF SPINAL CORD TRANSECTION ON NEUROPEPTIDE FF RECEPTORS: A AUTORADIOGRAPHIC STUDY.

Ch. Gouradères, C. Advokat', and J-M Zajac. Institut de Parmacologie et de Biologie Structurale, CNRS, 205 Route de Narbonne, 31077 Toulouse-Cédex, France. Dept of Psychology, 236 Audubon Hall, Louisiana State University, Baton Rouge, LA 70803, USA.

Neuropeptide FF (NPFF) acts as a modulator of opioid functions. In particular, spinal administration of NPFF in the rat produces i) antinociception decreased by opioid antagonists; ii) enhancement and prolongation of spinal opioid analgesia. NPFF binds with high affinity to specific receptors distinct from opioid receptors a part of which are carried on primary afferent fibers. In order to reveal the presence of NPFF and opioid receptors on descending fibers, we measured their densities in rats submitted 14 days before to a complete mid-thoracic (T6) spinal transection. The binding was estimated in each side of the injury site in the superficial layers of the dorsal horn by quantitative autoradiography using highly selective iodinated ligands. [D.Tyr¹,(NMe)PHe³]NPFF, FK33824 and [D.Ala²] deltorphin-I to label NPFF, μ and δ sites, respectively. Analysis of the comparative distribution of NPFF and opioid binding sites in the sham operated and transectioned rats showed that the lesion did not induce significant changes in labelling except a 25% decrease in the density of δ sites, caudal-proximal to the injury. These results suggest that NPFF and opioid receptors not associated with primary afferent fibers are not located on descending fibers, but present on spinal neurons. Supported by PHS 02845.

EFFECT OF BICUCULLINE ON HALOTHANE-INDUCED REDUCTIONS OF RAT DORSAL HORN LOW-THRESHOLD RECEPTIVE FIELDS.

H. Iwakura*, T. Tsukamoto, S. G. Shimada, J.G. Collins. Department of Anesthesiology, Yale University School of Medicine, New Hayen, CT 06510

We have identified a series of effects of anesthetics on spinal dorsal horn neurons, including reduction of low-threshold receptive field (RF) size and are now using those effects as tools to examine the pharmacology responsible for such changes. We hypothesize that, rather than acting by a unitary mechanism, anesthetics, in an agentspecific way, modulate sensory transmission by influencing the actions of neurotransmitter systems. This is part of a series of ongoing studies designed to examine the role that the inhibitory neurotransmitter GABA may play in anestheticinduced reduction of low-threshold receptive field RF size.

Extracellular activity of single spinal dorsal horn neurons was recorded in halothane-anesthetized, spinally-transected rats. After mapping the low-threshold RF in the presence of 1.1% (1 MAC) and 1.6% (1.5 MAC) halothane, animals received two injections of 0.5 mg/kg bicuculline intravenously to a cumulative dose of 1.0 mg/kg. Following each bicuculline injection, we reevaluated RF size.

To date, 7 neurons have been examined Increasing the depth of halothane anesthesia produced a significant reduction in RF size. The administration of bicuculline induced a partial but not complete, significant reversal of the halothaneinduced reduction of the low-threshold RF size.

As we have seen with other inhalation anesthetics and the GABA antagonist

picrotoxin, GABA appears to play only a partial role in halothane reduction of RF size. These data support site- and drug-specific actions, rather than a unitary mechanism of action for general anesthetics. Supported, in part, by NIH GM 44954

RAT THORACIC SPINAL CORD CONTAINS M2, M3, AND M4, BUT NOT M1. MUSCARINIC RECEPTOR (mAchR) SUBTYPES. A. U. Höglund* and H. A. Baghdoyan. Department of Anesthesia, The Pennsylvania State University, College of Medicine, Hershey, PA 17033. Intrathecal administration of cholinomimetics produces antinociception (Anesthesiol. 80:1338, 1994) and increased blood pressure (Brain Res. Bull. 27:47, 1991). These responses have been proposed to be mediated, in part, by M2 (J. Pharmacol. Exp. Ther. 270:1301, 1994) and by M1 and/or M2 mAChRs (J. Pharmacol. Exp. Ther. 266:329, 1993). These functional studies led us to test the hypothesis that spinal cord contains multiple mAChR. Subtypes A. witten Ther. 266:329, 1993). These functional studies led us to test the hypothesis that spinal cord contains multiple mAChR subtypes. In vitro autoradiography performed on 5 thoracic spinal cords revealed: no M1 receptors; M2 receptors in Rexed laminae I-III (20-30 fmol/mg), IV, VI, VII, IX, and area X; M3 receptors in laminae I-III. with the highest densities in laminae I/II (20-25 fmol/mg). Saturation binding assays using [3H]-pirenzepine (PZ) in spinal cord homogenates confirmed the absence [³H]-pirenzepine (PZ) in spinal cord homogenates confirmed the absence of M1 mAChRs. Competition of [³H]-N-methyl scopolamine binding with PZ yielded a competition curve with a Hill coefficient (n_H) of 0.95±0.01 and a $K_i \! = \! 164.5 \! \pm \! 30.5$ nM, indicating the presence of M3 mAChRs. Competition with methoctramine (METH) resulted in a curve (n_H = 0.99±0.02) with a $K_i \! = \! 24.5 \! \pm \! 1.5$ nM, indicating the presence of M2 mAChRs. AF-DX 116 and METH + atropine showed shallow competition curves with n_H=0.76±0.05 and n_H=0.61±0.08, respectively. The fitted K_i constants indicated that AF-DX 116 recognized M2 and M4 mAChRs, and that METH + atropine recognized M3 and M4 receptors. Localization of M2 and M3 mAChRs to laminae 1-III is consistent with the possibility that these mAChR subtypes may modulate antinociception. The laminar distribution of M4 mAChRs remains to be identified. Support: MH-45321 (HAB), HL-47749 (RL), B96-99Z-11159-02 (AUH), Departments of Anesthesia and Comparative Medicine.

IN VIVO, WHOLE-CELL RECORDINGS FROM SPINAL SUB-STANTIA GELATINOSA (LAMINA II) NEURONS OF ADULT RATS. A. R. Light*, and H. H. Willcockson. Department of Physiology, University of North Carolina, Chapel Hill, NC 27599-7545

We developed a procedure for in vivo, whole-cell recording in adult rats to compare to in vitro techniques (Schneider and Light, Soc. Neurosci. Abstr. 20: 1730, 1994). Rats weighing ~250 g were anesthetized with sodium pentobarbital and chloral hydrate, respired, paralyzed with pancuronium bromide and suspended in a spinal frame. Following stabilization and lumbar laminectomy, recordings were made with patch-clamp electrodes (5-8 MQ, K-gluconate internal solution with ATP, GTP, and biocytin), using an Axo-Clamp in the bridge balance mode. Standard cell attached recordings with initial impedances >1 G Ω , were reduced with gentle suction and rupturing of the membrane to 200-500 M Ω . Thirty neurons were recorded (receptive fields: lateral leg, and hip): 12 slow brush, 11 nociceptive, 2 cooling, and 5 without receptive fields. These cell types are similar to those found in previous conventional recordings in cats and monkeys. Resting membrane potentials were -45 to -65 mV. postsynaptic potentials were observed with amplitudes <10 mV. Summed evoked EPSP's were often as large as 30 mV leading to 30-80 mV action potentials. Labeling three neurons with biocytin confirmed recording locations in the marginal zone (lamina I) and substantia gelatinosa. Supported by NINDS grants NS16433, NIDA DA04420 (A.R.L.) and P01NS14899 (Edward R. Perl, PI).

PHOSPHORYLATION OF CREB IN THE RAT SPINAL CORD FOLLOWING FORMALIN STIMULATION. R. R. Ji, D. Ginty and F. Rupp*. Dept. of Neurosci., Sch. of Med., Johns Hopkins Univ., Baltimore, MD 21205

Phosphorylation of the transcriptional factor CREB at serine 133 following tissue injury induced-inflammation and hyperalgesia has been examined. Unphosphorylated CREB present in most nuclei of spinal cord nurons and 10% DRG neurons. However phosphoCREB (pCREB) was only found in few nuclei in the normal spinal cord. Formalin injection into the left hindpaw induced a bilateral phosphorylation of CREB. Numerous pCREB-positive nuclei were found in laminae I, II, V and X of the spinal cord. The phosphorylation was very rapid and reached to the peak level in several min. The induction of pCREB was mainly postsynaptic, since only 5% DRG neurons with small size on both sides were labeled. In contrast c-Fos induction, appearing as early as 30 min after inflammation, was ipsilateral. The formalin evoked-pCREB and c-Fos in the spinal cord was distinctly suppressed by pretreatment of NMDA receptor antagonist MK-801 (i.p, 3.5 mg/kg) or by a brief halothane anesthesia. Our results suggest CREB phosphorylation, partially through an activation of NMDA recepor, may be involved in a long-term facilitation of the spinal cord neurons following tissue injury and hyperalgesia, b) CREB phosphorylation may be necessary but not sufficient for c-fos expression.

C-FIBER RESPONSES OF DORSAL HORN NEURONS ARE FACILITATED FOLLOWING STIMULATION OUTSIDE THEIR RECEPTIVE FIELD. J. Li*1, D.A. Simone1 and A.A. Larson2. Dept. of Psychiatry¹ and Vet. Pathobiology², Univ. of Minnesota,

Minneapolis, MN 55455. Hyperalgesia is mediated, in part, by enhanced excitability of dorsal horn neurons. "Wind-up" of dorsal horn neurons refers to the progressive potentiation of C-fiber response during trains of electrical stimulation and "wind-up" has been used as a model of synaptic plasticity. Increase in the number of responses of dorsal horn neurons have been demonstrated following injury to or inflammation of the receptive field. We investigated whether stimulation outside the receptive field facilitates responses to C-fiber input, as evident by facilitation of wind-up. Recordings were made from wide dynamic range neurons in the dorsal horn of anesthetized rats. Responses evoked by 12 trials of electrical stimuli at low frequency (0.5Hz) and constant intensity to the cutanous receptive field were summed. Responses of dorsal horn neurons were evaluated by monitoring C-fiber input, "wind-up", and the total number of spikes evoked by C-fiber activity in response to the 12 stimuli. We found that electrical stimulation outside the receptive field increased the total number of C-fiber spikes (146%) and caused an increase in C-fiber input (166%) evoked by electrical stimulation inside the receptive field. These data indicate that stimulation outside the receptive field may increase C-fiber responses to stimulation applied within the receptive field. Supported by NIH grants NS31223 and DA04090.

INTRADERMAL INJECTION OF CAPSAICIN (CAP) EVOKES SPINAL FOS-LABELING AND EXCITES DORSAL HORN NEURONS. E. R. Stevens, J. Li, D. A. Simone, and K. C. Kajander*. Depts. of Psychiatry, Oral Science, and Cell Biology & Neuroanatomy, and Grad. Prog. in Neuroscience, University of Minnesota, Minneapolis, MN 55455

In the spinal cord, immunocytochemical labeling for Fos-protein and electrophysiological responses increase after noxious stimulation, inflammation, or peripheral nerve injuries. We evaluated spinal Foslabeling and electrophysiological responses of spinal neurons in rats after intradermal injection of CAP (1, 10, or 30 μg —Fos experiments; 10 μg —electrophysiological experiments). In the Fos experiments, one hour after injection into the plantar surface of the hindpaw, rats were deeply anesthetized and perfused transcardially with saline followed by 4% paraformaldehyde. Spinal segments L4-L5 were removed, post-fixed, and cryoprotected. Spinal sections were processed using a Fos-protein antibody (Cambridge Research Biochemicals). Sections were evaluated and drawn using light microscopy, and labeled nuclei were counted off the drawings. As compared to the contralateral side, greater Fos-labeling occurred in the spinal gray matter ipsilateral to the injections (ANOVA, p<.01). Also labeling increased as CAP dose increased (p<.01). In electrophysiological experiments, CAP was injected into the receptive field of dorsal horn neurons characterized as responding to both innocuous and noxious stimulation (wide dynamic range neurons). Responses of these neurons upon CAP injection was vigorous and prolonged, usually lasting more than five minutes. These experiments demonstrate that intradermal injection of CAP excites rat dorsal horn neurons and increases spinal Fos-labeling. (Research supported by NIH grants NS29567 & NS31223)

REDISTRIBUTION OF CAPSAICIN FROM THE INJECTION SITE AND RESULTING EXCITATORY ACTIONS ON REMOTE SPINAL NEURONS, W.J. Roberts, and R.C. Kramis. R.S. Dow Neurol. Sciences Institute, Legacy Health Systems, Portland OR 97209

Local injections of capsaicin (100 μ g) are commonly used to excite primary afferent nociceptors and to change the excitability of nociceptors innervating the injection area. Studies with very large systemic doses of capsaicin (e.g 125 mg/kg) have demonstrated widespread depletion of neuropeptides in many afferent systems (Gamsel et al, 1981). In the present study we have found that injections of small amounts of capsaicin into the rat hindpaw (0.3-1.0 mg) result in widespread activation of dorsal horn neurons as evidenced by expression of c-fos in spinal segments anatomically distant from the injection site (e.g. cervical and contralateral lumbar segments). Transection of the nerve innervating the injection area reduces c-Fos immunoreactivity in ipsilateral lumbar segments but not that in cervical segments. These results suggest that capsaicin is redistributed via the circulatory system and that it subsequently induces transmitter release from nociceptors systemically, probably through actions on the central terminals or cell bodies of primary nociceptors. Redistribution of capsaicin beyond the injection site is likely to occur at all doses; the sensory consequences of the redistribution will depend on the resulting peripheral and central concentrations of the algogen. Supported by NIH (NS32316).

ULTRASTRUCTURAL COLOCALIZATION AND SYNAPTIC ASSOCIATION OF μ -OPIOID RECEPTORS AND SUBSTANCE P IN THE SPINAL DORSAL HORN. PY Cheng*1, SA Aicher1, S Sharma1, LY Liu-Chen², VM Pickel¹, ¹Dept of Neurology and Neuroscience, Cornell Univ Medical College, New York, NY, 10021. ²Dept. of Pharmacology, Temple Univ School of Medicine, Philadelphia, PA, 19140.

The spinal analgesic effects of opiates acting at the mu opioid receptor (MOR) are thought to involve presynaptic inhibition of substance P (SP)

release from primary afferents in the superficial laminae of the dorsal horn of the spinal cord. To determine if MOR has a cellular distribution that underlies this presynaptic action of opiates, we examined dual immunogold and immunoperoxidase labeling of SP and MOR in this region of the rat cervical spinal cord. By light microscopy, both MOR-like immunoreactivity (MOR-LI) and substance P-like immunoreactivity (SP-LI) were detected in varicose processes in lamina I and II of the spinal dorsal horn. Electron microscopic examination of these laminae showed that MOR-LI was localized mainly to the cytoplasmic surfaces of axons and terminals, as well as numerous dendrites. In contrast, SP-LI was mainly seen in dense core vesicles within unmyelinated axons and terminals. Dendrites more rarely contained detectable SP-LI. The MOR-LI was detected presynaptically in axon terminals containing SP and in dendrites receiving synaptic input from terminals containing the neuropeptide. These results suggest that the analgesic effects of opiates acting at MOR are attributable to both (1) decreased release of SP from dense core vesicles in primary afferents and (2) diminished postsynaptic responses to SP or coexisting neurotransmitters.

MICROINJECTION OF GLUTAMATE IN TRIGEMINAL SUBNUCLEUS CAUDALIS (Vc) PRODUCES EXCITATORY EFFECTS IN RAT JAW MUSCLES. C.-M. Tsai*, B.J. Sessle, and J.W. Hu. Dept. of Oral Physiology, Fac. of Dentistry, Univ. of Toronto, Toronto, Canada. M5G 166

We have previously shown in rats that lesions of Vc, an important brainstem relay of craniofacial nociceptive information, or preadministration of MK-801, a glutamate subtype (MMDA) antagonist, can reduce the increases of electromyographic (EMG) activity in digastric (DIG) and masseter (MASS) muscles reflexly evoked by injection of mustard oil into the temporomandibular joint region. We have also shown that electrical microstimulation in Vc produces excitatory responses in these jaw muscles and that the loci associated with the lowest response threshold and shortest latency are in the caudal Vc. To determine whether these responses are due to activation of neurones as opposed to fibres of passage in Vc, sodium glutamate (GLU), an excitatory amino acid and cell excitant, was microinjected into Vc. Twenty-four male Sprague-Dawley rats anaesthetized with halothane/N,O/O, were equally divided into four groups. GLU (0.5 M in saline; 40 nL) was injected via a micropipete into the exposed left caudal brainstem at a different site (rostral Vc, caudal Vc, C2 segment, or the adjacent reticular formation) in each group of rats. EMG activity was recorded bilaterally from DIG and MASS to determine the incidence, latency, amplitude and duration of any evoked jaw muscle activity. GLU injection into the caudal Vc evoked an increase ±S.D., 560±410 %) and MASS (530±430 %). The increased EMG activity had a latency of 4.2±2.8 s, peaked by the first min and lasted for 8.5±5.9 min. In contrast, GLU injection into the other loci. These findings indicate that the effectiveness of Vc lesions and preadministration of MK-801 in reducing the mustard oil-evoked EMG responses may be explained by their interference with glutamate-mediated excitatory effects on Vc interneurones involved in craniofacial n

OPIOID INHIBITION OF TRACT OF LISSAUER, BUT NOT DORSAL ROOT, STIMULATION-EVOKED FIELD POTENTIALS IN THE RAT SPINAL CORD SLICE PREPARATION. G.W. Terman*, and C. Chavkin^.

SPINAL CORD SLICE PREPARATION. G.W. Terman", and C. Chavkin". Departments of Anesthesiology* and Pharmacology^, University of Washington, Seattle, WA. 98195.

In vitro slice electrophysiology methods are powerful tools in the study of pharmacological mechanisms in many CNS regions. Such methods allow administration of known drug doses to the studied synapses and collections of the studied synapses and collections. allow administration of known drug doses to the studied synapses and facilitate mechanistic studies of physiological circuitry (including studies of pre vs post-synaptic effects, the importance of inhibitory interneurons and the specific ion channels activated). Slice studies in the spinal cord, particularly those involving presumed pain circuitry, have suffered from the inability to preferentially stimulate small fibers (i.e., those fibers most likely to carry nociceptive information) with spinal dorsal root electrical stimulation (DR). The present studies compare the properties of field potentials evoked by DR and Lissauer's tract stimulation (LT). Lissauer's tract is known to contain primary afferents likely to transmit nociception. Transverse slices were made from the lumbar spinal cord of 14-21 day old rats. The slices were placed in a chamber and perfused with O2-bubbled artificial CSF also containing bicuculline (10 µM) and strychnine (1uM). The dorsal root remnant and the tract of Lissauer were

(1µM). The dorsal root remnant and the tract of Lissauer were sequentially stimulated once every minute (at the S1/2 current intensity) and the resultant field potentials recorded in ipsilateral Lamina V with a 3M NaCl filled glass micropipette. DR produced a field potential with a minimum conduction velocity of 5m/sec, whereas the LT evoked field potentials had a 0.3m/sec minimum conduction velocity. Both stimulation sites produced field potentials greatly diminished by MgCl₂ (10mM)(n=4) or CNQX (10 μ M)(n=3). In contrast, only the LT evoked field potentials were significantly inhibited by the mu opioid receptor agonist DAMGO (1 μ M)(n=6). This inhibition was significantly reversed by naloxone (1 μ M)(n=5). Supported by DA00266.

Containing Terminals Contact Immunoreactive Dendrites in the Dorsal Horn of the Rat Spinal Cord. V. M Pickel*, S. Sharma, P. Y. Cheng and S.A. Aicher. Dept. of Neurol. & Neurosci., Cornell Univ. Med. College, NY, NY 10021

Substance P-containing terminals in the dorsal horn of the spinal cord predominantly belong to primary afferent fibers arising from the periphery and may play a role in the transmission of noxious stimuli to second-order neurons. These terminals are thought to also release glutamate as a neurotransmitter, and post-synaptic responses to glutamate release may be mediated through NMDA receptors. We combined immunocytochemical localization of Substance P (SP) and the NMDA-R1 receptor subunit, to determine if there may be direct pre- or post-synaptic interactions between these neurotransmitter systems. Regions of laminae I and II of the dorsal horn in the rat cervical spinal cord containing both labels were examined at the ultrastructural level. SP-like immunoreactivity was located primarily and axon terminals. NMDA-R1-like axons immunoreactivity (NMDA-LI) was seen mainly in dendrites, but also in perikarya, axons, axon terminals, and glial processes. SP was most often seen in large dense core vesicles in axon terminals forming asymmetric synapses with dendrites both with and without detectable NMDA-LI. SPlabeled terminals less frequently either (1) converged on a common target with another terminal containing NMDA-LI or (2) also contained immunolabeling for the NMDA receptor. These results support the conclusion that both the post-synaptic responses and pre-synaptic release of transmitter from SP-containing terminals are modulated by glutamate acting at NMDA receptors in the superficial laminae of the rat spinal cord. (Support: NIH #HL18974; Amer. Heart Assoc. Grant-in-Aid to SAA).

C-FOS EXPRESSION IN TRIGEMINAL NUCLEUS FOLLOWING EITHER SKIN INCISION OR MUSTARD OIL APPLICATION TO MAXILLARY SKIN. S. Chaisin, K.J. Heyeraas, A.R. Light and W. Maixner* Dental Research Center, School of Dentistry and Dept. of Physiology, School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7455

C-fos-like immunoreactivity (Fos-LI) has been shown to be a marker for cells which respond to nociceptive stimuli. We studied the somatotopic distribution of immunoreactive c-fos protein resulting from either a 12 mm incision of the maxillary skin or topical application of C-fiber stimulant mustard oil to the maxillary skin. Fos-LI distribution 2 hours after application of the noxious insult was determined. Both skin incision and mustard oil induced Fos-LI in the trigeminal nucleus caudalis and trigeminal nucleus interpolaris. Fos-LI ipsilateral to the site of skin incision or mustard oil treatment was greater (P<0.05) than on the contralateral side in discrete regions of trigeminal nucleus caudalis and trigeminal nucleus interpolaris. In contrast to these findings, the number of immunoreactive cells in the nucleus tract solitaris and ventrolateral medulla of the brain stem were not significantly different for the two treatment groups. Comparison of brain stem Fos-LI ipsilateral to the site of skin incision and mustard oil application revealed qualitative and quantitative differences. Mustard oil evoked greater Fos-LI compared to skin incision in trigeminal nucleus caudalis (P<0.05). Also, the somatotopic organization of Fos-LI in the superficial regions of the trigeminal nucleus caudalis was more discretely localized in response to skin incision compared to mustard oil. These findings suggest that the nociceptive responses to skin incision and mustard oil are likely mediated by neurons in trigeminal nucleus caudalis and trigeminal nucleus interpolaris. Further studies will investigate if skin and mustard oil stimulation activate different nociceptive pathways within the trigeminal nucleus. Supported by DE11661 (W.M.) and NS16433 (A.L.).

ACTIVATION OF NEURONS IN RAT DORSOMEDIAL TRIGEMINAL N. CAUDALIS (Vc) BY APPLICATION OF A SPECTRUM OF IRRITANT CHEMICALS TO THE TONGUE E. Carstens*, N. Künzler and H.O. Handwerker. Inst. Physiology & Exp. Pathophysiology., Univ. Erlangen (FRG) and Sect. Neurobiology, Physiology & Behavior, Univ. Calif., Davis, CA 95616.

To study trigeminal mechanisms of oral irritation, we recorded responses of neurons

To study trigeminal mechanisms of oral irritation, we recorded responses of neurons in brainstem Vc to application of irritant chemicals to the tongue in thiopental-anesthetized rats. Units in superficial layers of dorsomedial Vc responding to noxious heating of the ipsilateral tongue were tested with the following chemicals delivered epilingually: histamine (his), nicotine (nic), capsaicin (cap), piperine (pip), mustard oil (mo), serotonin (5HT), acid (phosphate buffer pH 4 to 1 = pH), NaCl and ethanol (EtOH). Dose-response relationship, and tachyphylaxis to repeated application at one concentration, were tested for each chemical.

31/32 units responded to at least one chemical, and 33% responded to all 9. The unit population responded to 133/173 (77%) of tested chemicals (incidence: his 88%, nic 85%, 5HT 65%, NaCl 74%, pH 94%, EtOH 85%, cap 74%, pip 56%, mo 50%). The incidence of responses was independent of the order of chemicals tested, except that cap reduced subsequent responses (desensitization). Onset and duration of averaged responses were longest for cap, pip and mo. Responses significantly increased in a dose-related manner for his (9x10⁻¹·10⁻⁴ M), NaCl (0.5-5M), EtOH (15-50%), and pH. Successive responses to repeated application decreased significantly only for nic, NaCl, 5HT, cap and pip. Spontaneous firing increased significantly 5-10 min after cap. Responses to his and nic were significantly reduced by ceterizine (HI antagonist) and mecamylamine, respectively.

These data support the idea of a common chemical sense ("chemesthesis"), whereby different irritant chemicals activate a common population of sensory neurons in Vc. presumably via independent peripheral transduction mechanisms.

THE EFFECT OF DORSAL COLUMN LESIONS UPON BONE PAIN A. Houghton*, E. James-Hewitt and K. N. Westlund. Marine Biomedical institute. University of Texas Medical Branch, Galveston, TX 77555-1069

Recent studies have shown that a lesion to the midline dorsal column of the spinal cord in rats can block visceral pain induced by colon distension. The aim of the present study was to determine if dorsal column lesions can also reduce bone pain. At present the only treatment for bone cancer pain is radiation and morphine.

present the only treatment for bone cancer pain is radiation and morphine. Experiments were performed on 14 male rats (240-350 g). In all rats bone pain was induced by making a hole (1mm diameter) through the tibia of the left leg with a hand drill under anaesthesia. In seven of the rats a lesion of approximately 1 mm in depth was made in the midline dorsal column of upper thoracic level of the spinal cord. The lesion was made after a small laminectomy under anaesthesia two days prior to the induction of the bone pain. No neurological defects were observed after the lesion was made. Hyperalgesia was quantified by measuring the paw withdrawal threshold to a mechanical stimulus. Four strengths of von Frey hair were used (8, 10, 50, 100 mN), and were presented to the anterior plantar surface of both hindlimbs ten times. Mechanical threshold was tested before the hole was drilled and at 30 min intervals for 4 hr afterwards. An increased percentage of paw withdrawals to the same strength hair was considered hyperalgesia, whereas response to a strength of hair which previously evoked no response was considered allodynia.

After the hole was drilled, both hyperalgesia and allodynia were observed. The mean response to the 50 and 10 mN hair strengths was increased from $23 \pm 9 \%$ to $71 \pm 12 \%$ (n = 7) and 0 % to $50 \pm 15 \%$ respectively, 2 hr post injury. In contrast, in the lesioned rats no hyperalgesia or allodynia was observed after the hole was drilled.

These studies suggest that information about deep pain is carried through the midline dorsal column and includes bone pain in addition to visceral pain. Thus, dorsal column lesions may prove to be an effective treatment for patients suffering from bone cancer pain. Supported by NIH grants RO1 NS28064 and NS11255.

RETROGRADE IDENTIFICATION OF LAMINA I NEURONS THAT PROJECT TO THE CAUDAL VENTROLATERAL MEDULLA (CVLM) IN THE CAT. K. Krout and A.D. (Bud) Craig. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, Arizona 85013.

The CVLM, where AI medullo-hypothalamic neurons are located, is involved in a variety of homeostatic responses to small-diameter somatic afferent input. Recent PHA-L results demonstrating bilateral input to the CVLM (and AI neurons) of cats and monkeys from lamina I indicate an ascending pathway for such inputs. Because different morphological types of lamina I cells correspond to distinct physiological classes responsive to nociceptive and thermoreceptive inputs (SN 20:547, 1994), we have sought to determine which types of lamina I neurons project to the CVLM with retrograde labeling.

Recordings made in the CVLM in isoflurane-anesthetized cats identified single units responsive to natural noxious (pinch, heat) and thermal (cold) stimuli over large receptive fields (eg hemi-body). Single iontophoretic injections of CTb (2µA, 20 min; to avoid uptake by fibers of passage) were made at such sites and, 1-2 wks later, spinal segments were processed with ABC/DAB. At all spinal levels, lamina I neurons were labeled bilaterally, and all three recognized types were included: fusiform, pyramidal and multipolar.

Our physiological and anatomical findings indicate that the CVLM receives activity from lamina I related to pain, temperature, and probably all aspects of the physiological condition of the body, consistent with a broad role for lamina I projections in homeostasis. Such inputs may be integrated in CVLM projections to the hypothalamus and the RVLM, providing a basis for control of autonomic responses to environmental challenges. (Supported by the Barrow Neurological Foundation)

RESPONSES OF NEURONS IN RAT VENTROLATERAL TRIGEMINAL N. CAUDALIS (Vc) TO APPLICATION OF A SPECTRUM OF IRRITANT CHEMICALS TO CORNEA AND PERIORBITAL TISSUE. N. Künzler, E. Carstens, R.L. Kitchell*, & H.O. Handwerker. Inst. Physiology Exp. Pathophysiol., Univ. Erlangen (FRG) and Neurobiology, Physiology & Behavior, UC Davis, CA 95616.

To study trigeminal mechanisms of corneal irritation, we recorded responses of single units in ventrolateral Ve to application of irritant chemicals to cornea/periorbital skin in thiopental-anesthetized rats. Units responsive to noxious corneal heating were tested with: histamine (his), nicotine (nic), capsaicin (cap), piperine (pip), mustard oil (mo), serotonin (5HT), acid (phosphate buffer pH 4 to 1 = pH), NaCl and ethanol (EtOH). Dose-response relationship, and tachyphylaxis to repeated application at one concentration, were tested for each chemical.

14/30 units had mechanoreceptive fields restricted to cornea and eyelids, and the rest had larger facial fields encompassing the cornea. 28/30 responded to >1 chemical delivered topically to the cornea. The population responded to 115/177 (65%) of tested chemicals (EtOH 85%, nic 83%, cap 82%, pH 73%, NaCl 67%, pip 62%, mo 58%, his 46%, 5HT 25%). Responsiveness appeared to be independent of the order of chemical application (cap, pip and mo were tested last to avoid desensitization). Averaged responses to NaCl and mo peaked more slowly; duration of responses to pH and cap were longest. Responses significantly increased in a dose-related manner to his (9x10⁻¹-10⁻⁴ M), nic (6x10⁻¹-10⁻⁴ M), NaCl (0.5-5M), pH, cap (3x10⁻³-10⁻⁵ M) and mo (8-50%). Successive responses to repeated application decreased significantly for nic, EtOH, and mo, tended to decrease for cap, pip and 5HT, and remained constant for the others. Responses to nic were significantly attenuated by prior corneal application of mecannylamine.

Activation of individual trigeminal neurons by many irritant chemicals delivered to cornea and periorbital tissue provides further support for a "common chemical sense".

CARDIOPULMONARY SYMPATHETIC AFFERENT INPUT EXCITES CUNEATE-THALAMIC NEURONS IN MONKEYS. M.J. Chandler*, J. Zhang and R.D. Foreman. Dept. Physiology, Univ. of Okla. HSC, Okla. City. OK 73190

Stimulation of cardiopulmonary sympathetic afferent fibers (CPSA) excites thoracic and cervical spinothalamic tract neurons which respond primarily to noxious somatic inputs. Neurons in dorsal column (DC) nuclei respond primarily to innocuous somatic inputs. Recent evidence in rats shows that neurons in gracilis nucleus are excited or inhibited by noxious stimulation of pelvic organs. The hypothesis of this study is that CPSA input excites relay neurons in cuneate nucleus. Extracellular action potentials of 11 neurons antidromically activated from ventroposterolateral (VPL) thalamus were recorded in cuneate nucleus of 4 anesthetized male monkeys. Electrical stimulation of the ipsilateral stellate ganglion to activate CPSA excited 7 cells and did not affect activity of 4 cells. Transection of DC + ipsilateral dorsal lateral pathways (DLF) at C4 eliminated CPSA excitation in 2 of 2 cells. Of 10 cells examined for somatic field characteristics, 6 were low-threshold (LT), 2 were wide dynamic range, 1 was high-threshold, and no somatic field was found for 1 cell; receptive fields were located on small areas of upper body regions. Of 7 cells excited by CPSA, 3 were excited by noxious somatic input, 3 were LT, and 1 cell was not tested for somatic field. These results showed that CPSA input travels in DC and/or DLF to activate cuneate nucleus neurons which project to contralateral VPL Thus, these neurons might participate in integration of nociceptive information from the heart. (NIH grant HL22732)

341.16

RESPONSE PROPERTIES OF INTRACRANIAL MENINGEAL AFFERENTS IN RAT SUGGEST THESE FIBERS CONTRIBUTE TO HEADACHE PAIN. <u>A.M. Strassman', S.A. Raymond and R. Burstein</u>, Dept. Anesthes., Beth Israel Hosp. and Harvard Med. Sch., Boston, MA 02215.

Theories of migraine headache have focused on the possible activation of intracranial meningeal sensory afferents by mechanical or chemical stimuli, or both. However, there is little direct data on the responses of meningeal afferents, and none on their possible chemosensitivity. We have recorded the activity of rat trigeminal ganglion cells that innervate the dural venous sinuses during mechanical and chemical stimulation of their dural receptive fields. Such cells were identified by their response to electrical stimulation of the dura overlying the ipsilateral transverse sinus. The majority of neurons (22/32) that were activated by dural shock exhibited mechanosensitive receptive fields on the dura from which they could be activated by punctate probing with von Frey hairs or by stroking with a blunt rod. A subset of the neurons (17/23) exhibited chemosensitivity in response to topical application of algesic or inflammatory agents to the dura, including solutions of hypertonic sodium chloride, potassium chloride, capsaicin, high or low osmolarity, and a soup of inflammatory agents (histamine, serotonin, bradykinin, and prostaglandin E2, pH 5). Sensitization was investigated by determining von Frey thresholds before and after topical application to the receptive field of pH 5.0 buffer or the inflammatory soup. Lowered mechanical thresholds were found in 7 of 9 neurons tested. These properties of meningeal afferents (chemosensitivity and sensitization to mechanical stimuli) could account for the intracranial mechanical hypersensitivity that is characteristic of many types of clinically occurring headaches. We suggest that non-painful cardiac pulsation or head movement may become painful during migraine because of chemically induced mechanical sensitization of meningeal afferents. (Supported by the National Headache Foundation, NIH, and BIH Dept. Anesthes.)

CENTRAL MECHANISM OF VASCULAR HEAD PAIN - SENSITIZATION OF TRIGEMINOTHALAMIC, TRIGEMINOHYPOTHALAMIC AND TRIGEMINO PARABRACHIAL NEURONS INNERVATING THE INTRACRANIAL SINUSES. RANDAGONIAL NEURONS INNERVATING THE INTRACHANIAL SINUSES.

R. Burstein, A. Malick and A. Strassman, Department of Anesthesia, Beth Israel Hospital, Department of Neurobiology, Harvard Medical School, 220 Longwood Ave. Boston MA, 02115

Although different theories have been proposed about migraine, most are based on the notion that the headache results from the sensitization and/or excitation of trigeminal sensory neurons that innervate cranial blood vessels. However, direct evidence for the development of sensitization in trigeminovascular neurons is almost entirely lacking. In the present study we have determined the effects of potentially-sensitizing chemical stimuli on the ongoing activity and responsiveness of central trigeminal neurons innervating the intracranial dural sinuses and determined to which brain areas they project.

Trigeminal neurons responding to stimulation of intracranial dural sinuses were identified in the brainstem. The size of their visceral and cutaneous receptive fields and thresholds of mechanical and thermal stimuli were determined before and after exposing the sinus to chemical irritants.

Antidromic stimulation technique was then used to map their axons.

Fifteen trigeminovascular neurons recorded in C1, Vc and Vi exhibited dural and cutaneous receptive fields. Following application of chemical irritants to the dural sinus, several changes developed in the studied neurons: their thresholds to mechanical stimulation of the sinus and to mechanical, heat and cold stimulation of the facial skin decreased; the size of the dural receptive field increased; and in some cases they developed ongoing activity. Some neurons were antidromically activated from the parabrachial nucleus,

neurons were anutorinically activated from the paragrachial nucleus, ventroposterior medial thalamus, or lateral hypothalamus.

These findings suggest that irritation of cranial blood vessels can sensitize central trigeminal neurons that project to brain areas involved in somatosensory and affective responses to head pain.

SOMATOSENSORY RESPONSE PROPERTIES OF SPINOHYPOTHALAMIC TRACT NEURONS IN THE UPPER CERVICAL SEGMENTS OF RATS. X. Zhang*, A.P. Gokin and G.J. Giesler, Jr., Dept. of Cell Biol. & Neuroanat., Univ. of Minn., Minneapolis, MN 55455.

Morphological studies in rats have shown that about 30% of the entire population of spinohypothalamic tract (SHT) neurons is located in upper cervical segments. The aim of this study was to characterize somatosensory response properties of these neurons. Eighteen neurons in segments C1-2 of urethane-anesthetized rats were antidromically activated using pulses of ≤30 μA in the contralateral hypothalamus. The recording points were located in the lateral reticulated area (16) and nucleus proprius of the dorsal horn (2). The mean antidromic latency from the hypothalamus was 2.5 ms (1.5-5.1 ms); the mean conduction velocity was 10 m/s (4.7-15.6 m/s). Cutaneous receptive fields (RFs) were determined using innocuous and noxious mechanical stimuli. Each of 15 tested neurons responded exclusively or preferentially to noxious stimuli. Twelve were classified as high threshold and 3 as wide dynamic range. Five neurons had RFs that were restricted to the head and neck. Four had large RFs that included the head, neck, forelimbs and parts of the trunk and hindlimbs. Six had RFs that covered the entire body. The receptive fields were generally bilateral with the most sensitive regions consistently located on the generally bilateral with the most sensitive regions consistently located on the ipsilateral cheek. Bilateral antidromic mapping was done in the hypothalamus to determine the trajectories of 13 axons. Ten axons terminated in the contralateral hypothalamus, and 3 crossed the midline and terminated in the ipsilateral hypothalamus. These results indicate the somatosensory characteristics of SHT neurons in upper cervical segments differ from SHT neurons examined at all other levels of the cord. It appears that SHT neurons in upper cervical cord process and relay nociceptive information from widespread areas of the body to the hypothalamus. Supported by NS25932 and DA07234.

SPINODIENCEPHALIC TRACT (SDT) NEURONS IN THE THORACIC SPINODIENCEPHALIC TRACT (SDT) NEURONS IN THE THORACIC SPINAL CORD OF RATS: RESPONSES TO CUTANEOUS AND VISCERAL STIMULATION, A.P. Gokin*, X. Zhang, C.N. Honda, G.J. Giesler, Jr. Dept. of Cell Biol. & Neuroanat., Univ. Minnesota, Minneapolis, MN 55455.

Large numbers of neurons in the rat thoracic spinal cord project directly to

the hypothalamus (H), thalamus or both. The aim of this study was to characterize the responses of these neurons to somatic and visceral stimuli. In lower thoracic segments of urethane-anesthetized rats, 17 SDT neurons were antidromically activated using current pulses \leq 30 μ A. Twelve neurons were antidromically activated from both the contralateral thalamus and H (STT/SHT) and 5 were activated from only the posterior thalamus (STT). The axons of all examined neurons passed through or terminated in posterior thalamus. Axons of half of the studied STT/SHT neurons crossed the midline and entered the ipsilateral H; three appeared to terminate in the contralateral H. 16 SDT neurons were recorded in deep dorsal horn (DDH) and 1 in lateral spinal nucleus. Based on their responses to innocuous and noxious cutaneous stimuli, 4 SDT neurons were classified as low threshold, 5 as wide dynamic range, and 7 as high-threshold (HT). Cutaneous receptive fields were located ipsilaterally over the posterior rib cage and anterior and ventral abdomen. Responses to distention of the bile duct were examined for 6 SDT neurons (3 STT/SHT, 3 STT). In 4 cases, stimulation evoked excitatory (3) or inhibitory responses. The range of thresholds for responses to bile duct distention was 40-50 mmHg. Responses incremented gradually as pressure was increased to 65-80 mmHg. Responsive neurons were located in the DDH. Neurons that responded to distention of the bile duct were classified as HT (2) or WDR (2). These data indicate that SDT neurons in rat thoracic spinal cord are capable of conveying somatic and visceral nociceptive information directly to targets in the contralateral and ipsilateral hypothalamus and thalamus. Supported by NS25932 and DA07234.

PAIN MODULATION: ANATOMY AND PHYSIOLOGY-NEUROPATHIC PAIN

342.1

THE DEVELOPMENT OF TACTILE HYPERSENSITIVITY VARIES AMONG STRAINS OF THE MICE AFTER A PERIPHERAL NERVE INJURY. K. Chung*, H. Noh and J. M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The purpose of this study was 1) to determine whether neuropathic pain behaviors develop after peripheral nerve injury in mice and 2) if they do, whether there is any difference in neuropathic pain behaviors among different strains of mice.

Six different strains of adult male mice were used for this study. Under halothane anesthesia, neuropathic injury was produced by tightly ligating the spinal nerve (L4 or L5, left side) with 6.0 silk thread. Behavioral tests for evoked tactile sensitivity to von Frey hair (ranging from 0.03 to 5.5 g) stimulations were conducted for presurgery and 1 day (D), 4D, 7D, and 14D postoperatively. Tactile hypersensitivity was measured by determining the median 50% foot withdrawal threshold using the up-down method.

The data demonstrated that all tested strains of mice had lower (as compared to the normal) thresholds to tactile stimuli one day after the neuropathic surgery. However, the severity and duration of the tactile hypersensitivity varied greatly among different strains of mice. (Supported by NIH grants NS31680 and NS11255)

ENDONEURIAL INJECTION OF TNF-α OR CEREMIDE PRODUCES PATHOLOGIC CHANGES AND PAIN BEHAVIORS SEEN IN NEUROPATHIC PAIN STATES. R.R. Myers* and R. Wagner. Departments of Anesthesiology and Pathology, UC San Diego, La Jolla, CA 92093-0629

TNF is a proinflammatory cytokine produced by activated fibroblasts, endothelial cells, mast cells and macrophages in painful peripheral nerve injuries. Our recent observation that it is also produced by Schwann cells in these nerves prompted us to explore its role in primary nerve injury and pain. We injected $10 \mu l$ of a 2.5 pg/ml TNF- α solution or $10 \mu l$ of a 1mM ceremide solution into rat sciatic nerve. Ceremide is a second messenger produced by TNF receptor activation. Behavioral testing was performed 1, 3, and 5 days after injection. Separate animals were used for histology at the same timepoints. One day after TNF injection, animals displayed marked thermal hyperalgesia that persisted until day 5 (p<0.05, day 3). Allodynia was significant at days 1 and 5. Ceremide injections produced less thermal hyperalgesia, but significant allodynia at 3 and 5 days. Vehicle-injected animals had only minor mechanical allodynia (9g) at day 1. small injection volumes produced local neuropathic changes including edema initially, then myelin splitting, demyelination, and occasional axonal degeneration by days 3 and 5. Ceremide-induced pathology was slightly more severe, including more axonal degeneration. Vehicle-injected nerves showed only mild edema between days 1 and 3.

We conclude that local injections of TNF-α or ceremide into rat

sciatic nerve produces behavioral and neuropathologic changes observed in several models of severe neuropathic pain.

IMMUNOREACTIVITY FOR THE 55kD TNF-α RECEPTOR AT THE SITE OF PERIPHERAL NERVE INJURY PARALLELS THE DISPLAY OF NEUROPATHIC BEHAVIOR FOLLOWING CCI IN THE RAT R. Wagner*, J. Dolkas, and R.R. Myers, Department of Anesthesiology, UC San Diego, La Jolla, CA 92093-0629.

We recently observed an increase of TNF immunoreactivity (IR) at the site of injury in different neuropathic pain models. We chose to monitor the expression of the 55kD receptor of TNF following

peripheral nerve injury, as the 55kD receptor for TNF (rTNF) is known to moderate many of TNFs cytotoxic functions.

Rats received a chronic constriction injury (CCI) [Bennett and Xie, 1988] to one sciatic nerve at mid-thigh level and were then sacrificed after 18 hours, 3, 5, 7, 14, or 28 days (n=3 each group). Tissue from after 18 nours, 5, 5, 7, 14, 6) 28 days (11=5 each group). Itssue from the injury site, or from non-injured control animals, was removed and embedded in paraffin. Ten-micron-thick sections were stained immunocytochemically using DAB with Ni as a chromagen. rTNF-IR was present in endothelial cells, Schwann cells, and macrophages. Morphometric analysis of the entire tibial fascicle was used to quantify the ratio of rTNF-IR cells to total counts within the endoneurium. This analysis revealed that endoneurial cells demonstrating rTNF-IR significantly increased at 5, 7, and 14 days $[12.8\% \pm 2, 15.39\% \pm 0.5]$, and $15.8\% \pm 0.7$, respectively] compared to non-injured control sections $[7.2\% \pm 1.9]$. Measurements at 18 hours, 3 and 28 days were not significant from controls.

This study demonstrates that the site of injury exhibits significantly increased rTNF immunoreactivity at times associated with the display of thermal hyperalgesia in the rat following CCI.

PLASTICITY OF THE CIRCUITRY OF THE SUPERFICIAL DORSAL HORN OF THE RAT IN A MONONEUROPATHY MODEL OF NEUROPATHIC PAIN. Diane Daly Ralston*, Sandra Canchola, Xianwei Meng and Henry J. Ralston III. Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco CA 94143-0452.

The loose-ligature model of Bennett and Xie (1988) was used to induce an

The loose-ligature model of Bennett and Xie (1988) was used to induce an experimental mononeuropathy in female rats, the animals surviving for one to several weeks following unilateral placement of ligatures around the sciatic nerve. Hindlimb posture and the animal's behavioral responses to mechanical stimuli were assessed throughout the pre and postoperative periods. Two days prior to euthanasia, the rats were reanesthetized and the sciatic nerves of the ligated and sham-operated sides were microinjected with either wheat-germ agglutinin or choleragenoid conjugated to HRP (WGA-HRP or B-HRP), for the transganglionic labeling of fine diameter or large diameter (respectively) primary afferent projections to the dorsal horn. Vibratome sections of appropriate segments of the lumbar enlargement were processed for the demonstration of the transported markers and for GABA immunoreactivity (GABA-ir), and were subsequently examined and quantified by light and electron microscopy. and were subsequently examined and quantified by light and electron microscopy.

Behavioral testing revealed that some animals exhibited only modest postural

Behavioral testing revealed that some animals exhibited only modest postural changes and little or no allodynia or mechanical hyperalgesia of the limb of the ligated nerve, compared to preoperative behavior or to the sham operated limb postoperatively. Other animals revealed substantial postural changes, allodynia and mechanical hyperalgesia. Both groups of animals revealed modest to marked sprouting of B-HRP labeled afferents into lamina II on the ligated side. Changes in GABA-ir, however, were closely matched to the behavioral state of both groups, the numbers of GABA-ir neurons in laminae I and II being markedly reduced (p<0.05) as were GABA-ir synaptic contacts on dendrites of dorsal horn neurons on the ligated side of those animals exhibiting pain-related behaviors. We conclude that changes in GABA circuitry, rather than sprouting of large diameter afferent fibers per se, play a fundamental role in this model of neuropathic pain. Supported by NIH/NS 21445.

ELECTOPHYSIOLOGICAL PROPERTIES OF DORSAL COLUMN NEURONS IN THE RAT WITH EXPERIMENTAL NEUROPATHY K. Miki*, K. Iwata¹, Y. Tsubo¹¹, R. Sumino¹ and K. Noguchi Department of Anatomy and Neuroscience, Hyogo College of Medicine, Hyogo, 663, JAPAN, ¹Department of Physiology, School of Dentistry Nihon University, Tokyo, 101, JAPAN

We have previously reported that preprotachykinin mRNA is expressed in some large DRG neurons and that substance P immunoreactivity is increased in dorsal column (DCn) nuclei following peripheral nerve injury (J.Neurosci., 15,7633,95). Stimulus-evoked c-los expression in gracile nucleus (GN) was also reported ipsilateral to the nerve injury. Therefore, in addition to the spino-thalamic tract, DCn pathway may have a functional role in the sensory abnormalities seen in neuropathic pain models. To examine this, Sprague Dawley rats had unilaterally chronic constriction nerve injuries (CCl) of their sciatic nerves. Later, single-unit activity was recorded from GN in rats while they were anesthetized with sodium pentobarbital (50 mg/kg. i.p.) and halothane (2-3%). A total of 89 neurons were record from the GN. WDR and LTM neurons were found to be spatially intermingled within the DCn. Five WDR neurons were identified contralateral and 9 were identified ipsilateral to the CCl. Twenty-five LTM neurons were detected contralateral and 34 neurons were detected ipsilateral to the CCl. Spontaneous activity of DCn neurons from the ipsilateral side (mean ± SE, 13.3 ± 2.3 Hz) was slightly higher than those for the contralateral side (9.1 ± 2.2 Hz). Forty of 89 DCn neurons were antidromically activated following electrical stimulation of the ventro-lateral thalamic nuclei (antidromic latency; slightly righer than those for the contralateral side (9.1 \pm 2.2 Hz). For the of 89 DCn neurons were antidromically activated following electrical stimulation of the ventro-lateral thalamic nuclei (antidromic latency; ipsilateral: 3.6 \pm 1.5 msec, contralateral: 2.2 \pm 0.7 msec). Collectively, these data suggest that DCn neurons may be involved in CCI-produced sensory abnormalities by conveying their hyperactivity to the thalamic neurons. AN EXPERIMENTAL NEURITIS OF THE RAT SCIATIC NERVE PRODUCES IPSILATERAL HINDPAW ALLODYNIA AND HYPERALGESIA. E. Eliav, M.A. Ruda, and G.J. Bennett

Neurobiol. & Anesthesiol. Br., NIDR, NIH, Bethesda, MD 20892. The onset of painful peripheral neuropathies involves both axonal damage and an inflammation of the nerve. The role of the latter by itself was investigated by producing an experimental neuritis in the rat. The sciatic nerves were exposed at mid-thigh level and wrapped in 2mm-wide bands of hemostatic oxidized cellulose (Surgicel) saturated with either carrageenan (CARRA; 150 μ 1, 40 mg/ml) or undiluted complete Freund's adjuvant (CFA; 100 μ 1) on one nerve and saline on the other. In other rats, a myositis was created by implanting Surgicel/CFA into a pocket made in biceps femoris at a position adjacent to where the nerve was treated. The plantar hindpaws were tested daily thereafter for heat- and mechanohyperalgesia (HH, MH), and mechano- and cold-allodynia (MA, CA). Microscopic examination indicated that the neuritis (CFA) produced little or no axonal damage. Statistically significant HH, MH, MA and CA were present on the CARRA- and CFAtreated sides for 1-5 days, with normal responses thereafter. No abnormal pain was detected on the saline-treated side, or in rats with the myositis. We conclude that inflammation of the sciatic nerve, but not adjacent muscle, produces abnormal pain in the hindpaw and that this may contribute to the genesis of painful neuropathies. We speculate that a chronic neuritis might produce a neuropathic pain-like syndrome.

342.6

CHANGE IN EXPRESSION OF AMINO ACID RECEPTORS AND NEUROPEPTIDES IN THE SPINAL CORD AND DORSAL ROOT GANGLIA IN A RAT MODEL OF NEUROPATHIC PAIN T. Fukuoka, K. Miki, K. Noguchi* Dept. of Anatomy & Neuroscience, Hyogo College of Medicine, Nishinomiya, Hyogo 663, JAPAN We examined the change in mRNA expression of y-amino butyric acid (GABA)_A receptor subunits and some neuropeptides in primary afferent neurons of an experimental rat model of neuropathic pain. The distribution of fibers containing neuropentides' impunoreactivities in the

distribution of fibers containing neuropeptides' immunoreactivities in the dorsal horn was also studied in this model.

Male Sprague-Dawley rats (150-180g) received tight ligation of left L5 spinal nerves. Foot withdrawal latencies to radiant heat and sensitivity

L5 spinal nerves. Foot withdrawal latencies to radiant heat and sensitivity of the hind paw to mechanical stimulation with von Frey filaments were tested for the next 7 days. After the last evaluation was done, L4,5 dorsal root ganglia (DRG) and L4-L6 spinal cord were dissected out and processed for immunohistochemistry and in situ hybridization.

In normal DRG, most of the large neurons expressed GABAA receptor γ2 subunit mRNA. The level of this mRNA was significantly decreased, while the levels of neuropeptide Y (NPY) and preprotachykinin (PPT) mRNAs were increased in some large L5 DRG neurons ipsilateral to the ligation. Spinal nerve ligation had little effect on these mRNA levels in other DRGs. Immunohistochemistry with calcitonin gene-related peptide and NPY antibodies revealed that increased immunostating in terminals

other DRGs. Immunohistochemistry with calcifonin gene-related peptide and NPY antibodies revealed that increased immunostaining in terminals and fibers in laminae III-IV of L4-6 segments of the spinal cord.

We report the decrease of presynaptic inhibition by downregulation of GABAA receptor and increased content of neuropeptides in primary afferent terminals in laminae III-IV of L4-6 spinal cord segments. This finding may be involved in the abnormalities of signal transmission through intact L4 primary afferent and contribute to the pathomechanisms of neuropathic pain pathomechanisms of neuropathic pain. (Supported by the MESC of Japan and Hyogo College of Medicine.)

NOREPINEPHRINE CHANGES THE MECHANORECEPTOR ACTIVITY IN SYMPATHECTOMIZED NEUROPATHIC RAT. D. H. Lee* and J. M. Chung, Marine Biomed. Inst., Depts. of Anat. & Neurosci. and Physiol. & Biophys., Univ. of Texas Med. Br., Galveston, TX 77555

The aim of this study was to investigate the physiological basis for the rekindling of mechanical allodynia elicited by subcutaneous injection of norepinephrine (NE) in sympathectomized neuropathic rats.

Neuropathic injury was produced by tightly ligating the left L5/L6 spinal nerves of the rats. One week after neuropathic injury, a bilateral lumbar sympathectomy was done. One week after the sympathectomy, single unit activity was recorded from fascicles of the L4 dorsal root (uninjured segment). After determining the type of mechanoreceptor and receptive field into the paw, NE (0.05 mg) was subcutaneously injected to the receptive field. Responses to mechanical stimuli were compared before and after NE injection.

There were numerous mechanoreceptors which showed an increased discharge rate and/or a change in discharge pattern after the subcutaneous injection of NE. The changes were observed in both slowly adapting and rapidly adapting mechanoreceptors.

The data suggest that NE interact with mechanoreceptors at the receptor level to rekindle mechanical allodynia in sympathectomized neuropathic rats. (Supported by NIH grants NS31680 and NS11255)

INDUCTION OF BRADYKININ BINDING SITES AFTER CHRONIC NERVE CONSTRICTION IN RAT SENSORY NEURONS. A.S. Eckert, G. Segond on Banchet, B. Heppelmann, M. Petersen and K.-D. Kniffki* Institute of Physiology, University of Würzburg, 97070 Würzburg, Germany.

Bradykinin (BK), an endogenous pain producing nonapeptide, acts via specific receptors. It has been documented that only the B2 subtype is expressed under normal conditions whereas under chronic inflammatory conditions also the B1 subtype is expressed. We asked whether a chronic mechanical injury of a peripheral nerve affects the expression of BK receptors on sensory neurons. Therefore, we studied changes of the expression of BK binding sites in isolated dorsal root ganglion cells from adult rats following a unitateral tight ligation of the sciatic nerve at midthigh level. After two or ten days, the ganglia L4 and L5 were excised on both sides. As a control, corresponding ganglia from uninjured rats were used. Neurons were enzymatically isolated and grown on coverslips. After 0.8 or 1.8 days in culture BK binding stess were visualized by silver enhanced gold labeled BK and quantified using an image analyzing system. Data were pooled from three cultures and 293 to 542 cells each. From normal rats 47% of the neurons express BK binding sites at day 0.8 and about 85% at day 1.8 in culture. Following a tight ligation of 2 or 10 days the percentage of BK binding neurons from the ligated side was significantly increased to 83% or 90% at day 0.8 in culture and stayed at about this level at day 1.8. Surprisingly, on the contralateral side there was also an upregulation to 83% following a 2 day ligation on day 0.8 in culture. However, this upregulation was transient, because after a 10 day ligation on day 0.8 in culture only in 60% of neurons BK binding sites were detected. Density of BK binding sites increased on individual cells of both sides following a 2 day ligation but only of the ligated side following a 10 day ligation after 0.8 or 1.8 days in culture. These results indicate that a nerve injury increases the proportion of BK binding cells and the density of BK binding sites increases the proportion of BK binding cells and the density of BK binding sites increases the proportion of BK binding cells and and the den

342.11

PERIPHERALLY AXOTOMIZED DRG CELLS EXHIBIT ALTERED INTRINSIC MEMBRANE PROPERTIES IN A RAT MODEL OF NEUROPATHIC PAIN. S.K. Hong*, Y.I. Kim, H.S. Na, S.L. Shin, M.G. Lee, S.H. Nahm and H.C. Han, Neurosci. Res. Inst. and Dept. of Physiol., Korea Univ. Coll. of Med., Seoul. KOREA

Several pieces of evidence suggest that abnormal electrical signals arising from axotomized DRG cells are critical for the induction and/or maintenance of neuropathic pain from peripheral nerve injury. In order to gain some insight into the neurophysiological mechanisms underlying the abnormal signals, we examined various membrane properties of axotomized DRG cells in a rat model of neuropathic pain.

This model, where the signs of neuropathic pain are localized in the tail, was produced by unilateral transection of the superior and inferior caudal trunks at the level between the S3 and S4 spinal nerves. The S1-3 DRGs ipsilateral to the injury were resected out 7-14 days postoperatively for *in vitro* electrophysiological experiments. The results of intracellular recordings show that the cells in these DRGs were not significantly different from control cells (i.e., cells in the S1-3 DRGs contralateral to the injury and S1-3 DRG cells of sham-operated animals) with respect to spike amplitude, threshold and AHP amplitude and duration. On the other hand, the results demonstrate that: (1) the cells in the ipsilateral DRGs had significantly less negative resting membrane potential (though not spontaneously active), higher input resistance, lower rheobase and longer action potential duration than control cells and (2) a large proportion of the cells in the ipsilateral DRGs (>40%) exhibited "hump"-type action potential (i.e., spike having a shoulder in the repolarizing phase) unlike control cells (<15%); in some additional experiments where the distance between the S1-2 DRGs and the injury site was reduced by transection of the caudal trunks at more rostral levels (i.e., levels between S1 and S2 and between S2 and S3 spinal nerves), the proportion of cells with "hump"-type spike was even greater (>70%).

The present results suggest that, following partial peripheral nerve injury, profound changes occur in some intrinsic membrane properties of axotomized DRG cells making these cells more excitable and that emergence of a certain membrane property in a given axotomized cell is related to the distance between cell body and injury site. (Supported by KOSEF and Biotech 2000).

EVIDENCE FOR PERIPHERAL NITRIC OXIDE (NO) ACTIVITY IN A RAT MODEL OF CHRONIC NEUROPATHIC PAIN. D. Levy and D.W. Zochodne* University of Calgary, Calgary, Alberta, Canada T2N 4N1

Partial injury to a peripheral nerve may result in severe chronic neuropathic pain. Recently, putative changes in dorsal horn NO have suggested a role for NO in an animal model of chronic neuropathic pain. In this study we sought to investigate a possible action of peripheral NO by examining local changes in nerve blood flow prior and following inhibition of nitric oxide synthase (NOS).

Chronic constriction injury (CCI) was induced in male Sprague-Dawley rats

Chronic constriction injury (CCI) was induced in male Sprague-Dawley rats (250-350 g) by placing 4 x 4.0 chromic gut sutures around the sciatic nerve. Forty eight hours, 7 and 14 days postoperation, the rats had evidence of thermal hyperalgesia and mechanical allodynia. Changes in sciatic blood flow (NBF) were measured at these times, using Laser Doppler flowmetry (LDF) proximally and distally to the constriction site and from sham exposed nerve. Following baseline testing rats were injected either with L-NAME or D-NAME (10 mg/kg; IP injection) followed by repeated LDF measurements (15-20 min. postinjection). Further doses of L-NAME (0.1 and 1 mg/kg) were also studied.

CCI resulted in significant elevation in NBF distal to the constriction 48 hr. postoperation. Injection of L-NAME increased NBF in the sham operated side but reduced NBF in a dose dependent manner distal to the lesion. Injection of D-NAME did not have any effect.

The data may indicate a possible role for peripheral NO, perhaps locally elaborated by macrophages distal to the constriction, in producing changes in sciatic blood flow in CCI. Local NO might have other actions in this model as well.

(Supported by Muscular Dystrophy Association of Canada)

342.10

The abnormal discharges from injured $A\delta$ - and C-afferents are thought to produce the central sensitization that underlies the neuropathic pain. However, it was reported that about half of the units displaying abnormal discharges after injury were $A\beta$ -fibers. In the present study, we investigated the role of injured large diameter afferents in the development of the pain behaviors in a rat model, produced by transection of the superior caudal trunk between the S3 and S4 spinal nerves. The fact that nerve injury near birth, unlike the one during adulthood, destroys most large diameter fibers was utilized to indirectly assess the role of large diameter fibers.

Nerve injury within 24 hours after birth (n=23, NEO group) destroyed most large, as well as small, diameter fibers. Whereas, nerve injury at 7 weeks of age (n=23, YOUNG group) preserved the majority both large and small diameter fibers. The behavioral tests were performed 2,6,7,8,10,14,18 weeks after the surgery in both groups. The signs of mechanical alliodynia in response to mechanical stimuli applied to the tail with von Frey hairs (4.9-mN or 19.6-mN bending force) were more robust in NEO group than in YOUNG group. Also, the signs of thermal allodynia, inferred from the decrease in the tail response latency to the cold (4°C) or warm (40°C) water immersion, were more pronounced in NEO group.

These results are consistent with gate-control hypothesis for pain. (Supported by Non-Directed Research Fund, KRF)

342.12

NITRIC OXIDE SYNTHASE INHIBITOR (L-NAME) DECREASES MECHANICAL ALLODYNIA IN A RAT MODEL OF NEUROPATHIC PAIN. Young Wook Yoon*, Backil Sung¹, and Jin Mo Chung² Dept. of Physiol., Korea University College of Medicine, Seoul, 136-705, Korea, ²Marine Biomed. Inst., Univ. Texas Medical Br., Galveston, TX, 77550, U.S.A.

The partial injury to a peripheral nerve may produce a painful abnormal sensations such as allodynia and hyperalgesia. The sensitization of spinal cord is thought as a basic mechanism to manifest abnormal pains. Recent data indicate that nitric oxide (NO) modulates mechanical, thermal and chemical nociceptive signals in somatosensory pathway at spinal cord level. The aim of this study was to observe whether NO modulates the behavioral signs of neuropathic pain in a rat model.

Neuropathic injury was made by tight ligation of L5 and L6 spinal nerves unilaterally in Sprague-Dawley rats under enflurane anesthesia. Behavioral tests were performed to examine the presence of mechanical allodynia. All drug tests were carried out from 3 days to 3 weeks after ligation of spinal nerves. During this period, mechanical allodynia was fully expressed and was not expect to diminish without any interventions according to our previous observation. In order to examine the effects of nitric oxide on the neuropathic pain, L-NAME (10 to 500 $\mu\text{M/kg})$, D-NAME (100, 500 $\mu\text{M/kg})$, and saline was injected intraperitoneally and behavioral tests were conducted.

Intraperitoneal injection of L-NAME reduced the behavioral signs of mechanical allodynia in dose-dependent manner, while D-NAME or saline did not change the mechanical allodynia.

The data show that mechanical allodynia observed in rat following partial peripheral nerve injury can be abolished by L-NAME. It is possible that manipulation of the L-arginine-NO system by blockade of the production of NO may be useful in alleviating neuropathic pain.

ATTENUATION OF TRANSSYNAPTIC ALTERATION OF SPINAL CORD DORSAL HORN NEURONS AND NEUROPATHIC PAIN IN RATS BY INHIBITING NITRIC OXIDE-ACTIVATED POLY(ADP-RIBOSE) SYNTHETASE J. Maoʻ, D.D. Price, J. Lu, J. Zhuʻ and D.J. Mayer, Depts. Anesthesiol. and Neurosurgʻ, Medical College of Virginia, Richmond. VA 23298

Transsynaptic alteration of spinal cord dorsal horn neurons (so-called 'dark' neurons) occurs in a rat model of neuropathic pain induced by chronic constrictive nerve injury (CCI). The incidence of dark neurons in CCI rats has been proposed to be mediated by neurotoxicity. We examined whether inhibiting the nitric oxide (NO)-activated poly(ADP-ribose) synthetase (PARS), a nuclear enzyme critical to glutamate-induced neurotoxicity, would reduce dark neurons and attenuate neuropathic pain in CCI rats. Dark neurons were observed bilaterally (with ipsilateral predominance) within the dorsal horn of CCI rats eight days after unilateral sciatic nerve ligation but not after sham operation (P< 0.05). The number of dark neurons was reliably reduced in CCI rats receiving once daily intrathecal treatment (x 7 days) with a PARS inhibitor benzamide (400, 200 nmol. but not 100 nmol benzamide or saline, P< 0.05). Concurrently, thermal hyperalgesia, mechanical hyperalgesia, and low threshold mechano-allodynia also were reliably reduced in CCI rats treated with either 200 or 400 nmol benzamide (P< 0.05). Once daily intrathecal treatment (x 7 days) with an NO synthase inhibitor N^G-nitro-L-arginine methyl ester (40 nmol) resulted in similar reductions of both dark neurons and signs of neuropathic pain in CCI rats (each P< 0.05). These results provide in vivo evidence indicating that NO-mediated PARS activation may be an underlying mechanism of nerve injury-induced 'dark neurons' and that such morphological changes contribute to behavioral manifestations of neuropathic pain in CCI rats. The present data provide new insights into mechanisms of intractable neuropathic pain syndromes in humans

INFRAORBITAL NERVE LIGATION SUPPRESSES JOR AND ELEVATES CALBINDIN AND PKC EXPRESSION. M. A. Matthews* M. L. Fogg and S.L. Liles. Dept. Anat., L.S.U. Med. Ctr, New Orleans, LA

Chronic constrictive injury (C.C.I.) of the rat's infraorbital nerve (ION) increases expression of CAL and second messengers in the trigeminal nucleus. Altered firing thresholds and activation of Ca++-sensitive protein kinase C (PKC) should occur but evidence for this is lacking in the present model. The jaw opening reflex (JOR) was tested in ION-ligated rats by stimulating the maxillary incisor pulp and recording evoked digastric EMG. Stimulus thresholds increased contralateral to the ION by 4 days but differences between control and experimental animals were reduced by 8 and 12 days. EMG response latencies increased ipsilaterally at 8-12 days. The response amplitude was suppressed at 8-12 days suggestive of descending inhibition Frozen sections were exposed to antisera against either CAL or PKC BII. CAL labeling was most intense in the ipsilateral Sp.V, contralateral thalamic reticular nucleus (TRN) and dentate hilar region. PKC labeling occurred bilaterally in the Sp. V, suggestive of potentiation of SpV neurons, and the anterior pretectal nucleus, a region known to inhibit the JOR (Chiang et al. 91). A concurrent colorimetric assay of PKC activity in Sp.V. revealed a 38% increase ipsilaterally and 22% increase contralaterally (P<0.01) in activity at 12 days following the ligation. These findings indicate that ION CCI causes NMDA receptor mediated translocation and activation of Ca++sensitive protein kinase C and descending modulation of nociceptive reflex function suggestive of initiation of a neuropathic central sensitization within the trigeminal complex. STIMULATION-PRODUCED ANTINOCICEPTION FROM THE PERIAQUEDUCTAL GRAY MATTER IN NEUROPATHIC

RATS. J.-H. Sohn*, B.H. Lee1, I. Yi and S.H. Park, Dept. of Psychology, Chungnam Nat'l University, Taejeon 305-764, Dept. of Physiology, School of Medicine, Ajou University¹, Suwon 442-749,

It has been shown that there is opioid resistance in neuropathic pain. This indicates that descending opioid pain inhibition system may not be involved in neuropathic pain. Recently we found that selective injury of the distal sciatic nerve branches produces neuropathic pain syndrome in rats. This present study sought to determine whether stimulation of descending pain inhibition system may produce analgesia in the animal neuropathic model we developed.

Linder ketamine anesthesia male Struggue-Dawley rats were

in the animal neuropathic model we developed.

Under ketamine anesthesia, male Sprague-Dawley rats were chronically implanted with stimulating electrodes in the periaqueductal gray matter (PAG) and both tibial and sural nerves in the sciatic nerve were completely cut. Pain sensitivity was measured using von Frey filament and acetone applied to the sensitive area for 1 week postoperatively (p.o.). Rats with neuropathic pain syndrome after transection of the tibial and sural nerves were stimulated with bipolar electrodes in the PAG for additional 2 weeks.

Electrical stimulation of PAG was turned out highly effective in alleviating neuropathic pain. Mechanical allodynia to von Frey filament and cold allodynia to acetone were reduced by PAG stimulation.

stimulation.

These results suggest that activation of descending pain inhibition system including PAG can reduce neuropathic pain syndrome. (Supported by KOSEF)

FOLLOWING PERIPHERAL NERVE INJURY: EVIDENCE FOR NEUROIMMUNE ACTIVATION IN ANIMAL MODELS OF NEUROPATHIC PAIN. R.W. Colburn (a), J.A. Deleo*(a,b), A.J. Rickman(b). Dept. of Pharmacology(a) and Anesthesiology(b), Dartmouth-Hitchcock Medical Center, Lebanon, NH 03756. SPINAL MICROGLIAL ACTIVATION AND INCREASES IN IL-6 mRNA

We have previously demonstrated increases in spinal immunoreactive-like proinflammatory cytokines (IL-1β, IL-6, TNF-α) following peripheral nerve injury that results in neuropathic pain-like behaviors. Cytokines induced both peripherally and centrally after nerve injury are likely to be involved in synaptic plasticity and subsequent spinal hyperexcitability, the pathologic correlate to neuropathic pain. It has been demonstrated that glial cells are capable of producing and/or releasing cytokines. Toward a better understanding of the spinal neuroimmunologic cascade of events following nerve injury, immunocytochemical detection of microglial activation using OX-42 monoclonal antibody and in situ hybridization of IL-6 activation using 0.7-42 monocional antioody and in still nyonalization of 11-5 mRNA were compared after sciatic nerve cryoneurolysis (SCN) or spinal nerve cryoneurolysis (SCN) or spinal nerve cryoneurolysis (SCN) or spinal nerve cryoneurolysis (SPCN) at various post-lesion time points (5-6 rats/group). Male Holtzman rats underwent SCN or SPCN where the sciatic nerve or L5 spinal nerve was frozen in a freeze-thaw-freeze cycle using a clinical cryoprobe. Preliminary data indicated that 0X-42 like immunoreactivity peaked at 14 days in the dorsal horn and 7 days in the ventral horn after SCN using computer assisted image analysis. There was evidence of intense microglial proliferation and activation after SPCN specific to the region of lumbar innervation. IL-6 mRNA was increased in the spinal lumbar region following SPCN as compared with normal, unlesioned rats. These data indicate that cells within the spinal cord are capable of producing mRNA for cytokines in response to a peripheral nerve injury. It also suggests that microglia, the intrinsic immuneffector cell of the CNS, functions as an early sensor to nervous system injury. Interfering with microglia function and/or cytokine expression may provide a novel therapy in the prevention and/or attenuation of neuropathic pain in humans. Supported by NIH (DA10042).

PAIN MODULATION: ANATOMY AND PHYSIOLOGY-SPINAL CORD I

BIOPHYSICS OF RECEPTOR MEDIATED DENDRITIC TRANSFORMATION. V. S. Markin, T. H. Le and D. L. Tanelian, Dept. of Anesthesiology and Pain Mgt., UT Southwestern Medical Center, Dallas, TX 75235

Stimulation of the nervous system by substance P, a G proteincoupled receptor, and subsequent receptor internalization causes dendrites to change their shape from homogeneous cylinders to a defidites to change their shape from homogeneous cyndicists to heterogeneous string of swollen varicosities (beads) connected by thin segments (Mantyh et. al., 1995). We have biophysically and mathematically analyzed this phenomenon and propose quantitative mechanisms for how dendritic transformation takes place. Our theory predicts the relationship between the initial dendrite radius and the average radii of the transformed dendritic varicosities and connecting segments, as well as the periodicity of the string of varicosities. The results of our model are in good agreement with published experimental observations of this beading phenomenon in the spinal cord and brain.

Biophysical analysis of action potential propagation along these small diameter beaded neuronal process reveals three possible outcomes: normal impulse propagation, action potential reflection, and conduction block. When action potential reflection is the prevailing condition, it can lead to both linear and nonlinear filtering of the incoming action potential train. Functionally, this process of dendritic transformation may serve as a mechanism for information processing along fine peripheral and central neuronal terminals.

MORPHINE DOES NOT REDUCE THE ENHANCEMENT OF NOXIOUS STIMULUS-EVOKED INTERNALIZATION OF THE SUBSTANCE PRECEPTOR THAT OCCURS IN SPINAL CORD OF RATS WITH PERSISTENT HINDPAW INFLAMMATION C. Abbadie*, J.A. Trafton, P.W. Mantyh and A.I. Basbaum. Dept. of Anatomy, UCSF, San Francisco and VAMC, Minneapolis.

We previously reported that noxious stimulation of the hindpaw induces internalization of the substance P receptor (SPR) in lamina I neurons of the dorsal horn and in dorsally-directed dendrites of lamina III neurons, but not in SPR immunoreactive (IR) cell bodies of lamina III-VI. Here we assessed the effect of hindpaw stimulation in rats that have persistent hindpaw inflammation, a condition associated with significant plasma membrane upregulation of the SPR. We produced hindpaw inflammation by injection of complete Freund's adjuvant (CFA). Three days later, under pentobarbital anesthesia, we stimulated the hindpaw with continuous noxious pinch, or non-noxious brush. Five min later, we perfused the rats and identified neurons with an immunofluorescence/confocal protocol. In some animals, we injected morphine (10 mg/kg s.c.) 30 min prior to stimulation. Noxious stimulation of the inflamed hindpaw produced internalization of the SPR in almost 100% of SPR-IR neurons of lamina I at the L4 segment; the extent of internalization did not vary with stimulus duration. Noxious stimulation also evoked internalization in about 50% of SPR-IR neurons in laminae III-VI of CFA rats. Even non-noxious stimulation, which is without effect in intact animals, evoked internalization, in approximately 75% of lamina I and 40% of lamina III neurons. Finally, morphine did not alter internalization evoked by noxious stimulation in CFA or intact rats. We suggest that diffusion of SP from terminals located in laminae I and II mediates the induction of SPR internalization in neurons of the deep dorsal horn by noxious stimulation of the inflamed paw. Peripheral sensitization of nociceptive afferents probably underlies the effects of non-noxious stimuli. Stimulation-evoked SPR internalization in the CFA rats may also be increased by central sensitization of dorsal horn neurons that occurs in the setting of persistent inflammation. The lack of effect of morphine argues against an opioid regulation of SP release from primary afferent nociceptors under the conditions of these experiments. Supported by INSERM (France) and NS21445 and DE23671.

ANTINOCICEPTION PRODUCED BY MICROINJECTING SUBSTANCE P NEAR THE A7 CATECHOLAMINE CELL GROUP MAY BE REDUCED BY STRUCTURAL CHANGES IN TYROSINE HYDROXYLASE IMMUNO-REACTIVE DENDRITES. B.A. Heidenreich, K. Nuseir, and H.K. Proudfit, Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

Cell surface tachykinin receptors translocate to the cell interior in the presence of agonists such as substance P (SP: Mantyh et al., Science, 268, 1629, 1995). Receptor internalization is accompanied by structural changes in small dendrites which become varicose. These changes may reduce the effectiveness of SP and could explain the results of a previous report which demonstrated that the dose-response curve for the antinociception produced by microinjecting SP in the A7 cell group is attenuated at high doses (Yeomans and Proudfit, Neurosci., 49, 681, 1992).

The present experiments determined whether SP-induced structural changes in the dendrites of A7 noradrenergic neurons are related to the reduced antinociceptive effects of this peptide at high doses. More specifically, SP was microinjected in a range of doses just dorsal to the A7 cell group in lightly anesthetized rats. Antinociception was assessed using the tail flick test and structural changes in tyrosine hydroxylase-immunoreactive (TH-ir) A7 neurons were assessed by light microscopy. SP produced dosedependent antinociception, but the antinociceptive effect of 32.5 pmol was less than that of a 3.25 pmol dose. The 32.5 pmol dose produced many varicosities in A7 cell dendrites, but the 3.25 pmol dose produced many varicosities in A7 cell dendrites, but the 3.25 pmol dose produced only a few dendritic varicosities. These results suggest that SP-induced receptor internalization and/or structural changes in the dendrites of A7 neurons reduces the responsiveness of these cells to SP. This work was supported by PHS grant DA03980 from the National Institute on Drug Abuse.

SPINAL NEUROKININ2 RECEPTORS CONTRIBUTE TO THE INCREASED EXCITABILITY OF NOCICEPTIVE FLEXOR REFLEX DURING PERSISTENT PERIPHERAL INFLAMMATION. Yuping Jia* and V.S. Seybold. Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

The role of endogenous NKA in changes in the excitability of spinal neurons during adjuvant-induced, peripheral inflammation was examined by determining the effect of a selective neurokinin2 receptor antagonist, GR103537A, on the nociceptive flexor reflex. The flexor reflex was evoked in decerebrate, spinalized rats by stimulation of sural nerve with electrical current that maximally activated C-fibers. Action potentials were recorded in the ipsilateral hamstring muscles. Two days after injection of adjuvant the flexor reflex ipsilateral to the inflamed paw was enhanced two-fold compared to the reflex evoked in untreated animals, and the increased activity occurred in conjunction with thermal hyperalgesia. Intrathecal administration of GR103537A (5 mmol and 14.0 mmol in 10 µl) dose dependently attenuated the increased activity of the flexor reflex in CFA treated rats from 10-30 min after administration of antagonist, but had no effect in normal rats. The higher dose of GR103537A (14 mmol) enhanced the reflex in both groups of animals 5 min after drug injection. The preferential activity of GR103537A at NK2 receptors was confirmed by blockade of the facilitation of the reflex by NKA but not SP (7 mmol/10µl) in normal rats. These results indicate that endogenous NKA has a role in the increased excitability of spinal neurons during persistent peripheral inflammation. Supported by NIH NS17702.

AN INCREASE IN FOS AND NITRIC OXIDE SYNTHASE EXPRESSION IN SPINOTHALAMIC NEURONS IN RATS AFTER COLON INFLAMMATION. Z. Ye, Y. Lu*, J. Wu, C.-C. Wang and K.N. Westlund. Dept. of Anatomy and Neurosciences, Univ. Texas Med. Branch, Galveston, TX 77555-1069

Immunofluorescent techniques in combination with retrograde tract tracing were used in an animal model of visceral inflammation to investigate changes in the expression of FOS and NOS in response to colon inflammation in spinal neurons. including spinothalamic tract neurons. The chemical irritant, mustard oil (2.5% in 0.5ml peanut oil), was introduced 7cm into the colon with PE90 tubing repeatedly over a one week period (2-6X). The ventral posterolateral nucleus in four rats was injected with fluorogold (3-4 µl total in 7 sites; 2-4%) and 3-4 days allowed for retrograde transport. Animals were perfused with 4% buffered paraformaldehyde and processed with standard immunofluorescent methods using rabbit anti-FOS (1:2.500: Oncogene) or anti-bNOS (1:20: Transduction Labs).

Oncogene) or anti-bNOS (1:20; Transduction Labs).

In control rats, a few cells immunoreactive for NOS were localized primarily in laminae X and no cells were immunoreactive for FOS. After colon inflammation, the number of cells in the sacral spinal cord (S1) expressing NOS increased by about 26%. Localization of NOS in spinothalamic tract cells was observed in lamina X of the sacral cord in the inflamed rat but not in the normal rat. Some spinothalamic tract cells localized in the superficial lamina I expressed FOS. NOS has not been colocalized with FOS after noxious hindlimb pinch (Lee et al., 1993). These results indicate that NOS is involved in visceral nociceptive transmission in the spinothalamic projection neurons in lamina X. The intermediate early gene, FOS, may be involved in some lamina I spinothalamic tract cells activated after prolonged colon irritation with mustard oil.

5-HT2 RECEPTOR IS INVOLVED IN THE NOCICEPTIVE AND HYPERALGESIC MECHANISMS OF SEROTONIN IN THE PERIPHERY. A. Tokunaga, M. Saika-Doi and E. Senba*, Dept. of Anatomy & Neurobiology, Wakayama Med. Coll., Wakayama. 640, Japan

Although it is generally believed that peripheral serotonin (5-HT) induced nociceptive responses are mediated by peripheral 5-HT3 receptors, there are still controversies. The present study was designed to investigate which subtypes of 5-HT receptors are involved in such noxious responses using c-fos expression as a marker of neuronal activation as well as behavioral assessment for hyperalecsia.

Each solution of 5-HT and various agonists for 5-HT receptor subtypes (5-HT1A, 2, 3) was intradermally injected into the rat hindpaw under light anesthesia. For the detection of Fos-like immunoreactivity (FLI) in dorsal horn neurons 2 hr after the injection, the spinal cord were immunostained using ABC method. For the behavioral assessment, paw-withdrawal latency to radial heat stimulation was examined every 15 min for 2 hrs.

Injection of 5-HT2 receptor agonists (DOI, a-methyl 5-HT) evoked FLI neurons in laminae 1 and II of the ipsilateral dorsal horn dose dependently, in the same manner as 5-HT did, while only a few neurons were detected after injection of other agonists including 5-HT3 receptor agonists (m-CPG, 2-methyl 5-HT) at any doses examined. Injection of 5-HT (30 μ g) and 5-HT2 receptor agonist (α -methyl 5-HT), 0.86 mg/kg) significantly reduced the paw-withdrawal latency. On the other hand, injection of 5-HT3 receptor agonist (m-CPG/8 mg/kg) showed a tendency to increase the latency. Furthermore, pre-treatment of 5-HT2 antagonist (ketanserin), but not 5-HT3 antagonist (tropisetron) reduced the expression of FLI neurons and attenuated the behavioral response after the injection of 5-HT.

This study provides morphological and pharmacological evidence to suggest that not 5-HT3, but 5-HT2 receptor subtype is involved in the 5-HT-induced activation of sensory nerve terminals and subsequently induced hyperalgesia in the rat.

RELATIONSHIPS OF NMDA, AMPA, AND METABOTROPIC TYPES OF GLUTAMATE RECEPTOR SUBUNITS TO SPINOTHALAMIC TRACT CELLS-LIGHT AND EM STUDIES. Z. Ye*, K.N. Westlund. Dept. of Neuroscience & Anatomy, UTMB, Galveston, TX 77555.

Glutamate and its receptors have been shown to play key roles in spinal nociception.

Glutamate and its receptors have been shown to play key roles in spinal nociception. Combined retrograde tracing and pre-embedding immunocytochemistry was used to localize NMDA, non-NMDA and metabotropic receptors in and on STT cells at the light and electron microscopic levels. A retrograde tracer. WGA-HRP, was injected into ventral posterolateral nucleus of thalamus of rats. After three days survival time and perfusion (2.5% glutaraldehyde, 1% paraformaldehyde, 0 in PBS), lumber cord tissue was cut at 50μm. HRP was visualized by tetramethylbenzidine (TMB) and stabilized with ammonium paratungstate and 3,3°-diaminobenzidine hydrochloride (DAB). This procedure makes the peroxidase reaction product assume a large, dense crystalline appearance which can be easily distinguished from the amorphous peroxidase product generated in the subsequent immunostaining steps. Tissue sections were then stained for AMPA receptor subunit GluR2/3. NMDA receptor subunit GluNR1, or metabotropic receptors mGluR1α and mGluR2/3. Steps include primary antibody, biotinylated secondary antibody, avidin-biotin-peroxidase complex, and visualization with the DAB. After treatment with 0sO4, embedding in groxy resin and cutting, sections containing STT cells were examined under an electron microscope. Most of the double labeled cells were located in lamina IV. V and X. Staining for NR1 (NMDA) and R2/3 (AMPA) subunits were found in cytoplasm associated with rough ER, and postsynaptic membrane of STT cell bodies and dendrites. Staining for metabotropic receptors was associated with the membrane for the soma and proximal dendrites. The light level distribution of the mRGlu1 is concentrated in laminae I, II, and the distribution of mRGlu2/3 was in lamina III while almost devoid in laminae I and II. The postsynaptic localization for NR1 and metabotropic receptor types were found apposed by medium and large terminals with round. clear vesicles. Many NMDA positive terminals were found, particularly on STT dendrites. These data indicate that some ST

COMPARISON OF EFFECTS OF INTRADERMAL CAPSAICIN ON CELLS IN THE PRIMATE SPINAL TRIGEMINAL AND DORSAL COLUMN NUCLEI. P.M. Dougherty*, L.R. Rowland, A.T. Zirh, F.A. Lenz, and A.H. Schwartz. Dept. of Neurosurgery, Johns Hopkins University, Baltimore MD 21287-7509.

The acute and delayed responses of neurons in the pars caudalis of the trigeminal nucleus of the anesthetized primate (Macaca fascicularis, young adult, male, 4.8-8.0 kg) to intradermal injection of capsaicin (0.1ml 3%) were compared to those of neurons in the dorsal column nuclei (N. gracilis, N. cuneatus). A total of 22 cells have been surveyed, 13 in the dorsal column nuclei (9 in N.g. and 4 in N.c) and 9 in the spinal trigeminal nucleus. All dorsal column neurons were low threshold (LT) cells with baseline mechanical receptive fields over small areas of skin confined to the limbs best activated by innocuous stimuli. The trigeminal neurons included three types of neurons, LT, wide-dynamic range (WDR) and nociceptive specific (NS) cells. The baseline receptive fields of these cells were usually confined to an area of skin on the face in one division of the trigeminal nerve (maxillary or mandibular). Background activity was present in both groups of cells (trigeminal and lemniscal) but was widely variable in rate (0.3-22Hz).

Two dorsal column neurons showed responses to intradermal capsaicin characterized by an acute increase in discharge rate and an increase in the responses to mechanical stimulation of the receptive field. One dorsal column neuron showed evidence of an expansion in size of the receptive field. These changes following capsaicin were reversed by injection of 0.1ml 2% lidocaine to the capsaicin site. In contrast, all trigeminal WDR and 2 of 3 NS neurons but no LT cells, showed responses to capsaicin evidenced by an acute increase in discharge rate sustained over the entire post-capsaicin recording period, an increase in responses to stimulation of the RF, and an expansion in RF margins. These changes were also reversed by injection of lidocaine to the capsaicin site. Supported by a grant to PMD from the NIH (P01 NS32386-Proj. 2).

CAPSAICIN-SENSITIVE NERVES MEDIATE FORMALIN-INDUCED HYPERALGESIA AND SPINAL PROSTAGLANDIN RELEASE. N.A. Calcutt*1 X-Y Hua² and A.B Malmberg³ Depts. of Pathology¹ and Anesthesiology² UCSD, La Jolla, CA 92093 and Dept. of Anatomy³ UCSF, San Francisco CA 94143.

This study was performed to investigate the contribution of capsaicin-sensitive neurons to formalin-evoked inflammation, behavior and the concurrent increase in spinal levels of amino acids and PGE₂. Adult concurrent increase in spinal levels of amino acids and POE2. Adult Sprague-Dawley rats treated neonatally with capsaicin (NC) and age matched controls (C) were tested for paw thermal response latencies and then implanted with an intrathecal dialysis probe with the active site at the lumbar enlargement. Dialysis (10µl/min) was performed two days later and effluent collected in 10 min fractions. After 40 min baseline collection, 50µl of 0.5% formalin was injected into the dorsal surface of right hind paw and dialysate collected for a further 40 min along with counting of formalin-evoked flinching. NC rats showed thermal hypoalgesia (18.4±0.9sec: mean±sem) compared to C (14.2±0.6sec) and swelling of the paw following formalin injection was reduced (C=1.57±0.15mm vs NC=0.98±0.11mm). NC rats exhibited reduced flinching 0-9 min (23±2) and 20-40 min (11±4) after formalin compared thinching 0-9 min (23±2) and 20-40 min (11±4) atter formalin-compared to C (32±2 and 39±6 respectively). There was no change in basal or formalin-evoked levels of glutamate, aspartate citrulline or taurine, while formalin-evoked PGE₂ levels were reduced in NC rats (280±341 vs 1245±308pg/10 min) These data suggest that capsaicin-sensitive neurons contribute to formalin-induced flinching and increased spinal PGE₂ but not to formalin-evoked increases in spinal amino acids.

AB-FIBRE EVOKED WIND-UP OF WITHDRAWAL REFLEXES IN MONOARTHRITIC RATS: INVOLVEMENT OF GABA RECEPTORS H.-R. Weng*, J.M.A. Laird², F. Cervero² and J. Schouenborg¹. Dept. of Physiology and Neuroscience, University of Lund, Lund, Sweden⁽¹⁾ and Dept. of Physiology and Pharmacology, University of Alcalá de Henares, Madrid, Spain(2

Activation of Aβ afferent fibres from areas of secondary hyperalgesia evokes pain (allodynia). This is due to a change in the central processing of inputs from low threshold afferents whereby their activity gains access to nociceptive systems. Here we have examined whether a process normally evoked only by afferent C-fibres (wind up of withdrawal reflexes) could also be triggered by Aβ afferents in arthritic animals

We have recorded, in decerebrate-spinal rats, multiunit e.m.g. activity in the semitendinosus and peroneal muscles evoked by electrical stimulation of A-fibres in the sural nerve. The nerve volley was monitored continuously to ensure that only A fibres were activated. Responses were compared in control and monoarthritic rats (induced at least 4 hours before recording by injection of carrageenan and kaolin into the ipsilateral knee joint). Reflex wind up was examined by delivering trains of 16 stimuli to the sural nerve at 0.1 to 1Hz.

In control rats, wind up of the reflexes was never seen when afferent Afibres were stimulated. In contrast, wind up could be evoked in monoarthritic animals by activation of $A\beta$ afferents at 0.3 to 1Hz. Bicuculline (0.03-0.5 mg/kg i.v.) dose-dependently inhibited this A-fibre evoked wind up.

These results indicate that in arthritic rats, AB fibres gain access to spinal cord mechanisms normally activated only by C-fibres (such as wind up). The sensitivity of this process to GABA_A receptor blockade suggests a role for primary afferent depolarization via a presynaptic link between A and C-fibres. (Supported by MRC, Sweden, and by DGICYT, Spain)

CEREBRAL C-FOS EXPRESSION IN UNANAESTHETIZED RATS EXPERIENCING CAPSAICIN-INDUCED ACUTE CARDIAC PAIN.

G.J. Ter Horst,* B.J. Arkies, F. Postema, R.W.M. Hautvast and M.J.L. De Jongste. Biol. Psychiat. & Cardiol., Univ. & Acad. Hospital Groningen, The Netherlands.

Spinal cord stimulation in angina pectoris increases exercise capacity and reduces both anginal attacks and ischemic electrocardiographic signs, but the underlying mechanisms are not understood. To show effects of neurostimulation in the brain we need an acute cardiac pain rat model. The aim of this study is to validate a rat model that is based on infusion of capsaicin (45 μ l, 0.3 ng/ μ l; 2 μ l/min.) into the pericardial space of freely moving rats. Cerebral c-fos expression was employed to analyze the effects of cardiac pain in the brain. The pericardial space of male Wistar rats was catheterized via the diaphragm. The catheter was fixed to the head to allow easy access. The rats were allowed post-operative survival times of 3 days. Solvent infusions into the pericardial space and capsaicin infusions into the thoracic cage served as controls. During the infusion of capsaicin into the pericardial space the animals scratched the chest and then they immobilized for 15 20 min. Two hours after the infusion the animals were fixed to allow immunocytochemical detection of c-fos like proteins in brain and spinal cord sections. Increased c-fos expression was found in laminae I and II of the thoracic spinal cord, the solitary tract nucleus, the peri-ambiguus area, the parabrachial nucleus, the peri-aqueductal gray, the dorsal thalamus, the hypothalamus, the central amygdala and the insular and prelimbic cortices. Controls exhibited significantly less c-fos expression. Many of the affected regions participate in cardiovascular regulation. The behavioral and immunocytochemical data show that the model can be used to induce acute cardiac pain in unanaesthetized rats and may serve as a model to study effects of neurostimulation in the brain.

343.10

GABA-A RECEPTOR BLOCKADE INHIBITS CAPSAICIN-INDUCED BRUSH RESPONSES OF NOCICEPTOR-SPECIFIC (NS) NEURONS: A ROLE FOR PRIMARY AFFERENT DEPOLARISATION IN ALLODYNIA?

Jennifer M.A. Laird* and Fernando Cervero. Dept. of Physiology and Pharmacology, University of Alcalá de Henares, 28871 Madrid, Spain

In areas of secondary hyperalgesia, innocuous mechanical stimuli evoke pain (allodynia). We have proposed that this is produced by a central presynaptic interaction whereby Aβ-fibers evoke activity (dorsal root reflexes) in nociceptive afferent C-fibers (Cervero & Laird 1996 NeuroReport 7, 526). Here, we have tested this hypothesis by examining the effect of GABA_A receptor antagonism on the responses to mechanical stimuli of NS spinal dorsal horn neurons after capsaicin injections in their receptive fields (RF)

NS neurons were recorded in the lumbar spinal cord of anaesthetised adult female Wistar rats. The RF was mapped, and the responses to 20s periods of brush, cotton bud, pinch and heat were tested. Capsaicin (50 μ g) was injected intradermally in the RF, and excited 80% of neurons. Capsaicin-responsive neurons showed increased pinch responses (152 ± 37 to 358 ± 155 spikes) and novel responses to brush and cotton bud. Picrotoxin (0.5 mg/kg i.v.) reversed the enhanced pinch responses and attenuated the brush (35 \pm 9 to 11 ± 5 spikes) and cotton bud responses (45 ± 8 to 10 ± 7 spikes). In NS neurons with no capsaicin response, picrotoxin produced small increases in pinch responses and in some cases, in RF area. In contrast, strychnine (3 mg/kg) enhanced the capsaicin-induced changes.

We conclude that the capsaicin-induced changes in the mechanical responses of dorsal horn neurons involve GABA_A receptors. These results support our hypothesis that allodynia is mediated by pre-synaptic interactions whereby Aβ-fiber activation excites nociceptive afferent C-fibers (Supported by DGICYT grant PB-93-0491 and by Boehringer Ingelheim)

VISCERAL PAIN AND HYPERALGESIA IN RATS WITH AN EXPERIMENTAL URETERIC STONE: PERIPHERAL AND SPINAL MECHANISMS Carolina Roza, Jennifer M.A. Laird & Fernando Cervero*. Dept. of Physiology & Pharmacology, University of Alcalá de Henares, 28871 Madrid, Spain

Ureteric calculosis evokes intense pain and referred hyperalgesia in man. A similar syndrome is seen in rats with an artificial calculosis (Giamberardino et al 1995 Pain 61, 459). Here we have investigated the underlying mechanisms. An artificial stone was implanted in the left ureter in adult female rats under

halothane anaesthesia. After 1-8 days the rats were reanaesthetised, the left ureter cannulated close to the bladder and its motility recorded as changes in intraureteric pressure. The amplitude of ureteric contractions was larger than in normal rats, reaching 25 - 30 mmHg (normal nociceptive threshold), even in rats in which the stone had been eliminated. In 17 rats the response of single dorsal horn neurons in the T13-L1 spinal cord to noxious distension of ureter (UD; 30s, 10-100 mmHg) was also tested. In rats with a stone, the proportion of neurons with ureteric input was higher than in control rats (52% vs. 42%), and 68% of them showed changes in their cutaneous receptive field area after UD. In rats with a stone, 3 of 28 neurons with ureteric input were low threshold (class 1) and 2 of them also showed changes in their input properties after UD. In contrast, none of the neurons with ureteric input in control rats were class 1 and none showed changes in their input properties after UD.

We conclude that spinal neurons processing ureteric input are more excitable during and after the passage of a stone as shown by the greater proportion excited by ureteric stimulation and increased numbers with low threshold cutaneous inputs. The hypermotility of the ureter evoked by the stone, which persists after it has passed, is a peripheral event that contributes to maintaining this increase in central excitability. (Supported by DGICYT grant PB-93-0491 and by Boehringer Ingelheim).

KNEE JOINT INFLAMMATION: SPINAL C-FOS EXPRESSION RNEE JOINT INFLAMMATION: SPINAL C-FOS EXPRESSION AND THE EFFECT OF SECONDARY NOCICEPTIVE STIMULATION. 'L.Ch. Yang*, 'J. Orendacova, 'M. Marsala, 'T. L.Yaksh 'Department of Anesthesiology, Chang Gung Memorial Hospital, Taiwan, 'Institute of Neurobiology, Kosice, Slovakia, 'Anesthesiology Res. Lab., Univ. of California San Diego, CA 92093-0818

In the present study, the spinal expression of c-fos products after knee joint inflammation and the effect of a superimposed secondary nociceptive stimulus (incilateral paw formalism) was studied. In male Sprague.

joint inflammation and the effect of a superimposed secondary nociceptive stimulus (ipsilateral paw formalin injection) was studied. In male Sprague-Dawley rats after induction with 1.5% halothane the right knee joint was injected with 3% kaolin/carrageenan mixture (C/K). Animals then survived for 1, 2, 6, or 24 hrs. In a separate group of animals, as a subsequent stimulus, formalin (50μl/5%) was injected subcutaneously into the dorsum of the paw ipsilateral to the C/K injection 4 hrs after initial C/K injection. After formaline injection animals survived for an additional 2 hrs. After perfusion fixation with 4% paraformaldehyde, frozen transverse sections (40μm) were prepared and processed for the presence of c-fos-protein-like immunoreactivity. Carrageenan-induced knee joint inflammation evoked a transient c-FOS protein expression in the neurons localized in the apical immunoreactivity. Carrageenan-induced knee joint inflammation evoked a transient c-FOS protein expression in the neurons localized in the apical region of laminae 1-III with the peak activity observed 2 hrs after inflammation (12±3 cells; mean±sd). No c-Fos-positive neurons after longer (i.e. 6 or 24 hrs) survival periods were detected. Ipsilateral paw formalin injection, if administered 4 hr after knee inflammation, evoked significantly fewer c-FOS positive neurons in laminae I-V as compared with formalin injected animals without knee joint inflammation (46±15 cells vs. 120±8). These data indicate that primary acute or subacute nociceptive input may evoke central processes that are characterized by an induceable form of central inhibition. NALOXONE INCREASES *c-FoS* EXPRESSION IN THE SPINAL TRIGEMINAL NUCLEUS FOLLOWING OROFACIAL INFLAMMATION. <u>Y-O, Lee</u>^{1*} and <u>A</u>, <u>L Beitz</u>². Graduate Programs in Oral Biology¹ and Neuroscience², University of Minnesota, St. Paul, MN 55108.

We have utilized an animal model of orofacial inflammation (Haas et al., 1992) to assess the effect of the opioid receptor antagonist, naloxone, on the level of c-Fos expresssion in the spinal trigeminal nucleus (STN) (Hathaway et al., 1995). Orofacial inflammation was induced by paraperiosteal injection of mustard oil (10 μ l of 20 % allyl isothiocyanate in mineral oil: Aldrich Chemicals Co.) into the periarticular temporomandibular joint (TMJ) tissue of anesthetized rats.

temporomandibular joint (TMI) tissue of anesthetized rats.

Sixteen male and 16 female Sprague-Dawley rats were randomly assigned into one of the following four groups: 1) naloxone and TMI mustard oil (MO) injection group, 2) saline and TMI/MO group, 3) naloxone and TMI saline (SAL) injection group, and 4) saline and TMJ/SAL group. Naloxone or saline was given i.p. 10 min before TMI injection and again every 20 min after the initial injection until sacrifice. Two hours after injection of mustard oil or saline into the TMI, animals were perfused transcardially with 4 % paraformaldehyde and subsequently processed for immunocytochemical staining using an antiserum against c-Fos (Santa Cruz Biotechnology, Inc.). Additional animals with only peritoneal injections and animals with anesthesia only were processed in parallel to rule out any effect of repeated i.p. injection or anesthesia.

There was a statistically significant effect of treatment (naloxone vs saline) (p<0.01). The naloxone group contained a greater number of c-Fos labeled neurons in the STN subnucleus caudalis than the saline control group after TMJ injection of mustard oil. There was also a statistically significant effect of gender (male vs female) (p<0.01). The female TMJ/MO group exhibited a greater number of c-Fos labeled neurons than the male TMJ/MO group. It is likely that the endogenous opioid system is active during orofacial inflammation induced by injection of mustard oil into the TMJ. In addition, there seems to be a gender difference in the response of cells in the STN to the injection of mustard oil into the TMJ. (Supported by NIH grant DE/06682 & NS31318)

Dose dependent changes in behaviour and trigeminal c-fos expression after intracisternal capsaicin infusion.

R.H.A. Kemper, M.B. Spoelstra, L. Vosmeijer, M.G. Postma, M.J.L. De Jongste*, W.J. Meyler, G.J. Ter Horst, Biol. Psychiat., Anaesthesiol. & Cardiol., Academic Hospital Groningen, The Netherlands

The mechanisms causing migraine are still under debate. Animal models therefore focus on direct stimulation of the principal afferent nerve system of the head: the trigeminal nerve system. We demonstrate c-fos expression in the trigeminal nucleus caudalis, lamina I and II₀ (TNC) and behavioural data caused by capsaicin infusion into the cisterna magna (CM) of unanaesthetised rats. All rats received a cannula that was inserted into the CM via the cranium. After 3 days, capsaicin or vehicle solution was infused over a 2 minutes period. Behaviour was recorded on video tape. Two hours after infusion, rats were perfused and brain sections were stained for c-fos. Expression of c-fos was quantified at levels -1,-2,-3,-4,-5 and -6 mm. from obex and averaged.

Capsaicin infusion in the cisterna magna of freely moving rats dose-dependently induces c-fos expression in the TNC. Exploring behaviour dose dependently decreases and rats predominantly demonstrate passive coping behaviour (head immobilisation) at lower capsaicin concentrations and active coping behaviour (head grooming/scratching) at the highest concentration. CORNEAL STIMULATION BY MUSTARD OIL: EFFECTS OF NK1 AND NK2 RECEPTOR ANTAGONISM ON FOS-LI WITHIN SPINAL RIGEMINAL NUCLEUS, ON PLASMA ACTH AND ON AUTONOMIC RESPONSES IN THE RAT. D.F. Bereiter, D.A. Bereiter, B.H. Tonnessen and D.B. MacLean*. Depts. of Neuroscience & Surgery, Brown Univ./RI Hospital, Providence, RI 02903 and Pfizer Central Research, Groton, CT 06340

The cornea is well-supplied by afferent nerves that contain neuropeptides. To assess the role of neuropeptide receptors in mediating the responses to corneal stimulation, chloralose-anesthetized male rats were pretreated with the NK1 antagonist, CP99,994 (0.1-50 nmol icv), or the NK2 antagonist, MEN10,376 (0.01-1 nmol icv) 20 min prior to topical application of mustard oil (5 µl, 20% sol.). After 2h survival, brainstems were processed for Fos-like immunoreactivity (Fos-L1). Fos-L1 increased (Pc.0.01) in two distinct transition regions of the spinal trigeminal nucleus (ViVc and Vc/C1) in saline controls and after the inactive NK1 enantiomer, CP100,263. The highest dose of CP99,994 reduced Fos-L1 (P<0.05) among neurons in laminae 1-II at Vc/C1, but had no effect at Vi/Vc. NK2 antagonism caused a significant dose-related decrease in Fos-L1 (P<0.001) in laminae 1-II at Vc/C1 and had no effect at Vi/Vc. In parallel experiments, arterial plasma ACTH, blood pressure and heart rate were assessed after corneal stimulation. Both NK1 and NK2 antagonism blocked the plasma ACTH response to corneal stimulation, but neither drug affected the plasma ACTH response to hemorrhage. Neither the NK1 nor NK2 antagonist altered cornea-evoked blood pressure or heart rate responses. These results suggest that multiple parallel pathways control the pituitary and autonomic responses to corneal stimulation. Both NK1 and NK2 receptors act afferent to the hypothalamus to mediate an increase plasma ACTH, whereas neither receptor subtype is necessary for the cardiovascular responses to corneal stimulation. NK1 receptor activation has only minor effects on expression of c-fos in central trigeminal neurons after selective small fiber irritant stimulation of the cornea, whereas NK2 receptors contribute only to Fos produced in the most caudal portions of the spinal trigeminal nucleus. L5 SPINAL NERVE INJURY INDUCES RAPID SPROUTING OF A-FIBER PRIMARY AFFERENTS INTO SUBSTANTIA GELATINOSA OF THE ADULT RAT SPINAL CORD. P. Shortland¹, E. Kinnman^{2*} & C. Molander^{1,2}, Person of I) Neuroscience & (2) Dept. of Surgery, Divn. of Rehabilitation, Neurogenic Pain Unit, Karolinska Institutet, Stockholm, Sweden.

Recently, an animal model has been developed for the study of neuropathic pain mechanisms that involves the section or ligation of the spinal nerves (Kim & Chung, 9'29. Pain 50:355). These rats show behaviour interpreted as spontaneous pain, allodynia & hyperalgesia. We have shown previously that A-fibers sprout into lamina II after spinal nerve section (Shortland et al., '95 Neurosci. Abstr. 21:356.13). We have now examined the time-course of spinal nerve section-induced sprouting in adult male rats. BHRP was injected into the L5 DRG (to label injured afferents). The contralateral, uninjured L5 DRG, used for control injections, showed labelling in lamina I and III-V, leaving lamina II devoid of labelling. Changes in the laminar distribution of A-fibers began 24 hours following spinal nerve section. Labelling was seen throughout laminae I-V in the L4-5 dorsal horn by 3 days post-injury. The results indicate that injured AB afferents begin sprouting into lamina II very shortly after nerve injury. The changes in the laminar distribution after spinal nerve injury occur with a similar time-course as changes in mechanical hypersensitivity (Kinnman & Levine, '95, Neurosci-64-751) suggesting that injured AB fibers may directly contribute to the state of central sensitisation which gives rise to mechanical hypersensitivity. CENTRALLY ADMINISTERED MORPHINE SUPPRESSES C-FOS EXPRESSION FOLLOWING A NOXIOUS THERMAL STIMULUS IN THE DEVELOPING RAT. <u>D.K. Yi* and G.A.Barr</u>, Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th Street, NY, NY 10032.

Mechanisms involved in antinociception are not well understood in the developing animal. In this study, morphine-induced analgesia following a noxious thermal stimulus in the neonatal rat was examined using behavior, and the expression of the c-fos gene as a marker for neuronal activity. Three- and 14 - day old rat pups were given morphine (0, 0.1, 0.3, 3.0, and 10 μg) intracerebroventrically 15 minutes prior to the application the stimulus. The rat's forepaw or the hindpaw was immersed in a hot water bath (52° C), allowing the pups to withdraw the paw. If the withdrawl latencies were less than 5 seconds, then the paw was held in the water bath for a total of 5 seconds. The pups were tested in this manner every 5 minutes for 20 minutes, and were sacrificed 2 hours after the end of the testing session. Either the cervical or the lumbar cord was processed for Fos immunohistochemistry. The behavioral results showed that at both ages the forepaw was analgesic in the thermal test, with the 3-day-old pups being more analgesic tan the 14-day-old animals. In the hindpaw, however, no analgesia was observed at either age at any morphine dose. Anatomically, morphine suppressed the Fos immunoreactivity in both the cervical and the lumbar spinal cord, reducing the number of Fos labeled nuclei in the expericial layer were more resistent to morphine than were in the deeper layers in the 14-day-old lumbar cord. Although there was a positive correlation between behavior and Fos immunoreactivity when the forepaw was tested, in the hindpaw the suppression of Fos appearance occurred in the absence of analgesia. It is speculated that mechanisms of morphine-induced analgesia are different in developing animals than adults, and that morphine may induce analgesia using different mechanisms of a different segmental levels in the maturing animal. 344.2

THE TIME-COURSE OF AB-EVOKED C-FOS EXPRESSION IN NEURONS IN THE DORSAL HORN AND GRACILE NUCLEUS AFTER PERIPHERAL NERVE INJURY. C. Molander ** & P. Shortland**, Depts. of (1) Neuroscience, &

(2) Surgery, Divn. of Rehab. & Phys. Med. Karolinska Inst. Stockholm, Sweden.
Peripheral nerve injury alters the laminar distribution of myelinated and unmyelinated primary afferents in the spinal cord. It also alters the expression of cfos in dorsal horn cells. Normally, only noxious stimulation is effective in producing fos protein in second order cells. After injury, however, low-threshold electrical stimulation can evoke for expression in the dorsal horn and gracile nucleus (GN). Here we have investigated the time-course of this abnormal expression. Electrical stimulation of the sciatic nerve at Aß-fiber strength (0.1mA, 0.5ms, 5Hz, 10 mins) was performed 3 days to 1 year following either sciatic nerve section or sciatic nerve crush in adult rats. Stimulation of the intact contralateral sciatic nerve was made for comparison. Stimulation of the normal sciatic nerve at AB strength resulted in no labeled neurons in the dorsal horn or GN. Stimulation of the crushed sciatic nerve resulted in c-fos expression in cells in laminae I-V of the dorsal horn and GN only from 1-3 weeks post injury. Stimulation after sciatic section also resulted in fos expression in the dorsal horn after 1 week and this expression persisted at all timepoints studied. In the GN fos expressing cells were seen at 1-4 weeks but not at longer survival times. The results indicate that abnormal c-fos expression may be correlated with the onset of Aß sprouting which occurs after nerve injury. When nerve regeneration is successful, AB-evoked for expression returns to normal in both the cord and GN. When regeneration is prevented then AB-evoked for persists in the dorsal horn but not in the GN. This suggests that (1) abnormal fos expression in the dorsal horn may be regulated by the loss of some retrograde signal from the periphery and (2) abnormal fos expression in the GN may be under some other control since its expression is independent of whether or not regeneration occurs Supported by Tore Nilsons fond.

CHEMICAL CYSTITIS INDUCED FOS PROTEIN EXPRESSION IN ADULT RAT

CHEMICAL CYSTIIS INDUCED FOS PROTEIN EAPRESSION IN ADDL'IT RAT BRAIN: EFFECTS OF CAPSAICIN AND SPINAL CORD INJURY. M.A. Vizzard*. Univ. of Vermont, Depts. of Neurol./Anat. and Neurobiol., Burlington, VT. Immunohistochemical detection of the protein product (Fos) of the c-fos immediate early gene was used to study neuronal activation in the brain of unanesthetized rats following induction of chemical cystitis by cyclophosphamide (CVP). CYP is metabolized to acrolein, an irritant eliminated in the urine. Injection of CYP (n=10; 75 mg/kg, i.p.) three hrs prior to euthanasia significantly increased Fos expression in a variety of supraspinal sites, including: the pontine micturition center, locus coeruleus, subcoeruleus, parabrachial nucleus, ventrolateral periaqueductal gray, A5, A7, ventrolateral medulla, hypothalamus and visceral regions in the cerebral cortex. In ventrolateral medium, hypothalamus and visceral regions in the creation cortex. In vehicle-treated animals (n=10), Fos expression was minimal except in the inferior colliculus where the greatest numbers of Fos-immunoreactive cells were present. To determine if the Fos expression was mediated by A-delta and/or C-fiber bladder afferents, animals were pretreated with capsaicin (Cap), a C-fiber neurotoxin (20 mg/ml; 125 mg/kg; s.c.; n=5). Control animals (n=5) received a corresponding volume of vehicle. Three to four days after the last Cap injection, animals were treated with CYP. To check the effectiveness of Cap pretreatment, an eye-wipe test was conducted before CYP injection. In control animals, the number of defensive eye-wiping movements induced by topical application of Cap solution (100 µg/ml) to the eye averaged 29.5±1.3 in 2 min. No eye-wiping movements were detected in Cap-pretreated animals. In both Cap and control (vehicle-treated) animals, CYP increased Fos expression in the same supraspinal sites as observed in untreated (no Cap or vehicle) animals injected with CYP. To determine if CYP-induced Fos expression in the brain was mediated by spinal pathways, CYP was injected in chronic (3-4 week) spinal cord transected (SCT; T10) animals (n=3). CYP injection in SCT animals did not elicit Fos protein in any supraspinal site. These results demonstrate: (1) CYP-induced chemical cystitis elicits supraspinal site: Intese results demonstrate. (1) of 19-induced clientical systatis effects Fos expression in supraspinal sites previously identified as playing a role in bladder function; (2) CYP-induced Fos expression in brain is mediated by spinal pathways originating below T10; (3) CYP sensitive, bladder A-delta fibers play a role in CYP-induced Fos expression in brain. [PVA-SCRF (1461-01), APA (VB1-9402-1), ICA]

EVOKED ACTIVITY IN NOCICEPTIVE DORSAL HORN NEURONES AFTER 5-HT_{1A} AND 5-HT_{1B} RECEPTOR STIMULATION. J. Gjerstad, A. Tjølsen* and K. Hole. Department of Physiology, University of Bergen, Arstadveien 19 5009 Bergen, Norway

The role of spinal 5-HT_{1A} and 5-HT_{1B} subreceptors in regulation of nociception was investigated. Extracellular recordings were made from single WDR neurones in spinal laminae III-VI of intact anaesthetized rats. The skin was stimulated electrically (16 pulses, 0.5 Hz) at 1.5 x threshold for C-fibre response (1.95-4.50 mA). The Aβ-, Aδ- and C-fibre responses and post-discharge were recorded. The 5-HT_{1A} agonist 8-OH-DPAT, the 5-HT_{1A} antagonist WAY100635 and the 5-HT_{1B} agonist CP93,129 were applied directly onto the spinal cord. 8-OH-DPAT (50-500 nmol) mainly affected the Aō- and C-fibre responses and the post-discharge: C-fibre response was reduced in 71%, increased in 6% and little affected in 23% of the cells. The inhibition was weaker with increasing control C-fibre response, and increased with increasing wind-up in the control measurements (p<0.001). The inhibitory effect of 8-OH-DPAT was totally blocked by coadministration of WAY100635 (50 nmol). CP93,129 (50 nmol) inhibited the Aō-fibre response to approxi mately 60 % of the control response.

In conclusion, the effect of spinal 5-HT₁₄ receptor stimulation was mainly an inhibition of the response to Aδ- and C-fibre stimulation. This effect seems to be related to the wind-up properties of highly convergent neurones. 5-HT. receptor stimulation specifically inhibited the response to Aδ-fibre stimulation The effects of 5HT, receptor stimulation may be partly due to presynaptic mechanisms

AUTORADIOGRAPHIC EVIDENCE THAT m4 MUSCARINIC RECEPTORS MODULATE NOCICEPTION IN THE HUMAN SPINAL CORD, MT Borenstein, M Santiago, HH Valentine and LT Potter*, Molecular and Cellular Pharmacology, U of Miami School of Medicine, P.O. Box 016189, Miami, FL.

Three lines of evidence indicate that M1 (m1 and/or m4) receptors are involved in the modulation of nociception. (1) Autoradiography with 20 nM ³Hpirenzepine demonstrates that M1 receptors are concentrated in lamina II (substantia gelatinosa) of the human spinal cord (Villiger and Faull, Brain Res 345,196,1985). (2) Muscarinic agonists and esterase inhibitors administered into the lumbar subarachnoid space in animals cause a dose-dependent increase in the latency of hot-plate and tail-flick responses. Antinociceptive effects are reduced by atropine and pirenzepine, but not by naloxone, strychnine, picrotoxin, curare or methysergide and phentolamine (Yaksh et al, Eur J Pharmacol 117,81,1985; Iwamoto and Marion, JPET 266,329,1993). (3) A new orally-active muscarinic agent developed by Novo Nordisk and Eli Lilly is as effective as, but 10-40 times more potent than morphine in reducing nociception in animals, and analgesia does not appear to be mediated by m1 or M3 receptors (Sauerberg et al, Life Sciences 56,807,1995). To go further, we have utilized m1-toxin and m4-toxin to delineate the subtypes of muscarinic receptors most prominent in the human spinal cord. Sections of fresh lumbar cord were prepared in a cryostat, exposed to radioligands, washed, dried and apposed to film. Studies with one nM³H-N-methylscopolamine confirmed the work of many previous investigators showing muscarinic receptors in lamina II. m4-Toxin markedly reduced this binding, whereas m1-toxin reduced binding slightly. 125 I-m4-Toxin was prepared by a chloramine-T method. Studies with this ligand firmly establish a dense concentration of m4 receptors in lamina II. [Supported by AG 06170].

NMDA AND 5-HT2 RECEPTOR ANTAGONISTS REDUCE FOS-LI WITHIN SPINAL TRIGEMINAL NUCLEUS AFTER INFLAMMATION OF THE TMJ REGION IN THE RAT. D.A. Bereiter*, J.F. Crary and S.L. Masia. Depts. of

REGION IN THE RAT. <u>D.A. Bereiter*</u>, <u>I.F. Crary</u> and <u>S.L. Masia</u>. Depts. of Neuroscience & Surgery, Brown Univ,/RI Hospital, Providence, RI (2903 Injury of the temporomandibular joint (TMI) region produces persistent pain that is poorly localized. The neural basis for TMI pain is not well defined, but glutamatergic and serotonergic mechanisms may be involved. To assess the role of NMDA and 5-HTZ receptors in activation of central trigeminal neurons after inflammation of the TMI region, barbiturate-anesthetized male rats were pretreated with the NMDA antagonist, MK-801 (0.02-2 mg/kg iv), or the 5-HTZ antagonist, ketanserin (0.03-3 mg/kg iv) 15 min prior to mustard oil (25 µl, 20% sol.) injection into the TMI region. After 2h survival, brainstems were processed for Fos-like immunoreactivity (Fos-LI) and neural activation was estimated from the number of Fos-positive neurons in spinal trigeminal n. (Vsp). Fos-LI was found mainly at two distinct transition regions of Vsp (subnucleus interpolaris/caudalis, Vi/Vc and caudalis/upper cervical cord, Vc/C1) after inflammation. MK-801 and ketanserin affected differentially the magnitude and pattern of Fos-LI produced within the Vsp. MK-801 caused a dose-related decrease in Fos-LI among laminae within the Vsp. MK-801 caused a dose-related decrease in Fos-L1 among laminae I-II neurons at the ipsilateral Vc/C1 transition (-5 to -6.5mm to obex) and at mid-caudalis levels (-2 to -3.5mm to obex) with high dose causing 71±5% and 78±10% reduction, respectively, vs saline, (P<0.01). Ketanserin did not affect the number reduction, respectively, vs saline, (P<0.01). Ketanserin did not aftect the number of Fos-positive neurons in these caudal regions. By contrast, at periobex levels of Vsp, all doses of ketanserin reduced Fos-LI (P<0.01) bilaterally at the ViVC transition (Vi/Vc-DM, Vi/Vc-VL, and Pa5 regions, +0.5 to -1mm to obex), whereas only higher doses of MK-801 reduced Fos-LI in these regions. These results suggest that NMDA receptors preferentially contribute to activation of neurons in the most caudal portions of Vsp, whereas 5-HT2 receptors selectively affect activation of neurons at the periobex levels of Vsp after inflammation of the TML region. Supported by El Hospital TMJ region. Supported by RI Hospital.

TYROSINE HYDROXYLASE- AND SEROTONIN-IMMUNOREACTIVE VARICOSITIES APPOSE PROPRIOSPINAL NEURONS IN THE RAT C₁-C₂ SPINAL SEGMENTS. K.E. Miller*, M.J. Chandler, and R.D. Foreman, Dept. Anatomical Sciences, Dept. Physiology & Biophysics, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190

Physiological and anatomical studies from our laboratories have demonstrated that neurons in upper cervical spinal segments have descending projections to thoracic and lumbar spinal cord segments. Many of these propriospinal neurons appear to mediate inhibition of thoracic and lumbar dorsal horn neurons produced from somatic and visceral afferent input. In order to further understand the neurochemical circuitry involved in regulating or modulating this propriospinal system, the present study examined if norepinephrine or serotonin fibers contacted upper cervical, propriospinal neurons. Fluorogold was injected into the rat lumbosacral spinal cord to retrogradely label propriospinal neurons in the C₁-C₂ spinal segments. Following retrograde transport, tissue sections from the C1-C2 segments were processed for tyrosine hydroxylase (TH) or serotonin (5-HT) immunofluorescence. Retrogradely labeled neurons were abundant on both ipsilateral and contralateral sides in the lateral cervical and spinal nuclei, nucleus proprius, ventral horn, and the central gray region (lamina X). Many retrogradely labeled neurons were apposed by TH- and 5-HT-immunoreactive fibers. We conclude from these results that descending monoaminergic pathways from the brainstem are situated anatomically to modulate the activity of C₁-C₂ propriospinal neurons. These brainstem pathways could influence the propriospinal mediation of spinal neurons in lower spinal segments. Supported by NIH#27213 (KEM), NIH#22732 (RDF) and Presbyterian Health Foundation.

344.8

AN NMDA RECEPTOR ANTAGONIST BLOCKS THE INCREASE IN [3H]-PHORBOL 12,13-DIBUTYRATE BINDING IN SPINAL CORD DORSAL HORN INDUCED BY NOXIOUS CHEMICAL STIMULATION. T.J. Coderre* and K. Yashpal. Pain Mechanisms Lab, Clinical Research Institute of Montreal, 110 Pine Ave. West, Montreal, QC, Canada, H2W 1R7.

We have previously suggested that both spinal excitatory amino acids (EAAs) and protein kinase C (PKC) contribute to persistent pain in the formalin test. The present study examines the interactive effects of EAAs and PKC by determining the effects of an NMDA antagonist, MK-801, on the increase in membrane-associated PKC in spinal cord dorsal horn induced by injection of formalin into the rat hind paw. Changes in the levels of membraneassociated PKC, as assayed by quantitative autoradiography of the specific binding of 3H-phorbol-12,13-dibutyrate (3H-PDBU) in lumbar spinal cord sections, were assessed in rats given a hind paw injection of 50 µl of 2.5% formalin, following intrathecal (i.t.) treatment with MK-801 (150 nmoles) or vehicle. The specificity of the assay, at measuring noxious stimulus-induced changes in membrane-associated PKC, was also assessed by determining the effects of GM₁ ganglioside (80 nmoles, i.t.), which inhibits the translocation of PKC, on formalin-induced [3H]-PDBU binding in spinal dorsal horn. Intrathecal treatment with either MK-801 or GM₁ ganglioside produced a significant suppression of the increases in [3H]-PDBU binding in spinal dorsal horn induced by hind paw injection of formalin. The data provide support for a role of NMDA receptors in noxious stimulus-induced translocation of PKC in spinal cord dorsal horn (Supported by an MRC of Canada grant to T.J.C.).

PROLONGED DECREASE OF SUBSTANCE P BINDING IN RAT SPINAL CORD DORSAL HORN INDUCED BY NOXIOUS CHEMICAL STIMULATION OF THE HIND PAW WITH FORMALIN, K. Yashpal*, J.L. Henry and T.J. Coderre. Pain Mechanisms Laboratory, Clinical Research Institute of Montreal, and Department of Physiology, McGill University, Montreal, Quebec, Canada, H2W 1R7,

Previous data (Yashpal et al., NeuroReport 5:2101; 1994) indicate that noxious thermal stimulation leads to a brief decrease in [1251]BH-substance P binding in spinal cord dorsal horn. It was suggested that the decreased binding was due to occupation of receptors by endogenous ligand, following a noxious stimulus-evoked release of substance P. The present study used a similar technique to examine whether the persistent nociceptive responses to hind paw formalin injection are associated with a prolonged release of substance P in the spinal cord in rats. Rats were decapitated either 5, 25 or 60 min following an injection of 50 µl of either 1% or 5% formalin into the plantar surface of the hindpaw, and 20 µm sections from the lumbar spinal cord were incubated with [125]]BH-substance P. Compared with unstimulated control rats, substance P binding was significantly reduced in rats given hind paw injections of formalin. Decreased substance P binding was most pronounced in the superficial dorsal horn. Both 1% and 5% formalin injections produced significant decreases in substance P binding at each of the three measured time points. Assuming that decreased radioligand binding reflects increased competition by endogenous ligand, these data suggest that both low (1%) and high (5%) concentrations of formalin produce a prolonged release of substance P within the dorsal horn of the spinal cord. (Supported by MRC of Canada grants to T.J.C. and J.L.H.).

BETWEEN CAPSAICIN-SENSITIVE PRIMARY AFFERENT CENTRAL TERMINALS AND GABA- AND MET-ENKEPHALINERGIC INTERNEURONS IN THE SUBSTANTIA AND SPINAL TRIGEMINAL NUCLEUS A. Hiura*, F. Nasu, M. Kuwahara and H. Ishizuka. GELATINOSA CAUDALIS. Dept. of 2nd Oral Anat., Tokushima Univ. Sch. of Dent., Tokushima 770, Japan.

Investigation of the synaptic relations between primary afferent central endings and interneurons in the superficial dorsal horn is a key study to understand the nociceptive transmission. Recently, we have shown that capsaicin-sensitive primary afferent central terminals (CI-terminals) make presynaptic contacts with interneurons in the substantia gelatinosa (Hiura & Ishizuka, 1995).

In order to directly demonstrate the synapses between CI-terminals and GABAand Met-Enkephalinergic interneurons, capsaicin treatment and immunolabeling methods were utilized. Superficial layer of the lumbar spinal cord dorsal horn and spinal trigeminal nucleus candalis of the mouse were examined by electron microscopy after post-embedding immunogold labeling procedures. Double-labeling with different size of IgG gold was used for GABA (15nm) and Met-Enk(5nm).

Glomerular CI-terminals made presynaptic contacts with surrounding dendrites exhibiting GABA and Met-Enk immunoreactivities(IR). Nonglomerular CI-terminals also made presynaptic contacts with GABA- and Met-Enk-IR soma. Frequently a single dendrite and somata showed double labeling, i.e. GABA and Met-Enk might coexist in some of the interneurons. The present findings strongly suggest that nociceptive primary afferent neurons modulate the pain transmission by themselves via inhibitory GABAergic and Met-Enkephalinergic interneurons in the superficial layer of dorsal horn and spinal trigeminal nucleus caudalis.

PARAVENTRICULAR HYPOTHALAMUS, THE SOURCE OF SPINAL VASOPRESSIN FIBERS IN THE RAT

Martin Hallbeck*, Ola Hermanson, Anders Blomqvist, Dept. Cell Biology, University of Linköping, S-581 85 Linköping, Sweden.

Vasopressin (VP) has been proposed to be involved in pain modulation, which is thought to be mediated by vasopressinergic fibers in lamina I of the spinal cord. To clarify the origin of these fibers we have used retrograde tract tracing combined with in situ hybridization for VP.

Rats were injected into the cervical spinal cord with the retrograde tracer cholera toxin B, which was demonstrated by immunocytochemistry. In situ hybridization was performed with a 35S-labelled 0.6 kb RNA probe complementary to preproVP (ppVP). The sections were pretreated with proteinase K, hybridized for 18 h at 59°C and then posthybridized under high stringency conditions followed by autoradiography.

Several areas contained ppVP, such as the suprachiasmatic n., supraoptic n., and bed nucleus of stria terminalis. However, ppVP was not found in DRG, n. tractus solitarius, or the locus coerulcus, which all have been suggested to contain spinallyprojecting VP neurons. The only area with spinal projections that contained ppVP was the paraventricular hypothalamic nucleus (PVH). The posterior parts of PVH displayed large numbers of double-labeled neurons, located primarily in the lateral parvocellular division and in the ventral part of the medial parvocellular division. Almost no double-labeled neurons were seen in the posterior magnocellular division, rich in vasopressin, or in the dorsal parvocellular division, rich in descending neurons.

These findings suggest that PVH is the sole source of spinal VP. Further, they show that the spinally-projecting VP neurons in PVH are parceled into anatomically distinct cell groups that constitute a subset of the spinally-projecting PVH neurons. In conclusion these findings show that a putative role for VP in pain modulation must involve the PVH.

DIFFERENTIAL EFFECTS OF DORSAL RHIZOTOMY ON MU AND DELTA OPIOID RECEPTOR-LIKE IMMUNOREACTIVITY (LI) IN THE CERVICAL SPINAL CORD OF THE RAT. M.-C. Lombard*, C. Abbadie, R. Elde, J.-M. Besson and A.J. Basbaum. INSERM U161, Paris, France, Dept. Anatomy, UCSF, San Francisco and Depts. Cell Biology and Anatomy, U. Minnesota, Minn. MN.

To address the pre and postsynaptic distribution of mu and delta opioid receptors, we used quantitative ICC in 1) rats that underwent dorsal rhizotomy (C4-T2); 2) rats

that underwent dorsal rhizotomy C4-C6 and C8-T2, sparing C7; 3) sham-operated rats that underwent laminectomy without rhizotomy. Seven days after surgery, we immunostained lumbar spinal cord with antisera that distinguish MOR and DOR and then densitometrically measured immunostatining in laminae 1-II. To normalize immunostaining, we compared the density ipsilateral and contralateral to the lesion. In laminae 1-II, MOR-LJ is found in axon terminals and in somatic and dendritic profiles; DOR-LJ is in varicose axons. Dorsal rhizotomy (C4-T2) reduced MOR-LJ in all segments, most notably in lamina I and outer II, dense labelling persisted in inner II. By contrast, residual DOR-LI was evenly distributed in lamina I and II. In the most deafferented segment (C7) we recorded a 44.2% reduction of MOR-LI. For DOR-LI. the decrease was 64.2%. We estimate that C7 MOR-LI afferents distribute as follows: C4-7.5%, C5-14.3%, C6-16%, C7-22.9%, C8-13.7%, T1-11.5%, T2-14.1%. For DOR-LI we found: C4-5.8%, C5-19.8%, C6-14.6%, C7-25.1%, C8-11.9%, T1-10.9%, T2-14.10%. 11.9%. For both receptors there is a greater rostral than caudal arborization. Finally, we estimate that 27% and 34% of the primary afferent-derived MOR and DOR-LI, respectively, derive from dorsal roots rostral and caudal to C7. Besse et al. (1990) found that up to 75% of mu and 65% of delta opioid receptor binding in dorsal horn is primary afferent-derived. Conceivably, we found more postsynaptic MOR-LI, because antibodies readily stain cytoplasmic and membrane receptor. The equivalent delta numbers suggest a predominant axonal location for this receptor. If there is no induction of opioid receptor in deafferented cord, our results and those of Besse et al. indicate that the dorsal horn contains both pre and postsynaptic mu *and* delta opioid receptors and suggest that incompletely overlapping populations of small diameter primary afferents generate these different labelling patterns. ESTROGEN RECEPTORS ARE PRESENT IN DORSAL HORN ENKEPHALINERGIC NEURONS. A. Amandusson, O. Hermanson & A. Blomqvist, Dept. of Cell Biology, Faculty of Health Sciences, Univ. of Linköping, S-581 85 Linköping, Sweden.
There is increasing evidence that pain sensitivity is influenced by gonadal

hormones such as estrogen, but the mechanisms by which estrogen modulates pain-processing are not known. In a previous immunohistochemical study we demonstrated that large numbers of neurons in the superficial dorsal horn of rats expressed estrogen receptors (Amandusson et al., Neurosci. Lett. 196:25-8, 1995). This finding raised the possibility that estrogen may influence dorsal horn enkephalin expression, since enkephalinergic neurons are localized to the same part of the dorsal horn. To explore this possibility we used a double-labeling procedure, combining immunohistochemical staining with in situ hybridization, to demonstrate estrogen receptor-like immunoreactivity (ER-IR) and preproenkephalin-A (ppENK) mRNA in the medullary and spinal dorsal horn of female rats. Both markers labeled large numbers of neurons in the substantia gelatinosa and its trigeminal homologue. Many of these neurons were double-labeled, displaying both ER-IR and ppENK mRNA. Cell counts showed that 60-70% of the enkephalinergic neurons in the superficial dorsal hom expressed ER-IR, whereas enkephalinergic neurons in other parts of the spinal and medullary gray matter were single-labeled.

Previous studies have shown that estrogen receptors can bind to the promotor region of the ppENK gene, and studies on the hypothalamus have demonstrated that estrogen regulates enkephalin expression in select neuronal populations. The present results demonstrate that enkephalinergic neurons in the superficial dorsal horn contain estrogen receptors and suggest that estrogen may play an important role for the modulation of sensory and nociceptive processing Supported by the Swedish Medical Research Council (#7879)

NOCICEPTIVE AND NEUROPATHIC PAIN ARE REDUCED IN MICE LACKING THE GAMMA ISOFORM OF PROTEIN KINASE C (PKCy). A.B. Malmberg^{1*}, C. Chen², S. Tonegawa² and A.I. Basbaum¹, ¹Depts of Anatomy and Physiology and W.M. Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143, and ²HHMI, MIT, Cambridge, MA 02139.

A variety of second messenger systems are implicated in the tissue and nerve

injury-evoked hyperexcitability of dorsal horn neurons that underlies nociceptive and neuropathic pain, respectively. Here, we studied mice that carry a null mutation in the gene encoding for the neuronal specific isoform PKCy. We evaluated pain behavior after intraplantar injection of 10 μ l 2% formalin and studied capsaicin-induced plasma extravasation of Evan's Blue dye in skin punches. To induce nerve injury, we made a partial ligation of the sciatic nerve and assessed mechanical allodynia with von Frey hairs and thermal hyperalgesia in the Hargreaves model. To study the anatomical consequences of nerve injury we performed immunocytochemistry for the Fos protein, substance P (SP), SP receptor (SPR) and neuropeptide Y (NPY) on spinal cord sections.

Baseline mechanical and thermal withdrawal thresholds were similar in PKCγ knock-out and wild-type mice. In the knock-out mice, we recorded a significantly less (56%) second phase paw licking behavior in the formalin test, less paw swelling (21%) and reduced ipsilateral superficial dorsal horn Fos-ir (32%) compared to wild-type mice; capsaicin-evoked plasma extravasation was also less than in wild-type mice (44%). The magnitude of allodynia and hyperalgesia was also significantly reduced in the knock-out mice as were the anatomical changes (decreased SP, and increase SPR and NPY) that characterize this neuropathic pain model. These results indicate that the PKCy isoform contributes to the development of both nociceptive and neuropathic pain and to the anatomical consequences of nerve injury.

CHARACTERIZATION OF ALPHA-2A RECEPTOR IMMUNOREACTIVITY IN THE RODENT SPINAL CORD: RELATIONSHIP TO NORADRENERGIC TERMINALS AND NEUROPEPTIDE CONTENT. L.S. Stone* 1-3, C. Broberger*, G.L. Wilcox* 1-2, T. Hökreit* and R. Elde* 1-3 (Torduate Program in Neuroscience, Department of P

of ²Pharmacology and ³Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 53455. ⁴Department of Neuroscience, Karolinska Institutet, 17173 Stockholm, Sweden. Activation of α_{2A} -adrenergic receptors mediates many physiological effects including analgesia. mRNA for the receptor has been detected in many regions of brain and spinal cord as well as in small diameter dorsal root ganglia (DRG) neurons. We have developed an anti-peptide antiserum in rabbits directed against the carboxy-terminal portion of the rat RG20 (α_{2A}) clone. The resultant serum revealed α_{2A} -immunoreactivity (α_{2A} -ir) on the membranes of MDCK cells transfected with α_{2A} , but not the α_{2B} or α_{2C} subtypes, or untransfected cells. Staining was blocked by preabsorption of the serum with the cognate peptide in both cells and tissue sections. We have investigated the relative distribution of α_{2A} -ir in the spinal cord and brainstem of both rats and mince. Staining was observed in the superficial layers of the dorsal horn of the spinal cord and the spinal tract of the trigeminal nerve, both of which receive input from primary sensory neurons. In order to determine if the receptor is located on the terminals of DRG neurons or on second order spinal neurons, we double-labeled tissue sections with antibodies to either Substance P (SP) or CGRP, both of which are synthesized in DRG neurons. A high degree of co-localization was observed between α_{2A} -ir and SP-ir in both spinal cord and brainstem, whereas CGRP-ir co-localized only partially with α_{2A} -ir. In addition, dorsal rhizotomy decreased both α_{2A} -ir and SP-ir in addition, dorsal rhizotomy decreased both α_{2A} -ir and SP-ir ipsilateral to the severed roots. This result suggests that α_{2A} -receptors are synthesized and trafficked into the spinal cord almost exclusively by SP-containing neurons, some of which are likely to be nociceptors. Interestingly, an antibody directed against dopamine β-hydroxylase, which is involved in t

AN IMMUNOHISTOCHEMICAL STUDY OF LUMBAR SPINAL DURA AND POSTERIOR LONGITUDINAL LIGAMENT. S Kallakuri, JM Cavanaugh', DC

Blagoev. Bioengineering Center, Wayne State University, Detroit, MI 48202.

Understanding the pattern and type of innervation of the lumbar dura may offer more insight into the etiology of low back pain. Our objective was to investigate the innervation in lumbar dura and posterior longitudinal ligament (PLL) using immunocytochemistry. Methods: Primary antibodies included the general neuronal marker protein gene product (PGP 9.5), substance P (SP), calcitonin gene related peptide (CGRP) and the sympathetic nervous system marker tyrosine hydroxylase (TH). The tissues were processed for immunochemistry based on the Avidin Biotin Peroxidase Complex method. Nine lumbar dorsal dura, ventral dura and PLL were obtained from adult male New Zealand White rabbits. Results: PGP 9.5: In dura, large bundles and very small diameter immunoreactive fibers concentrated in nerve root sleeves and along the lateral margins were observed. PLL showed an extensive longitudinal network of parallel bundles and interconnected fibers. Some transverse fibers at the intervertebral region of PLL suggest a supply into the disc. SP: In the dura very intensely stained small diameter immunoreactive fibers were seen at the nerve root sleeves and on the lateral margins. SP immunoreactivity in PLL included large bundles and small diameter fibers along the entire length and also at the intervertebral region. CGRP: A sparse distribution of immunoreactive fibers were found in all the three tissues and these fibers appeared to innervate the deep layers. TH: Small diameter immunoreactive fibers and bundles were seen in both dura and PLL. Their density and distribution appeared to be similar to that of CGRP immunoreactive fibers. Controls: In tissues stained without the primary antibody no nerve fibers were observed. Discussion: Our results indicate that the dura is well innervated near the nerve root sleeves and on lateral margins. As reported by others the PLL is also well innervated An extensive distribution of SP immunoreactive fibers implicate dura and PLL in the pathogenesis of low back pain. TH immunoreactivity support a role for the sympathetic system in some cases of low back pain. Supported by NIH grant AR41739 (JMC).

EFFECTS OF STIMULUS PARAMETERS ON BEHAVIOUR AND RESPONSES OF TRIGEMINAL BRAINSTEM NEURONES TO TOOTH-PULP STIMULATION IN CATS. <u>D. Banks*1 and B. Matthews.</u> (SPON: Brain Research Association). Department of Physiology, University of Bristol, BS8 1TD and ¹Department of Physiology, UMDS, St Thomas' Hospital, London SE1 9RT, England.

In our laboratory, bipolar electrical stimulation of tooth-pulp (TP), at 0.5Hz with stimuli up to 1mA intensity, 1ms duration in chronically-prepared, conscious cats produces no signs of aversive behaviour. This result was unaffected by the type of anaesthetic used during the initial surgery, the type and timing of surgical procedures or the type of conditioning of the animals during pre-operative laboratory visits (Soc Neurosci. Abstr. 24, 320.5, 1994). We have now investigated the behavioural effects of brief trains of higher frequency TP stimulation and recorded the activity of neurones in the trigeminal brainstem under anaesthesia using the same stimulus parameters. Three male cats were prepared for chronic recording as described previously (J. Neurosci. Meth. 38, 35-40, 1991; 46, 83-88, 1993). With 100ms trains of stimuli, aversive responses were observed with stimulus intensities of 100-200μA and stimulus durations of 0.1-0.5ms at frequencies above 30Hz (range 30-1000Hz). Recordings were made from 43 neurones with oro-facial receptive fields in the rostral part of the trigeminal spinal nucleus in the same cats under light anaesthesia. Of these, 14 responded to TP stimulation but all responded to single shocks of below 100μ A and 0.1ms duration and none required the temporal summation provided by a train of stimuli to evoke a response. With 7, a 100ms train of stimuli near threshold evoked more spikes than single shocks of maximum intensity. It is concluded that, in the cat, temporal summation is required to produce aversive responses to TP stimulation but the site of this summation has not been identified. In man (McGrath et al., Pain 15, 377-388, 1983), temporal summation has less effect on the threshold of pain produced by TP stimulation

LOCALIZATION OF NK2 AND NK3 RECEPTOR-LIKE IMMUNO-REACTIVITY IN RAT SPINAL CORD. B.R. Southwell¹, V.S. Seybold², A. Portbury¹ and J.B. Furness¹. Dept. of Anatomy and Cell Biology, University of Melbourne, Parkville 3052,VIC, Australia and ²Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

Although receptor autoradiography has provided information on the regional distribution of NK2 and NK3 receptors in the spinal cord, the cellular localization of these receptors has not been resolved. Antisera generated against unique sequences in the C-terminal region of each receptor were used in conjunction with immunofluorescence and confocal microscopy to examine the distribution of NK2 and NK3 receptor-like immunoreactivity in spinal cords from rats perfused with Zamboni's fixative. NK2 receptor-like immunoreactivity was localized primarily to short, fine, processes in the superficial regions of the white Immunofluorescent processes also occurred in the pia. Within the gray matter, immunoreactive processes also occurred in the pia. Within the gray matter, immunoreactive processes were most prominent in the superficial laminae of the dorsal horn. Immunoreactive perikarya were rare. This pattern of staining suggests that NK2 receptors occur on axons. In contrast, the pattern of NK3 receptor-like immunoreactivity was consistent with a distribution on dendrites and perikarya. Immunofluorescence in perikarya was greatest at the cell membrane. Immunoreactive perikarya was greatest at the cent memorane. Immunoreactive perikarya were sparsely distributed in the dorsal horn and immunoreactive processes were dense in the superficial laminae of the dorsal horn. Thus NK2 and NK3 receptors may mediate effects of tachykinins at different cellular sites. This work was support by NIH NS17702 (VSS) and NH&MRC 963213 (JBF).

PATCH CLAMP CHARACTERIZATION OF SYNAPTIC PLASTICITY IN DEEP DORSAL HORN NEURONS IN TRANSVERSE SLICES OF NEONATAL RAT SPINAL CORD. S.M. Garraway*, S. Pockett, & S. Hochman, Dept. Physiology, University of Manitoba, Winnipeg, MB, Canada R3E 0W3.

Chronic pain syndromes may arise from long-term alterations in excitability of neurons in the spinal cord. Neurons possibly involved include ascending tract cells, which send nociceptive information to the brain, and wide-dynamic range neurons, which receive inputs both from nociceptive and non-nociceptive afferents. Since both cell types are found in laminae IV-VI, we sought to determine whether long-lasting alterations of the synaptic properties of neurons in these regions of the cord could be induced by bursts of conditioning primary afferent activity

Whole-cell patch clamp recordings were made from neurons in laminae IV-VI in 500-1000 µm slices of the neonatal rat lumbar spinal cord (P3-P6). One stimulating electrode placed in the dorsal root entry zone was used to evoke primary afferent excitatory postsynaptic currents (epscs) and another in the contralateral anterior commissure or ventrolateral funiculus was used to identify antidromically ascending tract or long propriospinal neurons. Only recordings where series resistance and leak conductance values were unaltered for the duration of data collection were accepted for analysis (n=9). The lowest stimulation intensity which could evoke an epsc was 100-500 µs and 500 µA. Test epscs were evoked at threshold stimulation strength. In the absence of support solution we observed significant run-down of evoked synaptic currents. In the presence of a support solution (4 mM ATP, 1 mM GTP) the test epsc displayed a stable amplitude which could be maintained for over an hour. Conditioning stimuli at threshold or higher stimulation strengths were capable of evoking either LTP or LTD. Adjustment of conditioning stimulation parameters could interconvert synaptic depression and potentiation in individual cells. COMPARISONS OF RESPONSES OF DORSAL HORN CELLS TO TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION (TENS) IN CATS WITH INTACT AND TRANSECTED SPINAL CORDS. D.W. Garrison * and R.D. Foreman, Depts. of Physical Therapy and Physiology. Univ. of Okla. HSC, Oklahoma City, Okla 73190.

We have shown that TENS applied to somatic receptive fields decreases spontaneous and noxiously evoked dorsal horn cell activity. It is proposed "gating" is contributing to the decrease which may involve segmental and/or supraspinal mechanisms. We hypothesized that TENS would equally decrease activity of dorsal horn neurons in animals with intact and transected cords.METHODOLGCY: Using alpha chloralose anesthetized cats with intact or T-12 transected cords(x-cut), spontaneous and noxiously (nox.) evoked (mechanical clamp/left hind limb) activity was recorded from the lumbar cord. Stimulating variables in the "Norm" mode were frequency (10-125 Hz), intensity (10-60 m&mps) and pulse duration (100 usec). TENS application was continuous for either 30 s. or 5 m. RESULTS are given in % decrease in mean activity (imp/s) from control levels. Of the four comparison categories between intact and cord cut animals, only nox. 30 s was statistically significant (p < .04).

	Spont. 30s	Spont. 30s	Spont. 5 m	Spont.5 m
	Intact	X-Cut	Intact	X-Cut
% Reduction	63%	40%	58%	42%
during TENS	n = 48	n = 49	n ≈ 30	n = 14
	Nox. 30 s	Nox. 30s	Nox. 5 m	Nox. 5 m
	Intact	X-cut	Intact	X-Cut
% Reduction	72%	44%	62%	42%
during TENS	n = 36	n = 25	n = 21	n = 8
CONCLUSION:	The data s	upport the	involvement	of a spinal

modulatory mechanism during TENS reduction of cell activity but not a significant supraspinal one. (HL722732 4 OCAST HR1-063)

EFFECT OF INTRATHECAL SOMATOSTATIN AND ITS ANALOGS ON MECHANICAL ALLODYNIA IN THE RAT J.S. Kroin*, A.V. Maioriello, R.D. Penn. Dept. of Neurosurgery, Rush Medical College, Chicago, IL 60612

Somatostatin-14 (SOM) and its stable analog octreotide provide pain relief when administered intrathecally in patients, and SOM inhibits firing in nociceptive dorsal horn neurons when applied locally. Using an animal model of neuropathic pain (the chronic constriction injury model of Bennett and Xie) SOM and analogs were tested intrathecally for their effectiveness to reduce tactile allodynia. Male Sprague-Dawley rats were implanted with an intrathecal catheter and 5 days later the sciatic nerve was ligated to produce a withdrawal response to the light touch of von Frey hairs on the plantar surface of the foot. Octreotide ($2\mu g$) caused a moderate suppression of allodynia, with the withdrawal threshold increasing 2.2g (%MPE=18%). Lower doses of octreotide did not produce significant blockage of allodynia. Neither SOM (up to $4\mu g$) nor lanreotide (up to $3\mu g$) reduced allodynia. Higher doses produced transient hindlimb motor block. In conclusion, the clinical pain relief seen in patients cannot be explained by the results here, which only show a moderate effect of octreotide and no effect of SOM in this rat model of allodynia.

345.3

ACTIVATION OF PROTEIN KINASE C OR cAMP TRANSDUCTION CASCADES AUGMENT PEPTIDE RELEASE FROM RAT SPINAL CORD SLICES. L.A. Barber*, S. Frayer, M.D. Southall, R.L. Michael, M.R. Vasko. Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, 46202.

Activation of either the cAMP or the protein kinase C (PKC) transduction cascade enhances nociceptive behaviors in animal studies and augments

neuropeptide release from isolated sensory neurons. To address whether these transduction pathways regulate peptide release from sensory nerve terminals in the spinal cord, we examined if activators of adenylyl cyclase or PKC alter capsaicin-induced release of substance P (SP) and calcitonin gene-related peptide (CGRP) from rat spinal cord slices

Spinal cords from adult Sprague Dawley rats were removed, chopped and each half of the lumbar cord placed into separate perfusion chambers. The tissue was superfused with Kreb's buffer in the presence or absence of various drugs and peptide release stimulated using 500 nM capsaicin. Superfusates were assayed for SP and CGRP using radioimmunoassay. Exposing spinal cord tissue to 100 nM phorbol 12,13 dibutyrate (PDBu)

increased capsaicin-evoked release of SP from 1.9 \pm 0.3 to 4.3 \pm 0.8 % of total content and CGRP release from 4.9 \pm 0.5 to 10.5 \pm 1.4% of total content. This augmentation of peptide release was attenuated by pretreating tissue with 1 μM of the PKC inhibitor, bisindolylmaleimide I. An inactive PDBu analog, 4α-PDBu (1μM) did not alter peptide release In the presence of 10 μM forskolin, capsaicin-evoked release of SP increased from 1.4 \pm 0.2 to 3.0 \pm 0.4 % of total content, whereas CGRP release increased from 2.7 \pm 0.5 to 5.0 \pm 0.7 % of total content.

These results indicate that activation of cAMP or PKC transduction cascades augment evoked release of peptides from spinal cord slices and this could contribute to hyperalgesia. (Supported by NS 34159)

SPINAL NK1 RECEPTOR MEDIATES THERMAL HYPERALGESIA AND PROSTAGLANDIN RELEASE

X.-Y. HUA*, P. CHEN, M. MARSALA & T.L. YAKSH Dept. of Anesthesiology, Univ. of California, San Diego, CA 92093-0818, USA.

Previous study has indicated that acticvation of spinal tachykinin NK1 receptor-induced nociception may be mediated by cyclooxygenase products¹. We have recently carried an in vivo study in the rats with intrathecal loop dialysis catheters² to correlate intrathecal substance P (SP)-induced thermal hyperalgesia with the levels of prostaglandin and glutamate in spinal fluid. Intrathecal application (i.t.) of SP 20nmol in 10µl artificial cerebral spinal fluid (ACSF) induced a significant reduction in the latency of thermal paw withdrawal response. The peak effect occurred at 10 min (Baseline: 11.8±0.8 vs. SP: 7.6±0.6 sec, n=7) and returned to baseline around 30 min. SP-induced thermal hyperalgesia was associated with an increase in the levels of prostaglandin E2 (PGE2) (342±43% of baseline, n=8) and the levels of prostaglandin E2 (PGE2) (342±43% of baseline, n=8) and glutamate (285±95% of baseline, n=7) in intrathecal space. Lt. application of same volume of ACSF produced neither hyperalgesia nor spinal PGE2/glutamate release (n=5-7). A selective NK1 receptor antagonist RP 67580 3µg (n=8) applied (i.t.) 10 min prior SP 20nmol (i.t.) completely blocked the SP-induced hyperalgesia, whereas an inactive form of the NK1 antagonist, RP 68651, at the same dose (n=8) did not cause any inhibition. RP 67780 10 to 10 67580 10µg (n=5) also blocked the SP-induced PGE2 release, but had no effect on the glutamate release evoked by SP. These results further support the hypothesis of the involvement of NK1 receptor in spinal nociceptive transmission, and provide direct evidence that activation of spinal NK1 receptor and subsequent generation of cyclooxygenase products mediates SP-

induced hyperalgesia.

HYPERALGESIA INDUCED BY PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) AND ITS RELATIONSHIP TO IMMUNOHISTOCHEMICAL LOCALIZATION IN THE MOUSE SPINAL CORD. M. Narita¹* S. L. Dun², N. J. Dun² and L. F. Tseng¹. 'Dept. of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226, ²Dept. of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699. Pituitary adenylate cyclase activating polypeptide (PACAP) is a newly discovered neuropeptide belonging to the secretin-, glucagon-, vasoactive intestinal polypeptide-family of peptides. The aim of the present study was to evaluate the distribution of PACAP-like immunoreactivity in the mouse spinal cord using an antibody against PACAP38 and to determine the behavioral profiles, particularly with respect to hyperalgesia, of PACAP38 given intrathecally (i.t.) in male ICR mouse. Immunoreactivity to PACAP38 was detected in numerous nerve fibers in the superficial layers of the dorsal horn of cervical, thoracic, lumbar and sacral segments and a few fibers extended of cervical, thoracic, lumbar and sacral segments and a few fibers extended into the deeper layers of the spinal cord. In addition, PACAP-like immunoreactivity were seen in the intermediolateral cell column of the thoracic immunoreactivity were seen in the intermediolateral cell column of the thoracic and sacral segments. In behavioral studies, PACAP (0.05 to 0.5 μg) produced a dose-dependent decrease of the tail-flick latency when given i.t. At higher doses (1 to 10 μg), PACAP38 given i.t. elicited scratching, biting and licking behaviors immediately after i.t. injection. Similar to substance P, these behaviors produced by PACAP can be considered as pain-like syndrome. I.t. pretreatment with a protein kinase A (PKA) inhibitor, KT5720, and a protein kinase C (PKC) inhibitor, calphostin C, 10 min prior to i.t.-challenge of PACAP38 dose-dependently attenuated the PACAP38-induced scratching, biting and licking behaviors. These findings suggest that PACAP may be one of the putative sensory neurotransmitter involved in nociceptive signaling in the mouse spinal cord. Furthermore, the i.t.-administered PACAP38-induced hyperalgesia is mediated by the activation of PACAP receptors, which are linked to PKA and PKC systems (Supported by NIH grant, DA 03811, NS18710 and HL51314).

Heregulin Modulates Cansaicin-evoked Release of iCGRP from

Heregulin Modulates Capsaicin-evoked Release of iCGRP from Sensory Neurons.

NO. Dybdal* Y. Ulrich+, C. Harding-Rose+, B. Huerter, K. Hagler, C.M. Flores+, M.X. Sliwkowski∞, D. Mortensen, R. Clark, K.M. Hargreaves+. Depts. of Pathobio. and ∞Pro. Chem., Genentech, Inc., S.S.F., Calif 94080 and +Dept. of Rest. Sci., Univ. of Minnesota, MPLS, MN 55455 Neuregulins are a family of alternatively spliced gene products that serve as ligands for ErbB3 and ErbB4. A number of pleiotrophic activities are now known to be attributed to this family of polypeptide growth factors. Two of these isoforms, glial growth factor (GGF) and heregulin (HRG), have been shown to be potent mitogens for Schwann cells. We have observed that chronic administration of HRG has effects on small diameter peptidergic neurons of sensory origin. In the present small diameter peptidergic neurons of sensory origin. In the present study, we evaluated whether chronic administration of rHRGB1177-2. modulated the activity of capsaicin-sensitive peptidergic neurons. Adult female Sprague Dawley rats (n=4-5/group) were implanted sc with miniosmotic pumps which provided vehicle, or heregulin at 0.1 or 1.0 mg/kg/d for 14 days. At the end of the administration period, animals mg/kg/d for I4 days. At the end of the administration period, animals were sacrificed and their trigeminal ganglia (TGG) removed. TGG were chopped into 200 μm slices and placed into superfusion chambers (4 TGG per chamber) which were pumped with oxygenated Krebs buffer. After a recovery period, the TGG were then pulsed with capsaicin (30 μM). Superfusate levels of iCGRP were measured by RIA. Capsaicin stimulation evoked a 2-3 fold increase in release of iCGRP in vehicle-treated animals. In contrast, HRG treated animals demonstrated an attenuated iCGRP release in response to capsaicin at both the 0.1 and 1.0 mg/kg/d doses. Collectively, these data indicate that HRG modulates capsaicin-sensitive pertidergic neurons. The mechanism for this effect capsaicin-sensitive peptidergic neurons. The mechanism for this effect may be either direct, e.g., reduction in peptide content or indirect, e.g., release of an inhibitory factor from Schwann cells. THE NEUROTENSIN ANTAGONIST SR48692 ALTERS PAIN MODULATION BY NEUROTENSIN IN THE RAT. <u>D.J. Smith, D.L. Smith, D. Gully and P.J. Monroe</u>. Dept. of Anesth., Robert C. Byrd HSC, Morgantown, WV 26506, & Sanofi Recherche, Toulouse Cedex, France.

Neurotensin (NT) has a dose dependent biphasic role on pain modulation following its microinjection into the rostroventral medial medulla (RVM). High doses are antinociceptive, while lower doses (< 30 pmol) are either inactive or produce hyperalgesia, but are antinociceptive in the presence of a NT receptor antagonist (JPET. 265:580, 1993). In the current study, the ability SR48692 to discriminate between these actions of NT was evaluated in awake rats chronically prepared with guide cannula over the RVM. In the presence of 30-3000 fmol of SR48692, a marked antinociceptive effect (tail flick test) was observed with an otherwise inactive (30 pmol) dose of NT. In contrast, lower doses (0.1-0.3 fmol) of SR48692 blocked antinociception produced by 10 nmol NT. The NT response returned to control levels as the dose of antagonist was increased, and was again depressed at still higher doses of antagonist. Thus, at least two NT receptors exist in the RVM: one with a high affinity for NT, a low affinity for SR48692, and which mediates a hyperalgesic response; the other has a lower affinity for NT, a higher affinity for SR48692, and is associated with antinociception. A third NT receptor may explain the effect of high antagonist doses, however, other explanations are possible. Physiologically, it appears that the antianalgesic component of NT action may be most prominent, since the activation of NT neuronal processes from the PAG to the RVM in response to systemically or PAG administered morphine is potentiated by SR48692 injected into the RVM. On the other hand, the highest dose of the antagonist continues to have diminished effectiveness.

EVIDENCE FOR ENDOGENOUS SUBSTANCE P (SP) NH2-TERMINAL

EVIDENCE FOR ENDOGENOUS SUBSTANCE I' (SF) NH₂-TERMINAL ACTIVITY IN THE FORMALIN AND WRITHING ASSAYS IN MICE. V.M. Goettl* and A.A. Larson. Graduate Program in Neuroscience, University of Minnesota, St. Paul, MN 55108 USA.

Intrathecal (i.t.) injection of SP(1-7) produces short- and long-term antinociception in the acetic acid-induced writhing assay and long-term hyperalgesia in Phase I of the formalin assay. To investigate whether antinociception in the acetic acid-induced writhing assay and long-term hyperalgesia in Phase I of the formalin assay. To investigate whether endogenous SP NH2-terminal fragments modulate nociception acutely, the effect of the SP(1-7) antagonist, D-SP(1-7), injected i.t., was examined in these two nociceptive assays. Although low doses (5-100 pmol) of SP(1-7) inhibited writhing and 1 nmol of D-SP(1-7) blocked this effect, D-SP(1-7) produced no effect on writhing when administered alone until relatively high doses (10-100 nmol). At these doses, D-SP(1-7) was antinociceptive, suggesting that endogenously SP NH2-terminal activity is pronociceptive, at a site that is relatively insensitive to D-SP(1-7). In contrast, in the formalin assay D-SP(1-7) increased Phase I responses at relatively low doses (2-1000 pmol) whereas higher doses had no effect. Endogenous SP NH2-terminal activity appears to be antinociceptive at sites that are relatively sensitive to D-SP(1-7). The U-shaped dose-response curve for D-SP(1-7) in this assay suggests possible additional hyperalgesic activity of the SP NH2-terminus at sites that are relatively insensitive to D-SP(1-7). Mixed activity of the SP NH2-terminus in the formalin assay would explain the lack of effect of acute, exogenous SP(1-7) on Phase I responses at any dose tested. Although SP NH2-terminal activity is the same in both the writhing and formalin assays, i.e. antinociceptive at D-SP(1-7)-sensitive sites, acetic acid appears to induce only pronociceptive activity endogenously whereas formalin induces both. These data are consistent with ¹³HJSP(1-7) binding studies in which 2 binding sites are described in the spinal cord. [NIDA DA07234 to VMG & DA04090 to AAL]

CALCIUM MEDIATION OF HYPERALGESIC EFFECTS OF SUBSTANCE P IN RAT SPINAL CORD. J.L. Henry, K. Yashpal, J. Reid and D.D. Samulack*, Depts. of Physiology & Psychiatry, McGill University, McGill University, Montreal, QC H3G 1Y6

Evidence from in vitro electrophysiological studies has implicated both a Ca²⁺ current and intracellular Ca²⁺ release in excitatory responses of spinal nociceptive neurones to substance P (Murase, Brain Res. 365: 369, 1986; Womack et al., Nature 334: 351, 1988). The present study determined the effects of L-type Ca2+ channel blockers and of depletion of intracellular stores of Ca²⁺ on the hyperalgesic response to intrathecal (it.) administration of substance P in the tailflick test. Male Sprague-Dawley rats (200-250 g) were implanted with chronic it. catheters to the lower lumbar spinal cord (L5-L7). Substance P (6.5 nmol) decreased the tail-flick latency to approx. 25% of baseline at 1 min after administration. This effect was followed by an overshoot of the response at 4 and 7 min. The L-type Ca2+ channel blockers verapamil (50 μ g) and diltiazem (100 μ g) blocked these effects of substance P, while the vehicle, artificial CSF, had no effect on the substance P response. Thapsigargin (2 μ g), an inhibitor of the endoplasmic reticulum Ca²⁺ ATPase, reduced the responses to substance P; DMSO, the vehicle, was without effect on this substance P response. The results implicate both a Ca²⁺ current and intracellular Ca2+ release in excitatory responses of spinal nociceptive mechanisms to substance P. Thus, the findings from the in vitro studies translate to the in vivo systems level. Supported by the Canadian MRC

OPPOSITE MODULATION OF CAPSAICIN-EVOKED SUBSTANCE P (SP) RELEASE FROM TRIGEMINAL SLICES BY SUBTYPE SELECTIVE GLUTAMATE RECEPTOR AGONISTS M.C. Cuesta*, H. Suarez-Roca, G. Cano, J.L. Arcaya, G. Gomez and W. Maixner. Inst. Investigaciones Clinicas. Univ. of Zulia; INBIOMED, Maracaibo, Apartado 1151, Venezuela and Dental Research Center, The Univ. of North Carolina, Chapel Hill, NC 27599-

We previously reported that 10 nM glutamate (GLU) inhibits capsaicinevoked SP release from trigeminal slices by a mechanism sensitive to 5 uM (±) MCPG, a selective metabotropic GLU receptor antagonist. We now report the effect of the selective GLU receptor agonists: L-CCG-IV (NMDA subtype agonist) and L-AP4, DHPG and 1S,1R-ACPD (metabotropic subtype agonists), on capsaicin-evoked SP release from trigeminal slices. L-CCG-IV (10 μ M) enhanced (323 ± 95%) capsaicin-evoked SP release. This facilitatory effect was blocked by 0.3 μ M MK-801, a selective NMDA receptor antagonist. Both L-AP4 and DHPG (1-30 uM) inhibited capsaicin-evoked SP release and showed similar efficacy and potency. ACPD (30 uM) did not alter capsaicin-evoked SP release. Thus, SP released from primary afferents may be under inhibitory and excitatory control by metabotropic and NMDA GLU receptors, respectively. (Supported by TW00305, CONDES171695 & DE07509).

PHOSPHOINOSITIDE SECOND MESSSENGER RESPONSES IN THE SPINAL CORD DURING HYPERALGESIA J.L. Fuchs, K.J. Blanton and H.D. Schwark* Dept. Biological Sciences, University of North Texas, Denton TX 76203.

The search for central changes underlying hyperalgesia has focused on neurotransmitters and their receptors. Substance P receptors (NK-1), which are concentrated in the upper laminae of the dorsal horn, increase as hyperalgesia develops (Stucky et al., 1993). However, stimulation of substance P receptors can result in their rapid internalization (Mantyh et al., 1995), presumably making them less available for neurotransmission. One approach to determining the functional implications of receptor changes is to examine the second messenger responses, such as phosphoinositide (PI) turnover initiated via NK-I receptors

To localize PI responses, we used a modification of the method developed by Hwang et al. (1990). Slices of lumbar spinal cord were taken from rats untreated or 2 days after injection of complete Freund's adjuvant in one hindpaw. Slices were submerged in oxygenated Krebs buffer and incubated with [3H]cytidine as precursor to membrane-bound [3H]CDP-DAG. In the presence of LiCl, neurotransmitter agonists for substance P or ACh (carbachol) were added to initiate PI turnover. Slices were then sectioned for film autoradiography.

Pl labeling in response to substance P was coextensive with the distribution of NK-I receptors. Pl labeling decreased in the upper dorsal horn ipsilateral to the inflamed paw (15%, p<0.03, n=6 rats), in contrast to the increased substance P binding. It is unlikely that there was a general down-regulation in PI turnover because carbachol-induced PI labeling increased ipsilaterally (29%, p<0.02, n=6). The results are compatible with a functional decrease in responsiveness to substance P in the ipsilateral dorsal horn during the development of hyperalgesia (Supported by MH41865 & IBN9221956)

NEONATAL CAPSAICIN ABOLISHES MORPHINE'S MULTIPHASIC EFFECT ON SUBSTANCE P RELEASE FROM RAT TRIGEMINAL SLICES. H. Suarez-Roca*, G. Cano, J.L. Arcaya, G. Gomez and W. Maixner. Instituto de Investigaciones Clinicas, Univ. of Zulia; INBIOMED, Maracaibo, Apartado 1151, Venezuela and Dental Research Center, The Univ. of North Carolina, Chapel Hill, NC 27599-7455.

We previously found that morphine produces a dose-dependent multiphasic effect (inhibition or facilitation) on K^+ -evoked substance P release from trigeminal slices, dissociated sensory neurons and on capsaicin-evoked substance P release from trigeminal slices. In the present study, we evaluated morphine's effect on K*-evoked substance P release from trigeminal slices of rats neonatally treated with capsaicin. Neonatal capsaicin, at 25-50 mg/kg i.p., produced depletion of trigeminal substance P, a dose-dependent prolongation of hotplate latencies, and loss in the ability of capsaicin to evoke substance P release. Both 25 and 50 mg/kg capsaicin abolished the multiphasic effect of morphine on substance P release. In contrast, in rats treated with the vehicle, 0.1 nM, 1uM and 10 uM morphine inhibited (56 \pm 6%), enhanced (133 \pm 25%) and inhibited (69 ± 9%) K+-evoked substance P release, respectively. These results further suggest that the multiphasic effect of morphine is exerted on type-C primary affectes and thus, is of relevance in the modulation of nociceptive transmission. (Supported by TW00305, CONDES171595 & DE07509).

SYSTEMIC RESINIFERATOXIN DECREASES mRNAs ENCODING SP IN LUMBAR DRGs OF THE RAT BUT NOT THE NUMBER OF SP-POSITIVE SENSORY NEURONS

A. Szallasi*, T. Farkas-Szallasi, J. B. Tucker, J. M. Lundberg, T. Hökfelt and J. E. Krause. Dept. Pharmacology and Dept. Neuroscience, Karolinska Institute, 171 77 Stockholm, Sweden; Dept. Anatomy & Neurobiology, Washington Univ. Med. Sch., St.Louis, MO 63110.

Capsaicin is believed to deplete the sensory neuropeptide substance P (SP) in the adult rat due to a combination of neuron loss and decreased synthesis in the surviving cells. In this study, the effects of resiniferatoxin (RTX), an ultrapotent capsaicin analog, were examined on the expression of SP in lumbar DRGs and the corresponding segment of the spinal cord of the adult rat. The number of DRG neurons showing an in situ hybridization client. hybridization signal for preprotachykinin mRNAs encoding SP was not altered following RTX (300 $\mu g/kg$ s.c.) treatment (up to 8 weeks), though the signal was perceptibly weaker. In accord, 2 weeks), though the signal was perceptibly weaker. In accord, 2 weeks after RTX administration a 60% decrease was observed in the steady-state levels of SP-encoding mRNAs using Northern blot analysis, leaving the ratio of β - and γ -preprotachykinin mRNAs unchanged. SP-like immunoreactivity was likewise reduced in the spinal cord of RTX-treated animals. The present findings suggest that, unlike capsaicin, RTX does not kill SP-positive neurons, though it suppresses the synthesis of SP. This reduced SP synthesis is likely to play a central role in the known analgesic as well as antiinflammatory actions of RTX (Supported by the Swedish MRC and by NIH grant NS21937)

EFFECT OF TETRODOTOXIN ON EXPERIMENTAL TACTILE ALLODYNIA IN THE RAT: ALTERATION BY NEONATAL CAPSAICIN TREATMENT. Chaplan SR*, Scott BP, Hua X-Y, Yaksh TL, Anesthesiology Research Lab, UCSD, 9500 Gilman Drive, La Jolla CA 92107-0818

Spontaneous activity in the peripheral nervous system, attributed to alterations in Na+ channel distribution, density and function, has been hypothesized as a basis for persistent anomalous pain states after nerve injury. Functionally differing Na+ channels may be predominantly associated with specific fiber types and with the regenerating state. We have used a model of allodynia, as paw withdrawal thresholds (PWT) to von Frey filaments, generated by tight nerve ligation (Kim and Chung 1992) to investigate the effects of treatments affecting Na+ channel function. Expt 1: IV tetrodotoxin (TTX) 30 µg/kg (maximum sublethal dose) had a small but statistically significant effect on PWT compared to saline (15.9 ± 5% maximum possible effect, MPE). Lumbar intrathecal TTX in the maximum dose not causing motor flaccidity had no effect. Expt 2: Rats were neonatally treated with capsaicin, 50 mg/kg, SQ, or vehicle, and underwent nerve ligation at appropriate body weight. Resulting PWT were significantly increased in capsaicin-treated rats (70.9 ± 19% MPE). No diminution of previously described lidocaine effect was seen due to capsaicin treatment (74.5 ± 16% MPE). CGRP and substance P levels were significantly lower in lumbar dorsal spinal cords of capsaicin-treated arts (P<.05) by RIA. We conclude that capsaicin treatment results in increased suppression of allodynia by TTX, presumably by a mechanism affecting the population of Na+ channels present, without altering effects of systemic lidocaine. (Support: NIH NS 017691)

CAPSAICIN (CAP) BINDS TO THE INTRACELLULAR SURFACE OF CAPSAICIN-ACTIVATED ION CHANNEL UOh, SW Hwang, JY Kwak, and J Yang Seoul National University, College of Pharmacy, Kwanak-Gu, Seoul 151-742, Korea and Dong-A Central Research Institute, Seoul, Korea.

CAP activates sensory neurons by increasing ion conductances. Recently, we identified a CAP-activated ion channel. The channel was gated and blocked by CAP and capsazepine (CZP), a competitive antagonist of CAP receptor. Although kinetic properties of the channel have been characterized, location of the binding site of CAP to the channel complex was not yet known. Because CAP is a lipophilic substance, this lipophilicity of CAP raise a question whether specific binding site of CAP is located in the extracellular face of the channel complex. The present study was thus directed to identify the location of the binding site of CAP to the CAP receptor or channel. Extracellular application of CAP activated single-channel currents in cultured DRG neurons. This activation by extracellular CAP was blocked by CZP applied to the intracellular surface of patch membrane. CAP applied to the bath (intracellular side) in inside-out patches also activated single-channel current greatly The activation of the channel by intracellular CAP was blocked by co-application of CZP. These results indicate that biding sites of CAP or CZP are located in the intracellular surface of the cell membrane. Since CAP and CZP are highly solub lipid, these results are not conclusive. We, thus further studied the location of CAP-binding sites by using a soluble form of CAP analogue, DA-5018•HCl (DA). DA greatly activated the ion channel when applied to the intracellular surface of insideout patches. The activation of the channel by intracellular DA was blocked by CZP. In contrast, DA in the pipette (extracellular side) failed to activate the single-channel currents in inside-out patches. In the same patches, application of DA to the bath (intracellular side) greatly activated single-channel currents. These results thus clearly indicate that ligands bind to the intracellular structures of CAP-receptor or channel. Supported by RCNDD-KOSEF and Genetic Engineering Grant of Korea.

DIFFERENTIAL ACTIVATION AND DESENSITIZATION OF SENSORY NEURONS BY RESINIFERATOXIN Acs. G., Biro, T., Acs. P. and Blumberg, P. M.*, Molecular Mechanism of Tumor Promotion Section, LCCTP, NCI, NIH, Bethesda, MD 20892

The ability of capsaicin to deactivate primary sensory neurons, a phenomenon termed desensitization, provides a basis for the use of vanilloids as analgesics. Recently, using art dorsal root ganglion (DRG) neurons we have been able to dissociate the binding affinities of vanilloids from their potencies to induce "Ca uptake into the cells, suggesting the existence of distinct classes of receptors (Acs, G. et al, Mol Brain Res, 55, 173-182, 1996). Further support for this conclusion is that vanilloids bind to DRG neurons with positive cooperativity but induce "Ca uptake in a noncooperative manner. In the present study, we have demonstrated that the ultrapotent capsaicin analog resiniferatoxin (RTX) is able to desensitize the rat DRG neurons to the subsequent induction of "Ca uptake by capsaicin. The ED $_{50}$ for desensitization, $80\pm10\,\mathrm{pM}$ (mean $\pm\,\mathrm{SEM})$, was similar to that for [PH]RTX binding (48 $\pm\,3.5\,\mathrm{pM}$) and contrasted with the 10-fold higher RTX concentration required for induction of "Ca uptake. Furthermore, RTX desensitized the cells in a positive cooperative fashion with Hill coefficient 1.51 $\pm\,0.11$ (mean $\pm\,\mathrm{SEM})$. At 100 pM RTX, the half-time for desensitization was approximately 1 hour. The effect of RTX pretreatment could not be attributed to receptor down-regulation, since receptor density remained constant over this time period. We conclude that the "Ca uptake induction and the desensitizing effects of vanilloids are mediated by distinct sublasses of vanilloid receptors with distinct pharmacology. Optimization of ligands for the receptor coupled to desensitization provides a promising strategy for design of novel vanilloids for human therapy.

EVIDENCE THAT ENDOGENOUS CAPSAICIN-LIKE SUBSTANCE IS INVOLVED IN GENERATING INFLAMMATORY PAIN. Ju Young Jung, Ji Yeon Kwak, Young-Shin Park, Kwang-Jin Kim, Uhtaek Oh, Seoul National University, College of Pharmacy, Kwanak-Gu, Seoul 151, Korea.

Capsaicin (ČAP) plays an important role in pain transmission. CAP receptors in sensory neurons were largely predicted by the presence of CAPspecific agonists and antagonists or high-affinity binding sites found in sensory neurons. Recently, we characterized a non-selective cation channel activated by CAP and its analogs. The presence of CAP-activated channel further implies the existence of CAP-like substance endogenous to the periphery. This study was, therefore, directed to test whether endogenous CAP-like substance played a role in pain transmission during inflammation. To test this, we hypothesized that Fos immunoreactivity as a marker for nociceptive neural signals induced by inflammation would be reduced by pretreatment of capsazepine (CZP), a CAP receptor antagonist. Carrageenan (CAR, 6 mg, 150 µl) injected to the rat hind paws intradermally induced Fos-like immunoreactivity (Fos-LI) in the dorsal horn of the lumbar spinal cord. CZP (25 mM, 150 µl) pretreatment, however, reduced the Fos-LI in the spinal cord induced by CAR. Intradermal injection of CAR together with CZP showed 29 ± 3 (n=13) Fos-LI per section of the ipsilateral spinal cord while injection of CAR and vehicle to the contralateral hind paw showed 66 ± 17 Fos-LI per section of the spinal cord. The reduction by CZP of CAR-induced Fos-LI was dose dependent. Intradermal pretreatment of CZP in 1, 5, 10, and 25 mM showed -11 ± 8, 30 ± 5, 46 ± 8, and 56 ± 4% reduction, respectively, in Fos-Li when compared to the vehicle pretreatment. CZP pretreatment also exhibited a significant increase in paw-withdrawal latency, showing a significant analegsic effect. These results thus suggests that capsaicin-like substance plays a role in producing nociceptive signals in the inflamed tissue. Supported by KOSEF-RCNDD of Korea.

RESPONSES OF THE NON- (OR LESS)- PUNGENT CAPSAICIN ANALOGUE, OLVANIL, ON RAT TRIGEMINAL GANGLION NEURONS L. Liu and S.A. Simon*. Departments of Neurobiology and Anesthesiology, Duke University Medical Center, Durham, NC 27710.

Capsaicin, the pungent ingredient in chili pepper that activates polymodal nociceptors is used clinically as an antinociceptive and anti-inflammatory compound. One clinical disadvantage of using capsaicin is that its initial application produces marked pain. Various capsaicin analogues were synthesized with the goal of finding one that will reduce the initial pain. Olvanil (N-(3-methyoxy-4-hydroxybenzyl)oleamide is the best studied less-pungent capsaicin analogue. Olvanil was mostly characterized behaviorally and using whole nerve DRGs recordings but the reasons for its lower pungency were not elucidated. To address this question we performed whole cell patch-clamp studies on rat trigeminal neurons. We previously showed (J. Neurophysiol. 75: 1503 1996) that capsaicin activates a variety of currents that can activate with a time to peak (tp) of about 4 s and also more slowly with tp's to 40 s. In neurons held at -60 mV, 1 μ M olvanil also activated a variety of kinetically distinct currents, but unlike for capsaicin the majority of these were the slowly-activating type. As with capsaicin, the olvanil-activated currents were reversibly inhibited by $10\,\mu$ M capsazepine and had an apparent dissociation constant of = 0.7 μ M. Olvanil induced tachyphylaxis to a significantly larger extent than 1 μ M capsaicin. That is, after three 30 s applications followed by 2.5 min washes the peak current was inhibited about 40% and 90% for capsaicin and olvanil, respectively. We speculate that the lower pungency of olvanil arises because of its slower activation kinetics which gives it more time to inhibit voltage-dependent ion channels while only slowly activating vanilloid receptors. This work was supported in part by NIH grant DC-01065.

5-HT, RECEPTOR ANTAGONIST, ONDANSETRON, FAILED TO BLOCK ANTERIOR PRETECTAL NUCLEUS INDUCED ANTINOCICEPTION IN RATS P.S. Chen*, H. Rees, and W.D. Willis, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, Texas, 77555-1069, U.S.A.

We have shown in previous experiments that APtN activates noradrenergic bulbospinal neurons that modulate the flow of nociceptive information at the level of the spinal cord. This is supported by the fact that microdialysis administration of alpha-2 noradrenergic receptor antagonists reversed APtN-evoked antinociception as shown by paw withdrawl latency to a radiant heat source and dorsal horn cell responses to cutaneous stimulation. The purpose of this study was to determine the importance of 5-HT, receptors in anterior pretectal nucleus (APth) evoked antinociception by administering a specific 5-HT₃ receptor antagonist, Ondansetron, through a microdialysis fiber placed in the spinal dorsal horn of rats. Electrophysiological recordings were used to measure changes in dorsal horn cell responses to brushing, pressing and pinching the peripheral receptive field. Male Sprague-Dawley rats (270-350g) were used for this study. APtN stimulation was achieved using a 333 Hz DC current through a monopolar stimulating electrode. Extracellular recordings of dorsal horn cell responses to brush, press and pinch stimuli were used to measure changes of cell responses during APtN-evoked antinociception during microdialysis administration of artificial CSF, 0.1 mM, 1.0 mM and 5.0 mM Ondansetron. Responses of dorsal horn cells to cutaneous brush, press and pinch stimuli were inhibited by electrical stimulation of APtN. 5-HT, receptor antagonist, Ondansetron, did not block the APtN-evoked antinociception at any dosage. The baseline responses remained unaffected by Ondansetron as compared with ACSF control responses. The role of 5-HT₃ receptors in spinal dorsal horn to APtN-evoked antinociception remains unclear. A second 5-HT₃ receptor specific antagonist needs to be tested to further elucidate the possible role of 5-HT, receptors. 5-HT_{1B} AGONIST ANALGESIA IN GENETIC MOUSE MODELS OF OPIATE ANALGESIC MAGNITUDE. H.S. Hain, J.S. Mogil, D.J. Feller*, R. Hen, and J.K. Belknap. Dept. Of Behavioral Neuroscience, Oregon Health Sciences University, Portland, OR 97201 and Center for Neurobiology and Behavior, Columbia University, New York, NY 10032.

A quantitative trait locus for morphine analgesic magnitude was mapped to chromosome 9 near the Htr/b gene which encodes the 5-HT_{1B} receptor $(5-HT_{1B}R)$, suggesting that it may play a role in sensitivity to opiate analgesia. To examine this hypothesis. $5-HT_{1B}$ agonists were administered to genetic mouse models differing in opiate analgesic sensitivity: DBA/2J (D2) vs. C57BL/6J (B6), HAR vs. LAR, HA vs. LA, and *Htr1b* gene knockout (KO) mice vs. their wild-type (WT) littermates. Nociceptive sensitivity was assessed using the 49°C tail-withdrawal (TW) test, before and 20, 50, 120, and 240 min after drug injection. The putative 5-HT_{1B} agonist, CGS-12066A (i.p.; 0-75 mg/kg), was administered. Mice exhibiting high and low opiate (morphine) analgesic sensitivity also exhibited high or low CGS-12066A analgesic sensitivity, respectively. The opposite pattern was observed in the KO vs WT mice suggesting that CGS-12066A may be producing its effects through the 5-HT_{1A} receptor in the KO mice. Anpirtoline, another 5-HT_{1B} agonist (i.p., 0-40 mg/kg), produced effects in the expected direction. These results further support a role for the 5-HT_{1B}R in sensitivity to opiate analgesia. The data also question CGS-12066A's specificity as an agonist at the 5-HT_{1B}R. Supported by an NIDA training grant (HSH). a NRSA post-doctoral fellowship (JSM), and a VA Merit Review (JKB).

OPIATE SUPRASPINAL ANALGESIC SYNERGY BETWEEN THE AMYGDALA AND PERIAQUEDUCTAL GRAY IN RATS. Z.W. Pavlovic* and R.J. Bodnar. Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Functional supraspinal analgesic interactions have been demonstrated between the periaqueductal gray (PAG) and rostroventromedial medulla using both antagonist and synergy studies. Microinjections of opiates and opioids into the amygdala elicit analgesia which is blocked by microinjection of general and delta₂ opioid antagonists into the PAG. The present study examined whether sub-threshold or near-threshold doses of morphine administered into the amygdala and PAG produced an analgesic synergistic interaction on the tail-flick and jump tests in rats. Morphine (1-5 ug) microinjections into either the amygdala alone or PAG alone dose-dependently increased nociceptive latencies and thresholds. Simultaneous administration of morphine into the amygdala (1 ug) and PAG (1 ug) produced profound analgesia on the jump, but not tail-flick tests that was significantly greater than analgesia elicited from either the PAG alone (1 or 2 ug) or amygdala (1 or 2 ug) alone. Analgesic interactions were significantly greater following a PAG morphine dose of 1 ug and amygdala morphine doses of 50 or 250 ng than following a PAG morphine dose of 250 ng and an amygdala morphine dose of 1 ug. These data are consistent with a direct role of the PAG in inhibiting nociceptive input, and demonstrate primarily a modulatory role for the amygdala in descending supraspinal brainstem paininhibition. DIFFERENTIAL CONTRIBUTIONS OF SPINAL, MEDULLARY, THALAMIC AND AMYGDALOID SEROTONIN TO THE ANTINOCICEPTIVE ACTION OF MORPHINE ADMINISTERED INTO THE PERIAQUEDUCTAL GRAY. $\underline{G.~S.}$ Borszcz*, C. P. Johnson, M. V. Thorp and D. H. Williams. Department of Psychology, Dartmouth College, Hanover, N.H. 03755.

Increases in the thresholds of spinal motor reflexes (SMRs), vocalizations during shock (VDSs), and vocalization afterdischarges (VADs) generated by the injection of morphine into the ventrolateral periaqueductal gray (vPAG) were challenged by the administration of the serotonin receptor antagonist methysergide. Responses were generated by applying graded electric current to the tail. Methysergide was injected either intrathecally (IT) or into the rostral ventromedial medulla (RVM), amygdaloid central nucleus (ACe), or nucleus parafascicularis thalami (nPf).

The minimum effective doses of vPAG administered morphine that elevated VAD,

VDS and SMR thresholds were 1µg, 2.5µg and 5µg, respectively (BNS, 1995, 109, 502). Antagonism of morphine-induced threshold increases was found to depend on: 1) the dose of morphine (1µg - 10µg) administered into the vPAG, 2) the response being assessed, and 3) the site at which methysergide (2.5µg - 40µg) was injected. being assessed, and 3 tites the a winter interpretage to 2.5 gr -4.0 gr, was injected. Increases in SMR thresholds generated by 5µg and 10µg morphine were antagonized by administration of methysergide either IT or into RVM. Increases in VAD and VDS thresholds generated by 10µg morphine were partially antagonized by IT methysergide. Increases in VDS thresholds generated by 2.5 µg and 5µg morphine were antagonized by administration of methysergide into either RVM, ACe or nPf. Increases in VAD thresholds generated by 5µg morphine were partially antagonized by methysergide administered into RVM. Increases in VAD thresholds generated by $\mu_{\rm S}$, 2.5µg and 5µg morphine were antagonized by administration of methysergide into ACe and nPf.

As these pain-elicited behaviors are organized at different levels of the neuraxis the results reveal vPAG morphine-induced, serotonin-mediated antinociception at spinal (SMRs), medullary (VDSs), and forebrain (VADs) levels.

ALTERATIONS IN SWIM STRESS-INDUCED ANALGESIA FOLLOWING SEROTONERGIC ANTAGONISM IN THE ROSTROVENTROMEDIAL MEDULLA OF RATS. E. Hopkins, M. Spinella, Z.W. Pavlovic and R.J. Bodnar*. Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Microinjections of general, 5HT2 or 5HT3 serotonergic antagonists into the rostroventromedial medulla (RVM) significantly decreases morphine analgesia elicited from the periaqueductal gray without altering basal nociceptive thresholds. Analgesia elicited by continuous coldwater swims (CCWS, 2°C, 3 min) is mediated by spinal delta2 opioid receptors and supraspinal 5HT2 receptors, while analgesia elicited by intermittent cold-water swims (ICWS, 18 10 s swims and recoveries) is mediated by supraspinal mu opioid receptors and spinal 5HT, receptors. The present study examined whether microinjection of the general serotonergic antagonist, methysergide (5-10 ug) into the RVM altered CCWS and ICWS analgesia on the tail-flick and jump tests in rats. CCWS produced analgesia on the tail-flick (30-60 min) and jump (30-120 min) tests which was significantly and dose-dependently enhanced for both peak (tail-flick: 41%; jump: 43%) and total (tail-flick: 72%; jump: 21%) effects by RVM microinjections of methysergide. In contrast, ICWS analgesia on the tail-flick (30-120 min) and jump (30-120 min) tests was minimally reduced by RVM microinjections of methysergide. Thus, medullary serotonergic mechanisms differentially modulate pharmacologically-distinct analgesic responses possibly through collateral inhibition. (Supported by PSC-CUNY Grants 666237 & 667248)

 \mbox{ALPHa}_2 ADRENERGIC TONIC CONTROL IN RATS WITH CARRAGEENAN-INDUCED HYPERALGESIA. SPON: Brain Research Association.

Juan F. Herrero & Fernando Cervero. Dept. de Fisiología y Farmacología. Universidad de Alcalá de Henares, 28871 Madrid, Spain

Involvement of α_2 adrenergic systems in the processing of nociception is well documented. It is not clear whether an endogenous tonic α_2 adrenergic control is active in animals with an intact central nervous system. We have studied this possibility in normal and hyperalgesic conditions.

Single motor units (SMU) were recorded from hind limb muscles of male

Single motor units (SMU) were recorded from hind limb muscles of male Wistar rats (300-450g) under α-chloralose anaesthesia. Three groups were compared: i) control, ii) carrageenan-inflammation (intraplantar) and iii) carrageenan monoarthritis (knee joint). Thermal and electrical stimulation (wind-up) was applied to the peripheral receptive field of the SMUs in 3.5min cycles. The α₂ adrenoceptor antagonist Idazoxan was injected iv in cumulative doses from 20 to 320μg/kg. The μ opioid fentanyl (2 to 16/32μg/kg) was also tested before and after Idazoxan. In control animals, responses to either heat or electrical stimulation remained unchanged after the administration of Idazoxan. In animals treated with carrageenan, however, a dose-dependent increase of the activity evoked by heat was seen, with a maximum effect of 38±9.2% (ρ<0.01). The enhancement was significant respect to the results obtained in the control group (p<0.01) but there was no difference between the 2

in the control group (p<0.01) but there was no difference between the 2 groups of animals with carrageenan. Also in these animals, the antinociceptive effectiveness of fentanyl was reduced by 2.5 fold after the injection of Idazoxan.

We conclude that in anaesthetised animals with an intact central nervous system, an endogenous control involving α_2 -adrenergic systems is activated by carrageenan-induced hyperalgesia. Since the potency of fentanyl is also modified, the control may involve endogenous opioids. (Supported by DGICYT PB-93-0491)

SYMPATHETIC EXCITATION OF SENSORY NEURONS INDUCED IN THE DRG BY PERIPHERAL NERVE INJURY IS MEDIATED BY ALPHA-2 ADRENOCEPTORS. J.W. Leem*, E.J. Choi, Y.S. Gwak, T.S. Nam and K.S. Paik. Dept. of Physiology, Yonsei Univ. Col. Med., Seoul, 120-752, Korea.

The aim of this study is to determine which subtype of adrenoceptor is involved in sympathetically elicited excitation of sensory neurons induced after spinal nerve ligation.

Rats that received a unilateral ligation of L5-L6 spinal nerves 10-15 days previously were used. Under anesthesia, dorsal roots with ligated spinal nerves were cut near the root entry zone, and recording was made from afferents in microfilaments teased from the distal cut end of dorsal roots. Sympathetic excitation of the recorded afferents was elicited by stimulating T13 and L1 ventral roots.

All afferents that responded to stimulation of ligated spinal nerve produced spontaneous discharges. About one-fourth of active afferents responded with increased discharges to sympathetic stimulation. This sympathetically evoked afferent excitation was mimicked by clonidine, blocked by yohimbine (not by prazosine nor by propranolol), and was not affected by conduction block between the DRG and ligated site.

The results suggest that after spinal nerve ligation, sympathetic postganglionic fibers sprout in the DRG where adrenaline released from sympathetic endings excites sensory neurons by acting on alpha-2 adrenoceptors. (Supported by KOSEF 961-0701-008-2)

ANALGESIC EFFECT OF OXOTREMORINE ON BRIEF REFLEXIVE AND PERSISTENT NOCICEPTIVE MODELS. F. Pavone*, F. Capone°, A.M. Aloisi^, D. Pullia. Inst. of Psychobiology & Psychopharmacology, Via Reno 1, 00198 Roma, Italy; "Dept. Genetics & Molecular Biology, , "La Sapienza" University, Roma, Italy, Inst. Human Physiology, University of Siena, Siena, Italy. The neural pathways involved in the modulation and transmission of noxious

The neural pathways involved in the modulation and transmission of noxious stimuli, as well as the effects of drugs on nociception seem to be different depending on the nature of the stimulus and its duration. The aim of this study was to investigate the effects induced by the muscarinic cholinergic agonist oxotremorine on the response to a long-lasting painful stimulus induced by formalin in comparison with the well known antinociceptive properties of this drug observed after a brief thermal stimulus measured in the tail-flick test. The modulation of the effects of coxtremorine by morphine was successively assessed in both tests. Different groups of CD1 mice were used. For the formalin test mice were injected with saline solution or oxotremorine (from 0.01 to 0.05 mg/kg i.p.) fifteen minutes before they received a subcutaneous injection in the dorsal part of the right hind paw of a diluted solution of formalin (5%) or a sham injection. The time spent in licking of the injected paw was measured for 30 minutes following injection. Oxotremorine induced a dose and time dependent analgesic effect on both early and late phases. A simultaneous injection of 1 mg/kg of morphine with 0.03 mg/kg of oxotremorine, doses not effective by themselves in this test, significantly reduced the time of licking. An interaction of morphine with the effects of cholinergic stimulation was also observed in the acute pain induced by thermal stimulus in the tail-flick test. Oxotremorine (0.005 and 0.01 mg/kg) in combination with morphine (2.5 mg/kg) induced a clearcut and long lasting analgesic effect in mice in comparison with mice injected with these drugs alone. These results suggest that oxotremorine is able to modulate both phasic and tonic pain and that this action is at least in part modulated by the opioid system.

PRIMARY AFFERENT INHIBITION OF SPINAL LAMINAE I AND II NEURONS, J. Bao, J. Li* and E. R. Perl, Department of Physiology, CB# 7545, Univ. North Carolina, Chapel Hill, NC 27599.

Primary afferent activation produces inhibitory effects on some neurons of the superficial spinal dorsal horn (Laminae I and II). To obtain evidence on synaptic mediators of such inhibition, we prepared transverse spinal cord slices with dorsal rootlets (DR) attached from deeplyanesthetized hamsters. The slices were maintained in vitro by superfusion with an artificial cerebral spinal fluid, equilibrated with O2/CO2, to which agents were added. In tight-seal, whole cell voltage- clamp recordings at a holding potential of -60 mV, 30 of 78 neurons from Laminae I and II exhibited mixed fast inward and outward evoked currents differentially related to DR stimulation intensity; a rare neuron mainly showed an outward current. Bicuculline (10µM), an established GABAA channel antagonist had no effect on either outward currents or on overall DRevoked responses in neurons recorded within Lamina II. In contrast, the glycine action blocker, strychnine (10µM), consistently eliminated outward current components and enlarged the fast inward currents evoked by DR stimuli from neurons within Lamina II. In some Laminae I-II_o cells, DR-evoked outward currents were partially suppressed by both bicuculline and strychnine. We conclude that DR-evoked inhibitory actions in Lamina II are principally mediated by glycine whereas for some Laminae I-II. neurons both glycine and GABAA channels are involved. Supported by grant NS-10321 from the NINDS.

EFFECTS OF YOHIMBINE ON NALOXONE-INDUCED ANTINOCICEPTION IN A RAT MODEL OF UNILATERAL INFLAMMATION. M. Tsuruoka* and W.D. Willis, Marine Biomedical Institute, UTMB, 301 University Blvd, Galveston, TX 77555-1069

In order to explain the analgesic effects induced by low doses of opiate-antagonist naloxone, the existence of autoreceptors for some endogenous opioid peptides has been proposed. The present study addresses the involvement of noradrenergic mechanisms in producing naloxone-induced antinociception in a rat model of inflammatory hyperalgesia.

Male Sprague-Dawley rats were divided into the following two groups: 1) rats receiving an administration of the α 2-adrenoceptor antagonist yohimbine (3 mg/kg, ip.) prior to naloxone injection and 2) rats receiving the administration of saline. In each group, rats had a single s.c injection of carrageenan (6 mg in 0.15 saline), and effects of a low dose of naloxone (5 mg/kg, ip.) on thermal nociception were examined for 28 days following the induction of unilateral hindpaw inflammation. The analgesic effect was assessed by the prolongation of the paw withdrawal latency (PWL) to noxious thermal stimult.

In rats receiving the administration of saline prior to naloxone injection, the low dose of naloxone significantly prolonged PWL in both the inflamed and the non-inflamed paws 4 h and 7 days after carrageenan. In rats receiving the administration of yohimbine, the low dose of naloxone failed to induce prolongation of PWLs 4 h after carrageenan, whereas naloxone produced analgesia 7 days after carrageenan. At 28 days, in both groups of rats, the low dose of naloxone induced hyperalgesia in the inflamed paw but not in the non-inflamed paw. The result supports our previous finding that the locus coeruleus is involved in naloxone-induced antinociception during the acute phase of inflammation. EFFECT OF CHRONIC INTRATHECAL ADMINISTERED GLYCINE ON NERVE INJURY-INDUCED NEUROPATHIC DISORDER. W. Huang and R. K. Simpson*. Dept of Neurosurgery, Baylor Col. of Med., TX., 77030.

We studied the effects of chronic intrathecal administered glycine on the mechanical and thermal hyperalgesia, and neuropathic gait and posture following unilateral ligation of the sciatic nerve in rats. Glycine or saline was intrathecally administered to low lumbar region immediately after the nerve lesion, by an osmotic pump (Alzet model 2002) 0.5 µL per nour for 14 days. The rats which were treated with saline (0.9%, pH7.4) displayed typical ipsilateral mechanical and thermal hyperalgesia with a typical neuropathic gait and posture from day 3 to 16. The rats with intrathecal glycine (0.1, 0.2 µg / 0.5 µL, pH7.4) displayed a significant reduction in mechanical hyperalgesia on injuried paw through day 3 to 12, as compared to the animals with intrathecal saline (n = 9, p < 0.05), and became normal sensation to mechanical stimuli on day 16 (2 days after absence of glycine administration, n = 9, p < 0.05). About 50% of these rats showed an abnormal gait and posture on the injuried paw on day 6 and became recovered on day 9 to 12. By the day 16, 90% of them regained their normal gait and posture, which were significantly different than animals treated with saline (n = 9, p < 0.05). The animals in the same group showed typical ipsilateral thermal hyperalgesia from day 3 to 16, similar to animals treated with saline (n = 9, p > 0.05). The result supports the hypothesis that spinal glycinergic activity prevents development of the mechanical hyperalgesia as well as accompanied neuropathic changes on gait and posture, but not thermal hyperalgesia. This study also suggests that the loss of spinal glycinergic receptors or neurotransmission may be the underlying mechanism of nerve compression-induced neuropathic disorder. The study is supported by Medtronic Inc.

EFFECTS OF L-PHENYL-ISOPROPYL ADENOSINE ON RATS SENSITIZED BY MUSTARD OIL. T. Sumida, M.A. Smith, Y. Maehara, J.G. Collins, and L.M. Kitahata*. Dept. of Anesthesiology, Yale Univ. School of medicine, New Haven, CT 06510

Recent studies suggest that spinally located adenosine receptors may be involved in pain signalling pathways within the spinal cord. This study was carried out to assess the spinal effects of the adenosine receptor agonist L-phenyl-isopropyl adenosine (L-PIA) on dorsal horn nociceptive neurons in rats sensitized by mustard oil.

This protocol was approved by our institutional Animal Care and Use Committee. Male Sprague-Dawley rats (340-420g) were anesthetized with halothane (2.0-3.0% during surgery, 0.75-1.0% during measurement) and paralized with pancuronium bromide (0.5mg/kg/h, i.v.). Extracellular activity from spinal wide dynamic range (WDR) neurons was recorded through a tungsten microelectrode. Evoked responses to noxious radiant heat stimuli (51°C, 8sec) were recorded as impulses per second at 5 minute intervals. After baseline measurements, mustard oil (N-allyl isothiocyanate, 5% in mineral oil) was applied topically to an area 10-20 mm above the ipsilateral ankle joint (i.e., outside the receptive field). 30 minutes after the application of mustard oil, L-PIA was administered intrathecally at doses of 0.625nmol, 2.5nmol, 10.0nmol, and 50.0nmol in 50µl saline. As a control, 50µl saline alone was also administered intrathecally.

Mustard oil produced a long-lasting sensitization of spinal WDR neurons. L-PIA (0.625nmol, 2.5nmol, 10.0nmol, and 50.0nmol) caused 48.5+/-10.79%, 64.6-/-14.09%, 75.7+/-13.59%, and 84.1+/-7.2% suppression of evoked activity, respectively (Mean+/-SEM: p<0.05 compared to saline control). This finding suggests that further studies concerning the involvement of adenosine receptors in pain modulation at the spinal level is indicated. (Supported by NIH grant NS-09871)

L-PHENYLISOPROPYL-ADENOSINE MEDIATED SUPPRESSION OF SPINAL NOCICEPTIVE NEURONS RESPONDING TO VISCERAL PAIN: ANTAGONISM BY 8-PHENYLTHEOPHYLLINE. Y.Maehara*, M.A.Smith, T.Sumida, J.G. Collins, L.M. Kitahata, Department of Anesthesiology, Yale University School of Medicine, New Haven, CT 06510.

We have previously demonstrated that the A₁ adenosine receptor agonist Lphenylisopropyl adenosine (L-PIA) mediates dose dependent supression of spinal dorsal horn nociceptive neurons (DHNN) responding to noxious visceral stimulation in rats. This study was designed to investigate the ability of the adenosine receptor antagonist 8phenyltheophylline (8-PT) to attenuate this action of L-PIA on DHNN.

This protocol was approved by our institutional Animal Care and Use Committee. Twenty three male Sprague-Dawley rats were laminectomized from T12 to L1 vertebral levels for extracellular recording of lumbar spinal dorsal hom activity under pentobarbital anesthesia. After baseline evoked activities (ips) to CRD were recorded, 10nmol of 8-PT or saline in a volume of 50µl was administered intrathecally. 2.5 nmol L-PIA (50µl volume) was administered 15 min following 8-PT application. Evoked neuronal activities to CRD were recorded every 5 min thereafter for 60 min. All evoked activities were converted to percent change of baseline value.

Intrathecal application of 8-PT alone caused a 16.5% increase of in the mean evoked

Intrathecal application of 8-PT alone caused a 16.5% increase of in the mean evoked activity of DHNN for the 5-60 min recording period. The mean suppression of evoked activity of DHNN between 45 and 60 min after i.t. application of 2.5 mmol L-PIA in the absence of 8-PT was 39.8%; in the prescence of 8-PT, the mean suppression by i.t. 2.5 mmol L-PIA during the same time period was only 10.4%.

This study demonstrates that 1) endogenous adenosine may tonically modulate activity of DHNN, and 2) suppression of spinal DHNN responding to noxious visceral stimulation by i.t. L-PIA is antagonized by the adenosine receptor antagonist 8-PT. (Supported by NIH grant NS-09871.)

SIGNIFICANCE OF OPIOID AND HISTAMINERGIC MECHANISMS IN SKF92374-INDUCED ANTINOCICEPTION, B.Y. Li*, J.W. Nalwalk, and L.B. Hough, Dept. Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208.

A recent study showed that SKF92374, a structural analog of the H_2 antagonist cimetidine, induces hot plate- and tail flick- antinociception after intraventricular (ivt) injection in the rat (Li et al., JPET 276:500, 1996). This compound lacked significant activity on H_1 or H_2 receptors, and had only weak activity (Kd = 5.2 μ M) on H_3 receptors. To test the hypothesis that SKF92374-induced analgesia is mediated by an action on H_3 receptors, the effects of the H_3 agonist $R\text{-}\alpha\text{-}methylhistamine}$ (RAMH) and the H_3 antagonist thioperamide (both given by ivt administration) were investigated on SKF92374 antinociception in rats. Male Sprague-Dawley rats chronically implanted with lateral ventricular cannulas were maintained in a reversed light cycle (lights on 1900 - 0700) and tested by hot plate (52° C) and tail flick nociceptive tests. Animals were tested for baseline responses, received ivt injections (5 μ l), and were re-tested 5, 10 and 30 min later. On both hot plate and tail flick tests, SKF92374-induced antinociception was slightly enhanced by thioperamide (30 μ g). But was unaffected by a range of doses of RAMH (up to 2 μ g). Furthermore, SKF92374-induced analgesia (10 min) was not reduced by large doses of systemically-administered antagonists (30 min pre-treatments) of $H_1,\ H_2$, or opiate receptors (pyrilamine: 10 mg/kg, i.p.; zolantidine: 20 mg/kg, s.c.; GT-2016: 30 mg/kg, i.p.; naltrexone: 5 mg/kg, i.p., respectively). These findings show that the novel agent SKF92374 induces antinociception by a non-opiate analgesic mechanism that does not utilize $H_1,\ H_2$ or H_3 receptors.

STIMULUS PROPERTIES AND ANTINOCICEPTIVE EFFECTS OF CANNABINOIDS IN MODELS OF INFLAMMATORY NOCICEPTION IN RATS. J.T. Roach^{1*}, S.L. Broom¹, S.M. Graham², M.A. EISohly^{3,5}, A.B. Jones^{3,5}, S.A. Ross^{4,5} and K.J. Sufka^{1,2}. Depts of Psychol.¹, Pharmacol.², Pharmaceutics³, Pharmacognosy⁴, Res. Inst of Pharmaceutical Sci.⁵, University of Mississippi, Oxford, MS 38677. Research has documented the role of cannabinoids in the mediation of

Research has documented the role of cannabinoids in the mediation of inflammatory nociception and has suggested that Δ -9-THC possesses therapeutic potential against chronic inflammatory pain. The present study examined the antinociceptive and reinforcing properties of low-potency marijuana (2.5% Δ -9-THC/cigarette; smoke delivered over a 10 min interval; ADL/II Smoking System) in models of inflammatory nociception. Exposure to 1 cigarette produced antinociception on both early (0-5 min) and late (30-50 min) phases of the formalin response (50 μ) of 2.5% formalin). Marijuana-treated rats displayed significantly fewer nociceptive behaviors compared to no-smoke controls (both formalin phases) and compared to placebo (< .01% Δ -9-THC) controls (late phase only). In the conditioned place preference paradigm incorporating the Freund's adjuvant (100 μ I, ipl) model of chronic inflammatory pain, multiple exposures to low-potency marijuana cigarettes did not produce significant reinforcing or aversive effects in either inflamed or non-inflamed rats. Comparison of preference scores for marijuana-treated rats across inflammation treatment conditions indicates a modest negative reinforcing effect (analgesia) in inflamed rats. Taken together, these data suggest that low doses of THC may offer therapeutic effects against inflammatory pain while possessing little addiction liability.

THERMAL NOCICEPTION IS ATTENUATED BY NICOTINIC AGONISTS IN TWO MODELS OF PERIPHERAL INFLAMMATION IN THE RAT. <u>S. Kilo*</u>, <u>K.M. Hargreaves, C.M. Flores</u>. Lab. of Neuropharmacol., UMN. Mpls, MN 55455.

Previous studies showed that nicotine is able to enhance the capsaicin induced release of calcitonin gene-related peptide (CGRP) from peripheral primary afferent terminals in an *in vitro* superfusion model. The purpose of the present study was to assess the effects of nicotine or its potent congener epibatidine on peripheral thermal nociception *in vivo*.

In one experiment, male Sprague Dawley rats were coinjected into one hindpaw with capsaicin (20µg/40µl) and nicotine bitartrate (0.165-16.5mMl). In a second experiment, rats got an additional injection of the same dose of capsaicin into the other paw. In a third experiment, animals received a unilateral epibatidine injection (1-100µmol) and -20 min. later a second injection with carrageenan (2mg/100µl) into the same paw. To assess thermal nociception, paw withdrawal latencies (PWL) to radiant heat were measured before the first injection and up to 120 min after the last injection.

Capsaicin alone showed a decrease in PWLs (-7.1+/-1.7s) within minutes after injection. Cotreatment with nicotine dose-dependently attenuated this decrease in PWL ipsilateral to the capsaicin/nicotine injection, but was less effective in the contralateral paw (capsaicin only). Epibatidine pretreatment dose dependently reduced the carrageenan induced hypersensitivity. Additionally, the highest dose of epibatidine was able to substantially block the edema associated with the injection of carrageenan. Injection with epibatidine alone evoked a transient reddening of the paw skin but did not lead to a significant reduction in PWLs.

These data indicate that nicotine exhibits antinociceptive activity in two models of peripheral inflammation. These studies further suggest that nicotine in addition to its previously documented effects in the central nervous system has a peripheral site of action to inhibit nociceptive neurotransmission.

SKF92374 AND BURIMAMIDE INDUCE ANTINOCICEPTION IN MICE J.W. Nalwalk, J.N. Finkell, and L.B. Hough*, Dept. Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208.

Previous studies have shown that the H_2 antagonist cimetidine and a structural analog (SKF92374) induce antinociception in rats when given into the lateral ventricle (ivt, Li et al., JPET 276:500, 1996); the effect does not depend on H_1 , H_2 , H_3 or opiate receptors (Li, et al, this volume). Presently, the analgesic actions of SKF92374 and another analog, burimamide (BUR) were assessed in male Swiss-Webster mice. Animals were housed in either a normal light cycle (lights on 0700-1900) or reversed cycle (lights on 1900-0700) and tested with the hot water (55° C) tail immersion nociceptive test (cutoff 8 sec). Following baseline testing, subjects received an ivt injection under ether anesthesia, and were retested 10, 20 and 40 min later. Under reverse-cycle conditions, SKF92374 and BUR produced time-dependent (ED50s of 3.0 and 3.45 μ g, respectively) antinociception. Under normal lighting conditions, SKF92374 also induced complete antinociception, but with a lower potency (ED50 = 7.35 μ g). These findings show that: 1) SKF92374 is a potent antinociceptive agent in mice, similar to results previously found in rats; 2) BUR inhibits spinally-mediated nociceptive responses in mice, extending recent findings with supraspinally-mediated tests (Lamberti et al., Pharm. Biochem. Behav. 53:567, 1996); 3) SKF92374 antinociception in mice exhibits diumal changes. Further studies to elucidate the mechanism of action of this novel non-opiate analgesic are in progress.

The analgesic effects of R(+)-WIN 55,212-2 Mesylate, a high affinity cannabinoid agonist, in a rat model of neuropathic pain. \underline{U} Herzberg* 1 , G. J. Bennett 2 , E. Eliav 2 and I. J. Kopin 1 . 1 Clinical Neuroscience Branch, National Institute of Neurological disorders and Stroke. 2 Neurobiology and Anesthsiology Branch, National Institute of Dental Research, 9000 Rockville Pike, Bethesda, MD 20892.

The effects of a high affinity cannabinoid receptor agonist were evaluated in rats subjected to chronic constriction injury of the sciatic nerve (CCI) as well as sham operated animls. Intraperitoneal (i.p.) injections of the active, but not the inactive enantiomer, alleviated the pain behavior exhibited by animals subjected to CCI in a dose dependant manner. Moreover, at doses ranging from 0.43 to 4.3 mg/kg effects on sensitivity to a heat stimulus were observed neither in the paw contralateral to the sciatic ligation, nor in animals subjected to sham surgery. Animals subjected to CCI and treated with the high drug dose exhibited hypoalgesia in the paw ispilateral to the ligated sciatic, i.e. heat hyperalgesia was completely reversed and a presumed sensory deficit due to nerve injury was revealed. Interestingly, even this high dose showed no effects on animals subjected to sham surgery. Although side effects were present in some animals subjected to the high dose treatment, a moderate dose (2.14 mg/kg) exhibiting complete alleviation of thermal hyperalgesia, with minimal side effects was identified. Using this dose, the sensitivities to von Frey hairs, pin prick and cold stimulus are being tested in animals subjected to CCI and sham surgery. In addition to identifying a potential drug treatment for painfull mononeuropathy, this study points to possible changes in cannabinoid receptors in animals subjected to unilateral mononeuropathy. SR 141716A, A CANNABINOID RECEPTOR ANTAGONIST, INDUCES NMDA-DEPENDENT HYPERALGESIA. J.D. Richardson*, L.M. Aanonsen¹, K.M. Hargreaves, Depts. of Restorative Sciences and Pharmacology, Univ. of MN, Mpls, MN 55455 and ¹Dept. of Biology, Macalester College, St. Paul, MN 55105.

We have recently reported that intrathecal administration of the cannabinoid receptor antagonist SR 141716A produces hyperalgesia in mice with an ED₅₀ of 0.0012 fmol (Abs. Soc. Neurosci, 20:128, 1994). It has also been reported that cannabinoids inhibit glutamatergic synaptic transmission in the hippocampal cultures (Shen et al, J. Neurosci, in press). Because glutamate is a well-established modulator of hyperalgesia, we tested the hypothesis that there is a glutamatergic component of SP 141716A induced hyperalgesia.

component of SR 141716A-induced hyperalgesia.

Baseline hot plate latencies were recorded from male Swiss-Webster mice. One of the following was administered intrathecally in a 5µl volume: saline, SR 141716A (0.005 fmol), SR 141716A (0.005 fmol) + AP5 (5 pmol), or SR 141716A (0.005 fmol) + MK-801 (0.025-2.5 pmol). Hot plate latencies were re-tested 5 min after drug administration. Data were analyzed with ANOVA and Duncar's test.

orug administration. Data were analyzed with ANOVA and Duncan's test. SR 141716A induced significant hyperalgesia when compared with the saline controls (-6.1 sec vs 0 sec, F[7, 88] = 7.10). This was reversed by 5 pmol AP5, an NMDA antagonist (-1.1 sec, F[7, 88] = 7.10). The SR 141716A-induced hyperalgesia was also reversed dose-dependently by 0.025, 0.25, and 2.5 pmol MK-801, another NMDA antagonist (-6.3, -3.4, -0.4 sec respectively, F[1, 22] = 7.48). These results suggest that there is an NMDA component of SR 141716A-induced

These results suggest that there is an NMDA component of SR 141716A-induced hyperalgesia. One potential mechanism for SR 141716A-induced hyperalgesia is tonic activation of the cannabinoid receptor resulting in the inhibition of glutamate release from some component of the spinal nociceptive system. According to this hypothesis, injection of the cannabinoid antagonist would result an increase in glutamate release leading to activation of central mechanisms of hyperalgesia.

RETINAL RECEPTORS AND CHANNELS

347.1

THE MGLUR6 L-AP4 RECEPTOR IS EXPRESSED IN BOTH ROD AND CONE ON BIPOLAR CELLS IN PRIMATE RETINA. R.M. Duvoisin 1 and N. Vardi 2. 1 Dyson Vision Research Institute, Dept. Ophthalmology, Cornell Med. College, New York, NY10021; 2 Dept. Neuroscience, U. Penn., Philadelphia, PA19104.

The depolarization of ON bipolar cells in response to light is mediated by an L-AP4-sensitive metabotropic glutamate receptor. This receptor (now known as mGluR6) has been cloned from rat retina and localized to dendritic terminals of rat bipolar cells. It remained unclear whether mGluR6 is expressed also by certain or all ON cone bipolar cell types. We wished to address this question in primate retina where ON cone bipolar cells are well identified and their connections with cones are well described. However, antisera raised against rat mGluR6 carboxy-terminus (Nomura et al., 1994) did not stain primate retina, suggesting that the primate carboxy-terminal sequence is different. We therefore cloned the human mGluR6 cDNA by screening a human retina cDNA library (generously provided by J. Nathan) with the rat mGluR6 as probe, determined the deduced carboxy-terminal human sequence and raised antisera against this sequence in two rabbits. Staining was highly localized to bipolar dendritic tips of both rod and cone bipolar cells in the OPL. Faint staining could be seen in somas located high in the INL, where ON cone bipolar cells reside. Roughly half of the cone bipolar cells were stained, indicating that most or all cone bipolar cell types express this receptor. Thus we conclude that the same L-AP4 receptor is expressed in both rod and cone bipolar cells. (Supported by EY11105, EY08124, EY09534, and RPB)

PET-SUBSTITUTED cGMP ANALOGS: NOVEL ANTAGONISTS OF ROD PHOTORECEPTOR cGMP-GATED CHANNEL

J.-Y. Wei, E. D. Cohen, Y.-Y. Yan, H.-G. Genieser# and C. J. Barnstable* Dept. Ophthalmol. & Vis. Sci., Yale Univ. Sch. of Med., New Haven, CT, #BIOLOG Life Sci. Institute, Bremen, Germany

The exocyclic NI and N2 of the guanine ring of cGMP are thought to play a key role in activating the rod CNG channels. To test this hypothesis, studies have been undertaken with four synthetic cGMP analogs: PET-cGMP, 8-Br-PET-cGMP, Rp-8-Br-PET-cGMPs and Sp-8-Br-PET-cGMPs, all of which contain a phenyl-substituted 5-membered ring system fused to the amino group in position 2 and the nitrogen in position 1 of the purine ring. The compounds were tested on excised patches from Xenopus oocytes expressing \(\alpha\)-substituted 5-membered ring system fused to the amino group in position 2 and the rat rod channel and in Xenopus oocytes expressing \(\alpha\)-substituted 5-membered ring system fused to the purine ring. The compounds were tested on excised patches from Xenopus oocytes expressing \(\alpha\)-substituted 5-membered ring system fused to detectable currents. Both Rp-8-Br-PET-cGMPs and Sp-8-Br-PET-cGMPs at millimolar concentrations did not lead to detectable currents. When co-applied with subsaturating concentrations of cGMP, it increased the responses of cGMP to the maximal response. 8-Br-PET-cGMP acted as a very weak partial agonist and an antagonist when co-applied with cGMP. Together the results suggest that the cGMP sites altered directly by PET substitution play a major role in rod CNG channel activation. The oxygen atoms of the cyclic phosphate moiety have a small but measurable effect on channel activity. Sp-8-Br-PET-cGMPS will be a useful tool for studying the effects of cGMP because although it acts as a potent CNG channel antagonist, it is a good activator of cGMP-dependent protein kinase. Supported by the NIH and the Kemper fund.

Ligand-gated currents of the rod dominant A17 amacrine cell of the cat retina E.D. Cohen Dept. of Ophthalmology and Visual Science, Yale Univ. Med. School, New Haven, CT 06520-8061

We have examined the ligand- gated conductances of A17 amacrine cells in a retinal slice preparation. This large wide-field amacrine cell forms reciprocal synapses to rod bipolar axon terminals and is thought to contain both serotonin and GABA. Retinal slices were prepared similar to the methods of Cohen et al. J. Neurophysiol.72:1260-1269,1994. A17 amacrine cells were voltageclamped using Cs⁺-filled low chloride containing electrodes at a holding potential of -70mV. Lucifer yellow was included in the patch pipette for cellular identification. Cadmium (1mM) and TTX (200nM) were used to block synaptic transmission. Drugs were bath applied. Large inward currents were seen to GABA (200µM), while glycine (200µM) produced small currents. The GABA current reversed near the reversal potential for chloride. A large portion (45-80%) of the GABA-induced current was blocked by 20-100µM bicuculline, while 120μM picrotoxin blocked any remaining current. Application of the excitatory amino acid agonists kainate 30µM and AMPA 30µM both evoked prominent inward currents that reversed near 0mV. In contrast, application of 200µM NMDA even under Mg2+-free (200µM Cd2+) conditions evoked little or no inward current. Thus the glutamatergic bipolar inputs to this amacrine cell are predominantly from AMPA/kainate receptors. Supported by NIH EY10617 to EDC.

347.4

ACTIVATION OF NMDA OR KAINATE RECEPTORS MODULATES CGMP-LIKE IMMUNOREACTIVITY IN TURTLE RETINA: INVOLVEMENT OF NITRIC OXIDE SYNTHASE. W.D. Eldred*, T.A. Blute and J. De Grenier. Department of Biology, Boston University, Boston, MA 02215.

In retina, cGMP gates ion channels and modulates gap junction conductivity in many cell types. Because excitatory amino acids are the transmitter used by many retinal neurons, we examined the effects of stimulating NMDA or kainate (KA) receptors on levels of cGMP-like immunoreactivity (cGMP-LI). Following *in vitro* incubations with KA or NMDA, immunocytochemistry with a cGMP antibody was used to examine cGMP-LI in specific retinal neurons. KA and NMDA increased cGMP-LI in bipolar and amacrine cells, and in somata in the ganglion cell layer. In response to each ligand, there were clear regional differences seen in the labeled cell types, in the numbers of labeled cells and in the intensity of labeling. In the inferior retina, NMDA stimulated intense cGMP-LI in bipolar and amacrine cells, and in three bands in the inner plexiform layer (IPL). In superior retina, NMDA increased cGMP-LI less intensely in amacrine cells and in two bands in the IPL. In contrast, KA stimulated cGMP-LI in bipolar and amacrine cells, and in three bands in the IPL in all retinal regions. To test the involvement of nitric oxide synthase (NOS), we used the NOS inhibitors 7-NI and L-NNA. Both inhibitors blocked almost all of the increases in cGMP-LI seen in response to KA or NMDA receptor activation. KA and NMDA increased cGMP-LI in different cell types, which suggests more than one postsynaptic cell was involved. These results indicate that activation of ionotropic glutamate receptors can lead to the stimulation of the cGMP second messenger system in a wide variety of select retinal neurons.

SOMATOSTATIN RECEPTOR SUBTYPES (SSTR2) IN THE RABBIT RETINA. A. Vasilaki, E. Hatzilaris#, G. Liapakis, Z. Georgoussi# and K. Thermos*. Lab. of Pharmacology, Univ. of Crete, Sch. of Med., 71110 Iraklion, and #Inst. of Biology, N.C.S.R. "Democritos", 153 10, Athens, GR. To address the role of somatostatin and its mechanism of action in the retina,

we have engaged in studies to identify and characterize somatostatin receptors in the rabbit retina. In the present study we employed selective ligands for the recently cloned receptors (SSTR1-5) and examined their ability to inhibit [1251]Tyr11-somatostatin binding to rabbit retinal membranes. SMS201-995, [1251]1yr11-somatostatin binding to rabbit retinal membranes. SMS201-999. MK678, and BIM23014, more selective for the SSTR2, displayed IC50 values of 0.026±0.002, 0.09±0.06 and 1.0±0.6 nM, respectively, while BIM23052 more selective for SSTR5, displayed an IC50 value of 18±3 nM. GTPγS reduced the [1251]Tyr11-somatostatin binding to rabbit retinal membranes, and reduced the [1251]Tyr11-somatostatin binding to rabbit retinal membranes, and shifted the somatostatin inhibition dose-response curve to the right. Using a series of anti-peptide antisera generated against the C-terminal decapeptides of Gi / Go proteins, the pertussis-toxin sensitive G-proteins Gi2 α , Gi1 α , and Go α , were immunoprecipitated. In addition, employing photocrosslinking methodology, the somatostatin receptor was studied further, using isoelectric focusing and lectin chromatography. The results from the above studies suggest that the somatostatin receptor in the retina is a slightly acidic N-glycosylated protein, linked to pertussis toxin sensitive G-proteins, with pharmacological characteristics similar to those of SSTR2. To substantiate the pharmacological findings, RNA blotting studies are in progress to examine with more precision at the molecular level, the differential expression of mRNAs for the somatostatin receptor subtypes in the retina. (This study was funded by a grant from the Greek Ministry of Research and Development, PENED 91ED665).

KINETIC ANALYSIS OF THE L-TYPE CALCIUM CHANNEL OF THE HORIZONTAL CELL BASED ON TIME AND FREQUENCY DOMAIN MEASUREMENTS. E.C. Hymel*, C.R. Murphey, L.E. Moore, and B.N. Christensen. Dept. of Physiology & Biophysics, Univ. of Texas Medical Branch, Galveston, TX 77555-0641.

In enzymatically isolated catfish cone horizontal cells, the L-type calcium channel was investigated by fitting both time and frequency domain voltageclamp responses. Under conditions where all other channels were pharmacologically blocked, the cell membrane potential was stepped from rest (-65 mV) to various test potentials. After obtaining the large-step current response, small signal sinusoidal stimuli (2-3 mV RMS, 0.3 to 1000 Hz) were used to measure the frequency-dependent response of the cell at each test potential. The frequency domain admittance functions and the time domain step responses for a range of potentials were fitted with a Hodgkin-Huxley type kinetic model that allows for activation and inactivation of the Ca^{2+} current. Passive characteristics of the cell were also estimated

Results obtained show that L-type channel inactivation is not strongly voltage dependent in this cell, while activation characteristics are consistent with previous results. The methods here differ from conventional analyses since linear voltage perturbations (frequency domain responses) are used to extract kinetic information, with non-linear voltage step responses used to constrain the estimated parameters to fits which produce appropriate step clamp responses. Supported by grants NEI-01897 from the NIH and F30-MH11169- $\,$ 01 from the NIMH (to E.H.)

STIMULATION OF AMACRINE CELLS ELICITS SYNAPTIC INPUTS TO GANGLION CELLS MEDIATED BY GABAa RECEPTORS. C.R. Shields, P.D. Lukasiewicz* Depts. of Ophthalmology and Anatomy & Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

GABA-evoked responses in retinal ganglion cells have been reported to be mediated primarily by GABAa and to a lesser extent by GABAc receptors (Zhang & Slaughter, 1995, J. Neurophysiol. 74:1583). We determined the types of GABA receptors that mediate synaptic inputs to ganglion cells by electrically stimulating amacrine cell processes with a concentric bipolar electrode placed at the inner plexiform layer of the tiger salamander retinal slice preparation. GABAergic synaptic currents were measured in ganglion cells with whole-cell patch clamp techniques. Glycinergic synaptic inputs were blocked with 2μM strychnine and glutamatergic inputs were blocked with 10μM CNQX and 40μM D-APV. The GABAergic synaptic currents reversed polarity near ECI and were completely blocked by the GABAa receptor antagonist bicuculline (100 µM), indicating that these synaptic inputs were mediated exclusively by GABAa receptors. In contrast, amacrine cell inputs to bipolar cells were composed of both bicuculline sensitive and insensitive components, indicating that these synaptic inputs were mediated by both GABAa and GABAc receptors. Puffing GABA onto ganglion cell dendrites or bipolar cell terminals yielded similar results: responses in ganglion cells were blocked by bicuculline whereas only a component of the responses in bipolar cells was sensitive to bicuculline. These data show that amacrine cell synaptic inputs to ganglion cells are mediated by GABAa receptors and that GABAc receptors play little or no role

ELECTROPHYSIOLOGICAL AND MOLECULAR CHARACTERIZATION OF A K* CHANNEL IN PHOTORECEPTORS OF THE HORSESHOE CRAB, *LIMULUS POLYPHEMUS*. Chaves, D.*1, Jeziorski, M.C.², Battelle, B.-A.², Renninger, G.H.¹, Department of Physics, University of Guelph, Guelph, Canada, N1G 2W1. ²Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

Light depolarizes the photoreceptor cells of the horseshoe crab, Limulus polyphemus. Voltage-gated ion channels shape this electrical response. One ion channel found by patch-clamp recordings of photoreceptor cells dissociated from the compound eye is a voltage-dependent native K+ channel characterized by fast transient openings. The channel has a mean patch conductance in the cell-attached configuration of 9.0 ± 3.4 pS (n = 18). Solution exchange experiments performed on inside-out excised patches confirmed that this is a K* channel. The kinetics of this channel are reminiscent of Shaker-type K* channels.

Using RT-PCR with degenerate primers designed against the Shaker family of K+ channels, we isolated a 1 kb fragment from ventral eye RNA that exhibits homology with known Shaker-type K+ channels. Subsequent cloning strategies were used to isolate the 5' and 3' fragments of this cDNA from ventral eye. Preliminary studies suggest this sequence is also represented in the lateral eye.

By expressing the channel in Xenopus laevis oocytes and performing two-electrode voltage clamp and patch clamp experiments, we hope to compare the functional properties of the cloned K^* channel to the native K^* channel. Characterization of this photoreceptors will contribute to a complete understanding of phototransduction.

EVIDENCE FOR A DIHYDROPYRIDINE-INSENSITIVE CALCIUM CURRENT IN DISSOCIATED RETINAL GANGLION CELLS OF THE TIGER SALAMANDER. <u>D.</u> <u>Henderson*¹, R. Nitzan², and R. F. Miller^{1,2}</u>. ¹Graduate Program in Neuroscience, ²Department of Physiology, University of Minnesota, Minneapolis, MN 55455

Calcium imaging techniques, based on ratiometric FURA-2 fluorescence changes, were used to study the mechanisms of calcium accumulation in retinal ganglion cells. Ganglion cells were labeled with a retrograde dye (tetramethylrhodamine - "TMR") prior to dissociation and FURA-2 loading. An increase in [Ca⁺⁺]_{in} in TMR labeled cells was observed in response to an elevation in external K This K⁺ induced change in [Ca⁺⁺]_{in} was blocked by However, 1-10 µM nimodipine, which completely blocked the $\mathbf{K}^{\scriptscriptstyle{+}}$ induced increase in photoreceptors, did not significantly affect the K⁺ induced change in ganglion cells. The type of calcium channel that supports this pharmacology in ganglion cells is under study using both calcium imaging and electrophysiological techniques

EXPRESSION OF SOMATOSTATIN RECEPTOR SUBTYPE 2A (SSTR2A) IN THE RABBIT RETINA. J. Johnson*, H. Wong, J.H. Walsh and N.C. Brecha. Depts. of Neurobiol. and Med., CURE, UCLA and WLA-VAMC, LA, CA 90073

UCLA and WLA-VAMC, LA, CA 90073

The neuropeptide somatostatin is likely to act as a neuromodulator by interacting with specific G-protein coupled membrane receptors SSTR1 to SSTR5. Somatostatin is widely expressed in the central nervous system including the retina. The cellular expression pattern of SSTR2A in the rabbit retina was determined using an affinity purified polyclonal antibody directed to the C-terminus of SSTR2A. Antibody specificity was tested by precedentian of the primary antibody with 10.5 M SSTR2Act 1200 preadsorption of the primary antibody with 10-5 M SSTR2A361-369 preadsorption of the primary antibody with 10⁻⁵ M SSTR2A₃₆₁₋₃₆₉. SSTR2A immunoreactivity is predominantly localized to rod bipolar cells and it is also observed in sparsely occurring amacrine cells. SSTR2A immunostaining in rod bipolar cells is strongest in the axon and axon terminals, and weak in the cell body and dendrites. Double-labeling experiments with the rod bipolar cell selective marker protein kinase C showed that all rod bipolar cells express SSTR2A immunoreactivity. In horizontal sections of retina, SSTR2A immunoreactivity. In horizontal sections of retina, SSTR2A immunoreactivity. Section of rod bipolar cells. SSTR2A immunoreactive amacrine cells occur very infrequently. They have a round cell body and are located at the border of the INL and IPL. They are likely to be multi-stratified and give rise to thin processes that ramify in laminae 2 and 4 of the IPL. These observations indicate that somatostatin, which is known to be localized to displaced amacrine cells, modulates the rod to be localized to displaced amacrine cells, modulates the rod pathway through its interaction with SSTR2A expressed by rod

bipolar cells. Supported by EY04067 and DK41301 and VA Research Funds.

IDENTIFYING A SUBREGION CRITICAL FOR HOMOMERIC EXPRESSION OF FUNCTIONAL GABA p SUBUNITS. Dongxian Zhang*, Zhuo-Hua Pan, Johanna A. Koolen, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

We have previously shown that rat GABA ρ 1 and ρ 2 subunits can form heteromeric receptors with properties similar to GABA_C receptors in the rat retina. However, unlike the rat ρ 1 subunit and other GABA ρ subunits in human and fish, the rat p2 subunit is unable to form functional In thinain and 1811, the fat ρ 2 stoucht is unable to form functional homomeric receptors. In order to understand the subunit interaction of the putative pentameric receptor, we identified regions that are critical for the homomeric expression of rat GABA ρ subunits. Chimeric subunits were constructed by substituting 5 different subregions of the rat ρ 1 subunit with corresponding subregions of the $\rho 2$ subunit. These chimeras were tested for their ability to form functional homomeric receptors mediating GABA-evoked currents in *Xenopus laevis* oocytes. By testing mediating GABA-evoked currents in *Xenopus idevis* oocytes. By testing six chimeric subunits, we show that the subregion of the $\rho 1$ subunit that is located 5' to the cys-cys loop (residues 94-214) is the only region absolutely required for homomeric expression. Since this subregion of the rat $\rho 2$ subunit is highly homologous to the human $\rho 2$ subunit (97%) identity), we substituted this subregion of the human for the rat. This rat ρ2 mutant gained the ability to form functional homomeric receptors. In contrast, two additional rat ρ 2 mutants, engineered to contain a few amino acid residues from this subregion in the rat ρ 1 subunit, failed to express functional receptors. Thus, the integrity of the subregion may be critical for homomeric expression, and further mutants are being constructed to test this hypothesis.

347.13

SYNAPTIC LOCALIZATION OF GLYCINE AND GABA, RECEPTORS IN THE DEVELOPING RAT RETINA. M. Sassoè-Pognetto 1.2, P. Panzanelli *2 and H. Wässle 1. Wax-Planck-Institut für Hiruforschung, D-60528 Frankfurt am Main, Germany; 2 Department of Anatomy, Pharmacology and Forensic Medicine, University of Turin, I-10126 Turin, Italy.

The mechanisms by which neurotransmitter receptors are clustered at postsynaptic sites of neurons are largely unknown. The 93 kDa peripheral membrane protein gephyrin has been shown to be essential for the formation of postsynaptic glycine receptor clusters, and there is now evidence that gephyrin can also be found at GABAergic synapses. In this study, we have analysed the synaptic localization of glycine receptors, GABA_A receptors, and the anchoring protein gephyrin in the inner plexiform layer of the developing rat retina, using immunofluorescence with subunit specific antibodies.

At early postnatal stages, the antibodies produced a diffuse staining, suggesting that early retinal neurons can express glycine and GABA_A receptors. A clustered distribution of the subunits in "hot spots" was also observed. The number of the hot spots increased during development and reached adult levels in about two weeks. Electron microscopy showed that synapses of the conventional type are present in the inner plexiform layer of the postnatal retina and that the hot spots correspond to an aggregation of receptors at postsynaptic sites. Gephyrin was also localized to hot spots, and double immunofluorescence revealed a colocalization of gephyrin with the α2 subunit of the GABAA

receptor.

These results indicate that clustering of receptor subunits occurs in parallel with the formation of morphologically identifiable synaptic specializations and suggest that gephyrin may be involved in clustering of GABAA receptors at postsynaptic sites

Supported by grants from the DFG (SFB 269) and MURST (40% and 60%).

GLYCINE TRANSPORTER AND GABA, RECEPTORS COLOCALIZE IN DAPI-3 CELLS IN RABBIT RETINA. C. L.

Zucker*, B. Ehinger, A. Bruun, N. C. Danbolt, J. Storm-Mathisen. Department Of Ophthalmology, University Of Lund, Sweden; Department Of Anatomy, University Of Oslo, Oslo, Norway; Schepens Eye Research Institute, Harvard Medical School Boston, MA 02114.

DAPI-3 cells are a recently described type of amacrine cell in the retinal They have a characteristic distribution of processes in two discrete sublayers in the inner plexiform layer of the retina (Ehinger and Zucker 1996). Their uniquely high concentration of GABA_A receptors (subtypes α_1 and β_2/β_3) can be used as a reliable identifier, and we have used this to analyze their content of glycine transporter membrane protein (GLYT1) which is considered a marker for glycinergic neurons. GABA_A receptors were visualized with a commercially available antibody (BD17) in conjunction with an antibody directed against the C-terminus of the glycine transporter protein (GLYT1).

GLYT1 immunoreactive cell bodies had the distribution characteristic of glycinergic amacrine cells, and emitted varicose processes throughout the IPL without discernible sublayering. Strong immunoreactivity for ${\rm GABA_A}$ receptors appeared in amacrine cells of the DAPI-3 type. These cells were always seen to be immunoreactive for GLYT1 as well. Cell bodies and processes with weak GABA. receptor immunoreactivity were glycine transporter immunonegative.

With Lucifer Yellow microinjection experiments we have previously shown that strongly $GABA_A$ receptor immunoreactive cells are DAPI-3 cells. The present demonstration of GLYT1 immunoreactivity in their cell membrane suggests that glycine is a DAPI-3 cell transmitter in the rabbit retina. Independently, Wright and Vaney have reached a similar conclusion, using glycine immunohistochemistry (personal communication Nov. 1995).

METABOTROPIC GLUTAMATE RECEPTORS IN THE RAT RETINA. J.H. Brandstätter^{1*}, P. Koulen¹, R. Kuhn², and H. Wässle¹ Planck-Institut für Hirnforschung, Deutschordenstr. 46, D-60528 Frankfurt am Main, Germany; ²CNS Research, CIBA, CH-4002 Basel, Switzerland.

In recent years, there has been an increased awareness of the important role that metabotropic glutamate receptors (mGluRs) play in the synaptic events that underlie the processing of visual information.

We have studied the cellular and subcellular distribution of mGluR2, 3, 4 and 7 in the rat retina using specific anti-peptide antisera. Of the four receptors examined, mGluR3 was not found in the retina. MGluR2 was expressed by amacrine cells. At the subcellular level, mGluR2 was localized to amacrine cells postsynaptic to both rod and cone bipolar cells. MGluR4 was distributed throughout the inner plexiform layer (IPL) and was found postsynaptically in amacrine cell and ganglion cell processes. MGluR7 labelling was localized to discrete strata in the IPL. At the subcellular level, mGluR7 was found at ribbon synapses, presynaptically in cone bipolar cells, and postsynaptically in amacrine cells. Presynaptically, mGluR7 was found at only one part of the

active zone of the ribbon synapse, facing only one of the postsynaptic neurons.

During development, a gradual shift from receptor labelling of somata and processes to a preferential labelling of processes ocurred. This redistribution of mGluRs during development might correspond to a clustering of the receptor proteins during the formation of synapses.

Our data suggest that each mGluR plays a distinct role in retinal synaptic circuitry. The pre- and postsynaptic distribution of mGluRs at ribbon synapses in the IPL, suggests that the release of glutamate is highly regulated. Supported by the Deutsche Forschungsgemeinschaft (SFB 269/B4).

IMMUNOCYTOCHEMICAL ANALYSIS OF NEURONAL TRANSPORT OF GABA ANALOGUES IN THE DEVELOPING RABBIT RETINA. D.V. Pow. D.K. Crook and D.I. Vaney*. Vision, Touch and Hearing Research Centre. Dept. of Physiology and Pharmacology, University of Queensland, Brisbane 4072.

We have generated antibodies against non-endogenous GABA analogues including γ-vinyl GABA and have shown that in the adult retina γ-vinyl GABA is γ-vin) GABA and have shown that in the adult retina γ-vini) GABA is specifically accumulated by all the GABAergis amacrine cells. In this study we examined the transport of γ-vinyl GABA into neurons in the developing retina and compared this transport with the distribution of GABA and glycine in serial semithin sections. We demonstrate that at 1 dpn retinal ganglion cells can take up γ-vinyl GABA, but lose this capacity later in development, concomitant with a which contained glycine but not GABA failed to accumulate γ-vinyl GABA. γ-vinyl GABA was accumulated into many GABAergic amacrine cells at 1 dpn, however there were clear mismatches, some cells accumulated γ -vinyl GABA but did not contain detectable endogenous GABA and vice-versa. In addition some cells accumulated γ-vinyl GABA weakly whilst others showed strong accumulation, irrespective of the amount of GABA in these neurons, indicating that re-uptake of GABA plays a variable role in overall GABA homeostasis in different cell populations. These mismatches were markedly reduced by 10 dpn. To assess whether our results might be influenced by some amacrine cells changing from a GABA-containing to a glycine-containing phenotype we quantified the ratio of glycine-immunoreactive to GABA-immunoreactive (or y-vinyl GABA - accumulating) neurons in retinae from 1 dpn to adult. Surprisingly, our data shows that by as early as 5 dpn the ratio of GABA-containing to glycine-containing amacrine cells is the same as that observed in the adult. We are now examining by immunocytochemistry whether the capacity of glycinergic neurons to transport glycine analogues shows analogous developmental changes. Funded by grants from NH&MRC (Australia) to DVP.

DISTRIBUTION OF CONNEXIN43 IMMUNOREACTIVITY IN THE RETINAS OF DIFFERENT VERTEBRATES <u>U. Janssen-Bienhold, R. Dermietzel and R. Weiler</u> Neurobiology, FB 7, Carl von Ossietzky University of Oldenburg, D-26111 Oldenburg, F.R.G.

In the retina, the main subclasses of cells employ gap junction channels as means of intercellular communication, and homologous as well as heterologous coupling has been demonstrated. However, while many informations have been collected regarding the regulation of gap junctions in the retina mediated by neurotransmitters and second messengers, only little is known about the expression of the hemichannels forming connexin proteins in the different retinal cells. Here we have used polyclonal antibodies (rb) against a synthetic oligopeptide of the Cwe have used polyclonia anticoduse (bi) against a symmetric diagoperate of the terminal of connexin43 (rat, corresponding to AS 362-382) to investigate the occurence and distribution of connexin43 in the retinas of fish (carp and zebrafish), turtle, chicken and rat. The specifity of the antibody was analyzed by immunoblotting, where it localized two broad bands of 43-47 kDa (monomer) and 92-98 kDa (dimer) in samples of rat heart homogenates. The 43 kDa component also occured in retina samples of all tested species, while the dimer was more recommentation by in the fich and rat retinal homogenates. The retinas of all species prominent only in the fish and rat retinal homogenates. In the retinas of all species a substantial immunolabeling of the margins of neighbouring pigment epithelium cells was observed. Both fish retinas also showed an intense punctuate connexin43 immunoreactivity (IR) at the level of the outer limiting membrane and the outer plexiform layer, most likely resulting from the presence of connexin43 in Mueller glia cells. In addition, a population of amacrine cells ramifying at layers one and three of the inner plexiform layer revealed an intense punctuate immunolabeling in the zebrafish retina. In accordance with the presence of connexin43 IR in Mueller glia cells, the rat retina also showed immunoreactive puncta at the level of the inner limiting membrane, which is formed by Mueller glia cells. In summary, our data demonstrate the expression of connexin43 in the vertebrate retina Supported by the Deutsche Forschungsgemeinschaft

CLONING OF A GAP JUNCTION GENE FROM THE RETINA OF THE GIANT DANIO T.L.E. Wagner*, D.G. McMahon, and D.K. Department of Physiology, University of Kentucky, Lexington, KY 40536; 1 Department of Biology, Utah State University, Logan, Utah 84322

Gap junctions are closely apposed areas of cell membranes which contain gap junctional channels, or connexons. Gap junctions in the retina serve a variety of functions and are an excellent model for electrical synapses found throughout the nervous system.

We have cloned from the retina of the giant danio (Danio aequipinnatus) a full length cDNA (DACX43) which shares high sequence homology and similarly predicted structural features with previously cloned connexins. A partial clone was isolated from retinal RNA using reverse transcriptase polymerase chain reaction (RT-PCR). We then created a giant danio retinal cDNA library and used the partial clone to isolate a full length clone. The cDNA predicts an amino acid sequence of 382 residues with a molecular weight of 43.4 kDa. The cloned sequence was compared to those of previously sequenced connexin genes in nucleic and amino acid forms (PCGENE, IntelliGenetics). Identity to rat CX43 at the nucleotide level is 75%, and at the amino acid level is 78%. Consensus phosphorylation sites for PKA, PKC, PKG, and CAKII were found in the C terminus.

We synthesized a 14 aa peptide corresponding to the cytoplasmic loop sequence

of DACX43. Eight copies were joined to form a MAP (multiple antigenic peptide) and injected into mice to create antibodies. In addition to the positive response of the hyper-immune serum, several monoclonals reacted with horizontal cells, as well as other cells in the inner nuclear layer. We are continuing to characterize these monoclonals for use as antibodies. Supported by NIH EY09256, NS01734, and EY09038 to DKV.

IMMUNOBLOT AND IMMUNOCYTOCHEMICAL ANALYSES OF CATFISH RETINAL PROTEINS USING ANTIBODIES RAISED AGAINST RAT CONNEXINS: CX43,CX32 AND CX26. L.J. Giblin and B.N. Christensen* Dept. Physiology & Biophysics, Univ. of Texas Medical Branch, Galveston, TX 77555.

Gap junctions have been identified throughout the teleost retina; most notably connecting horizontal cells, photoreceptors, amacrine cells and, presumably, Mueller cells. While the electrophysiology and modulation of the gap junctions present in teleost retina have been extensively studied, the connexin proteins forming them have yet to be isolated or cloned. To determine whether catfish retinal connexins might be recognized as homologues of known connexins, we performed immunoblot and immunocytochemical (IC) analyses of catfish retina using polyclonal (PAb) and mono-

protein in the catfish retina with great specificity. IC staining resulted in punctate

different proteins in the catfish retina. Most notable were proteins having apparent molecular weights ~15kD, ~26kD, ~32kD ~60kD and ~200kD. IC staining resulted in diffuse signal throughout the inner retina. A monoclonal antibody directed against the same region failed to recognize any proteins from the catfish retina.

Our results suggest that the 43 kD protein found in the teleost retina may be a gap junction protein present in photoreceptor cell bodies. Furthermore, the Mueller cells may also contain a Cx26 homologue. Supported by Grant NEI-01897 from the NIH.

PARTIAL SEQUENCE OF A GAP JUNCTION FROM THE HYBRID STRIPED BASS RETINA C. Lu, D.G. McMahon and D. Speck*. Department of Physiology, University of Kentucky, Lexington, KY 40536.

Gap Junctions are widely distributed in all synaptic layers of the retina and are of

fundamental importance in transmitting and shaping visual signals. Retinal gap junctions serve as an excellent model for gap junctions found throughout the nervous

We have detected expression of connexin 43 in retina and heart tissue of both rat and bass by Northern analysis using rat connexin 43 cDNA as probe. We have successfully cloned a partial cDNA (HBRET-1) from hybrid striped bass retina which shares high sequence homology and predicted structural features with previously cloned connexins. This 434 base pair clone was isolated from bass retinal RNA using reverse transcriptase polymerase chain reaction (RT-PCR) and a set of degenerate primers based on conserved areas of previously cloned connexins. This clone showed a positive hybridization to rat connexin 43 cDNA. Sequence analysis (PCGENE, IntelliGenetics) revealed that HBRET-1 is most similar to rat connexin 43. In comparison the equivalent partial sequence of rat connexin 43, HBRET-1 exhibits identity at the nucleotide level is 77.1%, and 79.2% homology at the amino acid level. HBRET-1 has also been confirmed as part of the hybrid bass genome by Southern analysis. We are currently localizing further the cell-specific expression of HBRET-1 in the hybrid bass retina using single cell PCR and in situ hybridization. Supported by NIH EY09256 and NS01734.

clonal (MAb) antibodies directed against rat connexins: Cx43, Cx32 and Cx26.

PAb's directed against the C-terminal region of rat heart Cx43 recognized a 43kD labeling of the outer nuclear layer.

PAb's directed against the second cytoplasmic domain of Cx26 also recognized proteins in the catfish retina, with apparent molecular weights of ~70kD and -19kD. IC staining resulted in labeling of the Mueller cells, especially the outer limiting membrane. A MAb directed against the same region recognized only the 70kD pro-

PAb's directed against the second cytoplasmic domain of Cx32 recognized many

DEFICITS AND RECOVERY OF FIRST- AND SECOND-ORDER MOTION PERCEPTION IN PATIENTS WITH UNILATERAL PARIETAL LESIONS. D. L. Braun _(1), M. Fahle (1) & P. Schönle (2) (1) Sektion Visuelle Sensorik, University Eye Clinic, Waldhörnlestr. 22, D-72072 Tübingen, Germany. (2) Neurological Rehabilitation Clinic Schmieder, D-78473 Allensbach, Germany.

Unilateral lesions in the posterior parietal cortex can degrade motion perception in the contralateral visual field. Our aim was to test whether the effects may be differential for first- and second-order motion, and to investigate the time scale of any potential recovery. We tested nine patients with circumscribed lesions in the parietal cortex. Thresholds were measured for the discrimination of the direction of motion of stimuli presented 5.5 deg peripherally in the visual hemifields ipsi- and contralateral to the lesion. Subjects had to indicate whether a small rectangular region (1.6 deg x 3 deg) embedded in a dynamic random noise background moved up or down. The region contained moving dots (signal) and flickering dots (background) and moved for one second at a speed of 2.36 deg/sec. Signal dots were either (a) coherently moving in the same direction as the region (1st-order), (b) stationary (2nd-order), or (c) coherently moving in the opposite direction (theta). Thresholds were defined as the percentage of signal dots within the region yielding 75% correct responses.

All patients had higher thresholds for second-order motion than for first-order motion. When contra- and ipsilesional thresholds were compared, three patients showed proportional threshold elevations for all three types of motion stimuli in the field contralateral to the lesion. Two of these three patients were tested again five months later. Both showed considerable recovery: In one patient the deficit was no longer present, in the other reduced by about half. None of our patients had lesions differentially affecting first- or second-order motion; lesions always affected first- and second- order motion in the same way. Due to the surprisingly good recovery, deficits might be detectable only

MOTOR CONTROL PRINCIPLES CONTRIBUTE TO THE APPARENT MOTION OF A HUMAN BODY. R. Osu¹, Y. Uno¹, T. Inui², H. Ando¹*, & M. Kawato¹. ¹ATR Human Inf. Processing Res. Labs., Kyoto, Japan. ²Dept. of Psychol., Fac. of Letters. Kyoto Univ.

We examined the apparent motion of non-rigid articulated objects like the human arm. Subjects saw pairs of alternating simple stick figures of a human upper arm viewed from above. The subjects adjusted the positions of dots displayed between the figures to remain on the path along which they saw the motion of a hand. For comparison, they also judged the apparent motion path of rigid objects, which were composed only of the forearm part of two joint figures.

According to the previous purely perceptual theory of apparent motion, motion paths are independent of the object. The following two hypotheses have been derived from the theory: 1) the shortest possible (straight) hand path, and 2) a) rotation or b) translation and rotation of the rigid part (forearm). We examine another class of theories in which models utilized in generating arm movements are also utilized in perceiving arm movements. According to motor control are ariso utilized in perceiving arm movements. According to motor control theory, arm trajectories are planned in body space so that intrinsic variables such as joint angles or joint torques are at their smoothest possible. The following two hypotheses are possible along this line. If the vision system considers the kinematics of arm movements, one possible hypothesis is 3) the smoothest possible movement in joint angle space. If the vision system additionally considers the dynamics of the arm, one possible hypothesis is 4) the minimumtorque-change trajectory, which is the optimum trajectory considering the dynamics of the musculoskeletal system. In the case of rigid sticks, the subjects reported paths closest to those expected by hypothesis 2) b). In the case of human arm stick figures, however, the subjects reported paths closest to 4). The results suggest that information on motor control contributes to the motion perception of a human body.

CONTRAST SENSITIZATION IN HUMAN MOTION PERCEPTION PSYCHOPHYSICAL EVIDENCE. C. Wehrhahn*. Max-Planck-Institut für biologische Kybernetik, Tübingen, Germany.

In an attempt to identify the neuronal mechanisms underlying human motion perception, I investigated whether human observers are able to detect subthreshold line, when a suprathreshold stimulus is presented next to it.

Foveal contrast detection thresholds for a vertical line were measured on a

color monitor with 60 Hz frame rate using a two-alternative forced-choice procedure. Dark or bright lines were shown on a grey ground at ± 5 arcmin eccentricity for 1 frame. Line length and width were 20 and 1 arcmin, respectively

These thresholds served as control values throughout.

An 'inducing line' of twice the detection threshold (either bright or dark) was presented at the centre of gaze and contrast thresholds were measured for test lines shown at variable distances to the left or right of the inducing line. Simultaneous presentation of inducing and test lines at 3 arcmin distance with equal contrast sign elevated detection thresholds of the test line. A delay of 1 frame between inducing and test line yielded thresholds at the control value. When line distance was increased, synchronous presentation of inducer and test lines decreased thresholds to 70-80% of the control. A delay further decreased thresholds to values below 50% of the control. When line contrasts had the same sign, this value was reached within a delay of 1 frame. With opposite sign of contrasts, 2-3 frames were required to reach that value.

These results are consistent with earlier experiments in which temporal thresholds were measured using high contrast apparent motion stimuli [Wehrhahn & Rapf (1992) J. Neuroscience 12: 2247-2250]. The experiments described, therefore, provide evidence for contrast sensitization, which may underly human motion perception [Exner 1894]. ELECTROPHYSIOLOGICAL CORRELATE OF THE 'FILEHNE ILLUSION' IN MAN. T. Haarmeier*, P. Thier. Sekt. f. Vis. Sensomotorik, Neurologische Universitätsklinik, 72076 Tübingen, Germany.

During smooth pursuit eve movements made across a stationary background an illusionary motion of the background is perceived (Filehne illusion=FI). This illusionary movement of the background is widely assumed to result from a neu-ronal comparison of retinal image slip and an imperfect estimate of the eye movement. We have recently demonstrated that the FI can be modified in a predictable way by visual motion unrelated to the pursuit eye movement and, moreover, preceding it (Vis. Res., 36: 741-750). In the present event-related potential (ERP) study we made use of the fact that identical constellations of retinal image slip and eye movement can yield different percepts of illusionary background motion in order to locate the neuronal substrate underlying the comparison of the two neuronal signals. Towards this end, ERPs obtained under two conditions, which were identical physically but gave rise to very different FIs (high vs low Filehne condition), were compared. ERP responses were collected from ten naive subjects, who performed 12% rightward smooth pursuit eye movements in front of a stationary background (a 27%27° random dot pattern, presented for 300ms). Under both conditions ERPs showed an initial positive peak (P1; peak latency about 120ms), a first negative peak (N2; 180ms) followed by a second negative component (N3; 300ms) and a huge positive peak (P3; 450ms). While the P1, the N2, and the P3 were the same for the low and the high FI condition, only the amplitude of the N3, which was most prominent in the parietooccipital leads, depended significantly (p<0.01) on the size of the illusion with higher peaks for higher FIs. It is generally accepted that the N2 reflects activity in motion processing area MT. The fact that the N3, the first potential whose amplitude reflects the size of the FI, follows the N2 by 120ms suggests that the N3 arises from a later stage in the hierarchy of cortical motion processing. PERCEPTUAL STABILITY CORRELATES WITH ACTIVITY IN EARLY VISUAL AREAS. G.K. Humphrey, M.A. Goodale*, C.V. Bowen, J. S. Gati, B.K. Rutt and R.S. Menon. Departments of Psychology and Medical Biophysics, University of Western Ontario; Advanced Imaging Labs, Robarts Research Institute, London, Ontario, Canada

Vertically oriented shading gradients (as in the disks in A) produce a strong and stable percept of 'concave' and 'convex' elements. If the shading gradients are rotated 90°, as in B, the depth percept is reduced and much more

ambiguous. In a 3-D fMRI study at 1.5T, we found significantly less activation in area V1 and neighbouring low-level visual areas of cortex when subjects viewed displays that led to a stable depth percept (composed of disks as in A) than when they viewed displays that led to weak and ambiguous depth percepts (as in B). There was no reliable difference in activation for the control stimuli that lacked depth structure and ambiguity (C and D). The study demonstrates that the difference in strength and stability of a depth percept that occurs when a shading gradient is rotated 90° is accompanied by a corresponding change in the level of activation in early visual areas of the human brain. The reduced activation with stable visual displays may reflect top-down modulation of early visual processing or an intrinsic bias in neural networks in V1 and neighbouring areas.

OBJECT ENUMERATION IN EQUILUMINANT AND LOW CONTRAST VISUAL DISPLAYS

G.Patel*, S.Peterson, K.Sathian & T.J.Simon Program (GP) and Dept. of Neurology (KS), Emory University; School of Psychology, Georgia Institute of Technology (SP,TJS); Atlanta, GA.

Humans can rapidly enumerate (subitize) small sets of four or fewer objects, their reaction time (RT) increasing by about 50 ms per object in this range. For sets numbering over four items, RT increases more steeply, by about 300 ms per item. We studied the effect on object enumeration of selectively interfering with the function of either the magnocellular (M) or parvocellular (P) visual pathway.

To selectively impair the M system, we presented green objects on a perceptually equiluminant red background. RT was significantly prolonged relative to a control condition where the objects were much brighter than background. This effect was specific to the subitizing range, suggesting that subitizing may preferentially depend on the M system. In another experiment, the objects were gray on a white background, with Michelson contrasts of 20% or 5%. At the lower contrast, where the P system is relatively inactive compared to the M system, RT was significantly longer than at high contrast. This effect was present both within and outside the subitizing range and may result from a non-specific decrease in object visibility or dependence on the P system for object individuation. Supported intra-murally.

IS PRE-SACCADIC VERNIER DISTORTION RELATED TO PERI-SACCADIC MISLOCALIZATION? R.H.Cai*. A.Pouget, M.Schlag-Rey & J. Schlag, Brain Research Institute, UCLA, Los Angeles, CA 90095-1761

In a 3-dot vernier alignment test, if the outer dots are continuously lit while the middle dot is flashed shortly before a saccade, a distortion in vernier alignment is perceived (Cai, et.al. ARVO 1996). Is this phenomenon related to pre-saccadic mislocalization? It is known that a spot of light flashed before a saccade is mislocalized in the direction of the saccade. However, such mislocalization is suppressed if the visual stimulus is continuously lit. If we hypothesize that in the three-dot vernier test as described, the mislocalization of the two outer dots is suppressed, whereas the mislocalization of the middle dot is not, a relative distortion in the relationship among the 3 dots can result. Under this hypothesis, one would predict that if all three dots were flashed at the same time before a saccade, they would all be mislocalized by the same amount, the vernier distortion would disappear. Here, we tested this prediction. All three dots for vernier alignment were flashed at the same time for 4ms shortly before a 4° rightward saccade. The results were compared with those obtained when only the middle dot was flashed before saccade and when no saccade occurred. For all subjects, there was no difference in the vernier bias between the all-3-dot-flash trials and the no-saccade trials. Such results are consistent with the hypothesis that pre-saccadic vernier distortion is related to peri-saccadic mislocalization of visual stimuli. (Supported by USPHS grants EY05879 and EY02305)

3D VECTOR MODEL FOR EGOCENTRIC SPACE PERCEPTION. . Matin* and W. Li. Dept. of Psychology, Columbia University, New York, NY 10027

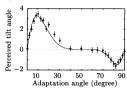

The orientation of a single dim line in darkness is sufficient to generate large systematic (nearlinear) influences on the perception of elevation (small circular target set to appear at eye level; VPEL) and of orientation within a frontal plane (small test line set to appear vertical; VPV). These influences on visual spatial localization and orientation (as well as manual reaching) are almost as large as are measured with complexly-structured, well-illuminated, pitched and rolled visual fields, respectively. The influences on both VPEL and VPV are negatively accelerated exponentials of total line length with space constants in the 10° - 20° range. The influence on VPEL is essentially independent of head and eye orientation. The central vertical meridian (CVM) and circumference of the midfrontal plane (CMFP) of a projection sphere centered at the monocularly-viewing eye provide the two qualitative dimensions of projected line orientation; line length provides the intensitive dimension. These three dimensions are the bases of a vector structure that encloses the two major opponent processes for perceived elevation and perceived orientation within a frontal plane. The similarity of the treatment to the treatment of brightness and hue within color e is striking. Several experiments support the view that processing of VPEL is mediated in parietal cortex. Supported by NIH EY10534 and AFOSR F49620-94-1-0397.

TILT ILLUSIONS AND DYNAMIC DECORRELATION: A THE

TILI ILLUSIONS AND DYNAMIC DECORRELATION: A THEORY OF LATERAL INTERACTIONS OF THE ORIENTATION
SELECTIVE CELLS IN STRIATE CORTEX (V1). Dawei W. Dong*.
California Institute of Technology, 139-74, Pasadena, CA 91125.

Natural images possess significant correlations. We explore the hypothesis
that visual information in V1 is adaptively transformed into a decorrelated
representation through lateral interactions of the orientation selective cells.
Although retina and LGN do spatial and temporal decorrelation to incoming
images (Dong and Atick 1994), only the lowest order correlations are eliminated. Therefore, the signal sent to V1 is still correlated and the activities of nated. Therefore, the signal sent to VI is still correlated and the activities of the orientation selective cells are correlated because of the high order correlations in the signal. Using some recently measured high order statistical properties of natural images, we predict the form of the lateral interactions in VI which reduces the high order correlations. The predicted lateral interactions are anisotropic. The theory not only agrees with the physiological experiment by Gilbert and Wiesel (1990), but also gives a unified and quantitative explanation of the psychophysical experiments on tilt or orientation illusions as shown below. The solid curves are the theoretical predictions: the data points are from Westheimer (1990) on orientation contrast (left) and Campbell and Maffei (1971) on orientation adaptation (right). Maffei (1971) on orientation adaptation (right).

THE CONTRIBUTION OF 3-DIMENSIONAL INFORMATION DURING VIEWPOINT DEPENDENT OBJECT RECOGNITION. S. Nishina and T. Inui*. Dept. of Psychol., Fac. of Letters, Kyoto Univ., Kyoto 606-01 JAPAN

Recent research has suggested that humans can recognize a novel view of an object by interpolating known views of it. On the other hand, Shepard & Metzler (1971) suggested that there is a process called mental rotation, which rotates the 3-dimensional structure of objects. In order to separate these two processes, we performed a recognition experiment using two types of distractors. One type of the distractor was 3-dimensionally different from the target, but a 2-dimensional silhouette of it was equivalent to the target's view presented during testing. The other type was created to be completely unrelated to the target. Each trial consisted of one learning and one testing. A stimulus shown during testing was either one type of the distractors or a rotated target. Under the "short" condition, the stimuli was only shown for one second during testing; the subjects had to respond within that duration. There was no time limit for the "long" condition.

The correct ratio over a rotated angle can be modeled as the combination of 2-dimensional view matching and 3-dimensional structure matching. The calculated range(o) of view matching was about 20°, which is narrower than the result of Logothetis et al. (1994); it is possible that 3-dimensional matching was included in their result. The result from a simulation using GRBF (Poggio and Edelman, 1990), which theoretically could not be affected by 3-dimensional information, is close to our result. These results show that 3-dimensional structure matching would be performed especially for larger rotation

EVIDENCE FOR BLINDSIGHT IN PATIENTS WITH HOMONYMOUS HEMIANOPIA. A.J. Butler*, W.G. Darling, M. Rizzo, T.B. Shoen. Departments of Exercise Science and Neurology, University of Iowa, Iowa City, IA 52242.

"Blindsight", the perception of and/or action upon visual stimuli in the absence of

acknowledged awareness, has been used to explain residual abilities in the fields of a visual cortical scotoma. However, the extent of these abilities requires further definition. We investigated these issues by studying residual reaching into the blind hemifield in 2 patients with MRI defined visual cortical lesions. The subjects reached to visual targets in 4 different experimental conditions: (1) Visual presentation (brief flash of target light), reach to remembered target location with no vision of hand. (2) Visual presentation (brief flash of target light), reach to remembered target location with vision of hand; (3) Visual presentation, reach to actual target with no vision of hand; (4) Visual presentation, reach to actual target with vision of hand. Subjects were instructed to focus on a stationary, green light emitting diode (LED) positioned directly in front of them, and to utilize only peripheral vision to observe the target light. Movements were performed in complete darkness. Visual feedback on hand position was provided by illumination of a LED on the hand. Optoelectronic (WATSMART) records of fingertip positions were analyzed for movements to both hemifields. The results were that both subjects made much larger errors in direction when pointing to visual target locations in the blind visual hemifield. Yet, there was a statistically significant relationship between target location and fingertip location in the blind hemifield and performance even improved when vision of the limb was available. The findings indicated residual vision in the blind hemifields of both subjects that was, however, of insufficient quality to permit target acquisition (supported by NIH/NIA grant AG00214-05 to AB and NIH PO NS 19632 to WD and MR:

VISUAL PERCEPTION PROBLEMS IN MS. E. Vandenbussche^{1*}, L. Vleugels², C. Lafosse¹, A. van Nunen² and P. Ketelaer². ¹Lab. Neuropsychologie, KULeuven Campus Gasthuisberg, B-3000 Leuven, Belgium, 2 Nat. Center for MS, Melsbroek, B-1820, Belgium.

Purpose. To study prevalence and nature of behavioral consequences of visual CNS disorders in a MS population using neuropsychological and psychophysical testing. Methods. 112 MS patients were randomly selected. An effort was made to ophthalmological, neurological, psychiatrical neuropsychological condition that might hamper interpretation or test performance. 49 subjects meeting all criteria were submitted to a comprehensive neuropsychological test battery of 33 representative visual indices including tests such as the Hooper VOT, the Benton Facial Recognition Test and Form Discrimination and the Judgment of Line Orientation Test. Temporal resolution capacity of early visual pathways was evaluated with a Double Flash Threshold determination (DFT). Here, the neuropsychological part is highlighted. Results. MS patients showed a significantly (p<0.005) greater number (mean 3.68, SD 3.42) of failed tests than a group of properly matched normal controls (NC) (n=30) (mean 1.8. SD 2.41). True rate of visual disorders in our sample is estimated at 32% Among MS DFT proved to be a significant predictor of this number of failures. Based on the neuropsychological testing 37% of the MS and 12% of the NC could be classified as impaired. The four most sensitive tests assessed color perception and aspects of object or of space perception. Among these the Farnsworth Munsell 100 Hue Test was the most sensitive (39% failures). Conclusion. Although the increased DFTs, suggesting impairment of the magnocellular system. The MS patients failed in the neuropsychological tests boundary on the dorsal as well as on the central pathway in the cortex. Data further suggest that MS damage may primarily affect both dorsal and ventral stream functions. As much surprisingly, the predictive value of presence of magnocellular pathway disturbances seems to extend to either kinds of higher visual problems.

HEIGHT AND DISTANCE IN THE VISUAL FIELD: CALIBRATING A MONOCULARLY GUIDED REACH J.J. Marotta* and M.A. Goodale. Vision and Motor Control Laboratory, Univ. of Western Ontario, London, Ontario, Canada, N6A-5C2

It remains unclear as to which of the many available depth cues humans use to calibrate manual prehension. If a target sphere is presented in the same location in one of two predictable arrays (varying height or varying distance) would subjects learn to use relative position information to calibrate their reach and grasp? Thirteen subjects reached out in the dark to one of 3 illuminated styrofoam spheres presented one at a time on a rod placed in a board. In one block of trials, spheres were placed at one of 3 different distances at eye-level (20, 30 and 40cm from the board). In the other block of trials, spheres were placed at one of 3 different heights (eye-level, 5cm above and 5cm below) at a distance of 30 cm from the board. Grasping movements directed at spheres placed at eye-level, 30 cm from the board, in both series were compared. Reaches to the spheres in the series in which distance was varied took longer, reached lower peak velocities, and had longer deceleration periods than reaches made to spheres in the series in which distance was varied. The visuomotor system is able to use relative height better than it can use relative distance to program and control reaching and grasping movements under monocular viewing. Supported by NSERC grant A6313.

FORM FROM COLOR DISCRIMINATION FOR BOTH ISOLUMINANT AND ISOBRIGHT STIMULI IN A SUBJECT WITH CEREBRAL ACHROMATOPSIA. R.W.Kentridge1*, C.A.Heywood1 & A.Cowey2. 1:Psychol. Dept., Univ. of Durham, Durham DH1 3LE, UK. 2:Psychol. Dept., Univ. of Oxford, South Parks Road, Oxford OX1 3UD, UK.

The cerebral achromatopsic subject MS can discriminate equiluminant forms defined by color even though he cannot discriminate colors themselves, luminance being defined by flicker photometry. This ability persists even in the presence of random luminance masking. Moreover, his chromatic contrast sensitivity was indistinguishable from that of normal subjects. We tested the hypothesis that this may be because of differences in the subjective brightnesses of colors at low temporal frequencies in comparison to those obtained by flicker photometry. In particular, red/green mixtures (yellow to us) may be perceived as less bright than photometrically equiluminant reds or greens at low temporal frequencies. In an isoluminant red/green sinusoidal grating of spatial frequency f such red/green subadditivity can be compensated for by adding luminance isochromatically at a frequency of 2f at a phase of 90°. Using a motion slowing paradigm we show that both MS and normal subjects perceive red/green 3.8 cycles per degree gratings, moving at 1.84 Hz as being most uniform in brightness with the addition of a 5% luminance contrast compensation grating to a photometrically isoluminant stimulus. We show that the ability of MS to discriminate grating orientation is not diminished when using this compensated isobright stimulus in comparison to an isoluminant stimulus. We conclude that evidence for separate form from color and color discrimination processes cannot be accounted for by subjective brightness artefacts.

USING ASSOCIATIVE LEARNING TO TEST ZEBRAFISH COLOR VISION, <u>L.A. Fetsko, E. Cohen, J.B. Sheffield*, M.I. Mote</u>. Dept. of Biology, Temple University, Philadelphia, PA 19122.

In an attempt to determine if zebrafish can learn and if they are capable of using their four types of cones to learn, an associative learning paradigm was designed. Zebrafish were first trained to choose a color in the visible spectrum vs. dark and were then trained to choose between two color stimuli. Results show that they can discriminate red, orange, and blue from dark. They can also discriminate blue from yellow, blue from orange, blue from green, blue from UV, blue-green from UV, and yellow from orange. They do not seem to discriminate blue from blue-green. Results also support that the zebrafish are discriminating on the basis of color and not brightness.

DIFFERENCES BETWEEN VISUALLY TEXTURED MATERIALS. R.Y. Cho', V. Yang, and P.E. Hallett. Dept. of Physiology, U. of Toronto, Toronto, Ont., Canada M5S 1A8.

The behavioral differentiation between textured materials could, in principle, be based on very detailed representations, considering the diversity of receptive field types in the primary visual cortex at each point. Our results suggest otherwise. Subjects made two types of comparisons of pairs of textures: judgements of overall dissimilarity (Δ); judgements of specific dissimilarity according to each of six candidate attributes ($\Delta^{\rm h}$), e.g. "coarseness", "regularity", "lightness", etc. Regression and cross-validation methods have demonstrated that we could make good predictions of the Δ judgements with 3 to 4 of the $\Delta^{\rm h}$ judgements as predictors. Multidimensional scalings of Δ judgements are also low-dimensional. Dimensionality judgements are also low-dimensional. Dimensionality was reduced by increased viewing distance or low

lighting. phting. These results suggest that, despite the rich "" neural representation, the behavioral early neural representation, the behavioral discrimination of textures is actually based on a much sparser representation.

ROD MODULATION OF COLOR-OPPONENT CHANNELS. T.E. Frumkes*, E. Lembessis, and J. Vollaro. Department of Psychology, Queens College of CUNY, Flushing, NY 11367

Three general theories could account for the rod contribution to color vision: a) rod-photic stimulation provides an excitatory input to the "blue-cone" trichromatic zone (Trezona, 1970); b) rod-photic stimulation provides an excitatory input to the "luminosity" channel (Lie, 1963; Stabell and Stabell, 1967); and c) rod-adaptation modulates the output of cone-mediated, coloropponent mechanisms. In the parafoveal retina of normal psychophysical observers, we compared the influence of rod-light and rod-dark adaptation upon chromatic vision using monochromatic stimuli chosen to approximate the unique hues of blue (472 nm), green (512 nm), yellow (577 nm), and red (632 nm). Observers obtained specific (hue-identification) thresholds, and additionally estimated hue and saturation of 5 td stimuli using the "4+1" scaling procedures of Abramov Gordon, and Chan (1994). Our results suggest that dark-adapted rods slightly reduce the output of the blue/yellow opponent mechanism, and much more strongly reduce the output of the red/green opponent Although rods may additionally provide a direct contribution to color, our results are entirely consistent with a modulatory influence upon cone-mediated color channels.

SPATIAL FREQUENCY TUNING FUNCTIONS AND CONTRAST SENSITIVITY IN THE HUMAN VISUAL FIELD: MEG MEASUREMENTS. H.-W Chen, C. Aine-Y. E. Flynn, and C. C. Wood. Biophysics Group, MS D454, Los Alamos National Laboratory, Los Alamos, NM 87545

The human luminance spatial frequency contrast sensitivity function (CSF) has been well studied using psychophysical measurements by detecting spatial frequency (SF) grating patterns at threshold. Since the CSF is measured near threshold, it is quite possible that only the most sensitive retinal or LGN M (magnocellular) cells may contribute to the measured CSF. Therefore, measurements of SF tuning functions at different contrast levels (from near threshold to suprathreshold) may reveal information on the relative contributions between M and P (parvocellular) cell groups. It is still a controversial issue whether the ratio of M to P cells in the ratio and 1/CN in the contrast levels.

menis of SF tuning functions at different contrast levels (from near threshold to suprathreshold) may reveal information on the relative contributions between M and P (parvocellular) cell groups. It is still a controversial issue whether the ratio of M to P cells in the retina and LGN of macaque varies with eccentricities of the visual field. Some results suggest that the human M cells should have a higher contrast sensitivity and a lower spatial resolution than those in macaques. It is of interest to investigate these problems in humans using noninvasive MEG techniques. In this study, we measured the SF tuning functions as well as the CR functions at different suprathreshold contrast levels and different eccentricities of the visual field. Evoked magnetic fields were recorded with a BTi 7-channel SQUID-coupled gradiometer system in a magnetically-shielded chamber. Four subjects with normal vision participated in this study. Transient target stimuli (circular sinusoid, 266 ms duration and ~1 Hz rate of presentation) were presented at 5 different contrast. The estimated SF tuning curves were fitted by a two-stream (M & P) model. These results are consistent with the two stream (M and P) theory; at low contrast levels, the majority of responding cells may be M-type (which prefer low contrast and low SFs), resulting in lower peaks in the SF tuning curves. With an increase in contrast level, more P-type cells (which prefer high contrast levels and high SFs) may be activated, resulting in curves with peaks shifted in the direction of higher SFs. As predicted by the two-stream model, the M system shows a narrow-band low-pass SF tuning property, whereas the P system shows a broad-band band-pass SF tuning property, whereas the P system shows a broad-band band-pass SF tuning property, which is consistent for all the 4 subjects. The results also indicate that the techniques developed in this study may provide useful information on the relative involvement of magno-like and parvo-like systems at different eccentricities.

INTEGRATION ACROSS SPATIAL FREQUENCY CHANNELS IN SPEED

DISCRIMINATION. D. Ascher¹, L. Welch², N. M. Grzywacz^{3*}

¹Department of Cognitive and Linguistic Sciences and ²Department of Psychology, Brown University, Providence RI 02912, ³Smith-Kettlewell Eye Research Institute, 2232 Webster Street, San Francisco CA 94115.

There is converging evidence from psychophysics (Anderson & Burr, 1985; Watson, 1986) and physiology (Holub & Morton-Gibson, 1981) that the channels response sible for single grating detection have relatively narrow spatial-frequency bandwidths (1 to 2 octaves). These channels are widely assumed to provide the information used to compute retinal speed. Existing data indicate that in detection tasks information from multiple channels is not combined to increase performance. We examined whether the visual system performs such a combination when computing speed.

We report the results of experiments testing speed discrimination as a function of the spectral content of the stimuli. Subjects performed forced-choice discriminations in one of three blocked conditions: a 1 cycle per degree (cpd) sinusoidal grating, a 6cpd graton time blocked conditions, a 1-year-pet pet open standard partings upon time of the gratings superimposed. In each 150-trial block, subjects viewed gratings moving at one of five speeds centered around 2° s⁻¹, and judged whether the stimulus speed was faster or slower than the mean speed. By fitting a cumulative Gaussian to the proportion of "fast" responses for each speed, an estimate of the discrimination threshold was obtained for each condition. Low contrasts (randomized between 4% and 8%) and short stimulus durations (120ms) were used to avoid ceiling effects.

Our results indicate that speed discrimination is better for displays containing two gratings of equal speeds but differing by 2.5 octaves in spatial (1cpd and 6cpd) and temporal frequencies (2Hz and 12Hz) than for displays containing only the component gratings. These results are compatible with several models of speed perception and are predicted by models that posit integration of speed measures across multiple spatial scales. Our data are compared to a version of the Grzywacz & Yuille (1990) model, modified

INTERACTIONS BETWEEN SPATIAL FREQUENCY, LUMINANCE CONTRAST AND BINOCULAR DISPARITY IN MOTION COHERENCY Gene R. Stoner* and Thomas D. Albright, Salk Institute, La Jolla. CA 92037.

Plaid patterns composed of component gratings that differ in spatial frequency (SF), luminance contrast (LC) or binocular disparity (BD) tend not to cohere (Adelson and Movshon, Nature, 300: 523-525, 1982; Adelson and Movshon, J. Opt. Am. A, 1:1266, 1984). Moving plaid patterns configured to mimic one occlusive grating overlying another also fail to cohere (Stoner et al., Nature, 244:153-155, 1990; Trueswell and Hayhoe, Vis. Res., 33:313-328, 1993). We hypothesized that plaids with dissimilar components fail to cohere because these components are interpreted as occlusive surfaces lying in different depth planes.

It is known that when depth-from-occlusion and depth-from-binocular disparity cues support the same depth-ordering, both segmentation in depth and motion non-coherency are more likely to be perceived than when these two cues conflict. To test our hypothesis, component gratings of either different SF or different LC were superimposed and the BD between them varied from trial-to-trial. Subjects judged whether the gratings occupied the same depth plane on one set of trials. Motion coherency was judged in a second set. We predicted that if relative SF and LC elicited a particular occlusion-based depth-ordering, both types of judgments should depend upon which grating was stereoscopically in front of the other.

We found that whether subjects were likely to report the component gratings to lie in the same plane depended upon which grating (i.e. high vs. low LC or high vs. low SF) was stereoscopically closer. Perceptual motion coherency exhibited a parallel dependency. We conclude that although these types of plaid patterns are not intentionally configured to mimic occlusive superimposition, the visual system does its best to interpret such stimuli in terms of real-world surfaces. Channel and non-fourier motion accounts of motion coherency are rendered insufficient by these results. Supported by MH 50706.

THE EXTRAORDINARILY RAPID DISAPPEARANCE OF ENTOPTIC IMAGES. <u>D. M. Coppola* and D. Purves</u>, Department of Neurobiology, Duke University, Durham, NC 27710.

It has been known for more than 40 years that images fade from perception when they are kept at the same position on the retina by abrogating eye movements. The time course of image degradation, typically studied by close-fitting contact lenses with reflectors to stabilize the retinal image, has generally been reported to be a few seconds to a minute or more, depending upon the conditions. We have recently examined a different sort of stabilized image, the shadows of retinal vessels that can be generated by illumination with an appropriate source. As described in detail by Helmholtz, vascular shadows can be visualized by rapid movement of a point source of light at the focal point of the eye, but disappear when shadow motion across the retinal surface is stilled. To explore the duration of such images, we constructed a device that translated a light over a 6 mm horizontal path at frequencies between 1-15 Hz; a computer program started and stopped the movement of the light source, controlled its velocity, and recorded the subjects' responses. Our results show that: (1) images of entoptic vascular shadows in central vision disappear less than 80 msec after the movement required for their perception ceases; (2) the retinal image motion necessary to maintain the percept of entoptic images is several times greater than that which can be generated by eye movements. The disappearance of these perceptions implies an active and extraordinarily rapid (>10 Hz) mechanism of image erasure and creation [Supported by NIH grant NS29187].

349.11

CONFIGURATION-DEPENDENT PHYSIOLOGICAL SUM-MATION IN HUMAN FOVEAL VISION. <u>U. Polat* and A. M. Norcia</u> Smith-Kettlewell Eye Research Institute San Francisco, CA. 94115

Collinear (co-axial and co-oriented) long-range spatial interactions predominate over other iso-orientation interactions psychophysically (Polat & Sagi, 1993, 1994) and neurophysiologically in humans (Polat & Norcia, 1996) and in single units of cat V1 (Mizobe et al, ARVO 1996). In these studies, facilitation for collinear configurations was found only near contrast threshold and suppression occurred for higher contrasts. Herein, we explored the shape and extent of the spatial summation region governing contrast thresholds for collinear and non-collinear patterns using the human VEP. The stimuli were either symmetrical or elongated Gabor signals that were temporally modulated at 4.1 Hz. Contrast thresholds were estimated using a swept contrast technique. The Gabor envelope orientation was either vertical, oblique or horizontal and the carrier grating orientation was vertical. Thresholds improved more as the Gabors were elongated for collinear combinations than they did for the non-collinear ones. The response was also larger and faster for collinear configurations, but only near threshold. The pattern of results is consistent with an elongated mechanism that pools signals preferentially along the orientation axis. This mechanism may enhance the saliency of extended contours. Supported by EY06579.

EVIDENCE FOR STRIATE CORTEX SITE FOR BINOCULAR RIVALRY. J.Beusmans.* Nissan Cambridge Basic Research, 4 Cambridge Center, Cambridge, MA 02142, USA.

When shown different images to each eye, humans experience "binocular rivalry," a continual alternation between perceiving the left and right eye image. I present evidence that rivalry is caused by competition between neuronal populations that are not in extrastriate cortex (as suggested by Leopold et al., ARVO, 1996) and that are not exclusively monocular. Let P1 be a clockwise (/) diagonal, blue-white square-wave grating, and let

Let P_1 be a clockwise (/) diagonal, blue-white square-wave grating, and let P_2 be a counter-clockwise (\) diagonal, orange-white grating (both gratings cpd, 10 deg in diameter, with a contrast of 0.3). A vertical chimera $V(P_1P_2)$ combines the left half of P_1 with the right half of P_2 . Shown $V(P_1P_2)$ to the left and $V(P_2P_1)$ to the right eye, subjects alternately perceived the P_1 and P_2 patterns, but not the vertical chimeras. The same holds for horizontal chimeras, although some subjects now perceived the chimeras occasionally. This eliminates competition between exclusively monocular channels.

This eliminates competition between exclusively monocular channels. To determine whether competition is at or before extrastriate cortex, I used dritting gratings. Now P1 drifts towards the upper-left (UL) and P2 towards the upper-left (UR). Shown P1 and P2 dichoptically through circular apertures, subjects perceived either P1 with UL motion or P2 with UR motion, never upward motion (the pattern or plaid motion if the motion signals of P1 and P2 had been combined). With the corresponding drifting vertical chimeras, subjects also perceived either P1 with UL or P2 with UR. They never perceived upward motion, even though the motion in each vertical chimera was unambiguously upward. Assuming that humans have an MT-like extrastriate area, that is involved in motion perception and whose neurons are virtually all binocular and receive their input mainly from striate cortex, these results suggest that competition is at the level of striate cortex.

349.10

EFFECT OF EARLY ENUCLEATION ON THE VISUOMOTOR CONTROL OF GRASPING IN PIGEONS <u>D.Musumeci</u>, <u>G.Cesaretti</u>, <u>C.Kusmic and M.Matteoni</u> Dep. of Physiol. and Bioch., Univ. of Pisa, Italy. (SPON: Eur. Brain and Behav. Soc)

The pecking in pigeons is characterized by head fixation stops interspersed with rapid forward head thrusts, during which animals evaluate position, depth and size of the target, since the last pecking phase is ballistic. It is assumed that binocular vision enhances the accuracy and the precision of pecking. In the present research we compare the features of reaching bidimensional (2D) targets and of grasping three dimensional (3D) targets, in both reversible (intact) and chronically (early enucleated) monocular viewing. Posthatced pigeons were enucleated under general and local anesthesia and they were trained and tested by adult. The experimental setup consisted of a modified Skinner box in which the frontal panel was a 9° bbw VGA monitor sloped by 45° out. A "behavioral fixation" procedure ensured a constant head fixation. A single seed ($\emptyset = 4$ or 7,5 mm) was delivered after a peck to a 2D target ($\emptyset = 7,6$; 3,5; 2 mm), displayed on the monitor. Pecking sequences at spots and seeds were videorecorded and off-line analyzed. Time, distance of fixation, grasp efficiency and bill gape were measured. The main results concerning 2D targets show a remarkable impairment of early enucleated pigeons in calibrating the opening of the beak to the target size, whereas pigeons tested in reversible monocular condition did not behave very differently than in binocular vision. As regard to 3D targets, only the early enucleated pigeons developed a peculiar feature during target fixation, in fact they showed head movements (about 5 mm) of approaching to the seed. Summarizing, the occurrence of binocular interactions seems to be essential for a suitable visuomotor control in the reaching and the grasping. However, monocular strategies are able to compensate some few aspects of the deficit, namely the control on the bill gape in relation with three dimensional features of the target; of the target of the target of the target of the target of the target of the target of the target.

CHARACTERIZATION OF POTASSIUM CURRENTS IN THE RAT INFERIOR COLLICULUS USING THE IN VITRO BRAIN SLICE. M. E. Wisgirda* L.-Y. Wang and L.K. Kaczmarek. Depts. of Pharmacol., Cell. & Mol. Physiol., Yale University School of Medicine, New Haven, CT 06520. The inferior colliculus (IC) is a major center for integration of information in the auditory system. Several members of the Shaker and Shaw potassium channel gene

families have been shown to be highly expressed in this nucleus. We have used the whole cell patch clamp recording method to study potassium currents in the rat IC. Brain slices (200 μ m) containing the IC were obtained from P8-14 rats and

maintained at room temperature in oxygenated saline until use.

Current clamp recordings revealed three response patterns to a series of current steps (-0.5 to 2 nA, 150 ms). In one class of cells, suprathreshold current steps evoked only a single action potential (AP). In a second class, increasing current steps evoked multiple APs near the beginning of the step. In the third class, increasing current steps evoked increasing numbers of regularly spaced APs. Similar firing patterns have been described in intracellular recordings and are termed onset, adapting, and regular patterns, respectively (D. Peruzzi, pers. comm.) In all cells tested, application of 1 mM TEA broadened the AP, reduced the afterhyperpolarization, and reduced the total number of APs.

IC neurons express large outward currents that begin to activate at between -80 and -60 mV. Voltage steps to as high as +60 mV were never sufficient to saturate the current. Application of 1 mM TEA produced a blockade of between 15-60% of the total current. In 8 of 16 cells, the TEA-sensitive component was very slowly activating, suggesting the presence of a Ca-activated potassium current. 100 nM DTX produced a 40-60% blockade of current in 3 of4 cells tested, and had no effect in one cell. These results indicate that IC neurons express multiple potassium currents, and suggest that different neurons within the IC express different complements of potassium channels. Supported by NIH grant GM 48851.

DISCRETE IBOTENATE LESIONS OF RAT INFERIOR COLLICULUS ALTER PERFORMANCE OF A SOUND-GUIDED NAVIGATION TASK. M.C. Zrull*, R.E. Bowman, and A.J. Trivette. Department of Psychology, Appalachian State University, Boone, NC 28608

Perceptual or proximal cued locomotor tasks are often used to examine sound localization behavior and its neural control. The present study examines the role of inferior colliculus (IC) in mediating spatial navigation when distal sound cues provide salient information about the location of a goal objective. Adult, male hooded rats learned to navigate through a modified Hebb-Williams maze to obtain a water reward. Sighted (V+A, N=12) and surgically blinded (AUD, N=12) rats received sequential, spatially distinct noise bursts (125 ms, 2-16 kHz, 50 dB) as cues to avoid blind alleys. A control group (VIS, N=12) had only intra-maze visual cues to guide navigation. After a series of 22 sessions with 8 trials each, half of the rats were anesthetized and bilateral ibotenate (IBO, 63 mM, 1.0 µL) lesions targeted at the central nucleus of IC were made. A second series of 22 sessions was then conducted. Performance was quantified as the percent of trials with at least 1 blind alley error for the final 2 expected and final 6 sessions unexpected maze sessions. AUD and V+A rats with IC lesions ran more error trials than during pre-lesion sessions, and all sham operated controls and VIS rats with lesions ran fewer post-surgery trials with errors in both expected (p<05) and unexpected mazes (p<05). Trials with errors increased over baseline by 4.8% and 12.1% for the AUD lesion group and by 69.0% and 58.4% for V+A rats with lesions in expected and unexpected mazes, respectively. Cell counts of Nissl stained material indicate similar IC lesions in all groups receiving IBO injections. These results suggest that the IC may contribute to integration of localized acoustic information into a useful neural representation of the environment. Supported by NIDCD grant DC02476.

GABA IN INFERIOR COLLICULUS OF AWAKE, FREELY MOVING RAT: MICRODIALYSIS AND STEREOTAXIC COORDINATES. D.C.Jackson, Y.Hu and K.L. Drew! Institute of Arctic Biology, Univ. of Alaska Fairbanks, Fairbanks, AK 99775.

Significant age related changes in GABAergic neurotransmission have been observed previously in rat inferior colliculus (IC) and may be related to neural presbycusis. However, little is known about how sound or other neurotransmitters regulate GABA release in this central auditory nucleus and implantation of microdialysis probes into the IC are complicated by its proximity to the transverse sinus. The purpose of the present study was to establish a technique for using microdialysis to sample extracellular GABA in the IC of awake, freely moving rats. Stereotaxic coordinates which spared rupture of the sinus and placed cannula in the IC of out of 6 times in 390 to 490 g rats were as follows: With the incisor bar raised to 9.7 mm and the micromanipulator arm tilted 13° lateral to perpendicular probes were implanted 2.1 mm anterior to interaural line, 3.0 mm lateral to lambda and 5.0 mm ventral to brain surface. Basal perfusate concentrations of GABA in awake rats sampled 48 and 72 hrs following implantation of 2.0 mm CMA/11 probes perfused at a rate of 1.0 µl/min with aCSF were (mean +/-SEM) 0.055+/-0.03 and 0.025+/-0.008 pmol/10 µl. Basal levels reported here are 50 times lower than reported by Goldsmith et al., 1995 in ketamine/xylazine anesthetized guinea pigs. Use of microdialysis to sample from the IC without confounding effects of anesthetics will contribute to the study of sound and drug-induced changes in neurotransmitter release in young and aged rats. EFFECTS OF ACUTE SPIRAL GANGLION LESIONS ON THE TUNING PROPERTIES AND TONOTOPIC ORGANIZATION OF NEURONS IN THE CAT INFERIOR COLLICULUS. R.L. Snyder, D.G. Sinex*, E.J. Walsh, and J.D. McGee. Dept. of Otolaryngology, Univ. of California, San Francisco, CA 94143, Dept. of Speech and Hearing Science, Arizona State Univ., Tempe, AZ 85287, Boys Town National Research Hospital, Omaha, NE 68131.

Many studies have reported plastic changes in the frequency organization of central auditory areas. These studies have employed mechanical or acoustic disruption the organ of Corti, altering its mechanical and physiological characteristics. In this study mechanical lesions were made in a restricted region of the spiral ganglion, leaving the organ of Corti intact. In addition, the consequences of the lesions were assessed immediately after their production, without prolonged recovery periods. Initially, CAP audiograms were constructed, and then the tonotopic organization of the inferior colliculus (IC) was mapped by obtaining single and multiunit response areas at 100 micron intervals. At each location, response areas were acquired to contralateral, ipsilateral, and binaural tones. Following this initial mapping, a 1 mm segment of the contralateral spiral ganglion was then destroyed. The extent and completeness of the lesion was confirmed by reconstructing the CAP audiogram. Then the IC was re-mapped. As expected, IC neurons were less sensitive to frequencies represented within the lesioned area as demonstrated by broadened frequency tuning curves and elevated minimum thresholds. However, they were more sensitive to edge frequencies, i.e., those represented within areas adjacent to the lesion, as indicated by broader tuning curves without elevated minima, more neurons tuned to edge frequencies, broader spatial tuning curves and steps in the normally smooth frequency gradient. These results suggest that the 'plastic' changes reported by previous studies require little of no experience and occur within 24-36 hrs following the lesion.

PHARMACOLOGICAL STUDIES OF ACTIVITY-DEPENDENT INHIBITION IN THE INFERIOR COLLICULUS OF THE RAT USING A PAIRED-CLICK PARADIGM: A NOVEL MECHANISM OF INHIBITION IN THE AUDITORY

W.S. Szczepaniak and A.R. Moller*, Dept. of Neurological Surgery, Univ. of Pittsburgh Sch. of Med., Pittsburgh PA, 15213.

It is well known that neurons of the inferior colliculus (IC) receive a considerable amount of both GABAergic and Glycinergic inhibitory influence, and that these inhibitory mechanisms play an essential role in the processing of auditory information by neurons of the IC. We studied activity-dependent inhibition on neurons of the IC by recording evoked potentials from the IC to paired click stimuli (94dB,Pe SPL), and varying the interval between the first and second click (interstimulus interval (ISI)). We show that the amplitude of a peak (generated postsynaptically in the IC) in the response that is elicited by the second click is depressed by about 80% of the amplitude of the peak that is elicited by the first click when the ISI is 1ms, and that this depression decreases slowly with increasing ISI to about 20% when the ISI is 100ms. A microinjection of the GABA, antagonist bicucullene, did not reduce this depression, and in fact, caused a small, but statistically significant, increase in this depression. Microinjection of the GABA_B antagonist phaclofen, and the glycine antagonist strychnine, did not affect this relationship. We interpret these findings to show that very brief acoustic stimuli can elicit inhibitory mechanisms within the IC that are active for a very long time and influence subsequent input, and that the mechanism(s) responsible for this phenomenon do not involve any of the major inhibitory systems known to influence neurons of the IC. We are currently studying the effects of other pharmacological agents on this phenomenon.

MONAURAL EVOKED RESPONSES IN THE RAT'S INFERIOR COLLICULUS AFTER BLOCK OF THE CONTRALATERAL DORSAL NUCLEUS OF THE LATERAL LEMNISCUS AND INFERIOR COLLICULUS. L. Li* and J. B. Kelly. Lab. of Sensory Neuroscience, Psychology Dept., Carleton Univ., Ottawa, Canada K1S 502.

We have previously shown that binaural inhibition in the central nucleus of inferior colliculus (ICC) is due in part to a GABAergic projection from the contralateral dorsal nucleus of the lateral lemniscus (DNLL). In the present study we have investigated the effects of suppression of neural activity in the contralateral DNLL and contralateral inferior colliculus (IC) on monaural evoked potentials (EPs) recorded in the ICC with microelectrodes, before and after local injection of kynurenic acid (KYNA) into the contralateral DNLL or contralateral IC kynurenic acid (KYNA) into the contralateral DNLL or contralateral IC. Following KYNA injection into the contralateral DNLL, the EPs recorded in the ICC to monaural ipsilateral stimulation were enhanced. In contrast, KYNA injection into the contralateral IC decreased the responses in the ICC to ipsilateral stimulation. Responses to contralateral monaural stimulation were not substantially affected by injections into either the contralateral DNLL or the contralateral IC. The data suggest that in the rat's ICC evoked responses to ipsilateral contralateral productions are accountly feelible to the response to ipsilateral contralateral contra stimulation are generally facilitated by neural activity in the contralateral IC and suppressed by activity in the contralateral DNLL.

AUDITORY SPATIAL TUNING OF INFERIOR COLLICULUS NEURONS IN THE GUINEA PIG

S.J. Sterbing*, K. Hartung*, K.-P. Hoffmann*, J. Blauert*, Lehrst. f. allg. Zoologie und Neurobiologie*, Lehrst. f. allg. Elektrotechnik und Akustik*, Ruhr-Universität Bochum, 44780 Bochum, Germany

The head related transfer functions (HRTFs) of pigmented guinea pigs were measured under free-field conditions with miniature microphones placed in the external ear canal. The complete upper hemi-field was sampled $(-10^{\circ} \text{ to } 90^{\circ}$ elevation, 10° resolution, and 0° to 345° azimuth, 15° resolution). The interindividual differences of the monaural and binaural cues of the HRTFs made it necessary to create the stimuli (virtual sound sources) for the electrophysiological experiments by filtering white noise bursts with individual HRTF. The stimuli were pseudorandomly presented via earphones. The single-unit activity of the central nucleus of the inferior colliculus (ICc) was recorded with glass micropipettes in parallel dorsal to ventral tracks. In addition to the recordings of the spatial tuning characteristics, the frequency and sound pressure level tuning as well as coventional bin- or monaural characteristic were determined by using pure tone stimulation. More than 90% of the ICc units were sharply tuned in azimuth and elevation. Although the majority of the neurons preferred directions in the central and lower contralateral hemi-field. preference for frontal or back positions and upper elevation positions also occurred frequently. It turned out that the classification based on binaural pure tone stimulation (best interaural delay, best interaural level difference, EE-, EI-, E0-classification etc.) cannot predict the space position tuning of an ICc neuron. One exception, however, is when individual HRTFs are taken into account.

DIRECTIONAL MECHANISMS AND SPATIAL PREFERENCES OF SINGLE UNITS IN THE CAT'S INFERIOR COLLICULUS (IC). Pointer, F.K. Samson and T.J.Imig, Dept. of Physiology, Kansas Univ. Med. Ctr., Kansas Cty, KS, 66160. Directional mechanisms and spatial preferences of high-frequency azimuth-sensitive cells to broad band noise burst stimulation are similar in the primary auditory cortex (A1) and medial geniculate body (MGB) of barbiturate-anesthetized cats. Binaural-directional (BD) cells were azimuth-insensitive or unresponsive to monaural stimulation. BD tuning derives from binaural inhibitory (EI), facilitatory (FC) or inhibitory/facilitatory (FI) interactions. Monaural directional (MD) cells were azimuth-sensitive to monaural noise stimulation. MD cells received either exclusively monaural (EO) or EI inputs. To elucidate where those mechanisms appear in the ascending auditory pathway and to assess colliculo-thalamic transformations in spatial preferences, recordings were obtained in the IC under conditions similar to those used in the MGB or A1. MD and BD proportions in the IC were similar to those in the MGB and A1, indicating a segregation of these mechanisms in the IC. IC BD cells exhibited binaural interactions similar to those found at higher levels. In addition to MD-EO and MD-EI cells, some IC MD cells exhibited FAC or FI interactions. IC BD-EI cells preferred exclusively contralateral positions whereas at higher levels some preferred ipsilateral positions. Moreover, spatial preference of IC MD cells was limited to contralateral positions. Moreover, spatial preference. Correspondingly, all IC cells were excited principally by the contralateral erwhereas MGB or A1, a few MD cells also exhibited ipsilateral preference. Correspondingly, all IC cells were excited principally by the contralateral erwhereas MGB or A1 tells were excited principally by the contralateral erwhereas MGB or A1 tells were excited principally by the contralateral erwhereas at a lower level than previously thought (supported by FCAR, FRSQ and NID

FORWARD MASKING DIFFERENTIALLY AFFECTS RESPONSIVENESS IN RAT INFERIOR COLLICULUS. <u>P.G. Finlayson</u>. Dept. of Surgery, Rotary Hearing Centre, University of British Columbia, Vancouver, B.C. Canada, V6T-2B5. Extracellular single unit responses of neurons in the central nucleus of

Extracentular single unit responses of neurons in the central nucleus of the inferior colliculus (ICC) of anaesthetized Long-Evans rats were examined with a forward masking paradigm. Pure tone "probe" stimuli were presented at the same frequency and intensity as preceding "masking" pure tone stimuli. The intervals between monaural and binaural masking and probe stimuli were 2, 8, 32, 128, 512, and 2014 ms. The effect of masking on responses of ICC neurons was dependent on the temporal response pattern of discharge to 200 ms tones.

on the temporal response pattern of discharge to 200 ms tones.

The majority (~2/3) of ICC neurons exhibited short-term adaptation, as responses to probe stimuli were decreased following an equal intensity masking tone. The level of responsiveness recovered slowly over time. These ICC neurons exhibited transient excitatory responses.

Probe tone responses were facilitated at delays of 32 or 128 ms, and minimal at long delays following 200 ms masking stimuli in ICC neurons with bimodal response patterns. These cells exhibited a transient response, a pause in activity, followed by sustained activity. Shortening the duration of the masking tone produced predictable effects: i) following 50 ms maskers, no responses to probe tones were present at short delays (2 to 32 ms), and responses increased at longer delays. ii) following 100 ms maskers, responses to probe tones were facilitated at short delays.

facilitated at short delays.

Masking shapes ICC neuron responses over periods of hundreds of milliseconds. These processes may be important for detecting patterns in complex sounds and may be involved in noisy listening conditions.

MODULATION OF AUDITORY RESPONSE BEHAVIOR IN THE RAT INFERIOR COLLICULUS BY BEHAVIORAL CONTEXT. C.Felsheim*, J.Ostwald, Dept. of Animal Physiology, University of Tuebingen, D-72076, Germany.

Evidence from recent studies in the auditory cortex suggest that the auditory system is dynamic and depends on the behavioral context. Modulation of neuronal responses on subcortical levels due to the behavioral context, however, is still unknown. To test for such modulations, we recorded from the IC of behaving rats in two different behavioral paradigms.

The influence of learning was studied in an operant conditioning task in which the animals learned to respond to a pure tone stimulation and to ignore independently presented noise pulses. Unit responses after learning were compared to those recorded before and during the learning phase.

In the second paradigm, attentional effects on neuronal responses was investigated by quickly changing the behavioral significance of auditory stimuli. This could be achieved by presenting the same stimulus first in a discrimination task and second, shortly thereafter, as an behaviorally irrelevant stimulus after animals were rewarded for their response.

In both tests it could be shown that already on a subcortical level auditory evoked neuronal responses are modulated by the behavioral context of a stimulus.

EFFECTS OF EAR PLUGGING ON RESPONSES OF AZIMUTH-SENSITIVE NEURONS IN MEDIAL GENICULATE BODY (MGB) AND PRIMARY AUDITORY CORTEX (AI) OF BARBITURATE-ANESTHETIZED CATS. F.K. Samson, P. Poirier, W.A. Irons and T.J. Imig*.

Imig*.

Directionality of high-frequency neurons to broad band noise bursts in AI depends upon monaural and binaural interactions. Monaural directional (MD) cells are sensitive to the azimuth of monaurally presented stimuli. Some of them are monaural (MD-E0) and others exhibit binaural inhibition (MD-E1). Binaural directional (BD) cells are unresponsive to monaurally presented noise bursts or insensitive to their azimuth. They exhibit binaural inhibition (BD-EI), or facilitation in the presence or absence of inhibition (BD-FAC). The MGB contains neurons with the same MD/BD characteristics as AI and they are distributed in about the same proportions (i.e., MD, 30%; BD, 70%). However, MD-EI and BD-FAC cells were more numerous in AI than in the MGB (MD-EI: AI, 64%; MGB, 36% of all MD cells. BD-FAC: AI, 66%; MGB, 51% of all BD cells). A recent report from this laboratory shows that AI contains a higher proportion of azimuth-sensitive cells with nonmonotonic level tuning (NM) than the MGB and suggests that there is synthesis of NM azimuth-sensitive responses in AI. To find out whether this difference in proportions is common to all azimuth-sensitive neurons or is related to a particular MD/BD response category, we have compared the level tuning of MD and BD cells in the MGB and AI. We found that AI contains a greater proportion of NM cells than the MGB in all cell categories, suggesting that the proposed synthesis is not related to a particular MD/BD response category. INTEGRATION OF SYNAPTIC INPUTS IN IDENTIFIED NEURONS IN THE INFERIOR COLLICULUS. <u>G. Reetz*, G. Ehret.</u> Dept. Comparative Neurobiology, University of Ulm, 89069 Ulm, Germany.

One important function of the central nucleus of the inferior colliculus

One important function of the central nucleus of the inferior colliculus (ICc) is the integration of ipsi- and contralateral afferent inputs from almost every auditory brainstem nucleus. We recorded intracellularly from neurons of the ICc in brain slice preparations to investigate the relative contribution of excitatory and inhibitory inputs from the ipsilateral lemniscus lateralis (iLL), the commissure of Probst (CP), and the commissure of the IC (CoIC). Bipolar stimulation electrodes were placed in the iLL, the CP, and the CoIC. Morphology of the cells was revealed by iontophoretic injection of biocytin and subsequent staining using HRP and DAB.

Neurons in all regions of the ICc predominantly responded to depolarisation by intracellular current injection with a phasic-tonic spike pattern (onset-sustained, 20 out of 40 cells). Few neurons with an onset response (N=8) were most often found in the ventral ICc. Neurons with a tonic (N=5) or with a delayed response (N=7) were located in the dorsal or rostral ICc. All neurons were identified as multipolar cells, with variations of shapes of somas and of dendritic trees. The axons projected either into adjacent laminae of the ICc, to the brachium of the IC, into the ICx, to the CoIC, or to the LL.

All neurons received excitatory inputs. A composed excitatory/inhibitory postsynaptic potential (E/IPSP) was observed in 47% of the cells. In general, EPSPs or IPSPs upon stimulation of all of the three fibre bundles arrived with latencies of 1.5 to 10 ms, indicating that the multipolar neurons receive both direct synaptic inputs and/or indirect inputs via interneurons. Our data indicate that these neurons are involved in intrinsic and ascending information processing.

THE POST-MOVEMENT EVOKED MAGNETIC FIELD: A MANIFESTATION OF SOMATOSENSORY FEED-BACK OR MOTOR FEED-FORWARD? IT Davis*, JD Lewine, R Thoma, D Hill, K Paulson, WW Orrison, Jr, The New Mexico Ridgecrest Dr., SE, Albuquerque, NM, 87108

Self-paced movements are associated with a complex movement-related

neuromagnetic signal with several components including a pre-movement readiness field, and a large amplitude post-movement evoked signal that has been demonstrated previously to originate from somatosensory cortex. The post-movement signal is generally interpreted as generated by peripheral feedback, but direct evidence in support of this interpretation is weak. Recently, we have used a whole-head, 122-channel sensor array to record movement related activity while subjects perform self-paced thumb extensions. As has been reported previously, the movement related field shows multiple sub-components. At approximately 50 msec prior to movement the premovement signal peaks as the primary motor field. The motor field is unilateral and has its origin in area 4 of the precentral gyrus contralateral to the side of movement. The post-movement field typically peaks 50-70 msec after movement. In contrast to the primary motor field, the post-movement field is BILATERAL in many subjects. This activity is best described by two equivalent current dipoles, one located

in each of the right and left primary somatosensory cortices, with the contralateral source activity peaking approximately 15 msec before the ipsilateral activity.

The median nerve was electrically stimulated and the response used for comparison with post-movement field. Following electrical stimulation of the median nerve, contralateral somatosensory cortex is activiated at and after 20 msec post-stimulus. The neuromagnetic signal remains specifically unilateral until 70-90 msec post-stimulus at which time ipsilateral SII activity is seen. Ipsilateral SI activity is not seen. The implication of the movement-related and somatosensory results is that the post-movement activity seen originating from SI on the side ipsilateral to movement does not reflect somatosensory feedback, but rather, some type of motor feedforward. Given this, the origin of the contralateral SI activity is also likely to reflect, at least in part, feedforward mechanisms.

EFFECTS OF REACTION TIME ON VISUOMOTOR INTERACTION: SPATIOTEMPORAL PATTERNS OF INTRA- AND INTERHEMISPHERIC CORTICAL ACTIVATION. C.D. Saron*, H.G. Vaughan, Jr., G.V. Simpson, and J.J. Foxe. Depts. of Neurosci. and Neurol., Albert Einstein Coll of Med. Bronx, NY, 10461.

This study extended our previous work which suggested differing activations of interhemispheric routes (motor or visual) for fast vs. slow reaction times (RTs) during a lateralized visuomotor task. We used a large number of responses (1512/condition) to allow examination of the effects of small differences (10 ms) in response speed. Event-related potentials (ERPs) from 62 scalp sites were elicited from 2 right-handed males using wedge-shaped checkerboards in the left or right hour visual fields in a simple (left or right hand response) RT task. Control conditions used stimuli without responses and responses without stimuli. The 16 ms stimuli were 2° from fixation, 3° in extent and had an ISI of 1-4 s. Subsequent analyses included topographic mapping of scalp current density (SCD) and spatio-temporal dipole analysis. Initial analyses for one subject were based upon twelve sets of ERPs per condition associated with RTs in 10 ms bins from 220 to 330 ms (mean n=95). Spherical spline interpolated Laplacian waveforms from left and right central sites showed that responses contralateral to the responding hand had consistent increasing negativity with decreasing RT peaking at approx. 150 ms post-stimulus (ps). Interestingly, a second wave of activity 150-250 ms ps was only present for RTs above the median suggesting two neural response modes for fast vs. slow RTs. Occipital waveforms revealed smaller effects, with prolonged N160 components for the slower responses, and for RVF stimuli particularly, decreased P100 amplitudes. Individual complexity of the spatiotemporal patterns of visuomotor activation is exemplified by this subject who manifests activation of the right motor cortex by way of central transcallosal projections when performing a left

CORTICAL DYNAMICS OF THE HUMAN EEG ASSOCIATED WITH BEHAVIORAL Phase Transitions in an Auditory-Motor Task J.R. Meaux, G.V. Wallenstein, A.J. Nash*, S.L. Bressler, J.A.S. Kelso Program in Complex Systems and Brain Sciences, Center for Complex Systems, Florida Atlantic University, Boca Raton FL 33431.

Cortical rerouting strategies were investigated as a function of changes in behavioral performance. 61-channel EEG recordings were collected from six subjects during performance of a coordinative auditory-motor task. Subjects (N = 6) were instructed to flex their right finger in between periodically-delivered tones (syncopation). The presentation rate of the tones increased from 1.0 to 3.0 Hz in 0.25 Hz increments after every 10 cycles. Spontaneous behavioral transitions were observed in which syncopation changed to quasi-synchronization (i.e. finger flexion coinciding with tone onset).

Fourier analysis indicated a concentration of EEG power at the frequency corresponding to the stimulus presentation rate. Relative phase measures between the EEG at the stimulus frequency and the stimulus (calculated from the negative peak in the EEG signal to tone onset) showed similar transitions from around 180 degrees (syncopation) to around 0 degrees (synchronization). To-pographical maps of EEG power at the stimulus frequency revealed that these ase changes were associated with spatial shifts of neural activity. Differences in topographical pattern between syncopated and synchronized cycles suggest a reorganization of cortical activity. Motor-only and auditory-only control conditions revealed that the topography associated with performance of the sensorimotor task involves additional areas than would be expected from the task's individual component behaviors (listening and flexing).

EFFECT OF TRAIN OF STIMULI ELICITED BY WHOLE HAND (MESH GLOVE) AFFERENT INPUT BELOW CONSCIOUS SENSATION ON EXCITABILITY OF PARIETAL AND MOTOR CORTEX MM Dimitrijevic', FE Pollo, MR Dimitrijevic. Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030

A recent study reported on how daily stimulation with a mesh-glove can modify altered motor control and improve voluntary wrist extension movement in stroke subjects with chronic neurological deficits (1). Mesh-glove stimulation targets the whole hand as a common anode to a pair of cathodes over the wrist flexors and extensors. Earlier work into the electrophysiological characteristics of single stimuli with mesh-glove afferent stimulation demonstrated that at the subthreshold level, somatosensory evoked potentials (SSEPs) could not be elicited. Extending this work in 4 healthy subjects, we examined the effects of a conditioning train (0.5 sec @ 50 Hz) below conscious sensation on a test SSEP elicited by a stimuli above sensory and motor level. The effects of an identical conditioning stimulus was also tested on motor cortex evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS). In both series of investigations, there were no profound changes in the size of the tested SSEP and MEP responses. In order to further identify underlying mechanisms involved in mesh-glove stimulation, pilot work is in progress utilizing functional MRI (fMRI) for evaluation of brain cortical activity immediately after this form of stimulation. Preliminary results have indicated that mesh-glove afferent input is projected to the posterior portion of the parietal lobe, close to the visual cortex. This discrepancy in the projection of exteroceptive and proprioceptive input to the parietal lobe might contribute to the understanding of the electrophysiological and fMRI results.

Event related desynchronization studied in an auditory SRTT paradigm P. Zhuang*, N. Dang, L.G. Cohen, C. Gerloff, M. Hallett. Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892

To investigate cortical physiology during motor learning of sequences, we studied 6 right-handed, normal hearing subjects who performed a variation of the auditory SRTT. The stimuli consisted of 4 pure tones of 4 different frequencies, 500, 1000, 1500, and 2000 Hz, lasting 200 ms. The stimuli were presented binaurally at 60 dB intensity with a constant interstimulus interval of 2 sec. The subjects were instructed to push one of four buttons with a different finger of the right hand corresponding to the 4 different tones. After practice, when the subjects were able to discriminate 4 tone signals (indicated by < 5% errors), the experimental procedure started. The first and the last blocks had a random sequence as a control. The test sequence, which began with the second block, was a repetitive cycle of 10 tones. ERD was calculated within the alpha (8-12 Hz) band from EEG recording of 30 scalp positions from -1 to 1 sec around keypresses. During the task performance, all subjects developed implicit knowledge, reflected by ability to generate the sequence.

In a previous study using a visual-motor SRTT task, we demonstrated that ERD maps revealed localized alpha power changes overlying the contralateral central or central-parietal-occipital areas with a peak of desynchronization when knowledge became explicit. In the present study, an alpha ERD was found which To investigate cortical physiology during motor learning of sequences, v

knowledge became explicit. In the present study, an alpha ERD was found which localized over central-parietal and temporal regions. A peak of desynchronization was found when the subjects first demonstrated full explicit knowledge. These electrophysiologic data suggest that transient functional "plasticity" in association with learning is related both to primary motor cortex and sensory, association areas. Both visual and auditory stimuli activate the parietal region during the SRTT suggesting that the parietal lobe plays a crucial role in sensorimotor integration of sequences

EEG BRAIN ACTIVITY: STATIC TORQUE DIRECTION AND MAGNITUDE DIFFERENCES IN THE UPPER EXTREMITY OF HUMAN SUBJECTS

A.L. Ricamato*, J.D. Given and J.P.A. Dewald, SMPP, Rehab. Inst. of Chicago, and Dept. of PM&R, Northwestern University Medical School, Chicago, IL 60611.

We have identified differences in 3D topographic voltage maps of EEG activity as a function of torque direction and magnitude using statistical analysis. We sought to determine whether there was a relationship between cortical activity and static joint torque magnitude and direction by combining EEG and EMG recordings during mechanically controlled static torque exertions in four directions and two magnitudes in the upper extremities of three subjects.

Subjects were seated with their wrists casted to a 6 degree of freedom load cell which measured the respective elbow and shoulder torques. Subjects were trained to produce elbow and shoulder torque ramps of 2 seconds duration followed by a 2 second steady state hold using visual torque feedback. Four target directions, separated by 90° and corresponding to elbow flexion-extension and shoulder abduction-adduction torques, were used in our paradigm. For each target direction, two torque load levels were used: 25% and 40% of the corresponding maximum elbow or shoulder torque. EMGs were recorded from four elbow and six shoulder muscles using surface electrodes. EEG signals were recorded from a total of 121 electrodes placed in a cap on the subjects' head. 80-100 trials of recorded EEG epochs were aligned using torque onsets and then ensemble averaged for each direction yielding SNR's > 15.

Cross-correlation analysis confirmed the validity of using t-tests on the voltage maps. Subsequently, a statistical assessment of subject specific 3D voltage maps showed statistically significant differences (p < .05) in topographic brain activity as a function of target direction (i.e. between the various elbow/shoulder torque directions). In addition, statistically significant differences in EEG responses were observed between the two torque magnitudes in the same direction. These results appear to indicate cortical activity is related to both static joint torque direction and magnitude. Supported by NIDRR H133P20016 & H133B0024.

EEG-BASED BRAIN-COMPUTER INTERFACE (BCI) COMMUNICATION: THE ROLE OF FEEDBACK IN PERFORMANCE. <u>D. J. McFarland*</u>, L. <u>McCane</u>, L.A. <u>Miner</u>, T.M. <u>Vaughan and J.R. Wolpaw</u>. Wadsworth Center, NY State Dept of Health and State University of New York, Albany, NY 12201.

Individuals can learn to control the amplitude of the 8-12 Hz mu rhythm or related higher frequency activity in the EEG recorded over sensorimotor cortex and use it to move a cursor to a target on a video screen (Electroenceph clin Neurophysiol 78:252-259, 1991 and 90:444-449, 1994). In the standard trial sequence, a target appears, the cursor appears and moves controlled by the subject's EEG, the cursor hits (or misses) the target, the target flashes for a hit (or disappears for a miss), and, after a brief pause, the next target appears. This design provides two types of feedback to the subject: cursor movement during the trial and the target flashing (or disappearing) at the end of the trial. We are studying the role of this feedback in performance.

To date, we have studied two subjects who had begun to master one-dimensional cursor control over 10 40-min sessions, each consisting of 8 3-min runs (of 20-30 trials each) separated by 1-min breaks. In the two subsequent sessions, runs of three different types were interspersed: 1) standard feedback, 2) no cursor, and 3) no cursor and no target flash (or disappearance). Trials of type 3 terminated after 4 sec. Accuracy was 79.6% with the cursor present, and 80.1% with the cursor absent. Values for R² (EEG variance associated with up vs. down targets) were 0.232 for cursor present, 0.265 for cursor absent, and 0.246 for no feedback.

These initial results indicate that, at least for short periods, trained subjects can perform satisfactorily without feedback. Thus, their EEG control is not dependent on specific visual stimulation. The importance of feedback in maintaining performance over longer periods remains to be determined. (Supported in part by NIH HD30146.)

EEG-BASED BRAIN-COMPUTER INTERFACE (BCI) TRAINING IN A MAN WITH ADVANCED AMYOTROPHIC LATERAL SCLEROSIS (ALS). <u>L.A. Miner*</u>, <u>L. McCane</u>, <u>T. Vaughan</u>, <u>D.J. McFarland</u>, and <u>J.R. Wolpaw</u>, Wadsworth Center, New York State Dept of Health and State Univ of New York, Albany, NY 12201. Humans can learn to use the amplitude of the mu rhythm or related higher frequency

Humans can learn to use the amplitude of the mu rhythm or related higher frequency EEG components to control movement of a cursor on a computer screen in one or two dimensions (Electroenceph clin Neurophysiol 78:252-259, 1991 and 90:444-449, 1994). Brain-computer interface (BCI) technology may provide a new means of communication and control for individuals with paralysis or other severe motor disorders.

The subject is a 55-year-old man almost completely paralyzed by amyotrophic lateral sclerosis (ALS). He is ventilator-dependent and currently communicates by eye movements or an eyebrow switch. He is learning BCI communication with our standard training protocol. In this protocol, 64 EEG channels are digitized and stored while he learns to use mu-rhythm activity over the sensorimotor cortex to control cursor movement. He completes 2-3 one-hour sessions per week. Over his initial sessions, high-resolution EEG frequency and topographic analysis of the stored data was used to select optimal EEG channels, spatial filtering method, and frequency band. Changes in the online algorithm derived from this analysis, combined with his gradual mastery of EEG control, are producing a progressive improvement in the speed and accuracy of cursor movement. His rate of learning is comparable to that of non-disabled

These data, and comparable results from other disabled subjects, suggest that, with further development, EEG-based BCI communication could be of substantial value for those with severe movement deficits. We are currently exploring options for converting one-dimensional cursor control into a useful single-switch control system. (Supported by The National Center for Medical Rehabilitation Research, NICHHD, NIH (HD30146).)

EEG-BASED BRAIN COMPUTER-INTERFACE (BCI) COMMUNICATION: OFFLINE ASSESSMENT OF ALTERNATIVE CONTROL ALGORITHMS. H. Ramoser*, D.J. McFarland*, and J.R. Wolpaw², 'Graz Univ of Tech, Graz, Austria and ²Wadsworth Center, NYS Dept of Health & SUNY, Albany, NY 12201.

People can learn to control the amplitudes of certain EEG components (i.e., specific frequency bands at specific scalp locations) and use them to move a cursor in one or two dimensions to a target on a video screen (Electroenceph clin Neurophysiol 78:252-259, 1991 and 90:444-449, 1994). We are trying to improve the rapidity and accuracy of cursor control by improving the online algorithms that translate EEG components into cursor movement. Present algorithms use electrodes over sensorimotor areas, common average or LaPlacian spatial filtering methods, autoregressive frequency analysis, 8-12 Hz or 20-24 Hz frequency bands, and linear equations to calculate cursor movement. Online evaluation of alternatives is extremely time-consuming. Thus, we are developing offline methods for estimating the online performance of alternative algorithms.

Sixty-four channels of EEG are digitized and stored for later offline analysis while subjects control cursor movement using current algorithms. Offline analyses simulate the performances that would have occurred had other algorithms been employed online. The simulated performances are compared to each other and to the algorithm that was actually used online. Algorithms tested include nonlinear equations, histogram methods, neural nets, and learning vector quantization.

This simulated performance has several limitations. First, it cannot predict the effect on performance of change in feedback caused by the new algorithm. Second, it is limited to the body of EEG data provided by the online algorithm, so that some simulated trials may end inconclusively. Nevertheless, it allows assessment of a much wider range of alternatives than could be assessed online and should prove to be an important tool in BCI development. (Supported by FFWF Project P9043 (Austria) and NIH HD30146 (USA).)

BASAL GANGLIA: ANATOMY II

352.1

NITROTYROSINE IMMUNOLABELING IS PRESENT IN AXONS AND GLIAL PROCESSES IN THE GLOBUS PALLIDUS OF NORMAL ADULT RAT BRAIN.

RR Trifiletti*, EA Bolan and VM Pickel. Department of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021.

The globus pallidus is the major target of striatal efferents essential for normal motor activity involving close functional interactions between nitric oxide (NO) and GABAergic neurons. Nitric oxide derived free radicals, such as peroxynitrite, are thought to be involved in nitration of proteins at tyrosine residues. Accordingly, the product nitrotyrosine (NT) is present in regions containing neurons that produce NO, these include the caudate-putamen nuclei and globus pallidus. We examined the cellular sites that might locally accumulate NT in the globus pallidus by light and electron microscopy using an anti-nitrotyrosine monoclonal antibody generated against tetranitromethane treated KLH. The antibody was localized by the avidin-biotin horseradish peroxidase method. In coronal sections through the globus pallidus examined by light microscopy, a punctate and diffuse immunoperoxidase label was selectively absorbed with nitrated bovine serum albumin. Electron microscopy showed intense labeling in selective glial processes and unmyelinated axons and axon terminals. Many of these labeled terminals formed symmetric synapses characteristic of GABAergic neurons. The NT-like immunoreactivity (NT-LI) in these terminals was mainly seen in aggregates near the plasma membrane resembling endosomes. We postulate that NT may locally accumulate in axon terminals where NO is known to presynaptically modulate the release of GABA from striatopallidal neurons. Such accumulations may be important in various movement disorders. (Supported by grants from NIMH, MH 40342)

352.2

DIFFERENTIAL DISTRIBUTION OF GAD65 AND GAD67 mRNA IN THE ENTOPEDUNCULAR NUCLEUS OF THE RAT. A. E. Johnson*, P.-Q. Yuan, C. Grânâs, L. Källström, J. Yu, K. Huhman, D. Larhammar, H. E. Albers and F.-A. Wiesel, Psychiatry Department, Uppsala University, S-75017 Uppsala, Sweden.

The entopeduncular nucleus (EP) is one of the major output nuclei of the basal

The entopeduncular nucleus (EP) is one of the major output nuclei of the basal ganglia which plays an important role in the expression of dyskinetic motor functions associated with the interruption of dopaminergic (DA) transmission. Anatomical studies have shown that the EP is also interconnected with limbic structures and thus is involved in cognitive function. The limbic and motor neurons of the EP are topographically distributed with limbic neurons in rostral subregions and motor circuit neurons located caudally. The synthesis of the primary transmitter of the EP, GABA, is regulated by the enzyme glutamic acid decarboxylase (GAD) which exists in two isoforms, GAD65 and GAD67. Previous studies have indicated that both isoforms of GAD were evenly distributed throughout the EP. However, these studies examined a limited region of the EP. In the present experiments, we examined the distribution of GAD65 and GAD67 mRNAs throughout the entire rostro-caudal extent of the EP using oligodeoxyribonucleotide probes and in situ hybridization techniques. In agreement with previous studies, Northern analysis of whole rat brain preparations showed that the GAD65 and GAD67 probes used in the present studies labeled mRNAs of S.8kb and 3.7kb, respectively. Film autoradiographic analysis revealed that GAD65 and GAD67 mRNAs were differentially distributed in the EP with GAD65 and GAD67 mRNAs were differentially distributed in the EP with GAD65 and GAD67 mRNAs were differentially distributed in the EP with GAD65 and GAD67 hold by the two GAD probes (pc.0002, two-way ANOVA). In the rostral EP, the percentage of cell body area covered by silver grains was 47.8±1.0 for GAD65 and 17.2±2.7 for GAD67. In the caudal EP, GAD67 labelling increased to 39.6±3.0 while GAD65 labelling was reduced to 22.4±3.2. No differences were detected in the number of neurons labeled by the two probes at any level of the EP. These results provide evidence that GABAergic transmission in limbic and motor subregions of the EP may be differentially regulated.

THE ALPHA4 NICOTINIC RECEPTOR SUBUNIT IS FOUND AT SYNAPSES ON TYROSINE HYDROXYLASE IMMUNONEGATIVE NEURONS IN THE RAT SUBSTANTIA NIGRA. <u>E.M. Sorenson*, T. Shiroyama, and S.T. Kitai,</u> Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

Cholinergic neurons in the pedunculopontine nucleus have been shown to project to the substantia nigra which contains cholinergic axons and axonal boutons throughout. Cholinergic neurotransmission can be mediated by muscarinic and/or nicotinic receptors and evidence indicates that the dopaminergic neurons in the substantia nigra pars compacta (SNc) express both. In particular, we have previously shown that the majority of dopamine neurons express the alpha4 nicotinic receptor subunit. We now report that non-dopaminergic neurons in the SN also express the alpha4 nicotinic receptor subunit.

The alpha4 and beta2 nicotinic receptor subunits where immunohistochemically localized using mAb 299 and mAb 270 (gifts of Dr. Jon Lindstrom), respectively. Single label experiments showed that both subunits are expressed in SNc and SNr neurons. In sections labelled for TH, the synthetic enzyme for dopamine, and the alpha4 subunit, it was found that a number of TH immunonegative neurons, particularly in the reticulata, were labeled for the alpha4 subunit. At the ultrastructural level, reaction product for the alpha4 subunit was located in TH

immunonegative cell bodies and dendrites in the nigra, including at some synapses.

Since TH immunonegative neurons in the SN are likely to be GABAergic, we conclude that alpha4 containing nicotinic receptors are found on presumed GABAergic neurons and suggest that they are likely to be involved in cholinergic neurotransmission at these neurons

THE IMMUNOCYTOCHEMICAL LOCALIZATION OF TYROSINE HYDROXYLASE IN THE HUMAN STRIATUM: AN ULTRASTRUCTURAL STUDY. L. Kung*, M. Force, D.J. Chute, J. Smialek and R.C. Roberts, Maryland Psychiatric Research Center, Departments of Psychiatry and Pathology, University

of Maryland School of Medicine, Baltimore, MD 21228.

Electron microscopic observations of human brain are scarce due to the difficulty in obtaining tissue with very short postmortem intervals [PMI]. The goal of this study was to describe the ultrastructural organization of tyrosine hydroxylase (TH), the synthesizing enzyme for dopamine, in the human striatum. Striatal tissue from four normal control males [ages 35-79, PMI<4.5hrs] was obtained from the Maryland Brain Collection. Tissue was placed in 4% paraformaldehyde and 1% glutaraldehyde in 0.1M phosphate buffer for 7-14 days. Free floating vibratomed sections $[40\mu m]$ were processed for the immunocytochemical localization of TH [1:1000, 36-44 hrs] and flat embedded for electron microscopy. THimmunoreactivity [TH-i] was present in myelinated and unmyelinated varicose axons. Both varicosities [usually 0.75-1.5 μ m] and intervaricose segments [typically 0.2-0.3 μ m] formed synapses with spines and dendrites. Most synapses formed by TH-i profiles were symmetric axospinous or symmetric axodendritic. An occasional asymmetric axodendritic synapse was observed. Synapses formed by TH-i profiles were short in length [typically 0.12-0.25µm], often being present in only 2-4 serial sections, and had non-perforated postsynaptic densities. TH-i profiles formed synapses with both the head and neck of spines. Typically, the TH-i bouton was apposed to both a spine and a nonlabeled terminal which formed an asymmetric synapse with that spine. Appositions, characterized by parallel synaptic membranes and a density within the cleft, were seen between TH-labeled and nonlabeled boutons forming asymmetric synapses. These results indicate that apart from immunoreactivity in some myelinated axons, the pattern of TH-i in the human striatum is very similar to that of other species. PERMANENT PREPARATIONS OF DYE-INJECTED NEURONS IN RAT AND HUMAN POSTMORTEM BRAIN, IN COMBINATION WITH STAINING FOR ACETYLCHOLINESTERASE, L.D. Loopuijt*, H.J. Groenewegen and F. G.

Wouterlood, Department of Anatomy, Free University Amsterdam, the Netherlands. Intracellular injection of Lucifer yellow (LY) into neurons in slices of fixed brain is used with success to study neuronal morphology. We developed a method to investigate the morphology of human striatal neurons in postmortem brain tissue in sections stained also for acetylcholinesterase (AChE) in order to mark striatal compartments. Preparations had to be permanent for the purpose of building up a library. Thus we introduced immunocytochemical stabilization using anti-LY an tibodies. Because bloodvessel-borne erythrocytes interfere with immunostaining, a bleaching procedure using UV-irradiation of the tissue prior to the intracellular LY-injection and AChE staining was conducted. The procedure was developed in postmortem rat brain and then transferred to human postmortem brain tissue. Brain tissue was immersion-fixed for 30 min in a phosphate-buffered aldehyde fixative. Slices (350 µm thick) were stained with 4',6-diamino-2-phenylindole and exposed for 20 minutes to UV-irradiation via a standard 10X Neofluar objective in a Zeiss epifluorescence microscope (100W mercury bulb). Then, selected neurons were intracellularly injected with 4% LY or 2% LY / 2% biocytin according to the method published by Buhl and Schlote [Acta Neuropathol. 75(1987):140-146]. After postfixation for 1 hr, the slices were cut into 40 µm thick sections and histochemically stained for AChE [Hardy et al. Neurosci. Lett. 3(1976):1-5] Afterwards, the injected LY was visualized immunocytochemically or via treatment with avidin/biotin/peroxidase (ABC) complex

We obtained satisfactory results with this method, i.e., good visualization of LY-injected neurons together with AChE staining, without erythrocyte-associated background staining. Outside the irradiation spots in irradiated sections as well as in non-irradiated control sections, we noticed dense erythrocyte-associated staining. Supported by LDL Research Funds.

Dopamine and Glutamate Co-localized in Substantia Nigra Neurons:

Dopamine and Glutamate Co-localized in Substantia Nigra Neurons: Immunocytochemical Evidence. T.Shiroyama, C.D.Richards* and S.T.Kitai. Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

Previous evidence has suggested that neurons in the substantia nigra (SN) which are immunopositive for tyrosine hydroxylase (TH), i.e. dopamine neurons, are also immunopositive for glutaminase, a marker for glutamate and GABA neurons. Separate studies have indicated that most, if not all, TH-positive neurons in the substantia nigra are immunonegative for glutamic acid decarboxylase (GAD), a marker for GABA neurons. In addition, it has been suggested that TH-positive neurons are also immunopositive for glutamate. In order to ascertain whether neurons in the substantia nigra co-localize glutamate and dopamine, we have employed immunocytochemical double- and triple-labelling techniques in the rat, using antibodies against TH, glutaminase and GAD, and both fluorescent and light-level markers.

We found that many TH-positive neurons throughout the substantia nigra pars compacta (SNc) were also immunopositive for glutaminase. However, we found that no TH-positive SNc neurons were also labelled for GAD. Within the SN, and particularly in the pars reticulata, glutaminase-positive neurons were found which were also GAD-positive, i.e. GABA neurons. These results indicate that the TH-positive neurons in the SNc which are also immunopositive for glutaminase are glutamate and not the SNc which are also immunopositive for glutaminase are glutamate

in the SNc which are also immunopositive for glutaminase are glutamate

in the SNC which are also immunopositive for glutaminase are glutamate and not GABA neurons.

We therefore conclude that a sub-population of neurons within the substantia nigra co-localize dopamine and glutamate.

MULTIARCHITECTONIC STEREOTACTIC ATLAS OF THE HUMAN BASAL GANGLIA: FUNCTIONAL COMPARTMENTALIZATION OF CALCIUM-BINDING PROTEINS IN THE STRIATUM AND PALLIDUM. F. Loup, D. Jeanmonod, M. Magnin and A. Morel*. Lab. for Functional Neurosurgery, University of Zurich, CH-8091 Zurich, Switzerland. Stereotactic surgery at the pallidal level has proven beneficial in the treatment of Parkinson's disease. To provide accurate target localization, we

are developing a multiarchitectonic atlas of the basal ganglia. Human brains obtained at autopsy were cut stereotactically into blocks comprising the basal obtained at autopsy were cut stereotactically into blocks comprising the basal ganglia and neighboring structures. Serially cut sections in the frontal or horizontal plane were stained for Nissl, myelin, or acetylcholinesterase, or immunohistochemically for calretinin (CR), calbindin (CB), or parvalbumin. The differential neuropil distribution of these calcium-binding proteins allowed delineation of distinct striatal and pallidal territories. Within the rostral striatum, staining for CR showed a low-to-high dorsolateral to ventromedial gradient. A complex and highly heterogeneous pattern of ventromedial gradient. A complex and highly heterogeneous pattern of immunostaining was present in the ventral striatum where regions with high CR were in close spatial register with patches low in CB. This intense CR immunoreactivity (IR) extended to most of the basal forebrain and hypothalamus. By contrast, CB-IR was confined largely to the basal ganglia. Staining of the striatal extrastriosomal matrix was most intense in the ventral striatum and less intense, but still significant, in most of the caudate nucleus and rostral putamen. Within the globus pallidus, CB-IR was highest in the ventral pallidum, rostral pole of the external segment (GPe), and ventromedial part of the rostral internal segment (GPi). It was also high in dorsomedial GPe and GPi. Thus, immunostaining for CR and CB permits delimitation of limbic and associative territories from the sensorimotor region in the human striatum and pallidum. Atlas reconstruction of these data should facilitate the determination of selected targets for the treatment of should facilitate the determination of selected targets for the treatment of motor disorders.

PHOSPHATASE CONTROL OF DYNORPHIN EXPRESSION IN ORGANOTYPIC CULTURES OF DEVELOPING STRIATUM. F.-C. Liu' and A.M. Graybiel. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139; Institute of Neuroscience, National Yang-Ming University, Taipei, Taiwan 11221, R.O.C.

Our previous work has shown that inhibition of protein phosphatase-1 and -2A (PP-1, PP-2A) results in phosphorylation of the cAMP response element (CRE)-(PP-1, PP-2A) results in pinospinorylation of the cAMP response element (CRE)-binding protein (CREB) in organotypic cultures of neonatal striatum (Liu and Graybiel, 1995). Okadaic acid and calyculin, inhibitors of PP-1 and PP-2A, induced immunodetectable Ser¹³⁸ phosphorylated CREB (PCREB) throughout the cultured striatum. Among candidate downstream striatal targets of CREB phosphorylation is prodynorphin, a CRE-containing gene that can potentially be surplated by CREB extinction and in the expensed in the advantage of well at the regulated by CREB activation and is expressed in the developing as well as the mature striatum. In the present study we asked whether protein phosphatases could regulate dynorphin expression in slice cultures of developing striatum. Immunostaining showed that dynorphin was down-regulated in neonatal striatal cultures by 3 days in vitro. Incubation of such striatal cultures with okadaic acid $(0.1, 1 \ \mu M)$ or calyculin $(0.1, 1 \ \mu M)$ for 2 hr strikingly induced dynorphin immunoreactivity in numerous dynorphin-positive neurons in both striosome and matrix of the cultured striatum. This homogenous pattern of dynorphin induction paralleled that of CREB phosphorylation. By contrast, inhibition of calcineurin (protein phosphatase-2B) with FK506 (10, 100 μ M) did not increase dynorphin immunostaining in the cultured striatum, nor did it induce CREB phosphorylation. Our findings suggest that striatal dynorphin expression is negatively regulated by constitutively active PP-1 and/or PP-2A, possibly through dephosphorylation of PCREB. Thus striatal neuropeptide expression is under rigid dephosphorylation control by specific protein phosphatases. Supported by NIH 2 R01 HD28341 and the Science Partnership Fund at MIT.

THE STRIATONIGRAL NEURON: ITS DA RECEPTOR EXPRESSION PATTERN. M. Ray, K.L. Noblett, J.Y. Wang, and M.A. Ariano*. Dept. Neuroscience, Finch University Health Sciences/The Chicago Medical School, North Chicago, IL 60064.

Sciences/The Chicago Medical School, North Chicago, IL 60064. Patterns of gene expression and receptor protein for the five DA receptor subtypes were detected in identified striatonigral neurons. The mRNA was marked by enzymatic incorporation of fluorescent dUTP (FIST) following hybridization of a unique sequence for oligonucleotide primers derived from previous in situ hybridization studies. Immunofluorescence using subtype specific anti-peptide antisera assessed protein staining (Meth. Neurosci. 25:455, 1995). Striatonigral neurons were identified by retrograde transport. Both the gene and protein expression were visualized simultaneously in individual medium sized neurons of the striatal region. Separate examination of gene and protein expression confirmed that mRNA and protein translation for each receptor subtype occur in neurons of the striatonigral pathway. In additional experiments, simultaneous staining of gene and protein expression was visualized on identified striatonigral neurons. These findings demonstrated a high level of homologous coincidence for gene and protein expression for all five subtypes of DA receptors in striatonigral neurons. The level of staining for the D_{1A} and D₂ signals were robust, whereas D_{1B}, D₃, and D₄ were less intense. Acutely isolated striatonigral neurons were used to analyze further functional attributes of the different DA receptor subtypes. This work was supported by USPHS NS 33277.

STRIATAL CELLS CONTAINING AROMATIC AMINO ACID DECARBOXYLASE (AADC): A NEW NEURONAL CLASS. A. Mura. V.A. Andrus. J.C. Linder* S.J. Young and P.M. Groves. Dept. Psychiatry, Univ. Calif. San Diego, La Jolla , CA 92093-0603

We recently described a group of cells that were immunolabeled for AADC in the rat neostriatum and obtained evidence that these neurons may produce dopamine in the presence of exogenous L-DOPA (Mura et al., Brain Res. 704:51-60, 1995). Thus, these cells may be significant for the pharmacotherapy of Parkinson's disease. Here we further characterize these cells in an attempt to determine whether they form a subclass of one of the previously-described categories of striatal neurons, or if these AADC cells represent a novel cell type. Sections of striatum from rats with unilateral 6-hydroxydopamine MFB lesions were single- or double-immunolabeled for a variety of neurochemicals (AADC, dopamine, calrettinin, somatostatin, parvalbumin, VIP, calbindin, GABA) using standard methods. The morphology of the AADC cells (small, uni- or bipolar, aspiny) does not correspond to that of the spiny projection neurons or to the larger or more polygonal classes of interneurons, such as those containing acetylcholine, parvalbumin/GABA, somatostatin/ neuropeptide Ynitric oxide synthase, or VIP. The distribution of the AADC cells (dorsal striatum, just below the corpus callosum) did not overlap that observed for parvalbumin/GABA or calbindin-containing cells or that reported for cholecystokinin. The AADC cells most closely resemble the small calretini interneurons, but we did not find any cells double-labeled for calretinin and AADC. However, we did find that the majority of AADC cells were double-labeled for GABA. These cells were among those with the most intense GABA labeling and therefore appear distinct from projection neurons and most interneurons that are reported to stain weakly for GABA. While parvalbumin interneurons do label intensely for GABA, their morphology and distribution differs from that of the AADC cells. We conclude that AADC cells contain GABA but not calretinin or calbindin and probably represent a new class of striatal interneurons.

GLUTAMATE-ENRICHED CHOLINERGIC TERMINALS IN THE BASAL GANGLIA OF THE RAT. N. P. Clarke, M. D. Bevan, C. Cozzari, B. K. Hartman & J. P. Bolam*. MRC Anatomical Neuropharmacology Unit, Mansfield Road, Oxford, OXI 3TH, U.K.; Instituto Biologia Cellulare CNR, Rome Italy (CC); University of Minnesota, Minnespolis, Minnesota 55455, U.S.A. (BKH).

NRC Anatomical Neuropharmacology Unit, Mansheld Road, Oxford, OX1 3TH, U.K.; Instituto Biologia Cellulare CNR, Rome Italy (CC); University of Minnesota, Minneapolis, Minnesota 55455, U.S.A. (BKH).

The output nuclei of the basal ganglia i.e. the entopeduncular nucleus (EP) and substantia nigra (SN), and the subthalamic nucleus (STN) receive a cholinergic innervation derived from the mesopontine tegmentum (MTg). It has been proposed that at least some of the cholinergic neurons of MTg also contain glutamate, implying that acetylcholine and glutamate are co-released. The object of the present study was to determine whether the terminals of cholinergic neurons in the basal ganglia have elevated levels of glutamate. Vibratome sections of the basal ganglia of perfuse-fixed rat brain were reacted to reveal choline acetyltransferase (ChAT) immunoreactivity using peroxidase methods with diaminobenzidine as the chromogen. After re-embedding, ultra-thin sections were subjected to post-embedding immunocytochemistry to reveal GABA and glutamate. The density of immunogold particles overlying ChAT-immunopositive terminals and non-labelled terminals forming asymmetrical synapses was then normalised by expressing them as a ratio of that overlying non-labelled GABA-positive terminals forming symmetrical synapses. In the STN, GABA-positive terminals forming symmetrical synapses had an index of glutamate immunoreactivity of 1.0347±0.103 (n=67), ChAT-immunopositive terminals had a significantly greater index (2.8554±0.185; n=75; p <0.0001) as did non-labelled GABA-negative terminals forming asymmetrical synapses (4.690€tb.27; n=52; p <0.0001). These results demonstrate that ChAT-immunopositive terminals in the STN, which are probably derived from the MTg, are enriched in glutamate suggesting that at least some of these terminals or e-clease glutamate as a neurotransmitter. Similar experiments are in progress to examine the levels of glutamate-immunoreactivity in cholinergic terminals in the EP and SN.

ULTRASTRUCTURAL CHARACTERIZATION OF AROMATIC L-AMINO ACID DECARBOXYLASE (AADC)-POSITIVE CELLS IN THE STRIATUM OF RATS WITH 6-OHDA LESIONS. A.A. Alcantara*. A. Mura. G.N. Ato. J.C. Linder. S.J. Young and P.M. Groves. Departments of Neurosciences and Psychiatry, University of California, San Diego, La Jolla CA 92093-0603.

The most common treatment for Parkinson's disease (PD), a disorder characterized by the loss of the nigro-striatal dopaminergic pathway, is administration of L-DOPA). An apparent paradox is that exogenous L-DOPA is effective in PD despite the severe loss of the nigral afferents which are a main source of striatal AADC, the enzyme that converts L-DOPA to dopamine. Recently, a small population of striatal neurons immunoreactive (IR) for AADC has been discovered in the rat that may be relevant to PD since dopamine-IR cells similar in morphology and location were observed in the dopamine deafferented striatum following L-DOPA administration (Mura et al., 1995).

seen discovered in the rat that may be relevant to PD since dopamine-IR cells similar in morphology and location were observed in the dopamine deafferented striatum following L-DOPA administration (Mura et al., 1995).

To characterize the ultrastructure of these neurons, we combined immunocytochemical with electron microscope (EM) techniques. AADC-IR cells identified at the light level were selected for EM. Cell somata were round or oval and ~10 microns in diameter. In some cases, axo-somatic contacts were observed. Cell nuclei were round or elongated and centrally localized with occasional shallow or deep invaginations and surrounded by a scant amount of cytoplasm. AADC immunoreaction product was present in the cell cytoplasm and dendrites, but absent from the nucleus. AADC-IR cells displayed EM features which may distinguish them from common medium spiny neurons, including their smaller size, less cytoplasm, and more prominent unclear indentations. These EM features most resembled calretinin-positive interneurons; however, the discrete localization of these cells in the dorso-medial striatum in combination with LM double labeling results (Mura et al., Soc. Neurosci., 1996 indicate that these AADC-IR cells are previously unidentified class of striatal neurons. To further define the morphology of these neurons and possibly differentiate them from other striatal classes, we are currently using serial section EM to characterize synapses and axons, and to examine dendrites for such features as varicosities and spines. STRIATAL REGIONALIZATION AS DETERMINED BY DIFFERENTIAL DISPLAY. W.J. Rushlow*, N. Rajakumar, C.C.G. Naus and B.A. Flumerfelt. Dept. of Anatomy & Cell Biology. Dept. of Psychiatry, University of Western Ontario, London, Canada, N6A 5C1

Differential display is a powerful new approach that can be used to identify mRNA species uniquely expressed in different regions of the brain. It is a reverse transcriptase-polymerized chain reaction (RT-PCR) based technique that allows for the visual identification of candidate cDNA's by directly comparing banding patterns present on a polyacrylamide gel. In the present study, differential display was used to identify novel, regionally expressed mRNA's in the rat striatum. Total cellular RNA was isolated from punches obtained from the caudate-putamen of adult Sprague-Dawley male rats using a guanidine isothiocyanate technique. Following the RT-PCR reaction, samples were run on a 6% polyacrylamide gel, and differentially expressed bands were identified. Reamplified cDNA bands were used to generate probes for in situ hybridization and to screen a rat striatal or rat brain cDNA library. More than 75 candidate genes have been identified thus far using different primer combinations. Screening of several of these candidates has yielded 5 novel cDNA's. These cDNA's are currently being characterized and sequenced. Supported by the Medical Research Council of Canada

THE ONTOGENESIS OF NITRIC OXIDE SYNTHASE IN THE BASAL GANGLIA OF THE MOUSE. X. Chen*, J. W. Langston, and M. W. Jakowec. The Parkinson's Institute, Sunnyvale, CA, 94989.

We are interested in understanding the role of nitric oxide in the developing basal ganglia and in models of neurodegeneration and We used immunocytochemistry with antibody probes against both neuronal and inducible forms of nitric oxide synthase (NOS) to determine the pattern of expression in the developing mouse basal ganglia. Our results indicate that the neuronal NOS protein is expressed in a subset of interneurons scattered throughout the adult striatum with strong staining of cell bodies and their processes. Neuronal NOS is also expressed at high levels in the subthalamic nucleus, and at low, but detectable, levels in the substantia nigra pars compacta especially along the lateral aspect of the region. A similar pattern of expression was seen in the neonate except neuronal NOS was seen at higher levels in corresponding regions. Using the antibody probe against the inducible form of NOS our results indicate that this protein is not detectable on cell bodies in either the striatum, subthalamic nucleus, or substantia nigra of the adult. However, neuropil staining in the striatum was present.

ULTRASTRUCTURAL EXAMINATION OF 5' NUCLEOTIDASE ACTIVITY IN PATCH/MATRIX COMPARTMENTS OF RAT NEOSTRIATUM. M. E. Martone*, K. Tang, Z. Nebyelul, Y. Jones, S. J. Young and M. H. Ellisman, Natl. Ctr. for Microscopy and Imaging Research, Univ. California San Diego, 92093-0608.

Microscopy and Imaging Research, Univ. California San Diego, 92093-0608.

5'-nucelotidase (5NT) is a glial-associated ectoenzyme that delineates the patch/matrix compartments in adult rat neostriatum. We examined the ultrastructural distribution of 5NT in the patch and matrix compartments of rat neostriatum using conventional and high voltage electron microscopy (HVEM). Vibratome sections of neostriatum fixed with 4% paraformaldehyde were processed for 5NT histochemistry using the method of Schoen and Graybiel (J. Comp. Neurol., 322: 566, 1992). In the light microscope (LM), 5NT activity appeared as discrete dark patches against a lighter staining background. Regions containing clearly delineated patches were selected for further electron microscopic examination. Alternate thick (3-5um) and thin (100nm) sections were cut from the same block and mounted on high transmission grids. The thick sections were first photographed under LM to provide correlated images for electron microscopy. The dark patches of 5NT activity were visible under LM in 3-5 um thick sections but not in thinner sections. The thick sections were then examined directly using HVEM at 400 keV or 1 meV. Adjacent thin sections were examined at 80 keV, using the light micrograph of the thick section as a guide to identify patch regions. In the electron microscope, 5NT reaction product was found extracellularly associated with the plasma membrane of neuronal and glial processes. Stereopairs of thick sections revealed that 5NT activity was distributed in a fine filigree pattern, forming nets around neuronal processes, cell bodies and blood vessels. 5NT activity was found in both patch and matrix compartments but the staining in patches was more intense and the amount of labeling also appeared to be greater than outside the patches. The distinction between patch and matrix was still detectable in thin sections when the LM images were used to identify the border between patch and matrix and the 3-dimensional organization of the border region. MORPHOLOGY AND IMMUNOCYTOCHEMISTRY CHARACTERISTICS OF THE MARGINAL DIVISION IN MONKEY STRIATUM, S.Y. Shu and X.M. Bao, Dept. Neurobiology, Zhu-Jiang Hospital, Guangdong, China.

In our previous study, a new area, the marginal division(Mr.D.), was observed in the rat striatum. The Mr.D. is located at the caudal border of the striatum and is more densely filled with many neuropeptidergic terminals. The neuronal somata in Mr.D. are mostly fusiform. The function of Mr.D. is supposed to correlate to the learning, memory and nociceptive responses. The present study described the Mr.D. in the monkey(Macaca Mulatta) striatum. Using Nissl staining, A band of packed small fusiform neurons with medially located scattered large fusiform neurons were observed at the caudomedial border of the monkey striatum. Some of them are AchE positive, or SP-,NPY-, Enk-, NT-immunohistochemistry positive reacted. Two bands of SP-, M- & L-Enk-, NPY- and NT- immunoreacted fibers and terminals were found at the caudomedial edge of the striatum and the rostolateral edge of the globus pallidus respectively. Pedunculopontine fibers were reported projecting to the caudomedial portion of the putamen in the squirrel monkey. It is proposed that the Mr.D. is better developed in the monkey brain than that in the rat brain and has special afferent connections, so that the Mr.D. probably plays more important role in the monkey brain. (supported by NSFC).

LOCALIZATION OF N-METHYL-D-ASPARTATE (NMDA) RECEPTOR SUBUNIT PROTEINS IN THE NIGROSTRIATAL PATHWAY

D.G. Standaert* and S.W. Weiss. Dept. of Neurology, Mass. Gen. Hosp., and Harvard Medical School, Boston, MA 02114.

NMDA glutamate receptors in the substantia nigra pars compacta (SNpc) regulate the bursting activity of dopamine neurons, while in the neostriatum NMDA receptors appear to influence the release of dopamine from presynaptic terminals. We have used dual-label immunofluorescence and confocal laser microscopy to study the localization of NMDAR1, NMDAR2A, and NMDAR2B proteins within dopaminergic neurons identified by the presence of immunoreactivity (-ir) for tyrosine hydroxylase (TH) in the rat. In the SNpc, NMDAR1-ir was prominent in the cytoplasm and proximal dendrites of TH-ir neurons, and moderate amounts of NMDAR2A-ir and NMDAR2B-ir were present. Immunoreactivity for the variably spliced segments of NMDAR1 (N1, C1, C2) was scarce. In the neostriatum. NMDAR1-ir, NMDAR2A-ir, and NMDAR2B-ir were present within neuronal cytoplasm, proximal dendrites, and fine punctate varicosities within the neuropil. Neurons and the neuropil also contained abundant NMDAR1 C1-ir and C2-ir. No colocalization of NMDA subunit immunoreactivity with TH-ir processes in the striatum was observed. Following unilateral 6-OHDA lesions, TH staining of the striatum was absent, but the expression of NMDA subunit immunoreactivity in the neuropil was not altered.

These data demonstrate that dopaminergic neurons of the nigrostriatal pathway express NMDAR1, NMDAR2A, and NMDAR2B receptor subunit proteins, and that these proteins are restricted to the somatodendritic compartment. Supported by the National Parkinson Foundation & NS31579.

BASAL GANGLIA: FUNCTION II

353.1

NEURONAL GENE EXPRESSION ASSOCIATED WITH DOPAMINE SUPERSENSITIVITY IN RAT STRIATUM. G.J. LaHoste* and J.F. Marshall. Departments of ¹Physical Medicine & Rehabilitation and ²Psychobiology, University of California, Irvine, CA 92717-4550.

Dopaminergic systems within the mammalian brain are characterized by a striking degree of plasticity. For example, following extensive injury to dopamine (DA)containing cell bodies within the mesencephalon, DA receptors in telencephalic target regions become supersensitive to agonists with respect to behavioral, electrophysiological, neurochemical and genetic response. In addition, the density (but not the affinity) of D2 receptors is increased following injury. For many years this increase in D2 receptor density was believed to be the cause of agonist supersensitivity. However, several lines of evidence demonstrate convincingly that receptor upregulation cannot account for the high degree and early appearance of supersensitivity. Assuming that changes in gene expression may underlie the changes in receptor sensitivity, we have attempted to elucidate the mechanism(s) of supersensitivity using differential display of mRNA. In this method, subsets of mRNA species are labelled, amplified and displayed in adjacent lanes of a high resolution polyacrylamide gel. Adult male rats received injections of 6-hydroxydopamine (6-OHDA; 8 µg) into the ascending medial forebrain bundle. Rats with confirmed extensive lesions were sacrificed several weeks after 6-OHDA and their caudate-putamens (CPu) rapidly dissected. RNA was isolated, reverse transcribed into cDNA and amplified using polymerase chain reaction (PCR) in the presence of ³³P-dATP. Primers for PCR were from the GenHunter RNAimage kit. To date, several cDNA fragments have been identified that are differentially expressed in control and 6-OHDA-treated CPu. Some are expressed in 6-OHDA tissue but not control tissue, while others are expressed in control but not 6-OHDA tissue. We are in the process of confirming and characterizing the differentially expressed genes. Funded by MH 49690, NS 22698.

353.2

ADENOSINE A_{2a} ANTAGONISTS MODULATE DOPAMINE DEPENDENT TURNING BEHAVIOR AND C-FOS EXPRESSION IN 6-HYDROXYDOPAMINE LESIONED RATS <u>M.Morelli,*</u> A.<u>Pinna, S. Fenu, S. Cabiddu, G. Di Chiara</u>. Department of Toxicology, University of Cagliari, Italy.

The interaction between adenosine A₁ and A_{2a} antagonists and dopamine (DA) D₁ and D₂ agonists was evaluated in rats with a unilateral 6-hydroxydopamine (6-OHDA) lesion of the dopaminergic nigrostriatal pathway, by studying the contralateral turning behavior induced by DA receptor agonists and the activation of the early-gene cfos, as measured by Fos-like-immunoreactivity (FLI). Selective blockade of adenosine A_{2a} receptors by SCH 58261 strongly potentiated the contralateral turning behavior and increased FLI induced by the D₁ agonist SKF 38393 in the 6-OHDA lesioned striatum. At variance, the A₁ receptor antagonist DPCPX induced a small potentiation of D₁mediated turning behavior while FLI was not modified. SCH 58261 positively modulated also turning behavior induced by stimulation of D₂ receptors by quinpirole or by stimulation of D₁/D₂ receptors by L-DOPA. The degree of potentiation of D2-mediated turning behavior was however smaller as compared to that obtained after D₁ receptor stimulation. FLI induced by quinpirole and L-dopa in the globus pallidus and striatum was also potentiated by SCH 58261. Blockade of A2a receptors positively influences the functional expression of D1 and D2-mediated responses in dopamine denervated rats, suggesting new therapeutic approaches for the treatment of Parkinson's disease.

DOPAMINE DEPLETION IN THE RAT ALTERS RESPONSES OF SUBTHALAMIC NUCLEUS NEURONS TO APOMORPHINE AND THE D₁ RECEPTOR AGONIST SKF 38393. D.S. Kreiss', K.A. Allers,

M.J. Twery, and J.R. Walters. ETB, NINDS, Bethesda MD 20892.

The subthalamic nucleus (STN) plays a critical role in the regulation of basal ganglia output. Evaluation of STN neuronal activity during basal stimulation as well as during exogenous dopaminergic (DAergic) agonist stimulation is essential for understanding the role of the STN in Parkinsonian symptomology. Previous studies from this laboratory characterized the regulation of STN neuronal activity in the normal rat. The present study examines the STN in the DA-depleted rat 6-16 weeks post treatment with 6-OHDA. The basal firing rate of STN neurons in the DA-depleted rat (18.1 \pm 1.7 spikes/sec, n = 47) was markedly elevated relative to basal rates in normals (8.4 \pm 0.7 spikes/sec, n = 54). This was probably not a result of altered NMDA receptor-mediated glutamatergic tone as the glutamate antagonist MK 801 (0.1 mg/kg) did not alter firing rates. Whereas the D_1/D_2 agonist apomorphine (APO, 0.3 mg/kg) increased firing in the normal rat, APO decreased STN neuronal firing rates to 59% (n = 9) of basal values in the DA-depleted rat. Alteration of APO's effects in the DA-depleted rat could not be explained by responses to selective D₁ and D₂ receptor agonists. The excitatory effects of SKF 38393 seen in normals were potentiated by DAdepletion: a dose that was ineffective in normals (10 mg/kg) significantly increased firing in the STN of lesioned rats. The D2/D3 receptor agonist quinpirole (0.3 mg/kg), however, did not alter firing rates in normal or DAdepleted rats. Understanding the mechanisms mediating the regulation of the STN under conditions of DAergic deficiency may lead to improved treatments for Parkinson's disease using pharmacotherapy and/or neurosurgery. CONSEQUENCES OF NIGROSTRIATAL DENERVATION ON THE FUNCTIONING OF THE BASAL GANGLIA. M. Vila, R. Levy, M.-T. Herrero'. M. Ruberg, B. Faucheux, J.A. Obeso', Y. Agid' and E. C. Hirsch, INSERM U289, Hôpital de la Salpêtrière, 75013 Paris, France. 'University of Murcia, 30071 Murcia, Spain. 'Quiron Clinic, 20012 San sebastian, Spain.

In Parkinson's disease (PD), the loss of nigral neurons provokes a cascade of changes in the basal ganglia which may account for the motor parkinsonian syndrome. To examine the consequences of nigrostriatal denervation and chronic levodopa (L-dopa) treatment on functional activity of the basal ganglia, we analysed, using in situ hybridization, the cellular expression of the mRNA encoding for cytochrome oxidase (subunit I, COI mRNA), a metabolic marker for functional neuronal activity, in the basal ganglia. This analysis was performed in patients with PD and in monkeys rendered parkinsonian by 1-methyl-4-phenyl-1,2,3,6-tertahydropyridine (MPTP) intoxication, some of which had been receiving L-dopa. In MPTP-intoxicated monkeys compared to control animals, COI mRNA expression was increased in the subthalamic nucleus (STN, +85%) and in the output nuclei of the basal ganglia: internal segment of the globus pallidus (GPi, +70%) and substantia nigra pars reticulata (SNpr, +82%). This increase was partially reversed by L-dopa treatment. In PD patients, who had all been chronically treated by L-dopa, COI mRNA expression was unchanged in the output basal ganglia nuclei but increased in the STN (+71%). In both, MPTP-intoxicated monkeys and PD patients, COI mRNA expression in the external segment of the globus pallidus (GPe) remained unchanged. These results are in agreement with the accepted model of basal ganglia organization, mychich the output nuclei of the basal ganglia are considered to be overactive after. These results are in agreement with the accepted model of basal ganglia organization, in which the output nuclei of the basal ganglia are considered to be overactive after in which he output interest on the basis gainging are considered to be observed that the among on interest and activity of excitatory afferents from the STN. Yet, our results are also in contradiction with this model since the overactivity of the STN does not seem to be due to an hypoactivation of the GPe. Thus, the hyperactivity of the STN might perhaps be due to a hyperstimulation of fibres originating in the cerebral cortex and/or in the thalamus. Supported by INSERM, NPDF, MESR and MEC.

NEUROPEPTIDE mRNA EXPRESSION IS SELECTIVELY AFFECTED BY SUICIDE TRANSPORT LESIONS OF STRIATONIGRAL AND STRIATOPALLIDAL NEURONS. M.B.Harrison* and R.G.Wiley, Univ. of Virginia, Charlottesville VA 22908 and 'DVAMC, Nashville TN 37212.

Injections of volkensin (VOLK) into the SN or OX7-saporin (OX7) in the GP produce lesions of striatal projection neurons ,and demonstrate differential distribution of recentor subtypes between striatonigral or striatopallidal neurons (Harrison 1990, 1992a and b, 1993, 1994; Pollack 1993). Histologic evaluation of projection and interneurons showed appropriate specificity; however the area of maximal effect was not examined separately (Roberts 1993). In the present study, effects on preproenkephalin (PPE) mRNA in striatopallidal and preprotachykinin (PPT) mRNA in striatonigral neurons were compared at 10 days survival. Rats received stereotactic injections of VOLK (2.5 ng) in the SN (n=5) or OX7 (0.5µg) in the GP (n=4). In situ hybridization was performed on alternate sections and film autoradiographs analyzed for optical density in the maximally affected region of the striatum. In a separate series of animals treated with VOLK (n=7), cell counts of PPE neurons were performed on emulsion dipped slides to assess if an increase in PPE by remaining neurons could mask cell loss. In the VOLK lesioned animals, PPT mRNA decreased by 60% (0.075 ± 0.01 vs $0.188 \pm 0.03^{*}$; mean± se, ipsi- vs contralateral to the injection), while PPE was unchanged ($0.464 \pm$ $0.02 \text{ vs } 0.460 \pm 0.03$). Cell counts of PPE-positive neurons showed a slight *increase* on the lesioned side (282±70 vs 229±42/150 μ m²*). In OX7 lesioned animals, PPE decreased by 41% (0.300 ± 0.06 vs 0.508 ± 0.11*); PPT was unchanged (0.163 ± 0.03 vs 0.166 ± 0.03) In these animals, D1 and D2 receptor binding changes were similar to those reported previously (VOLK: D1 49% decrease, D2 16% decrease; OX7: D1 12% decrease, D2 28% decrease). These results indicate that the effects of suicide transport toxins on striatal projection neurons are selective and suggest that 40-60% of the targeted neurons in the maximally affected area are lost at 10 days. *P < 0.05, t test Supported by NINDS NS 01454; American Parkinson Disease Assn.; Veterans Admin

SELECTIVE INCREASES IN 5-HT1B AND 5-HT2 BINDING SITES IN THE RAT BASAL GANGLIA FOLLOWING SEROTONERGIC LESIONS.

V. Compan¹, M.-C. Buhot², L. Segu²* and A. Daszuta¹. Lab.

Neurosci, Comportementales & Cognitives, CNRS-URA 339, Univ. Bordeaux I, Talence², France

Talence*, France.

The distribution and regulation of 5-HT1B and 5-HT2 binding sites labelled with S-CM-G[¹²⁵I]TNH2 and [¹²⁵I]DOI, respectively, were examined by autoradiography in the basal ganglia of adult rats. In some of the animals, the serotionergic (5-HT) neurons were lesioned by injections of 5,7-dihydroxytryptamine in the dorsal and medial raphe nuclei (three weeks survival). In controls, the 5-HT1B binding sites were homogeneously distributed in the core and shell of the nucleus accumbens, as well as in the rostro-caudal levels of the caudate putamen (head, body and tail), the higher densities were observed in the ventral part of the body. 5-HT2 binding sites density increases progressively from the head to the tail of the caudate putamen. In the body of the caudate putamen, higher densities were found in the medio-dorsal region. In the nucleus accumbens, higher densities were detected in the shell than in the core.

In lesioned animals, there is a lack of changes in 5-HT binding sites density after a large but still incomplete lesion of 5-HT neurons, inducing a 80% decrease in 5-HT tissue level in the structures examined. Following a complete lesion of 5-HT neurons, a 20% increase in 5-HT1B binding sites was observed in the substantia nigra, while no changes were detected in the globus pallidus or the striatum. This kind of lesion induced a 40% increase in 5-HT2 binding sites in the medial part of the body of the caudate putamen. Weaker increases were observed in the dorsal regions, and no significant changes were detected in the head or tail of the caudate putamen. Taken together, these results suggest the existence of selective up-regulations of 5-HT receptors in the basal ganglia following complete 5-HT denervation.

SUBSTANTIA NIGRA PARS RETICULATA (SNpr) NEURONS EXHIBIT SLOW OSCILLATIONS IN FIRING RATE THAT PERSIST AFTER A 60HDA-INDUCED LESION OF MIDBRAIN DOPAMINE NEURONS. M. J. Twery* 1, D. A. Bergstrom 1, Y.-X. Li 2, J. Rinzel 2, and J. R. Walters 1. ETB, NINDS and 2 MRB, NIDDK, NIH, Bethesda, MD 20892. The expression of motor behaviors associated with thalamo-cortical circuitry has been closely linked to the level of output from basal capable centers including the SNpr. Thalamic and collicular targets of

circuitry has been closely linked to the *level* of output from basal ganglia centers including the SNpr. Thalamic and collicular targets of SNpr neuronal projections exhibit oscillatory activity patterns which may be a principal mode of regulating neurotransmission. The present study reveals that prominent oscillatory firing patterns also occur in SNpr neurons and that the basal expression of these patterns does not appear to be solely dependent on endogenous dopamine. SNpr neuronal activity was recorded extracellularly in locally-anesthetized, paralyzed rats and was recorded extracellularly in locally-anesthetized, paralyzed rats and was characterized by plotting instantaneous spike frequencies and power spectra obtained from 3-10 min spike trains. In normal rats, all neurons (n=18) exhibited a slow oscillation in firing rate with periods of 15-63 sec. This rhythmic pattern was superimposed on faster oscillations (0.8-2 sec). In 60HDA-lesioned rats (10-17 weeks post lesion), 24 of 28 neurons exhibited the long period oscillations (6-50 sec). Only 14 of 24 neurons clearly exhibited the short period oscillations (0.6-1.8 sec). A combination of fast and slow oscillatory patterns occurred in 12 of the 24 neurons from 60HDA-lesioned rats. Intravenous administration of quinpirole and/or SKF 38393 to lesioned rats altered the regularity of oscillations compared subjectively with baseline in 14 neurons. The presence of spike frequency oscillations in SNpr neurons raises the possibility that temporal relationships in firing pattern as well as the overall level of neuronal output govern the expression of motor behavior through basal ganglia circuitry. (Funding: DIR, NINDS).

THE EFFECTS OF GLOBUS PALLIDUS LESIONS ON DOPAMINE DI- AND D2-RECEPTOR MEDIATED MOTOR BEHAVIOUR IN RATS. W. Hauber*, S. Lutz and M. Münkle. Biologisches Institut, Abt. Tierphysiologie, Universität Stuttgart, Pfaffenwaldring 57, D-70550 Stuttgart; Germany.

The striatum is the main input structure of the basal ganglia and projects via two different pathways to the basal ganglia output nuclei. A direct pathway involves striatal projections to the substantia nigra pars reticulata and to the entopeduncular nucleus. An indirect pathway projects from the striatum via the globus pallidus (GP) to these output nuclei. Dopamine (DA) plays a critical role in regulating the activity of striatopallidal and striatonigral projection neurons which involves different receptor subtypes, respectively. In the striatum, the D1- subtype of DA receptors is almost exclusively expressed by striatonigral neurons, whereas the DA D2-receptor subtype is selectively expressed by striatopallidal neurons. Little is known about the relative functional significance of striatonigral and striatopallidal neurons with regard to motor control. Therefore we investigated the effects of bilateral GP lesions on motor behaviour mediated by DA D1- or D2-receptors. Results show that (1) GP lesions (AP:-0.4 mm; L: 2.8 mm; V: 4 mm) induced by quinolinic acid reduced spontaneous and d-amphetamine (1 mg/kg, i.p.)induced locomotor activity as well as spontaneous and d-amphetamine (3 mg/kg, i.p.)-induced sniffing. (2) GP lesions reduced catalepsy induced by the DA D1antagonist SCH 23390 (0.75 and 1 mg/kg, i.p.) and the DA D2-antagonist raclopride (1.25 and 5 mg/kg, i.p.). Based upon recent models of basal ganglia functions, it could be predicted that pallidal destruction should lead to motor hypoactivity. Accordingly, GP lesions reduced spontaneous locomotion and sniffing and amphetamine-induced hyperactivity. However, modified models of basal ganglia functions will be required to incorporate the finding that GP lesions reversed catalepsy induced by a DA D1- or D2-receptor blockade. Supported by the Deutsche Forschungsgemeinschaft (HA 2340/1-1).

EFFECTS OF 1-DOPA-THERAPY ON DOPAMINE D₁ AND D₂ RECEPTOR mRNAs IN THE STRIATUM OF MPTP PARKINSONIAN MONKEYS. M.-T. Herrero*, S.J. Augood', H. Asensi, E.C. Hirsch', Y. Agid', J.A. Obeso*, P.C. Emson', Experimental Neurology. University of Murcia. Spain. 'Babraham Institute. Cambridge, UK. 'INSERM U289, Hôpital de la Salpêtrière. Paris. France. *Quirón Clinic, San Sebastian, Spain

The cellular expression of both dopamine D₂ receptor (DA D₂) and dopamine D₁ receptor (DA D₁) mRNAs was examined in striatal (caudate nucleus and putamen) neurons of 12 Macaca fascicularis monkeys by quantitative in situ hybridization using human specific ³S-labelled oligonucleotides. Nine monkeys were rendered parkinsonian by systemic injection of MPTP, 3 of them also received chronic 1-DOPA-therapy. Three control monkeys were untreated and received neither MPTP nor I-DOPA. In these control brains, a substantial DA D2 and DA D1 receptor hybridization signal was detected overlying on the medium-sized striatal neurons. Moreover, some large (putatively cholinergic) neurons, in both the caudate nucleus and putamen, were hybridized with DA D₂ ³⁵S-labelled probe. Neurons from the lateral and medial regions of the caudate nucleus, and from the dorsal and ventral regions of the putamen were analysed separately. A significant increase (p < 0.05) in the cellular abundance of DA D_2 receptor mRNA was seen in the striatum of all MPTP-treated monkeys: this increase being restricted to the population of medium-sized striatal cells. However, no such increase in DA D2 receptor mRNA was observed in (dyskinetic) 1-DOPA-treated monkeys. In constrast, the significant decrease (p \leq 0.05) observed in the cellular abundance of DA D_1 receptor mRNA in the striatum of all parkinsonian monkeys was reversed after 1-DOPA-therapy The implications of these findings in relation to the dissociation of D2 and D3 coupling in the striato-pallidal pathways must be important for the development of I-DOPA-induced dyskinesias. EFFECTS OF CORTICAL LESIONS IN RAT PUPS ON PSANCAM EXPRESSION AND AXONAL PLASTICITY. Kunihiro Uryu*, Amy Butler, Victoria Morehouse, Geneviève Rougon and Marie-

Françoise Chesselet, Dep. of Pharmacol., Inst. of Neurol. Science, U. of Pennsylvania, Philadelphia, PA 19104 and U. of Aix-Marseille, France The developmental conversion of the neural cell adhesion molecule (NCAM), from its highly polysialiated (PSA-NCAM) to its mature form, follows synapse formation in rat striatum (Szele et al. '94). We have shown that PSA-NCAM loss is delayed in the striatum after lesions of the cerebral cortex on postnatal day 14 (P14), prior to the formation of cortico-striatal synapses (Butler et al., 1994). We have now examined the cellular location of PSA-NCAM immunoreactivity in the striatum ipsilateral to the lesion and determined whether axonal sprouting and compensatory synaptogenesis occur in the denervated striatum. Rat pups received a thermocoagulatory lesion of the sensory-motor cortex at P14 and were sacrificed at P25. Ultrastructural analysis showed that PSA-immunoreactivity was maintained in both pre and post-synaptic elements in the striatum on the side of the lesion. The number of asymmetric synapses (the type formed by corticostrial projections) was similar in control and denervated striatum, indicating that reactive synaptogenesis had occured. PSA-NCAM positive growth cone-like structures were more numerous in lesioned pups, suggesting axonal growth. Injections of the anterograde tracer fluoro-ruby suggesting axonal growth. Injections of the anterograde tracer fluoro-ruby into the contralateral cortex revealed a marked increase in contralateral corticostriatal projections in lesioned pups. Based on the results of Di-tracing which revealed that, during normal development, crossed corticostriatal projections are minimal after P7, the data indicate that P14 cortical lesions, which delay PSA-NCAM loss in striatal neurons, induce compensatory sprouting from the contralateral cortex and reactive synaptogenesis, suggesting that corticostriatal inputs play a role in the regulation of PSA expression. ROLE OF THE SUBTHALAMIC NUCLEUS IN CANNABINOID AC-TIONS IN THE BASAL GANGLIA OF THE RAT M. Clara Sañudo-Peña and J. Michael Walker. Schrier Research Laboratory, Departments of Psychology and Neuroscience, Brown University, Providence, RI 02912.

Receptors for cannabinoids (active principles of marijuana) are known

to be highly concentrated in brain areas that control movement. The highest concentrations are located in the substantia nigra reticulata (SNR). To date, the only known source of cannabinoid receptors to the SNR is the striatum. Previous work from this laboratory (Neurosci. Lett. 1996, 206(1):21-24) led us to propose the subthalamic nucleus as a source of cannabinoid receptors to the SNR. This hypothesis was supported by the fact that the subthalamic nucleus (major excitatory input to the SNR) has moderate levels of mRNA for the cannabinoid receptor. Also, the subthalamic input to the nigra is tonically active, in contrast to the striatonigral pathway (major inhibitory input to the SNR) which is mainly silent. The last fact might suggest the subthalamic nucleus is the main site of cannabinoid action in the SNR under basal conditions, and would agree with the study cited above. To study the possibility of the subthalamic nucleus as a second source of cannabinoid receptors in the SNR, the effect of the cannabinoid agonist WIN 55,212-2 on the activity of SNR neurons after subthalamic nucleus stimulation was recorded. A knife cut was performed to isolate the subthalamic nucleus from the rostral areas of the basal ganglia. The cannabinoid agonist WIN 55,212-2 reversed the increase in activity of SNR neurons induced by stimulation of the subthalamic nucleus. Furthermore, the effect of the cannabinoid agonist was reversed by the cannabinoid receptor antagonist SR 141716A. Therefore, cannabinoids might be exerting important actions in the basal ganglia through their modulation of the subthalamic input to the SNR.

MOTOR AND SOMATOSENSORY DEFICITS INDUCED BY UNILATERAL AND BILATERAL THERMOCOAGULATORY LESIONS OF THE CORTEX IN THE ADULT RAT.

J.A. Napieralski*, R.J.A. Banks, and M.F. Chesselet. Dept. of Pharmacology, Univ. of Pennsylvania., Phila, PA 10104
Previous studies in our laboratory have shown that contralateral cortical

neurons undergo axonal sprouting in the denervated striatum of the adult rat following a lesion of the sensorimotor cortex induced by thermocoagulation of pial blood vessels (Napieralski et al., 1995). We have examined the behavioral effects of either unilateral or bilateral thermocoagulatory lesions of the sensorimotor cortex in adult rats. Male Sprague-Dawley rats were tested to determine limb use asymmetry by analyzing 1), coordinated forelimb placement and 2), paw use preference when rearing. Their responsiveness to somatosensory stimulation was tested by analyzing 1), the latency to remove sticky tape on the ventral surface of the paw and 2), vibrissae-stimulated forelimb placing. The following day, rats received either a unilateral or bilateral thermocoagulatory lesion of the cortex, or were sham operated controls. The tests performed prior to surgery were re-administered on 4, 8, 12, 16, and 20 days after the surgery. Animals with a unilateral lesion showed a deficit in contralateral limb surgery. Animals with a unilateral tesion showed a deficit in contralateral muse and responsiveness to somatosensory stimulation which was maximal at 8 days after the surgery and returned to or near control responsiveness by day 20. Animals with a bilateral lesion showed a greater deficit in both categories with less recovery than the unilaterally lesioned animals. The data indicate that unilateral thermocoagulatory lesions of the sensorimotor cortex induce transient sensory and motor deficits in the contralateral contex induce transient sensory and motor deficies in the contralateral lesions may be due to morphological changes in neurons of the homotypic contralateral cortex as previously indicated by the presence of sprouting axons after this type of lesion. Supported by PHS grant NS-29130.

PSA-NCAM IN THE DEVELOPING STRIATUM: REGULATION BY MK-801 DURING A CRITICAL PERIOD OF DEVELOPMENT. A.K. Butler*, G. Rougon, and M-F Chesselet. Inst. of Neurol. Sci., and Dept

of Pharmacol., U. of Penn. Phila, PA19104 and U. Aix-Marseille, France. Polysialic acids associated with the Neural Cell Adhesion Molecule (PSA-NCAM) play a critical role in the development of the nervous system. In the rat striatum, loss of PSA-NCAM immunoreactivity occurs after the formation of corticostriatal synapses, which use the neurotransmitter glutamate (Szele et al. '94). Peripheral injections of the non-competitive antagonist of the NMDA type of glutamate receptor, MK-801, from postnatal day 14 (P14), before corticostriatal synapses formation, until P24, after the number of corticostriatal synapses has reached the adult level, result in a precocious loss of PSA-NCAM in the striatum and cortex, but not hippocampus (Butler loss of PSA-NCAM in the striatum and cortex, but not hippocampus (Butler et al '95). We have now determined the critical period of MK-801 actions by examining shorter treatment periods. Sprague Dawley rat pups were injected with MK-801(0.25 mg/kg once daily, ip), either starting at P14 (before cortico-striatal synapse formation) or P18, (when corticostriatal synapses reach a peak). Striatal sections were processed for immunohistocehmistry with an antibody recognizing specifically PSA residues associated with N-CAM in mammalian brain (Rougon et al, 1986). No loss of PSA-NCAM expression was observed when rats were treated with MK-801 from P14 to P16 or P18. In contrast, treatment with MK-801 from P14 to P16 or P18. In contrast, treatment with MK-801 from P18 to P20 or P22, but not P18 and P19 only, resulted in a precocious loss of PSA-NCAM in the striatum and cerebral cortex. The data identify periods of NMDA-independent and NMDA-dependent PSA expression in rat forebrain. The latter corresponds to the emergence of spontaneous activity in corticostriatal afferents and a decrease in the expression in a foreignment the latter corresponds to the emergence or spontaneous activity in corticostriatal afterents and a decrease in the number of corticostriatal synapses, suggesting that PSA-NCAM may play a role activity-dependent synaptic plasticity during striatal development. Supp. by PHS grants NS-29230 and 1 F31 MH10794-01.

PUTATIVE PROPERTIES FOR A PACE MAKER FIRING MODE IN SUBTHALAMIC NUCLEUS NEURONS. A STUDY IN RAT BRAIN SLICES. \underline{C}_{\cdot} Beurrier, J. Audin and B. Bioulac*. CNRS UMR 5543, Univ. Bordeaux 2, 33076 BORDEAUX FRANCE.

BORDEAUX FRANCE.

The subthalamic nucleus (STN) is part of the indirect striato-pallidal pathway of the basal ganglia (BG). STN neurons form the glutamatergic subthalamo-pallidal bundle and exert an excitatory effect upon the globus pallidus internalis, i.e. the main outpout structure of BG. A current hypothesis, concerning Parkinson's disease, infers an overactivity of this glutamatergic pathway. In order to reach a better understanding of the physiology of STN neurons and thereby their possible dysfunctions, we have analyzed their membrane properties in rat brain slices.

A first forestartivity of these neurons is their conveneurs are a really fine neuron.

A first characteritic of these neurons is their spontaneous pace maker firing mode (22.8 Hz, n=15). However, the main observation is the presence, for all these neurons (n=18), of a low threshold spike (LTS or slow action potential, SAP). SAP is obtained in neurons with a membrane potential around -70 mV after the offset of an obtained in neurons with a membrane potential around -70 mV after the offset of an hyperpolarizing pulse ($^{\circ}$ 0.1 to 0.5 nA) and leads to a burst of action potentials. The SAP is blocked by a Ca^{2+} free medium (with Co^{2+} , Cd^{2+} or Mg^{2+}) and may be linked to the activation of T type Ca^{2+} channels. Moreover, membrane responds to an hyperpolorizing pulse by a clear anomalous rectification. Finally, in some cases (n=7), a weak depolarizing pulse (0.05 to 0.1 nA) elicits a slow depolarizing potential (SDP) in neurons with a membrane potential around -60 mV. Again SDP is abolished by a Ca^{2+} free medium (with Co^{2+} , Cd^{2+} or Mg^{2+}) and could correspond to the activation of Lype Ca^{2+} channels.

abolished by a Ca⁻⁺ Tree medium (with Co⁻⁺, Cd⁺⁺ or Mg⁺⁺) and could correspond to the activation of L type Ca²⁺ channels.

The interplay between these two Ca²⁺-dependent mechanisms and the anomalous rectification could contribute to generate the pace maker firing mode. Experiments, with more specific Ca²⁺ channels blockers, are currently carried out to precise the respective role of Ca²⁺ channels in SAP and SDP. Further works will attempt to study how, after lesion of dopamine neurons as in parkinsonism, the pace maker firing mode of STN neurons becomes hyperactivated.

ANTICONVULSANT EFFECTS OF FOCAL INHIBITION OF THE SUBTHALAMIC NUCLEUS. <u>D. Dybdal 'and K. Gale</u>. Deptartment of Pharmacology, Georgetown Univ. Med. Ctr., Washington DC, 20007. The subthalamic nucleus (STN) plays a crucial role as a regulator of basal ganglia outflow by providing excitatory drive into the substantia nigra (SN) and the entopeduncular nucleus (EPN). This excitatory influence has been shown to be mediated by glutamatergic neurons projecting from STN to SN/EPN, and to be subject to GABA-ergic inhibition at the level of STN. Because focal blockade of glutamate transmission within SN or EPN has been shown to have an anticonvulsant effect we hypothesized that has been shown to have an anticonvulsant effect, we hypothesized that focal, pharmacological inhibition of STN would also reduce seizure susceptibility. To test this hypothesis, the GABAA agonist, (200 pmol), was infused uni- or bilaterally into the STN of awake, behaving rats prior to seizure induction.

behaving rats prior to seizure induction.
Limbic motor seizures were evoked either focally from area tempestas, an epileptogenic trigger site in the pre-piriform cortex, or by intravenous injection of bicuculline. Unilateral pretreatment with muscimol in STN produced postural asymmetry but had no significant protective effect in either model of seizure induction. Bilateral pretreatment with muscimol in STN, 5 min prior to evoking seizures from area tempestas, resulted in a STN, 5 min prior to evoking seizures from area tempestas, resulted in a reduction in both severity and frequency of seizures compared to saline pretreatment in STN. Bilateral pretreatment with muscimol in STN also protected against seizures evoked by intravenous bicuculline. Anticonvulsant effects were site specific inasmuch as bilateral injections of muscimol into areas adjacent to STN were without effect. These results indicate that inhibition of STN is capable of reducing seizure susceptibility, and are consistent with the view that the STN is an important source of excitatory drive to SN and EPN.

CONTROL OF POSTURE AND MOVEMENT: MOTOR LEARNING

354 1

ADAPTIVE LEARNING GENERALIZES ACROSS DIFFERENT MOVEMENTS. M. A. Conditt*, F. Gandolfo, F. A. Mussa-Ivaldi. SMPP, Rehab. Inst. Of Chicago, Chicago, IL 60611 and Dept. of Brain and Cog. Sci., MIT, Cambridge, MA 02139.

It has been shown (Flash and Gurevich, 1992; Shadmehr and Mussa-Ivaldi, 1994) that

the human motor control system adapts to changes in the dynamics of the environment while performing point-to-point reaching movements. Furthermore, Gandolfo et al. (in press) have shown that the effects of adapting to a particular force field are limited to a region surrounding the states (positions and velocities) explored during the training period. The purpose of this study was to determine whether adaptation is restricted to the particular trajectories that have been exposed to the field. The first objective was to determine whether adaptive behavior is evident in movements other than reaching movements. We found that subjects were able to adapt to a viscous field while performing more complex movements. The second objective was to determine whether adaptive learning transfers to different movements across the same region of state space. This is an important issue because the inability to transfer adaptation between different movements would contradict the hypothesis that adaptation is achieved by means of an internal model of the environmental forces. To address this issue, we asked subjects to execute reaching movements in different directions within a field of viscous perturbing forces until the reaching movements were fully adapted. Immediately following adaptation, we asked the subjects to execute circular movements that passed through many of the same positions and velocities as during the adaptation phase, albeit in a different temporal order. We found that in all our subjects, adaptation was preserved during the execution of the circular movements. Our results indicate that adaptation is a property of the visited states and does not depend upon the temporal order in which these states have been explored. This provides evidence that the internal model of the environment responsible for adaptation may be implemented in a manner functionally independent of the representation of the planned movement trajectory. FORWARD INTERFERENCE IN MOTOR LEARNING.

Ralph and Marian C. Falk Medical Research Trust Fund.

A Thoroughman*, and R Shadmehr. Dept. of Biomedical Engineering, Johns Hopkins Univ., Baltimore, MD 21205.

We have conducted psychophysical studies in which human subjects learn to make reaching movements in novel dynamic environments (Shadmehr and Mussa-Ivaldi, J. Neurosci. 1994). Here we show evidence that learning one force field can interfere with the ability to learn a second field. This forward interference occurred if subjects were exposed to a second field immediately after the first, but not if there was a five-hour delay between fields. We have trained other groups of subjects with thirty minutes or two hours between the fields, and have shown that the forward interference diminshes gradually with increased delay. We have measured EMG signals from the arms of subjects learning one field, then a second field either immediately after or six hours after the first. When subjects initially move in the first field, muscles around the shoulder and elbow cocontract. With continuous practice, however, this cocontraction decreases and muscles selectively activate to appropriately resist the force created by the robot. Subjects who are presented the second field with no delay after the first retain the same pattern of muscle activation. even though this pattern is inappropriate for the new field. Subjects with the six-hour delay, however, rapidly produce an activation pattern appropriate for the new field. These results suggest that the subjects build model of the force field and activate muscles to balance the predicted force. When subjects are presented with a second field immediately after the first, they erroneously rely on the model of the first field. With a delay between fields, subjects gain the ability to quickly build a new model for the new environment. Funded by Whitaker Foundation and ONR.

ESTIMATION OF PRIMITIVES FOR MOTOR ADAPTATION . Gandolfo* and E. Bizzi

Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

We studied the mechanism of the adaptation to perturbations during arm movements. We asked human subjects to execute planar arm movements while grasping a manipulandum which was used both to record kinematic data and to perturb the subjects. The perturbations, normal to the movement and proportional to the movement velocity, significantly altered the trajectories. We tested the subjects after the perturbing forces were discontinued and observed aftereffects as a mirror image of the perturbed trajectories. We interpreted the aftereffects as evidence for an internal model, defined as a mapping between the limb state and the torques to compensate for the external disturbances.

Adaptation to disturbances is local in the sense that the changes affect the perturbed trajectories and a small region around them. We present evidence that the size of the affected region depends on the experienced states, and can therefore be adjusted to the smoothness of the perturbation. We investigate how far the resolution of the system can be pushed and how it can be manipulated by training.

The experiments were carried out both on human subjects and in simulation. In the simulation, the compensatory torque field is estimated using smooth local kernels modulated by the adaptation process. For each simulated movement, the model uses the current map and updates it to incorporate the

We show that the procedure converges onto a smooth map which models the perturbations. We successfully simulated psychophysical experiments on humans. The model produces comparable results not only with regard to the generalization properties of adaptation, but also to the time course of learning. INTERNAL MODELS OF DYNAMICS IN MOTOR LEARNING AND CONTROL. J.R. Flanagan*, A.M. Wing. Queen's University, Kingston, Canada, MRC Applied Psychology Unit, Cambridge, U.K.

We examined movements of a hand-held object under

inertial, viscous, and elastic load conditions. The grip force used to hold the object, the load, and the movement trajectory were measured. Under all load conditions, we observed that grip force was modulated in phase with fluctuations in load force. This finding indicates that the motor controller is able to precisely predict acceleration-, velocity-, and position-dependent loads. This prediction is presumably based on an internal model of the dynamics of the motor apparatus and external load.

Over the initial trials with the unfamiliar viscous load, the velocity profile evolved from an irregular to a smooth pattern. However, during this period (with the exception of the very first trial) grip force was still modulated in phase with the load. This indicates that the controller was able to predict the load before learning the commands required to generate smooth movements. These results suggest that learning to move an unfamiliar load involves two processes: (1) a rapid updating of the internal model of dynamics and (2) a slower adaptation of central commands to achieve a desired trajectory.

Optimization Criteria Driving Adaptation in Manipulative Hand Movements. K.E. Novak, L.E. Miller, J.F. Baker *, and J.C. Houk.

Northwestern University Physiology Dept.; 303 E. Chicago Ave.; Chicago, IL 60611
This study aimed to understand the processes driving motor adaptation in rapid manipulative hand movements. Subjects grasped a grooved knob and made brisk turning motions to various LED targets, similar to turning a radio dial. A motor attached to the knob shaft could be configured to apply a destabilizing negative viscous load. Following a period of practice with no load, the load was applied, typically resulting in target overshoots and subsequent corrective movements. After about an hour and nearly 1000 trials, subjects again learned to move accurately and rapidly in the new dynamical environment, returning their performance near previous levels. Measures of performance included the accuracy of the primary movement, the frequency and amplitude of corrective movements, task success rate, mean squared jerk and mean displacement from a no load condition velocity template. Subject tended to make discrete corrective movements towards the target during the decelerative phase of the movement and/or after the primary movement in order to improve upon the end point accuracy of the primary movement. Both the amplitude and frequency of corrective movements decreased during adaptation as the subjects made fewer target overshoot errors. These results are consistent with the adjustable pattern generator array model of cerebellar motor learning (Berthier et al., 1993, J. Cog. Neuroscience 5: 56-78), in which adaptation of the motor controller is driven by the occurrence of corrective movements signalling errors in primary movement endpoint accuracy. It is believed that the smoothness of movements, which some hold as the optimization criterion in adaptation, is instead a secondhand result of the increased accuracy and decreased occurrence of corrective movements resulting from motor adaptation. A more biologically plausible optimization criterion is the minimization of the occurrence of corrective movements or the effect of applied perturbations, which are proposed to

trigger climbing fiber "training signals" for adaptive change in the cerebellum.

DYNAMIC COORDINATION OF BODY PARTS DURING THROWING AT VISUAL TARGETS <u>B.E. Greger, T.A. Martin, W.T. Thach.</u> Dept. of Anat. and IWJ Rehab. Res. Inst., Washington Univ. School of Med., St. Louis, Mo, 63110. In throwing at a visual target while wearing laterally displacing wedge prisms,

subjects adaptively widen the gaze-throw angle. Over a short term (=50 throws), subjects widen this angle (adaptation). The new calibration is retained for a day or longer. Over a longer term (3900 throws, 2 weeks) of alternate prism/no-prism throws, subjects acquire a wide gaze-throw prism calibration in addition to the

narrow no-prism calibration (learning) (Martin et al., 1996). Having acquired the 2nd calibration subjects hit the target upon each first throw, prism or no-prism. We asked the question: does the widened gaze-throw angle consist of a fixed relation among body parts, or instead a changing and interdependent relation among body parts? In two long term prism/no-prism trained subjects we video-recorded positions of head, shoulders, and arm while throwing with and without prisms. Knowing that eyes foveated the target we computed the angular positions of eyes-in-head, head-on-trunk, trunk-on-arm and ball-on-target. In each subject, the gaze adjustment was not confined to any one set of 2 members (e.g. eyes-in-head), but instead was distributed across all 3 sets of coupled body parts. Each subject had a different distribution of coupling across the 3 sets of body parts. The distribution of the coupling changed unpredictably both within a single throwing session and across sessions. The angular variation among the 3 sets of coupled body parts was in most cases substantially larger than the angular variation of the hits on the target. The data indicate that the coupled body parts must be changed interdependantly in order to account for the high accuracy of ball-on-target.

Previously, we created a schematic model based on the knowledge that the

revolutisty, we created a scientiatic moder based on the knowledge that the cerebellum plays roles both in the coordinated movement of multiple body parts and in motor learning (Thach et al., 1995). The data supports this model by showing a high degree of coupling across body parts; and by demonstrating a dynamic and generalized solution as evidenced by the distribution of the gazethrow adjustment across body parts. THE TIME-COURSE OF PRISM ADAPTATION IN A MONKEY GIVEN

THE TIME-COURSE OF PRISM ADAPTATION IN A MONKEY GIVEN DELAYED VISUAL INFORMATION. S. KITAZAWA*, AND T. KIMURA, Neurosci. Section, Electrotechnical Lab., PRESTO, Japan.

The ability to accurately reach toward a visual target is impaired when the visual field is displaced by prisms, but returns with practice (prism adaptation). When the prisms are removed, subjects misreach in the opposite direction (after-effect), but eventually adapt again. Previously, we reported that such adaptation in humans is dependent on the availability of visual information within 50 msec after the completion of the movement (Kitazawa et al., 1995, J Neurosci, 15:7644). The present study involves a monkey trained to reach rapidly (within 300 msec) at a target on a tangent screen (200 mm away). Vision was always blocked during the reaching movement, but was unblocked for 300 msec after the monkey's index finger touched the screen. In the experimental phase (n=112), the visual field was displaced by prisms (25 diopter) in one of eight directions (0, 45, 90, was displaced by prisms (25 diopter) in one of eight directions (0, 45, 90, etc, to 315 deg) and vision was unblocked after the finger touch without was uispractory prisms (2) dopler) in the origin directions (0, 43, 80, etc., to 315 deg) and vision was unblocked after the finger touch without delay. The monkey misreached in the direction of visual displacement. Errors decreased with practice by an amount proportional to the error in the preceding trial, as was observed in our human studies. After the prisms were removed, vision was available only after a delay period of 0-500 msec, while the monkey maintained its final pointing position. The monkey misreached in the opposite direction initially, but again the error decreased with practice. The rate of decrease of error was generally largest when the delay was 0 msec, diminished when the delay was 50 msec (p<0.06), and was significantly smaller thereafter (100-500 msec, p<0.05). When the contralateral arm was used after removal of the prisms, no significant aftereffect was observed, even in the initial trials. The results suggest that the underlying changes occur in the part of the nervous system that controls unilateral arm movement and that these changes are primarily produced by visual information that closely correlates with the motor output in a given time domain. LEARNING THE DYNAMICS OF A VIRTUAL OBJECT: PRACTICE BUILDS AN INTERNAL MODEL. G. Robles-De-La-Torre and R. Sekuler*. Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We developed a novel paradigm to study how human performers acquire and use internal models of the dynamics of unfamiliar, virtual objects. A performer tries to maintain alignment between a virtual object and a static target whose position in one dimension is randomly perturbed every few seconds. By applying a series of discrete forcepulses, performers try to drive the object as quickly as possible into alignment with the target. The virtual object's responses to force pulses are governed by differential equations equivalent to an n-stage network of mechanical resistors and springs. By minimizing complexity of visual and motor components, the paradigm allows us to characterize the internal model (IM) that arises out of interactions with the virtual object. We compared the behavior of human performers to the behavior of an Ideal Performer (IP), a predictive control system that minimizes performance error. Over hundreds of trials, subjects' performance approached that of the IP. Given that the IP uses complete knowledge of the virtual object's physics (its differential equations), subjects' improvement suggests that their IMs also incorporate basic features of this physics. We discuss experiments to distinguish between an abstract IM (incorporating function-like information about the underlying physics, as the IP does) and an IM based on manipulation of exemplars, without explicit knowledge of the task's physics.

ADAPTATION OF THROWING TO VERTICALLY-SHIFTING PRISMS IS NOT LIMITED TO TIMING OF RELEASE, BUT INVOLVES THE MODIFICATION OF SEVERAL PARAMETERS. <u>T.A. Martin* and W.T. Thach.</u> Dept. of Anatomy and Neurobiology and IWJ Rehab. Res. Inst., Washington University School of Medicine, St. Louis, MO, 63110.

Hore et al. (J.Neurophysiol., 75, 1996) have hypothesized that the normal variance in vertical error while throwing at visual targets may be due to changes in any of three throw parameters: hand translational velocity, hand location in space, and hand orientation. From an analysis of skilled throwers, they concluded that the vertical error correlated best with the variance in hand orientation which was related to the timing of ball release

We have previously reported that adaptation of throwing to laterally-shifting wedge prisms is an automatic and gradual process resulting in a widening of the horizontal gaze-throw angle (Martin et al., 1996; Thach et al., 1995). We demonstrated that the widened gaze-throw angle (approximately 17.5° for 30 diopter prisms) is distributed among three sets of coupled body parts -- eyes-in-head, head-on-shoulder, and shoulder-on-arm.

We were interested in the types of modifications that would occur when subjects adapted throwing while wearing vertically-shifting prisms (with the prisms placed base up or down). Presumably, the gaze-throw angle would similarly widen but in the vertical direction.

Video-based motion analysis shows that timing of release is not the only variable modified during adaptation of throwing to vertically-shifting prisms. Modifications of both position and velocity of the hand play an important role in the adaptation. While Hore et al. may be correct in their analysis of normal, over-practiced throwing, from our results, we conclude that during learning, more degrees of freedom and sources of potential error are modified to achieve the gaze-throw recalibration required to hit the target. A FUNCTIONAL MRI STUDY ON INTERNAL MODELS OF DYNAMIC TRANSFORMATIONS DURING LEARNING A VISUOMOTOR TASK. H. Imamizu*¹, S. Miyauchi², Y. Sasaki², R. Takino², B. Pütz², and M. Kawato¹ATR Human Information Processing Research Labs., Kyoto, Japan; ²Communications Research Labs., Tokyo, Japan

Some recent computational studies have stated that the central nervous system (CNS) acquires internal models of the kinematics and/or dynamics of controlled objects and environments for rapid and smooth control (e.g. Kawato & Gomi, 1992, TINS, 15, pp. 445-453). However, it is still unclear as to which part of the CNS is involved in acquiring these models during the control of visually guided limb movements. Using fMRI (1.5T, Siemens VISION, echo planar imaging) we examined cortical and subcortical activity in normal human subjects learning a visuomotor task under the dynamic alteration of visual feedback of the hand position. The task for the subjects was to move a computer mouse so that the cursor follows the target moving on the screen as closely as possible (a modification of the task used in Flament et al. 1994, Soc. Neuosci. Abst. p. 20). The position of the cursor was altered by a dynamic transformation of the mouse movement, namely integration of the previous mouse positions, in learning periods whereas no transformation was imposed in control periods. The errors, measured by taking a distance between the cursor and the target, decreased with practice in the learning period. Images (8-10 slices, 7-10 mm thick, through the cerebellum, occipital, parietal and part of the frontal lobes) scanned in both periods were compared with cross correlation. We found that the MR signal intensity in the biventer lobule of the cerebellum and parietal areas 5 and $\tilde{7}$ was significantly higher in the learning period. The results suggest that these areas are involved in error correction by comparing visual information and kinesthetic information and in acquiring the internal models of the imposed dynamic transformation

INCREASED KINEMATIC INFORMATION IS ENCODED BY PRIMATE CEREBELLAR THALAMIC NEURONES DURING MOTOR LEARNING E.G.Butler*, D.W.Bourke, M.C.Harvey, D.I.Finkelstein and M.K.Horne Dept of Anatomy, Monash Uni., Clayton, Victoria, Australia, 3168.

To date, there is limited evidence of involvement of the cerebello-thalamo-cortical

(CTC) pathway in the learning of voluntary movement. If learning a voluntary movement is dependent on cerebellar function, the resulting signal must pass via the CTC pathway to modify a cortically-generated movement. The aim of this study was to determine whether cerebellar thalamic neurones exhibit changing discharge over time with motor learning. Chronic single cell recordings were made in 2 macaques trained to perform a visually-cued reaction time task of the wrist, in which the gain between the manipulandum and the visual display was changed (to 0.5 or 2.0) to elicit a learning response. During motor learning a number of kinematic parameters were scaled, including peak velocity and acceleration, duration of movement and positional error. Time to peak velocity was usually invariant. Recordings were made from 35 wrist-related cerebellar thalamic neurones. During the recording of 20/35 neurones, the monkeys exhibited stereotyped control movements which were comneurones, the monkeys exhibited stereotyped control movements which were com-pared with novel movements which the animal learnt or attempted to learn. For 10/20 cells (50%) there was scaling of the amplitude of neuronal discharge (ND) over time during the learning phase of a novel gain, compared with 4/20 cells (20%) during the stereotyped control movement. Also, there was a significant correlation between ND and one or more of the kinematic parameters listed above for 10/20 cells (50%) during motor learning, compared with 1/20 cells (5%) during the control movement. These preliminary results demonstrate that during the acquisition of a motor skill there is a significantly increased number of cerebellar thalamic neurones which exhibit changes in neuronal discharge over time, typically concurrent with learning-dependent changes in movement kinematics

DIFFERENCES IN GENERALIZATION OF ADAPTATION TO ALTERED GAINS AND DISPLAY ROTATIONS IN REACHING MOVEMENTS. J.W.Krakauer, Z.M.Pine* and C.Ghez. Dept. Neurology., Dept. Rehab.

Med., Ctr. Neurobiol. & Behav., Columbia Univ , New York, NY 10032
Previous work suggests that reaching movements to visual targets are planned vectorially, as an extent and a direction. We have recently shown that learning a new scaling factor for visual to hand-space representations is more rapid than learning a new directional map. The present study further analyzes differences in learning by examining generalization, with training limited to a single movement origin and target location. Subjects made out-and-back movements of their hand from a central location to a circular array of equidistant targets on a horizontal tablet. Targets and a cursor were displayed on a vertical computer monitor. In a control cursor were displayed on a vertical computer monitor. In a control condition, the gain of the path display (hand:screen) was 1:1 and the upward screen direction from the origin corresponded to straight ahead for the hand. In training, hand to screen mapping was changed either by altering the gain (1.5 or 0.67) or by rotating direction 30°CCW while subjects practiced reaching to a single target location. Adaptation was rapid in both cases. However, this learning was generalized only for the gain condition but not for the rotation. Movements made without feedback after adaptation to display rotation were only accurate for the training. after adaptation to display rotation were only accurate for the training direction and fell to zero within about 45° on either side.

The more rapid learning and generalizability of learned scaling suggests that local training allows subjects to acquire a metric rule for scaling responses to a range of locations. The substantial failure of generalization of direction suggests that the directional maps are learned locally. Generalization may require training in multiple directions and a working memory buffer. Supported by NS22715, HD01018 and T32NS07155.

PATTERNS OF REGIONAL BRAIN ACTIVATION ASSOCIATED WITH DIFFERENT ASPECTS OF MOTOR LEARNING C.Ghez. M.F.Ghilardi. J.R.Moeller, V.Dhawan and D.Eidelberg Ctr.Neurob.Behav, Columbia Un NYS PI, New York; INB-CNR, Milan; North Shore Un.Hosp, Cornell Un,Manhasset New York.

On, mannasset new York.

To examine the variations in regional cerebral blood flow during execution and learning of reaching movements, we employed a family of kinematically and dynamically controlled motor tasks in which cognitive, mnemonic and executive features of performance can be differentiated and characterized quantitatively.

During each 90' scan using ¹⁵O-H₂O PET,12 right-handed subjects

bring each 9 scan hand on a digitizing tablet from a central location to equidistant targets displayed with a cursor on a computer screen in synchrony with a 1/s tone. Movement conditions were: M1, movements to predictable targets; M2, learning of a new visuomotor transformation where cursor motion on the screen was rotated by 30-60°; M3, discovering target sequence of 6 to 8 elements using visuospatial working memory. Control condition, S, was observing screen displays and tones. Subtraction images were analyzed with Statistical Parametric Mapping (SPM) to identify significant foci of brain activation. SPM on M1-S subtraction images showed significant foci of brain activation. SPM on M1-5 subtraction images snowed activation of left putamen and areas 4, 7, ight cerebellar hemisphere and bilateral cerebellar vermis and SMA.. For M2-M1 contrast, SPM detected activations of right areas 6, 46/9, 7 and cerebellum. Finally for M3-M1 contrast images SPM showed significant bilateral increases in areas 6, 46/9, 7 and cerebellum. These findings indicate that while motor execution is mediated by contralateral activation of motor cortex, striatum and cerebellum, by contrast visuomotor transformations and the learning of spatial sequences is mediated by the activation of additional frontal parietal and cerebellar regions. Supported by NS 22715

LIMITED IMPROVEMENT OF FAST MULTIJOINT COORDINATION WITH

EXTENDED PRACTICE. S.G. Massaquoi* K. Irfan, A. Bryant and M. Hallett. Human Motor Control Section, Medical Neurology Branch, National Institute of Neurological Disorders and Stroke, Bethesda, MD, USA, 20892-1430.

Three normal, healthy, male subjects (ages 29, 38, 64) performed 1740 left-to right, planar, high but sub-maximal velocity hand movements in an effort to trace accurately a visibly straight (corrected for curvature illusion) template with a feltaccurately a visiny staggin confected to culvature mission (employed with a telephone tripped marker. Movements were performed in blocks of 60 trials, 2-4 blocks per session, I session every 2 days on average. Subjects' arms had free rotation at only elbow and shoulder. To prevent visual feedback in transit, the movements themselves were made in darkness, and subjects viewed tracings after 1-3 trials on average.

Studied movements were from the first block of each session and had durations of 235 ± 20 msec (peak hand velocities in the range of 3-6 m/sec). The range chosen eliminated any trend in movement time across the training. Error measures were: Peak Path Curvature (PPC) and Root Integrated Square Error (RISE). Trends in neasures were assessed using linear regression versus day of testing.

Two subjects (ages 29, 64) showed a significant decline of PPC over the 9 sessions

(p<0.048, p<0.096) typically developing flatter, S-shaped paths (having two-lobed deviations) without a decline in RISE. The third subject developed a three-lobed, wave-like path with significant decline in RISE (p<0.004) but without decline in PPC. None of the subjects generated any movements having PPC < 0.5 radian/meter (a small but clearly visible curvature). Of the 149 movements with criterion speed, only four achieved a RISE < 0.002 meter^{3/2} (corresponding to a path which deviates

only four actineved a RISE 2 O.02 interest (Corresponding to a paint which deviates by less than the thickness of the marker trace) and these had PPC > 2.0.

1740 repetitions enabled improvement of path linearity in terms of either peak path curvature or separation from template but not both, and neither measure was perfected to the limits of error visibility. There may exist limitions in the neural motor control system which practically prevent complete inversion of high-speed multijoint arm dynamics and yield different approximation strategies. Alternatively, complete dynamic inversion may require extremely long or more intensive training

BRAIN NETWORKS MEDIATING IMPLICIT AND EXPLICIT ASPECTS OF MOTOR LEARNING REVEALED BY PRINCIPAL COMPONENT ANALYSIS. JR Moeller, C. Ghez, MF Ghilardi. V. Dhawan and D. Eldelberg. Ctr.Neurob.Behav, Columbia Un, NYS PI, New York; INB-CNR, Milan; North Shore Un.Hosp, Cornell Un,Manhasset New York.

We examined the variations in regional cerebral blood flow during execution and learning of reaching movements to visual targets using ¹⁵O-H₂O PET. During 90' scan, 12 subjects moved their right hand on a digitizing tablet from a central location to equidistant targets in synchrony with a 1/s tone. Success was signaled when the correct target was reached in a time window centered on the tone. A sensory control without movement(S, scrambled visual and auditory display) and three movement conditions were examined: M1, movements to predictable targets; M2, adaptation to a rotated hand-path display; M3, discovering target sequence adaptation to a rotated nano-parti display, M.J., discovering target sequence by frial and error using visuospatial working memory. Improvement in spatial and timing errors as well as a global performance score were computed for each test. Subtraction images were analyzed by Subprofile Scaling Model (SSM) with principal component analysis to identify regional covariance patterns. Individual scores for pattern expression in SSM were correlated with changes in errors and performance scores. M1-S, improvements in spatial accuracy were predicted by pattern-related increases in left striatum spatial accuracy were predicted by patient-related increases in *Iner* situation with covariant reductions in premotor cortex. <u>M2-M1</u>: adaptive changes in mean direction errors were predicted by network-related increases on the *left* in areas 7, 6, 46, 24, and SMA with covariant decreases in putamen. <u>M3-M1</u>: Rate of sequence learning was correlated with increased activation in *right* hippocampus and reductions in area 24. Specific aspects of motor learning are expressed by distinct brain networks which are evident using principal component analysis. Supported by NS 22715.

THE EFFECT OF PRACTICE ON THE MANUAL INTERCEPTION OF MOVING OBJECTS. H. Carnahan*1, C. Hall², and C. Doerksen¹. ¹Dept. of Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada, N2L 3G1. ²Dept. of Kinesiology, Univ. of Western Ontario, London, ON

How does practice alter our integration of environmental information into our motor map and how is timing represented in this process? Two studies were conducted that address these issues. In the first study, 6 subjects performed 5 trials picking up a small stationary object. Then they performed 80 consecutive trials picking up a moving object. Finally, they performed 5 stationary post-test trials. Results showed that when performing reaches to stationary objects subjects sped up across trials. When subjects were intercepting moving targets the speed of their reach and the speed of hand closure around the object slowed with practice. In a second study, 10 subjects performed 120 trials of reaching to grasp a static object. After a rest they performed 10 additional stationary trials , and 10 moving object trials. A second group of 13 subjects performed 120 trials of reaching to grasp a moving object. These subjects performed the same retention tests as the static trained group. Results showed that for the static trained group. reaching speed increased with practice. However, for the group trained with moving targets, there was a trend to decrease speed with practice. For the static retention test, static trained subjects moved more slowly than those trained with the moving target. For the moving target retention test, subjects training with the moving target were much slower than the static trained subjects. These findings support a specificity of training perspective. As well, they suggest that learning a dynamic visuomotor task involves developing a perceptual model of target motion and integrating this representation into a sensory-motor map. (Supported by NSERC)

PRACTICE VARIABILITY DURING MOTOR SKILL ACQUISITION

LB. Fineman* & A.M. Gentile, Teachers College, Columbia Univ., NY 10027.

When several variations of a motor task are learned concurrently, contextual interference studies (c.f. Magill & Hall, 1990) have typically found better retention and transfer with random practice (trial-to-trial task-variations) than blocked (successive trials on one variation before switching to next). However, contradictory results (blocked better than random) have been reported (Barth et al. 1994, Pinto-Zipp & Gentile, 1906). Placked wavelength probling a wavenum topological which 1995). Blocked practice purportedly stabilized movement topology which is required in early learning. Prior studies reporting a random practice is required in early learning. Frior studies reporting a random practice benefit simply required scaling an available movement pattern; thus, subjects were beyond an initial learning phase. We examined whether initial learning is enhanced by high or low variability during practice. The task required using chopsticks to transport Small, Medium or Large buttons to a receptacle as rapidly as possible. Three practice conditions were used: Random (R)-5 trials on each button in random order. Blocked were used: Random (R)-3 trials on each outton in random order. Biocked (B)-5 successive trials with each button, Consistent (C)-15 trials with M button. During acquisition (ACQ), 24 adults were trained using a crossover design involving 4 schedules: R/B; B/R; R/C; C/R. Dependent variable was movement time. Retention was tested on M button only (10variable was movement time. Retention was tested on M button only (10-min & 7-days later); transfer tested on button sizes outside original range. During ACQ, having random practice first produced a significant benefit when switched to blocked or consistent; whereas the reverse orders did not. Retention was best when initial practice was random (R/C; R/B); poorest when initial practice was consistent (even though C/R had more trials on M button). Transfer effects were not found. Hence, during initial learning, switching practice conditions from high to low variability facilitated motor skill acquisition extending prior findings of contextual interference effects favoring random practice.

A MOTOR TASK WHICH REQUIRES MOTOR LEARNING IN MONKEY ARM MOVEMENTS. EIZO MIYASHITA, TOSHIHIRO MATSUL BUNYA KUZE, SHIGEMI MORI, Lab. of Neurobiol., Natl. Inst. Physiol. Sci., Okazaki, 444, Japan

The aim of the study was to devise a motor task which requires motor learning in monkeys. A coil was attached on the bottom surface of a freely movable handle (within a area of about 30 cm × 30 cm on the horizontal plane) which had been connected to a pole with two arms and joints. The position of the handle was detected using a digitizer and displayed as a cursor on a computer display (17 inch), surface of which was perpendicular to the surface of the digitizer. Two visual targets (target C with a radius of 1 cm in the center and target P with a radius of 1 cm in the periphery of the display) were displayed successively on the same computer display. The position of the target P in each trial was randomly chosen from eight different positions on a concentric circle with a radius of 10 cm. Two monkeys (macaques) were trained to hold the handle to keep the cursor within the target C for 3 seconds then to move the handle to move the cursor within the target P within 5 seconds. The distance between the surface of the computer display and the monkeys eyes was about 50 cm. Positions of the handle and the joints of the elbow and shoulder during the task were captured by using a high speed video camera (250 frames/s). The accomplishment of this motor task seems to require motor learning because the decrease of the movement time and of the variability of trajectories was observed with training progression. Supported by a grant from Uehara Memorial Foundation to EM.

MOTOR SKILL ACQUISITION AND RETENTION IN ELDERLY WOMEN M. Zichettella & A. M. Gentile*. Teachers College, Columbia Univ. NY 10027; University of Scranton, PA 18510.

Learning and retention (10 days) of a novel motor task were examined in 10 young (age 18-28 yrs) and 10 elderly women who were divided into two groups: Young Elderly (Ey) 65-70 yrs; & Old Elderly (Eo) 71-80 yrs. A follow-up study examined long-term retention (20 months later) for all Ey and 7 young subjects. Task involved donning a molded ankle-foot orthotic, commonly used with stroke patients. Subjects were shown the orthotic's final position on foot/leg; movements to reach this goal were not demonstrated or described. Performance on 5 consecutive days of acquisition (ACQ) and on retention tests was video taped. Two scores were derived from time-coded video: (a) movement time to successful task-completion (MT): (b) number of strategic variations (shifts in overall strategy or lower-limb support positions). Data were analyzed using multifactor regression models. Overall, elderly had significantly longer MTs than young in ACQ (p=.03). MT decreased linearly for young and Ey; for Eo, however, the trend was quartric (p=.03). By ACQ-Day 5, all groups performed comparably. In the 10-day retention test, elderly performance declined; young did not Elderly were not simply slower; they had significantly more variations during learning. After the 20-month interval, Ey had no retention loss; whereas, young subjects' performance declined significantly (p=.04) and was poorer than Ey. Differences in long-term retention seem due to intrinsic variability (strategic variations) during learning. Young subjects quickly derived a movement strategy during ACQ and simply repeated it with little variation which led to efficient performance but did not promote long-term retention. In contrast, the elderly's many strategic variations during ACQ increased MT but reflected active and ongoing problem-solving that seemed to enhance retention.

CORRELATION BETWEEN SINGLE-UNIT ACTIVITY AND THE AUDITORY EVOKED RESPONSE TO PAIRED CLICK STIMULI IN THE RAT. K.A Flach^{1*}, R. Johnson³, G.M. Rose^{2,3}, G.A. Gerhardt^{1,2}, L.E. Adler

P. Bickford^{2,3}, Univ. of Colorado Health Sci. Ctr., Depts. of Psychiatry¹

Pharmacology² and Medical Research Services VAMC³, Denver, CO 80262. L.E. Adler and

A prominent symptom of schizophrenia is the inability to filter or gate sensory information. One quantitative measure of of a subject's ability to filter sensory information is the ratio of vertex recorded P50 auditory-evoked potential responses to two click stimuli spaced 500 milliseconds apart, a conditioning-testing paradigm often used to demonstrate the activity of inhibitory neuronal pathways. Normal subjects have a smaller response to the second (test) click, than to the first (conditioning) click, a phenomenon that is an example of auditory sensory gating. The test response of normal controls is often less than 15% of their conditioning response, whereas the test response of schizophrenic patients is often more than 85% of their conditioning response. In order to further understand the correlation between neuronal firing and the evoked potential response, we implanted multiwire electrodes (NB Labs, Texas) into four different regions of the rat brain thought to be involved in sensory gating; the CA3 hippocampus, the entorhinal cortex, the medial septal nucleus and the striatum. Simultaneous recordings from up to eight neurons per rat in each of the four areas were made in addition to recording the local auditory-evoked responses in each of the four areas. A clear auditory response was seen in all four areas. The auditory response was consistently gated in the CA3 region of the hippocampus and the septum. In each area, sensory responsive cells were identified. Most cells were excited by the click stimulus, although some cells were inhibited. Correlations between single-unit activity and gating, and single-unit activity and the evoked responses will be presented. Supported by BNS9110308, BIR913392, MH01121, MH50787, MH44212 and the VARMS

TRANSNEURONAL ANALYSIS OF HIPPOCAMPAL CIRCUITRY USING PSEUDORABIES VIRUS S. D. Styren*, S.T. DeKosky, M. E. O'Malley, G. C. Styren R.Y. Moore and J.P.Card Depts. of Psychiatry, Neuroscience, Neurobiology, and Neurology Western Psych. Inst. & Clinic, Univ. of Pittsburgh and Univ. of Pittsburgh Sch. of Med. Pittsburgh, PA

The hippocampal formation is responsible for integration of information from a

variety of afferent projections that arise from both cortical and subcortical regions. These projections segregate to discrete, architectonically defined sub-regions within hippocampus, where information is then disseminated to other hippocampal subfields by a complex network of intrinsic connections. Defineation of these circuits is essential to our understanding of hippocampal function and how synaptic architecture is reorganized during learning or injury. We used the retrograde transneuronal tracer pseudorables virus (PRV) to study the origin and distribution of afferent input to hippocampal subfields and intrinsic hippocampal circuitry. We injected 1 μl (~1.410x10⁹ PFU/ml) of PRV into stratum lucidum, dentate gyrus and CA fields of male Sprague Dawley rats (n=24) under stereotaxic guidance. After 36 hours, the brains were serial sectioned and routine immunohistochemistry for PRV antigen was performed. Stratum lucidum injections resulted in infection of a subpopulation of ipsilateral dentate granule cells and first order infection of numerous ipsilateral, layer two, entorhinal cortex (ERC) neurons; contralateral staining was restricted to a few enformal cortex (EHC) neurons; contralateral staining was restricted to a few layer two ERC neurons. Direct injection in the dorsal leaf of dentate gyrus resulted in extensive dorsal granule cell infection throughout the ipsilateral hippocampus. Injection into CA2/3 resulted in infection of few ipsilateral layer 2 ERC neurons while numerous layer 5 neurons were intensely stained for PRV antigen. Our data suggest that use of PRV as a retrograde tracer will not only enable confirmation and clarification of previous reports of hippocampal formation and serve as a valuable tool for characterizing anatomical rearrangements and sources of axonal sprouting following injury

CYTOARCHITECTURE AND IMMUNOCYTOCHEMISTRY OF CALCIUM

CYTOARCHITECTURE AND IMMUNOCYTOCHEMISTRY OF CALCIUM-BINDING PROTEIN-POSITIVE NEURONS IN HIPPOCAMPAL FORMATION OF WHALES AND TERRESTRIAL MAMMALS 'P.J. Morganet.* '11.Glezer.' 'P.R. Hof, 'C. Vavasis. '1. Ioannou, and '1. David. 'Dept. Pharmacol., Univ. New Engl., Biddeford, Maine 04005., 'Dept. Cell Bio. & Anat Sci. CUNY Med. Sch. NY, NY 10031, 'Dept. of Neurobiol., Mount Sinai Sch. Med..NY, NY 10029.

Cytoarchitectonics and distribution of calcium-binding protein (CaBP)-positive neuronal populations were studied in ventral hippocampus (VH), fascia dentata (FD), subiculum (SU) and entorhinal cortex (EC) in several species of toothed and baleen whales, and in various terrestrial mammals (marsupials, monotremes, chiropterans, carnivores and primates). In cetaceans, two types of hippocampal cytoarchitectonic patterns are found: a linear, where FD and VH are parallel to each other (found in spotted and bottlenose dolphins) and b) interlocked, analogous to that in terrestrial mammals but where FD and VH have the shape of two interlocked arches. This type is prevalent in baleen whales and, among odontocetes, in the related narwhales and beluga whales. Generally, immunocytochemical and cytoarchitectonic features of the hippocampal formation of baleen whales are essentially similar to those in terrestrial mammals than in toothed whales. In cetaceans, the absolute and relative linear dimensions of FD to VH, as well the FD cell packing density, are significantly lower (p<0.001) than in terrestrial mammals. In the hippocampal formation and in the entorhinal cortex of terrestrial mammals all three CaBP types of neurons are present whereas in all cetacean species only calretinin- (CR+) and calbindin-positive (CB+) neurons are found, with CR+ neurons being most prevalent. Parvalbumin-positive (PV+) neurons are totally absent in cetaceans. In this regard, the ratios between different CaBP in the hippocampal formation and entorhinal cortex in cetaceans are similar to those in other parts of the brain of these species (Glezer et between different CapP in the hippocampar formation and command of the command of

MEDIAL PERFORANT PATH EVOKED TRANSMISSION IN THE DENTATE GYRUS OF AWAKE RATS IS ENHANCED DURING DENTATE SPIKES.

C.R. Bramham Department of Physiology, University of Bergen, Årstadveien 19, N-5009, Bergen, Norway.

Dentate spikes (DSs) are positive-going, high-voltage EEG spikes which occur intermittently in the dentate hilus during alert wakefulness and slow-wave sleep, and which have been suggested to reflect synchronous activity of perforant path afferents and hilar interneurons on granule cells (Bragin et al., J. Neurophysiol. 73: 1691-1705, 1995). As part of a functional analysis of DSs e asked whether neuronal transmission in the dentate gyrus was altered during DSs in freely moving rats. The medial perforant pathway (MPP) was selectively stimulated and a vertical recording electrode array with 6 tips spaced from the dentate hilus into the CA1 field was used to monitor evoked field potentials and spontaneous EEG events. DSs were readily identified and distinguished from hippocampal sharp waves on the basis of their characteristic depth profile, amplitude, duration, and state-dependency. Using on-line detection of DSs, the timing of MPP stimulation relative to peak DSs could be controlled. MPP responses evoked at different stimulus pulse intensities during peak DSs were compared with responses elicited by manual stimulation. All evoked potentials were collected during alert wakefulness. There was a marked enhancement in granule cell excitability during DSs as reflected by larger population spike amplitudes and, in some cases, the occurrence of double population spikes. The results suggest that transmission through the MPP is transiently enhanced during the positive peak of DSs.

ELECTROPHYSIOLOGICAL CHARACTERIZATION OF MORPHOLOGICALLY-IDENTIFIED HILAR INTERNEURONS OF THE RAT DENTATE GYRUS. H.E. Scharfman Neurology Res. Ctr., Helen Hayes Hosp., West Haverstraw, NY 10993-1195, and Depts. of Pharmacol. & Neurol., Columbia University, NY, NY 10032

The hilus of the dentate gyrus contains neurons of diverse morphologies. Many are thought to be inhibitory interneurons using GABA as a neurotransmitter. Very little is understood about the electrophysiological properties of these interneurons and how these properties vary with morphology. Therefore, sharp microelectrode recordings were made from 85 putative hilar interneurons of adult rats in hippocampal slices. Electrodes were filled with Neurobiotin to label each cell. These cells were compared to 29 interneurons sampled from the granule cell layer.

The electrophysiological characteristics of hilar interneurons demonstrated similar heterogeneity as those described for pyramidal-shaped cells located at the granule cell layer/hilus border (H.E. Scharfman, Hippocampus 5:287-305, 1995). Intrinsic properties demonstrated a wide range of resting potentials, input resistances, time constants, and action potential durations, but dv/dt ratio was more consistent (1.3-2.1). Weak adaptation, dv/dt ratio, and fast EPSP kinetics were the best predictors of cell type when comparing interneurons to mossy cells and granule cells. There was no particular morphology (soma size, dendritic orientation, axonal plexus) that correlated with any specific electrophysiological characteristic that was tested.

Synaptic responses were heterogeneous. like intrinsic properties, and again similar to those of interneurons in the granule cell layer. Responses to stimulation of area CA3 were more robust than responses to molecular layer stimulation in many cells. emphasizing that dentate hilar interneurons receive strong input from CA3 or afferents passing through CA3. The results emphasize the previously mentioned heterogeneity of interneurons in the dentate gyrus and suggest that the interneurons of the granule cell layer overlap with those in the hilus in electrophysiological and perhaps functional roles. Supported by NIH grant NS 30831.

SELECTIVE CHANGES IN HIPPOCAMPAL NEUROPEPTIDE Y NEURONS FOLLOWING REMOVAL OF THE CHOLINERGIC SEPTAL INPUTS. <u>T.A.</u> Milner'*, R.G. Wiley², O.S. Kurucz', S.R. Prince' and J.P. Pierce' Dept. Neurol. Neurol., VAMC, Nashville, TN 37212 ²

The number and distribution of hilar interneurons containing neuropeptide Y (NPY), somatostatin 28 (SOM) or y-aminobutyric acid (GABA) were examined in the dentate gyrus following removal of the cholinergic septal inputs using 1921gGsaporin. One, 2, 4, 8, 12 & 24 wks after ICV injections of 192IgG-saporin, the rats were processed simultaneously with controls for NPY, SOM or GABA-immunolabeling. At all time-points, the number of NPY-labeled neurons was significantly less in the injected rats (65 - 80% of control value). The number of SOMcontaining neurons in injected rats tended to be less than controls but was only significant at 2 wks. In contrast, the number of GABA-labeled neurons in injected rats was near control values at every time-point except 24 wks where it was significantly lower (80-90%). Fields in adjacent nissl sections were examined with the optical disector method to calculate the total number of small cells (dia. 5µm) within the same portion of the hilus. Cell number was less at 8 and 12 wks post-injection and reached significance at 24 wks (82%). (Although hilar volume was markedly reduced in injected rats at 8-24 wks, cell densities did not differ.) Additional dual labeling studies found that only a small portion of the NPY and SOM-labeled neurons in the hilus colocalized GABA-immunoreactivity (18% and 5%, respectively). These studies demonstrate that: (1) removal of the cholinergic septal inputs can cause selective decreases in NPY-immunoreactivity in hippocampal interneurons; (2) at 8-24 wks post-192lgG injections, this decrease most likely reflects cell death rather than lack of expression of NPY; and (3) the small decreases in GABAergic neurons seen at 24 wks post-injection may reflect colocalization with NPY. Supported by MH42834.

COMPUTER MODELING OF DENTATE GYRUS USED TO DEVISE PHYSIOLOGICAL TESTS OF CONNECTIVITY
Kevin M. Hellman, William W. Lytton, Steven E. Kornguth*, Thomas P.
Sutula Dept. of Neurology, Neuroscience Training Program, and Middleton Veterans Administration Hospital, University of Wisconsin, Madison, WI

In vitro study of dentate gyrus has demonstrated the detailed firing pat terns of three major constituent neuron types and given an indication of which cell types are connected. Anatomical study has revealed their approximate relative numbers. However, these studies cannot adequately assess convergence and divergence among these different populations. A computer model of dentate gyrus was developed in NEURON to determine how different patterns of stimulation could be used to infer connectivity from exper imentally observable single neuron responses. Granule cell (GC), mossy cell and inhibitory aspiny interneuron (AC) model current-clamp responses and synaptic currents were matched to physiology where available. The network simulation was validated by accurately simulating response to perforant path stimulation both with and without GABAA blockade. Comparison of single pulse and paired pulse stimulation of the perforant path was assessed as a probe of the relative effect of mossy fiber sprouting (MFS, equal sprouting to GC and AC) versus AC cell death in a simulated epilepsy slice model. In both the normal and MFS network, both single and paired pulse stimulation produced 1 spike in the GC. AC cell death could be detected since paired pulse now produced a 2 spike GC response, irrespective of whether or not MFS was present. MFS could be detected by using GC depolarization, since paired pulse produced 2 spikes without MFS and 1 with MFS. The computer network model could be used to explore more complex stimulation paradigms to determine physiological experiments to probe network architecture. ULTRASTRUCTURAL LOCALIZATION OF NEUROTRANSMITTER IMMUNOREACTIVITY IN MOSSY CELL AXONS AND THEIR SYNAPTIC TARGETS IN THE RAT DENTATE GYRUS. H.J. Wenzel*, P.S. Buckmaster, N.L. Anderson, M.E., Wenzel and P.A., Schwartzkroin, Dept. of Neurological Surgery, University of Washington, Seattle, WA 98195

In the normal brain, mossy cells have been hypothesized to function as excitatory cells which use glutamate as neurotransmitter. However, putative neurotransmitters have yet to be immunocytochemically demonstrated in identified mossy cell axon terminals or their postsynaptic targets. Electrophysiologically-identified and intra-cellularly biocytin-labeled mossy cells of the rat dentate hilus were studied using electron microscopy and post-embedding immunogold techniques. Immunocyto chemistry for the excitatory neurotransmitters glutamate and aspartate, and for the inhibitory neurotransmitter GABA were used to provide 1) more detailed information about the nature of the mossy cell neurotransmitter and 2) to identify the transmitter(s) of their postsynaptic targets. Examination of single and double immunolabeled preparations indicated: that 1) mossy cell axon terminals made asymmetric contacts onto postsynaptic targets in the hilus and stratum moleculare of the dentate gyrus, and showed immunoreactivity primarily for glutamate, occasion ally for aspartate (light labeling), but never for GABA; 2) in the hilus, glutamatepositive mossy cell axon terminals targeted primarily GABA-positive dendritic shafts of hilar interneurons, and occasionally glutamate-positive spines; and 3) in the molecular layer, the mossy cell axon formed asymmetric synapses exclusively with dendritic spines associated with glutamate-positive (presumably granule cells) dendrites. The results of this study indicate that excitatory (glutamatergic) mossy cell terminals prefentially contact GABAergic interneurons in the hilar region and glutamate-positive granule cells in the str. moleculare. This pattern of connectivity is consistent with the view that mossy cells provide excitatory feedback to granule cells in a dentate gyrus associational network, and also activate local hilar inhibitory elements. CALRETININ IMMUNOREACTIVE MOSSY CELLS IN THE HILUS OF THE MOUSE DENTATE GYRUS. NOBORU FUILSE', NOBUAKI HORI?, TOSHIO KOSAKA!*, ¹Dept. of Anat. and Neurobiol., Fac. of Med. and ²Dept. of Dental Pharmacol., Fac. of Dent., Kyushu Univ., Fukuoka 812-82, Japan.

Pharmacol., Fac. of Dent., Kyushu Univ., Fukuoka 812-82, Japan.

In the hilus of the ventral dentate gyrus (DG) of the mouse, calretinin immunoreactive(CR-IR) large multipolar cells were clustered, whereas they were rare in the dorsal DG. These large hilar CR-IR cells bore characteristic grape-like spiny appendages on the proximal portions of their dendrites. None of them were GABA/GAD-IR or somatostatin-like-IR. These observations indicated that these CR-IR cells were mossy cells. We confirmed this identification with several methods. Mossy cells identified with the intracellular injection of Lucifer Yellow were CR-IR. Electron microscopic (EM) analysis of CR-IR elements clearly revealed structural features of mossy cells such as typical synapses on CR-IR thorny excrescences from mossy fiber terminals. At the supragranular (SPG) zone, a well-known target zone of mossy cell axons, a dense CR-IR band was seen, where numerous CR-IR punctae and fibers packed. Tracers (BDA or PHA-L) injected into the inner one-third of the molecular layer or into the hilus labeled nerve fibers in this SPG zone as well as granule cells and mossy cells; some of these labeled nerve fibers and terminals at the SPG zone were CR-IR. In lesion experiments, the isolation of the dorsal hippocampus from the ventral hippocampus resulted in a drastic reduction of the CR immunoreactivity as well as degeneration of many axon terminals at the SPG zone even when the connection from the supramammillary nucleus, one possible source of CR-IR axons at the SPG zone, was preserved. However the transection of fimbria, which was assumed to disconnect the DG from the supramammillary region, did not induce any remarkable change of the SPG CR-IR band. Furthermore EM observations showed that many CR-IR axon terminals in the SPG zone made asymmetrical synapses on putative granule cell dendrites and spines. On the basis of these findings, we concluded that large CR-IR cells in the ventral hilus of the mouse were mossy cells, the principal neurons in the dentate

AREA 30 (LE) IN THE MACAQUE MONKEY: CYTOARCHITECTURE AND CONNECTIVITY.

R. Morris*, M. Petrides and D.N. Pandya. Montreal Neurological Institute, McGill University, Montreal, CANADA and Boston University School of Medicine, Boston, MA, USA.

Recently, a study examining the sources of frontal input to the hippocampal system that might bypass the entorhinal cortex was carried out by means of autoradiography in the macaque monkey (Morris et al., 1995). This study revealed the existence of a monosynaptic projection originating in the mid-dorsolateral frontal cortex that courses, as part of the cingulum bundle, and which ends in the retrosplenial cortex. Careful architectonic analysis was carried out to decipher which portion of the retrosplenial cortex receives the frontal inputs. This analysis revealed that area 30 is the recipient of the projection from the mid-dorsolateral frontal cortex. It has been proposed that the retrosplenial cortex might be a critical relay-station along the fronto-hippocampal pathway which might subserve working memory processing. Injections of tritiated amino acids or fluorescent retrograde tracers confined to area 30 were performed in order to confirm this hypothesis. The results revealed that area 30 projects posteriorly to areas TH and TF of von Bonin and Bailey as well as to the subicular complex and, rostrally, to the mid-dorsolateral frontal cortex. The injections of retrograde tracers have confirmed that the mid-dorsolateral frontal cortex is the only portion of the frontal lobe that projects to area 30. Together, these findings confirm that area 30 is closely affiliated with the fronto-hippocampal association fiber system that might subserve certain aspects of working memor

CHARACTERIZATION OF VIP-IMMUNOREACTIVE NEURONS IN THE ENTORHINAL CORTEX OF THE RAT. C.L. Dolorfo*, J. Staiger and T.F. Freund. Institute of Experimental Medicine, Hungarian Academy of Sciences, Budapest, Hungary H-1450.

Recent analyses of interneuronal networks of the hippocampus demonstrate that interneurons play an important role in the modulation of rhythmic oscillations of principal neurons and in synaptic plasticity. While hippocampal interneurons have been well characterized, little is known about the organization of interneuronal networks of the entorhinal cortex (EC), a structure that is initimately connected to the hippocampus. As part of an ongoing study characterizing local circuits of the EC, the vasoactive intestinal polypeptide-immunoreactive (VIP-ir) interneurons in the EC was examined. Sections through the EC from two male rats were either immunostained for VIP or double-immunostained for VIP and the neuropeptide somatostatin or one of three calcium binding proteins (parvalbumin, calbindin, calretinin). The majority of VIP-ir cells were located in deep portions of layer I and layer II; few were found in layers III-VI. Many were bipolar and bitufted cells with radially oriented dendrites that often spanned layers I-V. While all EC layers received VIP-positive input, fibers and terminals distributed mainly to layer II. VIP-ir terminals frequently encircled unstained somata in layer II. VIP-ir terminals contacting the soma and proximal dendrites of other VIP-ir cells were common. Double-immunostaining revealed that VIP-ir interneurons innervate the soma or proximal dendrites of somatostatin-, calbindin-, and calretinin-positive cells. VIP-ir terminals rarely surrounded parvalbumin-positive somata. immunostaining for GABA demonstrated that postsynaptic targets of VIP-ir boutons included somala and dendrites of GABA-positive and -negative cells. The laminar organization and target specificity of VIP-ir fibers and terminals allows the possibility for modulation of principal cells, as well as other interneurons that may participate in the regulation of entorhinal intrinsic circuits and EC output to the hippocampus and other structures. A putative GABAergic cell type in the outer molecular layer of the rat fascia dentata projecting to the subiculum, J. Lübke*, K. Ceranik, ²P. Jonas and M. Frotscher, Anatomisches Institut, Albertstraße 17 and Physiologisches Institut, Hermann-Herder-Str. 7. Universität Freiburg, D-79104 Freiburg, Germany

Dentate gyrus interneurons play an important role in inhibitory processes in the hippocampus. Here we describe morphological and physiological characteristics of a novel, putative GABAergic cell type in the outer molecular layer (OML) of the rat fascia dentata with a back-projection from the dentate gyrus to the subiculum across the hippocampal fissure. Recordings were made from 70 neurons in the OML in hippocampal slices taken from postnatal (P) 10 - P30 rats using the whole-cell patch clamp configuration. Neurons were visually identified by infrared interference contrast videomicroscopy. During recording, cells were filled with biocytin for subsequent light- and electron microscopical analysis. Neurons projecting to the subiculum were found throughout the entire OML. GAD in situ hybridization revealed the GABAergic nature of OML neurons. They had small somata (15 μm) and a fusiform to multipolar dendritic morphology. Neurons had two distinctive axonal domains: 1) a long range (1 mm), tangential projection within the OML, with few collaterals in the inner molecular layer, and 2) a dense vertical and tangential projection (1 mm) within layer 1 and stratum pyramidale of the subiculum. Synaptic contacts were formed on dendritic shafts of granule cells of the fascia dentata and pyramidal neurons of the subiculum as revealed by electron microscopy. Neurons were physiologically classified as GABAergic cells by their maximal action potential frequency (50 - 100 Hz) and by a strong afterhyperpolarization following the action potential. The mean input resistance was 278 ± 78 MΩ (174 - 381 MΩ) and the membrane time constant was 10.7 ± 6.7 ms (6.3 -11.7).

Our data suggest that OML-neurons are involved in feed-forward inhibition of at least two types of target cells, the dentate granule cells and pyramidal neurons of the subiculum. (Supported by the Deutsche Forschungsgemeinschaft)

HIPPOCAMPAL OUTPUT TO PERIRHINAL CORTEX IN THE RAT ORIGINATES FROM THE DISTAL PORTION OF CAI. B. W. Leonard*, C. L. Dolorfo and T. F. Freund. Institute of Experimental Medicine, Hungarian Academy of Sciences, Budapest, Hungary H-1450.

The hippocampal formation originates cortical projections from the CA1 region of Ammon's horn in addition to those that originate from the subiculum. An unresolved issue about the CA1 efferent system is the topographic and laminar organization of its terminal field in the perirhinal cortex. As part of an ongoing study on the postsynaptic targets of the CA1 region, we have accumulated anterograde tracing data that clarify some aspects of this organization and its relationship to the organization of CA1 efferents to the entorhinal cortex. Iontophoretic injections of *Phaseolus* vulgaris leucoagglutinin or biotinylated dextran amine were made into distal (toward the subiculum) or more proximal (toward CA2) portions of CA1 in male rats (n=12). Injection sites and terminal fibers were visualized using standard immunocytochemical techniques. Sections were counterstained for Nissl. Terminal fibers were observed in the perirhinal and dorsolateral entorhinal cortices only if the injection site involved the most distal portion of CA1. Such injections at septal or mid septotemporal levels resulted in terminal labeling in layers V-VI of caudal areas 35 and 36 and terminal labeling in layers V, III, II and I of mid rostrocaudal and caudal levels of dorsolateral entorhinal cortex. Injections in more proximal portions of CA1 (n=4) resulted in the previously reported terminal field organization in the subiculum (Amaral, Dolorfo & Alvarez-Royo, 1991) but did not result in terminal labeling in areas 35 and 36. To date, one of our injections involved the distal portion of ventral CA1 and resulted in a dense terminal field at mid rostrocaudal and caudal levels of entorhinal cortex only. Because direct projections to CA1 originate from superficial layers of both entorhinal and perirhinal cortices, the present results suggest that hippocampal output from CA1 may have greater direct feedback influence on its cortical input originating from entorhinal cortex than on its cortical input originating from perirhinal cortex. COMPARISON OF ELECTROPHYSIOLOGY AND MORPHOLOGY OF LAYER III AND LAYER II CELLS IN THE ENTORHINAL CORTEX. S. v.d. Linden, M. Witter*, and F.H. Lopes da Silva. Dept. Exp. Zoology, University of Amsterdam, 1098 SM Amsterdam, The Netherlands.

Cortical input to the hippocampus is mediated by the superficial layers of the Entorhinal Cortex (EC), giving rise to the perforant path. Layer II and layer III of the EC receive different inputs, and, on their turn, project to different areas of the hippocampus (Dentate Gyrus and CA1 area, resp.). Layer II EC cells have already been described. The study presented here was done to investigate the intrinsic characteristics, the morphology, and synaptic responses of layer III cells in comparison with layer II cells. Layer III predominantly stellate cells are found. Intracellular measurements, using current clamp mode in in vitro slices, revealed that, in comparison with layer II EC cells, layer III cells i) had a larger Ri; ii) did neither display sag responses to hyperpolarizing current pulses, nor a rebound at the end of these pulses; iii) had a more depolarised firing threshold, and action potentials with a slower rate of decay and lacking a DAP; iv) more often had a strong adapting firing pattern upon depolarizing current pulses, and displayed no subthreshold oscillations; and v) upon deep layer stimulation responded with an EPSP that could trigger a single spike, and that was followed by a pronounced hyperpolarization. These data suggest that layer III cells are less excitable than layer II cells, but tend to display brief spike discharges to stimulation of the deep layers of the EC, which stands in contrast with the IPSP displayed in layer II cells. This may have consequences for the transfer of EC inputs (layers II and III) to the different subareas of the hippocampus. Supported by the HFSPO.

BURSTING BEHAVIOR OF DEEP LAYER PRE/PARASUBICULAR NEURONS EVOKED BY STIMULATION OF SUBICULUM AND ENTORHINAL CORTEX. M. Funahashi* and M. Stewart. Dept. of Physiology, State Univ. of New York, Health Science Center at Brooklyn., Brooklyn, NY 11203.

M. Funahashi* and M. Stewart. Dept. of Physiology, State Univ. of New York, Health Science Center at Brooklyn., Brooklyn, NY 11203.

Recent studies suggest an important role of the retrohippocampal region in the transmission of information between neocortex and hippocampus. The connectivity of retrohippocampal neurons, including pre/parasubicular cells, has been studied anatomically. Electrophysiological and morphological data from pre/parasubicular neurons are virtually absent. To examine the properties of pre/parasubicular neurons, intracellular recordings and single-cell dye injections were performed in 300 µm horizontal slices obtained from brains of 170-280g male albino rats. Electrophysiologically, 125 recorded cells, sampled from all layers were similar to one another, regardless of cell shape. Each exhibited repetitive single spiking in response to depolarizing current injection and had similar passive membrane properties. Deep layer cells of both pre- and parasubiculum exhibited a massive burst response that often included afterdischarges in response to single stimuli (100 µs, <1 mA) delivered to subiculum, or to deep layers of medial entorhinal cortex. All deep layer cells could exhibit this bursting behavior; such behavior was never observed in superficial layer cells. The majority of deep layer cells responded to both inputs. Responses to either input were indistinguishable. Burst durations varied from 100 to 400 ms. In many cells, short-latency EPSPs were observed in response to weak single stimuli. These were clearest when stimuli were applied to subiculum. To examine subthreshold synaptic potentials which may be related to the bursting behavior, long-duration hyperpolarizing current pulses were applied 50 ms after subicular stimulation. In some cells, a subthreshold EPSP was isolated, however, burst responses in many deep layer cells were unaffected by injections of as much as 1 nA. In 2 cells, burst responses could be triggered by depolarizing current injection. These massive burst responses by

MEDIAL VERSUS LATERAL ENTORHINAL CORTEX PATHOLOGY IN ALZHEIMER'S DISEASE. <u>J.C. Augustinack¹, A. Solodkin^{1,2}, and G.W. Van Hoesen^{1,2*}</u> Departments of Anatomy¹ and Neurology², University of Iowa, Iowa City, IA 52242.

The entorhinal cortex of the nonhuman primate and human brain can be parcellated into several cytoarchitectural subdivisions. However, beyond cytoarchitecture, data is sparse on the individual differences among subdivisions, and several lines of evidence still support a rather simple medial versus lateral distinction. Tyrosine hydroxylase and acetylcholinesterase staining support this separation as do entorhinal efferent projections to the dentate gyrus and hippocampal formation in both monkeys and humans. Entorhinal abnormalities in temporal lobe epilepsy and schizophrenia also are skewed toward medial locations. We have studied the topography of neurofibrillary tangles and ALz-50 staining in 33 Alzheimer's disease patients and have observed that in short duration of illness cases the numbers of neurofibrillary tangles are skewed laterally in layers II and IV and only occur medially as the disease progresses. Alz-50 staining mimics this pattern, but inversely so, as the prevalent formation of extraneuronal tangles laterally reduces or diminishes immunoreactivity. In control cases, SMI-32 immunolabeling is more distinct in layers II and IV alterally and sparse to non-existent medially throughout the entire rostro-caudal extent of the entorhinal cortex. The mechanisms that underlie these topographical differences are unknown, but their frequency is sufficient to suspect that medial and lateral entorhinal areas have unique functional roles. If this is the case, their functions would subtend and cut across cytoarchitectural differences in the entorhinal cortex. Supported by NS 14944 and 19632.

AN ELECTROPHYSIOLOGICAL ANALYSIS OF THE PROJECTION FROM THE PERIRHINAL CORTEX TO THE SUBICULUM IN THE RAT USING CURRENT SOURCE DENSITY ANALYSIS. K.J. Canning* and L.S. Leung. Depts. of Physiology and Clinical Neurological Sciences, University of Western Ontario, London Health Sciences Centre, London, Ontario, Canada.

The inputs to the dentate gyrus (DG) and subiculum (SUB) from the perirhinal cortex (PRC) were evaluated in the urethane anaesthetized rat. Employing standard stereotaxic techniques Teflon coated steel electrodes (125 µm dia.) were placed in the PRC (angled at 24° away from midline, 6.0P, 4.0L, \sim 7.0V to skull surface), contralateral CA1 (4.5P, 3.5L, 2.5V) and medial perforant path (MPP) (8.0P, 4.0L, 3.0V). A glass recording micropipette filled with pontamine sky blue was lowered through the right SUB/CA1 and DG (angled at 30° toward midline, 6.3P, 6.0L). Evoked responses were recorded at 50 μm intervals deep to surface following alternating stimulation of the PRC, MPP or contralateral CA1. Stimulation of the deep cerebral white matter underlying PRC evoked short latency (~4 ms) sinks at the outer molecular layer (oml) of the dorsal DG. These sinks exhibit little paired pulse facilitation (PPF) (~5%) at an interpulse interval of 50 ms. The DG oml projection did not come from the PRC since bilateral ibotenic acid lesion of the PRC and adjacent areas did not attenuate short latency sinks at the DG oml. The latter sink may arise from stimulation of perforant path fibers originating perhaps from the anterior parts of the entorhinal cortex. In normal animals (n=8) stimulation of the superficial PRC evoked sinks at the stratum lacunosum moleculare (SLM) of SUB/CA1. The SLM sink (presumed excitation) occurred at ~8-10 ms latency without DG oml activation; and showed large PPF (~50%). In conclusion, the present study suggests that the PRC provides a direct and sizable input to the distal dendrites of the SUB/CA1 without activating the DG at the same septo-temporal location. RESPONSES OF PROJECTION CELLS OF THE ENTORHINAL CORTEX TO REPETITIVE SYNAPTIC STIMULATION, T. Gloveli, D. Schmitz, R. M. Empson* and U. Heinemann, Institut für Physiology der Charité, Humboldt Universität zu Berlin, Tucholskystr. 2, 10117 Berlin

The entorhinal cortex provides a major gateway for sensory information into the hippocampal formation. The perforant path, which originates in superficial layers of the entorhinal cortex (EC) project from layer II cells to the dentate gyrus and CA3 region and from layer III to the CA1 region and the subiculum. The mechanism by which these separate input pathways of the hippocampus are selected is not known We studied differences between synaptic properties of the projection cells in layer II and III of the medial EC by repetitive synaptic stimulation. Trains of 30 stimuli applied at various frequencies showed that in response to low frequency stimulation applicativations independent and the properties of the dependency stimulation of 10 or more Hz, action potentials began to appear, but this only occurred during the later part of the train and in spite of the continued hyperpolarisation of the cell. In contrast high frequency stimulus train (>10 Hz) applied to the layer III cells resulted in very little firing during the train since the cell became either extremely hyperpolarized or strongly repolarised during the train thus preventing any further firing of the cell. We propose that a high frequency switch operates to prevent output of the layer III cells whilst layer II cells are capable of firing. In particular the prolonged inhibitory postsynaptic potential following the stimulus trains in layer III projection cell could be involved in the frequency dependent switching. Pharmacological analysis shows that the slow hyperpolarisation could be divided into 3 component: i. a 1 s GABA-B, ii. a 6 s atropine and iii. a 20 s naloxone sensitive component. These mechanisms may provide a control of information flow from layer II and layer III cells to hippocampus at various frequencies.

ENTORHINAL CORTICAL TRANSFER FUNCTION: ANALYSIS OF LATERAL OLFACTORY TRACT IMPULSE EVOKED POTENTIALS USING ROOT LOCUS METHODS IN RAT. K. F. Ahrens* and W. J. Freeman, Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

The limbic system receives olfactory input via the lateral olfactory tract

The limbic system receives olfactory input via the lateral olfactory tract (LOT), primarily at synapses on the apical dendrites of layer II stellate cells and layer III pyramidal cells in the entorhinal cortex (EC). The primary input to the hippocampus, the perforant path, originates in the superficial layers of the EC, as well. Furthermore, there are local interneurons and collateral projections which are likely to mediate inhibitory and excitatory feedback to the principal neurons of the EC, respectively. In order to describe the transformation of the olfactory neural activity as it impinges upon the EC, we recorded local field potentials in anesthetized and awake Sprague Dawley rats using bipolar wire electrodes, as well as a 16 channel silicon microelectrode. The evoked field potentials, which had the characteristic form of damped sinusoids in the awake animals were elicited by a brief (0.01-0.03ms) voltage pulse that was applied to the LOT and was just above threshold.

We blocked polysynaptic activation within the entorhinal cortex with deep pentobarbital anesthesia, effectively reducing the feedback gain. Progressively greater doses caused a reduction in the damped oscillation until only a brief (<20ms) negative deflection remained. As the effects of the drug wore off, the normal oscillatory response returned. A series of recordings taken during this period were fitted with sums of exponentials and damped sinusoids. From this data a root locus plot was made, showing the change in the poles of the transfer function as the feedback gain was manipulated. Funding: MH06686

PRESUBICULAR AXON TERMINALS SYNAPSE WITH PARVALBUMIN-IMMUNOREACTIVE INTERNEURONS IN THE MEDIAL ENTO-RHINAL CORTEX OF THE RAT. F.G. Wouterlood*, B. Martin-Clemente, T. van Haeften, and M.P. Witter, Research Institute Neurosciences Amsterdam. Department of Anatomy and Embryology. Vrije Universiteit. 7 van der Boechortstraat, 1081 BT Amsterdam, The Netherlands.

Projections from the presubiculum selectively terminate in layers I and III of the medial entorhinal cortex. The superficial layers of the entorhinal cortex harbor neurons giving rise to the perforant pathway to the hippocampus, the so-called principal neurons. In addition, various types of GABAergic neurons are present in these layers including a specific subset that contains the calcium-binding protein parvalbumin (PV). Previously, we observed that entorhinal principal cells are among the targets of presubicular input (Caballero and Witter, 1994). This means that neurons in the presubiculum might be able to influence activity carried by way of the perforant pathway. Since the activity of entorhinal principal neurons is under strong inhibitory control by interneurons, such as PV-positive basket neurons, one interesting question is whether these entorhinal interneurons receive synaptic input from presubicular axon terminals. In the present study we set out to answer this question by injecting an neuroanatomical tracer, biotinylated dextran amine (BDA) into the presubiculum and by identifying presumed entorhinal interneurons via immunocytochemistry using antibodies against PV. In the light microscope we found a dense BDA-labeled fiber plexus in layers I and III of the ipsi-and contralateral medial entorhinal cortices, with numerous close appositions of BDAlabeled varicosities with PV-immunoreactive cell bodies and dendrites. In the electron microscope, we observed asymmetrical synapses between BDA-labeled axon terminals and PV-immunopositive dendrites. Thus, presumed inhibitory, PVimmunopositive neurons in the superficial layers of the entorhinal cortex may be influenced directly by inputs from the presubiculum.

THE CAT'S ORBITO-INSULAR CORTEX IS A HIGH-LEVEL ASSOCIATION AREA WITH WIDESPREAD SENSORY, MOTOR AND LIMBIC TRANSCORTICAL INPUTS. Alfonso Llamas*, Francisco Clascá and Fernando Reinoso-Suárez. Dept. of Morphology. Autónoma University, School of Medicine, Madrid, SPAIN 28029. We have investigated the cortical connections of the areas recently identified in the orbito-insular region (OIR) of the cat's cerebral cortex (Clascá et al., Submitted). We used single cortical microinjections of Wheat-Germ Agglutinin-Horseradish Peroxidase in a large (n=37) series wheat-term Agglutinin-Horseradish Peroxidase in a large (h=5/) series of cases. Qualitative and quantitative analysis of the retrograde cortical labeling revealed that a remarkably broad, functionally heterogeneous array of cortical inputs may interact in OIR. Dorsally located OIR areas receive widespread cortical connections. In the case of the Granular Insular area (GI) these inputs arise in somatosensory (SIV, SII, 3a, 2 3b and SV), motor (6 and 4), lateral prefrontal and perirhinal (area 35) cortices, whereas in the case of the Anterior Sylvian area (AS) they arise in extrastriate visual, nontonotopic auditory, lateral prefrontal, cingulate and perirhinal (area 36) cortices. More ventral parts of OIR such as the Dysgranular Insular area, or the ventral part of AS receive connections mainly from adjacent GI or dorsal AS and the perirhinal cortex, as well as from few other adjacent areas. The cortex hidden in the anterior rhinal and pseudosylvian sulci (Agranular Insular and Parainsular areas) is densely connected with neighboring OIR areas as well as with the ventral prefrontal, infralimbic, and prepyriform cortices. This convergent pattern of transcortical inputs suggest that in the brain of carnivores, the orbito-insular region has evolved into a high-order, multimodal association cortex. THE CONVERGENCE OF AXON TERMINALS FROM THE MEDIODORSAL THALAMIC NUCLEUS AND VENTRAL TEGMENTAL AREA ON PYRAMIDAL CELLS IN LAYER V OF THE RAT PRELIMBIC CORTEX. M. Kuroda*, K. Murakami, H. Igarashi, A. Okada. Dept. of Anatomy, Toho Univ. Sch. of Med., Tokyo 143, Japan.

We investigated the ultrastructural basis of the synaptic convergence of the afferent fibers from the mediodorsal thalamic nucleus (MD) and the ventral tegmental area (VTA) on prefrontal cortical neurons of the rat by examining the synaptic relationships between thalamocortical or tegmentocortical terminals labeled with anterograde markers, which were of lesion-induced degeneration or transport of wheat germ agglutnin conjugated to horseradish peroxidase (WGA-HRP), and unlabeled apical dendrites of layer V pyramidal cells in the prelimbic cortex which were randomly selected. WGA-HRP labeled terminals from VTA were small to large in size (0.7-2.8 μ m in diameter) and established both asymmetrical and symmetrical synaptic contacts with relatively large dendritic profiles, possibly proximal segments of apical dendritic shafts and spines from layer V pyramidal cells. Symmetrical synapses, i.e., inhibitory synapses were more often seen than asymmetrical ones. Degenerating terminals from MD formed exclusively asymmetrical synapses on dendritic spines or occasionally on small dendritic shafts of apical dendrites from layer V pyramidal cells, which received tegmentocortical synapses, mostly within layer III. Accordingly, thalamocortical synapses were more distally distributed over common apical dendrites than tegmentocortical synapses although some of them overlapped. Regarding the numerical density of direct synaptic inputs from MD and VTA, identified synapses were low in number. These results suggest that fibers from VTA exert their inhibitory effects directly as a promited dendrite dendrite dendrite intention and control to the propriet dendrite dendrit

These results suggest that fibers from VTA exert their inhibitory effects directly on pyramidal cells in layer V via synaptic junctions with apical dendrites of these pyramidal cells, and that the tegmentocortical fibers are in an ideal anatomical position to modulate the reverberatory circuits between MD and the prelimbic cortex.

COGNITIVE EFFECTS OF LEFT MEDIAL THALAMIC STIMULATION IN TWO PATIENTS WITH DEEP BRAIN ELECTRODES FOR RELIEF OF CHRONIC PAIN. P.C. Rinaldi', E.S. Parker, J. Chodakiewitz, and R.L. Young, Dept. of Neurosurgery, University of California, Irvine, CA, 92717.

Dept. of Neurosurgery, University of California, Irvine, CA, 92717.

Two patients with stimulating electrodes in left periventricul gray (PVG) and left ventroposteriorlateral region of the thalamus (VPL) for deep brain stimulation (DBS) in relief of chronic pain were evaluated for possible cognitive effects of stimulation. A brief repeatable neuropsychological battery (oral fluency, verbal episodic memory, auditory digit span) sensitive to left fronto-limbic regions was administered with electrical stimulation (double blind) at varying levels. Patient 1, a 49 year old, right-handed woman was tested in one session under five conditions one year after DBS surgery. Highest verbal memory scores were in the two conditions when both stimulators were on and when the patient was obtaining maximal pain relief: she recalled 23 words with both PVG and VPL on, 17 with both off, 17 with both continued off, 20 words with PVG on and VPL off, and 24 words with both PVG and VPL on. No significant variation was observed on either oral fluency or digit span. Patient 2, a 43 year old right-handed woman was tested, only a few days post surgery, under four conditions. Oral fluency paralleled the stimulators with m of words generated per minute being 7 with both off, 17 with PVG on and VPL off, 11 with both off, and 15 with both on. Highest generation of words was observed in the two conditions when stimulators were on with the highest level associated with PVG stimulation. This patient became loquacious when PVG was turned on, corresponding to her fluency score. No systematic relationship was seen between electrode condition and either verbal episodic memory or auditory digit span. These findings indicate that cognitive impairment is not a consequence of analgesic levels of stimulation in PVG or VPL. Moreover, the enhanced performance on verbal episodic memory and oral fluency point to a role of medial thalamic structures and their interconnections to orbital-frontal regions

THALAMIC PULVINAR CONNECTIONS WITH THE PARIETAL CORTEX IN THE ADULT MACAQUE Corinna Darian-Smith* and Ian Darian-Smith. Dept. of Anat. and Cell Biol. Link of Melbourne. Victoria. Australia 302.

We are currently investigating aspects of the neural circuitry of the thalamic pulvinar complex and associated parietal cortical areas, in the adult macaque monkey. A combination of retrogradely transported fluorescent dyes (Fast Blue and Diamidino Yellow) and anterograde markers (Biotin Dextran amine and Lucifer Yellow dextran) were injected into either the thalamus or cortex. Following dye njections into pulvinar nuclei, we were able to visualise local circuit (interneurons), thalamic reticular and corticothalamic neurons from the cortex. Similarly, thalamic relay cells and corticothalamic axons could be seen following the placement of injections into cortical locations. The dendritic morphology of neurons was visualised by injecting Lucifer Yellow into backlabeled neurons in thick fixed slices. These were immunoreacted and examined using a 3-dimensional tracing system. Following the combined injection of an anterograde and retrograde dye into the medial and lateral subdivisions of the pulvinar, two corticothalamic neuron populations could be visualised within cortical layers 5 and 6 within posterior parietal cortical areas and cingulate cortex (area 23). Corticothalamic neurons within layer 6 were invariably smaller and more numerous than those observed in upper layer 5, but these two populations were not always present together in each cortical subdivision. Two corticothalamic neuron types were also observed within the pulvinar following injections into the posterior parietal areas 7a, and 7b. These included fine calibre axons with side branches and diffuse terminal fields, and a second coarse, unbranched type with focal terminal field. Similar corticothalamic populations have been reported within the visual pulvinar (Rockland, 1994 NeuroReport 5 1865-1868, 1996 nr press), the somatic motor nucleus, VPLo (Darian-Smith, unpublished) and the ventrobasal complex (Tan and Darian-Smith, unpublished), indicating their ubiquity within the sensorimotor thalamus. Our data, combined with recent EM studies by other gr

THE LIMBIC THALAMIC PROJECTIONS DISTINGUISH THE SUBICULAR CORTICES.

Th. van Groen*, I. Kadish and J.M. Wyss. Dept. of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294, USA.

The limbic thalamic nuclei are an important link in the transfer of information between the hippocampal formation and many areas of neocortex. Previous studies demonstrated that the anterior thalamic nuclei have distinct projections to each of the subicular cortices. The present study tested the hypothesis that the projections from the subicular cortices would show a similar specificity. Sprague Dawley rats were injected with anterogradely transported tracers in the subicular cortices. Two weeks later the animals were sacrificed, and the brains were sectioned and analyzed. The postsubiculum projects predominantly to the laterodorsal nucleus of the thalamus, but a few labeled terminals are present in the anteroventral nucleus. The dorsal subiculum projects mainly to the dorsal part of the anteroventral nucleus, but the ventral subiculum projects predominantly to the parataenial and paraventricular nuclei of the thalamus, but a few terminals are present in the dorsal part of the laterodorsal nucleus. The presubiculum projects to the rostral tip of the anteroventral and anterodorsal nuclei, and to the rostral part of the laterodorsal nucleus. The parasubiculum projects to the rostral part of the anteroventral nucleus. Furthermore, all four areas of subicular cortex have collateral projections to the reticular nucleus of the thalamus. These data demonstrate that the projections from the subicular cortices to the limbic thalamic nuclei are distinctive, and that they are predominantly reciprocating the thalamic projections. SYNAPTIC CONNECTIONS OF CALRETININ-IMMUNOREACTIVE NEURONS IN THE HUMAN TEMPORAL NEOCORTEX. M.R. Del Río and J. DeFelipe*. Instituto Cajal (CSIC), 28002 Madrid. Spain.

Previous immunocytochemical studies in the human neocortex have shown that the calcium-binding protein calretinin (CalR) labels specific subpopulations of GABAergic and non-GABAergic aspiny interneurons (del Río and DeFelipe, J. Comp. Neurol., in press). The aim of the present study was to further characterize morphologically and chemically the microcircuitry of CalR-immunoreactive neurons in the human temporal neocortex. Combination of immunocytochemistry for CalR and GABA, CalR and the calcium-binding proteins parvalbumin (PV) and calbindin (CalB), or for CalR and non-phosphorylated neurofilament protein (identified by antibody SMI 32), showed CalR multi-terminal endings frequently innervating the distal apical dendrite or the cell body and proximal dendrites of SMI 32- or CalB-immunoreactive pyramidal cells, respectively. The cell body of interneurons immunoreactive for CalB or PV were only occasionally innervated by CalR multi-terminal endings, whereas certain GABA neurons were commonly surrounded by these endings. Furthermore, CalR-immunoreactive axon terminals form either symmetric (the majority) or asymmetric (the minority) synapses with a variety of postsynaptic elements. These results indicate that different subpopulations of CalR interneurons exist which are specialized for the selective innervation of the somatic or dendritic regions of certain pyramidal and non-pyramidal neurons.

DIVERGENT "FEEDBACK-TYPE" CONNECTIONS FROM AREA TF IN THE MACAQUE MONKEY. B. J. Wellman* and K. S. Rockland. Div. of

Neurosurgery and Dept. of Neurology, Univ. of Iowa, Iowa City, IA 52242
Feedback cortical connections have been extensively characterized within the visual, auditory, and somatosensory pathways. Feedback terminations are, by definition, scant in layer 4, dense in layer 1, and they typically diverge over large distances (1.0 - 2.0 mm). There are also layer 1, "feedback-type" connections from higher order cortical areas, but these have been less investigated, despite their potentially important role in associational processes. For example, are these systems organized as "point-to-point" or are they spatially divergent, as has been found within early sensory areas?

We injected PHA-L into area TF of the parahippocampal gyrus in two monkeys. Layer 1 projections occurred in several posterior visual areas (Rockland and Drash, in press), as well as in several polymodal association cortices. Seven axons have been analyzed so far in serial reconstruction: three to medially adjacent area TH, two to laterally adjacent area TE, and three to insular cortex Terminal fields in layer 1 of area TH extended over 0.75 - 1.5 mm. Those to the insula had an elongated shape, 3.5 - 4.0 mm in length, as did those to area TE (along the lower bank of the anterior middle temporal sulcus). Previous reports using other tracers indicate that these connections are reciprocal, but the present indings suggest that feedback connections from area TF to area TE and to the insula are more divergent that the feedforward. They are also more divergent than feedback connections from area V2 to V1. They are, however, comparably divergent with feedback connections from area TF to posterior visual areas including V2, V3, and V4. This highly divergent configuration, in specific visual as well as polymodal areas, implies contacts with large numbers of spatially distributed neurons and is consistent with a non-topographic, integrative organization. (Supported by NS 19632).

SYNAPTIC TARGETS OF INTRINSIC AND ASSOCIATIONAL CORTICAL PROJECTIONS OF PYRAMIDAL NEURONS IN MONKEY PREFRONTAL CORTEX. D.S. Melchitzky*, S.R. Sesack, and D.A. Lewis. Depts. of Psychiatry and Neuroscience, University of Pittsburgh, Pittsburgh, PA 15213.

In primate prefrontal cortex (PFC), the intrinsic axon collaterals of supragranular pyramidal neurons spread horizontally for considerable distances and give rise to discrete, stripe-like clusters of axon terminals in layers I-III. The principal axons of at least some of these neurons furnish associational projections within the ipsilateral PFC that arborize to form stripe-like clusters of axon terminals spanning all six cortical layers. In order to compare the synaptic targets of the intrinsic and associational projections from layer III pyramidal neurons, injections of 10% biotinylated dextran amine were placed in area 9 of macaque PFC. Intrinsic axon terminals were sampled from the same area and associational axon terminals were sampled from insilateral area 46. Both the anterogradely-labeled intrinsic and associational axon terminals formed exclusively asymmetric synapses. In addition, for both types of terminals, 95% of the postsynaptic structures were dendritic spines. The remaining targets were dendritic shafts, which had the characteristic features of local circuit neurons. Conversely, in a random sample of the adjacent neuropil, only 80% of asymmetric synapses were onto spines, indicating that intrinsic and associational projections of pyramidal neurons exhibit some degree of target specificity. Thus, both intrinsic and associational projections of PFC pyramidal neurons target predominantly dendritic spines of other pyramidal neurons, suggesting that their primary function is the coordinated activation of spatially-segregated populations of these neurons. SEROTONIN INNERVATION OF NEUROCHEMICALLY IDENTIFIED INTERNEURON SUBTYPES IN THE MONKEY PREFRONTAL CORTEX R.L. Jakab* and P.S. Goldman-Rakic, Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Imbalance of the serotonin system and reduction of GABAergic interneurons in the prefrontal cortex have recently come to the forefront in the pathophysiology of schizophrenia. Evidence from this laboratory has recently shown that inhibitory schizophrenia. Evidence from this laboratory has recently smooth that inhibitory interneurons are heavily innervated by serotonin axons (Smiley and Goldman-Rakic, 1996; J.Comp.Neurol.); a finding that not only provides a possible link between these two putative deficits in schizophrenia but may aid elucidating the role of serotonin in cognitive functions. These considerations prompted us to further explore the serotonin innervation of the various subtypes of (local circuit) interneurons in dorsolateral prefrontal cortical tissues of adult macaque monkeys (Macaca mulatia). In double label immunocytochemical experiments, antisera against serotonin and the interneuron markers calbindin, parvalbumin, calretinin, substance P receptor (SPR) and serotonin receptor (5HT2R) were used. These markers allowed us to determine interneuron subtypes not only by their neurochemical identity but also by the morphology of their dendritic arbor.

Serotonin innervation of the interneuron subtypes varied in density and layer-specificity. The somata and proximal dendrites of calretinin-stained "double bouquet" neurons in cortical layers II-III were regularly contacted by serotonergic axon varicosities and terminals while virtually all of these neurons in deeper layers were vithout such input. SPR-stained "basket" cells received a less dense innervation and these neurons were usually innervated at more distal portions of their dendritic arbors. Parvalbumin- and calbindin-containing interneurons were preferentially contacted by serotonin fibers on their perikarya. 5HT2R-containing neurons, particularly those in the white matter were seen to receive multiple contacts with serotonin fibers. Since the output of the various local circuit neuron subtypes is highly specific, these data may provide important clues in estimating the mode and range of serotonin influence in cortical circuits.

POSTNATAL DEVELOPMENT OF SEROTONIN TRANSPORTER-IMMUNOREACTIVE AXONS IN MONKEY PREFRONTAL CORTEX. C.H. Kye*, T.U. Woo, and D.A. Lewis. Depts. of Psychiatry and Neurosci., Univ. of Pittsburgh, Pittsburgh, PA, 15213.

Developmental abnormalities in the serotonin innervation of the prefrontal cortex (PFC) have been implicated in the pathophysiology of both schizophrenia and depression. However, little is known about the normal postnatal development of serotonin systems in the primate PFC. In this study, we examined the the density and laminar distribution of serotonin transporterimmunoreactive (SERT-IR) axons in the PFC of 23 rhesus monkeys (Macaca mulatta) ranging in age from newborn to adult. Emphasis was placed on comparisons across medial PFC areas 14r, 32, and 9 because of their differences in cytoarchitecture and afferent input. The density of SERT-IR axons in these regions progressively increased from birth through the first 6 months of postnatal life, with minimal changes in older animals. At birth, SERT-IR axons in layer III appeared clustered in patches, but their distribution became more uniform with increasing age. At all ages, the density of SERT-IR axons increased from ventral (area 14r) to dorsal (area 9) regions. This ventral-dorsal gradient was most marked in layers I and II. In contrast to the protracted postnatal maturation of the dopamine innervation of primate PFC, the adult pattern of serotonin innervation is achieved much earlier, suggesting that these afferent systems may play substantially different roles in the maturation of PFC functions. In addition, the ventral-dorsal gradient in the density of SERT-IR axons in the medial PFC may be consistent with a preferential serotonin innervation of limbic-related regions. Funded by grant MH 45156.

THE INTRINSIC CONNECTIVITY OF MONKEY PREFRONTAL CORTEX: AN IN VITRO ELECTROPHYSIOLOGICAL STUDY. G.R. Gonzalez-Burgos*, G. M. DiBlasi, D.A. Henze, D.A. Lewis, and G. Barrionuevo. Departments of Neuroscience, Psychiatry, and Center for the Neural Basis of Cognition, University of Pittsburgh, Pittsburgh, PA 15260.

In the primate prefrontal cortex (PFC), the axon collaterals of layer III pyramidal neurons form a stripe-like pattern of intrinsic connectivity (Levitt et al. 1993). To evaluate the electrophysiological characteristics of this pattern of excitatory connections, we have developed an in vitro slice preparation of monkey PFC. Coronal slices (500 µm thick, 6-8 mm long) were obtained from a tissue block removed from PFC area 9 of anesthetized cynomolgus monkeys. Action potentials (APs) were recorded extracellularly in layer III using glass micropipettes (1 M NaCl). APs were elicited by electrical stimulation of layer III, with electrodes placed at varying distances (200-1,400 μm) from the recording site. The spatial pattern of activation was assessed by determining the probability of eliciting APs in layer III as a function of the horizontal distance from the recording site. When APs were recorded from slices with intact $GABA_{\lambda}$ ergic inhibition, the probability of AP firing in some slices decayed monotonically with distance, reaching zero at $600\text{-}800~\mu\text{m}$. In contrast, in other slices the probability of AP firing was bimodal. Peak values were seen at distances of 400-500 μm, and at 800-900μm, a spatial pattern predicted by the arrangement of intrinsic connections observed in anatomical studies (Levitt et al. 1993). When 0.25 µM bicuculline was added to the perfusion medium, the horizontal spread of activity increased up to 1,300 µm. In addition, APs fired in bursts of 3-8 spikes, whose latencies were longer than in control medium and increased as a function of distance. These findings indicate that the inhibitory circuitry of the PFC is preserved in the slice, and that in the presence of bicuculline, propagation of activity may occur via polysynaptic pathways. Supported by MH51234 and MH45156.

3-D PATTERN OF CATECHOLAMINERGIC INNERVATION ON INTRACELULARLY LABELED LAYER III PYRAMIDAL CELLS IN THE PREFRONTAL CORTEX OF THE RHESUS MONKEY.

L. S., Krimer and P.S. Goldman-Rakic*. Section of Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06510.

There is now considerable anatomical and functional evidence to indicate that dopamine is an important modulator of excitatory transmission in pyramidal neurons. Dopamine axons have been shown to terminate on pyramidal cells in the prefrontal cortex of rhesus monkeys but knowledge of the density and distribution of these axons on particular neurons is not available, nor is it known whether neurons within various regions and/or different layers of the cortex are differentially innervated by dopamine axons. In order to begin to address these questions and to analyze the catecholaminergic innervation of the cerebral cortex in further detail, we have to date analyzed approximately 30 pyramidal cells that we labeled with Lucifer Yellow in paraformaldehyde fixed slices of monkey medial and dorsolateral prefrontal cortex. Each labeled cell was serially sectioned and then stained according to a double-label immunohistochemistry protocol employing anti-tyrosine hydroxylase (TH) and anti-Lucifer Yellow antisera. Dendritic tree reconstruction and synaptic contact assessment was carried out using a Neurolucida software program and Axioskop Zeiss microscope with DIC and high optical resolution (Planapo 63x, 14. NA objective; 1.4 NA object on the proposition of the dendrites and The labeled boutons and observe their direct apposition. Preliminary results indicate that 1) TH labeled axons preferentially target the distal dendrites and spines of layer III neurons while avoiding soma, first order basal dendrites and spines of layer III neurons while avoiding soma, first order basal dendrites and spines of layer III neurons while avoiding soma, first order basal dendrites and spines of layer III neurons with enterons in other layers and the servotonergic versus TH innerva

THE ULTRASTRUCTURAL BASIS OF LOCAL CIRCUITS IN PREFRONTAL CORTEX AS IDENTIFIED BY COMBINING IN VITRO INTRACELLULAR RECORDING, BIOCYTIN FILLING AND NO SYNTHASE IMMUNOCYTOCHEMISTRY. M. Lubin* C.S. Leonard and C. Aoki. Center For Neural Science, New York University, NY, NY 10003.

We show the successful light-(LM) and electron-microscopic (EM) labeling of neuronal nitric oxide synthase-immunoreactive (nNOS-ir) cells in sections contain single neurons first physiologically identified in coronal slices of guinea pig medial prefrontal cortex and then intracellularly filled with biocytin. Dual labeling was achieved using the silver-intensified gold (SIG) and peroxidase methods interchangeably. Examples include a layer V neuron that showed typical firing properties of a regular-spiking pyramidal cell which were modified by bath application of carbachol. LM verified the cell as pyramidal by its somatic shape and rominent basal and apical spiny dendrites that bifurcated in layer III. EM verified the cell's spines and also revealed a non-convoluted nuclear envelope. Recordings from a layer III-V neuron showed regular-spike firing but also showed a prominent after-depolarization and an initial spike doublet. LM verified that this neuron was non-pyramidal with a vertical, sparsely spiny dendritic tree. EM confirmed the presence of spines receiving unlabeled excitatory terminal contact or apposing nNOSir and unlabeled terminals. Another layer III neuron was confirmed as non-pyramidal without physiological recordings by its lack of spines (as seen by LM and EM) and the presence of gold-labelled terminals making inhibitory synaptic contacts. EM analysis of ~ 300 um of both non-pyramidal cells' dendritic perimeters revealed that < 10% of the apposing terminals were synaptic. nNOS-ir soma and processes, including dendritic spines, were seen coursing near to the filled cell's processes These observations suggest that nitric oxide's modulation of non-pyramidal neurons may occur by the paracrine mode rather than point-to-point synaptic transmission. CALCIUM-DEPENDENT DENDRITIC RHYTHMOGENESIS IN MAMMALIAN THALAMIC NEURONS. C. Pedroarena and R. Llinás*, Dept. Physiology & Neuroscience, New York University Medical Center, 550 First Avenue, New York, NY 10016.

The synchronization of fast rhythmic activities in thalamo- cortical loops has been

proposed as serving to bind sensory inputs into single cognitive events. This temporal coherence appears to relate to the intrinsic oscillatory properties of the thalamo-cortical system neurons. To characterize such oscillatory properties at the single thalamic cell level, intracellular recordings were obtained from guinea pig slices maintained at 35°C. Direct somatic depolarization of thalamic projecting neurons can generate fast membrane potential oscillation (20-50 Hz). The ionic bases for these oscillations were studied using ionic channels blockers and changing the ionic composition of the extracellular milieu. The addition of TTX (µg/ml) to the bathing solution, or replacement of sodium by choline blocked fast spike and the bathing solution, or replacement of sodium by choline blocked fast spike and plateau potentials without affecting calcium dependent low threshold spikes. Surprisingly, the high frequency oscillations were not blocked by these two procedures indicating that sodium was not the charge carrier for rapid thalamic oscillations. Cadmium at 200 µM blocked the surviving high frequency oscillation, but not the low threshold spike. The amplitude of the oscillations were best observed by replacing calcium by barium. The data indicate that rhythmogenic properties of thalamic cells are in fact subserved by calcium conductances. Since HVA calcium conductances are mostly dendritic, these findings suggest that high frequency oscillation in thalamic cells originate at the dendrites. This is supported by the finding that bath applied TEA decreases the threshold for high frequency oscillations, probably by increasing the dendritic length constant. Dendritic oscillations could be a highly efficient mechanism for rhythmicity entrainment, resonance and synchronization of synaptic inputs, especially those in remote dendrites, as is the case for the cortico-thalamic input. These distal dendritic branches may in fact serve as frequency amplifiers to the thalamo-cortico thalamic resonance may in fact serve as frequency amplifiers to the thalamo-cortico thalamic resonance loop. THALAMIC MODULATION OF HIGH FREQUENCY (GAMMA-BAND) OSCILLATING POTENTIALS IN RAT AUDITORY CORTEX D.S. Barth* and K.D. MacDonald Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Spontaneous and evoked electrocortical oscillations in the gamma frequency band (~40 Hz) have received recent attention because of their possible association with sensory information processing. Yet, the neurogenesis of these oscillations is poorly understood. We have recently reported that both spontaneous and evoked gamma oscillations are constrained to primary and secondary auditory cortex in the rat, cortical regions that also receive dense afferent projections from the dorsal and ventral divisions of the medial geniculate nucleus (MGd and MGv). The object of the present study was to explore what role, if any, the thalamus may play in their

Spontaneous and evoked potentials were recorded from 5 lightly anesthetized rats using an 8x8 electrode epipial array covering auditory cortex. The MGd, MGv and posterior intralaminar nucleus (PIL) were electrically stimulated with 500 msec trains of pulses (10 KHz). As in previous studies, bursts of spontaneous gamma oscillations were localized to areas 36 and 41. Stimulation of the MGd and MGv resulted in a large steady potential for the duration of the train, localized to area 36 and area 41 respectively. During the steady potential, spontaneous gamma was suppressed. In contrast, stimulation of PIL resulted in evoked gamma oscillations for the duration of the train and no steady potential. Both evoked and spontaneous gamma were of similar frequency and spatial distribution. These results suggest that the PIL may serve as a modality specific modulator of gamma oscillations ir auditory cortex. They also demonstrate a dissociation between gamma modulation and synaptic drive provided by the specific afferent projection nuclei.

MODELS OF CORTICALLY INDUCED CORRELATION OBSERVED IN LGN NEURONS K. Kirkland and G.L. Gerstein*, Dept. of Neuroscience, Univ. of Pennsylvania, Philadelphia PA 19104

Two cat lateral geniculate nucleus (LGN) cells, separated by 1-4 visual degrees, and co-stimulated by a moving bar or drifting grating, show significant excess correlation of their spike trains after correction for firing rates; no such excess correlation occurs when the visual cortex is removed (Sillito et al., 1994) Nature 369:479-82). Much of the correlation occurs during short, high frequency Nature 369:479-82). Much of the correlation occurs during short, high frequency bursts, suggesting that the low-threshold (LT) calcium channel might be involved. We have explored this and other possible mechanisms, as well as aspects of the necessary connectivity, using the simulator GENESIS. LGN cells were modeled using 2 compartments, with the soma often containing LT channels. Input to the LGN was from both retinal ganglion cells and a large area of cortex. The cortex received input from the LGN layer, had inhibitory and excitatory lateral connections, and a feedback projection to the LGN. Input to the retinal standard institute of the apparature to the retinal standard institute of the apparature to the retinal standard institute and the apparature to the standard connections. nal network mimicked a moving bar. Replication of the experimental results depended most strongly on the details of the corticogeniculate projection and on the presence or absence of the LT channel. The most successful matches to experiment, including the temporal details of the correlation, use the LT channel and have a center-surround corticogeniculate projection, with a direct excitatory center and a ring of indirect inhibitory connections. In this model the inhibition from the cortex leads the bar motion, thus deinactivating the LT channel and from the cortex leads the bar motion, thus deinactivating the LT channel and resulting in an LGN burst response to the stimulus. Other choices in model parameters either fail to produce LGN correlation or produce correlation with a time structure differing from the experimental data. In the successful model, groups of synchronized cortical cells form, disrupping the continuity of the cortical map; these groups are initially weakly formed by corticocortical activity, but are greatly strengthened, becoming distinct clusters, as the cortex influences the temporal pattern of its LGN inputs via the corticogeniculate path. CURRENT SOURCE DENSITY ANALYSIS OF NEOCORTICAL SPIKE-AND-WAVE PATTERNS: COMPARISON WITH SPECIFIC AND NON-SPECIFIC THALAMIC NUCLEI-EVOKED POTENTIALS A Kandel* and G Buzsáki. CMBN, Rutgers University, Newark, NJ 07102

Thalamocortical neuronal oscillations underlie various field potential patterns that are expressed in the neocortex, including sleep spindles and high voltage spike-and-wave spindles (HVS). Movable 16-site silicone probes (100 mm site intervals) and 20 mm wire electrodes were implanted medial to the barrel cortex. Neocortical field potentials and extracellular unit recordings were obtained simultaneously during HVS, and thalamically derived evoked potentials. Current source density (CSD) analysis of the spike component of HVS indicated sinks in layer IV. Ipsilateral VPL evoked potentials (EP) elicited sinks in the same position as the spike component of HVS. Another current sink was present in layer 1/11. EP elicited from non-specific thalamic nuclei had similar distribution of sinks and sources. Neuronal activity in all layers was associated with the spike component of HVS. Occasionally population spikes were observed during the spike component as well as on the evoked field. THe spike component was often associated with fast field oscillations (100-200 Hz "ripples"), which in turn, correlated with rhythmic neuronal discharge. The findings indicate (1) the cooperative involvement of both specific and non-specific thalamic inputs in the generation of HVS and that (2) the major sinks, associated with these patterns, are due the activation of thalamocortical synapses with lesser involvement of intracortical connections. ABSENCE OF DIFFERENTIAL LAMINAR DISTRIBUTION OF IPSPS IN NEOCORTICAL ASSOCIATION CELLS OF CATS IN VIVO. N.Dürmüller*, D. Contreras and M. Steriade, Lab. Neurophysiol., Sch. Medicine, Laval Univ., Québec, CANADA GIK

We studied the laminar distribution of cortical- and thalamic-elicited IPSPs in association cortex (area 5 and 7) neurons in barbiturate-anesthetized cats. Cells were classified as regular-spiking, fast-spiking, and intrinsically-bursting. Upon release from hyperpolarization or upon depolarization, a subpopulation of cells showed doublets or triplets of action potentials that had a tendency to rhythmic activity at 20-40 Hz; they were called fast-bursting cells. IPSPs were evoked by stimulating either the thalamic lateroposterior nucleus or the cortex in the vicinity of the recording micropipette. In 26 out of 40 neurons recorded with K+acetate filled pipettes, IPSPs (measured at -60 mV) had amplitudes between 3 and 20 mV, peaked at 30 ms, and had durations at half width of 40 to 200 ms. Cortical-elicited IPSPs were consistently of higher amplitude and longer duration than those triggered by thalamic stimulation. Only occasionally had the IPSPs a clear biphasic aspect, although a second longer-lasting component of the IPSP could be revealed by its effect on the firing frequency of cells. Recordings with KCl-filled pipettes completely reversed the IPSPs, giving rise to bursting upon stimulation, and revealed the compound nature of the synaptic response that is normally cut off by the IPSP. The amplitude and duration of IPSPs showed no correlation with cell location in different laminae or cell-type. In conclusion, no simple rules can be applied to the distribution of inhibition in association cortex in cats.

NEOCORTICAL ACTIVATION: MODULATION BY MULTIPLE PATHWAYS ACTING ON CHOLINERGIC AND SEROTONERGIC SYSTEMS. Hans C. Dringenberg and C.H. Vanderwolf*. Neuroscience Program & Psychology Dept., University of Western Ontario, London, Ontario, Canada, N6G 2V4.

In urethane-anesthetized rats, electrical 100 Hz stimulation of the amygdala, the dorsal raphe, the locus coeruleus area, the superior colliculus, and the orbitofrontal but not of the entorhinal or cingulate cortex, electrocorticographic (ECoG) activation (amplitude < 0.5 mV, including frequencies above 10 Hz). Activation elicited from the amygdala, the locus coeruleus area, and most orbitofrontal sites was abolished by administration of the cholinergic muscarinic antagonists scopolamine (5 mg/kg, i.p.) or atropine (50 mg/kg, i.p.) The activation elicited from the raphe or superior colliculus was largely resistant to anti-muscarinic treatment but could be abolished by the serotonergic antagonists methiothepin (5 mg/kg, i.p.) or ketanserin (5 mg/kg, i.p.). Electrical single pulse stimulation of the amygdala and the locus coeruleus area enhanced firing of about 60 % of extracellularly-recorded basal forebrain (BF) neurons that increased their firing during the presence of ECoG activation (putative cholinergic cortically-projecting cells). About 80 % of BF cells that fired at higher rates during periods of ECoG deactivation were inhibited by single pulse stimulation of the amygdala or locus

Widely distributed neuronal systems produce ECoG activation by acting through mechanisms sensitive to anti-muscarinic or anti-serotonergic drugs, suggesting that these activating influences depend on the release of acetylcholine and/or serotonin. Neural systems that produce atropine-sensitive (i.e., putative cholinergic) LVFA, believed to be dependent on the cholinergic innervation of the cortex arising in the BF, may produce ECoG activation by a dual action to excite BF cells that may contribute to ECoG activation (putative cholinergic cells) and inhibit other BF cells that may suppress activation. (Supported by NSERC Canada).

CELLULAR SUBSTRATES OF THE SLEEP K-COMPLEX AND ITS DETECTION WITH THE WAVELET TRANSFORM. F. Amzica* and M. Steriade.

DETECTION WITH THE WAVELET TRANSFORM. F. Amzica* and M. Steriade. Lab. Neurophysiology, Sch. Medicine. Laval University, Quebec, Canada G1K 7P4. The sleeping cortical network generates a slow (<1 Hz) oscillation (Steriade et al., J. Neurosci., 1993, 13:3252). Intracellularly, this is seen as an alternation between depolarization and hyperpolarization of membrane potential. Simultaneous intracellular and focal field potential recordings in anesthetized cats disclosed a close relationship between the onset of the cellular depolarization and depth-cortical negative field potentials. Since these field potentials are reversed at the cortical surface, where they look similar to the EEG K-complexes seen in humans, we performed multi-site extracellular and field potential recordings in cortical areas 4, 5, 7, 17 and 18 of chronically implanted, naturally sleeping cats. It appeared that K-complexes, which are present at the onset of sleep, are the same waves that characterize the slow (<1 Hz) sleep oscillation. The depth-negativity (surface-positivity) was associated with increased neuronal firing. Under these conditions, K-complexes appeared rhythmic, repeating at a mean frequency of 0.7 Hz. The laminar distribution of the K-complex shows a potential reversal at a depth of 0.25-0.5 mm and the presence of a large sink in cortical layers II-III. The presence of k-complexes and their rhythmicity are better disclosed if their shape is considered, rather than by and their rhythmicity are better disclosed if their shape is considered, rather than by spectral analysis with Fourier transforms. This is why we approached the detection of R-complexes with the Wavelet Transform. The detection procedure included direct transform based on Daubechies' wavelets (the most similar to the K-complex), windowing and inverse transform, thus providing a signal devoid of all components but the K-complexes. This approach revealed that K-complexes are rhythmic at the frequency of the slow oscillation. It also unveiled their dynamic progression through various sleep stages and their relation with other sleep oscillations such as spindles. It is shown that, at sleep onset, K-complexes are the triggering factor of spindles. As sleep deepens, the hyperpolarization of thalamocortical neurons favors the development of thalamic delta oscillations and prevents spindles.

SIMULATION OF ACTIVITY DYNAMICS IN CORTEX-LIKE STRUCTURES: PATCHY PROJECTIONS SHOW AN INTEGRATIVE ADVANTAGE OVER DIFFUSE CONNECTIVITY. B.M. Ramsden*, G.K. Egan² and R.B. Silberstein¹. ¹Centre for Applied Neurosciences, Swinburne University of Technology, Hawthorn, Vic 3122 Australia, ²Dept. of Computer & Electrical Engineering, Monash University, Clayton Vic 3168 Australia.

Patchy intracortical neuronal populations are pervasive structural features of the superficial layers of primate neocortex, but the functional consequence of this connectivity remains unclear. Using a CRAY-YMP supercomputer, we implemented a large-scale computational simulation that compared activity dynamics in cortex-like structures featuring patchy or diffuse local connectivity.

Cortex-like structures consisted of single or multiple layers of two-dimensional (64x64) arrays of neuronal populations or "segregates" (250 µm diameter domains). Segregate activity was modeled using equations incorporating physiologically and anatomically plausible parameters. Structures were stimulated

with transient increases of synaptic drive of varying strengths.

Segregates receiving patchy local projections from beyond 5mm showed enhanced linearization of input-output signal transfer relationships above a critical response threshold. In contrast, diffusely connected configurations, and segregates receiving patchy projections from less than 5mm distance, showed predominant 'level-detection' behavior, with diffuse connections yielding highest thresholds.

The superficial layers of primate prefrontal and posterior parietal cortex are reported to incorporate especially extensive patchy connectivity of up to 7mm lateral reach. These simulation results suggest that such connectivity characteristics may provide a dynamical advantage for these association regions by enhancing their ability to integrate coincident bursts in corticocortical drive from other nodes of the cortical network

ANALYSIS METHODOLOGY FOR MEG DATA USING MODERN SPECTRAL TECHNIQUES B. Pesaran¹, P.P. Mitra^{1*}, E. Kronberg², U. Ribary², and R. Llinás², ¹Bell Laboratories, Lucent Technologies, Murray Hill, NJ 07974 and ²Department of Physiology and Neuroscience, NYU Medical Center, 550 First Ave., New York, NY 10016

Due to poor signal to noise, conventional applications of magnetoencephalography to the study of brain function involve heavy averaging over trials. This is inconvenient for studying spontaneous brain activity as manifested in such data. In particular, activity at frequencies higher than 20 Hz is both transient and low in amplitude. This has given rise to controversy regarding the spectral content of the data. In part, this is due to the continued use of outdated techniques for spectral analysis that are not sufficiently refined to reveal the full structure of the signal.

We have used a combination of singular value decomposition (principal components analysis) and multiple window spectral techniques to analyze multichannel MEG data, analysis) and mutiple window spectral techniques to analyze muticianne MEO data, in particular, data gathered continuously during different brain states. The recordings were obtained using two 37 channel "magnum" BTi MEG System. The spontaneous activity was recorded form normal individuals in waking conditions. The line frequency (60 Hz) and heart beats were removed by appropriate methods. A critical step is the reduction of the dynamic range of the spectra by pre-whitening using an autoregressive filter determined from a smooth estimate of the spectrum. The spectra of the autoregressive filters decayed monotonically in the frequency range of interest (10-100 Hz) by two orders of magnitude. The whitened multichannel data was processed in two different ways. Firstly, the data were projected onto the first few spatial modes obtained in a space-time SVD, and then spectrally analyzed using a moving time window and a multi-window spectral estimate. This provided a time frequency analysis of the spectral content of the data. The second method employed a space-frequency SVD, which concern or the data. The second method employed a space-frequency SVD, which revealed the distribution of coherence over channels in a manner localized simultaneously in time and frequency. The results are exemplified by the average spectrum of the spontaneous, awake data where well defined spectral peaks were obtained centered at 10, 20 and 45 Hz. Support: Charles A. IN VIVO LABELING OF MITOCHONDRIAL COMPLEX I WITH [3H]DIHYDROROTENONE. Deepa J Talpade*, James G Greene, Donald S Higgins, Jr. and J Timothy Greenamyre. Department of Neurology and Program in Neuroscience, Emory University, Atlanta, GA 30322

Mitochondrial enzymes play a critical role in neuronal homeostasis, and defects in mitochondrial function have been implicated in neurodegenerative disorders. Moreover, the activity of these enzymes and defects in mitochondrial function have been implicated in neurodegenerative disorders. Moreover, the activity of these enzymes may be used to map functional changes in synaptic firing patterns. However there is no method available for in vivo assessment of mitochondrial enzymes. We previously developed an in vitro autoradiographic assay to study complex I using binding of [³H]dihydrorotenone (DHR) to the rotenone binding site (J. Neurochem. 59:746,1992). We now present a technique to label complex I in living animals. Briefly, male Sprague -Dawley rats recieved a jugular infusion of [³H]DHR (500 mCi/kg) and were sacrificed by decapitation 2.5 hrs after drug administration. Brains were rapidly removed and frozen. Slide-mounted cryostat sections were exposed to Hyperfilm (Amersham) for 4-12 weeks; adjacent sections were stained for 2 other mitochondrial enzymes, succinate dehydrogenase (SDH) and cytochrome oxidase (CO). Across 46 brain regions, DHR binding was highly correlated with both SDH (r = 0.95) and CO activity (r = 0.91). Specificity of DHR binding for complex I was demonstrated by local inhibition of binding by intracerebral injection of rotenone and enhancement of binding by injection of NADH. This technique represents the first method to allow in vivo evaluation of an electron transport enzyme, and it raises the possibility of using PET scanning for this purpose. Supported by a Mallinckrodt Scholar Award and USPHS grant AGI1755.

COMPARISON OF THE DEVELOPMENTAL EXPRESSION OF THE NEURONAL GLUCOSE TRANSPORTER, GLUT3, WITH SYNAPTIC PROTEINS IN POSTNATAL RAT BRAIN. Rebekah R. Clark, Lisa B. Seaman and Susan J. Vannucci*. Dept. of Pediatrics, Hershey Med Ctr-Penn State Univ., Hershey, PA 17033.
Glucose is the primary fuel for the immature, as well as adult, brain and a constant supply is essential for normal cerebral development. GLUT3, the

neuron-specific glucose transporter, is expressed at very low levels in perinatal (P1-P7) rat brain but increases during the period of neuronal maturation and synaptogenesis. The purpose of this developmental study was to correlate regional GLUT3 expression in postnatal rat brain with proteins representative of the energetic and functional state of the neuron, i.e. Na-K ATPase (neuron-specific α_3 subunit), and the synaptic proteins, SNAP-25 and synaptophysin. Rats were studied at 7, 10, 14, 21 and 28 days of postnatal age. Five regions: cortex, hippocampus, thalamus, brain stem and cerebellum, were rapidly dissected and snap-frozen on dry ici Membrane samples were analyzed by Western blot, relative to brain membrane "standard" and results expressed in standard units. Other brains were frozen for *in situ* hybridization histochemistry. The results of this study indicate that in the forebrain regions of cortex, hippocampus and thalamus GLUT3 expression correlates closely with SNAP-25 and synaptophysin, whereas Na-K ATPase levels were already at 50% adult levels by P7. In the brain stem, this early expression of Na-K ATPase was matched by GLUT3; the synaptic proteins displayed a more gradual time course of expression. However, in the late-maturing cerebellum, all 4 proteins followed a similar linear pattern, increasing through P21. The results of this study indicate that in forebrain regions, the expression of GLUT3 which provides the energy for neuronal function, is most closely related to synaptic function. Supported by Whitaker Summer Scholarship (RRC) & HD31521,NICHD.

LOCALIZATION OF GLUCOSE TRANSPORTERS 1 AND 3 IN HUMAN POSTMORTEM BRAIN. A. McCall*, A. VanBueren, V. Nipper, R. Roberts, and G. Murdoch. Depts. of Cell & Dev. Biol., Med., Neurol. and Path., Ore. Health Sc. Univ., VA Med. Ctr., Portland, OR, 97201, and MD Psych.Res. Ctr.

Localization of the major glucose transporters, GLUT1 and GLUT3, in human brain parenchyma by immunocytochemistry (ICC) has been hampered by the modest affinity of available antibodies. We generated polyclonal antisera against the C-terminus of the human GLUT3 (ALM3H-S) and against GLUT1 (ALM1-K; JCBFM 16:69-76,1996). On immunoblot, ALMH3-S (1:2,500) identifies a 46 kDa band in human hippocampus and testis. It is also positive for COS-7 cells transfected with a hGLUT3 construct (Dr. C. Burant); reactivity is abolished with 10 μg/mL peptide. Human red cells, rat brain homogenates, and vector only transfected COS-7 cells are negative. For GLUT1, we used ALM1-K (1:10,000). ICC of human brain for GLUT3 shows discrete, laminar- and region-specific neuropil staining with no white matter staining. In hippocampus, dense GLUT3 ICC staining is found in the molecular layer, the lacunosum moleculare, strata oriens and radiatum in CA1, CA2 and CA3 subfields. Similar to rat, no staining of large perikarya is observed in the pyramidal cells or dentate granule cells. GLUT3 staining is much less in cerebellum and frontal cortex than hippocampus. In occipital cortex (area 17) laminar GLUT3 staining is found in layers 1, 4 and 6 For GLUT1 this same cortical area shows staining in layers 2 through 5 with less discrete lamination. In hippocampus, GLUT1 ICC staining is seen in molecular layers and extends to the granule cell layer. Heterogeneous, laminar- and regionspecific density of GLUT1 and GLUT3 suggest the possibility of local regulation of glucose availability to brain by transport proteins. GLYCOGEN DEPOSITION IN NEURONS OF THE BRAIN STEM AND HYPOTHALAMUS IN THE OPOSSUM <u>L.A. Cavalcante¹</u> and <u>P.C. Barradas*1,2</u> 1. Inst. Biofisica, UFRJ, 21941-590; 2. Inst. Biologia, UERJ, 20551-030 Rio de Janeiro, Brazil.

Neurons are heterogeneous cells with respect to size and shape, electric signals, neurotransmitter systems and enzymes related to energy metabolism. However, studies in small rodents have led to the view that glycogen deposition is low or non-existent in normal, mature neurons. We have used a modified histochemical method with alcoholic solutions and basic fuchsin (E-bF) to minimize glycogen elution and check for its storage in central neurons in the opossum. E-bF+ cell groups were found in the V mesencephalic nucleus and the somatic and special visceral efferent columns of the brainstem as previously shown in developing, small rodents. Scattered E-bF+ neurons also appear in a presumptive homologue of the primate raphe interpositus nucleus, and in sparse cells of the dorsal thalamus and basal forebrain. A striking, often Golgi-like accumulation of glycogen has been found in many neurons of all divisions of the supra-optic and paraventricular nuclei and in the infundibular/arcuate nucleus. Our results suggest that the patterns of glycogen storage are common to several vertebrates and may be a constant although not exclusive property of cells with axonal endings outside the blood-brain barrier. Apparent differences with respect to small-sized placentals may be related to specific metabolic rates

DISSIMILARITIES IN PARENCHYMAL DISTRIBUTION OF GLUCOSE AMONG BRAIN AREAS AND BETWEEN TWO RAT STRAINS. J. D. Fenstermacher*, L. Wei, D. Bereczki, V. Acuff, K. Davies, F.-J. Hans, and C. Patlak. Henry Ford Hospital, Detroit, MI 48202 and SUNY, Stony Brook, NY 11794.

3-O-methylglucose (3OMG) is a non-metabolizable marker of glucose transport with a steady-state distribution space of 50 ml/100 g (50%) in brain, less than the water space (65-80%) but greater than interstitial space (10-20%). Glucose transporters facilitate the flux of 3OMG both across the blood-brain barrier (BBB) and into brain cells, but the rates appear to be different. We postulate and test in young adult Wistar-Kyoto (WKY) and spontaneously hypertensive (SHR) rats that 3OMG transport across the BBB is modest and "rate-limiting" and uptake into brain cells is very rapid. ¹⁴C-labeled 3OMG was intravenously infused into WKY and SHR for 15-45 sec, plasma and tissue ¹⁴C-activity determined, and the 15-45 sec space of 3OMG distribution estimated. The flux of 3OMG across the BBB was moderately rapid and nearly identical in SHR and WKY. Indicating very fast cellular uptake in support of the hypothesis, the 15-45 sec space of 3OMG distribution was essentially 50% in 30 (of 35) brain areas of SHR and 11 (of 35) areas of WKY. In 5 brain areas of SHR and 24 areas of WKY, the 15-45 sec space of distribution was 10-20%, suggestive of relatively similar rates of BBB influx and cellular uptake contrary to the hypothesis. In conclusion, glucose distribution between interstitium and cells may vary among brain areas and rat strains and be relatively slow, particularly in WKY. "AEROBIC GLYCOLYSIS" DURING & AFTER SENSORY STIMULATION: ALTERED FLUX OF GLUCOSE CARBON INTO METABOLITES SYNTHESIZED MAINLY IN NEURONS OR GLIA. G. A. Dienel*, R. Y. Wang, & N. F. Cruz, Lab. of Cerebral Metabolism, NIMH, Bethesda, MD 20892.

Brain appears to use disproportionately larger amounts of glucose compared to O2 during and after brain work in well-oxygenated tissue, i.e., the so-called phenomenon of "aerobic glycolysis". Because the basis for aerobic glycolysis is unknown we developed a rat model in which the O2/glucose uptake ratio into brain was reduced during and after sensory stimulation; lactate accumulation in brain and lactate efflux from brain did not account for the excess uptake of glucose (Madsen et al., J. Cereb. Blood Flow Metab. 15, S77, 1995). We, therefore, examined the flux of [6-14C]glucose into metabolite pools before, during, and after sensory stimulation (n 6/group). Brain glucose levels and specific activities were stable throughout the activity cycle. Brain glycogen content was reduced 20-30% during and after stimulation, and glycogen specific activity doubled during recovery compared to rest and stimulation (p<0.05). Thus, both synthesis and degradation of glycogen (located mainly in glial cells) were enhanced during recovery. The level and specific activity of glutamine, known to be synthesized in glia, did not change with activity phase (p>0.05). In contrast, labeling of GABA, a neuronal marker, rose 25% (p<0.05) during activation compared to rest and recovery; GABA content did not change During stimulation, the level of aspartate decreased by 20% whereas labeling of aspartate increased about 40% compared to rest and recovery; glutamate levels and labeling increased 6 and 16%, respectively, during activation, then normalized (p<0.05). Thus, flux of glucose carbon into metabolites synthesized mainly in neurons or in glia varies during the activity cycle; labeling of GABA but not glutamine (both are derived from glutamate) increased during stimulation. Depletion and filling of metabolic pools explain, in part, the excess consumption of glucose compared to O₂ during and after stimulation. (Funded by NIMH Intramural Program)

357.6

IN VIVO RELEASE OF NORADRENALINE BY IDAZOXAN ACTIVATES GLYCOGENOLYSIS IN RAT NEOCORTEX AND HIPPOCAMPUS M. Fara-On, C.W. Harley, J.H. Evans, R.A.M. Brown, and R.E. Adamee* Dept of Psychology, Memorial University, St. John's, Newfoundland, Canada A1B 3X9

Glycogen and its catabolic enzyme, active glycogen phosphorylase (aGP) are localized primarily in glia. Although the modulation of glycogenolysis by neuronally-secreted substances suggests a metabolic coupling between neurons and glia, the functional significance of this metabolic interaction has yet to be determined. Functional adrenergic receptors are expressed by glial cells. Noradrenaline (NA) and its agonists have previously been reported to activate glycogenolysis in mouse cerebral cortex in vitro.

In our study, we induced *in vivo* NA release in rats through IP administration of idazoxan (5mg/kg). Drug effects on glycogenolysis were assayed by histochemical assessment of aGP 45 minutes following injection of drug or saline. Relative optical density (ROD) measures of regions of the neocortex and hippocampus were taken using computer-assisted densitometric software (MCID). Large increases in levels of aGP were found in somatosensory cortex (layers 3, 4, 5a, 5b, and 6), in stratum lacunosum moleculare of CA1 and in the neuropil between the granule cells and CA4 in dentate gyrus. No significant increases in aGP levels were found in corresponding layers of the primary motor cortex, or in corpus callosum.

The novel finding that NA release activates glycogenolysis in two regions of

The novel finding that NA release activates glycogenolysis in two regions of hippocampus suggests activation of glycogenolysis may be involved in the effects of NA in this region. Our neocortical results are consistent with previous data showing significant increases in aGP in the somatosensory cortex following medial forebrain bundle stimulation, suggesting an important interaction between sensory processing and noradrenergic modulation of glycogenolysis.

HYPERGLYCEMIA-INDUCED LEUKOCYTE ADHERENCE IN CEREBRAL VENULES J.M. Gidday, J.W. Beetsch, E.R. Gonzales, A.R. Shah, R.G. Maceren, Y.-B. Lee, J.H. Thurston*, T.S. Park. Departments of Neurosurgery and Neurology, and St. Louis Children's Hospital, Washington University School of Medicine, St. Louis, MO 63110

Acute hyperglycemia has been shown to affect cerebral blood flow, endothelium-dependent vascular reactivity, amino acid transport, cerebral metabolism, and ischemic outcome. We examined the possibility that hyperglycemia could initiate an inflammatory response in the cerebral circulation. We studied three groups of anesthetized newborn pigs: One group (n=5) was rendered acutely hyperglycemic (blood glucose = 250-300mg/dl [14-17µmol/ml]) by intravenous glucose, a second group (n=6) was rendered asphyxic for 9 min by discontinuing ventilation, and a third group (n=8) served as normoglycemic, non-asphyxic controls. Adherence of rhodamine 6G-labelled leukocytes to cerebral venules was monitored over time through a closed cranial window using epifluorescent videomicroscopy. The number of adherent leukocytes (above baseline) per mm² vessel surface during the initial 2 h following each intervention is shown for the three animal groups:

	30 min	60 min	120 min
Control	119 ± 68	156 ± 62 *	319 ± 107 *
Hyperglycemia	281 ± 118	583 ± 159 *#	959 ± 292 *#
Asphyxia	592 ± 149 *#	706 ± 128 *#	1413 ± 209 *#

[* p<0.05 versus baseline; # p<0.05 versus control group]

These results show that acute hyperglycemia causes a progressive increase in leukocyte-endothelial adherence to an extent not significantly different from that which follows a severe asphyxic insult. The potential pathophysiologic significance of this vascular inflammatory response to hyperglycemia remains to be determined. (NIH NINDS 21045 and 32568).

BLOOD-BRAIN BARRIER GLUCOSE TRANSPORT AND THE INFLUENCE OF DIABETES AND ANESTHESIA. Q.R. Smith.* M. Hokari. M. Aoyagi. N.M. Appel. S.J. Vannucci. and I.A. Simpson. NIA and NIDDK, Bethesda MD 20892; FDA, Laurel, MD 20708; and Dept. of Pediatrics, Penn. State Univ., Hershey, PA 17033.

Brain energy metabolism is based principally on the oxidation of

Brain energy metabolism is based principally on the oxidation of D-glucose which is taken up into brain by a saturable transporter (GLUT1) at the blood-brain barrier. Studies differ on the kinetics of blood-brain barrier glucose transport and whether uptake is affected by anesthesia or chronic diabetic hyperglycemia. To address this, we examined the kinetics of sugar influx into brain using the *in situ* rat brain perfusion technique (Am J Physiol 247:H484, 1984). Cerebral D-[1-1^4C]glucose uptake was sodium-independent and linear for 20 s during perfusion with physiologic saline. The concentration dependence of saturable D-glucose influx followed Michaelis-Menten kinetics with a $V_{\rm max}$ of 4.02 \pm 0.51 μ mol/min/g and a $K_{\rm m}$ of 8.2 \pm 0.9 mM (mean \pm SD) in the parietal cortex. Relative affinities (1/Km) of 2-deoxy-D-glucose and 3-O-methyl-D-glucose were 1.56 \pm 0.20 times and 0.63 \pm 0.08 times, respectively, that of D-glucose. Blood-brain barrier D-glucose transport was not significantly reduced by either pentobarbital anesthesia (40-50 mg/kg, i.p.) or chronic streptozotocin diabetes (3 weeks duration; plasma [glucose] = 35 \pm 2 mM). Similarly, diabetes did not decrease the level of GLUT1 protein in brain microvessels. In summary, the results provide a new kinetic analysis of glucose uptake into brain which suggest that transport is less sensitive to barbiturate anesthesia or diabetic hyperglycemia than previously reported. (Supported by NIA and NIDDK).

EFFECT OF PROPOFOL-INDUCED ANESTHESIA ON REGIONAL CEREBRAL BLOOD-FLOW: A POSITRON EMISSION TOMOGRAPHY (PET) STUDY.

P. Fiset, T. Paus*, T. Daloze, G. Plourde, N. Hofle, N. Haji-Ali, A. Evans. Anaesthesia Dept., Royal Victoria Hospital and Brain Imaging Center, Montreal Neurological Institute; McGill University, Montreal, QC, Canada. H3A 1A1.

This study was designed to examine the effect of different levels of propofol-induced anesthesia on global and region-specific changes in brain activity, as indexed by cerebral blood-flow (CBF). In five healthy volunteers, propofol was administered throughout a 2-hour PET session. After two baseline (awake) 3-minute scans, a computer controlled infusion of propofol was started, targeting three plasma concentrations: 0.5, 1.5 and 2.5-3.0 µg/mL. Two scans were acquired at each level. At the highest propofol level, all volunteers were unresponsive to verbal stimuli.

Absolute values of CBF were calculated using a two-compartment model of Ohta et al. (1996). A significant decrease in global grey-matter CBF was observed at the highest propofol level vs baseline (37.9±10.5 vs. 48.2±11.4 ml/100 g/min, p=0.01). CBF data were then normalized for the global grey-matter CBF changes, and the relationship between propofol plasma concentration and regional CBF was evaluated with linear regression. This analysis revealed significant (12) >3.5) negative correlation between plasma propofol and CBF in the ventro-medial thalamus, orbitofrontal, and posterior and medial occipital cortex. There was a positive correlation between plasma propofol and CBF in the cerebellar vermis. In addition, a significant co-variation was observed between CBF in the thalamus and that in midbrain reticular formation, indicating a coordinated blood-flow response to the changing propofol level. In conclusion, propofol appears to induce not only global CBF decreases, but it also affects brain activity in a region-specific manner. Changes in rCBF observed in the thalamus and midbrain reticular formation support the importance of these structures in the control of consciousness. Supported by MRC SP-30 fund as a pilot project.

CEREBRAL VASODILATOR RESPONSES TO BRADYKININ AND HYDROGEN PEROXIDE ARE DEPENDENT ON ACTIVATION OF Ca**-DEPENDENT K* CHANNELS. <u>Frank M. Faraci,* Christopher G. Sobey, and Donald D. Heistad</u>, University of Iowa, Iowa City, IA, 52242.

The goal of this study was to test the hypothesis that vasodilator responses of cerebral arterioles to hydrogen peroxide (H₂O₂) involves activation of Ca**-dependent K* channels. Diameter of cerebral arterioles was measured using cranial windows in anesthetized rabbits and rats. In rabbit cerebral arterioles (baseline diameter= 102±5 μm), H₂O₂ (10⁻⁵ M - 3x10⁻⁴ M) produced concentration-dependent dilatation that was inhibited completely by catalase (100 U/ml). Iberiotoxin (5x10⁻⁸ M), a selective inhibitor of Ca⁺⁺-dependent K⁺ channels, inhibited dilatation in response to H_2O_2 by approximately 60%. In rat cerebral arterioles (baseline diameter=38±2 μm), bradykinin (10-8-10⁻⁶ M) produced concentration-dependent dilatation that was inhibited completely by catalase (100 U/ml). Tetraethylammonium (10- 3 M, an inhibitor of Ca ** -dependent K * channels) or iberiotoxin markedly inhibited vasodilatation in response to bradykinin. These findings suggest that dilatation of cerebral arterioles in response to exogenous H_2O_2 , or H_2O_2 produced endogenously by bradykinin, is mediated by activation of Ca**-dependent K* channels. Thus, activation of K* channels may be a major mechanism of cerebral vasodilatation in response to reactive oxygen species.

PROPOFOL ATTENUATES pCO2 MEDIATED INCREASE IN CEREBRAL BLOOD FLOW (CBF) IN NORMAL VOLUNTEERS. MG Byas-Smith¹, MA Frolich¹, JR Votaw², and JM Hoffman²³* Department of Anesthesiology¹, Department of Neurology² and Emory University PET Center², Emory University School of Medicine, Atlanta, Georgia 30022.

The effect of propofol on the CNS has been reported. Propofol does not prevent pCO2 induced rises in CBF(Stephan H, et. al., 1987). This study was performed to determine the effects of propofol on CBF using positron emission tomography (PET). Ten volunteers participated. Prior to positioning in the scanner, lines were inserted. The O-15 water bolus technique was utilized. Subjects were scanned in a Siemens ECAT scanner. Nine scans were performed, 3 resting, 3 sedation and 3 anesthetic scans Sedation was defined as no spontaneous responses. Anesthesia was defined as responsive only to deep pressure over the sternum. Subjects breathed spon taneously. The targeted tissue concentrations for sedation and anesthesia were 2 mcg/ml and 6 mcg/ml respectively. Arterial blood gases were taken after each scan. PET images were normalized by calculating absolute blood flow using the non-linear-squares method of Koeppe (JCBFM, 1985). Regression and paired t tests were used for data analysis. The CBF increased whenever the pCO2 was above baseline. When the pCO2 was at baseline, the CBF decreased. The elevations in CBF were less than predicted (2-4% increase in CBF for each 1 mmHg rise in pCO2) during sedation (p<0.02) and approached significance for anesthesia (p<0.08). Propofol may attenuate the pCO2 CBF effects.

BLOCKADE OF NEUROPEPTIDE Y Y₁ RECEPTORS DOES NOT AFFECT VASCULAR RESPONSES TO ADRENERGIC NERVE STIMULATION. M. Adner, S.P. Duckles, L. Edvinsson* and D.N. Krause. Dept Internal Med, Lund Univ Hospital, Lund, Sweden and Dept Pharmacology, Univ of California, Irvine, CA, 92717, USA.

The 36-amino acid neuropeptide Y (NPY), an adrenergic co-transmitter, is known to potentiate vasoconstriction of the rat tail artery. The aim of

The 36-amino acid neuropeptide Y (NPY), an adrenergic co-transmitter, is known to potentiate vasoconstriction of the rat tail artery. The aim of this study was to characterize the postjunctional NPY receptor mediating potentiation in tail artery segments in vitro and to investigate the role of endogenous NPY in mediating contractile responses to adrenergic nerve stimulation. The Na⁺-channel inhibitor tetrodotoxin (1 μM) totally abolished contractile responses to adrenergic nerve stimulation (15 V, 0.3 msec, 16 Hz). NPY (10 nM) elicited no contraction by itself but potentiated contractions to adrenergic nerve stimulation (10 pulses) at 0.5, 1 and 2 Hz (141±11%, 136±12% and 130±14% of control, respectively). Exposure to the selective NPY Y₁ receptor antagonist BIBP3226 (1 μM) did not cause any effect by itself but abolished NPY-induced potentiation at all frequencies tested (10 pulses; n=7), indicating that NPY induced-potentiation is mediated by the Y₁ receptor. To test whether endogenous NPY contributes to contractile responses, adrenergic stimulation was increased to 100 pulses (1-16 Hz). However, contractile responses to adrenergic nerve stimulation were not affected by BIBP3226 at any of the frequencies tested (n=3, 8-9 segments). This study suggests that NPY, acting on Y₁ receptors, potentiates norepinephrine-induced contraction, but endogenous release of NPY does not appear to contribute to contractile responses to adrenergic nerve stimulation in the rat tail artery.

IMMUNOFLUORESCENT IDENTIFICATION OF OXYTOCINERGIC NERVES IN CORTICALVESSELS. C. Thore, ^{1*} F. Bari^{1,2}, M. Morris¹ and D. W. Busija¹. ¹Bowman Gray School of Medicine, Winston-Salem, NC 27157 and ²Albert Szent-Györgyi Medical University, Szeged, Hungary H-6720.

We have shown previously that oxytocin is a potent dilator agent in the cerebral circulation of piglets, but possible sources of this peptide are unclear. The purpose of this study was to determine whether perivascular nerves are immunopositive for oxytocin. Brain arteries were removed from the brain surface, immediately fixed in 4% formaldehyde, and the presence of oxytocin assessed using indirect immunofluorescence. Using an antibody known to crossreact with neurophysin-oxytocin (NPOT) and neurophysinvasopression (NPVP), we observed an extensive network of immunostaining in large arteries and their branches. Additional experiments using a specific antibody against NPOT showed similar but less intense immunostaining, while use of a specific antibody against NPVP revealed little staining. Arteries stored overnight at 4°C before fixation showed no immunoreactivity. Lastly, arteries from piglets exposed to 5-10 minutes of brain anoxia showed no NPOT immunoreacivity. We conclude that cerebral arteries are innervated by oxytocinergic fibers in piglets. Supported by HL 30260, HL 46558 & HL 50587

HYPOXEMIA INCREASES BLOOD FLOW THROUGH THE RETINAL CIRCULATION IN CATS; A STUDY USING FLUORESCENT MICROSPHERES. J. Ahmed and R.A. Linsenmeier*. Dept. Of Biomedical Engineering, Northwestern University, Evanston, IL 60208-3107

The purpose of this study was to develop a method of measuring blood flow through the retinal circulation and to determine what effects hypoxemia had on retinal blood flow.

Experiments were done on urethane-anesthetized cats. 5 eyes from 4 cats were used. Retinal blood flow was measured using fluorescent microspheres (Molecular Probes, Eugene, OR; Yellow/Green, Scarlet, and Blue polystyrene microspheres; 10 and 15 µm diameters). Approximately 5 million microspheres were injected into the left ventricle via a cannula inserted through the femoral artery. A reference sample was taken using a withdrawal pump connected to a cannula in the other femoral

Hypoxemia was induced by decreasing oxygen levels in the breathing gas to 5-8% O_2 , resulting in arterial PO_2 s of 24.2 \pm 6.9 mmHg (n=3). Retinas were fixed in 10% formol-saline and wholemounted. Microspheres were counted using a fluorescent microscope and a ccd camera

Hypoxemia increased retinal blood flow by 286 ± 94% (n=3). This difference was statistically significant (P< 0.01; paired t-test). Control experiments in which no hypoxemia was presented showed an increase in the blood flow measurement of 41 ± 22% (n=2) between the first and second microsphere doses. This increase was not statistically significant.

These data show that the retinal circulation is very sensitive to tissue hypoxia and responds with a large decrease in its resistance. Future experiments will be geared towards understanding the chemical mechanism of this hypoxia-induced vasodilation as well as other aspects of the control of blood flow through the retinal circulation. Supported by NIH grant EY-05034 and the Whitaker Foundation

GENDER DIFFERENCES IN MYOGENIC REACTIVITY IN RAT CEREBRAL ARTERIES. G.G. Geary, D.N. Krause and S.P. Duckles*. Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717, USA.

Although the myogenic reactivity of male rat cerebral arteries has been documented, response to pressure of female arteries has not been characterized. Therefore, the goal of the present study was to compare the myogenic reactivity of large and small middle cerebral arteries (MCA) from male and female rats. Pressure of cannulated, isolated cerebral arteries was maintained without flow by a pressure-servo system, and lumen diameter was monitored by a video dimension analyzer. Although a Ca++-sensitive myogenic tone (10-20%) was present in both male and female MCA (>250 µm), only female arteries constricted (20-30%) to 10 mm Hg step increases in pressure (20-80 mm Hg). In contrast the diameter of male MCA increased with pressure. When BK_{Ca} channels were blocked with tetraethylammonium (TEA⁺), myogenic responses were unmasked in the male MCA and enhanced in the female. Since myogenic reactivity of cerebral arteries has been shown to vary with location, we also determined if gender influences myogenic responses of small cerebral arteries (<150 μ m). In contrast to larger arteries, a pressure-dependent reduction (30%) in diameter occurred in smaller male pressure-response reduction (30%) in diameter occurred in smaller male and female arteries. However, the range of myogenic responses in male arteries (20-80 mm Hg) was greater than in female (20-50 mm Hg). Thus gender and location influence myogenic reactivity of cerebral arteries of the rat. Concurrent activation of K⁺ channels during changes in pressure modulates myogenic responsiveness, and these effects may be gender-related. be gender-related. Supported by NIH grant R01HL50775

GABAERGIC REGULATION OF RESTING TONE IN CEREBRAL MICROVESSELS OF THE RAT. A. Fergus* & K.S. Lee. Neurological Surgery & The Neuroscience Graduate Program, Univ. of Virginia, Charlottesville, VA 22908.

Converging lines of evidence suggest that local neurons are participants in the regulation of cerebral blood flow. Interneurons are often closely associated with parenchymal microvessels suggesting that they may be capable of signalling microvascular responses. The present study examined the role of GABAergic signalling in the regulation of resting tone in microvessels of the rat. The effects of endogenous activation of GABA receptors on the tone of hippocampal and cortical microvessels were examined using computer-assisted videomicroscopy in conjunction with extracellular recording

The resting diameter of the microvessels examined ranged from 9um to 24μm in the hippocampus and from 30μm to 50μm on the surface of the cortex. Treatment with the GABAB receptor antagonist, 2-hydroxysaclofen, does not elicit a significant vascular response in either the hippocampus or the cortex. In contrast, GABA_A receptor antagonists elicit dose-dependent constriction in hippocampal microvessels. The competitive GABA_A receptor antagonist, bicuculline (100 μ M), elicits a 27.6 $\pm 2.7\%$ constriction. However, bicuculline (up to $200\mu M$) does not elicit a significant response in cortical vessels. In the hippocampus, blockade of action potential propagation with tetrodotoxin does not significantly attenuate the bicuculline-induced constriction. These findings indicate that the tonic activation of GABA_A receptors contributes to resting dilatory tone in hippocampal microvessels These data implicate GABAergic interneurons in the signalling of parenchymal but not surface blood vessels under resting conditions. Supported by NIH grant # HL49396 to KSL.

ASTROCYTES ACCUMULATE [14C]ACETATE BY THE MONOCARBOXYLATE TRANSPORTER. R. A. Waniewski* and D. L. Martin, Wadsworth Center, NY State Dept. Health and Dept. Env. Health and Tox., SUNY, Albany, NY 12201.

Exogenous acetate is believed to be preferentially accumulated and metabolized by astrocytes in the CNS. We are examining the biochemical basis for this. Transport studies with [14C]acetate were conducted to determine the mechanism of its accumulation by rat cortical astrocytes in culture. The rapid loss of label from the cells necessitated 0.25-min incubations at low temperatures (4-6°C) with very rapid washing procedures (3 x 1ml in 5 sec). This was done to slow metabolism and reduce efflux of accumulated label. Under these conditions, acetate uptake was time-dependent for up to 1 min and consisted of a saturable, low-affinity component and a non-saturable, presumably diffusional, component. With acetate concentrations down to 0.04 mM, there was no evidence for a separate, higheraffinity component of transport. The saturable component displayed the properties of the proton-coupled monocarboxylate transporter. Uptake was inhibited up to 95% by coincubation with 5mM α -cyano-4-hydroxycinnamate (CN4HC), and was inhibited stereospecifically by lactate. At 0.2 mM acetate, the IC50 was 2.2 mM for L-lactate and 19 mM for D-lactate. A 15 min preincubation of astrocytes in a glucose- and monocarboxylate-free buffer eliminated most of the CN4HC-sensitive uptake. Preincubation with 10 mM L- but not D-lactate completely restored acetate uptake. This is similar to the trans-accelerating effect of intracellular Llactate on pyruvate and lactate uptake by the monocarboxylate transporter observed in other cell systems. The most remarkable property of the acetate transporter in astrocytes is its very rapid kinetics. The V_{max} for uptake is 522 nmol/mg protein x min and the K_m is 14 mM. This K_m is similar to that reported for low-affinity lactate transport by astrocytes while the $V_{\rm max}$ for acetate is 3 times higher than that for lactate. Work is in progress to determine whether neurons transport acetate in the same manner as astrocytes. Supported by the Wadsworth Center.

STATISTICAL APPROACHES TO PLACE FIELD ESTIMATION AND NEURONAL ENSEMBLE DECODING. 1 E.N. Brown*, 2 L. Frank and 2 M. Wilson. 1 Dept. of Anes., MGH, Boston, MA 02114. 2 Dept. of Brain and Cogn. Sci., MIT, Boston, MA 02139.

The firing of CA1 place cells in the rat hippocampus correlates with the animal's position in its environment. The recorded shape of the field depends on the structure of the environment and the task the animal is required to perform. During random foraging the fields are nearly circular whereas in maze experiments, they are constrained by the structure of the apparatus. To develop better quantitative descriptions of place field properties, we estimated place field firing maps using formal statistical procedures. We model the firing pattern of a place cell as an inhomogeneous Poisson model whose instantaneous firing rate is a function of time and the animal's position in the cell's field. We approximate the noncircular geometry of the fields with ellipses. Using recordings from place cells which fired at least 50 times during free foraging, we show that the model parameters and their standard errors can be estimated by maximum likelihood analysis. Based on our analyses, the firing maps of many of the cells are better described by ellipsoidal rather than circular geometry. The model can be used to derive a linear position decoding algorithm that takes account of the observed firing pattern of the cells, the locations of the field centers, and the field geometries. We further refine the position estimate by incorporating theta rhythm modulation of the place cell firing into the decoding algorithm. This approach holds promise for giving a better quantitative description of place field characteristics during behavioral experiments and for improving neuronal decoding algorithms.

DISCHARGE CORRELATES OF HIPPOCAMPAL NEURONS IN RATS PASSIVELY DISPLACED ON A MOBILE ROBOT V. V. Gavrilov, S. I. Wiener, A. Berthoz*. CNRS-Collège de France LPPA. 15. rue de l'École de Médecine. 75270 Paris CEDEX 06 FRANCE Spatial and movement-selective discharge correlates of hippocampal neurons was studied in male Long-Evans rats. To detect contributions of inertial (and vestibular) cues to this activity. the water deprived rats were restrained in a sling mounted on a mobile robot. Single CA1 complex-spike cells were recorded extracellularly with glass micropipettes during translations and rotations of the robot in a square enclosure with black curtain walls. To maintain the attention of the animal, it received a drop of water as the robot arrived at a visually cued corner of the arena. Of 57 recordings sessions in four rats 15 were repeated in the light and in darkness. Fourteen neurons were selective for approaches to certain arena corners from two directions. Twenty selective for approaches to certain arena corners from two directions. Twenty seven of the hippocampal neurons significantly (t-test, p<.05) increased or decreased their firing rates when the rat was passively displaced in certain parts of the experimental arena. However spatial selectivity was for much broader regions than found in dorsal hippocampal cells of freely moving rats suggests that voluntary movements may be required for small firing fields. These discharges were often also associated with specific movement states like translation, rotation or immobility. In addition, 4 of 15 neurons analysed translation, rotation or immobility. In addition, 4 of 15 neurons analysed demonstrated similar spatial or behavioral discharges correlates in in light and darkness. These results confirm those from similar experimental recordings of rat hippocampal EEG¹ and monkey hippocampal neurons. Indicating that there is a role of inertial inputs for the organization of activity of hippocampal neurons. Supported by EC/ESPRIT/BRA 3149 and 6615 MÜCOM, the Human Frontiers Scientific Program. Behavioral correlates of nucleus accumbens neurons in rats performing a water search task in an open field. R. Shibata, O. Trullier, D. Raballand, A. CNRS-Collège de France LPPA, B. Mulder, A. Berthoz, S. I. Wiener Paris, France.

In order to determine the dependence of discharge correlates upon the reference cue used for ongoing behavior in a region receiving hippocampal system outputs, we trained three male Long-Evans rats to perform two tasks on a rotatable 1.8m diameter elevated platform centered in a 3m X 3m cuecontrolled chamber enclosed by black curtains. Advanceable, multiple fine wire electrodes were stereotaxically implanted in the shell region of the nucleus accumbens. Four identical alcoves were equally spaced along the edge of the platform; each contained a visual cue which could be illuminated as well as a water trough under automated control. The thirsty rats ran between diametrically opposite alcoves. In the visual cue task, cues were lit to indicate the reward-containing alcoves and these were alternated periodically. In the *landmark cue* task, the rewards were always located at alcoves at fixed positions relative to the room

Of 29 neurons analysed, none were spatially selective in the reference frame of the platform. No clear changes in discharge correlates were found when the rat shifted between the two tasks. Five discharged selectively for several seconds prior to or after reward delivery. Nine other neurons had marked decreases in firing rate for 1-2 sec prior to and after reward delivery. These are comparable to task-related discharge correlates recorded in CA1 neurons of the hippocampus 1. Thus the nucleus accumbens maintains these representations and could help mediate hippocampal influences on other brain structures. TASK-DEPENDENT REPRESENTATIONS IN RAT HIPPOCAMPAL PLACE NEURONS HIPPOCAMPAL PLACE NEURONS.

Tsunevuki Kobayashi*¹, Hisao Nishijo¹, Masaji Fukuda², Jan Bures³, and Taketoshi Ono¹. Depts. ¹Physiol. & ²Behav. Sci., Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-01, Japan, and ³Institute Physiol, Academ. Sci., Prague, Czech.

It is suggested that the hippocampal formation (HF) is essential to spatial representations by flexible encoding of diverse information during navigation. In the present study, we investigated how various types of information are represented in the HF, by recording HF complex-spike cells from rats that performed 3 types of place learning tasks in a circular open field using intracranial self-stimulation (ICSS) as reward. First, complex-spike cell activity was compared between the following 2 tasks: the rat (1) randomly explored the open field; (2) went back and forth between two specific places. Of 43 complex-spike cells recorded, 37 had displayed place fields under the first task. Although reward and place correlates of the place-neuron activity did not change, neuronal correlates to movement speed, direction, and turning angle increased in the second task in which the behavioral trails during navigation were more constant than in the first task. Second, 6 of 31 place neurons tested with the tind task, in which the reward place was located outside the original place field, shifted place fields. The results indicated that neuronal correlates of most place neurons flexibly increased their sensitivity to relevant information in a given context and environment, and some place neurons changed the place field *per se* with place-reward association. These results suggest two strategies of HF neurons how to incorporate incredible variety of perceptions into a unified representation of the environment: flexible use of information, and creation of new representations.

HOW TWO CUES CONJOINTLY CONTROL HIPPOCAMPAL PLACE CELL

FIRING FIELDS. A.A. Fenton* and R.U. Muller. SUNY Brooklyn, NY, Previous work showed that the locations of place cell firing fields are controlled by a single white card on the wall of a gray cylinder. Specifically, rotations of the card position caused equal rotations of firing field locations in the absence of other polarizing stimuli. Here we describe how firing fields are controlled by two cue cards. These preliminary data are from 47 firing fields of 45 place cells recorded from one rat.

We recorded place cells while rats ran inside a 76 cm diameter gray cylinder with one white and one black cue card pasted on the wall. Each card occupied 45 deg of arc of the cylinder wall. In the "standard" arangement, the positions of the two cards were fixed in the labratory frame and the mid-points of the two cards were separated by 135 deg such that the black card was clockwise to the white card. Three experimental modifications of the standard arrangement were made. In the first, the two cards were rotated equally so that their separation remained 135 deg. This caused equal rotations of firing fields. indicating stimulus control by the two-cue configuration. The second manipulation was to remove one or the other of the two cards and then rotate the remaining card 45 deg. This also caused firing fields to rotate equally, demonstrating the salience of each card.

The third manipulation was to move the two cards closer together or further apart by

25 deg and then to rotate the altered configuration 45 deg. Changing the distance between the cards did not cause fields to stretch or compress; their shapes were unchanged. This is contrary to most theories of how firing fields are determined by sensory information. In addition, the position of each firing field changed as a function of its distance from the cue cards. Fields near the black card moved along with the black card, fields near the white card moved along with the white card and fields between the cards moved with the mean position of the two cards. Since the relationships between firing fields change, the place cell representation of space may not be uniform and rigid. Support: NIH Grant NS20686

INTERACTION OF THE HIPPOCAMPUS AND THE BASOLATERAL AMYGDALA INPUTS TO THE NUCLEUS ACCUMBENS OF THE RAT. A.B. Mulder* and F.H. Lopes da Silva. Grad. School Neurosci., Inst. Neurobiol., Fac. Biol., Univ. Amsterdam, Amsterdam, The Netherlands.
This study was conducted to determine the termination patterns and the

interaction of the hippocampal (HIP) and the basolateral amygdaloid (BLA), projections to the nucleus accumbens (Nacb). In halothane anaesthetized male Wistar rats, stimulation electrodes were placed in the BLA and the fornix/fimbria fibers (Fo/Fi: the output fibers of the HIP) and a glass recording electrode in the Nach. In 12 rats, Nach single unit activity was evoked by stimulation of the Fo/Fi (n=162) and of BLA (n=55). The cell discharges were on the peaks of the respective evoked field potentials (positive for Fo/Fi, negative for BLA stimulation). The mediodorsal shell only received HIP input, whereas in the ventrolateral shell and the ventral core only BLA driven activity could be found. Convergence of input (n=31) was found in the medial shell and the medial core regions of the Nacb. In the latter neurons successive activation of BLA then Fo/Fi pathways resulted in an enhancement of the firing probability, while in reverse sequence activation led to a depressed response (n=6: intervals 25-200 ms). Furthermore, tetanization of the Fo/Fi to Nacb pathway caused decremental homosynaptic long-term potentiation in the Nacb pathway caused decremental homosynaptic long-term potentiation in the Nacb, accompanied by a heterosynaptic long-term depression of the non-tetanized BLA to Nacb pathway (n=4). This suggests that the HIP to Nacb pathway performs inhibitory gating of the BLA to Nacb pathway, whereas the BLA stimulation facilitated or even enhanced the Fo/Fi to Nacb pathway. This could play a role in behaviours like conditioned place preference in which the place learning is dependent on the presentation of reward. Supported by NWO-MW program grant 900-550-093

THE SPATIAL ARRANGEMENT OF 3-DIMENSIONAL OBJECTS INSIDE THE ARENA INFLUENCES THEIR CONTROL OVER THE POSITIONAL FIRING OF PLACE CELLS. A. Cressant¹, B.Poucet*1, R.U. Muller². ¹Ctr. Res. in Cognitive Neuroscience, CNRS, Marseille, 13402 France and ²Dept. of Physiology, SUNY, Brooklyn, NY 11203.

The angular positions of place cell firing fields are precisely controlled by a single white cue card attached to the wall of a cylinder. In contrast, angular positions are poorly controlled by 3 objects arranged in a right triangle inside the cylinder where each object is about 1/3 cylinder radius away from the center (Poucet et al., SFN Abstr, 1995, 21:946). Here we ask if the inability of objects to control spatial firing is due to the nature of the objects themselves or due to the arrangement of the objects. Place cell recordings were made while hungry rats chased pellets in a gray cylinder with 3 different objects on the floor. In the "objects at periphery" condition (16 cells), the objects were against the cylinder wall as a isosceles right triangle. In the "clustered objects" condition (18 cells), the 3 objects touched each other and were arranged in a line centered along a chord 10 cm from the cylinder wall. In each condition, the relative object locations and their distances from the cylinder wall were fixed. Recordings were made either with the objects in a "standard" position in the laboratory frame or with the objects rotated as a rigid set around the center of the cylinder. In either condition, the angular position of the firing field of all cells could be precisely predicted from the angular position of the object set. The results demonstrate that the lack of stimulus control when the objects are near the cylinder center is due to the object arrangement and not to their specific sensory qualities. A more complete understanding of which configurations of the object set permit a stable reference frame should reveal interesting computational properties of the rat navigational system Support: NIH, CNRS

CHARACTERIZATION OF PLACE CELL ACTIVITY IN THE HIPPOCAMPUS OF THE FREELY BEHAVING MOUSE T.J. McHugh and M.A. Wilson* Departments of Brain & Cognitive Sciences, and Biology, MIT, Cambridge, MA 02139

As an initial step in our efforts to apply electrophysiological recording techniques in genetically engineered animals, we have adapted the parallel multi-electrode ensemble recording system developed for use in the freely behaving mouse. Microdrive assemblies containing four independently tetrodes were implanted on the skulls of wild-type CBL6/J mice and used to monitor the simultaneous activity of between 20-40 individual neurons per animal in the pyramidal cell layer of the CA1 region of the hippocampus. The activity of these neurons were recorded as the mice were exposed to a variety of environments, both novel and familiar. Pyramidal complex spike cells and inhibitory theta interneurons were identified and their firing patterns were examined for place-specific activities. The results of these experiments indicate that the cells in the hippocampus of the mouse behave in a manner very similar to those already characterized in the rat. Pyramidal cells demonstrated place and directional specific firing activity in a variety of environments with low overall firing rates. Upon exposure to novel environments inhibitory theta cell activity markedly decreased during initial exploration. The adaptation of the multielectrode recording system to the mouse will now allow us to examine, on a much more sensitive level, the deficits in learning and memory present in "knock-out" mice generated by gene targeting methods

EARLY VISUAL DEPRIVATION DOES NOT PREVENT HIPPOCAMPAL PLACE CELL FIRING IN THE RAT. Save, E., Cressant, A., Thinus-Blanc*, C., and Poucet, B. Centre de Recherche en Neurosciences Cognitives, CNRS,

Previous studies have shown that the location-specific firing of hippocampal pyramidal cells is controlled by visual and non visual cues. Once established, firing pyramidal ceris is controlled by visual and non-visual cues. Once established, in fields can be maintained as the animal locomotes through the environment in the absence of salient visual landmarks (Quirk et al., J. Neurosci., 10:2008). Nevertheless, the use of non visual cues may depend on the pre-requisite formation of a stable visuospatial frame of reference. As early visual deprivation has been suggested to markedly alter such build up, we asked whether the hippocampus of totally blind rats would develop normal place cell activity by using non visual cues. Newborn rats were enucleated and four months later were implanted with electrodes. Recordings of hippocampal units were made while the rats were retrieving food pellets in a gray cylinder (76 cm in diameter) containing three different cue-objects placed along the wall in a triangular configuration. Whenever possible, cells were recorded for several sessions allowing verification of the stability of the firing fields (sessions 1 and 2) and manipulation (90° rotation) of the cue-object configuration (sessions 3 and 4). Twenty two cells that displayed location-specific firing were recorded from four rats. Surprisingly, most cells (17) had unstable firing patterns over successive sessions. The activity of the remaining five cells was found to be controlled by the objects. In contrast, all cells recorded in intact rats were controlled by the objects. These results show that place cell activity does not depend on a functional visual system. However, the lack of stability of the firing fields over sessions for most cells suggests that the system might not be able to maintain a stable frame of reference based on non visual cues.

FIRING PATTERNS OF HIPPOCAMPAL CELLS IN MICE EXPLORING A CUE-CONTROLLED ENVIRONMENT Y.H. Cho*, H. Tanila and H. Eichenbaum. Ctr for Behav. Neurosci. SUNY, Stony Brook, NY 11794.

Hippocampal CA1 and CA3 cells were recorded from C57 bl/6 male mice as they navigate in a cue-controlled environment. The apparatus used was a cylinder equipped with a white cue card on its inner wall. To determine to what extent the cue controlled firing patterns of the (place) cells, the cue was either rotated 90° or deleted. Cue manipulation trials were intermixed with baseline trials

A large proportion of the hippocampal cells exhibited locationspecific firing properties. Place fields of some cells either rotated with the cue or remained unchanged, whereas other cells developed different spatial correlates of firing such that the place field either moved to a new place, or rotated to unpredictable angular locations or disappeared. Removing the cue card left the firing patterns unchanged relative to those of the preceding baseline trial or instead created new place fields that, in some cases, covered the zone of the maze where the cue had previously been placed. Furthermore, spatial correlation between the baseline trials decreased as animals experience changes in the environment

The data indicate that the hippocampal cells in mice also exhibit spatial firing properties similar to those observed in rats, and that constant remapping occurs in the hippocampal spatial representation with repeated changes in the environment. HIPPOCAMPAL PLACE FIELD PLASTICITY AND DIRECTIONALITY IN A SPATIAL MEMORY TASK. P.D. Martin and J. O'Keefe*. Department of

Anatomy, University College London, London, UK.

Rats were trained in an enclosed "cue controlled environment" (CCE) containing six spatial cues which identified the goal. These cues were rotated by random multiples of 90° between trials to eliminate the relevance of the background cues. After training the rats were able to correctly select the goal platform at the end of the trial even when the six spatial cues were taken out of the CCE mid-way through the trial.

Hippocampal place fields are governed by the six spatial cues such that rotation of the six spatial cues causes concomitant rotation of the place fields (O'Keefe and Speakman, 1987). However upon cue removal the place fields persist. Thus although the place fields are governed by the six spatial cues they are not dependent on them.

In addition to the unit behavior previously recorded in this situation we report two new responses. Some hippocampal place units decease or cease place specific firing upon cue removal. Others increase or initiate place specific firing upon cue removal. Thus for these cells place fields appear to be governed by the six spatial cues in two senses. Their location is dependent on the location of the six spatial cues and their intensity is governed by the presence or absence of the six spatial cues

Previous work has shown that place fields show directionality when a rat traversed an area in a stereotypical and invariant manner. Rats trained on the CCE spatial memory task were constrained to run in designated directions in order to insure uniform platform coverage. The place fields

recorded in this situation were also found to display directionality.

DISCHARGE OF HIPPOCAMPAL NEURONS (INCLUDING PLACE CELLS) CAN BE TRIGGERED BY PERIODIC LIGHT FLASHES. R.U. Muller*, A.A. Fenton, A. Rotenberg and M. Stead. Dept. of Physiology, SUNY-Brooklyn, Brooklyn, N.Y. 11203

There is a great deal of evidence that the activity of hippocampal place cells is controlled by visual cues in the environment. For example, when place cells are recorded as a rat runs around inside a 76 cm diameter cylinder, the angular coordinate of the cells' firing fields is reliably determined by the angular coordinate of a cue card pasted to the cylinder wall. It is generally observed that rotating the card's position causes firing fields to rotate equally. Seminal work by O'Keefe and Conway (1978) indicates that non-visual stimuli also can control the location of firing fields, although the nature of the control has not been as well explored as for visual stimuli.

Given that place cell activity is so strongly tied to static (unchanging) visual and non-visual cues, we were led to ask if their activity could also be affected by brief, periodically applied stimuli. Accordingly, we recorded from place cells and other hippocampal neurons (including "non-place" pyramidal cells and interneurons) during pellet chasing while a strobe light was flashed at 1Hz or when a loudspeaker click was generated at 1 Hz. In the auditory domain, we found that a rather loud click sounded in either the light or the dark caused no alteration in discharge for any cell so far recorded. In contrast, a strobe flash (presented while the room is otherwise dark) evoked activity from some (but not all) place cells, many theta cells and some (but not all) cells that did not fit either of the other categories. When present, the latency of the response ranged between about 40 and 70 msec. We think that the ability to activate hippocampal neurons with a stimulus that does not affect reward contingencies is really neat and suggests that the hippocampal representation can be be dynamically modified by ongoing events.

PLACE CELLS RECORDED FROM FREELY MOVING MICE: DIFFERENCES BETWEEN WILD-TYPE AND TRANSGENIC ANIMALS INCAPABLE OF SOLVING A NAVIGATIONAL PROBLEM. A. Rotenberg*, 1 M. Mayford, 2 R.D. Hawkins, E.R. Kandel, and R.U. Muller, Dept. Physiology, SUNY Brooklyn, NY, 11203 and ²Center for Neurobiol. & Behav., Columbia University, NY, NY 10032.

To address the link between LTP and hippocampal place cells, we have begun to examine transgenic mice expressing a constitutively active form of CaMKII. These mice have selective loss of LTP in the theta frequency range and are unable to solve the Barnes spacial maze (Bach et al., 1995). We therefore asked if the inability to solve the Barnes maze is reflected in the properties of hippocampal place cells, since place cells are thought be essential components of the rat navigational system. Such cells discharge rapidly only when an animal is inside a cell-specific part of the environment (the firing field) and are virtually silent elswhere.

By adapting standard place cell recording methods for mice, we find that place cells in the hippocampus of wild-type mice strongly resemble those in rat: their firing fields are stable across days, and are controlled by sensory stimuli in much the same way as in rat. Preliminary results indicate that place cells in CaMKII transgenic mice have normal appearing firing fields, but that some of these fields are less stable than those in wild-type animals.

SUBICULAR CELLS RECORDED IN FREELY MOVING RATS SHOW SIMILAR SPATIAL FIRING PATTERNS IN TWO GEOMETRICALLY AND VISUALLY DIFFERENT ENVIRONMENTS. P.E. Sharp*. Dept. of Psych., Box 208205, Yale Univ., New Haven, CT, 06520.

Cells in both the hippocampus and subiculum show location related firing

ceils in both the hippocampus and subiculum show location related firing patterns, so that the firing rate of a cell codes for the spatial location of the rat as it navigates (O'Keefe & Dostrovsky, Br. Res., 1971; Barnes et al., Prog. Br. Res., 1990; Sharp & Green, J. Neurosci., 1994). Since the subiculum receives a strong input from the hippocampus, it seems possible that the subicular spatial patterns are simply driven by the spatial signals from hippocampal place cells.

Data presented here, however, suggest that the two areas code space in fundamentally different ways. Spatial firing patterns of individual hippocampal and subicular cells were studied as rats navigated in two different environments: a cylinder and a square, of equal area. For some rats the two chambers had similar

visual stimulus characteristics, while for others, the two were very different.

Most subicular cells showed very similar firing patterns in the two cha regardless of whether the chambers were visually similar or different. Interestingly, these results are similar to those from entorhinal cells (Quirk et al., J. Neurosci., 1992). In contrast, as predicted by earlier results (e.g. Thompson & Best, J.Neurosci, 1989), hippocampal cells showed different patterns in any two chambers. These results suggest that subicular cells have the ability to transfer a single, abstract spatial representation from one environment to another. This pattern is

assistance spatial representation from one environment to another. This pattern stretched to fit within the boundaries of the current environment. Thus, the subicular cells seem to provide a generic representation of the geometric relationships between different locations in an environment. This could possibly contribute to abilities such as dead reckoning, and novel route generation.

In contrast, it appears that hippocampal place cells provide a spatial representation which is unique for each environment and which is strongly influenced by the particular stripulus attributes of each environment.

particular stimulus attributes of each environment.

EVIDENCE FOR MOTOR COMMAND SIGNAL INFLUENCES ON ANTICIPATORY HEAD-DIRECTION CELLS. B.W. Lipscomb*, H.T. Blair &

P.E. Sharp. Dept. of Psychology, Yale University, New Haven, CT 06520-8205. Head-direction (HD) cells are thought to rely on information about angular head velocity to track directional changes during head turns (McNaughton et al., 1991). HD cells are influenced by passive velocity cues, such as optic flow and vestibular signals (Blair & Sharp, in press; Knierim et al., 1995), and may also depend on motor command (MC) signals during locomotive behavior (Taube, 1995; Wiener, A major difference between passive signals (vestibular/optic flow) and MC signals is that passive signals are not generated until after the rat begins to turn its head, whereas MC signals may reach HD cells before the rat begins to turn its head.

HD cells in anterior thalamus anticipate the rat's future head direction, and therefore, they shift their directional preference slightly during head turns (Blair & Sharp, 1955). To test for the possible influence of MC signals, we examined the activity of anterior thalamic HD cells during moments just prior to a head turn. We found that on average, cells began to shift their directional preference about 20 msec before the rat began to turn its head. This suggests that anticipatory HD cells may receive MC signals, allowing them to track a turn before it actually begins to occur.

In our accompanying abstract (Blair, Lipscomb, & Sharp), we report that individual HD cells in the anterior thalamus are tuned to anticipate the rat's future head direction by anticipatory time delays (ATDs) ranging from -10 to +50 msec. Interestingly, cells with long ATDs did not begin to signal turns earlier than cells with short ATDs (r=.11; p=n.s.). However, the amount by which a cell shifted its preferred direction during the turning state was directly proportional to the cell's ATD (r=.66; P<.001). We conclude that all HD cells in anterior thalamus begin to signal head turns about 20 msec before the turn begins, but they shift their preferred directions by different amounts during the turn, resulting in different ATDs.

MICROSTIMULATION OF SCHAFFER COLLATERALS EVOKES SINGLE PYRAMIDAL CELLS AND INTERNEURONS IN THE CA1 REGION OF BEHAVING RATS. M. Stead*, R.U. Muller. SUNY Brooklyn, NY, 11203.

By implanting a bundle of Pt/Ir microwires into the Schaffer collaterals of CA3 and a second bundle of recording electrodes into CA1 we are able to selectively evoke single units in CA1. Stimuli are delivered at low frequencies (0.3-0.5 Hz) as a rat performs a pellet chasing task in a familiar environment while its position is tracked with LEDs mounted on its head. The stimulus intensity is set such that the probability of evoking the unit is near 0.5. This arrangement allows us to probe the excitability of the cell at precise moments in time and space, and to make inferences about the network input to the cell at those times

Interneurons recorded from stratum oriens of CA1 are evoked at short latency by CA3 stimulation. The post stimulus time histogram (PSTH) also reveals a characteristic 20-25 ms period of inactivity immediately following the evoked activity that we suspect is due to GABAA inhibition. The type of stimulation necessary to stimulate some interneurons also appears to reset the theta rhythm. Whether this phenomenon is restricted to the vicinity of the recorded cell or is global is not known at this time. The positional excitability of some interneurons shows a high correlation with their spontaneous positional firing rate maps but others show a flat excitability profile as a function of position.

Pyramidal cells in CA1 have a higher threshold of activation than interneurons. PSTHs of these cells also reveal a characteristic 200 ms period of inactivity; suspect this post-evocation silence is due to GABAB inhibition. All pyramidal cells investigated so far have been place cells. The positional excitability profiles of place cells have a high correlation with their spontaneous firing rate maps.

We are currently doing drug studies to test our hypotheses about the post stimulus inactivity periods and examining the state of excitability as a function of EEG state Support: NIH Grant NS20686

TEMPORAL TUNING OF ANTICIPATORY HEAD-DIRECTION CELLS IN THE ANTERIOR THALAMUS OF THE RAT. H.T. Blair*, B.W. Lipscomb &

 P.E. Sharp. Dept. of Psychology, Yale University, New Haven, CT 06520-8205.
 Head-direction (HD) cells are tuned to fire action potentials only when a rat's head faces in a specific direction (Ranck, 1984). HD cells in the anterior thalamus are anticipatory, so that their firing rate is best correlated with the rat's future head direction (Blair & Sharp, 1995; Taube & Muller, 1995). Here, we report evidence that each HD cell in anterior thalamus is temporally tuned to anticipate the rat's future head direction by its own specific anticipatory time delay (ATD)

Anterior thalamic HD cells were recorded as rats navigated freely in a cylindrical chamber. The ATD value for each session was measured using an updated version of the method described by Blair & Sharp (1995). The mean ATD for all sessions was 19.5±3.7 msec, but values for single sessions varied greatly, ranging between -7.59 and +74.1 msec. Statistical analysis of 16 cells recorded over repeated sessions revealed that a large portion of this variance was due to variation between different cells, rather than within single cells (df=15,40; F=8.48; p<.0001). That is, the same cell usually showed similar ATDs when it was recorded over multiple sessions, but different cells tended to show different ATDs. This trend could not be accounted for by other variables such as animal, hemisphere, turning speed, turning distance, or session length. Interestingly, each cell's ATD value correlated positively with its directional tuning width (r=+0.77, p<001) and negatively with its peak firing rate (r=-0.43, p<0.02). Thus, cells with longer ATDs had broader tuning widths and slower firing rates than cells with shorter ATDs.

The average ATD value for all anterior thalamic cells we recorded (n=33) was about +20 msec, but individual cells showed values ranging between -10 and +50 msec. This suggests that the anterior thalamus might contain a temporally distributed representation of the rat's future head trajectory over the next 50 msec. EXPERIENCE-DEPENDENT MODIFICATION OF BI-NARAL INTERACTIONS IN PIRIFORM CORTEX. <u>D.A. Wilson* and R.M. Sullivan</u>. Department of Zoology. University of Oklahoma. Norman, OK 73019

The anterior piriform cortex (aPCX) receives input from the ipsilateral nare via the ipsilateral olfactory bulb and lateral olfactory tract (LOT). The most direct input from the contralateral nare reaches the aPCX from the contralateral nareiro olfactory nucleus (AON) via the anterior commissure. These bilateral inputs are segregated in aPCX layer I, with ipsilateral LOT terminals on distal portions of pyramidal cell dendrites (layer Ia) and commissural terminals (along with intra-cortical fibers) on proximal portions of the dendrites (layer Ib). The anterior commissure develops postnatally in the rat, and therefore, might be expected to be particularly sensitive to postnatal experience. The present report examined the effects of unilateral olfactory deprivation on the relative strengths of these bi-naral inputs to the aPCX

Wistar rats had a single nare sealed on postnatal day 1. On postnatal day 25-35, evoked potentials were recorded in layer 1 of the aPCX to stimulation of the ispilateral olfactory bulb and the contralateral AON. Recordings were made in both the deprived hemisphere and the undeprived hemisphere of each animal, as well as in naive controls. Evoked potentials recorded in the aPCX to ipsilateral MOB and contralateral AON stimulation were similar, although AON-evoked responses were much smaller in amplitude and longer in latency than MOB-evoked responses. Reduced olfactory stimulation produced a significant depression (30%) of ipsilateral MOB-aPCX responses in deprived hemispheres. In undeprived hemispheres, which received increased airflow during the unilateral deprivation. there was a significant enhancement (>30%) of ipsilateral MOB-aPCX responses compared to controls. Crossed projections were depressed in both hemispheres compared to controls. Preliminary anatomical results suggest early deprivation also modifies the thickness of termination zones, particularly layer la.

SYNAPTIC PLASTICITY IN THE CHICKEN HIPPOCAMPUS T.W. Margrie, J.A.P. Rostas* & P. Sah. The Neuroscience Group, Fac. of Med & Health Sci., University of Newcastle, Callaghan 2308, NSW, Australia

Health Sci., University of Newcastle, Callaghan 2308, NSW, Australia.

The avian hippocampus has been shown to be important for spatial memory and several types of spatial learning including homing and cache recovery. Since synaptic plasticity is believed to be the physiological mechanism underlying learning and memory, we have investigated excitatory synaptic transmission and synaptic plasticity in the hippocampus of the chicken. Coronal sections (500 µm thick) of adult chicken brain (>12 weeks) were cut in ice-cold Ringer and allowed to equilibrate at room temperature for at least 1 hr before in vitro intracellular and whele sell recordings were made all the middle 1/2 of the whole-cell recordings were made. All recordings were made in the middle 1/3 of the hippocampus at room temperature. Intracellular recordings were made with sharp electrodes filled with 3 M KCl or 3 M KMeSO₄ and 2% biocytin. Whole-cell recordings were made with patch pipettes filled with a Cs based internal solution. recordings were made with patch pipettes filled with a Cs based internal solution. Bipolar stimulating electrodes were placed along the midline if the hippocampus, superior and inferior to the recording electrode. Cells had a resting membrane potential of -56 ± 3 mV and a input resistance of > 100 MΩ. Single stimuli elicited an excitatory post synaptic potential (EPSP) followed by an inhibitory post synaptic potential (IPSP). The IPSP was blocked by bicuculline (10 μM), indicating that it is mediated by GABA_A receptors. Biocytin-filled cells were identified as multipolar neurons. At their resting membrane potential the EPSP was blocked by 10 μM CNQX indicating that the primary excitatory neurotransmitter at these synapses is glutamate. At +20 mV, the EPSP had a slow component which was blocked by 25 μM D-APV. Tetanic stimulation (2 x 100 Hz seperated by 20 s) induced a large increase in the initial slope of the FPSP (225% at 60 min) which induced a large increase in the initial slope of the EPSP (225% at 60 min) which was stable for > 60 min. This potentiation was synapse specific and was not blocked by D-APV (50-100 μ M). We conclude that, like the mammalian hippocampus, this structure in birds demonstrates certain forms of plasticity which are believed to be important for learning and memory. FUNCTIONAL OVERLAP AND CONNECTIVITY OF HIPPO-CAMPAL NEURONS IN MULTIPLE DISCRIMINATIONS OF ELEMENTAL, CONFIGURAL AND SUCCESSIVE STIMULI IN THE RAT. Y. SAKURAI. Dept. of Psychology., Toyama Med. & Pharm. Univ., and PRESTO, Research Development Coop. of Japan, Toyama 930-01, Japan.

This study aimed to know whether each individual hippocampal neuron was involved in one, two or all of memory-processes of different features of stimuli. The elemental discrimination task employed four compound discriminative stimuli (AX, AY, BX, BY). simultaneous combinations of two auditory (A, B) and two visual (X, Y) stimuli. The positive stimuli in which the rat had to respond were those which included tone A (AX, AY). In the configural discrimination task, only the combination of A and X (AX) was positive. In the successive discrimination task, a short interval was intervened between the auditory and the visual stimuli and only the combination of A and X (A-X) was positive. Around 30% of the recorded CA1 and CA3 neurons showed differential activation between the positive and the negative discriminative stimuli in one or two of the tasks. There were no neurons which showed such differential activation in all tasks. A cross-correlation analysis among the neurons showed that some of the functional connectivity changed among the tasks.

BEHAVIOR AND NEURONAL ACTIVITY IN RAT HIPPOCAMPUS AFTER LOW AND HIGH FREQUENCY ELECTRICAL STIMULATION M. FUKUDA and T. ONO* Dept. of Behav. Sci. and Physiol.**, Fac. of Med., Toyama Med. and Pharmaceut. Univ., Sugitani, Toyama 930-01, IAPAN.

Long-term potentiation or long-term depression in the hippocampus is related to learning and memory. We studied the effects of tetanic electrical stimulation on Schaffer collateral fibers on behavior and neuronal activity of CA1 hippocampal cells. Rats motivated by ICSS were trained to explore a circular open-field. ICSS was delivered whenever the animal entered reward areas that were set randomly (RW) or fixedly (SN). In the RW task, spontaneous unit activity was suppressed by tetanic stimulation (100Hz, 100 pulses). Behavior of animals was disrupted, and trails were along the wall of the open field. After training that included 20 trials of the SN task during the course of two days, the stimulation induced a similar suppression of spontaneous unit activity and place field, and impaired movement. However, a place field might be different from the control state after recovery from task performance. The low frequency stimulation (1Hz, 100 pulses) may not induce apparent changes in behaviors and unit activity. These suggest that high frequency electrical stimulation might disrupt spatial information processing in the hippocampus and then alter behavior due to spatial learning. DARKNESS DOES NOT PREVENT PLACE NAVIGATION OF RATS ON AN INCLINED ARENA. M. C. Miniaci, M. Moghaddam and J. Bures (SPON: ENA). 'Fisiologia Umana, University of Reggio Calabria, Catanzaro, Italy and Institute of Physiology, Academy of Sciences, Prague, Czech Republic.

Cognitive maps, representing the relationships between any point of the charted environment and prominent landmarks allow the subject to find its position and to plot the shortest path to a known goal. Non-visual place navigation was examined in rats (n=9) trained to find among four equidistant feeders the baited one, located in the center of the upper left quadrant of a tilted (5.7°) arena (lm radius). With the slope direction changing randomly from trial to trial rats required twenty 8-trial sessions to reach the asymptotic level of 88% first choices correct when started from the center. After further training from starts at the lowest, highest and intermediate points at the perimeter of the arena rats continued to choose the correct feeder in 66% first choices. Since darkness did not impair navigation, rats were obviously able to recognize the start position according to the angle between the wall of the arena and the direction of the slope and to use their cognitive map of the arena to plot the course to the goal. This assumption was confirmed by starting the rats in darkness from randomly distributed points about 30 cm distant from the wall and the nearest feeder. Computer plotted startgoal tracks showed that the rats typically moved up the slope till they reached the wall and took then a more direct course to the goal. It is concoluded that the vestibular orienting gradient allows path integration based navigation from the perimeter of the arena to any point of its surface. HIPPOCAMPAL ENSEMBLE ACTIVITY DURING DELAYED-NON-MATCH-TO-SAMPLE OLFACTORY DISCRIMINATION IN RATS. S. P. Wiebe* and U. V. Staubli. Center for Neural Science, New York University, New York, NY 10003.

The hippocampus has long been implicated in cognitive processing during learning and performance of working memory tasks. In recent years, evidence has accrued which indicates that this processing is not focused purely on sensory events but rather dependent on conjunctive multimodal input and higher-order, contextual features associated with task contingency. To investigate the nature in which spatial, olfactory and task-specific components are represented in ensemble hippocampal firing patterns during performance of a working memory task, simultaneous recordings of multiple single-units from a microwire electrode array positioned in the CA3 and CA1 fields of the dorsal hippocampus were acquired during execution of a DNMS olfactory discrimination task. Prior to surgery, hooded Long-Evans rats were trained to perform a 2-odor DNMS task within a Y-maze apparatus at delays of 0-50 sec. Sample odors were presented in the stem of the Y-maze, with the location of the match and nonmatch odors in the test phase at the remaining two arms being randomized across trials. Neural spike events were isolated by a DSP-based spike sorter and digitized along with behavioral events. Preliminary data suggest the ensemble spatiotemporal hippocampal encoding of task-relevant events is, to a degree, separable along spatial, olfactory and contextual/cognitive dimensions.

EFFECT OF INTRA- AND EXTRA-MAZE CUES ON PLACE FIELD LOCATION. D.B. Matthews* & P.J. Best. Cen. for Neuro. Res./ Dept. of Psv., Miami Univ., Oxford OH, 45056.

The hippocampus is critical for spatial cognitive processing as evidenced by the fact that lesions to the hippocampal system impair the learning of spatial tasks. Also, electrophysiological recordings of single pyramidal neurons, place cells, demonstrate that these neurons have spatially sensitive firing characteristic

The location in which place cells maximally fire, the place field, has been thought to be determined by the constellation of distal, spatial cues. However, it was recently shown that proximal, non-spatial cues (Young Fox & Eichenbaum., 1994; Shapiro, Tanila & Eichenbaum, 1995) or a single distal cue can control the location of the place field (Shapiro et al., 1995). In the former study (Y,F&E) the environment contained no distal cues and a rich array of proximal cues while in the later study (S,T&E) the environment contained a few salient distal cues and a rich array of proximal cues

The present study investigates if place field location is primarily determined by a constellation of distal, spatial cues or if the location is by influenced by proximal, non-spatial cues in an environment where the saliency of the distal and proximal cues are similar. Preliminary results indicate that the location of the place field is controlled by the constellation of distal spatial cues and is only minimally influenced by proximal, non-spatial cues

PROACTIVE INTERFERENCE EFFECTS DURING SPATIAL TASK PERFORMANCE IN RATS. N. Kurzina, A. Kozlov, L. Bakanova, M. Druzin, E. Malinina Dept. Psychophysiology, Ukhtomsky Physiol. Inst., St. Petersburg Univ., Pavlov Physiol. Dept., Inst. Exptl. Med., St.

Petersburg, Russia
Effects of the preceding conditional reaction on the present conditional act performance were studied. Rats were trained delayed and non-delayed spatial task in Y-shaped maze. Two error types were analyzed. First type errors, when rats run to the same arm of the maze as in the previous trial were termed as repetition errors (RE). Second type errors when rats run to the other arm of the maze in comparison with the previous trial were termed as errors of alternation (AE). It was shown that RE occurs more often under a short intertrial interval (II) and non-delayed choice. The AE occurs more frequently under a long II and delayed choice. The data obtained support the idea that not only the cue presentation and delay periods are important for a successful task performance, but the whole structure of the task influences the organization of complex behavioral acts.

SPATIAL LEARNING AND MEMORY IMPAIRMENT IN AGED RATS: CORRELATION WITH IMMUNOLOGICAL ANGIV BINDING WITHIN CA1 PYRAMIDAL CELLS OF THE HIPPOCAMPUS.

E. A. Kramár, *¹ E.S. Pederson, ¹A.V. Miller-Wing,² L. Stubley-Weatherly,³

A.E. Ball,¹ J.W. Harding¹²³ and J.W. Wright¹²³. Program in Neuroscience and Departments of Veterinary and Comparative Anatomy, Pharmacology

and Physiology² and Psychology³, Washington State University, Pullman, WA

Since the initial discovery of a novel angiotensin receptor subtype (AT₄) that binds to Angiotensin IV(AngIV) in bovine adrenal tissue, autoradiograph studies have revealed binding sites for AngIV in numerous species and tissues including, guinea-pig and rat hippocampus, neocortex and cerebellum; these structures are classically associated with learning, memory and motor function Cognitive testing in the rat has shown that intracerebroventricular(icv) AnglV treatments can enhance both memory acquisition and retrieval in a passiveavoidance paradigm. Along these lines, icv AnglV treated rats have displayed Fos-like immunoreactivity localized within the pyramidal cell layers of the hippocampus suggesting that AnglV is effective in activating specific brain neuronal pathways associated with cognitive function.

The present study utilized a circular water maze task to investigated learning

and memory in aged Sprague-Dawley, Wistar-Kyoto and Spontaneously Hypertensive Rats. Our results indicate that the greatest learning and memory deficits were observed in 2 yr old rats, followed by 1.5 yr old rats as compared to 1 yr old rats. Immunoreactivey to AngIV in the CA1 region of the hippocampus indicates that significant differences exist among aged rats. Taken together, these results suggest that the cognitive impairment seen in aged rats may be due to a decrease in number and affinity of the AT4 receptor

VISUAL DISCRIMINATION LEARNING TASK INCREASES REM SLEEP. Z. Xie,* R. A. Stickgold, E. Pace-Schott, J.A. Hobson. Laboratory of Neurophysiology, Department of Psychiatry, Harvard Medical School, Boston, MA 02115

The relationship between REM sleep and learning was studied in nine subjects. Their sleep states were recorded for six days using the Nightcap, a two-channel recording device which distinguishes wake, REM sleep and NREM sleep. The average of Nightcap-measured sleep stage percentages recorded on the first three nights served as baseline. Subjects performed the human visual discrimination (HVD) task¹ on Day 4 between 8:00 p.m. and 10:00 p.m. and subsequent changes in sleep examined on Nights 4 through 6.

examined on Nights 4 through 6. Our findings were as following: (1) There was no significant difference in % REM sleep among the first three days (ANOVA, F[2, 12] = 0.99, p = 0.40, n.s.). (2) Baseline % REM sleep was comparable to % REM sleep on Nights 5 and 6. (3) The % REM sleep on the night following HVD task training (41.3% \pm 2.8, MEAN \pm SEM) was significantly increased as compared to baseline (33.4% \pm 2.1), Night 5 (35.3% \pm 3.7) and Night 6 (31.4% \pm 4.0)(F[3,24] = 3.06, p<0.05, post-hoc LSD

Karni and Sagi² have shown that learning on the HVD task occurs during REM sleep on the night following training. Our results suggest that HVD task training also increases the amount of subsequent REM sleep, suggesting a bi-directional interaction between REM sleep and HVD learning. (Supported by NIMH #MH-48,832 and MacArthur Foundation Mind Body Network).

A METHODOLOGY FOR PRODUCING A P-300 EVOKED POTENTIAL IN RATS WHICH WAS ELIMINATED BY EXTINCTION AND RECOVERED DURING RE ACQUISITION OF A DISCRIMINATED OPERANT RESPONSE W. D. Klipec*, S. Faux, L. Sauer, C. Corey, J. Miskimins, E. Hegel and S. Lebeda

Department of Psychology, Drake University, Des Moines, IA 50311
While an extensive literature documents the P-300 evoked potential in humans, only a few studies have demonstrated P-300 like evoked potentials in rats. In the present experiment, stainless steel electrodes, insulated except for 2-mm at the tip, were implanted 1mm into the brain, 1mm (Pz) posterior to Lambda, and 3-mm (Cz) and 7-mm (Fz) anterior to Lambda. Two additional electrodes implanted 8-mm anterior to Fz on each side of the midline served as an indifferent (Nz) and an

isoground. Rats were shaped to press a lever for food reinforcement where a 4.4 KHz target tone cued the insertion of the bar which retracted following a single reinforced response. The target tone was presented on a variable time (VT) 30-sec schedule, while a 2-KHz nontarget tone was presented on a truly random VT 15-sec schedule. Following extensive training, a strong P-300 response was observed at Fz, Cz (see insert) and Pz. Following additional training, a single session was conducted

in which a baseline P-300, recorded at all three sites, was substantially diminished when the target tone failed to predict lever insertion (extinction), and reinstated when the lever was reactivated (reacquisition). The methodology necessary to produce a robust P-300 response in rats, presented in detail in the poster, makes possible pharmacological manipulation of the P-300 response

ORAL INGESTION OF LEAD IMPAIRS SPATIAL LEARNING

MRAIKS STATIAN LEARNING
B.F. Petrie* Department of Psychology, New
Mexico Tech, Socorro, NM, USA 87801
Long-Evans rats were given ad lib access to
lead (Pb) in their drinking water (250ppm) for
90 days. These animals were then tested for
acquisition and retention of a moving platform place task version in the Morris water maze, and their performance was compared to Long-Evans rats that had been given ad lib access to distilled water only. All animals were swum for 18 days (8 trials per day; 60 seconds maximum per trial), with the platform being moved from one discrete location to the next in a systematic daily order. On 16 of the 18 days, the Pb exposed rats took longer on average to find the platform than did the control rats. Analysis of the swim pa indicated that the Pb animals selected Analysis of the swim paths ineffective strategies, consistent with the hypothesis that chronic lead ingestion in rodents impairs cholinergic function.

SLEEP EFFECTS IN ELECTROPHYSIOLOGICAL MEASURES OF MEMORY IN INFANTS, M.R. Letterman*, V. M. Little, and D. G. Thomas Department of Psychology, Oklahoma State University, Stillwater, OK 74075.

Event-related potential (ERP) data from awake 5-month-old infants showed that average ERP peak amplitude increased from Day 1 to Day 2 for a familiar stimulus but not for a novel one. Trial-to-trial latency variability decreased from Day 1 to Day 2 for the familiar stimulus but not for the novel. This pattern of results was most robust at Fz less so at Cz and was not found at T3. The present study used this same paradigm to investigate 24-hr memory in i-month-old infants during a quiet sleep state. On Day 1, ERPs were recorded to 100 identical auditory stimuli (400 Hz or 700 Hz tones). On Day 2, 50 of the familiar stimuli and 50 novel stimuli were presented. The amplitude of the N2 peak of the average ERP was larger on Day 2 for the familiar stimuli compared with ERPs on Day 1 at the T3 electrode site. There was a larger average amplitude of the positive peaks (P2 and P3) on Day 2 for the familiar stimuli compared with Day 1 stimuli at the Cz electrode site. This response is similar to that found in same-age awake infants; however, the pattern is less robust Analyses of latency variability indicated a non-significant trend for decreased variability from Day 1 to Day 2 for the familiar stimuli but not for the novel. The trend for a decrease in variability for the familiar response on Day 2 corresponds to that found with awake infants. This suggests that the organization of the neural ensemble on Day 2 is less well-defined with sleeping subjects than with awake infants. However, there is a trend towards a more stable (more "experienced") and less variable neural response. The research reported here was aided by Social and Behavioral Grants 12-0877 and 12-FY95-0025 from the March of Dimes Birth Defects Foundation.

A LONGITUDINAL STUDY OF INFANT AUDITORY EVENT-RELATED POTENTIALS. V. M. Little*, M. R. Letterman, and D. G. Thomas. Dept. of Psychology, Oklahoma State University, Stillwater, OK 74078.

Recently, investigation into the neurophysiological aspects of memory has extended to recognition memory in human infants. Previous studies suggest that auditory ERP peak latencies and latency variability show a general decrease while peak amplitudes show a general increase during development. In this study, event-related potentials (ERPs) were obtained from 24 infants at 5, 8, 11, 14, and 17 weeks of age. Auditory ERPs were recorded from frontal (Fz) and central (Cz) electrodes. Changes in the average ERP amplitude (component N2) were assessed in relation to latency variability and single-trial Results indicate significant developmental amplitude. trends in the average amplitude, average latency, latency variability, and single-trial amplitude. Changes in the average amplitude were primarily accounted for by single-trial amplitude and secondarily, but also significantly, by latency variability. This suggests the magnitude of the response and temporal consistency, to a lesser degree, explain most of the change in the ERP average amplitude. The research reported here was aided by Social and Behavioral Sciences Research Grants 12-0877 and 12-FY95-0025 from the March of Dimes Birth Defects Foundation and by Oklahoma Center for the Advancement of Science and Technology Contract 1690.

NEURONS IN HUMAN TEMPORAL CORTEX THAT DIFFERENTIATE BETWEEN WORD PAIR ASSOCIATIONS THAT WILL OR WILL NOT BE SUBSEQUENTLY LEARNED BY AN

NILL OR WILL NOT BE SUBSEQUENTLY LEARNED BY AN INDIVIDUAL SUBJECT G. Ogenann.* J. Schoenfeld-McNeil. Dept of Neurol Surg. Univ of Washington, Seattle WA 98195 In our previous study of neuronal activity in human temporal neocortex during paired-associate learning (NeuroReport 6:688, 1995), neurons that changed activity with overt word reading showed overall partition and the deficiency of the substitution of the substitutio activity when word pair associations were learned that differentiated subjects who learned pairs rapidly from those who learned pairs poorly, subjects who learned pairs rapinly from mose who learned pairs poortive with high levels of activity characterizing rapid learners. This effect was also evident on the initial presentation of the word pairs, though few pairs were actually learned then (unpublished). In recordings from the same area in a new series of subjects during the same paired associate test, we have identified a subset of neurons inhibited by word reading compared to a visual perception control, that increased activity during paired associate learning with significantly greater levels of overall activity on the initial presentation of those pairs that this subject will learn rapidly and reliably compared to pairs that the same subject will learn unreliably or not at all. Neurons of this type have been recorded from both temporal lobes in separate subjects; they did not all show significant changes in activity during recent memory for the same words. These neurons are part of the pool of neurons establishing verbal associations in humans.

SEMANTIC PRIMING IMPAIRMENT IN HIV L Nielsen-Bohlman*, D Boyle, C Biggins, F Ezekiel & G Fein Psychiatry Dept., UCSF & Veterans Administration Medical Center, San Francisco

HIV+ subjects have shown impairment on tests of automatic attention and verbal processing. This verbal impairment may be associated with disruption of automatic semantic activation. We examined behavioral and event-related potential (ERP) measures of priming in a lexical decision task in which all words had an obvious antonym ('deep') and two-thirds were presented as sequential antonym pairs ('enter' 'exit'). The 39 HIV+ and 22 HIV- subjects had no history of substance abuse, neurologic or psychiatric disorder unrelated to HIV. HIV+ subjects were divided into cognitively normal and cognitively impaired subgroups on the basis of a neuropsychological battery of 15 tests. Unlike control and cognitively normal HIV+ subjects, cognitively impaired HIV+ subjects showed no evidence of reaction time priming (unrelated versus primed words control t_{20} =3, p<0.005, normal HIV+ t_{15} =5, p<0.001, impaired HIV+ t_{22} =1; group by stimulus interaction; impaired HIV+ vs control, $F_{1,40}$ =4, p<0.05, vs. normal HIV+ $F_{1,37}$ =9, p<0.01). Cognitively impaired HIV+ subjects also showed a reduction in N4 amplitudes at frontal sites (at Fz, unprimed-primed difference wave, 375-425 msec, control -2.4 μ V, normal HIV+ -1.8 μV, impaired HIV+ -0.6 mV, control vs. impaired, F₁ $_{40}$ =4, p<0.05, normal vs. impaired $F_{1,37}$ =3, p=0.09). The associated reduction of reaction time priming and N4 amplitude in cognitively impaired HIV+ subjects suggests that the processing of linguistic stimuli in these patients may involve reduced activation semantic networks. AN EXTENDIBLE OBJECT-RELATIONAL DATABASE SCHEMA FOR NEUROPHYSIOLOGICAL AND BEHAVIORAL DATA, J.S. Grethe

Wehrer, R.F. Thompson, T.W. Berger, M.A. Arbib.

Neurosciences Program, Univ. of Southern California, Los Angeles, CA 90089-2520.

To address the problems associated with managing the increasingly large To address the problems associated with managing the increasingly large and diverse datasets collected throughout the neuroscience community, a novel extendible object-relational database schema has been developed. Since one can not hope to describe a priori all the experimental protocols and research data that neuroscientists will want to incorporate in a neurophysiological database the core database design needs to be easily modifications in the database's overall structure. By exploiting the object-oriented properties of new database technologies one is able to create a database schema that is completely modifiable while maintaining a standard core structure. To achieve this, the core database schema contains various super-tables that allow user defined sub-tables to be attached to the various super-tables that allow user defined sub-tables to be attached to the core database schema in an inheritance hierarchy. Researchers can use this method to extend their database to contain relevant information concerning the research subjects used in their laboratory, the experimental data collected, the experimental protocols used and any annotations or statistics (metadata) normally included in their experiments.

Another important issue that must be addressed is that there will not be a single monolithic database which will store all neuroscience data. Rather, there will be a federation of databases throughout the neuroscience community. In order to be able to connect and access other databases, certain "hooks" have been included in the core database schema to foster such communication.

Reduced Orienting Response after Human Hippocampal Damage R.T. Knight*, Department of Neurology and Center for Neuroscience, University of California, Davis, Martinez Veterans Medical Center, 150 Muir Rd., Martinez, CA, 94553

Lesion and intracranial data have shown that the hippocampal formation is part of a cortico-limbic network subserving the orienting response. Focal hippocampal damage alters central markers of the orienting response as revealed by reductions in the fronto-central scalp P300 response to unexpected visual, auditory and somatosensory stimuli. Intracranial recordings from hippocampal electrodes report large, habituating responses to novel somatosensory stimuli. in the current experiment, sympathetic skin potentials (SSR) to irrelevant wrist shocks were recorded in normals and patients (n=6) with unilateral damage in the posterior hippocampus due to infarction of the artery of Uchimura. Electrical shocks set to elicit an opponens pollicis twitch were delivered randomly within an interstimulus interval of 12-20 seconds while subjects viewed a silent movie. Normals generated a large (7 mV) skin potential to the shock stimuli. The SSR was severely reduced in the hippocampal patients (1 mV; P< 0.02). The results suggest the hippocampal formation is part of a system that maintains a template of recent sensory events. Sufficient deviations from this code initiate a peripheral and central orienting response to facilitate processing of unexpected environmental events. Supported by NINDS grant NS21135.

AN ON-LINE NEUROPHYSIOLOGICAL AND DATABASE FOR THE NEUROSCIENTIST, M.A. Arbib*, BEHAVIORAL

Wehrer, J.R. Mureika, J. Tracy, X. Xie, R.F. Thompson, T.W. Berger, Neurosciences Program, Univ. of Southern California, Los Angeles, CA 90089-2520. In order to address the problems associated with managing the increasingly large datasets of neurophysiological data collected in laboratories around the world, a neurophysiological database has been developed by the University of Southern California Brain Project (USCBP). The USCBP University of Southern California Brain Project (USCBP). The USCBP neurophysiological database consists of two primary components: 1) The database component, a novel extendible object-relational database schema implemented in Illustra (J.S. Grethe et al. 1996). A time series datatype has been constructed, implemented in Illustra as a datablade which defines a new base type and associated functionality, that allows neurophysiological data to be stored and manipulated in the database. 2) An on-line notebook that provides a laboratory independent "standard" for viewing, storing and retrieving data across the internet. The notebook interface was developed using Java and HTML 3.0 specifications. Currently, two different neurophysiological experiments, from two laboratories involved in the USCBP, have been brought on-line.

USCBP, have been brought on-line.

The first experimental dataset concerns single unit recordings from neurons The first experimental dataset concerns single unit recordings from neurons in the deep cerebellar nuclei. This data is used to construct a single unit map of the response patterns of these cells following eyeblink conditioning in the rabbit (J. Tracy 1995). The second experimental dataset concerns electrophysiological recordings at the perforant path-dentate granule cell synapses in hippocampal slices of adult rabbits (X. Xie 1996). Field EPSPs are recorded in the molecular layer of the DG and are evoked by stimulating perforant path evons. Electrical and pharmacological manipulations are are recorded in the molecular layer of the DG and are evoked by stimulating perforant path axons. Electrical and pharmacological manipulations are added to the preparation to investigate the induction of LTP and LTD. On-line information can be found at http://www-hbp.usc.edu:8376/HBP/TSDB/Supported in part by the Human Brain Project Consortium grant NIMH (5P01MD/DAS2194), NSF (IBN-9215069) to RFT, NIMH (MH00343) to TWB and an NSF Graduate Research Fellowship to JSG

CENTRAL EFFECTS OF GONADOTROPIN-RELEASING HORMONES (I AND II) AND BETA-ENDORPHIN ON COURTSHIP BEHAVIOR IN FEMALE WHITE-CROWNED SPARROWS. <u>D. Maney 1, R. D. Richardson 2, and J. C. Wingfield 1, Program in Behavioral Neuroscience and Department of Zoology 1, and Department of Psychology 2, University of Washington, Seattle, WA</u>

Like most vertebrates, birds have two forms of gonadotropin-releasing hormone (GnRH). Chicken GnRH-I is released at the median eminence to elicit gonadotropin release. Chicken GnRH-II, though its function is unknown, is hypothesized to act as a neurotransmitter controlling reproductive behavior. In the present study, we chronically cannulated the third ventricle of female white-crowned sparrows to test the effects of both forms of GnRH on courtship behavior. Female sparrows give a copulation solicitation display characterized by fluttering the wings while raising the tail and head. This behavior can be elicited in captive, estrogen-primed white-crowned sparrows by playing a recording of male song. We quantified the behavioral response to recorded song 30 minutes after i.c.v. infusion of GnRH-I, -II, and saline. GnRH-II, but not GnRH-I, increased solicitation behavior compared with saline. This suggests a central role for GnRH-II in reproductive behavior that may be independent of GnRH-I.

In addition, solicitation was suppressed by infusion of beta-endorphin, an endogenous opioid known to inhibit reproductive function and behavior in other vertebrates. This suppression was reversed by infusion of the opiate antagonist naloxone. Naloxone alone caused an increase in solicitation, suggesting that endogenous opioids may tonically inhibit the behavior. We discuss a multisynaptic model for the neuroendocrine control of solicitation display and its regulation during stress.

D, DOPAMINE RECEPTOR AGONIST (SKF38393) INDUCTION OF FOS-IR IN PROGESTIN RECEPTOR CONTAINING AREAS IN FEMALE RAT BRAIN.

J.M. Meredith*, A.P. Auger, J.D. Blaustein, Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Intracerebroventricular (i.c.v.) and intrahypothalamic injections of dopamine and dopamine receptor subtype agonists facilitate lordosis in estrogen-primed female rats. The D, receptor specific agonist, SKF38393 appears to facilitate lordosis in estradiol-primed female rats via a progestin receptor (PR)-mediated pathway. The current experiment was designed to examine whether SKF38393 induces Fos-immunoreactivity (Fos-Ir) in PR containing areas of the female rat brain associated with lordosis. Rats were ovariectomized, and guide cannulas were inserted immediately above the third ventricle. Ten to 14 days following surgery, animals were injected with 5 µg estradiol benzoate. Forty eight hours later animals were injected i.c.v. with 100 ng of SKF38393 (a dose previously reported to facilitate sex behavior in estradiol primed rats) or saline. One hour following injection animals were perfused and brain sections immunostained for Fos and Fos/PR. Sections were analyzed using computer-assisted image analysis for total number of Fos-Ir cells and for changes in optical density (OD) of Fos-Ir cells. SKF38393 increased Fos-Ir cell number in the midventromedial hypothalamic nucleus/ventrolateral aspect (mVMHVL), the caudal VMHVL, the paraventricular nucleus and the caudate putamen. SKF38393 also increased OD of Fos-Ir cells in the medial preoptic area, the rostral VMHVL and the arcuate nucleus (Arc). SKF38393 did not increase Fos-Ir cell number or OD in the medial preoptic nucleus (MPO), the dorsomedial hypothalamic nucleus the medial amygdala or the ovarian receptor containing area associated with the rVMHVL that extends dorsolaterally towards the fornix (rVMHVL-CRA). SKF38393 increased Fos-Ir in a population of PR-Ir cells in the cVMHVL but not in the rVMHVL-ORA, MPO or the Arc. (MH10650, NS19327 and RSA MH00850).

EFFECTS OF PELVIC AND PUDENDAL NERVE TRANSECTION ON FOS INDUCTION IN FEMALE RAT BRAIN FOLLOWING VAGINOCERVICAL STIMULATION. C.B. Coopersmith*, C. Manitt, & J.G. Pfaus. CSBN, Department of Psychology, Concordia University, Montréal, QC, Canada H3G 1M8.

In the female rat, the genito-somatosensory input received during sexual stimulation is conveyed to the central nervous system primarily through the pelvic and pudendal nerves. The present study examined the relative contribution of both nerves in the expression of Fos immunoreactivity (IR) within brain regions previously shown by us and others to induce Fos IR after mating or manual vaginocervical stimulation (VCS). Bilateral transections of either the pelvic or pudendal nerves, in addition to sham neurectomies, were performed on ovariectomized, sexually-experienced rats. After recovery, the females were primed with estradiol benzoate and progesterone and given either 50 manual VCSs with a lubricated glass rod over the course of 1 hr or allowed to mate in a bilevel chamber for 1 hr with a sexually vigorous male. Females were sacrificed 75 min after the first VCS or intromission and their brains processed for Fos immunochemistry. Overall, in sham-neurectomized females allowed to mate or given VCS, Fos IR was increased in different brain regions compared to unstimulated controls. Bilateral transection of the pelvic, but not pudendal, nerve reduced Fos IR in many of these areas, including the mPOA, lateral septum, BNST, VMH, and MEA. All females given VCS, except those with pelvic neurectomy, displayed a characteristic neck hunching and immobility during VCS. These data confirm that the pelvic nerve is largely responsible for the neural and behavioral effects of VCS. Supported by the Medical Research Council of Canada (MT-13125).

MEASUREMENT OF HYPOTHALAMIC SEROTONIN OVERFLOW IN STEROID-PRIMED RATS DURING LORDOSIS BEHAVIOR. S. Voorhis. T. Westin, D. Liu and K. Renner* Department of Biology, University of South Dakota, Vermillion. SD 57069

In an earlier study we demonstrated that progesterone (P) treatment decreased extracellular serotonin in the hypothalamus of anesthetized rats primed with estrogen (Farmer et al., <u>Brain Res.</u>, 711:8-4, 1996). To further examine the effects of P-influenced changes in hypothalamic 5HT function, we monitored 5HT overflow in steroid-primed females during lordosis behavior using microdialysis. In addition, we simultaneously monitored behavior and extracellular hypothalamic 5HT after pharmacological manipulations.

Two to six days after implantation of a guide cannula directed towards the ventromedial hypothalamus, rats were primed with 5 µg E. The rats were implanted with a dialysis probe 21 hrs later and injected with 0.5 mg P. In the first experiment, lordosis behavior was tested after the 5HT baseline was stable for 3 consecutive samples. Hypothalamic 5HT overflow was not significantly altered during or following the behavioral test. In the second experiment, steroid-primed females were pretested for behavior 4 hrs following implantation of the dialysis probe. These rats were treated with ip saline or 3 mg/kg of 1-(m-trifluoromethylphemyl)piperazine (TFMPP), a concentration of the 5HT receptor agonist which elevates hypothalamic 5HT in males (Auerbach et al., Neuropharm., 30:307, 1991). TFMPP treatment completely blocked lordosis behavior and increased hypothalamic 5HT approximately 600 % in the first post-treatment sample. The drug effects on both hypothalamic 5HT and behavior were reversed after 3 hrs. Additional doses of TFMPP are being evaluated. These results suggest that the proposed facilitatory role of 5HT is not mediated as a result of increased 5HT release in the hypothalamus during mating. The results obtained with TFMPP are consistent with an inhibitory role of hypothalamic 5HT in the regulation of lordosis but evaluation of the effects of lower drug doses is required. (supported by NSF grant 1BN-9596009 and HHIM 71195-539501)

360.4

C-FOS EXPRESSION IN BRAINS OF MATED AND UNMATED FEMALE RATS AND MACAQUES. R. P. Michael*, A. N. Clancy and D. Zumpe. Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, GMHI, 1256 Briarcliff Rd., Atlanta, GA 30306.

Immunoreactive c-fos expression was examined in brains of sexually experienced, ovariectomized rats treated with estradiol and progesterone and intact rhesus monkeys. Comparisons of the labeling distributions were made between animals that were either mated or unmated. Stimulus males were allowed to ejaculate with sexually receptive females; females were then killed by an overdose of sodium pentobarbital within an hour after ejaculation and perfused transcardially. Brains were dissected for immunocytochemical processing. Unmated females were not paired with stimulus males but were killed, perfused and processed as controls. Adjacent sections were incubated with three different anti-c-fos antibodies and sections from mated and unmated monkeys and rats were processed concurrently by the ABC immunoperoxidase method using identical immunoreagents. species, c-fos was observed in the nuclei of neurons in several brain areas including the medial preoptic area, several hypothalamic regions such as the paraventricular, ventromedial and arcuate nuclei, and the medial amygdala. In rats, with each antibody, c-fos expression occurred in recently-mated but not in unmated animals. Preliminary analysis of monkey sections also showed that mated monkeys expressed more c-fos labeling than unmated animals, but two of the anti-c-fos antibodies produced some labeling in the brains of unmated animals. A polyclonal sheep antic-fos antibody obtained from Cambridge Research Biochemicals produced the largest difference between mated and unmated monkeys. Results suggest that in primates with complex neocortical development and cognitive skills, c-fos in brain regions implicated in sexual behavior may also be expressed in unmated females when they are maintained in rooms together with other conspecifics. (Supported by USPHS Grant MH 19506.)

360.6

VAGINOCERVICAL STIMULATION INDUCES FOS WITHIN GLUTAMATE-CONTAINING NEURONS OF THE RAT VMH. J.G. Pfaus* and C. Sabongui. CSBN, Department of Psychology, Concordia University, Montréal, QC, Canada H3G 1M8

Fos is induced within the ventrolateral aspect of the ventromedial hypothalamus (VMH) in female rats following copulation with intromission or manual vaginocervical stimulation (VCS). Although the VMH is considered facilitatory for lordosis, infusion of glutamate to this region inhibits lordosis. Interestingly, moderate-tolarge amounts of VCS facilitate pacing at the expense of lordosis, and lead to increased rejection responses and a faster termination of estrus. Given that large amounts of VCS or glutamate infusions to the VMH both decrease lordosis, we examined whether Fos is co-localized with glutamate in the VMH following different amounts of VCS. Ovariectomized rats, primed either with estrogen and progesterone or the oil vehicle, were given 1, 10, 30, or 50 VCSs over the course of an hour with a lubricated glass rod, after which their brains processed for Fos immunoreactivity. A significant proportion of Fos cells in the ventrolateral VMH was co-localized with glutamate across all VCS conditions in the oil-treated females but far less co-localization was observed across conditions in the hormone-treated females except following 50 VCSs. These data suggest that hormone treatment blunts the ability of VCS to activate glutamate neurons in the VMH. Supported by the Medical Research Council of Canada (MT-13125).

IMMUNOCYTOCHEMISTRY FOR FOS AND TYROSINE HYDROXYLASE FOLLOWING MATING IN FEMALE HAMSTERS. S.M. Ramos*, J.F. DeBold. Psychology Department, Tufts University, Medford, MA 02155.

Several lines of evidence suggest that dopamine (DA) is involved in sexual receptivity. It has been shown that estradiol regulates specific DA receptor levels and DA receptor binding in the striatum of female rats. In hamsters DA levels increase in the striatum and nucleus accumbens during lordosis. However, the role of DA in female mating behavior has not been fully elucidated. Fos, an indicator of neuronal activation, is induced in specific brain areas as a result of factors associated with mating. To determine changes in the activity of dopaminergic neurons as a result of these factors, ovariectomized female hamsters were given hormone replacement and (1) placed alone in new cage for 10 minutes, (2) allowed to receive 15 mounts only from a male, or (3) allowed to receive 15 mounts with intro-missions from a male. Double immunocytochemistry to Fos (rabbit polyclonal anti c-fos, Santa Cruz Biotechnology, Santa Cruz, CA) and tyrosine hydroxylase (TH) (mouse monoclonal anti tyrosine hydroxylase, Sigma Immuno Chemicals, St. Louis, MO) was then performed on the brain tissue. Areas assessed to date include: the ventral tegmental area, substania nigra, interfascicular nucleus, lateral habenula and paraventricular nucleus. In the LHb only cells expressing Fos were detected. Analysis of the VTA, SN, IFN and PVN is preliminary but suggests that these areas contain cells which express Fos under these conditions and those which contain TH, and that these populations of cells are, in general, distinct from each other. SEXUAL RESPONSE OF FLINDERS LINE FEMALE RATS. G. P. Dohanich*, J. M. Daniel, A. J. Fader, S. C. Wolff, P.M. Gallogly, and D. H. Overstreet. 1 Department of Psychology, Tulane University, New Orleans, LA 70118 and 1Skipper Bowles Center for Alcohol Studies, University of North Carolina, Chapel Hill, NC 27599.

The Flinders Sensitive Line of rats was bred for increased cholinergic sensitivity as indicated by enhanced physiological and behavioral responses to cholinergic agonists (Overstreet, Neurosci. Biobehav. Rev. 17:51, 1993). In this study, the sexual responsiveness of Flinders Sensitive Line (FSL) females was compared to that of Flinders Resistant Line (FRL) and Long Evans (LE) females. Ovariectomized FSL females exhibited significantly higher incidences of lordosis and solicitation behaviors than ovariectomized FRL and LE females over a range of estrogen doses (2, 3, 4, 5, 20 $\mu g/kg$ at 48 hours before testing) in combination with progesterone (1, 2 mg/kg at 5 hours before testing). In addition, the muscarinic antagonist, scopolamine, inhibited lordosis behavior strongly in FRL females over a range of doses (0.25, 0.5, 1, 2, and 4 mg/kg), but only weakly inhibited lordosis in FSL females. Consequently, FSL females are highly sensitive to gonadal steroid effects and resistant to the effects of scopolamine. Results are consistent with previous reports of cholinergic supersensitivity of FSL rats. NSF award BNS-9021447.

REPRODUCTIVELY-RELEVANT STIMULI ACTIVATE PROGESTIN RECEPTORS IN FEMALE RAT BRAIN. A.P. Auger*, C. A. Moffatt and J.D. Blaustein. Neuroscience & Beh. Prog., Univ. of Massachusetts, Amherst, MA

Recent studies suggest that progestin receptors may be activated *in vivo* in the absence of ligand by treatment with modulators of protein phosphorylation. Intracerebroventricular infusion of a dopamine agonist or gonadotropin-releasing hormone (GnRH) increases sexual receptivity in estradiol-primed rats, and treatment with progesterone antagonists blocks this facilitation suggesting that the facilitation occurs via ligand-independent activation of progestin receptors. However, it is not known if ligand-independent activation of progestin receptors occurs under natural conditions. One potential pathway by which this proposed mechanism could occur in females is via somatosensory information provided by a male. As both progesterone and vaginal-cervical stimulation (VCS) increase expression of the immediate early gene product, Fos, within progestin receptor-containing neurons, and both dopamine and GnRH appear to be released in the brain by mating stimuli, we hypothesized that VCS-induced Fos-IR would be reduced by a progesterone antagonist

Ovariectomized rats were injected with estradiol followed 48 hrs later by either the progesterone antagonist RU486 or oil vehicle. One hour later, all rats received VCS or control perineum stimulation and were perfused one hour later. VCS increased Fos-IR in all areas examined. However, VCS-induced Fos-IR was reduced by the progesterone antagonist RU486 in the medial preoptic area (MPO) and ventromedial hypothalamus (VMH). In ovariectomized/adrenalectomized rats, VCSinduced Fos-IR was reduced by RU486 within the MPO, VMH, and the bed nucleus of the stria terminalis. Thus, some of the VCS-induced Fos-IR is dependent upon the availability of unoccupied progestin receptors. The results suggest that somatosensory information provided by VCS increases Fos-IR possibly via ligand-independent activation of progestin receptors. (supported by NS 19327 from NIH and RSDA MH

A POTENTIAL ROLE OF cGMP IN THE REGULATION OF LORDOSIS BEHAVIOR IN FEMALE RATS. H. -P. Chu*, J. C. Morales, and A. M. Etgen. Depts. Neurosci. & Psychiat., Albert Einstein Coll. Med. Bronx, NY 10461

Nitric oxide (NO) has been suggested to play a crucial role in the regulation of lordosis via activation of cGMP accumulation (Proc. Natl. Acad. Sci. USA. 91 6468-6472, 1994). Whalen and Lauber (Neurosci. & Biobeh. Rev. 10: 47-53. 1986) hypothesized that many agents known to facilitate lordosis act through cGMP. 1H-[1,2,4]oxadiazolo[4,3-a]quinoxalin-1-one (ODQ), which has been shown to selectively inhibit NO-stimulated cGMP production (Mol. Pharmacol. 48: 184-188, 1995), was used to investigate the effects of cGMP on lordosis behavior. Female rats were ovariectomized bilaterally and implanted with cannula aimed at the lateral or third ventricles by stereotaxic surgery. Behavioral testing was performed seven days later, after animals were injected subcutaneously with 2 µg of estradiol benzoate 48 and 24 hours followed by 200 µg of progesterone 4 hours prior to the testing. Animals with lateral ventricle cannulation were given ODQ (1 μ l of 80 μ M) or vehicle (1 μ l of 8 mM DMSO) at the time of progesterone treatment or 20 min before testing. ODQ significantly decreased lordosis quotient (LQ) and quality of lordosis (QL) at both intervals of drug infusion (LQ: p = 0.001; QL: p < 0.001; n = 3 - 7). Locomotor activities, measured as line crossing and rearing in an open field, were not affected by ODQ DMSO, however, seemed to increase rearing, because animals with ODQ or vehicle administration showed higher rates of rearing in the open field than animals without any infusion. ODQ also strongly inhibited LQ and QL in the animals receiving drug in the third ventricle (n = 2 for both drug and control groups). We conclude that cGMP is an important modulator of female rat sexual

DEFICITS IN REPRODUCTIVE BEHAVIOR IN DIABETIC FEMALE RATS ARE DUE TO HYPOINSULINEMIA RATHER THAN HYPERGLYCEMIA. G.B. Karkanias*, A.M. Etgen, J.C. Morales and C. Li Dept. Neuroscience, Albert Einstein Coll. Med., Bronx, NY 10461

These studies determined whether deficits in reproductive behavior observed in streptozotocin(STZ)-induced diabetic female rats are caused by hyperglycemia loss of insulin. Female Sprague-Dawley rats were ovariectomized and made diabetic by a single i.p. injection of STZ (75mg/kg). Reproductive behavior was measured 10 days after the onset of hyperglycemia (diabetes) following the injection of estrogen and progesterone in doses known to restore reproductive behavior in non-diabetic rats. Rats in which STZ produced diabetes showed significantly reduced receptive and proceptive sexual behaviors. Normalization of blood glucose levels either by restricting diet or by phlorizin treatment failed to restore reproductive behavior in diabetic animals. However, doses of insulin which produced normal blood glucose prevented the STZ-induced behavioral deficit. No changes in general activity were observed in any experimental group as assessed by open field activity (grid crossing and rearing). The density of the norepinephrine transporter, as measured by 3H-nisoxetine binding, was reduced in the cortex but not in the brain stem, hypothalamus or hippocampus of diabetic animals. Insulin treatment prevented the loss of cortical ³H-nisoxetine binding, and even partial normalization of blood glucose levels either by restricting diet or by phlorizin treatment restored the level of cortical ³H-nisoxetine binding. These findings suggest that diabetes-induced reproductive deficits are due to hypoinsulinemia and cannot be corrected simply by the normalization of blood glucose whereas reductions in cortical norepinephrine transporter are the result of hyperglycemia. THE EFFECT OF POSTNATAL EXPOSURE OF POLYCHLORINATED BIPHENYLS (AROCLOR 1254) ON THE SEXUAL BEHAVIOR OF RATS. Y.-W. Chung and L.G. Clemens*, Department of Zoology, Michigan State University, East Lansing, MI 48824.

Department of Zoology, Michigan State University, East Lansing, MI 48824.

Polychlorinated biphenyls (PCBs) are long-lasting environmental pollutants that have been reported to reduce male fertility, as well as cause abnormal embryonic development in several species (Kholkute et al., 1994; Sager et al., 1987). Although there are many reports of reproductive abnormality after PCB exposure (Fein et al., 1984), we know very little about the effect of PCBs on sexual behavior. We examined the effect of postnatal PCB exposure on the sexual behavior in laboratory rats. After parturition, 12 lactating rats were treated with Aroclor 1254 (Fisher Scientific), a mixture of PCBs containing 54% chlorine, by interperitoneal injection for one week. Thus, pups were exposed to Aroclor 1254 through dam's milk. Control females were given sesame oil. At 60 days of age, the female pups were ovariectomized, rehoused and allowed 7 days to recover from the surgery. The ovariectomized rats were primed with estrogen and progesterone and tested for sexual behavior. The male pups were tested after 90 days of age. When tested in a situation where the female could escape from the male after a copulatory event, PCB-treated females returned to the male with shorter latencies after intromission than did control females. In addition, the lordosis quotient of PCB-treated females was significantly lower. PCB-treated male rats, on the other hand, had longer mount latencies. The results of the behavior tests suggest that postnatal exposure of PCBs disrupts sexual behavior of both male and female rats. This research was supported by NSF grant IBN-9511971.

EFFECTS OF INTRACRANIAL ESTROGEN IMPLANTATION ON FEMALE RATS PACED COPULATORY BEHAVIOR. <u>L. Xiao</u>* and J. B. Becker^{1,2,3}, Department of Psychology¹. Reproductive Sciences Program², Neuroscience Program³, The University of Michigan, Ann Arbor, MI 48104.

When the female rat is allowed free access to and can also withdraw from a

compartment containing a sexually active male rat, she will actively regulate the temporal pattern of sexual contact with that male. This is called pacing behavior. As compared to nonpaced mating, paced mating by the female is more likely to initiate the neuroendocrine reflexes that induce a physiological condition necessary for pregnancy. Experimental evidence indicates that the display of pacing behavior is directly dependent upon the intensity of vaginocervical stimulation received from the male. However, the central neuroendocrine mechanism(s) mediating pacing are poorly understood. A previous study in this laboratory has demonstrated enhanced extracellular dopamine release in the striatum and the nucleus accumbens of female rats engaged in pacing. Since the striatum is involved in sensorimotor integration, we postulate that estrogen activation of the striatum plays a role in interpreting the signals relaying information about the intensity of vaginocervical stimulation, thus facilitating the appropriate motor response to the stimuli. The present study is designed to investigate the role of hormonal activation of the striatum and/or designed to investigate the role of normona activation of the stratum amount accumbens on pacing behavior using intracranial hormone implantation. Results indicate that 30% estradiol-178 administered to the striatum for 4 hr enhances pacing behavior measured by increased percent exits from the male after intromission and delayed contact-return latency after ejaculation. When a "pure" steroidal antiestrogen, ICI 182, 780, is implanted (10%) into the striatum, the sterotal antiestrogen, ICI 162, 760, is implanted (10%) find one stratum, opercent exits after each type of sexual contact are significantly decreased. However, the contact-return latency is not affected by the treatment. Therefore, certain components of pacing behavior are mediated by hormonal activation of the striatum. RELATION OF THE MEDIAL PREOPTIC AREA TO THE TEMPORAL PATTERN OF FEMALE SEXUAL BEHAVIOR IN RATS. L. Y. Yang* and L. G. Clemens. Neurosci. Prgm. & Dept. of Zool., Michigan State University, East Lansing, MI 48824.

MPOA lesions have been reported to increase the lordosis response in the female rats (Powers and Valenstein, 1972). Transections made anterior-dorsal to the MPOA also facilitated lordosis (Yamanouchi and April 1977). Recede of these results it has been suggested that the MPOA anterior-dorsal to the MPOA also facilitated fordosis (Yamanouchi and Arai, 1977). Based on these results, it has been suggested that the MPOA inhibits female sexual behavior. However, MPOA lesions significantly decreased the time that the female spent with the male (Whitney, 1986) suggesting that the MPOA may play a role in facilitating female sexual behavior. The objective of this study was to investigate the relation of the MPOA to the temporal pattern of female sexual behavior in rats. Experiment 1 investigated the effect of electrolytic lesions (1.5 mA for 20 Experiment I investigated the effect of electrolytic lesions (1.5 mA for 20 seconds) of MPOA on the pacing of copulation by the female. Females were tested in a situation where they could escape from the male following sexual contacts. Results indicated that MPOA lesions significantly increased the female's intromission return latency (IRL) and postejaculatory refractory period (PER). Experiment 2 examined the effect of ibotenic acid lesions (0.4 u L per side at a dose of 10 ug ibotenic acid/u L 0.1 M phosphate buffer, pH 7.40) of MPOA on female pacing. Results for ibotenic acid lesions were similar to electrolytic lesions suggesting that the alteration of timing in lesion females results from loss of MPOA cells and not fibers passing through MPOA. Ginton and Merari (1977) reported that MPOA lesions significantly lengthened the male's interintromission interval (III) and postejaculatory interval (PEI). Our results showed that the MPOA lesions had parallel effects in the female. Based on these results, we suggest that the MPOA plays a similar role in both males and females with regard to regulating the temporal pattern of copulation. This research was supported by NSF grant IBN-9511971.

FUNCTIONAL DIFFERENCES BETWEEN TWO G PPOTEIN ISOFORMS, $G\alpha_{i1}$ and $G\alpha_{g}$: Evidence from the use of antisense oligo-DEOXYNUCLEOTIDES (ODNs) IN THE STUDY OF LORDOSIS L.-M. Kow*, D.W. Pfaff and S. Ogawa. The Rockefeller University, 1230

York Ave., New York, NY. 10021.

Based on previous findings (Kow et al., Neurosci. Biobehav. Rev. 18:251, '94), it was hypothesized that α_1 -adrenergic agonists, such as methoxamine (MA), act on the hypothalamic ventromedial nucleus (VMN) to facilitate lordosis by activating the G proteins of the Gq family. To evaluate this hypothesis, ovariectomized rats were pretreated (7 intra-VMN infusions at 12-hr intervals) with three phosphorothioated 18-mer ODNs (1 μ g/0.2 μ L/side, bilateral). Two of the ODNs, $G\alpha_{11}\text{-AS}$ and $G\alpha_{q}\text{-AS},$ have sequences antisense to mRNA for $G\alpha_{11}$ and $G\alpha_{q},$ respectively; and the third, $G\alpha_{11}\text{-Scr},$ serving as a control, has a scrambled sequence for $G\alpha_{11}\text{-AS}$. Approximately 4 hrs after the last ODN infusion, the lordosis quotients (LQs) of the rats, which were primed with estrogen 2 days earlier, were measured in pre- and post-tests with an intra-VMN infusion of MA in between. MA infusion increased the LQ (mean±SEM, pre- to post-test) significantly in rats pretreated with $G\alpha_q\text{-AS}$ (44±7 to 79±8, n=9, p<.01, ANOVA), or the control $G\alpha_{11}$ -Scr (55 \pm 13 to 84 \pm 10, n=5, p<.01), or saline (30 to 70, n=2). Such a MA-induced lordosis facilitation was blocked by $G\alpha_{11}$ -AS (51±8 to 66±8, n=8, p>.12). Pretreatment with ODNs also reduced body weight. But, in contrast to that on lordosis, the effect on body weight was significant only in rats receiving $G\alpha_q\text{-AS}$ or $G\alpha_{11}\text{-Scr},$ and not $G\alpha_{11}\text{-AS}$ or saline. These results suggest that, in VMN, $G\alpha_{11}$ is involved in the mediation of lordosis facilitation, while its closely homologous isoform, $\mbox{G}\alpha_{\!\scriptscriptstyle q},$ has different functions. BEHAVIORAL TESTS OF MOTIVATION BY FEMALE RAT TO WORK FOR ACCESS TO MALE RAT. T. James Matthews, M. Grigore, L.-M. Kow, L. Tang and D.W. Pfaff,* New York University and Rockefeller University, New York, N.Y.

While many neurochemical or molecular manipulations after mechanisms for lordosis behavior directly, others may influence preceding behaviors which normally lead to reproduction. We devised formal tests of motivation in which female rats could perform arbitrary responses to gain access to a stud male rat followed by an encounter with a single intromission. Physiological variables might alter incentive value of the male or reward value of the encounter. In some tests, the female's response also immediately released male odors (cage bedding or preputial glands). We found that females will work for access to the male, whether or not the male's presence is signalled by odors. The odors themselves supported only low response rates. Both nose-poking and bar-pressing responses by the female were successfully used. Response rates were much higher and more reliable if ovariectomized females were treated with estradiol or estradiol supplemented with progesterone. Response patterns on fixed ratio schedules differed markedly from the quantitative results expected from food-reinforced responding. Preliminary results with antisense DNA reagents suggested that these motivated approach responses might vary when lordosis performance does not. In summary, we can use learned responses to assay the sensitivity of motivational processes to hormone actions in brain

CHANGES IN HYPOTHALAMIC PROGESTERONE RECEPTOR DENSITY OVER THE 4-DAY ESTRUS CYCLE IN THE RAT E.M. van der Beek1*, V.M. Wiegant^{1,2} Dept Human & Animal Physiol, Agricult Univ, Wageningen; Dept Med

Pharmacol, Rudolf Magnus Inst Neurosci, Utrecht University, the Netherlands The timing and height of the proestrus LH surge as well as the degree and duration of sexual receptivity are determined by the feedback effects of progesterone (P) on the brain. Both the preoptic area (PO) as well as the ventromedial hypothalamus (VMH) are crucial for the regulation of these functions and contain progesterone receptors (PR) which are thought to mediate the feedback effects of P. In the present study, we determined the number of PR in the PO and VMH at different times of the estrus cycle. Female rats (LD 12:12, lights on at 5:00) with regular 4-day cycles were sacrificed at $10:00\,h$ on the day of met- $(M;\,n=2),\,di$ - $(D;\,n=2),\,pro$ - $(Pam;\,n=3)$ and estrus $(E;\,n=3)$ n=2), and, in addition, at 16:00 h on the afternoon of proestrus (Ppm; n=3) Sections of the hypothalamus were immunocytochemically stained for PR, and the number of PR was quantified in the rostral and medial part of the PO, and in the ventrolateral and caudoventral VMH using the NiH Image analysis program. The number of PR was lowest on M and increased twofold at D in both the PO and VMH. On Pam the number of PR was not clearly different from D levels, but showed a large variation. By the afternoon of proestrus (Ppm), the number of PR was increased fourfold in the PO and VMH compared to M levels. The number of PR on the morning of E was comparable to that found on Ppm. The present results show that PR are present at all stages of the estrus cycle, and that the number of PR increases dramatically on the day of proestrus. Although P levels start to rise at proestrus, and PR are thought to be down regulated by P, the number of PR was not decreased on the morning of E compared to levels at Ppm.

STEROID HORMONE AND NEUROTRANSMITTER MODULATION OF SEXUAL RECEPTIVITY IN PROGESTERONE RECEPTOR NULL MUTANT

MICE. S. K. Mani*, J. D. Blaustein and B. W. O'Malley, Dept. of Cell Biology, Baylor College of Medicine, Houston, TX 77030 and §Neuroscience Behavior Program, University of Massachusetts, Amherst, MA 01003.

Estradiol followed after a suitable interval by progesterone is effective in inducing high levels of sexual receptivity in ovariectomized female mice. Preliminary studies using parental strains, C57BL/6 and the E129, indicated that repeated weekly using parental strains, C57BL/6 and the E129, indicated that repeated weekly hormonal priming and testing experience were required for the induction of maximal levels of sexual receptivity in mine. Estradiol alone was not capable of inducing lordosis response in either strains, suggesting that progesterone is essential for the induction of sexual receptivity in female mice of these strains. The female offspring from mutant mice generated by disrupting progesterone receptor (PR) gene by gene targeting (Lydon et al, 1995) were analyzed for hypothalamic cytosol PRs. In vitro one-point binding analyses of estradiol-induced cellular PRs in the mediobasal hypothalamus demonstrated a 70% reduction in binding in the homozygous (knockout,) females, while heterozygous females had 40% fewer as compared to the wild types. Ovariectomized mice were injected with estradiol and progesterone and tested for sexual behavior in response to mating by male mice. Both wild type and heterozygous females exhibited high levels of lordosis, while the homozygous females showed minimal response. In earlier studies, we demonstrated the necessity of PRs in mediating the effects of dopamine on female sexual behavior in rats. In order to test mediating the effects of dopamine on female sexual behavior in rats. In order to test further this hypothesis, we have examined the facilitation of sexual behavior by a dopamine agonist in the null mutants. Intracerebroventricular (iev) administration of a D₁ receptor agonist, SKF-38393 facilitated high levels of lordosis in wild type females containing the full complement of PR, while the homozygous females having reduced cytosolic PRs showed low levels of lordosis. These studies provide further evidence that PRs are required for at least one behavioral effect of dopamine in female rodents. (Supported by HD-07857, and NS 19327)

THE EFFECTS OF GONADAL STEROIDS ON LORDOSIS BEHAVIOR IN THE ESTRADIOL BENZOATE (EB) PRIMED FEMALE RAT: COMPARISONS TO THE MALE. P.C. Butler, M.A. Malstrom, D.D. Saxton, S.E. Huber, J.S. Sovereign, G.J. Bloch* Dept. of Psychology, BYU, Provo, UT 84602.

In a previous study, we reported that testosterone (T) and progesterone (P), but not dihydrotestosterone (DHT) and P, acted synergistically to inhibit lordosis in EB primed male rats. In addition, we found that P did innibit fordosis in EB primed male rats. In addition, we found that P did not override the inhibitory effects of DHT in the male (Bloch et al. Neurosci 21, '95). To obtain sex comparisons, the present study tested for effects in females using identical treatments as used previously in males. Adult gonadectomized female rats were given blank (BK), T, P, DHT, T+P, or DHT+P-filled Silastic capsules. Behavioral tests for lordosis were administered once a week in EB primed females for 4 consecutive weeks. Striptical applying revueled three tear differences in the lardoric response to Statistical analysis revealed three sex differences in the lordosis response to gonadal steroids. First, in contrast to males, T+P did not act synergistically to inhibit lordosis in females (For example, fourth week LQ means teally to inhibit to rioriosis in temales (For example, fourth week LQ in \pm SEM: 73.3 \pm 36.0 vs. 36.0 \pm 10.5 for males). Second, although DHT inhibited lordosis behavior in both females and males, females were inhibited significantly more so (LQ: 22.5 \pm 6.8 vs. 52.7 \pm 10.5). Third, although the inhibition of lordosis by DHT was nullified by P in the female (LQ scores rose to 85.0 ± 8.7), this overriding effect of P was not apparent in the male (LQ scores remained at 49.4 ± 7.8). Thus, T+P acts synergistically to inhibit lordosis in the male but not in the female; DHT inhibits lordosis behavior in both males and females but has a greater inhibitory effect in females, and P nullifies the inhibitory effects of DHT in females but not males. WEIGHT LOSS DOES NOT IMPROVE REPRODUCTIVE FUNCTION IN OBESE ZUCKER FEMALE RATS. C.L.M. Bivens* & D.H. Olster. Dept. of Psychology. & Neuroscience Research Institute., Univ. of Calif., Santa Barbara,

Genetically obese Zucker rats have several reproductive abnormalities, such as delayed puberty, abnormal estrous cyclicity, and decreased sexual behavior. It is ossible that excessive body weight itself provokes those reproductive abnormalities. To address this fundamental issue, obese Zucker female rats were food restricted to match their body weight to those of their lean counterparts. Pubertal onset (as indicated by vaginal opening), subsequent estrous cyclicity, and sexual behavior were monitored in lean, obese, and food-restricted obese (diet obese) rats. Preventing excessive weight gain failed to accelerate vaginal opening in diet obese rats, which occurred 1.5 weeks after vaginal opening in lean rats. Immediately after vaginal opening, all lean rat displayed normal, 4 or 5 day estrous cycles while both obese and diet obese rats exhibited abnormal estrous cyclicity. After collecting estrous cyclicity data, all rats were ovariectomized, treated with estradiol benzoate (EB, 15 µg/kg sc) or EB plus progesterone (P, 2 & 20 mg/kg sc), and tested for reproductive behaviors. After EB alone, sexual receptivity was extremely low (LQ<3%) in all rats and proceptive behaviors were never observed. After treatment with EB plus P (2 mg/kg), lean rats were maximally receptive (LQ=92±4%) and proceptive (PRO=8.8±2 events/min) while both obese and diet obese rats were only marginally receptive and proceptive (LQ=30±8%, PRO=3.8±2 events/min; LQ=50±20%, PRO=4.4±2 events/min, respectively). Increasing the progesterone dose to supraphysiological levels (20 mg/kg) elicited vigorous sexual receptivity (LQ=94-99%) and robust proceptivity (PRO=16.15-20 events/min) in all rats. These data suggest that excessive body weight per se does not contribute to the reproductive abnormalities in obese Zucker rats. (Supported by NIH HD 28636 and American Psychological Association)

DRUGS OF ABUSE: COCAINE-DA-5-HT INTERACTIONS

361 1

SEROTONIN MEDIATION OF THE EFFECTS OF COCAINE ON EXTRACELLULAR DOPAMINE IN THE

SEROTONIN MEDIATION OF THE EFFECTS OF COCAINE ON EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS. C. M. Andrews* and I. Lucki Depts. of Psychiatry and Pharmacology, Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Several studies have shown that serotonin (5-HT) facilitates dopamine (DA) release (Benloucif and Galloway, 1993). We examined the ability of 5-HT to modulate extracellular DA levels in the nucleus accumbens (NAc) following cocaine administration. In vivo microdialysis techniques, in awake unrestrained Sprague-Dawley rats, were used that measure both DA and 5-HT levels in dialysis samples using a HPLC with electrochemical detection. Animals were treated with 150 mg/kg p-CPA on two consecutive days, starting 3 days prior to the experiment, in order to deplete 5-HT. A microdialysis probe was implanted into the nucleus accumbens 48 h after the first p-CPA injection. The day after surgery samples were collected for 2 hours to establish baseline values. Baseline levels of 5-HT in the p-CPA treatment group were undetectable. Pretreatment with p-CPA reduced the effect of systemic administration of cocaine (25 mg/kg) from increasing NAc DA concentrations 600% in non-treated animals to only a 400% increase in p-CPA treated animals. Pretreatment with p-CPA also reduced the effect of infusion of cocaine (10 mM) through the microdialysis probe from increasing NAc DA levels by 1000% to only a 575% increase over basal in p-CPA treated animals. Systemic administration of 25 mg/kg cocaine in the presence of 10 mM occaine infusion decreased NAc DA levels by 30%, presumably by acting at VTA autoreceptors, but decreased NAc DA levels by 55% in p-CPA treated animals. These data suggest that serotonin potentiates cocaines ability to increase dopamine in the nucleus accumbens. Supported by NIDA DA05186.

RESPONDING FOR COCAINE-ASSOCIATED STIMULI IS MODIFIED BY PHARMACOLOGICAL MANIPULATION OF DOPAMINE AND SEROTONIN TRANSMISSION. F. Weiss*, C.S. Maldonado-Irizarry, D. Smith and G.F. Koob.

Dept. Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. Clinical and neuropharmacological studies suggest that drug seeking behavior for cocaine, opiates, and alcohol can be elicited by environmental stimuli associated with the rewarding effects of these drugs of abuse. The present experiments sought to examine the effects of pharmacological manipulations of dopamine and serotonin neurotransmissions on the efficacy of cocaine-associated stimuli to maintain drug-seeking behavior in the absence of the primary reinforcer. Rats were trained to respond on a [FR5:FR5] multiple schedule with alternating food and intravenous cocaine reinforced components during which food was paired with a tone, and cocaine infusions were paired with a stimulus light. After acquisition, each session began infusions were paired with a stimulus light. After acquisition, each session began with a 5 min conditioned stimulus component (CSC) during which responding on either of two levers (FR1) resulted only in the presentation of stimuli associated with primary reinforcers. Effects of SCH-23390 (D1 antagonist; 0-10.0 μg/kg; SC), flupenthixol (D1/D2 antagonist; 0-50.0 μg/kg; IP), PD 128,907 (D3 agonist; 0-3.0 mg/kg; IP), CGS-12066 (5-HTB1 agonist; 0-10.0 mg/kg; IP) and tropisetron (5-HT3 antagonist; 0-60 μg/kg; SC) on responding during CSC and the multiple schedule were tested in separate groups. SCH-23390 suppressed behavior maintained by both conditioned stimuli while flupenthixol, PD 128,907 and tropisetron, at these doses, produced no significant behavioral changes during the CSC. CGS-12066 significantly attenuated responding for the food-associated cue and tended to enhance responding for the cocaine cue. On the multiple schedule. SCH-23390 significantly suppressed the cocaine cue. On the multiple schedule, SCH-23390 significantly suppressed responding for both food and cocaine. PD 128,907 attenuated responding for food and cocaine at the highest dose. CGS-12066 produced a trend toward decreased responding for food but had no effects on cocaine reinforced responding. In contrast, flupenthixol and tropisetron, at these doses produced no behavioral changes. Together, these findings confirm the role for dopamine and serotonin systems in motivational processes related to cocaine seeking behavior. (Supported by NIDA DA07348).

CONVERGENCE OF SEROTONIN AND DOPAMINE IN CAUDATE/PUTAMEN OF

CONVERGENCE OF SEROTONIN AND DOPAMINE IN CAUDATE/PUTAMEN OF RAT, MOUSE, AND RABBIT. G. Villareal, M. Russell, L. Mery, F. Makilan, P. Broderick, and C. Phelix, 1- Division of Life Sciences, Univ. of Texas at San Antonio, TX 78249; 2-Dept. Pharmacology, CUNY Medical School, New York, NY 10031 Interaction of serotonin (SHT) and dopamine (DA) in the nucleus accumbens (NAco) of the ventral striatum has been described anatomically. However, the neurochemical interaction of 5HT and DA in the dorsal striatum is equally interesting and demonstrates regional variation in response to cocaine administration. Since we observed such dramatic correlation between anatomical and functional convergence of 5HT and DA in the NAcc, we now examine the anatomical interaction between 5HT and DA axons in the dorsal striatum of rat and mouse. We are especially interested in the rabbit because it has a distinct caudate and putamen. Formaldehyde fixed brains were stained with sensitive immunocytochemical procedures using a selective silver intensification. Antibodies used were directed against 5HT or tyrosine hydroxylase as a marker for DA. SHT staining was most intense in the wild strain white footed mouse. There was not an evident patch/matrix arrangement of 5HT terminals in any species examined by comparison to the prominence with DA terminals. Due to greater density overall of 5HT axons in the putamen of rabbit there was more convergence with DA axons than in the caudate, although DA terminals were perfuse and very dense (i.e., greater in matrix than patch). Evaluation of rat and mouse caudate/putamen complex with comparison to rabbit indicates that only the dorsal medial neostriatum, medial to the internal capsule, of the former two correspond to the caudate and the vast remainder corresponds to the putamen. This is consistent with the greater convergence of 5HT and DA axons in the CP of rat and mouse. Support: HLO2914-02.

CHRONIC CONTINUOUS ADMINISTRATION OF MONOAMINE UPTAKE INHIBITORS PRODUCES BEHAVIORAL TOLERANCE BUT NOT A COCAINE-LIKE ACTIVITY PATTERN. P.M. Kunko*, F.I. Carroll and S. Izenwasser. Psychobiology Section, NIDA, Division of Intramural Research, Addiction Research Center, Baltimore, MD 21224 and Research Triangle Institute, Research Triangle Park, NC 27709.

Four hours after cocaine pumps (50 mg/kg/day) are implanted in rats, locomotor activity levels are increased, as compared to saline controls, with an even greater effect observed 24 hours later. Partial tolerance to this effect develops over the course of five activity levels are increased, as compared to saline controls, with an even greater effect observed 24 hours later. Partial tolerance to this effect develops over the course of five days, with activity levels diminishing, but still significantly higher than those in saline-pump rats. These behavioral effects are not due to changes in the amount of cocaine or its metabolites benzoylecgonine or eegonine methyl ester in either the blood or the brain, since those did not vary significantly over the course of the week. Since cocaine inhibits the uptake of all of the monoamines, it is not known which of these pharmacological effects play a role in the production of this behavior. In this study, male Sprague-Dawley rats were treated for seven days with a continuous infusion of a selective inhibitor of the uptake of either dopamine [GBR 12909 (30 mg/kg/day)] or RTI-117 (3.62 mg/kg/day)], norepinephrine (nisoxetine (0.1 mg/kg/day)), or serotonin [fluoxetine (1.0 mg/kg/day)]. These doses were chosen based on a ratio of known affinities for their respective transporters, as compared to cocaine. Locomotor activity levels were measured for one hour each day, on seven consecutive days, beginning 4 hours after pump implantation. Both of the dopamine uptake inhibitors significantly increased locomotor activity; however, unlike cocaine, the highest levels were observed when animals were tested four hours after the pumps were implanted. Partial tolerance to both compounds occurred, within 24 hours for GBR and over five days for RTI. Neither fluoxetine nor nisoxetine significantly altered locomotor activity at these doses, suggesting a limited role for norepinephrine or serotonin. The pattern of behavior observed with cocaine is unique and is not fully mimicked by any of the selective uptake inhibitors. The results suggest that some combination of the uptake inhibitors is required to produce a cocaine-like effect, or that kinetic differences between cocaine and the selective dopamine uptake inhibitors are responsible for the diff

TOLERANCE AND SENSITIZATION TO COCAINE ARE MEDIATED VIA INDEPENDENT MECHANISMS. D. French and S. Izenwasser*. Section, NIDA Division of Intramural Research, Baltimore, MD.

Tolerance or sensitization to the locomotor activating effects of cocaine occurs depending upon the treatment regimen that is used. When cocaine is injected on a daily basis, sensitization occurs, whereas continuously infused cocaine leads to partial tolerance. Male Sprague-Dawley rats were treated with a continuous infusion of cocaine (50 mg/kg/day) via subcutaneously implanted osmotic minipumps. Locomotor activity was measured for one hour each day for eight days, after which the pumps were removed. Rats with cocaine pumps exhibited large increases in locomotor activity, compared to saline controls, 24 hours after the pumps were implanted. Partial tolerance to this effect developed over the course of five days, with activity levels diminishing to a level still significantly higher than that in salinepump rats. Activity levels of the cocaine-pump rats dropped to saline levels within four hours after the pumps were removed, and were significantly lower than the saline-treated group during the first three days of withdrawal, after which they returned to saline levels. Some rats were challenged with an injection of cocaine (7.5, 15, or 30 mg/kg) either two or ten days after pump removal. Two days after the pumps were removed there were no differences between cocaine-pump or saline-pump rats in the amount of locomotor activity produced by the challenge injections. However, cocaine-pump rats injected 10 days after pumps were removed (withdrawal day 10) exhibited a significant tolerance, as evidenced by a shift to the right of the cocaine curve, as compared to saline controls. When the rats were injected again on the next day (withdrawal day II), the activity levels of both groups increased, as compared to the effects observed on withdrawal day 10. Thus, although the cocaine-pump rats were the effects observed on withdrawal day 10. Thus, although the cocame-pump rats were still tolerant as compared to the saline-pump rats, they were sensitized as compared to their previous response to a challenge injection. These findings indicate that tolerance and sensitization can exist simultaneously, which suggests that they are mediated by separate mechanisms. (Supported by NIDA).

LONG LASTING EFFECTS OF THE NOVEL TROPANE ANALOG WF23 AT DOPAMINE AND SEROTONIN TRANSPORTERS. L.J. Porrino*, J.B. Daunais, S.L. Hart, S.R. Letchworth, H.R. Smith, T. Sexton, S.R. Childers, H.M.L. Davies¹. Dept Physiol/Pharmacol, Bowman Gray School of Medicine, Winston Salem, NC, ¹SUNY Buffalo, Natural Science and Math Complex,

Recent reports have described the synthesis of a series of novel tropane analogs that are highly potent at dopamine and/or serotonin transporters (Davies et al, 1993; 1994). Although these compounds share many of the properties of cocaine, their actions in vivo and in vitro have been reported to be of longer duration than those of cocaine itself. In order to study the time course of the behavioral effects of WF23, which is both highly potent and relatively nonselective, this analog (1mg/kg) was administered to male Sprague-Dawley rats and activity assessed 1, 4, 8, 12, 24, 48, 120, and 240 hours after injection. WF23 elicited significant increases in spontaneous locomotor behavior for up to 24 hours, as compared to cocaine- or vehicle-treated rats tested at the same time points. Assessment of the occupancy of dopamine transporters in striatal homogenates from these rats indicated that [1251]RTI-55 binding was inhibited by as much as 50% 48 hrs post injection, but had returned to control levels by 240 hrs. Measured autoradiographically, WF-23 administration inhibited both [3H]CFT and [3H]citalopram binding to dopamine and serotonin transporters respectively, in all structures examined, following a similar time course to binding in homogenates. There is, then, a slow dissociation of WF23 from both dopamine and serotonin transporters. This persistence of effects may have important implications for this compound as a potential therapeutic agent for

COMBINED SEROTONERGIC AND DOPAMINERGIC AGONISTS ATTENUATE ORAL INTAKE OF DRUGS OF ABUSE IN MICE: d-FENFLURAMINE/PHENTERMINE. M. Ehrlich, M. Martinez, D.M. Patterson and B.G. Hoebel*. Dept. of Psychology, Princeton University, Princeton, NJ 08544.

Princeton, NJ 08544.

Combinations of monoamine agonists might be helpful in the treatment of drug abuse and withdrawal-related symptoms (Hitzig, 1993). To test this in female C57BL/6J mice, the combination of 20 mg/kg d-fenfluramine plus 20 mg/kg phentermine (d-FEN/PHEN) was injected i.p. with a 24 hour two-bottle choice of a drug solution and water. d-FEN/PHEN reduced ingestion of 10% ethanol solution by 50.7%, 0.02 mg/ml nicotine solution by 46.9%, 0.6 mg/ml caffeine solution by 28.6%, and 50% chocolate syrup solution by 37.1% compared to intake following i.p. saline. With d-FEN/PHEN treatment subjects in the ethanol, nicotine, and caffeine choice groups increased water consumption roughly corresponding to the decrease in drug solution intake, such that no significant change in total fluid intake was observed. d-FEN/PHEN had no effect on the choice of water and a solution containing 0.075 mg cocaine effect on the choice of water and a solution containing 0.075 mg cocaine plus 0.045 mg heroin per ml. Subjects pre-exposed to either 10% ethanol or 0.02 mg/ml nicotine consumed significantly more 0.05 mg/ml cocaine than naive subjects, and the d-FEN/PHEN treatment significantly tnan naive subjects, and the d-FEN/PHEN treatment significantly attenuated subsequent cocaine intake in the two-bottle choice tests for both groups. Treatment with another combination of monoamine agonists, 20 mg/kg fluoxetine plus 20 mg/kg bupropion, decreased intake of 10% ethanol solution by 50% compared to i.p. saline treatment in the two-bottle test; this was similar to the result with d-FEN/PHEN. The efficacy of both treatments may rest, in part, in their ability to raise serotonergic and dopaminergic activity simultaneously. Supported by PHS grant #NS30697.

TROPANE ANALOGS DISSOCIATE SLOWLY FROM DOPAMINE AND SEROTONIN TRANSPORTERS IN CULTURED CELLS. J.J. Harp, R.S. Martin and C.K. Hollingsworth. H.M.L. Davies¹, J.M. Paris^{*} and B.A. Bennett, Center for Neurobiological Investigation of Drug Abuse, Dept. Physiol/Pharmacol, Bowman Gray School of Medicine, Winston-Salem, NC; SUNY Buffalo, Natural Science and Math Complex, Buffalo, NY

Cocaine and tropane analogs share many of the same properties in their interactions with amine transporters. However, we, and others, have reported that tropanes differ from cocaine by possessing a longer duration of action. Using an in vitro culture system, we have examined several tropanes (synthesized by Davies et al, 1993; 1994) and cocaine to determine the time course of transporter occupancy after a brief (3 hr) exposure. Uptake experiments were performed using midbrain cultures obtained from fetal rat brains (E15) after exposure to the tropanes (WF-11, WF23, WF-31) or cocaine on day 7 in vitro. Separate cultures were obtained possessing either dopaminergo or serotonergic neurons. The concentration of the drugs was chosen based on their affinity for the transporters and was approximately 10-fold greater than their respective IC_{50} 's. There was a decrease in the ability of the respective cultures to transport dopamine or serotonin after the administration of the tropanes based on washout time as well as affinity. Tropanes with high affinity for either the dopamine or serotonin transporter required 1-3 days of washout before uptake values approached control values. Our data suggest that these tropanes bind to and reduce transporter function for prolonged periods of time and that compounds with the highest affinity may produce a pseudo-irreversible inhibition of transporter function. These findings may Appearance infinition of infinitions for drug abuse pharmacotherapy Supported by NIDA grants P50 DA006634 and DA06301 (HMLD).

ALTERATIONS IN THE SEROTONIN TRANSPORTER mRNA FOLLOWING CHRONIC EXPOSURE TO COCAINE, FLUOXETINE, OR GBR 12909: GENDER DIFFERENCES. D. Dow-Edwards, Y. Hurd and G. Frick. Lab. of Cerebral Metabolism, Department of Pharmacology, SUNY Brooklyn, NY 11203 and Department of Clinical Neuroscience, Psychiatry Section, Karolinska Hospital, Stockholm, Sweden

Chronic exposure to cocaine, fluoxetine, the selective serotonin (5-HT) transporter blocker, or GBR 12909, the selective dopamine (DA) transporter blocker, during the preweaning period of development in the rat produces long-term alterations in behavioral responses to psychopharmacological agents which interact with the DA and 5-HT systems (e.g. Neurotoxicol. Teratol. in press, 1996). When cerebral glucose metabolism is examined at 21 days of age following injection of the transporter blockers, specific patterns of functional alterations are obtained (Dev. Brain Res. 88:158, 1995) In females, cocaine, GBR and fluoxetine stimulate regional glucose metabolism while in males cocaine and GBR stimulate metabolism and fluoxetine reduces metabolism in a small number of regions. In order to assess the effects of these treatments on function within the 5-HT system, sections from the raphe region were examined for concentrations of the 5-HT transporter using in situ hybridization histochemistry Sections were incubated with a sequence complementary to amino acid bases 108-156 of the rat 5-HT transporter gene. Densitometry of the resulting auto-radiographs indicated that cocaine increased the transporter density by 50% in males and had only minor effects in females. Fluoxetine had no effect in males but reduced the transporter density by 50% in females. GBR 12909 had virtually no effect. Together, these data indicate that both cocaine and fluoxetine produce gender-specific effects on the 5-HT transporter but that the effects of the two transporter blockers are quite different from each other These and other results suggest that cocaine upregulates the 5-HT system in males but this effect does not appear to be mediated by blockade of the 5-HT transporter. In females, cocaine conversely seems to down-regulate the 5-HT system, an effect apparently mediated by blockade of the 5-HT transporter.

SEROTONIN-1B RECEPTOR STIMULATION ENHANCES COCAINE REINFORCEMENT, COCAINE-INDUCED INCREASES IN NUCLEUS ACCUMBENS DOPAMINE AND COCAINE-INDUCED DECREASES IN VENTRAL TEGMENTAL AREA GABA. L.H. Parsons*, G.F. Koob and F. Weiss. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The involvement of serotonin-1B (5-HT-1B) receptors in the modulation of cocaine

reinforcement and cocaine-induced alterations in mesolimbic neurotransmission was examined in male Wistar rats using the 5-HT-1B agonist RU 24969. Pretreatment with RU 24969 (0.1 - 1.0 mg/kg, SC) dose-dependently (p<0.05) enhanced the reinforcing effects of cocaine self-administration (0.125 mg/injection, IV; FR5) as indicated by increased intervals between drug injections. RU 24969 pretreatment (1.0 mg/kg, SC) also shifted the dose-effect function for cocaine self-administration (0.03 - 0.5 mg/injection, IV; FR5) to the left (p<0.05). These findings indicate that 5-HT-1B receptor stimulation enhances the reinforcing effects of cocaine. To investigate the neurochemical basis for the effects of 5-HT-1B receptor-mediated alterations in cocaine reinforcement, dual probe in vivo microdialysis was used to monitor changes in nucleus accumbens (NAcc) dopamine (DA) efflux and ipsilateral ventral tegmental area (VTA) GABA efflux in drug-naive rats following RU 24969 pretreatment and subsequent cocaine challenge. Pretreatment with RU 24969 (1.0 mg/kg, SC) significantly reduced VTA dialysate GABA levels by 25% (p<0.05), but produced no significant changes in NAcc dialysate DA levels. In the animals pretreated with RU 24969, cocaine challenge (10 mg/kg, IP) produced significantly greater increases in NAcc dialysate DA levels (382% increase; p<0.01), and significantly greater decreases in VTA dialysate GABA levels (59% decrease; p<0.05) as compared with saline pretreated control animals, which displayed a 231% increase in NAcc dialysate DA and a 37% decrease in VTA dialysate GABA. These data suggest that 5-HT-1B receptor stimulation enhances cocaine reinforcement by increasing mesolimbic DA neurotransmission, potentially via an interaction with terminal 5-HT-1B heteroreceptors on VTA GABA neurons. (support: NIDA DA05564)

THE 5-HT1B/1D ANTAGONIST GR127935 DECREASES THE EFFECTS OF COCAINE ON C-FOS EXPRESSION AND LOCOMOTION.

N. Castanon, J.J. Lucas, K. Scearce, and R. Hen*. Center for Neurobiology and

Behavior, Columbia University, New York, NY 10032.

The reinforcing and locomotor activating effects of cocaine are mediated by the mesostriatal and mesolimbic dopamine pathways. However, a contribution of the 5-HT system has also been suggested. In particular, the ventral midbrain 5-HT_{1B} receptors (the rodent counterpart of the human 5-HT1DB receptors) have been postulated to modulate the activity of DA neurons. Furthermore, our previous studies indicate that mice lacking the 5-HT₁B receptor respond differentially to cocaine than wild type mice which suggests an involvement of 5-HT1B receptors in the response to cocaine

The 5-HT1 agonist RU24969 stimulates both c-Fos immunoreactivity (IR) in the caudate putamen and locomotor activity. Both effects are absent in mice lacking the 5-HT_{1B} receptor and are therefore probably mediated by this receptor. In order to test that hypothesis, we examined the effect of the recently developed 5-HT_{1B/1D} antagonist GR127935. A 10 mg/kg i.p. dose of GR127935 was able to completely block the effect of a 5 mg/kg i.p. dose of RU24969 both on c-fos IR and locomotion, demonstrating the ability of GR127935 to antagonize 5-HT1B receptors in vivo.

Since cocaine has been suggested to act as an indirect 5-HT1B receptor agonist, we also tested the ability of GR127935 to antagonize the effects of cocaine. Interestingly, GR127935 produced a dramatic reduction in c-Fos IR and locomotion induced by a 30 mg/kg i.p. dose of cocaine.

These results suggest that some of the reinforcing effects of cocaine may also

be antagonized by 5-HT_{1B/1D} antagonists.

SELECTIVE BLOCKADE OF COCAINE CONDITIONED BEHAVIOR WITH BUSPIRONE. Ernest N. Damianopoulos* and Robert J. Carey. Psychiatry, SUNY Health Science Center and Research and Development Service -151, VA Medical Center, Syracuse, NY 13210

Pavlovian conditioning of cocaine drug effects contributes to the development of cocaine sensitization, craving and relapse. Suggestive evidence implicates Nmethyl D-aspartate (NMDA) and serotonergic (5-HT) receptors as neurosubsrate mechanisms mediating the conditioned cocaine effects. Thus, we assessed the effects of the NMDA agonist, cycloserine, and antagonist, dizocilpine (MK-801), as well as the 5-HT agonist, buspirone, and antagonist, MPPI, on the expression of conditioned cocaine behavior. A differential conditioning procedure was used to induce conditioned cocaine hyperlocomotion. Adult male rats received saline in one test chamber and saline or cocaine in a second chamber in 5 daily treatments. The animals were injected immediately prior to placement into each test environment and tor behavior was recorded for 10 min using a video-image analysis system. Weekly tests followed with saline or NMDA/5HT drug on 1 of 2 test days separated by a non-test day and, 2 days later, by 1 saline/cocaine reconditioning treatment. All saline and all drug tests, except for buspirone, showed equivalent levels of conditioned hyperlocomotion. Buspirone (3.0 mg/kg ip) completely blocked the conditioned hyperlocomotion response but had no effect on the locomotion of each animal in the first test (non-cocaine) environment nor did it show any effect on the saline/saline control treatment animals, thus, ruling out non-specific motoric effects as factors in the observed blocking effect. As an anxiolytic drug buspirone is primarily a 5-HT1A agonist; but it also impacts upon dopaminergic transmission as well as corticosterone stress responses. While it is unclear which mechanism is critical for the observed pharmacological blocking, the results support clinical evidence of buspirone as a useful adjunct drug in the treatment of cocaine abuse

CONTINUOUS ON-LINE STUDIES OF SYNAPTIC MESOACCUMBENS BEHAVING FAWN-HOODED ANIMAL MODEL OF DEPRESSION P.A. Broderick^{1,2}, T. Kunwar¹, B. Gardiner¹, O. Hope², C. Okonji², P. Jeannor², P.J. Baptiste², S.A. Green³, H. Charleton², C. S. Aulakh³, CUNY Med. Sch. & Grad. Sch., N.Y. 10031³; MARC, MBRS Program, CCNY, N.Y. 10031² and Nat'l Inst. Mental Health, MD. 20892³. DOPAMINE AND SEROTONIN RELEASE AFTER COCAINE IN THE

The Fawn-Hooded (FH) rat is suggested to be a genetic model of depression and is known to have a platelet storage deficiency of serotonin (5-HT) (Aulakh, et al., JPET: 262, 1992). Further, our laboratory has shown evidence of a deficiency of dopamine (DA) and 5-HT in the Nucleus Accumbens of the FH rat (manuscript in progress). Cocaine (10 mg/kg IP) was administered to freely moving and behaving male FH rats in a novel chamber. Using in vivo voltammetric (electrochemical) techniques, 5-HT was detected concurrently yet separately with DA, within a temporal resolution of seconds in one voltammogram. Voltammograms were recorded up to ten months. Detection occurs by means of a graphite stearate microelectrode (Broderick, P.A. Brain Res. 495: 115, 1989). Behavior, i.e., locomotor activity (ambulation), rearing, stereotypy and central ambulations were also studied concurrently with infrared photobeam detection. Cocaine's effects in the FH rat were remarkable because the usual increase in DA and 5-HT release did not occur as usually occurs in the Sprague-Dawley (SD) rate model (Broderick et al. *Pharmacol. Biochem. Behav.* 46: 715, 1993). Instead, the animals sat in one corner and exhibited rotational behavior. These striking observations further compel us to strongly support 5-HT's role as a mediator in cocaine's mechanism of action (Broderick and Phelix, Neurosci. and Biobehav. Rev., in press, 1996). Withdrawal data from the FH rat also showed differences vis-a -vis the SD rat. (Supp: PSC/CUNY RF666221, NIH NIGM 07639 & 08168)

CHRONIC EXPOSURE TO COCAINE OR THE SEROTONIN 5-HT $_{\rm 1.A/1B}$ AGONIST RU24969 DECREASES 5-HT $_{\rm 1B}$ RECEPTOR SENSITIVITY:

Aduntist Ru24999 DECRASES 3-11B REFERRAL SHIFTHT LOCOMOTOR ANALYSES. A.C. McCreary* and K.A. Cunningham. Dept. Pharmacol. Univ. Texas Medical Branch, Galveston, TX, 77555-1031.

Both cocaine (COC) and the 5-HT_{1A/1B} agonist Ru24969 (RU) elicit hyperactivity, however, repeated treatment with COC and RU appears to result differentially in behavioral sensitization (McCreary & Marsden, Neuropharm 32: 387, 1993) and tolerance (Oberlander et al. EJP 139: 205, 1987), respectively. We assessed the cross-adaptation to COC and RU in male S.D. rats pretreated with saline (SAL), COC (15mg/kg i.p.) or RU (2mg/kg i.p.) BID for 7 days. Locomotor activity and stereotypy scores were recorded on Days 1 and 7 and on days 8, 10, and 11 upon challenge with SAL, COC, and RU, respectively. During COC treatment all activity measures, apart from rearing, showed a behavioral enhancement between days 1 and 7 (p < 0.05). On the other hand, tolerance developed to chronic RU treatment as measured by a decrease in horizontal (-67%, p < 0.0001), central (-71%, p < 0.0001) and peripheral activity (-67%, p<0.0001), but not rearing or stereotypy. Upon COC challenge, RU-pretreated rats displayed elevated central activity (+177%, p < 0.05) vs. SAL rats, other activity measures were elevated but failed to reach statistical significance. Sensitization to the COC challenge was seen in COC-pretreated rats. After RU challenge, COC-pretreated rats had diminished horizontal (-32%, p<0.05) and peripheral activity (-32%, p<0.05) vs. SAL rats. Thus, tolerance to the locomotor effects of RU appears to be associated with sensitization to COC. These data suggest that repeated COC and RU exposure result in a reduced sensitivity of 5-HT_{1B} receptors which may contribute to the expression of COC-induced sensitization. Cocaine Sensitization, Tolerance and 5-HT₃ Receptors. G.R. King¹, M. Mattell², and P. Little^{3*}, Departments of Psychiatry¹, Psychology², and Pharmacology³, Duke University Medical Center, Durham, NC 27710

Previous research has demonstrated that 5-HT3 receptor activation can induce dopamine release in a variety of corticolimbic areas, suggesting that 5-HT3 receptors may be important for the development of cocaine sensitization and tolerance. The present poster presents the results from two experiments. In the first experiment, rats received continuous saline or cocaine for 14 days. On day 7 of withdrawal slices from the nucleus accumbens were obtained. The slices were stimulated with 25 mM K+ in the absence and presence of mCPBG (0-50 μ M), a 5-HT $_3$ agonist, and DA release measured with HPLC-EC. The results indicated that continuous cocaine induced a functional down-regulation of accumbens 5-HT₃ receptors. In the second experiment, rats received either intermittent or continuous cocaine (40 mg/kg/day) for 14 days; during this 14 day pretreatment regimen, the rats also received sc injections of a 5-HT₃ antagonist (0-1.0 mg/kg/day). The results indicated that ondansetron blocked the development of both behavioral sensitization and tolerance, as assessed by a cocaine challenge injection on day 7 of withdrawal from the pretreatment regimen. The overall pattern of results therefore suggest that 5-HT3 receptors may be critical for the development of cocaine tolerance and sensitization

NEUROTRANSMITTER RELEASE IN THE MESOLIMBIC SYSTEM OF RATS TRAINED IN THE CONDITIONED PLACE PREFERENCE PARADIGM WITH COCAINE. E.A. Jones*, H.L. Williams, R.D. Myers and B.A. McMillen. Dept. of Pharmacol., Sch. of Medicine, East Carolina Univ., Greenville, NC 27858.

Cocaine-HCl, 5.0 mg/kg injected i.p., produced a significant conditioned place preference (CPP) in rats trained in a three compartment chamber. The chamber consisted of a central neutral compartment and two dissimilar outer chambers. Cocaine was administered to the treatment animal immediately before placement in one chamber for 15 minutes. Saline was administered to the control animals immediately before placement in the alternate chamber. After four daily sessions, the cocaine treated rats exhibited a preference for the cocaine paired chamber. The saline treated rat did not show any preference for the saline paired chamber. In order to determine possible differences in neurotransmitter release between cocaine and saline treated animals, microdialysis of the medial prefrontal cortex. nucleus accumbens and ventral tegmental area was performed on cocaine and control animals during exposure to the respective training chamber. The effect of amperozide, a 5-HT₂ receptor antagonist, shown to block cocaine (5.0 mg/kg) CPP, on neurotransmitter release was also examined. (Suppt. by USPHS grant AA-04200-13)

DIFFERENTIAL EFFECTS OF COCAINE ON DISTINCT COMPONENTS OF 8-OH DPAT-INDUCED SEROTONIN SYNDROME IN RATS. B. Ahmad, N. Uray* and N.A. Darmani. Depts. of Pharmacology and Anatomy, Kirksville College of Osteopathic Medicine, Kirksville, MO 63501. It is thought that the different components of serotonin syndrome (SS) such

It is thought that the different components of serotonin syndrome (SS) such as lateral head-weaving (LHW), forepaw treading (FPT), hind leg abduction (HLA), straub tail (ST), tremor (T) and flat body posture (FBP) are mediated via the activation of postsynaptic 5-HT_{1A} receptors. We have previously shown that acute cocaine administration inhibits the DOI-induced 5-HT_{2A} receptor-mediated head-twitch response. The aim of the present study was to investigate the acute effects of cocaine (1.25 - 10 mg/kg, i.p.) and selective 5-HT (sertraline), NE (nisoxetine) and DA (GBR 12935) uptake inhibitors (1.25 mg/kg, i.p.) on the SS produced by the 5-HT_{1A} agonist, 8-OH DPAT (1.75 mg/kg, i.p.). The cited drugs were administered 10-min prior to 8-OH DPAT injection and individual rats were observed continuously for the next 20 min. Relative to controls, cocaine (5 and 10 mg/kg) significantly enhanced LHW, FPT and HLA to a greater extent in 1.25 versus 5 mg/kg 8-OH DPAT-injected rats. Sertraline, nisoxetine and GBR 12935 at 1.25 mg/kg also produced similar effects on the cited doses of 8-OH DPAT-induced symptoms. On the other hand, varying doses of cocaine had no effect on FBP induced by either dose of 8-OH DPAT but significantly increased ST and T at 10 mg/kg produced by the 5 mg/kg dose of 8-OH DPAT. Unlike cocaine, sertraline, nisoxetine and GBR 12935 potentiated FBP but had no effect on ST and T produced by 1.25 mg/kg 8-OH DPAT. Furthermore, sertraline only significantly decreased T but nisoxetine and GBR 12935 had no effect on ST and FBP produced by 5 mg/kg 8-OH DPAT. These results indicate that cocaine via its monoamine components produces different effects on the 8-OH DPAT-induced SS. This study was supported by NIDA grant DA 07627.

COCAINE BLOCKS SEROTONIN-INDUCED MOBILIZATION OF PLATELET INTRACELLULAR CALCIUM, S. M. Delisi, L. M. Konopka, J. W. Crayton*. Biological Psychiatry Section, Hines V. A. Hospital, Hines, IL 60141. USA..

The mechanisms by which cocaine increases cardiovascular morbidity and mortality, as is frequently observed in cocaine abuse patients, may involve direct effects on platelet reactivity. However results obtained to date by others have been inconclusive. Both proaggregatory and platelet activation inhibitory effects have been reported. Since mobilization of intra-platelet calcium ([Ca++] i), represents a critical step in platelet activation, and since serotonin is a potent activator of platelets, we explored the effects of cocaine on the serotonin-evoked rise in [Ca++] i. Human platelets were isolated over a Sepharose 2B gel and then loaded with the calcium-sensitive fluorophore fura-2 AM. The elevation in [Ca++] i following stimulation with 10 µM 5-HT was measured in the presence of 1.0 µM to 1.0 mM cocaine HCl. In this dosage range, cocaine produced a dose-dependent attenuation (41.55% reduction at 1mM cocaine) of the serotonin-induced rise in [Ca⁺⁺]. In order to determine whether cocaine's effect was the result of local anesthetic effects, we examined the influence of lidocaine HCl on the 5-HT induced increase in [Ca⁺⁺]_i. Lidocaine had no effect on [Ca⁺⁺]_i at any dose studied (1.0 µM to 1.0 mM). Cocaine's inhibitory effect does not extend to all promoters of platelet activation since it had no effect on thrombin-induced rises in [Ca++] 1

DRUGS OF ABUSE: COCAINE I

362.1

GENDER DIFFERENCES IN COCAINE-INDUCED HPA ACTIVATION. Cynthia M. Kuhn* and Reynold Francis. Dep't of Pharmacology, Duke University Medical Center. Durham NC 27710

Enhanced sensitization of both amphetamine and cocaine-induced locomotion have been reported in female rats. As CRF has been implicated as a contributing factor in this sensitization, we investigated the possibility that gender differences in cocaine-induced CRF release would lead to enhanced HPA activation in female rats. To investigate this possibility, we treated male and female rats with saline or cocaine and evaluated serum ACTH levels 30 minutes after treatment. Female rats exhibited higher ACTH secretion following challenge with 5, 10, or 20 mg/kg of cocaine relative to males. To investigate the role of different monoamine systems in this gender difference, responses to varying doses of fluoxetine, desipramine and GBR 12909 were evaluated. Females showed enhanced responses to all three uptake inhibitors. In addition, females showed enhanced responses to CRF (0.1 or 1 ug.s.c.). Finally, the impact of gonadectomy on ACTH responses to cocaine was evaluated. Male and female rats were treated with saline or cocaine 1 week after gonadectomy, and serum ACTH evaluated as before. Gonadectomy lowered ACTH responses in females, but had no effect in males. These results support a role for estrogen and/or progesterone in the enhanced HPA response of female rats to cocaine and other monoamine uptake inhibitors. (Supported by DA-9079)

362.2

DISSOCIATION BETWEEN BEHAVIORAL ACTIVATION AND NEUROEN-DOCRINE STRESS RESPONSES TO COCAINE <u>Wilkinson.C.W.</u>, <u>Sarkar.D.K.°</u>, <u>Peskind,E.R.*</u>, <u>Rasmussen,D.D.</u> VA Medical Center and University of Washington, Seattle, WA 98195 and "Washington State University, Pullman, WA 99164.

In rats, i.v. administration of low-dose (e.g., 0.5 and 1 mg/kg) 1 min pulses of cocaine is reinforcing; higher i.v. dosages are aversive (Nomikos and Spyraki, 1988). Since investigations of neuroendocrine responses to cocaine have commonly used higher dosages, more non-physiological (e.g., i.p.) routes of administration, and/or naive rats for which the unfamiliar subjective response to cocaine may induce novelty stress, we reasoned that demonstrated neuroendocrine responses may be in part due to non-specific stresses. Consequently, we have developed a model in which "experienced" rats receive low dose (0, 0.3, 0.6 mg/kg/pulse) 1 min i.v. cocaine pulse infusions at signaled 10 min intervals during the dark (active) photophase to produce and sustain (for 3 h) plasma cocaine levels which have been demonstrated to be associated with reinforcement. The 0.6 mg/kg cocaine pulses produced and sustained plasma cocaine levels of approximately 300 ng/ml, and increased activity levels (videotaped; behavior scoring scale) throughout the 3 h infusion period. However, this cocaine stimulation did not significantly increase plasma adrenocorticotropin (ACTH) or corticosterone (CORT) concentrations at 30, 60, 180 or 360 min after initiation of the pulsatile infusions; both saline- and cocaine-treated rats exhibited low (e.g., non-stressed) ACTH (<30 pg/ml) and CORT (<30 ng/ml) levels at all time points. In contrast, i.p. administration of 10 mg cocaine/kg to naive rats in a parallel experiment greatly increased plasma CORT levels at 30 min (cocaine: 271±21 ng/ml vs saline: 85±13 ng/ml), as previously reported. These results demonstrate that acute atraumatic induction of physiologically meaningful plasma cocaine levels and associated behavioral activation does not necessarily stimulate the neuroendocrine stress axis. Ongoing analyses will further characterize potential interactions with other related endocrine systems (NIH/NIAAA Grant AA10567 and Dept of Veterans Affairs)

362.3

CONDITIONED NEUROENDOCRINE EFFECTS OF STIMULI ASSOCIATED WITH COCAINE. A.C. DeVries, S.E. Taymans and A. Pert* Biological Psychiatry Branch and Developmental Endocrinology Branch, NIMH, Bethesda, MD 20892.

Elevated levels of corticosterone may be an important factor in determining individual vulnerability to drug abuse. Stress-induced corticosterone (CORT) secretion facilitates behavioral sensitization to drug effects and may enhance the positive reinforcing effects of abused substances. The purpose of the present study was to confirm and extend a previous finding that endocrine responses to cocaine do not exhibit tolerance or sensitization following repeated cocaine treatment, and to evaluate changes in blood CORT levels in response to situational stimuli associated with cocaine. In the first study there was no significant difference in the cort response to an acute cocaine challenge (30 mg/kg) in rats treated for the previous 7 days with saline or cocaine. The CORT levels of both groups differed from the control group which received saline injections for all 8 days. The second study assessed the conditioned endocrine effects of cocaine. The rats were randomly assigned to 3 groups, the first group of rats (paired) were injected with cocaine and immediately placed into a locomotor activity chamber for 30 min. One hour after being returned to heir home cages the rats were injected with saline. The second group (unpaired) was treated in a similar manner, except that the rats received an injection of saline prior to being placed in the locomotor chamber and cocaine one hour after being returned to their home cages. The intri group (control) received an injection of saline prior to being placed into a locomotor activity chamber and another saline injection one hour after being returned to their home cages. This routine was repeated daily for one week. On the 8th day, the rats were placed directly into the locomotor chambers without receiving an injection. After 30 min. the rats were removed from the chambers one at a time, decapitated, and their blood collected. The CORT levels and locomotor activity were significantly higher in the paired group than those in the unpaired and control groups, indicating conditioned in

362.4

MAINTENANCE OF COCAINE SELF-ADMINISTRATION IS NOT AFFECTED BY PHARMACOLOGICAL BLOCKADE OF BRAIN CRF RECEPTORS, S.H. Ahmed, M.P. Epping-Jordan, P.S. Griffin, A. Markou, S.C. Heinrichs*, E. B. De Souza, J. Rivier, G.F. Koob, Department of Neuropharmacology, The Scripps Research Institute, La Jolla, California

Numerous studies have implicated the endogenous release of central corticotropin-releasing factor (CRF) in the genesis of anxiety-related behaviors in rodents exposed to challenging environmental situations. Because anxiety is regarded as an important determinant of cocaine abuse in humans, central CRF could be a potential modulator, along with other neurotransmitters, in the maintenance of cocaine self-administration (SA). The CRF antagonist, D-Phe CRF $_{12-41}$ (5 to 10 times more potent than α -hel CRF $_{4-41}$ in blocking stress-induced behavioral alterations, Menzaghi et al., 1994, J. Pharmacol. Exp. Therap., 269: 564-572) was tested on male Wistar rats that had acquired stable baseline cocaine SA (FR5 TO 20 sec; cocaine dose: 0.25 mg per infusion; 2-hours daily session). The results obtained show that at all doses (0.04; 0.2; 1; 5 µg), icv injection of D-Phe CRF $_{12-41}$ has no effect on the total number of cocaine infusions per session. This finding was confirmed in a more detailed analysis in which D-Phe-CRF $_{12-41}$ had no effect either on the latency to self-administer the first infusion or on the number of infusions during the 1st 10 min of the SA session. This lack of effect of D-Phe CRF $_{12-41}$ and cocaine SA is not dependent on the relatively low dose of cocaine used since a similar result is also observed in rats self-administering a four-fold higher dose of cocaine (1mg per infusion). These data suggest that brain CRF receptor stimulation is not critical for the maintenance of cocaine SA. Future studies will be required to determine the role of brain CRF receptors on other aspects of cocaine SA, such as initiation and reinstatement of cocaine SA.

INTERACTION OF COCAINE WITH SOCIAL DEFEAT STRESS ON FOS IMMUNOHISTOCHEMISTRY IN N. RAPHE AND VENTRAL TEGMENTAL AREA OF MOUSE BRAIN. E.M. Nikulina*, J.E. Marchand, R. Kream and K.A. Miczek. Department of Anesthesiology and Department of Psychology, Tufts University, Medford, MA 02155

Stress and cocaine may have a common mechanism in the activation of the mesocorticolimbic dopamine system and development of behavioral sensitization to psychostimulants. In order to examine neuronal activation in dopamine and serotonin soma after cocaine and social stress we studied Fos immunohistochemistry in ventral tegmental area (VTA) and dorsal (DR) and medial (MR) raphe nuclei. "Social stress" was defined as defeat and display of submissive behavior after brief confrontation with an aggressive resident mouse and subsequent exposure to the resident's threats in a protective cage. Mice were injected with cocaine (20 and 40 mg/kg, i.p.) and perfused I hour after injections or social stress. Social stress alone in naive mice increased Fos-positive cells in DR, but not in VTA or MR, when compared to saline or untreated mice. Cocaine induced Fos immunoreactivity in DR and MR; this Fos expression was significantly attenuated in mice that were defeated. Fos-positive staining after cocaine in combination with social stress was the same as in saline control mice. In contrast, in VTA neither social stress nor cocaine injection induced pronounced Fos immunohistochemistry. Thus, acute cocaine and social stress induced large changes in Fos expression in raphe neurons, but not in VTA, and these results suggest a role for serotonin neurons in development of stress-induced sensitization to cocaine. (Supported by INVEST grant from NIDA, DA04128 and DA02632).

STRESS SUBSTITUTES FOR COCAINE IN RATS TRAINED USING A DRUG DISCRIMINATION DESIGN J.R. Mantsch*, G.F. Guerin, N.E. Goeders. Department of Pharmacology & Therapeutics, LSU Medical Center, Shreveport, LA 71130.

The ability of the interoceptive cues produced during stress to substitute for the discriminative stimulus properties of cocaine was investigated. Adult male Wistar rats were trained to discriminate cocaine investigated. Adult male Wistar rats were trained to discriminate cocaine (10 mg/kg i.p., n=12; or 20 mg/kg i.p., n=6) from saline using a two-choice, operant, food-reinforced, drug discrimination task. Restraint stress (15 min.), intermittent electric footshock (15 min. session, 0.6 mA, 0.5 msec duration, every 30 sec.), and conditioned fear (10 sec. tone and stimulus light paired with the delivery of electric footshock under an random-interval 5 min. schedule during daily 60 min. sessions for 2 weeks) each partially substituted for both doses of cocaine (10 and 0.0 sec/les). Design that the stress the first was defined as the second cocaine (10 and 10 sec/les). Design that the stress the stress that the second cocaine (10 and 10 sec/les). 20 mg/kg). During test sessions, substitution was defined as the percent 20 mg/kg). During less sessions, substitution was defined as the percent responding on the cocaine-appropriate response lever prior to the delivery of the first reinforcer when each stressor was administered following an injection of saline (i.p.). Experiments designed to investigate the ability of increasing doses of chlordiazepoxide (3.0, 5.6, 10.0 mg/kg, i.p.) to block the substitution of stress for cocaine as well as the discrimination of the training doses of cocaine were also performed. Additionally, studies designed to determine the potential involvement of dopamine, serotonin, and corticosterone will be discussed. Similarities between the discriminative stimulus properties of stress and cocaine would support the hypothesis that these interoceptive cues are produced by the activation of common effector

GLUCOCORTICOIDS INCREASE THE REINFORCING EFFECTS OF AND INDUCE REINSTATEMENT ADMINISTRATION.

V. Deroche, M. Marinelli, M. Le Moal and P.V. Piazza.* Psychobiologie des Comportements Adaptatifs. INSERM U. 259, 33077 Bordeaux Cedex, France.

Several data suggest that corticosterone (CS) could facilitate the reinforcing properties of psychostimulant drugs and be an important factor in the vulnerability to develop and relapse substance abuse. We studied the influence of CS on intravenous self-administration (SA) of cocaine: i) as a function of CS plasmatic concentration, ii) as a function of the dose of cocaine per infusion, and iii) in a reinstatement paradigm. In a first experiment, we tested, in adrenalectomized (ADX) rats, the effects of different CS substitutive treatments on SA of 0.8 mg/kg/inf. of cocaine. Once the CS substitutive treatment reversing the effects of ADX was identified, a full dose-response curve (0.025, 0.05, 0.1, 0.2, 0.4, 0.8 mg/kg/inf) for cocaine SA was performed comparing controls. ADX rats and ADX rats receiving the CS substitutive treatment. We showed that ADX decreases cocaine SA by decreasing the maximal effect of the drug. This effect was dosedependently reversed by CS; a complete restoration being obtained for stressinduced levels of the hormone. In a second experiment, we tested the effects of an i.v. administration of CS (0.09, 0.18, 0.37, 0.58 mg/kg) on the reinstatement of SA behavior in intact rats submitted to extinction after acquisition of cocaine SA at 0.25 mg/kg/inf. We showed that CS dose-dependently precipitated the reinstatement of cocaine SA; the maximal effect being obtained for a dose of CS producing stress levels of the hormone. In conclusion, our results suggest that glucocorticoids may be a determinant factor in the vulnerability to psychostimulants abuse and open new therapeutic strategies for drug addiction

EFFECTS OF CHRONIC COCAINE ADMINISTRATION ON BASAL STRESS-INDUCED CORTICOSTERONE SECRETION AND COGNITIVE FUNCTIONS IN RATS. Z. Sarnyai^{1, 2}, C. D. Conrad¹, Y. Kuroda¹, M. J. Kreek² and B. S. McEwen¹, Lab. of Neuroendocrinology¹ and Lab. of Biology of Addictive Diseases², The Rockefeller University, New York, NY 10021
Chronic use of cocaine may lead to cognitive disturbances characterized by

persistent memory deficits and impaired attention in humans. We studied restraint stress-induced corticosterone (CORT) response before and after chronic binge pattern cocaine administration (BPCA: 15 mg/kg cocaine i.p., 3 inj/day for 21 days) and hippocampus-dependent cognitive functions after BPCA by using a days) and hippocampus-dependent cognitive functions after BPCA by using a spatial maze (Y-Maze). BPCA produced an adrenal hypertrophy and elevated basal CORT levels compared to pre-BPCA values. Furthermore, after BPCA, rats with smaller CORT elevations during their initial stress test prior to BPCA commencement (low responders, LR) showed significantly higher post-stress recovery CORT levels compared to high-responders (HR, high CORT response to initial stress) and controls. Cocaine-treated HR and control animals showed similar maze performance by identifying the novel arm. Although, cocaine-treated LR animals also recognized the novel arm quickly, they entered the novel arm more often than the other arms throughout the Y-Maze testing period, while controls and HR cocaine-treated rats did not show arm preference after the first few min These data show that BPCA leads to a chronic overstimulation of the few min. These data show that BPCA leads to a chronic overstimulation of the hypothalamic-pituitary-adrenal (HPA) axis with a possible disturbance in inspontatamic-pitultary-adrenal (HFA) axis with a possible disturbance in negative glucocorticoid feedback in a subgroup of animals. In previous studies using the Y-Maze, curiosity for the novel arm has been shown to decrease rapidly with time in intact animals. Animals with altered HPA functions after BPCA tend to show cognitive changes suggesting that they have difficulties inhibiting this behavior. The results imply involvement of hippocampus and frontal cortex. This work was supported by the Arthur Vining Davis Foundation and MH41256 from the NIH/NIMH to BSM.

362.8

THE EFFECTS OF DAILY CORTICOSTERONE PRETREATMENT ON THE ACQUISITION OF INTRAVENOUS COCAINE SELF-ADMINISTRATION IN RATS N.E. Goeders*, G.F. Guerin, J.R. Mantsch. Departments of Pharmacology & Therapeutics and Psychiatry, LSU Medical Center, Shreveport, LA 71130.

It has been previously demonstrated that daily exposure to electric feathful facilities the second of t

footshock facilitates the acquisition of low-dose cocaine selfadministration in rats and that this is positively correlated with plasma corticosterone (CORT). The following experiments were designed to investigate whether these effects could be mimicked by a daily CORT pretreatment regimen which produced increases in plasma CORT similar in magnitude and duration to those occurring during stress. Following the establishment of baseline responding, adult male Wistar rats were tested for the intravenous self-administration of increasing doses of cocaine (0, 0.031, 0.0625, 0.125, 0.25, 0.5, and 1.0 mg/kg/infusion) nder a fixed-ratio 1 (FR1) schedule of reinforcement during daily 1 hour sessions. Rats were treated daily, 15 minutes prior to each self-administration session with a CORT suspension (2.0 mg/kg in saline, i.p., n=10) or saline (n=10). Rats were initially exposed to a low dose of cocaine (0.031 mg/kg/infusion), and this dose was doubled weekly. Rats pretreated with CORT acquired self-administration at a lower dose of cocaine versus saline-pretreated controls (0.0625 or cocame versus same-pretreated controls (0.0025 vs. 0.125 vs. 0. will also be discussed. (Supported by USPHS grant DA06013 from NIDA)

STRESS AND COCAINE INJECTIONS REINSTATE COCAINE-SEEKING AFTER PROLONGED EXTINCTION. S. Erb. Y. Shaham. and J. Stewart*. Center for Studies in Behavioral Neurobiology, Psychology Dept., Concordia University, Montreal, Quebec, Canada

Rats were trained to self-administer cocaine and were given tests for reinstatement in which they were exposed to priming injections of cocaine and to intermittent footshock stress. Footshock stress was found to induce relapse to cocaine-taking behavior after prolonged extinction sessions and after a 4- to 6-week drug-free period; the effect was comparable to relapse induced by a priming injection of cocaine. Animals were initially allowed to self-administer cocaine HCl (1.0 mg/kg/infusion, IV) during one 3-h session/day for 12 days. Subsequently, extinction conditions were introduced by substituting saline for cocaine. Extinction conditions were maintained until saline for cocaine. Extinction conditions were maintained until animals reached a baseline level of responding of 10 responses or less over a 3-h period (5-13 days). Subsequently, animals were tested for reinstatement of cocaine-taking behavior in response to a non-contingent injection of cocaine (2.0 mg/kg, IV) and exposure to intermittent footshock (10 min, 0.5 mA, 0.5 sec on, mean off period of 40 sec). After an additional 4 - to 6-week drug-free period, tests for reinstatement were repeated. Reinstatement of cocaine-taking behavior was observed in both sets of tests in response to footshock and cocaine. These results extend previous reports from this laboratory that footshock stress is an effective stimulus for reinstatement of drug-taking behavior in the rat.

EFFECTS OF CHRONIC DESIPRAMINE TREATMENT ON EXTINCTION AND REINSTATEMENT OF COCAINE SELF-ADMINISTRATION BEHAVIOR. R.A. Fuchs*, L.T.L. Tran-Nguyen, S.E. Specio, R.S. Groff, and J.L. Neisewander.

Dept. Psychology, Arizona State University, Tempe, AZ 85287.

Craving is a major factor in recidivism of cocaine abuse. However, animal models of craving have not been well established. Extinction of self-administration behavior, as well as reinstatement by cocaine-associated stimuli, may provide a behavior, as well as reinstatement by cocaine-associated stimuli, may provide a useful animal model of craving. The present study examined the predictive validity of the extinction/reinstatement model. Rats were trained to lever press for cocaine (0.75 mg/kg/0.1 ml infusion) or received yoked infusions of saline during daily 3-br sessions. A stimulus light and tone were presented with the cocaine infusions. After responding stabilized on a VR 5 schedule of reinforcement, rats received an additional 14 days of training. They then underwent 11 days of withdrawal during which half of each group received either daily injections of desmethylimipramine (DMI, 10 mg/kg, IP) or saline (N=6-10). On day 12 of withdrawal, rats were allowed to respond under extinction conditions (extinction phase). After 1 hr without any responses had elapsed, the cocaine-paired stimuli were presented repeatedly (reinstatement phase). Across the cocaine groups, rats treated with DMI exhibited fewer responses relative to those treated with saline during the first 60 min of extinction. However, all groups exhibited a similar number of responses during fewer responses relative to those treated with saline during the first 60 min of extinction. However, all groups exhibited a similar number of responses during reinstatement. Regardless of cocaine history, DMI-treated rats exhibited a lower rate of responding during extinction. During reinstatement, however, DMI-treated cocaine rats exhibited a lower rate of responding relative to cocaine controls, whereas DMI-treated saline rats did not differ from saline controls. Regardless of DMI treatment, cocaine animals exhibited similar extinction latencies during both extinction and reinstatement phases. The modest decrease in responding during extinction and the reduced response rate during reinstatement produced by DMI in cocaine rats lend support to the predictive validity of this model. (Supported by DA07730 and HHMI).

362.13

BLOCKADE OF D-1 AND D-2 DOPAMINE RECEPTORS ATTENUATES "RELAPSE" ELICITED BY COCAINE-ASSOCIATED ENVIRONMENTAL STIMULI FOLLOWING PROLONGED EXTINCTION. C. S. Maldonado-Irizatry*, D. Smith, G. F. Koob and F. Weiss. The Scripps Research Institute, Department of Neuropharmacology, La Jolla, CA 92037.

The clinical literature suggests that subjective feelings of craving contribute significantly to the perpetuation of drug abuse or to relapse after a period of abstinence. This literature also suggests that drug taking behavior can be elicited by adstinence. This includes also suggests that dug dashing behavior can be christed developed for drug-related environmental stimuli. The goal of the present experiments was to develop procedures that would permit the study of cocaine-seeking behavior elicited by environmental stimuli associated with cocaine availability. Rats were subjected to 3 daily 1-ht IV self-administration sessions in which either saline or cocaine (0.25). mg/kg) was available on a FR1TO20s schedule in a random sequence. Animals were trained to discriminate a stimulus context predictive of cocaine availability (S+) from a stimulus context predictive of saline availability (S-). Following training, rats were given daily extinction sessions in which both the discriminative stimuli and cocaine or saline infusions were withheld. These animals met extinction criterion (less than 4 responses) by 24 sessions. Re-introduction of the cocaine S+ but not the S- elicited responses) by 24 sessions. Re-introduction of the cocaine S+ but not the S- elicited and maintained responding in the continued absence of the primary reinforcer. Rats initially exposed to the S- during the relapse phase also showed cocaine seeking behavior when presented with the cocaine S+. Pharmacological tests during the relapse phase, conducted in different groups of rats showed that SCH-23390 (D-1 antagonist; 10, 20 µg/kg, SC) or Raclopride (D-2 antagonist; 50, 100 µg/kg, SC) decreased cocaine seeking behavior. The present findings illustrate that drug-seeking behavior elicited by the present procedures is sensitive to pharmacological manipulation. Furthermore, blockade of DA neurotransmission attenuated the motivational properties of the drug-associated environmental stimuli, thus, implicating the DA system in cocaine seeking behavior elicited by environmental stimuli, funorored by NIDA DA07348) stimuli. DRUG-SEEKING BEHAVIOUR MEASURED USING A SECOND-ORDER SCHEDULE OF I.V. COCAINE REINFORCEMENT: EFFECTS OF WITHDRAWAL FROM FREE-ACCESS TO COCAINE

WITHDRAWAL FROM FREE-ACCESS TO COCAINE

M. Arroyo, A. Markou, T.W. Robbins and B.J. Everitt.

Dept Experimental Psychology, University of Cambridge, Cambridge CB2 3EB, UK and The Scripps Research Institute, La Jolla. California 92037, U.S.A.
Rats were trained to self-administer cocaine (0.25mg/infusion I.V.) under a second-order schedule (FI15min:FR10:S). Initially, each infusion of cocaine was made contingent on a response on one of two identical levers and was paired with a 20s light conditioned stimulus (CS). When rats acquired stable rates of self-administration, the response requirement for cocaine was increased progressively to administration, the response requirement for the CS+ was also increased to 10 [i.e. FR10;FR10;SI). At this point, an overall fixed interval (FI) second-order schedule was instigated, whereby the LV. cocaine infusion was earned following the completion of the first FR10 responses (and CS presentation) after 15 minutes had elapsed [i.e. a second-order schedule F115min(FR10;SI)]. Rats received 5 cocaine etapsed (i.e. a second-order sciencific Firming Fi(1),3). Rats feeded 3 Cotaling infusions per day under this schedule and were allowed to stabilise responding for several days before being allowed free-access to cocaine during a 12h self-administration session ("binge"). Their responding under the second-order schedule for a single infusion of cocaine was then measured at 6, 12, 24, 48 and 72h after this cocaine "binge". All animals showed marked reductions in responding for cocaine at 6 and 12h which recovered transiently at 24h, but then continued at significantly low levels for the next 2 days. By contrast, the same animals under control conditions (i.e. no cocaine withdrawal) showed increased responding for cocaine when the usual 5 daily infusions were reduced to 1 (as used under the withdrawal conditions described above). These results indicate that withdrawal from cocaine is associated with significant reductions in cocaine-seeking babanisms. behaviour.

REINSTATEMENT OF COCAINE-SEEKING BEHAVIOR IN A NONHUMAN PRIMATE MODEL OF RELAPSE. R. L. Barrett-Larimore and R. D. Spealman*. NERPRC, Harvard Medical School, Southborough, MA, 01752.

Relapse to drug abuse is a distinctive feature of drug addiction and

elapse to arrug abuse is a distinctive feature of arrug adaction and aperhaps the most difficult to treat. Clinical and experimental evidence implicates drug-associated environmental stimuli and drug priming as important determinants of the relapse process. The present study investigated the role of these factors in the reinstatement of cocaineseeking behavior using a nonhuman primate model of relapse and examined the attenuation of reinstatement by selective DA receptor antagonists. Squirrel monkeys were trained to self-administer cocaine under a second-order schedule of i.v. injection. Completion of every tenth response (FR 10) during a 10-min interval (Fl 10-min) produced a brief (2 sec) visual stimulus. The first FR 10 completed after the 10-min Fl elapsed visual stimulus. The lists have to complete a driet interfuential or elapsea produced both the brief stimulus and an injection of cocaine. High rates of responding (0.8-2.0 resp./sec) were maintained under these conditions by 0.3 mg/kg/injection cocaine. Responding was subsequently reduced or eliminated during a series of extinction sessions in which saline was eliminated auring a series of extinction sessions in which saline was substituted for cocaine and the brief stimulus was omitted. Following extinction, responding could be reinstated by administering a priming injection of cocaine before the session, by restoring the brief stimulus previously associated with cocaine injections, or maximally by both. Under the later condition, cocaine-induced reinstatement was dose- and time-dependent and could be attenuated by the $D_{\rm I}$ receptor antagonist SCH-39166, the D_2 antagonists eticlopride and nemonapride, and the novel D_3/D_4 antagonist YM-43611. The putative dopamine autoreceptor compounds (-) antagonst YM-43611. The putative dopamine autoreceptor compounds (-) 3-PPP, (+) UH-232, or (+) AJ-76 were largely ineffective in blocking cocaine-induced reinstatement. The results suggest that this model can provide an empirical means for studying pharmacological and environmental factors contributing to relapse and for evaluating potential anti-relapse medications. Supported by DA00499, MH07658, MH14275 and RR00168.

362.14

DOPAMINE OVERFLOW IN THE AMYGDALA DURING WITHDRAWAL FROM SELF-ADMINISTERED COCAINE. L.T.L. Tran-Nguyen*, R.A. Fuchs, G.P. Coffey, D.A Baker, L.E. O'Dell, J.L. Neisewander, Department of Psychology, Arizona State University, Tempe, AZ 85287-1104.

Cocaine and cocaine-associated stimuli elicit cocaine craving in humans and

reinstate extinguished cocaine self-administration (SA) behavior in rats. It has been suggested that craving and reinstatement of cocaine SA behavior may be mediated by enhanced dopamine (DA) neurotransmission. To test this, experimental rats were trained to lever press for cocaine (0.75 mg/kg/0.1 infusion) 3 hr daily for 14 days. Control rats received yoked infusions of saline. A stimulus light and tone were paired with cocaine infusions during training. Rats were then withdrawn from cocaine or saline for 7-8 or 30-31 days (N=4-7) per group). In vivo microdialysis was then used to measure DA overflow in the basolateral amygdala during 1) baseline, 2) extinction of lever presses. 3) reinstatement of lever presses by the cocaine-paired stimuli and 4) reinstatement of lever presses by cocaine (15 mg/kg, IP). Cocaine rats exhibited more lever presses relative to controls during extinction and cocaine reinstatement phases. However, there were no differences in lever presses between the two cocaine groups undergoing different periods of withdrawal. There were no differences in DA overflow between controls and the cocaine group tested on day 7-8 of withdrawal in any of the test phases. However, there was a significant increase in baseline DA overflow, as well as cocaine-elicited DA overflow, in the cocaine group tested on day 30-31 relative to the two other groups. The results suggest that there is a time-dependent increase in DA overflow in the basolateral amygdala following withdrawal from self-administered cocaine. The results also suggest that there is no correlation between lever presses and DA overflow in the basolateral amygdala. (Supported by DA07730, HHMI, and MH-19547)

EFFECTS OF COCAINE AND DOPAMINE AGONISTS ON COCAINE-SEEKING BEHAVIOR IN RATS: A SECOND-ORDER SCHEDULE OF REINFORCEMENT. A. Markou', M. Arroyo and B.J. Everitt. The Scripps Research Institute, La Jolla, California, U.S.A. and University of Cambridge, U.K.

A second-order schedule of drug reinforcement allows the assessment of: (a) the motivation to self-administer a drug (drug-seeking behavior) before any drug administration or after drug injections; and (b) the control exerted by conditioned stimuli or reinforcers (CSs) over drug-seeking behavior. Rats were trained to respond for intravenous (IV) cocaine (COC, 0.25 mg/inj) under a fixed interval 15 min schedule, during which time CSs paired with COC were presented on a fixed ratio 10. Non-contingent intraperitoneal (0, 10, 15, 20 mg/kg) or IV (0.25 mg) COC increased the latency to initiate responding and decreased the number of CSs earned, which can be interpreted as a decrease in drug-secking behavior. By contrast, contingent IV COC (0.25 mg/kg) decreased the latency to initiate responding and increased the number of CSs earned, which may be interpreted as an increase in drugseeking behavior and/or increased control over responding by the CR. Furthermore, non-contingent injections of quinpirole, a relatively selective dopamine D2 receptor agonist (0, 0.5, 0.1, 0.3 mg/kg, SC), had similar effects to non-contingent COC. Finally, low doses (0, 0.003, 0.01, 0.03, 0.1 mg/kg, SC) of a relatively selective D3 dopamine receptor agonist, PD-128,907 hydrochloride, had no consistent effect on drug-seeking behavior, while higher doses (0.3, 0.6 mg/kg) had non-specific effects on performance. In summary, drug-seeking behavior can be reliably measured in rats who will work for 15 min and emit hundreds of responses to gain access to COC. Furthemore, contingent COC increases, while non-contingent COC and quinpirole, a D2 agonist, decrease cocaine-seeking behavior, demonstrating the significance of contingent versus non-contingent injections. Finally, PD-128,907 hydrochloride, a D3 agonist, appeared to have no effect on cocaine-seeking behavior. (Supported by DA00213 to AM and MRC G9407194N to BJE).

ELECTROPHYSIOLOGICAL AND BEHAVIORAL CHARACTERIZATION OF AN ANIMAL MODEL OF COCAINE WITHDRAWAL. T.E. Koeltzow* D.C. Cooper, A.J. Vartanian and F.J. White. Neuropsychopharmacology Lab, Dept

Neuroscience, Finch Univ Hlth Sciences/Chicago Med Sch, North Chicago, IL 60064.

During withdrawal, cocaine addicts may experience anergia, depression, anhedonia, anxiety and cocaine craving. Previous animal models have produced anhedonia and anxiety, but not anergia/depression. Using an escalating, binge-like regimen of cocaine administration, we describe a model of cocaine withdrawal characterized by nocturnal hypoactivity and decreased activity of VTA dopamine neurons. Rats received 3 daily injections (1 hr apart between 9 am and 11 am) of cocaine or saline as follows: days 1-2, 10 mg/kg; days 3-4, 20 mg/kg; days 5-7, 30 mg/kg. Prior to behavioral testing on day 8, all animals received a cocaine challenge (10 mg/kg) to verify locomotor sensitization to cocaine in cocaine treated rats. When locomotor activity was monitored continuously for 72 hrs, cocaine withdrawn rats were significantly hypoactive during the 12 hr dark cycles compared to controls. No differences in locomotor activity were observed during light cycles. To characterize possible electrophysiological alterations in the mesoaccumbens dopamine system, conducted cells/track analysis using extracellular recording techniques in the VTA. Preliminary results obtained on day 8 (no cocaine challenge) indicate a significant decrease (~70%) in spontaneously active dopamine neurons in animals receiving cocaine compared to controls. On day 12 (5 days withdrawal), this effect was no longer present. No significant differences in basal firing rates were observed on These findings contrast with earlier reports of enhanced dopamine cell activity during early withdrawal from intermittant or continuous cocained administration. Our results suggest that this model may parallel certain symptoms of the withdrawal syndrome observed in human cocaine addicts, and that reduced dopamine neuronal activity may contribute to anergia and psychomotor depression. ALTERED ACTIVITY OF MIDBRAIN DOPAMINE NEURONS FOLLOWING 7-DAY WITHDRAWAL FROM CONTINUOUS OR INTERMITTENT

COCAINE PRETREATMENT. W.Y. Gao. T.H. Lee and E.H. Ellinwood.

Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Using in vivo single-unit recording, effects of continuous and intermittent cocaine pretreatment regimens on the spontaneous activity of A₂ and A₁₀. dopamine (DA) neurons were compared 7 days after withdrawal. Rats were pretreated for 14 days with: (1) saline injections (1 ml/kg, s.c., qd); (2) cocaine injections (40 mg/kg, s.c., qd); or (3) continuous cocaine infusion (40 mg/kg/day, s.c., osmotic minipumps). Predetermined blocks in the midbrain were sampled by passing the recording electrode nine times; the number of spontaneously active DA neurons as well as their firing rates and bursting patterns were determined

In the A_a area, the continuous group exhibited a significantly reduced number of neurons without changes in the firing rates or bursting patterns, while the injection group showed no differences in any of the indices. After an acute sulpiride injection (50 mg/kg, i.p.) 1 hour before sampling, the reduction in the continuous group was no longer demonstrable, suggesting a supersensitivity of D2 receptors (autoreceptors), rather than a depolarization block, as an underlying mechanism. Daily injections of apomorphine (100 µg/kg, s.c., qd) between withdrawal days 1 and 5 selectively prevented the

reduced number of active A₃ DA neurons in the continuous group.

In the A₁₀ area, continuous infusion reduced the bursting activity without affecting the number of active DA neurons, while the intermittent group showed an increased number of neurons without changes in the bursting pattern. Sulpiride reversed the changes in the both pretreatment groups again suggesting involvement of D₂ receptors. Our results will be compared and contrasted to those from previous studies. CHOOSING BETWEEN COCAINE AND COMBINATIONS OF DOPAMINE DI AND D2 AGONISTS IN SELF-ADMINISTRATION TESTS, J.D. Belluzzi*, J.A. Del Rio, A. Manzardo and L. Stein, Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717

We have previously reported that rats will self-administer solutions containing combinations of dopamine D₁ and D₂ agonists. Response rates and patterns induced by the combinations were nearly identical to those induced by cocaine. Here we test whether rats prefer cocaine to a D₁/D₂-agonist combination in a choice test. Daily 3-hr tests were made in a 2-lever box. During training, cocaine (750 μ g/kg/inj, i.v.) was available at either the right or left lever and the active side was alternated daily. After rates stabilized ($\pm 10\%$ for 2 days), different groups were offered cocaine (750 μ g/kg/inj) at one lever and cocaine 250 μ g/kg/inj, cocaine 1500 μ g/kg/inj, or the dopamine D_1/D_2 agonist combination (PHNO 0.3 μ g/kg/inj + SKF 82958 3 μ g/kg/inj) at the other lever. Choice of Coc 750 was 89% vs Coc 250 (Fig; *p<0.01) and 51% vs Coc 1500,

indicating the following order of 750≈1500>>250. preference: However, choice of Coc 750 was only 59% vs the D₁/D₂ agonist combination (PH:SK). Since rats did not significantly prefer cocaine to the D₁/D₂ combination, we conclude that dopamine agonist combinations can largely substitute for, and may be indistinguishable in reinforcement value from, cocaine in self-administration tests (Supported by NIDA grant DA07747)

THE EFFECT OF ANTAGONIST PRETREATMENT ON DOPAMINE D3 RECEPTOR MEDIATED ROTATION IN 6-OHDA LESIONED RATS P.M. Robinet*, C.K. Akins, C.R. Goetz, J.M. Dose & M.T. Bardo. Dept. of Psychology, University of Kentucky, Lexington, KY 40506

In two experiments, rats received unilateral injections of 6-OHDA into the A9/A10 cell body region. Only rats that turned in a robust manner to 1 mg/kg apomorphine were included in the experiments. Both experiments used a mixed factor design with pretreatment as a between groups measure and drug dose as a repeated measure using a pseudo-latin square such that each dose order was accounted for. In Experiment 1, the rats were pretreated with either the D2/D3 antagonist eticlopride (0.1 mg/kg) or saline. Fifteen min later they were injected with a D3 agonist, either 7-OH-DPAT (0.0, 0.001, 0.10 or 1.0 mg/kg) or PD123389 (0.0, 0.01, 0.1 or 1.0 mg/kg) and the number of rotations were recorded for 30 min. Both 7-0H-DPAT and PD123389 increased the number of rotations dose dependently and 7-OH-DPAT induced a greater magnitude of rotations than PD123389. However, pretreatment with eticlopride did not affect rotation in either the 7-OH-DPAT or PD123389 treated animals. In Experiment 2, rats were pretreated with either eticlopride (1.0 mg/kg), the D1 antagonist SCH23390 (0.3 mg/kg) or saline. Fifteen min later the rats were injected with PD123389 (0.0, 0.5, 1.0, 1.5 or 2.0 mg/kg) and the number of rotations were recorded for 30 min. PD123389 induced rotation at all doses; however, the number of rotations did not differ across drug doses. Pretreatment with eticlopride significantly decreased rotation in response to PD123389; however, pretreatment with SCH23390 had no effect on the number of rotations. Taken together, these results suggest that, at higher doses, PD123389-induced rotation is mediated by D2/D3 rather than D1 receptors.

ENVIRONMENTAL INFLUENCES ON THE PSYCHO-MOTOR RESPONSE TO INTRAVENOUS COCAINE: A DOSE-EFFECT INVESTIGATION.

Kaitlin E. Browman*, Aldo Badiani and Terry E. Robinson.
Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48109-1109.

It was reported previously that unsignalled intravenous (IV) infusions of 1.0 mg/kg of amphetamine produced a very small acute response and no sensitization if rats were given drug treatments in their HOME cage, relative to rats that received the same treatments in a physically identical but NOVEL test cage (Crombag et al., 1996). The present experiment was designed to determine if there is a similar effect of environmental condition on the response to IV cocaine (CoC), and the extent to which the effect may be dose-dependent. We compared, therefore, the response to IV administrations of COC in unilaterally DAdenervated rats, in which rotational behavior was used as an index of the psychomotor response. Rats received one IV infusion of COC a day for five days (0.0, 0.5, 1.0, 2.0, 4.0, 6.0, 8.0, or 12.0 mg/kg), either at HOME using a remotely activated infusion pump, or following placement in a NOVEL environment. As with previous studies using i.p. drug administration (Badiani et al., 1995), there was no effect of environmental condition on the acute response to COC. Preliminary data suggest, however, that there was an effect of environment on sensitization to the psychomotor activating effects of COC. (Grant #DA 04294)

ASSOCIATIVE FACTORS CONTROL ACCUMBENS CELL FIRING DURING COCAINE SELF-ADMINISTRATION IN RATS. R.M. Carelli* and S.A. Deadwyler. Center for the Neurobiological Investigation of Drug Abuse, Dept. of Phys./Pharm. Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157

We have previously reported that a subset of nucleus accumbens (NA) neurons exhibit 4 types of patterned discharges relative to the cocaine reinforced response following the onset of stable self-administration behavior in rats (JPET 277:385,1996). Preliminary findings indicate that NA phasic firing which occurred following the response during the time of cocaine delivery (0.33 mg/inf, 5.8 sec) paired with a tone-houselight stimulus (20 sec) may reflect a conditioned stimulus-related activation (Synapse, in press). The purpose of the present study was to examine further whether NA post response-related cell firing was controlled by stimulus presentation, drug delivery, and/or the drug-reinforced response. Of 286 cells recorded in 11 well-trained selfadministering rats, 73 cells (25%) exhibited phasic changes (increases or decreases) in activity following the response. Removal of the stimulus during the session (after 10-12 self-administration trials) did not alter established NA post response-related discharges. This finding indicates that the response which produces cocaine infusion is sufficient to maintain NA post response-related activity. Response-independent random presentation of the stimulus in the absence of cocaine similarly activated NA phasic firing, however, no changes in NA cell firing were observed during respon independent cocaine delivery in the absence of the stimulus. Furthermore, selfadministration behavior was extinguished when animals responded for the stimulus only in the absence of cocaine. These findings indicate that cocaine self-administration may either require or is greatly facilitated by the presence of a conditioned sensory stimulus paired with cocaine delivery. The basis for this seems to be the selective activation of NA neurons by the stimulus and not the drug

INFLUENCE OF COCAINE TRAINING DOSE ON SUBSTITUTION BY COCAINE AND (+)-AMPHETAMINE IN A 3-LEVER VS. A 2-LEVER DRUG DISCRIMINATION PROCEDURE. <u>C.A. Amendoia*</u>, <u>M.A.Edwards</u>, <u>A. Lefevour and K.M. Kantak</u> Department of Psychology, Boston University, Boston, MA 02215.

Rats were trained to discriminate between saline, a high dose (10 mg/kg) and a low dose (3 mg/kg) of cocaine in a food reinforced, 3-lever drug discrimination procedure. After 200 to 230 daily training sessions, 2 of 4 subjects met the training criteria of >90% lever-appropriate responses, with no more than 4 incorrect responses before delivery of the first reinforcer for 10 consecutive sessions. In substitution tests with cocaine (0.1-17.8 mg/kg) and saline, 3.0 mg/kg cocaine engendered >90% low dose-appropriate responses, while higher and lower doses of cocaine engendered >90% responses on the high dose- and salineappropriate levers, respectively. In substitution tests with (+)amphetamine, 1.0 mg/kg engendered >90% responses on the high doseappropriate lever, while 0.1 mg/kg engendered >90% responses on the saline-appropriate lever. A dose of 0.56 mg/kg (+)-amphetamine engendered responses primarily on the low dose-appropriate lever. These data indicate that rats are able to successively discriminate between a high and a low dose of cocaine and saline. In addition, the substitution profiles are similar to those reported using a 2-lever drug discrimination procedure where training dose of cocaine was independently varied (Kantak et al., 1995).

CONDITIONING OF LOCOMOTION AND REINFORCING PROPERTIES TO DISCRETE STIMULI THROUGH ASSOCIATION WITH INTRAPERITONEAL COCAINE ADMINISTRATION. L. V. Panlijo* and C. W. Schindler. Preclinical Pharmacology Laboratory, NIH/NIDA DIR, Baltimore, MD 21224.

Studies of conditioned locomotor activity have demonstrated that excitatory properties are conditioned to a distinctive environment that has been associated with psychomotor-stimulant administration. Unlike traditional studies of classical conditioning, conditioned-activity studies have used the entire environmental context as the conditioned stimulus. It is not clear whether conditioned locomotion can be elicited by specific, discrete stimuli. To test this possibility, rats (n=24) were injected ip with saline prior to daily, 30-min sessions in a locomotor activity chamber. Interspersed (1-2 times/week) with these baseline sessions, rats were injected with occaine (20mg/kg) and placed in the chamber, where a tone or flashing light was presented. While baseline levels of activity remained stable, sensitization occurred (i.e., locomotion increased) over 6 drug-stimulus pairings. When a cocaine challenge was administered in the absence of the conditioned stimulus was present (indicating conditioned sensitization). When the rats were presented with tone or light without receiving cocaine, locomotor activity increased significantly above baseline (indicating conditioned locomotion). To determine whether incentive-motive properties were also conditioned to tone and light, the rats were then tested in an operant chamber containing two nose-poke holes. Responding in one hole produced a 2-sec conditioned-stimulus presentation. Response rates were significantly higher in this hole than in the other, inactive hole (indicating conditioned reinforcement). Thus, locomotor activity can be conditioned to discrete stimuli, and the incentive-motive properties conditioned to these stimuli in the locomotor-activity chamber can transfer to other environments. In this respect, the drug-conditioning effects seen in rodents may be analogous to the physiological responses and self-reports of craving obtained when drug abusers are presented with discrete, drug-related stimuli. SINGLE NEURONAL ACTIVITY IN MESOLIMBIC SYSTEM DURING COCAINE AND HEROIN SELF-ADMINISTRATIONS IN FREELY MOVING RATS.. J.-Y. Chang*. and D. J. Woodward. Department of Physiology and Pharmacology. Bowman Gray School of Medicine, Winston-Salem, NC 27157.

An effective approach to examine the neuronal mechanism(s) underlying cocaine and heroin self-administration is to investigate and compare the neuronal activities in the mesolimbic areas during self-administration behaviors. Using a chronic, multi-channel, single unit recording technique, up to 32 neurons were simultaneous recorded from medial frontal cortex/nucleus accumbens and ventral tegmental area/amygdala of rats trained in different essions to self administer occaine and heroin. Sessions either started with cocaine (Img/kg per infusion) and were followed by heroin (30µg/kg per infusion) self-administration, or started with heroin and followed by cocaine self-administration. Self-administration of mixture of cocaine and heroin (0.5mg/kg cocaine+15µg/kg heroin and Img/kg cocaine+30µg/kg heroin per infusion) was also tested. Neurons in these mesolimbic areas exhibited responses both before (anticipatory responses) and after cocaine and heroin self-administration. About 40 to 50 percent of neurons displayed no response in medial frontal cortex and nucleus accumbens during both cocaine and heroin self-administration. A small percent of neurons (<10%) showed the same responses either before or after both cocaine and heroin during the operant task of self administration. Combining cocaine and heroin uning the operant task of self administration. Combining cocaine and heroin self-administration alone. Some anticipatory responses associated with cocaine and heroin disappeared when cocaine and heroin in combination was employed but could be recovered by injection of naloxone (1mg/kg, i.p.). Synergistic effects on post-drug neuronal response were found with combinations of cocaine and heroin. These synergistic effects were readily blocked by naloxone. The result suggests different neuronal circuits in mesolimbic system may be involved in the behavior produced during cocaine and heroin self-administration. The interaction of these neuronal circuits may be related to "speedball effects" produced by combinations of co

EFFECTS OF CONTINGENT VS NONCONTINGENT INTRAVENOUS COCAINE INFUSIONS ON THE FIRING PATTERNS OF INDIVIDUAL NEURONS IN THE NUCLEUS ACCUMBENS OF RATS. <u>L.L. Peoples*, A.J. Uzwiak, and M.O. West</u> Dept. of Psychology, Rutgers, The State University, New Brunswick, NJ, 08903.

Male Long Evans rats (N=20) were chronically implanted with arrays of microwires, positioned in the Nucleus Accumbens (NAcc), and with jugular catheters. During cocaine self-administration training sessions, each lever press was followed by an infusion of cocaine (0.7 mg/kg/infusion). Individual NAcc neurons showed phasic changes in firing rate time-locked to cocaine self-infusion. To determine whether these changes may be related to appetitive behavior, we conducted a within-neuron within-session yoked control test. After an initial phase in which the rat attained a stable drug level (calculated), the session was conducted according to an ABAB design in which cocaine infusions were alternately response-contingent (C) in A phases and response-noncontingent (NC) in B phases. Each phase included 5-10 infusions (i.e., 5-10 trials). The pattern of C infusions was determined by the rat, as during training sessions. The pattern of NC infusions was yoked (i.e., equal) to the pattern of preceding C infusions. Stereotypic behavior and drug level were the same during the C and NC phases. Interspike-interval histograms were used to identify single neurons (N=85). The most common short-duration change in firing rate time-locked to C infusions (i.e., increase during first few seconds after self-infusion) was absent or diminished during NC trials devoid of lever presses. The most common long-duration change in firing rate time-locked to C infusions (i.e., decrease during 2 minutes after infusion followed by a progressive increase that culminated at the next infusion) was blunted during NC trials. Changes in firing during occasional NC trials in which the rat made a lever press (nonreinforced) were comparable to those time-locked to C infusions. The data suggest that the most common firing patterns time-locked to cocaine self-infusion contribute to drug-directed appetitive behavior and are not determined solely by direct actions of the drug or by the cues associated with the infusion. Supported by DA 06886.

STIMULANT AND REWARDING PROPERTIES OF COCAINE FOLLOWING INTRA-VENTRICULAR OR INTRA-AMYGDALA INFUSIONS. L.E. O'Dell*, A.N. Sussman, K.L. Meyer, and J.L. Neisewander. Department of Psychology, Box 871104, Arizona State University, Tempe, AZ 85287-1104.

The effects of intracerebroventricular (ICV) or intra-amygdala infusion of the control of the contr

The effects of intracerebroventricular (1CV) or intra-amygdala infusions of cocaine on locomotion, conditioned place preference (CPP), and conditioned activity were assessed. Five two-day conditioning trials were conducted in a 2-compartment apparatus over 10 consecutive days. On one day of the trial, rats received either ICV or intra-amygdala infusions of cocaine at doses of 0 (n=12, 11), 25 (n=3, 9), 50 (n=7, 10), and 100 (n=10) μg/0.5 μl/per side and were placed into a distinct compartment for 30 min. On the other day, rats received sham infusions and were placed into the other compartment for 30 min. Locomotion was assessed during conditioning using a photocell system. CPP was assessed 24 hr after conditioning as an increase in time spent in the cocaine-paired compartment relative to the other compartment. Conditioned activity was assessed 24 hr after CPP as an increase in locomotion in the cocaine-paired compartment incocaine-treated rats relative to controls following sham infusions. Cocaine infusions into either region produced a dose-dependent increase in locomotion, and the magnitude of this effect was greater following ICV relative to intra-amygdala infusions. Only the ICV dose of 50 μg produced CPP. In contrast, only the intra-amygdala doses of 50 and 100 μg produced conditioned activity. (Supported by DA07730, NIMH/MNTP grant MH-19547, and HHMI).

PHASIC FIRING PATTERNS RECORDED FROM INDIVIDUAL NUCLEUS ACCUMBENS NEURONS DURING COCAINE APPETITIVE BEHAVIOR. A.J. Uzwiak, M.O. West* and L.L. Peoples. Dept. Psychology, Rutgers, The State University of New Jersey, New Brunswick, NJ 08903.

Previous studies have characterized phasic firing patterns in ventral striatal neurons during cocaine self administration. This study characterized phasic firing patterns attributable to neurons (n=110) that were either in the subterritories of the nucleus accumbens (NAcc) or in the anterior olfactory nucleus, posterior (AOP) and that were verified to be single units by interspike interval analysis. Individual male Long Evans rats (n=29) were implanted with a microwire array positioned in the NAcc and AOP and a jugular catheter. Following the attainment of an asymptotic drug level, patterns time-locked to within ±10 seconds of the cocaine (0.7 mg/kg/inf) reinforced lever press (Fixed Ratio 1) were characterized. Two basic types of patterns were identified--single phase and multiple phase. The single phase pattern was sub-typed depending on whether the change in firing rate occured before the lever press, after the lever press, or began before and ended after the lever press. The single phase change patterns were further characterized by the direction (i.e. increase or decrease), duration and latency of the change in firing rate. The multiple phase change pattern was characterized by the number and direction of changes in the firing rate. Although the patterns observed in this study replicated some of the patterns described in previous studies, there appears to be a differential distribution of these patterns among ventral striatal brain areas. Our findings suggest that the multiphasic firing patterns are limited to the most anterior NAcc and AOP. Research supported by DA06886

ACUTE COCAINE DOES NOT ENHANCE SENSITIVITY TO SOMATOSENSORY STIMULI IN AWAKE BEHAVING RATS. E. M. Gould*1, D. M. Devilbiss¹, J. P. Druhan² and B. D. Waterhouse¹. ¹Dept. Neurobiology and Anatomy, ²Division of Behavioral Neurobiology, Dept. of Psychiatry, Medical College of Pennsylvania and Hahnemann University, Philadelphia. PA 19102.

Previous studies from this laboratory have shown that acutely administered systemic cocaine alters the central processing of afferent signals from the rat mystacial vibrissae in halothane anesthetized rats. In the present study, we examined whether acute IP cocaine administration altered sensory signal processing in awake behaving rats trained to detect whisker pad stimulation in an operant discrimination task. A bipolar electrode for delivering subcutaneous stimuli was permanently implanted under the whisker pad, and the animals were required to press one of two levers to obtain food after brief presentations of whisker pad stimulation, or on the alternative lever on trials with no stimulation. Stimulus-response functions were then obtained by varying the intensity of the stimulation and determining the tendency to respond on the stimulation appropriate lever after each stimulus. The effects of cocaine (1, 2, 4, 10 and 20 mg/kg) on the stimulus-response function was then determined. One, two, four, ten mg/kg cocaine did not alter the responses to whisker pad stimulation. Only at 20 mg/kg was there a significant change in the animals' response pattern to the stimuli. This dose decreased stimulation lever responses at all intensities, so that rats responded to higher currents as though they were lower. Response measures obtained during the intertrial interval (ITI) indicated that this dose also increased the rate of unrewarded responding, but did not affect the distribution of un-cued responses on the two levers during this period. These data suggest that cocaine does not enhance rats' sensitivity to sensory cues, and actually decreases detection of whisker pad stimulation at high doses. Supported by NIDA DA 05117 to BDW.

ACUTE SYSTEMIC COCAINE ALTERS THE PROCESSING OF SENSORY INFORMATION FROM THE RAT VIBRISSAE. J. J. Rutter K. L. Simpson and B. D. Waterhouse. Dept. Neurobiology and Anatomy, MCPHU, Philadeliphia, PA 19102-1192.

The impact of occaine on neural networks innervated by monoamines other than dopamine has been inadequately studied. In order to characterize the effects of cocaine on activity transmitted

The impact of cocaine on neural networks innervated by monoamines other than dopamine has been inadequately studied. In order to characterize the effects of occaine on activity fransmitted through noradrenergically and serotoninergically innervated pathways, we have been evaluating the drug's ability to alter the central processing of afferent signals from the rat mystacial wibrissae. This system was chosen as a well-characterized sensory pathway which receives prominent norepinephrine (NE) and serotonin (5-HT) innervation at both cortical and subcortical relay sites. In the present study, extracellular responses to graded, mechanical displacement of individual whiskers on the contralateral face were recorded from single units in the ventral posterior medial (VPM) fhalamus of halothane-anesthetized rats. Previous results from this laboratory had shown that both the magnitude and latency of such stimulus-evoked discharge could be altered following acute cocaine challenge (0.75 mg/kg, iv). When an effect was observed, cocaine invariably decreased response latency; however, changes in response magnitude could occur in either direction from control. Our more recent results support the notion that low concentrations of NE may have a facilitating effect on evoked signals, but that increasing the concentration of NE can depress the same signal. We hypothesized, therefore, that this bimodal shift in response may be due, in part, to the differential efficacy of a single dose of cocaine on fluctuating basal levels of 5-HT and NE. To test this, the sensitivity of a VPM unit to a range of whisker deflections was first determined, and then a fixed level of stimulation from the middle of the curve was identified and chosen for testing. The whisker was then driven at this level of stimulation and cell responses were recorded before and after administration of iv occaine in a cumulative dose paradigm (0.25-2 mg/kg, dose every 10 min.). Drug-induced changes in cell responses were determined from quantitative analysis of post-st

363.15

SEX HORMONES MODULATE DOPAMINE RESPONSE TO COCAINE M. N. Cook and B. C. Jones*. Department of Biobehavioral Health, The Pennsylvania State University, University Park, PA 16802.

In our laboratory, we have observed sex differences in dopaminergic response to cocaine, particularly in the medial prefrontal cortex of C57BL/6 mice(B6). Males and females of this strain had opposing dopaminergic responses to ip injection of 15 mg kg⁻¹ cocaine. Cocaine increased dopamine utilization, as evaluated by the ratio of HVA/DA, in males and decreased utilization in females. To further investigate the sex differences in C57BL/6 mice, we undertook the present study. Male and female mice, 60 days of age, from the C57BL/6 mouse strain were either sham-operated or gonadectomized. Gonadectomized animals were implanted with one of several hormone pellets: placebo, estradiol, testosterone, dihydotestosterone, progesterone or the combination of estradiol and progesterone. One week following gonadectomy, animals were given either a single injection of 0.9% sterile saline or 15 mg kg 1 cocaine and killed ten minutes post-injection. The medial prefrontal cortex (MPFC), nucleus accumbens (NACC), caudate-putamen (CP) and ventral midbrain (VMB).were assayed, by HPLC, for Dopamine and Serotonin and their metabolites, HVA and DOPAC and 5HIAA respectively. Sex differences in dopamine utilization in the medial prefrontal cortex were replicated in this study. We also observed that, in the MPFC cocaine-related change in dopamine utilization in B6 castrated males treated with estradiol was similar to that of intact B6 females and ovariectomized B6 females treated with testosterone displayed dopaminergic response similar to that of intact B6 males. These preliminary data suggest that sex hormones are capable of modulating dopaminergic response to cocaine. Supported by USPHS Grant DA 07171

ACTIONS OF COCAINE (COCA) IN SOMATOSENSORY CORTEX: CORRELATIONS WITH CELL TYPES, MONOAMINES AND CHANGES IN EXCITABILITY. F.M. Sessler*, J. Zhai, T.N. Felder, F. Chen, A.E.K. Kosobud, B.D. Waterhouse, R.C.S. Lin and J. Lehmann, Depts. of Neurobiol. & Anat. and Neurosurg., Med. Col. of Pennsylvania and Hahnemann Univ., Philadelphia, PA 19102, and Dept. of Psychol., Indiana Univ. IN 47405. In previous studies we reported differential actions of COCA in somatosensory cortex. We further examined the impact of this drug on

In previous studies we reported differential actions of COCA in somatosensory cortex. We further examined the impact of this drug on processing capabilities of sensory neurons, by characterizing its effects on input resistance (RN) and rheobase (Rh) of four major types of identified layer by pyramidal neurons. In addition, we used amphetamine (AMPH) and fenduramine (FENF) to mimic COCA actions on these neurons. Intracellular recordings were conducted in slices from rat somatosensory cortex. Non-local anesthetic concentration of COCA (1uM) decreased IR and increased Rh in 54% of the cells tested. This was mimicked by AMPH (1uM) but not by FENF (1uM). In contrast, IR increased in 75% of the cells tested with local anesthetic concentration of COCA (100uM). Changes in conductance reflecting possible local anesthetic effects of COCA were not mimicked by 100uM AMPH or FENF. In comparing drug actions on different cell types, we found that Rh was increased and IR decreased by COCA (1uM) in all the intrinsic bursting (IB) and in 67% of doublet spiking (DS) cells, resulting in decreased cell excitability. 55% of non-adapting and adapting regular spiking (NA-RS & A-RS) neurons showed an increase in excitability with increase in IR and decrease in Rh. Thus, most of the excitatory influences of COCA were found on RS neurons, and little or none on DS and IB cells. These observations suggest that an understanding of the impact of drug abuse on sensory processing within cortical circuits requires a characterization of both, monoaminergic influences and drug action on different cell types. CELLULAR ACTIVATION DURING COCAINE EXPOSURE: A FOCUS ON THE HABENULA, J.L.Petrie*and G.D.Ellison Department of Psychology, UCLA, Los Angeles, CA, 90095.

Previous studies have shown that continuous exposure to cocaine will produce degeneration of fasciculus retroflexus, the major efferent of the habenula. 2-DG autoradiography indicates that the glucose utilization of the terminals in this area is reduced by cocaine. This study focuses on the cellular activity by using c-fos to continue the mapping of metabolic activity.

Three cocaine treatments were used: 1)single acute injection (40mg/kg), 2)five day pellet + single injection on day 6, 3)five day pellet + single injection on day 19. Cocaine was shown to significantly increase c-fos expression in animals treated with cocaine versus controls. However, there was no difference in expression between the three cocaine treated groups. The increase in cellular activity paired with a known decrease in terminal activity suggests a GABA-ergic afferent pathway. The lack of either a tolerance or sensitivity to the drug indicates that this may be a piece of the circuit involved in the psychotomimetic syndrome of stimulant psychosis.

A HISTORY OF RESPONDING MAINTAINED BY SHOCK POSTPONEMENT DOES NOT ALTER THE DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE. <u>T.A. Tatham's</u>, <u>T.A. Hasling's</u>, <u>J.E. Baznett</u>, 'Posychiatry Department, Uniformed Services University, Bethesda, MD 20814; ²CNS Division, Wyeth-Ayerst Research, Princeton, NJ 08543.

Behavioral history can alter the effects of drugs on behavior. For example, cocaine (COC) normally decreases food-maintained responding that is punished by the presentation of mild shocks. This laboratory has demonstrated, however, that COC increases punished responding following a history of responding maintained by postponement of shock. This outcome is especially interesting, for decreases in punished responding are consistent with the effects of anxiogenic drugs, whereas increases are the hallmark of anxiolytic compounds.

The present experiment examined whether cocaine shares discriminative stimulus (DS) effects with well-established anxiolytics mediated through the benzodiazepine (BZ) receptor following a history of responding maintained by shock postponement. Four squirrel monkeys were trained to discriminate COC from saline. On alternate days COC (0.56 mg/kg, i.m.) or saline (SAL) was injected. Ten-min later, 30 presses on the left lever produced food after SAL injections, whereas 30 presses on the right lever were reinforced after COC injections. After the monkeys performed accurately, tests were conducted in which COC (1 - .56 mg/kg), midazolam (MDZ, 1 - .56 mg/kg) or pentobarbital (PB, 1.0 - 5.6 mg/kg) was injected and responding on either lever produced food. COC dose-dependently occasioned responding on the drug lever, whereas MDZ and PB engendered SAL-appropriate responding. Discrimination training was then suspended and 10 sessions were conducted in which pulling a chain postponed mild tall shocks. Discrimination training was reinstated and dose-response curves were redetermined. Dose-response curves for COC were not affected by the shock postponement history. MDZ and PB again occasioned only SAL-appropriate responding. These results suggest that the DS effects of COC do not resemble those of anxiolytic drugs mediated by the BZ receptor following a behavioral that changes COC's effect on punished responding from anxiogenic-like to anxiolytic-like.

SECOND-ORDER SCHEDULES OF COCAINE REINFORCEMENT IN RATS S. R. Goldberg*, E.B. Thorndike, C.W. Schindler & M. Shoaib. Preclinical Pharmacology Laboratory, National Institute on Drug Abuse, D.I.R., N.I.H., Baltimore, MD 21224. Response rates in drug self-administration are relatively low for rats in comparison to

primates. Most of the current intravenous drug-self administration experiments performed in rodents have used simple fixed ratio (FR) schedules of reinforcement; rats are required to emit a fixed number of responses which produces an injection of drug. Since, intermittent presentation of stimuli (e.g. tone or light) associated with cocaine injection has been shown to effectively increase response rates in primates under second-order schedules of drug injection, the present experiments sought to establish self-administration of cocaine under second-order schedules in rodents. Male Sprague Dawley rats were trained to nose-poke for injections of cocaine (0.66 mg/kg/inj) under two different second-order schedules. Each drug injection was associated with a 2 sec period of light oscillation (5Hz). One group was trained to respond under a FR5 (FR5:s) schedule where every 5 nose-pokes produced a 2 sec light oscillation, and every fifth FR completion produced both light oscillation and an intravenous injection of cocaine. The other schedule used was a VI 180sec (VR 8:s) schedule, in which every variable ratio (VR) completed during the 3 min variable interval (VI) produced a 2 sec period of light oscillation; the first VR completed after the interval produced both the brief stimulus and intravenous injection of cocaine. Relatively high overall rates of responding were maintained by both schedules (0.14 res/sec and 0.18 res/sec respectively). Under tests of extinction, omission of cocaine resulted in marked decreases in behaviour within a session under both schedules. However, when both the brief stimulus and cocaine were omitted, extinction was more profound for the group of rats trained under the FR5 (FR5:s) schedule. When the brief stimulus was omitted, but cocaine was still injected, response rates did not change, although under the FR5 (FR5:s) schedule, the latency to self-administer the first cocaine injection in the 2-hr session increased. These findings demonstrate that high rates of responding can be maintained under second-order schedules of cocaine injection in rats, although clear facilitation of responding by the brief stimuli was observed under restricted conditions (e.g. FR5 (FR5:s)). COCAETHYLENE POTENTIATES MEDIAL FOREBRAIN BUNDLE INTRACRANIAL SELF-STIMULATION. M. A. Raven *, C. R. Devinney, L. M. Gatzke and A. Ettenberg. Behavioral Pharmacology Laboratory, Department of Psychology, University of California at Santa Barbara, Santa Barbara, CA 90316.

Cocaethylene is a psychoactive metabolite of cocaine produced only in the presence of ethanol. Although its reinforcing and rewarding properties have been identified in drug self-administration and conditioned place preference studies, its effects on brain stimulation reward have not been examined. Drugs identified as "reinforcing" in other paradigms often serve to enhance the reinforcing properties of intracranial stimulation. This study was designed to test the effects of several doses of i. p. administered cocaethylene (0, 5, 10, 20, 40 mg/kg) on intracranial self-stimulation in animals pressing for medial forebrain bundle stimulation. Rats were implanted with chronic indwelling monopolar electrodes and trained to press for an ascending series (150-600 μA) of square-wave 0.5 s trains of brain stimulation. All subjects received all doses of cocaethylene in a counterbalanced order with a minimum of 2 days between successive test trials. Results indicate that cocaethylene reliably decreased the current required to maintain half maximal lever pressing indicating that cocaethylene, like other reinforcing drugs, enhances the reinforcing effects of medial forebrain bundle self-stimulation.

COCAINE AND ETHANOL SUBSTITUTE FULLY FOR A COCAINE-ETHANOL MIXTURE J. Jenkins, B. Rocha and M. Emmett-Oglesby*. Department of Pharmacology, University of North Texas, Fort Worth, TX 76107

Drug abuse often involves the use of more than one drug, alone or in combination. The combination of ethanol and cocaine use produces a potent metabolite, cocaethylene, which could produce a unique discriminative stimulus. The goal of the present study was to determine if the discriminative stimulus produced by a mixture of cocaine and ethanol is unique or is the sum of the component drug stimuli. Male Long Evans rats were trained in a two-lever choice task to discriminate a mixture of cocaine (5.6 mg/kg) and ethanol (EtOH, 0.56 g/kg) from saline under a fixed ratio 10 (FR10) schedule of food reinforcement. The mixture substituted for itself in a dose-related manner. Either cocaine or EtOH alone also substituted fully for the mixture. These data support the hypothesis that the stimulus produced by the mixture of cocaine and EtOH is the sum of the component stimuli, not a new, unique entity. Supported by R01 AA9378 and AA10545.

Dopaminergic and glutamatergic mechanisms mediate induction of FOS-like protein by cocaethylene. <u>Judith Horowitz*</u>, <u>Jean DiPirro</u>, <u>Mark Kristal and German Torres</u>. Behavioral Neuroscience Program. Department of Psychology. State University of New York at Buffalo. Buffalo, New York 14260

Cocaethylene is an ethyl metabolite of cocaine formed by liver carboxylesterases in the presence of ethanol. The temporal induction of FOS-like protein in rat brain was examined following IP administration of 20 mg/kg cocaethylene. Immunoreactivity for the protein was detectable at 1 hour in striatal neurons and had virtually disappeared 6 hours after drug treatment. Administration of specific dopaminergic (SCH23390) and glutamatergic (MK-801) receptor antagonists prior to cocaethylene indicated a significant role for D1 and NMDA receptors in mediating the nuclear induction of the aforementioned transcription factor protein. In sharp contrast, no marked effects on FOS-like protein in discrete nerve cells of the caudate putamen were found when spiradoline (U-62066), a kappa opioid receptor agonist, was administered either IP or directly into the brain parenchyma. Although cocaethylene treatment resulted in behavioral activation (e.g. rearing and sniffing), this activation was significantly less robust than in rat cohorts treated with a comparable dose of cocaine. These findings indicate both common and disparate effects of cocaethylene and its parent compound, cocaine, on receptor pathways that regulate alterations in gene expression and on neural systems associated with behavior.

DRUGS OF ABUSE: COCAINE III

364.1

DIRECT ADMINISTRATION OF κ-AGONISTS INTO THE NUCLEUS ACCUMBENS PREVENTS THE DEVELOPMENT OF BEHAVIORAL SENSITIZATION TO COCAINE. Ch. A. Heidbreder * & T.S. Shippenberg Neuroscience Branch, Neuroimaging & Drug Action Section, NIH/NIDA, P.O. Box 5180, Baltimore, MD 21224, USA.

Repeated cocaine administration produces persistent adaptations within the mesolimbic dopamine (DA) system. These changes in DA neurotransmission are thought to mediate the behavioral sensitization that develops to cocaine following its repeated administration. Manipulations of endogenous x-opioid systems by the administration of exogenous agonists prevent sensitization to both the behavioral and neurochemical effects of occaine. At present, however, the site of action of x-opioid receptor agonists in modifying the effects of cocaine is unknown. The present study sought to characterize the effects of the direct administration of the x-opioid receptor agonist U-89593 (0.9 mnoliday x 5 days) or its vehicle into the nucleus accumbens (ACB) on occaine-induced behavioral sensitization. To this end, the same animals were pretreated simultaneously with either repeated cocaine (20 mg/kg/day x 5 days) or saline (1.0 ml/kg/day x 5 days). In separate groups of animals, the x-opioid receptor antagonist nor-ball programme (nor-BN) was directly infused into the ACB before the one daily injection of either saline, cocaine (20 mg/kg/day), or U-69593 (0.32 mg/kg/day)

Cocaine-pretreated animals exhibited an enhanced motor response to a cocaine challenge 2 days after cessation of cocaine treatment. In contrast, a significant reduction in the response to occaine occurred in animals that had received U-69593 in the ACB in combination with systemic cocaine. Whereas systemic U-69593 pretreatment blocked both the acute and sensitized locomotor effects of cocaine, infusion of nor-BNI into the ACB completely reversed the effects of the x-opioid receptor agonist. These findings demonstrate that direct activation of x-opioid receptors within the ACB may prevent alterations in mesolimbic DA transmission, which occur following repeated administration of occaine, and that this action may underlie the prevention of behavioral sensitization to cocaine.

ENDOGENOUS GABA RELEASE FROM STRIATAL SLICES OF COCAINE SENSITIZED RATS <u>B.J., Jung*</u>, R. <u>Dawson, S.A., Sealey, P.A. Walker, and J. Peris</u>, Dept of Pharmacodynamics, College of Pharmacy, Univ. of Florida, Gainesville, Fl. 32610 Repeated occaine use results in a phenomena known as occaine sensitization, which can be

Repeated cocaine use results in a preromera known as occaine sensitization, which can be measured in rats by observing behavioral stereotypy (head bobbing, repetitive motions) and locomotion. Previously it has been demonstrated that sensitized rats show decreased GABA, receptor number and function (JPET 226: 1002-8, 1996). It is important to determine whether post-synaptic GABA receptor changes are compensatory responses to changes in pre-synaptic GABA release. To address this possibility, we examined whether the endogenous release of GABA from striatal slices is modified in rats treated with cocaine. Male Sprague-Dawley rats were randomly assigned to wor treatment groups: saline and cocaine (15mg/kg). Rats were injected daily (ip) with their assigned treatments for 14 days. Rat behavior was rated on a five point scale on days 1, 7 and 14. Animals were killed 20-26hr after their last injection and their brains were quickly removed. Striatal slices (400µm) were then stimulated with 30mM K* for 5 min while fractions were collected for a 25 min period. Endogenous GABA in collected fractions and brain slices was quantified by HPLC-EC.

Cocaine treated rats showed a significant increase in behavioral stereotypy from day 1 compared to day 14 (p-0.05) and a 25% decrease in total GABA release compared to saline treated rats. There was no significant change in total endogenous GABA caused by cocaine. When a similar experiment was performed using a non-sensitizing dose of cocaine (7.5mg/kg), there were no significant differences caused by cocaine. These data are consistent with an overall decrease in GABA transmission in the striatum of sensitized rats, both pre and post-synaptically. These changes are contradictory to the hypothesis that decreases in GABA, receptors are a compensatory response to increases in GABA release. An overall decrease in inhibitory GABA transmission in striatum could contribute to enhanced striatal output and this indicates that other mechanisms besides DA transmission may be altered during the development of sensitization. Supported by a grant from the Alcoholic Beverage Medical Research Foundation.

DIAZEPAM PRETREATMENT MASKS COCAINE
SENSITIZATION IN RATS
L.J. Coughlin', C.W. Coffman, and W.P. Jordan
Biology and Psychology, St. Mary's College of Maryland,
St. Mary's City, MD 20686
After several doses of cocaine (COC), a rat's motor behavior

becomes sensitized to subsequent doses. In the current study, COC (10 mg/kg, i.p.) produced significant increases in repetitive head-bobbing after 4 intermittent doses across 10 days. Because diazepam (DZP) is a well-established treatment for cocaine-induced diazepain (DZF) is a wen-established treatment for cocaine-induced seizures, this study explored diazepam antagonism of cocaine sensitization. Pretreatment of rats with DZP (2.5 mg/kg, i,p.) prior to COC prevented head-bobbing behavior. Head-bobbing emerged in these rats when given only COC in a post-test, suggesting GABA facilitation masks but does not prevent the development of sensitization to COC. The joint effect of DZP and COC prevented the habituation of locomotion across days, whereas DZP or COCalone did not. Thus, DZP can both mask a COC-sensitized behavior, head bobbing, and mask the expression of a non-sensitized behavior, locomotion. These masking effects, however, disappear when animals are challenged with a COC-alone test.

SENSITIZATION TO COCAINE MAY EXIST IN A NMDA DEPENDENT OR INDEPENDENT

SENSITIZATION TO COCAINE MAY EXIST IN A NMDA DEPENDENT OR INDEPENDENT FORM. C. Gambarana', M. G. De Montis, Q. Ghiglieri, A. Tagliamonte. Institute of Pharmacology, University of Siena, Siena 53100, Italy.

The NMDA receptor system has been involved in several processes of neuronal plasticity related to learning and memory. In particular, NMDA receptor antagonists have been used to prevent the occurrence of the behavioral and neurochemical modifications which mediate the long-term effects of some psychotropic drugs. Sensitization and tolerance to central stimulants are among the phenomena prevented by the concomitant NMDA receptor inhibition along the induction phase. Moreover, we recently reported that rats previously sensitized to cocaine and then infused with dizoclipine plus a daily injection of cocaine for 7 days, after a day wash-out show an almost complete extinction of sensitization, which instead appears day wash-out show an almost complete extinction of sensitization, which instead appears unmodified if dizocilpine is administered alone (1). In the present study, rats exposed to a continuous influsion of discollipline (100µg/kg/day, s.c. x 14 days) during a cocaine sensitization protocol (46mg/kg/i.e. every other day x 14 days), became sensitized to cocaine. However, such a sensitization (measured in terms of stereotipy scores) was evident only when animals were challenged with cocaine (10mg/kg, i.p.) under discollipline effect (100µg/kg, i.p.). In addition, rats previously sensitized to cocaine and then infused with dizocipine for a week and daily treated with 10 mg/kg of cocaine, during the first days of treatment presented a clearly decreased degree of sensitization. On the other hand, also in these animals on days 6 and 7 of cocaine administration an intense stereotyped response to cocaine re-appeared, which was completely absent after 2 days of dizocilpine wash-out. That is, rats sensitized under continuous NMDA receptor inhibition were still hyperresponsive to cocaine only in the presence of acute dizocilpine, and those which shifted into an NMDA independent sensitization had a standard response to the challenge with cocaine alone After a 7 day wash-out, animals of both groups maintained the same degree and specificity of sensitization. Thus, it appears that two distinct mechanisms of sensitization to cocaine exist: one dependent on and the second independent of NMDA receptor activity.

ALTERATIONS IN NUCLEUS ACCUMBENS (NAc) NEURONS AFTER REPEATED COCAINE TREATMENT: IN VITRO ELECTROPHYSIOLOGICAL STUDIES. X.-T. Hu* and F.J. White. Neuropsychopharmacology Lab, Dept. Neuroscience, FUHS/Chicago Medical School, North Chicago, IL 60064.

Our previous in vivo electrophysiolgical studies identifed a functional supersensitivity of NAc neurons to dopamine (DA), DA D₁ receptor (D₁R) selective agonists (SKF 38393) and cocaine after repeated cocaine administration which paralled the persistence of behavioral sensitization. Subsequent in vivo recordings also suggested reduced sensitivity to glutamate - in particular, to non-NMDA receptor stimulation - whereas in vitro studies indicated that NAc neurons were more hyperpolarized at rest, and were less sensitive to intracellular depolarizing current injection. The present study sought to determine whether these alterations observed in slice preparations in vitro are related to the previous finding of DA D1R supersensitivity. supersensitivity. Confirming our previous results, we observed that repeated administration of cocaine for 5 days (15 mg/kg/day, i.p., 3-day withdrawal): (1) significantly hyperpolarized resting membrane potentials of NAc neurons as compared to controls, (2) significantly reduced responses to depolarizing current injection, and (3) significantly decreased action potential amplitudes. Superfusion of DA (50 μM , 2-3 min) caused small hyperpolarizations, inhibited action potential generation, and reduced spike amplitudes in saline-pretreated, but not in cocaine-pretreated, NAc neurons. SKF38393 (50 μM) exerted effects that were similar to, but more pronounced than, those of DA on saline-pretreated neurons, but again, not on cocaine-pretreated neurons. In fact, there was no significant difference in the electrophysiological properties of control NAc neurons recorded with DA or SKF 38393 as compared to cocaine-pretreated NAc neurons without DA or SKF 38393. We are now determining whether the results in cocaine-pretreated NAc neurons are due to tonic release of DA stimulating supersensitive D1Rs or to alterations in transduction events normally engaged by D1Rs (Support: DA 04093 and DA 00207).

364.4

BILATERAL IBOTENIC ACID LESIONS OF THE DORSAL PREFRONTAL CORTEX BLOCK THE EXPRESSION OF BEHAVIORAL SENSITIZATION TO COCAINE. R.C. Pierce*, J. Hicks, D. Reeder, Z.R. Morgan and P.W. Kaliyas, Alcoholism and Drug Abuse Program, Washington State University, Pullman, WA 99164.

Recent studies indicate that excitatory amino acid (EAA) transmission in the nucleus accumbens plays an important role in the expression of cocaine-induced behavioral sensitization (see Pierce et al., J. Neurosci., 16:1550-1560, 1996). In order to assess the influences of the various EAA projections to the nucleus accumens, bilateral ibotenic acid (5 μg/μl/side) or sham lesions of the ventral or dorsal prefrontal cortex (PFC), basolateral amygdala, fimbria-fornix or cortex (PFC), basolateral amygdala, limbria-form of periventricular thalamus were made two weeks after seven daily injections of cocaine (2 X 15 mg/kg, 5 X 30 mg/kg, ip). One week after surgery, all animals received a challenge injection of 15 mg/kg cocaine, ip. The expression of behavioral sensitization to cocaine was not influenced by any of the sham surgeries. The sensitized behavioral response was significantly attenuated only by a lesion of the dorsal PFC. which sends afferents to the core subregion of the nucleus accumbens. A separate experiment demonstrated that dorsal PFC lesions do not influence the behavioral response to an acute injection of cocaine. Taken together, these results indicate that alterations in the activity of the EAA pathway projecting from the dorsal PFC to the nucleus accumbens core contribute to the expression of behavioral sensitization. Supported by USPHS grants DA-03906, MH-40817 and DA-05589.

364.6

BOTH IONOTROPIC GLUTAMATE RECEPTOR ANTAGONISTS AND MEDIAL PREFRONTAL CORTEX (mPFC) LESIONS PREVENT NUCLEUS ACCUMBENS (NAc) DOPAMINE DI RECEPTOR SUPERSENSITIVITY AFTER REPEATED COCAINE TREATMENT. Y. Li*, M.E. Wolf and F.J. White. Dept. Neuroscience, FUHS/The Chicago Med. Sch., North Chicago, IL 60064

Behavioral sensitization after repeated cocaine treatment is mediated, in large part, by the mesocorticolimbic dopamine (DA) system. The underlying mechanisms of behavioral sensitization include both short and long-term cellular neuroadaptations within the system, such as VTA DA autoreceptor subsensitivity in the initiation of sensitization, and NAc DI receptor supersensitivity in the expression of sensitization. Accumulating evidence also suggests a crucial role for excitatory amino acid (EAA) transmission in the development of sensitization, especially the EAA projections from mPFC to the NAc and VTA. Both EAA receptor antagonists and mPFC lesions prevent the development of sensitization. We previously demonstrated that both ionotropic EAA receptor antagonists and mPFC lesions prevent VTA DA autoreceptor subsensitivity after repeated cocaine treatment. The present study investigates the role of EAA transmission in the development of NAc D1 receptor supersensitivity following repeated cocaine treatment. Since D1 receptor supersensitivity lasts for at least one month following repeated cocaine treatment, the experiments were performed after 4 to 8 days of withdrawal. Using microiontophoresis and single unit extracellular recordings, we found that co-administration of either the NMDA receptor antagonist MK-801 or the AMPA receptor antagonist NBQX with cocaine, in a protocol that prevents sensitization, also prevents NAc D1 receptor supersensitivity. We next lesioned the mPFC bilaterally with ibotenic acid. Subsequent repeated cocaine treatment failed to induce D1 receptor supersensitivity in the NAc. These results indicate that EAA transmission originating from mPFC is critical in the development of NAc D1 receptor supersensitivity. (Supported by DA 04093 & 00207 to FJW, and DA 07735 to MEW.)

364.8

INVOLVEMENT OF G B1 IN ESTABLISHMENT OF COCAINE SENSITIZATION X.B. Wang@*, M. Funada@, H. Ujike@, R.S. Revay@, K. Dehghani@, J.T. You@, & G.R. Uhl@#. @Molec. Neurobiology Br., NIH/NIDA, IRP; #Dept. Neurol. & Neurosci., JHUSM, Balto., MD 21224

Repeated doses of cocaine or amphetamine lead to long-lasting behavioral manifestations that include enhanced responses termed sensitization through biochemical mechanisms that remain currently largely unknown. To seek candidate biochemical mechanisms for these drug-induced neuroplastic behavioral responses, we have employed an approach termed subtracted differential display (SDD) to identify genes whose expression is regulated by these psychostimulants. $rG\beta_i$ is one of SDD products that encodes a rat G protein beta subunit expressed at high levels in neurons in the nucleus accumbens shell region, a major center for psychostimulant effects in locomotor control and behavioral reward. Cocaine and amphetamine each change levels of brain $rG\beta_i$ expression in region-specific patterns. Antisense treatments that attenuate $rG\beta_1$ expression in regions including the nucleus accumbens abolish the development of behavioral sensitization when they are administrated during the repeated cocaine exposures that establish sensitization. These treatments fail to alter acute behavioral responses to cocaine, and they are ineffective at blocking the expression of cocaine sensitization that is established prior to oligonucleotide administrations. Full, regulated $rG\beta_1$ expression is a biochemical component essential to establishment of a long-term consequence of cocaine administration.

NUCLEUS ACCUMBENS 6-OHDA LESIONS DO NOT PREVENT THE EXPRESSION OF A SENSITIZED LOCOMOTOR RESPONSE TO COCAINE. B.M. Prasad*, L. Churchill, P. Duffy and B.A. Sorg. Dept. VCAPP, Washington State University, Pullman, WA 99164

Psychostimulant-induced sensitization has been divided into two phases: initiation, which occurs in the VTA, and expression, believed to result from increased dopamine (DA) transmission in the nucleus accumbens (NAcc). However, recent work also implicates an important role for NAcc glutamate in the expression of sensitization (Pierce et al. J. Neurosci.16:1550). The present study therefore examined whether NAcc DA was necessary for the expression phase of sensitization. Male Sprague-Dawley rats were given 7 days of saline (n=5) or cocaine (n=5, 15 mg/kg on days 1 and 7 in photocell cages, 30 mg/kg on days 2-6 in home cages). Two weeks after the last injection, rats were pretreated with DMI and infused with 6-OHDA into the NAcc (4 µg/µl, 3 µl over 12 min). Lesions resulted in DA depletion in the NAcc of 88±4% and no significant effect on norepinephrine (NE) levels. Medial prefrontal cortex DA was depleted by 67±5% with no effect on NE levels, while there were no effects of 6-OHDA on dorsolateral striatal DA or NE levels, while there were no effects of 6-OHDA on dorsolateral striatal DA or NE levels. Twelve to 14 days later, all rats were monitored for activity after a saline challenge component or activity were found between daily saline and cocaine pretreated groups after saline challenge. Cocaine challenge did not elicit locomotion in 6-OHDA-lesioned rats pretreated with daily saline, in agreement with previous reports. However, lesioned rats pretreated with daily cocaine demonstrated a significant two-fold increase in activity for up to 30 min compared to saline controls, similar in magnitude and duration to the sensitized component routinely observed in non-lesioned rats. These results suggest that NAcc DA may not be required for the expression of long-term behavioral sensitization to cocaine. Alternatively, 6-OHDA lesions in the NAcc may after the circuitry used to express cocaine sensitization. This work was supported by USPHS Grants

THE 5-HT_{LA} ANTAGONIST WAY 100635 ATTENUATES COCAINE-INDUCED LOCOMOTOR HYPERACTIVITY, BUT NOT BEHAVIORAL SENSITIZATION. R. De La Garza II* and K.A. Cunningham. Department of Pharmacology, University of Texas Medical Branch, Galveston, TX 77555-1031.

The mesolimbic dopamine (DA) system is known to mediate the behavioral effects produced by cocaine (COC), while serotonin (5-HT) systems possess modulatory actions on DA systems and thus may potently modulate the effects of COC. For example, we have previously demonstrated that the 5-HT₁₃ agonist 8-OH-DPAT (DPAT) dose-dependently enhanced acute and chronic COC-induced hyperactivity localized to the periphery of photobeam activity monitors. To determine whether an attenuation of COC-induced hyperactivity would occur with an antagonist, we tested the 5-HT_{1A} antagonist WAY 100635 (WAY: 0.1 mg/kg. sc; N=8 rats/group) or saline (SAL) 15 min prior to an injection of COC (15 mg/kg, ip) or SAL twice daily for 7 days. On DAY 1, acute WAY significantly attenuated COC-induced hyperactivity without effecting baseline behaviors. On DAY 7, WAY pretreatment produced a similar attenuation of COC-induced hyperactivity. During withdrawal, challenge with COC alone produced similar levels of hyperactivity in animals exposed to the chronic WAY regimen (WAY+COC) vs. SAL+COC controls. Thus, WAY did not block the development of COC sensitization. Therefore, a 5-HT_{IA} agonist (DPAT) can enhance, while an antagonist (WAY) attenuates acute COC-induced locomotor hyperactivity, but these compounds do not modify the long-lasting changes that comprise behavioral sensitization.

COMPARISON OF SENSITIZATION TO COCAINE'S MOTOR ACTIVATING AND REINFORCING PROPERTIES PRODUCED BY COCAINE PREEXPOSURE <u>S. Schenk* and B. Partridge</u> Texas A&M University, Dept. Psychology, College Station, TX 77843

Repeated, intermittent administration of psychostimulants produces an enhancement of the subsequent behavioral effects of these drugs. This effect can be manifest as an increase in the magnitude of cocaine-induced hyperlocomotion or as a reduction in the latency to acquisition of cocaine self-administration. In the present study, we compared a number of preexposure conditions on the ability to sensitize rats to the motor activating or reinforcing effects of cocaine. Rats were pretreated with daily injections of cocaine (10.0 or 20.0 mg/kg) for 5 days. They received either a single injection per day or 2 injections separated by one hour. Context-dependent effects of preexposure were minimized by administering the pretreatments in a distinct environment from the testing environment. Three days following the last treatment, the acute motor activating effects of cocaine (5.0, 10.0 or 20.0 mg/kg) or the latency to acquisition of cocaine self-administration (0.25 mg/kg/infusion) were determined. Sensitization to both of the effects of cocaine was obtained. However, a less stringent preexposure regimen was required for sensitization to the motor activating effects of cocaine to be observed.

MICROINJECTIONS OF SCH23390 INTO THE VENTRAL PALLIDUM BLOCK THE DEVELOPMENT OF SENSITIZATION TO CHRONIC COCAINE. P.I. Johnson* and T.C. Napier. Neurosci. & Aging Inst. Div. for Res. on Drugs of Abuse Dept. of Pharmacology, Loyola Univ. Chicago, Sch. of Med., Maywood, IL 60153.

Chronic cocaine exposure is known to result in a sensitized motor response when animals, in withdrawal, are challenged with an acute cocaine injection. It is thought that the ventral tegmental area (VTA) is critical for the <u>development</u> of this sensitized response, whereas the nucleus accumbens (NAC) is important for the expression of the behavior. Given the direct projection from the NAC to the ventral pallidum (VP), the direct VTA dopaminergic projection to the VP, the importance of dopamine (DA) in psychostimulant sensitization, and the probability of generalized system alterations following chronic drug exposure, it is likely that the VP plays a role in the sensitization phenomenon. To investigate this possibility, three groups of rats were tested: a S-S group (n=4) received intra-VP microinjections of the DA D1 antagonist SCH23390 (2.5 µg/0.5 µl/side) 10 min prior to an i.p. saline injection, a S-C group (n = 3) received intra-VP microinjections of SCH23390 10 min prior to a cocaine (10 mg/kg i.p.) injection, and a V-C group (n = 5) received intra-VP microinjections of vehicle (0.3% tartaric acid/0.5 µl/side) 10 min prior to an i.p cocaine injection. This procedure was repeated daily for 5 consecutive days. Two days after the final injection, all rats received an acute cocaine (10 mg/kg, i.p.) challenge with no intra-VP microinjection pretreatment. ANOVA analysis revealed that the rats in the V-C group displayed a sensitized motor response to the acute cocaine challenge (914% increase over baseline activity; p < 0.01) when compared to either the S-S group (210% increase) or the S-C group (249% increase). There was no difference between the S-C and S-S groups (p = .81). Thus, the data collected to date suggest that the VP is important in the sensitization phenomenon as DA D1 receptor blockade in the VP appears to inhibit the development of cocaine-induced sensitization. EXTINCTION CAN ELIMINATE COCAINE CONDITIONED BEHAVIOR BUT LEAVE COCAINE SENSITIZATION INTACT. R. J. Carey* and J. Gui. Psychiatry, SUNY Health Science Center and Research and Development Service 151, VA Medical Center, Syracuse, NY 13210.

Repeated cocaine treatments in the same environment can lead to the development of a conditioned cocaine response and to context specific cocaine behavioral sensitization. The conditioned cocaine response is elicited by the environmental cues in the absence of cocaine whereas, the sensitization effects occur as an augmentation of the behavioral response evoked by the cocaine treatment. Since both phenomenon are linked to specific environmental cues, both are considered to involve association processes. A minimalist interpretation of these effects is to consider that the conditioned cocaine effects summate with the direct cocaine effects that the combination generate the behavioral sensitization effect. We directly investigated this possibility by comparing the cocaine sensitization effect in rats in which a conditioned cocaine response was maintained as compared to animals in which the cocaine response had been extinguished by six successive daily 20 min placements in the test environment following saline injections. Our findings showed that the six non-drug parings led to extinction of the cocaine conditioned response but did not modify the cocaine behavioral sensitization effects. We used five daily cocaine treatments (10 mg/kg) to induce conditioning and the control conditions included saline treated as well as unpaired cocaine (10 mg/kg) treatment groups which received the five cocaine treatments thirty min after each test session in the homecage. The behavioral measures of the cocaine response were determined with the use of a video image analysis system which tracked the location of the animal's head in a 60×60 cm open-field. Both locomotion distance and center zone entries were monitored and both measures showed conditioning and sensitization effects. The present findings support the proposition that conditioning and sensitization are distinct phenomenon and also point to the limitation of strictly behavioral treatments such as extinction to treat drug abuse problems.

PHARMACOLOGICAL SENSITIZATION TO COCAINE DEPENDS ON SIMILARITY BETWEEN INJECTION AND TESTING CONDITIONS. G. N. Carmona, S. R. Goldberg and C. W. Schindler*. NIH/NIDA Division of Intramural Research, Preclinical Pharmacology Laboratory, Baltimore, MD 21224

When animals are injected repeatedly in their home cages and tested in a different environment, pharmacological sensitization is assumed to have occurred if the response to the drug is larger than for animals injected repeatedly with saline. Having a different test environment is intended to control for conditioning that may contribute to sensitization when animals are injected repeatedly in the test environment. However, subtle similarities between the home cage and the test conditions may also allow conditioning to contribute to any apparent pharmacological sensitization. To test this possibility, we injected rats in their home cages with either 20 mg/kg ip cocaine (n = 18) or saline (n = 18) for 4 days. On the fifth (test) day, all animals were injected with 20 mg/kg cocaine in a different environment (locomotor activity cages). Half the rats were given their injections by the same individual who administered their previous injections and tested in locomotor activity chambers that contained the same wood chips used for bedding in their home cages (SIMILAR groups). The other half of the rats were injected by a different individual and tested in the same activity chambers with no bedding (NOVEL groups). Clear sensitization for distance traveled was observed for the cocaine-treated SIMILAR group, but not for the NOVEL group, despite the fact that they had the same experience with cocaine. These results indicate that conditioning contributed to the apparent pharmacological sensitization, even though the sites of the repeated injections and final test environment were different. The observation of an increased locomotor response to cocaine (sensitization) was dependent on the similarity of the chronic injection and test conditions. (Supported by NIDA DIR)

BEHAVIORAL CROSS-SENSITIZATION BETWEEN QUINPIROLE AND COCAINE IN PREWEANING RATS. E. Tirelli* & R. Schoonbroodt Pharmacopsychology Lab., University of Liège, Sart-Tilman Campus Bldg. B-32, B-4000 Liège-1, Belgium.

We have previously shown that preweaning rats are able to express behavioral sensitization to cocaine following regimens of 2 and 4 daily injections (submitted manuscripts). In this study, we examined the ability of preweaning pups to express cross-sensitization between the D2/D3 agonist quinpirole and cocaine, and conversely. In a first experiment, 7-, 14- and 21day-old pups were injected daily with either saline or cocaine (15 mg/kg, i.p.) over 3 consecutive days and challenged 24 hours later with either saline or quinpirole (0.025, 0.05 or 0.1 mg/kg, i.p.). In a second experiment, pups received 3 daily injections of either saline or quinpirole (0.05 mg/kg, i.p.) and were tested for cocaine responsiveness (7.5, 15 or 30 mg/kg, i.p.) on the fourth day. The testing context was kept constant throughout the pharmacological treatment. On test day, pups were filmed from underneath for 45 min and the video-records scored with a time-sampling technique. Behavioral categories mainly included locomotion, jumps, rearing and head movements. It appeared that 21-day-old pups expressed cross-sensitization from cocaine to quinpirole (locomotion, jumps), and vice versa (locomotion but not jumps), whereas younger pups showed no sign of cross-sensitization. Moreover, sensitization to quinpirole alone was weak in 14- and inexistant in the 7-day-old pups. These results contrast with our previous results showing cocaine-induced sensitization in pups of the same ages. Although higher doses of quinpirole need to be tested, the results suggest a neonatal immaturity of some of the dopaminergic mechanisms subserving sensitization to dopaminergic agonists. It might be the case that these mechanisms are not indispensable for cocaine-induced sensitization to be expressed. (Supported by the FNRS, Belgium)

BEHAVIORAL SENSITIZATION AND CROSS-SENSITIZATION FOLLOWING REPEATED TREATMENTS WITH COCAINE AND/OR MORPHINE. B.A.Mattingly*, J.K. Rowlett, L. Rice, T. Snyder, & C. Mossholder, Department of Psychology, Morehead State University, Morehead, KY 40351 & Department of Psychiatry & Human Behavior, University of Mississippi Medical Center, Jackson, MS, 39216.

Locomotor sensitization has been reported after repeated cocaine or morphine treatments. The present study evaluated the effects of repeated treatments of cocaine and morphine combined on the development of sensitization. In 3 experiments, male Wistar rats (250-300 g) were injected (IP) daily for 7 days with cocaine alone (0.0, 5.0, 10.0, 15.0, or 20.0 mg/kg), morphine alone (0.0, 1.25, 2.5, 5.0, or 10.0 mg/kg), or cocaine (0.0, 1.25, 2.5, or 5.0, or 10.0 mg/kg), or cocaine (0.0, 1.25, 2.5, or 5.0, or 10.0 mg/kg), were measured for 60 min in automated activity boxes (Med Assoc.). On Days 8-14, all rats were given vehicle-only injections prior to testing. On days 15 & 16, all rats were tested after a challenge injection of cocaine or morphine. Cocaine produced a dose-dependent progressive increase in activity across days (i.e., sensitization). Morphine alone also increased activity over days, but only at the intermediate dose (2.50 mg/kg). Crosssensitization was observed between cocaine and morphine on some, but not, all activity measures. The addition of morphine did not enhance the sensitizing effect of repeated cocaine treatments. Thus, the stimulating effects of cocaine and morphine do not appear to be additive.

EFFECTS OF CHRONIC AND CROSS TREATMENTS WITH N-[1-(2 BENZO(B)THIOPHENYL)CYCLOHEXYL)PIPERIDINE (BTCP) AND COCAINE ON EXTRACELLULAR DOPAMINE CONCENTRATION IN RAT STRIATUM. R. Martin-Fardon, L.M. Kamenka, W. Koek*, A. Privat and J. Vignon, INSERM U 336, CNRS UPR 9008, INSERM U 249, 34053 Montpellier, *Centre de Recherche Pierre Fabre, 81106 Castres, France.

BTCP and cocaine (Coc) both inhibit dopamine (DA) uptake, but bind to different

sites on the DA transporter (DAT). Male Wistar rats were submitted to 16 days chronic treatment (ChT: BTCP 10 mg/kg, Coc 20 mg/kg) followed by one week withdrawal or cross-treatments at the same doses (CrT: Coc 3 days/BTCP 10 days or BTCP 3 days/Coc10 days). The effects on extracellular DA concentrations ([DA]: no-nct-flux method), and on the amount of DA (QDA) in the striatum were investigated by a repeated in vivo microdialysis procedure.

On the first day of the ChT, Coc and BTCP similarly increased QDA (+76 and +107% respectively). During the Coc treatment, [DA]_e increased up to 250 % at day 7 and then, decreased to its initial value at day 13. In BTCP treated animals, [DA]_edid not vary markedly. During both withdrawal periods, [DA]_e remained stable. Qoa collected after drug challenges during ChT, paralleled the evolution of [DA]_e. A maximum at day 7 was observed with Coc (+2500 %). The effects of BTCP during day 7 to 16 represented about 60 % of its initial value. At the end of the withdrawai periods, both drugs increased Opa similarly to their initial effects.

In cross treatment experiments, BTCP pretreatment prevented Coc induced increases of [DA]s and partially, of QoA. Conversely in Coc-pretreated animals BTCP did not maintain the Coc induced increase of [DA]s. During the first day of its substitution, the effects of BTCP were increased (cross-sensitization), but up to the end of the treatment its effects were significantly lower than those of Coc.

Together, the results show that the effects on striatal DA produced by Coc exhibit sensitization, whereas those produced by BTCP exhibit tolerance. Their different binding sites on the DAT are suggested to be involved in their differential effects after chronic administration.

PHENCYCLIDINE-INDUCED LOCOMOTOR ACTIVATION DOES NOT CROSS-SENSITIZE TO COCAINE IN THE RAT. S. M. Melnick Clark and A. Ettenberg. Behavioral Pharmacology Laboratory, Department of Psychology, University of California at Santa Barbara, Santa Barbara, CA

The sensitization of locomotor activity induced by the psychostimulants, amphetamine and cocaine, has been well established. Several laboratories including our own have also reported the development of a sensitized locomotor response induced by phencyclidine (PCP). In the current study each rat received five injections at 48 hr intervals immediately prior to 90minute locomotor activity sessions. For the first four treatments, half the subjects were administered PCP (5 mg/kg IP) while the other half received physiological saline. On test day, subjects were further divided into a total of four groups. Rats pretreated with PCP received either PCP (a PCP-PCP group) or saline (a PCP-SAL group). Subjects pretreated with saline were administered either PCP (a SAL-PCP group) or saline (a SAL-SAL group). A sensitized locomotor response was only observed in the PCP-PCP group on test day. No within-group increases in locomotion were observed in the PCP-SAL, SAL-PCP or SAL-SAL groups on test day. In a second experiment, subjects that were similarly pretreated with either PCP (5 mg/kg IP) or saline received one of 3 doses of cocaine (10, 15, or 20 mg/kg IP) on test day in order to assess whether cross-sensitization occurs between the two compounds. Activity levels induced by the three doses of cocaine were not significantly different in rats pretreated with PCP when compared to rats pretreated with saline. These data suggest that cocaine-induced locomotor activity does not rely on substrates altered by chronic PCP exposure.

REDUCED VOLUME OF PREFRONTAL LOBE IN POLYSUBSTANCE ABUSERS: A MAGNETIC RESONANCE IMAGING STUDY. X. Liu*, J.A. Matochik, J.L. Cadet, E.D. London, Brain Imaging Section, Intramural Research Program, National Inst. on Drug Abuse, Baltimore, MD 21224.

The present study was conducted to test the hypothesis that structural deficits in the prefrontal cortex are associated with substance abuse disorder. Volumes of the prefrontal lobe in subjects with histories of polysubstance abuse were measured and compared with those in normal volunteers, using high-resolution magnetic resonance imaging (MRI)

Twenty men with histories of polysubstance abuse and thirteen male controls, 22-41 years old, participated in this study. Polysubstance abusers were abstinent from drugs of abuse (except nicotine) for at least 15 days before MRI scanning.

The total volumes of the prefrontal lobe (left and right hemispheres) were significantly smaller in the substance abuse group than in control group. When the prefrontal lobe was segmented for gray and white matter, subjects in the substance abuse group had significantly smaller volumes of gray but not of white matter than the normal volunteers. These results indicate that hypoplasia and/or atrophy in the prefrontal cortex accompany substance abuse, and suggest that structural deficits in the prefrontal cortex may play an essential role in the neuropathological basis of functional impairments in substance abuse disorder, as demonstrated by functional brain imaging and cognitive studies.

PHOSPHOLIPASE A2 ACTIVITY IS DECREASED IN THE BRAIN OF CHRONIC COCAINE ABUSERS. B.M. Ross*, A. Moszczynska, and S.J. Kish. Human Neurochemical Pathology Laboratory, Clarke Institute of Psychiatry, Toronto, Ontario, Canada. M5T1R8.

Dopaminergic transmission is most commonly associated with altered cyclic AMP levels via the modulation of adenylyl cyclase activity. However, dopamine receptors may also be linked to other signal transducing mechanisms such as the formation of prostaglandins and leukotriene second messengers via the 'arachidonic acid cascade'. The initial rate limiting step of this pathway is the hydrolysis of phospholipids to form free fatty acid, a reaction catalysed by the enzyme phospholipase A₂ (PLA₂). Thus, PLA₂ activation may be an important signal transducing mechanism for dopamine. and may contribute to the effects of drugs such as cocaine. In order to explore this hypothesis, PLA2 activity was measured in the autopsied putamen, occipital and frontal cortices, subcortical white matter, and cerebellum of 10 subjects who had been previously been taking cocaine regularly for a period of at least 12 months, and compared to that in 10 age and sex matched control subjects. The activity of PLA2 in the putamen was found to significantly (Student's t-test; P<0.01) decreased by 36% in cocaine abusers compared to control subjects, but was unchanged in the other brain areas examined (P>0.40 in all comparisions). Our data suggest that chronic cocaine use reduces the rate of membrane breakdown in areas of high dopamine receptor density, possibly as desensitising mechanism to the presence of the drug. Supported by NIDA grant 07182.

THE NEUROANATOMY OF DRUG CRAVING IN CRACK COCAINE ADDICTION: A PET ANALYSIS. J. Schweitzer. K. Drexler. C. Quinn. F. Muhammad. R. Gross. T. Faber. J. Hoffman and C. Kills Departments of Psychiatry, Neurology, and Radiology, Emory Center for PET, and the Atlanta VA, Emory University, Atlanta GA 30322

The high rate of recidivism associated with the treatment of crack cocaine dependence is plausibly related to frequent and intense drug craving. We have used a PET neuroactivation analysis to define the functional organization of the craving human brain in crack dependence. Subjects were right-handed african-american males admitted to the VA for treatment of crack cocaine dependence. Study inclusion criteria included the absence of opiate, ethanol or marijuana dependence, and above-average mental imagery ability and a positive history of drug craving. Individualized scripts were constructed from the memory content of the physiological reactions and environmental contexts of crack cocaine use or of an anger-provoking scene. Positron Emission Tomography (PET) images were acquired using the blood flow tracer H₂¹⁵O. Sessions included image acquisitions during a resting condition, and during imagery of binaurally presented control (beach or forest), cocaine use, or anger scenes. Subjects reported vivid imagery for all scenes, and moderate to intense craving or anger associated with imagery of the respective scenes. Imagery-induced drug craving, compared to control scene imagery, was associated with activation of temporal, frontal and cingulate sites, predominantly lateralized to the left hemisphere. The amygdaloid complex was not activated during craving induction. Induced drug craving and anger were associated with comparable increases in heart rate. Imagery-induced anger, accordated with activation in the order and accordance with activation of the left amygdaloid complex, and orbital frontal, cingulate and temporal cortex. Common sites of activation in the orbital frontal, middle temporal and cingulate cortex were associated with induced drug craving and anger. These results support the use of script-guided mental imagery in functional neuroimaging of drug craving. Funded by the Emory Center for PET.

BRAIN CORRELATES OF CUE-INDUCED COCAINE AND OPIATE CRAVING A.R. Childress, W. McElgin, D. Mozley, M. Reivich, and C.P. O'Brien*. Addiction Treatment Research Center, Univ. of Penn. School of Medicine, and Philadelphia VA Medical Center, Philadelphia, PA 19104

Drug-related cues (e.g., drug users, drug talk, drug locations, drug paraphernalia, etc.) can trigger profound desire in users of opiates and cocaine, but the brain correlates of this "craving" state are just beginning to be delineated. In a recently completed study, cocaine patients showed rCBF (regional cerebral blood flow) increases in amygdala, anterior cingulate and temporal pole during craving induced by exposure to a cocaine video. Systematic activation did not occur in non-limbic comparison regions, nor in response to a comparison non-drug video. Control subjects did not experience craving during the cocaine video, and did not show systematic rCBF increases to either video type. These results suggested limbic activation may be one component of cue-induced cocaine craving.

We are investigating whether limbic brain areas will be similarly activated in opiate patients during exposure to opiate vs. non-drug cues. Increased drug desire and sympathetic arousal are common to both cocaine and opiate cue reactivity, but other phenomenological features (e.g., the salience of drug-like vs. drug-opposite symptoms) can differ substantially. As in the prior study, rCBF is imaged in opiate patients during exposure to videos of both non-drug and opiate-related scenes. Imaging of rCBF is videos of both holl-drug and oplate-leaded scenes. Intaging of ICM is accomplished with PET (Positron Emission Tomography) scans, using radioactively-labeled (O-15) water as the flow tracer. PET scans for each subject are co-registered with an MRI (magnetic resonance image) to permit anatomical localization of radioactivity. Results from the opiate patient sample will help determine whether the limbic activation found in cocaine NIDA P-50-DA-05186 craving is generalizable to other drug craving states.

EFFECTS OF ACUTE PRETREATMENT WITH RISPERIDONE ON RESPONSES TO COCAINE IN COCAINE-DEPENDENT HUMANS. <u>L.H.</u> Price.* G.H. Pelton, C.J. McDougle, R.T. Malison, P. Jatlow, L. Carpenter, P.D. Kirwin, D.W. O'Brien, G.R. Heninger. Clinical Neuroscience Research Unit, Dept of Psychiatry, Yale Univ. School of Med., 34 Park St., New Haven, CT. 06519. Although antagonism of the dopamine (DA) and serotonin (5-HT) systems has

Although antagonism of the dopamine (DA) and serotonin (5-HT) systems has been shown to attenuate the effects of cocaine (COC), conventional neuroleptics have not been useful in the clinical treatment of COC addiction because of adverse effects. However, the novel neuroleptic risperidone (RISP), a D2/5-HT2 antagonist, is better tolerated than conventional agents. To evaluate the clinical potential of this agent in humans, we administered RISP to COC addicts and assessed their response to intranasal COC. METHOD: 16 hospitalized subjects (11 males, 5 females) with a DSM-IV diagnosis of COC dependence received three intranasal COC challenges (2.0 mg/kg), each preceded by acute pretreatment with RISP 0, 2, or 4 mg po. The sequence of test sessions was determined in randomized, double-blind fashion. Subjective effects (e.g., intensity of "high" on visual analog scales), biochemical effects (e.g., neuropadogring personness), physiological effects (e.g., RP and HR), and effects (e.g., neuroendocrine responses), physiological effects (e.g., BP and HR), and adverse effects (e.g., extrapyramidal symptoms) were assessed. **RESULTS:** When adverse effects (e.g., extrapyramidal symptoms) were assessed. RESDL18: When data from all 16 subjects were analyzed, RISP showed no clear effect on the subjective "high" response to COC. However, when the analysis was limited to only those subjects manifesting a robust "high" response to the COC test dose (n=8), effects of RISP were highly significant (p<.008). RISP 2 mg resulted in a 42% (p<.002) attenuation of the "high" response, whereas RISP 4 mg caused a 32% (p<.051) attenuation. CONCLUSION: In COC addicts who report a robust subjective response to intranasal COC, acute pretreatment with RISPattenuates COC-induced euphoria. This effect of RISP is suggestive of an inverted U-shaped dose-response curve, with the 2-mg dose clearly more effective than placebo and somewhat more effective than the 4-mg dose. Since RISP was well-tolerated in our subjects, further examination of RISP as a treatment for COC addiction is warranted Funding Source: National Institute on Drug Abuse

NEUROCHEMICAL ALTERATIONS IN THE HUMAN BRAIN FOLLOWING ACUTE COCAINE ADMINISTRATION ASSESSED BY 'H MAGNETIC RESONANCE SPECTROSCOPY. S-J. LI*, J. Pankiewicz#,

FOLLOWING ACUTE COCAINE ADMINISTRATION ASSESSED BY 'H MAGNETIC RESONANCE SPECTROSCOPY, S-J. LI\$, J. Pankiewicz#, Y. Wang\$, A.S. Bloom¹, L.C. Terry¹¹, and E.A. Stein§8-¹, §Biophysics Research Institute and Departments of 'Pharmacology, 'Neurology and 'Psychiatry. Medical College of Wisconsin, Milwaukee, WI 53226.

Little is known about the acute neurochemical and metabolic consequences of cocaine administration in the human CNS. This study utilized 'H MR spectroscopy to follow the effects of a single acute injection of cocaine. Generally healthy, cocaine dependent subjects were recruited from the general population (n=5). All met DSM IV criteria for cocaine abuse and gave informed consent following IRB approval. Following a urine drug screen, subjects presented for an inpatient drug run-up protocol to assure drug safety, prior to MRS scanning. MR experiments were performed on a GE 0.5 whole body imaging system. A 4" flexible surface coil was used for both image localizer and PRESSCSI spectroscopy. A 1.5 x 2.5 x 1.5 cm region of interest was defined over the left frontal lobe. Spectra were obtained every 4 min for 16 min prior to and 40 min after a 40 mg IV injection of cocaine. Absolute peak spectra intensities were used to quantify neurochemical changes using the GE Medical Systems SA/GE package. Levels of N-acetyl aspartate, creatine/phosphocreatine and choline were unchanged after drug injection, while glutamine/glutamate levels decreased at 10 min. In contrast, inositol levels progressively decreased in a time-related manner after cocaine and remained more than 12% below baseline for 40 min post drug, indicating a decline in the levels of free inositol containing phopholipids. These data may in part reflect a cocaine-induced alteration in the functioning of inositol based second messenger systems. Supported in part by USPHS grant DA-09465 to EAS.

MOTOR FUNCTION DEFICIT IN COCAINE ABUSE. P.B. Vrtunski* and R.A. McCormick, Cleveland VAMC and Department of Psychiatry, CWRU School of Medicine, Cleveland, OH 44141.

There has been little systematic investigation on motor deficits in cocaine addiction. Also, when dealing with other clinical groups (schizophrenics or affective disorders) where patients may have had a history of drug abuse, its confounding effect is not known. We present here two studies with a force control (FC) technique comparing normal controls and cocaine addicts. The principal question raised was whether the cocaine addicts show any deficit in force control function, and if so, how large the deficit is. In the first study a group of 31 control subjects were compared to 34 agematched cocaine addicts from the VA Drug Abuse treatment program. The FC task consisted of 90 6-second long trials in which the subject was instructed to match a target light with a response light. The response was patients' index-finger pressure on a force-sensitive button. There were 10 targets of increasing force (5 to 562 centi-Newtons), each presented 9 times. The steadiness of force maintenance was the dependent variable. In the second study, 16 control and 15 cocaine addicts, matched for age, education and hand-strength, were compared with a similar test at three force ranges (9-235, 17-478 and 26-717 cN). Results indicated that addicts had a deficit in capacity for fine motor control in both studies and throughout the force output range (F(1,63) = 4.80, p < 0.05 and F(1,29) = 5.02, p < 0.05, respectively). Based on these findings we suggest that a) cocaine addiction may be accompanied by a small but discernible deficit in fine motor control, and b) that in assessment of patients from other clinical populations this confounding factor should be taken into account. (Supported by the Veterans Administration and USPHS grant MH-46630)

PHENOMENOLOGY OF INPATIENT COCAINE WITHDRAWAL, D.A. Gorelick*, R. Stauffer, J.-K. Zubieta# and J.J. Frost#. NIDA/NIH Div. of Intramural Research, Balt., MD 21224, & #Dept. of Radiology, Johns Hopkins Univ. School of Medicine

To better understand the psychological and physiological manifestations and time course of cocaine withdrawal, we prospectively evaluated 11 physically healthy, cocaine-dependent (DSM-IIIR), medication-free subjects (10 men, 10 African-American, 1 white, mean [SD] age 31 [3.7] years, lifetime cocaine use 5.5 [4.1] years, using 3.5 [1.5] g/week, last use 13.1 [16.5] hours before admission) housed on a closed research ward for 28 days. Pulse and blood pressure stabilized in the normal range over the first 2-3 days, computerized digit symbol substitution test performance and sleep duration and quality improved over the first 3-5 days, and mood scores (within normal range at admission) and cocaine craving progressively declined over the first 7-10 days. All variables remained stable over the last 2-3 weeks. These findings suggest that signs and symptoms of moderate cocaine withdrawal progressively normalize over 7-10 days without medication in an inpatient setting, and are not consistent with the previously reported triphasic model of outpatient cocaine withdrawal Supported by NIDA intramural research funds

ROLE OF CENTRAL ADRENERGIC RECEPTORS AND CHOLINERGIC NEURONS IN THE PRESSOR RESPONSE TO CENTRAL INJECTION OF COCAINE. J.A. Davis, II. L.C. Shuster, G.S. Doetsch* and J.J. Buccafusco, Depts. of Pharmacology and Toxicology, and Neurosurgery, Medical College of Georgia, and Dept. Veterans Affairs Medical Center, Augusta, GA, 30912.

Activation of both central and peripheral sympathetic sites can contribute to the cardiovascular symptoms associated with cocaine administration. However, very little is known concerning the mechanism for cocaine's central sympathetic actions. Although cocaine can indirectly activate central adrenergic receptors, the drug recently has been reported to interact directly with muscarinic receptors. This latter action of cocaine is relevant because stimulation of central cholinergic (muscarinic) neurons can evoke a sympatho-excitatory response. The purpose of this study was to determine whether direct central injection of cocaine could increase mean arterial pressure (MAP) and heart rate (HR), and whether such changes were mediated through central α-adrenergic receptors or cholinergic neurons. Lateral ventricular injection of cocaine HCl (24-96 µg) produced a dose-dependent increase in MAP up to 26 mmHg in conscious, freely-moving normotensive rats. However, intracisternal (i.c.) injection of 48 µg of cocaine evoked a significantly greater increase in MAP of 41 mmHg with no significant change in HR. The increase in MAP began within 1 min after injection and lasted about 10 min. I.c. pretreatment with 20 µg of the acetylcholine depleting agent hemicholinium-3 did not significantly alter resting MAP or HR, but inhibited the expression of the pressor response to subsequent (1 hr later) injection of 48 μg of cocaine by 63%. Blockade of central αadrenergic receptors following i.e. pretreatment with 27.8 or 55.6 μg of tolazoline did not significantly alter resting blood pressure. Moreover, tolazoline did not significantly reduce the expression of the pressor response to subsequent injection of cocaine. These results are consistent with a lower brainstem (rather than diencephalic) site of action of cocaine, and for the possibility that local cholinergic 'pressor' neurons (rather than α-adrenergic receptors) play an important role in the sympathoexcitatory action of the drug. Supported by the Dept. Veterans Affairs Medical Research Service.

THE EFFECTS OF GAMMA-VINYL GABA ON COCAINE-INDUCED LOWERING OF BRAIN-STIMULATION REWARD THRESHOLDS. <u>S.A.</u> Kushner*, S. L. Dewey¹, and C. Kornetsky. Departments of Pharmacology and Psychiatry, Boston University School of Medicine, Boston, MA 02118 and ¹Chemistry Department, BNL, Upton, NY 11973.

Gamma-vinyl GABA (GVG), a suicide inhibitor of GABA:2-oxo-glutarate aminotransferase (GABA-T), raises levels of GABA in nerve terminals. An experiment by Chen et al. (Neuroscience Abstracts, 767.5, 1995) found that GVG inhibits striatal dopamine (DA) release and attenuates the increases in extracellular striatal DA and locomotor activity induced by cocaine administration. In order to examine potential modulatory effects of GABA on DA-mediated reward, the effects of GVG on brain stimulation reward (BSR) thresholds were determined in 6 male F-344 rats with bipolar electrodes implanted in the medial forebrain bundle (MFB). GVG dose-dependently raised BSR thresholds at doses of 200, 300, and 400 mg/kg without significant effects on motor performance. In order to determine if GVG had similar modulatory effects on cocaine-induced lowering of BSR thresholds, the effective doses of GVG were co-administered with 2.5 and 5.0 mg/kg cocaine, doses that significantly lower BSR thresholds. Only the 400 mg/kg dose of GVG significantly blocked the lowering of thresholds seen at each dose of cocaine Cocaine in combination with 200 or 300 mg/kg GVG, doses of GVG that significantly raise BSR thresholds, resulted in thresholds not significantly different from those obtained with cocaine alone. These data suggest that GABA may play a greater role in modulating basal reward thresholds than in modulating thresholds lowered by cocaine, and thus GABA may be less effective in mediating drug-induced enhancement of the DA system than in mediating basal dopaminergic activity. IN VIVO ELECTROCHEMICAL STUDIES OF DOPAMINE CLEARANCE IN THE CORE AND SHELL OF RAT NUCLEUS ACCUMBENS. D.J. David*, N.R. Zahniser, and G.A. Gerhardt. Depts of Pharmacology & Psychiatry, and the Neuroscience Training Program, University of Colorado Health Sciences Center, Denver, CO 80262.

The nucleus accumbens (NAc) has been subdivided into core, which is thought to be functionally related to neostriatum, and shell, which is considered to be part of the limbic system. In vivo microdialysis studies have shown that psychomotor stimulants preferentially increase extracellular dopamine (DA) levels in NAc shell, as compared with core. (Pontieri et al. Proc. Natl. Acad. Sci. USA 92:12304, 1995) In the present study, in vivo electrochemical recordings were performed in the core and shell of the NAc of urethane anesthetized rats in order to investigate the effects of cocaine on DA clearance, a measure of DA transporter (DAT) activity. Measurements involved local application of DA from micropipettes positioned 300 ± 25 μm from Nation-coated single carbon fiber electrodes, and changes in extracellular DA were recorded using rapid (5Hz) chronoamperometric measurements. DA (5-20 picomoles) was applied by pressure ejection at 5-min intervals. Once reproducible signals were obtained, the effects of cocaine (20 mg/kg; i.p.) were investigated. Preliminary results suggest that cocaine produced a more robust increase in the amplitude of the DA signal in the shell, as compared to the core. However, cocaine administration did not appear to have a differential effect on the DA clearance times in the two areas. These results support the hypothesis that the proposed preferential effects of drugs, like cocaine, on extracellular DA concentrations in shell, versus core, of NAc may be due to a differential responsiveness of the DAT in these two subregions of NAc. (Supported by USPHS grants NS-09199, DA-00174, DA-04216, and NIH training grant HD7408).

D1 RECEPTOR MODULATION OF GABA TRANSMISSION IN THE VENTRAL TEGMENTAL AREA OF THE RAT.

C.D. Fiorillo* and J.T. Williams. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201

In the Guinea Pig, activation of presynaptic dopamine D1 receptors enhances GABA_B-mediated IPSPs in dopamine cells of the ventral

In the Guinea Pig, activation of presynaptic dopamine D1 receptors enhances GABA_B-mediated IPSPs in dopamine cells of the ventral tegmental area. One to two weeks after cessation of chronic treatment with cocaine or morphine, D1 activation inhibits GABA transmission through simultaneous activation of presynaptic adenosine A1 receptors. In addition, endogenous levels of adenosine are elevated. Because little is known about the behavioral aspects of chronic treatment with addictive drugs in the guinea pig, we are now examining these same physiological phenomena in brain slices from Wistar rats sensitized to the locomotor stimulant effects of cocaine. The locomotor effect of cocaine (10 mg/kg) was tested one day before and 7 days after 14 daily injections of saline or cocaine (20 mg/kg). Intracellular recordings were performed 10-20 days following the cessation of daily injections. The D1 agonist SKF 82958 (1 µM) caused an 80% increase in the amplitude of the IPSP in saline-treated rats. In cocaine-treated rats, SKF 82958 produced a 30% increase in the IPSP. The A1 antagonist DPCPX, which augmented the IPSP by 10% in saline-treated animals, had variable effects in cocaine-treated animals but caused a mean increase of 70%. It appears that the D1- and A1-mediated changes in synaptic efficacy in the VTA induced by chronic cocaine treatment are qualitatively the same in rats and guinea pigs.

ROLE OF DA RECEPTOR SUBTYPES IN LOCOMOTOR STIMULANT EFFECTS OF COCAINE. <u>D.A. Lytle, M.J. Forster, S.A. Wild, C.S. Elsken, D.E. Johnston Jr, H. Lal, D.L. Barker*, and R.R. Luedtke.</u> Dept. Pharmacology, University of North Texas Health Science Center at Fort Worth, Fort Worth, TX 76107.

The purpose of the present study was to investigate the relationship between affinity of DA antagonists at D1 receptors and their potency to either suppress locomotor activity or antagonize the locomotor-stimulant effects of cocaine. Competition curves for 14 DA antagonists were performed against ³H SCH-23390 in caudate harvested from Swiss-Webster mice to determine their Ki values. Locomotor activity was measured in separate groups of nonhabituated Swiss-Webster mice following each DA antagonist alone or in combination with a maximal stimulant dose of cocaine. The ${\rm ID}_{50}$ (dose producing 1/2 maximal depressant activity) and ${\rm AD}_{50}$ (dose attenuating cocaine-induced stimulation by 50%) were calculated for each antagonist and compared with binding data. There were significant positive relationships between the affinity at D1 receptors and potency for depression of locomotor activity (ID₅₀) and potency for antagonism of cocaine-induced stimulation (AD₅₀). The Ki values were most closely associated with potency for antagonism of cocaine-induced locomotor stimulation. [Supported by U.S.D.H.H.S.-P.H.S contract NO1-DA-2-9305.]

IN VIVO MICRODIALYSIS IN AWAKE SQUIRREL MONKEYS: EFFECTS OF COCAINE ON EXTRACELLULAR DOPAMINE. L. L. Howell*, P. W. Czoty, J. B. Justice and J. E. Majors. Yerkes Reg. Primate Res. Ctr., Emory Univ., Atlanta, GA 30322.

In vivo microdialysis experiments were conducted in two awake squirrel monkeys seated in a standard primate chair to characterize cocaine-induced changes in extracellular dopamine. Under general anesthesia, guide cannulae were implanted bilaterally into caudate, and subjects were allowed 2-3 weeks recovery. During test sessions, analytical probes were inserted into the cannulae and perfused with aCSF at a flow rate of 2 µl/min. Samples were collected at 10-min intervals and assayed by microbore HPLC with electrochemical detection. Dialysate dopamine concentrations stabilized during a 2-3 hr equilibration period. Several concentrations of dopamine (10-100 nM) were added to the perfusate during 30-min periods, and the point of no net gain or loss estimated basal tissue levels at 14-22 nM. Cocaine (1.0 mg/kg) administration i.m. increased extracellular dopamine approximately 3-fold, and levels returned to baseline within 30-50 min. Repeated, biweekly sampling through the same cannulae yielded consistent results during 4 determinations. Pretreatment with the serotonin uptake inhibitor, alaproclate, had no effect on cocaine-induced changes in extracellular dopamine. This study establishes a useful model to investigate the neuropharmacology of cocaine in awake, nonhuman primates. (Supported by USPHS Grants DA-01162 and RR-00165).

COCAINE EFFECTS ON DOPAMINE IN RAT NUCLEUS ACCUMBENS: MICRODIALYSIS STUDIES. G.T. Golden*, T.N. Ferraro, F.A. Grau, G.R. Cupples. W.H. Berrettini, W.H.Vogel. Department of Veterans Affairs Medical Center, Coatesville, PA 19320 and Jefferson Medical College of Thomas Jefferson University, Philadelphia, PA 19107
Prevailing evidence suggests that the behavioral effects of cocaine are mediated by increased dopaminergic transmission in nucleus accumbens (NAC); however, direct evidence that mesocorticolimbic dopaminergic transmission correlates with voluntary cocaine consumption is lacking. In the present study male Sprague-Dawley rats were characterized by basal extracellular microdialyzate DA levels in NAC and studied with respect to the DA response in NAC to an acute injection of cocaine (20mg/kg, ip). NAC dialysates showed a wide range of baseline extracellular DA levels (range 13.2 - 74.5 pm/ml, mean 37.9 pm/ml, s.d. 16.1). There was a significant positive correlation (r = 0.68, p=.006) between baseline DA levels in NAC were usually reestablished within one hour following cocaine injection and there was high reliability (r=+0.88, pc.0001) between baseline DA measures taken prior to and following in injection of cocaine. A paired t-test comparison of pre-cocaine baseline DA levels with post-cocaine baseline DA levels showed no significant differences. These same rats are currently in a two-bottle (0.2% saccharin-water vs. 0.2% saccharin-cocaine 2%) choice paradigm in order to determine voluntary cocaine intake. Voluntary cocaine consumption will be correlated with reference baseline DA and acute cocaine-evoked DA levels in NAC. Supported by the Department of Veterans Affairs and NIH grant R01 DA 08848-02.

DIFFERENTIAL EFFECTS OF LOCALLY APPLIED AND I.V. SELF-ADMINISTERED COCAINE ON ACETYLCHOLINE RELEASE IN THE RAT NUCLEUS ACCUMBENS. G. P. Mark* & A. S. Keys. Dept. of Behavioral Neuroscience, Oregon Health Sciences Univ. Portland, OR 97201

An intravenous cocaine (COC) self-administration paradigm and reverse-dialysis perfusion were used to study the effects of COC on acetylcholine (ACh) release by microdialysis in the nucleus accumbens (NAc). In the first study, ACh release in the NAc was measured before, during and after 15 min COC (0.01, 0.03, 0.1 & 1 measured before, during and after 15 min COC (0.01, 0.03, 0.1 & 1 mM) perfusions via the microdialysis probe. Intra-accumbal infusion of 10 or 30 μ M COC did not alter ACh output. Conversely, during 100 μ M COC, ACh release was mildly depressed and at 1 mM release was decreased to 53% of control levels. These effects were possibly due to the local anesthetic property of COC at these doses. For the second experiment rats were implanted with jugular catheters and accumbens guide shafts and trained to lever-press for i.v. infusions of 0.4 mg/kg COC. After training, probes were inserted through the guide shafts and NAc ACh output was monitored in 15 min intervals before, during and after 3 hr sessions of drug availability. In response to self-administered COC, ACh release steadily increased to a maximum of 200% of pre-drug levels and remained elevated for an maximum of 200% of pre-drug levels and remained elevated for an additional 1.25 hr following drug availability. These results suggest a differential effect on NAc ACh release depending on the method of cocaine administration.

SYNERGISTIC EFFECTS OF COCAINE AND DIZOCILPINE (MK-801) ON BRAIN STIMULATION REWARD. R. Ranaldi*, P. Bauco and R.A. Wise. Dept. of Psychol., Concordia Univ., Montreal Canada H3G 1M8

The synergistic effects of dizocilpine (MK-801), a noncompetitive

N-methyl-D-aspartate (NMDA) antagonist, and cocaine on lateral hypothalamic brain stimulation reward were evaluated. Eight male Long-Evans rats were trained to perform a lever-press operant to deliver trains of cathodal rectangular pulses directly into the lateral hypothalamus. Rate-frequency functions were determined by logarithmically decreasing the number of pulses in the stimulation train from a value that sustained maximum responding to one that did not sustain responding (thresholds). After thresholds had stabilized each rat was tested under 4 treatment conditions; saline+saline, dizocilpine (0.05 mg/kg, ip, 30 min before test)+saline, saline+cocaine (4 mg/kg, ip, 5 min before test) and dizocilpine+cocaine. The saline+saline and dizocilpine+saline treatments did not affect brain stimulation reward thresholds or maximum responding. The saline+cocaine treatment appeared to produce a small, non-significant reduction of thresholds and no effect on maximum responding. The dizocilpine+cocaine treatment produced large reductions in thresholds to levels significantly lower than those in the saline+cocaine treatment indicating a synergism between the two drugs and a role for the NMDA receptor in brain stimulation reward. These synergistic effects of dizocilpine and cocaine stand in contrast to the putative antagonism by dizocilpine of cocaine's psychomotor-sensitizing action. Supported by the National Institute on Drug Abuse (DA01720).

ROLE OF PROTEIN KINASE C ON THE ACQUISITION AND EXPRESSION OF COCAINE CONDITIONING PLACE PREFERENCE IN RATS. L. Cervo, S. Mukherjee, A. Bertaglia, S. Consolo* and Rosario Samanin, Istituto di Ricerche Farmacologiche "M. Negri". Milano, Italy.

A balanced conditioning place preference (CPP) paradigm was used to

study the role of protein kinase C (PKC) on the acquisition and expression of cocaine place conditioning. H7, a non specific inhibitor of PKC, administered intracerebroventricularly at 10 (but not 1) µg/10 µL immediately after cocaine conditioning during the training phase, significantly blocked the establishment of place conditioning. The same dose had no effect when administered before cocaine during the training phase or before testing for place preference in the absence of cocaine phase or before testing for place preference in the absence of cocaine (expression). Chelerythrine, a specific PKC inhibitor, partially reduced the establishment of cocaine CPP when administered intracerebroventricularly immediately after cocaine conditioning at 3 (but not 1) μg/10 μL. The results suggest that PKC is not involved in the primary reinforcing properties of cocaine or in the behaviour elicited by the stimuli previously associated with the drug action (CPP expression). the stimun previously associated with the drug action (CPP expression). The PKC seems to play a selective role in some processes involved in the consolidation and storage of information. Since H7 blocks also protein kinase A, which is involved in drug addiction, experiments are in progress to examine the role of this kinase on the acquisition and expression of cocaine CPP.

The study was supported by Consiglio Nazionale delle Ricerche, Rome, Italy, Convenzione Psicofarmacologia.

ISCHEMIA: GLUTAMATE

PRIOR ETHANOL TREATMENT DECREASES GLUTAMATE RELEASE DURING ISCHEMIA AND POTENTIATES GLUTAMATE RELEASE POST-ISCHEMIA IN GERBIL HIPPOCAMPUS, S. McCrea*, T. Wishart, H. Miyashita, S. Ijaz, W. Howlett and A. Shuaib. Saskatchewan Stroke Research Centre, Univ. of Saskatchewan, Saskatoon, Sask. Canada S7N 0W8

Previous studies have found that prior ethanol consumption may aggravate stroke outcome. Gerbils were administered subcutaneous chronic ethanol injections for 21 days at dosages of 1 and 4 g/kg. Nine days after cessation of injections subjects underwent bilateral carotid occlusion while simultaneously monitoring amino acid neurotransmitter levels in the hippocampus with in-vivo microdialysis. Both the low and high dose ethanol groups demonstrated markedly decreased glutamate release as compared to the saline-injected group immediately post-ischemia. Progressive increase in the extracellular concentrations of glutamate post-ischemia in the ethanol treated groups was also noted. These results are consistent with developing ethanol-induced NMDA receptor sensitization, both pre- and post-synaptically. Apparent ethanolic protection of ischemic striatal neurons highlights the need for further study of the role that prior ethanol consumption may play in the altered neurochemistry and outcome in stroke. This research was supported by a grant from the Heart and Stroke Foundation of Saskatchewan to A. Shuaib.

SPATIAL AND TEMPORAL ALTERATIONS IN THE EXPRESSION OF THE NEURONAL GLUTAMATE TRANSPORTER IN HIPPOCAMPUS FOLLOWING TRANSIENT GLOBAL FOREBRAIN ISCHEMIA. W.R. Woodward*, M.G. Klein, N. Lessoy, S.G. Amara and G.H. Murdoch. Depts. Of Neurology and Pathology and the Vollum Institute, Oregon Health Sci. Univ., Portland, OR 97201. Following ischemic injury in the mammalian central nervous system a

complex cascade of cellular changes is initiated that culminates in the death of selectively vulnerable populations of neurons. We investigated the spatial and temporal sequence of changes in the expression of one of the neuronal, high affinity transporters for glutamate (EAAT₃) in specific populations of hippocampal neurons following a defined, reproducible ischemic insult. Transient forebrain ischemia (15 min, 25 torr bp) was induced in male Sprague Dawley rats using the Siesjö 2-vessel occlusion model. Animals were sacrificed at times ranging from 1 hr to 14 days after ischemia by transcardial perfusion, and

times ranging from 1 nr to 14 days after ischerina by transcalular pertusion, and 40 µm frozen sections were reacted with antibodies for EAAT₃. Antigens were localized in the tissue using the avidin-biotin complex staining procedure. Immunoreactivity for EAAT₃ is normally present throughout the neuropil of the hippocampus and stains perikaryal membranes and proximal dendritic processes of CA1-CA3 pyramidal neurons and granule cells of the dentate gyrus. EAAT₃ staining increased in pyramidal cells between 6 and 24 hours then remained constant for at least 14 days postischemia despite the death of CA1 pyramidal neurons after 2-days. The persistence of EAAT₃ staining in CA1 neurons after 2-days likely represents membranes of deceased neurons not yet cleared from the tissue. EAAT₃ staining faded to background in the neuropii of CA1 (strata oriens and radiatum) and in lacunosum moleculare by 2-days postischemia, reflecting the death of the CA1 neurons. These alterations in the pattern of EAAT₃ immunostaining appear to be the result of both changes in EAAT₃ expression and subcellular localization and may be an attempt by these cells to mount a protective response to the insult. Supported by NS17493, NS33273 and the Howard Hughes Medical Institute.

ANARYSIS OF DISTINCT BIPHESIC GLUTAMATE RELEASE USING A DIALYSIS ELECTRODE IN RAT ACUTE BRAIN ANOXIA. S. Asai^{1*}, Y. Iribe¹, T. Kohno² and K. Ishikawa¹. ¹Department of Pharmacology, Nihon University School of Medicine, Tokyo 173, Japan: ²Frontier Technology Research Institute, Tokyo Gas Co., Yokohama 230, Japan

Glutamate plays a key role in acute brain anoxia. We report here the successful application of a real-time method for monitoring the glutamate in the extracellular

Glutamate plays a key role in acute brain anoxia. We report here the successful application of a real-time method for monitoring the glutamate in the extracellular space ([Glu]e). A dialysis electrode (Sycopel International, U.K.), consisting of a microdialysis probe with a built-in platinum electrode, that was continuously perfused with glutamate oxidase and ferrocene conjugated with high molecular weight molecules, BSA, to avoid diffusing out through the dialysis membrane. During the measurement, the mixture of the ferrocene conjugated BSA and glutamate oxidase was perfused at constant flow rate (0.5µl/min). This method permitted real-time measurement of a distinct biphasic [Glu]e elevation during anoxia.

When rats were subjected to anoxic insult, the flat EEG pattern changed within 10 sec. A sharp and rapid [Glu]e peak occurred approximately 2 minutes later (1st phase) and the [Glu]e elevation shifted, continuing to rise throughout the anoxic period (2nd phase). We analyzed the biphasic [Glu]e elevation by a dialysis electrode combined with focal microinjection. Focal microinjection of KC1 (300 mM, 1 µl x 2) induced a sharp and rapid [Glu]e elevation to occur. With anoxic insult immediately after the KC1 microinjection, the 1st phase of [Glu]e elevation disappeared and a gently-sloping [Glu]e increase was observed. On the other hand, this gently-sloping [Glu]e elevation was increased by focal microinjection of KC1 (300 mM, 1 µl) and decreased by that of NaCl (300 mM, 1 µl). These findings suggest that the 1st phase of [Glu]e elevation was derived from "neurotransmitter pools" of neuronal cells, and the 2nd phase from their "metabotropic pools" by regarding as the so-call phenomenon of "reversed uptake". (Supported by the Science Research Promotion Fund from Japan Private School Promotion Foundation.)

ISCHAEMIA ACTIVATES LATENT NMDA RECEPTORS IN THE RECURRENT EXCITATORY PATHWAY BETWEEN CA1 NEURONES.T., Lozovaya*, Tsintsadze, N., Klishin, A. and Krishtal, O. Bogomoletz institute of Physiology, 252024, Bogomoletz str. 4, Kiev, Ukraine

By using in situ patch clamp in hippocampal CA1 mini-slices we measured excitatory postsynaptic currents (EPSC) varying the strength of the stimulus applied to the axons of CA3 neurones. The kinetics of the EPSC was initially independent on the stimulus strength. The postishaemic potentiation of the EPSC was observed in 60-80 min after the brief periods (10 min) of anoxia/aglycaemia. The potentiated EPSC got significantly slowed down in the great majority of examined neurones. In 11 cases out of 16 its kinetics acquired the stimulus dependence strength: slower corresponded to the large stimulus. The latter effect was abolished under either N-methyl-D-aspartate (NMDA) or nonNMDA receptors blocker (D-2-amino-5-phosphonovaleric acid or 6-cyano7-nitroquinoxaline-2,3-dione respectively) indicating the long-term recruitment by the transient ischaemia of the latent predominantly NMDA synapses between CA1 neurones.

PRETREATMENT WITH ANTISENSE OLIGONUCLEOTIDES AGAINST mrna to the NMDA GLUTAMATE RECEPTOR IS NEUROPROTECTIVE IN RODENT MODEL OF NEONATAL ISCHEMIC-HYPOXIA: BEHAVIORAL AND MORPHOMETRIC ANALYSES. <u>E.M.Jansen*</u>, <u>C.D.Keene and W.C.Low</u>, Depts. of Neurosurgery and Physiology, Grad. Prog. in Neuroscience, Univ. of Minnesota, Mpls., MN 55455.

Perinatal ischemic-hypoxia (IH) in humans creates severe neurologic injury that often manifests in motor deficits. Such injury is thought to involve the NMDA receptor. We investigated whether AON directed against the NRI subunit of the NMDA receptor could provide neuroprotection from subsequent IH. We utilized an established model of neonatal IH that creates unilateral striatal, cortical and hippocampal damage (Ann. Neurol., 9:131, 1981). On postnatal days (pnd) 5 and 6, twice a day, Wistar rat pups received intracerebroventricular injections (1µ1) of either AON (15nmol) or vehicle (saline). On pnd 7, animals underwent unilateral carotid artery ligation and were then exposed to 2.5 hours of hypoxia (8% O₂, 92%) N₂, 37°C). Animals were reared normally; sensorimotor and locomotor abilities were assessed using a rotating treadmill throughout development (Rota-Rod, Ugo Basile) and apomorphine-induced rotations as adults (lmg/kg). Animals that received AON before the IH injury were able to remain on the treadmill 134 ± 15.8% longer than control animals that also underwent the IH but received vehicle alone (p<0.01, Student's T-test). AON treated animals showed 75% less rotational asymmetry than did controls (p<0.03, Student's T-test). Following behavioral asymmetry than did controls (p<0.03, Student's T-test). Following behavioral studies, animals were perfused, brains were vibratione sectioned, Nissl stained, and volumetric studies were performed using the software program PC3D. Right hemispheric volume was 153% greater in AON treated animals than in animals receiving vehicle alone (p<0.05. ANOVA). These results suggest that AON directed against mRNA of the NR-1 subunit of the NMDA receptor can confer neuroprotection prior to ischemic-hypoxia and prevent the onset of neurologic deficits. (Supported by NIH predoctoral NRSA MH10617 (EMJ), the United Cerebral Palsy Association, and PHS R01-NS-24464.)

GLUTAMATE RECEPTORS, NEUROFILAMENT AND CALCIUM-BINDING PROTEINS DISTRIBUTION IN THE DOG HIPPOCAMPUS AND NEOCORTEX, P.R. Hof1, Y.E. DISTRIBUTION IN THE DOG HIPPOCAMPUS AND NEOCORTEX. P.R. Hot 1, Y.E. Bogaer 2, R.E. Rosenthal 2, and G. Fiskum^{2*}. Dept of Neurobiol., Mount Sinia Sch. Med., New York, NY 10029, ²Depts of Biochem. and Mol. Biol., Emerg. Med., and Neurosci. Program, George Washington Univ., Washington, DC 20037. Neurophysiological experiments in carnivores have revealed the existence of a large number of cortical regions and an organization of sensory systems quite similar to that

found in primates. However, the cyto- and chemoarchitecture of the cerebral cortex is relatively poorly known in carnivores. We analyzed the distribution and typology of relatively poorly known in carnivores. We analyzed the distribution and typology of classes of neurons containing glutamate receptor subunit proteins GluR2, GluR3, Glur5-7, and NMDAR1, neurofilament protein (NFP) or the calcium-binding proteins (CaBPs) parvalbumin, calbindin, and calretinin in the hippocampus and six neocorrical regions of the dog brain. The GluRs were present in most of the hippocampal and neocortical pyramidal neurons, whereas NFP labeled distinct subgroups of pyramidal neurons. The three CaBPs were found in morphologically diverse inhibitory interneurons subsets. NFP and CaBP immunoreactivity exhibited substantial inter-regional and laminar differential distribution, whereas the GluRs were founded to the control of the capture exhibited a more homogeneous distribution. In addition, while these markers are found in morphologically comparable neuronal types in dog, monkeys, and humans, many differences exist in their regional distribution patterns between carnivores and primates. The dog may represent a highly valuable for the characterization of potential printings. The dog inlay represent a righty variable for the characterization of specific recultural changes in the distribution and expression of specific neurochemical markers in the context of biochemical and morphologic effects of global brain ischemia and reperfusion (I/R) following cardiac arrest. In this model, we observed a reduced number of GluR5-7- and GluR2-immunoreactive pyramidal neurons, and NFPenriched neurons were selectively affected by the ischemic episode and the time of reperfusion, whereas CaBP-containing neurons were resistant to I/R. The present data represent a normative database for the study of the relative vulnerability of morphologically and biochemically identifiable neuronal subsets during brain I/R. Supported by NIH NS34152, Emerg. Med. Fndtn, and the Souers Stroke Fund.

NMDA CHANNEL ACTIVITIES OF HIPPOCAMPAL NEURONS FOLLOWING TRANSIENT HYPOXIC-ISCHEMIC CHALLENGE.

Yu Zhang, Shokrollah S. Jahromi*, Jame H Eubanks and Liang Zhang Playfair Neuroscience Unit, Toronto Hospital Research Institute, Depts of Medicine (Neurology) and Surgery (Neurosurgery). University of Toronto. Toronto, ON, Canada M5T 2S8

CA1 hippocampal neurons exhibit delayed death following a transient ischemic insult, whereas neurons in dentate gyrus are less vulnerable to the insult. To investigate whether the vulnerability is related to the NMDA receptor function, we recorded NMDA single channel activities from these two types of neurons in brain slices. When recorded in the cell-attached configuration and exposed to an "external solution" that contained 10µM glycine, 5 µM NMDA and 0.3-1.5 mM Ca²⁻, CA1 neurons of control slices showed stable channel activities which lasted for up to several min. Stabel and appeared to be enhanced NMDA channel activities were also observed in CA1 neurons that experienced transient in vivo global ischemia or an in vitro hypoxic challenge. Whereas recorded in similar conditions, controlled dentate gyrus neurons often showed fast desensitization in NMDA channel activities. Removing Ca2+ from the recording solution induced relatively stable NMDA channel activities in dentate gyrus neurons, suggesting a Ca2dependent desensitization. We are currently examining whether NMDA channel activities are altered in dentate gyrus neurons following the ischemic or hypoxic insult

Supported by MRC and the Heart and Stroke Foundation of Canada.

HALOTHANE PROVIDES PARTIAL PROTECTION AGAINST NMDA EXCITOTOXICITY IN RAT MIXED CORTICAL CELL CULTURE, IP Beirne , GD Bonaros, GW Massey, RD Pearlstein, DS Warner* Depts of Anesthesiology and Surgery, Duke Univ Med Center, Durham NC 27710 Several *in vivo* studies have shown potent protection from volatile

anesthetics against ischemic insults. These drugs possess a variety of pharmacologic properties. One effect is antagonism of glutamatergic neurotransmission at the NMDA receptor. This study examined the potential for halothane to reduce neuronal excitotoxic lesions caused by the competitive agonist, NMDA. Primary cultures were prepared and allowed to mature 13-16d. A dose-response curve was generated using a 30 min exposure to 0, 10, 30, 100, 300, or 1000 μ M NMDA. Cellular lethality was assessed by measurement of LDH 24 hrs later. 30µM NMDA caused ≈80% of maximal LDH release. This dose was used in further studies. In Experiment 1, culture wells (n=8) were treated with 0, 0.19, 0.70. 1.76, 2.64, or 3.96 mM halothane in the presence/absence of 30µM NMDA. A maximal effect was observed at 0.70 mM (= 2.1 vol%) wherein a 32% reduction in LDH release occurred (p<0.001). Additional cultures were exposed to 30µM NMDA in the presence/absence of 10µM MK-801 or 1, 10, or 100µM ACEA 1021 (a glycine antagonist). Both MK-801 and ACEA 1021 were completely effective in blocking NMDA-stimulated increases in LDH release. These data confirm that halothane has modulatory effects at the NMDA receptor but potency of this drug is less than that of specific antagonists of either glutamate or glycine. These results suggest that in vivo halothane protection can be partially explained by anti-excitotoxic properties although other mechanisms of action are probably also important. Funded by NIH GM39771.

CERESTAT® PROTECTS AGAINST LONG-TERM BRAIN INJURY FROM HYPOXIC-ISCHEMIA (HI) IN NEONATAL RATS. <u>D. Zhou*, S. Wang, D. Lawson, and W. F. Holl, Pharmacology</u> Department, Cambridge NeuroScience, Inc., Cambridge, MA 02139

In a previous study we demonstrated that the noncompetitive NMDA antagonist, CERESTAT® (aptiganel hydrochloride/CNS 1102) can reduce the total infarct volume by >90% for brains evaluated at 48 hours after an HI insult in the neonatal rat. We report here the long-term effects of CERESTAT® on HI-induced brain injury in the neonatal rat. A total of seventeen rats were used in the present study. HI was induced by ligating the left common carotid artery and then placing 8-9 day-old rat pups for 1.5 hours in an incubator filled with 7.8% O2 at 36.5°C. CERESTAT® was administered intraperitoneally immediately after HI at a dose of 6.8 mg/kg. 90 days after the HI insult, brain damage was evaluated by counting the total number of viable neurons for a particular brain region in a given microscope field. The results were expressed as the percentage of surviving pislateral neurons, compared to the number of neurons on the contralateral side of the brain. In the vehicle-treated control group (n=9) only 37%±13, 52%±11 and 72%±9 of the neurons survived in the regions of the rostral hippocampus, the caudal occipital cortex and the rostral striatum. In contrast, the neuronal survival rate in animals treated with CERESTAT® (n=8) was 84%±12, 94%±2, and 95%±4 in the same regions, respectively. CERESTAT®-treated rats had significantly (p<0.05) more surviving neurons in the hippocampus and the cortex regions examined compared with vehicle-treated control rats. These results suggest that glutamate mediates HI-induced brain damage in neonatal rats and that the NMDA ion-channel blocker CERESTAT® can provide long-term (at least 90 days) protection against such lesions in rats.

CERESTAT is a registered trademark of Cambridge NeuroScience, Inc. CERESTAT is being jointly developed by Cambridge NeuroScience, Inc. and Boehringer Ingelheim, GmBH.

EFFECT OF CNS1102 ON ISCHAEMIC BRAIN DAMAGE AND NEUROLOGICAL AND BEHAVIOURAL DEFICITS IN RATS AFTER PERMANENT MCAO. L. A. Lione, A. Hudson, D. Nutt, P. King, C. Campbell and A. J. Hunter*. SmithKline Beecham Pharmaceuticals, New Frontiers Science Park, Harlow, Essex CM19 5AD. UK.

Harlow, Essex CM19 5AD. UK.

Histological assessment has traditionally been the most frequently used endpoint in pharmacological studies of cerebral ischaemia, now, however, the importance of behavioural assessment is recognised. This study evaluates the behavioural deficits induced by permanent left mid-cerebral artery occlusion (MCAO) and the effect of the non competitive NMDA antagonist, CNS1102 on these deficits. Male SD ratio (300-350g, n=12-15 per group) were trained on grip strength and rotarod tasks 6 times daily for 6 days. MCAO was produced on day 6 as described by Longa et al (1989, Stroke, 20, 84). CNS1102 (1.13mgk) and 0,9% saline vehicle were administered bolus i.v. 15 min post MCAO. All behavioural and neurological tests (8-point scale) were repeated and scored 22 hrs later (day 7). Animals were then perfusion fixed at 24 hrs post MCAO and brains histologically assessed. Rotarod performance was significantly reduced in the vehicle and CNS1102 MCAO groups when compared to the sham operated controls (3.5 ± 0.88, 12.3 ± 4.9s and 52.4 ± 4.3s on day 7 respectively, p<0.0001 ANOVA). A significant reduction in contralateral right paw grip strength was observed in the vehicle and CNS1102 MCAO groups when compared to the sham operated controls (71.5 ± 12.3g, 99.4 ± 13.4g and 259 ± 9.7g on day 7 respectively, p<0.0003 ANOVA). There was also a significant effect of MCAO on the lpsilateral left paw grip strength. (p<0.003) in vehicle and CNS1102 groups as compared to shams (177.7 ± 15.3g, 187.7 ± 16.9 and 222.6 ± 11.9g) on day 7, respectively, p<0.003 ANOVA). No significant difference was observed however between the vehicle and CNS1102 MCAO groups in the neurological and behavioural tests, nor did CNS1102 reduce total infarct volume significantly compared with controls (234 ± 9mm¹ in the control group and 186 ± 27mm¹ in the CNS1102 group; p>0.05 ANOVA). These data suggest that 24 hour permanent left MCAO produce quantifiable neurological deficits which were not ameliorated by CNS1102.

The glycine antagonist GV150526A protects somatosensory evoked potentials and reduces the infarct area in the MCAo model of focal ischemia in the rat.

<u>Claudio Pietra*, Fabio Bordi, and Angelo Reggiani</u>. Pharmacology Dept., GlaxoWellcome Medicines Ctr., Via Fleming 4 37100 Verona (Italy).

The neuroprotective activity of the novel, selective glycine antagonist GV150526A was assessed in the middle artery occlusion (MCAo) model of focal ischemia by using somatosensory evoked potential (SEP) responses recorded from the primary somatosensory cortex of rats under urethane anesthesia. The SEP functional responses were then correlated with precise anatomical evaluations. Occlusion of the middle cerebral artery (MCAo) produced experimentally 7 days prior to electrophysiological testing, induced a clear reduction in the SEP amplitude. To evaluate the neuroprotective effects of the GV150526A, two groups of animals were treated either 1 hr post- (n=9), or 6 hr post-MCAo (n=10). GV150526A (3mg/kg, i.v.) was able in both groups to protect SEP responses recorded from the hind-paw cortical field. SEP responses recorded from the fore-paw cortical field, an area closer to the core of the ischemic damage, were significantly protected only in the group treated 1 hr post-MCAo. Histological evaluation of the rat brain regions showed a correlated decrease in the ischemic area of GV150526A groups were statistically different from the MCAo group (p<0.05). These findings demonstrate that the GV150526A is able to protect both the ischemic damage assessed histologically and the functional correlates of the ischemia evaluated by the electrophysiological SEP measurements.

SPINAL NMDA ANTAGONISM DOES NOT ALTER DORSAL HORN NEURONAL HYPERACTIVITY EVOKED BY SPINAL CORD ISCHEMIA.

1 Jan Galik , Martin Marsala, Tony L Yaksh*, University of California, San Diego, CA-92093;
1 Institute of Neurobiology, Kosice, Slovakia.

Ischemia of nervous tissue is a devastating process which triggers a cascade of events leading to significant CNS dysfunction. In our previous studies [1] we have shown, using a spinal cord ischemic model of thoracic aortic occlusion induced by placement of 2F Fogarty balloon catheter via the femoral artery, an increase in firing frequency as well as in number of spontaneously active units in rat spinal dorsal horns after 30 minutes of transient spinal cord ischemia. To examine possible mechanisms involved in this hyperactive state, the NMDA receptor antagonist MK-801 was applied intrathecally during reperfusion. The activity of dorsal horn neurons in halothane (1.5%) anesthetized, artificially ventilated rats before, during and after 30 min of aortic occlusion was recorded. The peak of increased neuronal activity was observed typically from 60 to 90 minutes during reperfusion. The high dose (30µg in 20µl) of NMDA antagonist MK-801 was administered intrathecally after 1 hour of reperfusion. Control recordings were made after intrathecal injection of the same volume (20µl) of vehicle (saline). No significant change in spontaneous activity after MK-801 injection was observed. These results suggest that involvement of the NMDA receptor during this initial postischemic spinal hyperactivity is not significant. The origin of this spinal activity may be: i) depolarization due to an increase in extracellular potasium or excitatory transmitters released from degenerating terminals; or ii) increased afferent drive derived from peripheral ischemic terminals. (This work was supported by NIH NS32794, M.M.)

MK 801 DECREASES TUMOR NECROSIS FACTOR LEVELS IN THE CEREBRAL CORTEX AFTER FOCAL ISCHEMIA R. Bertorelli¹, M. Adami¹, E. Di Santo², P. Ghezzi² and E. Ongini* ¹ Schering-Plough Research Institute, Milan 20132 ²Mario Negri Research Institute, Milan, 20157 Italy

It has been reported that focal cerebral ischemia in rats produces elevated levels of tumor necrosis factor- α (TNF- α) mRNA and protein in ischemic neurons. The neuronal expression of the TNF α appears to facilitate the infiltration of inflammatory cells that, in turn, can further exacerbate tissue damage in cerebral ischemia and might contribute to increase sensitivity and risk in focal stroke (Liu et al., 1994; Stroke 25:1481-1488). To understand the possible role of this cytokine on ischemic processes we carried out experiments on ischemia-induced cortical infarction and TNF production in a permanent focal model in the rat. TNF was measured by the degree of cytotoxicity on L929 cells, using human recombinant TNF as standard.

Middle cerebral artery (MCA) occlusion resulted in the development of an ipsilateral cortical infarction. MK 801 (3 mg/kg, ip), a non-competitive NMDA receptor antagonist, exerted significant protection on total volume of infarction (47% of reduction; p<0.01 vs ischemic-control). The maximal expression of TNF was observed 12 h after MCA occlusion (2783±299 pg/g). This effect was specifically related to focal ischemia, since no detectable TNF was measured in the ipsilateral cortex of sham-operated animals (<50 pg/g) or in the contralateral cortex of both ischemic (117±24 pg/g) or sham-operated animals (<50 pg/g). MK 801 reduced the TNF production in the ipsilateral cortex of ischemic animals by 61% (p<0.01) vs ischemic-control). The results indicate that TNF is involved in the process underlying cerebral ischemia and its levels are modulated by NMDA receptor activity. Further studies are needed to understand whether TNF levels are directly linked to the degree of neuronal injury or depend on specific mechanisms of neurotoxicity. Supported by SPRI.

Effects of the glycine antagonist GV150526A on learning and memory. Fabio Bordi*, Claudio Pietra, and Angelo Reggiani. Pharmacology Dept., GlaxoWellcome Medicines Ctr. Via Fleming 4 37100 Verona (Italy).

The effects of the glycine antagonist GV150526A were studied on learning and memory. First, the effects of the GV150526A on perforant path-dentate gyrus long-term potentiation (LTP) were tested in rats. GV150526A (3mg/Kg, i.v.) injected 30 min or 150 min prior to tetanization did not block potentiation of the EPSP slope and population spike amplitude. To compare these effects to those of the N-methyl-D-aspartate (NMDA) receptor antagonist, a group of animals was treated with MK801 (Img/Kg, i.p.) 150 min before tetanization. MK801 produced a clear block of LTP in EPSP slope and population spike amplitude. In a second set of experiments, the effects of GV150526A were examined on two behavioral measures of learning and memory formation: the Morris Water Maze in rats and the passive avoidance in mice. Rats injected with GV150526A (10 mg/Kg or 60 mg/Kg, p.o.) did not show any impairment in learning if compared to control. The NMDA antagonist MK801 (0.08 mg/Kg, i.p.), on the other hand, significantly affected the acquisition to locate the escape platform in the Water Maze. Furthermore, mice injected with GV150526A (0.3-30 mg/Kg, i.v.) 20 min before the test, performed in the passive avoidance test as well as control group. These findings show that the GV150526A is devoid of amnestic side effects even at doses well above the neuroprotective range of action. This drug has a therapeutic potential with a much greater margin of safety than NMDA channel blockers or competitive NMDA antagonists.

Supported by GlaxoWellcome S.P.A. Verona, Italy

IN VITRO CHARACTERIZATION OF A NOVEL NMDA RECEPTOR GLYCINE SITE ANTAGONIST: GV150526A. B. Bunnemann, C. Carignani, S. Palea, M. Corsi, M. Mugnaini, D.G. Trist, A. Reggiani. Dept. of Pharmacology, GlaxoWellcome S.p.A., Medicines Research Centre, 37135 Verona, Italy.

The strychnine-insensitive glycine site on the N-methyl-D-aspartate (NMDA) receptor represents a target for the development of a variety of therapeutic agents, such as antiischemics, anticonvulsants, anxiolytics or antidepressants. In the present study, we have characterized the activity of a new glycine site in the present study, we have characterized the activity of a new glycine site antagonist GV150526A by using membrane binding assays, receptor autoradiography, electrophysiology on primary cultured cells, as well as on recombinantly expressed NMDA receptor subunit combinations. 1] Membrane binding: GV150526A completely displaced specific [4]-Glycine binding to rat cerebral cortex membranes. Displacement characteristics are in agreement with a single binding site model. A pKi value of 8.49 ± 0.02 [n=5] has been determined. On the other hand GV150526A did not specifically displace [H]-CPP binding. 2) Receptor autoradiography: highest binding densities were present in all hippocampal subfields and the cerebral cortex. Medium binding intensity could be observed in thalamic areas. Small amounts of binding sites were present in the striatum and the cerebellum. 3) Patch clamp recordings: in embryonic spinal cord and hippocampal neurons glutamate and glycine induced currents were competitively antagonized by GV150526A with similar potency. The estimated p_{N_3} was 7.93 (7.92-7.94) and 8.08 (8.03-8.13) for spinal cord and hippocampal neurons, respectively. Correspondingly, recordings on recombinantly expressed NMDA receptor subunit combinations revealed an inhibition of glutamate/glycine induced currents. In conclusion, GV150526A represents a highly potent and selective antagonist at the glycine site of the NMDA receptor complex.

THE EFFECTIVENESS OF AMPA RECEPTOR ANTAGONISTS MAY BE INFLUENCED BY TRANSPORT MEDIATED EFFLUX FROM THE CNS, S.A. Borosky*, D. F. Welty, M. G. Vartanian and G. P. Schielke. Parke-Davis Pharmaceutical Research, Division Warner-Lambert Co., Ann Arbor MI, 48105
PNQX, (PD 152247) is a novel quinoxalinedione AMPA receptor antagonist which reduces ischemic brain damage and has anticonvulsant properties. Previous studies demonstrated that probenecid, a competitive inhibitor of organic anion transport, enhanced the anticonvulsant action of another quinoxalinedione, NBQX. It is unclear if this effect is due to inhibition of drug transport at the kidney (increasing plasma levels) or at the blood-brain/CSF barriers (decreasing brain efflux), or both, since probenecid blocks organic anion transport at these sites. In order to address this issue we studied 1.the effects of probenecid and nephrectomy on PNQX anticonvulsant activity and plasma levels, and 2.the effect of PNQX and NBQX on probenecid sensitive organic anion uptake in freshly isolated choroid plexus.

Following a 3 mg/kg IV bolus of PNQX, both pretreatment with

Following a 3 mg/kg IV bolus of PNQX, both pretreatment with 200 mg/kg probenecid and bilateral nephrectomy elevated PNQX plasma levels above controls. Probenecid increased the magnitude and plasma levels above controls. Probenecid increased the magnitude and duration of the protective effect of PNQX in maximal electroshock seizures while nephrectomy had no effect. In freshly isolated choroid plexus, probenecid, NBQX and PNQX inhibited uptake of the organic anion ¹⁴C PAH. Additionally, uptake of ¹⁴C PNQX was saturable and partially reduced by probenecid and PAH. These results suggest that the effect of probenecid is not due to the elevated plasma levels of PNQX, but rather may be a result of reduced efflux from the brain via organic anion transporters at the choroid plexus and blood-brain barrier. METABOTROPIC GLUTAMATE RECEPTOR NEUROPROTECTION INVOLVES REGULATION OF INTRACELLULAR CALCIUM.

L Ahmad* L. Kim, M. TenBroeke, L. Kue, and K. Maiese. Dept. of Neurology, Ctr. for Molecular Med. Wayne State Univ. Sch. of Med., Detroit, MI, 48201 Metabotropic glutamate receptor (mGluR) agonists are neuroprotective during anoxia and nitric oxide toxicity (Maiese, et al. Neurochem (in press)). The mechanisms that mediate neuroprotection by this group of receptors are not well defined, but may rely on the modulation of signal transduction pathways, such as intracellular calcium. The present study examines the role of micalellular calcium (Ca₁²⁺) concentration on the neuroprotective effects of mGluR agonism. The mGluR agonists, (±)-1-aminocyclopentane-trans-1,3-dicarboxylic acid (trans-ACPD) and L(+)-2-amino-3-phosphonopropionic acid (L-AP4), and the mGluR antagonist, dibutyryladenosine 3', 5'-cyclic monophosphate (L-AP3), were administered in increasing concentrations (50μM to 1000μM) with changes in Ca₁²⁺ imaged with Indo-1. The trans-ACPD doses of 50μM to 500μM, which do not significantly alter survival during neuronal injury, produced 60-100% increases in Ca₁²⁺ over baseline (n=10, p<0.001). In contrast, the neuroprotective doses of trans-ACPD of 750μM and 1000μM yielded only an approximate 20-30% increase in Ca₁²⁺ over baseline (n=10, p<0.001). In contrast, the neuroprotective doses of trans-ACPD of 750μM and 100μM was able to significantly reduce, and in some cases, prevent the release of trans-ACPD induced Ca₁²⁺ release. Our work suggests that neuroprotection during anoxia and NO toxicity by the trans-ACPD intrans-ACPD induced Ca₁²⁺ release. Our work suggests that neuroprotection during anoxia and NO toxicity by the trans-ACPD intrans-ACPD intracellular calcium. Protection by the mGluR agonist L-AP3 (1000μM) with trans-ACPD intracellular calcium. Protection by the mGluR agonist load neuronal death. LACK OF DESENSITIZATION OF AMPA-RECEPTORS IN ISCHEMIC SPINAL CORD INJURIES, Mia von Euler*, Mo LiLi, and Erik Sundström Dept. of Clinical Neuroscience and Family Medicine. Karolinska Institutet, Huddinge

University Hospital, 141 86 Huddinge, Sweden.

We have previously shown that AMPA receptors mediate part of the secondary degeneration after an ischemic spinal cord injury. To investigate if desensitization of AMPA receptors limits neurodegeneration after experimental spinal cord injury, we studied the effect of systemic and local administration of cyclothiazide, a known inhibitor of desensitization of the AMPA-receptor. Photochemical thrombosis was induced at Th 9 in adult female Sprague-Dawley rats (B&K Universal, Sweden). Cyclothiazide (RBI) was dissolved in 99% ethanol or in 86mM NaOH and injected sc 10 mg/kg 5 minutes after ischemia. For controls, the two different vehicles or NaCl were administred. To rule out problems with drug administration, another experiment concerned intrathecal administration of cyclothiazide dissolved in 52% ethanol (200µg/kg) and given 5 minutes after ischemia. No effect could be seen of any of the cyclothiazide treatments on morphological evaluation of lesion volume in cresyl violet stained sections of spinal cord samples at 2 weeks post-ischemia. Neither were any differences seen between the different treatment groups or controls in the neurological evaluation. To certify that cyclothiazide blocks desensitization of spinal cord AMPA receptors in the same manner as has been shown in the brain, the effect of cyclothiazide on the binding of ³H-AMPA to spinal cord synaptic membranes was studied. Preliminary results showed that ³H-AMPA-receptor binding to membrane preparations from brain and spinal cord was reduced similarly by 300 $\,\mu M$ cyclothiazide in both regions. Thus, we conclude that AMPA receptors do not desensitize during the process of degeneration after spinal cord ischemia.

THE NOVEL AMPA RECEPTOR ANTAGONIST, PD 152247 (PNQX), REDUCES LESION SIZE IN A DOSE DEPENDENT MANNER FOLLOWING TRANSIENT FOCAL ISCHEMIA IN THE RAT. N.C. Kupina, J.J. Kinsora and G.P. Schielke*. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI. 48105

The discovery of compounds which selectively block AMPA receptors has generated considerable study into the role of non-NMDA glutamate receptors in ischemic brain injury. PNQX is a novel quinoxalinedione with activity at the AMPA (IC₅₀ = 0.063µM), kainate (0.37µM), and glycine (0.37µM) sites. We previously demonstrated PNQX to be neuroprotective when given IP in a model of focal ischemia. This study examines the IV dose response relationship for neuroprotection in transient focal ischemia. Ischemia was induced in male Sprague Dawley rats by temporary occlusion of both carotid arteries and the middle cerebral artery with micro clips. Immediately following the occlusion, drug or vehicle was infused for 5h. All clips were removed after 3h. Brains were removed 72h later for stereological analysis of the lesion. Lesion volumes (mm³±SE) in each group were: vehicle control (259±20), 0.1mg/kg/hr (130±21), 1mg/kg/hr (170±11), 2.5mg/kg/hr (110±23) and 5mg/kg/hr (150±22). The reduction in lesion size was statistically significant in all but the lowest dose. Body temperature, measured by telemetry for 72h, did not vary between groups. These The discovery of compounds which selectively block AMPA receptors measured by telemetry for 72h, did not vary between groups. These results demonstrate that the AMPA antagonist, PNQX, can reduce ischemic brain damage when administerd IV at a dose as low as 1 mg/kg/hr, and that hypothermia did not contribute to this neuroprotective effect. (Supported by Warner-Lambert)

PROTEIN KINASE C INHIBITORS ATTENUATE THE PROTECTIVE EFFECT OF CLASS I METABOTROPIC GLUTAMATE RECEPTOR AGONISTS AGAINST HYPOXIC/HYPOGLYCEMIC INJURY IN HIPPOCAMPAL SLICES. J. Breder, U. H. Schröder, T. Jäger, T. Opitz, C. F. Sabelhaus, D. Balschun* and K. Reymann. Federal Institute for Neurobiology and Research Institute Applied Neurosciences Ltd., D-39008 Magdeburg, Germany.

During hypoxia and ischemia an excessive release of glutamate eventually leads to sustained neuronal damage. To investigate the influence of metabotropic glutamate receptors (mGluRs) on neuronal injury caused by cerebral hypoxia/ischemia, we employed an in vitro model of hypoxia/hypoglycemia. Hippocampal slices from 7-week-old male Wistar rats were transiently

exposed to an oxygen and glucose-free environment in an interface chamber. The synaptically evoked population spike in the CA1 region was taken as a measure of neuronal viability.

Under control conditions the population spike amplitude recovered incompletely (48.5 \pm 3.6 % of baseline values) within one hour after termination of the hypoxic/hypoglycemic event. The specific class I mGluR agonists trans-azetidine2,4-dicarboxylic acid (trans-ADA, 100 μ M) and 3,5-dihydroxyphenylglycine (DHPG, 10 μ M) were highly protective (89.3 ± 3.8 % and 93.8 ±2.1% of baseline values respectively) when applied before the event. Coapplication of the protein kinase C (PKC) inhibitors staurosporine (100 nM) and chelerythrine (30 μ M) reduced the recovery rate to 39.3 \pm 7.9 % and 57.1 ± 11.7% of baseline values respectively.

Our data suggest that the activation of the phospholipase C pathway prior to hypoxia/hypoglycemia exhibits a pronounced protective effect which depends on protein phosphorylation. They indicate that the protective effect of class I mGluR agonists is mediated by PKC which must be activated prior to

the onset of the hypoxic/hypoglycemic event. This work was supported by BMBF grant BEO 21-0319998B

A NON-INFECTIOUS TECHNIQUE FOR THE IDENTIFICATION OF HIV BINDING SITES IN THE HUMAN BRAIN. F. J. Denaro'. Dept. of Neurology, Texas Tech Univ. Health Sciences Center, Lubbock, TX 79430.

Histological studies which include immunocytochemistry and in situ hybridization have been useful in identifying the location of HIV in the brain. When these techniques have been coupled with methods of increased sensitivity and resolution, such as electron microscopy or confocal microscopy, it is also possible to identify the cell types which are infected. Double labeling is also very helpful in this identification process. Such approaches are believed to reflect the in vivo infection of the HIV virus in the brain. In the present study, purified, synthetic HIV peptides (GP140) bound to either peroxidase or colloidal gold were used to demonstrate binding areas in brain tissue sections. By incubating fresh frozen brain tissue with these peptides, it was possible to identify areas of increased viral binding. This approach in part reproduces what has been identified in the infected brain. Positive binding was identified in human postmortem brain tissue. Pre-incubation with antibodies to CD4 or binding with unlabeled peptide prevents binding of the labeled GP120 probe. Neurons and astrocytes did not present with substantial binding. Further studies are in progress to assess for binding in the neuropile, white matter, and endothelial cells. Such a technique can give insight into how HIV binds in the brain and where there may be increased viral susceptibilities. Grant NS31857.

PRELIMINARY BEHAVIORAL AND TOXICITY ASSESSMENT OF THALIDOMIDE IN THE RHESUS MACAQUE. T.A. Patterson*, W. Slikker, Jr., W.L. Zielinski*, J.C. Reepmeyer* and J.A. Sandberg. Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR 72079 and Division of Drug Analysis/FDA, St. Louis, MO 63101.

Thalidomide (THAL), although not yet approved for use in the United States, is currently being evaluated for its therapeutic potential in AIDS and AIDS-related conditions. THAL has been reported to produce a painful, dose-limiting peripheral neuropathy in patients after chronic administration. The present study was designed to determine if escalating doses of THAL could produce changes in home cage behavior that may indicate toxicity or the onset of peripheral neuropathy. Rhesus monkeys (N = 3) were orally dosed once a day with the same dose of THAL for seven consecutive days using a buffered corn syrup (pH = 5.0)/biscuit vehicle. The dosing began with 10 mg/kg/day and increased up to 100 mg/kg/day over eight weeks using an alternating weekly dosing/washout (vehicle only) regimen. A 10 mg/kg dose of THAL has previously been shown to produce peak plasma concentrations in the rhesus monkey that correspond to peak plasma concentrations in the rhesus monkey that correspond to peak plasma concentrations with 100 mg/kg of THAL produced peak plasma concentrations of 2-10 μ g/mL after five hours. High plasma levels of THAL (> 2 μ g/mL) were still present 28 hours after dosing in 2 of the 3 animals. In summary, no overt signs of toxicity, changes in body weight or alterations in home cage behavior were observed in rhesus monkeys administered doses of THAL that produced plasma levels greater than those typically encountered therapeutically. Supported by NIEHS IAG #Y01-ES-10187.

EFFECT OF ZIDOVUDINE (AZT) AND SAQUINAVIR ON RETROVIRAL INFECTION OF THE CENTRAL NERVOUS SYSTEM (CNS). <u>Bodnar RJ</u>, and <u>Hamilton RL*</u>, Division of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA 15213

In HIV encephalitis, the CNS is an important reservoir of retrovirus. It is unknown whether current antiretroviral therapy is able to cross the blood brain barrier (BBB) and reduce CNS viral burden. We used a murine retroviral encephalitis model to evaluate the ability of anti-retroviral drugs to reduce retroviral levels in the CNS. Our model uses a temperature-sensitive neurotropic retrovirus (ts-1) which is inoculated into newborn mice and causes a non-inflammatory spongiform encephalopathy primarily in the subcortical areas. Mice were treated with either AZT, Saquinavir or a combination of the two drugs beginning age 4 weeks. Total RNA was extracted from subcortical tissue and cortex from mice sacrificed at 14 weeks. Semiquantitative RT-PCR was used to measure levels of ts-1 pol and env mRNAs relative to GA3PDH mRNA. Northern blot analysis was performed to confirm the PCR assessment. Our results correlate with previous findings using immunohistochemistry and XC assay that current antiretroviral therapies may reduce but do not eliminate virus from the CNS. This model can be used to test other antiretroviral therapeutic agents for their efficacy in reducing viral burden in the **CNS**

IMMUNOCYTOCHEMICAL IDENTIFICATION OF HUMAN CD4 PROTEIN IN THE BRAIN OF THE HUMAN-CD4 TRANSGENIC MOUSE. S. Frankl*, F. J. Denaro. Dept. of Neurology, Texas Tech Univ. Health Sciences Center, Lubbock, TX 79430.

The CD4 molecule has been found on the helper T lymphocyte and to a lesser degree on other lymphocytes. CD4 functions as a receptor for the entry of HIV into the cell. Understanding CD4's role in the life cycle of HIV infection is important to understanding the development of pathology in AIDS. Advances in HIV research will, in part, depend on the development of animal model systems to study HIV infection and for the development of antivirals. The development of a transgenic mouse which expresses the human CD4 molecule may help with the examination of some of the characteristics of HIV-CD4 binding. In the present study, the expression of human CD4 was mapped in the brain of the human CD4 transgenic mouse. By use of monoclonal antibodies to human CD4, it was possible to identify those cells which were positive for CD4. Lymphocytes in the brain parenchyma were identified as positive. Endothelial-like structures also appeared to be positive, but increased resolution may be needed to differentiate endothelium from lymphocytes which may be migrating through it or microglia in close association to them. The next step will be to study the effects of live virus or viral peptides in this model system. Supported by grant NS31857.

Cytokine and neurotrophic factor expression in HIV-infected human fetal brain microspheres transplanted in SCID mice striatum V.J. Sanders*, E.A. Bonaroti, G. Wang, R.J. Bodnar, P.G. Sarnacki, and C.L. Achim. Div. of Neuropathology, Univ. of Pittsburgh, PA 15213. In vitro studies have shown that infection of microglia with HIV

In vitro studies have shown that infection of microglia with HIV causes an increase in the production of various neurotrophic factors (NTF) and cytokines. Aggregates of human fetal CNS cells containing microglia and neurons may be grafted into the brain of SCID mice. We propose that HIV-infected grafts in SCID mice striatum will show altered NTF and cytokine production compared to uninfected grafts. Immunoflourescent laser confocal microscopy was used to study the expression of the cytokines: IL-6, TNF-alpha, and TGF-beta, and NTF: brain-derived neurotrophic factor (BDNF), NT-3, glial-derived neurotrophic factor (GDNF), and hepatocytic growth factor (HGF). Cellular localization was determined by double-labelling with cell markers. Relationship between NTF and cytokine expression and viral burden was determined by staining for HIV. Cellular localization and percentage of cells stained were compared with that seen in uninfected grafts at one, two, and four months after transplantation. A higher percentage of neuroglia expressed cytokines, NTF, and receptors in the HIV-infected grafts. The uninfected transplants were also used to study the role of NTF in neuronal survival in transplants. Mice with infected grafts serve as an animal model of HIV encephalitis. Production of NTF following microglial infection with HIV suggests that NTF may play a role in the neuronal damage seen in HIV encephalitis. [VJS supported by NM 18273]

ANTISENSE OLIGONUCLEOTIDES: A POTENTIAL GENE THERAPY FOR HIV DEMENTIA. C. Power, C. Liu, J. Paterson*, M. Anazodo, J. Wright, A. Friesen. Departments of Internal Medicine, Anatomy, and Medical Microbiology, University of Manitoba; Genesys Pharma, Winnipeg, MB.

HIV-1 is a neurotropic retrovirus which productively infects brain cells, resulting in the clinical development of HIV dementia. Antisense oligonucleotides (ASO) targeting different HIV-1 genes have been shown to reduce replication of homologous viruses. The objective of these studies was to determine the extent to which ASO targeting the HIV-1 gag and reverse transcriptase encoding regions inhibit replication of nonhomologous HIV-1 strains derived from brain (JRFL), cerebrospinal fluid (SF162) and blood (LAV) and whether ASO cross the blood-brain barrier. Replication of HIV-1 in peripheral blood mononuclear cells (PBMC) was determined by reverse transcriptase activity and immunoblot. 35S-labeled thioated ASO parenterally injected into mice were detected by autoradiography and radioactivity counts in tissues at 24 and 72 hour postinjection. ASO treatment (1.0 µM) of infected PBMC resulted in reduced replication of all viruses (JRFL-65%; SF162-40%; and NL43-100%) compared to control and inverted oligonucleotide-treated PBMC 7 and 10 days following infection. Pharmacokinetic studies indicated that radiolabeled ASO were detectable in brain and other tissues Autoradiography revealed foci of radioactivity above background, localized in the neuropil and perikarya. These studies suggest that ASO can markedly diminish replication of diverse HIV-1 strains and are able to enter the brain; thus ASO may be potential therapeutic agents for the treatment of HIV dementia. CEREBELLAR DYSFUNCTION IN PATIENTS WITH AIDS. V. Das^{1,4}, A. Das⁴, S. Suneja^{1,3}, C.O. Trouth², and R.M. Millis^{2*}. Depts. of Family Practice & Comm. Hlth; ²Physiology & Biophysics; ³Radiology; ⁴HUH - CARES, Coll. of Med., Howard Univ., Washington, D.C. 20059

The first reported case of AIDS by CDC was in 1983 and subsequent findings have implicated HIV in the etiology of the disease; however, no cure has yet been found. Antiretroviral agents and prophylactic therapy may prolong life. With the progress of the disease there is deterioration of cerebellar Neurological testing revealed ataxia, horizontal nystagmus, dysmetria, scanning speech, dysdiadochokinesia, wide-based gait and significant decrements in voluntary/involuntary activities and two-point discrimination. These findings suggest an AIDS-related increase in susceptibility to accidents and injuries. The pathophysiology of this AIDSrelated cerebellar dysfunction remains unknown; however, it is postulated that glial cells may express CD4 antigens that play a permissive role in HIV infection, the HIV envelope being homologous to neuroleukin which may inhibit production of nerve growth factor(s).

CONDITIONED MEDIA FROM HIV-INFECTED MACROPHAGES DECREASES SODIUM-DEPENDENT GLUTAMATE UPTAKE IN SK-N-MC NEUROBLASTOMA CELLS. T.C. Pappas*, S. Alagarsamy¹, R.B. Pollard and M. Nokta. Dept. of Internal Medicine, 'Dept. of Pharmacology and Toxicology, University of Texas Medical Branch. Galveston TX 77555-0882. HIV envelope proteins and cytokines released from HIV-infected brain macrophages $(M\phi)$ have been implicated in neurotoxicity associated with HIV infection via their interaction with receptors on neuronal and glial cells. We have found that products from HIV-infected Mø act on the Na⁺-dependent glutamate (GLU) transport as well. SK-N-MC (neuroblastoma) cells express electrogenic GLU transporters that are pharmacologically similar to EAAT1 and EAAT3. Conditioned media from HIV-infected PBMC-derived M ϕ (HIV-M ϕ CM) decreased total GLU uptake in SK-N-MC to 80.6% (\pm 6.8%) of control levels in as rapidly as 4 hr. Na*-dependent GLU uptake was decreased to 70.5% (\pm 7.8%) of controls at this time point. GLU uptake saturation kinetics revealed that HIV-M ϕ CM decreased transporter V_{max} without a significant change in the magnitude of the K_{mi} . This reduction in V_{max} was evident with HIV-M ϕ CM treatment from 4-120 hr, and in as little as 2.5% CM. HIV_{SF162}, HIV_{JR-CSF} and a $M\phi$ -tropic patient viral isolate produced $HIV-M\phi$ CM that could reduce GLU uptake. CM from uninfected M ϕ or M ϕ infected with heat-inactivated HIV had no effect on GLU uptake. HIV-M ϕ CM were not effective at suppressing GLU transport until 7 d post-infection, suggesting that virus production may have a role in the reduction of GLU transport. Consistent with this notion, SK-N-MC treated for 4 hr with gp120 (10 nM) showed reduced GLU transport similar to HIV-M ϕ CM-treated cells. Supported by the James W. McLaughlin Fellowship Fund.

HIV MODULATES D-ASPARTATE UPTAKE IN U251 HUMAN ASTROGLIOMA CELLS. J.J. Kort* Department of Medicine, Albany Medical College, Albany, New York 12208.

In HIV-associated disease of the central nervous system uptake of excitatory amino acids into astrocytes may be impaired by neurotoxic factors secreted by activated macrophages and microglial cells or by HIV infection, leading to excitotoxicity mediated by NMDA-receptor stimulation in neurons. D-[3H]Aspartate (D-Asp) uptake in U251 human astroglioma cells was measured in the presence or absence of candidate neurotoxins, including tumor necrosis factor alpha (TNF- α), arachidonic acid , and recombinant HIV_{SF2} gp120 envelope glycoprotein. In addition, D-Asp uptake was studied in HIV $_{SF162}$ -infected U251 cells. Arachidonic acid (20 μ M, -39%), TNF- α (100 ng/ml, -25%), and gp120 (10⁻⁷ M, -15%) dose-dependently reduced D-Asp uptake in U251 cells (p<0.05, student t test). Interestingly, uptake of D-Asp was increased (+50%) in HIV_{SF162}-infected U251 cells. [³H]ouabain binding studies showed a twofold increase in the number of functional $\rm Na^+/K^+$ -pumps in $\rm HIV_{SF162}$ -infected U251 cells. However, intracellular $\rm Na^+$ concentrations were not elevated in $\rm HIV$ -infected cells. Since uptake of glutamate and D-Asp into astrocytes is primarily via Na+-dependent amino acid carrier systems, increased D-Asp uptake in HIV-infected U251 cells may be due to the increased transport capacity for Na⁺ by the Na⁺/K⁺-pumps The mechanism for upregulation of functional Na⁺/K⁺-pumps in HIVinfected astroglioma. cells is currently being investigated. MOLECULAR AND BIOCHEMICAL CHARACTERIZATION OF HIV-1 NEURAL CELL INTERACTIONS. Y. Mizrachi*, ® N. Smalheiser, J. Aleja Bubinstein, Albert Einstein College of Medicine, Bronx NY 10461, of Chicago, Chicago IL, 60637.

MONDAY PM

Although neural cells do not carry the CD4 receptor, HIV-1 plays an important role in a broad spectrum of pervous system disorders. Our studies have shown that soluble CD4 does not inhibit gp120 binding to, HIV-1 fusion with or HIV-1 infection of CD4 negative neural cells. This suggests the existence of non CD4 gp120 binding molecule(s) on the surface of neural cells. We have previously identified by immunoprecipitation a 69KDa gp120 binding protein on the surface of neural cells. These findings have lately been confirmed and expanded using a more sensitive western blot technology. Membrane preparations from neuroblastoma and mammalian brains were solubilized, separated by gel electrophoresis at 10% gel and reducing conditions, and blotted onto a nylon membrane. Using gp120 and its antibodies we have identified six distinct gp120 binding proteins with molecular weights of 52, 63, 69, 79, 89 and 93 kDa. Gp120 binding was Ca⁺⁺ dependent. These gp120 binding proteins were removed from the membranes by 6M urea extractions and were retained on WGA lectin column. The gp120 binding proteins in neural cells are also being evaluated by transfection of Rat2 cells with neural cells DNA. These Rat2-DNA transfected cells do not express the CD4 receptor, however, they became susceptible to HIV-1 infection. The long term goal of this study is to develop methods to interfere

with HIV-1 adverse effects on neural cells.

HUMAN ASTROCYTES ARE RESISTANT TO APOPTOSIS BY HIV-1 INDUCED NEUROTOXINS. R. A. Angel, G. Dbaibo[†], S.W. Perry, L.G. Epstein, S. Dewhurst8, Y. Hannun1, and H.A. Gelbard*. Depts. of Neurology and

*Microbiology and Immunology, Univ. of Rochester, Rochester, N.Y. 14642,

†Duke University Medical Center, Durham, NC 27710.

We have previously demonstrated that astrocytes in brain tissue of patients with
HIV-1 encephalitis do not exhibit TUNEL-stained nuclei (Gelbard et al., 1995). In
contrast, numerous adjacent neurons in this brain tissue demonstrate evidence of apoptosis. To investigate the molecular basis for this, we examined the effects of the HIV-1 gene products gp120 and Tat, and the HIV-1-induced neurotoxins tumor necrosis factor alpha (TNF α) and platelet activating factor (PAF) on cultures of astrocytes prepared from HIV-1 negative human fetal cerebral cortex. All these astrocytes prepared from FIV-1 legative limital teat cerebral cortex. All these substances are capable of inducing neuronal apoptosis. In contrast, gp120 (1 mM) induced <5% of the total astrocytes to undergo apoptosis, while Tat (500 nM) failed to induce apoptosis. TNFα (10 ng/ml) and carbamyl PAF (125 ng/ml, resistant to metabolism by brain acetylhydrolases) also failed to induce apoptosis. 2-chloro adenosine (100 μM, positive control) induced apoptosis in ~25% of total astrocytes. Because we have demonstrated that TNFα and PAF, at doses used in these studies, increase reactive oxygen species (ROS) and that TNF α increases ceramide production in neurons, we further examined if TNF α and PAF also increase ROS production and ceramide in astrocytes. Both TNF α and PAF failed to increase ROS as measured by oxidation of dichlorofluorescin using inverted fluorescence microscopy and FACS. Neither substrate affected ceramide production in astrocytes, but we did see an increased production of the second messenger diacylglycerol. Taken together, these results suggest that two intracellular events (generation of ROS and ceramide) that results suggest that two intracentual events (generation or ROS and ceramide) that may mediate apoptotic signals after stimulation with TNFα and PAF do not occur in human astrocytes. Current studies are focusing on whether the astrocyte's ability to undergo proliferation or increases in GFAP (neuropathologic features of HIV-1 encephalitis) may play a role in inhibiting generation of these pro-apoptotic signals. (Supported in part by NIH grants and the Dana Foundation).

367.12

EXPRESSION OF THE HIV-1 COAT PROTEIN GP120 IN BRAINS OF TRANS-GENIC MICE CAUSES OPPOSITE CHANGES IN SHORT- AND LONG-TERM POTENTIATION IN CAI HIPPOCAMPUS. T. Krucker*, S.M. Toggas, L. Mucke G.R. Siggins. AIDS Research Center & Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. "Gladstone Molecular Neurobiology Program

& Dept. of Neurology, Univ. of California, San Francisco, CA 94141.

The HIV-1 envelope glycoprotein gp120 is shed from infected cells and thus can diffuse and interact with uninfected neurons. Transgenic animals constitutively expressing gp120 from astrocytes in the brain (gp120 mice) display neuronal and glial pressing gp120 from astrocytes in the brain (gp120 mice) display neuronal and glial changes resembling abnormalities in HIV-infected human brains (Toggas et al., Nature 367, 1994). To assess the physiology of gp120 mice and determine whether gp120 expression impairs synaptic plasticity, we examined CA1 population excitatory postsynaptic potentials (pEPSPs) in hippocampal slices from these animals. Compared with slices from non-transgenic littermate controls, slices from gp120 mice showed: (1) a strong tendency for larger normalized pEPSP amplitudes; (2) slightly larger paired pulse facilitation (PPF) before and after induction of long-term potentiation (LTP) at 20 and 50 ms interpulse intervals (statistically significant only at 50 ms after LTP induction); (3) a tendency for pEPSPs to be smaller, whereas after LTP induction, mean peak PPF at 50 ms interpulse intervals was bigger; (4) markedly elevated short-term potentiation (STP) after 10 and 20 shocks at 100 Hz; and (5) a significant reduction in the magnitude of CA1 LTP. In slices from transgenic animals expressing lacZ from the same promoter (GFAP-lacZ mice), PPF and LTP were normal. These results indicate that brain slice preparations from gp120 mice can be normal. These results indicate that brain slice preparations from gp120 mice can be used to assess pathophysiological effects of gp120 on neuronal networks. Because STP involves presynaptic mechanisms, our results suggest that gp120 expression in these mice enhances either presynaptic glutamate release or postsynaptic glutamate receptor function, or both; these changes could lead to increased Ca⁺⁺ influx, contributing to neuronal dysfunction and injury. As LTP is a cellular model of learning and memory, our LTP results may relate to memory impairments seen in patients

INDUCTION OF MATRIX METALLOPROTEINASES IN MICE TRANSGENIC FOR HIV-1 gp120 AND IN gp120-TRANSFECTED GLIAL CELLS D.C.L. Marshall, M.F. Pietropaolo, T. Wyss-Coray, L. Mucke, M. Oscar-Berman*, and C.R. Abraham. Boston Univ. Sch. Med., Boston, MA 02118, Gladstone Molecular Neurobiology Program and Univ. Calif. San Fransisco, CA 94141.

Significant neurodegeneration has been observed in the CNS of patients with HIV encephalitis. Similar changes have been identified in brains of transgenic mice expressing the HIV-1 envelope protein gp120 (Nature 365:188). We are interested in the mediators of HIV-induced brain damage. Host factors that could contribute to neurodegeneration include proteases which degrade the extracellular matrix and may thereby impair the functioning of neurons and other CNS cells. Here, we demonstrate that C6 glioma cells stably transfected to express gp120 show prominent increases in the activity (by gelatin zymography) of matrix metalloproteinase-2 (MMP-2) and MMP-9 compared to mock-transfected controls. In contrast, the activities of tissue inhibitor of metalloproteinase-1 (TIMP-1) in gp120 and mock-transfected cells were similar (by reverse zymography). Brains of gp120 transgenic mice, which show neuropathology similar to that in AIDS dementia, show increased levels of MMP-2 activity in comparison to non-transgenic controls. These results indicate that the expression of viral products such as HIV-1 gp120 within the CNS can result in increased activity of MMPs. This process may play an important role in the development of HIV associated neurodegeneration. This work was supported by the NIH.

DEFICITS IN COGNITIVE AND MOTOR PERFORMANCE IN SIV INFECTED RHESUS MACAQUES. J.K. Marcario*, L.A.M. Raymond, B.J. McKiernan, S.V. Joag, L. Foresman, O. Narayan, P.D. Cheney. Dept. Physiol. & MRRC; Microbiol., Molec. Gene. & Immunol., Univ. Kansas Med. Cntr., Kansas City, KS 66160, USA.

It is well established that HIV infection can lead to neurocognitive disorder and dementia. The purpose of this study was to detect motor and cognitive impairments in SIV infected monkeys using five different behavioral tasks: progressive ratio (PR), simple reaction time (SRT), choice reaction time (CRT), turntable (TT) and working memory (WM). In addition, home cage behavior was videotaped each week and scored for activity level, general health and abnormal behavior. Of the 9 Rhesus macaques trained, 4 served as controls. The remaining 5 were infected with strains of SIV_{mac}239 (R71 and 17E) by bone marrow injection. Of the 5 infected monkeys, one remains asymptomatic with no performance deficits. The other 4 monkeys developed end-stage simian AIDS and were euthanized. Two monkeys did not show appreciable performance decreases. Two other monkeys exhibited performance deficits when their motivation, as measured by the PR task, was normal. One monkey showed loss of accuracy in ballistic movements as reflected by a decline in TT performance. Another monkey showed loss of motor skill as reflected by a decline in TT, and increased error rates in WM, SRT and CRT. The results of this study show that behavioral deficits associated with SIV infection vary greatly with the individual, as in HIV infection. In addition, these results support the use of this test battery for detecting cognitive and motor impairments in SIV infected monkeys. (Supported by NINDS grant #552232, NICHD grant

MOTOR EVOKED POTENTIALS IN A RHESUS MACAQUE MODEL OF NEUROAIDS. P.D. Cheney*, L. Raymond, J. Marcario, O. Narayan, N.E. Berman S.V. Joag, L. Foresman, Smith MRRC. and Depts. of Physiology, Anatomy and Cell Biol. and Microbiol, Immunol. and Mol. Genetics, Univ Kansas Medical Center, Kansas City, KS 66160

Motor system dysfunction is among the many neurologic abnormalities associated with HIV disease in humans. Damage to the corticospinal system is a common finding, particularly in pediatric AIDS. The purpose of this study was to investigate the integrity of the cortical motor system in SIV infected rhesus macaques. Five monkeys were inoculated by bone marrow injection with a combination of two strains of SIVmac239 (R71 & E17) known to be neurovirulent. Four uninfected monkeys served as controls. Transcranial electrical stimulation of motor cortex was used to evoke EMG potentials (MEPs) in lateral gastrocnemius and abductor hallicis of the hindlimb and extensor digitorum communis and abductor pollicis brevis of the forelimb. MEPs from stimulation of the cervical and lumbar spinal cord provided measures of peripheral conduction time. Central conduction time was estimated by subtracting the latency of spinal cord MEPs from those evoked by stimulation of motor cortex. Within 13 weeks of inoculation, 4 of 5 monkeys had developed end stage simian AIDS. Fifteen weeks after inoculation, one monkey remains asymptomatic. Of the four monkeys that progressed to AIDS, two showed abnormal motor evoked potentials in association with end stage disease. Both peripheral and central conduction times were increased. In one monkey, the threshold for cortical MEPs increased two-fold. This monkey also exhibited other motor signs including ataxia, tremors and clonus. These results further establish the R71 and E17 strains of SIV mac239 as a model of neuroAIDS. (Supported by NIH grants NS552232 and HD02528)

Changes in NMDA receptor complex binding characteristics in a murine model of AIDS.

J. A. English¹, G. Nowak^{1/2*}, and I. A. Paul¹. ¹Dept. of Psychiatry and Human Behavior, U. of MS Med. Center, 2500 N. State St, Jackson, MS, 39216,USA, and ²Institute of Pharmacology, Polish Acad. of Science, Smetna St. #12, Krakow 31-343, Poland.

Infection of C57/Bl6 mice with the LPBM-5 murine leukemia virus causes an acquired immunodeficiency syndrome (MAIDS), leading to immunosuppression, neurological and behavioral disturbances, and eventual death. Previous studies have shown that LP-BM5 causes learning deficits and increases CNS quinolinic acid levels. These studies suggest that effects of LPBM-5 infection on EAA neurotransmission may contribute to the learning deficits observed in infected mice. Here we report that LPBM-5 infection altered NMDA receptor binding characteristics in mouse frontal cortical homogenates. C57/Bl6 mice were inoculated with virus, then sacrificed at 0, 3, 6, 9, and 12 weeks post-inoculation. LPBM-5 infection was followed by time-dependent increases in binding of [³H]5,7 DCKA and [³H]CGP 39653 (competitive antagonists at the glycine and glutamate sites, respectively, of the NMDA receptor. LPBM-5 also produced a time-dependent decrease in the potency of glycine to displace [³H]5,7 DCKA from the glycine site. These results are consistent with the hypothesis that behavioral and learning deficits after LPBM-5 infection are mediated by changes in the binding characteristics of the NMDA receptor complex.

MULTIMODAL SENSORY EVOKED POTENTIALS AS INDICATORS OF SIV DISEASE PROGRESSION. <u>L. A. M. Raymond*1, J.K. Marcario*1, S. V. Joag*2, L. Foresman*2, O. Narayan*2, N. E. J. Berman*3 and P. D. Cheney*1, Opens of Physiol. and Men. Ret. Res. Cntr. ¹, Microbiol., Mol. Genet. & Immunol*2, and Anat. & Cell Biol. ³, Univ. of Kansas Med. Cntr., Kansas City, KS 66160. USA</u>

The Human Immunodeficiency Virus (HIV) infects the central nervous system (CNS) early in its progression and as many as 20% of HIVpatients later develop neurological signs that include impaired congnitive ability and psychomotor slowing. The studies of evoked potentials from HIV infected patients show many abnormalities in both asymptomatic as well as symptomic subjects with and without neurological deficits (Somma-Mauvais, Neurophysiol-Clin. Nov.22 (5): 369-84, 1992.) In an attempt to further establish an animal model of neuroAIDS, we recorded multimodal sensory evoked potentials (EPs) from five behavorially trained rhesus macaques infected with R71/E17, passaged strains of SIV_{MAC}239, as well as from four age and sex-matched controls prior to and at one month increments following infection (PI). The latencies and amplitudes of somatosensory (SEP) potentials from fore and hind limbs, flash visual (VEP), brainstem (ABR) and cortical (AEP) auditory potentials were measured. No changes were seen in the EPs from the control animals. All infected monkeys exhibited abnormal evoked potentials. Combining data from all five infected monkeys, decreases in amplitude and increases in latency were observed for each EP type, further supporting the SIV model of neuroAIDS. Supported by NIH grants NS552232 & HD02528.

PREFERENTIAL AND PROGRESSIVE FRONTAL CORTICAL CHANGES IN QUANTITATIVE EEG ACTIVITY AFTER FIV INFECTION IN THE ADULT CAT. M. Podell*, D. Ruehlmann, E. Chen, L. Mathes, Dept. Vet. Clin. Sciences and Vet. Biosciences, The Ohio State Univ., College of Veterinary Medicine, Columbus, OH 43210

Quantitative EEG (QÉEG) was performed on 5 feline immunodeficiency virus (FIV-MD) infected adult cats and 5 control cats 10 and 16 mo post-infection (PI). All cats were anesthetized with isoflurane gas anesthesia and controlled for changes in end-tidal $\rm CO_2$ and $\rm O_2$ saturation levels. Subdermal needle electrodes were placed in a modified 10-20 recording system. A minimum of 4 minutes of artifact free EEG activity was analyzed from each cat.

Power spectral analysis (PSA) group comparisons between FIV and control cats demonstrated a significantly slower median frequency of activity in the left frontal cortex only at 10 mo PI. At 16 mo PI, FIV cats had significantly slower median frequencies in all frontal cortical recording sites. The difference in the PSA between individual FIV cats and group control data was calculated at specific frequencies. Comparison of these individual differences showed a significant shift toward slower frontal cortex activity in the 16 mo recordings in 4 of 5 FIV cats. No change in coherence was found at 10 mo PI. At 16 mo PI, FIV cats exhibited significantly lower frontal interhemispheric and left and right intrahemispheric coherence compared to control cats considering all recording frequencies. The greatest difference in coherence was found for delta activity between the frontal cortices. These results show that FIV infection in the cat induces a frontally dominant slowing of EEG activity due to possible disruption of both intracortical and subcortical pathways. These changes appear analogous to QEEG changes seen in HIV-1 infected people.

ANTI-DEPRESSANT LIKE ACTIVITY OF HU-211, A NOVEL NMDA ANTAGONIST. A. Bar-Joseph, Berckovitch and A. Biegon*. Pharmos LTD, Kiryat Weizman 76326. Rehovot, Israel

NMDA antagonists have demonstrated anti-depressant like activity in animal models. HU-211 is a novel NMDA antagonist devoid of the severe side effects characteristic of many NMDA antagonists. In the present study we examined its anti-depressant activity, in three in vivo models. Male BALB/c mice were used in all studies (n=6-10 per group). HU-211 5, 10, 20, 30 and 40 mg/kg was administered IP, and compared to amytriptiline 15 mg/kg, MK-801 0.5 mg/kg and the appropriate vehicles in all three models. In the open field test, the high dose levels of HU-211 reduced the area traveled by treated mice by 40% (p<0.05), similar to that seen with Amtriptiline (55%) and in contrast to the hyperactivity seen with MK-801 (70%, p<0.05). A similar effect was also evident in other motor parameters (crossing and rearing). No other effects were detected with HU-211, while a significant hypothermia of 3°c (p<0.05), was seen with amytriptiline. A dose related effect of decreased immobility time was evident with HU-211 treated mice in the forced swim test (FST). These effects, induced by HU-211 20-40 mg/kg (40%) and amytriptiline (70%) were statistically significant (p<0.05). MK-801 increased immobility time by 30% (p<0.05 vs. vehicle). HU-211 treated mice performed in a similar manner in the tail suspension test (TST), 35% decrease in immobility time in the 20 mg/kg dose (p<0.05). This effect disappeared with the highest dose, 40 mg/kg. Amytriptiline and MK-801 reduced the immobility time by 75% (p<0.05) in conclusion, the present work demonstrated the ability of HU-211 to induce antidepressant like activity.

MOTOR ACTIVITY AND VARIATION OF MOOD IN DEPRESSION. M.R. Lemke*, A. Broderick, M. Zeitelberger, W. Hartmann. Psychiatric Clinic, General Hospital, D-85049 Ingolstadt, and Dept. Psychiatry, University of Kiel, Germany

Objective: Diurnal variation of mood in depressed patients represent a diagnostic criteria (DSM-IV) for the melancholic type of depressive disorder. Whether circadian variation of symptom intensity include changes in spontaneous motor activity, remains unclear. Therefore, the relation of motor activity and mood was studied at different times of the day in patients with major depression.

Methods: Inpatients (n=21) were included if they fulfilled DSM-IV criteria for major depression, melancholic type, and experienced diurnal variations of mood. Motor activity was measured by actigraph (activitybased monitoring) (ZAK, Germany) from 7 to 9 a.m. and p.m.. Patients recorded their mood on a visual analogue scale (VAS) during this time.

Results: VAS scores were significantly lower in the morning (p<0.01). Counts of activity units were significant greater in the morning (p<0,01) and showed an invers correlation with VAS scores (p<0,01).

Conclusions: Activity measured by actigraphy may not cover all aspects of psychomotor activity. However, increased motor activity may represent an observable, psychobiological behavioral equivalent of self experienced depressed mood and may serve as a biological function to elevate depressed mood via modification of neuronal serotonergic activity. (Supported by General Hospital, Ingolstadt, Germany)

VALPROIC ACID TREATMENT FOR MAJOR DEPRESSIVE DISORDER: GABA AND MOOD DISORDERS. L. L. Davis*, F. Petty, VAMC and Univ. Texas Southwestern Med. School, Dallas, TX 75216

Valproic acid is a GABA agonist anticonvulsant which is also an effective treatment for mania. We studied valproic acid as a treatment for non-bipolar major depressive disorder (MDD), since a deficit in GABA is well established in MDD. 28 outpatients who met research criteria for MDD, with no history of mania or hypomania were enrolled in an open trial with valproic acid for 4 weeks with a 4 week extension. 23 patients completed 4 weeks of treatment with valproic acid, completed the 4 week extension. At week 4, 13 of the 23 completers demonstrated a clinical response, and mean Hamilton depression (HD) scores for all patients decreased from baseline 22 ± 5 to 11 ± 6 (p < 0.0001). At week eight, 17 of the 19 (89%) completers demonstrated clinical improvement, and HD scores decreased 7 ± 4 (p < 0.0001). For all subjects (intent to treat analysis at week eight), 61% were responders and HD scores decreased 52 %). Patients with melancholia were as likely to respond to valproic acid as non-melancholic depressives. These data suggest that valproic acid may be an effective and well-tolerated treatment for unipolar major depressive disorder. Double-blind, placebo-controlled trials are needed to further document the efficacy of valproic acid in the treatment of MDD. A role for GABA in depression is supported.

13HIR041-1049 BINDING TO MONOAMINE OXIDASE-A IN THE LOCUS COERULEUS IS NOT ALTERED IN MAJOR DEPRESSION. G.A. Ordway* V. Klimek, J.G. Richards, J.C. Overholser, H.Y.Meltzer, G.Dilley and C.A. Stockmeier. Dept. Psychiatry & Human Behavior, Univ. of Mississippi Med. Ctr., Jackson, MS; Depts of Psychiatry & Psychology, Case Western Reserve Univ., Cleveland, OH; Pharma Division, F. Hoffmann-La Roche Ltd., Basel, Switzerland.

Recent studies have revealed an abnormal expression of certain noradrenergic proteins (e.g. tyrosine hydroxylase, norepinephrine transporters) in the locus coeruleus of subjects with major depression and/or victims of suicide. Monoamine oxidase-A (MAO-A), another key enzyme in the metabolism of norepinephrine, is also expressed in noradrenergic neurons of the locus coeruleus and inhibitors of MAO-A are effective in the pharmacological management of major depression. In this study, the binding of [3H]Ro41-1049 to MAO-A was measured at multiple levels along the rostral-caudal axis of the locus coeruleus from 10 subjects with major depression and 10 age- and post-mortem interval-matched, control subjects who were psychiatrically normal. Post-mortem toxicology revealed no antidepressants in the blood or bile of any subjects. The binding of [3H]Ro41-1049 to MAO-A was unevenly distributed along the rostral-caudal axis of the locus coeruleus, parallelling uneven numbers of noradrenergic neurons throughout the nucleus. Accordingly, there was a significant correlation between the number of noradrenergic cells per section and the specific binding of [³H]Ro41-1049 at any particular level of the LC from control subjects (r²=0.28; p<0.0001) and from major depressives (r²=0.23; p<0.0001). There was no correlation between the age and the amount of [3H]Ro41-1049 binding to MAO-A in control subjects or in major depressives. Unlike tyrosine hydroxylase and norepinephrine transporters, MAO-A in the LC appears to remain unchanged in major depressives as compared to psychiatrically normal control subjects. (Supported by MH46692 and MH45488.)

NEUROPSYCHOLOGICAL IMPAIRMENTS IN UNIPOLAR DEPRESSION: THE ROLE OF PERCEIVED FAILURE, <u>B.J. Sahakian*</u>, <u>R. Elliott, A.P.McKay, J.J. Herrod, T.W. Robbins and E.S. Paykel</u> Departments of Psychiatry and Experimental Psychology, University of Cambridge, Cambridge, CB2 2QQ, U.K

Depression has been associated with various neuropsychological impairments but no consensus explanation of these deficits has emerged. In an attempt to characterise the neuropsychological profile of depression more fully, this study used a highly sensitive test battery with strong neurological validation to assess the cognitive deficits associated with depression.

The CANTAB battery of neuropsychological tests was used to compare the performance of 28 medicated patients with unipolar depression to that of 22 matched controls. These tests assessed visuo-spatial memory, attentional set-shifting working memory and planning. The patients were impaired on almost all tests studied with 92% of patients showed at least some impairment. Both accuracy and latency of performance were compromised. Intact performance on the test of attentional set-

performance were compromised. Intact performance on the test of attentional setsifiting suggests that these deficits were not purely motivational. Deficits in the tests of visual memory correlated with severity of depression. An important finding was the detrimental effect of failure on subsequent performance; having solved one problem incorrectly, patients were significantly more likely than controls to fail the subsequent problem, even after controlling for overall failure rates. Comparisons with other patient groups showing similar levels of impairment indicated that this effect was specific to depression. Patients with frontal lobe damage, temporal lobe damage, schizophrenia or Parkinson's disease were no more likely than controls to respond to one failure with another. Also the impairment did not normalise on clinical recovery suggesting that it may represent a trait factor for depression. recovery suggesting that it may represent a trait factor for depression.

Oversensitivity to negative feedback may therefore be an important determinant of

performance in depressed patients, interacting with general neuropsychological impairments. This demonstartion of a possible interface between mood and cognition has important implications for our understanding of the disorder.

VENLAFAXINE: SAFE AND EFFECTIVE ANTIDEPRESSANT THERAPY IN PATIENTS ON CONCOMITANT MEDICATIONS,

B. Zimmer, R. Kant, D. Zeiler, M. Brilmyer and L.H. Schneider* Dept. Psychiatry and Neuropsychiatric Institute, Allegheny General Hospital Pittsburgh, PA 15212 and Innova Biomed, INC., Irvington, NY 105331 Pittsburgh, PA 15212 and Innova Biomed, INC., Irvington, NY 105331 Venlafaxine is a novel antidepressant agent which inhibits the reuptake of both serotonin and norepinephrine. Venlafaxine has been shown to be safe and effective monotherapy in a substantial number of clinical studies with depressed patients. Compared with traditional antidepressants (TCAs and MAOIs) and the selective serotonin reuptake inhibitors (SSRIs), venlafaxine has lower protein binding and less impact on cytochrome P450 isoenzyme systems (Richelson, 1994). Thus, venlafaxine should reduce the risk of drugdrug interactions in depressed patients requiring concomitant medications.

Our study sought to assess the safety and efficacy of venlafaxine in a population of depressed patients with medical comorbidities which required continuation of concomitant medications. Twenty-six patients completed the study. Baseline evaluations included medical and blood pressure measures, as well as psychiatric evaluation. Blood pressure was monitored and clinical global improvement (CGI score) was rated when venlafaxine therapy ended. Data were analyzed by appropriate nonparametric statistical tests which classified patients into young (13-55; n=11) and old (65-82; n=15) groups.

classified patients into young (13-55; n=11) and old (65-82; n=15) groups. Antidepressant efficacy was found in 64% of young and 73% of old patients, whose total daily dosages of venlafaxine [mg/day; mean (sem)] were 185.2 (24.7) and 131.7 (15.7), respectively. No interactions between venlafaxine and concomitant medications were apparent. Systolic (SBP) and diastolic (DBP) blood pressure changes over treatment were [mm Hg; mean (sem)]: Young 0.82 (5.09) SBP and 2.72 (1.97) DBP vs. old 0.73 (3.45) SBP and 4.53 (1.72) DBP. These results suggest that venlafaxine is a safe and effective first-line antidepressant for vulnerable depressed patients on concomitant medications. [Supported in part by Innova Biomed, Inc.]

FLUOXETINE AND DULOXETINE SIMULTANEOUSLY RELEASE SEROTONIN (5-HT), DOPAMINE (DA) AND NORADRENALINE (NAD) IN THE FRONTAL CORTEX OF FREELY-MOVING RATS: WAY 100,635 SELECTIVELY POTENTIATES THE INDUCTION OF 5-HT RELEASE. A Gobert*, J-M. Rivet, M. Spedding, L. Cistarelli, S. Girardon and M.J. Millan, 1 D.R.S., 125 Chemin de Ronde, 78290 Croissy, France.

 $\label{eq:while_the_sol} While the $5-HT_{1,A}$ receptor antagonist, $(N-\{2-[4-(2-methoxyphenyl)-1-piperazinyl|ethyl\}-N-(2-pyridinyl)$ cyclo-hexanecarboxamide) $(WAY 100,635)$$ WAY) potentiates 5-HT release provoked by fluoxetine (FLX), its influence upon DA and NAD release remains unexplored. We examined this question employing FLX, a further uptake inhibitor, duloxetine (DLX), and dialysis in freely-moving rats implanted with a cannula in frontal cortex (FCX). Doses (base) are in mg/kg, s.c. Samples were taken every 20 min and analysed by HPLC/ coulometric detection. Three basal values were taken, WAY (0.16) injected, and, 20 min later, FLX (10.0) or DLX (5.0) administered. Levels (Means±S.E.M.) were determined at 60-120 min.

	VEH +	VEH+	VEH +	WAY +	WAY +	WAY +
	VEH	FLX	DLX	VEH	FLX	DLX
5-HT(0.9)	103 ± 6	186 ± 10#	209 ± 13#	113 ± 11	306 ± 24*	423 ± 27*
DA (1.1)	98 ± 3	$148 \pm 5 \#$	155 ± 9#	95 ± 3	130 ± 4	146 ± 10
NAD (1.0)	108 ± 5	$187 \pm 7 \%$	441 ± 20#	104 ± 9	141 ± 8	453 ± 38
Levels are % basal (= 100%). Absolute, basal levels (pg/20 min) are in parentheses						
VEH = vehic	le; # P < 0	05 vs VEH/	VEH; *P < 0	0.05 vs VEH	/FLX or VE	H/DLX.

WAY selectively and markedly potentiated the FLX- and DLX-induced increase in 5-HT, but not DA and NAD. We conclude that, under these conditions, FLX releases 5-HT as well as DA and NAD in FCX. However, the 5-HT_{1A} antagonist, WAY

likely via an action at 5-HT_{1A} autoreceptors, selectively enhances the FLX- and DLX-induced release of 5-HT as compared to DA and NAD in FCX.

EFFECTS OF CHRONIC ANTIDEPRESSANT TREATMENT ON PLASMA CORTICOSTERONE AND PROGESTERONE AFTER SWIM STRESS AND ACUTE CHALLENGE WITH FLUOXETINE. G.E. Duncan*, D.J. Knapp and G.R. Breese. Univ. of North Carolina Neuroscience Ctr, Univ. of North Carolina, Chapel Hill, NC 27599.

Although the acute pharmacological actions of antidepressant drugs are well characterized, the adaptive changes induced by chronic treatment with antidepressant drugs that are responsible for therapeutic mechanisms of action are unknown. The well documented association between stress and depression suggests that investigation of the effects of chronic antidepressant administration on stress responses could help to elucidate the mechanism of antidepressant action. In the present study the effects of chronic treatment (3 weeks) with saline, imipramine (20 mg/kg), or fluoxetine (5 mg/kg) were investigated on corticosterone and progesterone secretion induced by swim stress (Porsolt et al., 1978) in male rats. The final drug injection was given 24 hrs before the test swim. Swim stress increased plasma corticosterone (14 fold) and progesterone (22 fold) and the time course of response for the two hormones was similar. Chronic treatment with imipramine reduced stress-induced progesterone levels by 50-60% at the different times but did not alter stress-induced levels of corticosterone. By contrast, chronic treatment with fluoxetine did not alter the stress-induced changes in either hormone. Effects of chronic fluoxetine treatment were also investigated on the hormonal responses to acute challenge with fluoxetine. Injection of fluoxetine (5 mg/kg) after chronic saline robustly elevated corticosterone and progesterone to an extent comparable to that observed for swim stress. After 3 weeks treatment with fluoxetine acute administration of the drug did not alter plasma levels of either hormone. These data suggest that an adaptive responses occurred in serotonergic pathways related to the regulation of adrenal cortical secretion after chronic fluoxetine treatment. The failure of chronic fluoxetine to alter the homonal responses to acute swim stress suggest that different neural mechanisms are responsible the elevation of corticosterone and progesterone after acute stress compared to acute challenge with fluoxetine. EFFECTS OF IMIPRAMINE ON 5-HT2CR mRNA AND A NOVEL DEPRESSION RELATED GENE (DRF24) EXPRESSION.

M. Tohda1*, Y. Nomura 1,2 & H. Watanabc1, 1 Res. Inst. for Wakan-yaku (Traditional Sino-Japanese Medicines), Toyama Med. & Pharm. Univ., Toyama 930-01 and ² Fac. of Pharmaceutical Sci., Hokkaido Univ., Sapporo 060, Japan,

We previously reported that some antidepressants act as serotonin 2C subtype receptor (5-HT2C) antagonists. Here, we examined the influences of antidepressants on 5-HT2C mRNA and novel type of gene expression in the rat brain. Imipramine was orally administered to male Wistar rats (8 w, 220 - 250g) once daily for 4 days. The 5-HT2C mRNA expression in the brain was detected by in situ hybridization methods using the digoxigenin-labeled antisense cRNA probe coding the third intracellular loop. Imigramine treatment produced more intense hybridization signals in nearly all regions stained, such as the hippocampus, choroid plexus, habenular nucleus and dorsomedial hypothalamic nucleus, than the control in a dose-(2 - 20 mg/kg) and a time- (1 - 14 days) dependent manner. Mianserin (20 mg/kg) and desipramine (20 mg/kg) also extended the 5-HT2C mRNA expression but nomifensine (20 mg/kg) was ineffective. These findings corresponded with the antagonistic effects of antidepressants to 5-HT2C. Since the 5-HT2C gene has been suggested to act as a protooncogene, we also searched for genes newly expressed after imipramine treatment by the differential display methods. We found a novel gene (DRF24) and read the sequence: DRF24 is 160 bp which may be a partial sequence. DRF24's mRNA existed in the basolateral amygdaloid nucleus of the imipramine-treated rat brain. We are now studying the whole sequence of the gene and its functions.

PAROXETINE CHALLENGES DO NOT AFFECT PLASMA PROLACTIN LEVELS. P. Hicks*, S. Peterson, J. Richter AND J. Browning. Dept. of Psychiatry and Behavioral Science, Scott and White Clinic, Temple 76508

A variety of pharmacological agents (e.g. clomipramine and fenfluramine) have been used to evaluate the neurochemical state of depressed patients using neuroendocrine responses. The role of serotonin in the neuroendocrine response has been studied using the serotonin precursor L-tryptophan and m-CPP (nonspecific 5-HT-2A/2C agonist). L-tryptophan enhances prolactin release which is reversed by the 5-HT-1 antagonist pindolol indicating that prolactin release is mediated by 5-HT-1 receptors (Smith et al., 1991). M-CPP enhances prolactin release which is reversed by ritanserin (5-HT-2A/2C antagonist) (Seibyl et al., 1991). Thus, there are multiple 5-HT receptor subtypes that modulate the release of prolactin. We have assessed the use of a very selective 5-HT uptake inhibitor, paroxetine, in the release of prolactin in normal volunteers.

Normal volunteers ages 20-50 years were given blinded oral challenges with either paroxetine (0, 30 or 60 mg) or clomipramine (0, 50 or 100 mg) and their prolactin levels monitored for up to 6 hours after drug exposure.

mg) and their protactin levels monitored to appear exposure.

The results indicate that paroxetine did not induce prolactin release in men or women normal volunteers (p > .86; F=0.14; df 2.32). There was a prolactin response to clomipramine, however (p< .05 using Dunnet's Method to compare with the control group).

Paroxetine is known to be a potent and selective inhibitor of serotonin uptake. The fact that paroxetine did not induce prolactin release suggests that other neurotransmitter systems may be important in the release of prolactin induced by the serotonin uptake inhibitor clomipramine or the serotonin releasing agent fenfluramine. Precaution should be taken in the interpretation of pharmacological challenges evaluating the central serotonergic state with such agents.

DESMETHYLIMIPRAMINE REVERSES REWARD IMPAIRMENTS OBSERVED DURING AMPHETAMINE WITHDRAWAL: VALIDATION OF A MODEL OF DEPRESSION. D. Y. Lin, M. P. Epping-Jordan*, G. F. Koob, A. Markou. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

Major affective disorder in humans is accompanied by significant deficits in reward and motivation. Animal models of psychostimulant withdrawal have demonstrated similar robust and quantifiable impairments in reward processes as demonstrated similar robust and quantinate impairments in reward processes as assessed by changes in intracranial self-stimulation (ICSS) thresholds. These models may, therefore, provide insights into the neurobiology of depression that may, in turn, lead to pharmacological therapies that would alleviate reward and motivational impairments. A previous study that used ICSS thresholds to assess changes in reward state showed that repeated administration of desmethylimipramine (DMI), a tricyclic antidepressant, shortened the duration of elevations in ICSS thresholds in cocaine-withdrawing animals. In the present study, the effects of repeated DMI administration in naive animals and animals undergoing amphetamine withdrawal (systemic amphetamine administration: 1-5 mg/kg i.p., 3 times daily for 4 days) were explored. Following the amphetamine exposure regimen, DMI was administered twice daily at either of four doses (0, 2.5, 5, 10 mg/kg i.p.) and estimates of ICSS thresholds were obtained on successive days of withdrawal. In amphetamine-exposed animals, chronic DMI treatment reduced the duration of ICSS threshold elevations in a dose-dependent manner. Interestingly, acute administration of DMI did not reduce ICSs thresholds in amphetamine-withdrawing rats at any dose. In fact, acute DMI actually elevated thresholds in naive rats (non-withdrawing) at the 5 and 10 mg/kg doses. The reversal of amphetamine withdrawal effects on ICSS reward following repeated DMI administration provides validation for the use of this model in the development of novel pharmacotherapies to treat the reward and motivational dysfunctions associated with depression. BIOCHEMICAL STUDIES OF YM992: A NOVEL ANTIDEPRESSANT AS SELECTIVE SEROTONIN RE-UPTAKE INHIBITOR SEROTONIN-2A ANTAGONIST. Y. Tasaki, K. Hatanaka, T. Nomura, H. Yatsugi and T. Yamaguchi.* Neuroscience Gastrointestinal Research Lab. Institute for Drug Discovery Research, Yamonouchi Pharmaceutical Co., Ltd., 21 Miyukigaoka, Tsukuba 305 Japan.

Our biochemical studies have confirmed that YM992, (S)-2-[[7-fluoro-4indanyl)oxy]methyl]morpholine monohydrochloride, has a novel selective serotonin re-uptake inhibition (SSRI) with 5-HT_{2A} antagonistic activity in vitro and in vivo. In the present study, we investigated 5-HT release in the frontal cortex of the rats using microdialytic teuniques. The rats were chronically treated with an antidepressant, such as citaroplam, fluoxetine, or YM992. The 5-HT release induced by YM992 was more than that induced by the other antidepresents. In addition, the effect of YM992 on endocrine changes was examined. Many studies reported that corticotropin-releasing factor(CRF) and adrenal glucocorticoid-hormones were increased in depressive patients. Therefore, we first examined one of the adrenal glucocorticoid-hormones, corticosterone, in immobilized rats treated with the antidepressants. In a single injection of these drugs, there were no significant changes in serum corticosterone concentration of all groups. In chronic treatment of these drugs(14 days), however, only YM992 showed significant decrease of serum corticosterone concentration compared with the other antidepresants. These results suggested that the antidepressive effect of YM992 appear earlier than that of other SSRIs

ROLE OF 5-HT1A AND 5-HT2A RECEPTORS IN THE ANTIDEPRESSANT ACTIVITY OF YM992 IN THE MOUSE TAIL SUSPENSION TEST.

S. Yatsugi, H. Takeuchi, S. Hayashibe, S. Tsukamoto, K. Koshiya, S. Usuda, A. Iwai* and T. Yamaguchi. Institute for Drug Discovery Research, Yamanouchi Pharmaceutical Co., Ltd., 21 Miyukigaoka, Tsukuba, Ibaraki 305, Japan.

YM992 ((S)-2-[[(7-fluoro-4-indanyl)oxy]methyl]morpholine monohydrochloride) has selective affinities for serotonin (5-HT) uptake sites (Ki = 21 nM) and 5-HT2A receptors (Ki = 86 nM). YM992 shows more robust antidepressant activity in the mouse tail suspension test than selective 5-HT reuptake inhibitors (SSRI), such as titalopram or fluoxetine. A likely explanation for this characteristics of YM992 could be a synergistic effect of its dual action. Here we investigated the possible involvement of 5-HT2A antagonism of YM992 in its antidepressant activity in the mouse tail suspension test by comparing the efficacy of a typical SSRI citalopram, a selective 5-HT2A antagonist MDL100907, and their combined treatment. we examined the effect of selective 5-HT1a antagonist, WAY 100, 635, on the antidepressant activity of YM992. Mice were intraperitoneally or subcutaneously dosed with drugs 30 min before test. They were suspended with the tail for 6 min, and the duration of immobility was measured. MDL100907 alone did not affect the immobility time in a dose range of 0.01 to 0.3 mg/kg (ip). Citalopram neither showed significant effect at a dose of 10 mg/kg (ip). However the coadministration with ineffective doses of the both compounds exerted a marked reduction in the immobility This effect was almost equipotent to that of 10 mg/kg (ip) of YM992 Although WAY 100,635 (0.1 and 0.3 mg/kg, sc) alone did not affect the immobility time, it dose-dependently antagonized the effect of YM992. These results suggest that the robust effect of YM992 in this model is due to its 5-HT_{2A} antagonistic activity in addition to 5-HT re-uptake inhibition activity, and the stimulation of 5-HT1A receptors with 5-HT, which is potentiated by 5-HT2A receptors blockade, plays an important role in the antidepressant activity of YM992.

LITHIUM-INDUCED ENHANCEMENT OF 5-HT $_{2\Lambda}$ RECEPTOR FUNCTION IS NOT ASSOCIATED WITH ALTERATIONS IN RECEPTOR NUMBERS. J.M. Moorman and R.A. Leslie* Oxford University SmithKline Beecham Centre for Applied Neuropsychobiology, University Department of Clinical Pharmacology, Radcliffe Infirmary, Oxford, OX2 6HE, England.

Lithium is used in the treatment of bipolar affective disorder, yet its mechanism of action is poorly understood. We investigated the effects in rats of chronic treatment with lithium on 5-HT2A receptor-mediated behavioural responses, Fos expression, and the density of this receptor subtype in the brain. Rats received either control or lithium-containing (0.1% LiCO₃) chow for 3 weeks prior to challenge with the 5-HT_{2A/CC} agonist 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI). DOI-induced head shakes were then counted and locomotor activity was monitored for 30mins. Animals were killed 120mins later and their brains removed for immunohistochemical localisation of Fos protein. Another group of rats, also receiving either control or lithiumcontaining chow, had their brains analysed for the distribution and density of 5receptor binding sites by quantitative [3H]ketanserin (2nM) autoradiography (± 500nM unlabelled spiperone). Treatment with lithium was found to have no effect on DOI-induced head shakes, but it significantly enhanced both DOI-induced locomotor activity and DOI-induced Fos expression throughout the cerebral cortex. In contrast, such treatment had no effect on the density of [3H]ketanserin binding to 5-HT2A receptors in any brain region examined. Throughout plasma lithium levels, measured by atomic absorption spectroscopy, were between 0.4 and 0.6mEq/l. Since the enhancing effect of lithium on DOI-induced locomotor activity and Fos expression are not mediated by a change in the density of 5-HT_{2A} receptor binding sites, another mechanism such as an alteration in second messenger function (eg phosphatidyl inositol turnover) must be considered

368.17

CHANGES IN NA+,K+-ATPase ALPHA ISOFORM SUBTYPES IN LYMPHOBLASTOID CELL LINES FROM BIPOLAR PATIENTS. Li, T. Buss and R.S. El-Mallakh*. Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine, Louisville, KY 40292.

There are many lines of evidence suggesting that cation distribution and regulation may be abnormal in patients with manic-depression. For example, fresh lymphocytes derived from bipolar individuals fail to show the normal increase of Na+,K+-ATPase activity seen when cells are exposed to ethacrynic acid in vitro. We have investigated the response of immortalized lymphoblastoid cells to ethacrynate. Lymphoblastoid cells from Old Order Amish bipolar patients (n=9) and normal controls (n=7) were treated with ethacrynic acid (10 μ M) or vehicle for 72 hours. [³H]-Ouabain binding, and alpha subunit protein expression were analyzed. Ethacrynic acid induced an increase (134%) in [3H]-Ouabain binding in lymphoblasts derived from normal individuals, however, lymphoblasts from bipolar patients exhibited a slight decrease (89%). A similar pattern was observed by Western blot in which there was a decrease in the $\alpha 1$ isoform of the Na⁺,K⁺-ATPase in ethacrynic acid-treated cells from patients compared to normal controls. (The $\alpha 2$ and $\alpha 3$ isoforms were never expressed in either normal or bipolar lymphoblasts.) We conclude that the absence of adaptive responses of Na+,K+-ATPase to ethacrynic acid that occurs in fresh lymphocytes also occurs in lymphoblastoid cell line from bipolar patients, and it is related to variations in $\alpha 1\ Na^+, K^+-ATPase$ protein expression.

368.14

COMBINED ADMINISTRATION OF THE 5-HT $_{\rm ID}$ ANTAGONIST GR127935 AND SERTRALINE SYNERGISTICALLY INCREASES EXTRACELLULAR 5-HT LEVELS IN GUINEA PIG HYPOTHALAMUS

AND SERTRALINE SYNERGISTICALLY INCREASES EXTRACELLULAR 5-HT LEVELS IN GUINEA PIG HYPOTHALAMUS T. Clarke, J. Sprouse, D.W. Schulz and H. Rollema* Department of Neuroscience, Pfizer Central Research, Groton CT 06340 The 5-HT_{18/10} terminal autoreceptor is a potential target for drugs aimed at enhancing serotonergic transmission, since blockade or activation of this receptor is expected to increase or decrease 5-HT release, respectively. We studied the effects of the 5-HT₁₀ antagonist, GR127935, on 5-HT release by microdialysis in guinea pig hypothalamus. Experiments were performed under basal conditions and following pretreatment with the SSRI sertraline. At 0.3 mg/kg, GR127935 had no effect on basal 5-HT release, but a dose of 5 mg/kg produced a small increase (to 135% of basal levels) in 5-HT release in guinea pig hypothalamus. Low doses of sertraline (2 mg/kg sc) increased extracellular 5-HT to the same extent (to 130% of basal levels). The combined administration of this dose of sertraline with 0.3 mg/kg sc of GR127935 had marked synergistic effects: the maximal 5-HT increase was much higher (200% of basal) than the sum of the effects of either drug given alone. In addition, the 5-HT levels remained elevated for more than 5 hours, resulting in at least 4 times greater AUC values for the combination than for the additive AUC's of each individual drug. When 2 mg/kg sertraline was combined with 5 mg/kg GR127935, the maximal 5-HT increase was somewhat higher (to 250% of basal) and longer lasting than with 0.3 mg/kg GR127935. These data demonstrate that activation of 5-HT₁₆₀ terminal autoreceptors reduces the net effect of SSRI's on extracellular 5-HT levels and that the combination of a SSRI with a 5-HT₁₀ antagonist could be useful in augmenting and/or hastening the onset of antidepressant effects.

antidepressant effects.

ELEVATED INTRACELLULAR CALCIUM IN IMMORTALIZED B-LYMPHO-BLASTS IN BIPOLAR-I DISORDER. M. Emamghoreishi, L. Schlicter, P.P. Li, S. Parikh, J. Sen, A. Kamble and J.J. Warsh*. Clarke Institute of Psychiatry and Playfair Neuroscience Institute, University of Toronto, Toronto, ON, Canada Increasing evidence implicates altered calcium (Ca⁻²) signaling mechanisms in the

pathophysiology of bipolar affective disorder (BD). Higher resting ([Ca⁺²]_B) and agoniststimulated ([Ca+2]s) intracellular calcium concentrations have been found in platelets and [Ca+2], in lymphocytes from untreated manic and depressed BD patients compared with unipolar depressed patients and heathy controls (Dubovsky et al., Am. J. Psychiatry 149:118, 1992; Eur. Arch. Psychiatry Clin. Neurosci. 243:229,1994). To clarify whether such changes are trait-related, we determined [Ca*2]_B in Epstein-Barr virus-immortalized B-lymphoblasts obtained from physically healthy subjects with DSM-IV diagnoses of BD (bipolar I [BP-I], N=28; bipolar II [BP-II], N=10), major depression (MDD, N=13), non-mood psychiatric disorder (NMD, N=14), and no psychiatric disorder (N=20). [Ca⁺²], was measured by ratiometric fluorescence assay using fura-2. [Ca⁺²]₈ and phytota "j, was measured by rationerine into rescence assay using tura-2. [Ca]_B and phyto-haemagglutinin-(PHA, $10\mu g/ml$) stimulated [Ca⁺²]_B were also determined in freshly isolated T-lymphocytes from these same subjects. [Ca⁺²]_B was significantly higher (13%) in transformed lymphoblasts from BP-I (63.3 \pm 9.4, mean \pm SD, nM), but not BP-II (58.8 \pm 3.9), MDD (57.5 \pm 7.3) or NMD (54.8 \pm 5.3) patients compared to healthy subjects ± 3.57, MDB (3.7.5 ± 7.3) (wND (3.4.5 ± 3.5) patients compared to heatiny subjects (55.9 ± 8.25) (ANOVA, 7-4.01, d²-4.79; p=0.005). [Ca²]₈ values did not correlate with age or blood pressure, nor was there any significant interaction between gender and diagnosis on [Ca²]₈ in lymphoblasts. [Ca²]₈ was also significantly higher (30%) in T-cells from BP-I, but not BP-II or MDD subjects compared with healthy controls (ANOVA, F=2.34, d²+4.66; p=0.06). [Ca²]₈ did not differ between subject groups but there was a significant reduction in the % response relative to [Ca²]₈ in BP-I compared with healthy subjects, most likely a result of the elevated [Ca+2]B values in the former group. These findings provide additional evidence suggesting that trait-dependent factors account, at least in part, for elevations in $[Ca^{-2}]_B$ in lymphocytes from BP-I subjects. (Supported by Medical Research Council of Canada grant MT 12851).

AN ANIMAL MODEL FOR MANIA: PRELIMINARY EVIDENCE FOR SENSITIZATION TO OUABAIN

R.S. Levy.* R. L. R. S. El-Mallakh, L. T. Harrison, D. G. Changaris, and G.Bao. Depts. of Psychiatry, Biochemistry, Neurology, and Laboratory of Biological Psychiatry, University of Louisville School of Medicine, Louisville, KY 40292. Mood-state-related reduction of erythrocyte Na,K-ATPase pump activity is a consistent trait seen in manic or depressed bipolar patients. We have

previously demonstrated that chronic intracerebroventricular (ICV) infusion of the Na,K-ATPase inhibitor, ouabain, in male Sprague-Dawley rats can produce either hyperactivity or hypoactivity. These ouabain-induced changes in behavior can be prevented by lithium preadministration, and ameliorated when lithium is given after induction of the behavioral change. Effects of other antimanic agents such as valproic acid are currently under investigation. We recently have found preliminary evidence that this technique may model yet another characteristic of human mania -- sensitization. In human mania this manifests as a worsening course of illness as a function of prior manic episodes. ICV cannulae were placed stereotactically under anesthesia. Four days later the animals were given a single ICV injection of 5 μL ouabain 10-3M over 30 seconds. Three weeks later the rats were rechallenged with a chronic infusion of ouabain 10 3M or artificial cerebrospinal fluid (aCSF) at 5 $\mu L/hr$ (via an ALZET osmotic mini pump). Locomotor activity was quantified using an infrared beam activity monitor before chronic ouabain infusion (baseline) and again at days 3, 10, 14, 21, 28 and 35. Baseline behavior was not different between the animals. After 10 days of ouabain infusion, activity was increased to 424% of baseline, while animals receiving aCSF experienced an increase in activity of only 115%. Without prior sensitization with ouabain, activity typically increases 140% of baseline

MOOD STABILIZERS AND ENDOGENOUS ADP-RIBOSYLATION. L. T. Young*, C. M. Woods, V. Asghari and I. Patelis-Siotif. Departments of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 325.

Bipolar disorder (BD) is associated with increased levels and function of the G-protein, Go₃, which may be normalized by treatment with mood stabilizing medications (i.e. lithium, valproic acid and carbamazepine). Since ADP-ribosylation of Go₃, has been shown to increase turnover of this protein, we examined whether mood stabilizers affected this process in cultured cells, or in platelets from patients with BD, before and after treatment. In C6 glioma cells, endogenous ADP-ribosylation of a 50 kDa protein was markedly increased by lithium chloride (+83%, P<0.005) and decreased by valproic acid (-48%, P=0.07) whereas carbamazepine had no effect. In contrast, levels of endogenous ADP ribosylation of a 50 kDa protein were significantly higher (p<0.05) in platelet membranes from drug free BD patients (1.92±0.41 densitometric units, N=13, Mean Age 33±2.7yr), compared with controls (1.17±0.17, N=13, Mean Age 27±2.0) and lithium treated euthymic patients with BD (1.21±0.20, N=13, Mean Age 33±2.5). These results suggest a mechanism of action for lithium distinct from the anticonvulsants which may be important to G-protein function and which occurs in brain but not in peripheral tissues. BEHAB, THE GENE FOR A CNS SPECIFIC HYALURONAN-BINDING PROTEIN, MEDIATES INVASION OF GLIOMA CELL LINES IN WITRO AND IN VIVO. H. Zhang, G. Kelly, D. Jaworski and S. Hockfield*, Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Malignant astrocytomas (gliomas) aggressively invade the surrounding normal brain, a feature not shared by brain metastases of non-glial tumors, which grow as circumscribed masses with well demarcated borders. Tissue- or tumor-specific extracellular proteins are prime candidates for mediating the distinctive invasive behavior of primary brain tumor. The gene for a brain-specific extracellular protein, BEHAB, is expressed during periods of gliogenesis, but is not detectable in normal adult human cortex. BEHAB mRNA is expressed in surgical samples of astrocytoma, and has not been detected in any tumor of non-glial origin. Glioma cell lines maintained in vitro do not express BEHAB, however, BEHAB expression can be induced in glioma cell lines when grown as intracranial grafts. Only glioma cell lines that grow invasively express BEHAB; BEHAB is not induced in intracranial grafts of cell lines that do not show invasive properties (Jaworski et al., Cancer Res. 56:2293). Together these results demonstrated that BEHAB is a unique and selective marker for astrocytoma and suggested that it may be an important element in brain tumor invasion.

may be an important element in brain tumor invasion.

A possible role for BEHAB in tumor invasion has been tested by transfecting 9L gliosarcoma cells with BEHAB. 9L cells do not express BEHAB in vitro, and, when grown as intracranial grafts, form non-infiltrating masses that do not express BEHAB. 9L cells transfected to express BEHAB show increased invasion both in vitro and in vivo. In a matrigel in vitro invasion assay, transfected 9L cells show an increased ability to migrate through an artificial matrix, and this ability is potentiated by the presence of hyaluronan. Intracranial grafts of transfected 9L cells develop small cell clusters distant to the site of implantation. These data provide strong support for an important role for BEHAB in glioma invasion and suggest possible therapeutic strategies.

OLIGODEOXYNUCLEOTIDE-MODULATED EXPRESSION OF METALLOTHIONEIN IN NEUROBLASTOMA IMR32 CELL. H. El Refaey. P.L. Iversen. R. Bashir. M.L. Heidrick. F.M. Hamada J. Mata. A.M. Earle. and M. Ebadi. Depts. of Pharmacology, Neurology, Biochemistry, Cell Biology and Anatomy, Univ. of Neb. Coll. of Med., Omaha, NE 68198-6260

Human neuroblastoma (NB) is a malignant tumor of neural crest origin, and is the most common extracranial solid neoplasm in children Cytogenetic studies have revealed that the most common abnormalities in neuroblastoma are homogeneously staining regions which corresponds to genomic N-myc amplification, and rapid tumor progression. In addition, it has been shown that proto-oncogenes such as Ha-ras and Trk, which encodes a receptor for nerve growth factor are associated with a favorable prognosis; whereas the expression of Bcl2-proto-oncogene is strongly associated with an unfavorable histology. The overexpression of metallothionein (MT) represents one mechanism of resistance to a subset of clinically important anticancer drugs and oligonucleotide-mediated alteration of MT gene exhibits specificity in inhibiting MT synthesis. Therefore, we delineated the effects of antisense oligonucleotide probes on viability, proliferation, and cell cycling, of a number of tumor cell lines, including MCF-7WT and MCF-7/Adr; KB and KBV; Colo 320, Hct116, Lovo, and HT29 IMR32; and U373MG. Studies using immunohistochemistry and the 3-(4,5dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT) assay along with apoptotic data revealed that antisense oligonucleotide of MT inhibited the viability and survival of neuroblastoma, glioma and colon cancer cell lines In view of the fact that MT possesses a protective role against oxygen nitrogen, and carbon centered free radicals, we conclude that MT may have a wide-spread but selective importance in cell survival. (Supported in part by a grant from USPHS-NS34566).

OLIGODENDROCYTE MRNAS CAN BE USED TO PREDICT THE EXTENT OF NEOPLASTIC INFILTRATION IN GLIAL TUMORS. Landry, C.F.*, Cherman, L., Verity, M. A., Yates, A.¹ and Campagnoni, A.T., MRRC, UCLA School of Medicine, Los Angeles, California 90024 and ¹Div. Neuropath., Ohio State, Columbus, Ohio.

The identification of biochemical markers specific for glial neoplasms would contribute greatly to an understanding of the cell biology of these tumors. We have applied non-radioactive in situ hybridization histochemistry to an analysis of the expression of glial and neuronal mRNAs in a range of glial tumors. We found that low grade tumors contained a high number of proteolipid protein (PLP) positive cells and that the number of PLP stained cells decreased markedly with increasing tumor grade. In addition, the ratio of PLP to MBP stained cells in low grade astrocytoma was 2:1 but approached 1:1 with increasing tumor grade. Interestingly, gemistocytic astrocytomas and post-radiation gliomas that are generally considered to be highly invasive contained a high number of PLP positive cells and a PLP to MBP ratio close to 2:1 similar to normal tissue and low grade tumors. In addition, gemistocytes were consistently found to be strongly vimentin positive, to contain little or no GFAP mRNA and not to stain for PLP or MBP mRNA. These results highlight the selective expression of glial mRNAs within astrocytic tumors and suggest that these molecular markers can be used to predict the extent of tumor infiltration in specific astrocytomas. ONCOSTATIN M (OSM) INHIBITS PROLIFERATION AND INDUCES DIFFERENTIATION IN HUMAN GLIOMA CELLS. F. Stögbauer*, P. Young, E.B. Ringelstein, R. Westermann and H. Halfter. Dept. Neurology, University of Münster, D-48129 Münster, Germany
OSM is a member of a family of pleiotropic cytokines named neuropoietic

OSM is a member of a family of pleiotropic cytokines named neuropoietic cytokines exerting various effects on certain cell types in vitro and in vivor. This includes growth inhibition and differentiation as well as proliferation of tumor cell lines. We have recently described three new established cell lines of human glioma origin in terms of expression of receptors and ligands of members of the neuropoietic cytokine family. All cell lines express receptor components for ciliary neurotrophic factor (CNTF), leukemia inhibitory factor (LIF) and OSM as well as the ligands CNTF and LIF.

In order to investigate potential effects of OSM on tumor cells we performed cell growth and differentiation assays. Incubation with OSM (10 ng/ml) induces remarkable inhibition of cell proliferation as determined by reduced DNA synthesis in BrdU-labeling assays compared to control cultures. Morphological signs of apoptosis could not been detected. However, after four to five days of treatment with OSM a morphological change of the glioma cells could be observed. Cells switched from a unique polygonal morphology to a cell type characterized by two to three outgrowing processes resembling an astrocytic phenotype indicating differentiation of the malignant cells. Treatment with OSM induces remarkable expression of c-fos within fifteen to thirty minutes demonstrating a specific effect of the protein on cell proliferation and differentiation. This is supported by the finding that these cells express glycoprotein-130 the known binding molecule of OSM.

Future studies will include the putative effects of OSM in animal models of glioma as well as the analysis of the intracellular signal transduction induced by the cytokine.

CHARACTERIZATION OF A PUTATIVE NEUREGULIN/ERBB RECEPTOR AUTOCRINE LOOP IN SCHWANN CELL NEOPLASIA. P. W. Frohnert*, S. L. Carroll. Div. of Neuropathology, Washington Univ. Sch. of Med., St. Louis,

Schwannomas frequently share common genetic alterations, whether they arise sporadically or as part of the hereditary neoplastic syndromes neurofibromatosis types 1 (NF1) and 2 (NF2). Ablation of the NF1 tumor suppressor gene, however, does not produce neurofibromatosis in transgenic mice and it is believed that other, as yet unidentified, mitogenic factors drive proliferation in both sporadic and inherited schwannomas. The neuregulins (NRGs), a recently described family of growth and differentiation factors, may be among the unknown agents promoting neoplastic Schwann cell proliferation as NRGs are potent Schwann cell mitogens in vitro and high levels of a NRG-like activity are present in human schwannomas. We have examined the expression of the NRGs and their in numan schwannomas. We have examined the expression of the NRGs and their receptors, the erbB membrane tyrosine kinases, in the rat JS1 schwannoma cell line. We have found that JS1 cells express extremely high levels of NRG mRNAs, representing a mixture of GGF (glial growth factor) and SMDF (sensory and motor neuron-derived factor) splice variants. Of the four known erbB receptors, JS1 cells express only erbB2 and erbB3. Immunoblots of JS1 cell lysates probed with an antiphosphotyrosine antibody demonstrate a 185kD band, suggesting that the erbB2 and/or erbB3 receptors are constitutively activated. Full-length cDNAs of the Schwann cell erbB2 and erbB3 receptors have been isolated, characterized and used to construct "dominant negative" mutations whare being stably transfected into JS1 cells. Based on our observation that JS1 cells express both NRGs and NRG receptors, we propose that these schwannoma cells stimulate their own proliferation via an autocrine NRG/erbB loop and predict that erbB receptor "dominant negative" mutants will disrupt this putative autocrine loop, thereby diminishing JS1 proliferation.

DIFFERENTIAL FEFECTS OF TYRPHOSTIN AG 1478 ON HUMAN GLIOMA CELLS EXPRESSING TRUNCATED OR WILD-TYPE EGFR Yuchun Han*1, Anil Nanda¹, Webster K. Cavenee², H.-J. Su Huang², Cornelio G. Caday¹. ¹Neurosurgery, Louisiana State Univ. Med. Center, 1501 Kings Highway, Shreveport, LA 71130;
²Medicine, Univ. of California at San Diego, La Jolla, CA 92093.

Epidermal growth factor receptor (EGFR) gene truncation and amplification have been frequently demonstrated in and are closely linked to the pathogenesis of human gliomas. Screening anti-glioma inhibitors specific for mutated EGFR gene targets offers a greater therapeutic advantage over those general inhibitors that may also target the normal EGFR. In this study, we tested the effects of a new EGFR tyrosine kinase inhibitor, tyrphostin AG 1478, on three glioma cell lines; human U87MG expressing endogenous levels of wild-type EGFR, U87MG transfected and overexpressing either amplified wild-type (U87MG.wtEGFR) or truncated (U87MG.\DeltaEGFR) EGFR. Our results revealed that transfecting U87MG cells with truncated EGFR resulted in enhanced DNA synthesis and constitutive autophosphorylation of 140 and 155 kD truncated EGFR. Following treatment with tyrphostin AG 1478, cell growth (Alamar Blue assay), DNA synthesis ([3H]incorporation assay), EGFR tyrosine kinase activity (ELISA assay) and its autophosphorylation (Western Blot) of all cell lines were inhibited in a dose-dependent manner. In addition, the most significant inhibitory effects of AG 1478 were oted on U87MG.ΔEGFR cells. The increased sensitivity of cells with truncated EGFR to AG 1478 is due to more selective inhibition of the constitutive autophosphorylation of the 140-155 kD truncated EGFR. Our results indicated that tyrphostin AG 1478 represents the first inhibitor that preferentially inhibits truncated EGFR. This finding has significant implication for chemotherapy since the truncated EGFR is frequently expressed in glioblastomas as well as in breast and lung cancers.

INTERFERON REGULATORY FACTOR 2 ELEVATION IN ASTROCYTOMAS C. B. Soults, C. Wu and P. T. Massa* Depts. of Neurosurgery and Neurology, SUNY HSC, Syracuse, NY, 13210

The system of interferon regulated genes is increasingly being recognized as an important part of normal growth and tumorgenesis. Interferon Regulatory Factor 1 (IRF-1) activates genes that in general function as growth and tumor suppressors while the structurally similar Interferon Regulatory Factor 2 (IRF-2) antagonizes the function of IRF-1. Fresh human astrocytomas removed in the course of normal treatment were examined for the expression of IRF-1 and IRF-2. As controls, human brain tissue removed in the course of various nontumorous neurosurgical procedures was used. Cytoplasmic and nuclear proteins, as well as RNA, were extracted. Gel mobility shift assay demontstrated a specific increase in IRF-2 binding activity in high grade astrocytomas compared to control brain or lower grade tumors. Western blot and PCR data confirmed an increase of IRF-2 protein and mRNA in high grade astrocytomas. These data demonstrate that in some astrocytomas there is an alteration of the interferon regulatory system with an elevation of IRF-2. The increase in IRF-2 may offset the normal IRF-1/IRF-2 balance and be permissive for tumor progression.

EPIDERMAL GROWTH FACTOR RECEPTOR GENE TRUNCATION IN HUMAN GLIOMA CELL LINES: AN UPSTREAM MECHANISM THAT NON-MUTATIONALLY INACTIVATE WILD-TYPE p53. Anil Nanda*¹, Yuchun Han¹, Cornelio G. Caday¹, Webster K. Cavenee², H.-J. Su Huang², ¹Neurosurgery, Louisiana State Univ. Med. Center, 1501 Kings Highway, Shreveport, LA 71130; 2Medicine, Univ. of California at San Diego, La Jolla, CA 92093.

Epidermal growth factor receptor (EGFR) gene truncation and p53 gene mutation are intimately involved in the pathogenesis of many human cancers. In the present study, their relationship with respect to human glioma tumorigenesis was investigated using U87MG human glioma cells. We have, for the first time, demonstrated immunocytochemically that U87MG cells overexpressed wild-type p53 which involved both cytoplasm and nucleus. Transfecting U87MG cells with truncated EGFR resulted in significantly decreased levels of wild-type p53. After treatment with typhostin AG 1478, a preferential inhibitor of the truncated EGFR, protein levels of wild-type p53 increased in a dose-dependent manner. These results suggested a non-mutational inactivation of wild-type p53 mediated by the truncated EGFR. It was further shown that following treatment with AG 1478, p53-dependent apoptosis was induced, thus representing a novel mechanism different from DNA-damaging agents. Cell cycle analysis revealed that EGFR gene truncation resulted in a significant increase in the 5 phase as compared with the parental cells. This increase in S phase was shifted into G1 phase in response to AG 1478 treatment. Since EGFR gene truncation results in constitutive autophosphorylation of the 140-155 kD truncated EGFR that lead to enhanced cell proliferation and aggressiveness, combined with current data, it was concluded that EGFR gene truncation functions as an upstream mechanism that, on one hand, enhances glioma cell proliferation; on the other hand, inactivates function of wild-type p53, the suppressor of tumor cell growth, thereby making glioma cells more aggressive.

CELL CYCLE REGULATION OF INTERLEUKIN-6 SECRETION FROM HUMAN GLIOBLASTOMA CELLS. Garret L. Yount* and Mark A. Israel. The Preuss Laboratory for Molecular Neuro-Oncology, The Brain Tumor Research Center, University of California San Francisco, CA 94143-0520.

Astrocytes and microglia are known to synthesize interleukin-6 (IL-6) when stimulated by other cytokines such as IL-1 and TNF-α. IL-6 is synthesized and released from nearly all IL-1 and 1NF-0. IL-6 is synthesized and released from nearly all glioblastoma cell lines and high levels of IL-6 have been found in the cerebral spinal fluid of patients with gliomas. *In vitro* studies of the IL-6 gene promoter have demonstrated that p53 and pRB may function as transcriptional repressors to diminish IL-6 mRNA expression. We examine whether IL-6 secretion was regulated during cell cycle progression of U-87 MG glioblastoma cells. Performing ELISA analysis on cells synchronized in the cell cycle by mitotic selection, we found that IL-6 secretion increases 5-fold at the G1/S phase transition. Competitive RT-PCR analysis confirms that IL-6 mRNA levels were elevated at PCR analysis confirms that IL-6 mRNA levels were elevated at this point in the cell cycle. Subsequent analyses using a panel of U-87 derived cell lines transfected with vector DNA or DNA encoding a dominant negative mutant p53 revealed that wild-type p53 function was required for the regulation of IL-6 secretion during cell cycle progression. Clones in which wild-type p53 function was disrupted show constitutively high levels of IL-6 secretion throughout G1 phase and the G1/S phase transition. This work is supported by The Robert Steel Foundation for Pediatric Oncology Research and the Brain Tumor Research Center Program Project Grant.

GROWTH OF MENINGIOMA CELLS IN CULTURE AND AS

GROWTH OF MENINGIOMA CELLS IN CULTURE AND AS TRANSPLANTS. K. Yoo*1.2, A.F. Krisht², Q. Al-Mefty² and D.L. Davies¹. Depts. of Anatomy¹ and Neurosurgery², Univ. of Arkansas for Med. Sci., Little Rock, AR 72205.

Meningiomas are common intracranial tumors; due to the invariable abundance of high affinity somatostatin receptors on meningioma cells, these tumors have been successfully imaged using a radiolabled somatostatin analog, octeotide. In an endeavor to assess the potential vulnerability of meningioma cells to octreotide toxicity, cell cultures prepared from surgically excised meningiomas (n=4) were administered octreotide (50 nM - 50 μM) for 7 days. The cultures consisted predominately of cells immunopositive for vimentin and fibronectin. The astrocyte marker GFAP and endothelial marker Factor VIII were not detected. To date, epithelial membrane antigens and desmoplakins Types I & II positive for whether and information. The astrocyte marker Granand endothelial marker Factor VIII were not detected. To date, epithelial membrane antigens and desmoplakins Types I & II have not been found. In octeotide exposed cultures, cell counts and MTT assays revealed a dose- and time-related suppression in culture growth. Similar responses were obtained from cultures of normal meninges. Cultures derived from the same surgical specimens have also been transplanted subcutaneously in a Matrigel® matrix into nude mice. Preliminary findings indicate that the resultant tumors exhibit the cytological features of *in situ* meningiomas. The results suggest that meningioma cells retain key morphological features in cell culture and animal based models which would permit further investigation of adjunctive therapy targeted to the somatostatin receptors on meningioma cells. Supported by: Arkansas Sci. & Technol. Authority Basic Res. Prog. 96-B-01 (A.F.K.) and Am. Cancer Soc. Instit. grant IRG-187 (A.F.K.).

GANGLIOSIDE BIOSYNTHETIC GENE EXPRESSION IN MURINE BRAIN TUMORS. J.A. Ecsedy*, M.G. Manfredi, M.M. El Abbadi, and T.N. Seyfried. Department of Biology, Boston College, Chestnut Hill, MA 02167-3811.

Department of Biology, Boston College, Chestnut Hill, MA 02167-3811.

Alterations in ganglioside biosynthesis occur in brain tumors. β-1,4-N-acetylgalactosaminyl transferase (GalNAc-T) and cytidine monophospho-N-acetylneuraminic acid hydroxylase (NeuAc-H) function in ganglioside biosynthesis. GalNAc-T adds a β-linked N-acetylgalactosamine (GalNAc) to the oligosaccharide chain of gangliosides GM3 and GD3 for the synthesis of GM2 and GD2, respectively. NeuAc-H synthesizes the sialic acid N-glycolylneuraminic acid (NeuGc) by hydroxylation of cytidine monophospho-N-acetylneuraminic acid (CMP-NeuAc). NeuGc-containing gangliosides are not present in neurons or glia, but are abundant in mouse non-neural cells. Using RT-PCR, we show that the GalNAc-T and NeuAc-H genes are expressed in two experimental mouse brain tumors. EPEN and CT-2A, when grown in vivo as solid tumors. In contrast, the GalNAc-T gene is not expressed in cultured EPEN cells, but is expressed in cultured CT-2A cells. The NeuAc-H gene is not expressed in cultured EPEN cells, but is expressed in cultured CT-2A cells. The NeuAc-H gene is not expressed in cultured CT-2A cells. The consistent with previous work on the distribution of GM2 and NeuGc-containing gangliosides in the solid tumors and cultured cell lines (Seyfried et al., J. Neurochem. 66: 2026-2033, 1996).

Macrophages and other host immune cells are known to infiltrate brain tumors and many of these cells synthesize GM2 and NeuGe-containing gangliosides. These infiltrating cells are eliminated during formation of the tumor cell lines, consequently, gangliosides and gene expression specific to host cells would not be present in the cultured tumor cells. We suggest that the difference in ganglioside biosynthetic gene expression between brain tumors grown in viva and in vitro results from the presence or absence, respectively, of non-neoplastic host infiltrating cells. Supported by the NIH grant 1R01NS/CA33640 and a grant from the Boston College Research Expense Fund.

CYTOKINE ANALYSIS BY HIGH RESOLUTION FT-ICR MASS SPECTROMETRY. Mark R. Emmett't, Charles A. Conradt, Touradj Soloukit and Alan G. Marshallt. †National High Magnetic Field Laboratory-FSU, Tallahassee, FL 32310 and Trinity Lutheran Hospital, Kansas City, MO 64108.

Cytokines play an important role in cell differentiation and tumor cell proliferation. The actual contribution of an individual growth factor to the growth of a specific neoplastic cell type is unknown. In fact, the most active form of many cytokines is unknown. Recombinant cytokine activity is determined by the cytokine's effect on the growth of specific cells in tissue culture (activity assay) and antibodies are used to quantitate cytokines from biological samples (immunoassay). Neither of these two assays provide mass or structural information of the active cytokine fragment.

In this study, the analytical technique of Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR/MS) will be used to analyze several cytokines that affect the proliferation of neuronal cell lines. These cytokines include TGF-alpha, EGF, FGF-basic and VEGF. FT-ICR/MS is unique in its ability to perform high mass resolution analysis of high molecular weight compounds and can also provide substantial sequence information as well. The goal of this work is to demonstrate the versatility of the FT-ICR/MS in the analysis of cytokines produced by specific tumors. It is anticipated that FT-ICR/MS will be a valuable tool in the elucidation of cytokine function in the proliferation of

neuronal tumors.

TUMOR-MEDIATED SUPPRESSION OF NITRIC OXIDE PRODUCTION BY RAT MICROGLIA IN VITRO. S.A.Walter, and W.J. Streit*. Dept. of Neuroscience, Univ. of Florida Brain Institute, Gainesville, FL 32610.

Our laboratory has previously shown that microglia respond to brain tumors by infiltrating them and assuming an activated morphology associated with tumor cytotoxicity in vitro. However, there is little evidence for tumor necrosis associated with microglia in vivo, suggesting that tumor cells may suppress the production of cytotoxic molecules by microglia. Nitric oxide (NO) production represents one of the major mechanisms of tumor cytotoxicity by microglia in vitro. Using NADPH-diaphorase histochemistry as an indicator of nitric oxide synthase (NOS) activity combined with lectin histochemistry to label microglia, we examined NOS activity in activated microglia associated with the rat RG2 glioma. While a select population of cortical neurons and all tumor cells exhibited NOS activity, the tumor-associated microglia did not. In vitro tests were carried out to examine the effect of tumor-derived soluble molecules on NO production by microglia. The Griess reaction was used to measure nitrite, the stable metabolite of NO. Microglial production of NO increased over time and in response to increasing levels of bacterial lipopolysaccharide (LPS) and interferon-gamma (IFN- γ). In preliminary experiments, conditioned medium from cultured RG2 cells prevented the induction of NO production by stimulated microglia in a dose-dependent manner. These results suggest that tumors can suppress the production of cytotoxic NO by microglia through the secretion of soluble factors. Supported by: The American Cancer Society Florida Division, Grant No. F95UF-3.

NORTHERN ANALYSIS OF PROTO-ONCOGENE EXPRESSION IN HUMAN GLIOMAS. Michael J. Keherly William W. Maggio Benjamin B. Gelman Amount of Neurosurgery/Department of Surgery, Division of Neuropathology/Department of Pathology. University of Texas Medical Branch at Galveston Texas 77555-0517.

Gliomas are the most common primary brain tumor, and present as or progress to highly malignant tumors. The malignant progression of gliomas is associated with an increasing number of alterations in both recessive and dominant proto-oncogene expression. These alterations include the loss of retinoblastoma (RB) expression, the loss of wild-type p53, overexpression of mutated p53, and an increase in c-fos expression. Previous studies have primarily focused on the loss or overexpression of these proto-oncogenes at the protein level. Therefore, we studied 27 gliomas of various type and grade at the RNA level using Northern analysis. Although previous studies found a loss of RB protein in higher grade gliomas, we found RB expression, at the transcript level, comparable to or greater than normal cortex RNA in a majority of the gliomas independent of type or grade. As with other studies, we observed aberrantly high expression of the p53 message predominantly in the higher grade gliomas. Analysis for c-fos expression showed unusually high expression in certain gliomas, especially those with oligodendroglial components. There was also an inverse relationship between c-fos and p53 expression, although not absolute. Further analysis of the expression of other proto-oncogenes is planned. The identification of specific proto-oncogene phenotypes in various glioma types and grades may provide clues to the aberrant cell cycle regulatory processes underlying glioma tumor progression.

NEURO-ONCOLOGY: TREATMENT AND DIAGNOSIS

370.1

BRAIN TUMOR CHEMOSENSITIVITY USING THE FLUORESCENT CYTOPRINT ASSAY. M.H. Friedberg*, M.J. Glantz, P. Meitner and L. Recht. Department of Neurosurgery (MHF) Tufts University School of Medicine. New England Medical Center, Boston, MA. 02111, Dept. of Clinical Neurosciences (MJG), Brown University School of Medicne, Prov. RI, Analytical Biosystems (PM), Warwick, RI. and Dept. of Neurology (LR), Univ. MA, Worcester, MA.

To individually tailor chemotherapy for patients with malignant gliomas according to tumor chemosensitivity, a rapid assay system which can be performed with high success rate is needed. The fluorescent cytoprint assay (FCA) can assess multiple chemotherpeutic agents using small (about 500 cells) tumor aggregates very quickly (about 1 wk). Tissue samples from 51 patients with malignant gliomas obtained either at the time of initial diagnosis (n=34) or at recurrence were assayed using this method. The assay success rate approached 90% in those culture samples which were histologically verified as tumor. A meaningful number of agents could be tested both on samples obtained by stereotactic biopsy (median.5) and on specimens from more extensive resections (median.6). One hundred ninty-three FCAs were performed on samples obtained from 36 patients. In only twenty six assays (14%) was an agent deemed sensitive (>90% cell kill) to a chemotherapeutic agent. 62% of sensitive FCAs were observed in tumors tested against the activated analog of cyclophosphamide, 4-hydroxyperoxycyclophosphamide (4HC), where a sensitivity rate (# samples sensitive/total tested against agent) of 64% (95% CI, 36.6-77.9%) was noted. This rate was significantly higher than with any other agent tested (p=0.012, two sided McNemar's test) and was not affected by age, histology, or disease status. We conclude that: (1) the FCA represents a feasible method for quickly assaying tumors for sensitivity to multiple chemotherapeutic agens; and (2) malignant gliomas may be particularly sensitive to 4 HC.

370.2

RAPID BRAIN UPTAKE OF L-META-SARCOLYSIN FOR THE TREATMENT OF BRAIN TUMORS. M. Hokari.* P.A. Crooks. and Q.R. Smith. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda MD 20892 and Div. of Med. Chem., University of Kentucky, Lexington, KY 40536.

The blood-brain barrier restricts the brain uptake of most chemotherapeutic drugs and limits their efficacy in the treatment of brain tumors. One way to overcome this problem is to design drugs that are shuttled into brain by the saturable nutrient transporters of the brain capillaries. Previously we showed that melphalan, the para-substituted nitrogen mustard derivative of L-phenylalanine, is taken up into brain by the large neutral amino acid transporter (System L1) of the blood-brain barrier. However, melphalan's affinity for the transporter is low ($K_{\rm m}=100\pm 5~\mu{\rm M})$ and it fails to reach therapeutic concentrations in brain except at toxic doses. With computer modeling, we predicted that the meta-isomer of melphalan would exhibit improved affinity and transport into brain via the System L1 transporter. To test this, we synthesized L-meta- $^{13}{\rm H}$]sarcolysin and studied its brain uptake in rats using the *in situ* brain perfusion technique (Am~J~Physiol~247:H484, 1984). With saline perfusion (T=10-30 s), brain uptake of L-meta- $^{13}{\rm H}$]sarcolysin was rapid with a cerebrovascular permeability-area (PA) product of 5.80 \pm 0.13 \times 10-2 $^{12}{\rm H}$ /s/g at tracer concentration. Influx was saturable and mediated by the cerebrovascular large neutral amino acid transporter with a $K_{\rm m}$ of 1.4 \pm 0.2 $\mu{\rm M}$. The results demonstrate that L-meta-sarcolysin is taken up into brain $^{\sim}$ 100 times more rapidly than melphalan and may be of use for the treatment of brain tumors. (Supported by NIA).

Potential Radiotherapy of Human Gliomas with [18F]fluorodeoxyglucose, M.A. Meyer, C.G. Caday*, Y. Han, B. Vickers and A. Nanda. Biomedical Research Institute, Louisiana State University Medical Center, Shreveport, LA 71130.

Survival of patients diagnosed with high grade gliomas is very poor. These patients eventually die, even after chemotherapy, radiotherapy or radiosurgery, due to recurrence of the tumor. The preferential *in vivo* uptake of [18F]fluorodeoxyglucose ([18F]FDG) in solid tumors is a basis for monitoring tumor progression and its potential regression following radiation therapy or chemotherapy. We have shown that intra-arterial injection improved the tumor to normal tissue ratio of [18F]FDG uptake in the human brain. This led us to consider whether [18F]FDG can be developed as a potentially novel radiotherapy to deliver therapeutic doses of [18F]FDG and selectively destroy cancer cells. This study showed that high doses of [18F]FDG inhibited DNA synthesis, arrested cell growth and subsequently caused cell death in the glioma cell lines tested in cell culture. Active uptake of [18F]FDG caused cell death while [18F-] was less effective in killing glioma cells. The IC50 for inhibition of DNA synthesis was 0.1-0.3 mCi/ml [18F]FDG while >90% of DNA synthesis was inhibited at ≥ 2 mCi/ml [18F]FDG. Studies using human glioma cells xenograft in nude mouse showed that [18F]FDG dramatically reduced the tumor volume without any apparent deleterious effect on the mouse. Taken together, these findings suggest a great potential of using high doses of [18F]FDG to be developed as a novel radiotherapy against solid tumors, including gliomas.

HYPOXIA POTENTIATES SURAMIN NEUROTOXICITY IN RAT DORSAL ROOT GANGLIA IN VITRO. X. Sun* and A. J. Windebank.

DORSAL ROOT GANGLIA IN VITRO. X. Sun* and A. J. Windebans. Molecular Neuroscience Program, Mayo Clinic, Rochester, MN 55905. Injury to neurons can be initiated by a variety of insults but the cellular events may be mediated by a final common pathway leading to cell death. Initiating events which converge on this pathway may interact with each other. If correct, these events may be antagonistic, additive, or synergistic. The mechanisms of hypoxia- and antineoplastic count recent included penul injury in the peripheral penulus system. additive, or synergistic. The mechanisms of hypoxia- and antineoplastic agent suramin-induced nerve injury in the peripheral nervous system have not been fully defined and the effect of double insults has been difficult to study. Our hypothesis was that both insults cause cell injury by a final common pathway resulting in apoptosis. Modified isobolographic analysis has been used to study the interaction between hypoxia and suramin neurotoxicity. Using primary dorsal root ganglion neuronal culture as an *in vitro* model system, we have studied the mechanism of interaction of the two insults. Bis-benzamide fluorescence dye was used to label nuclei. Phase-contrast and fluorescence micrographs were taken and cell numbers were counted. All data were converted into percentage of apoptotic cell number versus total cell numbers of the same treated group. The results showed that in the control group the average number of cells undergoing apoptosis was 0.6%. In the suramin-treated (300 µM) group, 1% cells were undergoing apoptosis. Hypoxia (95% N₂ plus 5% CO₂) for 2 h, caused 0.6% cells to show sign of apoptosis. Combination of 300 µM suramin and 2 h hypoxia caused 3.5% cells to undergo apoptosis. The present observation indicates that the combined insults potentiate each other by activating indicates that the combined insults potentiate each other by activating the same intracellular pathways triggering apoptosis (NIH, NS 29769).

IGF-1 R ANTISENSE AND NONSENSE OLIGONUCLEOTIDE THERAPY FOR 9L GLIOBLASTOMA RESULTS IN AN IMMUNE RESPONSE AGAINST AN UNRELATED SYNGENEIC TUMOR IN FISCHER 344 RATS. MAWallenfriedman*, G. Lee, P.C. Graupman, J.A. Conrad, L. Chiang, D.K.Y. Wen, W.A. Hall, W.C. Low. Depts of Neurosurgery and Physiology. Graduate Prog. in Neuroscience and the Cancer Center, Univ. of Minnesota, Mpls., MN 55455.

Previous studies have demonstrated that tumor cells transfected or simply incubated with antisense oligonucleotides to the IGF-1 receptor (IGF-1 R) are rejected following transplantation into immunocompetent hosts. Subcutaneous injections of these antisense-modified cells can activate the immune system of rast to recognize both transfected and non-transfected glioblastoma cells, whether implanted peripherally or centrally. In the present study we have examined the immunological specificity of this antisense-induced response. IGF-1 R antisense or nonsense oligonucleotides were injected directly into peripherally established glioblastomas on days 11, 13, 15. Control animals were either uninjected or injected with buffer. Tumor volumes were measured daily by an observer blinded to the treatment group. In contrast to controls, oligonucleotide-injected tumors regressed and were ultimately eliminated. These animals were resistant to further peripheral or central glioblastoma challenges. We then tested the specificity of this oligonucleotide-induced anti-tumor response with a peripheral injection of Mat B III breast carcinoma. Naive controls (n=5) reached average tumor volumes of 48,000 mm³ on day 23 before death. This is consistent with identically challenged rats (n=60) from previous experiments. In contrast, rats that had been previously cured of glioblastoma by intratumor injections of oligonucleotides had an enhanced immune response to Mat B III challenge. Their average tumor volume on day 23 was 22,000 mm³. 50% (n=10) were alive after the death of all controls and 20% were living on day 50. This is unlikely to result from recog

Inhibition of glioma invasiveness in vitro following treatment with interferon and anti-CD44. Wiranowska, M., Saporta, S. and Phelps, C.* Department of Anatomy, College of Medicine, University of South Florida, Tampa, FL

The treatment of malignant gliomas of the central nervous system is difficult in part due to their invasive character. Recently CD44, a transmembrane adhesion molecule found on glioma cells was implicated in glioma invasion. Interferon (IFN), which has antiproliferative glioma activity in vitro, was used in clinical trials of glioma patients with only modest responses. In this study we evaluated the effect of mouse MulFNα/β and anti-CD44 on the invasiveness of mouse glioma G-26 in vitro. Non-treated G-26 cells or cells treated for 2 or 3 days with MuIFN α/β at $8x10^2$ or 8x103 IU/ml were plated at 5 x 10 cells in Matrigel Invasion chambers and in control cell culture chambers in the presence or absence of MulFNα/B and/or anti-CD44 and incubated for 1 day. Filters from control and invasion chambers were fixed, stained with hematoxylin and eosin and invading cells counted in 10-40 microscopic fields. Invasiveness of G-26 was significantly inhibited (p<0.05) following IFN treatment at 8×10^3 IU/III (60%-70%) or anti-CD44 (60%). Treatment with a combination of IFN and anti-CD44 was synergistic, resulting in approximately 80% inhibition of invasiveness of (p<0.05)

DIEFERENT METABOLIC PATHWAY OF A THYMIDINE ANALOG IN RG2 BAT GLIOMA CELLS VS. RAT BRAIN MEASURED WITH 19F NMR SPECTROSCOPY. K.D. Bahk 12, B Pouremad¹, A.M. Wyrwicz^{1,2}, L.H. Pinto*1,2, ¹Center for MR Research, Evanston Hospital, Neurobiology and Physiology Dept., Northwestern University, Evanston, IL 60201

Trifluridine (trifluorothymidine, TFT) is a fluorinated thymidine analog with antiviral and antitumor properties that is incorporated into DNA and has a greater activity than fluorodeoxyuridine against adenocarcinoma 755 and L1210 Leukemia in mice. We have investigated the delivery of this compound to the brain and its metabolic fate in that tissue as well as in the RG2 rat glioma cells using fluorine-19 (19F) NMR spectroscopy. RG2 is a chemically induced rapidly proliferating cell line with the S-phase approaching 42%. Rats were given an IV injection of 150mg/kg TFT and euthanized 30 min. - 8 hrs after injection. Brain tissue was separated and extracted with a chloroform/methanol (2:1 v/v) solvent. Cells were incubated in DMEM media containing 100µM TFT for 12-72 hours, washed with saline, and extracted the same way. The aqueous/methanol layers of the extracts were dried and used for NMR spectroscopy. The primary metabolite detected in the ¹⁹F NMR spectra of brain extracts is trifluoromethyl uracil (TFMU), a product of TFT hydrolysis by thymidine phosphorylase. 5,6-dihydroxy-TFMU(TFMUG), a catabolite generated further along the oxidative pathway, as well as a small amount of residual TFT and its oxidation product (TFT-glycol) are also detected in the 19F spectra of the extracts. The product of TFT hydrolysis by thymidine phosphorylase (i.e. TFMU) is not detected in the spectra of the RG2 cell extracts. TFT is metabolized through both the oxidative (5,6-dihydroxy compounds) and the reductive (5,6-dihydro compounds) pathways in these cells. Phosphorylated products of the anabolic pathway were observed only in the cell extracts. The different metabolic products of TFT observed in rat brain and RG2 cells reflect differences in enzyme levels or activity between the two systems.

WAF1/CIP1 INCREASES THE SUSCEPTIBILITY OF p53 NON-FUNCTIONAL MALIGNANT GLIOMA CELLS TO CISPLATIN-INDUCED APOPTOSIS. S. Kondo*, B.P. Barna, Y. Kondo, J.W. Peterson and G.H. Barnett. The Cleveland Clinic Foundation, Cleveland, OH 44195.

Induction of apoptosis in tumor cells is an important determinant in the outcome of therapy. Molecular details of the apoptosis pathway, however, are still poorly defined. The recently discovered WAF1/CIP1 gene is a potent inhibitor of cyclin-dependent kinases and a mediator of tumor-suppressor p53-dependent apoptosis by DNA damage. In addition, WAF1/CIP1 expression is shown to be triggered through p53independent pathway. The relationship between WAF1/CIP1 and p53-independent apoptosis by DNA damage, however, remains unclear. In this study, we show that WAF1/CIP1 was induced in p53-dependent apoptosis of U87-MG glioma cells by cisdiamminedichloroplatinum (cisplatin), and overexpression of WAF1/CIP1 induced apoptosis in U87-MG cells without cisplatin treatment. In contrast, GL26 glioma cells did not express WAF1/CIP1 in p53-independent apoptosis by cisplatin. Overexpression of WAF1/CIP1 inhibited the DNA synthesis of GL26 cells, but did not induce apoptosis. Interestingly, WAF1/CIP1 increased the susceptibility of GL26 cells to cisplatin-induced apoptosis. These results suggest that overexpression of WAF1/CIP1 may have potential for the treatment of tumors with non-functional p53.

A 'SAFE' HERPES SIMPLEX VIRUS (HSV) VECTOR FOR TUMOR THERAPY OR GENE DELIVERY IN THE BRAIN.

S. D. Rabkin^{1,2}*. W. D. Hunter², K. C. New¹, M. Toda², R. L. Martuza² Departments of Microbiology & Immunology¹ and Neurosurgery², Georgetown Univ. Med. Ctr., Washington, DC 20007.

We have created a new, multi-gene mutant of HSV, designated G207. It is deleted at both γ34.5 loci and is ICP6 (large subunit of ribonucleotide reductase) deficient because of an insertion of the E. coli lacZ gene, yet is still replication-competent. Both of these HSV genes contribute to neurovirulence. G207 is able to replicate in tissue culture cells, including tumor cells and to function as a helper virus for the generation of defective HSV vectors. G207 inoculation of intracerebral human malignant gliomas or subdural meningiomas in nude mice causes prolonged survival and some apparent cures.

Defective HSV vectors with G207 as a helper virus considerably less toxic to primary neurons than were other helper viruses. G207 was 'safe' when injected (107 pfu) intracerebrally, intravenously or intraventricularly into young BALB/c mice. Intracerebral injection (10⁷ pfu) of HSV-sensitive non-human primates resulted in no long-term CNS pathology, whereas 103 pfu of the wild-type parental HSV was lethal within a week. MRI evaluation of G207 inoculated primates revealed no abnormalities. pathology observed with G207 suggests that it should be considered for clinical evaluation.

GENE TRANSFER TO HUMAN BRAIN TUMOR CELLS USING A NOVEL GENE TRANSFER TO HUMAN BRAIN TUMOR CELLS USING A NOVEL ADENO-ASSOCIATED/ HERPES VIRUS HYBRID VECTOR, Karen M. Johnston*, D. Jacoby, D. Schuback, P. Borghesani, P. Pechan, R. Dunn, F. Smith, Xandra O. Breakefield. Neurology Service Massachusetts General Hospital, Harvard Medical School, Boston, MA02114 and McGill Univ, Montreal (RD). AAV is a nonpathogenic DNA parvovirus demonstrated to stably integrate into human chromosome 19. Advantages of AAV for gene transfer include its ability to infect both nondividing and dividing cells. Using either adenovirus or herpes virus as helper, AAV is also able to undergo replication in a productive phase. AAV vectors have been used to deliver foreign genes to lung and brain. Gene transfer has been limited by both tires and the small size canactiv of the vector. Hernes virus, on the limited by both titres and the small size capacity of the vector. Herpes virus, on the other hand, can be grown to high titres and has a larger gene capacity. However, other hand, can be grown to night titres and has a larger gene capacity. However, toxicity and lack of stability of expression have presented ongoing problems. We therefore constructed an AAV/herpes amplicon hybrid vector with the purpose of combining the advantages of both systems to increase efficiency and stability of gene transfer. Constructs used in this 'study include HSV amplicon sequences in combination with a lac Z reporter gene flanked by the AAV ITR sequences. Constructs were generated with and without the rep gene to assess its importance in Constructs were generated with and without the Fig gene to assess its importance in the expression/ integration system. Control construct contains the herpes amplicon sequences and reporter gene but not AAV sequences. Optimal packaging and transfection conditions were determined prior to infection of U87, a human glioma cell line. A time course for comparison of stability of expression between constructs was determined. The amplicon without AAV sequences was associated with reporter gene expression for less than 1 week, expression for at least 3 weeks could be achieved with the AAV/amplicon infections. Interestingly, expression was higher for the rep+ as compared to the rep - construct. Ongoing studies will determine the integration status of these constructs as well as packaging efficiency. These experiments show that a hybrid vector such as AAV/herpes amplicon has potential use for gene transfer. These constructs will be tested for delivery of therapeutic genes to brain tumors in experimental animals. supported by Montreal General Hospital Research Institute and NINDS NS24279.

VISUALIZATION OF BRAIN TUMOR GROWTH AND NEURAL CELL MIGRATION IN VIVO USING RETROVIRAL VECTORS EXPRESSING GFP ¹KS Aboody-Guterman, ¹M Sena-Esteves, ¹U Herrlinger, ²EY Snyder, ¹XO Breakefield* ¹Molecular Neurogenetics Unit, Massachusetts General Hospital, Harvard Medical School, Charlestown, MA 02129, ²Depts. of Neurology and Pediatrics, Children's Hospital, Harvard Medical School, Boston, MA 02115

Hospital, Harvard Medical School, Boston, MA 02115
A retroviral vector was constructed expressing green fluorescent protein (GFP) under
the control of the mammalian phosphoglycerate kinase promoter (PGK), including an
internal ribosome entry site (IRES) and a neomycin selection gene (NeoR), IPGKGFP-IRES-NeoRJ, in order to track cell movements, on site gene product delivery, and
stability of transgene expression in vivo. Plasmid DNA was transfected into the
BOSC packaging cell line with approx. 50% efficiency as visualized by a strong
fluorescent signal in living cells. Rat gliomas (9L, D74, CNS1), mouse glioma
(GL261) and a multipotent mouse neural cell line (C17-2) were subsequently infected with retroviral supernatant. Human gliomas (U87, HGL21) were transfected directly After G418 (neomycin) selection, the brightest clones were isolated by visualization of fluorescence and expanded. Duration and strength of GFP transgene expression in cell culture is being followed. Selected cells will be grafted into a tumor model in living mice. This will enable evaluation of the sensitivity and stability of GFP expression and allow visualization of tumor growth *in vivo*. The C17-2 cell line already contains the lac Z gene, and from previous experiments involving C17-2 intratumoral injection, the lac Z gene, and from previous experiments involving C17-2 unfauthorat injection, we have determined that these cells migrate extensively throughout the tumor bed, without themselves becoming tumorigenic. By assessing their *in situ* GFP expression, we can evaluate the potential use for these cells as an on site gene product delivery system. The GFP labelled C17-2 cells will be grafted into a non-lablelled tumor bed and migration followed *in vivo*. Data on the full extent of migration will be obtained by post-sacrifice staining of the brain tissue for lac Z. These studies may

ordanied by post-seaturitie stanting of the oban tissue to a fact. This standard may enable us to optimize gene delivery to tumor cells in vivo.

PRE-EXISTING IMMUNITY AGAINST HERPES SIMPLEX VIRUS (HSV) MUTANT hrR3 DECREASES, BUT DOES NOT ABOLISH INFECTION OF D74 GLIOMA CELLS IN RAT BRAIN TUMORS. <u>U Herrlinger, KS Aboody-Guterman, CM Kramm, K Johnston, P Pechan*, M Chase, J Burwick, EA Chiocca, DN Louis,</u> XO Breakefield. Mol. Neurogenetics Unit, Mass. Gen. Hospital, Boston, MA 02129

We determined the impact of pre-existing anti-HSV immunity on the efficacy of

HSV-based gene therapy. CD Fisher rats were vaccinated intraperitoneally (IP) with 108 pfu of a HSV-1 mutant (hrR3), or sham-vaccinated with control media. Three to 4 weeks later 4x10⁴ syngeneic D74 rat glioma cells were injected intracranially into all rats. Four days later, rats were treated intratumorally (IT) with either 10⁸ pfu hrR3, or control media. Eleven vaccinated and treated rats (+/+), 11 non-vaccinated, but treated rats (-/+), and 11 non-vaccinated, non-treated rats (-/-) were assessed for survival. Histology was obtained from 2 rats per group on days 2 and 5 after virus. Median survival time was 20 days both in (+/+) (p=0.017, rank sum test) and (-/+) animals (p=0.008) as opposed to 18 days in (-/-) animals. Immunohistochemistry with anti-HSV-thymidine kinase (tk) Ab on day 2 after virus revealed numerous tk+ tumor and non-tumor cells in (-/+) rats, but very few tk+ cells in (+/+) rats. Neutralizing anti-HSV antibodies (Ab) in blood samples pooled from two rats per group were assessed in a complement dependent plaque inhibition assay. In (+/+) rats a titer of 1:1024 persisted from day 9 to day 25 after vaccination. IT virus challenge raised the titer to 1:4096 in (+/+) rats, while (-/+) rats showed a rise from >1:8 to 1:1024 on day 10 after 1T virus inoculation. Our results demonstrate a robust immune response to hrR3 after IP and IT application. As the life-prolonging effect of IT hrR3 application was not affected by vaccination, it appears that pre-existing immunity to hrR3 does was not aniected by Vaccination, it appears that pre-vasting immunity of the decision of completely curtail on site infection and virus replication. An immune reaction which markedly decreases the possible infection of neurons could be a benefit for gene therapy of brain tumors using HSV vectors. Supported by Deutsche Forschungsgemeinschaft (UH), Deutsche Krebshilfe (CMK), and NINDS grant NS24279 (KSA, PP, EAC, DNL, XOB).

ARA-C INDUCED APOPTOSIS IN C. GLIOMA CELLS TRANSFECTED WITH WILD-TYPE p53

J.X. Tong*, K.M. Rich, M.Giordano, and D.H. Gutmann. Department of Neurological Surgery and Neurology, Washington University School

Department of Neurological Surgery and Neurology, Washington University School of Medicine, St. Louis, MO 63110

Human gliomas display a variable response to commonly used DNA damaging agents. Mutations in the p53 gene are one mechanism by which these timors develop resistance to treatments that normally induce cell death via apoptosis. The rat glioma cell line, C4, contains a mutant p53 and is resistant to many DNA damaging agents. We created a C4 glioma cell line transfected with a zinc-inducible wild-type p53 gene to test the hypothesis that an apoptotic response to DNA damaging agents could be restored to these cells. We characterized the growth properties of the

agents could be restored to these cells. We characterized the growth properties of the clone, Ce-20-1, and examined its ability to undergo apoptosis after exposure to the DNA damaging agent, cytosine arabinoside (Ara-C).

Wild-type p53 was induced with zinc added to the culture media(100 µM). Growth curves were performed using Cs and Ce-20-1 cells in the presence and absence of zinc. Ce-20-1 cells grown in the presence of zinc showed a 41% decrease in growth rate when compared to Ce-20-1 grown in zinc-free media. In contrast, Cs cells grown with and without zinc had similar growth rates. Cells were exposed to 5 µM cytosine arabinoside and examined for the presence of apoptosis. The DNA-binding fluorescent dye Hoechst 33258 was used to assess the amount of DNA condensation present 72 hours following treatment with Ara-C. We found that Cs-20-1 cells maintained in media containing zinc underwent apoptosis (10% DNA condensation) following exposure to Ara-C. A much lower magnitude of apoptosis was observed in Cs-20-1 cells maintained in zinc-free media and in Cs cells following exposure to Ara-C. (1.8% and 1.9%, respectively, p < 0.01). Untreated Ce-20-1 and exposure to Ara-C (1.8% and 1.9%, respectively, p < 0.01). Untreated Cs-20-1 and Cs cells showed only 0.5% and 0.4% DNA condensation, respectively.

cours showed they 0.5% and 0.4% DNA condensation, respectively. In summary, we have constructed a Ca clone with plasmid that carries a zinc-inducible wild-type p53 gene. Activation of the transfected gene results in a decreased growth rate and an enhanced apoptotic response to cytosine arabinoside. (Supported by NIH Grant NS 29477)

370.14

ENCAPSULATED ADENOVIRUS: A NOVEL METHOD FOR THE INTRACEREBRAL DELIVERY OF ADENOVIRUS IN GLIOMA TREATMENT S.J. Beer, C.S. Stein, J.M. Hilfinger, Y. Tsume, V.C. Traynelis*, B.D. Davidson.

The University of Iowa, Iowa City, IA and TSRL, Inc., Ann Arbor, MI Current protocols for the treatment of intracerebral glioma using gene therapy rely on repeated intracerebral administrations of viral vectors. To circumvent the need for repeated injections, we have developed a method to encapsulate adenovirus (Ad) in a polymer which results in extended viral release.

Poly (lactic-glycolic) acid (PLGA) microspheres containing Ad were prepared using a double emulsion technique. [155]-metabolically radiolabeled Ad was encapsulated and quantitative release of virus from microspheres was measured Sixty percent of the encapsulated virus was released over 3 days and another 30 % was detected over the next 12 days. Viability of released virus was measured following encapsulation of AdRSVntLacZ, exposure to cells and X-gal staining. Again, viral release peaked within three days and was detected over 15 days. To test the ability of this formulation to deliver therapeutically relevant concentrations of Ad, virus containing the herpes simplex thymidine kinase gene (AdRSVTk) was encapsulated and cytotoxic effects on 9L gliosarcoma cells were measured. Encapsulated AdRSVTk was exposed to 9L cells in culture for 10 days. Ganciclovir (1.0 µM) was added and cell survival assessed 5 days later. Five percent of the encapsulated preparation resulted in 16 % cell kill. This is equivalent to the cytotoxicity seen when 106 unencapsulated particles of AdRSVTk are exposed to 9L cells. This dose of virus is achievable in vivo.

To summarize, we have demonstrated extended release of viable virus from PLGA microspheres. Such formulations may obviate the need for repeated intracerebral administrations in glioma gene therapy.

VASCULAR ENDOTHELIAL GROWTH FACTOR IN CEREBROSPINAL FLUID OF PATIENTS WITH BRAIN TUMORS. S. C. Cortez*. LeBlanc, P. Calabresi, M. H. Epstein, P. C. Song, L. G. Yee, W.M. Taylor, E. G. Stopa. Brown Univ. School of Medicine / RIH, Providence, RI.

Vascular endothelial growth factor (VEGF) has been shown to be a potent and Vascular endothelial growth factor (VEGF) has been shown to be a potent and highly specific endothelial cell activator that induces angiogenesis both in vivo and in vitro. VEGF mRNA is unregulated in primary brain neoplasms, particularly in malignant gliomas. Expression of VEGF is also seen in metastatic brain tumors. Since VEGF is normally present in conditioned tissue culture media, the present study was designed to assess whether VEGF could also be found in the cerebrospinal fluid (CSF) of patients with cerebral neoplasms. A solid phase ELISA using the Quantikine VEGF Immunoassay (R&D systems) was performed to determine the levels of VEGF. 30 cerebrospinal fluid samples from patients with high grade astrocytoma (anaplastic astrocytoma and glioblastoma multiforme), 37 samples from patients with metastatic and non-astrocytic brain tumors including lymphomas and patients with interastate and non-astrocyte oran turnos including lynpholinas and 14 non-tumor control samples were studied. 83.3% of samples with malignant astrocytoma and 27.0% of non-astrocytoma samples had detectable levels of VEGF. VEGF was not detectable in normal CSF samples. The levels of VEGF were generally higher in high grade astrocytomas than in non-astrocytic tumors. These results suggest that VEGF is detectable in cerebrospinal fluid and may be a potential marker for differentiating astrocytic from non-astrocytic tumors. Furthermore, this may be a potential target for tumor treatments

PERMEABILITY AND BLOOD VOLUME MEASUREMENTS IN INTRACRANIAL 9L RAT GLIOMA USING DYNAMIC CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING (MRI) S. Ostrowitzki¹, T.P.L. Roberts¹, J. Fick², D. M. Shames¹, K. Aklape², Z. Vexle¹*, M. A. Israel²,

T.P.L. Robers.' J. Fick. D. M. Shames.' K. Aldape.' Z. Vexler.'* M. A. Israel.' R. C. Brasch.' 'Dept. of Radiology, 'Dept. of Neurosurgery, 'Dept of Pathology, Univ. of California San Francisco, SF, CA 94143.

Hypervascularity and hyperpermeability are characteristic features of malignant brain tumors. We have established a method to non-invasively quantify blood volume and microvascular permeability in an animal model of intracranial malignant glioma by dynamic contrast-enhanced MRI. Eleven Fischer 344 rats were inoculated intracranially with 9L glioma cells. Dynamic MRI using Gd-DTPA was performed between day 13 and 16 post implantation. Blood volume and apparent permeability were derived from the enhancement data using a bidirectional two-compartment [plasma-interstitum] kinetic model. Histologic sections were stained with standard hematox Vilin-eosin and for factor VIII to evaluate the tumor vascularity. Tumors were hematoxylin-eosin and for factor VIII to evaluate the tumor vascularity. Tumors were well visualised on post-contrast images. Gd-DTPA leaked significantly (1105±151 µl/hr/cc of tissue, mean±S.E.M.) across the blood tumor barrier from the plasma space to the interstitium (p<0.0001 when compared to contralateral brain which was not involved with tumor). Blood volume as determined by MRI was significantly higher in tumors than in contralateral brain (p<0.0003). Immunohistochemistry revealed greater vascularity in the tumors compared to contralateral brain. We conclude that Gd-DTPA-enhanced dynamic MRI can be used to study microvasculature non-invasively in this glioma model because it provides good tumor visualisation on post-contrast images, quantitative estimations of tumor blood volume and a high dynamic range in apparent permeability between tumor and brain

Non-invasive characterisation of glioma microvasculature by MRI might be useful for tumor grading, chemotherapy planning and for investigation of newly developed therapies designed to inhibit angiogenesis. (Supported in part by a grant from the German Academic Exchange Service)

370.16

PROTON MAGNETIC RESONANCE SPECTROSCOPIC IMAGING OF BRAIN OF CHILDREN WITH CNS TUMORS J. A. Lazareff Ch. E. Olmstead, K. O'Hanlon, J. Abrajano, K.H.J.Bockhorst, J.R.Alger, R.S.Fisher, W.J.Peacock Neurological Surgery, Radiological Sciences, Neurobiology UCLA Sch. of Med., Los Angeles, CA 90095

We are interested in the effects of localized lesions on the global metabolism of the developing brain. In this study we have used H-MRSI as previously described (Child's Nerv Syst 1996 12:130-135) to evaluate the spatial distribution of choline compounds (Cho), creatine (Cre) and N-acetyl aspartate (NAA) signal amplitudes in every voxel ($7.5 \times 7.5 \times 15$ mm) of normal brain from 12 patients (18 months to 10 years of age) with pediatric supratentorial low-grade astrocytomas. The tumors were either hypothalamic (N=6) or hemispheric (N=6). We observed nonrandom distributions of all three measured compounds in each of the patients. (All ANOVA's p<.001). Cho and Cre were highest in those structures either of high density or with high energy requirements such as the hippocampus, superior colliculi, cerebellar vermis and thalamus, in that order. NAA was highest in the cerebellar hemispheres and cerebral cortex. The lowest values of all three compounds were seen in white matter, primarily internal capsule and cerebral peduncles.

SYMPOSIA THESDAY AM

SYMPOSIUM: CHEMICAL CODING AT CENTRAL AND PERIPHERAL SYNAPSES--THE SYNAPTIC VESICLE NEUROTRANSMITTER TRANSPORTERS. <u>L. E. Eiden</u>, NIH-NIMH (Chairperson); <u>J. B. Rand</u>, Okla. Med. Res. Found.; J. D. Erickson, NIH-NIMH; R. H. Edwards, Univ. California San Francisco; R. Jahn, Yale Univ.

The symposium focuses on what has been learned about the basis and evolution of chemically diversified neurotransmission from the molecular characterization of the vesicular monoamine and acetylcholine transporters, and from the neurogenetics

and bioenergetics of several vesicular neurotransmitter transport systems.

Neurotransmitter accumulation in vesicles as a fundamental mechanism of chemical coding at the synapse will be emphasized by summarizing recent and ongoing structural, developmental, mechanistic and neurogenetic studies of vesicular transporters from worm to human.

Lee Eiden will briefly discuss how knowledge about vesicular neurotransmitter

transporter structure has uncovered new aspects of chemical coding and the morphological basis of transmitter-specific neurosecretion. James Rand will discuss the neurogenetics of vesicular transporters in C. elegans, focusing on the nematode vesicular ACh transporter, required for synaptic efficacy in cholinergic motor neurons and part of an operon containing the acetylcholine biosynthett enzyme choline acetyltransferase. Jeffrey Erickson will discuss structural specialization of the twelve transmembrane-domain ACh and monoamine specialization of the twelve transmissional accountant Act and monograms. The transporters underlying recognition of amine neurotransmitter substrates and neuropharmacological agents. Robert Edwards will discuss how vesicular neurotransmitter transporters are partitioned among vesicle subtypes specialized for synaptic function and intracellular localization in central and peripheral neurons and neuroendocrine cells. Reinhard Jahn will compare mechanisms of neurotransmitter accumulation in storage vesicles from amino acid- versus amine-containing neurons and discuss the dynamics of exocytosis at chemically defined synapses.

SYMPOSIUM. MOLECULAR BIOLOGY OF PERCEPTION. G.M. Shepherd, Yale (Chairperson); D.A. Baylor, Stanford; G.M. Shepherd, Yale; S.C. Kinnamon, Colorado State; P. Dallos,

Analysis of sensory transduction at the molecular level is proceeding rapidly, but there is as yet little appreciation of the implications of these advances for concepts of sensory perception. The development of our understanding of the neural basis of perception will be briefly summarized. D. Baylor will describe mechanisms that mediate our perception of very dim light. Classic psychophysical experiments first suggested that single photons are registered. Recent physiological experiments reveal how the G-protein cascade in retinal rods minimizes noise and allows for accurate photon counting. Shepherd will discuss the interaction of odor molecules with olfactory receptors. Functional studies indicate that the odor molecules are encoded as odor images, in which individual molecular determinants are the basis for discrimination of smells. S. Kinnamon will discuss the diversity of mechanisms involved in taste transduction. Recent studies show that these mechanisms are expressed in different subsets of taste cells, which may provide a basis for discrimination of different taste qualities. P. Dallos will discuss molecular mechanisms of hair cell forward transduction and outer hair cell motor function and its modification by efferent transmitters. These processes will be placed in the context of auditory performance and its limitations.

SPATIO-TEMPORAL FREQUENCY COLUMNS IN CAT VISUAL CORTEX: A CONTINUOUS REPRESENTATION OR TWO STREAMS? D. Shoham*1, M. Hübener², T. Bonhoeffer² and A. Grinvald¹. ¹The Weizmann Institute of Science, Rehovot 76100, Israel, and ²Max-

Planck-Institut für Psychiatrie, Am Klopferspitz 18a, 82152 Martinsried, Germany.

We have recently used optical imaging to study the organization of spatial frequency columns across the cortical surface and their relationship to other columnar systems in cat visual cortex (Hübener et al, NS Abstr. 1995). Here we answer two unresolved

cat visual cortex (Hübener et al, NS Abstr. 1995). Here we answer two unresolved questions regarding the nature of stimulus representation by this columnar system.

The first question is whether the spatial frequency maps, which were obtained by comparing the cortical response to two different spatial frequencies, are part of a continuous representation of the spatial frequency domain, or whether they represent mixtures of only two neuronal populations, preferring low and high frequencies. To answer this question we used a wider stimulus set, containing gratings of several spatial frequencies spanning a range of more than 3 octaves. The resulting optical maps suggested a parcellation of the cortex into two sets of columns preferring preferring referring either low or. suggested a parcellation of the cortex into two sets of columns, preferring either low or high spatial frequency. Each of the stimuli we used activated preferentially one of the two sets. No stimulus was found which activated preferentially a different set of columns.

The second question is whether these two populations differ also in their velocity

preference, in addition to their spatial frequency preference. To test this we used stimuli of the same spatial frequency but moving at two different speeds. The resulting maps were weaker in amplitude but very similar in shape to those obtained with the high and low spatial frequencies. The low spatial frequency patches were preferentially activated by the faster moving stimuli, and the high frequency areas were activated more by the w stimuli. This result indicates that the two populations are also differentially tuned to velocity (or temporal frequency).

Since both of the above results show that there are separate regions preferentially responding to high spatial frequency/low speed and to low spatial frequency/high speed stimuli, we hypothesize that these spatio-temporal frequency columns are the cortical manifestation of the retino-thalamic parallel streams. Recent reports support this hypothesis (Boyd & Matsubara, ICN 365: p.659, 1996; Hübener et al, this volume). Supported by the ISF / Israel Academy and by the Human Frontier Science program.

376.3

SPATIO-TEMPORAL LUMINANCE AND CHROMATIC RECEPTIVE FIELD PROFILES OF MACAQUE STRIATE CORTEX SIMPLE CELLS.

N. P. Cottaris^{1,1}, S. D. Elfar² and R. L. De Valois^{1,2} Group in Vision Science¹ and Dept. of Psychology², Univ. of Calif., Berkeley, CA 94720.

The spatiotemporal (x-t) receptive field (RF) maps of monkey striate cortex simple cells have been mapped with luminance stimuli (Jacobson, Gaska, Chen, and Pollen, 1993). However, to characterize fully the RF of a simple cell, a cone input x-t RF map is necessary to predict responses to both color and luminance stimuli.

Toward this end, we recorded extracellularly the responses of simple

cells from striate cortex of anesthetized, paralyzed macaque monkeys. RF maps were obtained using two mapping techniques. A reverse correlation technique (Jones and Palmer, 1987), with small bars of the optimal orientation that activated one or all three cone types in phase or in antiphase, allowed us to measure simultaneously the luminance, cone, and color RFs of a cell. Individual cone input RF maps were also measured using the m-sequence method (Sutter, 1987). A 1- or 2-D Gabor function was fitted to the measured x or x-y profiles at different values of t and the following parameters were extracted: RF center, width and length, optimal spatial frequency, orientation, number of subregions and spatial phase. The variation of these parameters as a function of time was studied and compared for the luminance and the chromatic RF profiles. In addition, Fourier transforms of the x-t RF maps were calculated, and compared to the spatiotemporal tuning functions measured with sinewave gratings.

Preliminary data indicate that most cells exhibit similar spatial and

temporal structure in their luminance and chromatic RF maps However, a small number of cells have a more complex cone input RF Supported by NIH EY00014 map.

THE CODING OF EXTENDED COLORED FIGURES IN MONKEY VISUAL CORTEX. Rüdiger von der Heydt*, Hong Zhou, and Howard Friedman. Krieger Mind/Brain Institute and Depts. of Neuroscience and Biomed. Eng., Johns Hopkins University, Baltimore, MD 21205

We have studied the neural coding of extended colored figures. Single cells were recorded from parafoveal regions of V1 and V2 in alert, fixating monkeys. In V1 we have recorded mainly from cells in the upper layers. After determining the orientation and color selectivity of a cell, a static, square figure of uniform color on a gray background was placed at various positions relative to the cell's receptive field. The figure was much larger than the response field (typically 4°).

The vast majority of cells (75/89 in V1; 43/47 in V2) were activated only when an edge was located in the response field ("edge-only"), and few cells were activated when the receptive field was inside the figure ("surface"). Most of the latter also showed some edge enhancement. The relative frequency of color selective cells, judged by the differential responses to colors of similar luminance, was found to be as high in the "edge-only" group as in the "surface" group (26/69 vs 6/14 in V1; 12/37 vs 2/3 in V2). Also the distribution of a color selectivity index that estimates the volume in 3-d color space over which a cell responds was similar for both groups. Clearly, there are many more color selective "edge-only" cells than color selective "surface" cells. Most "edge-only" cells were selective for orientation,

and also many for edge polarity.

Thus, V1 and V2 seem to encode the color of extended figures by edge signals rather than isomorphic representation. Color filling-in might result from the decay of color specific edge signals rather than a spreading of color specific surround activity into the figure.

CYTOCHROME-OXIDASE BLOBS IN CAT VISUAL CORTEX COINCIDE WITH LOW SPATIAL FREQUENCY COLUMNS, M. Hübener*, S. Schulze, and T. Bonhoeffer. Max-Planck-Institut für Psychiatrie, Am Klopferspitz 18a, 82152 München-Martinsried, FRG.

Munchen-Matthistical, FRO. In the visual cortex of primates neurons located in the cytochrome-oxidase blobs are endowed with a set of specific receptive field properties: they are color selective, unoriented, and respond preferentially to low spatial frequencies. Recently cytochrome-oxidase blobs were also detected in the visual cortex of cats and ferrets. It is not known whether the blobs in these non-primate species bear a specific relationship to any of the columnar systems. To address this question we visualized the functional architecture of the visual cortex with optical imaging of intrinsic signals and compared the cortical maps with the blob-pattern.

Cats were stimulated with four different orientations at two spatial frequencies

presented separately to the left and right eye to obtain the orientation, spatial frequency, and ocular dominance maps. The visual cortex was cut horizontally and reacted for cytochrome-oxidase. Small amounts of fluorescent dyes injected at the end of the optical imaging experiment served as landmarks to align the functional maps with the cytochrome-oxidase stained sections.

We found a clear correlation between the spatial frequency map and the blob-pattern: low spatial frequency domains were in register with the blobs, while regions of the cortex preferring high spatial frequencies coincided with the lighter staining interblob-region.

We also performed injections of retrograde tracers into the cortical spatial frequency We also performed injections of retrograde tracers into the cortical spatial frequency columns. Preliminary results of these experiments indicate that LGN-cells projecting into the low spatial frequency columns tend to have larger somata than LGN-cells terminating in the high spatial frequency columns. In line with Boyd and Matsubara (J.Comp.Neurol., 365: 659, 1996) this indicates that the low spatial frequency columns respectively blobs receive a stronger input from geniculate Y-cells.

Taken together these observations suggest the presence of two parallel pathways in cat visual cortex, with the blobs devoted to low spatial frequency and perhaps motion processing and the interblob region dealing with high spatial frequency information. Supported by the Max-Planck-Gesellschaft.

COLOR & LUMINANCE PROCESSING IN MACAQUE V1: SPATIAL STRUCTURE REVEALED BY INTRINSIC OPTICAL IMAGING

D. Orbach¹*, R. Everson², and E. Kaplan³, ¹Biophysics Lab, Rockefeller Univ., NY, NY 10021, ³Ophthalmol. & ²Biomath, Mt. Sinai Med. Ctr., NY, NY 10029

We examined the spatial organization of color and luminance processing in macaque primary visual cortex by measuring visually-evoked intrinsic reflectance responses. Our extensions of principal components analysis allow more sensitive, robust, and quantifiable detection of spatial patterns than is otherwise possible.

The questions addressed were: (i) Is there a spatial structure in V1 that differentiates among isoluminant color stimuli of various hues, and luminance-varying stimuli? (ii) Is there a spatial structure that discriminates between different stimulus contrasts, where contrast is defined both in luminance and in color? (iii) Are there privileged axes in color space (e.g. RG vs. BY)? (iv) How does spatial frequency tuning in V1 compare between luminance-varying stimuli and isoluminant hue-varying stimuli? (v) How do color- and luminance-sensitive structures relate to the already-familiar columnar organization, such as ocular dominance and orientation? (vi) How does the spatial organization of color processing relate to the CO blobs and interblobs? In each case, the issue was addressed both by attempting to generate spatial maps of the cortical response to a given stimulus set, and by quantifying the strength of the cortical response across a range of stimulus intensities.

The results show that there is a spatial structure that is activated in response to different isoluminant stimuli, as well as a structure responsive to strong luminance contrast. Additionally, the responses to various isoluminant axes in color space (e.g. the red-green axis vs. the red-blue vs. the blue-yellow) can be differentiated from one another. However, there do not seem to be distinct structures involved in the detection of varying contrasts along a given isoluminant or luminance axis Support: EY4888, EY01867, MH50166, RPB, ONR N0014-93-12079

CORTICAL REPRESENTATION OF SURFACE BRIGHTNESS: INFLUENCES FROM BEYOND THE CLASSICAL RECEPTIVE FIELD, M. A. Paradiso*, W. Kim, and S. Nayak. Department of Neuroscience, Brown University, Providence, RI 02912

The brightness and color that a surface is perceived to have are based on light reflected from surfaces throughout the visual field. We explored the possible relationship between activity in striate cortex and perceived brightness by examining the temporal response patterns of striate neurons to stimuli within the classical receptive field (CRF) with and without the presence of surrounding stimuli. A neuron's CRF was stimulated with a single uniformly luminous patch of light of different sizes, while annular stimuli of various dimensions were presented at distances up to 15 deg from the receptive field. These experiments revealed extensive interactions from outside the CRF. In most neurons, stimuli beyond the CRF led to changes in both the magnitude and the timecourse of responses to stimuli within the CRF. The largest effects were seen in later phases of the response (e.g. 100 msec after the initial transient) suggesting that network interactions were involved. Over 50% of the neurons were significantly affected by stimuli outside the CRF, with the interactions falling into several categories. Most commonly, light outside the CRF had either a purely facilitatory or inhibitory effect. Often these effects progressively decreased as the luminance contrast edges of the surrounding stimulus moved further from the CRF. However, there were also neurons in which the surround effects increased in magnitude with distance. The spectrum of interaction types indicates that single neurons in striate cortex do not always respond in a manner consistent with perception. The larger unanswered question is whether integration of these responses can account for the diverse perceptual interactions seen in assimilation, induction, and brightness constancy Supported by NIH grant EY09050 and a grant from the Whitehall Foundation

SPATIAL RELATIONSHIPS BETWEEN CLASSICAL RECEPTIVE FIELD AND PROCESSES MEDIATING ORIENTATION AND DIRECTION CONTRAST. A.M. Sillito and H.E. Jones. Dept. of Visual Science, Inst. of Ophthalmology, London EC1V 9EL, UK

Cells signalling orientation and direction contrast effects have been described in primate visual cortex (Kmerim and Van Essen, J. Neurophysiol 67: 961-980 1992, Sillito et al. Nature 378: 492-496, 1995). We previously reported that the spatial scale of such effects can be strongly constrained to a circumscribed zone of visual space, which may be asymmetrically distributed around the receptive field and that different outer stimulus parameters can elicit modulatory effects from different locations (Jones et al. Soc. Neurosci. Abs. 21, 650 4, 1995) Here we have dissected the links between the classical receptive field (CRF) and context dependent mechanisms. We quantitatively documented the responses of 70 primate V1 cells using a range of stimuli (including concentric annular and circular patches of drifting grating and discrete grating patches positioned at various XY coordinates) to map CRF and surround mechanisms. Individual cells were studied for 6-12 hours. All effects were observed with simultaneous stimulation of CRF and surrounding areas at the same contrast. Sensitivity to orientation context was seen in oriented and non-oriented cells. Both orientation and direction context dependent effects were observed within, on the edge of, and significantly beyond the apparent confines of the CRF. The modulatory effect of a 1-2° second stimulus patch on the response to a stimulus overlying the CRF could be observed up to 3° or more away from the CRF. As this applied to receptive fields within 5° of the fovea with classical field dimensions in the range of 0.2-0.5°, it reflects a very significant horizontal convergence. We also observed strong directional influences on orientation contrast, even in nondirectional cells, suggesting that the influence of stimulus direction pervades more of primate V1 than the response to single stimuli indicates.

The pattern seen varied but the data suggest that the mechanisms detecting stimulus context could often overlie as well as extend beyond the classical receptive field and for at least some cells, should possibly be considered part of its organisation

CROSS-ORIENTATION INHIBITION IN HUMAN V1. <u>G.M. Boynton.</u>* <u>J.B. Demb.</u>, and <u>D.J.Heeger.</u> Dept. of Psychology, Stanford University, Stanford CA

Purpose: To measure and characterize cross-orientation inhibition in human using functional MRI.

Background: Neurons in primary visual cortex of cat and monkey respond superimposing orthogonal gratings (cross-orientation and are suppressed by superimposing orthogonal gratings (cross-orientation inhibition). The suppression is strongest when the orthogonal grating is at the neuron's preferred spatial frequency. Heeger (Vis. Neurosci., 9:181-197, 1992) proposed a formal model, known as the normalization model, to explain cross-orientation inhibition in single cells.

Methods: Stimuli were contrast-reversing sine-wave gratings (8Hz, 0.8 or 3.2 c/deg) and plaids (superimposed orthogonal gratings) of various contrasts, that alternated every 40 seconds with uniform fields. fMRI response was quantified as the amplitude of the (40 sec period) sinusoid that best fit each

pixel's time-series.

Results: For plaids with different spatial frequency components there is little cross-orientation inhibition; the responses to the plaids are about equal to the sum of the gratings responses for all contrasts. Suppression is apparent, however, when the grating components have the same spatial frequency; for all contrasts, responses to these plaids are clearly less than the sum of the grating responses. The normalization model fits the data well.

Conclusions: The normalization model is quantitatively consistent with fMRI measurements of human V1. Neurons in human V1 exhibit crossorientation inhibition.

orientation inhibition.

PREDICTING SYNAPTIC RESPONSES OF V1 NEURONS TO ARBITRARY TEMPORAL PATTERNS OF STIMULATION. S.B.

Nelson, J.A.Varela, J. Gibson*, K. Sen & L.F. Abbott Dept. Biology & Center for Complex Systems, Brandeis Univ., Waltham, MA 02254. Little is known about the cause of temporal filtering in V1. We apply a "synaptic decoding" method to electrically-evoked EPSCs and field potentials in vitro. This allows the prediction of postsynaptic responses to

arbitrary temporal patterns of input, and elucidates the role of synaptic depression in shaping V1 response properties.

Field potentials (N=14) and monosynaptic EPSCs (N=9) were obtained from layer 2/3 pyramidal neurons in rat visual cortical slices. Responses to random stimulus trains (delivered to layer 4) were used to calculate temporal weighting functions that predict the amplitude of successive responses as a function of interval. Response amplitudes within a train varied 2-5 fold due to cumulative synaptic depression. Fits, obtained by gradient descent, closely predicted (within a few percent) data from additional random or constant frequency trains not used in the fitting process. Results from field potentials and EPSCs were similar. The ting process. Results from field potentials and EPSCs were similar. The observed depression decays bi-exponentially $(\tau_1=200-500 \text{ ms}, \tau_2=3-10 \text{ s})$. It is presynaptic in origin, since it is reduced by modulators that decrease transmitter release (e.g. adenosine 5-50 μ M), but not by a similar degree of postsynaptic response reduction (CNQX 0.3-1.0 μ M). These measurements allow us to estimate the contribution of synaptic depression to the temporal properties of V1 responses. The amplitude and time course of the depression are sufficient to account for the greater transience and lower temporal frequency tuning of cortical neutrons.

transience and lower temporal frequency tuning of cortical neurons (relative to LGN neurons) and for the kinetics of contrast adaptation. Supported by NSF and Sloan Foundation.

CENTER-SURROUND CONTRAST EFFECTS IN MACAOUE CORTEX

James R. Müller¹, Benjamin Singer¹, John Krauskopf², Peter <u>Lennie</u>*1 Center for Visual Science, University of Rochester¹; Center for Neural Science, New York University²

A V1 or V4 neuron often shows inhibitory and excitatory interactions when stimuli of contrasting structure fall in its classical receptive field and in an enclosing region. We quantify these effects, and explore the size and spatial summation of the region outside the classical receptive field. From anesthetized m. fascicularis we recorded responses of V1 and V4 neurons to drifting sinusoidal gratings of optimal position, size, orientation, spatial frequency, and color. We then added enclosing or nearby gratings that varied in orientation, spatial frequency, position, or size. Excitatory interactions varied regularly with the orientation of the enclosing grating; for other dimensions of stimulus structure, the contrast effects were less clear. The smallest responses were usually caused by an enclosing stimulus that matched the one in the classical receptive field. Excitatory and inhibitory interactions grew smaller as the size of the enclosing grating was decreased, or as its distance from the receptive field

PRINCIPLES UNDERLYING THE MAPPING OF DIRECTION PREFERENCE IN PRIMARY VISUAL CORTEX. M. Weliky*, W.H. Bosking, L.C. Katz, D. Fitzpatrick, Dept. of Neurobiology, Duke Univ. Med. Cntr., Durham, NC 27710.

Optical imaging of intrinsic signals demonstrates that direction preference is systematically mapped within primary visual cortex (Weliky et al., *Nature* 379). Direction preference shifts slowly and continuously within numerous patches. These patches are separated by winding boundaries across which direction preference abruptly shifts by up to 180 degs. Direction fractures tend to intersect orientation pinwheel centers, and subdivide iso-orientation domains into patches selective for opposite directions of motion. Direction preference is typically orthogonal, or within 45 degs, to preferred orientation. Modeling was used to investigate the principles underlying the formation of direction preference maps. A patch of visual cortex was modeled as having initially weak and randomly distributed directional preferences, represented as vector variables. The directional preference at cortical preterences, represented as vector variations. The directional preterence at outcar sites was then modified through local excitatory/lateral inhibitory interactions. The resulting maps produced by these conditions consisted primarily of singularities or 360 deg. direction pinwheels, not line discontinuities or fractures as experimentally observed. In order to reproduce the experimental observations, the model was modified so that an orientation map was formed prior to the emergence of direction monned so that an orientation map was rollied pirio to the energetic of unection preference. At each site, direction preference was randomly chosen to be in one of two opposite directions orthogonal, or within 45 degs., to orientation preference. This orthogonality was maintained throughout the simulation. An organized direction map gradually emerged, consisting of long, winding fractures that intersected orientation pinwheels as experimentally observed. The time course of map development reveals that early fluctuations occur with a roughly fixed spatial scale, forming initially weak direction domains that expand and meet. Fractures form at the boundaries between these expanding domains. Changing the balance of excitatory and inhibitory cortical interactions systematically alters the pattern of direction fractures. Supported by NIH grant EY07690 (L.C.K.), EY11488 (D.F.).

FUNCTIONAL CONSEQUENCES OF SYNAPTIC DEPRESSION FOR RESPONSE PROPERTIES IN V1. L.F. Abbott*, K. Sen, J.A. Varela, J. Gibson & S.B. Nelson Department of Biology & Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Excitatory synapses in V1 depress during repeated stimulation and recover over two timescales. To study the functional significance of this, variance protected on security methods the description of twenty indepressions.

we incorporated an accurate mathematical description of synaptic depression into a model of a V1 simple cell. Responses to sinusoidal contrast modulation deviated from linearity in two important respects. Over short timescales (<1 s), the cell responded best to rapidly rising input signals, times ares (<15), the cert responded best to rapidly fishing input signlass but responded poorly to high temporal frequencies. Responses to low frequency (1-4 Hz) modulation were distorted and phase advanced, accurately matching intracellular recordings of responses to contrast modulation measured in vivo (Jagadeesh et al <u>Science</u> 1993). If the phase-shifted, non sinusoidal synaptic current arising from adapting synapses is combined with an unshifted, linear contribution from non-adapting synapses, the response of the model neuron becomes directionally and velocity selective. This mechanism could allow cells not receivable and rec

ing lagged LGN input to nevertheless achieve direction selectivity.

Over longer time scales (1-30 s), the slow component of recovery from depression causes responses to adapt. The strength and speed of the adaptation increase with temporal frequency as observed experimen-

tally. Also as observed, the adaptation can occur locally within the RF.

More generally, synaptic depression enhances the information carried
by neuronal firing. The firing of a neuron with adapting synapses is sensitive to the temporal pattern of synaptic input in a synapse-specific manner, making it sensitive to both spatial and temporal features of the pattern of synaptic input. Supported by NSF and Sloan Foundation.

SPATIALLY SELECTIVE ATTENTION GATES NEURONAL RESPONSES IN MACAQUE V1. T.R. Vidyasagar and G.H. Henry*. Centre for Visual Sciences and Div. of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, ACT2601, Australia.

To study whether attentional mechanisms influence neuronal responses in the primary visual cortex, two macaques (M. nemestrina) were trained on a conditional visual discrimination task. While maintaining fixation on a small spot, the monkey had to discriminate the orientation of the bars of a grating flashed briefly (60-80 ms) in a cued part of the visual field while ignoring the grating orientation in other simultaneously presented patches. In each trial, a different part of the visual field was cued and the monkey had to discriminate between vertical and horizontal orientations by making an appropriate motor response. A chamber was then implanted over the visual cortex under aseptic conditions and general anaesthesia. In implanted over the visual context inter aspect contents and general anterior subsequent electrophysiological recordings, one set of cells in V1 (CS or cuespecific neurons) fesponded vigorously to a presentation of the grating over the receptive field only when that grating was cued; when other positions were cued (non-cued trials), response to the same grating was significantly less. These cells usually had latencies of at least 70 ms. Another set of cells in V1 (CR or cue-related neurons) had more classical latencies of 40 to 80 ms; their early responses were similar for both cued and non-cued trials, but the response component beyond 100 ms was more marked for cued trials. It is proposed that an attentional feedback reaches V1 about 70 to 110 ms after the presentation of the grating stimuli in this paradigm and it facilitates the responses in the cued part of the visual field and/or inhibits responses in all non-cued regions ("attentional spotlighting"). Such feedback may underlie the more sustained response of CR cells in the attended region. The CR cells in turn may excite the CS cells which may provide the final output to the relevant higher areas for behaviorally significant visual discrimination. (Funded by the John Curtin School of Medical Research).

CARDIOVASCULAR REGULATION: VENTRAL MEDULLA II

377.1

CARDIAC SYMPATHETIC PREMOTOR NEURONS, R.M. McAllen* and R.R.

Campos Howard Florey Institute, University of Melbourne, Vic 3052, Australia Premotor neurons in the rostral ventrolateral medulla (RVLM) control the sympathetic supply to the heart as well as to blood vessels, but the distribution sympathetic supply to the heart as we as to shoot vessels, and actions of the cardiac neurons are ill-defined. We mapped cardiac sympathetic premotor neurons in 7 chloralose-anesthetized cats (70mg/kg, i.v.), by microinjecting glutamate (0.5 nmol) into 133 RVLM sites whilst recording activity from the ipsilateral inferior cardiac nerve. For comparison, muscle vasoconstrictor (MVC) activity was recorded simultaneously from the peroneal nerve. Baroreceptors were denervated. RVLM glutamate injections increased cardiac nerve activity by up to 395% and MVC activity by up to 487%. Most injections excited both nerves, but selective MVC responses could be obtained from the caudal end, and cardiac nerve responses from the rostral end, of the subretrofacial nucleus

Nine chloralose-anesthetized cats were adrenalectomized, vagotomized and given prazosin (1mg/kg, i.v.) to minimize blood pressure changes. The peak rate of pressure rise (dP/dt_{max}) was measured from a left ventricular cannula. Glutamate injections into 130 RVLM sites increased heart rate by up to 65% and dP/dt_{max} by up to ten-fold, indicating strong chronotropic and inotropic drives. Diastolic ventricular pressure usually fell, and the tachycardia per so (reproduced by atrial pacing) caused only a small increase in dP/dt_{max}. injections on the right caused stronger tachycardias than those on the left (36.8±19.5 vs. 14.9±14.2 beats/min), but inotropic responses to left and right stimuli were similar. The same pattern was seen in response to electrical stimulation of the left and right cardiac sympathetic nerves (3 animals).
We conclude that both chronotropic and inotropic sympathetic actions are

driven by RVLM premotor neurons, whose distribution is partly distinct from vasomotor pathways. Their projections to the heart are heavily ipsilateral. Supported by NH&MRC. RRC is a FAPESP (Brazil) postdoctoral fellow

CONVERGENT INPUTS FROM THE AORTIC AND VAGAL NERVES TO NEURONES OF THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) IN THE RAT. K.Ishizuka 1. A.Zagon* I. Rocha. and K.M.Spyer Dept. of Physiology, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF, U.K., 1 Dept. of Oral Physiology, The Nippon Dental University, School of Dentistry at Niigata, 1-8 Hamaura-cho Niigata 951, Japan.

Previous physiological studies have shown that the RVLM plays an important role in the integration of autonomic reflexes. In the present study we examined the existence of convergence between aortic (AN) and vagal (VN) afferent inputs using in vivo intracellular recordings. Data were obtained in anaesthetised (pentobarbitone sodium 60 mg/kg i.p., followed by \(\alpha \)-chloralose, 30 mg/kg/h i.v.) and artificially

Electrical stimulation of the insilateral cervical vagus (4-6 V, 0.1 ms, Electrical stimulation of the ipsilateral cervical vagus (4-6 V, 0.1 ms, 1 Hz) evoked EPSP, IPSP or multiphasic responses in RVLM neurons. Convergent inputs were observed in about two-third of the neurones where stimulation of the aortic nerve (parameters as above) evoked either an IPSP or EPSP. A tendency to receive common excitation or inhibition was evident. The onset latency of AN and VN inhibition was similar (20-47 and 24-51 ms) while the onset latency of VN excitation (19-57ms) was regularly longer than that of the AN response (14-41 ms). The neurones that received both aortic and vagal inputs were concentrated in the medial aspect of the RVLM.

A possible network of mediating VN and AN responses in the RVLM is suggested.

Supported by the British Heart Foundation.

SYMPATHO-EXCITATORY NEURONS OF THE ROSTRAL VENTROLATERAL MEDULLA OF RABBITS ARE ORGANIZED TOPOGRAPHICALLY Y. Ootsuka and N. Terui*. Institute of Basic Medical Sciences, University of Tsukuba, Tsukuba, Ibaraki 305, Japan

Our present experiments were undertaken to examine whether sympatho-excitatory reticulospinal neurons of the rostral ventrolateral sympanio-exertatory reucunospinai neurons or the rostral ventrolateral medulla (RVLM) are organized topographically or not. Micro-injections of a neuro-inhibitory agent, y-amino-n-butyric acid (GABA, 50 mM 10-30 nl), into the RVLM were done during simultaneous measurements of arterial pressure and blood flow of the kidney (with an ultrasonic-particular topographical program of the program of t Doppler cuff), the ear skin and muscles of fore- and hind-limbs (with laser-Doppler probes) in urethane-anesthetized and immobilized rabbits. Conductance of each vascular bed was calculated by mean arterial pressure (MAP) and each blood flow. Injection sites where the maximal changes in conductance of the vascular beds of fore- and hind-limb muscles were evoked were very close to the site where the maximal changes in MAP (MAP site) were evoked. More rostral sites to the MAP site were found to evoke the maximal changes in renal conductance. Neurons located in the medial sites to the MAP site affected conductance of the ear skin vessels. Because the preganglionic neurons that control vessels of the ear skin and the fore-limb muscles are located at the upper thoracic segments of the spinal cord and those that control the vessels of the hind-limbs are located at the lumber segments, these observations indicates that the sympatho-excitatory reticulospinal neurons in the RVLM are divided into subgroups and they are localized in the RVLM according to their function but not their anatomical characteristics.

CARDIORESPIRATORY NEURONS IN THE VENTROLATERAL MEDULLA RESPOND TO MULTIPLE INPUTS. C. Wu, P.C. Nolan and T.G. Waldrop*. Depts. of Molecular & Integrative Physiology, Neuroscience Program and College of Medicine, Univ. of Illinois, Urbana, IL 61801.

The ventrolateral medulla (VLM) is an important integrative site for

cardiorespiratory reflexes; neurons in this region are known to play a role in central chemoreception and are involved in baroreceptor and somatosympathetic reflexes. Previous studies from this and other laboratories have shown that many VLM neurons are excited by hypoxia and project to the intermediolateral cell column. The purpose of the present study was to determine if individual VLM neurons respond to multiple inputs or only one type of sensory modality. Extracellular, single unit activity of VLM neurons was recorded in anesthetized, male rats. VLM neurons were tested for responses to three somatosensory stimuli (activation of hair, skin and skeletal muscle receptors) applied to the hindlimbs. In addition, VLM neuronal responses to inhalation of hypoxic (10% 02/90% N2) and hypercapnic (5% CO2/95% 02) gases and to baroreceptor activation (phenylephrine-induced increases in arterial pressure) were examined. Over ninety percent of VLM neurons responded to hypoxia; the discharge frequency of a smaller proportion was altered during hypercapnia or baroreceptor stimulation. All of the hypoxia-sensitive neurons responded to at least one of the somatosensory stimuli including input from both ipsilateral and contralateral limbs. The majority of these neurons had basal discharge patterns related to cardiac and/or respiratory rhythms as revealed by computer signal averaging. Thus, cardiorespiratory neurons in the ventrolateral medulla integrate input from a variety of stimuli in order to produce appropriate cardiorespiratory responses during conditions such as exercise and hypoxic stress. (Supported by NIH HL06296)

Different Regions of the Rostral Ventrolateral Medulla (RVL) Regulate Sympathetic Nerve Activity or Regional Cerebral Blood Flow (rCBF) and EEG. D.J. Reis*, D.A. Ruggiero, and E.V. Golanov. Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021.

While stimulation of the RVL electrically, chemically or by hypoxia elevates arterial pressure (AP) and rCBF and synchronizes the EEG (Golanov and Reis,

While stimulation of the RVL electrically, chemically or by hypoxia elevates arterial pressure (AP) and rCBF and synchronizes the EEG (Golanov and Reis, Am. J. Physiol., 1994) the region maximally elevating rCBF is caudal to that exciting sympathetic neurons. We investigated whether the RVL was organized into functionally distinctive regions for regulation of AP, rCBF and EEG by stimulation of RVL, the nucleus tractus solitarius (NTS) or by brainstem hypoxia (NaCN). Rats (n=32) were anesthetized, spinalized, ventilated, and instrumented to record AP, cortical rCBF (laser-Doppler flowmetry), and EEG. The medulla was systematically explored by microstimulation with 5 sec trains (100 µA, 50 Hz). Stimulation within the sympathoexcitatory (C1) region of the rostral RVL (rRVL) increased rCBF within 2 sec by 20½3% and increased the power of the 4-6 Hz EEG rhythm. However, the rCBF responses were significantly larger (by 34±8%, p<0.05) from a caudal vasopressor region (RVLC). Micronipections of t-glutamate (5 nM, 40 nL) produced greater increases in rCBF from RVLc. Inactivation of the RVLc by procaine or electrolytic lesions reduced the increase in rCBF (by 70%, p<0.05) and EEG synchronization evoked from RVLr and NTS while inactivation of RVLr did not alter evoked changes in rCBF or EEG evoked from RVLc nor NTS. Tracing efferent projections from RVLr or RVLc with biotinylated dextran-amine (n=4) demonstrated RVLr projections terminating within the caudal paraambigual region corresponding to the RVLc and, reciprocally, RVLc projections terminating in RVLr. We conclude: (a) Neurons of the RVLc and projections terminating in RVLr. and NTS on rCBF and EEG; (b) neurons of the RVLc and increase sympathetic activity by a spinal sympathetic pathway; (c) regions of RVL exciting spinal sympathetic neurons are anatomically distinct from those regulating rCBF and EEG.

THE 10-HZ AND CARDIAC-RELATED (C-R) SYMPATHETIC RHYTHM GENERATORS CONVERGE ON BULBOSPINAL NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) AND CAUDAL MEDULLARY RAPHE (CMR) OF CATS. S.M. Barman* and G.L. Gebber. Den Pharmacology & Toxicology, Michigan State Univ. East Lansing, MI 48824.

Studies from this laboratory support the view that the generators of the 10-Hz

Studies from this laboratory support the view that the generators of the 10-Hz and C-R rhythms in sympathetic nerve discharge (SND) are comprised of different pools of neurons. The current study was designed to test the hypothesis that the outputs of the two generators converge at the level of bulbospinal neurons. One would expect that only brainstem neurons that project to the spinal cord would have activity correlated to both rhythms in SND if this hypothesis is correct. Thus we determined if RVLM and CMR neurons with activity correlated to both the 10-Hz and C-R rhythms in inferior cardiac postganglionic SND could be antidromically activated (AA) by electrical stimulation of the first segment of the thoracic spinal cord (T1SC) of urethane-nesthetized, vagotomized cats. The axons of 16 of 18 RVLM neurons with activity correlated to both rhythms projected to the T1SC. Also, 31 of 34 CMR neurons with activity correlated to both the 10-Hz and C-R rhythms in SND were AA by T1SC stimulation. These data support the hypothesis that the 10-Hz and C-R rhythm generators converge at the level of bulbospinal neurons. We also found 13 RVLM and 4 CMR neurons with activity correlated to only the 10-Hz or to only the C-R rhythm in SND. Only one of these RVLM and none of these CMR neurons could be AA by T1SC stimulation. These data reveal that a substantial proportion of RVLM neurons and a small group of CMR neurons with activity correlated to SND are not bulbospinal. The axonal trajectories and functions of these neurons remain to be determined. (Supported by NIH grant HL33266.)

HETEROGENEITY OF METABOTROPIC GLUTAMATE RECEPTOR EXPRESSION IN CARDIOVASCULAR REGULATORY REGIONS OF THE MEDULLA. M. Hay*, P. J. Conn‡, H. McKenzie, K. Lindsley, and E. M. Hasser. Dalton Cardiovascular Research Center, Dept. of Vet. Biomedical Sciences, University of Missouri, Columbia MO 65211 and ‡Dept. of Pharmacology, Emory University School of Medicine, Atlanta GA, 30322.

School of Medicine, Allanta GA, 30322.

The expression of mGluR1α, mGluR2/3, mGluR4α and mGluR7 was examined with immunocytochemistry and in situ hybridization in rat medullary regions known to be involved in cardiovascular control. Within the rostral and caudal extent of the nucleus tractus solitarius (NTS) studied in this report, there was no evidence for either mGluR1a protein or mRNA. Likewise, there was also an absence of mGluR2/3 immunoreactivity within the NTS. mGluR4α was identified within both cell bodies and fibers within the NTS while mGluR7 expression appeared to be limited to fibers and processes throughout the rostral and caudal extent of the NTS. The present study also revealed intense mGluR1α immunoreactivity within the n. ambiguus and an absence of any detectable mGluR2/3, mGluR4α or mGluR7 immunoreactivity within the .n. ambiguus. Within the donsal motor nucleus of the vagus (DMN), (+) immunoreactivity for mGluR1α, mGluR2/3, and mGluR4α was observed. Expression of mGluR2/3, while present in cell bodies and fibers in the caudal regions of the DMN, could be detected only in the neuropil and fibers in the rostral regions of the DMN. Of the mGluR(s) studied in this report, only mGluR2/3 was clearly evident in cell bodies and fibers within the area postrema. Expression of mGluR2/3 was clearly evident in cell bodies and fibers within the area postrema. In some cases, (+) mGluR2/3 processes were observed to transverse across the border of the area postrema into the adjacent NTS. Expression of mGluR4α was very dense and punctate within small perikarya of the area postrema. Within the caudal ventral lateral medulla (CVLM), (+) mGluR1α and mGluR4α immunoreactivity was observed within both cell bodies and processes. mGluR4α (+) labeling was also observed within to the Lel bodies and processes of the rostral ventral lateral medulla (RVLM). These results suggest a complex and subtype specific role for mGluR(s) within cardiovascular regulatory regions of the medulla. Supported by NIHL5004 to M.H. and NIHL4

VENTROLATERAL MEDULLA MEDIATES DEPRESSOR RESPONSES ELICITED BY ACTIVATION OF SODIUM-SENSITIVE NEURONS IN NUCLEUS TRACTUS SOLITARIUS, S. L. Hochstenbach* and J. Ciriello. Department of Physiology, University of Western Ontario, London, ON, Canada, N6A 5C1

We have previously shown that activation of sodium-sensitive sites in nucleus of the solitary tract (NTS) elicits depressor and bradycardic responses. However, the pathways mediating these effects are unknown. Experiments were done in male Wistar rats to identify anatomically and functionally the brainstem nuclei that may mediate the depressor responses elicited by activation of sodium-sensitive neurons in NTS. In the first series, the anterograde tract-tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) was iontophoresed unilaterally into NTS sites at which microinjection (20 nl) of a 150-175 mM NaCl solution elicited depressor responses. Injection sites were found to be localized to the caudal medial subnucleus of NTS (Sm). PHA-L labelled fibers and presumptive terminal boutons were found throughout the rostrocaudal extent of NTS. dorsal motor nucleus of the vagus, area postrema, ventrolateral medulla (VLM), and nucleus ambiguus bilaterally, with an ipsilateral predominance. In the second series of experiments, the effect of blocking synaptic transmission in VLM with cobalt chloride (CoCl₂, 5 mM, 100 nl) on the cardiovascular response elicited by microinjection (20 nl) of hypertonic saline (150-175 mM) into the ipsilateral Sm was investigated in the alphachloralose anesthetized, paralyzed and artificially ventilated rat. Microinjection of $CoCl_2$ into VLM, at sites shown in the previous experiment to receive efferent projections from Sm, significantly attenuated the depressor (60%) and bradycardic (80%) responses to stimulation of Sm. These data indicate that the sodium-sensitive region of the caudal Sm innervates VLM neurons and suggest that these VLM neurons are involved in mediating the depressor and bradycardia responses elicited by changes in the extracellular concentration of sodium. (Supported by the Heart and Stroke Foundation of Ontario.)

DISTINCT PATHWAYS WITHIN THE ROSTRAL VENTROLATERAL MEDULLA (RVL) MEDIATE PRESSOR AND BLOOD FLOW RESPONSES TO SCIATIC NERVE STIMULATION (SNS). Cravo, S.L.*; Possas, O.S.; Lones O'll Dent of Physiology Univ Federal de São Paulo, São Paulo, Brazil.

Lopes, O.U. Dept. of Physiology, Univ. Federal de São Paulo, São Paulo, Brazil.Sciatic nerve stimulation (SNS) produces hypertension, tachycardia and muscle vasodilation. Previous studies demonstrated that the RVL mediates heart rate and pressor responses to SNS, however, its role in the vasodilation remains unclear. Male adult Wistar rats were anesthetized (urethane, 1.2 g/kg, <u>iv</u>), paralyzed and artificially ventilated. The right carotid artery and jugular vein were catheterized for mean arterial blood pressure (MAP) and heart rate (HR) recordings and drug administration, respectively. Hindlimb blood flow (HBF) was recorded by Doppler administration, respectively. Finding the following the fo (mmHg). Results obtained demonstrate that: 1) SNS (square pulses, 1 ms duration, 20-50 Hz, 800-1200 μ A, 10 s) produced hypertension (+28 \pm 4.3 mmHg, N=5), tachycardia (+26 \pm 4.4 bpm) and increased HBF (134 \pm 7.7%) and HVC (105 \pm 2.2%); 2) after unilateral microinjection of kynurenic acid (2 nmol/100 nL) into the RVL contralateral to the sciatic nerve stimulated, MAP and HR responses to SNS were reduced to -1 ± 4.0 mmHg and 8 ± 5.5 bpm (p<0.05) whereas HBF response was not modified (120 \pm 4.6%), therefore the HVC response increased (122 \pm 5.7%, p<0.05); 3) when bicuculine (400 pmol/100 nL) was microinjected into the contralateral RVL, pressor response was not modified (+23 \pm 3.4 vs. 31 \pm 2.6 mmHg, N=7), tachycardia was reversed to bradycardia (+28 \pm 5.4 vs. -33 \pm 13.4 bpm, p<0.05), and increase HBF was abolished (134 \pm 8 vs. 94 \pm 5.2%, p<0.05), hence HVC decreased (106 \pm 6.8 vs. 73 \pm 3.3 %, p<0.05). These results suggest that glutamatergic afferents within RVL mediates pressor responses while GABAergic afferents modulates vasodilatatory responses to SNS Supported by FAPESP, Brazil.

A STUDY OF THE NATURE OF THE PROJECTIONS FROM NUCLEUS RAPHE OBSCURUS TO THE VENTROLATERAL MEDULLA, H. A. Futuro Neto, M. A. Dantas, M. P. Gilbey* and J. G. P. Pires. Dept. Ciências Fisiológicas, CBM, UFES, Vítória, ES 29040, Brazil.

Pressor responses induced by stimulation of nucleus raphe obscurus (NRO) are dependent on the functional integrity of the rostral ventrolateral medulla (RVLM; Campos Jr. et al., Braz. J. Med. Biol. Res. 26: 623-631, 1993). The present experiments were designed to investigate the participation of 5-HT receptors in this pathway. Adult male rats anesthetized with urethane (1.2 g kg $^{-1}$, iv) after ether induction were instrumented for BP, HR, respiratory movements and renal nerve activity (RN) recordings. Stainless steel electrodes were positioned within NRO for stimulation (100 Hz, 1 ms, 40-70 µA for 10 s). Test drugs or artificial CSF were microinjected bilaterally in the RVLM by means of microcannulas introduced through the dorsal surface of the medulla. Stimulation of NRO induced hypertension, bradycardia, sympathetic excitation and apnea. Microinjections in the RVLM of the 5-HT₁/5-HT₂ antagonist methiothepin (MT; 200 ng, 200 nl) did not alter basal BP, HR or RN and did not change the responses to NRO stimulation (control Δ BP +42.9 \pm 3.4 mmHg; Δ HR - 113 \pm 45 bpm; after MT Δ BP +43.0 \pm 4.3 mmHg; Δ HR - 128 \pm 33 bpm, n=6). Microinjections in the RVLM of the 5-HT₃ antagonist granisetron (GR; 10 ng, 200 nl) did not alter basal BP, HR or RN and did not change the responses to NRO stimulation(control ΔBP +36 \pm 3 mmHg; ΔHR - 41 \pm 24 bpm; after MT ΔBP +34 \pm 2.6 mmHg; ΔHR - 45 \pm 26 bpm, n=6). Glycine (5 μg , 200 nl) markedly reduced BP and HR responses to NRO stimulation. These results indicate that the pressor responses induced by NRO stimulation, that are dependent on the functional integrity of RVLM, are not mediated by 5-HT1, 5-HT2 and 5-HT3 receptors. The nature of this pathway is presently under investigation Supported by: CNPq, FCAA, FINEP and The British Council

BAROSENSITIVE NEURONS IN ROSTRAL VENTROLATERAL MEDULLA (RVLM) ARE INHIBITED DURING HEMORRHAGE-INDUCED SYMPATHOINHIBITION. A.M. Schreihofer*, D. Huangfu, R.L. Stornetta, P.G. Guyenet. Dept. of Pharmacology, University of Virginia, Charlottesville, VA 22908.

Hemorrhage initially stimulates sympathetic outflow by unloading arterial baroreceptor afferents. However, a further reduction of blood volume produces a vagally-mediated inhibition of most sympathetic nerves (renal. splanchnic, and lumbar, but not adrenal nerve). The present study examined whether this inhibition is correlated with a decrease in activity of RVLM neurons that provide the tonic drive to sympathetic vasomotor nerves. Chloralose-anesthetized rats were hemorrhaged to 50 mmHg (10 ml/kg) through a femoral catheter while AP, splanchnic nerve discharge (SND), and RVLM unit activity were recorded. Hemorrhage initially increased SND (25%, n=10), and then significantly decreased SND (-65% from baseline, p<0.01). The firing of 8 of 10 barosensitive RVLM units (1 unit/rat) mimicked the SND response pattern (baseline firing= 8.8/sec, initial increase of 35%, followed by a decrease of 50% from baseline, p<0.05.) In contrast, in 2 rats, RVLM unit activity progressively increased despite hemorrhage-induced inhibition of SND (SND decreased 76%, RVLM units increased 126%). To determine whether a suppression of central respiratory drive accompanies hemorrhage-induced inhibition of SND, phrenic nerve discharge (PND) was measured. In 4 rats PND was depressed, but in 3 rats PND was stimulated. These results suggest that hemorrhage-induced inhibition of SND may occur via an inhibition of RVLM vasomotor neurons. However, a population of RVLM barosensitive neurons exists that is only excited by hemorrhage. These cells may contribute to the stimulation of adrenal nerve activity during hemorrhage. In addition, although a suppression of central respiratory drive may occur with hemorrhage, it is not required for the production of sympathoinhibition. Supported by NIH R01-HL 28785, NIH training grant 5T32HL07284-19 and NIDA DA-07353.

FUNCTIONAL MAGNETIC RESONANCE IMAGING DURING BLOOD PRESSURE MANIPULATION. R.M. Harper*. R. Bandler, J. Alger, K.H.J. Bockhorst, J. Mintorovitch and D. Spriggs. Depts. of Neurobiology and Radiology, UCLA, Los Angeles, CA 90095; Dept. of Anatomy and Histology, University of Sydney. NSW, 2006.

In man, the brain structures involved in mediation of cardiovascular regulation are not well described. We examined activity changes in brain areas following challenges which altered blood pressure and heart rate by >15%. Magnetic resonance imaging, using echo-planar sequences designed to rapidly assess changes in brain tissue microcirculation, was performed in 6 healthy volunteers (22-52 yrs) using a Siemens 1.5 Tesla scanner (time of relaxation (TR): 3.5 sec; time of excitation (TE): 44.5 msec; slice thickness: 6 mm; flip angle: 90°; field of view (FOV): 31 cm). Twenty slices were collected 18 times under each experimental condition, with a total acquisition time of 60 sec. Images were collected during unilateral hand immersion in cold water, following a cold compress to the forehead, and during intervening baseline conditions. Images were averaged, values from experimental conditions were subtracted from baseline, and pixel-bypixel elements were subjected to t-tests with Bonferroni correction. Significant changes in image signal intensity consistently occurred in the posterior diencephalon, in regions near the bed nucleus of the stria terminalis, and in the ventral medulla. The findings confirm structural roles determined by other means in animal studies, and demonstrate a prominent role for rostral brain structures in mediating cardiovascular challenges. LONG-LASTING EXPRESSION OF FOREIGN GENES IN RAT CORTICAL CULTURES AFTER LIPOSOME-MEDIATED TRANSFECTION. F.A. Boeckman*, R.M. Whelan, K.A. Hartnett and E. Aizenman. Dept. of Neurobiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

Introduction of foreign genes into cultured neurons has previously been achieved by viral infection with high efficiency. The inherent problem with this technique is that viral infection is usually associated with severe cytotoxicity in which cells typically die 6 to 9 days post-infection. Alternatively, cationic lipid-mediated transfection has been useful in transformation of mammalian cell lines with relatively little associated cell death, but with moderate efficiency. Here, we compare the efficiency of three cationic lipid formulations (Lipofectamine, Tfx-50, Tfx-20) to one another in the transfection of rat embryonic (E16) cortical cells in culture. Optimized conditions for the three lipid formulations were developed using a luciferase reporter assay; the Tfx lipids proved to be substantially more effective than Lipofectamine. Transfection efficiency was assessed by counting βgalactosidase positive cells and was found to be 1.5% for neurons (11 DIV) in adherent cultures, as assessed 2 days post-transfection (at 13 DIV). Two weeks following transfection of these cultures, 0.4% of neurons was still positive for β-gal activity (25 DIV). An alternative protocol for transfection in suspension immediately following cell dissociation resulted in at least a two fold increase in transfection efficiencies in neurons. In addition, with this method nearly 1% of neurons were β -gal positive after four weeks in culture (28 DIV). This efficiency was not unique to β-gal as luciferase activity showed a similar pattern of expression The use of this technique with viable markers such as green fluorescent protein may prove useful in the study of the electrophysiological properties of neurons transfected with various genes of interest such as ion channels and receptors. DIFFERENTIAL LOCALIZATION OF DEFECTIVE PARTICLE AND HELPER VIRUS
GENE EXPRESSION FOLLOWING INJECTION OF DEFECTIVE HERPES SIMPLEX
VIRUS (HSV) VECTORS IN THE BRAIN.

J.-O. Hahm'*, K.C. New², R.L. Martuza¹ and S.D. Rabkin¹². Departments of Neurosurgery¹ and Microbiology & Immunology², Georgetown Univ. Med. Ctr., Washington, DC 20007.

Defective HSV vectors are being used for gene delivery in the CNS. A defective HSV vector stock consists of a mixed population of defective particles (containing genes of interest) and helper HSV particles. We have examined the pattern of reporter gene expression, from defective particles and helper virus, after inoculation into discrete regions of the brain.

Defective HSV vectors were generated containing the genes for human placental alkaline phosphatase (AP) or LacZ driven by the CMV $_{\rm E}$ promoter. Helper virus was detected histochemically for expression of β -galactosidase (insertion of the LacZ gene driven by the HSV ICP6 promoter) or immunohistochemically for the HSV immediate-early gene product ICP4. A 1µ1 volume of vector stock was injected over a 10 minute period into either the substantia nigra or somatosensory cortex of adult rats. 2-7 days post-inoculation, animals were sacrificed and their brains processed for detection of β -galactosidase, AP or ICP4.

Preliminary data indicates that lacZ (helper virus) and AP (defective) are expressed in different sites throughout the brain, as well as in overlapping sites. In the nigral injections, helper virus was only detected at the site of injection, whereas defective vector was taken up and retrogradely transported to multiple sites in the thalamus. Supported by a grant from NINDS.

SELECTIVE GENE TRANSFER IN VIVO INTO HIPPOCAMPAL GRANULE CELLS; LOCALIZATION AND SPECIFICITY, P.A. Serrano*, I. Cantallops, R.L. Neve¹ and A. Routtenberg. Cresap Neuroscience Laboratory, Northwestern University Institute for Neuroscience, Evanston, IL 60208; McLean Hospital and Harvard Medical School, Belmont, MA 02178.

The possibility of developmental compensatory mechanisms in null mutants and transgenic mice complicates the interpretation of results derived from this technique. Here we have begun to explore the use of viral vectors for gene transfer as an alternative strategy since it allows for gain of function or gene knockout in adult animals. The HSVmediated gene transfer may also be advantageous if target cell uptake selectivity is achieved. Using electrophysiological guidance we observed selectivity of the mutated herpes virus uptake into a particular cell type in the hippocampus. Under electrophysiological control, the viral vector was injected into the dentate hilus, which is rich in presynaptic terminals, the preferred route of entry of the viral vector. The vector had 1 of 2 cDNA inserts: a lacZ reporter or the neuron-specific protein, F1/GAP-43. With both vectors there was a similar selectivity of uptake into granule cells though terminals of pyramidal and hilar cells are present in this area. We considered two candidate mechanisms for the selective uptake: (1) the viral promoter entered all cells but only granule cells contained the transcription factors necessary for cDNA insert activation; (2) the receptors on presynaptic terminals necessary to allow uptake of this viral strain are only present on mossy fiber axons. Recent evidence indeed indicates that the herpes receptor is part of the TNF/NGF receptor superfamily.

We wished to determine the initial site of infection and subsequent "viral load" borne by

We wished to determine the initial site of infection and subsequent "viral load borne by the granule cells. Using an antibody specific for viral envelope glycoprotein C (gC; gift of P. Spear, NU), immunoreactivity was observed in the granule cell body and dendrites at 3d demonstrating a preferred uptake in granule cells. The presence of gC at 3 days indicates that the infected cells synthesize and transport HSV-1. RECOMBINANT ADENO-ASSOCIATED VIRUS (RAAV) PRODUCES SUSTAINED TRANSDUCTION OF MURINE CNS NEURAL CELLS. W.D. Lo *, R. Chen, G. Qu. T. Sferra, R. Clark, P. Johnson. Dept Pediatrics. Ohio State University. Columbus. OH. rAAV has promise as a viral vector for gene transfer, but most studies have

rAAV has promise as a viral vector for gene transfer, but most studies have shown only transient transduction of CNS cells. We used a rAAV vector that expresses the E. coli lacZ gene under the control of the IE CMV promoter (rAAV/b-gal) to determine the temporal pattern of viral-mediated transgene expression. A CsCl purified rAAV/b-gal viral stock was generated from adenovirus infected D6 "producer" cells (HeLa derived). This cell line contains all AAV helper genetic elements (rep. cap, and rAAV vector sequences) required for rAAV production. The right caudate nucleus of adult BALB/C mice was stereotactically injected with 10⁸ IU rAAV/b-gal (2 µl injection volume) or sterile diluent as a control. Three mice at each time point (5 days, 2, 4, and 8 wk after inoculation) were sacrificed and serial frozen brain sections were analyzed for b-galactosidase activity (X-gal stain). Five random sections containing positive cells were selected from each animal and the total number of positive cells per section was tabulated. Cells/section at 5 days were 76 (S.D. +/- 39), steadily increasing to 339 (S.D. +/- 38) at eight weeks (p = 0.06 by ANOVA, repeated measure).

We have demonstrated persistent (or increasing) transgene expression in CNS cells following rAAV/b-gal inoculation. This finding has implications for long-term gene transfer to cells of the CNS using high titer rAAV vectors. Supported by CHRF, NIAID, and Alkermes

Adenoviral Penton Protein Improves Transfection Efficiency of mRNA and Plasmid DNA in Primary Neuroglial Cells

Langer DJ. Fisher KJ. Malone RW. Hecker JA. Barnathan ES. Welsh FA* Dichter MA, Kariko K. Div. Neurosurgery & Cardiology, Univ. of PA, Phila., PA 19104, Dept. of Med. Pathol. UC Davis, Davis CA 95616

Cationic lipid delivery of RNA and DNA has shown utility both in vitro and in vivo. The mechanism of transfection with these nonviral systems has been shown to involve endosomal uptake, progressive acidification, and lysosomal fusion resulting in nucleic acid degradation and decreased transfection efficiency. In contrast, adenovirus transfection efficiency is thought to be higher, due at least in part to promotion of endosomal lysis enabling escape from lysosomal degradation. We hypothesized that the adenoviral penton protein itself might similarly enhance cationic lipid-mediated RNA or DNA transfection. Primary neonatal rat hippocampal neuroglial cells and NIH 3T3 cells were transfected with either firefly luciferase mRNA or DNA in the presence or absence of purified penton protein and Lipofectin. Control transfection resulted in a ~100 fold increase in luciferase activity over background. Penton protein addition resulted in a dose dependent, further 3-4 fold increase of luciferase level in both cell types whereas a control protein had no such effect. Similar stimulation was observed with DNA plasmid transfection as well. Addition of chloroquine, which blocks lysosomal degradation, did not block the stimulation, suggesting a potentially novel mechanism of action for penton. Penton-mediated delivery is a promising approach for gene transfer in neural cells.

Supported in part by NINDS Grant NS-29331

TARGETED MRNA DISPLAY AND RT-PCR APPROACH TO IDENTIFY GENES INVOLVED IN ISCHEMIC BRAIN TISSUE INJURY AND

REGENERATION. <u>U. Utans. H.P. Lorez. J. Sepinwall* and W. Lesslauer</u>. F. Hoffmann-LaRoche Ltd, Basel; Hoffmann-LaRoche, Inc., Nutley, NJ To identify novel genes potentially active in brain ischemic tissue injury and regeneration, a mRNA display screen was established using bised reiner designs treating and original resultation. All rich using biased primer designs targeting non-coding regulatory AU-rich elements common to a number of genes known to be active in tissue stress, injury and repair, and host defense mechanisms. The screen strategy was validated in a permanent MCAO rat stroke model; of 26 display bands analysed, 7 known genes were identified, 5 of which belonged to the targeted class of genes (eg. IL-1, VEGF, c-fos). In addition, several sequences were identified which were not found in data base searches and therefore might represent candidate genes of interest in the ischemic disease context. The identification of proinflammatory mediator expression in and around the ischemic itssue points to a neuroinflammatory reaction which may propagate and aggravate pathology. Therefore the time-sequential expression of other mediator and related genes was analysed in a semiquantitative RT-PCR study comparing infarct core, border zone and contralateral cortical tissue. Early and persistent induction of TNFa, IL-1b and IL-6 mRNA was found in core (1h to 2 weeks) and border zones (1 - 24 h). In contrast, TGFb1 transcripts were increased only at late times (24 h - 2 weeks) in the core, but not in border or contralateral zones. Elevated transcript levels of iNOS were identified in infarct core, but only a moderate increase at early time points was seen in the border zone (1 - 24 h). Differentially spliced isoforms of amyloid precursor protein (APP) were detected late and exclusively in the core.

THE YEAST SPLIT-HYBRID SYSTEM: IDENTIFYING FACTORS THAT DISRUPT PROTEIN: PROTEIN INTERACTIONS. P.S. Goldman 1, H.M. Shih 1, A.J. DeMaggio², M.F. Hoekstra², and R.H. Goodman¹*. Vollum Institute¹, Oregon Health Sciences University, Portland OR 97201 and ICOS Corp., Bothell WA 98021.

Health Sciences University, Portland OR 97201 and ICOS Corp., Bothell WA 98021. We have developed a variation of the yeast two-hybrid system that allows the identification of factors which disrupt the association of two interacting proteins. The "split-hybrid" system can also be used to screen for mutations which block specific associations. This yeast system turns the disruption of a protein:protein interaction into a positive selection by using the *E. coli* tet-repressor (TeR). We have engineered LexA binding sites upstream of the TetR gene, and have placed TetR binding sites (tet operators) upstream of a reporter gene, HIS3. Interaction of one protein fused to the LexA DNA binding domain with a second protein fused to the VP16 activation domain results in the expression of TetR, which binds to the tet operators, shutting off expression of HIS3 and consequently preventing yeast growth in media lacking histidine. As with the conventional yeast two-hybrid system, this method allows large numbers of clones to be screened rapidly and easily. In addition, the interaction of TetR with tet operators is a very high affinity, specific reaction, which can be abolished by tetracycline (Tc). Addition of Te is useful when the protein fused to the LexA DNA binding domain has intrinsic activating capability. Likewise, the drug 3 LexA DNA binding domain has intrinsic activating capability. Likewise, the drug 3-aminotriazole, a competitive inhibitor of the histidine pathway, can be used when the interaction of two proteins is relatively weak and unable to produce enough TetR to block histidine production fully. We have demonstrated that the interaction of CREB and its binding protein CBP are able to prevent the growth of yeast in the split-hybrid system. We have also shown that expression of CBP and a CREB mutant (CREB-Mt; Ser133Ala), which is unable to bind CBP, does not produce TetR, and allows the yeast to grow in the absence of histidine. This system should be useful for identifying proteins, peptides, and or drugs which disrupt the CREB:CBP interaction and perhaps interactions of other pairs of proteins as well. Support has been provided by NiH R01DK50014 and F32DK09396.

RAPID GENERATION OF STABLE CELL LINES FOR DRUG

R. A. Horlick, K. Sperle, L. A. Breth, E. S. Shen, C. M. Reid, G. M. Cooke, S. G. Culp* and B. L. Largent. Applied Biotechnology and CNS Departments, The DuPont Merck Pharmaceutical Co., Wilmington, DE 19880.

A human 293 cell line that stably expresses the Epstein Barr nuclear antigen I (EBNA1) supports the episomal replication of plasmids containing the Epstein Barr virus origin of replication (EBV ori). A 293EBNA (293E) cell line expressing the human conticotrophin releasing hormone receptor subtype I (CRHRI) from an episomal plasmid was generated (293CR1s), analyzed, adapted to spinner culture and scaled-up for production in less than six weeks. Fifty stable CHO cell lines transfected with CRHR1 were also isolated. Expression of the receptor in the best of these lines, CHO-R22, was compared to 293CR1s. Results indicate that use of episomal vectors in 293E cells (1) rapidly generates stable cell lines episomia vectors in 2332 cens (1) rapidly generates stable cent lines suitable for scale-up; (2) these lines retain a stable copy number of episomes, (3) express highly abundant levels of CRHR1 mRNA and (4) produce a steady level of CRHR1 even after 4 months in culture. The 293CR1s line expresses significantly more CRHR1 than the CHO-R22 line that was prepared using traditional methods. Our data support the idea that using the EBV ort-driven episomal system for gene expression results in greater production of protein in a comparatively very short period of time.

ANTISENSE TARGETING OF OXYTOCINERGIC HYPOTHALAMUS NEURONS INDUCES CYTOPLASMIC TRIPLE HELIX- LIKE IMMUNOREACTIVIY. <u>Jirikowski G.F.*¹. Prüfer</u> K.1, and J.S. Lee2. Dept. of Anatomy II, Friedrich Schiller Universität Jena, Germany and 2Dept. of Biochemistry, University of Saskatchewan, Saskatoon, Canada

Intracerebroventricular injections into intact rats with oligonucleotide probes complementary to oxytocin encoding transcripts resulted in a decrease of systemic and central oxytocin levels. Immunoreactive peptide and oxytocinergic hybridization signal in the magnocellular hypothalamic perikarya was reduced while signal for oxytocin within the neurohypophysial projections remained unaffected. Immunocytochemistry with a monoclonal antibody to triple helix resulted in an accumulation of cytoplasmic reaction product in many of the magnocellular oxytocin immunoreactive neurons. A fraction of the hypothalamo neurohypophysial processes and Herring bodies in the posterior lobe of the pituitary contained also specific triple helix immunostaining. Animals treated with the respective sense probe were devoid of cytoplasmic or axonal triple helix immunoreactivity. Immunostaining in antisense treated samples could be abolished by pretreatment of sections with RNase H. Our findings indicate that oxytocinergic transcripts form triple helix like aggregates upon specific antisense targeting rather than being degraded by endogenous RNases. Complexation of mRNA may in part be responsible for the onset of de novo transcription, thus accounting for the observed increased levels of oxytocinergic hybridization product. Cytoplasmic and axonal RNA complexes may be untranslatable and in addition may interact with peptide secretion from neurohypophysial nerve terminals. It is likely that further effects observed upon antisense treatment like protooncogene- or cytokine expression are also linked to these mechanisms

ENKEPHALIN-ENCODING SEQUENCES REPRESENT TARGETS FOR SPECIFIC DNA-BINDING FACTORS. G. Bakalkin*, T. Yakovleva, M. Telkov and L. Terenius. Department of Clinical Neuroscience, Karolinska Institute, S-17176 Stockholm, Sweden

The DNA targets for a variety of sequence-specific DNA-binding factors are generally located in the enhancer/promoter regions of different genes, at matrix associated regions, origins of replication *etc.* We here report that short, conserved and repetitive sequences encoding the Leu- or Met-enkephalin fragments in the opioid encoding the Lett- of Met-enkephalin fragments in the opioid prohormone genes represent the targets for specific DNA binding factors, LEF and MEFs, respectively. Whereas LEF demonstrated high affinity and specificity for the Leutenkephalin-encoding sequences (PNAS 92, 9024-9028, 1995), MEF1 and MEF2 are targeted either to the 3'-terminal Met-enkephalin-encoding sequence in the proenkephalin gene or to the Met-enkephalin/β-endorphin encoding fragment in the POMC gene, respectively. All factors are located in the cell purchase. The expression of the factors is tissue. located in the cell nucleus. The expression of the factors is tissue-specific and developmentally regulated. LEF inhibited the transcription of reporter genes through the binding to the Leuencoding fragment inserted between the transcription initiation site and coding region of the reporters. LEF, a 67 kDa protein was purified to apparent homogeneity and biochemically characterized. These observations suggest that the enkephalin-encoding sequences in the opioid prohormone genes also have regulatory functions realized through interaction with the specific DNA-binding factors.

DIFFERENTIAL GENE REGULATION BY DISTINCT PATTERNS OF ELECTRICAL ACTIVITY, A. Buonanno*, J. Stauffer, S. Calvo, J. Cheng and M. Nakayama, UMB, LDN, NICHD, NIH, Bethesda, MD 20892-4480.

Eccles and colleagues elegantly demonstrated in the 1960's that the contractile properties of skeletal muscle are plastic, and are regulated by the specific type of innervation and activity the muscle receives. We have analyzed the transcriptional regulation of the troponin I slow (TnIs) and fast (TnIf) genes by activity, as a model to identify the factors that control activity-dependent plasticity. We found that innervation. and depolarization of denervated skeletal muscle with specific frequencies that mimic endogenous motoneuron activity (10 Hz or 100 Hz), differentially regulated either the TnIs or the TnIf gene, respectively. Successive deletions of TnI promoter sequences were analyzed in transgenic mice and cultured myocytes to identify the cis- and trans-acting factors regulating TnI transcription in either slow- or fast-twitch muscles. A 128 bp slow enhancer was identified that, when linked to the -0.5 kb TnIs promoter, specifically confers transcription to slow-twitch muscles. Sequences directing fast-specific transcription were identified in transgenic mice harboring a construct containing the TnI slow -0.5 kb promoter fused to a 144 bp fast enhancer derived from the quail TnIf gene. Mice harboring this TnIf/TnIs chimera CAT construct expressed the reporter gene in fast but not in slow muscles. These results indicate that the 2 enhancers (128 and 144 bp) are sufficient to confer fiber-type-specific transcription. Sequence alignment of the rat TnIs and the quail TnIf enhancers indicates that there is a conserved spatial organization of cis-acting elements, namely an E box, a CCAC box, a homeotic-like A/T-rich sequence (homologous to a MEF-2 site), and a previously uncharacterized motif we denoted the CAGG box. These core elements were shown to bind their cognate regulatory factors using electrophoretic mobility shift assays. Mutations of the cis-elements demonstrated that these sites are necessary for muscle-type specific expression in transgenic mice. Our results suggest that the interaction of closely related transcriptional protein-DNA complexes are utilized to restrict TnI expression to specific fiber-types in response to specific depolarization frequencies

MICE LACKING MAOB SHOW MARKED INCREASES IN β-PHENYLETHYLAMINE AND ANTIDEPRESSANT LIKE RESPONSES IN THE PORSOLT'S FORCED SWIM TEST. J. Grimsby', M. Toth', F.F. Karoum', L. Klaidman', J.D. Adams', K. Chen' and J.C. Shih*¹. 'Dept Molec Pharmacol. & Toxicol, Sch Pharmacy, USC, Los Angeles, CA 90033, 'Dept Pharmacol, Cornell Univ Med Col, New York, NY 10021, 'Dept Psychol & Pharmacol, NIMH, St Elizabeth's Hosp, Washington, DC 20032. Monoamine oxidase (MAO) A and B are isoenzymes that play is the property of the property of the property of the property of the property of the property of the property of the players. To examine the in-

Monoamine oxidase (MAO) A and B are isoenzymes that play important roles in regulating biogenic amine levels. To examine the *in vivo* function of MAOB, we have specifically inactivated MAOB expression by targeted disruption of the mouse MAOB gene. In contrast to MAOA deficient mice, no changes in brain concentrations of serotonin, norepinephrine, dopamine and their metabolites were observed in MAOB knockout (KO) mice. Interestingly, MAOB deficient mice showed a 10-fold increase in urinary excretion of β-phenylethylamine (PEA) compared to wild-type mice. Mutant animals were less immobile in the Porsolt's forced swim test, suggesting that MAOB activity can mediate moods by regulating PEA levels. These results demonstrate that MAOA and MAOB degrade different biogenic amines and their deficieny results in stikingly different behaviors in mice. The MAOB KO mice will provide a valuable animal model for studying the molecular mechanism of antidepressants. ANALYSIS OF THE FUNCTION OF NEURONAL INTERMEDIATE FILAMENTS IN MAMMALIAN EMBRYOS BY TARGETING MOUSE PRIPHERIN GENE. M.Simonneau¹. M.Santha². J. Zakana³. A Zvara². T Kalmar². C. Mas¹ and I. Rasko². Neurologie du Développement & INSERM U120, Höpital Robert Debré, 75019 Paris, France. ² Institute of Genetics. Biological Research Center, H-6701 Szeged, Hungary. ³ Department of Zoology and Animal Biology, University of Geneva, Switzerland.

Peripherin is a neuron-specific type III intermediate filament protein expressed in well-defined populations of neurons projecting towards peripheral targets. Its biological function can be approached by generating null mutant mouse carrying a disrupted peripherin gene.

We first constructed a targeting vector containing the bacterial neomycin resistance and *lacZ* genes between two homologous regions of the peripherin gene (5.8 and 1.1 kb). Analysis of transgenic mouse lines expressing this construct showed that these upstream and intragenic sequences contains all regulatory elements essential for both spatial and temporal expression of the mouse peripherin gene during embryogenesis (Leconte *et al.*, Dev. Brain Res., 1996). The replacement targeting vector contains the diphteria toxin (DT-A) gene added at the 3'end of the vector. This replacement vector was introduced into either D3 or R1 embryonic stem (ES) cells, by electroporation. With D3 ES cells, 4 homologous recombinant clones out of 96 neo resistant colonies were obtained, indicating the high efficiency of DT-A gene as a negative selection marker. We did not get chimeric animals using aggregation of these clones with eight-cell stage embryos. With R1 embryonic cells, we obtained a high degree of chimerism and germ line transmission. Null mutant mice for the peripherin gene are under investigation. Supported by ARC, DRET n° 93-137, AFM, Fondation de France and Phare Accord 0157.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION II

POSSIBLE ROLE OF THE GLT-I GLUTAMATE TRANSPORTER IN REGULATING POA AND MBH GLUTAMATE LEVELS DURING THE PREOVULATORY LH SURGE. R. Unda, V. B. Mahesh*, and D. W. Brann. Dept. of Physiology and Endocrinology, Medical College of Georgia, Augusta, GA

Glutamate is the dominant excitatory neurotransmitter in the mammalian brain implicated in facilitating the LH surge. Previous work in our laboratory has demonstrated that progesterone suppression of glutamic acid decarboxylase (GAD), the enzyme that converts glutamate to GABA, appears to be a mechanism for increasing glutamate levels in the hypothalamus during the LH surge. In addition to GAD, GLT-1, EAAC1, GLAST, and EAAT are several glutamate transporters which are expressed in the hypothalamus and function to remove glutamate from the synaptic cleft. After standardizing the hybridization conditions with northern blots, dot blot studies revealed that the mRNA for the glial type glutamate transporter (GLT-1) was significantly reduced in the POA of the adult cycling animal during proestrus at 1200, 1400, 1600, and 1800 hrs. when compared to 1200 h metestrus. This reduction was attenuated by RU486 at 1200, 1400, and 1800 hrs. and abolished at 1600 h. Conversely, in the MBH GLT-1 mRNA levels showed dramatic increases at 1400 h and 1600 h in proestrus animals. The increase in GLT-1 mRNA levels during proestrus was prevented by the administration of RU486. Corresponding Western Blot analysis demonstrated that GLT-1 protein levels were also significantly reduced in the MBH by the administration of RU486 during proestrus at 1400 h and 1800 h. studies indicate that in addition to changing the activity of GAD, progesterone regulation of GLT-1 transporters levels may also play an important role in regulating glutamate levels in the POA and MBH during the preovulatory gonadotropin surge. Supported by Grant R29HD28964.

FSH-RELEASING FACTOR(S) ARE PRESENT IN THE HYPOPHYSEAL PORTAL CIRCULATION OF THE EWE. 1.S. Lee, F.J. Karsch, R.C. Thompson, P.C. Andrews, V. Padmanabhan*. Depts of Biological Chemistry. Pediatrics, Physiology, and the Reproductive Sciences Program, University of Michigan. Ann Arbor, MI 48109-0404. By exploiting the hypophyseal portal collection technique to characterize the secretory patterns of FSH close to the release site in sheep, we have shown that: 1) FSH secretion is episodic; 2) each GnRH pulse is associated with an FSH pulse; and 3) non-GnRH-associated pulses of FSH exist in both ovariectomized and luteal phase ewes. Further, injection of

By exploiting the hypophyseal portal collection technique to characterize the secretory patterns of FSH close to the release site in sheep, we have shown that: 1) FSH secretion is episodic; 2) each GnRH pulse is associated with an FSH pulse; and 3) non-GnRH-associated pulses of FSH exist in both ovariectomized and luteal phase ewes. Further, injection of the GnRH antagonist, Nal-Glu, completely abolishes LH pulsatility and GnRH-associated FSH pulses but fails to block FSH pulses not associated with GnRH pulses (Soc. Neurosci.: 20, Part 2:1058, 1994; Soc. Study Fertil., Abstr. Ser. #15:41, 1995). This suggests the non-GnRH-associated pulses of FSH are truly GnRH-independent. To test the hypothesis that hypophyseal portal blood contains factor(s) capable of releasing FSH, we validated an ovine pituitary cell bioassay sufficiently sensitive to detect FSH-releasing activity in hypophyseal portal blood. The assay involves culturing ovine pituitary cells in the presence of Nal-Glu to block GnRH action. Hypophyseal portal plasma stimulated FSH but not LH during the 4h bioassay period. Adding activitin, a potent but slow stimulator of FSH, neither elicited FSH release nor increased the threshold of FSH sensitivity to GnRH, within the time frame of the bioassay. Thus, the FSH-releasing activity in the hypophyseal portal blood is also independent of activin. Preliminary characterization studies suggest the FSH releasing activity in portal plasma is heat labile, not extractable into organic solvents, and unable to pass through membranes with molecular weight cut-offs of 10,000 or 30,000. Overall these studies suggest that hypophyseal portal blood contains FSH-RF(s) other than GnRH. Supported by NIH grants US4 29184 and P30 HD 18258.

IS AN INCREASE OF NITRIC OXIDE EFFLUX IN THE MEDIAL PREOPTIC AREA COUPLED TO THE PREOVULATORY GnRH SURGE? Put P.S. Kalra and S.P. Kalra, Depts. of Neuroscience and Physiology,

Univ. Fla. Col. Med., Gainesville, FL 32610

The medial preoptic area (MPOA) contains abundant nitric oxide (NO) synthase-positive neurons which lie in close proximity to GnRH neurons. Pharmacological studies from our laboratory demonstrated that NO is involved in both the preovulatory and the ovarian steroid-induced LH surge. We recently reported that measurement of extracellular cGMP levels by microdialysis in the MPOA is a reliable index of NO efflux. Therefore, microdialysis was performed in freely-moving rats to test the hypothesis that the MPOA NO efflux may increase in association with the LH surge. A guide cannula was implanted in the MPOA of cycling and long-term ovx rats between 1700-1800 h. On the next day, a CMA/12 probe was inserted and perfused at a flow rate of 5 µl/min with aCSF. The cGMP content was determined by RIA in dialysates collected at 20 min intervals between 1100-1800 h. Intriguingly, a significant afternoon increase of cGMP levels (p < 0.05) with a similar profile was evident not only on proestrus, but also on diestrus II and in ovx rats. While the onset of cGMP increase occurred at slightly different times, peak cGMP values (about 400% of basal) did not different statistically among groups. This afternoon increase was absent in pentobarbital anesthetized proestrous rats. An increase of cGMP efflux was also observed in estrogen-primed ovx rats in association with the LH surge, and this increase was augmented by progesterone. Cumulatively, these results show that there is an ovarian steroid-independent diurnal increase of the MPOA NO efflux which may trigger the GnRH surge only when the neural circuitry responsible for the genesis of this surge is appropriately primed with estrogen and progesterone. (Supported by NIH grant HD08634)

INTRACELLULAR Ca²⁺ OSCILLATIONS IN CULTURED LHRH NEURONS DERIVED FROM EMBRYONIC OLFACTORY PLACODE OF THE RHESUS MONKEY. W. K. Schanhofer and E. Terasawa* Wisconsin Regional Primate Res. Ctr. & Neurosci. Training Prog., Univ. of Wisconsin, Madison, WI 53715 Previously, we have reported that cultured LHRH neurons derived from the olfactory placode of monkey embryos release LHRH in a pulsatile manner, and that the presence of extracellular Ca²⁺ is necessary for LHRH pulsatility. To study the mechanism of LHRH pulse generation, we have examined whether cultured LHRH neurons exhibit intracellular Ca²⁺ [Ca²⁺] oscillations. The olfactory placode and the migratory pathway of LHRH neurons from monkey embryos at E35-37 were dissected out and cultured on glass coverslips in a growth medium. Two to five weeks later cultured cells were labeled with the calcium dwe fura-2 and examined for [Ca²⁺] is oscillations. [Ca²⁺]; changes were growth medium. Two to five weeks later cultured cells were labeled with the calcium dye fura-2 and examined for $[Ca^2+]_i$ oscillations. $[Ca^2+]_i$ changes were recorded every 10 sec for 30 to 100 min using a video imaging system. After recording, cells were fixed and immunostained for LHRH. Three types of cells were observed based on $[Ca^2+]_i$ activity: Type1 cells exhibited periodic $[Ca^2+]_i$ oscillations; Type 2 cells showed irregular $[Ca^2+]_i$ elevations; Type 3 cells showed no $[Ca^2+]_i$ folia. In 11 cultures 168 Type 1 cells (5-39 cells/culture) were recorded. $[Ca^2+]_i$ oscillations of Type 1 cells occurred with an interpulse interval (IPI) of 3.6-17.7 min (9.9±0.5, Mean±SE, n=168) and a pulse duration of 25.14 $[Ca^2+]_i$ and durations within a single cell were very interval (IPI) of 3.6-17.7 min (9.9±0.5, Mean±SE, n=168) and a pulse duration of 25-145 sec (87±3). IPIs and durations within a single cell were very consistent. Age of cultures was not related to the presence or periodicity of oscillations. Type 1 cells appeared to be LHRH neurons, while Type 2 and 3 cells appeared to be non-LHRH cells: Type 1 cells had long neurites and were found along long fiber bundles associated with the placode, which is characteristic of migratory LHRH neurons, while Type 2 and 3 cells lacked these characteristics. All cultures with Type 1 cells contained immunopositive LHRH neurons. These results indicate that LHRH neurons derived from embryonic olfactory placode exhibit spontaneous [Ca²+j] oscillations. Whether [Ca²+j] oscillations are related to pulsatile LHRH release remains to be determined. (Supported by NIH grants: HD15433, HD11355 & RR00167).

PROGESTERONE RECEPTOR ANTISENSE OLIGONUCLEOTIDES BLOCK LH SURGES IN OVARIECTOMIZED, ESTROGEN-PRIMED RATS. <u>P.E. Chappell and J.E. Levine</u>*. Dept. of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208.

Release of preovulatory LHRH and LH surges occurs subsequent to estroge (E_2) actions in brain and pituitary, and stimulation via a daily neural signal. We have proposed that integration of E_2 feedback and neural signals mediating surge initiation occurs through ligand-independent activation of E_2 -induced progesterone receptors (PRs). To further test this hypothesis, we assessed whether blockade of hypothalamic PR expression attenuates or blocks the surges in E₂-primed animals. Female rats were ovariectomized (OVX) and surges in E₂-primed animais. Permate rats were ovariectomized (UVX) and implanted stereotaxically with 22 ga. icv cannulae (anterior IIIrd ventricle). After 7d, rats received 30µg estradiol benzoate at 0900hrs to induce an LH surge on the following day. At 1800 hrs, rats were infused, via icv cannulae, with 1µl of 4nm PR antisense, missense, or sense oligos. A repeat infusion was administered at 0600 hrs the following day. Hourly atrial blood samples were taken from 1200hrs-2200hrs. In additional experiments, infusions were conducted similarly in intact proestrus females. RIA revealed that LH surges in rats receiving PR antisense oligos were completely blocked. By contrast, most rats receiving PR missense and sense oligos exhibited LH surges that were 6- to 8-fold higher. These data demonstrate that the LH surge in rats is dependent upon hypothalamic PR expression, even in the absence of ovarian P secretion. Our observations are consistent with previous findings using PR antagonists, and directly support the hypothesis that neuroendocrine integrative mechanisms leading to LHRH surges involve P-independent PR activation by neural signals. 379.4

EFFECT OF L-ARGININE ON NEUROPEPTIDE Y RELEASE IN VIVO IN THE FEMALE RHESUS MONKEY. C.L. Nyberg. W. Saltzman* and E. Terasawa. Wisconsin Regional Primate Res. Ctr., Univ. of Wisconsin, Terasawa. Wiscon Madison, WI 53715

The mechanism regulating pulsatile LHRH release is not fully understood. In previous studies we have shown that in the rhesus monkey pulsatile LHRH release in the stalk-median eminence (S-ME) is modulated by neuropeptide Y (NPY): NPY pulses occur simultaneously with or preceding LHRH pulses, and immunoneutralization of endogenous NPY suppresses LHRH pulses, while infusion of NPY stimulates LHRH release. Since nitric oxide (NO), in the form infusion of NPY stimulates LHRH release. Since nitric oxide (NO), in the form of L-arginine (L-arg), stimulates LHRH release, NO-induced LHRH release may be mediated by NPY neurons. In this study we examined the effects of L-arg on NPY release from prepubertal (15.50±1.66 months of age, n=4) and pubertal (38.38±1.35 months of age, n=8) female rhesus monkeys using pushpull perfusion. Perfusates were continuously collected in 10-min fractions for 14 h, and L-arg at 0.1 nM, 10 nM and 1µM was directly infused into the S-ME for 10 min at 90-min intervals. NPY and LHRH in aliquots of the same perfusates were measured by RIAs. L-arg induced significant increases in both NPY release (p<0.05 for all doses) and LHRH release (p<0.05 for all doses). Both NPY and LHRH peaks occurred at 10 min after L-arg infusions in prepulsatia and pubertal monkeys. Infusion of D-arg at all conceptifations in prepubertal and pubertal monkeys. Infusion of D-arg at all concentrations or of vehicle failed to induce any significant responses in NPY or LHRH in either group of monkeys. These results indicate that NO does stimulate both NPY release and LHRH release in the non-human primate, and that NO-induced LHRH release may be mediated by NPY. However, it is also possible that NO may be a common stimulator of NPY and LHRH pulses. The results further suggest that NO is not critical for the mechanism triggering the onset of puberty, since L-arg increased the release of NPY and LHRH similarly in prepubertal and pubertal monkeys. (Supported by NIH grants HD11355, HD15433 & RR00167).

379.6

THE MEDIAN EMINENCE: A POTENTIAL SITE FOR DEVELOPMENTAL MODULATION OF PULSATILE GNRH RELEASE IN THE RHESUS MONKEY A. R. Durrant and T. M. Plant*. Dept. of Cell Biology and Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Puberty in primates is triggered by reamplification of a pulsatile discharge of gonadotropin-releasing hormone (GnRH), a hypothalamic peptide that is secreted into the hypophysial portal circulation and drives the pituitary-gonadal axis. Although the mechanisms underlying this developmental event are poorly understood, previous studies in the monkey indicate that PSA-NCAM is expressed in hypothalamic areas containing GnRH neurons and that the pubertal amplification of pulsatile GnRH release is correlated with synaptic plasticity at the level of the GnRH perikaryon. The present study extended these observations by examining ultrastructure within the GnRH neuronal network at the level of the median eminence (ME): the convergence point where neuroendocrine GnRH neurons terminate and synchronously secrete intermittent pulses of their peptide into the portal vasculature. Specifically, we used immunohistochemistry and electron microscopy to examine whether afferent neuronal processes impinge on GnRH end boutons. Two adult ME were serially sectioned, and the GnRH end boutons were identified by post-immunogold-labeling with a GnRH-specific antibody (LR1). Electron micrographs revealed that GnRH end boutons contain small, clear synaptic and large dense core vesicles; GnRH was exclusively localized in the large dense core vesicles. As previously recognized in other species, GnRH end boutons were in direct apposition with neurophenotypic and astrocytic processes. These data suggest the possibility that cotransmission and multiple signals at the level of the GnRH end bouton may developmentally modulate the pulsatile secretion of GnRH into the hypophysial portal vasculature. (Supported by HD13254 & HD08160.)

CO-LOCALIZATION OF PROGESTERONE RECEPTORS WITH ENKEPHALIN mRNA IN THE MEDIOBASAL HYPOTHALAMUS: IMPLICATIONS FOR PHENOTYPIC CHANGE DURING HYPERPROLACTINEMIA. R. A. Baker* and G. E. Hoffman. Dept. of Neurobiology and Center for Research in Reproductive Physiology, University of Pittsburgh School of Medicine, Pittsburgh, PA, 15261

Physiologically elevated levels of prolactin (PRL), as occur during lactation or experimentally induced hyperprolactinemia, result in induction of enkephalin (ENK) mRNA in tuberoinfundibular dopamine (TIDA) neurons in the dorsomedial division of the hypothalamic arcuate nucleus (Arc). Recent evidence suggests that for a maximal effect of elevated PRL, progesterone must also be present. If so, one must also postulate that TIDA neurons that express ENK during hyperprolactinemia have progesterone receptors. Thus, we investigated the extent of co-localization of progesterone receptors (PRs) with ENK mRNA in the Arc using a combination of immunocytochemistry and non-radioactive in situ hybridization histochemistry. In intact female rats rendered hyperprolactinemic by pituitary implant under the kidney capsule, nearly all PR positive neurons in the dorsomedial Arc contained ENK mRNA. These same neurons also contained TH immunoreactivity. In contrast, ovariectomized estrogen-treated (OVX + E) rats had little or no ENK mRNA in the dorsomedial Arc, although PR-ir neurons there were prominent. In another hypothalamic area, the ventromedial nucleus, nearly all PR-containing neurons co-localized ENK mRNA, in both OVX + E rats and hyperprolactinemic rats. The data demonstrate that the TIDA neurons of the dorsomedial Arc that express ENK also contain PR, thus providing a morphological substrate for contribution of PR in the induction of ENK mRNA under conditions of high prolactin. Supported by NS 28730 and HD 07332.

PLASTIC CHANGES IN LHRH TERMINALS, GLIA AND PORTAL CAPILLARIES OF THE MEDIAN EMINENCE AS A FUNCTION OF OVARIECTOMY. J.C. King*, P.M. Ronsheim and B.S. Rubin Dept. of Anatomy and Cellular Biology, Tufts University School of Medicine, Boston, MA 02111

We have been investigating the median eminence (ME) of adult rats as a site of local regulation of LHRH secretion, leading to the LH preovulatory surge and ovulation. Previously, we delineated plastic changes in the relationship of LHRH terminals to portal capillaries on the day of proestrus, using confocal microscopy and immunocytochemistry. Primarily, the LHRH terminals of proestrous females were free of glial obstruction, i.e.the end-feet of tanycytes, which intruded between LHRH terminals and portal capillaries of females sacrificed on estrus or diestrus. In this study, we examined these relationships following ovariectomy. Tanycytic end-feet were interposed between LHRH terminals and portal capillaries in ovariectomized animals, potentially reducing the quantity of LHRH reaching the portal capillaries. In contrast, loops of portal capillaries originating from the primary plexus were as extensive in their invagination into the ME of ovariectomized animals, as in intact proestrous rats. These extensive capillaries provide expanded sites for secretion of LHRH and may counterbalance the glial barrier to the portal capillaries. The factors that generate or maintain these capillary loops in ovariectomized animals are currently undefined, but clearly are not dependent on ovarian steroids. Finally, a reduction in LHRH is indicated by the loss of LHRH processes and terminals from specific regions of the ME and the smaller size of variocosities and terminals. This loss may result from the uninterrupted secretion of LHRH in ovariectomized rats, despite continual synthesis, as suggested by our earlier electron microscopic studies NSF IBN-9310267 (J.C.K), HD 19174 (B.S.R).

CHANGES IN GONADOTROPIN RELEASING HORMONE RECEPTOR (GRRH-R) mRNA CONTENT OF THE RAT MEDIOBASAL HYPOTHALAMUS DURING THE ESTROGEN-PROGESTERONE-INDUCED LH SURGE. L. Jennes* and A. Centers. Dept. Anatomy & Neurobiol., Univ. Kentucky, Coll. Medicine, Lexington, KY 40536.

GnRH-R mRNA content in the mediobasal hypothalamus has been shown to change significantly during the course of a 4 day estrous cycle with highest levels during early morning of proestrus and lowest levels during the afternoon of proestrus. The present study was designed to characterize in detail with in situ hybridization the changes in GnRH-R content in the arcuate and ventromedial nuclei at 2 hour intervals beginning at 0800 and ending at 2200 hours and to correlate GnRH-R expression with circulating LH levels. The results show that in the arcuate nucleus GnRH-R mRNA levels peak between 0800 and 1000 hours before they decline rapidly by about 50% at 1200 hours. They remain low until 1600 hours before they begin to rise by 1800 hours and peak again at 2000 hours which is followed by a steep decline at 2200. GnRH-R mRNA content in the ventromedial nucleus parallels the changes in the arcuate nucleus for all time points except for the evening rise which was significantly smaller. Plasma LH levels begin to rise at 1600 hours and peak at 1800 hours. The results indicate that GnRH-R synthesis in the mediobasal hypothalamus is stimulated in the early morning, probably as a result of positive estradiol feedback in preparation of the GnRH-mediated LH surge as well as after the surge, probably as a result of homologous upregulation. Supported by NIH HD 24697.

SECRETION OF LUTEINIZING HORMONE-RELEASING HORMONE BY ENZYMATICALLY DISPERSED RAT HYPOTHALAMIC CELLS IN A PERIFUSION CELL CULTURE IS PULSATILE. M.J. Woller*, E. Nichols, B. Hackett, K.H. Hoeft, T. Herdendorf, M. Jarzynski, Biological Sciences, University of Wisconsin-Whitewater, Whitewater, WI 53190.

Hypothalamic release of luteinizing hormone-releasing hormone (LHRH) has been demonstrated to be pulsatile in a variety of species and model systems. After a considerable effort by many research groups, the driving force behind the generation of pulsatile LHRH release remains highly disputed. To address the question of how LHRH neurons coordinate their secretory events to elicit pulsatile release, we used cell perifusion of primary cultured enzymatically dispersed rat hypothalami. Each chamber contained cells derived from 1/2 of a hypothalamus. Perifusion media flowed past the cells at 1ml/10min and was collected at 10min intervals for 8-10hrs. Samples were frozen at -70C until measurement of LHRH by radioimmunoassay. We measured LHRH release from cells derived from 8 rats; 5 secreted LHRH at levels measurable in 50µl aliquots of media. PULSAR analysis of the assay results from these 5 cell preps revealed 41 pulses in a total of 45 hours of sampling, a pulse frequency of 0.91 pulses/hr. Mean pulse amplitude for the cell preps ranged from 1.28 to 3.5pg/ml, with an overall mean of 2.25pg/ml. These results demonstrate clear pulsatile release of LHRH from cells in which all of the physical cell-cell connections have been disrupted by enzymatic dispersion. This suggests not only an endogenous hypothalamic 'pulse generator', but implicates an endocrine mechanism for the coordination of this pulse generator. Our use of this model has yielded a very interesting piece of evidence in our quest for an answer to how LHRH neurons communicate, and provides a line of inquiry which may lead to our 'grail' of the mechanism underlying the generation of coordinated pulsatile LHRH release by the LHRH neurons which are not synaptically connected. TRANSCRIPTIONAL ACTIVATION OF THE HUMAN GNRH GENE BY THE IGF-1 RECEPTOR INVOLVES RAS AND IMMEDIATE-EARLY GENES IN THE NLT GNRH NEURONAL CELL LINE S. Zhen, and S. Radovick*, Division of Endocrinology. Children's Hospital/Harvard Medical School, Boston, MA 02115.

of Endocrinology, Children's Hospital/Harvard Medical School, Boston, MA 02115.

An immortalized GnRH-expressing neuronal cell line (NLT) established in this laboratory was used to investigate the signaling pathways involved in the regulation of human GnRH gene expression by [GF-1, NLT cells were developed by targeting the expression of the SV 40 T-antigen to the GnRH neurons in transgenic mice with the hGnRH gene "S-promoter sequence. These cells display neuronal morphology and express neuron-specific markers MAP-2 and Tau but not the glial cell marker GFAP. An RNase protection assay and immunocytochemistry demonstrated the expression of GnRH mRNA and the decapeptide, respectively, in NLT cells. Receptor binding assays indicated the presence of IGF-1 receptors on the cell membrane. Scatchard analysis revealed a single class of high affinity binding sites for IGF-1, with a Kd of 5.0×10⁻¹⁰M and a receptor number of 3.2×10⁵/cell. The NLT cells were transfected with DNA constructs containing hGnRH gene regulatory sequences fused to the luciferase reporter gene. A significant increase in reporter activity was induced by IGF-1 treatment of cells transfected with -412 bp of the hGnRH gene promoter. Sequence analysis revealed the presence of a unique AP-1 binding site in the human GnRH gene promoter region located between -402 and -396 bp. Mutation of this AP-1 binding site rendered the promoter unresponsive to IGF-1 stimulation. A significant increase in the expression of c-jun and c-fos was induced by IGF-1 treatment of the NLT cells. Transfection of these cells with a constitutively active Ras plasmid produced a similar increase in 412 hGnRH reporter activity and in the expression of c-jun and c-fos after treatment with IGF-1. Transfection of a dominantinterfering Ras plasmid decreased the IGF-1 induction of the hGnRH reporter construct. These results demonstrate that 1) IGF-1 receptors are expressed in the NLT GnRH-expressing neurons; 2) activation of IGF-1 receptors stimulates hGnRH gene expression: 3) Ras, c

μ-OPIOID RECEPTOR IMMUNOLABELING IS PRESENT IN GABAERGIC NEURONS AND THEIR TARGETS IN THE RAT NUCLEUS ACCUMBENS A.L. Svingos*¹, A. Moriwaki, J.B. Wang, G.R. Uhl and V.M. Pickel¹. Cornell Univ. Med. Col., Dept. of Neurol. & Neurosci., NY, NY, 10021¹, Intramural Res. Prog., NIDA and Depts. of Neurol. & Neurosci., Johns Hopkins Univ., Baltimore, MD, 21224. Stimulation of μ -opioid receptors (MOR) in the nucleus accumbens (NAC) can produce both hypo- and hyperactivity, that have been attributed to modulation of activities of local neurons, many of which contain y-aminobutyric acid (GABA). To anatomically test this hypothesis, we combined immunogold-silver detection of MOR with immunoperoxidase labeling of GABA. MOR-like immunoreactivity (MOR-LI) was mainly seen at extra-synaptic plasmalemmal sites in GABA immunoreactive spiny and aspiny neurons. From 524 examples of MOR/GABA associations, 46% were in dendrites that colocalized MOR and GABA immunolabeling. The remainder of MOR/GABA associations included contacts between differentially labeled neurons. The latter group included convergence of separately labeled MOR and GABA terminals onto common dendrites, and contact between terminals containing only GABA and MORlabeled dendrites. MOR has a subcellular distribution consistent with opiate roles in modulating 1) postsynaptic responses in dendrites of GABAergic neurons, and 2) presynaptic release of GABA from axons in the NAC. MOR ligands may also alter presynaptic and/or postsynaptic responses in non-GABAergic neurons subject to GABA inhibition. The multiple sites of MOR are likely to contribute to the diverse locomotor and rewarding effects of opiates in the NAC. REGIONALLY SPECIFIC UP-REGULATION OF MU AND DELTA OPIOID RECEPTOR BINDING IN ENKEPHALIN KNOCKOUT MICE, L. S. Brady*, M. Herkenham, R. B. Rothman, J. S. Partilla, M. König, A. M. Zimmer, and A. Zimmer. Section on Functional Neuroanatomy (LB, MH) and Unit on Developmental Biology (MK, AMZ, AZ), Laboratory of Cell Biology, NIMH, Bethesda, MD 20892 and Clinical Psychopharmacology Section (RR, JP), Addiction Research Center, NIDA, Baltimore, MD 21224.

Enkephalin (Enk) -/- mice, generated by gene targeting, were used to examine the physiological role of enkephalins in regulating the levels and functions of opioid receptors in brain. In fresh frozen brain sections, mu and delta receptors were labeled with [125]D-ala², N-me-phe⁴, gly⁵-olenkephalin or [125]deltorphin-II, respectively. In wild type Enk +/+ mice, moderate levels of mu binding were seen in the hypothalamus, annygdala, midline thalamus, rostral striatum, and nucleus of the solitary tract; lower levels of binding were seen in caudal striatum, cortex, hippocampus, brainstem, and spinal cord. In the Enk -/- mice, mu binding was greatly elevated in the ventral pallidum, preoptic area, hypothalamus, and amygdala. Increases in mu binding were also seen in the ventromedial striatum, midline and intralaminar thalamic nuclei, tectum, locus coeruleus, parabrachial nucleus, and nucleus of the solitary tract. In the Enk +/+ mice, moderate to dense levels of delta binding were seen in olfactory bulb, striatum, cortex, amygdala, and hippocampus. Significant elevations in delta binding in the Enk -/- mice were restricted to the neostriatum. The striking up-regulation of mu receptors in limbic areas, notably the amygdala, is consistent with the increased emotional and aggressive behaviors observed in the Enk -/- mice.

DISRUPTION OF THE MU-OPIOID RECEPTOR GENE IN MICE BY HOMOLOGOUS RECOMBINATION. H. Matthes, F. Simonin, S. Slowe, I. Kitchen, P. Dolle, R. Maldonado and B. L. Kieffer*. CNRS UPR 9050; ESBS Parc d'innovation Bld S. Brand 67400 ILLKIRCH, France.

Opioid receptors mediate the strong analgesic and addictive properties of opiates. Recently their genes have been cloned (for rev see Kieffer B. L. 1995 Cell Mol Neurobiol vol 15, 615) allowing study of their role *in vivo* by genetic tools. The mu receptor is considered as the primary target of morphine. To assess the specific contribution of this opioid receptor type in pain control and reward, we have disrupted its gene by homologous recombination. A 12 kb genomic fragment was obtained from a mouse library and the neomycin phosphotransferase gene (neo) under control of the PGK promoter was inserted into the coding sequence. The targeting vector was electroporated into D3 embryonic stem cells. We analysed 92 neomycin resistant colonies which we screened using a 5 BamHI probe. We found 7 positive clones, representing a targeting frequency of 1/13. Southern analysis using a 3' BamHI probe and the neo probe confirmed accurate integration of the neo gene. One positive clone was microinjected into mouse blastocysts and gave rise to chimaeric mice which in turn were bred with C57BL/6 females. Germline transmission occurred, leading to heterozygous offsprings which were further bred for the obtention of homozygous mice. Opioid receptor expression and response to morphine of these mice is currently under investigation.

We have requirely shy shown that

Using 293 cells transfected with epitope-tagged mu and delta opioid receptors, we have studied agonist-induced internalization using flow cytometry and immunocytochemistry. We have previously shown that opioid peptides and the alkaloid agonist etorphine induce rapid internalization of mu and delta receptors, whereas morphine does not induce internalization of either receptor. We have tested a number of additional opiate ligands for their ability to internalize receptors in order to ascertain which structural components are required for internalization. We have also analyzed internalization of mu opioid receptors in rat brain. As seen in the cell line, etorphine, but not morphine, triggers a dramatic redistribution of mu receptors from plasmalemma to intracellular vesicles. This internalization occurs in virtually all areas containing detectable receptor in somata and neuropil. In addition, after etorphine treatment there is enhanced staining in deeper layers of neocortex and in matrix-like compartments in the caudate putamen. In untreated animals, these areas contain little or no receptor staining. The mu receptor containing vesicles are shown to be intracellular when viewed by confocal microscopy. Double labeling with tranferrin receptor in cells that contain both receptors suggests that these vesicles are early endosomes.

CORTICOSTERONE REGULATES GENE EXPRESSION OF OPIOID RECEPTORS IN THE HIPPOCAMPUS. A. Ableitner, D. Fischer, J. Deicke, V.K. Patchev*, O.F.X. Almeida. Max Planck Institute of Psychiatry, Clinical Institute, 80804 Munich, Germany

The action of glucocorticoids upon the hippocampal formation plays

The action of glucocorticoids upon the hippocampal formation plays an important role in the regulation of the hypothalamo-pituitary-adrenal axis and the adaptation to stress. The hippocampal opioidergic system which is activated by several stressors might be a candidate for glucocorticoid-dependent adaptive changes resulting from alterations in the gene expression of opioid peptides or receptors. Using ribonuclease protection assays, the present studies were designed to examine the possibility of alterations in the gene expression of hippocampal μ -, δ - and k-opioid receptors in response to varying corticosterone levels. Removal of endogenous corticosterone by adrenalectomy (1 week) had no effect upon k-opioid receptor mRNA levels, while a trend for an increase in δ -opioid receptor transcripts was observed. Concentrations of mRNA encoding μ -opioid receptors were, however, significantly reduced in adrenalectomized animals, as compared to sham-operated controls, and this decrease was prevented by supplementation with physiological doses of corticosterone. These data indicate an interaction between glucocorticoids and the hippocampal opioidergic system, which may have implications in the behavioural and endocrine response to stress.

DESENSITIZATION AND DOWN-REGULATION OF THE HUMAN KAPPA OPIOID RECEPTOR. J. Zhu*, L.-Y. Luo, C. Chen, and L.-Y. Liu-Chen Dept. of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140

Activation of the k opioid receptor inhibits adenylate cyclase, enhances K+ conductance or reduces Ca++ conductance via pertussis toxin-sensitive G proteins. We recently cloned a human κ opioid receptor. In addition, we demonstrated that activation of the human k receptor expressed in CHO cells enhanced [35S]GTPγS binding. In this study, we examined desensitization and down-regulation of the human κ opioid receptor after exposure to the κ agonist U50,488H. Preincubation with U50,488H (1 µM) from 15 min to 4 h reduced in a time-dependent manner the magnitude of increase in [35S]GTPyS binding by the subsequent application of U50,488H. The B_{max} values of [3H]diprenorphine binding to the κ receptor were significantly reduced after a 4-h exposure to U50,488H (1 µM), but not after 15min or 1-h exposure. Pretreatment of cells for 4 h with 0.1 nM to 1 μM of U50,488H decreased in a dose-dependent fashion [35S]GTP γ S binding by the subsequent U50,488H incubation. Pretreatment with 10 nM or 100 nM U50,488H decreased B_{max} values by about 30%, similar to 1 μM of U50,488H, whereas 0.1 nM U50, 488H had no effect. Thus, desensitization and down-regulation of the k receptor occur following agonist exposure and represent two different adaptation processes. (Supported by NIH grants DA04745 and T32 DA7237

IMMUNOLOGICAL CHARACTERIZATION OF OPIOID BINDING SITES IN NG108-15 SUBCELLULAR FRACTIONS. <u>C. J. Coscia*</u>, <u>E. G. Ignatova</u>, and <u>M. M. Belcheva</u>, Dept. Biochem. and Mol. Biol., St. Louis Univ. Sch. of Med. St. Louis, MO 63104

C- and N-terminal-directed antipeptide antibodies to the δ opioid receptor were used to characterize opioid binding sites in NG108-15 subcellular fractions. In immunoblotting experiments, the C-terminal antibody detected two major bands in both plasma membrane-enriched (P20) and nuclear matrix preparations. The higher mol. wt. protein migrates at 64 kDa and another band was found at 33 kDa. In P₂₀ preparations the N-terminal antibody detected two lower mol. wt. proteins at 38 and 33 kDa in addition to higher mol. wt. bands. The intensity of all bands except that of the 38 kDa protein were reduced in nuclear matrix preparations. To determine which of the proteins are glycosylated, Pon membranes were solubilized and passed over wheat germ agglutinin columns. The N-terminal antibody detected a single band (72 kDa) in Nacetyl-D-glucosamine eluates. The results are consistent with crosslinking data suggesting that nuclear matrix associated opioid binding sites represent truncated forms of the glycosylated δ opioid receptor found in P20 membranes. Supported in part by NSF grant IBN-9121750.

OPIOIDS REGULATE THE DEVELOPMENT OF NEURONS, ASTROCYTES AND OLIGODENDROCYTES: MULTIPLE ACTIONS AND RECEPTORS SEGREGATE OPIOID FUNCTIONS AMONG DISSIMILAR CELL TYPES. K.F. Hauser*, A. Stiene-Martin, W. Maxson, and P.E. Knapp, Dept. of Anatomy & Neurobiology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536.

Opioids modify nervous system development through both direct and indirect mechanisms. To identify which classes of cells are directly affected by opioids during maturation, we systematically examined the role of μ , δ , and κ opioid receptors on the maturation of postnatal murine neuroblasts, astrocytes, and oligodendrocytes in vitro. Opioid receptor expression was assessed immunologically (antibodies courtesy Dr. R.P. Elde), and functionally by assessing growth. Cerebellar neuroblasts uniformly express μ and $\delta,$ but not $\kappa,$ opioid receptors. Treatment with δ agonists significantly inhibited cellular differentiation in newly postmitotic neurons, and preliminary results suggest that δ agonists also inhibited neuroblast division. In contrast, immature oligodendrocytes uniformly expressed μ , but not κ or δ , opioid receptors, and treatment with μ agonists caused about a 300% increase in DNA synthesis. Lastly, subpopulations of astrocytes possessed $\mu,\,\kappa,$ and/or δ opioid receptor immunoreactivity. Exposure to agonists selective for μ or κ opioid receptors significantly inhibited DNA synthesis in distinct subpopulations of astrocytes. Proliferation was unaffected by δ receptor activation; however, few astrocytes expressed δ receptors compared to μ or κ receptors. Importantly, our findings suggest that opioids intrinsically regulate neural development by differentially affecting the maturation of neurons, astrocytes, and oligodendrocytes. In addition, findings that opioid receptor types are segregated among classes of cells suggest a mechanism by which the endogenous opioid system discriminates among dissimilar cell types. Opioid diversity may permit the independent regulation and/or the coordination of separate developmental events in different neural cell types. Support NIH DA06204

OPIOIDS REGULATE CYTOSKELETON PROTEINS IN EMBRYONIC NEURONS. <u>D. Mangoura* and S. Leung</u>. Peds, The Univ. of Chicago Sch. of Med, Chicago, IL 60637.

We have been studying the mechanism of action of opioids in regulating the cytoskeleton in developing neurons. Using early

regulating the cytoskeleton in developing neurons. Using early postmitotic, presynaptic cultured neurons derived from chick embryo cerebral hemispheres (E6CH), we previously showed that the G-protein opioid receptor causes protein tyrosine phosphorylation of both kinases and cytoskeleton-associated proteins. Specifically, 1µM metenkephalin activated pp125FAK, a focal adhesion tyrosine kinase, and pp60sre+, the neuron-specific isoform of the cytosolic tyrosine kinase src. Met-enkephalin also caused tyrosine phosphorylation of vinculin, an actin binding protein. We have extended our studies to other cytoskeleton-associated proteins and known are substrates. We now cytoskeleton-associated proteins and known src substrates. We now report that p80/85, which forms complexes with src upon agonist stimulation, is tyrosine phosphorylated in response to opioids. The phosphorylation was seen as early as 2 min of incubation with metenkephalin, peaked by 5 min, and declined by 15 min. All metenkephalin-stimulated signaling was inhibited by the antagonist naloxone. We also found that several growth factors (namely EGF and FGF) acting through receptors with intrinsic tyrosine kinase activity, increased the phosphotyrosine content of p80/85 in E6CH neurons. These data further elucidate the actions of opioids early in development. Furthermore they suggest that cytoskeleton proteins may be the converging points of two different signaling pathways and therefore that the regulation of such proteins may serve as a crosstalk point between two pathways in orchestrating the complex homeostasis of the neuronal cytoskeleton. IDENTIFICATION OF NEW, HIGHLY ACTIVE LIGANDS FOR THE ORPHANIN RECEPTOR USING COMBINATORIAL LIBRARIES R.A. Houghten*, C. Spaeth, L. Toll1, C. T. Dooley, Torrey Pines Institute for Molecular Studies, San Diego, CA, 92121; ¹SRI International, Menlo Park, CA, 94025.

Orphanin FQ (nociceptin) is the natural ligand for ORL1, and it is thought that antagonists to this peptide may have a useful role in pain therapy. A tritiated form of the natural heptadecapeptide ligand for ORL1 has been prepared, and was used to develop a radioreceptor assay using rat brain homogenates. Binding data indicate the presence of a single binding site with a dissociation constant of $5 \pm 1.1 \text{ nM}$ and Bmax of 535 ± 85 fmoles/mg protein. Thirty-four analogues of orphanin FQ, including a complete alanine "scan" of orphanin FQ, and truncation analogues from both the N- and C- terminals were synthesized and tested. The data obtained indicate that the Nterminus plays a more critical role in binding than the C-terminus and that residues 1, 2, 4, and 8 are essential for binding. Using combinatorial libraries, new ligands from libraries containing millions of different compounds were identified. The compounds were found to be agonists, inhibiting electrically induced contractions of the mouse vas deferens.

STATISTICAL PARAMETRIC MAPPING (SPM) ANALYSIS OF PET IMAGES OF BRAIN MU OPIOID RECEPTORS REVEALS HIGHER REGIONAL BINDING IN HEALTHY WOMEN COMPARED TO MEN. N. Ilgin. B. Bencherif. M.Kruger, M.J. Stumpf, J.J. Frost*. The Johns Hopkins Medical Institutions, Baltimore, Maryland.

Sex differences in brain structure and function have been described but little is known about the relations of sex and opioid receptors in the human brain. Mu-opioid receptor binding was measured with PET and C-11 carfentani (CFN) in 10 male and 10 age-matched female controls. PET data was acquired with a GE 4096 PET scanner (FWHM resolution 7mm) following i.v. administration of 20±2 mCi C-11 CFN. Positioning in the PET scanner i.v. administration of 20±2 mCi C-11 CFN. Positioning in the P±1 scanner was standardized by using a thermoplastic mask and the amygdala-occipital cortex plane was localized using MRI. Specific binding images were obtained after summing images from 36-82 min. and correcting for nonspecific binding by use of the occipital cortex counts (fregion-occipitall) occipital.) Data were then spatially normalized to the Talairach atlas and smoothed (10 mm Gaussian filter). AnCova analysis was generated using adjusted means for the 2 pooled groups (males vs females) and the resulting SPM(t) maps were transformed to SPM(z) maps (threshold=2.33, ps20.05). Significantly were transformed to SPM(z) maps (threshold=2.33, pg0.05). Significantly higher mu opioid receptor specific binding was found in females compared to male controls in the hypothalamo-thalamic region (Z=3.54, p<0.05) and the same trend of higher binding was observed in anterior cingulate gyrus, amygdalae and temporal cortex with lesser Z scores. These results demonstrate that SPM analysis can detect higher brain mu opioid receptor binding in healthy females compared to age matched males. Differences in regional mu opioid receptors may play a role in mediating emotional and cognitive differences in men and women.

DEVELOPMENTAL GENETICS III

THE REELIN PARADOX: LACK OF CORRELATION BETWEEN EXPRESSION OF REELIN AND THE REELER PHENOTYPE. C. Lambert de Rouvroit. B. Bernier. S. Schiffmann, V. de Bergeyck, A.M. Goffinet*. Dept. Physiology, FUNDP Sch. Med., Namur, Belgium
Expression of the reelin gene is affected in five alleles of the reeler putation so that alterations of reelin are most probably the cause of the

mutation so that alterations of reelin are most probably the cause of the reeler phenotype.

In the present work, the expression of reelin mRNA and protein was studied during mouse brain development from embryonic day 13 (E13) to maturity. mRNA expression was followed using in situ hybridization of radiolabeled oligonucleotides or digoxigenin riboprobes, while the reelin protein was revealed with monoclonal antibodies generated against an *E.coli* fusion protein corresponding to an N-terminal segment of the reelin sequence. Both methods revealed consistent results, with strong reelin expression in developing Cajal-Retzius cells, olfactory bulb, cerebellar granule cells, spinal cord and retina, all of which are minimally affected in homozygous reeler mice. Moderate to low expression was found in tectum, striatum, basal forebrain, while no expression was seen in the cortical plate, radial glial cells, Purkinje cells and most of the hindbrain, all of which have been shown to be abnormal in reeler mice.

Those results demonstrate a lack of correlation between reelin mRNA and protein expression and the reeler phenotype. Those discrepancies probably indicate an indirect action of reelin on radial glial cells and/or on postmigratory neurons. Such an action could be explained by postulating that reelin acts in the extracellular matrix as a cell-repulsive molecule

SCRAMBLER AND REELER: MORPHOMOLECULAR ANALYSIS OF MUTANT CEREBELLA INDICATE ONE PHENOTYPE FROM TWO DIFFERENT GENES. D. Goldowitz*. E. Laywell. D. Steindler, G. D'Arcangelo¹. M. Sheldon¹, T. Curran¹, M. Davisson². K. Johnson². H. Sweet². Dept. of Anat. & Neurobiol., Univ. of Tenn. Coll. of Med. and 'Dept. Devel. Neurobiol., St. Jude Children's Res. Hosp., Memphis, TN, 38163; '2The Jackson Laboratory, Bar Harbor, ME.

The reeler mutation has profound effects on neuronal migration and cortical structure in the mouse. The gene mutated in reeler mice has been shown to cod² for a novel extracellular protein called Reelin (D'Arcangelo et al., 1995). More recently, a new neurological mutant mouse, scrambler, has been found that exhibits a phenotype very similar to that of reeler — but maps to a different region of the mouse genome (Sweet et al., in press). Developing and adult scrambler cerebella were studied to assess the number and placement of Purkinje cells, molecular markers of cerebellar compartments, and reelin gene expression. The scrambler cerebellum is marked by ectopic nests of calbindin-positive Purkinje cells that lie deep to a greatly reduced population of granule cells. The size, number, and placement of these Purkinje cell nests are similar to those seen in the reeler cerebellum. The number of ectopically and normally placed Purkinje cells is similar in both scrambler and reeler cerebella (Heckroth et al., 1988). Finally, scrambler Purkinje cells are partitioned into Zebrin II-positive and Zebrin II-negative parasagittal bands like those seen in the reeler cerebellum (Edwards et al., 1994). Aft postnatal day 6, GFAP and tenascin immunoreactivites are co-extensive and encircle the nests of scrambler Purkinje cells, as well as marking a midline raphe. These features are virtually identical to what is seen in the reeler mouse.

In spite of numerous phenotypic similarities, genetic analyses indicate that the scrambler mutant appears to be a neurological phenocopy of the reeler mouse, the genetics point to s

DEVELOPMENTAL CHANGES IN mRNA LEVELS IN SINGLE CAJAL-DEVELOPMENT AL CHANGES IN MINNA LEVELS IN SINOLE CAJAL-RETZIUS NEURONS P.B. Crino*1, T. Pribyl 2, K. Nakajima 3, T. Miyata 34, M. Ogawa 4, K. Mikoshiba 5, A. Campagnoni 2, J. Eberwine 1, 1 Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; 2 UCLA Hospital, Los Angeles CA; 3 RIKEN, Japan; 4 Kochi Medical Sch., Japan; 5 Univ Tokyo, Japan; Cajal-Retzius (C-R) neurons arrive first in layer 1 of the cortical plate and may

provide trophic cues to neurons destined for layers II-VI. The patterns of gene expression in C-R neurons during development may provide insight into how C-R cells effect cortical lamination. We used immunohistochemistry with single cell mRNA amplification to assess mRNA levels in individual C-R cells. Rat brain mRNA amplification to assess mRNA evens in individual C-R ceils. Rat brain sections at (E)16 and (E)18 were labeled with Golli-MBP (Golli) antibodies which label C-R and other neurons. Sections were also labeled with the CR-50 antibody to confirm the Golli C-R neurons. CR-50 specifically recognizes C-R neurons. CDNA synthesis from poly(A) mRNA was performed using an oligo-dT-TRNA polymerase primer-promoter and Avian myeloblastosis reverse transcriptase on Golli stained sections. Single Golli stained C-R neurons were aspirated into microelectrodes and double stranded cDNA was synthesized. 32PCTP radiolabeled aRNA was generated with T7 RNA polymerase and was used as a probe for reverse Northern blotting. Numerous candidate mRNAs were detected including mRNA encoding cytoskeletal elements (neurofilaments, internexin, and activity regulated encoding cytoskeletal elements (neurofilaments, internexin, and activity regulated cytoskeleton associated protein), neurotrophic factor receptor and transcription factor mRNAs at differing abundances between E16 and E18. GAD65 and several GABA A receptor subunit mRNAs were also detected at differing abundances which supports the hypothesis that C-R neurons are GABAergic. Changes in the relative abundance of multiple mRNAs during development in single immunohistochemically defined C-R neurons provides important insight into the role that C-R neurons play in cortical lamination. cDNA libraries from these single cells will help to determine the molecular fingerprint of C-R neurons and protein the second control of the potentially provide novel C-R cell markers for each stage of cortical development. TISSUE- AND DEVELOPMENTAL-SPECIFIC HUMAN MAPIA GENE EXPRESSION IS DETERMINED BY 1.5 KB OF 5' FLANKING SEQUENCE, A. Kume, J. Wilkowski, S.M. Jones, S. Rainier, T. Reinglass, T.L. Saunders, J.K. Fink* Univ. Michigan, Dept. of Neurology and GRECC, VAMC, Ann Arbor, MI 48109. Microtubule associated proteins (MAPs) regulate microtubule stability in axons and dendrites. Developmental changes in MAP gene expression suggest that MAPs present before birth (eg. MAPIb) are involved in neuronal cytoskeleton formation: MAPs present after birth (eg. MAPla) are involved in maintaining the neuronal cytoskeleton. We are interested in determining what regulates the developmental switch in MAPs gene expression. Previously, we cloned human the MAPIa gene, its 5' flanking sequence contained a consensus promoter (TATA) element. For the current study, we placed the β-gal gene under the control of 1.5 kb of MAPIa's 5' flanking sequence and prepared transgenic mice. 16 founders and their progeny were examined histologically for transgene expression. Transgene expression was confined to the CNS and appeared only in neurons and ependymal cells. The magnitude of transgene expression was variable between animals. We compared transgene expression at embryonic day 14, at birth, and older than 2 mo of age. Day 14 embryo showed no expression; mice examined at birth had approximately 10% of adult levels of β-gal. Our results correlate with developmental changes in MAPIa protein concentrations: in rats, MAPIa is detectable several days before birth and increases to a maximum by day 20. Our results indicate that 1.5 kb flanking MAPIa contains cis-acting elements that regulate developmental and tissue-specific MAPIa gene expression. This information will expedite discovery of trans-acting factors that regulate developmental and tissue-specific MAPIa gene expression. This information will expedite discovery of trans-acting factors that regulate developmental and tissue-specific MAPIa gene expression of the molecular regulation of the neuronal cytosk

A RANDOM MUTAGENESIS SCREEN FOR NEUROCRANIAL MUTATIONS IN THE MOUSE. P.M. Nolan*, S.A. Alivizadeh, C. Lo# and M. Bucan, Depts. of Psychiatry and Biology#, University of Pennsylvania, Philadelphia, PA 19104.

A random mutagenesis screen for dominant behavioral mutations in the mouse provides us with an additional class of mutations - those that affect neurocranial development. While in some cases abnormal behavior in heterozygous mice is indicative of disrupted neuronal development, the simple observation of heterozygotes with abnormal craniofacial features can also hint at a striking neurodevelopment defect in homozygotes (Matsuo et al., Genes and Development 9, 2646-2658, 1995). Based on the high incidence of mice with craniofacial anomalies in our F1 screen, we hypothesize that the C57BL/6J strain of mice, used here as a genetic background, is highly sensitized to neurocranial defects.

Here, we present phenotypic analysis of two mutations that affect craniofacial development: a novel mutation 4Z and the previosly described *Whl* mutation (Nolan et al., *Genetics* 140, 245-254, 1995; Pickard et al., *Brain Research* 705, 255-266, 1995). *Whl* has a complex neurological and behavioral phenotype in heterozygotes, while homozygotes die *in utero* between embryonic day (E) 9.5 and E11.5. Histological analysis indicates that homozygote embryos have severely underdeveloped forebrain and midbrain structures. The mutant locus maps to the subcentromeric region of mouse chromosome 4. Two candidate genes, *Brain2 (Brn2)* and *Embryo brain kinase (Ebk)*, and other embryonic markers are being used to further characterize the neurodevelopmental defect caused by the *WhI* locus.

INDUCTION OF NEURAL GENE EXPRESSION IN MUSCLE BY ECTOPIC EXPRESSION OF DOMINANT NEGATIVE REST. M. Frohman*, J. Weils, and Y. Zhang. Institute for Cell and Develop. Biology, SUNY Stony Brook, Stony Brook, NY 11794-8651

Numerous genes are expressed exclusively in neurons, such as the type II Na Channel, Synapsin, and SCG10. Exploration of such restricted neural specific gene expression in neural and non-neural cell lines has led to the general finding that most such genes are controlled in the important sense via negative regulation. The genes contain positive enhancer elements that encourage widespread expression, and negative enhancers that restrict expression to neural cells only. REST is a zinc-finger transcription factor that was identified as a silencing (repressing) factor that bound to the negative element of the Type II Na Channel gene and SCG10; it is now appreciated that at least 20 neural-specific genes contain this element and are potentially regulated by REST. Consistent with this hypothesis, REST is expressed in embryos in all non-neural cells. In addition, REST is expressed in neuroblasts, which also don't express the neural-specific genes described above. To determine the role of REST in vivo, we have ectopically expressed REST in vivo using the engrailed promoter to direct expression to the cerebellum, and have ectopically expressed dominant-negative REST in vivo to muscle, using a myosin-light-chain promoter. Inhibition of and ectopic expression of the neural genes described above was monitored using in situ hybridization. Preliminary results indicate that REST regulates neural differentiation, and that REST in muscle cells represents the only mechanism through which widespread neural gene expression in non-neural cells is normally prevented.

DEVELOPMENTALLY REGULATED EXPRESSION OF SENSE AND ANTISENSE TRANSCRIPTS OF HSP70.2 GENE IN MICE. A. K. Murashov* and D. J. Wolgemuth, Dept. of Obstetrics & Gynecology and Genetics & Development, Columbia Univ. Coll. of Physicians & Surgeons, NY 10032.

We have recently shown that the murine gene hsp70.2, discovered by virtue of its

abundant expression in germ cells during spermatogenesis, is also expressed in adult mouse brain. Moreover, we have made the surprising observation of hsp70.2 antisense transcription in several brain areas such as the cortex, hippocampus, superior and inferior colliculi, thalamic nuclei, cerebellum, and brainstem detected on both Northern and in situ levels. We now report that hsp70.2 sense and antisense transcripts are expressed in specific spatio-temporal patterns in the developing mouse central nervous system. In situ hybridization analysis revealed overlapping expression of the hsp70.2 sense and antisense transcripts in developing brain from embryonic d 9.5 to postnatal day 17 mice. In midgestation embryos the expression of sense and antisense transcripts was found in developing spinal cord, hindbrain, neocortex, and spinal ganglions. During postnatal development, particularly strong expression of both transcripts was observed in developing cerebellar and cerebral cortexes, hippocampus and olfactory bulbs.

Immunocytochemical analysis of the hsp70.2 protein encoded by the hsp70.2 sense strand was performed using A2 antibody (generously provided by M. Eddy) revealed that the pattern of hsp70.2 protein expression in the developing brain corresponded to that of its mRNA, suggesting that regulation at the level of translation is not a critical feature of the hsp70.2 antisense transcript. RT-PCR analysis using pairs of gene-specific primers showed that the hsp70.2 sense and antisense transcripts share at least 2.3 kb of genomic sequence.

TRACKING VIRTUAL TRAJECTORIES. Leland S. Stone*, Brent R. Beutter, & Jean D. Lorenceau, NASA Ames Res. Ctr., Moffett Field, CA 94035-1000.

Current models of smooth pursuit eye movements assume that it is largely driven by retinal image motion (e.g. Krauzlis & Lisberger, 1991). We tested this hypothesis by measuring pursuit of elliptical motion (3.2s, 0.9 Hz, 1.4° x 1.6°, 4 randomly interleaved phases) of either a small spot ("real" motion) or of a line-figure diamond viewed through apertures such that only the motion of four isolated oblique line segments was visible ("virtual" motion). Each segment moved sinusoidally along a linear trajectory yet subjects perceived a diamond moving along an elliptical path behind the aperture (Lorenceau & Shiffrar, 1992). We found, as expected, that real motion produced accurate tracking (N = 2) with mean gain (over horizontal and vertical) of 0.9, mean phase of -6° (lag), mean relative phase (H vs V) of 90±8° (RMS error). Virtual motion behind an X-shaped aperture (N= 4 with one naive) yielded a mean gain of 0.7, mean phase of -11°, mean relative phase of 87±15°. We also measured pursuit with the X-shaped aperture using a higher segment luminance which prevents the segments from being grouped into a coherently moving diamond while keeping the motion otherwise identical. In this incoherent case, the same four subjects no longer showed consistent elliptical tracking (RMS error in relative phase rose to 60°) suggesting that perceptual coherence is critical. Furthermore, to rule out tracking of the centroid, we also used vertical apertures so that all segment motion was vertical (N=3). This stimulus still produced elliptical tracking (mean relative phase of $84\pm19^\circ$), albeit with a lower gain (0.6). These data show that humans can track moving objects reasonably accurately even when the trajectory can only be derived by spatial integration of motion signals. Models that merely seek to minimize retinal or local stimulus motion cannot explain these results. NASA RTOP 199-16-12-37

SPATIAL SUMMATION OF MOTION SIGNALS IMPROVES SMOOTH PURSUIT. S.N.J. Watamaniuk*1 & S.J. Heinen². Wright State University, Dayton, OH 45435 and The Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115

Previous studies have shown that the smooth pursuit response is enhanced when stimuli larger than the traditional single spot are tracked (Pola & Wyatt, 1985; van den Berg & Collewijn, 1986). However, it is not known if this enhancement is due to the presence of more motion or more position information in the stimulus. Using a stimulus devoid of consistent position cues, we investigated the effects of increasing the motion signal on the smooth pursuit response. Eye movements were measured to random-dot cinematograms (RDCs) in which all dots moved in a single direction (left or right) at a constant speed. The width of the RDC was always 10 deg. We varied both the height of the display (dot density constant at 2 dots/deg²), and the density of the display (display height constant at 2 deg). Gain, initial acceleration, and latency were determined for each eye movement record. For the largest aperture size (10x10 deg), gain at the end of the open-loop period was consistently higher than for a single spot target. Eye acceleration, determined over a 20 msec bin centered at 90 msec after pursuit onset, increased when either aperture size or density were increased. In addition, pursuit latency decreased when either aperture size or density were increased. When equated for the number of moving dots, increasing aperture size had a larger effect on eye acceleration and latency than did increasing density. The differential effect of density and aperture size supports the notion that the input to the pursuit system arises from a nonlinear spatial summation of inputs from a population of motion detectors.

SHORT-LATENCY OCULAR FOLLOWING: EFFECTS OF CONFLICTING IMAGES MOVING IN THE SAME OR DIFFERENT DEPTH PLANES. C. Busettini*, G. S. Masson, and F. A. Miles. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892 and CRNC/CNRS, Marseille, France.

Movements of large patterns elicit ocular following (OFR) at ultra-short latency (monkeys, <60 ms; humans, <80 ms) and the very earliest responses can be elicited only by images moving in the plane of fixation: images with binocular dispartite exceeding a few degrees are ineffective (Busetini et al. 1996). In past studies, only one pattern was present, and we now report the effect on the initial OFR (of two monkeys) of introducing a second (interfering) pattern that moves with conflicting motion in the same or a different depth plane.

Visual stimuli, produced by back-projection onto a tangent screen, consisted of regularly spaced horizontal bands (3.36° thick) of random dots that could be moved horizontally to induce ocular following. However, the bands were organized into two groups such that alternate bands moved always together and opposite in direction to groups such that alternate bands moved always together and opposite in direction to the intervening bands. Using multiple projectors and crossed polarizers to confine images to one or other eye, one set of "drive" bands was imaged always in the plane of fixation, while the other set of "interfering" bands was imaged within or outside the plane of fixation by adjusting their horizontal disparity (range, 0-12.8° crossed and uncrossed). Trials started with all images stationary in the plane of the screen. In the wake of 10° centering saccades, shutters blanked the scene for 15 ms, after which the two sets of bands were revealed to be moving at 40% sin opposite directions.

For both monkeys, the initial OFR induced by the motion of the "drive" images showed strong dependence on the disparity of the "interfering" images. Based on measures of the change in version over the time period 60-77 ms (from the end of the blanking), initial OFR was weakest when the disparity was <0.5° and increased to a maximum as disparity increated to 2-5°; in 3/4 cases, measures declined with further increases in disparity (inverted Mexican hat vs. inverted bell profile). These data

increases in disparity (inverted Mexican hat vs. inverted bell profile). These data indicate that initial OFR can use binocular disparity to distinguish images moving in the plane of fixation from those moving in other depth planes.

MICROSTIMULATION IN DORSOMEDIAL FRONTAL CORTEX AFFECTS SMOOTH PURSUIT EYE MOVEMENTS S.J. Heinen. The Smith-Kettlewell Eve Research Institute, San Francisco, CA

Smooth eye movements have been previously evoked with electrical microstimulation from the dorsomedial frontal cortex (DMFC) in anesthetized monkeys (Tian, 1995). Single-unit recording experiments in our lab have implicated the DMFC in visually-guided (Heinen, 1995) and predictive smooth-pursuit control (Heinen, 1994). We show here that stimulation can affect smooth pursuit in alert primates. Results were obtained from a *Macaca mulatta* monkey that was trained to track a spot which moved at a constant velocity in discrete trials. We used relatively high target velocities (40-70 deg/sec), and a 300 msec gap to facilitate anticipatory eye movements. Stimulation was applied through a tungsten microelectrode that was lowered stereotaxically through a recording chamber mounted over the DMFC, at a location where single-unit activity related to pursuit had been recorded. Bipolar current was used with intensities and durations typically ranging from 100-300 μA and 100-500 msec respectively. We found that microstimulation applied during ongoing pursuit reduced eye velocity. However, microstimulation applied at the beginning of the trial facilitated initial eye acceleration (measured 90 msec after pursuit initiation) and/or anticipatory eye velocity (measured @ target onset). Interestingly, enhanced eye movements appeared to depend on the time of stimulation offset. This was evidenced by the finding that at the same site, stimulation that ended before pursuit initiation could facilitate pursuit, but stimulation that extended beyond pursuit initiation suppressed it. Sometimes stimulation at a given site affected both anticipation and initiation, but not always in the same direction. The results strengthen the notion that the DMFC plays a role in smooth pursuit, and that neuronal signals in this area may be involved in timing predictable target motion.

SMOOTH PURSUIT EYE MOVEMENTS FOLLOW THE 2/3 POWER LAW §SP. Viviani and SC. de'Sperati SFaculty of Psychology and Educational Sciences, University of Geneva, Carouge, Switzerland and ^sDepartment of Cognitive Science, Scientific Institute S. Raffaele, Milan, Italy.

Curvature and velocity of voluntary hand movements covary according to the socalled Two-thirds Power Law (Viviani & Schneider, 1991). Neurophysiological findings (Schwartz, 1995) suggest that this covariation originates from the dynamic properties of the motor cortex. We provide further confirmation of this hypothesis by showing that the Two-thirds Power Law applies also to the smooth pursuit movements of the eye. In the main experiment scleral search coils were used to record eye position while tracking 2D elliptic targets with 3 different eccentricities. In all cases the average velocity of the target was 8 deg/s. For each eccentricity, 7 targets were tested, only one of which complied itself with the power law. In the others the relation between velocity and curvature violated by a controlled amount this biological regularity. All aspects of oculomotor performance were affected by the amount of mismatch between the kinematics of the target and that predicted by the power law. Number and amplitude of catch-up saccades increased with the mismatch, and so did the retinal position error during the smooth phases of the pursuit. Moreover, the trajectory of the target was restituted faithfully only with biologically compatible targets. All the failures of the oculomotor system can be accounted by the hypothesis that, irrespective of target kinematics, the system is forced to comply with the Two-thirds Power Law. In a control experiment we ruled out the possibility that pursuit failures were due to the high accelerations present in non-biological targets. This was done by using non-elliptic targets having the same distribution of velocity as in the main experiment, but whose distribution of curvature along the trajectory was designed so as to satisfy the power law. In this case pursuit performance was considerably improved. The fact that a motor system whose plant dynamics is entirely different from that of the hand complies with the same motor rule strongly suggests a central origin of the rule.

SHORT-LATENCY VERSION AND VERGENCE EYE MOVEMENTS TO LARGE-FIELD MOTIONS: EVIDENCE FOR SHARED MOTION DETECTORS. G. S. Masson*, C. Busettini and F. A. Miles. CRNC/CNRS, Marseille, France and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Large-field motions applied dichoptically to the two eyes elicit tracking at ultra-short latency (<60 ms): conjugate motion at the two eyes (i.e., in the plane of fixation) evokes version responses, V_8 , and opposite motion (i.e., motion in depth) evokes vergence responses, V_8 (Miles et al 1986, Busettini et al 1996a,b). We here

report on the velocity tuning curves for these two kinds of response in 3 monkeys.

Animals faced a large tangent screen onto which two identical patterns were back-projected. A system of crossed polarizers ensured that each eye saw only one of the patterns, and mirror galvanometers controlled the horizontal positions of the images. Each trial started with the patterns superimposed and so imaged in the plane of the screen (distance, 33 cm). Then, the two patterns moved horizontally at the same constant speed (range, 5-240°/s) in either the same or the opposite direction.

Velocity tuning curves for Vg for motion-towards-the-observer and for Vs (based on ΔVg and ΔVs over time 60-77 ms measured from stimulus onset), had very similar forms—an initial steep rise to a peak followed by a gradual decay—with the peaks for both occurring at about the same retinal image speed $(=60^\circ)$ /s). The exact form of these V_g velocity tuning curves could be predicted by summing the V_S responses to matching monocular stimuli, i.e., summing ΔV_S for rightward motion when the right eye was patched with ΔV_S for leftward motion when the left eye was patched. For motion-away-from-the-observer, only, I animal produced ampreciable ΔV_S measures. eye was patched with ΔVs for leftward motion when the left eye was patched. For motion-away-from-the-observer, only 1 animal produced appreciable ΔVg measures, again predictable from the ΔVs for matching monocular motion stimuli; ΔVg for the other 2 animals to motion-away was extremely weak. It is known that the visual processing underlying these Vg and Vs responses to large-field binocular motions is not purely monocular (in which each eye independently tracks the motion it sees) but includes the processing underlying the processing various in danth and motion in the plane of involves binocular signals encoding motion-in-depth and motion-in-the-plane-of-fixation, respectively (Busettini et al, 1996a,b). However, the present data suggest

that these Vg and Vs responses may rely on the same (monocular) motion detectors.

MOTION DISPARITY AND LOOMING CUES FORM HIERARCHICAL INPUTS FOR SMOOTH PURSUIT OF TARGETS MOVING IN 3 DIMENSIONS, Gal. A Cohen* and Stephen G. Lisberger, Dept. of Physiology and W.M. Keck Foundation Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

Several cues are available to guide visual pursuit of 3D target motion. To dissociate the influence of looming from that of relative target motion on the two eyes, we presented virtual reality pursuit targets to 2 monkeys.

1) In the initial 100 ms of pursuit, the pursuit trajectory of one eye was influenced by visual input to the other eye. If looming was absent, and the right eye saw the same target motion over all trials, then the right eye's movement varied as a function of the left eye's input.

2) Visual input to one eye was sufficient to induce vergence pursuit motion in both eyes. Targets started straight ahead, on the plane of the screen, and were extinguished for the left eye at the time when the target began moving towards the monkey, so that the right eye saw nasal target motion. Under these conditions, a

monkey, so that the right eye saw nasal target motion. Under these conditions, a normal-looming monocular target induced both the right and left eyes to move nasally, and produced 60% of the convergence pursuit seen with a stereo target, as measured 300 ms after pursuit initiation. Inverse-looming monocular targets induced only 9% of the vergence observed with normal-looming monocular targets induced only 9% of the vergence observed with normal-looming monocular targets.

3) Looming is a much stronger cue for vergence pursuit in the absence of motion disparity information. Stationary monocular targets which grew or shrank in size successfully clicited strong convergence or divergence pursuit, respectively, in the absence of translational motion. Stereo targets that moved towards the monkey, but got smaller rather than larger (inverse-looming), induced ~85% of the vergence velocity seen with normal-looming stereo targets that had the same traigeters.

velocity seen with normal-looming stereo targets that had the same trajectory.

These data suggest that the pursuit system integrates target input from the 2 eyes into a 3D trajectory that is then transformed into commands for motion for the two eyes. When stereo information is ambiguous or underconstrained, monocular cues strongly influence 3D pursuit trajectory. Supported by ONR grant N00014-94-1-0269 and by NIII grant EY06544.

UNEOUAL AMPLITUDE SACCADES: THE USE OF DISPARITY INFORMATION AS A FUNCTION OF VIEWING DISTANCE.

J. Van der Steen 1 and P.Bruno2. Dept. of Physiology, Erasmus University Rotterdam¹, The Netherlands and Dip. di Elettrotecnica, Univ. of Trieste, Italy (SPON: European Neuroscience Organisation)

Under aniseikonic conditions, the ability to generate saccades with unequal amplitudes depends on viewing distance (Vision Res (35): 3459-3471, 1995). The finding that intrasaccadic vergence errors are small compared to far distance when only disparity information is available, is either an indication of a more effective use of disparity information at close distance (sensorial effect), or is directly related to the state of convergence of the two eves as a function of viewing distance (motor effect). To test these two alternatives, we instructed three subjects to make horizontal saccades (amplitudes 10, 20, 30, 40 and 50 degrees) while viewing two dichoptically presented aniseikonic images. Size differences between the two images were 0, 8 and 16 %. By shifting the relative horizontal positions of the two images in front of each eve, we simulated viewing distances varying between 100 and 0.25 meters. In all three subjects intrasaccadic vergence errors during leftward saccades, requiring divergence, were inversely related to viewing distance. For rightward saccades, requiring convergence, the opposite trend existed, although the effects were much smaller. On the other hand the maximum disparity that was tolerated before saturation occurred, was dependent on viewing distance. In conclusion, the effects of viewing distance on the capability to generate unequal amplitude saccades, can partially be explained by a distance dependent use of disparity information, partially by a more mechanistic mechanism based the initial state of convergence of the two eyes

Eye-Head Interactions During Coordinated Gaze Shifts in the Head Unrestrained Rhesus Monkey. Edward G. Freedman* and D. L. Sparks. Dept. of Psychology, Univ. of Pennsylvania, Phila., PA 19104.

We analyzed both the metrics and kinematics of over 8,000 gaze shifts made during the delayed gaze shift paradigm in order to assess the nature of the interactions between the eyes and head. We found that during gaze shifts directed along the horizontal meridian, average eye velocity increased as gaze shift amplitude increased from 5°-25°. During larger gaze shifts with significant head contributions, there was a pronounced reduction in eye velocity associated with the onset of the head component. As the head accelerated a clear reduction in the velocity of the eye component was observed, and this reduction was often larger than the increase in head velocity. During many movements there was a subsequent re-acceleration of the eyes before the end of the gaze shift. No re-acceleration of the head was observed, and as a result, during some phases of gaze shifts the eyes were decelerating while the head was accelerating, and subsequently the eyes were accelerating while the head was decelerating. Average eye velocity declined by \sim 50% as gaze amplitudes increased over a range from \sim 25°-70°, and this decrease in velocity was greater than the concurrent increase in head velocity over this same range of gaze shifts

During oblique gaze shifts the head contributed preferentially to the horizontal component, and the effect of head velocity on the eye velocity was along the vector of the head movement. As a result the duration of the horizontal components of oblique eye and gaze movements were often considerably longer than the duration of the vertical component. In contrast, the durations of the horizontal and vertical head movement components were approximately equal. Based upon this data and reports in the literature regarding the gain of the VOR during large amplitude gaze shifts, it is unlikely that this eye-head interaction is the result of the VOR. Some other source of head velocity information must be used to reduce the eye velocity of coordinated gaze shifts. Support: NEI grant# R37EY01189 and NIH grant#

FAST DISCONJUGATE SACCADE ADAPTATION. L. Averbuch-Heller, R.F. Lewis, D.S. Zee. Dept. of Neurology, Univ. Hosp., Cleveland, OH 44106 and The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21287

Horizontal saccades become immediately disconjugate when associated with gaze shifts in depth. The mechanism of this disconjugacy and its relation to disconjugate adaptation and phoria adaptation is unclear. Using prism-induced disparity, we tested disconjugate adaptation in one set of orbital positions, and examined generalization to other positions. Four subjects faced an LED array at 125 cm in front of the head. Movements of both eyes were recorded using search coils. Saccades and static ocular alignment were determined by subtracting left eye (LE) from right eye (RE) position, and measured during refixation between left 20, 0, and right 20° (L-C-R). A 10 diopter base-out prism, calling for convergence, was placed in front of the central field of RE, so that at L and R the eye viewed outside the prism. During 15 min of training, subjects made repetitive saccades riewing binocularly in the right field of vision (C-R-C). This required divergence for rightward (centrifugal) and convergence for leftward (centripetal) saccades. We compared static and dynamic alignment in both fields of vision (C-R-C-L-C) before and after training, during LE viewing. Following training, all subjects increased divergence for C-R saccades (range, 0.48 to 1.24°), convergence for R-C accades (-0.36 to -1.12°), and divergence for C-L saccades (0.33 to 0.65°); the changes were significant at the 95% confidence level. No consistent changes occurred for L-C saccades (-0.35 to 0.56°). Static alignment after training showed a tendency toward convergence in all positions of fixation (L: -0.36 to -2.08°; C: -0.31 to -2.36°; R: -0.28 to -1.13°). In 2 subjects relative convergence was greater on L fixation, in contrast with increased divergence during C-L saccades. Our results indicate some degree of transfer of disconjugate saccade adaptation to nontrained positions. Changes in dynamic alignment did not always correlate with changes in static alignment, suggesting differential control of these two processes. Supported by NIH grants EYO1849, NSO1656

MEMORY EVOKED SACCADES TO ANISEIKONIC TARGETS. Z. Kapoula*, M.P. Bucci. LPPA, CNRS-Collège de France, Paris, France.

Saccade disconjugacy appears immediately when the image is made larger for one eye and persists under monocular viewing. This suggests a fast learning mechanism. We propose an associative learning mechanism based on the pairing between disparity and saccades rather than a low-level adaptive readjustment of the saccades. To test this idea we examined memory evoked saccades to aniseikonic targets

Four subj wore an afocal magnifier (8%) in front of one eye. They were seated 123 cm in front of an arc of LEDs. Subj fixated a central LED spot. A target (a normal or a backward E subtending 0.4° x 0.2°), was then flashed to the left or to the right at 5°, 10°, 15° or 20°. The target size and its eccentricity was 8% larger in the eye with the magnifier. One second and a half after the flash, the central spot was turned off and the subi was asked to make a saccade in complete darkness to the remembered target location. Three subj were trained for 20 min and one subj for 10 min. Before and after training memory evoked saccades were also recorded under monocular viewing. Saccades were recorded binocularly with an IR device

Before training, memory evoked saccades showed only a small divergent disconjugacy (0.28°). Within 2 min of training, for all subj memory evoked saccades became larger in the eye with the magnifier. For the subj trained for 20 min the disconjugacy increased over time (mean of all training saccades 0.51°) and persisted under subsequent monocular viewing (0.89°). These results indicate that disparity information from a small target briefly flashed in the periphery can be memorized for a few seconds and used to program a disconjugate saccade. With longer training. a disconjugacy command becomes linked automatically to the saccade: memory evoked saccades remain disconjugate even in the absence of recent storage of peripheral disparity information. These findings support the idea of associative learning based on short or longer term memorization of visual disparity and capable of altering saccade conjugacy rapidly

DYNAMIC PROPERTIES OF HUMAN GOAL-DIRECTED HEAD MOVEMENTS H. Scherberger, D. Straumann, V. Henn, M. R. Duersteler* Neurology Dept., Zurich University Hospital, CH-8091 Zurich, Switzerland.

In head-unrestrained gaze shifts the contribution of the head is considerably smaller for vertical than horizontal movements, an anisotropy which might be due to the dynamic properties of head movements

We investigated head displacements during paradigms in which subjects were forced to move the head in the full amplitude of a gaze shift. Subjects were seated in front of a tangent screen (distance 1.2 m) with a central fixation spot. Additional fixation spots were placed in horizontal, vertical, and oblique directions at 30 deg distance from center. The left eye was occluded and head position was continuously monitored by the subject using a head-fixed laser beam projecting onto the screen. Without further instructions, subjects were asked to alternatively shift the laser beam from the center to the peripheral spots upon acoustic triggers, while rotational head velocity was recorded by an angular rate meter (sample frequency 1000 Hz).

In the four subjects tested we found peak angular head velocities higher in the horizontal (mean 67 deg/s) than vertical (56 deg/s) direction, while deviations from the correct target direction varied much stronger in oblique (SD 13.1 deg/s) than in purely horizontal or vertical directions (SD 8.1 deg/s)

The slower dynamics of the vertical component might explain, at least in part, the smaller head movement contribution during vertical gaze shifts. In addition, increased deviations of trajectories during oblique head displacements suggest separate horizontal and vertical channels for head movement control.

SYSTEMIC KAINIC ACID INDUCES A PERSISTENT THERMAL HYPERALGESIA IN THE MOUSE, <u>S.L. Giovengo* and A.A. Larson.</u> Department of Veterinary PathoBiology, University of Minnesota, St. Paul, MN 55108.

Noxious stimuli that lead to induction of a persistent hyperalgesic state are thought to be mediated, in part, by excitatory amino acid (EAA) activity. We tested the possibility that kainic acid (KA) activity at receptors on primary afferent C-fibers is sufficient to induce hyperalgesia. Injected intraperitoneally (i.p.), KA causes neurotoxicity in areas of the CNS containing high densities of KA receptors. We found that a subconvulsant dose of KA injected i.p., induces a long-term, irreversible (2 week) thermal hyperalgesia, as demonstrated by decreased latencies of response in the hot plate assay at 52.5°C and tail flick assay at temperatures of -10°C, 49°C, and 53°C. In contrast, there was no effect of KA on either chemical nociception or tactile allodynia. Neonatal capsaicin treatment alone, which causes degeneration of primary afferent C-fibers, increased the latency of nociceptive responses only when tested using the tail-flick assay at 49°C. However, neonatal capsaicin prevented KA-induced hyperalgesia when tested at higher temperatures, i.e. the tail-flick at 53°C and hot plate assay at 52.5°C. Hyperalgesia thus requires activity along primary afferent C-fibers for thermal nociception that is triggered by higher temperatures (52.5-53°C) and normally transmitted along larger, perhaps Aδ fibers. However, large-diameter, cold-sensitive (-10°C) pathways and small diameter, C-fiber pathways sensitive to warm (49°C) temperatures, do not require C-fibers for the induction of KA-induced hyperalgesia and may, therefore, be brought about by an action of KA at other sites in the brain or spinal cord. [Supported by NIH grant DAO4090]

SIZE DISTRIBUTION OF FOS IMMUNOHISTOCHEMICAL LABELED NEURONS IN THE DORSAL HORN OF RAT SPINAL CORD. S-F. WANG, M-Y. TASI, W-Z. SUN, B-C. SHYU. Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, 11529, R.O.C.

Laser stimulation induced c-fos expression in both superficial and deep layers in the dorsal horn of spinal cord. Repeated experiment showed high correlation (r=0.75). The labeled nuclei in the deep layer are significantly (p<0.05) larger than the ones in the superficial layer. The same phenomena happened while stimulating with 4, 8 or 12 W of laser stimulation. The labeled nuclei induced by 12 W laser stimulation were also significantly larger than the one induced by 8 W or 4W laser stimulation (p<0.05). This result demonstrated that laser induced FoS protein labeled by immunocytochemistry can be quantified and are repeatable. Therefore, it could be served as objective index of pain measurement. Furthermore, due to the size and location of the labeled FOS nuclei, the discovery of different layers of pain related dorsal horn neurons with different sizes may reflect different functions in sensory processing. The phenomena of higher intensity induced FOS protein in larger nuclei may reveal the possibility of recruitment order in the sensory system. This result could be applied to the studies of the therapeutic intervention of pain management by physical or chemical and pharmacological agents. With this established methods, the phenomena of chronic pain, such as reflex sympathetic dysfunction, could be studied in greater details in the spinal cord. Granted NSC 84-2331-B-0020089.

SUBTLE NEGLECT OF A NON-PAINFUL PART OF THE BODY IN A CHRONIC PAIN PATIENT REVERSED BY INTRALAMINAR THALAMOTOMY. F.A. Lenz', A.Hillis, R.H. Gracely, L.H. Rowland, M.C.Delano, T.S.Eckel, R.N.Bryan, P.M. Doughertv. Depts Neurosurgery Radiology, Hopkins Hospital, Baltimore, MD 21205 & NAB:NIDR:NIH.

The role of the intralaminar nuclei in nociception is suggested by findings in a 67 year old woman undergoing medial thalamotomy for treatment of intractable left dental pain without current somatic cause or testable sensory loss. Pre- and post-operative testing for inattention included dual simultaneous presentation of cutaneous, vibratory, proprioceptive, graphesthetic, visual and painful (mechanical and temperture) stimuli plus appropriate sensory controls. Cutaneous stimuli were also applied simultaneously to the face and contralateral hand (simultaneous bilateral heterogeneous stimulation - SBHS). Facial sensory stimuli were applied to the skin overlying the painful area. During preoperative testing the patient neglected stimulation of the right hand on 44% of presentations to the left cheek and right hand but never neglected the stimulation of the hand on presentations (three blocks, total of 156 presentations) to the right cheek and left hand (P<0.0001, Fisher exact). Postoperatively, the response to SBHS had changed significantly (P<0.0001, Fisher exact) so that the patient did not neglect either hand (three blocks, n=145). The MRI was negative pre-operatively but demonstrated a lesion of central median and parafascicularis nuclei postoperatively, when registered with the Schaltenbrand atlas. The reversal of subtle neglect following thalamotomy suggests that the intralaminar nuclei may have a role in directed attention to the painful area of the body. Support: NIH P01 NS32386-Proj. 1.

PCR DIFFERENTIAL DISPLAY IDENTIFIES RAT DORSAL ROOT GANGLIA mRNAS WHICH ARE REGULATED IN A NEUROPATHIC PAIN MODEL K.E. Rogers*, M.G. Erlander, K.D. Wild, S.K. Yagel, J.E. Galindo, and R.B. Raffa. Drug Discovery, The R. W. Johnson Pharmaceutical Research Institute, Spring House, PA 19477 and La Jolla, CA 92121

Animal models have recently been developed for the study of neuropathic pain (NP). The "Chung" model mechanism (Kim & Chung, Pain 50:355-363, 1992) is particularly attractive since the animals develop characteristics which closely mimic the clinical disorder, including allodynia, hyperalgesia, and lack of sensitivity to opioid analgesics. We have chosen to analyze this NP model in a differential display paradigm to identify specific transcriptional changes which occur with the development of this type of pain. Rat spinal nerves, L₅ and L₆ were tightly ligated and animals were tested for sensitivity of hind paw to stimulation with von Frey filaments. In order to meet the NP criteria and be included in the differential display analysis, animals needed to respond to < 4 g of pressure on post-operative (PO) day 7 by lifting the hind paw. Animals meeting the criteria were sacrificed on PO day 8 and L₅ and L₆ dorsal root ganglia (DRG) from both the ligated and non-ligated sides were removed. Total RNA was extracted from dissected DRGs and cDNA synthesis was subsequently performed to generate a template for differential display analysis. Differentially expressed mRNAs in ligated vs. contralateral control have been identified and will be presented.

CHANGES IN DISTRIBUTION OF CGRP PEPTIDE FOLLOWING SPINAL CORD HEMISECTION PROVIDE A MECHANISM FOR CHRONIC CENTRAL PAIN STATES, C.E. Hulsebosch* and M.D. Christensen. Anat.& Neurosci., Univ. of Texas Medical Branch, Galveston, TX, 77555-1069.

Spinal cord injury results in chronic pain states in which the underlying mechanism is poorly understood. To begin to explore possible mechanisms, calcitonin gene-related peptide (CGRP), a neuropeptide confined to fine primary afferent terminals in laminae I and II in the dorsal horn of the spinal cord and implicated in pain transmission, was selected. To test the temporal and spatial distribution of CGRP, immunocytochemical techniques were used to examine the spinal cord following T-13 spinal cord hemisection in adult male Sprague Dawley rats compared to controls (N=5) using standard immunocytochemical techniques. Spinal cords from spinally hemisected rats (N=5, per time point) were examined on post operative day (POD) 3, 5, 7, 14 and 108 following surgery. Image analysis techniques demonstrated an increased density of reaction product that was statistically significant, in laminae III and IV, both ipsilateral and contralateral to the lesion which extended at least two segments rostral and caudal to the hemisection site by POD 14, and remained significantly elevated as long as POD 108. Increases in density of CGRP were found in the dorsal roots, in Lissauer's tract, and in motor neurons in the ventral horn ipsilaterally. Sham operated rats displayed CGRP immunoreaction product in laminae I and II, Lissauer's tract and the dorsal roots. Since upregulation of CGRP would occur in an acute temporal window, these results are interpreted to be invasion of laminae III and IV by sprouting of fine primary afferents. These data indicate changes in density and distribution of CGRP following spinal hemisection which could contribute to the development of various pain states in human SCI. TRANSCRANIAL ELECTROANALGESIA (TEA): MRI STUDY OF INTRACRANIAL CURRENT DENSITIES (CD) AND PATHWAYS (CP) IN RABBIT. V. Lebedev*, M. Joy, J. Gati. Lab. of Electroanagesia, Pavlov Inst of Physiology, S.-Petersburg 199034, Russia, Inst. of Biomed. Engineering, Univ. of Toronto, Toronto, MSS 1A4, Canada. It was shown (Lebedev et al., '83, '88) that impulse current (C) of

special parameters applied sagittally (AS) could elicit a naloxonereversible analgesia in animals and humans, whereas the same C applied bilaterally (AB) was ineffective. Present study was done to estimate noninvasively, by means of MRI processing (Scott, 1991), intracranial CD and CP of CAS and CAB through the coronal and sagittal sections of rabbit brain. In contrast to CAB, which passed through brain tissue and intracranial spaces rather diffusely, CAS passed through areas containing cerebro-spinal fluid. The highest CD levels were observed below the brain in basal cisternas connected in series, and inside the brain in ventricles (V). The intaventricular CP included anterior horns of lateral V - foramina Monro - 3rd V - aqueduct - 4th V - foramina Luschka. The intreventricular and cisternal CP were interconnected in areas of infundibulum (through the ventral recess and thin bottom of 3rd V) and in lateral parts of medulla (through lateral recesses of 4th V). These MRI data demonstrated that CAS has an opportunity to pass the parts of brainstem-antinociceptive structures hypothalamus, midbrain and medulla, and provided the explanation of efficacy of TEA elicited by CAS.

CEREBRAL ACTIVITY IN ACUTE AND CHRONIC VISCERAL PAIN IN HUMANS. D.H.S. Silverman*. J. Munakata, H. Ennes. C.K. Hoh, M. Mandelkern, E.A. Mayer. Depts. of Medicine and Nuclear Medicine, UCLA Medical Center and West LA VA Medical Center, Los Angeles. CA 90095.

Perception of pain is altered in patients with certain chronic pain syndromes The purpose of this investigation was to determine regional cerebral responses to an acute visceral pain stimulus, in subjects with and without a chronic visceral pain disorder. Effects of distal intestinal pressure stimuli on regional cerebral blood flow discrete. Effects of distal intestinal pressure stimul on regional cerebral blood flow were assessed with O-15-valet positron emission tomography (PET) in 16 subjects, half with a chronic intestinal pain disorder, the irritable bowel syndrome (IBS). A balloon catheter was placed in the distal intestine 30 min prior to imaging sessions. Following IV administration of 40 mCi O-15 water, PET data were obtained in a 10-sec frame followed by 18 5-sec frames, and summed for all frames proceeding entry of tracer into the brain. PET scans were obtained at baseline, during delivery of non-painful pressure stimuli, and during both actual and simulated delivery of painful stimuli. Scans were interpreted using statistical parametric mapping and region of interest methods of analysis, and results were compared according to condition, and to subjects ratings of perceived intensity of painful stimuli. In healthy subjects, perception of pain during actual or simulated delivery of anticipated painful stimuli was significantly associated (p < 0.01) with activity of the anterior cingulate cortex (Brodmann's areas 24 and 32), while no anterior cingulate response to delivery or perception of non-painful stimuli was seen. In IBS patients, in contrast, the anterior cingulate cortex failed to respond to either actual or simulated delivery of painful stimuli. During the latter, however, significant activation (p < 0.01) of the left prefrontal cortex (maximal in Brodmann's area 10) of IBS patients was seen. In conclusion, perception of intestinal pain was associated with a specific pattern of regional cerebral activity involving most significantly the anterior cingulate cortex in healthy subjects. This pattern was aberrant in patients with a chronic intestinal pain disorder. RIGHT-HEMISPHERE PREPONDERANCE OF RESPONSES TO PAINFUL CO₂ STIMULATION OF NASAL MUCOSA. R. Hari*, K. Portin, B. Kettenmann, V. Jousmäki and G. Kobal. Brain Research Unit, Low Temperat. Laboratory, Helsinki University of Technology, 02150 Espoo, Finland, and Dept. Experimental and Clinical Pharmacology, Univ. Erlangen-Nümberg, 91054 Erlangen, Germany.

We recorded whole-scalp (Neuromag-122TM) cerebral magnetic fields from 9 healthy adults to painful CO₂ pulses (duration 200 ms, concentration 65–90%), embedded in a continuous airflow (140 ml/s, 36.5°C, humidity 80%). The stimuli were led to the left or right nostril in successive experiments once every 20 or 30 s. The subjects were trained to breathe through the mouth to avoid respiratory air flow in the nasal cavity. The recording passband was 0.03–90 Hz and 16 single responses were averaged per run. Five out of the 9 subjects showed replicable reponses 280–400 ms after stimulus onset, with shorter latencies with higher CO₂ concentrations. The signals originated in the insular region, close to the SII cortex, and were considerably stronger over the right than the left frontotemporal region. The right-to-left ratio of mean signal amplitudes, calculated across 16 channels over each hemisphere, was 2.3 for both left and right nostril stimuli. The results imply a clear right-hemisphere dominance in responses to painful CO₂ stimulation of the nasal mucosa.

Non-dominant hemispheric preference for pain affect: PET studies. Jen-Chuen Hsieh¹.².′, Bjorn A. Meyerson², Jan Hannerz², Per Hansson³, Martin Ingvar². ¹Dept. Anesthesiology, Veterans General Hospital-Taipei & Institute of Neuroscience, National Yang-Ming University, Taiwan, R.O.C. ²Dept. Clinical Neuroscience, ³Neurogenic Pain Unit, Karolinska Hospital, Sweden.

We reported three positron emission tomographic (PET) studies of pain syndromes to elucidate the preference of the right hemisphere in attributing emotional valence and attention to pain suffering. Right-handed patients with ongoing painful peripheral mononeuropathy (PMN), episodic cluster headache (CH) or painful trigeminal neuropathy (PTN) were investigated using PET. Pain alleviation was obtained using regional nerve block for PMN and electric extradural precentral gyrus stimulation for PTN. Nitroglycerin was employed to provoke CH attack. Comparisons were made between ongoing/provoked painful state vs. pain-alleviated/resting state. Regardless of painful side, the right Brodmann area (BA)24 of the ACC and the BA9/32, adjoining the MPFC (BA9) and the ACC (BA32) were preferentially engaged. The right temporopolar region (area 38), known to be involved in the emotion of fear, was additionally activated during the experience of excruciating CH attack. Our studies not only verifies the preferential role of the right hemisphere in the appreciation of pain suffering but further supports that sustained chronic pain, being devoid of the motivational component of an escape response, targets the right hemisphere. The differences between the activation patterns of acute intense pain and chronic sustained pain conform to the current neuropsychological theories of hemispheric asymmetries in the limbic regulation of affect and cognition.

DEFINING PROPERTIES OF TEMPORAL SUMMATION FOR SECOND PAIN SENSATIONS IN HUMANS. C. J. Vierck*, R. L. Cannon and A. J. Acosta-Rua. Dept. of Neuroscience, Univ. of Florida Col. of Med., Gainesville, FL 32610-0244.

A method of thermal stimulation is described which produces dramatic temporal summation of pain sensations, akin to the phenomenon of "windup" of central neuronal responses to input from unmyelinated nociceptors. Windup has been attributed to activation of NMDA receptors, and abnormal NMDA activation and temporal summation are frequently mentioned as mechanisms underlying certain chronic pain conditions. Therefore, it would be advantageous for clinical testing to assess whether temporal summation of pain sensations is abnormal, which requires definition of the time course of temporal summation and decay in normal subjects. The method of stimulation involved naturalistic brief contact (700 msec) of a preheated thermode (6 cm2) with the glabrous skin of either hand. Trained subjects rated the peak magnitude of second pain sensations (latencies greater than 2 sec) with a numeric rating scale that is linked to verbal descriptors (e.g., 20 = pain threshold; 90 = very, very strong pain). At repetition rates of 0.33 Hz, temperatures of 45 to 53 deg. C produced ratings below pain threshold on the first presentation, and temporal summation increased with temperature. Ratings of 80 (very strong pain) were obtained after 12 contacts at 53 deg. C. Temporal summation was inversely proportional to interstimulus interval and was absent at 7 sec. The decay of temporal summation was tested by presenting two series of 10 contacts (at 0.33 Hz) that were separated by intervals of 4, 5 or 6 sec. A rapid rate of decay was observed in these normal subjects (complete by 6 sec). Comparisons of temporal summation of sensations were made with skin temperature recordings from a thermistor inserted beneath the epidermis of anesthetized monkeys. Phasic increases in skin temperature immediately following each stimulus were constant over the repetition rates, and baseline temperatures (immediately before each stimulus) were not related to interstimulus interval in the same manner as the sensory ratings. COGNITIVE PERFORMANCE AND NUTRITIONAL STATUS IN INDIVIDUALS EVALUATED FOR SENILE DEMENTIA. G. Shor-Posner*, J. Button, J. Bean, J. Demirovic, MK Baum and RJ Prineas. Dept of Epidemiology and Public Health, U Miami School of Medicine, Miami, Florida.

An important role for B vitamins in neuropsychological function has been demonstrated. The present study evaluated cognitive performance and nutritional status in a subsample (n=120:37 men, 83 women) of 2,575 elderly subjects being examined for dementia. Cognitive impairment, as measured by SPMSQ error scores (adjusted for ethnicity and education), was observed in 28 men and 55 women (69% of the subsample, mean age 78.8 \pm 7 yrs). Logistic regression indicated that age and vitamin B_{12} status were significantly related to cognitive performance (p<0.05). Although serum albumin levels were within the normal range in the impaired and non-impaired groups, vitamin B_{12} levels and dietary B_{12} intake were significantly lower in the impaired group; 476 \pm 261 vs 634 \pm 351 non-impaired, (p<0.01), and 13 ± 13 vs 28 ± 45 mg/d (p<0.01), respectively. Moreover, serum vitamin B_{12} level was significantly correlated with SPMSQ adjusted error scores (p=0.05). Vitamin B_8 intake, which was significantly correlated with B_{12} intake (r=0.81, p<0.0001) was lower in the impaired group (ns), and positively related to Direct Assessment of Function Status scores in the women (r=0.35, p<0.004), but not the men (p<0.13). These results suggest that adequate intake of vitamins B_{12} and B_6 may be particularly important in maintaining cognitive function in aging individuals, and underscore the importance of gender-specific nutritional asssessments in relationship to cognitive performance.

INFORMATION PROCESSING IN MILD HYPOGLYCEMIA: A NEW METHOD FOR EXAMINATION R. Lobmann', B.G. Trümper', K. Wagner', G. Pottag', H.G. Smid', H.J. Heinze' and H. Lehnert'. Dept. of Neurophysiology. Otto-von-Guericke-University. Magdeburg. Germany Little is known about distinctive and topographically related effects of hypoglycemia on cognitive functions. We employed novel event- related potential

Little is known about distinctive and topographically related effects of hypoglycemia on cognitive functions. We employed novel event- related potential recording techniques (ERP's) in a hybrid selective-attention/response-choice task. We presented prespecified features for example red color. Other stimuli also occur in the task but were presented in different cognitive reaktion. Then we messured the onset of selection negativity as well as the response selection after stimulus selection. To study single components (stimulus selection, response choice, reaction time) of cognitive function impairement during a stepped hypoglycemic clamp (< 3mmob/l), two groups of 12 healthy volunteers were studied. One group performed different cognitive tasks during the following phases: englycemia-hypoglycemia-lypoglycemia. The second group had only three englycemic phases (randomized, single blind). The tasks consisted of recognition memory performance, selective attention and choice motor responses to colored letters. We also investigated 12 diabetic patients with IDDM and a group of 12 NIIDM patients. The ERP's related to selective identification of colored letters, to central activation of motor responses in primary motor cortex and reaction times to these letters were delayed during hypoglycemia as compared with the first phase of normoglycemia (32 msec, 72 msec, ps all 2-65). In particular we found that hypoglycemia impairs recognition memory and primarily affects early components of cognitive responses such as motor cortex activation and selection of input information. Our results suggest that hypoglycemia delays stimulus selection, with consecutively delayed central and motor processing.

EFFECTS OF SCOPOLAMINE ON THE PERFORMANCE OF RATS IN A DELAYED MATCHING TO POSITION TASK IN AN 8-ARM RADIAL MAZE. Poorheidari G, Stanhope KJ & Pratt JA SPON: Brain Research Association. Dept. of Physiology & Pharmacology, Univ. of Strathclyde, Glasgow UK. Cerebrus Ltd. Dept. of Neuropharmacology, Silwood Park, Ascot, Berkshire UK.

copolamine-induced "memory impairment" has been extensively used in various animal models of dementia including the radial arm maze. However, it has still to be resolved whether the putative cognitive effects can be separated from, or indeed are a consequence of, other psychopharmacological effects of the drug. A delayed matching to position task in the radial maze was employed to examine the effects of scopolamine. Male Long-Evans hooded rats were trained to find the only baited arm (as the sample) from the 8-arm radial maze (first trial). Then after a delay of 5 hours, rats were returned to the maze to find the baited arm (the same as the sample) on the second trial. In three experiments, scopolamine (0.25 mg/kg, i.p.) or saline were administered 20 min before the first trial, immediately after the first trial, and 20 min before the second trial, respectively. Three measurements were recorded: 1) the number of the arm entries before entering the baited arm in the second trial (errors); 2) time taken for the rats to find the baited arm in the first trial; and 3) time taken for the rats to find the batted arm in the second trial. In a separate experiment, the effect of scopolamine (0.25 mg/kg, i.p.) on locomotor activity was also measured. Analysis of the radial maze data revealed that when the drug was administered before either the first trial or the second trial, it took significantly longer for the scopolamine-treated group than the saline-treated group to find the baited arm on either of the trials. There was no significant differences between the two groups in the other measurements. However, scopolamine significantly increased the locomotor activity behaviour. These results question the specificity of the "cognitive" impairment induced by scopolamine in many radial arm maze tasks. This work was supported by SHERT and Iranian Ministry of Health

PRESERVED AND IMPAIRED MEMORY PERFORMANCE IN RETROGRADE AMNESIA: A CASE STUDY. E.A. Phelps*, J.D. Sweder, and K.S. LaBar. Dept. of Psychology, Yale University, New Haven, CT 06520.

We report a patient, T.A., who became amnesic following encephalitis. T.A. is a 50 year old man who performs in the low average range on most neuropsychological tests with the exception of those assessing memory where his performance is impaired, indicating a moderate to severe anterograde amnesia. In addition, T.A. reports no memory for events prior to his illness, suggesting a retrograde amnesia. On examination, T.A. is at chance on recognizing events that occurred over the past 40 years, although he does show above chance recognition of events that occurred in the first 10 years of his life. This temporally graded retrograde amnesia affects personal events, public events, pictures of famous individuals and family members, and meanings for words that were commonly used in only limited periods of his life. He also shows a marked change in personality and new preferences for food and music.

In contrast, T.A. shows relatively intact semantic memory as demonstrated by his ability to use language, solve simple arithmetic problems, and describe the system of government in the U.S.. This spared semantic memory is consistent with other reported cases of retrograde amnesia (e.g., Tulving et al., 1988; O'Connor et al., 1992). In addition, he demonstrates intact memory for complex skills, such as driving, billiards, bowling, and archery. T.A.'s intact memory for skills suggests a distinction between lifelong memory for events and complex skills.

NEURAL SUBSTRATES OF REASONING: AN fMRI STUDY OF RAVEN'S PROGRESSIVE MATRICES TEST. V. Prabhakaran 1*, J.A.L. Smith, ² J.E. Desmond², G.H. Glover³, J.D.E. Gabriell². Program in Neurosciences ¹, Depts. of Psychology ² and Radiology ³ Stanford University, Stanford CA 94305

Psychology² and Radiology³, Stanford University, Stanford, CA 94305.

The Raven's Progressive Matrices Test is a widely used measure of reasoning ability that reliably predicts performance in reasoning tasks from a number of different domains. fMRI was utilized in order to identify neural substrates involved in performing this reasoning task. Three types of problems were adapted from the Raven's test: 1. Easy problems consisted of a 3X3 block of patterns related by the pairwise constant rule (Carpenter & Just, 1990). The problems can be solved by a visuospatial strategy . 2. Hard problems consisted of patterns related by different rule sets (Distribution of 3, Distribution of 2, etc.) These problems cannot be solved by simple visuospatial strategy but require abstract/analytical reasoning. 3. Match problems consisted of nonsense blocks of 3x3 patterns. Subjects matched a pattern to one of eight choices given. The match problems served as a control for sensory and motor areas of activation irrelevant to the cognitive factors of interest. Three combinations of problems (st (match-hard, match-easy, and easy-hard) were presented to subjects in the scanner. Each set contained 12 problems (6 cycles of alternating problem types). Subjects were allowed 30 seconds per problem. Presentation of problem sets was counterbalanced across subjects(n=6). Imaging was performed at 1.5T, using a T2* sensitive gradient echo spiral sequence (TR=720 msec, TE= 40msec, flip angle=65*). Extensive activation was seen bilaterally in posterior parietal, inferior temporal, extra-striate, prefrontal, and premotor areas in the match-hard condition. Less activation was found for these areas in the match-easy condition. In the hard-easy condition high activation occurred in the left posterior parietal, area and bilateral prefrontal areas.

PRIMING AND INTERFERENCE PHENOMENA IN A MODEL OF COGNITIVE RESPONSE GENERATION, <u>Vijaykumar Gullapalli² and Jack Gelfand*¹</u>. Dept. of Psychology¹ and Dept. of Mech. Eng.², Princeton University, Princeton, NJ 08544. We present a general model of the brain mechanisms operating in

We present a general model of the brain mechanisms operating in cognitive tasks that involve the generation of responses to external stimuli. The model is consistent with the anatomy and physiology of cortical and subcortical structures involved and includes the dynamics of cortico-thalamo-basal ganglionic loops (Gullapalli and Gelfand, Proc. NYAS, 769:375-380, 1995). This model uses groups of neurons corresponding to cortical columns to form distributed representations of the internal state of the organism or external state of the environment. These representations, including the representation of the goal of the task, are used by dynamical processes in prefrontal cortico-thalamo-basal ganglionic loops to generate appropriate responses to stimuli in various tasks. In this study, we report on priming and interference phenomena that result from these dynamical processes in the model. We found that activation of a feature that is relevant to the task produces priming if the feature is related to the appropriate response given the task and the stimulus. If the feature is relevant but inappropriate for the task/stimulus combination, it results in interference, slowing down the selection of the response. We discuss this model in terms of the representation of input stimuli and goals and the role of prefrontal cortex circuits in working memory Supported by a grant from the James S. McDonnell Foundation.

HIPPOCAMPAL ACTIVATION DURING MEMORY ACQUISITION AND RETRIEVAL USING FUNCTIONAL MRI S.Y. Bookheimer*, M. Dapretto, G. Small, J. Wang, M. Cohen, Brain Mapping Division, UCLA School of Medicine, Los Angeles, CA 90024.

Los Angeles, CA 90024.
Lesions of the human hippocampus (HC) produce deficits in acquiring new memories, though retrieval of previously acquired information remains essentially intact. Nonetheless, single unit recording studies in animals and humans reveal neural activity in HC during memory retrieval as well as acquisition. We used functional MRI to measure changes associated with cerebral blood flow during the learning and recall of unrelated paired associates. This task is markedly impaired in patients with left mesial temporal lesions. Six normal volunteers underwent fMRI during 4 auditory presentations of 7 unrelated word pairs, interspersed with an attention control task in which they monitored for a tone. These were followed by retrieval blocks in which the first word in each pair was presented, and subjects silently generated the correct associate. Rest blocks were obtained prior to and after the activation sequence. Images were acquired on a GE 1.5 Tesla Signa MR scanner with an SPGR sequence (TR=70ms; TE=50ms; FA=45°; 128x256; 0.75 NEX) using oblique slices along the longitudinal axis of the left HC. Regions of interest (ROI's) were made on the basis of co-planar anatomical scans in the anterior hippocampal formation, and signal intensity (SI) was determined for each activation block. In comparison to the control tasks, the MR signal intensity in the HC was greater for both learning and recall. The magnitude of the SI changes increased over trials in correlation with the rate of learning, both in the learning and the retrieval blocks. During the interspersed attention control blocks, the SI returned to baseline levels. Our data are consistent with patient studies implicating the HC in forming new associations, and with single unit recording studies which demonstrate increased neural activity in the HC during memory retrieval. The data support a model HC function positing that, in addition to forming new associations, the HC is important in reconstructing memories from partial cues.

NEUROPHYSIOLOGY OF DUAL TASK PERFORMANCE: A PET 015 STUDY. T. E. Goldberg.* K. Fleming. K. F. Berman, J. Van Horn, G. Esposito, J. Ostrem, J. M. Gold, D. R. Weinberger. Clinical Brain Disorders Branch, IRP, NIMH Neurosciences Center at St. Elizabeths, Washington, DC 20032 USA

Introduction. The neurophysiological response to manipulations of information

Introduction. The neurophysiological response to manipulations of information processing demands in dual task paradigms has received little attention in functional neuroimaging. Thus, it has been unclear whether the effects of excessive cognitive load would increase or decrease local metabolism. Method, Fourteen normal subjects participated. As a primary working memory task they received a computerized, paced Wisconsin Card Sorting Test (WCST). As a secondary task they received rapidly paced shadowing (in which the subjects hear, then repeat words). PET cerebral blood flow measurements were made using the O15 water technique. Data were analyzed by Statistical Parametric Mapping. Results, A number of different conditions were contrasted. In the key comparison we examined whether the pattern of brain activation was different for simultaneously performing the WCST and shadowing words as opposed to the pattern when the two tasks were performed individually and then "summed." Significant deactivations were noted in prefrontal regions. This stands in contrast to numerous activation foci in prefrontal cortex produced when the WCST was performed alone. Thus, shadowing during the WCST produced an activation pattern "more" than the sum of its constituent tasks. In addition, large increases in cerebellar blood flow were observed. Discussion, A fundamental characteristic of prefrontal cortex appeared to be an attenuation of activation in the face of supramaximal demands for stimulus processing. A second physiological response to dual tasks that demand rapid attentional shifts and multiple stimulus response mappings involved large increases in neocerebellar activation, perhaps reflecting a time sharing function for this structure

384 9

EXTRASTRIATE AND FRONTAL CONTRIBUTIONS TO FACE AND LOCATION WORKING MEMORY: AN FMRI STUDY S.M. Courtney*, J.Ma. Maisog, L.G. Ungerleider, J.V. Haxby. SFBI, LPP, NIMH, Bethesda MD 20892.

Differences in the organization of working memory (WM) function in the dorsal/spatial and ventral/object vision pathways were investigated using functional magnetic resonance imaging. Face and location WM tasks were performed during 2 sessions, each with 8 sets of 88 scans (TR 3s) by 3 healthy volunteers. Subjects were presented with an alternating series of WM and sensorimotor control trials. Each WM trial consisted of 3 face pictures, shown one at a time, each in a different location on the screen, followed by a 9 sec delay, which was then followed by the presentation of a single face in a single location. For the face task, subjects indicated whether the fourth face was the same as one of the three faces in the memory set. For the location task, subjects indicated whether it appeared in one of the three locations. Time series data were analyzed using multiple regression in order to determine the relative contributions of visual stimulation, perceptual processing, and sustained activity during the memory delay. Both tasks produced activation in occipital, posterior ventral temporal, parietal, and prefrontal cortices. In prefrontal cortex, sustained memory delay activity in the posterior superior frontal sulcus, bilaterally, was greater during the location task than during the face task. Memory delay activity in bilateral inferior and mid-frontal cortices was greater during the face task than during the location task. In extrastriate cortex, bilateral regions in superior parietal and intraparietal sulcal cortex showed memory delay activity during the location but not the face task. By contrast, during the face task, a bilateral ventral temporal region showed memory delay activity that was smaller and less consistently observed than the parietal activity during the location task. These results demonstrate differences in the functional organization of WM processing in the dorsal and ventral pathways. Different prefrontal regions are associated with spatial and object WM. Moreover, extrastriate areas in the dorsal pathway play a greater role in location WM maintenance than extrastriate areas in the ventral pathway do in object WM.

DELAY-SPECIFIC ACTIVITY WITHIN PREFRONTAL CORTEX DEMONSTRATED DURING A WORKING MEMORY TASK: A FUNCTIONAL MRI STUDY. E Zarahn,* GK Aguirre, M D'Esposito

Department of Neurology, University of Pennsylvania, Phila, PA 19104 Single-unit recordings in non-human primates have revealed neurons in the prefrontal cortex that increase their firing during a delay between the presentation of information and its later use in behavior. Using the "cognitive subtraction" technique, several imaging studies have claimed that activity observed within human prefrontal cortex is a consequence of this delay period. It is possible, however, that this activity is also related to unsubtracted stimulus presentation and response components of the task. Using echoplanar hMRI at 1.5 T, we tested the hypothesis that the prefrontal cortex increases its functional activity specifically during the delay period of a spatial delayed response task. Subjects were presented pseudo-randomized no-delay and delay trials. Six runs were performed and combined for analysis, allowing observation of significant activity within individuals. A general linear model for correlated observations was used to assess the effects of three independent variables: 1) stimulus presentation, 2) delay, 3) response. This approach allowed signal changes to be correlated directly in time with various approach allowed signal changes to be correlated directly in time with various temporal components of the delayed response task. In two subjects, a region within prefrontal cortex displayed activity attributable to the delay period of the task. Premotor regions displayed activity in response to all three components of the task. In contrast, primary sensorimotor cortex displayed activity correlated only with response. The different profiles of activity observed in our task agree with findings of single unit electrophysiology experiments. This study identified and differentiated regions involved in stimulus processing, temporary storage of information, and response execution. This method of analysis represents an alternative to "cognitive subtraction" and may be suitable for analysis of other cognitive activation paradigms.

ACTIVATION OF IDENTICAL PREFRONTAL REGIONS BY DELAY AND NON-DELAY COMPONENTS OF A WORKING MEMORY TASK: A fMRI STUDY. M. D'Esposito,* GK. Aguirre, E. Zarahn, C Thompson. Dept. Neurology, Univ of Pennsylvania, Phila, PA 19104

Neurons in macaque dorsolateral prefrontal cortex increase their activity during delayed response tasks. In these tasks, neuronal activity is observed in response to memory and non-memory components. Using echoplanar fMRI, we tested the hypothesis that prefrontal activity in humans could be observed during processes in addition to working memory. Subjects performed a three condition experiment (memory, attention, rest). In the memory condition, subjects observed serially presented stimuli and determined if each stimulius was the same as that presented two stimuli back. determined if each stimulus was the same as that presented two stimuli back. Stimuli were either letters or white squares presented in various locations. In the attention condition, subjects were asked to identify a single predetermined letter or location. Three runs of each condition were performed and combined for analysis, allowing observation of significant activity within individuals. Data within prefrontal cortex were analyzed using a modified general linear model for correlated observations. In three subjects, both the verbal and spatial working memory conditions activated dorsolateral prefrontal cortex within middle frontal gyrus (areas 9/46). In addition, activation to a lesser degree was observed during the attention task (as compared to rest), within these same prefrontal regions. We conclude that this region of prefrontal cortex supports processes in addition to working memory. (i.e. the prefrontal cortex supports processes in addition to working memory, (i.e. the retention of information for subsequent action) such as sustained attention. The region of prefrontal cortex activated in this study may comprise distinct neuronal populations, beyond the spatial resolution of fMRI, that support separable components necessary for bridging perception to action across time. These results illustrate the need to consider the neural correlates of the control task in cognitive subtraction paradigms. Supported by McDonnell-Pew and NIH grant NS01762.

RECALL OF TOPOGRAPHIC APPEARANCE AND POSITION: A DISSOCIATION DEMONSTRATED WITH fMRI. $\underline{GK\ Aguirre}$,* $\underline{E\ Zarahn}$,

M D'Esposito Dept. of Neurology, Univ. of Penn., Phila., PA 19104

Patients with selective topographical disorientation appear to fractionate into those unable to recognize the visual features of places and those unable to recall the spatial relationships between places. To identify the neural basis of this dissociation we used fMRI to observe ss during their recall of topographic appearance and position information. Two ss learned to criterion a virtual-reality appearance and position information. Two ss tearned to criterion a virtual-reality town composed of sixteen distinctive, named, "places". During whole-brain scanning ss were presented with snapshots of the environment and a place name. During the Appearance $\{A\}$ task, ss indicated if the name matched the pictured place, while during the Position $\{P\}$ task, ss indicated the direction of the named place relative to the scene. A Control $\{C\}$ task required ss to alternate left-right responses to scrambled visual scenes and names. All tasks were 60 seconds in duration and self-paced. Multiple runs were collected and analyzed using a modified general linear model for correlated observations, allowing the using a modified general infear model for correlated observations, anowing incoherential observation of statistically significant results in a single subject. Maps were thresholded at p < 0.0167 (corrected). Both the A-C and P-C comparisons demonstrated bilateral posterior cingulate (area 30), posterior cuneus (19), posterior parietal (7) and left premotor (6) activity for both ss. Inferior, medial, temporal-occipital cortex (19/37) was active bilaterally in both subjects for only the A-C condition. The direct P-A comparison revealed a dorsal/ventral dissociation. Activity in the temporal-occipital area was significantly greater during the A condition (t=-5.4) while activity in the left premotor (both subjects, t=4.5, 5.4) and left posterior parietal cortex (one subject, t=4.9) was significantly greater during the P condition. The dissociated areas of activity observed during the recall of topographic appearance and position information are consistent with lesion sites that have been identified for the classes of topographical disorientation. This study provides evidence that representation of large scale space is in part subserved by separable neuro-anatomical components.

IN VITRO AUTORADIOGRAPHIC STUDY OF GUANYLYL-5'-[γ-[35S]THIO]-TRIPHOSPHATE BINDING STIMULATED BY 5-HT, AGONISTS IN GUINEA PIG BRAIN SECTIONS. C. Waeber and M.A. Moskowitz*. Stroke and Neurovascular Regulation Laboratory, MGH, Harvard Medical School, Charlestown MA 02129.

We have measured the stimulation of [1³S]GTPγS binding in guinea pig brain slices using the technique described by Sim et al (PNAS 92, pp. 7242-7246). Briefly, 18 μmthick sections were incubated in the presence of 2 mM GDP and 0.04 nM [$^{35}\text{S}]\text{GTP}\gamma\text{S}$ for 2 hours at 25°C. After 2 x 2 min. washing, the slides were dried and exposed to Kodak Biomax MR films along with 14 C standards. In the absence of agonist, 13 S]GTP γ S labeling was heterogeneous throughout the brain and was drastically decreased by increasing concentrations of GDP (from 1 to 8 mM). Under the study conditions (2 mM GDP), basal [35S]GTPyS binding was very high in the superficial laminae of the spinal cord and trigeminal nucleus and was overall higher in gray matter (in particular, substantia nigra, interpeduncular nucleus, hippocampus, neocortex, striatum) than in white matter. The 5-HT_{1A} agonist 8-OH-DPAT (10 nM to 1 µM) dose-dependently stimulated $[^{35}S]GTP\gamma S$ binding in hippocampus and deep cortical layers. At 1 μM , hippocampal binding was stimulated 3-fold over basal binding, this effect was inhibited by 1 μ M NAN-190. The stimulation obtained with the 5-HT_{1D/1F} agonists sumatriptan and CP-122,288 (0.1 to 10 μM) was much weaker: 10 μM sumatriptan and CP-122,288 induced a 30%, respectively 50%, increase in binding in the substantia nigra. Comparable increases were also found in the striatum, neocortex, central gray and superior colliculus. Interestingly, 2- (sumatriptan) and 5-fold (CP-122,288) increases in binding were observed in hippocampus, with a distribution identical to that seem with 8-OH-DPAT. The non selective agonist metergoline (10 µM) did not enhance binding in the substantia nigra but stimulated more than 5-fold in hippocampus. These results suggest that, in this system, 5-HT $_{1A}$ receptors display a more efficient coupling than 5-HT $_{1D/F}$ receptors, and that sumatriptan and CP-122,288, despite their 10-fold lower affinity at 5-HT $_{1A}$ receptors. tors, activate the latter to a larger extent than 5-HT $_{1DJF}$ receptors. P19 MOUSE EMBRYONAL TERATOCARCINOMA CELLS EXPRESS THE 5-HT, RECEPTOR IN THEIR NEURONALLY DIFFERENTIATED STATE. D. Benjamin* and L.A. Pohorecky. Division of Neuropharmacology, Center of Alcohol Studies, Rutgers University, Piscataway, New Jersey 08855.

Division of Neutropharmacology, Center of Alcohol Studies, Rutgers University, Piscataway, New Jersey 08855. The P19 mouse embryonal carcinoma cell line is used to study neuronal differentiation processes and provides a useful model system for NMDA receptor-mediated neurotoxicity. Four days of treatment with retinoic acid (500 nM) induces the P19 cell to terminally differentiate to a neuronal phenotype. In our ongoing studies of the 5-HT receptors, we tested P19 cells for the expression of 5-HT_{1,A} >-HT_{2,A} and 5-HT_{2,C} receptors on the P19 cells in their undifferentiated or neuronally differentiated state. Reverse-transcription polymerase chain reaction did not detect mRNA for the 5-HT_{2,A} or 5-HT_{2,C} receptors in the P19 cell in either state. The 5-HT_{1,A} receptor, however, was expressed at high density in the differentiated, but not undifferentiated P19 cells. Receptor binding studies with [3 H]-8-OH-DPAT showed high affinity (Kd \cong 2 nM), specific, and saturable binding in neuronally differentiated P19 cells. Reverse transcriptase-polymerase chain reaction studies confirmed the presence of mouse 5-HT_{1,A} message; studies are in progress to verify full sequence identity. Because the P19 cell is, to our knowledge, only the second cell line to constitutively express the mouse 5-HT_{1,A} receptor it should provide a useful model system to study the knowledge, only the second cell line to constitutively express the mosts 5-HT_{1s}, receptor it should provide a useful model system to study the regulation of the 5-HT_{1s} receptor, and because it also expresses a functional NMDA receptor it should be useful to study the effect of 5-HT on NMDA toxicity. (Partial support from MH52293 and AA10124).

CELLULAR LOCALIZATION OF 5-HT_{2A} AND 5-HT₄ RECEPTORS IN ENTERIC NERVE AND SMOOTH MUSCLE E. Fiorica-Howells1 S. Garlow² and M.D. Gershon^{1*}. ¹Dept. Anat. & Cell Biol., Columbia Univ. P.&S., New York, NY 10032 & ²Dept. Psych., Emory Univ. Atlanta, GA 30322.

Over 95% of the body's 5-HT is located in the gut. Because many

subtypes of 5-HT receptor are present on enteric nerves, muscle, and epithelium, cellular expression of receptors must be known to understand 5-HT's function. Studies were carried out to locate cells that express 5-HT_{2A} or 5-HT₄ receptors. RNA was extracted from isolated equinea pig myenteric ganglia and mucosa-free rat small intestine, reverse transcribed, and amplified by PCR. mRNAs encoding 5-HT_{2A} and 5-HT₄ receptors were detected respectively in the guinea pig ganglia and rat intestine. Immunocytochemistry and *in situ* hybridization (³⁵S-riboprobe) indicated that the 5-HT_{2A} receptor is expressed by myenteric neurons throughout the gut, by submucosal neurons in small and large intestines and business. intestines, and by circular muscle where 5-HT_{2A}-immunoreactive nerve fibers were also especially abundant. mRNA encoding the 5-HT₄ receptor was detected by *in situ* hybridization in enteric neurons (most abundantly in ileum and proximal colon), but not in muscle or mucosa. These data suggest that 5-HT₂A receptors play a role in enteric neuronal as well as muscle function; 5-HT₄ receptors are exclusively neuronal, but there are regional differences in the abundance of 5-HT₄-expressing neurons. A NF-AT LIKE TRANSCRIPTION FACTOR, FACTOR B, IS ESSENTIAL FOR THE EXPRESSION OF HUMAN SEROTONIN 5-HT_{2A} RECEPTOR GENE. Q.S. Zhu* and J.C Shih. Dept. of Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, 1985 Zonal Ave., Los Angeles, CA 90033.

A novel transcription factor, factor b, binding site was identified 62 bp upstream of the 5' most transcription initiation site of the human serotonin 5-HT2A receptor (5-HT2AR) gene. The DNA binding sequence of factor b was similar (15 out of 21 bp identical) to that of human NF-AT, a transcription factor for interleukin-2 (IL-2) production in activated T cells and the factor b DNA binding was displaceable by human NF-AT oligonucleotides in gel retardation assay. These results suggest that similar transcription factors may be involved in regulation of the 5-HT2AR and the IL-2 genes. Furthermore, the presence of factor *b* complex was correlated with 5-HT2AR mRNA level and promoter activity in all cell lines tested. Site-directed mutagenesis of the binding activity in all cell lines tested. Site-directed mutagenesis of the binding sequence abolished the factor b-DNA complex in a gel retardation assay and reduced the promoter activity to 35% of the wild type in a transient transfection assay (human growth hormone as a reporter gene). These results suggest that factor b may be essential for the expression of the 5-HT2AR gene. UV-crosslinking with synthetic factor b binding sequence showed a specific protein band with a molecular weight of ~49 kDa. Further characterization of this protein will help us better understand the nature of the factor b complex. (Supported by NIMH grants R37 MH39085 (MERIT Award), K05 MH00796 (Research Scientist Award), R01 MH37020 and Welin Professorship).

REDUCED DENTATE GYRUS LTP AND IMPAIRED PROCESSING OF SPATIAL CONTEXT IN 5-HT $_{\rm 2C}$ RECEPTOR MUTANT MICE. L. Tecott. S. Das S.F. Logue^{*1}, J.M. Wehner¹ and J.A. Kauer². UCSF Dept. Psychiatry, S.F., CA 94143; ¹Inst. Behav. Genetics, Univ. Colorado, Boulder, CO 80309; ²Dept. Neurobiology Duke Univ., Durham, NC 27710.

Serotonin systems have been implicated in the regulation of cognition and

hippocampal activity. To determine the contributions of the 5-HT_{2C} receptor to the serotonergic modulation of these processes, a 5-HT_{2C} receptor mutant mouse strain was examined (Tecott et al Nature 372: 542 '95). In mutant mouse strain was examined (Tecott et al Nature 372: 542 '95). In slice preparations, long term potentiation (LTP) was examined at each of four principle regions of the hippocampal complex: the dentate gyrus, CA3, CA1 and the subiculum. Using standard double blind methods of LTP induction, potentiation at medial perforant path-dentate gyrus synapses was selectively reduced (by approx. 50%) in mutant mice. To assess behavioral correlates of altered hippocampal function, contextual fear conditioning and defensive withdrawal responses were examined. Twenty-four hours after training for contextual fear, wild type mice froze more to the trained context than the altered expects, while the subnet the dip at discriptions between the than the altered context, while the mutants did not discriminate between the two contexts. In the second paradigm, the latencies of mice to emerge from a small enclosure into a brightly lit open field were assessed. Emergence neophobia has been found to correlate with levels of dentate gyrus LTP in rats (Maren et al *Psychobiology* 21: 2 '93). A 70% reduction in emergence latency was observed in the mutants, consistent with the reduction in perforant path LTP in these animals. Together, these results indicate that 5-HT_{2C} receptor mutant mice have impaired processing of contextual stimuli associated with a selective impairment of dentate gyrus function. ANTISENSE INHIBITION OF 5HT2 A RECEPTOR IMPAIRS CONTAINMENT OF STRESS RESPONSE. <u>E. Sibille</u>¹, <u>Z. Sarnyai</u>², <u>D.</u> Benjamin³, and M. Toth^{1*} Department of Pharmacology, Cornell Univ. Medical College, ² Laboratory of Neuroendocrinology, Rockefeller University, and ³Center of Alcohol Studies, Rutgers University.

Stress causes an abrupt and large change in neurotransmitter release. While this activation of neurochemical systems is beneficial in the body's and brain's response to stress, it is imperative that these responses are shut down when they become excessive. If containment does not occur, a vicious cycle may ensue in which elevated sympathetic activity and glucocorticoid level lead to diseases such as depression. We are interested in the involvement of the 5HT2A receptor (5HT2AR) in adaptation since it is well documented that its level is increased in suicide victims. Since drugs are not specific to 5HT receptors, a genetic approach was chosen to assess the relationship between 5HT2AR and behavior. Antisense oligo-nucleotides (AS) can specifically downregulate gene expression. A 19-mer AS, corresponding to the 5' translated region of the 5HT2AR or a control mismatched oligonucleotide (MS) were injected icv in mice (10µg, every 12 hours for 4 days). Animals were subjected to a swim stress that normally results in a gradual decrease of escape directed behavior as an adaptive containment of stress response. AS but not MS treatment decreased the development of this response to stress. In addition to hyperreactivity to stress, AS treated animals showed an increased ethanol tolerance, indicating a higher arousal state. Our results suggest that 5HT2AR is involved in the termination and containment of stress induced responses, such as hyperreactivity and hyperarousal. When 5HT2AR level is sub-optimal, delayed and incomplete containment can lead to excessive maladaptive responses to stress, resembling certain symptoms of depression. Supported by NARSAD.

SINGLE POINT MUTATION DIFFERENTIALLY AFFECTS TRYPTAMINE AND PHENYLISOPROPYLAMINE EFFICACY AT 5-HT2A RECEPTORS. BL Roth*, N Khan, and MS Choudhary, Departments of Biochemistry and Psychiatry, Case Western Reserve University Medical School, Cleveland, OH 44106.

Understanding the mechanisms by which drugs bind to and activate Gprotein coupled receptors (GPCR) remains a major unsolved problem for biochemists and pharmacologists. We have used the 5-HT2A receptor as a model system for understanding how agonists bind to and activate receptors. We have recently discovered a single point mutation (F340L) which appears to differentially alter the ability of structurally diverse agonists to activate second messenger production. For these studies stably transfected cell lines expressing the native and mutant 5-HT2A receptors were constructed (Roth et al, JPET, 1995). We discovered that the abilities of tryptamine agonists (5-HT, N,N'-DMT, 5-O-Me-DMT, α-Methyl-5HT) to activate phosphoinositide hydrolysis was virtually abolished by the F340L mutation, while several phenylisopropylamines (DOI, DOB, DOM) had efficacies ranging from 50-100% of that seen with the native receptor. For all groups of compounds, potencies were diminished to a much greater extent than binding affinities. In several cases, potencies were diminished by greater than 1000-fold while binding affinities for the high-affinity state was affected by less than 20-fold. Our results are consistent with a model in which agonist-induced movements of Helix 6 are an essential feature of receptor activation. RO1GM52213 to BLR.

LOCALIZATION OF 5-HT_{2C} RECEPTORS BY IMMUNO-HISTOCHEMISTRY AND CONFOCAL MICROSCOPY: PRESYNAPTIC 5-HT_{2C} RECEPTORS?

J.R. Backstrom, S. Schroeter*, R.D. Blakely, and E. Sanders-Bush. Department of Pharmacology and Center for Molecular Neuroscience, Vanderbilt University School of Medicine, Nashville, TN 37232.

Precise localization of serotonin 5-HT_{2C} receptors has not been possible due to the absence of 5-HT_{2C}-selective reagents. We have developed specific antibodies (anti-2C-CT) against a peptide within the carboxy-terminus that has enabled us to localize 5-HT_{2C} receptors with cellular resolution. Specificity of affinity-purified anti-2C-CT was examined in two cell lines expressing the 5-HT_{2C} receptor or the related 5-HT_{2C} receptor. The receptor in immunoblots from the 5-HT_{2C} but not the 5-HT_{2C} receptor cell line. In addition, anti-2C-CT only labeled cells expressing 5-HT_{2C} receptors in immunocyto-chemical experiments. 5-HT_{2C} receptor inmunoreactivity was localized in 40 µm sections of paraformaldehyde-perfused rat brain and detected by fluorescence or peroxidase. Confocal images of sections double-labeled with anti-2C-CT and anti-GFAP, to identify glial elements, revealed a distribution of 5-HT_{2C} receptors within the choroid plexus and neuronal layers including the hippocampus, cortex, and cerebellum. Anti-2C-CT also intensely labeled offactory regions such as the olfactory cortex and medial habenula. Receptor immunoreactivity was localized to Anti-2C-CT also intensely labeled olfactory regions such as the olfactory cortex and medial habenula. Receptor immunoreactivity was localized to axon-like structures which terminate in a network of fibers surrounding the surface of neuronal soma. Future experiments will include colocalization with presynaptic markers and lesioning of serotonergic nuclei to test the hypothesis that 5-HT_{2C} receptors are located at axon terminals. (Supported by NIH research grants DA07390, DA05181, MH34007, training grant MH19732, and a fellowship from PhaRMA Evandation.) Foundation)

IDENTIFICATION AND CHARACTERIZATION OF RNA EDITING WITHIN THE SEROTONIN 2C RECEPTOR. C.M. Burns*, H. Chu, S.M. Rueter, E. Sanders-Bush and R.B. Emeson. Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600.

Transcripts encoding the 2C-subtype of serotonin receptor (5-HT_{2C}R) undergo RNA editing events in which genomically-encoded adenosine residues are represented as guanosines in the 5-HT_{2C}R cDNA. Editing events at four major positions, termed A, B, C, and D, are predicted to alter amino acids within the second intracellular loop of the protein, encoding unique receptor isoforms with one to three amino acid substitutions (1157V, N159S and 1161V). Sequence analyses of individual cDNA isolates from microdissected rat bracegions have predicted the tissue-specific production of eight major protein isoforms encoded by eleven distinct RNA species. 5-HT_{2C}R transcripts isolated from the choroid plexus demonstrated lower levels of editing at the A and B sites (25%) than other brain regions (85%). The C site appeared to be edited with the most consistency in all areas examined (30-35%) while editing at the D site was most variable (45-80%).

Examinations of 5-HT_{xc}R pre-mRNA sequences identified the presence of a putative RNA duplex formed by the 3'-end of exon 3 and the proximal region of the third intron. Mutational analyses within this structure indicated a dependence of editing upon this duplex region similar to that previously observed for GluR-B RNA processing. The development of an in vitro 5-HT_{xc}R RNA editing system, using rat brain nuclear extracts fractionated by cation exchange chromatography and a 375 nt 5-HT_{xc}R transcript, revealed that this modification results from an adenosine to inosine conversion rather than the adenosine to guanosine alteration inferred from isolated cDNA sequences. Further characterization of cation-exchange fractions identified two distinct adenosine deaminase activities responsible for the processing of 5-HT_{2c}R transcripts. The first activity, mediated may modification at the A, B and C sites, co-eluted with the activity responsible for the processing of GluR-B at intronic position +60. The second peak of activity mediated the editing of the 5-HT_{2c}R D-site as well as the Q/R site of GluR-B. These results suggest that similar, or identical activities, are responsible for the editing of both 5-HT_{2c}R and GluR-B RNA transcripts. Supported by NIH grant NS33323.

THE EPH RECEPTOR CEK5 AND ITS LIGAND, CEK5L, HAVE COMPLEMENTARY DISTRIBUTIONS IN THE EARLY RETINA. J.A. Holash*, C. Soans L.D. Chong, and E.B. Pasquale, The Burnham Institute, La Jolla, CA 92122

J.A. Holash*, C. Soans L.D. Chong, and E.B. Pasquale, The Burnham Institute, La Jolla, CA 92122

Members of the EPH subclass of receptor tyrosine kinases appear to influence pattern formation. We have shown that the Eph receptor Cek5 has a polarized distribution in the chick retina suggesting that it plays a role in establishing retinotectal topography along the dorsal-ventral axis. Others have found that a similar, yet distinct, role is likely played by Cek4, which is expressed in a nasal-temporal gradient in the developing retina (Cheng et al., Cell 82:371-381, 1995). Cek4 and its ligand, Elf-1, have complementary distributions in the tectum. We have compared the distribution of Cek5 and an activating ligand, Cek5L, in the visual pathway using immunohistochemistry and in situ hybridization. In the embryonic day 8 chick tectum, neither receptor nor ligand can be detected to be expressed in a gradient, suggesting that their role in visual pathway development occurs prior to axons reaching the tectum. Interestingly, in the retina Cek5 and Cek5L have complementary distributions during axonogenesis, but as development progresses, their patterns of expression become overlapping. Both Cek5 and Cek5L are expressed in retinal ganglion cells. To examine the interaction of Cek5 and Cek5L fused to a human IgG domain. These molecules were used as substrates for cells dissociated from dorsal or ventral retina. Cells derived from ventral retina (expressing high levels of Cek5) showed enhanced attachment to ligand-coated plates, whereas cells from dorsal retina (expressing high levels of Cek5) showed enhanced attachment to ligand-coated plates, whereas cells from dorsal retina (expressing high levels of Cek5) interaction mediates cell adhesion and does not prevent neurite outgrowth. Funded by NIH and MRC-Canada.

FUNCTIONAL CHARACTERIZATION OF RAT SEROTONIN 5-HT_{3C}RECEPTOR EDITING ISOFORMS. <u>H. Chu, C. Burns, H. Canton, R.B. Emeson and E. Sanders-Bush*</u>, Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600.

We have accumulated evidence that RNA transcripts encoding the rat 5-HT_{2C} receptor undergo RNA editing events similar to those identified for the B-subunit of the AMPA subtype of glutamate receptor. Several adenosine to guanosine transitions were discovered within the exon that encodes the putative second intracellular loop of the receptor. The major products of 5-HT_{2c} RNA editing encode unique proteins with one to three amino acid substitutions (1157V, N159S and 1161V) in the second intracellular loop of the predicted protein. Analyses of mRNA from microdissected brain regions have revealed the existence of region-specific editing patterns predicting the production of eight major protein isoforms encoded by eleven edited RNA species. To assess the significance of RNA editing in 5-HT_{2C} receptor function, the major edited species were subcloned into the mammalian expression vector pCMV2 and transiently transfected into NIH 3T3 fibroblasts. Competition binding analyses revealed similar affinities of different ligands for all edited isoforms. Pharmacological characterization of the edited receptors in this model system showed that the potency of serotonin to activate the inositol lipid signaling cascade was markedly reduced in the fully edited form (5HT2C-VSV) compared to the non-edited form(5HT_{2C}-INI); the EC₅₀ for serotonin activation was 106.3 ± 21.1 vs 11.7 ± 4.7 nM, respectively. A similar functional difference was observed for another edited species (5HT_{2C}-ISV) that differed by only two amino acids. In both cases, the 5HT_{2C} receptor edited species with a serine at position 159 and a valine at position 161 were less potent than those with asparagine and isoleucine at the same positions. We propose that the simultaneous amino acid alterations at these two sites, as a result of RNA editing events, generates receptor isoforms which couple less efficiently to the intracellular signaling machinery and represents a novel mechanism for the regulation of G-protein coupled receptor activity. EPH FAMILY RECEPTORS AND LIGANDS ARE DISTRIBUTED IN COMPLEMENTARY DOMAINS IN THE MOUSE RETINOFUGAL PATHWAY. R.C. Marcus', R. Dhavan, N.W. Gale, C.S. Harlan, M.E. Morrison, C.A. Mason and G.D. Yancopoulos. Dept. of Pathology, Columbia Univ. Coll. of P &S, New York, NY 10032 and Regeneron Pharmaceuticals, Tarrytown, NY 10804. Eph family receptor tyrosine kinases and their ligands can be grouped into

either GPI-linked or transmembrane (TM) subclasses. We used receptor- and ligand-antibody fusion proteins from each subclass to localize their corresponding ligands and receptors in the developing mouse retinofugal pathway. In agreement with previous reports, we find that in the embryonic day 14 (E14) retina, receptors of the GPI-linked and TM subclasses are distributed in a high temporal-low nasal and a high ventral-low dorsal gradient, respectively. We now report that ligands from each subclass are also distributed in gradients within the retina, and that these gradients are opposite to those of their corresponding receptors. The presence of ligand in the retina suggests an intra-retinal role for Eph family members in addition to their proposed role in retinotectal mapping. The distinct distributions of the GPI-linked and TM members suggest that the different subclasses control retinal development in the naso-temporal and dorso-ventral axes.

development in the naso-temporal and dorso-ventral axes.

Eph family receptors and ligands also appear in complementary domains in the E14 optic chiasm. Retinal axons diverge to opposite sides of the brain within a radial glial palisade that straddles the chiasmatic midline. We find receptors of both the GPI-linked and TM subclasses localize in the zone occupied by these radial glia. Ligands of the GPI-linked subclass are located posterior to the chiasm, in a region occupied by a population of neurons thought to be inhibitory to retinal axon growth.

Thus Eph-family receptors and their ligands may direct retinal ganglion cell growth at multiple sites along the developing visual pathway.

Regulation of Topographic Projection in the Brain: Elf-1 in the Hippocamposeptal System. P.-P. Gaol, J.-H. Zhang¹, M. Yokoyama², B. Racey³, C. F. Dreyfus³, I. B. Black³, and R. Zhou¹. ¹Laboratory for Cancer Research, College of Pharmacy, Rutgers University; Piscataway, NJ 08855. ²M. Yokoyama, Trophix Pharmaceuticals, Inc., 40 Cragwood Road, South Plainfield, NJ 07080. ³B. Racey, C. F. Dreyfus, I. Black, Department of Cell Biology and Neuroscience, Robert Wood Johnson Medical School, Piscataway, NJ 08855

Although topographic organization and projection are general features of brain functional architecture, organizing mechanisms remain undefined. We now report that Elf-1, a membrane-bound eph family ligand, is a candidate molecular tag for the genesis of the hippocamposeptal topographic projection. Neurons project as a gradient from the medio-lateral hippocampus to dorso-ventral septal targets. Elf-1 was expressed in an increasing gradient from dorsal to ventral septum. Furthermore, Elf-1 selectively allows growth of neurites from topographically appropriate lateral hippocampal neurons, while inhibiting neurite outgrowth by medial hippocampal neurons, thereby playing a critical role in the development of the topographic projection. Complementary to the expression of Elf-1, an eph family receptor, Bsk, is expressed in the hippocampus in a lateral to medial gradient, consistent with a function as a receptor for Elf-1. Further, Elf-1 specifically bound Bsk, eliciting tyrosine kinase activity. We conclude that the Elf-1/Bsk ligand-receptor pair exhibits traits of a chemoaffinity system for the organization of hippocamposeptal topographic projections. RETINAL AXON PATHFINDING: DIFFUSIBLE CUES FROM THE CHIASM AND THE FLOOR PLATE SUPPRESS GROWTH OF ALL RETINAL AXONS L.-C, Wang*, A, Augsburger, R.A. Rachel, R.C. Marcus, and C.A. Mason, Depts. Pathology., Anat. and Cell Biol., Physiol. and Cell. Biophys., Chtr. Neurobiol. Behav., Columbia Univ., NY, NY 10032.

Retinal axons diverge to both sides of the brain near the midline of the optic chiasm. Recent in vitro studies demonstrated that cells from the chiasm elidiferential growth of crossed and uncrossed fibers, in patterns that mimic avoidance or growth across the midline (Wang et al., Neuron, 15:1349, 1995). These effects are believed to be contact-mediated. We also showed that diffusible cues from the chiasm suppress growth of axons from all poles of the retina to an equal extent (Wang et al., Soc. Neurosci. Abstr. 21: 1296, 1995). Such cues, if released and bound to the ECM, could produce divergence, or could slow axon growth in decision regions, thereby permitting responses to other more specific guidance cues. Here we demonstrate that this general growth-retarding activity is not present in the cerebellum and cortex, but is even stronger in another midline site, the floor plate, suggesting that the floor plate contains similar diffusible factors that suppress retinal axon growth. Since the floor plate is known to be rich in netrin-1, which can act as an attractant or repellant on different axon populations, retinal explants were cocultured with netrin-1-transfected COS cells (construct gift of M. Tessier-Lavigne) in collagen gels. Netrin-1 did not mimic the general growth-retarding effect, but, instead, promoted retinal axon growth. Further, neurites did not appear to orient toward netrin-1-positive cells, implying a trophic but not tropic influence on retinal neurite growth. These data suggest that a non-netrin-1 inhibitory factor is present at different axial levels, and together with our previous studies, emphasize that multiple guidance mechanisms may underlie retinal axon divergence.

underlie retinal axon divergence.

A CAM SIGNALING COMPLEX WITH POTENTIAL FOR INTEGRATING ADHESION SIGNALS FOR AXON GROWTH. H.E. Beggs, S. C. Baragona, J.J. Hemperly, and P.F. Maness*. Department of Biochemistry, Univ. of North Carolina, School of Medicine, Chapel Hill, NC 27599.

Growth cones respond to different substrates by rapid morphological changes and growth rate modification. We have shown that the src family tyrosine kinase p59fyn is necessary for NCAM-mediated neurite outgrowth (Beggs et al., J. Cell Biol. 127, 825-833). A molecular complex of the cell adhesion molecules NCAM and p59fyn, together with L1, was revealed by immunoprecipitation from developing mouse cerebellum. When different NCAM isoforms were transfected into COS cells or rat B35 neuroblastoma cell lines, NCAM 140 was found to associate strongly with p59fyn, whereas NCAM 180 associated to a much lesser degree. The presence of the VASE isoform in NCAM140 did not alter the association. In contrast, pp60c-src was not associated with either isoform of NCAM. Similarly, L1 bound strongly to p59fyn but not to pp60c-src+ in transfected cells. p59fyn kinase was transiently activated upon crosslinking of NCAM140 with antibodies to the extracellular region, indicating a functional association. In vitro kinase assays revealed an additional protein besides p59fyn as a component of the NCAM signaling complex, which was identified as the focal adhesion kinase p125FAK. This CAM/fyn/FAK complex may represent an important biochemical signal transduction mechanism for integrating multiple adhesion pathways during growth cone guidance. This work was supported by NIH grant NS52269.

PARTIAL RETINAL ABLATION IN EMBRYO ALLOWS THE UNCROSSED PROJECTION TO DEVELOP.

J.S.H. Taylor

Dept. Human Anatomy, University of Oxford, Oxford. OX1 3QX. U.K.

The optic chiasm is where the retinal axons from the two eyes meet and a sub-population turns into the ipsilateral optic tract forming the uncrossed projection. It has been shown in both mice (Godement et al., 1987. J. comp. Neurol. 255:97) and ferrets (Taylor, J.S.H. & Guillery, R.W. 1995. J. comp. Neurol. 357:331) that very early eye removal stops the uncrossed projection from the other eye from growing into the ipsilateral optic tract. However a contradictory finding has been published suggesting early enucleation has no effect on the uncrossed projection in mice (Sretavan & Reichardt 1993. Neuron 10:761).

Using exo-utero surgery, the dorso-nasal or temporo-ventral retina was removed on embryonic day 12 or 13. Embryos were fixed on E17.5 and Dil used to label the ipsilateral projection of the intact eye retrogradely or anterogradely. Ipsilaterally projecting labelled cells were counted in retinal flat mounts and showed no diminution of the temporal crescent when compared with control retinae. Dil labelling of the temporo-ventral retina in the intact eye showed a normal uncrossed projection had formed at the optic chiasm.

We have found no clear evidence for a differential effect of partial retinal lesion and conclude that there is no specific sub-population of contralaterally projecting axons that is required to guide the insilaterally projecting axons. These results may have implications for the interpretation of experiments in which monocular enucleation has been suggested to have no effect on the development of the insilateral retinal projection.

MIDLINE CROSSING MUTATION AFFECTS MOTONEURON PATHFINDING AND TARGET RECOGNITION B. Wolf, L. Faiman,* & A. Chiba Dept. of Cell & Struct. Biol., Univ. of Illinois, Urbana, IL 61801

We are interested in how disruptions in midline crossing of CNS axons influence the axons' subsequent responsiveness to local molecular cues. One model system is the commissureless (comm) mutants in Drosophila embryos. The comm gene encodes a putative transmembrane protein expressed on midline glia and when absent causes the failure of axons to cross the midline. The expression pattern has also been reported during early peripheral tissue development. We found that immunocytochemistry labeling of motoneurons using anti-Fasciclin II antibody in comm null mutants embryos (late stage 16) revealed abnormalities in the SNb nerve branch which contains midline-crossing motoneurons including RP3 and RP1. Using an enhancer-trap line which labels RP3 and RP1, two midline-crossing neurons that innervate muscles 6 and 7, and 13 respectively, we were able to observe the effects of *comm* mutations at the single cell level. In *comm* null mutants, RP3 axons extend ipsilaterally along the normal pathway and reach the ventral muscle region containing muscles 6 and 7, but fail to innervate the 6/7 cleft. Much of the axon pathway remains normal despite failing to cross the midline; only the final target recognition and innervation seemed to be affected. Other nerve branches which may or may not contain midline-crossing axons (SNa, SNc, and Snd) were also examined using anti-Fasciclin II. We observed similar abnormalities in comm null mutants, suggesting the existence of previously uncharacterized midline-crossing motoneurons or a direct interaction between those axons which normally cross the midline and those that do not. The results raise the possibility that midline crossing is responsible for altering molecular expression pattern in growth cones and is required to specify aspects of subsequent pathfinding and target recognition. In the absence of axonin-1 and NrCAM interactions the floor plate is inhibitory for the ingrowth of cultured commissural axons

E.T. Stoeckli, P. Sonderegger¹, G.E. Pollerberg², and L.T. Landmesser*, Case Western Reserve University, Cleveland, OH 44106;¹Institute of Biochemistry, University of Zurich, CH-8057 Zurich, Switzerland, ²MPI for Developmental Biology, 72076 Tuebingen, Germany

In vivo perturbation studies have shown that axonin-1 and NrCAM, two cell adhesion molecules of the Ig superfamily, are required for the normal growth of chick commissural axons across the floor plate in the chicken embryo spinal cord (Stoeckli, E.T., and L.T. Landmesser, Neuron 14(1995), 1165-1179). To further characterize their role in commissural pathfinding, we studied the behavior of commissural growth cones when they were interacting with floor plate explants in culture. In control cultures, commissural axons rapidly entered such explants. When either axonin-1 or NrCAM function was interfered with, commissural axons grew up to, but failed to enter the floor plate explants. Time lapse imaging revealed that in the presence of anti-axonin-1 antibodies filopodial contact with the floor plate triggered full collapse of the growth cones. In the presence of anti-NrCAM antibodies growth cones did not exhibit full collapse, but appeared unable to grow into the floor plate. These studies show that axonin-1 and NrCAM are crucial for the intimate interactions of commissural axons with the floor plate, which in turn is required for the guidance of these axons across the ventral midline.

FASCICLIN III MEDIATES BOTH AXON FASCICULATION AND TARGET RECOGNITION IN DROSOPHILA H. Kose, X. Zhu. D. Rose A Chiba & F. Meisami' Neurosci Program Univ. of Illinois, Urbana II. 61801

Rose, A. Chiba, & E. Meisami* Neurosci. Program, Univ. of Illinois, Urbana, It. 61801
Fasciclin III, an Ig-CAM, appears in specific subsets of motoneurons and muscle cells during *Drosophila* neuromuscular development and has been proposed to act as a "positive target recognition molecule" for at least one Fasciclin III-positive motoneuron (RP3) which normally innervates the Fasciclin III-positive target muscle cells. Here we further tested how this Ig-CAM may regulate growth cone pathfinding and/or target recognition. First, to determine Fasciclin IIIs possible roles during axon navigation, we generated both heat-shock inducible Fasciclin III overexpresser fly lines and an enhancer trap line ectopically expressing Fasciclin III in a small subset of motoneurons (e.g. aCC) which do not normally express this molecule. When the overexpresser embryos are heat-shocked before motoneuron axons reach the peripheral target regions and thereby all motoneuron axons are made to express Fasciclin III, the axons continue to extend but fail to defasciculate from each other at appropriate nerve branch points. In contrast, in the enhancer trap embryos, where only one or a few motoneuron axons ectopically express Fasciclin III in a given nerve, defasciculation occurs normally. This suggests that fasciclin III can mediate axon-axon fasciculation through homophilic adhesion. Second, to determine how Fasciclin III may mediate the motor growth cone-muscle interaction, we conducted a series of molecular (Fasciclin III) mismatch experiments using various genetic manipulations. The newly developed laser-mediated single cell gene activation method has also facilitated our ability to control the site and timing of Fasciclin III ectopic expression. The results suggest that the decision for a motoneuron growth cone to stop and initiate synaptogenesis on Fasciclin III-positive muscle cell(s) may require either Fasciclin III itself or other yet uncharacterized Fasciclin III receptors on the responding growth cone. Supported by NIH and NSF.

HB-GAM (HEPARIN-BINDING GROWTH ASSOCIATED MOLECULE) AND N-SYNDECAN PLAY A ROLE IN THE FORMATION OF THALAMOCORTICAL CONNECTIONS?

A. Kinnunen*, M. Niemi, R. Nolo, T. Kinnunen, M. Kaksonen and H. Rauvala. Laboratory of Molecular Neurobiology, Institute of Biotechnology, P.O.Box 56, 00014 University of Heisinki, Finland. ECM-molecules such as laminin, tenascin, chondroitin sulphate

ECM-molecules such as laminin, tenascin, chondroitin sulphate proteoglycans (CSPG) and heparan sulphate proteoglycans (HSPG) have been suggested to have "signpost" and directing roles in the formation of axonal projections and in the cortical development. We have discovered that the distribution of HB-GAM, an 18 kD neurite-outgrowth promoting protein, in the developing rat brain is spatio-temporally associated with the developing halamicortical pathways. Using in situ hybridization, thalamic neurons were shown to express N-syndecan mRNA, an HSPG shown to act as a receptor for HB-GAM. Thalamic E16 neurons showed repeatedly a typical growth pattern resembling the HB-GAM distribution when cultured on living brain slice preparation. In vitro thalamic neurons expressed more neurite outgrowth on HB-GAM than on laminin-coated matrixes. We also tested the effect of soluble heparin on the neurite outgrowth of E16 thalamic neurons in vitro on living slice-culture preparation and the effect of soluble heparin, N-syndecan, HB-GAM and chondroitin sulphate on culture wells coated with HB-GAM, laminin and poly-L-lysine. Neurite outgrowth of thalamic neurons was partially perturbed by soluble Ha-GAM, new process of the soluble heparin on His-GAM, N-syndecan and heparin on HB-GAM coated wells. Our results suggest that HB-GAM may function as an ECM bound cue for thalamic neurons that possess N-syndecan on their cell membrane. MECHANISMS OF GROWTH INHIBITION INDUCED BY THE NG2 CHONDROITIN SULFATE PROTEOGLYCAN

Joel M. Levine* and Chang-lin Dou¹, Dept. Of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY and ¹Dept. Of Cell Biology and Genetics, Memorial Sloan-Kettering Cancer Center, New York, NY

Proteoglycans (PG) comprise a heterogeneous class of glycoproteins that can inhibit or enhance neurite extension in vitro. One growth inhibitory chondroitin sulfate PG is NG2, a high molecular weight PG that is found on the surfaces of oligodendrocyte precursor cells in developing and adult animals. Neurite growth from neonatal rat cerebellar neurons on either laminin or L1-coated surfaces is inhibited by the NG2 core protein but the growth of embryonic DRG neurons is inhibited by NG2 only on laminin substrates (J,Neurosci., 14:7616,1994).

This growth inhibition may be mediated by specific cell surface receptors for

This growth inhibition may be mediated by specific cell surface receptors for NG2 that are linked to intracellular signaling pathways. In support of this hypothesis, we show that NG2 binds specifically and with high affinity to cerebellar granule neurons but not to 3T3 cells. Rat DRG neurons had approximately half the NG2 binding sites as did cerebellar neurons. Protein crosslinking and immunoprecipitation identified a 280kD protein from cerebellar neurons as an NG2-binding site. The inhibition of neurite outgrowth by NG2 on L1 surfaces was reversed by treating the neurons with pertussis toxin suggesting that the NG2 binding site is linked, either directly or indirectly, to G-protein-dependent signaling mechanisms. Pharmacological agents that raise intracellular calcium also reversed the NG2-induced growth inhibition. Interestingly, growth inhibition on laminin was not reversed by pertussis toxin.

These observations suggest that the ability of the NG2 PG to inhibit neurite growth on L1 substrates is due to an interaction of the PG with a neuronal receptor. NG2 binding to this receptor may modify the ongoing activity of L1-stimulated second messenger systems. Supported by NIH grant # NS 21198 to JML.

ERROR CORRECTION IN REELER BRAIN DEVELOPMENT.

Nuwan C. Kurukulasuriya and Walter L. Salinger*, Biology and Psychology Departments. University of North Carolina at Greensboro, NC 27412

In the reeler neocortex, many neurons achieve normal patterns of connections even though they are ectopically placed. This achievement requires changes in the timing and routing of axonal growth. Thus, DiI (Molecular Probes) labeled thalamic axons in reeler traverse the full extent of cortex by E15 while in the normal, the thalamocortical axons do not invade until much later, E18-P0 and never traverse the entire, developing cortex. How is molecular regulation of axonal growth altered in the reeler to permit these changes? Glycosylated protein conjugates, GPC's, labeled with biotinylated peanut agglutinin, PNA (Vector), are expressed much earlier in the reeler cortex, at least by E15, as opposed to E18-P0, in the normal. Furthermore, in the E15 reeler, PNA labeling is present throughout the thickness of the developing cortex, mottled and without evidence of the radially oriented concentration gradient that is typical for the normal. Contributing to the mottled PNA labeling pattern at E15 in the reeler are cell-sparse channels that are richer in GPC label than the surrounding cortex which also displays PNA label. However, these GPC rich channels do not seem essential for guidance of the invading thalamocortical axons since many such axons grow through GPC labeled cortical tissue outside of the GPC rich channels. The reeler timetable for and spatial distribution of PNA labeled GPC expression in developing neocortex thus reveals that GPC's may be permissive rather than instructive for thalamocortical axons in developing cortex. The deviations in reeler neocortex from normal patterns of GPC expression account for the altered timetable for the invasion of neocortex by thalamocortical axons in the reeler but not for their distinctive growth trajectories. The mechanism by which the temporal and spatial patterns of expression of GPC's in reeler brain are adjusted in compensation for ectopia remains to be described. (Supported by UNCG-RCG #3-19563)

POSTSYNAPTIC MECHANISMS: ELECTRICAL EXCITABILITY AND Ca2+ SIGNALLING

Phase Resetting of High Potassium Spiking Activity in Hippocampal Slices. A. Jahangiri and D.M. Durand* and J.C. Lin, Depts of Biomedical Engineering, Case Western Reserve University, Cleveland, OH. 44106. The theory of phase resetting can be used to predict the response of spontaneous oscillators to perturbations. Some oscillators have a property known as strong resetting in which a perturbation applied during the period of oscillation can shift the occurrence of the next period and thereby reset the oscillation. It has been shown that systems with this property also present a singularity. At the singularity, the response of the system is unpredictable and the perturbation can lead to annihilation of the response. We have applied the theory of phase resetting to quasi-periodic signals generated by epileptogenic agents in the hippocampus in-vitro. The purpose of the study was to determine whether the resulting oscillatory systems had the property of strong resetting and whether a singularity could be found. Hippocampal slices were perfused with high potassium solutions generating quasi-static periodic activity with a period of .8 to 1.3 Hz in the CA3 region. Current pulses in the range of 1 to 250uA were applied at various times between spikes (coupling intervals) with an electrode located in the CA3 somatic layer. The results indicate that for current amplitude below 80uA weak restting (no effect) is observed. For amplitude greater than 150uA, strong resetting is generated. For amplitudes between 90 and 110 uA at coupling latencies around .7, periodic activity was abolished and the latency of spikes was unpredictable. This singularity was observed in 5 out of 5 slices tested. This analysis of the interactions between interictal spikes and current stimulation has shown that the periodic epileptiform activity generated in high potassium is vulnerable and could potentially be annihilated with electrical stimulation.

IMAGING THE STEADY-STATE MEMBRANE POTENTIAL DISTRIBUTION OF PURKINJE CELLS IN SITU USING VOLTAGE-SENSITIVE DYES M.O.Thomann*, D.Heck and A.Borst. Friedrich-Miescher-Laboratory of the Max-Planck-Society, Spemannstraße 37-39, D-72076 Tuebingen, Germany

Planck-Society, Spemannstraße 37-39, D-72076 Tuebingen, Germany A new method, previously described for leech ganglion cells (Borst, A., Z. Naturforsch, 50c, 435-438, 1995), is applied which allows to image the steady-state distribution of membrane potential of single Purkinje cells in situ. The method consists of staining the tissue extracellularly with a voltage-sensitive dye (Di-4 or Di-8-ANEPPS) and injecting current into a single neuron using the whole-cell patch clamp configuration. A large series of images of the cell is taken at the appropriate excitation wavelength of the dye with a CCD camera while the neuron's membrane potential is shifted by a periodic current injection (PCI). Afterwards two groups of images are averaged separately: those images with the cell at rest and those while the membrane potential of the cell was manipulated. After subtraction of these averaged images, the resulting difference image only shows the cell whose membrane potential was manipulated periodically. The signal-to-noise ratio improves with the square-root of the number of images taken within an experimental session. Drift noise contaminating control and stimulus images in approximately the same way is further reduced in the resulting difference image due to the PCI averaging method. The method is applied to Purkinje cells in cerebellar slices of young rats (p11-17). The two-dimensional arborization pattern of these cells' dendrites makes them a favorable object to optically examine their passive membrane properties. Provided that the whole dendrite is aligned planparallel to the optics, one can image the steady-state voltage distribution in the whole cell. We see very little decrease of the optical voltage signal in the difference image from the soma to even distant dendritic branches. From this, we conclude that Purkinje cells of young rats are electrically very compact. These data are in accordance with what is known about their passive membrane properties so far (Shelton, D.P., Neuroscience 14, 111-131, 1985).

MOTION IN THE PREFERRED AND NULL DIRECTION CO-ACTIVATES EXCITATORY AND INHIBITORY INPUT TO VISUAL INTERNEURONS S. Single*, J. Haag and A. Borst. Friedrich-Miescher-Laboratory of the Max-Planck-Society, Spemannstr. 37-39, D-72076 Tübingen, Germany.

In the original model of visual motion detection (Reichardt W., Z. Naturforsch. 12b, 448-457, 1957) direction selectivity (DS) is aquired in two steps (Borst A. and Egelhaaf M., PNAS USA 87, 9363-9367, 1990): First local luminance values derived from neighboring retinal locations are correlated with each other after one of them has passed a temporal filter. This results in a signal with only a weak DS Full DS is acquired by subtracting the output signals of two such operations performed in a mirror-symmetrical way. The subtraction step has been proposed to be implemented on the large dendrites of the fly lobula plate tangential cells (LPTCs) by a combination of excitatory and inhibitory input synapses (Brotz T. and Borst A., J. Neurophysiol., submitted, 1996). If this were true, visual motion, e.g. in the preferred direction (PD), is predicfed to co-activate excitatory and inhibitory inputs onto these cells. We can clearly demonstrate such a co-activation by measuring the motioninduced change in input resistance of LPTCs before and after application of 10⁻⁴ M Picrotoxinin (a chloride channel blocker). In normal fly saline, PD-motion leads to a depolarisation ($\Delta V = +4.5 \text{mV}$) and ND-motion to an hyperpolarisation ($\Delta V = -3.5 \text{mV}$) depolarisation (Δ V= +4.5mV) and ND-motion to an hyperpolarisation (Δ V= -3.5mV). During PD-motion the input resistance drops by 14% (ND-motion:13%). After PTX-application the PD-response increases and the ND-response becomes positive. This fact can be explained in two ways: Either, PTX acts presynaptically and disinhibits excitatory inputs to the cells, or PTX blocks inhibitory inputs to the LPTCs which normally become co-activated. We find that after PTX, the input resistance during PDmotion drops only by 9%. This finding can only be reconciled by the second of the above alternatives and demonstrates that PD-motion and ND-motion both co-activate excitatory as well as inhibitory input to fly tangential cells. This work was supported by the Max-Planck-Society

CALCIUM CURRENTS IN ISOLATED HIPPOCAMPAL DENDRITES.

E.T. Kavalali*, M. Zhuo, H. Bito and R.W. Tsien. Dept. of Mol. and Cell. Phys., Beckman Center, Stanford University School of Medicine, Stanford, CA 94305.

We used the whole-cell recording configuration to study Ca²⁺ channel currents in

isolated dendrites acutely dissociated from rat hippocampi (A). Dendrites were isolated by gentle trituration of hippocampal slices following enzymatic treatment, and their identity was verified by immunocytochemistry. Ca²⁺ channel currents were evoked by depolarizations from a holding potential of -90 mV using 5 mM Ba²⁺ as the charge carrier (B). In the dendritic recordings, currents activated at low voltages

(-50 to -20 mV) were abundant and T-type Ca²⁺ current could be readily distinguished by its characteristic kinetics, including slowly deactivating tail currents. At 30 mV, for example, dendrites and cell bodies displayed similar current densities (-15.2 \pm 2.8 pA/pF vs. -18.3 \pm 3.3 pA/pF, n = 20 for both)(C). In contrast, with stronger depolarizations, the dendrites showed significantly smaller current density than somata (at -10 mV: -27.5 \pm 4.6 pA/pF vs. -67.5 \pm 10.2 pA/pF). Currents activated at high voltages were reduced by nimodipine, ω-conotoxin GVIA or ω-conotoxin MVIIC, indicating the contributions of L-, N- and P/Q-type Ca2+ channels. The total current blocked by these compounds in combination was ~65% at 0 mV. These results provide a direct estimate of the contribution of low voltage-activated Ca²⁺ channels in dendrites, in support of previous studies indicating their critical role in dendritic signal transduction. (Supported by a grant from NIH NS 24067)

A SUBTYPE OF ENDOPLASMIC RETICULUM IS A MAJOR CALCIUM BUFFER IN CA3 PYRAMIDAL DENDRITES. S. B. Andrews, L. D. Pozzo-Miller, N. Pivovarova, R. A. Buchanan, T. S. Reese*, and R. D. Leapman¹. Laboratory of Neurobiology, NINDS, and ¹Biomedical Engineering and Instrumentation Program, NCRR, NIH, Bethesda, MD 20892-4062.

The endoplasmic reticulum (ER) in neuronal dendrites is thought to buffer intracellular Ca^{+2} fluctuations via ATP-mediated uptake. However, there has been no direct correlation of the Ca content of ER with different states of neuronal activity. Here we report the effect of high-frequency afferent synaptic activity on the elemental composition, especially the total Ca content, of the dendritic ER of CA3 pyramidal neurons. After establishing stable evoked field potentials in the CA3 region of 7-day-old hippocampal slice cultures, slices were given either: 1) a single train of 50 shocks at 50 Hz; 2) four such trains at 0.06 Hz; or 3) four trains in the presence of 5 μ M TTX. Hz; 2) four such trains at 0.06 Hz; or 3) four trains in the presence of 5 µM TTX. Within 3 min of the last volley, slices were frozen against an LN₂-cooled metal block. Elemental concentrations in ER, mitochondria, and cytoplasm were measured in a VG HB501 scanning transmission electron microscope by EDX microanalysis of freezedried, ultrathin (90 nm) cryoscetions. This method gives the total concentrations of elements in mmol/kg dry weight, which for Ca is typically 10³-10⁴ higher than the corresponding free Ca⁺² concentration. Control slices frozen with or without 15-30 min incubation with 5µM TTX showed typically low values for ER Ca⁻⁴-9±1.2 mmol/kg dry weight (SFM). Following a single stimulus train, the total Ca within a subset of dry weight (SEM). Following a single stimulus train, the total Ca within a subset of ER (~55% of the cisterns in a dendrite), increased to >15 mmol/kg, the Ca content of a few cisterns exceeded 50 mmol/kg. Following four tetani, the Ca concentration increased even more dramatically in a slightly larger subset of ER (~45%) to 80 mmol/kg. (mean of non-Gaussian distribution), with some cisterns exceeding 100 mmol/kg. No Ca increase was found after stimulation in the presence of TTX. In all cases, there was no significant increase in mitochondrial Ca, and only a graded, modest rise in cyto-plasmic Ca. Tetanic stimulation increased Na in all compartments without changes in K. Mg. Cl. P and S. These findings identify a subtype of ER as a major, high-capacity cytoplasmic Ca⁺² buffer in CA3 pyramidal dendrites, during both mild and strong Supported entirely by NIH Intramural Research Program. synaptic activity.

INFLUENCE OF DENDRITIC SODIUM CHANNELS ON TRANSIENT RESPONSE PROPERTIES OF VISUAL INTERNEURONS. J. Haag* and A. Borst, Friedrich-Miescher-Laboratory of the Max-Planck-Society, Spemannstrasse 37-39. D-72076 Tuebingen, Germany

Voltage dependent sodium channels have been found in the dendrites of many nerve cells studied to date. To investigate the functional implications of active membrane properties in signal processing, we compared the transient responses of two types of non-spiking, motion-sensitive interneurons (CH- and HS-cells) of the fly visual system, only one of which (HS-cell) is equipped with a fast sodium inward current. Dual electrode recordings revealed that the fast sodium channels are located in the axon as well as in the dendrite of HS-cells. We stimulated CH- and HS-cells in two different ways: a) with oscillatory visual motion stimuli of various discrete frequencies, and b) with white noise motion stimuli. We found that cells with fast activating sodium currents can respond to temporal changes in their synaptic input signals up to higher frequencies than can those which lack such currents. A direct way of demonstrating the contribution of voltage-gated currents to the normal motion response of HS-cells is to inject a large depolarizing current into the cells, which inactivates voltage-gated sodium currents, while stimulating them synaptically with visual motion. At stimulus frequencies above 20 Hz, the response amplitudes are much reduced compared to the non-depolarized state. Thus, fast sodium currents lead to a frequency-dependent amplification of synaptic signals, enhancing cellular responses specifically to transient inputs which otherwise would be attenuated due to the passive properties of the dendritic tree.

FAST IMAGING OF CALCIUM TRANSIENTS IN DENDRITIC SPINES OF CULTURED HIPPOCAMPAL NEURONS. E. Korkotian and M Segal*, The Weizmann Institute, Rehovot 76100 Israel

Dendritic spines are unique calcium compartments, able to raise [Ca]i to high levels, in relative independence of their parent dendrites. Current methods for imaging [Ca]i have not been able to resolve differences in fast kinetics of [Ca]i changes in spines ([Ca]s) and dendrites ([Ca]d), and it is not entirely clear where are [Caji changes initiated and what are the sources of elevated [Caji in the spines. To address these questions we used a fast (0.75 ms time resolution) single line scan mode in a confocal laser scanning microscope, and monitored [Ca]i variations in dendritic spines of cultured hippocampal neurons. Cells were loaded with Calcium Green-1 through a micropipette and their dendritic arbors were scanned with a 63x water immersion objective. Low intensity laser light was focused through the long axis of the spine and its parent dendrite. Micropipettes containing glutamate or caffeine were placed near the recorded dendrite/spine pair and the responses of the pair to a puff application of the drug were monitored. Glutamate application caused a larger calcium change in the spine than in the dendrite. The latency to the spine response was shorter than that of the dendrite response by a mean of 15msec (n=18 spines). This may be caused by a difference in glutamate receptor density or properties or by travel time of a calcium wave from the spine to the dendrite. Topical application of caffeine caused a similar rise of both [Ca]s and dendrite. Topical application of carreine caused a similar lise of both [Cajs and [Ca]d (n=11 spines). The caffeine induced rise of [Ca]i, unlike that of glutamate, was not caused by an influx of calcium from the extracellular space, indicating release of calcium from spine-associated stores. In a separate series of experiments done with ratio imaging of Fura-2 loaded neurons, the response to glutamate was reduced significantly by the calcium pump antagonist, thapsigargin, indicating that part of the calcium rise seen with glutamate is also caused by mobilization of calcium from internal stores. TARGETING OF AUTOPHOSPHORYLATED CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II TO POSTSYNAPTIC GLUTAMATE

DEPENDENT PROTEIN RINASE II TO POSTSYNAPTIC GLUTAMATE RECEPTORS AND PROTEIN PHOSPHATASES. S. Strack* and R. J. Colbran. Dept. Mol. Physiol. & Biophys., Vanderbilt Univ., Nashville, TN 37232-0615 Ca²-s/calmodulin-dependent kinase II (CaMKII) is a major brain enzyme particularly enriched in the postsynaptic density (PSD), where it is thought to regulate synaptic efficacy by phosphorylating key substrates such as receptors and ion channels. We studied the mechanism by which CaMKII is targeted to the PSD using an *in vitro* binding assay with purified PSDs and recombinant [²⁸S-Met] CaMKII. Ca²⁺-dependent autophosphorylation at Thr286 (T286-P), which makes CaMKII independent of further stimulation by Ca²⁺, strongly enhances the binding of CaMKII to PSDs (app. EC₅₀ = 1.1 µM). We also localized [T286-P]CaMKII binding in brain sections using biotinylated CaMKII. localized [T286-P]CaMKII binding in brain sections using biotinylated CaMKII. Heaviest binding was observed to hippocampus, labeling dendrites and neuronal somata, but sparing neuronal nuclei, axons, and glia. We then analyzed the dephosphorylation of [T286-P]CaMKII by PSD-bound protein phosphatases (PPs). Previously bound [T286-P]CaMKII by PSD-bound protein phosphatases (PPs). Previously bound [T286-P]CaMKII is not released from the PSD, even after extensive dephosphorylation. Soluble [T286-P]CaMKII is a selective substrate for PSD-bound PP1, which has itself been implicated in synaptic plasticity. This results suggests that soluble and PSD-bound CaMKII may be differentially regulated by dephosphorylation. Upon binding to the PSD, [T286-P]CaMKII increases phosphorylation of the GluR1 subunit of the AMPA-type glutamate receptor and many other PSD proteins. Our results suggest a mechanism by which a rise in intracellular calcium mediated by synaptic activity leads to a translocation of activated CaMKII to the postsynaptic density, where it phosphorylates glutamate receptors leading to enhanced density, where it phosphorylates glutamate receptors leading to enhanced synaptic efficacy. This mechanism may also be involved in the translocation of CaMKII to the PSD seen under ischemic and hypoglycemic conditions. [Supported by NIH grant GM47973 to RJC, an AHA Established Investigator]

MECHANISMS OF CALCIUM-CALMODULIN KINASE II DIRECTED POTENTIATION OF POSTSYNAPTIC SENSITIVITY. A.M. Shirke & R. Malinow, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, and Dept. of Physiology & Biophysics, U. of Iowa, Iowa City, IA

Iowa City, IA

Calcium calmodulin kinase II (CaMKII) has been implicated in the induction and maintenance of long-term potentiation (Malinow, et al., 1989) by actions on postsynaptic receptors (McGlade-McCulloch, et al., 1993). Here we use theoretical and experimental techniques to examine possible mechanisms by which CaMKII might affect postsynaptic sensitivity.

Using the program Neuron (M. Hines), we employ a five-state model for receptor function which includes desensitization (Ambros-Ingerson & Lynch, 1993). Various hypothetical mechanisms whereby CaMKII might act predict different effects on the magnitude and timecourse of responses to transmitter.

The model predicts that either a decrease in desensitization rate or an increase in opening rate produce a larger, slower response. Changes in single channel current produce a change in response size, but not timecourse or the coefficient of variation (CV) across responses. Changes in the number of active receptors would change response size and CV but not

timecourse. We have also experimentally examined responses to puffed kainate. Kainate responses act as predicted for changes in desensitization (by applying cyclothiazide) and of single channel current (by changing driving force). We find that internal perfusion of pre-activated CaMKII (courtesy of T. Soderling, OHSU) increases kainate responses without a change in timecourse. In addition, kainate responses show a decrease in CV. These observations are consistent with the hypothesis that CaMKII potentiates responses by increasing the number of active postsynaptic receptors.

DECREASED PAIRED-PULSE FACILITATION ASSOCIATED WITH SYNAPTIC POTENTIATION INDUCED BY ACTIVATION OF POSTSYNAPTIC CA2+/CAM SIGNAL PATHWAYS. PAUL T. KELLY* & JIN-Hui WANG. Department of Neurobiology and Anatomy, University of Texas Medical School at Houston, Texas 77030.

We have shown that synaptic potentiation induced by postsynaptic injection of Ca²⁺/CaM is associated with significant decreases in paired-pulse facilitation (PPF) of synaptic transmission at CA1 synapses of hippocampal slices (*J. Neurophysiol. in press*). Since occlusion experiments showed that Ca²⁺/CaMinduced synaptic potentiation and tetanus-induced LTP share certain common mechanisms, we re-examined if PPF changes during LTP. We observed significant decreases in PPF ($45\pm7\%$ in intracellular recordings and $48\pm10\%$ in field potential recordings) during LTP induction and maintenance relative to baseline (100%). Interestingly, postsynaptic injections of pseudosubstrate inhibitors of CaM-KII and PKC [CaMKII(281-302)/PKC(19-31)] reversed these decreases in PPF to baseline values while blocking LTP maintenance in pre-potentiated compared to control pathways. In addition to synaptic potentiation and PPF attenuation induced by activating postsynaptic Ca²⁺/CaM pathways, we observed that inhibiting postsynaptic calcineurin (CaN) activity with FK-506 or CaN autoinhibitory peptide induced synaptic potentiation (212±18% or or CaN autoinhibitory peptide induced synaptic potentiation (212±18% or 203±12% vs. baseline 100%, respectively) and PPF attenuation (39±7% or 53±6% vs. baseline). The effects of postsynaptic FK-506 injections were blocked by co-injecting BAPTA, a calmodulin-binding peptide, a mixture of CaMKII(281-302) and PKC(19-31), or heparin plus dantrolene. Together, our results indicate that postsynaptic Ca²+/CaM pathways play a dual role in synaptic plasticity, synaptic potentiation and simultaneous attenuation of synaptic facilitation. We speculate that the same postsynaptic mechanisms enhance synaptic transmission and limit the degree of synaptic facilitation at central synapses. central synapses.

ALZHEIMER'S DISEASE: TAU AND ApoE

TAU PROTEIN PHOSPHORYLATION IN HEAT-SHOCKED FOLLOWING GONADECTOMY WITH AND WITHOUT SEX HORMONE REPLACEMENT THERAPY. S. Ch. Papasozomenos*. Dept. of Path., Univ. of Texas Med. Sch., Houston, TX 77030.

We have shown that heat shock induces rapid dephosphorylation of τ in both female and male rats followed by hyperphosphorylation only in female rats (J. Neurochem. 66:1140, 1996). To further investigate whether gonadal hormones play a role in the phosphorylation state of τ , 180 male and female rats were gonadectomized or sham-operated and heat-shocked at 42°C for 15 min following daily subcutaneous injections of testosterone propionate (1 mg/100 g) or estradiol benzoate (50 μ g/250 g) or sesame oil for 2-3 wk. SDS cerebral extracts were analyzed by qualitative and quantitative immunoblotting using 4 monoclonal anti- auantibodies that recognize phosphorylated and nonphosphorylated epitopes and the peroxidase-antiperoxidase technique or ¹²⁵I-labeled protein A. None of the above treatments prevented the rapid dephosphorylation of τ at 0 h after heat shock. In both orchiectomized and ovariectomized rats, τ became hyperphosphorylated between 3 and 6 h after heat shock. The degree of hyperphosphorylation decreased in orchiectomized and heat-shocked rats that were treated with testosterone propionate Also, in orchiectomized but not heat-shocked rats the degree of phosphorylation of τ was lower following daily injections of 2 mg than 0.5 mg of testosterone propionate. No differences were found between ovariectomized and heat-shocked rats with and without replacement therapy with estradiol benzoate. These findings suggest that (1) the heat shock-induced rapid dephosphorylation of τ is gonadal hormone independent; and (2) the subsequent hyperphosphorylation of τ is prevented and can be modified by circulating androgens in male rats but is estrogen-independent in female rats. Since τ is hyperphosphorylated in Alzheimer's disease, androgens may exert a protective effect.

CHEMICAL SIMILARITIES OF AHINDUCED NEUROFIBRILLARY DEGENERATION IN RABBITS WITH THOSE OF ALZHEIMER'S DISEASE USING PROBES FOR TAU, APP, β /A4, α 1-ANTICHYMOTRYPSIN, AND UBIQUITIN, <u>J. Savory, Y. Huang, M.R. Wills and M.M. Herman*,</u> Departments of Pathology, Biochemistry and Internal Medicine, University of Virginia, Charlottesv Departments of Pathology, Biochemistry and Internal Medicine, University or VIII (University or VIII) NA 22908; and Clinical Brain Disorders Branch, NIMH Neuroscience Center at St. Elizabeths, N.I.H., Washington, DC 20032

Administration of aluminum (AI) compounds directly into the CNS of rabbits produces marked neurofibrillary degeneration (NF) consisting of argyrophilic accumulations. Early studies indicated that these aggregates consisted of hyperphosphorylated neurofilament proteins (NF) and consequently were of limited value as an experimental animal model for Alzheimer's disease. We now show that other proteins characteristically seen in neurofibrillary tangles of Alzheimer's disease. are also present in NFD in rabbits. We administer Al maltolate (2.5 µmole) via the intracisternal route to 6- month -old male and female New Zealand white rabbits. Clinical symptoms are seen as early as 2 days and animals are sacrificed on days 2 through 7. Marked argyrophilic accumulations are observed by day 3, increasing to day 7. Immunohistochemical studies and Western blot analysis with tau mAbs (Tau-2, AT8, PHF-1, and Alz50) demonstrate that the accumulations contain abnormal tau. Amyloid precursor protein (APP), ubiquitin and cr1-antichymotrypsin (ACT) show increased immunohistochemical staining intensities in neurons containing NFDs, and the elevations are confirmed by Western blot analysis.

β/A4 is detected in neurons of Al-treated rabbits using immunohistochemistry with mAb β amyloid. Time studies demonstrate that intraneuronal immunostaining for APP, ACT, β /A4 and ubiquitin is distinctly positive by day 3 which correlates ance of NFD by day 3; abnormal tau accumulation is a later (day 6-7) event. Studies in aged rabbits (4-5 years) indicate that AI susceptibility is greater than in young adults as demonstrated by more severe neurological symptoms following intracistemal administration of 0.8 µmole of Al maltolate/kg of body weight to animals in both age groups. This animal system provides means of studying temporally-related changes in NFD and how aging may affect these events. Supported by the Virginia Center on Aging.

BUTYROLACTONE I, A CYCLIN-DEPENDENT KINASE INHIBITOR, INDUCES DEPHOSPHORYLATION OF TAU AND DIFFERENTIATES SYSY CELLS. 1.2T. Tanaka*, 1K. Iqbal, 1E. Trenkner, 2M. Takeda and 1I. Grundke-Iqbal. ¹Institute for Basic Research in Developmental Disabilities, Staten Is., NY 10314, USA. ²Dept. Neuropsychiatry, Osaka Univ. Med. Sch., Osaka, 565 Japan

The microtubule associated protein tau of the human neuroblastoma cell line SY5Y is hyperphosphorylated at several of the same sites as tau in Alzheimer disease (AD P-tau). Furthermore, like AD P-tau, the tau in SY5Y cells does not bind to microtubules (FEBS Lett. 360:5-9, 1995). Proline-directed kinases, MAP kinase, cdc2 kinase, cdk5, and glycogen synthase kinase-3 phosphorylate tau in vitro at sites found in AD P-tau. However, the identity of the kinase(s) responsible for the phosphorylation of tau in living cells is not established. Butyrolactone-I (BL-I, a generous gift from Dr. Okuyama, Banyu Pharmaceutical Company, Tsukuba, Japan), a non-cytotoxic and specific inhibitor of the cdk family including the neuron specific cdk5, was employed to investigate the phosphorylation of tau in SY5Y cells. By 2 days BL-I induced the extension of long neurites whereas under similar conditions neurites extension by treatment with retinoic acid was unremarkable. In the BL-I-treated cells, phosphorylation of tau at the PHF-1 site (Ser 396/404) was markedly decreased and the microtubule binding activity was restored. In contrast, olomoucine which inhibits both MAP kinase and cdk was strongly cytotoxic and was far less effective in differentiating cells. This study suggests that in SY5Y cells differentiation might be regulated by cdk and that the suggests that in 3131 cents and entertainment in figure to grant out of the and that the site(s) on that critical for microtubule binding are phosphorylated by this kinase(s). The restoration of the biological activity of tau and neuritogenesis by inhibition of cdk might have therapeutic implications in AD. (Supported by the NY State Office of Mental Retard. and Development. Disabil., the NIH grants NS18105, AG05892, AG08076 and Zenith Award from Alzheimer's Assoc. USA.)

LONGITUDINAL STABILITY OF CSF TAU LEVELS IN MID-STAGE ALZHEIMER PATIENTS. T. Sunderland*, B. Wolozin, D. Galasko, J. Levy, R. Motter, R. Dukoff, M. Bahro, S. Molchan, D. Rubinow, T. Lehtimaki, N. Noviet, R. Duson, and Delay and Mental Health, Bethesda, MD 20892-1264, Department of Neurosciences, University of California, San Diego, CA 92093, Department of Biomedical Sciences, University of Tampere, Finland and Athena Neurosciences, San Francisco, CA.

Antemortem levels of tau in the cerebrospinal fluid (CSF) of Alzheimer's disease (AD) patients have repeatedly been demonstrated to be elevated when compared to controls. While CSF tau has been found to be elevated even in very mild AD, it is unknown how tau levels change during the course of the disease. We have followed 29 mild-moderately affected AD subjects over two years with repeat CSF taps and found no significant overall change in CSF tau levels (548 ±355 vs. 557±275 pg/ml, NS). During this same period, CSF somatostatin levels have been shown to decrease significantly (42±13 vs. 34 ± 13 pg/ml, p=0.009) suggesting that not all CSF markers are stable over time. Similarly, clinical measures of dementia severity (Clinical Dementia Rating Scale, Global Determination Scale and Mini-Mental Status Examination) all showed significant changes consistent with a progression in the disease. None of these variables was significantly correlated with either baseline measures of CSF tau or delta CSF tau (last-first). The only significant relationship we found was between baseline CSF tau itself and delta tau (r= -0.72, p<0.01). Baseline CSF tau levels spanned a wide range but did not correlate with measures of clinical severity of APO E phenotype. These data suggest that CSF tau levels are stable over extended periods of time in a group of mild-moderately demented AD subjects and that tau levels do not predict the severity or rate of progression of AD.

CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II PHOSPHORYLATES TAU AT SER 262 BUT ONLY PARTIALLY INHIBITS ITS BINDING TO MICROTUBULES. T. J. Singh1*, J. Wang1, M. Novak², E. Kontzekova², I. Grundke-Iqbal¹ and K. Iqbal¹. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, New York 10314; ²Institute of Neuroimmunology, Slovak Academy of Sciences, 842-46 Bratislava, Slovak Republic.

PHF-tau, which is phosphorylated at ten ser/thr-pro and eleven non-ser/thrpro sites, is unable to promote microtubule assembly. Phosphorylation of the non-ser/thr-pro site, ser 262, is reported to be primarily responsible for this. The identities of kinase(s) responsible for ser 262 phosphorylation are still to be clarified. In this study we have used the monoclonal antibody 12E8, which recognizes P-ser 262 and P-ser 356 on tau, to survey different kinases for their abilities to phosphorylate ser 262 on human tau 3L (tau410). In decreasing order of effectiveness we found that ser 262 and ser 356 phosphorylation can be catalyzed by CaM kinase II >> C-kinase >> GSK-3 = Akinase>>CK-1. CaM kinase II and C-kinase were shown to phosphorylate both ser 262 and ser 356. The binding of tau to taxol-stabilized microtubules was decreased by 35% and 42% after phosphorylation by CaM kinase II and C-kinase, respectively. Of the fraction of tau that bound to microtubules, about 50% was phosphorylated at ser 262 and ser 356. These results suggest that ser 262 and ser 356 are very good substrates for CaM kinase II but their phosphorylations are not sufficient to achieve maximal inhibition of tau binding to microtubules. [Supported in part by NIH grants AG08076, AG05892 (K.I.), NS18105 (I.G.-I.), AG11932 (T.J.S.), and Howard Hughes Medical Institute grant 75195-547401 (MN, EK)]

IDENTIFICATION AND CHARACTERIZATION OF TAU PHOSPHOPEPTIDE EPITOPES RECOGNIZED BY ANTI-PAIRED HELICAL FILAMENT MONOCLONAL ANTIBODIES, R. Hoffmann, V.M-Y. Lee and L. Otvos, Jr.*. The Wistar Institute and Department of Pathology, University of Pennsylvania Medical School, Philadelphia, PA 19104

Increasing number of evidence indicates that theoretically abnormally hyperphosphorylated tau protein could be detected in normal body fluids (e.g. CSF In perpinsipholy activated the protection to detected in homat body intak (e.g. CsF) by diagnostic antibodies. The currently available anti-PHF mAbs, however, are not specific enough for further development. In the current study we used single, di- and triphosphorylated tau peptides to identify the location and required number of phosphate groups for full recognition by a panel of known and newly developed mAbs that recognized PHF-tau but not normal tau. We concentrated on peptides encompassing clustered phosphoamino acids between residues 210-220, 230-240 and 395-405. For all mAbs the governing feature of the antigen recognition could be identified as single phosphoserines or phosphothreonines. Some of the antibodies, however, needed multiple phosphates on the peptide antigens for full binding. For example, mAbs PHF-6 and AT180 recognized phosphorylated Thr231, and their recognition was not increased after phosphorylation of Ser235. In contrast, the antigen recognition of mAb PHF-27 (that recognizes the same Thr231) was increased after phosphorylation of Ser235. As the reverse-turn conformation of the corresponding non-phosphorylated, and single phosphorylated peptides was stabilized after dual phosphorylation, it appears that while mAbs PHF-6 and AT180 see only the presence of the phosphate group, mAb PHF-27 recognizes both the presence of the phosphate and the secondary structure of the antigen.

We model the extracellular stability of peptides with stability studies in human

serum. As the addition of phosphate groups to the epitopes may or may not increase the serum half-life of the synthetic peptides, these serum stability studies identify amino acid residues the phosphorylation of which can result in increased protease resistance and consequently help the accumulation of the hyperphosphorylated tau

protein in the affected brains.

Supported by NIH grant AG10670.

MONOCLONAL ANTIBODY PHF-9 RECOGNIZES SER404 OF TAU AND LABELS PAIRED HELICAL FILAMENTS. F.P. Zemlan* and G.E. Dean. Alzheimer's Research Center, University of Cincinnati Col, Med., Cincinnati, OH 45267-0559

Alzheimer's paired helical filaments (PHF) consist of phosphorylated MAP-tau. In PHF, phosphorylation occurs at ser/thr tau residues. Several of these ser/thr phosphorylation sites lie immediately C-terminal to the tau tubulin binding domain. The C-terminal ser³⁹⁶ to thr⁴¹³ tau region contains two or more phosphorylated residues and eight possible ser/thr phosphorylation sites. Immunologic studies and mass spectroscopy have identified ser3 as one of the phosphorylation sites but identification of more Cterminal phosphorylated residues has been hampered by the lack of Mabs that recognize defined epitopes in this region. raised Mabs against PHF purified from Alzheimer's brain. One of these Mabs, PHF-9, showed phosphorylation-dependent binding to purified PHF and recognized a phosphorylated epitope in the Cterminal portion of cyanogen bromide-digested PHF. Epitope mapping studies employing synthetic tau phosphopeptides indicated that PHF-9 labeled a 13-mer tau peptide phosphorylated at ser4 but not the corresponding non-phosphorylated peptide. PHF-9 demonstrated no immunoreactivity with a phospho-ser³⁹⁶ peptide indicating that the PHF-9 epitope is C-terminal to ser conclusion, the present study describes a Mab, PHF-9, which recognizes phosphphorylated ser⁴⁰⁴ of tau independently of phosphorylated ser³⁰⁶ and indicates that ser⁴⁰⁴ is phosphorylated in PHF.

A NEW MOLECULAR INTERACTOR FOR TAU PROTEIN.

G. Lee, S.L. Kwei, S.T. Newman, M. Lu* and Y. Liu. Center for Neurologic Diseases, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115

Tau protein is a microtubule-associated protein found in neuronal cells and is a prominent component of the neurofibrillary tangles of Alzheimer's disease. Using the yeast two hybrid system, we have identified a new protein that interacts with tau. This protein contains several copies of the WD repeats that are found in G protein β subunits as well as other proteins involved in signal transduction, regulation of cytoskeletal assembly, cell cycle, and RNA processing. Database searching revealed that this protein is likely to be the human homolog of the Drosophila extra sex combs (esc) gene product. The esc protein is involved in the stable long term repression of the homeotic genes and therefore is involved in maintaining spatial specific expression of genes. In addition, at various stages of Drosophila development, the esc protein is reported to be neuronal specific. We have isolated full length cDNA clones for the human protein from brain cDNA and have found that the amino terminus is alternatively spliced. Transfection of the isoform most commonly isolated indicated that the protein is cytoplasmic, consistent with the finding that the amino terminal sequence did not contain the nuclear targeting sequence identified in the Drosophila homolog. Conservation between the sequences was greatest in the domain containing the WD repeats. Examples of other known cytoskeletal proteins containing WD repeats are coronin and an intermediate chain of Chlamydomonas outer arm dynein. Supported by NSF and ADRDA.

NEURONS EXPRESSING PHOSPHORYLATED TAU PROTEIN ARE MORE RESISTANT IN VITRO TO APOPTOSIS INDUCED BY NMDA. M. Lesort, C. Yardin, F. Terro, C. Blanchard, J. Hugon*. Neurobiol. & Cell. Pathol. Unit, Lab. Histology and Cell Biology, Fac. Medicine, Limoges, 87025 FRANCE

Apoptosis is a programmed cell death occuring during brain development and in certain neurological diseases such as Alzheimer's disease (AD). Tau protein is a microtubule associated protein promoting microtubule polymerisation and stabilization. Phosphorylated tau protein is the major constituent of paired helical filaments which accumulate in neurons of patients suffering from AD. The goal of the present study is to compare the rate of apoptosis induced by the glutamate agonist NMDA in neurons expressing or not phosphorylated tau and in neurons expressing the Amyloid Precursor Protein (APP). Rat cortical neurons were exposed for 16 hours to $20\,\mu M$ NMDA or vehicule alone. After exposure, the percentages of apoptotic neurons evaluated by the TUNEL method are 32.4 $\% \pm 6.6$ % in treated cultures and 11.5 % \pm 4.3 % in control cultures. Treated and control cultures were processed for immunofluorescence study using AT8 antibody (Innogenetics) directed against tau phosphorylated epitopes, tau 1 antibody (Boehringer) directed against a non phosphorylated epitope or B amyloid 1/40 (Sigma) and stained with propidium iodide to evaluate apoptotic nuclei. The percentages of apoptotic neurons immunopositive for AT8 antibody are not stastistically different in NMDA-treated and control cultures (101 % of controls). At the opposite, the percentages of apoptotic neurons immunopositive for tau 1 and 1/40 antibodies stastistically increased in NMDA-treated cultures (respectively 230 and 190 % of controls). In addition a cellular APP release was observed around apoptotic neurons. In conclusion, AT8 positive neurons are clearly resistant in vitro to apoptosis compared to neurons expressing tau 1 and apoptosis is associated with the accumulation of extracellular and potentially amyloidogenic APP derivates.

INCREASING CEREBROSPINAL FLUID TAU LEVELS IN ALZHEIMER PATIENTS WITH APOLIPOPROTEIN E ALLELE & DURING 14 MONTHS FOLLOW-UP.

. Lannfelt*, M. Blomberg, M. Jensen, H. Basun, L.O. Wahlund. Karolinska Institute, Department of Geriatric Medicine, Huddinge University Hospital, S-141 86 Huddinge, Sweden

We and others have shown that tau concentrations are elevated in cerebrospinal fluid (CSF) from Alzheimer disease (AD) patients, suggesting that tau in CSF may be a useful biochemical diagnostic marker for this disorder. We have investigated CSF tau concentrations in AD (n=18), mild cognitively impaired individuals (MCI, n=9), and other dementing diseases (OD, n=9) by ELISA (Innogenetics hTau Antigen, Belgium). CSF was obtained on two occasions with a mean of 14 months in between. Mean CSF tau levels on the first occasion for AD, MCI and OD were 948±498 (pg/ml, SD), 372±90 and 568±258, respectively. Tau levels were significantly higher in the AD group than in MCI and OD groups. Twelve of the AD patients demonstrated increasing values of tau at follow-up and six showed diminished values. All AD patients with increasing tau were carriers of one or two ε 4 alleles of the apolipoprotein E (APOE) gene. Of those AD cases with decreasing tau levels only three individuals had the $\varepsilon 4$ allele. This difference was significant (p < 0.05). The MCI and OD groups did not show an increased CSF tau at follow-up. These preliminary findings suggest that there may be APOE isoform specific differences of tau regulation in AD.

MOLECULAR AND ANATOMICAL CHARACTERIZATION OF THE LOW DENSITY LIPOPROTEIN RECEPTOR RELATED PROTEIN (LRP), AN APOE AND APP RECEPTOR, IN ALZHEIMER'S DISEASE. B. T. Hyman*, A. Clatworthy, O. Berezovskaja, R. Christie, K. Page, G.W. Rebeck, and D. Strickland. Mass General Hosp, Boston, MA 02114 & Am Red Cross, Rockville, MD 20855

LRP is an APP-KPI receptor and the major neuronal apoE receptor. LRP is a >600KDa protein, whose gene contains 89 exons. We screened genomic DNA for polymorphisms, including a published polymorphism in the 5' untranslated region, and so far have found no allelic differences between AD and controls. We also examined the multiple ligand binding domain regions of cDNA but did not detect evidence for any splice form variants. By both immunostaining and in situ hybridization, LRP was prominent on neurons. The hippocampal formation and cerebellum contained highest levels of signal. By confocal microscopy of human brain and cultured H4 neuroglioma cells, the majority of LRP was observed in the Golgi and ER; LRP was also present in clustered patches on the cell surface and on proximal axons and dendrites. LRP colocalizes with the 39 kDa Receptor Associated Protein intracellularly but not on the cell surface. These data suggest that the expression of LRP on the neuronal cell surface is tightly regulated: it is expressed in brain as the full length protein, in association with RAP, and ultimately reaches the cell surface where it is highly localized, perhaps in clathrin coated pits. Supported by NIH AG12406

388.12

THE ABSENCE OF AN APOLIPOPROTEIN &4 ALLELE IS ASSOCIATED WITH A MORE AGGRESSIVE FORM OF ALZHEIMER'S DISEASE Y, Stern*, J. Brandt, M. Albert, D.M. Jacobs, K. Bell, K. Marder, M. Sano, S Albert, C. D. Castenada, F. Bylsma, B. Tycko and R. Mayeux. Neurology Dept., Columbia Univ., New York, NY 10032

We investigated the relationship between APOE genotype and rate of disease progression and survival in 99 patients with probable Alzheimer's disease who were followed biannually for up to 6 years. The rate of decline in modified Mini-Mental State Examination scores was slower (p<.05), the presence of extrapyramidal signs was decreased (p<.01), the development of myoclonus occurred later (RR= 0.08; CI=0.01-0.51), and the risk of mortality was decreased (RR= 0.38; CI=0.17-0.84) among patients with at least one APOE &4 allele compared to patients with other genotypes. Because the decline in mental ability as well as the development of myoclonus and extrapyramidal signs are consistent manifestations of disease progression, our results imply that APOE £4 is associated with a less aggressive form of Alzheimer's disease.

HIPPOCAMPAL VOLUMES IN APOLIPOPROTEIN E TYPE 4 HOMOZYGOTES BEFORE THE ONSET OF ALZHEIMER'S DEMENTIA. A. Uecker*, E.M. Reiman, S. Lewis, R.J. Caselli, D. Bandy, M. deLeon, S. DeSanti, and A. Convit. U. Ariz, Mayo Clinic, New York Univ., and the Samaritan PET Center, Good Samaritan Reg. Med. Center, Phoenix, AZ 85006 Patients with Alzheimer's dementia have abnormal reductions in regional glucose metabolism using positron emission tomography (PET) and abnormal reductions in hippocampal volume using magnetic resonance imaging (MRI). Subjects homozygous for the apolipoprotein E type 4 (APOE-£4) allele have similar PET abnormalities before the onset of cognitive abnormalities (Reiman et al, New Engl J Med, 1996). In this study, we investigated the ability of MRI measurements of hippocampal volume to provide preclinical evidence of AD in the same subject group.

APOE genotypes were characterized in 235 volunteers 50-65 yearsof age who reported a family history of probable AD. Neurologic, psychiatric and neuropsychological evaluations, PET measurements of regional glucose metabolism, and a T1-weighted volumetric MRI were performed in 11 &4 homozygotes and 22 controls matched for gender, age, and educational level. A blind rater characterized hippocampal volume (97% intra-rater reliability) and intracranial volume (99% intra-rater reliability) in each MRI.

We failed to detect significantly lower hippocampal volumes (one-tailed ttest p=.11), significantly lower ratios of hippocampal-to-intracranial volume (p=.34), or significantly greater differences between right and left hippocampal volumes (p=.17) in the cognitively normal £4 homozygote group. Using available image-acquisition and image-analysis techniques, PET measurements of posterior cingulate glucose metabolism appear to provide a more sensitive index of AD pathology than MRI measurements of hippocampal volume before the onset of cognitive impairment.

LONG-TERM POTENTIATION: PHYSIOLOGY II

Cerebellar LTD is Induced by NO+Ca²⁺ or cGMP+Ca²⁺. Varda Lev-Ram^{1*}, Jason Wood², David S. Lawrence², and Roger Y. Tsien^{1,3}, ¹Dept. of Pharmacology and ³Howard Hughes Med. Inst., UCSD, La Jolla, CA 92093-0647; ²Dept. of Chemistry, SUNY Buffalo, NY 14260-3000

Long-term depression (LTD) in the cerebellum is a prolonged reduction in the efficacy of the parallel fiber (PF) synapse onto Purkinje cells (PCs) and is

physiologically induced by activating PFs simultaneously with postsynaptic depolarization. We have previously shown in acute slices from young adult rats that nitric oxide (NO) uncaged inside PCs can completely replace PF activation (Lev-Ram et al. (1995) Neuron 15:407-415). We now find that Ca²⁺ uncaged from nitr-7 or azid-1 can completely replace postsynaptic depolarization and synergize with either PF activity or uncaged NO to trigger LTD. The ability of simultaneously uncaged NO and Ca²⁺ to induce LTD without any electrical activity proves that these two messengers are sufficient and that no other ionic signals are necessary. Ca2+ elevation must begin ≤10 ms after the end of NO production, suggesting a very short lifetime and limited diffusion distance of NO, and a precise coincidence detection mechanism. As previously suspected, NO acts via cGMP production, because ODQ and LY83583, which inhibit soluble guanylate cyclase (GC), block LTD induction by PFs or uncaged NO. This blockade could be circumvented by uncaged cGMP, but only when combined with a Ca²⁺ transient. Inhibition of cGMPndent protein kinase (PKG) with three different types of blockers, Rp-8Br-PETdependent protein kinase (FNO) with three tributes of the state of the sufficient for LTD induction; their coincidence is detected with ≈10 ms time resolution; NO acts via GC and PKG rather than other proposed transducing molecules; and cGMP elevation still has to coincide with a Ca²⁺ increase to induce LTD. Supported by HHMI and NIH NS27177.

INDUCTION OF LTD IN VISUAL CORTICAL NEURONS WITH STOCHASTIC PATTERNS OF AFFERENT STIMULATION. S. M. Dudck*, D. Egelmant, P. R. Montaguet, and M. J. Friedlander. Neurobiology Research Center,

Egelman'. P. R. Montague' and M. J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, Al. 35294, and 'Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Many neural network theories today make use of Hebb-type learning rules, resembling the phenomena of long-term potentiation (LTP) and long-term depression (LTD). One theory, put forth by Bienenstock, Cooper, and Munro (BCM), inspired a line of experiments leading to the development of a now commonly used method of inducing long-term depression (LTD) in the hippocampus (Dudek & Bear, 1992) and neocortex (Kirkwood et al., 1994). While these experiments established that the induction of LTD is dependent upon the frequency of afferent stimulation, the use of sustained trains at regular stimulation rates in those studies differs considerably from the less regular input that neurons may experience in vivo. To determine whether a more realistic version of this "afferent noise" can also induce LTD, we delivered more realistic version of this "affected noise" can also induce LTD, we delivered afferent stimulation in pseudo-random, stochastic patterns. The average frequency of the 900 pulses of stimulation was set by the experimenter in the range of 1 to $10~{\rm Hz}$ and delivered with interstimulus intervals in a Poisson interval distribution to produce the specified value. Intracellularly recorded compound PSPs from layer 2/3 neurons in slices of guinea pig visual cortex were evoked by stimulation in layer 4 and assessed for the expression of a long-lasting depression (>30 min.). LTD was induced in 10 of 10 cells that were given stimulation averaging 1 or 2 Hz ($\mathbb{X}=32.4\pm5.1\%$ and $2.33.4\pm5.0\%$, for 1 and 2 Hz respectively). Significant depression was not induced in any of the 4 cells tested at the 10 Hz-average stochastic stimulation ($\mathbb{X}=+1.4\pm5.0\%$). Induction of significant depression was highly variable at intermediate frequencies: LTD in 4 of 5 cells at 3 Hz-average ($\bar{\mathbf{x}}$ =-28.7±9.8%) and in 3 of 6 cells at 5 Hz-average ($\bar{\mathbf{x}}$ =-15.3±7.3%). The similar character of LTD induction for regular and stochastic stimulation suggests strongly that LTD induction is not an artifact of fixed rate stimulation. Supported by NIH grant EY05116 and HFSP grant RG69193 to M.J.F., and NIMH grant R0152797 to P.R.M.

A LATE PHASE OF CEREBELLAR LONG-TERM DEPRESSION (LTD) IS DEPENDENT UPON PROTEIN SYNTHESIS. <u>D.J. Linden* Department</u> of Neuroscience, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205. Cerebellar LTD is a cellular model of information storage in which a persistent attenuation of the parallel fiber-Purkinje neuron (PN) synapse is induced by conjunc-

Cerebellar LTD is a cellular model of information storage in which a persistent attenuation of the parallel fiber-Purkinje neuron (PN) synapse is induced by conjunctive stimulation of parallel fiber and climbing fiber inputs. LTD may be induced in the cultured mouse PN when glutamate pulses and PN depolarization, which mimic the effects of parallel and climbing fibers respectively, are co-applied. Amphotericin-patch recording from PNs with Cs-based internal saline has allowed for the recording of input-specific LTD which persists for >120 min. Bath application of the translation inhibitor anisomycin (10 uM), immediately, but not 30 min after glutamate/depolarization conjunction, produced a blockade of the late phase of LTD which became evident ~60 min later. No effect of anisomycin was seen on a separate control input which did not receive conjunctive stimulation. A similar blockade of late-phase LTD was seen using the transcription inhibitors actinomycin D (30 uM) or DRB (30 uM). Fura-2 microfluorimetry revealed that these three drugs did not significantly alter depolarization-induced Ca influx or mGluR-induced Ca mobilization at the concentrations used, suggesting that their effects were indeed mediated by protein synthesis inhibitors, rather than inhibitor for processes previously shown to be necessary for LTD induction. Finally, LTD was produced using glutamate/depolarization conjunction in a perforated outside-out macropatch of dendritic membrane. LTD in this preparation, which lacks nuclear material, returned to baseline with a time-course similar to that produced by protein synthesis inhibitors in intact cultured PNs, and was not further altered by application of actinomycin D. However, application of anisomycin to the dendritic macropatch resulted in a further shortening of the depressed time-course suggesting that local mRNA translation in the dendrite may contribute to the late phase. MECHANISMS FOR INCREASED NUMBER OF SITES OF SYNAPTIC TRANSMISSION DURING THE LATE PHASE OF CA3-CA1 LTP. H. Golan, V.Y. Bolshakov, E.R. Kandel, and S.A. Siegelbaum*. HHMI, Ctr. Neurobiology & Behavior, Columbia Univ., NY, NY 10032.

Several mechanisms could explain the increased number of peaks in the EPSC amplitude histogram that appear during L-LTP (see Bolshakov et al., above). First, there could be an insertion of new clusters of postsynaptic receptors under a single release site (with multiple peaks corresponding to multiple clusters of active receptors). We ruled this out by showing that elevation of external Ca shifted the EPSC amplitude distribution (more events now appear in peaks composed of multiple quanta) consistent with an increased number of release sites. We next ruled out the unmasking of silent synapses (sites with no active AMPA receptors but active NMDA receptors) during L-LTP. The NMDA (in Mg²⁺-free solution) and AMPA components of the unitary EPSCs exhibit a similar fraction of failures in control slices suggesting the initial absence of silent synapses. We thus conclude that L-LTP involves an increase in the number of release sites. Surprisingly L-LTP was accompanied by a 2-fold increase in the mean size and CV of spontaneous MEPSCs. However, this effect appears presynaptic since substituting Sr²⁺ for Ca²⁺ in the extracellular solution, so as to desynchronize release, decreased MEPSC size back to control values. Following the proposal of Korn and Faber that synchronized release of MEPSC can occur when a single bouton contains multiple active zones, our results are most consistent with the formation of perforated synapses by splitting of active zones into multiple sites. Supported by HHMI and NIMH IP50 MH50733.

STUDIES OF LTP IN MICE WITH KNOCK-OUT OF THE NEURONAL AND ENDOTHELIAL FORMS OF NOS. H. Son*, R.D. Hawkins, E.R. Kandel, P.L. Huangt, M.C. Fishmant. HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., New York, NY 10032; 'Cardiovasc. Res. Ctr., Mass. Gen. Hosp., Harvard Med. School, Charlestown, MA 02129.

Nitric oxide (NO) has been implicated as a retrograde messenger in hippocampal LTP. However, LTP is normal in mice with a knockout of the neuronal form of NO synthase (nNOS-1), suggesting that the endothelial, but not neuronal, form of NOS may be required for LTP (O'Dell et al., 1994). Therefore, we tested LTP in mice with a knock-out of neuronal NOS, endothelial NOS (eNOS-1-), or a double (neuronal and endothelial NOS) knock-out. LTP in the stratum radiatum of CA1 was normal in both nNOS-1 mice (212 ± 17%, n=4) and eNOS $^{\prime\prime}$ mice (199 \pm 6%, n=6) compared to wild-type (211 \pm 8%, n=16), but LTP was significantly reduced in double knock-out mice (142 \pm 4%, n=8). The amplitude of field EPSPs, paired-pulse facilitation, and LTD were normal in the double knock-out mice. In preliminary experiments, LTP in the stratum radiatum was significantly reduced by the NOS inhibitor, nitroarginine, in wild-type (133 \pm 8%, n=10) but not in double knock-out (141 ± 4%, n=2) mice. However, LTP in stratum oriens was not affected by nitroarginine (192 ± 5%, n=10) compared to control (200 \pm 7%, n=10) in wild-type mice, indicating that it is NOS-independent (Haley and Madison, 1995). LTP in stratum oriens was normal in the double knock-out mice (202 ± 24%, n=2), suggesting that the deficit in stratum radiatum LTP is not due to nonspecific effects in the double knock-out mice. These genetic results therefore support the idea that NO is involved in LTP, and suggest that the neuronal and endothelial forms can compensate for each other in the single knock-outs. INDUCTION OF THE LATE PHASE OF SCHAFFER COLLATERAL LTP LEADS TO AN INCREASE IN THE NUMBER OF SITES FOR SYNAPTIC TRANSMISSION. V.Y. Bolshakov*, H. Golan, S.A. Siegelbaum and E.R. Kandel. HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

LTP in the Schaffer collateral pathway between CA3 and CA1 pyramidal neurons exhibits an early phase (E-LTP) that is independent of protein synthesis and a late phase (L-LTP) that requires protein synthesis We previously studied the unitary synaptic connections between single CA3 and CA1 neurons and found that the EPSC amplitude distributions showed only a single quantal peak. This indicates that a single CA3 neuron makes only a single synaptic contact with a single CA1 neuron and that this contact contains only a single release site which releases a single quantum. With the production of E-LTP there was an increase in the probability of transmitter release (fewer failures) but no increase in the number of release sites or quantal amplitude. Does the same mechanism underlie L-LTP? To induce L-LTP we pretreated slices for 15 min with Sp-cAMPs (50 μ M). Recordings of unitary synaptic transmission, 2-4 hrs after washout of cAMP showed two major differences from untreated slices: 1. Similar to E-LTP, the fraction of failures of transmission was decreased; 2. Unlike E-LTP, there was an increase in the number of peaks in the EPSC amplitude distribution. Quantal amplitude was not altered. Both effects were blocked by the protein synthesis inhibitor anisomycin. These results suggest that L-LTP involves the addition of new sites of synaptic transmission (see Golan et al. below). Supported by HHMI and NIMH IP50 MH50733.

AMPA RECEPTOR EXPRESSION INCREASES DURING THE LATE PHASE OF ELECTRICALLY INDUCED LTP. <u>A.S. Nayak and M.D. Browning</u> University of Colorado Health Sciences Center, Denver, CO 80262.

LTP is a dramatic form of synaptic plasticity that is believed to underlie certain types of learning and memory. Considerable interest has focused on the potentiation of postsynaptic AMPA receptors in hippocampal LTP. Here we report that tetanus-induced LTP is accompanied by an increase in synthesis of GluR1 and GluR2/3 subunits of the AMPA-receptor. High frequency stimulation (HFS) was delivered to CA1 mini-slices using a special multi-electrode array (the "rake", a linear array of four monopolar electrodes), in order to optimize the fraction of synapses in each slice that received stimulation. Three hours after stimulation, tetanized slices showed a 51.6±10.5% increase in GluR21 synthesis and a 28.6±5.1% increase in GluR2/3 synthesis over unstimulated control slices, as determined by ³⁵S-methionine incorporation. Ninety minutes after stimulation, there was a similar but smaller increase in the expression of these subunits (not statistically significant). Western blot analysis confirmed that the increases observed at 3 hours were in total protein level and not merely in turnover rate. The effects at three hours were completely blocked by 100µM APV or 10µM MK-801, NMDA-receptor antagonists which block the induction of LTP. Frey et al. (1993, Science, 260,1661-4) have defined a late-phase LTP which begins three hours after HFS and requires protein synthesis and protein kinase A (PKA). The increases in GluR expression we observed 3 hours after HFS also require PKA, as these effects were completely blocked when slices were stimulated in the presence of 100µM Rp-cAMPS, a membrane permeable inhibitor of PKA. Interestingly, Sp-cAMPS, an activator of PKA, was able to induce a significant but small increase in GluR expression even in the absence of high frequency stimulation. These data suggest that increases in AMPA-receptor expression contribute to LTP-associated increases in synaptic responsiveness, and that cAMP/PKA may play a pivotal role in the expression of LTP by orchestrating these postsynaptic changes. NO ACTS AS A RETROGRADE MESSENGER DURING LONG-TERM POTENTIATION IN CULTURED HIPPOCAMPAL NEURONS.

O. Arancio*, V. Lev-Ram, R.Y. Tsien, E.R. Kandel, and R.D. Hawkins.

Columbia Univ., NY, NY 10032, and UC San Diego, La Jolla, CA 92093

Previous results suggest that long-term potentiation (LTP) at synapses between hippocampal neurons in dissociated cell culture involves presynaptic guanylylcyclase (Arancio et al., Nature 376:74-80, 1995). Since guanylyl-cyclase can be activated by several substances including NO, we have examined the role of NO in LTP using dissociated cell culture. LTP was blocked by postsynaptic but not presynaptic injection of an NO-synthase inhibitor, L-NMMA, and bath application of NO produced activity-dependent long-lasting potentiation (Arancio et al., Soc. Neurosci., Abstr. 21:1811, 1995). These results suggest that NO is involved in LTP, and that NO-synthase is located in the postsynaptic neuron. We now report that LTP was also blocked by delivery of a NO scavenger, oxymyoglobin to the bath (10 μ M, n=16) or through the patch pipette (50 μ M) to either the postsynaptic (n=10) or presynaptic (n=11) neuron. By contrast, potentiation by exogenous NO was blocked by oxymyoglobin in the presynaptic (n=8) but not the postsynaptic (n=8) neuron. These results suggest that NO must travel through the extracellular space to the presynaptic neuron to produce potentiation. As an additional test of the site of action of NO, we used a membrane-impermeant NO donor, CNO-4, that releases NO only upon photolysis with UV light. Intracellular injection of CNO-4 (20 µM) into the postsynaptic neuron followed by photolysis (estimated to release 10 nM NO) paired with activity caused long-lasting potentiation (n=8) that was blocked by extracellular oxymyoglobin (n=5). By contrast, photolytic release of NO in the presynaptic neuron paired with activity caused potentiation that was not blocked by extracellular oxymyoglobin (n=14), suggesting that the site of action of NO is in the presynaptic neuron. Taken together, these results strongly support the hypothesis that NO can act as an activity dependent retrograde messenger during LTP. Supported by NIMH and HHMI.

OVER-EXPRESSION OF Cu/Zn SOD and S100β GENES IS LINKED TO IMPAIRED LEARNING AND HIPPOCAMPAL LTP E. Gahtan, J.M. Auerbach*, Y. Groner and M. Segal The Weizmann Institute, Rehovot 76100, Israel.

The Marked Learning And FilePockampal Lip E. Gantan, J.M. Auerbach*, Y. Groner and M. Segal The Weizmann Institute, Rehovot 76100, Israel.

A link between Alzheimer's Disease (AD) and Down Syndrome (DS) has been based on the finding that most DS patients, who are characterized by trisomy of chromosome 21, develop AD pathology at young age. To investigate the role of chromosome 21 genes in brain and behavior, transgenic (Tg) mice were produced that overexpressed the human Cu/Zn SOD and S100β genes, located on human chromosome 21. Over-expression of SOD and S100β in brains of these mice was confirmed immunohistochemically.

Tg mice were found to be significantly more active then controls in an open

Tg mice were found to be significantly more active then controls in an open field and in activity-monitoring cage. Tg mice also had fewer defecations and greater frequency of rearing in the open field, suggesting decreased emotionality relative to controls. Tg mice demonstrated impaired performance in the Morris Water Maze. The Tg group had longer mean escape latencies across each of the 12 training trials, suggesting a deficit in spatial learning, and were impaired in a test of spatial memory conducted 24 hours after the last training trial. No difference was observed between Tg and controls in escape latency to a visible platform, indicating that sensory, motor and motivational factors are equivalent between orgups

motivational factors are equivalent between groups.

Population EPSP slopes in region CA1 of hippocampal slices from Tg and controls showed similar degrees of post-tetanic potentiation in response to tetanic stimulation (100Hz, 1s) of stratum radiatum fibers, but potentiation in Tg slices dropped off rapidly, falling to approximately half its initial level 10 min post tetanus. In contrast, potentiation in control slices remained stable for at least 30 minutes onst tetanus.

at least 30 minutes post tetanus.

The present experiments were conducted with Tg mice over-expressing 2 genes. Future studies will examine the contribution of each gene to the observed deficits. Supported by NIH HD21229 and Weizmann Institute grants.

ROLE OF THE TRK FAMILY OF RECEPTOR TYROSINE KINASES IN NEUROTROPHIN- AND SYNAPTICALLY-INDUCED POTENTIATION IN ADULT RAT HIPPOCAMPUS. <u>H.Kang¹*</u> AWelcher², E.M. Schuman¹, 'Division of Biology 216-76, Caltech, Pasadena, CA 91125 and ²Amgen Inc., Thousand Oaks, CA 91320

During development, the neurotrophins exert their effects through the Trk family of receptor tyrosine The widespread expression of Trk receptors in the adult hippocampus suggests the possibility that the neurotrophin-induced potentiation we have observed is mediated by these same receptors. Our previous studies with the K252 compounds support this possibility since K252a, an inhibitor of receptor tyrosine kinases, prevents this enhancement (Kang & Schuman, Science, 1995). However, to circumvent the potential non-specific effects of pharmacological inhibitors, we utilized specific function-blocking Trk antibodies to ascertain directly which receptors the neurotrophins interact with to bring about the synaptic enhancement. Pre-incubation of slices with TrkB antibody (Ab) dramatically attenuated the induction of synaptic enhancement upon exposure to brain-derived neurotrophic factor (BDNF, 50 ng/ml), although adjacent slices pre-incubated with pre-immune serum showed normal enhancement [mean % of baseline 1 hour after exposure: pre-immune. 186.6 \pm 12.2 (p<0.05, n=5); TrkB Ab, 110.3 \pm 5.2 (ns, n=5)]. Immunoprecipitation/western blot analysis of hippocampal slice homogenates also indicates that the full-length TrkB receptors are phosphorylated in response to BDNF treatment. In examining the relationship between neurotrophin-induced potentiation and synaptically-induced LTP, we previously showed that prior treatment with the neurotrophins does not significantly occlude the subsequent induction of early-phase LTP. In addition, the neurotrophin-induced potentiation was not affected by the presence of NMDA receptor antagonist. Here, we investigated whether treating slices with TrkB Ab would affect the induction of LTP by high-frequency stimulation. The same antibody which completely prevents BDNF-induced potentiation did not have any effect on tetanus-induced LTP [mean % of baseline 1 hour post tetanus: 180 ± 18.9 (p<0.05, n=5)]. These results support the idea that these two forms of plasticity involve at least partially independent cellular mechanisms for their early phases. This work was supported by the Alfred P. Sloan Foundation, John Merck Fund, and the PEW Charitable Trusts.

HIGH-FREQUENCY TETANUS RELEASES A FACTOR THAT BLOCKS HIPPOCAMPAL LONG-TERM POTENTIATION LOCALLY. <u>Julie A. Kauer* and Lori M. McMahon.</u> Dept. of Neurobiology, Duke University Med. School, Durham, NC 27710.

Extracellular recordings were made in the CA1 region of hippocampal slices from 3-4 week old rats. One stimulating electrode was placed in s. radiatum within 200 μ m of the recording electrode ("close"), with another >500 μ m away ("far"). Field EPSPs elicited by alternating stimulation to each site were stable over time. A brief high-frequency tetanus (100 Hz, 1 sec., 2 trains) to the close stimulating electrode produced little potentiation (15 min. post-tetanus: 126+/-9%, n=8). Subsequent tetanus to the far pathway triggered normal LTP at the same recording site (15 min. post-tetanus: 170 +/- 14%, n=6), suggesting that the postsynaptic recording region is apparently unharmed by nearby tetanic stimulation. Fiber volleys were closely monitored to ensure that presynaptic fibers were not damaged by a close tetanus.

We hypothesized that during a tetanus a diffusible factor that blocks LTP may be released locally. We therefore tetanized close and far pathways simultaneously. In support of the hypothesis, LTP was substantially attenuated in both, while LTP was triggered by a subsequent tetanus to the far pathway alone. We cannot overcome the block of LTP in a close pathway using antagonists of GABA_a or adenosine receptors (50 μ M picrotoxin; n=13 or 2-20 μ M CPT; n=4). Inhibition of NO synthase (100 μ M N-methyl-L-Arg; n=3) or of protein phosphatases involved in LTD (1 μ M calyculin A; n=3) is also ineffective. PTP is significantly smaller after close vs. far tetanus, suggesting a presynaptic action. We speculate that during high-frequency activity, axons in CA1 release a locally-acting factor that blocks LTP. Supported by NS30500-05 to J.A.K.

LONG-TERM POTENTIATION INDUCES PHOSPHORYLATION OF CREB IN THE HIPPOCAMPUS IN VIVO AND IN VITRO. P.J. Voulalas* and J.M. Sarvey. Dept. of Pharmacology, Uniformed Services University of the Health Sciences. Bethesda, MD 20814

of the Health Sciences, Bethesda, MD 20814.

The transcription factor CREB has been implicated as a key regulatory protein in the mediation of long-term changes in synaptic efficacy thought to underlie memory formation. Increases in CREB phosphorylation on Ser 133 reflect functional activation of this protein. We have carried out a time-course analysis of changes in the phosphorylation state of CREB following induction of LTP in rat hippocampal dentate gyrus in vivo and in vitro. Electrophysiological analyses were accompanied by Western blot analyses utilizing an antibody which specifically recognizes the phosphorylated form of CREB. LTP, which lasted several hours, was induced by theta burst stimulation in anesthetized rats, or by a 100Hz, 2s train in hippocampal slices. Increases in CREB phosphorylation in the anesthetized rat occurred within 10' after delivery of a train, and remained elevated for up to 60'. In the *in vitro* slice, CREB phosphorylation increased 5' after delivery of the train, and returned to baseline levels within 30'. MMDA receptor antagonists blocked these increases. These results imply that the time-course of phosphorylation of CREB occurs at a time between activation of membrane receptors (which increase intracellular calcium and cAMP) and increases in protein synthesis events. Supported by NIH NS23865.

GENESIS OF NEURONS AND GLIA: ADULT

390.

SPATIAL AND TEMPORAL PATTERNS OF NEUROGENESIS AND NEURONAL RECRUITMENT IN THE POST-LARVA AND ADULT FISH BRAIN. P. M. Ma* and A. Gilligan, Marine Science Center, Northeastern University, Nahant, MA 01908.

Adult fish brains retain the capacity to produce new neurons and to regenerate after ablation. To investigate the proliferative activity and the extent to which new neurons contribute to the functional organization of the normal and regenerated brain, we use bromodeoxyuridine immunocytochemistry to identify and follow newly-formed neurons in the postlarva and adult guppy and zebrafish brains. Major neurogenetic zones are seen along the ventricles in the telencephalon, preoptic and suprachiasmatic areas (SA), hypothalamus, tectum, and cerebellum. Activity within these zones is age-dependent. Neuronal recruitment occurs by two modes: active migration and displacement. Nuclei removed from the ventricles, such as nucleus glomerulosus (NG), recruit cells by active migration. In other areas, such as the dorsal telencephalon, younger neurons displace older ones from the ependyma. Recruitment is also age-dependent. For example, NG recruits neurons born between post-larval days 1-4, but rarely those born later. Neurons generated at the SA between days 1-5 remain in this area, whereas some of those born later migrate into the pituitary. Newly-formed neurons can apparently migrate to the correct destination and integrate into existing functional circuits in many regions of the adult fish brain and may contribute to functional recovery. [supported by NIMH]

POSTNATAL NEUROGENESIS IN THE DORSAL LATERAL GENICULATE NUCLEUS (LGN) OF THE CAT. J.P. Fedynyshyn* and R.E. Kalil. Center for Neuroscience and Department of Ophthalmology and Visual Sciences, University of Wisconsin Madison W 153706.

The neurons of the mammmalian central nervous system are derived from the mitotic division of undifferentiated neuronal precursor cells, and with few exceptions this neurogenesis occurs during embryonic development and prior to birth. However, many mitotic figures are seen in the LGN of early postnatal kittens. To explore the possibility that neurogenesis in the LGN of the cat may occur after birth, we have used immunofluorescent techniques to determine if cells undergoing mitosis in the postnatal LGN are neurons.

Neonatal kittens were perfused with 4.0% paraformaldehyde and 0.5% glutaraldehyde and sections through the LGN were labeled immunofluorescently with monoclonal antibodies specific for low (68kD), middle (160kD) and high (200kD) molecular weight neurofilaments (NFP) or for class III β tubulin. The primary antibodies were omitted in control sections. The labeled sections were counterstained for mitotic figures with propidium iodide and examined with epifluorescence/differential interference contrast microscopy or with a Bio-Rad MRC 1024 confocal microscope.

Present results suggest that both NFP and β tubulin class III immunoreactivity appear to co-localize with propidium iodide-labeled mitotic figures. These observations provide evidence for postnatal neurogenesis in the cat central visual pathway. Additional experiments with other probes are underway to confirm these results, and to rule out possible artifacts such as cross-reactivity with nonneuronal proteins

NEUROGENESIS IN THE DENTATE GYRUS OF THE ADULT TREE SHREW B.S. McEwen*, E.Gould, P.Tanapat, L.A.M.Galea and E.Fuchs. Lab. of Neuroendocrinology, Rockefeller Univ., New York, NY 10021 and German Primate Center, 37077, Gottingen, Germany. Although adult neurogenesis has been well-documented in the dentate

gyrus of rodents, the existence of this process in the brains of primates has not yet been described. The tree shrew (Tupaia belangeri) is considered to be phylogenetically between insectivores and primates. In order to determine whether the dentate gyrus of the adult tree shrew continues to produce new granule cells, we performed immunohistochemistry for the thymidine analog bromodeoxyuridine (BrdU) as well as for cell-specific markers on the brains of adult tree shrews. Adult tree shrews were injected with BrdU and perfused either 2 or 24h after injection. BrdU-IR cells were detected in the dentate gyrus of all adult tree shrew brains examined. Most of these BrdU-IR cells were located in the subgranular zone (sgz), the region between the granule cell layer (gcl) and the hilus. The vast majority of these cells had the morphology of immature granule neurons, i.e., medium-sized, round or oval cell bodies. A significant increase (>2x) in the number of BrdU-IR cells was detected between the 2 and 24h survival time points indicating that cells which had incorporated BrdU divided at least once in the 24h period. Examination of tissue stained for vimentin, a marker of immature glia, revealed or used standed for windermit, a marker of immature gra, revealed numerous cells with radial glial morphology. The triangular cell bodies of these glia typically resided in the sgz with radial processes extending through the gcl, suggesting that these cells might participate in the migration of immature granule cells.

APOPTOSIS AND SPREADING DEPRESSION. P.E Kunkler* and R.P. Kraig.

Department of Neurology, The University of Chicago, Chicago, IL 60637 Spreading depression (SD) induces gliosis in the CNS but not necrosis. Reactive gliosis is mostly thought of as a response to injury, but some evidence suggests that gliosis may also play a role in synaptogenesis and plasticity. Apoptosis occurs in the CNS under various physiological and pathophysiological conditions. It is possible that SD induced gliosis may be an event secondary to apoptotic cell death, however it is not known if apoptosis occurs following SD. Here we show that apoptotic cell death is not induced following cortical SD but is elevated following SD in the hippocampus. SD was elicited in Wistar male rats by micro-injection of 0.5M KCl into the left parietal cortex every 9 minutes for 3 hours. After survivals times of 0, 6, 24 or 72 hrs, sections collected throughout the rostral caudal extent of the brain were processed with ApopTag In Situ apoptosis detection kit. Counts of ApopTag positive cells were conducted and compared to the contralateral non-exposed hemisphere and to untreated controls. Hippocampal SD was elicited in a similar manner with the micro-injection placed instead in the caudal aspect of the hippocampus. Isolated ApopTag positive cells were found randomly throughout all cortical layers, though occasionally clustered. On average, 1-2 positive cells were observed per section, with an ocassional section containing up to 10 cells. Statistical analysis revealed no left to right difference between the exposed and non-exposed contralateral hemisphere or with untreated controls, though fewer cells overall were observed in the experimental animals. A nonsignificant left to right increase in the presence of small apoptotic bodies was observed in the dentate gyrus (DG) following hippocampal SD, but not in the proliferative subgranular zone of the DG. When compared to untreated brains, the total number of positive cells within the DG of hippocampal SD exposed animals approached significant values. The absence of either necrotic or apoptotic cell death following SD suggest that gliosis with SD may be approaching a physiologic phenomena which may more accurately reflect glial changes associated with brain plasticity rather than injury. NEUROGENESIS IN THE DENTATE GYRUS OF ADULT MICE. G. Kempermann*, H. G. Kuhn and F. H. Gage. Salk Institute for Biological Studies, Laboratory of Genetics, 10010 N. Torrey Pines Rd., La Jolla, CA 92037, USA., E-mail: gerd_kempermann@qm.salk.edu

Neurogenesis can be described by the three consecutive steps of proliferation, migration and differentiation. We compared two mouse strains (Balp/C and C57) at two ages (3 months and 1 year) to study neurogenesis in the adult hippocampus. Proliferating cells were labeled with bromodeoxyuridine (BrdU) and detected with antibodies against BrdU. In all four groups cell proliferation could be detected in the subgranular zone of the dentate gyrus. The number of proliferating cells decreased with the age of the mice and showed strain differences. Four weeks after injection of BrdU the number of BrdU-positive cells was very low, but some of these remaining newborn cells expressed the neuronal marker NeuN, while others stained positive for the astrocytic protein GFAP. In contrast to the analogous cells in rats, however, these cells had not migrated into the granule cell layer and did not express calbindin D28K which is a marker protein for differentiated granule cells. The polysialylated form of the neural cell adhesion molecule (PSA-NCAM) is considered to be involved in the regulation of migration and differentiation in certain distinct nerve cell populations. As PSA-NCAM is expressed in the subgranular zone of adult mice, we conclude that the expression of PSA-NCAM alone is not sufficient to promote neuronal migration and granule cell differentiation in the adult dentate gyrus. Thus mice might differ from rats with regard to other still unknown regulatory factors that are intrinsic to the population of precursor cells or to the environment of the dentate gyrus. These results emphasize that proliferation, migration and differentiation are independently regulated. Mice transgenic for genes or trophic factors that are involved in these distinct events might therefore provide a useful approach to studying the regulation and possible inducibility of neurogenesis in the adult brain

ALTERED NEUROGENESIS IN THE ADULT DENTATE GYRUS FROM SPREADING DEPRESSION. D. Dziewulska* P.E. Kunkler, J.D. Hunter and R.P.

Kraig. Department of Neurology, The University of Chicago, Chicago, IL 60637

The cellular and molecular mechanisms by which neural tissue might be salvaged or even regenerated after injury are only beginning to be explored. Glial cells are thought to affect both injury severity and the ability of brain to regenerate Accordingly, we are examining how gliosis influences neurogenesis and plasticity within the rodent dentate gyrus (DG) where neurogenesis continues in adulthood. Spreading depression (SD) was initiated within hippocampus by micro-injection of KCl in caudal hippocampus for 3 hrs and confirmed via more rostral DC recordings. Animals were allowed to recover and processed for GFAP and PCNA-based immuno-histochemical measurement of cellular proliferation. In controls we found significantly more (p<0.05; n=5) PCNA-positive cells in the subgranular zone of the lower (compared to upper) limb of the DG. This area also showed a significant increase (p<0.05) in PCNA-positive cells after SD compared to controls. Increased PCNA immunostaining was seen throughout the rostral caudal length of the DG. Total PCNA-positive cell counts within the entire DG after SD increased from controls (p=0.06; n=5). Finally, SD induced astrogliosis within the hippocampus, as evidenced by increased GFAP immunostaining compared to controls.

Cameron and colleagues (J. Neurosci, 1995) have shown that lesions of the entorrhinal cortex and blockade of excitatory synaptic transmission increase DG neurogenesis while increased excitatory activity by NMDA receptor activation retards neurogenesis. SD not only involves a massive release of glutamate to the interstitial space but also includes a propagating electrical silence. Thus, if events associated with SD and those ablative and pharmacologic experiments noted above are similar. our results suggest that a decrease in dentate neurogenesis is influenced more by electrical silence than glutamate release. Perhaps, diminished neuronal activity can trigger neurogenesis by co-activating astrocytes. (Supported by NS-19108.)

ADRENAL STEROIDS AND NMDA RECEPTOR ACTIVATION REGULATE NEUROGENESIS IN THE ADULT RAT DENTATE GYRUS THROUGH A COMMON PATHWAY. H. A. Cameron*, P. Tanapat, and E. Gould. Lab of Neuroendocrinology, Rockefeller Univ, NY, NY 10021. The rate of granule cell birth in the adult rat dentate gyrus is regulated by

both adrenal steroids and NMDA receptor activation. Parallels between the actions of these two factors suggest that they may affect cell birth through a common pathway. To test this hypothesis, we altered both of these factors simultaneously and determined whether their effects were additive, implying independent mechanisms, or whether one factor could block the effect of the other, indicating a common pathway. Adult male rats injected with the NMDA receptor antagonist MK-801 had significantly more ³H-thymidine-labeled cells in the dentate gyrus than saline-injected controls (≈3x increase), following a short (2 hour) survival period, while rats injected with corticosterone (cort) had significantly fewer labeled cells than uninjected controls ($\approx 1/3x$). In rats treated with both MK-801 and cort, the labeled cell density (≈3x control value) was not significantly different from that of rats treated with MK-801 alone, indicating that the NMDA receptor blockade completely blocks the effect of cort. In the converse experiment, removal of adrenal steroids through adrenalectomy (ADX) significantly increased 3H -thymidine-labeled cell density compared to sham-operated controls (=3x), and NMDA injection significantly decreased labeled cell density compared to saline injection (≈1/4x). Following ADX and NMDA injection, the density of labeled cells (≈1/3x control value) was not significantly different from that of NMDA treatment alone, indicating that NMDA receptor activation can block the effect of ADX on cell proliferation. These findings suggest that adrenal steroids act upstream of NMDA receptors in a common pathway Supported by MH52423 and NARSAD (E.G.).

EFFECTS OF INTRACEREBROVENTRICULAR ADMINISTRATION OF EGF AND FGF-2 ON PROLIFERATION AND DIFFERENTATION OF NEURAL PROGENITORS IN ADULT RATS: II. HIPPOCAMPUS AND SPINAL CORD. J. Winkler*, H.G. Kuhn, G. Kempermann, L.J. Thal and F.H. Gage. Dept. of Neurosciences, UCSD, La Jolla, CA 92161 and Laboratory of Genetics, Salk Institute, La Jolla, CA 92037.

To define EGF and FGF-2 actions on neural precursor cells in the adult brain we examined the hippocampus and the thoracic spinal cord of rats treated with 2 weeks of intraventricular EGF or FGF-2 (360 ng/day) or artificial cerebrospinal fluid (aCSF). Bromodeoxyuridine (BrdU; 50mg/kg) was injected daily during treatment. At the end of treatment, the hilus and the granule cell layer of EGF-treated animals showed an increase in BrdUlabeled cells in comparison with FGF-2 or aCSF-treated animals. Four weeks following withdrawal, the density of BrdU-labeled cells did not differ between the groups. However, in the molecular layer EGF-treated animals showed a significant increase in BrdU-labeled cells in comparison with all other groups at the end of the treatment and after withdrawal. In the thoracic spinal cord EGF and FGF-2 induced an increase of BrdU-labeled cells in comparison with aCSF-treated animals at both time points. These data indicate that EGF and FGF-2 caused a topographically selective proliferation of precursor cells in the adult CNS. Further characterization with glial and neuronal markers will reveal the phenotype of the newborn cells

Supported by NIH, Brookdale National Fellowship and Hereditary Disease Foundation.

EFFECTS OF INTRACEREBROVENTRICULAR ADMINISTRATION OF EGF AND FGF-2 ON PROLIFERATION AND DIFFERENTIATION OF NEURAL PROGENITORS IN ADULT RATS: I. SUBVENTRICULAR ZONE, STRIATUM AND OLFACTORY BULB. H.G. Kuhn*, J. Winkler, G. Kempermann, L.J. Thal and F.H. Gage. Laboratory of Genetics, The Salk Institute, La Jolla, CA 92037 and Dept. of Neurosciences, UCSD, San Diego, CA 92161.

In recent years the existence of proliferating neural progenitor cells in the adult brain has been demonstrated by both in vitro and in vivo studies. The current experiment analyzed the effects of chronic intracerebroventricular infusion of growth factors on progenitor populations in adult rat brain. Animals received EGF, FGF-2 (360ng/day) or artificial cerebrospinal fluid for 2 weeks via osmotic minipumps into the lateral ventricle, accompanied by daily systemic injections of BrdU (50mg/kg). At the end of the infusion and 4 weeks after withdrawal BrdU-positive subependymal cells of the lateral ventricle wall were significantly increased in EGF and FGF-2 treated rats. EGF infusion resulted in a massive thickening of the subependymal zone. BrdU positive cells were also found in the adjacent striatum of EGF-treated animals. In accordance with a recent study performed in mice (Morshead et al., 1996, J.Neurosci. 16:2649-58), confocal analysis partially identified these striatal cells as newborn neurons and glia. In contrast, EGF infusion decreased BrdU-positive cells in the olfactory bulb, in particular, in the rostral migratory stream, when analyzed at the end of infusion interval, and in the granule cell layer at 4 weeks post-infusion. These data indicate that EGF is capable to expand the population of subventricular progenitor cells. However, retarded rostral migration of neuronal progenitor cells into the olfactory bulb is observed following EGF infusion, Supported by NIH, Hereditary Disease Foundation and Brookdale National Fellowship.

EXPRESSION OF NOS, NCAM-H AND S100 PROTEIN IN THE GRANULE CELL GENERATION PATHWAY OF THE ADULT GUINEA PIG OLFACTORY BULB. A. T. M. S. Islam, K. Nakamura, T. Seki+, A. A. Banu, K. Hirata and M. Kawabuchi*. Dept. of Anatomy, Faculty of Med., Kyushu Univ., Fukuoka 812-82, Japan; 'Dept. of Anatomy, Sch. of Med., Juntendo Univ., Hongo, Tokyo 113, Japan.

In order to reveal the role of nitric oxide (NO) in the persistent adult neurogenesis and neuro-glial coherence in the neuronal migration process, we demonstrated a doublelabeled immunofluorescence cytochemistry under confocal laser scanning microscope, using antibodies against nitric oxide synthesizing enzyme, nitric oxide synthase (NOS), highly polysialylated isoform of neural cell adhesion molecule (NCAM-H), and astroglial marker in the brain, \$100 protein (\$100) in the whole length of subependymal layer as well as in the internal granular layer (IGr) of the adult guinea pig olfactory bulb. Different populations of blast like, beaded, clustered immature cellular elements positive for both NCAM-H and S100 were densely interlaced throughout the entire length of germinal subependymal layer; some S100 positive ependymoglial cells or tanycytes gave off side extensions into NCAM-H positive clusters. This layer was devoid of anti-NOS immunoreactivity. Dense network of irregular, punctate, radially oriented immature cellular elements both positive for NOS and NCAM-H were intermingled, overlapped and sparsely colocalized in the inner part of IGr, but in the outer part, NCAM-H expression was gradually being diminished, and mature bipolar, spherical-or sphindle- shaped granule cells with uniform cellular contour were only immunostained with anti-NOS antisera. Radially oriented astroglial cellular elements expressed close contact with NOS and NCAM-H immunoreactive cellular elements in IGr. Our results showed the morphological basis of astroglial role for neuronal migration and maturation; and specific spatio-temporal relation between NOS and NCAM-H in the course of continuous generation and growth of granule cells in the adult olfactory bulb.

POTENTIAL MYELIN REPAIR OF THE ADULT SUBVENTRICULAR ZONE, FOLLOWING CHEMICALLY INDUCED DEMYELINATION.

Nait-Oumesmar B., Lachapelle F., Vignais L., Bachelin C., Rougon G*, and Baron-Van <u>Evercooren A.</u> U 134 INSERM, Hôpital de la Salpêtrière, 75651 Paris cedex 13,

Several studies have provided evidence for the existence of oligodendrocyte progenitors and stem cells around the subventricular zone (SVZ) of the adult central nervous system (CNS). Such cells might be expected to be more responsive to demyelination and more competent to generate new oligodendrocytes. In order to demonstrate the involvement of the adult SVZ cells in remyelination, we have induced a chemical demyelinating lesion by stereotaxic injection of 2µl of lyso-phosphatidylcholine (LPC, 1%) into the corpus callosum of adult mouse. Using immunohistochemistry for embryonic N-CAM (E-NCAM) and Platelet-Derived immunohistochemistry for embryonic N-CAM (E-NCAM) and Platelet-Derived Growth Factor α-receptor (PDGF-αR), we have studied the SVZ at various time points after demyelination. After one week, cells expressing E-NCAM within the SVZ strongly increased over controls. E-NCAM-positive cells emerged from the SVZ and were observed along the fibre tracts of the lesioned corpus callosum, suggesting their migration towards the demyelinated area. These cells expressed also the PDGF-αR, thus suggesting that these cells were immature cells of the oligodendocyte lineage. Size increment of the SVZ was more obvious, two weeks after LPC injection. The number of cells, expressing the PDGF-αR and the embryonic form of N-CAM, which were localized along the corpus callosum white matter trace, extended. These selflocalized along the corpus callosum white matter tracts, strongly increased. These cells had the typical bipolar morphology of migrating cells. At this time, numerous PDGF-cR positive oligodendocyte progenitors were also visualized within the demyelinated area. These results demonstrate that cells from the adult SVZ, may be responsible for the generation of new oligodendrocytes following myelin damage. The involvement of adult progenitors in CNS remyelination will be further analyzed.

POLYSIALYLATED NEURAL CELL ADHESION MOLECULE IS ASSOCIATED WITH GABAERGIC NEURONS LOCATED ON THE VENTRICULAR SURFACE OF THE ADULT RAT FOREBRAIN. G. Alonso*, M. Prieto, N. Chauvet, A. Legrand and A. Privat. INSERM U 336, University Montpellier II, 34000 Montpellier, France.
In the developing central nervous system, virtually all the neurons express

an isoform of the neural cell adhesion molecule that is highly enriched in polysialic acid (PSA-NCAM). In the adult, the expression of this molecule is restricted to areas that contain either newly formed neurons or neurons that exhibit a particular capacity for morphological plasticity. In the present study, 50 to 75 μm thick sections cut frontally or sagitally through the forebrain of adult rats were treated for single, double or triple fluorescence immunostaining in order to detect and characterize PSA-NCAMimmunoreactive (IR) cells located on the ventricular surface. In intact brains, intense PSA-NCAM immunostaining was found to be associated with small spherical or fusiform cells located on the surface of (i) the third ventricle bordering the median eminence, and (ii) the lateral ventricles bordering the lateral septum or the dorsal portion of the hippocampus. These PSA-NCAM-IR cells were co-labelled by antibodies against GABA, MAP2, MAP5, and neurofilament. In brains that have received various types of surgical lesions through the forebrain, an increased number of such PSA-NCAM-IR neurons was detected on the surface of the lateral and third ventricles where they appeared either (i) as small spherical cells aggregated into clusters of various size, or (ii) as large isolated cells exhibiting very extended processes. In addition to the different neuronal markers detected in intact brains, these PSA-NCAM— and GABA-IR neurons were also found to be intensely immunoreactive to B-50 (GAP-43). It is suggested that this population of PSA-NCAM-IR GABAergic neurons represent neuronal precursors that remain on the ventricular surface of the rat forebrain throughout adulthood (Supported by IRME)

INTRAVENTRICULAR INFUSION OF BDNF IN ADULT RATS INCREASES THE PROLIFERATION OF CELLS DESTINED FOR THE OLFACTORY BULB. T. Zigova*1, S.J. Wiegand², R.M. Lindsay² and M.B. Luskin 1. Dept. of Anat. and Cell Biol., Emory Univ. Sch. of Med., Atlanta, GA 30322 and ²Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591

The olfactory bulb (OB) is one of the few regions of the brain that acquires new neurons in the adult; the neurons originate from progenitor cells of the subependymal zone (SEZ). In this study we examined the effect of BDNF on the proliferation and differentiation of cells destined for the olfactory bulb. right ventricles of adult rats were infused with either BDNF (12 μg/day) or PBS To label dividing SEZ cells, one group of animals received 5 i.p. injections of BrdU over an 8 hour interval on the 4th day of BDNF infusion; in the other group BrdU was added to the osmotic minipump used to deliver BDNF. All animals were perfused on day 12, and their olfactory bulbs were immunostained to reveal BrdU(+) cells. The number, position and phenotype of the BrdU(+) was determined. Neurons were identified by the neuron-specific antibody TuJ1, and astrocytes by anti-GFAP. Rats that received i.p. BrdU injections with BDNF infusion had > 40% more BrdU(+) cells in their OB compared to PBS controls. The majority of the BrdU(+) cells were in the SEZ. Moreover, many of these cells were TuJ1(+); only a few were GFAP(+). Following continuous infusion of BDNF combined with BrdU, numerous BrdU(+)/TuJ1(+) cells were present in both the SEZ and overlying granule cell layer. These results suggest that BDNF increases the proliferation and/or survival of cells with a neuronal phenotype that originate from the adult SEZ. Supported by NIH, March of Dimes. Emory Center for Neurological Sciences and Regeneron Pharmaceuticals, Inc.

FGF-2, EGF AND PDGF-A DIFFERENT IALLY ACTIVATE IN VIVO THE POTENTIAL OF GRAFTED CELLS DERIVED FROM THE ADULT SUBVENTRICULAR ZONE TO GENERATE MYELIN-FORMING OLIGODENDROCYTES Lachapelle F., Nait-Oumesmar B., Avellana-Adalid V Bargey N., Seilhent. D.and Baron-Van Evercooren A. U 134 INSERM, Hôpital de la Salpetrière F75651 Paris France

In order to identify new sources of oligodendrocytes in the adult CNS, fragments of various regions of the SVZ from 6 months-old normal mice were dissected, Hoechstlabelled and grafted into the corpus callosum of newborn shiverer mice. The absence of myelin basic protein (MBP) in the shiverer myelin allows to detect the myelin synthesized by grafted normal cells and Hoechst allows to vizualize their nuclei. Brains were examined 60 to 90 days after grafting. Hoechst-positive cells were found in 54% of the recipient brains. Five % contained MBP-positive myelin located around and at a short distance from the graft (less than 1 mm). In order to enhance the around and at a short distance from the graft (less than 1 mm). In order to enhance the potential of the adult SVZ to produce myelin-forming cells, donors were treated with a single intraperitoneal injection of FGF-2, EGF, or PDGF-A (5ng/g of living body) 17 to 72h before dissection and engraftment. FGF-2 not only increased the proportion of surviving grafts (84%) but also the proportion of brains containing MBP-positive myelin (84%). This effect was time-dependent since fragments grafted 17-24h after treatment, readwest englands the best distance from inythin (64.6). In a circle was undestignated since Inaginetia (gainet if 1/24) and treatment produced small patches of myelin located around and at short distance from the graft (less than 2mm), while SVZ fragments grafted 48-72h after treatment, synthesized large patches of myelin covering the entire section of the corpus callosum or the fimbria, and migrations were observed over more than 4 mm. Treatment with EGF only slightly increased the number of grafted brains containing Hoechst-positive cells (64%) and MBP-positive myelin (33%)which were found around the graft only. PDGF-A dramatically increased the number of grafted brains containing Hoechst-positive cells (94%) with only 55% containing small MBP-positive myelin patches which were dispersed and frequently located around blood vessels. Our data thus demonstrate that the adult SVZ is an effective source of myelin forming Ols in vivo and that injections of growth factors modulate the survival, migration and differentiation of these cells. Suported by INSERM and ARSEP

GAP JUNCTIONS PLAY A ROLE IN NEURONAL DIFFERENTIATION OF NTERA2/D1 HUMAN EMBRYONAL CELLS. M. Bani-Yaghoub, J.F. Bechberger, and C.C.G. Naus*, Department of Anatomy and Cell Biology, The University of Western Ontario, London, Ontario, N6A 5C1, Canada

Gap junction intercellular communication (GJIC) provides a mechanism for coordination and regulation of neighboring cells through the exchange of metabolic materials (MW<1200 D) and electrical signals. We have used Ntera2/D1 (NT2/D1) cells as human CNS neuronal precursors to study the role of gap junctions in neuronal differentiation. These cells are capable of differentiating to post-mitotic neurons (NT2-N cells) following retinoic acid (RA) treatment for 4-5 weeks and neurons (NTZ-N cells) following retinoic acid (RA) treatment for 4-5 weeks and mitotic inhibitors for 3 weeks, respectively. In order to block gap junctions, NT2/D1 cells were treated continuously with $18~\alpha$ -glycyrrhetinic acid (AGA) and dyecoupling in these cells was examined by pre-loading techniques. Cell proliferation was determined by estimating incorporation of [¹H]thymidine into DNA of NT2/D1 cells with or without AGA treatment during their differentiation upon RA induction. There was a reduction of about 40% and 80% in the number of cells incorporating l'H]thymidine when the GJIC in these cells was blocked with AGA for 1 day and 2 weeks, respectively. The proliferation was shown to be decreased to similar levels during neuronal differentiation of AGA treated NT2/D1 cells upon RA treatment for 2 weeks. The cell viability test with tryans blue showed a health vatter (more than 2 weeks. The cell viability test with trypan blue showed a healthy state (more than 85% viable) in all the samples used in this experiment. Thus, the prominent reduction 8.3% viable) in an ine samples used in this experiment. Thus, the prominent reduction of proliferation of AGA and RA treated NT2/D1 cells was not due to cytotoxicity. NT2/D1 cells treated with RA for 4 weeks expressed microtubule associated protein (MAP2) while cells treated with both RA and AGA for 4 weeks did not express MAP2. Interestingly, these cells started to express MAP5, MAP2 and neurofilament (NF200) after removing AGA from medium. On the other hand, vimentin expression, which is lost through neuronal differentiation of NT2/D1 cells, was present all time when the GIIC was blocked with AGA. There was no significant changes in cx43 immunoreactivity levels and localization between the untreated cells and those of treated with AGA. These results show that gap junction blockage inhibits neuronal differentiation in NT2/D1 cells. (Supported by MRC of Canada).

INHIBITION OF DNA SYNTHESIS IN CEREBELLAR GRANULE NEURON PROGENITORS BY DEPOLARIZING CONCENTRATIONS OF KCL. R.F. Bulleit* and X lin. Dept. of Pharmacology, Univ. of Maryland Sch. of Med., Baltimore MD 21201.

Cerebellar granule neurons arise during postnatal development from a proliferative population of cells in the external granule layer (EGL). Local cues in the EGL may direct granule cell progenitors to exit the cell cycle and begin terminal differentiation. These local cues may include depolarization by neurotransmitter receptor activation. To begin testing this hypothesis we examined whether depolarizing concentrations of KCl can inhibit DNA synthesis in granule neuron progenitors maintained *in vitro*. We isolated progenitors from the cerebellum of postnatal day 7 mice. Granule neuron progenitors were purified by percoll gradient sedimentation followed by panning steps on poly-L-lysine coated plates to remove residual glia. The cells were plated in 96 well tissue culture plates in serum free medium (MEM containing 6 mg/ml glucose, 10 mg/ml BSA, 100 ug/ml transferrin, 10 μM putrescine, 20 nM progesterone, 30 nM selenium). These cells form aggregates during over night culture. The next day we added KCl and ³H thymidine to the cultures and continued incubation for 24 hours. We collected cells using a cell harvester and thymidine incorporation was determine by liquid scintillation counting. KCl (25 mM) significantly reduced thymidine incorporation. This reduction could be prevented by the addition of 1.6 mM EGTA to the medium. Thus, KCl appears to inhibit DNA synthesis by increasing calcium influx into granule neuron progenitors. We are presently examining whether glutamate receptor activation has a similar effect on DNA synthesis. We will also use BrdU incorporation as an alternative measure of DNA synthesis.

ASCORBIC ACID INDUCES BIOCHEMICAL AND MORPHOLOGICAL CHANGES ON NEURAL PROGENITOR CELLS E. Bazán, C. Redondo,

M.A.López-Toledano, M.J. Asensio, C.L. Paino* and A.S.Herranz.

Depto. Investigación, Hospital Ramón y Cajal, INSALUD, 28034-Madrid, SPAIN

As a water-soluble vitamin, ascorbate participates in a number of life sustaining functions, including absortion of iron from the gut and the detoxification of organic radicals. During development, high levels of ascorbate have been found in the brain, indicating that ascorbate may be critical for the growth and initiation of proper biochemical functioning of certain neurons and glial cells.

The aim of this work is to study the effects of ascorbate upon the differentiation process of neuroepithelial progenitors cells.

Progenitor cells, obtained from E 15 rat embryo striatal eminence, were grown in DMEM:F-12 (1:1) supplemented with glucose, N2 components and 20 ng/ml EGF for a minimum of 5 passages, and then plated on poli-L-ornithine coated dishes or coverslips. Deprivation of EGF was performed at 3 days postplating, and ascorbate was added to the culture medium (0.5 mM) and maintained for 14 days. The cellular morphology was studied by immunocitochemistry, and the endogenous content of free amino acids neurotransmitters by HPLC (OPA-precolumn derivatization and fluorimetric detection).

Fourteen days of treatment with 0.5 mM ascorbate increases the number of neurons, stained with antibodies to β -tubulin III, as well as the length of the neurites, when we compare with control cultures. No changes were observed in the shape and number of glial cells, stained with antibodies to GFAP. The concentration of aspartate, glutamate, glutamine, and taurine was reduced about a 50% of control values, while GABA levels remained unchanged.

Our results suggest that ascorbate might play a role inducing the neuronal phenotype during the process of stem cell "in vitro" differentiation.

TEMPORAL EXPRESSION OF DIFFERENT GAP JUNCTIONS DURING NEURONAL DIFFERENTIATION. M. Morales R. Rozental*, M. Urban, M.F. Mehler, R. Dermietzel, J.A. Kessler and D.C. Spray. Depts. of Neurosci. & Neurol., Albert Einstein College of Medicine, Bronx, NY 10461 and Inst. Biophys. "Carlos Chagas Filho", Fed. Univ. Rio de Janeiro, Brazil.

We previously showed that cytokine treatment of immortalized hippocampal progenitor cells (MK31) regulates neuronal differentiation in vitro (Nature 362: 62, 1993), and that the onset of neuronal membrane excitability coincides with a decrease in strength of coupling via gap junction channels between cells (Dev. Biol. 167:350, 1995). Here, we have identified and characterized the types of gap junction proteins (connexins) expressed by these cells using immunocytochemical, molecular biological and electrophysiological techniques. Single channel conductances (γ_i) in untreated progenitor cells were 55 pS, typical of Cx43; presence of this Cx-type was confirmed by Northern blot, immunocytochemistry and RT-PCR assays. In differentiated neuroblasts (treated with IL-7, bFGF and TGF α), γ_i was 60 pS. By contrast, in neuroblasts induced to intermediate differentiation (treatment with IL-7 were 40 pS and 160 pS, conductances consistent with Cx37 and Cx40. RT-PCR analysis of theses cells, however, detected Cx33. Because Cx33 is reported to form nonfunctional channels, our findings raise the possibility that the progressive decline in coupling observed during neuronal differentiation may be due, in part, to the expression of a gap junction protein with dominant negative function.

THE SALVAGE PATHWAY OF PYRIMIDINE SYNTHESIS: DIVERGENCE OF SUBSTRATE SPECIFICITY IN BRAIN CELLS OF TWO RELATED SPECIES OF TELEOST FISH. G.K.H. Zupanc* and I. Horschke. Dpt. Physical Biology, Max Planck Institute for Developmental Biology, D-72011 Tübingen, FRG.

For nucleotide synthesis, cells use purine and pyrimidine nucleosides generated either through de novo synthesis or through utilization of salvage pathways. In the pyrimidine salvage pathway, thymidine (dThd) is taken up by transport proteins and phosphorylated by the enzyme thymidine kinase to thymidine monophosphate. All vertebrates analyzed thus far are able to use radioactively labelled dThd for the biosynthesis of nucleotides in brain tissue. However, when standard techniques for the detection of the incorporation of tritiated dThd and the dThd analogue 5-bromo-2'-deoxyuridine (BrdU) into DNA of postnatally generated brain cells were applied to two species of gymnotiform fish, a divergence in substrate specificity has been revealed.

Intraperitoneal injection of BrdU and processing of brain sections for BrdU immunohistochemistry resulted in a large number of labelled cells in each of the 60 individuals of Apteronotus leptorhynchus and in each of the 15 fish of Eigenmannia sp. examined. In contrast, experiments employing [3H]dThd autoradiography showed a picture completely divergent for the two species. In 14 individuals of Apteronotus leptorhynchus, a total of 649 sections through various regions of the cerebellum (which, based on the results obtained by BrdU immunohistochemistry, were expected to display high levels of mitotic activity) revealed not a single labelled cell. The identical protocol employed in Eigenmannia sp. resulted in labelled cells in 20 out of 21 fish. Similar results were obtained by quantifying the degree of incorporation of [³H]dThd into DNA of whole brain by liquid scintillation spectrometry.

We hypothesize that the inability to use dThd for nucleotide synthesis is caused

either by a defect in the transport system mediating the uptake of dThd or by a deficiency in the thymidine kinase of Apteronotus leptorhynchus. Supported by grants from NINCDS, FES, MPG, and BMFT.

LOW DOSES OF METHYLMERCURY AFFECT CELL CYCLE PROGRESSION IN DEVELOPING CORTEX, N.L. Hayes.", D. Fu'. 2, K.R. Reuhl' and R.S. Nowakowski!. 1 Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, and *Dept. of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ 08854.

Methylmercury (MeHg), a widespread environmental neurotoxicant, has a profound effect on cell proliferation in the developing CNS. A single injection of MeHg (2.5 or 10 μ g/g, i.p.) or saline was given to pregnant CD-1 mice on embryonic day 14 (E14) <u>between</u> two S-phase markers: 1 hr after ³H-thymidine (TdR) and 3 hrs before bromodeoxyuridine (BUdR). Thirty minutes after the BUdR injection embryos were fixed and processed for visualization of the two markers. Labeled and unlabeled nuclei in the ventricular zone of the neocortical anlage were counted and labeling indices (LI) calculated. Each tracer labels the nuclei in S-phase at the time of the injection; progression through the cell cycle is assessed by comparing the LI for the first, second and both tracers. LI:TdR-only is a measure of the proportion of nuclei which left Sphase during the interinjection interval, LI:BUdR-only is a measure of the proportion of nuclei which entered S-phase during the interinjection interval, and LI:TdR+BUdR is a measure of the proportion of nuclei that remained in S during the entire experiment. We found: 1) a decrease in both LI:TdR and LI:BUdR in both dosage groups with greater decreases following the higher dose of MeHg, 2) an increase in LI:TdR+BUdR that was slightly less than the sum of these decreases and 3) abnormally large nuclei labeled only with TdR between the S-phase zone and the ventricular surface. These data indicate that MeHg reduces entry of nuclei into S-phase by lengthening G1 and slows or blocks passage of nuclei through M. That these changes occur even at low doses of MeHg (i.e., $2.5 \mu g/g$) suggests that human developmental pathology produced by MeHg is consequent to such cell cycle progression changes. DNA SYNTHESIS FIDELITY AT SITE DIRECTED LESIONS AND IN VITRO ORIGIN-DEPENDENT REPLICATION USING EXTRACTS PREPARED FROM VARIOUS BRAIN CELLS. <u>Efrati E.¹ Eritja R.²</u> Goodman M.F.¹ & Tocco G.¹*, ¹Univ. Southern California, Los Angeles, CA ²European Molecular Biology Organization, Heidelberg, Germany 60912.

The ability of neuronal cells to maintain the integrity of their DNA is especially important in view of their relative long differentiated life span. It is generally assumed that DNA polymerase β is the enzyme primarily involved in the repair process. We therefore wanted to characterize B polymerase activity in cells of various cell lineage and in different cell cycles

Lysates from cultured neuroblastoma and astrocytoma cells as well as from rat brains were used to measure the fidelity of DNA synthesis using primed DNA templates. Fidelity measurements were made at normal template sites and at abasic and 8-oxo-G site directed lesions. Using a variety of inhibitors for the different polymerases we identified the presence of both α and β activities in all the examined lysates. However β activity was more important. These lysates were also capable of performing abasic lesion bypass synthesis preferentially in reaction conditions favoring β polymerase activity. Furthermore lysates from established cell lines were capable of supporting SV40 origin-dependent DNA replication

Our results suggest that it is possible to use crude cell lysates to measure various DNA polymerase activities. Furthermore, lesions bypass synthesis can occur in these extracts predominantly in conditions favoring \$\beta\$ polymerase activity

COORDINATION OF PROLIFERATION AND NEURONAL DIFFERENTIATION: ROLE OF p130 AND E2F1. M. Miyaijma and T. Neuman *. Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

Molecular mechanisms that regulate cessation of proliferation and Molecular mechanisms that regulate deseation of profileration and initiation of differentiation of neuroblasts are largely unknown. Expression of Rb family member Rb2/p130 is induced in several neuronally developing cells such as cortical neurons and teratocarcinoma PCC7 cells. Blocking expression of Rb2/p130 in PCC7 cells results in inhibition of neuronal differentiation. Also, cells with no induction of Rb2/p130 expression do not stop proliferation. Induction of Rb2/p130 during neuronal differentiation correlates well with the reduced activity of E2F transcription factors. Over-expression of E2F1 in neuronally differentiating PCC7 cells prevents neuronal differentiation and suppresses expression of neurofilament L (NF-L) gene at the transcriptional level. E2F1 protein binds to the sequences close to the transcriptional start site of NF-L gene and reduces transcriptional activity

Induction of Rb2/p130 expression in neuronally differentiating cells is likely regulated by the NeuroD family transcription factors. 5' regulatory region of the Rb2/p130 gene contains several E-box sequences and over-expression of NeuroD family members stimulates significantly Rb2/p130 promoter activity in transient CAT assays. PATHOLOGICAL CHARACTERIZATION OF TWO TRANSGENIC MOUSE LINES HARBORING THE TEMPERATURE-SENSITIVE SV40 TUMOR (T) ANTIGEN. E.K. Dutton*, P. Yamdagni¹, C. Mellilo¹, B. Berechid¹, E. Soly², D. Cramer², T. Adams², H.G. Polites³. Molecular Neurobiology¹, Drug Safety². Transgenics³, Neuroscience Therapeutic Domain, Hoechst Marion Roussel, Inc.. Bridgewater, NJ 08807.

Transgenic mice harboring the temperature-sensitive SV40 large tumor (T) antigen gene driven by the human vimentin promoter were produced for the generation of new immortalized neuronal cell lines. The T antigen expressed is a transcription factor that will bind DNA at 33° C but not at 39° C. Six founders in two different backgrounds (ICR and B6SIL) were produced with four of the six demonstrating mRNA transcription. Three mRNA positive lines tested produced T antigen protein as demonstrated by Western Blot.

Gross pathological analysis of G1 offspring from two lines revealed thymus enlargements that often encompassed the heart. G2 offspring appeared to develop such pathology at an earlier age with some animals developing enlargements in the neck, groin and axillary regions, and on the fore and hindlimbs. In addition, some G2's demonstrated poor hindlimb motor function with no apparent gross pathology presenting itself peripherally or in the CNS. One animal, however, with severe motor dysfunction, did display major necrosis of the cerebellum. Two additional animals, with no apparent dysfunction, had minor necrosis of the frontal cortex. Animals from two founder lines with different backgound strains demonstrating the most robust gross pathology were analyzed microscopically. Pathological analysis will be presented.

IDENTIFICATION OF REGIONS OF MEF2C THAT MODULATE TRANSCRIPTIONAL ACTIVATION. D.

MODULATE TRANSCRIPTIONAL ACTIVATION. <u>D.</u> Leifer*, Y. Chen and Y. Li. Dept. of Neurology, Yale University School of Medicine, New Haven, CT 06520.

The MEF2 transcription factors are expressed abundantly in brain and muscle and appear to be involved in cellular differentiation. One of these factors, MEF2C, is found preferentially in post-mitotic inhibitory interneurons in the cerebral cortex. The amino terminal region of the MEF2 proteins is necessary and sufficient for binding to the MEF2 DNA element ((C/T)T(A/T)2AAATA(A/G)). To identify regions of MEF2C that modulate transcription, we constructed plasmids with deletions of the carboxyl terminus of MEF2C. We transfected COS cells with these plasmids and with plasmids containing a reporter gene under control of the MEF2 element. Deletion of a small portion of the carboxyl terminus of MEF2C enhanced transcriptional activation, but mutants with larger deletions activated transcription less well. A new short isoform of MEF2C that we cloned from human brain has a variant carboxyl terminus and activates transcription less well than the previously identified isoforms. The MEF2C mutants that we constructed and the naturally occurring isoforms were all localized almost entirely to the cell nucleus by immunostaining. They all also have intact amino terminal DNA-binding domains, so the differences in their ability to activate transcription are likely to reflect altered interactions with other proteins. Our results suggest that the carboxyl terminus of MEF2C can repress transcriptional activation mediated by regions of the protein located towards the middle of its amino acid sequence.

ISOLATION AND CHARACTERIZATION OF NEURONAL CELLS IMMORTALIZED WITH THE TEMPERATURE-SENSITIVE SV40 TUMOR (T) ANTIGEN. P. Yamdagni¹, C. Mellilo², B. Berechid^{*}, H.G. Polites², P. Sander⁴, N. Ricdel³, E.K. Dutton¹, Molecular Neurobiology¹, Transgenics², Director of Research³, Neuroscience Therapeutic Domain, Hoechst Marion Roussel, Inc. Bridgewater, NJ 08807.

Neuronal cell lines have greatly facilitated investigations into cellular mechanisms and neuronal functions over the past years. Most neuronal cell lines, however, have been generated from the fusion of some proliferative glial cell and a neuron. Thus, neuronal cell lines often have glial characteristics and may not possess all the qualities of a neuron. Because of this, we have attempted to produce new immortalized neuronal cell lines that maintain neuronal properties by preparing neuronal cultures derived from transgenic mice harboring the temperature-sensitive SV40 T antigen gene driven by a human vimentin promotor.

Embryonic (E9-E15) neuronal cultures prepared from two transgenic lines were characterized by morphology, cell growth, and expression of neuronal specific proteins. Cells proliferated at 33° C in both fetal bovine and horse serum (H_S, containing medium. Morphologically, these cells were non-neuronal. When these cells were shifted to a neuronal differentiation and maintenance medium containing B27, without serum or with 1% HS, cells differentiated, even at 33° C. In HS/B27 medium, a monolayer of non-neuronal cells was maintained which supported differentiated neuronal-like cells. In B27 medium alone, there were few nonneuronal cells and more neuronal-like cells. To date, cells have been maintained at 33° C in serum containing medium and passaged at least 10 times. We are currently testing various conditions to select for a pure population of neuronal-like cells. Preliminary immunofluorescence results demonstrated T-antigen immunoreactivity at 33° C with less T-antigen immunoreactivity at 37° C. In addition, neurofilament immunoreactivity was observed in differentiated neuronal-like cells.

MYELIN BASIC PROTEIN GENE EXPRESSION DURING EARLY HUMAN DEVELOPMENT, M.Tosic, J.-M.Matthieu* and N.Zecevic CHUV, Lausanne 1011, Switzerland; Univ Connecticut, Farmington, Ct 06030

Myelin basic protein (MBP) is considered to be a marker for oligodendrocyte differentiation and myelination. Although the first myelinated axons in humans were observed at 11 gestation weeks (gw), MBP was detected in isolated neuroepithelial cells by immunocytochemical reaction already in 6 gw human embryos (Zecevic et al, 1994). Here we confirm early expression of the MBP gene using in situ hybridization on paraffine embedded sections of human embryos and fetuses obtained from medically indicated abortions with postmortem delay of 0-3 hours. 7-8mm sections were hybridized with DIG labelled antisense RNA probe transcribed from mouse cDNA clone corresponding to 14kD MBP isoform. Sense RNA from the same clone was used as a negative control. Expression of the MBP gene was followed during human development from 6 to 20 gw. In early embryos (6 gw) MBP specific mRNA was detected in rare isolated neuroepithelial cells from spinal cord to prosencephalon. Same type of cells had shown positive reaction using MBP specific antibodies. For the moment it is not possible to predict if these cells will develop in neuronal or glial types, neither to define the function of the MBP in nonmyelinating cells. At 10 gw, MBP specific mRNA positive cells were observed in the cortical anlage as well. Number of cells expressing MBP increased from age 13 gw to 20 gw, and their distribution reflected regions of myelination. Spinal cord and cerebellum were the regions with highest expression of the MBP gene. Since in this study we have confirmed MBP gene expression in human embryos much earlier that the beginning of myelination, our next goal is to distinguish between several possible transcripts on the MBP or Golli-MBP genes in early embryonic stages. EPITOPE RECOGNIZED BY AN ANTINEURONAL AUTOANTIBODY ASSOCIATED WITH PARANEOPLASTIC NEUROLOGICAL SYNDROME ARE CONSERVATIVE BETWEEN VERTEBRATE

K. Yoshimura*1, K. Kagai², A. Kaneko², Y. Sakamoto¹.

K. Kitamura¹, T. Hosokawa², K. Hamaguchi² and M. Nomura¹ Dept. of Physiology¹and Neurology², Saitama Medical School, Moroyama, Iruma-gun, Saitama 350-04, Japan

Moroyama, Iruma-gun, Saitama 350-04, Japan Paraneoplastic encephalomyelitis and paraneoplastic sensory neuropathy are usually associated with small cell lung cancer. We previously found that a patient with mediastinal neoplasm and paraneoplastic neurological syndrome harbored antineuronal autoantibody, named anti-Ta antibody in serum. At 25th Annual meeting for Neuroscience, we presented that anti-Ta antibody was similar to anti-Hu antibody, which reacts proteins with molecular weight of 39-44 kDa and recognizes cytoplasm and nucleus of neurons, considering neurological syndrome of the patient, immunohisto-and cytochemical study, and Western blot analysis using anti-Ta antibody.

immunohisto-and cytochemical study, and Western blot analysis using anti-Ta antibody.

At the present study, we examined whether anti-Ta antibody reacted or not with neurons of nervous system from human, rabbit, rat, mouse, frog, and carp in order to immunologically characterize the epitope of the antigens recognized. Neurons from all species investigated were recognized well by anti-Ta antibody. Since Hu antigens are believed to be RNA-binding proteins, which may paly a role in development and maintenance of neurons as well as Elav, the immunohistochemical study for anti-Ta antibody suggests that the epitopes of antigens would be conservative and the antigens may play a basic role associated with development and maintenance in neurons in vertebrate investigated. We examined the localization of the antigens in neurons using electron microscopy.

THE POSTEMBRYONIC DEVELOPMENT OF SOMATOSTATIN IMMUNO-REACTIVITY IN THE CENTRAL POSTERIOR/PREPACEMAKER NUCLEUS OF APTERONOTUS LEPTORHYNCHUS: A DOUBLE-LABELLING STUDY. T. Stroh* and G.K.H. Zupanc. Dpt. Physical Biology, Max Planck Institute for Developmental Biology, D-72011 Tübingen, FRG.

The neuropeptide somatostatin (SS) is widely distributed in the central nervous system (CNS) of vertebrates. While the embryonic development of SS in the CNS has been well-examined, nothing is known about the postembryonic development of this peptide. One well-suited brain system for studying this phenomenon is the central posterior/prepacemaker nucleus (CP/PPn) of Apteronotus leptorhynchus, a weakly electric gymnotiform fish. This nucleus consists of roughly 10,000 cells. In the ventricular zone of the CP/PPn, new cells are generated continuously and at a high rate throughout adulthood. Within the first days of their life, these cells migrate laterally and develop features characteristic of neurons (Zupanc GKH and Zupanc MM 1992: Proc Natl Acad Sci USA 89, 9539-9543; Zupane GKH and Horschke I 1995: J Comp Neurol 353, 213-233).

Since 5-10% of the total number of cells in the CP/PPn express SS, we set out to examine the development of SS-like immunoreactivity in the cells born during adulthood. This was achieved by labelling mitotically active cells with 5-bromo-2 deoxyuridine (BrdU) and by subsequent immunocytochemical detection of SS. By loying survival times of 2, 3.5, 5, 10, 28, and 100 days after the administration

of BrdU, we investigated whether newborn cells express SS within this time frame.

Expression of SS could not be detected at 2 days. However, in three out of four fish at 3.5 days, in all animals with survival periods of up to 28 days, and in three of four fish at 100 days double-labelled cells were found. In these fish, 1.0-7.6% of all BrdU-labelled cells were SS-positive. This percentage corresponds well to the fraction of somatostatinergic cells among the total population of cells in the CP/PPn.

THE USE OF RETROVIRAL VECTORS TO INVESTIGATE THE STEM CELL-LIKE BEHAVIOR OF EGF-GENERATED MULTIPOTENT SUBVENTRICULAR ZONE PROGENITOR CELLS R.E. Gross* and J.A. Kessler² Departments of Neurosurgery. Neurology, and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461. In contrast to hematopoietic cells, there are no definitive antigenic

markers to characterize and isolate neural stem cells. The definition of neural stem cells relies on the demonstration of multipotentiality and self-renewal. Cortical progenitors have been demonstrated to fulfill these criteria in single cell culture (Davis and Temple, 1994) Progenitor cells from embryonic and adult subventricular zone (SVZ) can be expanded in the presence of epidermal growth factor (EGF) and likely contain stem cells by the above criteria, but the difficulty in culturing these cells under clonal conditions limits further investigations of their stem-like properties
